SINUMERIK 840D sl / 828D Basic Functions

Function Manual

Valid for

Control system
SINUMERIK 840D sl / 840DE sl
SINUMERIK 828D

Software
NCU system software

Version
2.6 SP1

03/2010
6FC5397-0BP20-1BA0

Preface	
A2: Various NC/PLC interface signals and functions	1
A3: Axis monitoring, protection zones	2
B1: Continuous-path mode, Exact Stop, LookAhead	3
B2: Acceleration	4
D1: Diagnostics tools	5
F1: Travel to fixed stop	6
G2: Velocities, setpoint / actual value systems, closed-loop control	7
H2: Auxiliary function outputs to PLC	8
K1: Mode group, channel, program operation, reset response	9
K2: Axis types, coordinate systems, frames	10
N2: Emergency stop	11
P1: Transverse axes	12
P3: Basic PLC program for SINUMERIK 840D sl	13
P4: PLC for SINUMERIK 828D	14
R1: Reference point approach	15
S1: Spindles	16
V1: Feedrates	17
W1: Tool offset	18
Z1: NC/PLC interface signals	19
Appendix	A

Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

 DANGER
indicates that death or severe personal injury will result if proper precautions are not taken.
 WARNING
indicates that death or severe personal injury may result if proper precautions are not taken.
 CAUTION
with a safety alert symbol, indicates that minor personal injury can result if proper precautions are not taken.
CAUTION
without a safety alert symbol, indicates that property damage can result if proper precautions are not taken.
NOTICE
indicates that an unintended result or situation can occur if the corresponding information is not taken into account.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation for the specific task, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

 WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be adhered to. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of the Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

SINUMERIK® Documentation

The SINUMERIK documentation is organized in three parts:

- General documentation
- User documentation
- Manufacturer/service documentation

Information on the following topics is available at <http://www.siemens.com/motioncontrol/docu>:

- Ordering documentation
Here you can find an up-to-date overview of publications.
- Downloading documentation
Links to more information for downloading files from Service & Support.
- Researching documentation online
Information on DOConCD and direct access to the publications in DOConWEB.
- Compiling individual documentation on the basis of Siemens contents with the My Documentation Manager (MDM), refer to <http://www.siemens.com/mdm>.

My Documentation Manager provides you with a range of features for generating your own machine documentation.

- Training and FAQs

Information on our range of training courses and FAQs (frequently asked questions) is available via the page navigation.

Target group

This publication is intended for:

- Project engineers
- Technologists (from machine manufacturers)
- System startup engineers (Systems/Machines)
- Programmers

Benefits

The function manual describes the functions so that the target group knows them and can select them. It provides the target group with the information required to implement the functions.

Standard version

This documentation only describes the functionality of the standard version. Extensions or changes made by the machine tool manufacturer are documented by the machine tool manufacturer.

Other functions not described in this documentation might be executable in the control. This does not, however, represent an obligation to supply such functions with a new control or when servicing.

Further, for the sake of simplicity, this documentation does not contain all detailed information about all types of the product and cannot cover every conceivable case of installation, operation or maintenance.

Installation

Structure of this Function Manual:

- Inner title (page 3) with the title of the Function Manual, the SINUMERIK controls as well as the software and the version for which this version of the Function Manual is applicable and the overview of the individual functional descriptions.
- Description of the functions in alphabetical order (e.g. A2, A3, B1 etc.)
- Appendix with:
 - List of abbreviations
 - Fax template for feedback for documentation
 - Overview
- Index of terms

Note

For detailed descriptions of data and alarm see:

- Machine and setting data:
Detailed description of machine data (only electronically on DOConCD or DOConWEB)
 - NC/PLC interface signals:
Function Manual Basic Functions; NC/PLC Interface Signals (Z1)
Function Manual Extended Functions; NC/PLC Interface Signals (Z2)
Function Manual Special Functions; NC/PLC Interface Signals (Z3)
 - Alarms:
Diagnostics Manual
-

Notation of system data

The following notation is applicable for system data in this documentation:

Signal/Data	Notation	Example
NC/PLC interface signals	... NC/PLC interface signal: <signal address> (<signal name>)	When the new gear step is engaged, the following NC/PLC interface signals are set by the PLC program: DB31, ... DBX16.0-2 (actual gear stage A to C) DB31, ... DBX16.3 (gear is changed)
Machine data	... machine data: <Type><Number> <Complete Designator> (<Meaning>)	Master spindle is the spindle stored in the machine data: MD20090 \$MC_SPIND_DEF_MASTER_SPIND (Position of deletion of the master spindle in the channel).
Setting Data	... Setting data: <Type><Number> <Complete Designator> (<Meaning>)	The logical master spindle is contained in the setting data: SD42800 \$SC_SPIND_ASSIGN_TAB[0] (Spindle number converter)

Note

Signal address

The description of functions include as <signal address> of an NC/PLC interface signal, only the address valid for SINUMERIK 840D sl. The signal address for SINUMERIK 828D should be taken from the data lists "Signals to/from ..." at the end of the particular description of functions.

Quantity structure

Explanations concerning the NC/PLC interface are based on the absolute maximum number of sequential components:

- Mode groups (DB11)
- Channels (DB21, etc.)
- Axes/spindles (DB31, etc.)

Data types

The following elementary data types are used in the control system:

Type	Meaning	Value range
INT	Signed integers	-2147483648 ... +2147483647
REAL	Figures with decimal point acc. to IEEE	$\pm(2.2 \cdot 10^{-308} \dots 1.8 \cdot 10^{+308})$
BOOL	Truth values TRUE (1) and FALSE (0)	1, 0
CHAR	ASCII characters	Corresponding to code 0 to 255
STRING	Character string, number of characters in [...]	Maximum of 200 characters (no special characters)
AXIS	Axis names only	All axis identifiers in the channel

Type	Meaning	Value range
FRAME	Geometrical parameters for moving, rotating, scaling, and mirroring	
Arrays can only be formed from similar elementary data types. Up to 3-dimensional arrays are possible.		

Technical Support

If you have any questions, please contact our hotline:

Europe/Africa	
Phone	+49 180 5050 - 222
Fax	+49 180 5050 - 223
€0.14/min. from German landlines, cell phone prices may differ

Table of Contents

	Preface	3
1	A2: Various NC/PLC interface signals and functions	33
1.1	Brief description	33
1.2	NC/PLC interface signals	33
1.2.1	General	33
1.2.2	Ready signal to PLC	35
1.2.3	Status signals to PLC	36
1.2.4	Signals to/from panel front	37
1.2.5	Signals to channel	38
1.2.6	Signals to axis/spindle	39
1.2.7	Signals from axis/spindle	48
1.2.8	Signals to axis/spindle (digital drives)	50
1.2.9	Signals from axis/spindle (digital drives)	51
1.3	Functions	54
1.3.1	Screen settings	54
1.3.2	Settings for involute interpolation - only 840D sl	55
1.3.3	Activate DEFAULT memory	58
1.3.4	Read/write PLC variable	58
1.3.5	Access protection via password and keyswitch	62
1.3.5.1	Access protection via password and keyswitch	62
1.3.5.2	Password	64
1.3.5.3	Keyswitch settings (DB10, DBX56.4 to 7)	65
1.3.5.4	Parameterizable protection levels	66
1.4	Examples	67
1.5	Data lists	69
1.5.1	Machine data	69
1.5.1.1	Display machine data	69
1.5.1.2	NC-specific machine data	70
1.5.1.3	Channel-specific machine data	71
1.5.1.4	Axis/spindle-specific machine data	71
1.5.2	System variables	72
1.5.3	Signals	72
1.5.3.1	Signals to NC	72
1.5.3.2	Signals from NC	72
1.5.3.3	Signals to operator panel front	73
1.5.3.4	Signals from operator panel front	73
1.5.3.5	Signals to channel	73
1.5.3.6	Signals from channel	74
1.5.3.7	Signals to axis/spindle	74
1.5.3.8	Signals from axis/spindle	74
2	A3: Axis monitoring, protection zones	77
2.1	Brief description	77
2.1.1	Axis monitoring functions	77
2.1.2	Protection zones	77

2.2	Axis monitoring.....	78
2.2.1	Contour monitoring.....	78
2.2.1.1	Contour error.....	78
2.2.1.2	Following error monitoring.....	79
2.2.2	Positioning, zero speed and clamping monitoring.....	81
2.2.2.1	Correlation between positioning, zero-speed and clamping monitoring.....	81
2.2.2.2	Positioning monitoring.....	81
2.2.2.3	Zero speed monitoring.....	83
2.2.2.4	Exact stop and standstill tolerance dependent on the parameter set.....	84
2.2.2.5	Clamping monitoring.....	84
2.2.3	Speed-setpoint monitoring.....	92
2.2.4	Actual velocity monitoring.....	93
2.2.5	Measuring-system monitoring (systems with PROFIBUS drives).....	94
2.2.6	Limit switches-monitoring.....	95
2.2.6.1	Hardware limit switches.....	95
2.2.6.2	Software limit switch.....	96
2.2.7	Monitoring of the working area limitation.....	98
2.2.7.1	General.....	98
2.2.7.2	Working area limitation in BKS.....	100
2.2.7.3	Working area limitation in WKS/ENS.....	102
2.3	Protection zones.....	106
2.3.1	General.....	106
2.3.2	Types of protection zone.....	107
2.3.3	Definition via part program instruction.....	110
2.3.4	Definition via system variable.....	113
2.3.5	Activation and deactivation of protection zones.....	115
2.3.6	Protection-zone violation and temporary enabling of individual protection zones.....	119
2.3.7	Restrictions in protection zones.....	125
2.4	Supplementary conditions.....	126
2.4.1	Axis monitoring functions.....	126
2.5	Examples.....	127
2.5.1	Axis monitoring.....	127
2.5.1.1	Working area limitation in WKS/ENS.....	127
2.5.2	Protection zones.....	129
2.5.2.1	Definition and activation of protection zones.....	129
2.6	Data lists.....	139
2.6.1	Machine data.....	139
2.6.1.1	NC-specific machine data.....	139
2.6.1.2	Channel-specific machine data.....	139
2.6.1.3	Axis/spindle-specific machine data.....	140
2.6.2	Setting data.....	141
2.6.2.1	Axis/spindle-specific setting data.....	141
2.6.3	Signals.....	142
2.6.3.1	Signals to channel.....	142
2.6.3.2	Signals from channel.....	142
2.6.3.3	Signals to axis/spindle.....	143
3	B1: Continuous-path mode, Exact Stop, LookAhead.....	145
3.1	Brief description.....	145
3.2	Exact stop mode.....	148
3.3	Continuous-path mode.....	153
3.3.1	General functionality.....	153

3.3.2	Velocity reduction according to overload factor	154
3.3.3	Blending	157
3.3.3.1	Rounding according to a path criterion (G641).....	160
3.3.3.2	Rounding in compliance with defined tolerances (G642/G643)	162
3.3.3.3	Rounding with maximum possible axial dynamic response (G644)	165
3.3.3.4	Rounding of tangential block transitions (G645).....	169
3.3.4	LookAhead.....	171
3.3.4.1	Standard functionality	171
3.3.4.2	Free-form surface mode: Extension function.....	177
3.4	Dynamic adaptations	181
3.4.1	Smoothing the path velocity.....	181
3.4.2	Adaptation of the dynamic path response	184
3.4.3	Determination of the dynamic response limiting values	188
3.4.4	Interaction between the "smoothing of the path velocity" and "adaptation of the path dynamic response" functions	189
3.4.5	Dynamic response mode for path interpolation	193
3.4.6	Free-form surface mode: Basic functions	196
3.5	Compressor functions	200
3.5.1	NC block compression	200
3.5.2	Combining short spline blocks (option for 828D).....	204
3.6	Contour/Orientation tolerance.....	206
3.7	Tolerance and compression of G0 blocks	210
3.8	RESET response	213
3.9	Supplementary conditions.....	214
3.9.1	Block change and positioning axes	214
3.9.2	Block change delay	214
3.9.3	Rounding and repositioning (REPOS).....	215
3.10	Data lists	216
3.10.1	Machine data.....	216
3.10.1.1	General machine data.....	216
3.10.1.2	Channel-specific machine data.....	216
3.10.1.3	Axis/spindle-specific machine data	217
3.10.2	Setting data	218
3.10.2.1	Channel-specific setting data.....	218
3.10.3	Signals	218
3.10.3.1	Signals from channel	218
3.10.3.2	Signals from axis/spindle	218
4	B2: Acceleration	219
4.1	Brief description	219
4.1.1	General	219
4.1.2	Features	219
4.2	Functions.....	221
4.2.1	Acceleration without jerk limitation (BRISK/BRISKA) (channel/axis-specific)	221
4.2.1.1	General information	221
4.2.1.2	Programmable maximum value (axis-specific).....	222
4.2.1.3	Parameterization	222
4.2.1.4	Programming.....	223
4.2.2	Constant travel time (channel-specific).....	224
4.2.2.1	General information	224
4.2.2.2	Parameterization	225

4.2.3	Acceleration matching (ACC) (axis-specific).....	226
4.2.3.1	General information.....	226
4.2.3.2	Programming.....	226
4.2.4	Acceleration margin (channel-specific).....	227
4.2.4.1	General information.....	227
4.2.4.2	Parameterization.....	227
4.2.5	Path-acceleration limitation (channel-specific).....	227
4.2.5.1	General information.....	227
4.2.5.2	Parameterization.....	228
4.2.5.3	Programming.....	228
4.2.6	Path acceleration for real-time events (channel-specific).....	229
4.2.6.1	General information.....	229
4.2.6.2	Programming.....	230
4.2.7	Acceleration with programmed rapid traverse (G00) (axis-specific).....	231
4.2.7.1	General information.....	231
4.2.7.2	Parameterization.....	231
4.2.8	Acceleration with active jerk limitation (SOFT/SOFTA) (axis-specific).....	232
4.2.8.1	General information.....	232
4.2.8.2	Parameterization.....	232
4.2.9	Excessive acceleration for non-tangential block transitions (axis-specific).....	232
4.2.9.1	General information.....	232
4.2.9.2	Parameterization.....	233
4.2.10	Acceleration margin for radial acceleration (channel-specific).....	233
4.2.10.1	General information.....	233
4.2.10.2	Parameterization.....	235
4.2.11	Jerk limitation with path interpolation (SOFT) (channel-specific).....	235
4.2.11.1	General information.....	235
4.2.11.2	Maximum jerk value (axis-specific).....	237
4.2.11.3	Maximum jerk value (channel-specific).....	237
4.2.11.4	Parameterization.....	237
4.2.11.5	Programming.....	238
4.2.12	Jerk limitation with single-axis interpolation (SOFTA) (axis-specific).....	238
4.2.12.1	General information.....	238
4.2.12.2	Parameterization.....	239
4.2.12.3	Programming.....	239
4.2.13	Path-jerk limitation (channel-specific).....	240
4.2.13.1	General information.....	240
4.2.13.2	Parameterization.....	240
4.2.13.3	Programming.....	240
4.2.14	Path jerk for real-time events (channel-specific).....	241
4.2.14.1	General information.....	241
4.2.14.2	Programming.....	242
4.2.15	Jerk with programmed rapid traverse (G00) (axis-specific).....	243
4.2.15.1	General information.....	243
4.2.15.2	Parameterization.....	243
4.2.16	Excessive jerk for block transitions without constant curvature (axis-specific).....	244
4.2.16.1	General information.....	244
4.2.16.2	Parameterization.....	244
4.2.17	Velocity-dependent jerk adaptation (axis-specific).....	244
4.2.18	Jerk filter (axis-specific).....	247
4.2.18.1	General information.....	247
4.2.18.2	Parameterization.....	250
4.2.19	Knee-shaped acceleration characteristic curve.....	251
4.2.19.1	Adaptation to the motor characteristic curve.....	251
4.2.19.2	Effects on path acceleration.....	253

4.2.19.3	Substitute characteristic curve	253
4.2.19.4	Parameterization	256
4.2.19.5	Programming.....	257
4.2.19.6	Boundary conditions	258
4.3	Examples	260
4.3.1	Acceleration	260
4.3.1.1	Path velocity characteristic	260
4.3.2	Jerk	261
4.3.2.1	Path velocity characteristic	261
4.3.3	Acceleration and jerk	263
4.3.4	Knee-shaped acceleration characteristic curve	265
4.3.4.1	Activation.....	265
4.4	Data lists	267
4.4.1	Machine data.....	267
4.4.1.1	Channel-specific machine data.....	267
4.4.1.2	Axis/spindle-specific machine data	267
4.4.2	Setting data	268
4.4.2.1	Channel-specific setting data.....	268
4.4.3	System variables.....	268
5	D1: Diagnostics tools	269
5.1	Brief description	269
5.2	Description of diagnostic tools	270

6.5.1.1	Axis/spindle-specific machine data.....	333
6.5.2	Setting data.....	333
6.5.2.1	Axis/spindle-specific setting data.....	333
6.5.3	Signals.....	334
6.5.3.1	Signals to axis/spindle.....	334
6.5.3.2	Signals from axis/spindle.....	334
7	G2: Velocities, setpoint / actual value systems, closed-loop control	335
7.1	Brief description	335
7.2	Velocities, traversing ranges, accuracies.....	335
7.2.1	Velocities.....	335
7.2.2	Traversing ranges.....	337
7.2.3	Positioning accuracy of the control system.....	338
7.2.4	Block diagram of resolutions and scaling values.....	339
7.2.5	Input/display resolution, computational resolution.....	340
7.2.6	Scaling of physical quantities of machine and setting data.....	341
7.3	Metric/inch measuring system.....	345
7.3.1	Conversion of basic system by parts program.....	345
7.3.2	Manual switchover of the basic system.....	349
7.3.3	FGROUP and FGREF.....	355
7.4	Setpoint/actual-value system.....	358
7.4.1	General.....	358
7.4.2	Setpoint and encoder assignment.....	360
7.4.3	Adapting the motor/load ratios.....	364
7.4.4	Speed setpoint output.....	367
7.4.5	Actual-value processing.....	369
7.4.6	Adjustments to actual-value resolution.....	372
7.5	Closed-loop control.....	379
7.5.1	General.....	379
7.5.2	Parameter sets of the position controller.....	382
7.6	Optimization of the control.....	385
7.6.1	Position controller, position setpoint filter: Balancing filter.....	385
7.6.2	Position controller, position setpoint filter: Jerk filter.....	388
7.6.3	Position control with proportional-plus-integral-action controller.....	390
7.7	Data lists.....	393
7.7.1	Machine data.....	393
7.7.1.1	Displaying machine data.....	393
7.7.1.2	NC-specific machine data.....	393
7.7.1.3	Channel-specific machine data.....	393
7.7.1.4	Axis/spindle-specific machine data.....	394
8	H2: Auxiliary function outputs to PLC.....	397
8.1	Brief description.....	397
8.1.1	Function.....	397
8.1.2	Definition of an auxiliary function.....	398
8.1.3	Overview of auxiliary functions.....	399

8.2	Predefined auxiliary functions	405
8.2.1	Overview: Predefined auxiliary functions	405
8.2.2	Overview: Output behavior	417
8.2.3	Parameter assignment	420
8.2.3.1	Group assignment	420
8.2.3.2	Type, address extension and value	421
8.2.3.3	Output behavior	422
8.3	User-defined auxiliary functions	427
8.3.1	Parameter assignment	428
8.3.1.1	Maximum number of user-defined auxiliary functions	428
8.3.1.2	Group assignment	429
8.3.1.3	Type, address extension and value	429
8.3.1.4	Output behavior	431
8.4	Associated auxiliary functions	431
8.5	Type-specific output behavior	433
8.6	Priorities of the output behavior for which parameters have been assigned	435
8.7	Programming an auxiliary function	436
8.8	Programmable output duration	438
8.9	Auxiliary function output to the PLC	440
8.10	Auxiliary functions without block change delay	441
8.11	M function with an implicit preprocessing stop	441
8.12	Response to overstore	443
8.13	Block-search response	444
8.13.1	Auxiliary function output during type 1, 2, and 4 block searches	444
8.13.2	Assignment of an auxiliary function to a number of groups	446
8.13.3	Time stamp of the active M auxiliary function	447
8.13.4	Determining the output sequence	447
8.13.5	Output suppression of spindle-specific auxiliary functions	449
8.13.6	Auxiliary function output with a type 5 block search (SERUPRO)	452
8.13.7	ASUB at the end of the SERUPRO	457
8.14	Implicitly output auxiliary functions	463
8.15	Information options	464
8.15.1	Group-specific modal M auxiliary function display	464
8.15.2	Querying system variables	465
8.16	Supplementary conditions	468
8.16.1	General constraints	468
8.16.2	Output behavior	469
8.17	Examples	470
8.17.1	Extension of predefined auxiliary functions	470
8.17.2	Defining auxiliary functions	472
8.18	Data lists	476
8.18.1	Machine data	476
8.18.1.1	NC-specific machine data	476
8.18.1.2	Channel-specific machine data	476
8.18.2	Signals	477
8.18.2.1	Signals to channel	477
8.18.2.2	Signals from channel	477

8.18.2.3	Signals to axis/spindle.....	479
8.18.2.4	Signals from axis/spindle	479
9	K1: Mode group, channel, program operation, reset response	481
9.1	Brief description	481
9.2	Mode group (MG).....	484
9.2.1	Mode group Stop.....	487
9.2.2	Mode group RESET	487
9.3	Mode types and mode type change.....	488
9.3.1	Monitoring functions and interlocks of the individual modes.....	494
9.3.2	Mode change	494
9.4	Channel.....	496
9.4.1	Global start disable for channel	499
9.5	Program test.....	501
9.5.1	Program execution without setpoint outputs	501
9.5.2	Program execution in single-block mode	503
9.5.3	Program execution with dry run feedrate	505
9.5.4	Skip part-program blocks	507
9.6	Block search.....	509
9.6.1	Sequence for block search of Type 1, 2 and 4	510
9.6.2	Block search in connection with other NCK functions	512
9.6.2.1	ASUB after and during block search.....	512
9.6.2.2	PLC actions after block search	513
9.6.2.3	Spindle functions after block search	514
9.6.3	Automatic start of an ASUB after a block search.....	515
9.6.4	Cascaded block search.....	517
9.6.5	Examples of block search with calculation.....	519
9.7	Block search Type 5 SERUPRO.....	523
9.7.1	REPOS.....	529
9.7.1.1	Continue machining after SERUPRO search target found.....	529
9.7.1.2	Repositioning on contour with controlled REPOS	538
9.7.2	Acceleration measures via MD	541
9.7.3	SERUPRO ASUP.....	542
9.7.4	Self-acting SERUPRO	545
9.7.5	Inhibit specific part of the program in the part program for SERUPRO	546
9.7.6	Special features in the part-program target block.....	550
9.7.6.1	STOPRE in the part-program target block.....	550
9.7.6.2	SPOS in target block.....	551
9.7.7	Behavior during POWER ON, mode change and RESET.....	551
9.7.8	Special features of functions supported during SERUPRO	551
9.7.8.1	Travel to fixed stop (FXS)	552
9.7.8.2	Force Control (FOC)	552
9.7.8.3	Synchronous spindle.....	553
9.7.8.4	Couplings and master-slave.....	553
9.7.8.5	Axis functions	557
9.7.8.6	Gear stage change.....	558
9.7.8.7	Superimposed motion	559
9.7.8.8	REPOS offset in the interface	559
9.7.8.9	Making the initial settings more flexible	560
9.7.9	System variables and variables for SERUPRO sequence	561
9.7.10	Restrictions	562
9.8	Program operation mode	563

9.8.1	Initial settings	563
9.8.2	Selection and start of part program or part-program block	566
9.8.3	Part-program interruption	568
9.8.4	RESET command	569
9.8.5	Program status	570
9.8.6	Channel status	571
9.8.7	Responses to operator or program actions	572
9.8.8	Part-Program Start	573
9.8.9	Example of timing diagram for a program run	574
9.8.10	Program jumps	575
9.8.10.1	Jump back to start of program	575
9.8.11	Program section repetitions	577
9.8.11.1	Overview	577
9.8.11.2	Individual part program block	578
9.8.11.3	A part program section after a start label	579
9.8.11.4	A part program section between a start label and end label	580
9.8.11.5	A part program section between a Start label and the key word: ENDLABEL	581
9.8.12	Event-driven program calls	582
9.8.12.1	Function	582
9.8.12.2	Parameter assignment	586
9.8.12.3	Programming	591
9.8.12.4	Boundary conditions	592
9.8.12.5	Examples	592
9.8.13	Influencing the Stop events through Stop delay area	594
9.9	Asynchronous subroutines (ASUBs), interrupt routines	598
9.9.1	Function	598
9.9.1.1	General functionality	598
9.9.1.2	Sequence of an interrupt routine in program operation	600
9.9.1.3	Interrupt routine with REPOSA	602
9.9.1.4	NC response	602
9.9.2	Parameter assignment	603
9.9.3	Programming	608
9.9.4	Restrictions	611
9.9.5	Examples	611
9.10	User-specific ASUB for RET and REPOS	612
9.10.1	Function	612
9.10.2	Parameter assignment	612
9.10.3	Programming	613
9.11	Single block	616
9.11.1	Decoding single block SBL2 with implicit preprocessing stop	617
9.11.2	Single block stop: Suppression using SBLOF	617
9.11.3	Single block stop: inhibit according to situation	620

17	V1: Feedrates	1389
17.1	Brief description	1389
17.2	Path feedrate F	1392
17.2.1	General	1392
17.2.2	Type of feedrate G93, G94, G95	1394
17.2.3	Type of feedrate G96, G961, G962, G97, G971	1397
17.2.4	Feedrate with G33, G34, G35 (thread cutting)	1402
17.2.4.1	General	1402
17.2.4.2	Programmable run-in and run-out path for G33, G34 and G35	1403
17.2.4.3	Linear progressive/degressive thread-lead change with G34 and G35	1405
17.2.4.4	Stop for thread cutting	1408
17.2.5	Feedrate for G331/G332, rigid tapping	1412
17.2.6	Feedrate for G63, tapping with compensation chuck	1413
17.3	Feedrate FA for positioning axes	1414
17.4	Feedrate control	1416
17.4.1	General	1416
17.4.2	Feedrate disable and feedrate/spindle stop	1417
17.4.3	Feedrate override on machine control panel	1418
17.4.4	Programmable feedrate override	1423
17.4.5	Dry run feedrate	1424
17.4.6	Multiple feedrate values in one block	1426
17.4.7	Fixed feedrate values	1431
17.4.8	Feedrate for chamfer/rounding FRC, FRCM	1433
17.4.9	Non-modal feedrate FB	1434
17.4.10	Programmable single-axis dynamic response	1435
17.5	Supplementary conditions	1442
17.5.1	General boundary conditions	1442
17.5.2	Supplementary conditions for feedrate programming	1442
17.6	Examples	1444
17.6.1	Feedrate programming for chamfer/rounding FRC, FRCM	1444
17.7	Data lists	1446
17.7.1	Machine data	1446
17.7.1.1	NC-specific machine data	1446
17.7.1.2	Channel-specific machine data	1446
17.7.1.3	Axis/Spindle-specific machine data	1447
17.7.2	Setting data	1447
17.7.2.1	Channel-specific setting data	1447
17.7.2.2	Axis/spindle-specific setting data	1448
17.7.3	Signals	1448
17.7.3.1	Signals to channel	1448
17.7.3.2	Signals from channel	1448
17.7.3.3	Signals to axis/spindle	1449
17.7.3.4	Signals from axis/spindle	1449
18	W1: Tool offset	1451
18.1	Short description	1451
18.2	Tool	1454
18.2.1	General	1454
18.2.2	Compensation memory structure	1456
18.2.3	Calculating the tool compensation	1457
18.2.4	Address extension for NC addresses T and M	1458

18.2.7	Definition of the effect of the tool parameters	1469
18.3	Flat D number structure	1470
18.3.1	General.....	1470
18.3.2	Creating a new D number (compensation block).....	1470
18.3.3	D number programming	1471
18.3.4	Programming the T number	1474
18.3.5	Programming M6.....	1474
18.3.6	Program test.....	1475
18.3.7	Tool management or "Flat D numbers".....	1475
18.4	Tool cutting edge.....	1477
18.4.1	General.....	1477
18.4.2	Tool parameter 1: Tool type	1479
18.4.3	Tool parameter 2: Cutting edge position.....	1483
18.4.4	Tool parameters 3 - 5: Geometry - tool lengths	1484
18.4.5	Tool parameters 6 - 11: Geometry - tool shape	1486
18.4.6	Tool parameters 12 - 14: Wear - tool lengths	1487
18.4.7	Tool parameters 15 - 20: Wear - tool shape	1488
18.4.8	Tool parameters 21 - 23: Tool base dimension/adaptor dimension.....	1488
18.4.9	Tool parameter 24: Undercut angle	1490
18.4.10	Tools with a relevant tool point direction.....	1491
18.5	Tool radius compensation 2D (TRC)	1492
18.5.1	General.....	1492
18.5.2	Selecting the TRC (G41/G42).....	1493
18.5.3	Approach and retraction behavior (NORM/KONT/KONTC/KONTT)	1494
18.5.4	Smooth approach and retraction.....	1499
18.5.4.1	Function.....	1499
18.5.4.2	Parameters.....	1500
18.5.4.3	Velocities	1507
18.5.4.4	System variables	1509
18.5.4.5	Supplementary conditions.....	1509
18.5.4.6	Examples.....	1510
18.5.5	Deselecting the TRC (G40).....	1513
18.5.6	Compensation at outside corners	1513
18.5.7	Compensation at inside corners	1517
18.5.8	Collision detection and bottleneck detection.....	1519
18.5.9	Blocks with variable compensation value	1521
18.5.10	Keep tool radius compensation constant	1523
18.5.11	Alarm behavior	1526
18.5.12	Intersection procedure for polynomials.....	1527
18.5.13	G461/G462 Approach/retract strategy expansion	1528
18.6	Toolholder with orientation capability	1532
18.6.1	General.....	1532
18.6.2	Kinematic interaction and machine design	1539
18.6.3	Oblique machining with 3 + 2 axes	1546
18.6.4	Machine with rotary work table.....	1547
18.6.5	Procedure when using toolholders with orientation capability	1551
18.6.6	Programming.....	1556
18.6.7	Supplementary conditions and control system response for orientation	1557
18.7	Cutting data modification for tools that can be rotated	1560
18.7.1	Function.....	1560
18.7.2	Determination of angle of rotation.....	1560

18.7.3	Cutting edge position, cut direction and angle for rotary tools.....	1561
18.7.4	Modifications during the rotation of turning tools	1563
18.7.5	Cutting edge position for milling and tapping tools	1566
18.7.6	Modifications during rotation of milling and tapping tools	1567
18.7.7	Parameter assignment.....	1567
18.7.8	Programming.....	1569
18.7.9	Example	1572
18.8	Incrementally programmed compensation values	1574
18.8.1	G91 extension.....	1574
18.8.2	Machining in direction of tool orientation	1575
18.9	Basic tool orientation.....	1577
18.10	Special handling of tool compensations	1581
18.10.1	Relevant setting data	1581
18.10.2	Mirror tool lengths (SD42900 \$SC_MIRROR_TOOL_LENGTH)	1582
18.10.3	Mirror wear lengths (SD42920 \$SC_WEAR_SIGN_CUTPOS)	1583
18.10.4	Tool length and plane change (SD42940 \$SC_TOOL_LENGTH_CONST)	1585
18.10.5	Tool type (SD42950 \$SC_TOOL_LENGTH_TYPE)	1586
18.10.6	Temperature offsets in tool direction (SD42960 \$SC_TOOL_TEMP_COMP).....	1587
18.10.7	Tool lengths in the WCS, allowing for the orientation	1587
18.10.8	Tool length offsets in tool direction	1588
18.11	Sum offsets and setup offsets.....	1593
18.11.1	General	1593
18.11.2	Description of function	1594
18.11.3	Activation.....	1597
18.11.4	Examples	1603
18.11.5	Upgrades for tool length determination.....	1604
18.11.5.1	Taking the compensation values into account location-specifically and workpiece-specifically.....	1604
18.11.5.2	Functionality of the individual wear values.....	1609
18.12	Working with tool environments	1613
18.12.1	General	1613
18.12.2	Saving with TOOLENV	1613
18.12.3	Delete tool environment.....	1615
18.12.4	How many environments and which ones are saved?	1616
18.12.5	Read T, D, DL from a tool environment.....	1617
18.12.6	Read tool lengths, tool length components.....	1618
18.13	Tool lengths L1, L2, L3 assignment: LENTOAX	1625

A2: Various NC/PLC interface signals and functions

1.1 Brief description

Content

The PLC/NCK interface comprises a data interface on one side and a function interface on the other. The data interface contains status and control signals, auxiliary functions and G functions, while the function interface is used to transfer jobs from the PLC to the NCK.

