1.6 DC link options

1.6.1 Capacitor module with 2.8 mF, 4.1 mF or 20 mF

**Description**

The capacitor modules are used to increase the DC link capacitance. On one hand, a brief power failure can then be buffered, and on the other hand, the energy when braking can be buffered.

The modules differ as follows:

- Modules with 2.8 mF and 4.1 mF are used as dynamic energy storage devices
- Module with 20 mF is used to buffer power failures

The modules are available in the following versions:

- Central modules: 4.1 mF and 20 mF
  - SIMODRIVE housing type, are integrated in the system group.
- Distributed modules: 2.8 mF and 4.1 mF
  - New housing type, these are mounted decentrally in the cabinet and are connected to the SIMODRIVE DC link through an adapter terminal and cable.

The capacitor modules have a ready display which is lit above a DC link voltage of approx. 300 V. This allows internal fuse failures to be detected. This does not guarantee reliable monitoring of the charge condition.

The module with 2.8 mF or 4.1 mF does not have a pre-charging circuit. Because it is directly connected to the DC link, it can accept dynamic energy levels and can therefore operate as dynamic energy storage device. For these modules, the charge limits of the line supply modules must be observed.

Modules with 20 mF are pre-charged through an internal pre-charging resistor which limits the charge current and de-couples the module from the central pre-charging. This module cannot accept dynamic energy levels, as the pre-charging resistor limits the charge current. When the power fails, a diode couples this capacitor battery to the DC link of the system and supports this.

**Note**

The capacitor modules may only be used in conjunction with the line supply infeed modules of SIMODRIVE 611.

The central modules are suitable for internal and external cooling.

Calculation examples

The energy storage capacity in dynamic operation and for regenerative braking is calculated as follows:

Formula: \( w = \frac{1}{2} \times C \times (V_{\text{DC link max}}^2 - V_{\text{DC link n}}^2) \)

Assumptions for the example:

Capacitance of the capacitor battery \( C = 4.1 \text{ mF} \)

Nominal DC link voltage \( V_{\text{DC link n}} = 600 \text{ V} \)

Max. DC link voltage \( V_{\text{DC link max}} = 695 \text{ V} \)

\( \Rightarrow w = \frac{1}{2} \times 4.1 \times 10^{-3} \times (695 \text{ V})^2 - (600 \text{ V})^2 = 252 \text{ Ws} \)
The following applies for the energy storage capacity of the capacitor battery when the power fails:

Formula: \[ w = \frac{1}{2} \times C \times (V_{DC \, linkn}^2 - V_{DC \, linkmin}^2) \]

Assumptions for the example:

Capacitance of the capacitor battery \( C = 20 \, \text{mF} \)

Nominal DC link voltage \( V_{DC \, linkn} = 600 \, \text{V} \)

Min. DC link voltage \( V_{DC \, linkmin} = 350 \, \text{V} \)

\[ w = \frac{1}{2} \times 20 \times 10^{-3} \times (567^2 - 350^2) = 1990 \, \text{Ws} \]

For a DC link voltage of 680 V, the energy storage capacity increases to 2904 Ws.

Caution

\( V_{DC \, linkmin} \) must be \( \geq 350 \, \text{V} \).

For voltages below 350 V, the switched-mode power supply for the electronics shuts down.

The possible buffer time \( t_\Omega \) is calculated using the output DC link power \( P_{DC \, link} \) as follows:

\[ t_\Omega = \frac{w}{P_{DC \, link}} \]

Dynamic energy

DC link capacitors should be considered as battery. The capacitance and the energy storage capability are increased as a result of the capacitor module.

To evaluate the capacity required for a specific requirement in a certain application, the energy balance should be determined.

The energy balance depends on the following:

- All moved masses and moments of inertia
- Velocity, speed (and its change, acceleration, deceleration)
- Efficiency: Mechanical system, gearbox, motor, inverter (driving/braking)
- Buffer time, buffering
- DC link voltage and the permissible change, output value upper/lower limit value.

Often, in practice, there is no precise data about the mechanical system. If the mechanical system data are determined by making rough calculations or using estimated values, the adequate capacitance of the DC link capacitors can only be determined by carrying-out tests during the commissioning phase.

The energy for dynamic operations is obtained as follows:

When a drive brakes or accelerates within time \( t_V \) from one speed/velocity to another, then the following applies:

\[ w = \frac{1}{2} \times P \times t_V \]

for rotating drives with
1.6 DC link options

The central capacitor module should preferably be located at the righthand end of the system group. It is connected through DC link busbars.

### Engineering information

The torque M and force F which are generated depend on the moved masses, the load and the acceleration in the system.

If there is no precise data for the factors specified above, then generally the nominal/rated data is applied.

The torque M and force F which are generated depend on the moved masses, the load and the acceleration in the system.

If there is no precise data for the factors specified above, then generally the nominal/rated data is applied.

### Mathematical equations

For linear drives with

\[
P = F_{\text{Mot}} \times (V_{\text{Mot max}} - V_{\text{Mot min}}) \times 10^{-3} \times \eta_G
\]

with \( \eta_G \):

- **Braking**: \( \eta_G = \eta_M \times \eta_{WR} \)
- **Acceleration**: \( \eta_G = 1/(\eta_M \times \eta_{WR}) \)

### Variables

- \( P \) [kW]: Motor output
- \( t_V \) [s]: Duration
- \( M_{\text{Mot}} \) [Nm]: Max. motor torque when braking or accelerating
- \( F_{\text{Mot}} \) [N]: Max. motor force when braking or accelerating
- \( n_{\text{Mot max}} \) [RPM]: Max. speed at the start or end of the operation
- \( n_{\text{Mot min}} \) [RPM]: Min. speed at the start or end of the operation
- \( v_{\text{Mot max}} \) [m/s]: Max. velocity at the start or end of the operation
- \( v_{\text{Mot min}} \) [m/s]: Min. velocity at the start or end of the operation
- \( \eta_G \): Efficiency, overall
- \( \eta_M \): Efficiency, motor
- \( \eta_{WR} \): Efficiency, inverter

The central capacitor module should preferably be located at the righthand end of the system group. It is connected through DC link busbars.

PE cable is routed as close as possible to the P600/M600 cables on the mounting panel.

Cable length max. 5 m

Note:
The distributed capacitor module may only be mounted vertically.

Fig. 1-13 Capacitor module mounting location

Several capacitor modules can be connected in parallel depending on the line supply infeed used.

For capacitor modules with 2.8 mF and 4.1 mF, the total charge limit of the line supply infeed may not be exceeded (refer to Catalog NC 60, Section 10).

¹) When the monitoring modules are directly connected to the line supply without DC link connection, the monitoring modules do not have to be taken into account.

If, for direct line connection and simultaneous DC link connection (P500–P600 and N500–N600) the monitoring modules are connected to the same line supply as the line supply infeed, then the monitoring modules must also be taken into account.

A maximum of three monitoring modules may be connected.

The “without monitoring module” column is valid for the number of capacitor modules.

### Charge times, discharge times, discharge voltage

It should be carefully checked that the DC link is in a no-voltage condition before carrying-out any commissioning or service work.

#### Table 1-16 Charge/discharge times, discharge voltage

</tr>
</tbody>
</table>

If the system includes a pulsed resistor, in order to shorten the discharge time, after opening terminal 42, a fast DC link discharge can be initiated using terminals X221:19 and 50 (jumper).

**Warning**

The pulsed resistor modules can only convert a certain amount of energy into heat (refer to Table 1-18). The energy to be converted depends on the voltage.
Caution

In order to avoid causing damage to the infeed circuit of the supply infeed modules, when energizing terminal X221 terminals 19/50, it must be ensured that terminal 48 of the supply infeed module is de-energized (electrical isolation from the line supply).

The checkback signal contacts of the supply infeed module main contactor must be evaluated to evaluate whether this has dropped-out (X161 term.111, term.113, term.213).