This Description describes the functionality of interface signals, which are of general relevance but are not included in the Descriptions of Functions.

- Asynchronous events
- Status signals
- PLC variable (read and write)

1.2 NC/PLC interface signals

1.2.1 General

NC/PLC interface

The NC/PLC interface comprises the following parts:

- Data interface
- Function interface

Data interface

The data interface is used for component coordination:

- PLC user program
- NC
- HMI (operator components)
- MCP (Machine Control Panel)

Data exchange is organized by the basic PLC program.

Cyclic signal exchange

The following interface signals are transferred cyclically, i.e. in the clock grid of the OB1, by the basic PLC program:

- NC and operator-panel-front-specific signals
- Mode group-specific signals
- Channel-specific signals
- Axis/spindle-specific signals

NC and operator-panel-front-specific signals (DB10)

PLC to NC:

- Signals for influencing the CNC inputs and outputs
- Keyswitch signals (and password)

NC to PLC:

- Actual values of CNC inputs
- Setpoints of CNC outputs
- Ready signals from NC and HMI
- NC status signals (alarm signals)

Channel-specific signals (DB21, ...)

PLC to NC:

- Control signal "Delete distance-to-go"

NC to PLC:

- NC status signals (NCK alarm active)

Axis/spindle-specific signals (DB31, etc.)

PLC to NC:

- Control signals to axis/spindle (e.g. follow-up mode, servo enable, etc.)
- Control signals to drive (bytes 20, 21)

NC to PLC:

- Status signals from axis/spindle (e.g. position controller active, current controller active, etc.)
- Control signals from drive (bytes 93, 94)

Function interface

The function interface is generated by function blocks (FB) and function calls (FC). Function requests, e.g. to traverse axes, are sent from the PLC to the NC via the function interface.

References

For detailed information about the following subject areas, please refer to:

- Description of the basic PLC program:
→ Function Manual, Basic Functions, Basic PLC Program (P3)
- Description of the event-driven signal exchange (Auxiliary and G functions):
→ Function Manual Basic Functions; Auxiliary Function Output to PLC (H2)
- Overview of all interface signals, functional and data components:
→ List Manual

1.2.2 Ready signal to PLC

DB10 DBX104.7 (NC CPU Ready)

The NC CPU is ready and registers itself cyclically with the PLC.

DB10 DBX108.3 (HMI Ready)

SINUMERIK Operate is ready and registers itself cyclically with the NC.

DB10 DBX108.6 (Drive Ready)

Precondition: Readiness of all machine axes:

DB31, ... DBX93.5 == 1 (Drive Ready)

DB10 DBX108.7 (NC Ready)

The NC is ready.

1.2.3 Status signals to PLC

DB10 DBX103.0 (remote diagnosis active)

The HMI component reports to the PLC that the remote diagnostics (option) is active i.e. the control is done via an external PC.

DB10 DBX109.6 (ambient temperature alarm)

The ambient temperature or fan monitoring function has responded.

DB10 DBX109.7 (NCK battery alarm)

The battery voltage has dropped below the lower limit value. The control can still be operated. A control system shutdown or failure of the supply voltage will lead to loss of data.

DB10 DBX109.0 (NCK alarm pending)

The NC signals that at least one NC alarm is pending. The channel-specific interface can be scanned to see which channels are involved and whether this will cause a processing stop.

DB21, ... DBX36.6 (channel-specific NCK alarm pending)

The NC sends this signal to the PLC to indicate that at least one NC alarm is pending for the affected channel. See also:
DB21, ... DBX36.7 (NCK alarm with processing stop present)

DB21, ... DBX36.7 (NCK alarm with processing stop present)

The NC sends this signal to the PLC to indicate that at least one NCK alarm, which has interrupted or aborted the current program run (processing stop), is pending for the affected channel.

1.2.4 Signals to/from panel front

DB19 DBX0.0 (screen bright)

The screen blanking is disabled.

DB19 DBX0.1 (screen dark)

The operator panel screen is darkened.

If the interface signal is used to actively darken the screen:

- It is no longer possible to switch the screen bright again on the keyboard (see below).
- The first keystroke on the operator panel front already triggers an operator action.

Note

In order to prevent accidental operator actions when the screen is darkened via the interface signal, we recommend disabling the keyboard **at the same time**.

DB19 DBX0.1 = 1 **AND** DB19 DBX0.2 = 1 (key disable)

Screen darkening via keyboard/automatic screen saver

If no buttons are pressed on the operator panel front within the assigned time (default = 3 minutes):

MD9006 \$MM_DISPLAY_BLACK_TIME

(time for screen darkening), the screen is automatically darkened.

The screen lights up again the first time a button is pressed following darkening. Pressing a button to lighten the screen will not generate an operator action.

Parameter assignment:

DB19 DBX0.1 = 0

MD9006 \$MM_DISPLAY_BLACK_TIME > 0

DB19 DBX0.2 (key disable)

All inputs via the connected keyboard are inhibited.

DB19 DBX 0.3 / 0.4 (Delete cancel alarms / Delete recall alarms) (HMI Advanced)

Request to delete all currently pending alarms with Cancel or Recall delete criterion. Deletion of the alarms is acknowledged via the following interface signals.

- DB19 DBX20.3 (Cancel alarm deleted)
- DB19 DBX20.4 (recall alarm deleted)

DB19 DBX0.7 (actual value in WCS, 0=MCS)

Switching over of actual-value display between machine and workpiece coordinate system:

- DB19 DBX0.7 = 0: Machine coordinate system (MCS)
- DB19 DBX0.7 = 1: Workpiece coordinate system (WCS)

DB19 DBB13 (control of the file transfer via hard disk) (HMI advanced only)

Job byte to control file transfer via hard disk. The jobs relate to the user control file in the interface signals:

DB19 DBB16 (parts program handling: Number of the control file for user file names)

DB19 DBB17 (parts program handling: Index of the file to be transmitted from the user list)

DB19 DBB16 (control of file transfer via hard disk) (HMI Advanced only)

Control byte for file transfer via hard disk to define the index for the control file (job list). This file is handled according to the job in the interface signal:

DB19 DBB13

DB19 DBB17 (part program handling: Index of the file to be transferred from the user list)

Control byte for file transfer via hard disk to indicate the line in the user control file in which the control file to be transferred is stored

DB19 DBB26 (part program handling: status)

Status byte for current status of data transfer for "select", "load" or "unload", or if an error occurred during data transmission.

DB19 DBB27 (error program handling)

Output byte for error values for data transfer via hard disk.

1.2.5 Signals to channel

DB21, ... DBX6.2 (delete distance-to-go)

The rising edge on the interface signal generates a stop on the programmed path in the corresponding NC channel with the currently active path acceleration. The path distance-to-go is then deleted and the block change to the next part-program block is enabled.

1.2.6 Signals to axis/spindle

DB31, ... DBX1.0 (drive test travel enable)

If machine axes are traversed by special test functions such as "function generator", an explicit drive-test-specific enable is requested for the movement:

DB31, ... DBX61.0 = 1 (drive test travel request)

The movement is carried out once the movement is enabled:

DB31, ... DBX1.0 == 1 (drive test travel enable)

NOTICE
It is the sole responsibility of the machine manufacturer/system startup engineer to take suitable action/carry out appropriate tests to ensure that the machine axis can be traversed during the drive test without putting personnel or machinery at risk.

DB31, ... DBX1.3 (axis/spindle disable)

Axis disable when machine axis is at rest

No traversing request (manual or automatic) is carried out for a machine axis at rest and NC/PLC interface signal:

DB31, ... DBX1.3 == 1 (axis / spindle disable)

The traversing request is maintained. If the axis disable is cancelled when a traversing request is pending DB31, ... DBX1.3 = 0 the movement is carried out.

Axis disable when machine axis in motion

When machine axis is in motion and NC/PLC interface signal DB31, ... DBX1.3 == 1 the movement of the machine axis is decelerated to a standstill via the axis-specific brake characteristics currently active or, if it is part of an interpolated path movement or coupling, it is decelerated on a path or coupling-specific basis.

The movement is continued if the axis disable is canceled by another pending traversing request: DB31, ... DBX1.3 = 0.

Spindle disable

The response is determined by the current spindle mode:

- Control mode: Speed setpoint = 0
- Positioning mode: See above "Axis disable".

DB31, ... DBX1.4 (follow-up mode)

"Follow-up mode" is only effective in conjunction with the NC/PLC interface signal:

DB31, ... DBX2.1 (controller enable)

DB31, ... DBX2.1	DB31, ... DBX1.4	Function
1	Ineffective	Normal operation (machine axis in closed-loop control mode)
0	1	Follow-up
0	0	Hold

Function: Follow-up

During follow-up, the setpoint position of the machine axis is continuously corrected to the actual position (setpoint position = actual position).

The following interface signals have to be set for the follow-up function:

DB31, ... DBX2.1 = 0 (controller enable)

DB31, ... DBX1.4 == 1 (tracking mode)

Feedback:

DB31, ... DBX61.3 = 1 (follow-up mode active)

Note

When the controller enable is set from follow-up mode, if the part program is active, the last programmed position is approached again internally in the NC (REPOSA: Approach along line on all axes). In all other cases, all subsequent movements start at the current actual position.

During "follow-up", clamping or zero-speed monitoring are **not active**.

Function: Hold

The hold function does not correct the setpoint position of the machine axis to the actual position. If the machine axis moves away from the setpoint position, a following error (difference between setpoint and actual position) is generated. This error is corrected "suddenly" when the controller enable is set by the position controller, without observing the axial acceleration characteristic.

The following interface signals have to be set for the hold function:

DB31, ... DBX2.1 = 0 (controller enable)

DB31, ... DBX1.4 == 0 (follow-up mode)

Feedback:

DB31, ... DBX61.3 = 0 (follow-up mode active)

During "hold", clamping or zero-speed monitoring are **active**.

NOTICE

With the "hold" function, once the controller enable has been set, the setpoint/actual-value difference is corrected: directly by the position controller, i.e. without following the axial acceleration characteristic.

Application example

Positioning response of machine axis Y following clamping when "controller enable" set. Clamping pushed the machine axis from the actual position Y_1 to the clamping position Y_k .

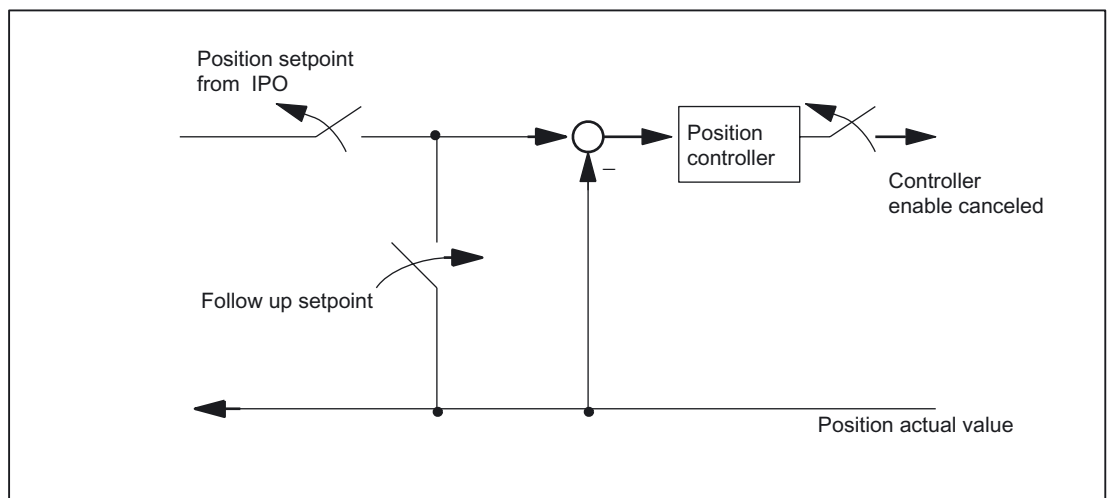

Figure 1-1 Effect of controller enable and follow-up mode

1.2 NC/PLC interface signals

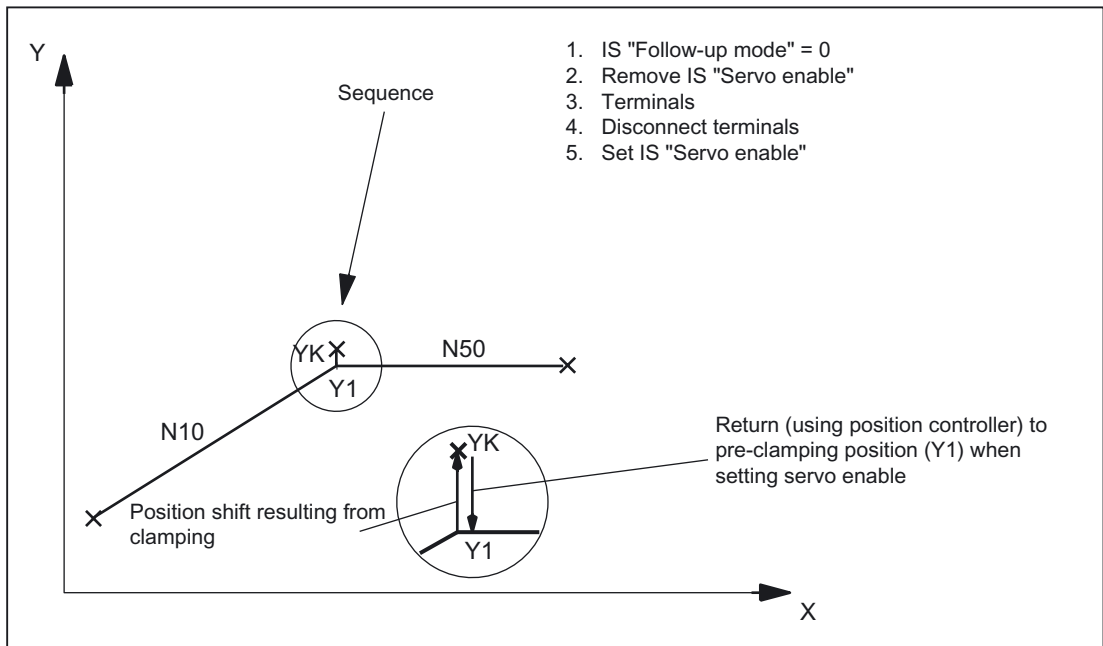

Figure 1-2 Trajectory for clamping and "hold"

Figure 1-3 Trajectory for clamping and "follow-up"

Drives with analog setpoint interface

A drive with an analog setpoint interface is capable of traversing the machine axis with an external setpoint. If "follow-up mode" is set for the machine axis, the actual position continues to be acquired. Once follow-up mode has been cancelled, homing is not required.

The following procedure is recommended:

1. Activate follow-up mode:
 - DB31, ... DBX2.1 = 0 (controller enable)
 - DB31, ... DBX1.4 = 1 (follow-up mode) (in the same or preceding OB1 cycle)
 - The axis/spindle is operating in follow-up mode
2. Deactivate external controller enable and external speed setpoint
 - Axis/spindle moves with external setpoint
 - NC continues to detect the actual position and corrects the setpoint position to the actual position
3. Deactivate external controller enable and cancel external speed setpoint
 - Axis/spindle stops
4. Canceling follow-up mode
 - DB31, ... DBX2.1 = 1 (controller enable)
 - DB31, ... DBX1.4 = 0 (follow-up mode)
 - NC synchronizes to current actual position. The next traversing movement begins at this position.

Note

"Follow-up mode" does not have to be canceled because it only has an effect in combination with "controller enable".

Canceling follow-up mode

Once follow-up mode has been canceled, the machine axis does not have to be homed again if the maximum permissible encoder limit frequency of the active measuring system was not exceeded during follow-up mode. If the encoder limit frequency is exceeded, the controller will detect this:

- DB31, ... DBX60.4 / 60.5 = 0 (homed/synchronized 1 / 2)
- Alarm: "21610 Encoder frequency exceeded"

Note

If "follow-up mode" is deactivated for a machine axis, which is part of an active transformation (e.g. TRANSMIT), this can generate movements as part of repositioning (REPOS) other machine axes involved in the transformation.

Monitoring

If a machine axis is in follow-up mode, the following monitoring mechanisms will not act:

- Zero-speed monitoring
- Clamping monitoring
- Positioning monitoring

Effects on other interface signals:

- DB31, ... DBX60.7 = 0 (position reached with exact stop fine)
- DB31, ... DBX60.6 = 0 (position reached with exact stop coarse)

DB31, ... DBX1.5 / 1.6 (position measuring system 1 / 2)

2 measuring systems can be connected to one machine axis, e.g.

- Indirect motor measuring system
- Direct measuring system on load

Only one measuring system can be active at any one time. All closed-loop control, positioning operations, etc. involving the machine axis always relate to the active measuring system.

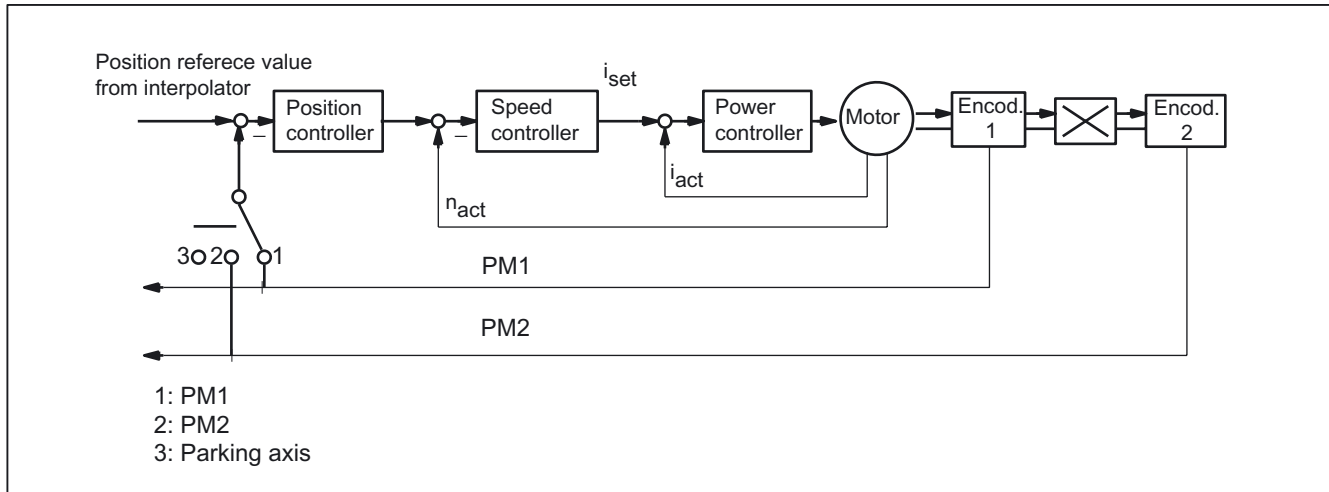

Figure 1-4 Position measuring systems 1 and 2

The table below shows the functionality of the interface signals in conjunction with the "controller enable".

DB31, ... DBX1.5	DB31, ... DBX1.6	DB31, ... DBX2.1	Function
1	0 (or 1)	1	Position measuring system 1 active
0	1	1	Position measuring system 2 active
0	0	0	"Parking" active
0	0	1	Spindle without position measuring system (speed-controlled)
1 -> 0	0 -> 1	1	Switchover: Position measuring system 1 → 2
0 -> 1	1 -> 0	1	Switchover: Position measuring system 2 → 1

DB31, ... DBX2.1 (controller enable)

Setting the controller enable closes the machine axis position control loop. The machine axis is in position control mode.

DB31, ... DBX2.1 == 1

Canceling the controller enable opens the machine axis position control loop and, subject to a delay, the machine axis speed control loop:

DB31, ... DBX2.1 == 0

Activation methods

The closed-loop controller enable for a machine axis is influenced by:

- PLC user program by means of the following NC/PLC interface signals:
 - DB31, ... DBX2.1 (controller enable)
 - DB31, ... DBX21.7 (pulse enable)
 - DB31, ... DBX93.5 (drive ready)
 - DB10, DBX56.1 (EMERGENCY STOP)
- NCK-internal
Alarms that trigger cancellation of the controller enable on the machine axes. Alarms, which cancel the controller enable, are described in:

References:

/DA/ Diagnostics Manual

Canceling the controller enable when the machine axis is at standstill:

- The machine axis position control loop opens
- DB31, ... DBX61.5 = 0 (position controller active)

Canceling the controller enable when the machine axis is in motion:

If a machine axis is part of an interpolatory path movement or coupling and the controller enable for this is canceled, all axes involved are stopped with a fast stop (speed setpoint = 0) and an alarm is displayed:

Alarm: "21612 Controller enable reset during movement"

- The machine axis is decelerated taking into account the parameterized temporal duration of the brake ramp for error states with a fast stop (speed setpoint = 0):
MD36610 \$MA_AX_EMERGENCY_STOP_TIME (max. time duration of the braking ramp in event of errors)

An alarm is displayed:

Alarm: "21612 Controller enable reset during movement"

Note

The controller enable is canceled at the latest when the cutout time expires:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME

- The machine axis position control loop opens. Interface signal:
DB31, ... DBX61.5 = 0 (position controller active).
The time for the parameterized cut-off delay of the controller enable is started by the machine data:
MD36620 \$MA_SERVO_DISABLE_DELAY_TIME (switch-off delay controller enable)
- As soon as the actual speed has reached the zero speed range, the drive controller enable is canceled. Interface signal:
DB31, ... DBX61.6 = 0 (speed controller active)

- The position actual value of the machine axis continues to be acquired by the control.
- At the end of the braking operation, the machine axis is switched to follow-up mode, regardless of the corresponding NC/PLC interface signal. Zero-speed and clamping monitoring are not effective. See the description above for the interface signal:

DB31, ... DBX1.4 (follow-up mode).

Synchronizing the actual value (homing)

Once the controller enable has been set, the actual position of the machine axis does not need to be synchronized again (homing) if the maximum permissible limit frequency of the measuring system was not exceeded during the time in which the machine axis was not in position-control mode.

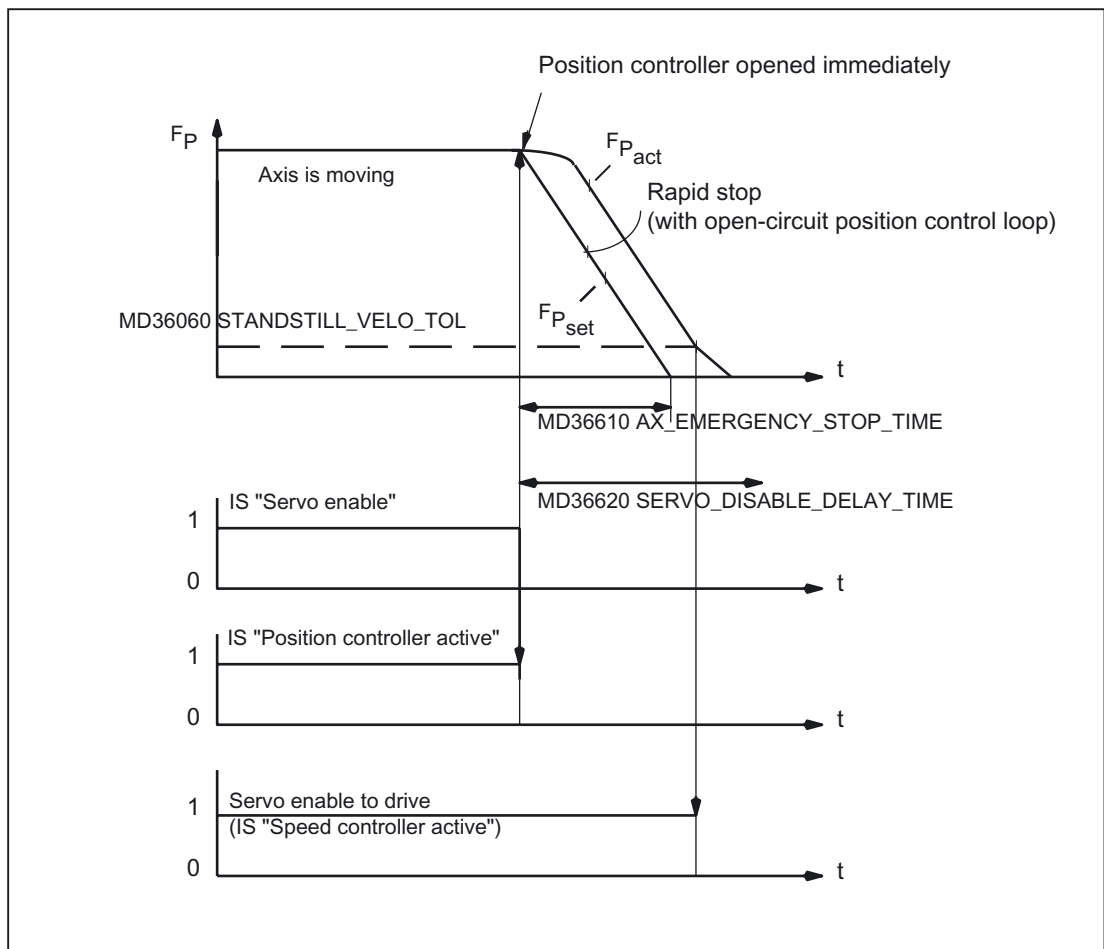

Figure 1-5 Canceling the controller enable when the machine axis is in motion

DB31, ... DBX2.2 (spindle reset (axis/spindle-specific))

"Delete distance-to-go" is effective in AUTOMATIC and MDA modes only in conjunction with positioning axes. The positioning axis is decelerated to standstill following the current brake characteristic. The distance-to-go of the axis is deleted.

Spindle reset

A detailed description of the spindle reset can be found in:

References:

/FB1/ Function Manual Basic Functions; Spindles (S1)

DB31, ... DBX9.0 / 9.1 / 9.2 (parameter set servo)

The PLC user program sends a **binary** code request via the "controller parameter set selection" to activate the corresponding parameter set of the NC.

DBX9.2	DBX9.1	DBX9.0	Parameter-set number
0	0	0	1
0	0	1	2
0	1	0	3
0	1	1	4
1	0	0	5
1	0	1	6
1	1	0	6
1	1	1	6

Parameter-set changeover must be enabled via the machine data (not required for spindles):

MD35590 \$MA_PARAMSET_CHANGE_ENABLE = 1 or 2

More information about parameter set changeover can be found in:

References:

/FB1/ Function Manual, Basic Functions; Spindles (S1);

Chapter: Configurable gear adjustments > parameter set selection during gear stage change

Parameter set changeover when machine axis is in motion

The response to a parameter-set changeover depends on the consequential change in the closed-loop control circuit gain factor Kv:

MD32200 \$MA_POSCTRL_GAIN (KV factor)

- "Identical servo gain factors" or "position control not active":
The NC responds immediately to the parameter-set changeover. The parameter set is also changed during the movement.
- "Non-identical servo gain factors" or "position control active":
In order to effect a changeover as smoothly as possible, changeover is not activated until the axis "is stationary", i.e. once the parameterized zero speed has been reached or undershot:

DB31, ... DBX61.4 = 1 (axis/spindle stationary)

MD36060 \$MA_STANDSTILL_VELO_TOL (threshold velocity/speed 'axis/spindle stationary')

Parameter set changeover from the parts program

For parameter-set changeover from the parts program, the user (machine manufacturer) must define corresponding user-specific auxiliary functions and evaluate them in the PLC user program. The PLC user program will then set the changeover request on the corresponding parameter set.

More information about auxiliary function output can be found in:

References:

/FB1/ Function Manual, Basic Functions; Auxiliary function output (H2)

DB31, ... DBX9.3 (disable parameter-set default setting by NC)

Parameter-set changeover request will be ignored.

1.2.7 Signals from axis/spindle

DB31, ... DBX61.0 (drive test travel request)

If machine axes are traversed by special test functions such as "function generator", an explicit drive-test-specific enable is requested for the movement:

DB31, ... DBX61.0 == 1 (drive test travel request)

The movement is carried out once the movement is enabled:

DB31, ... DBX1.0 == 1 (drive test travel enable)

DB31, ... DBX61.3 (follow-up mode active)

The machine axis is in follow-up mode.

DB31, ... DBX61.4 (axis/spindle stationary ($n < n_{\min}$))

"Axis/spindle stationary" is set by the NC if:

- No new setpoints are to be output **AND**
- The actual speed of the machine axis is lower than the parameterized zero speed:
MD36060 \$MA_STANDSTILL_VELO_TOL (threshold velocity axis stationary)

DB31, ... DBX61.5 (position controller active)

The machine axis position control loop is closed and position control is active.

DB31, ... DBX61.6 (speed controller active)

The machine axis speed control loop is closed and speed control is active.

DB31, ... DBX61.7 (current controller active)

The machine axis current control loop is closed and current control is active.

DB31, ... DBX69.0 / 69.1 / 69.2 (parameter set servo)

Active parameter set Coding accordingly:

DB31, ... DBX9.0 / 9.1 / 9.2 (controller parameter set selection)

DB31, ... DBX76.0 (lubrication pulse)

Following a control POWER ON/RESET, the signal status is 0 (FALSE).

The "lubrication pulse" is **inverted** (edge change), as soon as the machine axis has covered the parameterized traversing distance for lubrication:

MD33050 \$MA_LUBRICATION_DIST (distance for lubrication by PLC)

1.2.8 Signals to axis/spindle (digital drives)

DB31, ... DBX21.0 / 21.1 / 21.2 (parameter set selection A, B, C)

Request to change over drive parameter set:

DBX 21.2	DBX 21.1	DBX21.0	Parameter-set number
0	0	0	1
0	0	1	2
0	1	0	3
0	1	1	4
1	0	0	5
1	0	1	6
1	1	0	7
1	1	1	8

The feedback signal is sent via the interface signals:

DB31, ... DBX93.0,1 / 93.2 (active drive parameter set)

DB31, ... DBX21.3 / 21.4 (Motor selection A, B)

Selection of motor/operating mode.

DBX 21.4	DBX 21.3	Motor number	Mode
0	0	1	1
0	1	2	2
1	0	3	3
1	1	4	4

Only operating modes 1 and 2 are valid on main spindle drive:

- Operating modes 1: Star
- Operating modes 2: Delta

DB31, ... DBX21.5 (Motor selection done)

The PLC user program sends this signal to the drive to indicate successful motor selection. For example, in the case of star/delta switchover on the SIMODRIVE 611D or 611U, a message or signal must be provided when the motor contactor has switched. The pulses are then enabled by the drive.

DB31, ... DBX21.6 (integrator disable, n-controller)

The PLC user program inhibits the integrator of the speed controller for the drive. The speed controller is thus switched from PI to P controller.

Note:

If the speed controller integrator disable is activated, compensations might take place in certain applications (e.g. if the integrator was already holding a load while stationary).

Feedback via the interface signal:

DB31, ... DBX93.6 = 1 (integrator n-controller disabled)

DB31, ... DBX21.7 (pulse enable)

The pulse enable for the drive module is only requested if all enable signals (hardware and software) are pending:

- Trigger equipment enable
- Controller and pulse enable
- Pulse enable (safe operating stop)
- Stored hardware input
- Setpoint enable
- "Ready to run state"
 - No drive alarm (DClink1 error)
 - DC link connected
 - Ramp-up completed

See also:

DB31, ... DBX93.7 (pulses enabled)

1.2.9 Signals from axis/spindle (digital drives)

DB31, ... DBX92.1 (ramp-function generator disable active)

The drive signals back to the PLC that ramp-function-generator fast stop is active. The drive is thus brought to a standstill without the ramp function (with speed setpoint 0).

DB31, ... DBX93.0, 1, 2 (active drive parameter set A, B, C)

The drive module sends this checkback to the PLC to indicate which drive parameter set is currently active. With bit combination A, B, C, eight different drive parameter sets can be selected by the PLC.

DB31, ... DBX93.3, 4 (active motor A, B)

The drive module (MSD) sends this checkback to the PLC to indicate which of the 4 motor types or motor operating modes is active.

The following selections can be made on the main spindle drive:

- Star mode (A=0, B=0)
- Delta mode (A=1, B=0)

DB31, ... DBX93.5 (DRIVE ready)

Checkback signal indicating that the drive is ready. The conditions required for traversing the axis/spindle are fulfilled.

DB31, ... DBX93.6 (integrator n-controller disabled)

The speed-controller integrator is disabled. The speed controller has thus been switched from PI to P controller.

DB31, ... DBX93.7 (pulses enabled)

The pulse enable for the drive module is available. The axis/spindle can now be traversed.

DB31, ... DBX94.0 (motor temperature prewarning)

The motor temperature has exceeded the warning threshold. If the motor temperature remains at this level, the drive will be stopped after a defined time (drive MD) and the pulse enable removed.

DB31, ... DBX94.1 (heatsink temperature prewarning)

The heatsink temperature has exceeded the warning threshold. The pulse enable will be removed for the drive module in question after 20 seconds.

DB31, ... DBX94.2 (ramp-up completed)

This signal indicates that the actual speed value has reached the new setpoint allowing for the tolerance band set in drive machine data:

MD1426 \$MD_SPEED_DES_EQ_ACT_TOL (indicate tolerance band for 'nsoll=nist')

The acceleration procedure is thus completed. Any subsequent speed fluctuations due to load changes will not affect the interface signal.

DB31, ... DBX94.3 ($|M_d| < M_{dx}$)

This signal indicates that the current torque $|M_d|$ is lower than the parameterized threshold torque M_{dx} :

MD1428 \$MD_TORQUE_THRESHOLD_X (threshold torque)

The threshold torque is entered as a percentage of the current speed-dependent torque limitation.

DB31, ... DBX94.4 ($|n_{act}| < n_{min}$)

This signal indicates that the actual speed $|n_{act}|$ is lower than the set minimum speed n_{min} :

MD1418 \$MD_SPEED_THRESHOLD_MIN (n_{min} for ' $n_{act} < n_{min}$ ' message)

DB31, ... DBX94.5 ($|n_{act}| < n_x$)

This signal indicates that the actual speed $|n_{act}|$ is lower than the set threshold speed n_x :

MD1417 \$MD_SPEED_THRESHOLD_X (n_x for ' $n_{act} < n_x$ ' message)

DB31, ... DBX94.6 ($n_{act} = n_{set}$)

An indication on the the PLC states that the actual speed n_{act} has reached the new setpoint allowing for the tolerance band set in drive machine data:

MD1426 \$MD_SPEED_DES_EQ_ACT_TOL (tolerance band for ' $n_{set} = n_{act}$ ' message)
and that it is within the tolerance band.

1.3 Functions

1.3.1 Screen settings

Contrast, monitor type, foreground language, and display resolution to take effect after system startup can be set in the operator panel front machine data.

Contrast

MD9000 \$MM_LCD_CONTRAST (contrast)

For slimline operator panel fronts with a **monochrome** LCD, the contrast to be applied following system startup can be set.

There are 16 different contrast settings (0: dark, 15: light).

Monitor type

MD9001 \$MM_DISPLAY_TYPE (monitor type)

Indicate the relevant monitor type for optimum color matching.

Foreground language

MD9003 \$MM_FIRST_LANGUAGE (foreground language)

In the case of SINUMERIK 840D sl, 2 languages are available simultaneously. The foreground language can be used to set the language to be displayed following control ramp-up.

The language can be changed in the DIAGNOSTICS operating area on the HMI user interface. Once the control has ramped up, the foreground language will be restored.

Display resolution

MD9004 \$MM_DISPLAY_RESOLUTION (display resolution)

The number of places after the decimal point for the position display of the axes is defined in the display resolution. The position display consists of max. 12 characters including sign and decimal point. The number of digits after the decimal point can be set to between 0 and 5.

The default setting for the number of digits after the decimal point is 3, corresponding to a display resolution of 10⁻³ [mm] or [degrees].

REFRESH suppression

MD10131 \$MN_SUPPRESS_SCREEN_REFRESH (screen refresh in case of overload)

Default setting for screen-refresh strategy with high NC utilization:

- Value 0: Refresh of current values is suppressed in **all channels**.
- Value 1: Refresh of current values is suppressed in **time-critical channels**.
- Value 2: Refresh of current values is **never** suppressed.

1.3.2 Settings for involute interpolation - only 840D sl

Introduction

The involute of the circle is a curve traced out from the end point on a "piece of string" unwinding from the curve. Involute interpolation allows trajectories along an involute.

Figure 1-6 Involute (unwound from base circle)

Programming

A general description of how to program involute interpolation can be found in:

References:

/PG/ Programming Manual Fundamentals

In addition to the programmed parameters, machine data are relevant in two instances of involute interpolation; these data may need to be set by the machine manufacturer/end user.

Accuracy

If the programmed end point does not lie exactly on the involute defined by the starting point, interpolation takes place between the two involutes defined by the starting and end points (see illustration below).

The maximum deviation of the end point is determined by the machine data:

MD21015 \$MC_INVOLUTE_RADIUS_DELTA(end point monitoring for involute)

Figure 1-7 MD21015 specifies the max. permissible deviation

Limit angle

If AR is used to program an involute leading to the base circle with an angle of rotation that is greater than the maximum possible value, an alarm is output and program execution aborted.

Figure 1-8 Limited angle of rotation towards base circle

The alarm display can be suppressed using the following parameter settings:

MD21016 \$MC_INVOLUTE_AUTO_ANGLE_LIMIT = TRUE (automatic angle limitation for involute interpolation)

The programmed angle of rotation is then also limited automatically and the interpolated path ends at the point at which the involute meets the base circle. This, for example, makes it easier to program an involute, which starts at a point outside the base circle and ends directly on it.

Tool radius compensation

2 1/2 D tool-radius compensation is the only tool-radius compensation function permitted for involutes. If 3D tool-radius compensation is active (both circumferential and face milling), when an involute is programmed, machining is interrupted with alarm 10782.

With 2 1/2 D tool-radius compensation, the plane of the involute must lie in the compensation plane. or else alarm 10781 will be generated. It is however permissible to program an additional helical component for an involute in the compensation plane.

Dynamic response

Involutes that begin or end on the base circle have an infinite curvature at this point. To ensure that the velocity is adequately limited at this point when tool-radius compensation is active, without reducing it too far at other points, the "Velocity limitation profile" function must be activated:

MD28530 \$MC_MM_PATH_VELO_SEGMENTS > 1 (number of memory elements for limiting the path velocity)

A setting of 5 is recommended. This setting need not be made if only involute sections are used, which have radii of curvature that change over a relatively small area.

1.3.3 Activate DEFAULT memory

GUD start values

The DEF... / REDEF... NC commands can be used to assign default settings to global user data (GUD). These default settings must be permanently stored in the system if they are to be available after certain system states (e.g. RESET).

The memory space for this is taken from the memory area that was assigned via the machine data:

MD18150 \$MM_GUD_VALUES_MEM (number of additional parameters according to MD18170)

The setting for activating the stored default values is made in machine data:

MD11270 \$MN_DEFAULT_VALUES_MEM_MASK (activation default values for NC language elements)

References:

/FB1/ Function Manual Basic Functions; S7: "Memory Configuration"

/PGA/ Programming Manual Job Planning

1.3.4 Read/write PLC variable

High-speed data channel

For high-speed exchange of information between the PLC and NC, a memory area is reserved in the communications buffer on these modules (dual-port RAM). Variables of any type (I/O, DB, DW, flags) may be exchanged within this memory area.

The PLC accesses this memory using 'Function Calls' (FC) while the NCK uses '\$ variables'.

Organization of memory area

The user's programming engineer (NCK and PLC) is responsible for organizing (structuring) this memory area.

Every storage position in the memory can be addressed provided that the limit is selected according to the appropriate data format (i.e. a DWORD for a 4-byte limit, a WORD for a 2-byte limit, etc.).

The memory is accessed via the data type and the position offset within the memory area.

Access from NC

To allow the NC to access PLC variables (from a part program) quickly, \$ variables are provided in the NCK. The PLC uses a function call (FC) to read and write \$ variables. Data are transferred to and from the NCK immediately.

\$ variables can be accessed (by the NCK) during preprocessing and in synchronized actions.

Data type information is determined by the \$ variable data type, the position index is specified as an array index (in bytes).

The following \$ variables are available:

\$A_DBB	Data byte (8 bits)
\$A_DBW	Data word (16 bits)
\$A_DBD	Data double word (32 bits)
\$A_DBR	Real data (32 bits)

Ranges of values

\$A_DBB(n)	$\leq x \leq 255$
\$A_DBW(n)	$-32768 \leq x \leq 3276$
\$A_DBD(n)	$-2147483648 \leq x \leq 2147483647$

Access from PLC

The PLC uses function calls (FC) to access the memory. These FCs ensure that data are read and written in the DPR immediately, i.e. not just at the beginning of the PLC cycle. FCs receive data type information and the position offset as parameters.

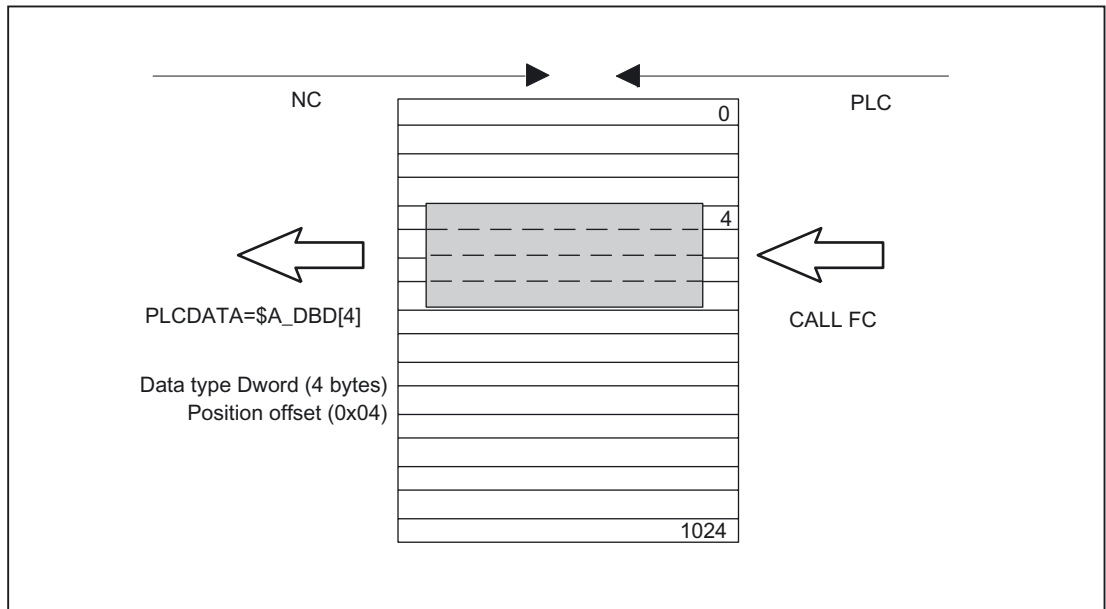

Figure 1-9 Communications buffer (DPR) for NC/PLC communication

Supplementary conditions

- The user's programming engineer (NCK and PLC) is responsible for organizing the DPR memory area. No checks are made for inconsistencies in the configuration.
- A total of 1024 bytes are available in the input and output directions.
- Single-bit operations are not supported and must be linked back to byte operations by the user (programming engineer).
- Since the contents of variables are manipulated directly in the communications buffer, the user must remember that intermediate changes in values occur as a result of multiple access operations where a variable is evaluated several times or when variables are linked (i.e. it may be necessary to store values temporarily in local variables or R parameters or to set up a semaphore).
- The user's programming engineer is responsible for coordinating access operations to the communications buffer from different channels.
- Data consistency can be guaranteed only for access operations up to 16 bits (byte and word). The user's programming engineer is responsible for ensuring consistent transmission of 32-bit variables (double and real). A simple semaphore mechanism is provided in the PLC for this purpose.

- The PLC stores data in 'Little Endian' format in the DPR.
- Values transferred with \$A_DBR are subject to data conversion and hence to loss of accuracy. The data format for floating-point numbers is DOUBLE (64 bits) on the NCK, but only FLOAT (32 bits) on the PLC. The format used for storage in the dual-port RAM is FLOAT. Conversion takes place respectively before/after storage in the dual-port RAM.

If a read/write access is made from the NCK to a variable in the dual-port RAM, the conversion is performed twice. It is impossible to prevent differences between read and written values because the data are stored in both formats.

Example

Bypassing the problem by means of comparison on "EPSILON" (minor deviation)

Block number	Program code
N10	DEF REAL DBR
N12	DEF REAL EPSILON = 0.00001
N20	\$A_DBR[0]=145.145
N30	G4 F2
N40	STOPRE
N50	DBR=\$A_DBR[0]
N60	IF (ABS(DBR/145.145-1.0) < EPSILON) GOTOF ENDE
N70	MSG ("error")
N80	M0
N90	END:
N99	M30

Activation

The maximum number of simultaneously writable output variables is adjustable via: MD28150 \$MC_MM_NUM_VDIVAR_ELEMENTS (number of elements for writing PLC variables)

Example

A WORD is to be transferred from the PLC to the NC.

The position offset within the NCK input (PLC output area) should be the fourth byte. The position offset must be a whole-number multiple of the data width.

- Writing from PLC:

Program code (extract)	Comment
. . .	
CALL FC21 (
Enable :=M10.0,	;if TRUE, then FC21 active
Funct :=B#16#4,	
S7Var :=P#M 104.0 WORD1,	
IVAR1 :=04,	

1.3 Functions

Program code (extract)	Comment
IVAR2 :=-1, Error :=M10.1, ErrCode :=MW12); . . .)	

- Reading in part program

Program code (extract)	Comment
. . . PLCDATA = \$A_DBW[4]; . . .	//Read a word

Behavior during POWER ON, block search

The DPR communications buffer is initialized during "POWER ON".

During a "block search", the PLC variable outputs are collected and transferred to the DPR communications buffer with the approach block (analogous to writing of analog and digital outputs).

Other status transitions have no effect in this respect.

1.3.5 Access protection via password and keyswitch

1.3.5.1 Access protection via password and keyswitch

Access authorization

Access to functions, programs and data is user-oriented and controlled via 8 hierarchical protection levels. These are subdivided into:

- Password levels for Siemens, machine manufacturer and end user
- Keyswitch positions for end user

Multi-level security concept

A multi-level security concept to regulate access rights is available in the form of password levels and keyswitch settings.

Protection level	Type	User	Access to (examples)
0	Password	Siemens	All functions, programs and data
1	Password	Machine manufacturer: Development	defined functions, programs and data; for example: entering options

Protection level	Type	User	Access to (examples)
2	Password	Machine manufacturer: Startup engineer	defined functions, programs and data; for example: Bulk of machine data
3	Password	End user: Service	Assigned functions, programs and data
4	Keyswitch position 3	End user: Programmer, machine setter	less than the protection level 0 to 3; established by the machine manufacturer or end user
5	Keyswitch position 2	End user: Skilled operator without programming knowledge	less than the protection level 0 to 3; established by the end user
6	Keyswitch position 1	End user: Trained operator without programming knowledge	Example: Program selection only, tool wear entry, and work offset entry
7	Keyswitch position 0	End user: Semi-skilled operator	Example: no inputs and program selection possible, only machine control panel operable

Access features

- Protection level 0 provides the greatest number of access rights, protection level 7 the least.
- If certain access rights are granted to a protection level, these protection rights automatically apply to any higher protection levels.
- Conversely, protection rights for a certain protection level can only be altered from a higher protection level.
- Access rights for protection levels 0 to 3 are permanently assigned by Siemens and cannot be altered (default).
- Access rights can be set by querying the current keyswitch positions and comparing the passwords entered. When a password is entered it overwrites the access rights of the keyswitch position.
- Options can be protected on each protection level. However, option data can only be entered in protection levels 0 and 1.
- Access rights for protection levels 4 to 7 are only suggestions and can be altered by the machine tool manufacturer or end user.

1.3.5.2 Password

Set password

The password for a protection level (0 – 3) is entered via the HMI user interface.

Example:

DIAGNOSTIC operating area, softkey: SET PASSWORD

References:

Commissioning Manual SINUMERIK 840D sl base software and HMI sl

Delete password

Access rights assigned by means of setting a password remain effective until they are explicitly revoked by deleting the password.

Example:

DIAGNOSTIC operating area, softkey: DELETE PASSWORD

References:

Commissioning Manual SINUMERIK 840D sl base software and HMI sl

Note:

Access rights and password status (set/deleted) are not affected by POWER OFF/ON!

Maximum number of characters

A password may contain up to eight characters. We recommend that you confine yourself to the characters available on the operator panel front when defining the password. Where a password consists of less than eight characters, the additional characters are interpreted as blanks.

Defaults

The following default passwords are defined for protection levels 1 to 3:

- Protection level 1: SUNRISE
- Protection level 2: EVENING
- Protection level 3: CUSTOMER

Note

Following NC-CPU ramp-up in commissioning mode (NCK commissioning switch: position 1) the passwords for protection levels 1 – 3 are reset to the default settings. For reasons of data protection, we strongly recommend that you change the default settings.

1.3.5.3 Keyswitch settings (DB10, DBX56.4 to 7)

Key switch

The keyswitch has four positions, to which protection levels 4 to 7 are assigned. The keyswitch comprises a number of keys in a variety of colors, which can be set to different switch positions.

Switch position	Retraction pos.	DB10, DBB56	Protection level
Position 0 	-	Bit 4	7
Position 1 	0 or 1 black key	Bit 5	6
Position 2 	0 or 1 or 2 green key	Bit 6	5
Position 3 	0 or 1 or 2 or 3 red key	Bit 7	4

Figure 1-10 Switch positions 0 to 3

Switch positions

Switch position 0 has the most restricted access rights. Switch position 3 has the least restricted access rights.

DB10, DBX56.4 / .5 / .6 / .7 (switch positions 0 / 1 / 2 / 3)

Machine-specific enables for access to programs, data and functions can be assigned to the switch positions. For detailed information, please refer to:

References

/IAM/ Startup CNC Part 2 (HMI); Access Protection

Default settings via the PLC user program

The keyswitch switch positions are transferred to the NC/PLC interface via the basic PLC program. The corresponding interface signals can be modified via the PLC user program. In this context, from the point of view of the NC, only one switch position should ever be active, i.e., the corresponding interface signal set to 1. If, from the point of view of the NC, a number of switch positions are active at the same time, switch position 3, i.e., the keyswitch position with the least restricted access rights, will be activated internally by the NC.

1.3.5.4 Parameterizable protection levels

Parameterizable protection level

The parameter level can be freely parameterized for a variety of functions and data areas. The protection level is set via operator-panel machine data, designated as follows:

\$MM_USER_CLASS_<Function_DataArea>

Examples:

\$MM_USER_CLASS_READ_TOA	Read tool offsets
\$MM_USER_CLASS_WRITE_TOA	Write tool offsets
\$MM_USER_CLASS_READ_PROGRAM	Read part programs
\$MM_USER_CLASS_WRITE_PROGRAM	Write/edit part programs

Default values

On delivery or following standard commissioning, with very few exceptions, the default value for the protection level will be set to 7, i.e. the lowest protection level.

1.4 Examples

Parameter set changeover

A parameter-set changeover is performed to change the position-control gain (servo gain factor) for machine axis X1 from $v = 4.0$ to $K_v = 0.5$.

Preconditions

The parameter set changeover must be enabled by the machine data:

MD35590 \$MA_PARAMSET_CHANGE_ENABLE [AX1] = 1 or 2 (parameter set change possible)

The 1st parameter set for machine axis X1 is set, in accordance with machine data with index "0" NC/PLC interface:

DB31, ... DBX9.0 - DBX9.2 = 0 (controller parameter set)

Parameter-set-dependent machine data

Parameter-set-dependent machine data are set as follows:

Machine data	Comment
MD32200 \$MA_POSCTRL_GAIN [0, AX1] = 4.0	Servo gain setting for parameter set 1
MD32200 \$MA_POSCTRL_GAIN [1, AX1] = 2.0	Servo gain setting for parameter set 2
MD32200 \$MA_POSCTRL_GAIN [2, AX1] = 1.0	Servo gain setting for parameter set 3
MD32200 \$MA_POSCTRL_GAIN [3, AX1] = 0.5	Servo gain setting for parameter set 4
MD32200 \$MA_POSCTRL_GAIN [4, AX1] = 0.25	Servo gain setting for parameter set 5
MD32200 \$MA_POSCTRL_GAIN [5, AX1] = 0.125	Servo gain setting for parameter set 6
MD31050 \$MA_DRIVE_AX_RATIO_DENOM [0, AX1] = 3	Denominator load gearbox for parameter set 1
MD31050 \$MA_DRIVE_AX_RATIO_DENOM [1, AX1] = 3	Denominator load gearbox for parameter set 2
MD31050 \$MA_DRIVE_AX_RATIO_DENOM [2, AX1] = 3	Denominator load gearbox for parameter set 3
MD31050 \$MA_DRIVE_AX_RATIO_DENOM [3, AX1] = 3	Denominator load gearbox for parameter set 4
MD31050 \$MA_DRIVE_AX_RATIO_DENOM [4, AX1] = 3	Denominator load gearbox for parameter set 5
MD31050 \$MA_DRIVE_AX_RATIO_DENOM [5, AX1] = 3	Denominator load gearbox for parameter set 6
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA [0, AX1] = 5	Counter load gearbox for parameter set 1
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA [1, AX1] = 5	Counter load gearbox for parameter set 2
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA [2, AX1] = 5	Counter load gearbox for parameter set 3
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA [3, AX1] = 5	Counter load gearbox for parameter set 4
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA [4, AX1] = 5	Counter load gearbox for parameter set 5
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA [5, AX1] = 5	Counter load gearbox for parameter set 6
MD35130 \$MA_AX_VELO_LIMIT [0...5, AX1]	Setting for each parameter set*)
MD32800 \$MA_EQUIV_CURRCTRL_TIME [0..5, AX1]	Setting for each parameter set*)
MD32810 \$MA_EQUIV_SPEEDCTRL_TIME [0..5, AX1]	Setting for each parameter set*)
MD32910 \$MA_DYN_MATCH_TIME [0...5, AX1]	Setting for each parameter set*)
*) The appropriate line must be specified separately for each parameter set according to the applicable syntax rules.	

Changeover

In order to switch over the position-control gain, the PLC user program selects the 4th parameter set for machine axis X1.

- Request by PLC user program:
DB31, ... DBX9.0 – DBX9.2 = 3 (parameter set servo)
 - A request to change over to the 4th parameter set is sent for machine axis AX1.
 - The parameter set is changed over once a delay has elapsed.
 - Parameter set 4 is now active, in accordance with machine data with index "3"
- Feedback by NC:
DB31, ... DBX69.0 – DBX69.2 = 3 (parameter set servo)
 - The NC confirms/acknowledges the parameter-set changeover.

1.5 Data lists

1.5.1 Machine data

1.5.1.1 Display machine data

Number	Identifier: \$MM_	Description
SINUMERIK Operate		
9000	LCD_CONTRAST	Contrast
9001	DISPLAY_TYPE	Monitor type
9004	DISPLAY_RESOLUTION	Display resolution
9008	KEYBOARD_TYPE	Keyboard type (0: OP, 1: MFII/QWERTY)
9009	KEYBOARD_STATE	Shift behavior of keyboard during booting
9010	SPIND_DISPLAY_RESOLUTION	Display resolution for spindle values
9011	DISPLAY_RESOLUTION_INCH	Display resolution for INCH_system of units
9012	ACTION_LOG_MODE	Set action mode for action log
9020	TECHNOLOGY	Basic configuration for simulation and free contour programming

A3: Axis monitoring, protection zones

2.1 Brief description

2.1.1 Axis monitoring functions

Function

Comprehensive monitoring functions are present in the control for protection of people and machines:

- Contour monitoring
- Position monitoring
- Zero-speed monitoring
- Clamping monitoring
- Speed-setpoint monitoring
- Actual-velocity monitoring
- Measuring System monitoring
- Limit switches-monitoring
- Monitoring of the working area limitation

2.1.2 Protection zones

Function

With the help of protection zones, elements of the machine (e.g. spindle chuck, tool changer, tool holder, tailstock, movable probe, etc.) and the workpiece can be protected against collisions.

During automatic execution of part programs in the AUTOMATIC or MDA mode, the NC checks at the start of every part-program block whether a collision between protection zones can occur upon moving along the programmed path.

After manual deactivation of an active protection zone, the zone can be entered. After leaving the protection zone, the protection zone automatically becomes active again.

The definition, activation and deactivation of protection zones takes place via part program instructions.

2.2 Axis monitoring

2.2.1 Contour monitoring

2.2.1.1 Contour error

Contour errors are caused by signal distortions in the position control loop.

Signal distortions can be linear or nonlinear.

Linear signal distortions

Linear signal distortions are caused by:

- Speed and position controller not being set optimally
- Different servo gain factors of the feed axes involved in creating the path

With the same servo gain factor for two linear-interpolated axes, the actual position follows the set position along the same path but with a time delay. With different servo gain factors, a parallel offset arises between the set and actual path.

- Unequal dynamic response of the feed drives

Unequal drive dynamic responses lead to path deviations especially on contour changes. Circles are distorted into ellipses by unequal dynamic responses of the two feed drives.

Nonlinear signal distortions

Nonlinear signal distortions are caused by:

- Activation of the current limitation within the machining area
- Activation of the limitation of the set speed
- Backlash within and/or outside the position control loop

When traversing a circular path, contour errors occur primarily due to the reversal error and friction.

During movement along straight lines, a contour error arises due to a reversal error outside the position control loop, e.g. due to a tilting milling spindle. This causes a parallel offset between the actual and the set contour. The shallower the gradient of the straight line, the larger the offset.

- Nonlinear friction behavior of slide guides

2.2.1.2 Following error monitoring

Function

In control engineering terms, traversing along a machine axis always produces a certain following error, i.e., a difference between the set and actual position.

The following error that arises depends on:

- Position control loop gain
MD32200 \$MA_POSCTRL_GAIN (servo gain factor)
- Maximum acceleration
MD32300 \$MA_MAX_AX_ACCEL (Maximum axis acceleration)
- Maximum velocity
MD32000 \$MA_MAX_AX_VELO (maximum axis velocity)
- With activated feedforward control: Precision of the path model and the parameters:
MD32610 \$MA_VELO_FFW_WEIGHT (factor for the velocity feedforward control)
MD32800 \$MA_EQUIV_CURRCTRL_TIME (Equivalent time constant current control loop for feedforward control)
MD32810 \$MA_EQUIV_SPEEDCTRL_TIME (equivalent time constant speed control loop for feedforward control)

In the acceleration phase, the following error initially increases when traversing along a machine axis. After a time depending on the parameterization of the position control loop, the following error then remains constant in the ideal case. Due to external influences, more or less large fluctuations in the following error always arise during a machining process. To prevent these fluctuations in the following error from triggering an alarm, a tolerance range within which the following error may change must be defined for the following-error monitoring:

MD36400 \$MA_CONTOUR_TOL (Contour monitoring tolerance range)

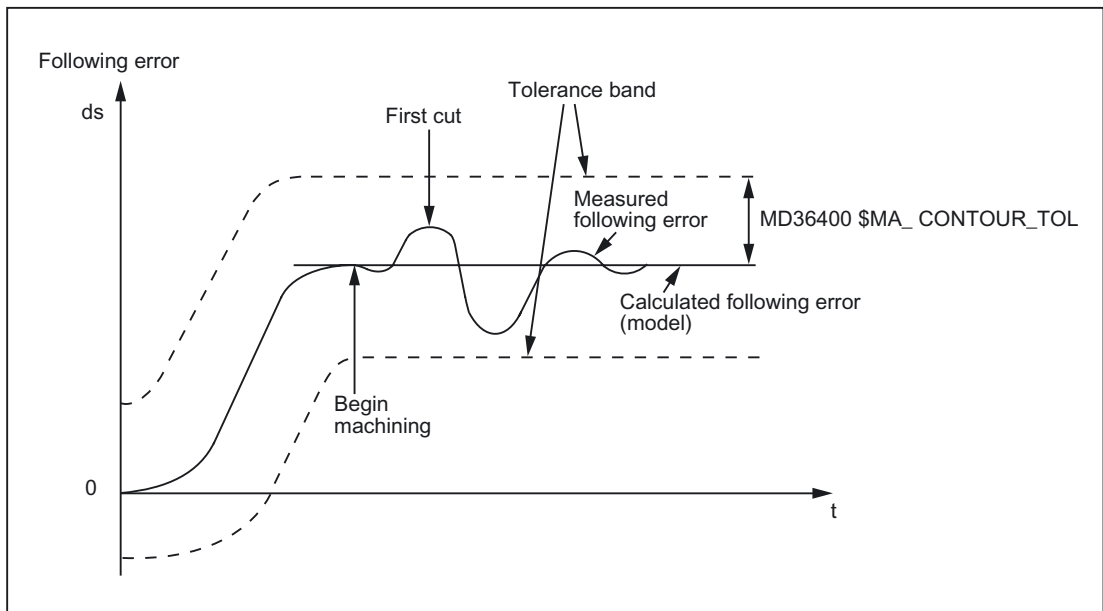

Figure 2-1 Following-Error Monitoring

Effectivity

The following-error monitoring only operates with active position control and the following axis types:

- Linear axes with and without feedforward control
- Rotary axes with and without feedforward control
- Position-controlled spindles

Fault

If the configured tolerance limit is exceeded, the following alarm appears:

25050 "Axis <Axis identifier> Contour monitoring"

The affected axis/spindle is stopped via the configured braking ramp in follow-up mode:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME

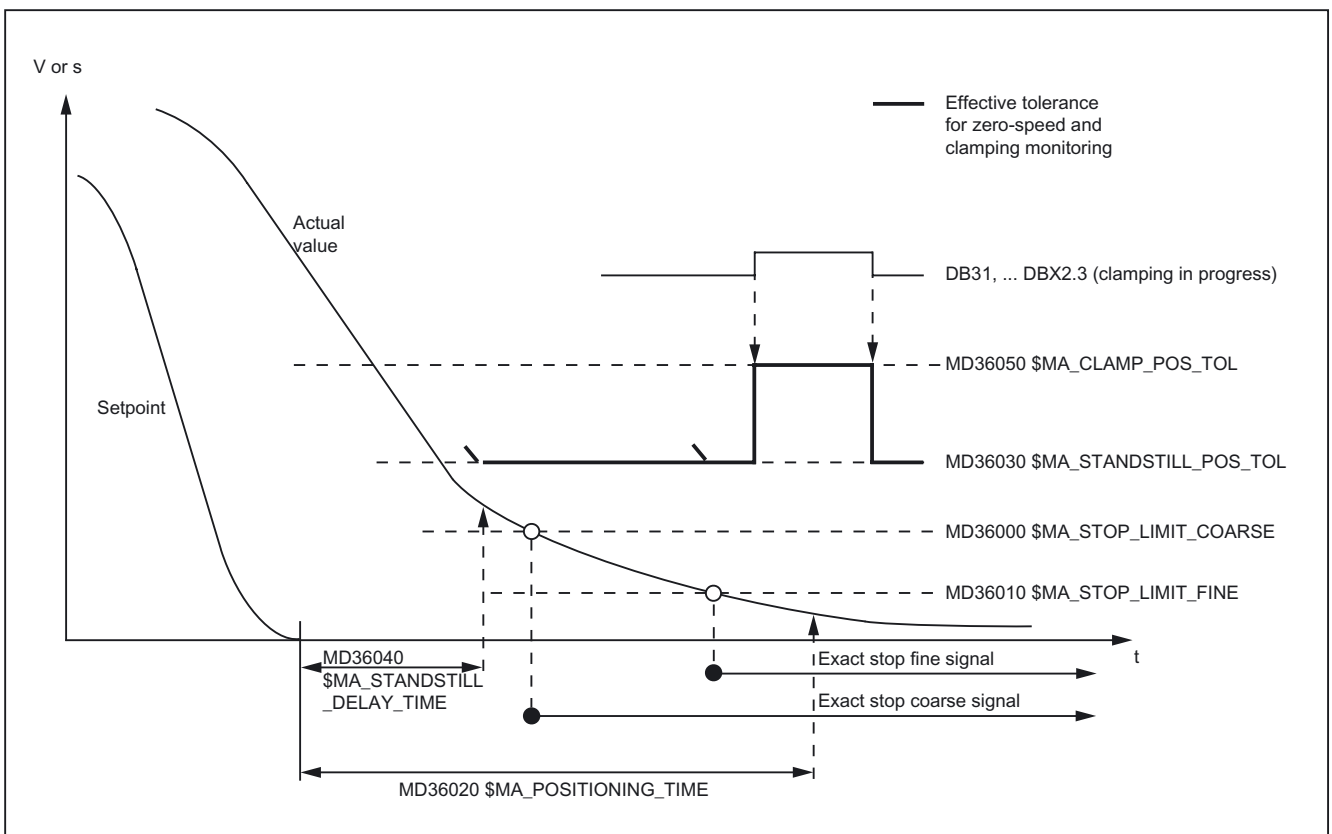

(Maximum time for braking ramp when an error occurs)

2.2.2 Positioning, zero speed and clamping monitoring

2.2.2.1 Correlation between positioning, zero-speed and clamping monitoring

Overview

The following overview shows the correlation between the positioning, zero speed and clamping monitoring functions:

2.2.2.2 Positioning monitoring

Function

At the end of a positioning operation:

- Set velocity = 0 **AND**
- DB31, ... DBX64.6/64.7 (motion command minus/plus) = 0

checks the position monitoring to ensure that the following error of every participating machine axis is smaller than the exact-stop fine tolerance during the delay time.

MD36010 \$MA_STOP_LIMIT_FINE (exact stop fine)

2.2 Axis monitoring

MD36020 \$MA_POSITIONING_TIME (delay time exact stop fine)

After reaching "Exact stop fine", the position monitoring is deactivated.

Note

The smaller the exact stop fine tolerance is, the longer the positioning operation takes and the longer the time until block change.

Rules for MD setting

MD36010 \$MA_STOP_LIMIT_FINE	MD36020 \$MA_POSITIONING_TIME
large	can be selected relatively short
small	must be selected relatively long

MD32200 \$MA_POSCTRL_GAIN (servo gain factor)	MD36020 \$MA_POSITIONING_TIME
small	must be selected relatively long
large	can be selected relatively short

Effectivity

The position monitoring only operates with active position control and the following axis types:

- Linear axes
- Rotary axes
- Position-controlled spindles

Fault

If the configured position-monitoring time is exceeded, the following alarm appears:

25080 "Axis <Axis identifier> Position monitoring"

The affected axis is stopped via the configured braking ramp in follow-up mode:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME
(Maximum time for braking ramp when an error occurs)

2.2.2.3 Zero speed monitoring

Function

At the end of a positioning operation:

- Set velocity = 0 **AND**
- DB31, ... DBX64.6/64.7 (motion command minus/plus) = 0

checks the zero-speed monitoring to ensure that the following error of every participating machine axis is smaller than the standstill tolerance during the delay time.

MD36040 \$MA_STANDSTILL_DELAY_TIME (Zero-speed monitoring delay time)

MD36030 \$MA_STANDSTILL_POS_TOL (standstill tolerance)

After reaching the required exact-stop state, the positioning operation is completed:

DB31, ... DBX60.6/60.7 (position reached with exact stop coarse/fine) = 1

The position-monitoring function is deactivated and is replaced by the zero-speed monitoring.

Zero-speed monitoring monitors the adherence to the standstill tolerance. If no new travel request is received, the machine axis must not depart from the standstill tolerance.

Effectivity

The zero-speed monitoring only operates with active position control and the following axis types:

- Linear axes
- Rotary axes
- Position-controlled spindles

Fault

If the delay time and/or the standstill tolerance is exceeded, the following alarm appears:

25040 "Axis <Axis identifier> Zero-speed monitoring"

The affected axis is stopped via the configured braking ramp in follow-up mode:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME

(Maximum time for braking ramp when an error occurs)

2.2.2.4 Exact stop and standstill tolerance dependent on the parameter set

Common factor for position tolerances

For adaptation to different machining situations and/or axis dynamics, e.g.,:

- Operating state A: High precision, long machining time
- Operating state B: Lower precision, shorter machining time
- Changing of the mass relationships after gear change

the positioning tolerances:

- MD36000 \$MA_STOP_LIMIT_COARSE (exact stop coarse)
- MD36010 \$MA_STOP_LIMIT_FINE (exact stop fine)
- MD36030 \$MA_STANDSTILL_POS_TOL (standstill tolerance)

can be weighted with a common factor depending on the parameter set:

MD36012 \$MA_STOP_LIMIT_FACTOR (exact stop coarse/fine and standstill factor)

Because the factor applies in common for all three position tolerances, the relationship between the values remains constant.

2.2.2.5 Clamping monitoring

Clamping monitoring

For machine axes that are mechanically clamped upon completion of a positioning operation, larger motions can result from the clamping process (> standstill tolerance). As a result, zero-speed monitoring is replaced by clamping monitoring during the clamping process.

Clamping monitoring monitors the adherence to the configured clamping tolerance:

MD36050 \$MA_CLAMP_POS_TOL (Clamping tolerance)

Activation

The clamping monitoring is activated by the following interface signal:

DB31, ... DBX2.3 (clamping in progress)

Note

The clamping monitoring is not active in "follow-up mode" (DB31, ... DBX1.4 = 1).

Fault

If the clamping tolerance is exceeded, the following alarm appears:

26000 "Clamping monitoring"

The affected axis is stopped via the configured braking ramp in follow-up mode:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME

(Maximum time for braking ramp when an error occurs)

Automatic stopping for removal of the clamp

If a clamped axis must be traversed again in continuous-path mode, the NC stops the path motion for Look Ahead at the start of the motion block of the clamped axis until the clamped axis can once again be traversed. If the clamping is released before stopping, the path motion is not stopped.

Parameterization:

MD36052 \$MA_STOP_ON_CLAMPING = 'H01' (Special function for clamped axis)

Note

The NC detects whether an axis is clamped based on the "servo enable" state of the axis:

DB31, ... DBX2.2 = 0: no servo enable ⇒ axis is clamped

DB31, ... DBX2.2 = 1: servo enable ⇒ axis is not clamped

Prerequisites for the PLC user program

- The axis is always removed from the clamp when a travel command is pending.
- The following is always valid for the axis:
 - DB31, ... DBX2.2 (servo enable) = 0: Axis is clamped.
 - DB31, ... DBX2.2 (servo enable) = 1: Axis is not clamped.

The following image shows an example of the interface signals and states upon releasing of the axis clamp:

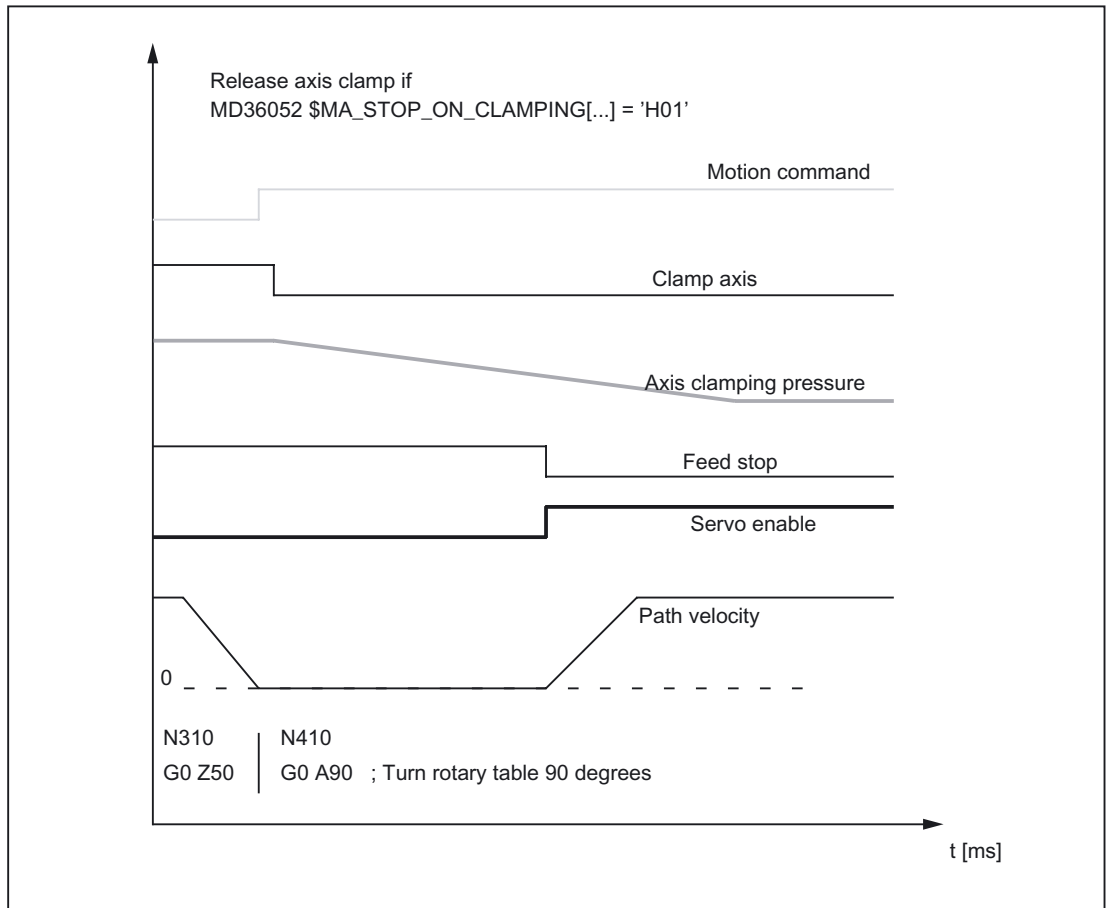

Figure 2-2 Release axis clamp if MD36052 \$MA_STOP_ON_CLAMPING = 'H01'

The part-program blocks N310 and N410 refer to the following programming example:

```

N100    G0 X0 Y0 Z0 A0 G90 G54 F500
N101    G641 ADIS=.1 ADISPOS=5
N210    G1 X10                                ; Edit
N220    G1 X5 Y20
N310    G0 Z50                                ; Retraction
N410    G0 A90                                ; Turn rotary table
N510    G0 X100                                ; Approach
N520    G0 Z2
N610    G1 Z-4                                ; Edit
N620    G1 X0 Y-20
    
```

Optimized releasing of the axis clamp via travel command

If a clamped axis is to be traversed in continuous-path mode, a travel command is issued for the clamped axis in the rapid traverse blocks ($G0$) immediately before the traversing block of the clamped axis. This way, the PLC user program can release the axis clamp again in time. (The travel command is set a maximum of two rapid travers blocks prior (including intermediate blocks) to retain the reference to the initiating part program block).

Parameter assignment:

MD36052 \$MA_STOP_ON_CLAMPING = 'H03' (Special function for clamped axis)

Prerequisites regarding the PLC Application programs

- The axis is removed from the clamp as soon as a travel command is pending.
- The axis may be removed from the clamp even if only during positioning ($G0$).

The following image shows an example of the interface signals and states upon releasing of the axis clamp:

Figure 2-3 Release axis clamp if MD36052 \$MA_STOP_ON_CLAMPING = 'H03'

Automatic stopping for setting of the clamp

If an axis is to be clamped in continuous-path mode, the NC stops the path motion before the next "Non-rapid traverse block" if the axis has not been clamped by then, i.e. the PLC has set the feedrate override value to zero.

Parameter assignment:

MD36052 \$MA_STOP_ON_CLAMPING = 'H04' (Special function for clamped axis)

Prerequisites regarding the PLC Application programs

- The axis is always clamped when no travel command is pending.
- The axis does not have to be clamped during positioning of the other axes.

It can be seen whether the axes are being positioned depending on whether rapid traverse (G0) is programmed.

The stop command is therefore not set immediately at the beginning of the block containing the axis, but at the beginning of the next machining block (traversing block, that is not traversed with rapid traverse).

- The axis is clamped if the feed rate override of a machining block is not equal to 0.

If the axis is clamped before the next machining block, i.e. the feedrate override is other than 0 again, no stop is generated.

The following image shows an example of the interface signals and states upon setting of the axis clamp. The part program blocks N410, N510, N520 and N610 refer to the schematic example under certain boundary conditions.

Figure 2-4 Set axis clamp if MD36052 \$MA_STOP_ON_CLAMPING = 'H04'

Constraints

Continuous-path mode

For the above-mentioned functions:

- Automatic stopping for releasing the clamps
- Optimized release of the axis clamp through traverse command
- Automatic stopping for setting the clamps

the "Look Ahead" function must be active.

Part-program blocks without path motion (e.g. M82/M83) interrupt continuous-path mode and thus also the "Look Ahead" function.

Example:

The part-program blocks N320 and N420 are inserted in the programming example used.

```

N100      G0 X0 Y0 Z0 A0 G90 G54 F500
N101      G641 ADIS=.1 ADISPOS=5
N210      G1 X10                                ; Edit
N220      G1 X5 Y20
N310      G0 Z50                                ; Retract
N320      M82                                    ; no path motion
N410      G0 A90                                ; Turn rotary table
N420      M83                                    ; no path motion
N510      G0 X100                               ; Approach
N520      G0 Z2
N610      G1 Z-4                                ; Edit
N620      G1 X0 Y-20

```

The function behaves as follows:

- MD36052 \$MA_STOP_ON_CLAMPING = 'H03'

No longer has an effect.

The travel command is set in Look Ahead mode only for blocks with active continuous-path mode. M82 generates a stop and thus interrupts the continuous-path mode. The Look Ahead stopping on N410 would not be necessary because stopping occurs anyway.

- MD36052 \$MA_STOP_ON_CLAMPING = 'H04'

Generates a stop irrespective of M83, which is executed as a function of "feedrate override 0%". The axis is thus stopped before the first machining block.

Note

MD36052 \$MA_STOP_ON_CLAMPING = 'H01' or 'H04'

Both functions can be used irrespective of the clamping of axes:

- MD36052 \$MA_STOP_ON_CLAMPING = 'H01'
Generates a Look Ahead stop for the path motion if no servo enable signal is active for the relevant axis.
- MD36052 \$MA_STOP_ON_CLAMPING = 'H04'
Generates a Look Ahead stop for the path motion if the feed rate overrate = 0% at the transition from the part-program blocks with rapid traverse to part-program blocks without rapid traverse.

Both functions ensure that the path motion in continuous-path mode is already stopped before the start of the relevant part-program block and not just within the part-program block.

Block-change criterion: Clamping tolerance

After activation of clamp monitoring:(DB31, ... DBX2.3 = 1) the block-change criterion for traversing blocks, in which the axis stops at the end of the block, no longer acts as the corresponding exact-stop condition but the configured clamping tolerance:

MD36050 \$MA_CLAMP_POS_TOL (clamping tolerance with interface signal "Clamping active")

Behavior upon releasing of the clamp

If the axis was moved by the clamping process, it is returned by the NC to the position setpoint after releasing of the clamp and setting of the servo enable state. Repositioning depends on whether "Follow-up mode" was activated for the axis:

Without follow-up mode:	Repositioning by position controller
With follow-up mode:	Repositioning by interpolator

See also interface signal:

DB31, ... DBX1.4 (follow-up mode)

Note

The following interface signals can be evaluated by the PLC user program as the criterion for activation of the "Follow-up mode":

DB31, ... DBX60.6 / 60.7 (position reached with exact stop coarse / fine)

2.2.3 Speed-setpoint monitoring

Function

The speed setpoint comprises:

- Speed setpoint of the position controller
- Speed setpoint portion of the feedforward control (with active feedforward control only)
- Dift compensation (only for drives with analog setpoint interface)

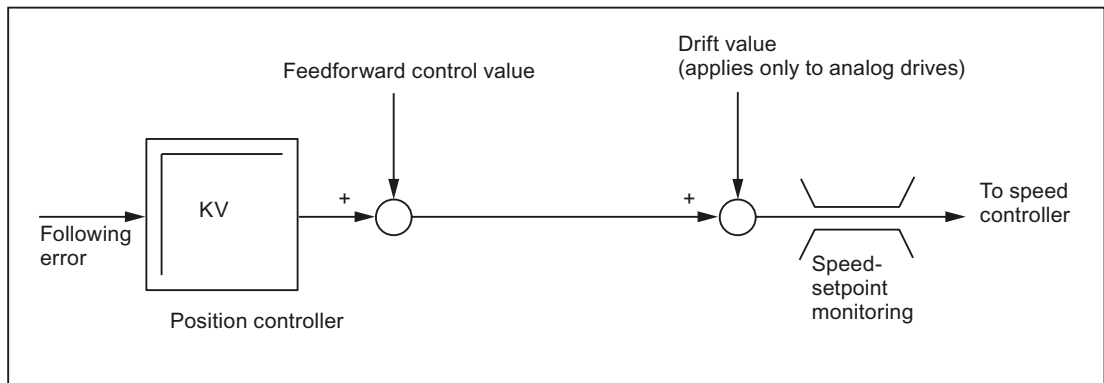

Figure 2-5 Speed setpoint calculation

The speed-setpoint monitoring ensures by limiting the control or output signal (10V for analog setpoint interface or rated speed for digital drives) that the physical limitations of the drives are not exceeded:

MD36210 \$MA_CTRLOUT_LIMIT (Maximum speed setpoint)

Figure 2-6 Speed setpoint limitation

Speed-setpoint monitoring delay

To prevent an error reaction from occurring in every speed-limitation instance, a delay time can be configured:

MD36220 \$MA_CTRLLOUT_LIMIT_TIME (Speed-setpoint monitoring delay)

Only if the speed limitation is required for longer than the configured time does the corresponding error reaction occur.

Effectivity

The speed-setpoint monitoring is only active for closed-loop position-controlled axes and cannot be deactivated.

Fault

If the configured delay time is exceeded, the following alarm appears:

25060 "Axis <Axis identifier> Speed-setpoint monitoring"

The affected axis is stopped via the configured braking ramp in follow-up mode:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME

(Maximum time for braking ramp when an error occurs)

Note

Upon reaching the speed-setpoint monitoring, the position feedback loop of the axis becomes non-linear due to the limitation. Contour errors result if the axis is involved in generating the contour.

2.2.4 Actual velocity monitoring

Function

The actual-velocity monitoring checks that the current actual velocity of a machine axis/spindle does not exceed the configured threshold:

MD36200 \$MA_AX_VELO_LIMIT (velocity-monitoring threshold)

The threshold should be 10-15% above the configured maximum velocity.

- For axes:

MD32000 \$MA_MAX_AX_VELO (maximum axis velocity)

- For spindles:

MD35110 \$MA_GEAR_STEP_MAX_VELO_LIMIT[n] (maximum speed of gear stage)

If you use this setting the speed will not normally exceed the velocity-monitoring threshold (exception: drive error).

Activation

The actual-velocity monitoring is activated as soon as the active measuring system returns valid actual values (encoder limit frequency not exceeded):

DB31, ... DBX1.5/1.6 (position measuring system 1/2)

Effectivity

The actual-velocity monitoring only operates with active position control and the following axis types:

- Linear axes
- Rotary axes
- Open loop controlled and position controlled spindles.

Fault

If the threshold is exceeded, the following alarm appears:

25030 "Axis <Axis identifier> Actual-velocity alarm limit"

The affected axis is stopped via the configured braking ramp in follow-up mode:

MD36610 \$MA_AX_EMERGENCY_STOP_TIME

(Maximum time for braking ramp when an error occurs)

2.2.5 Measuring-system monitoring (systems with PROFIBUS drives)

The NC has no direct access to the measuring-system hardware for systems with PROFIBUS drives and therefore measuring-system monitoring is mainly performed by the drive software.

References:

Drive Functions SINAMICS S120

/FBU/ SIMODRIVE 611 universal Function Manual

Encoder-limit-frequency monitoring

In the case of systems with PROFIBUS drives, encoder-limit-frequency monitoring is also performed in the NCK.

Zero-mark monitoring

PROFIBUS drives with incremental encoders

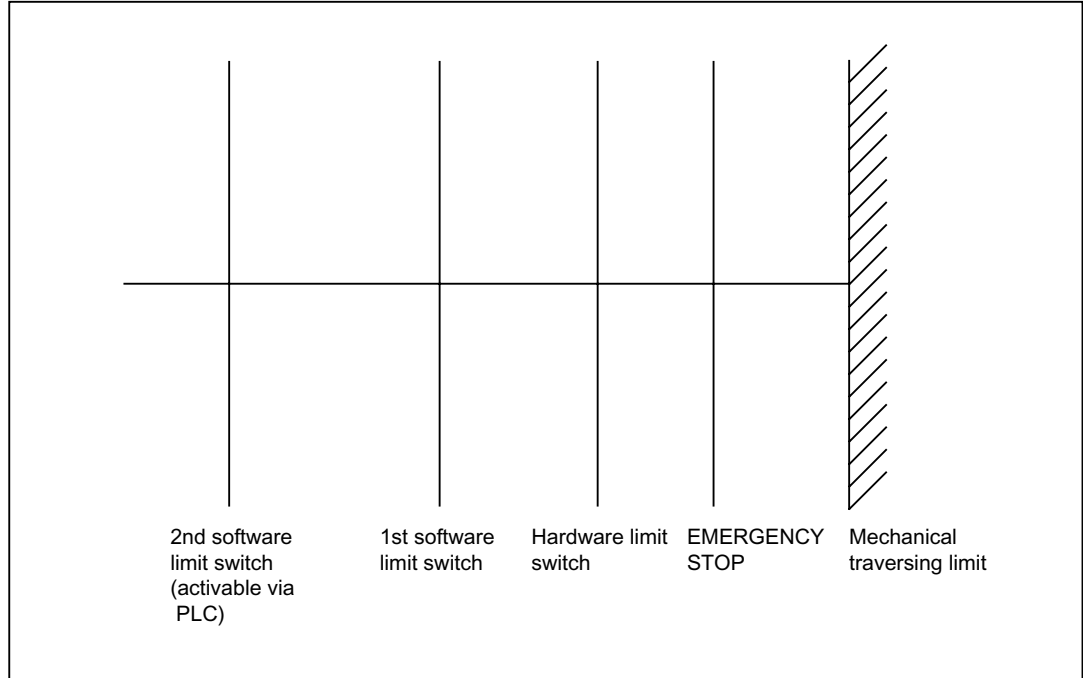

Zero-mark monitoring is performed by the drive software.

PROFIBUS drives with absolute encoders

The drive software performs the monitoring function, while the plausibility check is carried out in the NCK (as for SIMODRIVE 611D systems).

2.2.6 Limit switches-monitoring

Overview of the end stops and possible limit switch monitoring:

2.2.6.1 Hardware limit switches

Function

A hardware limit switch is normally installed at the end of the traversing range of a machine axis. It serves to protect against accidental overtravelling of the maximum traversing range of the machine axis while the machine axis is not yet referenced.

If the hardware limit switch is triggered, the PLC user program created by the machine manufacturer sets the corresponding interface signal:

DB 31, ... DBX12.0 / 12.1 = 1 (Hardware limit switch minus / plus)

Parameterization

The braking behavior of the machine axis upon reaching the hardware limit switch is configurable via the machine data:

MD36600 \$MA_BRAKE_MODE_CHOICE (Braking behavior on hardware limit switch)

Value	Significance
0	Braking with the configured axial acceleration
1	Rapid stop (set velocity = 0)

Effectivity

The hardware limit-switch monitoring is active after the control has ramped up in all modes.

Effect

Upon reaching the hardware limit switch, the following occurs:

- Alarm 21614 "Channel <Channel number> Axis <Axis identifier> Hardware limit switch <Direction>"
- The machine axis is braked according to the configured braking behavior.
- If the axis/spindle is involved in interpolation with other axes/spindles, these are also braked according to their configured braking behavior.
- The traversing keys of the affected machine axis are blocked based on the direction.

2.2.6.2 Software limit switch

Function

Software limit switches serve to limit the traversing range of a machine axis. Per machine axis and per traversing direction, two (1st and 2nd) software limit switches are available:

MD36100 POS_LIMIT_MINUS (1st software limit switch minus)

MD36110 POS_LIMIT_PLUS (1st software limit switch plus)

MD36120 POS_LIMIT_MINUS2 (2nd software limit switch minus)

MD36130 POS_LIMIT_PLUS2 (2nd software limit switch plus)

By default, the 1st software limit switch is active. The 2nd software limit switch can be activated for a specific direction with the PLC user program:

DB31, ... DBX12.2 / 12.3 (2nd software limit switch minus / plus)

Effectivity

The software limit switches are active:

- immediately after the successful referencing of machine axis.
- in all operating modes.

Constraints

- The software limit switches refer to the machine coordinate system.
- The software limit switches must be inside the range of the hardware limit switches.
- The machine axis can be moved to the position of the active software limit switch.

- **PRESET**
After use of the function `PRESET`, the software limit-switch monitoring is no longer active. The machine must first be re-referenced.
- **Endlessly rotating rotary axes**
No software limit-switch monitoring takes place for endlessly rotating rotary axes:
`MD30310 $MA_ROT_IS_MODULO == 1` (Modulo conversion for rotary axis and spindle)
Exception: Setup-rotary axes

Effects

Automatic operating modes (AUTOMATIC, MDA)

- Without transformation, without overlaid movement, unchanged software limit switch:
A part program block with a programmed traversing motion that would lead to overrunning of the software limit switch is not started.
- With transformation:
Different reactions occur depending on the transformation type:
 - Behavior as above.
 - or
 - The part program block with a programmed traversing motion that would lead to overrunning of the software limit switch is started. The affected machine axis stops at the active software limit switch. The other machine axes participating in the traversing motion are braked. The programmed contour is left during this process.
- With overlaid motion
The part program block with a programmed traversing motion that would lead to overrunning of the software limit switch is started. Machine axes that are traveling with overlaid motion or have traveled with overlaid motion stop at the active software limit switch in question. The other machine axes participating in the traversing motion are braked. The programmed contour is left during this process.

Manual operating modes

- JOG without transformation
The machine axis stops at the software limit switch position.
- JOG with transformation
The machine axis stops at the software limit switch position. Other machine axes participating in the traversing motion are braked. The preset path is left during this process.

General

- Changing of the software limit switch (1st ↔ 2nd software limit switch)

If the actual position of the machine axis after changing lies behind the software limit switch, it is stopped with the maximum permissible acceleration.

- Overrunning the software limit switch in JOG mode

If the position of the software limit switch is reached and renewed pressing of the traversing button should cause further travel in this direction, an alarm is displayed and the axis is not traversed farther:

Alarm 10621 "Channel <Channel number> Axis <Axis identifier> is at the software limit switch <Direction>"

2.2.7 Monitoring of the working area limitation

2.2.7.1 General

Function

The "working area limitation" function can be used to limit the traversing range of a channel's geometry and special axes to a permissible operating range. The function monitors compliance with working area limits both in AUTOMATIC mode and in JOG mode.

The following versions are available:

- Working area limitation in the Basic Coordinate System (BCS)

The traversing range limits are specified relative to the Basic Coordinate System.

- Working area limitation in the workpiece coordinate system (WCS) or adjustable zero system (AZS)

The traversing range limits are specified relative to the workpiece coordinate system or to the adjustable zero system.

The two types of monitoring are independent of each other. If they are both active at the same time, the traversing range limit which most restricts the access will take effect, depending on the direction of travel.

Reference point at the tool

Taking into account the tool data (tool length and tool radius) and therefore the reference point at the tool when monitoring the working area limitation depends on the status of the transformation in the channel:

- **Transformation inactive**

Without transformations during traversing motion with an active tool the position of the tool tip P is monitored, i.e. during the monitoring the tool length is considered automatically.

Consideration of the tool radius must be activated separately:

MD21020 \$MC_WORKAREA_WITH_TOOL_RADIUS (Consideration of the tool radius in the working area limitation)

- **Transformation active**

In the case of certain transformations the monitoring of the working area limitation may differ from the behavior without transformation:

- The tool length is a component of the transformation (\$MC_TRAFO_INCLUDES_TOOL_X = TRUE):

In this case the tool length is not considered, i.e. the monitoring refers to the tool carrier reference point.

- Transformation with change in orientation:

In the case of transformations with changes in orientation, monitoring is always based on the tool center point. MD21020 has no influence.

Note

The machine data \$MC_TRAFO_INCLUDES_TOOL_... is analyzed only in certain transformations. Condition for a possible evaluation is that the orientation of the tool with respect to the base coordinate system cannot be changed by the transformation. With standard transformations, the condition is only fulfilled for the "inclined axis" type of transformation.

Response

Automatic operating modes

- With / without transformation

The parts program block with a programmed traversing motion that would lead to overrunning of the working area limits is not executed.

- With superimposed motion

The axis, which would violate the working area limitation due to a superimposed motion, is braked with maximum acceleration and without jerk limits (`BRISK`), and will come to a stop in the position of the working area limitation. Other axes involved in the movement are braked according to current acceleration behavior (e.g. `SOFT`). The path correlation may be lost due to different braking accelerations (contour violation).

Manual operating modes

- JOG with / without transformation

The axis is positioned at the working area limitation and then stopped.

Power-up response

If an axis moves outside the permissible working area when activating the working area limits, it will be stopped promptly with the maximum permissible acceleration.

Overrunning of the working area limitation in JOG mode

In JOG mode, an axis is moved to no further than its working area limit by the control system. When the traverse button is pressed again, an alarm is displayed and the axis does not traverse any further.

Geo-axis replacement

Through the following machine data it is adjustable, whether during geometry axis change the active working area limitation is retained or deactivated:

MD10604 \$MN_WALIM_GEOAX_CHANGE_MODE = <value>

Value = 0: The working area limitation is deactivated during the geometry axis change.

Value = 1: The working area limitation remains activated during the geometry axis change.

2.2.7.2 Working area limitation in BKS

Application

Using the "working area limitation in BKS", the working area of a machine tool is limited so that the surrounding devices (e.g., tool revolver, measuring stations) are protected against damage.

Working area limits

The lower and upper working area limits of each axes are adjusted through setting data or programmed through part program instructions:

Working area limitation through setting data

The adjustments are done through the immediately effective axis-specific setting data:

SD43420 \$SA_WORKAREA_LIMIT_PLUS (Working area limitation plus)

SD43430 \$SA_WORKAREA_LIMIT_MINUS (Working area limitation minus)

Programmed working area limitation

The programming is done using the G commands:

G25 X... Y... Z... lower working area limitation

G26 X... Y... Z... upper working area limitation

Figure 2-7 Programmed working area limitation

The programmed working area limitation has priority and overwrites the values entered in SD43420 and SD43430.

Activation/deactivation

Working area limitation through setting data

The activation/deactivation of the working area limitation for each axis takes place in a direction-specific manner via the immediately effective setting data:

SD43400 \$SA_WORKAREA_PLUS_ENABLE (Working area limitation active in the positive direction)

SD43410 \$SA_WORKAREA_MINUS_ENABLE (Working area limitation active in the negative direction)

Value	Significance
0	The working area limitation in positive or negative direction is switched off .
1	The working area limitation in positive or negative direction is active .

Programmed working area limitation

Activation or deactivation of the overall "working area limitation in the BCS" is arranged via part program instructions:

<code>WALIMON</code>	Working area limitation ON
or	
<code>WALIMOF</code>	Working area limitation OFF

Changing the working area limitation

Working area limitation through setting data

HMI user interface: Operating area "Parameter"

- Automatic modes:
 - Changes: possible only in the RESET state
 - Effective: immediately
- Manual operating modes:
 - Changes: always possible
 - Effective: at the start of the next traversing motion

Programmed working area limitation

The working area limitation can be changed in the part program via: `G25` or `G26` <axis identifier> <value>

The change takes effect immediately.

New working area limitation values are retained after NC RESET and power on if the back-up process has been activated in the NCK's retentive data storage for SD43420 and SD43430:

```
MD10710 $MN_PROG_SD_RESET_SAVE_TAB[0] = 43420
```

```
MD10710 $MN_PROG_SD_RESET_SAVE_TAB[1] = 43430
```

Reset position

The reset position for the working area limitation (`WALIMON` or `WALIMOF`) is configurable via:

```
MD20150 $MC_GCODE_RESET_VALUES (RESET position of G groups)
```

2.2.7.3 Working area limitation in WKS/ENS

Application

The working area limitation in the workpiece coordinate system (WCS) or adjustable zero system (AZS) is mainly intended for defining working area limits in conventional lathes. This allows "stops" to be defined for the channel axes, thereby enabling workpiece-specific limits to be defined for the working area.

Working area limitation group

There are working area limitation groups available containing all the data which is of relevance to the working area limitation. As such, there is no need to write the working area limitations afresh every time while switching the transformation or the active frame, for example.

A working area limitation group comprises the following data:

- Working area limits for all channel axes
- A reference system, i.e. the coordinate system on which the working area limitations are based

The number of the working area limitation groups used is set in the machine data:

MD28600 \$MC_MM_NUM_WORKAREA_CS_GROUPS

Working area limits

Both the activation of the working area limitation and the working area limits for the individual channel axes are defined by the following channel-specific system variables:

\$AC_WORKAREA_CS_PLUS_ENABLE[<GN>, <AN>]	Activation of working area limitation in a positive traversing direction for axis <AN> in group <GN>
\$AC_WORKAREA_CS_LIMIT_PLUS[<GN>, <AN>]	Limit value in a positive traversing direction for axis <AN> in group <GN> Only effective if: ..._PLUS_ENABLE[<GN>, <AN>] = TRUE
\$AC_WORKAREA_CS_MINUS_ENABLE[<GN>, <AN>]	Activation of working area limitation in a negative traversing direction for axis <AN> in group <GN>
\$AC_WORKAREA_CS_LIMIT_MINUS[<GN>, <AN>]	Limit value in a negative traversing direction for axis <AN> in group <GN> Only effective if: ..._MINUS_ENABLE = TRUE

Parameters

- <GN> Number of the working area limitation group
<AN> Channel axis number

The definition is given by writing the system variables through the user interface or in the part program.

Selection of the reference system

The reference system for the group's working area limitations is selected by means of the channel-specific system variable:

\$AC_WORKAREA_CS_COORD_SYSTEM [WALimNo]

Value	Significance
1	Working area limitation based on the WCS
3	Working area limitation based on the AZS

Activation

The working area limitations for a working area limitation group are activated by means of the NC program command `WALCSn`, where n is the number of the working area limitation group:

`WALCS1` Activating working area limitation group No. 1
`WALCS2` Activating working area limitation group No. 2
 ...

Deactivation

Working area limitations are deactivated by the NC program command:

`WALCS` Deactivation of the working area limitations

Changing the working area limitation

- **Working area limits**

`$AC_WORKAREA_CS_PLUS_ENABLE[<GN>, <AN>]`
`$AC_WORKAREA_CS_LIMIT_PLUS[<GN>, <AN>]`
`$AC_WORKAREA_CS_MINUS_ENABLE[<GN>, <AN>]`
`$AC_WORKAREA_CS_LIMIT_MINUS[<GN>, <AN>]`

- Changes

The system variables can be changed at any time through the user interface and the part program.

- Effectivity

The changes take effect the next time the corresponding working area limitation group is selected.

- **Working area limitation groups**

- Changes

The working area limitation group can be changed at any time in the part program via the program commands `WALCS1 ... WALCS10`.

- Effectiveness

Changes are immediately effective.

Data storage and security

Data storage

The values of the system variables for the definition of the "working area limitations in WKS/ENS" are stored in the static NC memory.

Note

For the storage of the limiting values for the linear axes, the default setting is considered for the system of units (MD10240 \$MN_SCALING_SYSTEM_IS_METRIC).

Data backup

The values of the system variables can be saved in specific backup files:

Backup file	For the backup of:
_N_CHx_WAL	Values of the system variables for the channel x.
_N_COMPLETE_WAL	Values of the system variables for all channels.

Note

The values of the system variables for the definition of the "working area limitations in WKS/ENS" are also component of the file "_N_INITIAL_INI".

Effects

JOG mode

If in the JOG-mode several geometry axes are traversed simultaneously (e.g., using several handwheels) **and** a rotating frame is active between the base coordinate system and the reference coordinate system of the working area limitation (WCS or AZS), then a response of the monitoring leads to the fact that the movements of the involved geometry axes are continued in a straight line and stopped at the working area limits.

Reset response

The reset behavior or reset position of the working area limitation in the WCS/AZS can be set via the following machine data:

MD20150 \$MC_GCODE_RESET_VALUE[59] (reset position of G groups)

MD20152 \$MC_GCODE_RESET_MODE[59] (reset behavior of G groups)

- Certain working area limitation group as a reset position

MD20152 \$MC_GCODE_RESET_MODE[59] = 0

MD20150 \$MC_GCODE_RESET_VALUE[59] = n

A reset causes the activation of working area limitation group n in accordance with $WALCS_n$.

- Last working area limitation group active in the part program as a reset position

MD20152 \$MC_GCODE_RESET_MODE[59] = 1

2.3 Protection zones

2.3.1 General

Function

Protection zones are static or moveable in 2- or 3-dimensional ranges within a machine to protect machine elements against collisions.

The following elements can be protected:

- Permanent parts of the machine and attachments (e.g. tool-holding magazine, swiveling probe). Only the elements that can be reached by possible axis constellations are relevant.
- Moving parts belonging to the tool (e.g. tool, toolholder)
- Moving parts belonging to the workpiece (e.g. parts of the workpiece, clamping table, clamping shoe, spindle chuck, tailstock).

Protection zones are defined via part program instructions or system variables so that they completely surround the element to be protected. The activation and deactivation of protection zones also takes place via part program instructions.

Protection-zone monitoring by the NC is channel-specific, i.e. all the active protection zones of a channel monitor one another for collisions.

Definition of a protection zone

It is possible to define 2-dimensional or 3-dimensional protection zones as polygons with a maximum of ten corner points. The protection zones can also contain arc contour elements.

Polygons are defined in a previously defined plane.

Expansion in the third dimension can be limited between $-\infty$ to $+\infty$.

The following four cases are possible:

- Dimension of the protection zone from -1 to +1
- Dimension of the protection zone from -1 to upper limit
- Dimension of the protection zone from lower limit to +1
- Dimension of protection zone from lower limit to upper limit.

Coordinate system

The definition of a protection zone takes place with reference to the geometric axis of a channel in the basic coordinate system.

Reference

- Tool-related protection zones
Coordinates for tool-related protection zones must be given as absolute values referred to the tool carrier reference point F.
- Workpiece-related protection zones
Coordinates for workpiece-related protection zones must be given as absolute values referred to the zero point of the basic coordinate system.

Note

If no tool-related protection zone is active, the tool path is checked against the workpiece-related protection zones.

If no workpiece-oriented protection zone is active, protection-zone monitoring does not take place.

Orientation

The orientation of the protection zones is determined by the plane definition (abscissa/ordinate), in which the contour is described, and the axis perpendicular to the contour (vertical axis).

The orientation of the protection zones must be the same for the tool and workpiece-related protection zones.

2.3.2 Types of protection zone

Machine-defined and channel-defined protection zones

- Machine-defined protection zone
Data for machine-related protection zones are defined once in the control. These protection zones can be activated by all channels.
- Channel-defined protection zones
Data for channel-related protection zones are defined in a channel. These protection zones can be activated only by this channel.

Example: Double-slide turning machine

- The tool-related protection zones are assigned to channel 1 or 2.
- The workpiece-related protection zones are assigned to the machine.
- The coordinate system must be identical for both channels.

Maximum number of protection areas

The maximum definable number of machine- and channel-related protection zones is set via:

MD18190 \$MN_MM_NUM_PROTECT_AREA_NCK (Number of files for machine-related protection zones)

MD28200 \$MC_MM_NUM_PROTECT_AREA_CHAN (Number of files for channel-specific protection zones)

Coordinates

The coordinates of a protection zone must always be programmed as absolute values with respect to the reference point of the protection zone. When the protection zone is activated via the part program it is possible to apply a relative offset to the reference point of the protection zone.

Examples

In the following figures some examples for protection zones have been presented:

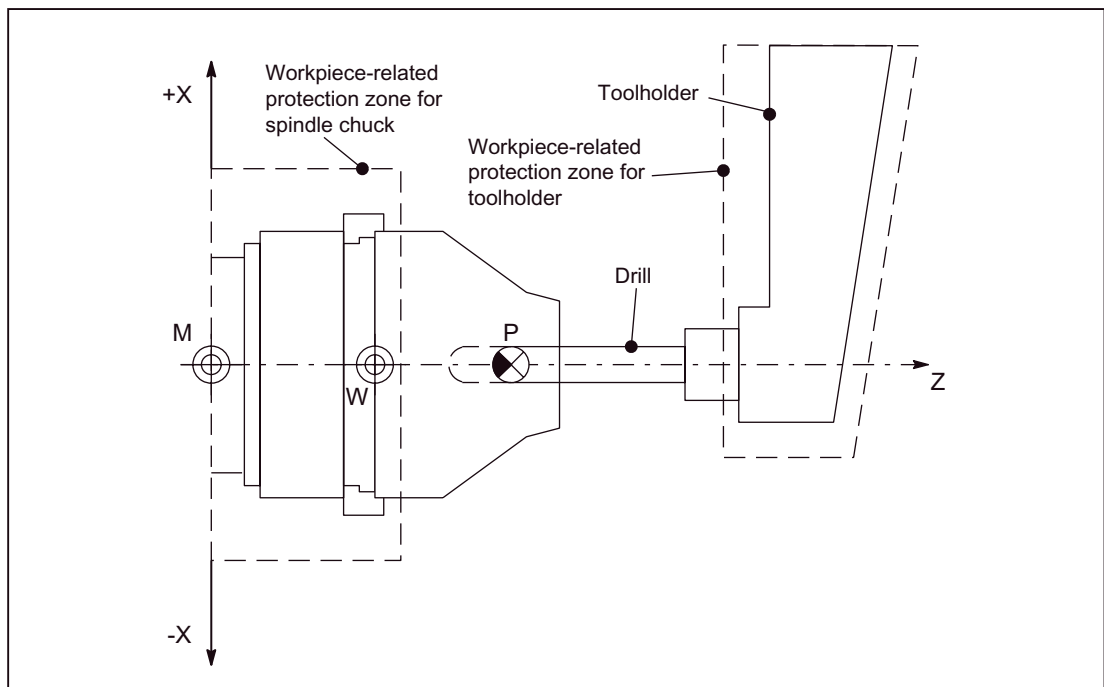

Figure 2-8 Example of application on turning machine

Figure 2-9 Example of a milling machine

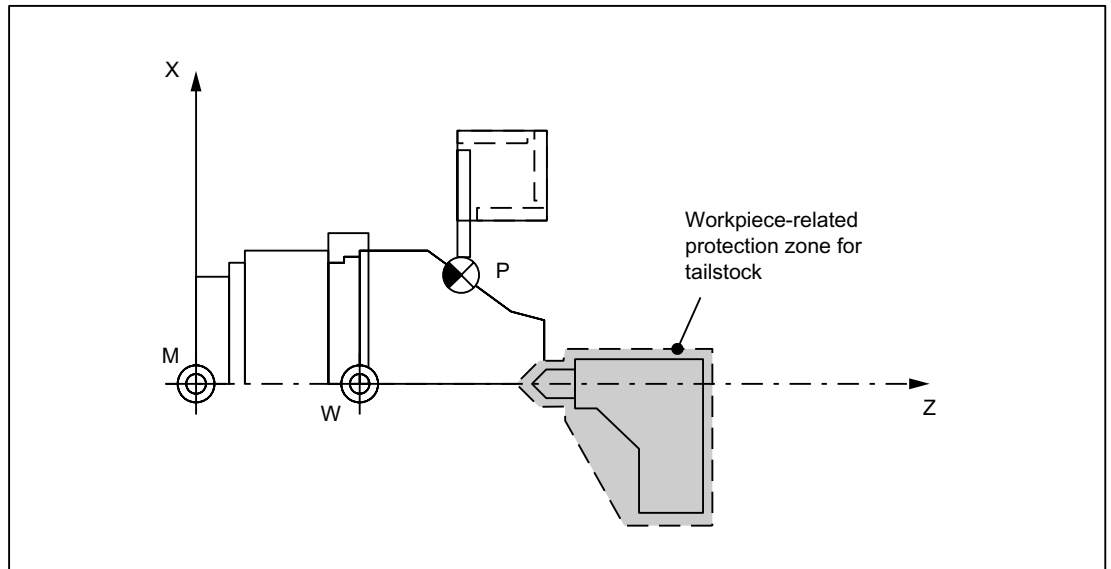

Figure 2-10 Example of a turning machine with relative protection zone for tailstock

2.3.3 Definition via part program instruction

General

A protection-zone definition must contain the following information:

- Protection zone type (workpiece- or tool-related)
- Orientation of the protection zone
- Type of limitation in the third dimension
- Upper and lower limits of the protection zone in the third dimension
- Activation type ("Protection zone immediately active": only possible via system variable)
- Contour elements

Definition of protection zones

The following systematics must be maintained in the definition of protection zones:

- Definition of the working plane: G17, G18 or G19
- Definition beginning
 - Channel-specific protection zones: CPROTDEF(...)
 - Machine or NC-specific protection zone: NPROTDEF(...)
- Contour description for protection zone
- End of definition: EXECUTE(...)

Definition of the working plane

The desired working plane to which the contour description of the protection zone refers must be selected with G17, G18, G19 before start of the definition. It may not be changed before the end of the definition. Programming of the applicate is not permitted between start and end of the definition.

Definition beginning

The definition start is defined by the corresponding subroutine:

- CPROTDEF(n, t, applim, appplus, appminus)
- NPROTDEF(n, t, applim, appplus, appminus)

Parameters	Type	Description	
n	INT	Number of defined protection zone	
t	BOOL	Protection zone type	
		TRUE	Tool-oriented protection zone
		FALSE	Workpiece-related protection zone
applim	INT	Type of limitation in the third dimension	
		0	No limitation

Parameters	Type	Description
		1 Limit in plus direction
		2 Limit in minus direction
		3 Limit in positive and negative direction
appminus	REAL	Value of the limit in the negative direction in the 3rd dimension ¹⁾
appplus	REAL	Value of the limit in the positive direction in the 3rd dimension ¹⁾
¹⁾ The following must be true: $appplus > appminus$		

Contour description for protection zone

The contour of a protection zone is described with traversing motions. These are not executed and have no connection to previous or subsequent geometry descriptions. They only define the protection zone.

The contour of a protection zones is specified with up to eleven traversing movements in the selected working plane. The first traversing movement is the movement to the contour. The last point in the contour description must always coincide with the first point of the contour description. In the case of rotation-symmetrical contours (e.g. spindle chuck), the whole contour must be described (not merely the contour to the turning center).

The valid protection zone is the zone left of the contour:

- Internal protection zone

The contour of an internal protection zone must be described in the counter-clockwise direction.

- External protection zones (permitted only for workpiece-related protection zones)

The contour of an external protection zone must be described in the clockwise direction.

Figure 2-11 Examples: External and internal protection zone

Tool-related protection zones must be convex. If a concave protection zone is required, the protection zone must be divided up into several convex protection zones.

Figure 2-12 Examples: convex and concave tool-related protection zones

Contour elements

The following contour elements are permissible:

- G0, G1 for straight contour elements
- G2 for circle segments in the clockwise direction

Permissible only for workpiece-related protection zones.

Not permissible for tool-related protection zones because they must be convex.

- G3 for circular segments in the counter-clockwise direction

A protection zone cannot be described by a complete circle. A complete circle must be divided into two half circles.

The sequence G2, G3 or G3, G2 is not permitted. A short G1 block must be inserted between the two circular blocks.

Constraints

During the definition of a protection zone, the following functions must not be active or used:

- Tool radius compensation (cutter radius compensation, tool nose radius compensation)
- Transformation
- Reference point approach (G74)
- Fixed point approach (G75)
- Dwell time (G4)
- Block search stop (STOPRE)
- End of program (M17, M30)
- M functions: M0, M1, M2

Programmable frames (TRANS, ROT, SCALE, MIRROR) and configurable frames (G54 to G57) are ineffective.

Inch/metric switchovers with G70/G71 or G700/G710 are effective.

End of definition

The end of definition is defined by the following subroutine:

```
EXECUTE (NOT_USED)
```

Parameters	Type	Description
NOT_USED	INT	Error variable has no effect in protection zones with EXECUTE.

The definition of a machine-specific or channel-specific protection zone is completed with the subroutine EXECUTE (n).

2.3.4 Definition via system variable

General

If the protection zones are defined with part program instructions (see Chapter: Definition for each part program instructions), the protection zone data are stored in system variables. The system variables can also be written directly so that the definition of protection areas can also be performed directly in the system variables.

The same supplementary conditions apply for the definition of the contour of a protection zone as for a protection-zone definition via part program instructions.

System variables

The protection zone definitions cover following system variables:

System variable	Type	Significance
\$SN_PA_ACTIV_IMMED[n] \$SC_PA_ACTIV_IMMED[n]	BOOL	Activation type The protection zone is active/not active immediately after the power up of the control and the referencing of the axes.
		FALSE not immediately active
		TRUE immediately active
\$SN_PA_T_W[n] \$SC_PA_T_W[n]	INT	Protection zone type
		0 Workpiece-related protection zone
		1 reserved
		2 reserved
\$SN_PA_ORI[n] \$SC_PA_ORI[n]	INT	Orientation of the protection zone, i.e. polygon definition in the plane of:
		0 1st and 2nd geometry axis
		1 3rd and 1st geometry axis
		2 2nd and 3rd geometry axis

2.3 Protection zones

System variable	Type	Significance
\$SN_PA_LIM_3DIM[n] \$SC_PA_LIM_3DIM[n]	INT	Type of limitation in the third dimension
		0 No limitation
		1 Limit in plus direction
		2 Limit in minus direction
		3 Limit in positive and negative direction
\$SN_PA_PLUS_LIM[n] \$SC_PA_PLUS_LIM[n]	REAL	Value of the limit in the positive direction in the 3rd dimension
\$SN_PA_MINUS_LIM[n] \$SC_PA_MINUS_LIM[n]	REAL	Value of the limit in the negative direction in the 3rd dimension
\$SN_PA_CONT_NUM[n] \$SC_PA_CONT_NUM[n]	INT	Number of valid contour elements
\$SN_PA_CONT_TYP[n, i] \$SC_PA_CONT_TYP[n, i]	INT	Contour type[i], contour type (G1, G2, G3) of the nth contour element
\$SN_PA_CONT_ABS[n, i] \$SC_PA_CONT_ABS[n, i]	REAL	End point of the contour[i], abscissa value
\$SN_PA_CONT_ORD[n, i] \$SC_PA_CONT_ORD[n, i]	REAL	End point of the contour[i], ordinate value
\$SN_PA_CENT_ABS[n, i] \$SC_PA_CENT_ABS[n, i]	REAL	Center point of the circular contour[i], absolute abscissa value
\$SN_PA_CENT_ORD[n, i] \$SC_PA_CENT_ORD[n, i]	REAL	Center point of the circular contour[i], absolute ordinate value
<p>\$SN... are system variables for NC and machine-specific protection zones. \$SC... are system variables for channel-specific protection zones. The index "n" corresponds to the number of the protection zone: 0 = 1st protection zone The index "i" corresponds to the number of the contour element: 0 = 1st contour element The contour elements must be defined in ascending order.</p>		

Note

The system variables of the protection-zone definitions are not restored with REORG.

Data of the protection-zone definitions

Data storage

The protection-zone definitions are stored in the following files:

File	Blocks
_N_NCK_PRO	Data block for NC-specific protection zones
_N_CHAN1_PRO	Data block for channel-specific protection zones in channel 1
_N_CHAN2_PRO	Data block for channel-specific protection zones in channel 2

Data backup

The protection-zone definitions are saved in the following files:

File	Blocks
_N_INITIAL_INI	All data blocks of the protection zones
_N_COMPLETE_PRO	All data blocks of the protection zones
_N_CHAN_PRO	All data blocks of the channel-specific protection zones

2.3.5 Activation and deactivation of protection zones

General information

The activation status of a protection zone is:

- Preactivated
- Preactivated with conditional stop
- Enabled
- Deactivated

A protection zone is monitored for violation only when it is activated.

Activation

The activation of a protection zone can take place through:

- Part program instruction
- Automatically after the control powers up
- PLC user program

For activation through the PLC user program, the protection zone must be first preactivated via a part program.

The preactivation, deactivation and activation of all protection zones always takes place channel-specifically. A protection zone can also be active in multiple channels simultaneously (application example: Double-slide single-spindle machine with one quill and two machining slides).

Protection zones are activated immediately after the runup of the control, if the corresponding system variable \$SN_PA_ACTIV_IMMED[n] or \$SC_PA_ACTIV_IMMED[n] has been set.

Note

Machine-related protection zones are activated after the runup of the control in all channels.

An activated protection zone is only taken into account after the successful referencing of all participating geometry axes.

Preactivation

Only preactivated protection zones can be activated from the PLC user program.

Figure 2-13 Example: Turning machine with preactivated protection zone for a sensor.

Preactivation with conditional stop

In the case of preactivation with condition stop, the system does not always stop in front of a preactivated protection zone which has been violated. The stop only occurs if the protection zone has been activated. This facilitates uninterrupted processing if the protection zones have only been activated in special cases. N.B. The system may move into the protection zone as a result of the braking ramp if the protection zone is only activated immediately prior to positioning.

Deactivation

A protection zone can be deactivated from a part program. Additionally an active, preactivated protection zone can be set again in the preactivated (= ineffective) state through the PLC user program.

RESET response

The activation status of a protection zone is retained even after NC-RESET and program end.

Memory requirements

The memory requirement of the persistent memory is determined with following machine data:

MD18190 \$MN_MM_NUM_PROTECT_AREA_NCK (Number of available machine-defined protection zones)

MD28200 \$MC_MM_NUM_PROTECT_AREA_CHAN (Number of available channel-defined protection zones)

The memory requirement in the dynamic part with regard to the protection zones is established with following machine data:

MD28210 \$MC_MM_NUM_PROTECT_AREA_ACTIVE (Maximum number of protection zones that can be activated simultaneously in the channel)

MD28212 \$MC_MM_NUM_PROTECT_AREA_CONTUR (Maximum number of definable contour elements per protection zone)

Deactivation, preactivation, activation via part program

The activation status of a channel- or machine-specific protection zone is defined by the corresponding subroutine:

- Channel-specific protection zone:
CPROT (n, state, xMov, yMov, zMov)
- Machine or NC-specific protection zone:
NPROT (n, state, xMov, yMov, zMov)

Parameters	Type	Description
n	INT	Number of protection zone
state	INT	Activation status
		0 deactivated
		1 preactivated
		2 activated
		3 preactivated with conditional stop
xMov, yMov, zMov	REAL	Offset values of the previously defined protection zone in the geometry axes

Offsets

During preactivation or activation of the protection zone, an offset can be entered in 0 to 3 dimensions. The offset refers to:

- Workpiece-related protection zones: Machine zero
- Tool-related protection zones: Tool holder reference point F

Note

A protection zone cannot be activated in a single channel with different offsets simultaneously.

Activation via PLC user program

A protection zone preactivated in the part program can be activated in the PLC user program.

Preactivated protection zones

The NC indicates the preactivated protection zones:

DB21, ... DBX272.0 to 273.1 (machine-related protection zone 1 - 10 preactivated)

DB21, ... DBX274.0 to 275.1 (channel-specific protection zone 1 - 10 preactivated)

Protection-zone violation

Activated and preactivated protection zones that are or would be violated by the programmed traversing motions of the current part-program block if the PLC user program would activate the preactivated protection zone:

DB21, ... DBX276.0 to DBX277.1 (machine-related protection zone 1 - 10 violated).

DB21, ... DBX278.0 to DBX279.1 (channel-specific protection zone 1 - 10 violated).

Activate

The preactivated protection zones can be activated from the PLC user program:

DB21, ... DBX8.0 to DBX9.1 (Activate machine-related protection zone 1 - 10)

DB21, ... DBX10.0 to DBX11.1 (Activate channel-specific protection zone 1 - 10)

Deactivation

Protection zones activated from the part program cannot be deactivated by the PLC user program.

Note

It follows from the rules listed above that protection zones that should be activated via the PLC user program are intended specially for this. Preactivation in the part program is only useful for these protection zones.

For protection zones that are known only in the part program and not in the PLC user program, only activation in the part program makes sense.

Automatic activation after the control powers up

The configuration for automatic activation of a protection zone after the control powers up is performed via the following system variable:

- Channel-specific protection zone:
\$SC_PA_ACTIV_IMMED[n]
- Machine or NC-specific protection zone:
\$SN_PA_ACTIV_IMMED[n]

With automatic activation, no relative offset of the protection zone is possible.

Block search with calculation

For block search with calculation, the last programmed activation state of a protection zone is always taken into account.

Program test

In automatic modes, activated and preactivated protection zones are monitored even during program control: PROGRAM TEST.

2.3.6 Protection-zone violation and temporary enabling of individual protection zones

Function

Workpiece and tool-related protection zones that are activated or deactivated are monitored for collision. If a protection-zone violation is detected, behavior in the individual operating modes is as follows.

Terminating temporary enabling

Temporary enabling of a protection zone is terminated after the following events:

- after `NC RESET`
- Operating modes AUTOMATIC or MDA End of block is outside the protection zone
- Manual operating modes: End of movement is outside the protection zone
- Activating a protection zone

On `NC RESET` all the enabled protection zones become active again. If the part program or jog mode is started again, the protection zones must be re-enabled. If the current position lies within a protection zone that becomes active again after `NC RESET`, this protection zone must be enabled again on the first path movement.

Preactivated protection zones

Protection zones can be preactivated with part programs. To make them fully operative, they must also be set to the "operative" state by the PLC.

In contrast to AUTOMATIC mode, a change in the NC/PLC interface signals "Make preactivated protection zones operative" only has an effect on stationary axes in the geometry system. This means: If an inoperative protection zone is made "operative" once a motion has been started, it is not evaluated until the axes have stopped, possibly resulting in the output of an alarm.

If a preactivated protection zone is made "operative" during traversing, the alarm 10704 "Protection-zone monitoring is not guaranteed" and the PLC interface signal are set:

DB31, ... DBX39.0 (protection-zone monitoring not guaranteed).

Deactivation of tool-related protection zones

Tool-related protection zones can be deactivated only in the part program or, if they have been preactivated, by being rendered "inoperative" by the PLC.

Geometry axis change and transformation change

Through the following machine data it is adjustable, whether active protection zones are retained or deactivated during the geometry axis change or transformation change:

MD10618 \$MN_PROTAREA_GEOAX_CHANGE_MODE

Bit	Value	Significance
0	0	Protection zones are deactivated during the transformation change.
	1	Active protection zones remain active after a transformation is changed.
1	0	Protection zones are deactivated during the geometry axis change.
	1	Active protection zones remain active after a geometry axis change.

Monitoring of overlaid motion

Axes that have been assigned to another channel are not taken into account. The last position to be approached is taken to be the end position. It is not taken into account whether the axis has traversed after changing channels.

Behavior in the AUTOMATIC and MDA operating modes

Protection zones are not overrun in Automatic modes:

- If the movement in a block is from outside into the protection zone (N30), deceleration is executed toward the end of the previous block (N20) and the movement is stopped.
 - If the protection zone is preactivated but not activated by the PLC, machining is continued (case 1).
 - If the protection zone is activated or preactivated and activated by the PLC, machining is stopped (case 2).
- If the starting point of the block is inside the protection zone, the movement is not started.

In case of violation of protection zone for the workpiece-related protection zone, the alarm: 10700 "NCK-protection zone in AUTOMATIC or MDA violated" or 10701 "channel-specific protection zone in AUTOMATIC or MDA violated" is given.

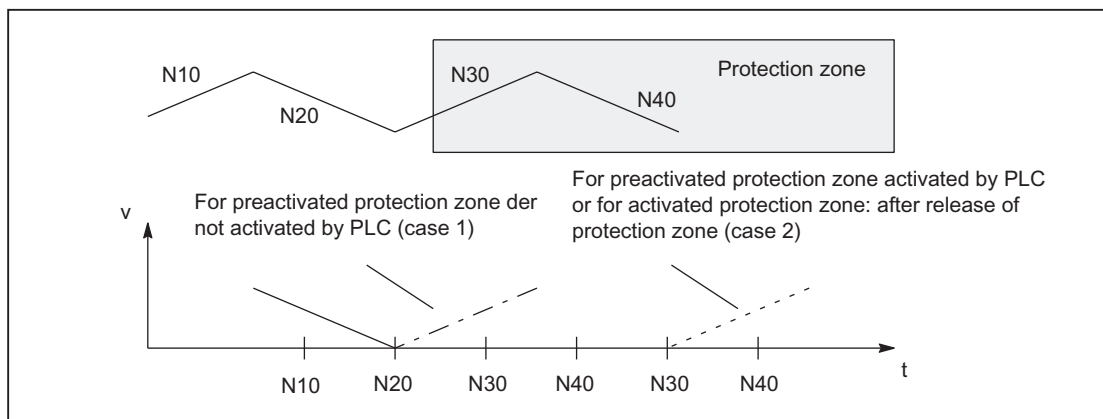

Figure 2-14 Behavior of the path velocity when entering a protection zone

Overlaying several axis motions

Overlaid motions of external ZO (zero offsets) or DRF are taken into account if they are executed at a sufficiently early point in time.

If an overlaid motion occurs while a protection zone is active or operative, an alarm is output as a warning. This alarm has no effect on the machining operation and resets itself if the transferred motion has been fully taken into account. The PLC interface signal is set at the same time as alarm 10704:

DB31, ... DBX39.0 (protection-zone monitoring not guaranteed).

Enabling of workpiece-related protection zones

When a workpiece-related protection zone has been violated, the operator can enable it temporarily with NC start in the AUTOMATIC and JOG modes so that it can be traversed. This clears the alarm and travels into the protection zone in the AUTOMATIC and MDA operating modes.

Only workpiece-related protection zones can be enabled temporarily with NC start and traversed by all tool-related protection zones including the programmed path.

If on `NC-START` the preactivated tool or workpiece-related protection zone is deactivated by the PLC after the alarm, machining is continued without the protection zone being enabled temporarily.

If a fully operative, preactivated protection zone causes a machining interruption and the output of an alarm owing to protection-zone violation, machining can be resumed on NC start if the PLC makes the zone inoperative again.

If enabling of a protection zone is to be safeguarded better than with a simple NC start, NC start must be disabled or made dependent on other conditions in the PLC user program when this alarm is triggered.

If the user does not want to permit overrunning the protection zone, he can terminate the traversing movement with `NC RESET`.

If several protection zones are violated at the same time by the movement, acknowledgment is required for each of these protection zones. With NC start the individual protection zones can then be enabled one after the other.

Application for temporary enabling:

Drilling a turned part: The drill is allowed to enter the protection zone of the spindle chuck.

Monitoring of overlaid motion

On preparation of the NC blocks, part of the offsets of geometry axes resulting from the overlaid motions are taken into account.

If further offsets occur that could not be taken into account on preparation of the blocks, the channel-specific PLC interface signal is set.

DB31, ... DBX39.0 (protection-zone monitoring not guaranteed).

This signal is set while offsets are active that cannot be taken into account. The signal can be set and reset within a block.

Simultaneously with the PLC interface signal, a self-canceling alarm 10704 "Protection-zone monitoring is not guaranteed" is output.

The following overlaid motions of geometry axes are taken into account in the preparation of blocks:

1. DRF offsets
2. Work offsets external
3. Fine tool offsets
4. Rapid retraction
5. Offsets generated by compile cycles
6. Oscillation
7. Concurrent positioning axes
8. Positioning axes

The alarm is canceled or the PLC interface signal reset when the offsets from the overlaid motions are taken into account again or when the offsets are reduced to zero again.

Note

The end position for positioning axes is taken to be a position in the whole block. This means that the alarm 10704 "Protection zones not guaranteed" is output when the positioning axis starts to move. The overlaid motions themselves are not limited, nor is there any intervention in processing of the program.

Behavior in JOG mode

Overlaying several axis motions

In JOG mode traversing can be performed simultaneously in several geometry axes even when protection zones are active. However, safe monitoring of protection zones can then no longer be guaranteed. This is indicated as follows:

- Alarm: " 10704 Protection-zone monitoring is not guaranteed"
- DB31, ... DBX39.0 = 1 (protection-zone monitoring not guaranteed)

The traversing range of the geometry axes is limited in all directions by the protection zones with the same effect as they had at the start point.

Figure 2-15 Motion boundaries of axes

When the geometry axes have completed their movements (end of interpolation), the alarm is automatically reset and the final position checked to see whether it is within one or several protection zones.

There are three possible situations in this case:

1. If the position is outside all active protection zones, the next traversing motion can be started normally. The appropriate PLC interface signals "Machine-specific or channel-specific protection zone violated" are set for the protection zones that are enabled or just preactivated, but not yet operative.
2. If the position is within an active protection zone, the alarm "Protection zone violated in JOG" is generated, thereby disabling any traversing motions. The appropriate PLC interface signals "Machine-specific or channel-specific protection zone violated" are also set.

The alarm is reset by:

- Temporary enabling of the affected protection zones
 - Deactivation of the relevant protection zones if they are preactivated
 - Deactivation of the protection zone in MDA
3. If the position is on the protection zone limitation (position is still valid), no alarm is generated.

Note

While any one axis in the geometry system is still oscillating, the status "Motions of axes in geometry system completed" cannot be reached.

The warning remains active, the other axes in the geometry system can continue to traverse.

The alarm "Protection zone reached in JOG" is not output if the motion of the first axis to be started is terminated by the limitation determined prior to the motion.

Monitoring (pre)activated protection zones

(Pre)activated protection zones are also monitored in manual modes (JOG, INC, handwheel).

Limitation of traversing motion of an axis

Axis motions are limited in JOG mode by means of software limit switches or the working area limitation. The protection zones are an additional limiting element on the traversing motion of the geometry axes.

If the traversing motion of an axis is limited because it has reached a protection zone, then a self-resetting alarm "Protection zone reached in JOG" is generated. The alarm text specifies the violated protection zone and the relevant axis. It is assured that no protection zone will be violated when one axis is traversing in JOG. (This response is analogous to approaching software limit switches or a working area limitation).

The alarm is reset:

- when an axis is traversed along a path that does not lead into the protection zone
- when the protection zone is enabled
- on NC RESET.

If an axis starts to move towards a protection zone when it is at a protection zone limit, then a self-resetting alarm "Protection zone reached in JOG" is output and the motion is not started.

Enabling of workpiece-related protection zones

When a workpiece-related protection zone has been violated, the operator can also enable it temporarily in JOG mode so that it can be traversed. This resets the alarm and the motion is started in the manual operating modes after a new travel command.

Temporary enabling of protection zones

Protection zones can be enabled in JOG mode when:

1. the current position is within a protection zone (alarm active)
2. a motion is to be started on the protection zone limit (alarm active)

A protection zone is enabled when:

- a positive signal edge arrives at the PLC interface "Temporary enabling of protection zones" (this enable resets the active alarm).
- if the axis then starts to move again into the same protection zone.

Start of the motion causes:

- the protection zone to be enabled
- the appropriate PLC interface signals "Machine-specific or channel-specific protection zone violated" to be set.
- the axis to start moving.

The enabling signal is canceled if a motion is started that does not lead into the enabled protection zone.

If the current position is located in other active protection zones or the limit for other protection zones must be crossed with the motion that has been started, then alarms 10702, 10703 or 10706, 10707 are output. The PLC interface signal "Temporary enabling of protection zones" can be set again to enable the protection zone for which an alarm is output.

The enabling signals for the individual protection zones are still valid on switchover to operating modes AUTOMATIC or MDA, and vice versa, the enabling signals of protection zones that were output in AUTOMATIC and MDA remain valid.

If the end position is located outside the relevant protection zone the next time the axes in the geometry system stop:

- the enabling signals of the individual protection zones are canceled
- the appropriate PLC interface signal "Machine-specific or channel-specific protection zone violated" is reset.

2.3.7 Restrictions in protection zones

Restrictions in protection-zone monitoring

No protection-zone monitoring is possible under the following conditions:

- Orientation axes
- Protection-zone monitoring for fixed machine-related protection zones with transmit or peripheral surface transformation.

Exception: Protection zones defined with rotation symmetry around the spindle axis. Here, no DRF offset must be active.

- Mutual monitoring of tool-related protection zones

Positioning axes

For positioning axes, only the programmed block end point is monitored.

An alarm is displayed during the traversing motion of the positioning axes:

Alarm: "10704 Protection-zone monitoring is not guaranteed".

Axis exchange

If an axis is not active in a channel because of an axis replacement, the position of the axis last approached in the channel is taken as the current position. If this axis has not yet been traversed in the channel, zero is taken as the position.

Machine-related protection zones

A machine-related protection zone or its contour is defined using the geometry axis, i.e. with reference to the basic coordinate system (BCS) of a channel. In order that correct protection-zone monitoring can take place in all channels in which the machine-related protection zone is active, the basic coordinate system (BCS) of all affected channels must be identical (position of the coordinate point of origin with respect to the machine zero point and orientation of the coordinate axes).

2.4 Supplementary conditions

2.4.1 Axis monitoring functions

Settings

For correct operation of the monitoring, the following settings must be made or checked, in addition to the machine data mentioned:

General

- MD31030 \$MA_LEADSCREW_PITCH (Leadscrew pitch)
- MD31050 \$MA_DRIVE_AX_RATIO_DENOM (Denominator load gearbox)
- MD31060 \$MA_DRIVE_AX_RATIO_NUMERA (Numerator load gearbox)
- MD31070 \$MA_DRIVE_ENC_RATIO_DENOM (Denominator measuring gearbox)
- MD31080 \$MA_DRIVE_ENC_RATIO_NUMERA (Numerator measuring gearbox)
- MD32810 \$MA_EQUIV_SPEEDCTRL_TIME (equivalent time constant speed control loop for feedforward control)
- Encoder resolution

The corresponding machine data is described in:

References:

/FB1/ Function Manual, Basic Functions; Velocities, Setpoint/Actual Value Systems, Closed-Loop Control (G2)

Only drives with analog speed setpoint interface

- MD32260 \$MA_RATED_VELO (Nominal motor speed)
- MD32250 \$MA_RATED_OUTVAL (Nominal output voltage)

2.5 Examples

2.5.1 Axis monitoring

2.5.1.1 Working area limitation in WKS/ENS

Available channel axes

4 axes are defined in the channel: X, Y, Z and A
The A-axis is a rotary axis (not modulo).

Parameterize number of working area limitation groups

Three working area limitation groups will be provided:
MD28600 \$MC_MM_NUM_WORKAREA_CS_GROUP = 3

Define working area limitation groups

Additionally 2 working area limitation groups will be defined:

Working area limitation group 1

In the first working area limitation group the axes in the ENS coordinate system will be limited:

- X axis in the plus direction: 10 mm
- X axis in the minus direction: No limitation
- Y axis in the plus direction: No limitation
- Y axis in the minus direction: 25 mm
- Z axis in the plus direction: No limitation
- Z axis in the minus direction: No limitation
- A axis in the plus direction: 10 degrees
- A axis in the minus direction: -40 degrees

The system variables are assigned as follows:

```
N1 $AC_WORKAREA_CS_COORD_SYSTEM[1] = 3           ; The working area limitation
                                                    of the working area
                                                    limitation group 1 applies
                                                    in the ENS.
N10 $AC_WORKAREA_CS_PLUS_ENABLE[1,X] = TRUE
N11 $AC_WORKAREA_CS_LIMIT_PLUS[1,X] = 10
N12 $AC_WORKAREA_CS_MINUS_ENABLE[1,X] = FALSE
```

```
N20 $AC_WORKAREA_CS_PLUS_ENABLE[1,Y] = FALSE
N22 $AC_WORKAREA_CS_MINUS_ENABLE[1,Y] = TRUE
N23 $AC_WORKAREA_CS_LIMIT_MINUS[1,Y] = 25
N30 $AC_WORKAREA_CS_PLUS_ENABLE[1,Z] = FALSE
N32 $AC_WORKAREA_CS_MINUS_ENABLE[1,Z] = FALSE
N40 $AC_WORKAREA_CS_PLUS_ENABLE[1,A] = TRUE
N41 $AC_WORKAREA_CS_LIMIT_PLUS[1,A] = 10
N42 $AC_WORKAREA_CS_MINUS_ENABLE[1,A] = TRUE
N43 $AC_WORKAREA_CS_LIMIT_MINUS[1,A] = -40
```

Working area limitation group 2

In the second working area limitation group the axes in the WKS coordinate system can be limited:

- X axis in the plus direction: 10 mm
- X axis in the minus direction: No limitation
- Y axis in the plus direction: 34 mm
- Y axis in the minus direction: -25 mm
- Z axis in the plus direction: No limitation
- Z axis in the minus direction: -600 mm
- A axis in the plus direction: No limitation
- A axis in the minus direction: No limitation

The system variables are assigned as follows:

```
N51 $AC_WORKAREA_CS_COORD_SYSTEM[2] = 1 ; The working area limitation
                                         of working area limitation
                                         group 2 applies in the WCS.
N60 $AC_WORKAREA_CS_PLUS_ENABLE[2,X] = TRUE
N61 $AC_WORKAREA_CS_LIMIT_PLUS[2,X] = 10
N62 $AC_WORKAREA_CS_MINUS_ENABLE[2,X] = FALSE
N70 $AC_WORKAREA_CS_PLUS_ENABLE[2,Y] = TRUE
N73 $AC_WORKAREA_CS_LIMIT_PLUS[2,Y] = 34
N72 $AC_WORKAREA_CS_MINUS_ENABLE[2,Y] = TRUE
N73 $AC_WORKAREA_CS_LIMIT_MINUS[2,Y] = -25
N80 $AC_WORKAREA_CS_PLUS_ENABLE[2,Z] = FALSE
N82 $AC_WORKAREA_CS_MINUS_ENABLE[2,Z] = TRUE
N83 $AC_WORKAREA_CS_LIMIT_PLUS[2,Z] = -600
N90 $AC_WORKAREA_CS_PLUS_ENABLE[2,A] = FALSE
N92 $AC_WORKAREA_CS_MINUS_ENABLE[2,A] = FALSE
```

Activate working area limitation group 2

In order to activate the working area limitation group 2, following instruction must exist in the part program:

```
| ...  
| N100 WALCS2 ...  
| ...
```

2.5.2 Protection zones

2.5.2.1 Definition and activation of protection zones

Requirement

The following internal protection zones are to be defined for a turning machine:

- One machine- and workpiece-related protection zone for the spindle chuck, without limitation in the third dimension
- One channel-specific protection zone for the workpiece, without limitation in the third dimension
- One channel-specific, tool-related protection zone for the toolholder, without limitation in the third dimension

The workpiece zero is placed on the machine zero to define the protection zone for the workpiece.

When activated, the protection zone is then offset by 100mm in the Z axis in the positive direction.

2.5 Examples

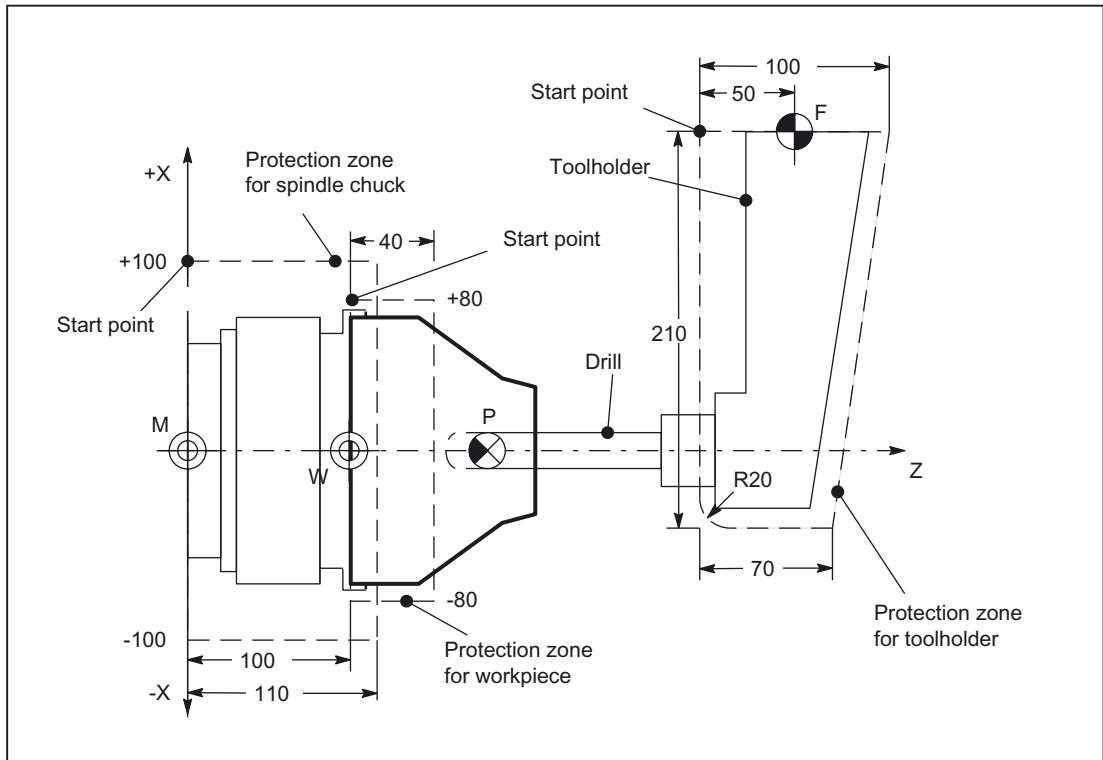

Figure 2-16 Example of protection zones on a turning machine

\$SN_PA_CONT_ORD[0,8]	0	; Endpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 8
\$SN_PA_CONT_ORD[0,9]	0	; Endpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 9
\$SN_PA_CONT_ABS[0,0]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 0
\$SN_PA_CONT_ABS[0,1]	110	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 1
\$SN_PA_CONT_ABS[0,2]	110	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 2
\$SN_PA_CONT_ABS[0,3]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 3
\$SN_PA_CONT_ABS[0,4]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 4
\$SN_PA_CONT_ABS[0,5]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 5
\$SN_PA_CONT_ABS[0,6]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 6
\$SN_PA_CONT_ABS[0,7]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 7
\$SN_PA_CONT_ABS[0,8]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 8
\$SN_PA_CONT_ABS[0,9]	0	; Endpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 9
\$SN_PA_CENT_ORD[0,0]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 0
\$SN_PA_CENT_ORD[0,1]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 1
\$SN_PA_CENT_ORD[0,2]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 2
\$SN_PA_CENT_ORD[0,3]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 3

\$SN_PA_CENT_ORD[0,4]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 4
\$SN_PA_CENT_ORD[0,5]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 5
\$SN_PA_CENT_ORD[0,6]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 6
\$SN_PA_CENT_ORD[0,7]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 7
\$SN_PA_CENT_ORD[0,8]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 8
\$SN_PA_CENT_ORD[0,9]	0	; Midpoint of contour[i], ordinate value ; Protection zone for spindle chuck, contour element 9
\$SN_PA_CENT_ABS[0,0]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 0
\$SN_PA_CENT_ABS[0,1]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 1
\$SN_PA_CENT_ABS[0,2]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 2
\$SN_PA_CENT_ABS[0,3]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 3
\$SN_PA_CENT_ABS[0,4]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 4
\$SN_PA_CENT_ABS[0,5]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 5
\$SN_PA_CENT_ABS[0,6]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 6
\$SN_PA_CENT_ABS[0,7]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 7
\$SN_PA_CENT_ABS[0,8]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 8
\$SN_PA_CENT_ABS[0,9]	0	; Midpoint of contour[i], abscissa value ; Protection zone for spindle chuck, contour element 9

Table 2- 3 Protection zone: Workpiece and tool holder

System variable	Value	Comment
\$SN_PA_ACTIV_IMMED[0]	0	; Protection zone for workpiece not immediately active
\$SN_PA_ACTIV_IMMED[1]	0	; Protection zone for tool holder not immediately active
\$SC_PA_TW[0]	" "	; Protection zone for workpiece, channel-specific
\$SC_PA_TW[1]	'H01'	; Protection zone for toolholder, channel-specific
\$SC_PA_ORI[0]	1	; Orientation of the protection zone: 1= 3rd and first geometry axis ; Protection zone for workpiece
\$SC_PA_ORI[1]	1	; Orientation of the protection zone: 1= 3rd and first geometry axis ; Protection zone for tool holder
\$SC_PA_LIM_3DIM[0]	0	; Type of limitation in the third dimension: 0 = no limitation ; Protection zone for workpiece tool holder 0

2.5 Examples

\$SC_PA_LIM_3DIM[1]	0	; Type of limitation in the third dimension: 0 = no limitation ; Protection zone for tool holder
\$SC_PA_PLUS_LIM[0]	0	; Value of limitation in positive direction in the third dimension ; Protection zone for workpiece
\$SC_PA_PLUS_LIM[1]	0	; Value of limitation in positive direction in the third dimension ; Protection zone for tool holder
\$SC_PA_MINUS_LIM[0]	0	; Value of limitation in negative direction in the third dimension ; Protection zone for workpiece
\$SC_PA_MINUS_LIM[1]	0	; Value of limitation in negative direction in the third dimension ; Protection zone for tool holder
\$SC_PA_CONT_NUM[0]	4	; Number of valid contour elements, ; Protection zone for workpiece
\$SC_PA_CONT_NUM[1]	5	; Number of valid contour elements, ; Protection zone for tool holder 1
\$SN_PA_CONT_TYP[0,0]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for workpiece, contour element 0
\$SN_PA_CONT_TYP[0,1]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for workpiece, contour element 1
\$SN_PA_CONT_TYP[0,2]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for workpiece, contour element 2
\$SN_PA_CONT_TYP[0,3]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for workpiece, contour element 3
\$SN_PA_CONT_TYP[0,4]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for workpiece, contour element 4
\$SN_PA_CONT_TYP[0,5]	0	; Contour type[i] : 0 = not defined, ; Protection zone for workpiece, contour element 5
\$SN_PA_CONT_TYP[0,6]	0	; Contour type[i] : 0 = not defined, ; Protection zone for workpiece, contour element 6
\$SN_PA_CONT_TYP[0,7]	0	; Contour type[i] : 0 = not defined, ; Protection zone for workpiece, contour element 7
\$SN_PA_CONT_TYP[0,8]	0	; Contour type[i] : 0 = not defined, ; Protection zone for workpiece, contour element 8
\$SN_PA_CONT_TYP[0,9]	0	; Contour type[i] : 0 = not defined, ; Protection zone for workpiece, contour element 9
\$SN_PA_CONT_TYP[1,0]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for tool holder, contour element 0
\$SN_PA_CONT_TYP[1,1]	3	; Contour type[i] : 3 = G3 f. Circuit element, counter-clockwise, ; Protection zone for tool holder, contour element 1
\$SN_PA_CONT_TYP[1,2]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for tool holder, contour element 2
\$SN_PA_CONT_TYP[1,3]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for tool holder, contour element 3
\$SN_PA_CONT_TYP[1,4]	1	; Contour type[i] : 1 = G1 for even, ; Protection zone for tool holder, contour element 4
\$SN_PA_CONT_TYP[1,5]	0	; Contour type[i] : 0 = not defined, ; Protection zone for tool holder, contour element 5

\$SN_PA_CONT_TYP[1,6]	0	; Contour type[i] : 0 = not defined, ; Protection zone for tool holder, contour element 6
\$SN_PA_CONT_TYP[1,7]	0	; Contour type[i] : 0 = not defined, ; Protection zone for tool holder, contour element 7
\$SN_PA_CONT_TYP[1,8]	0	; Contour type[i] : 0 = not defined, ; Protection zone for tool holder, contour element 8
\$SN_PA_CONT_TYP[1,9]	0	; Contour type[i] : 0 = not defined, ; Protection zone for tool holder, contour element 9
\$SN_PA_CONT_ORD[0,0]	-80	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 0
\$SN_PA_CONT_ORD[0,1]	-80	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 1
\$SN_PA_CONT_ORD[0,2]	80	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 2
\$SN_PA_CONT_ORD[0,3]	80	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 3
\$SN_PA_CONT_ORD[0,4]	0	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 4
\$SN_PA_CONT_ORD[0,5]	0	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 5
\$SN_PA_CONT_ORD[0,6]	0	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 6
\$SN_PA_CONT_ORD[0,7]	0	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 7
\$SN_PA_CONT_ORD[0,8]	0	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 8
\$SN_PA_CONT_ORD[0,9]	0	; Endpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 9
\$SN_PA_CONT_ORD[1,0]	-190	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 0
\$SN_PA_CONT_ORD[1,1]	-210	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 1
\$SN_PA_CONT_ORD[1,2]	-210	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 2
\$SN_PA_CONT_ORD[1,3]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 3
\$SN_PA_CONT_ORD[1,4]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 4
\$SN_PA_CONT_ORD[1,5]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 5
\$SN_PA_CONT_ORD[1,6]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 6
\$SN_PA_CONT_ORD[1,7]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 7
\$SN_PA_CONT_ORD[1,8]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 8
\$SN_PA_CONT_ORD[1,9]	0	; Endpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 9

2.5 Examples

\$SN_PA_CONT_ABS[0,0]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 0
\$SN_PA_CONT_ABS[0,1]	40	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 1
\$SN_PA_CONT_ABS[0,2]	40	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 2
\$SN_PA_CONT_ABS[0,3]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 3
\$SN_PA_CONT_ABS[0,4]	-50	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 4
\$SN_PA_CONT_ABS[0,5]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 5
\$SN_PA_CONT_ABS[0,6]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 6
\$SN_PA_CONT_ABS[0,7]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 7
\$SN_PA_CONT_ABS[0,8]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 8
\$SN_PA_CONT_ABS[0,9]	0	; Endpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 9
\$SN_PA_CONT_ABS[1,0]	-50	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 0
\$SN_PA_CONT_ABS[1,1]	-30	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 1
\$SN_PA_CONT_ABS[1,2]	20	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 2
\$SN_PA_CONT_ABS[1,3]	50	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 3
\$SN_PA_CONT_ABS[1,4]	-50	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 4
\$SN_PA_CONT_ABS[1,5]	0	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 5
\$SN_PA_CONT_ABS[1,6]	0	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 6
\$SN_PA_CONT_ABS[1,7]	0	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 7
\$SN_PA_CONT_ABS[1,8]	0	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 8
\$SN_PA_CONT_ABS[1,9]	0	; Endpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 9
\$SN_PA_CENT_ORD[0,0]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 0
\$SN_PA_CENT_ORD[0,1]	-190	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 1
\$SN_PA_CENT_ORD[0,2]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 2
\$SN_PA_CENT_ORD[0,3]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 3

\$SN_PA_CENT_ORD[0,4]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 4
\$SN_PA_CENT_ORD[0,5]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 5
\$SN_PA_CENT_ORD[0,6]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 6
\$SN_PA_CENT_ORD[0,7]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 7
\$SN_PA_CENT_ORD[0,8]	0	; Midpoint of contour[i], ordinate value ; Protection zone for workpiece, contour element 8
\$SN_PA_CENT_ORD[0,9]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 9
\$SN_PA_CENT_ORD[1.0]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 0
\$SN_PA_CENT_ORD[1.1]	-190	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 1
\$SN_PA_CENT_ORD[1.2]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 2
\$SN_PA_CENT_ORD[1.3]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 3
\$SN_PA_CENT_ORD[1.4]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 4
\$SN_PA_CENT_ORD[1.5]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 5
\$SN_PA_CENT_ORD[1.6]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 6
\$SN_PA_CENT_ORD[1.7]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 7
\$SN_PA_CENT_ORD[1.8]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 8
\$SN_PA_CENT_ORD[1.9]	0	; Midpoint of contour[i], ordinate value ; Protection zone for tool holder, contour element 9
\$SN_PA_CENT_ABS[0,0]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 0
\$SN_PA_CENT_ABS[0,1]	-30	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 1
\$SN_PA_CENT_ABS[0,2]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 2
\$SN_PA_CENT_ABS[0,3]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 3
\$SN_PA_CENT_ABS[0,4]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 4
\$SN_PA_CENT_ABS[0,5]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 5
\$SN_PA_CENT_ABS[0,6]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 6
\$SN_PA_CENT_ABS[0,7]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 7

2.5 Examples

\$SN_PA_CENT_ABS[0,8]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 8
\$SN_PA_CENT_ABS[0,9]	0	; Midpoint of contour[i], abscissa value ; Protection zone for workpiece, contour element 9
\$SN_PA_CENT_ABS[1.0]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 0
\$SN_PA_CENT_ABS[1.1]	-30	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 1
\$SN_PA_CENT_ABS[1.2]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 2
\$SN_PA_CENT_ABS[1.3]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 3
\$SN_PA_CENT_ABS[1.4]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 4
\$SN_PA_CENT_ABS[1.5]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 5
\$SN_PA_CENT_ABS[1.6]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 6
\$SN_PA_CENT_ABS[1.7]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 7
\$SN_PA_CENT_ABS[1.8]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 8
\$SN_PA_CENT_ABS[1.9]	0	; Midpoint of contour[i], abscissa value ; Protection zone for tool holder, contour element 9

Activation

Table 2- 4 Part program excerpt for activating the three protection zones for spindle chuck, workpiece, and toolholder:

```

NPROT(1, 2, 0, 0, 0) ; Protection zone: Spindle chuck
CPROT(1, 2, 0, 0, 100) ; Protection zone: Workpiece with 100mm offset in the
                        Z axis.
CPROT(2, 2, 0, 0, 0) ; Protection zone: Toolholder
    
```

2.6 Data lists

2.6.1 Machine data

2.6.1.1 NC-specific machine data

Axis monitoring

Number	Identifier: \$MN_	Description
10604	WALIM_GEOAX_CHANGE_MODE	Working area limitation during switchover of geometry axes
10710	PROG_SD_RESET_SAVE_TAB	Setting data to be updated

Protection zones

Number	Identifier: \$MN_	Description
10618	PROTAREA_GEOAX_CHANGE_MODE	Protection zone for switchover of geo axes
18190	MM_NUM_PROTECT_AREA_NCK	Number of files for machine-related protection zones

2.6.1.2 Channel-specific machine data

Axis monitoring functions

Number	Identifier: \$MC_	Description
20150	GCODE_RESET_VALUES	Initial setting of the G groups
21020	WORKAREA_WITH_TOOL_RADIUS	Allowance for tool radius with working area limitation
24130	TRAFO_INCLUDES_TOOL_1	Tool handling with active transformation 1.
24230	TRAFO_INCLUDES_TOOL_2	Tool handling with active transformation 2.
24330	TRAFO_INCLUDES_TOOL_3	Tool handling with active transformation 3.
24426	TRAFO_INCLUDES_TOOL_4	Tool handling with active transformation 4.
24436	TRAFO_INCLUDES_TOOL_5	Tool handling with active transformation 5.
24446	TRAFO_INCLUDES_TOOL_6	Tool handling with active transformation 6.
24456	TRAFO_INCLUDES_TOOL_7	Tool handling with active transformation 7.
24466	TRAFO_INCLUDES_TOOL_8	Tool handling with active transformation 8.
24476	TRAFO_INCLUDES_TOOL_9	Tool handling with active transformation 9.
24486	TRAFO_INCLUDES_TOOL_10	Tool handling with active transformation 10.

2.6 Data lists

Number	Identifier: \$MC_	Description
25106	TRAFO_INCLUDES_TOOL_11	Tool handling with active transformation 11.
25116	TRAFO_INCLUDES_TOOL_12	Tool handling with active transformation 12.
25126	TRAFO_INCLUDES_TOOL_13	Tool handling with active transformation 13.
25136	TRAFO_INCLUDES_TOOL_14	Tool handling with active transformation 14.
25146	TRAFO_INCLUDES_TOOL_15	Tool handling with active transformation 15.
25156	TRAFO_INCLUDES_TOOL_16	Tool handling with active transformation 16.
25166	TRAFO_INCLUDES_TOOL_17	Tool handling with active transformation 17.
25176	TRAFO_INCLUDES_TOOL_18	Tool handling with active transformation 18.
25186	TRAFO_INCLUDES_TOOL_19	Tool handling with active transformation 19.
25196	TRAFO_INCLUDES_TOOL_20	Tool handling with active transformation 20.
28600	MM_NUM_WORKAREA_CS_GROUPS	Number of coordinate system-specific working area limitations

Protection zones

Number	Identifier: \$MC_	Description
28200	MM_NUM_PROTECT_AREA_CHAN (SRAM)	Number of files for channel-specific protection zones
28210	MM_NUM_PROTECT_AREA_ACTIVE	Number of simultaneously active protection zones in one channel
28212	MM_NUM_PROTECT_AREA_CONTUR	Elements for active protection zones (DRAM)

2.6.1.3 Axis/spindle-specific machine data

Axis monitoring functions

Number	Identifier: \$MA_	Description
30310	ROT_IS_MODULO	Modulo conversion for rotary axis / spindle
30800	WORK_AREA_CHECK_TYPE	Type of checking of working area limits
32200	POSCTRL_GAIN [n]	Servo gain factor
32250	RATED_OUTVAL	Rated output voltage
32260	RATED_VELO	Rated motor speed
32300	MAX_AX_ACCEL	Maximum axis acceleration
32800	EQUIV_CURRCTRL_TIME	Equivalent time constant current control loop for feedforward control
32810	EQUIV_SPEEDCTRL_TIME	Equivalent time constant speed control loop for feedforward control
32910	DYN_MATCH_TIME [n]	Time constant for dynamic response adaptation
35160	SPIND_EXTERN_VELO_LIMIT	Spindle speed limitation via PLCC
36000	STOP_LIMIT_COARSE	Exact stop coarse
36010	STOP_LIMIT_FINE	Exact stop fine
36020	POSITIONING_TIME	Delay time exact stop fine

Number	Identifier: \$MA_	Description
36030	STANDSTILL_POS_TOL	Zero speed tolerance
36040	STANDSTILL_DELAY_TIME	Delay time zero-speed monitoring
36050	CLAMP_POS_TOL	Clamping tolerance with IS "Clamping active"
36052	STOP_ON_CLAMPING	Special functions for clamped axis
36060	STANDSTILL_VELO_TOL	Maximum velocity/speed "Axis/spindle stationary"
36100	POS_LIMIT_MINUS	1st software limit switch minus
36110	POS_LIMIT_PLUS	1st software limit switch plus
36120	POS_LIMIT_MINUS2	2nd software limit switch minus
36130	POS_LIMIT_PLUS2	2nd software limit switch plus
36610	AX_EMERGENCY_STOP_TIME	Maximum duration of the braking ramp for faults
36200	AX_VELO_LIMIT	Threshold value for velocity monitoring
36210	CTRLOUT_LIMIT	Maximum speed setpoint
36220	CTRLOUT_LIMIT_TIME	Delay time for speed-setpoint monitoring
36300	ENC_FREQ_LIMIT	Encoder limit frequency
36302	ENC_FREQ_LIMIT_LOW	Encoder limit frequency for encoder resynchronization
36310	ENC_ZERO_MONITORING	Zero mark monitoring
36400	CONTOUR_TOL	Tolerance band contour monitoring
36500	ENC_CHANGE_TOL	Maximum tolerance for position actual value switchover
36510	ENC_DIFF_TOL	Measuring system synchronism tolerance
36600	BRAKE_MODE_CHOICE	Deceleration behavior on hardware limit switch
36620	SERVO_DISABLE_DELAY_TIME	Cutout delay controller enable

Protection zones

None

2.6.2 Setting data

2.6.2.1 Axis/spindle-specific setting data

Axis monitoring functions

Number	Identifier: \$SA_	Description
43400	WORKAREA_PLUS_ENABLE	Working-area limitation active in positive direction
43410	WORKAREA_MINUS_ENABLE	Working-area limitation active in negative direction
43420	WORKAREA_LIMIT_PLUS	Working-area limitation plus
43430	WORKAREA_LIMIT_MINUS	Working-area limitation minus

Protection zones

None

2.6.3 Signals

2.6.3.1 Signals to channel

Axis monitoring functions

None

Protection zones

Signal name	SINUMERIK 840D sl	SINUMERIK 828D
Enable protection zones	DB21,DBX1.1	DB3200.DBX1.1
Feed disable	DB21,DBX6.0	DB3200.DBX6.0

B1: Continuous-path mode, Exact Stop, LookAhead

3.1 Brief description

Exact stop or exact stop mode

In exact stop traversing mode, all axes involved in the traversing motion (except axes of modal traversing modes) are decelerated at the end of each block until they come to a standstill. The transition to the next block occurs only when all axes involved in the traversing motion have reached their programmed target position with subject to the selected exact stop criterion.

Continuous-path mode

In continuous-path mode, the NC attempts to keep the programmed path velocity as constant as possible. In particular, deceleration of the path axes at the block limits of the part program is to be avoided.

LookAhead

LookAhead is a function for optimizing the continuous path mode.

Smooth machining of workpieces is necessary to ensure a high-quality surface finish. For this reason, path velocity variations should be avoided during machining whenever possible. Without LookAhead, the NC only takes the traversing block immediately following the current traversing block into consideration when determining the possible path velocity. If the following block contains only a short path, the NC must reduce the path velocity (decelerate in the current block) to be able to stop in time at the end of the next block, if necessary.

When the NC "looks ahead" over a configurable number of traversing blocks following the current traversing block, a much higher path velocity can be attained under certain circumstances because the NC now has considerably more traversing blocks and more path available for calculation.

This results in the following advantages:

- Machining with higher path velocities on average
- Improved surface quality by avoiding deceleration and acceleration processes

Smoothing the path velocity

"Smoothing the path velocity" is a function especially for applications (such as high speed milling in mold and die production) that require an extremely steady path velocity. Deceleration and acceleration processes that would cause high-frequency excitations of machine resonances are avoided with the "Smoothing the path velocity" function.

3.1 Brief description

This results in the following advantages:

- Improved surface quality and machining time by avoiding excitation of machine resonances.
- Constant profile of path velocity and cutting rates by avoiding "unnecessary" acceleration processes, i.e. acceleration processes that do not greatly improve the program run time.

Adaptation of the dynamic path response

In addition to "smoothing the path velocity", "dynamic path response adaptation" is another function for avoiding high-frequency excitations of machine resonances while optimizing the dynamic path response at the same time. To this end, highly frequent changes in path velocity are automatically executed with lower jerk or acceleration values than the dynamic response limit value parameters assigned in the machine data.

Thus, with low-frequency changes in path velocity, the full dynamic response limit values apply, whereas with high-frequency changes, only the reduced dynamic response limit values act due to the automatic dynamic response adaptation.

Dynamic response mode for path interpolation

Optimizing the path dynamic response also includes the technology-specific dynamic response settings which are preset for different processing technologies (including tapping, roughing, smoothing) and can be activated in the part program by calling the respective dynamic response mode.

Free-form surface mode

Any fluctuation in curvature or torsion leads to a change in path velocity. This generally results in unnecessary decelerating and accelerating during the processing of free-form surface workpieces, which may adversely affect the quality of the surfaces of the workpieces.

The following functions are available for processing free-form surfaces.

- "Free-form surface mode: Basic functions"

This makes the definition of the path velocity profile "less sensitive" to fluctuations in curvature and torsion.

- "Free-form surface mode: Extension function"

This extension in standard LookAhead functionality is used to calculate the path velocity profile during the processing of free-form surfaces.

The advantages of free-form surface mode lie in a more homogeneous workpiece surface and lower machine load.

NC block compression

When a workpiece design is completed with a CAD/CAM system, the CAD/CAM system generally also compiles the corresponding part program to create the workpiece surface. To do so, most CAD/CAM systems use linear blocks to describe even curved sections of the workpiece surface. Many interpolation points are generally necessary to maintain the required contour accuracy. This results in many linear blocks, typically with very short paths.

The "NC block compressor" function uses polynomial blocks to perform a subsequent approximation of the contour specified by the linear blocks. During this process, an assignable number of linear blocks is replaced by a polynomial block. Furthermore, the number of linear blocks that can be replaced by a polynomial block also depends on the specified maximum permissible contour deviation and the contour profile.

Use of polynomial blocks provides the following advantages:

- Reduction of the number of required part program blocks for describing the workpiece contour
- Higher maximum path velocities

Combine short spline blocks

A spline defines a curve which is formed from 2nd or 3rd degree polynomials. With spline interpolation, the controller can generate a smooth curve characteristic from only a few specified interpolation points of a set contour.

References:

Programming Manual, Advanced, Special motion commands,
chapter: Spline interpolation

The advantages of the spline interpolation as compared to the linear interpolation are:

- Reduction of the number of required part program blocks for describing a curved contour.
- Soft, mechanical system-limiting curve characteristic also during transition between the part program blocks.

The disadvantages of the spline interpolation as compared to the linear interpolation are:

- For a spline curve no exact curve characteristic, but only a tolerance band can be specified, within which the spline curve should lie.

3.2 Exact stop mode

As with linear interpolation, the processing of splines can produce such short blocks that the path velocity must be reduced to enable interpolation of the spline blocks. This is also the case, when the spline actually has a long, smooth curve. The "Combine short spline blocks" function allows you to combine these spline blocks such that the resulting block length is sufficient and does not reduce the path velocity.

Note

NC block compressor

The NC block compressor (COMPON, COMPCURV or COMPCAD) cannot be employed while compressing spline blocks since it can only be used to compress linear blocks.

3.2 Exact stop mode

Exact stop or exact stop mode

In exact stop traversing mode, all path axes and special axes involved in the traversing motion that are not traversed modally, are decelerated at the end of each block until they come to a standstill. The transition to the next block occurs only when all axes involved in the traversing motion have reached their programmed target position with subject to the selected exact stop criterion.

This results in the following response:

- The program run time is considerably longer compared to continuous path mode due to the deceleration of the axes and the wait time until "Exact stop" status is reached for all machine axes involved.
- In exact stop mode, undercuts can occur on the workpiece surface during machining.

Status "Exact stop"

The state of the machine axis based on the position difference relative to its position setpoint at the end of a traversing motion is also called an exact stop. The machine axis reaches the "exact stop" state, as soon as its following error is less than the specified position difference (exact stop criterion).

Application

Exact stop mode should always be used when the programmed contour must be executed exactly.

Activation

Exact stop mode can be activated on a modal basis or in blocks in the part program:

G command	Meaning
G60	Exact stop with modal effect
G9	Exact stop with block-by-block effect

Exact stop criteria "Exact stop coarse" and "Exact stop fine".

The exact stop criteria "Exact stop coarse" and "Exact stop fine" are used to specify tolerance windows for a machine axis reaching the "exact stop" state.

Figure 3-1 Tolerance windows of exact stop criteria

Parameters are assigned to the two exact stop criteria via the machine data:

MD36010 \$MA_STOP_LIMIT_FINE (exact stop fine)

MD36000 \$MA_STOP_LIMIT_COARSE (exact stop coarse)

Note

The tolerance windows of the exact stop criteria "Exact stop coarse" and "Exact stop fine" should be assigned in such a way that the following requirement is fulfilled:

"Exact stop coarse" > "Exact stop fine"

Exact stop criterion "Interpolator End"

In the case of the exact stop criterion "interpolator end" the block change to the next traversing block takes place, as soon as all path axes and special axes involved in the traversing motion, which do not traverse extending up to block, have reached their position according to set point programmed in the block. That is, the interpolator has executed the block.

3.2 Exact stop mode

The actual position and the following error of the relevant machine axes are not taken into consideration for exact stop criterion "Interpolator end". Thus, depending on the dynamic response of the machine axes, this can result in a relatively large smoothing of the contour at the block changes in comparison to the exact stop criteria "Exact stop coarse" and "Exact stop fine".

Activation of an exact stop criterion

An exact stop criterion is activated in the part program by programming the appropriate G command:

G command	Exact-stop criterion
G601	Exact stop fine
G602	Exact stop coarse
G603	Interpolator end

Block change depending on exact-stop criteria

The figure below illustrates the block change timing in terms of the selected exact stop criterion.

Figure 3-2 Block change accordance to selected exact stop criterion

Evaluation factor for exact stop criteria

A parameter set-dependent evaluation of the exact stop criteria can be specified via the following axis-specific machine data:

MD36012 \$MA_STOP_LIMIT_FACTOR (exact stop coarse/fine and standstill factor)

Applications:

- Adaptation of the positioning response to different mass ratios, such as after a gearshift
- Reduction in positioning time, depending on various machining states, such as roughing and finishing

Assignable specification of the active exact stop criterion

The active exact stop criterion can be permanently specified for the part program commands of the first G function group irrespective of the exact stop criterion programmed in the part program. This specification can be made independently for each of the following part program commands:

- Rapid traverse: G0
- Machining commands: G1, G2, G3, CIP, ASPLINE, BSPLINE, CSPLINE, POLY, G33, G34, G35, G331, G332, OEMIPO01, OEMIPO02, CT

The setting is done in a channel-specific manner via the following machine data:

MD20550 \$MC_EXACT_POS_MODE (exact stop conditions for G0 and G1)

Coding

Each exact stop criterion is location-coded:

MD20550 \$MC_EXACT_POS_MODE = <ZE>

- Ones position E: Rapid traverse
- Tens position Z: all other part program commands in the first G function group

Z or E	Active exact stop criterion
0	Programmed exact stop criterion
1	G601 (Exact stop window fine)
2	G602 (Exact stop window coarse)
3	G603 (Interpolator end)

Example

MD20550 \$MC_EXACT_POS_MODE = 02

Ones position = 2:

With rapid traverse, exact stop criterion G602 (Exact stop window coarse) is always active, irrespective of any programming in the parts program.

Tens digit = 0:

For traversing with all other parts program commands of the first G function group, the exact stop criterion programmed in the parts program is active.

Assignable exact stop criterion for rapid traverse transitions in continuous path mode

The behavior at the block transition of part program blocks before and after rapid traverse blocks can be parameterized as follows:

MD20552 \$MC_EXACT_POS_MODE_G0_TO_G1 = <value>

Value	Meaning
0	No additional stop at the block transition.
1	Stop at block transition: Same behavior as in the case of G601 (Exact stop window fine)
2	Stop at block transition: Same behavior as G602 (Exact stop window coarse).
3	Stop at block transition: Same behavior as G603 (Interpolator end).
4	Like 0, in addition, the override of the next non-G0 block is taken into account with LookAhead in the G0 block during the transition from G0 to non-G0.
5	Like 0; in addition, the override of the next block is taken into account with LookAhead during the transition from G0 to non-G0 and from non-G0 to G0.

3.3 Continuous-path mode

3.3.1 General functionality

Continuous-path mode

In the continuous-path mode the path velocity is **not** decelerated for the block change in order to permit the fulfillment of an exact stop criterion. The objective of this mode is to avoid rapid deceleration of the path axes at the block-change point so that the axis velocity remains as constant as possible when the program moves to the next block. To achieve this objective, the "LookAhead" function is also activated when the continuous path mode is selected.

Continuous-path mode causes the smoothing and tangential shaping of angular block transitions by local changes in the programmed contour. The extent of the change relative to the programmed contour can be limited by specifying the overload factor or rounding criteria.

Continuous-path operation causes:

- Contour rounding
- Shorter machining times through elimination of braking and acceleration processes that are required to comply with the exact-stop criterion
- Improved cutting conditions because of the more constant velocity

Continuous-path mode is suitable if:

- A contour must be traversed as quickly as possible (e.g. with rapid traverse).
- The exact contour may deviate from the programmed contour within a specific tolerance for the purpose of obtaining a continuous contour.

Continuous-path mode is suitable if:

- A contour is to be traversed precisely.
- An absolutely constant velocity is required.

Implicit exact stop

In some cases, an exact stop needs to be generated in continuous-path mode to allow the execution of subsequent actions. In such situations, the path velocity is reduced to zero.

- If auxiliary functions are output before the traverse motion, the previous block is only terminated when the selected exact-stop criterion is fulfilled.
- If auxiliary functions are to be output after the traverse motion, they are output after the interpolator end of the block.
- If an executable block (e.g. starting a positioning axis) contains no travel information for the path axes, the previous block is terminated on reaching the selected exact-stop criterion.

3.3 Continuous-path mode

- If a positioning axis is declared to be the geometry axis, the previous block is terminated at the interpolator end when the geometry axis is programmed.
- If a synchronized axis is programmed that was last programmed as a positioning axis or spindle (initial setting of the special axis is positioning axis), the previous block is ended at the interpolator end.
- If the transformation is changed, the block previously processed is terminated with the active exact-stop criterion.
- A block is terminated on interpolator end if the following block contains the changeover of the acceleration profile BRISK/SOFT.

References:

For more information about BRISK and SOFT, refer to the chapter "Acceleration (B2)".

- If the "empty buffer" function is programmed, the previous block is terminated when the selected exact-stop criterion is reached.

Velocity = 0 in continuous-path mode

Regardless of the implicit exact stop response, the path motion is braked down to zero velocity at the end of the block in cases where:

- Positioning axes are programmed with the instruction `POS`, and their traversing time exceeds that of the path axes. The block change occurs when the "exact stop fine" of the positioning axes is reached.
- The time taken to position a spindle programmed with the instruction `SPOS` is longer than the traversing time of the path axes. The block change is carried out when the "exact stop fine" of the positioning spindle is reached.
- The current block contains traversing commands for geometry axes and the following block traversing commands for synchronized axes or, alternatively, the current block contains traversing commands for synchronized axes and the subsequent block traversing commands for geometry axes.
- Synchronization is required

3.3.2 Velocity reduction according to overload factor

Function

The function lowers the path velocity in continuous-path mode until the non-tangential block transition can be traversed in one interpolation cycle while respecting the deceleration limit and taking an overload factor into account.

With the reduced velocity, axial jumps in velocity are produced with a non-tangential contour at the block transition. These jumps in velocity are also performed by the coupled motion synchronized axes. The jump in velocity prevents the path velocity dropping to zero. This jump is performed if the axial velocity was reduced with the axial acceleration to a velocity from which the new setpoint can be reached with the jump. The magnitude of the setpoint jump can be limited using an overload factor. Because the magnitude of the jump is axial, the minimum jump of the path axes which are active during the block change is considered during block transition.

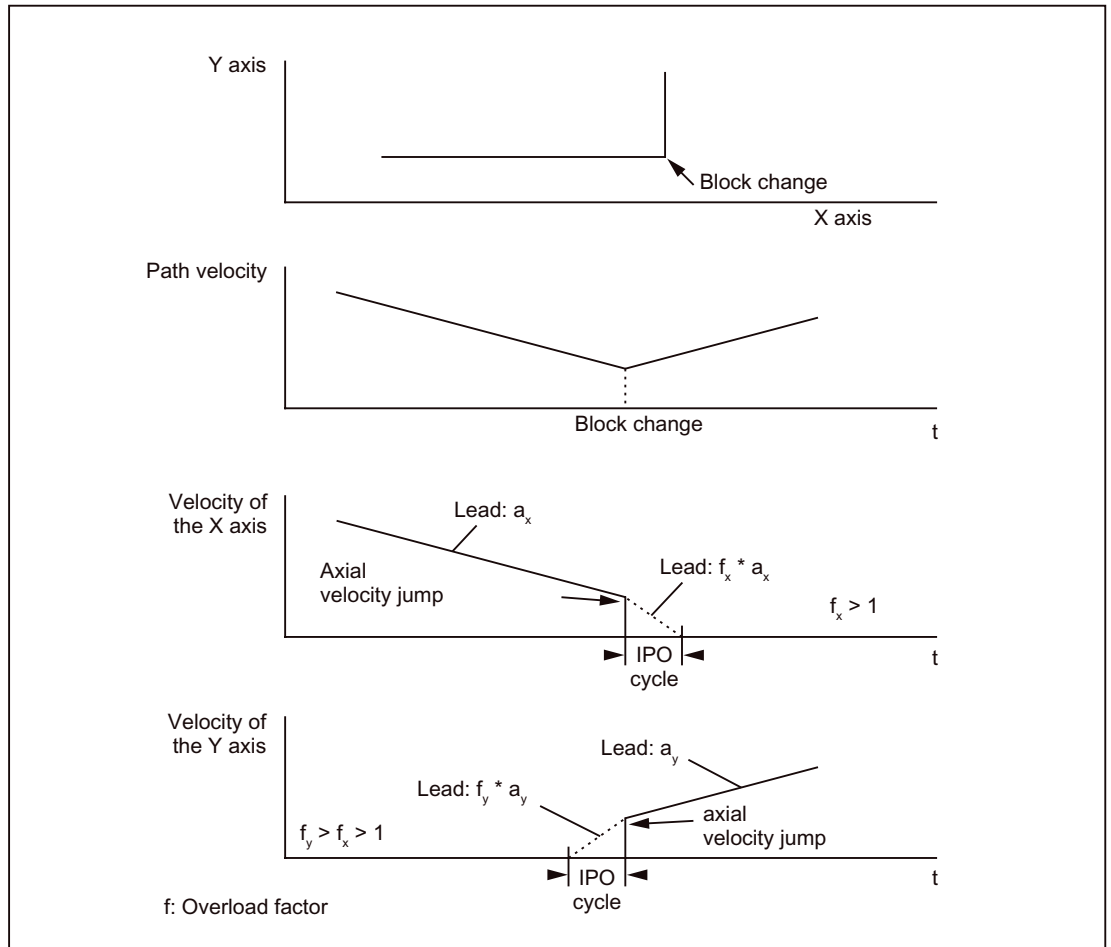

Figure 3-3 Axial velocity change on block transition

With a practically tangential block transition, the path velocity is not reduced if the permissible axial accelerations are not exceeded. This means that very small bends in the contour (e.g. 0.5 degrees) are overtraveled directly.

Overload factor

The overload factor restricts step changes in the machine axis velocity at block ends. To ensure that the velocity jump does not exceed the maximum load on the axis, the jump is derived from the acceleration of the axis.

3.3 Continuous-path mode

The overload factor indicates the extent by which the acceleration of the machine axis (MD32300 \$MA_MAX_AX_ACCEL) may be exceeded for an IPO cycle.

The velocity jump results as follows:

Velocity jump = axis acceleration * (overload factor-1) * interpolator cycle.

The overload factor is saved in the machine data:

MD32310 \$MA_MAX_ACCEL_OVL_FACTOR (overload factor for axial velocity jumps)

Factor 1.0 means that only tangential transitions with finite velocity can be traversed. For all other transitions, the velocity is reduced to zero by changing the setpoint. This behavior is equivalent to the function "Exact stop with interpolator end". This is undesirable for continuous-path mode, so the factor must be set to greater than 1.0.

Note

For startup and installation, please note that the factor must be reduced if the machine is likely to be subject to vibrations during angular block transitions and rounding is not to be used.

By setting the following machine data, the block transitions are rounded independent of the set overload factor with G641/G642:

MD20490 \$MC_IGNORE_OVL_FACTOR_FOR_ADIS

Activation/deactivation

Continuous-path mode with a reduction in speed according to the overload factor can be activated in any NC part program block by the modal command G64.

Selecting the exact stop which works on a block-by-block basis enables rounding to be interrupted (G9).

Continuous-path mode G64 can be deactivated by selecting:

- Modal exact stop G60
- Rounding G641, G642, G643, G644 or G645

Implicit continuous-path mode

If it is not possible to insert rounding blocks in continuous-path mode with rounding G641 due to the very short block path lengths (e.g. zero-clocked blocks), the mode is switched over to continuous-path mode G64.

3.3.3 Blending

Function

Rounding means that an angular block transition is changed to a tangential block transition by a local change to the programmed contour. This gives the area in the vicinity of the original angular block transition (including transitions between intermediate blocks inserted by the CNC) a continuous contour.

During rounding, it is not only the geometry axes that are taken into account, but all machine axes which traverse synchronously. The rounding function therefore smoothes the traversing path of orientation axes as well as general velocity step changes in synchronized axes.

Note

Rounding cannot and should not replace the functions for defined smoothing, i.e. RND, RNDM, ASPLINE, BSPLINE, CSPLINE.

If a rounding movement initiated by G641, G642, G643, G644 or G645 is interrupted, the corner point of the original contour will be used for subsequent repositioning, rather than the interruption point.

Synchronization

Rounding involves shortening discontinuously adjoining blocks and inserting one or two intermediate blocks at this point. The original block boundary is removed and can no longer be used for synchronization conditions (e.g. auxiliary function output parallel to motion, stop at end of block).

With rounding, all synchronization conditions are best referred to the end of the shortened first block and not to the end of the intermediate rounding block. The following block is thus not started and with a stop at end of block, the contour of the following block can still be changed.

Design

Rounding is only performed if the block transition is to be traveled with finite velocity. The maximum path speed is influenced by the curvature. The maximum acceleration values of the axes are not exceeded. A block without traverse information for the path axes requires velocity "zero" and therefore no rounding.

Rounding is also used if the traversal of the block transition requires a velocity that lies below the permissible velocity at the end of the block according to G64 (see overload factor).

No intermediate rounding blocks

An intermediate rounding block is not inserted in the following cases:

- The axis stops between the two blocks.

This occurs when:

- The following block contains an auxiliary function output before the movement.
- The following block does not contain a path movement.
- An axis is traversed for the first time as a path axis for the following block when it was previously a positioning axis.
- An axis is traversed for the first time as a positioning axis for the following block when it was previously a path axis.
- The previous block traverses geometry axes and the following block does not.
- The following block traverses geometry axes and the previous block does not.
- Before tapping, the following block uses G33 as preparatory function and the previous block does not.
- A change is made between BRISK and SOFT.
- Axes involved in the transformation are not completely assigned to the path motion (e.g. for oscillation, positioning axes).

- The rounding block would slow down the part program execution.

This occurs:

- between two very short blocks.

Since each block requires at least one interpolation cycle, the added intermediate block would double the machining time.

- If a block transition with G64 (continuous-path mode without rounding) can be traversed without a reduction in velocity.

Corner rounding would increase the machining time. This means that the value of the permitted overload factor (MD32310 \$MA_MAX_ACCEL_OVL_FACTOR) affects whether a block transition is rounded or not. The overload factor is only taken into account for rounding with G641 / G642. The overload factor has no effect in the case of rounding with G643 (this behavior can also be set for G641 and G642 by setting MD20490 \$MC_IGNORE_OVL_FACTOR_FOR_ADIS = TRUE).

- Rounding is not parameterized.

This occurs:

- in the case of G641 ADISPOS= 0 in G0 blocks (default!).
- In the case of G641 ADIS = 0 in non-G0 blocks (default!).
- For transition from G0 to non-G0 or non-G0 to G0, the smaller of the values for ADISPOS and ADIS will apply in the case of G641.
- For G642/G643, all axis-specific tolerances are zero.

- The block does not contain traversing motion (zero block).

This occurs when:

- Synchronized actions are active.

Normally, the interpreter eliminates zero blocks. However, if synchronous actions are active, this zero block is included and also executed. In so doing, an exact stop is initiated corresponding to the active programming. This allows the synchronous action to also switch.

- Zero blocks are generated by program jumps.

Synchronized axes

If a number of paths need to be synchronized (e.g. contour, special axis), then every path must always have its own rounding area.

There are no practical means of achieving this exactly. Therefore, on the basis of the specific meaning of the contour (geometry axis), the following procedure is applied:

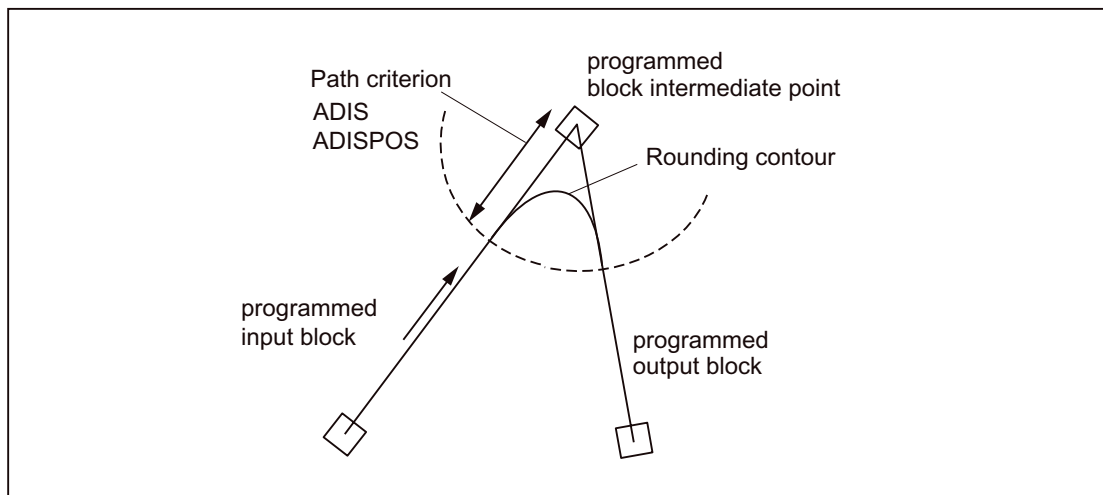

Rounding behavior with synchronized paths		
Original path for:		Rounding path outcome:
Geometry axes	Orientation/ synchronized axis	
Smooth	Smooth	Defined path is traversed exactly
Smooth	Angular	Intermediate blocks, the geometry axes follow the path exactly, all orientation/synchronized axis paths are smoothed.
Angular	Smooth	Intermediate block, the geometry axes perform rounding, all orientation/synchronized axis paths are smoothed.
Angular	Angular	Intermediate block, the geometry axes perform rounding, all orientation/synchronized axis paths are smoothed.

3.3.3.1 Rounding according to a path criterion (G641)

Function

In continuous-path mode with rounding according to a path criterion, the size of the rounding area is influenced by the path criteria ADIS and ADISPOS.

The path criteria ADIS and ADISPOS describe the maximum distances which a rounding block can occupy before and after a block.

Note

Acute angles produce rounding curves with a large degree of curvature and therefore cause a corresponding reduction in velocity.

Note

ADISPOS is programmed in the same way as ADIS, but must be used specifically for movements in rapid traverse mode G00.

Scope of the path criterion

- ADIS or ADISPOS must be programmed. If the default is "zero", G641 behaves like G64.
- If only one of the blocks involved is rapid traverse G00, the smaller rounding distance applies.

- If a very small value is used for ADIS, the control must make sure that every interpolated block, even an intermediate rounding block, contains at least one interpolation point. The maximum path velocity is thereby limited to ADIS / interpolation cycle.
- Irrespective of ADIS and ADISPOS, the rounding area is limited by the block length.

In blocks with short distances (distance $< 4 * ADIS$ and $< 4 * ADISPOS$ respectively), the rounding distance is reduced so that a traversable part of the original block is retained. The remaining length depends on the axis path and is approximately 60% of the distance still to be traversed in the block. ADIS or ADISPOS is therefore reduced to the remaining 40% of the distance to be traversed. This algorithm prevents a rounding block being inserted for a very small change in contour. In this case, switchover to continuous-path mode G64 is automatic until rounding blocks can be inserted again.

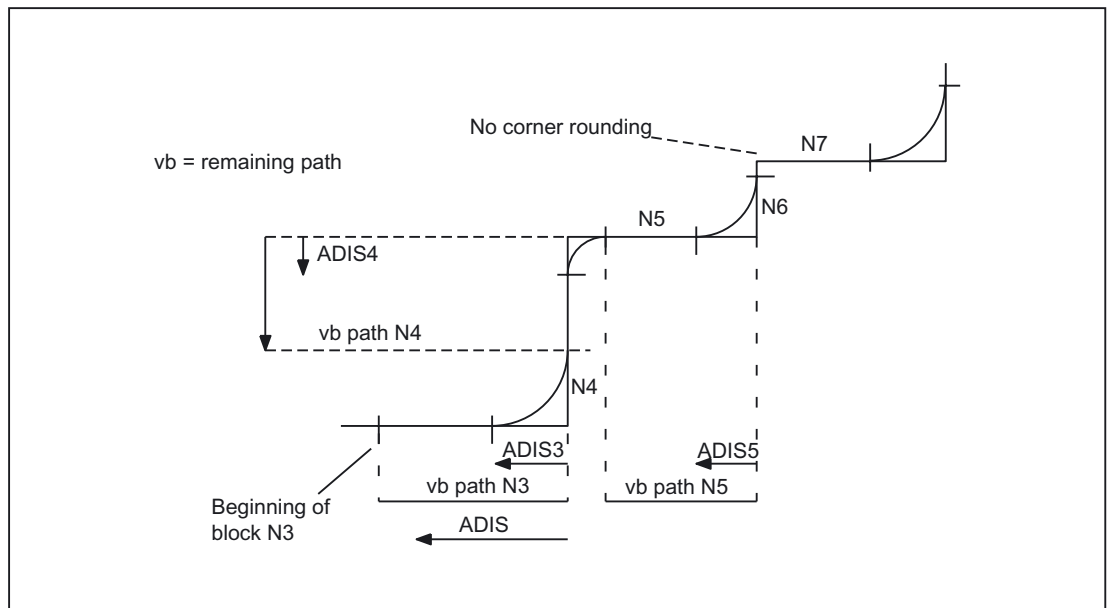

Figure 3-4 Path with limitation of ADIS

Activation/deactivation

Continuous-path mode with rounding based on a path criterion can be activated in any NC part program block by the modal command G641. Before or on selection, the path criteria ADIS/ADISPOS must be specified.

Selecting the exact stop which works on a block-by-block basis enables rounding to be interrupted (G9).

Continuous-path mode with rounding based on a path criterion (G641) can be deactivated by selecting:

- Modal exact stop (G60)
- Continuous-path mode G64, G641, G642, G644 or G645

Programming example

Program code	Comment
N1 G641 Y50 F10 ADIS=0.5	; Continuous-path mode with rounding based on a path criterion (rounding clearance: 0.5 mm)
N2 X50	
N3 X50.7	
N4 Y50.7	
N5 Y51.4	
N6 Y51.0	
N7 X52.1	

3.3.3.2 Rounding in compliance with defined tolerances (G642/G643)

Function

In continuous-path mode involving rounding in compliance with defined tolerances, the rounding normally takes place while adhering to the maximum permissible path deviation. Instead of these axis-specific tolerances, the maintenance of the maximum contour deviation (contour tolerance) or the maximum angular deviation of the tool orientation (orientation tolerance) can be configured.

Note

Expansion to include contour and orientation tolerance is only supported on systems featuring the "Polynomial interpolation" option. When rounding in compliance with the orientation tolerance, the additional option of "orientation transformation" is also necessary.

Activation

Continuous-path mode with rounding in compliance with defined tolerances can be activated in any NC part program block by the modal command G642 or G643.

Selecting the exact stop which works on a block-by-block basis enables rounding to be interrupted (G9).

Continuous-path mode with rounding in compliance with defined tolerances (G642/G643) can be deactivated by selecting:

- Modal exact stop (G60)
- Continuous-path mode G64, G641, G644 or G645

Differences between G642 - G643

With regard to their rounding behavior, commands G642 and G643 differ as follows:

G642	G643
With G642, the rounding path is determined on the basis of the shortest distance for rounding all axes. This value is taken into account when generating a rounding block.	In the case of G643, each axis may have a different rounding path. The rounding travels are taken into account axis-specifically and block-internally (⇒ no separate rounding block).
With G642, the rounding area results from the smallest tolerance setting.	Very different specifications for the contour tolerance and the tolerance of the tool orientation can only have effect with G643.

Parameter assignment

Maximum path deviation

The maximum path deviation permitted with G642 / G643 is set for each axis in the machine data:

MD33100 \$MA_COMPRESS_POS_TOL

Contour tolerance and orientation tolerance

The contour tolerance and orientation tolerance are set in the channel-specific setting data:

SD42475 \$SC_SMOOTH_CONTUR_TOL (maximum contour deviation)

SD42466 \$SC_SMOOTH_ORI_TOL (maximum angular deviation of the tool orientation)

The settings data can be programmed in the NC program and can in this way be specified differently for each block transition.

Note

The setting data SD42466 \$SC_SMOOTH_ORI_TOL is effective only in active orientation transformation.

Rounding behavior

Rounding behavior with G642 and G643 is configured via the machine data:

MD20480 \$MC_SMOOTHING_MODE (rounding behavior with G64x)

3.3 Continuous-path mode

The units positions (**E**) define the behavior for G643, the tens positions (**Z**) the behavior for G642:

Value E or Z	Description
0	All axes: Rounding by maintaining the maximum permitted path deviation: MD33100 \$MA_COMPRESS_POS_TOL
1	Geometry axes: Rounding by maintaining the contour tolerance: SD42465 \$SC_SMOOTH_CONTUR_TOL Remaining axes: Rounding by maintaining the maximum permitted path deviation: MD33100 \$MA_COMPRESS_POS_TOL
2	Geometry axes: Rounding by maintaining the orientation tolerance: SD42466 \$SC_SMOOTH_ORI_TOL Remaining axes: Rounding by maintaining the maximum permitted path deviation: MD33100 \$MA_COMPRESS_POS_TOL
3	Geometry axes: Rounding by maintaining the contour tolerance and the orientation tolerance: SD42465 \$SC_SMOOTH_CONTUR_TOL SD42466 \$SC_SMOOTH_ORI_TOL Remaining axes: Rounding by maintaining the maximum permitted path deviation: MD33100 \$MA_COMPRESS_POS_TOL
4	All axes: The rounding length programmed with <code>ADIS</code> or with <code>ADISPOS</code> is used (as in case of G641). Any axis-specific tolerance or contour and orientation tolerance specifications are ignored.

Profile for limit velocity

The use of a velocity profile for rounding in compliance with defined tolerances is controlled via the hundreds position in MD20480:

Value	Description
< 100:	A profile of the limit velocity is calculated within the rounding area, based on the defined maximum values for acceleration and jerk on the participating axes or path. This can lead to an increase in the path velocity in the rounding area and therefore to the acceleration of the participating axes.
≥100:	A profile of the limit velocity is not calculated for rounding blocks with G641/G642. A constant velocity limit is specified instead. This prevents the participating axes being accelerated into the rounding area during rounding with G641/G642. However, in certain cases, this setting can cause the rounding blocks to be traversed too slowly, especially in large rounding areas.
1xx:	No velocity profile for G641
2xx:	No velocity profile for G642

Note

MD28530 \$MC_MM_PATH_VELO_SEGMENTS (number of memory elements for limiting the path velocity)

Constraints

Restriction for protection zones with active radius compensation and tool orientation:

Although tool radius compensation is applied for a tool orientation, which is not perpendicular to one of the three datum planes of the basic coordinate system, the protection zones are not rotated onto the corresponding plane.

For G643 the following must apply:

MD28530 \$MC_MM_PATH_VELO_SEGMENTS > 0 (number of memory elements for limiting the path velocity)

If this condition is met, then it must be applicable for all axes:

MD35240 \$MC_ACCEL_TYPE_DRIVE = FALSE (acceleration characteristic line DRIVE for axes on/off)

3.3.3.3 Rounding with maximum possible axial dynamic response (G644)

Function

Maximizing the dynamic response of the axes is key to this type of continuous-path mode with rounding.

Note

Rounding with G644 is only possible if:

- all the axes involved contain only a linear motion in both the observed blocks.
- **no** kinematic transformation is active

In case an involved axis contains a polynomial (polynomial programmed, spline active, compressor active) or a kinematic transformation is active, the block transition is rounded with G642.

3.3 Continuous-path mode

Activation

Continuous-path mode with rounding with the maximum possible axial dynamic response can be activated in any NC part program block by the modal command G644.

Selecting the exact stop which works on a block-by-block basis enables rounding to be interrupted (G9).

Continuous-path mode with rounding with the maximum possible axial dynamic response (G644) can be deactivated by selecting:

- Modal exact stop (G60)
- Continuous-path mode G64, G641, G642, G643 or G645

Parameter assignment

Rounding behavior with G644 is configured via the thousands and tens of thousands places in the machine data:

MD20480 \$MC_SMOOTHING_MODE (rounding behavior with G64x)

Value	Description
Thousand's place:	
0xxx:	When rounding with G644, the maximum deviations for each axis specified by the following machine data are respected: MD33100 \$MA_COMPRESS_POS_TOL If the dynamics of the axis permit, then any specified tolerance is not utilized.
1xxx:	Input the maximum rounding path by programming ADIS=... or ADISPOS=... (as for G641).
2xxx:	Input the maximum possible frequencies of each axis in the rounding area using the machine data: MD32440 \$MA_LOOKAH_FREQUENCY (smoothing frequency for Look Ahead) The rounding area is defined so that no frequencies in excess of the specified maximum can occur while the rounding motion is in progress.
3xxx:	Any axis that has a velocity jump at a corner traverses around the corner with the maximum possible dynamic response (maximum acceleration and maximum jerk). SOFT: If SOFT is active, the maximum acceleration and the maximum jerk of each axis is maintained. BRISK: If BRISK is active, only the maximum acceleration and not the maximum jerk of each axis is maintained. With this setting, neither the maximum deviations nor the rounding distance are checked. The resulting deviations or rounding distances are determined exclusively by the dynamic limits of the respective axis and the current path velocity.
4xxx:	As in case of 0xxx, the maximum deviations of each axis specified with the following machine data are used: MD33100 \$MA_COMPRESS_POS_TOL Contrary to 0xxx, the specified tolerance is also utilized, if possible. Therefore, the axis does not attain its maximum possible dynamics.

Value	Description
5xxx:	As in case of 1xxx, the maximum possible rounding path is specified through programming of ADIS=... or ADISPOS= respectively. Contrary to 1xxx, the specified rounding path is also utilized, if possible. Therefore, the axes involved do not attain their maximum possible dynamics.
Ten thousands digit	
0xxxx	The velocity profiles of the axes in the rounding area are determined without jerk limiting for BRISK and with jerk limiting for SOFT.
1xxxx	The velocity profiles of the axes in the rounding area are always determined with jerk limiting, regardless of whether BRISK or SOFT is active.

When specifying the maximum axial deviations (MD33100 \$MA_COMPRESS_POS_TOL) or the maximum rounding distance (ADIS / ADISPOS) the available rounding path is normally not used, if permitted by the dynamics of the axes involved. Through this, the length of the rounding path depends on the active path feedrate. In case of lower path speeds, one gets lower deviations from the programmed contours. However, it can be set that in these cases the specified maximum axial deviation or the specified rounding distance is utilized, if possible. In this case the deviations depend on the programmed contour independent of the programmed path feedrate.

Note

Apart from the ones mentioned, the following limitation can also become active additionally:
The rounding distance cannot exceed half the length of the original participating blocks.

Jerk limitation

The smoothing of the velocity jump on each axis and thus the shape of the rounding path depends on whether an interpolation is performed with or without jerk limitation.

Without jerk limitation the acceleration of each axis reaches its maximum value in the entire rounding area.

3.3 Continuous-path mode

With jerk limitation, the jerk of each axis is limited to its maximum value within the rounding area. The rounding motion thus generally consists of 3 phases:

- **Phase 1**

During phase 1, each axis builds up its maximum acceleration. The jerk is constant and equal to the maximum possible jerk on the respective axis.

- **Phase 2**

During phase 2, the maximum permissible acceleration is applied.

- **Phase 3**

During phase 3, which is the last phase, the acceleration of each axis is reduced back to zero with the maximum permissible jerk.

3.3.3.4 Rounding of tangential block transitions (G645)

Function

In continuous-path mode with rounding, rounding blocks are also only generated on tangential block transitions if the curvature of the original contour exhibits a jump in at least one axis.

The rounding movement is defined here so that the acceleration of all axes involved remains smooth (no jumps) and the parameterized maximum deviations from the original contour (MD33120 \$MA_PATH_TRANS_POS_TOL) are not exceeded.

In the case of angular, non-tangential block transitions, the rounding behavior is the same as with G642 (see "Rounding in compliance with defined tolerances (G642/G643) (Page 162)").

Activation/deactivation

Continuous-path mode with rounding of tangential block transitions can be activated in any NC part program block by the modal command G645.

Selecting the exact stop which works on a block-by-block basis enables rounding to be interrupted (G9).

Continuous-path mode with rounding of tangential block transitions (G645) can be deactivated by selecting:

- Modal exact stop (G60)
- Continuous-path mode G64, G641, G642, G644 or G645

Comparison between G642 and G645

When rounding with G642, the only block transitions rounded are those which form a corner, i.e. the velocity of at least one axis jumps. However, if a block transition is tangential, but there is a jump in the curvature, no rounding block is inserted with G642. If this block transition is traversed with finite velocity, the axes experience some degree of jump in acceleration which (with the jerk limit activated!) may not exceed the parameterized limit (MD32432 \$MA_PATH_TRANS_JERK_LIM). Depending on the level of the limit, the path velocity at the block transition may be greatly reduced as a result. This constraint is avoided by using G645 because the rounding movement is defined here in such a way that no jumps occur in acceleration.

Parameter assignment

The following machine data indicates the maximum permissible path deviation for each axis during rounding with G645:

MD33120 \$MA_PATH_TRANS_POS_TOL

This value is only of relevance to tangential block transitions with variable acceleration. When angular, non-tangential block transitions are rounded, (as with G642) the tolerance from MD33100 \$MA_COMPRESS_POS_TOL becomes effective.

Free-form surface mode: Basic functions (Page 196)

3.3.4 LookAhead

3.3.4.1 Standard functionality

Function

LookAhead is a function which is active in continuous-path mode (G64, G64x) and determines a foreseeable velocity control for multiple NC part program blocks over and beyond the current block.

Note

LookAhead is only available for path axes, **not** for spindles and positioning axes.

If a part program contains consecutive blocks with very small paths, only one velocity is reached per block without LookAhead, enabling deceleration of the axes at the end of the block while maintaining acceleration limits. This means that the programmed velocity is not reached at all. With LookAhead, however, it is possible to implement the acceleration and deceleration phase over multiple blocks with approximately tangential block transitions, thereby achieving a higher feedrate with shorter distances.

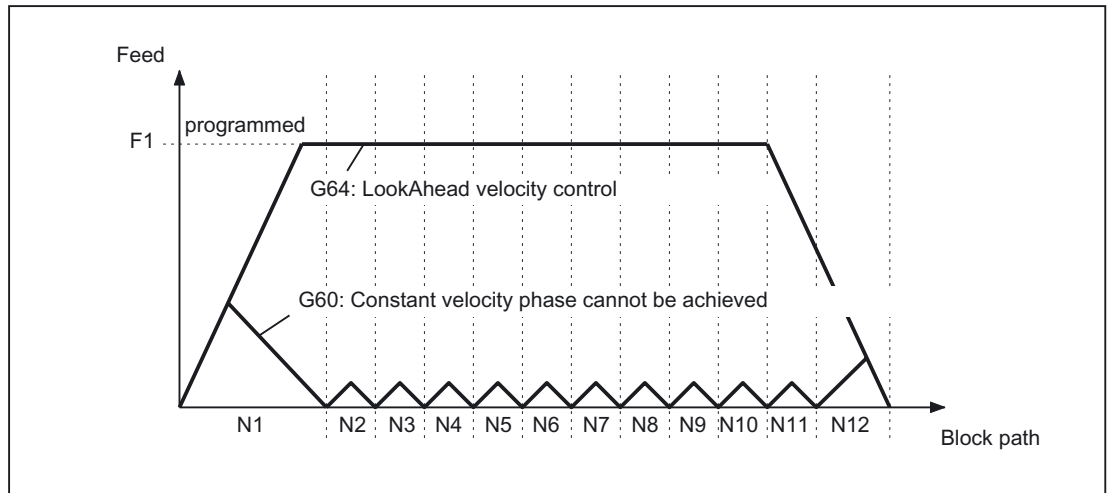

Figure 3-5 Velocity control with short distances and exact stop G60 or continuous-path mode G64 with LookAhead

Deceleration to velocity limits is possible with LookAhead such that violation of the acceleration and velocity limit is prevented.

LookAhead takes plannable velocity limits into consideration such as:

- Exact stop at block end
- Velocity limit in the block
- Acceleration limit in the block
- Velocity limit on block transition
- Synchronization with block change at block transition.

Principle

LookAhead carries out a block-specific analysis of velocity limits and specifies the required brake ramp profile based on this information. LookAhead is adapted automatically to block length, braking capacity and permissible path velocity.

For safety reasons, the velocity at the end of the last prepared block must initially be assumed to be zero because the next block might be very small or be an exact-stop block, and the axes must have been stopped by the end of the block.

With a series of blocks with high set velocity and very short paths, the speed can be increased in each block depending on the velocity value currently calculated by the LookAhead function in order to achieve the required set velocity. After this it can be reduced so that the velocity at the end of the last block considered by the LookAhead function can be zero. This results in a serrated velocity profile (see the following fig.) which can be avoided by reducing the set velocity or increasing the number of blocks considered by the LookAhead function.

Figure 3-6 Example for modal velocity control (number of blocks considered by the LookAhead function = 2)

Activation/deactivation

LookAhead is activated by selecting continuous-path mode G64, G641, G642, G643, G644 or G645.

Selecting the exact stop which works on a block-by-block basis enables rounding to be interrupted (G9).

LookAhead is deactivated by selecting the modal exact stop (G60).

Parameter assignment

Number of blocks

To achieve reliable axis traversal in continuous-path mode, the feedrate must be adapted over several blocks. The number of blocks considered by the LookAhead function is calculated automatically and can, if required, be limited by a machine data. The default setting is "1", which means that LookAhead only considers the following block for velocity control.

Because LookAhead is especially important for short blocks (relative to the deceleration path), the number of blocks required is of interest for LookAhead braking. It is enough to consider the path length to be equal to the deceleration path that is required to brake from maximum velocity to standstill.

For a machine with a low axial acceleration of $a = 1 \text{ m/s}^2$ and a high feedrate of $v_{\text{path}} = 10 \text{ m/min}$, the following number of $n_{\text{LookAhead}}$ blocks are allocated to the control where it has an attainable block cycle time of $TB = 10 \text{ ms}$:

$$n_{\text{LookAhead}} = \text{Deceleration path/Block length} = (v_{\text{path}}^2 / (2a)) / (v_{\text{path}} * TB) = 9$$

Considering these conditions, it is advisable to adapt the feedrate over 10 blocks. The number of blocks entered for the LookAhead function forecast does not change the LookAhead algorithm and memory requirement.

Since the machining velocity is very often set to a lower value than the maximum velocity in a program, more blocks than are required would be predicted, overloading the processor unnecessarily. For this reason, the required number of blocks is derived from the velocity which is calculated from the following multiplication:

- Programmed velocity * MD12100 \$MN_OVR_FACTOR_LIMIT_BIN
(when using a **binary**-coded feed-rate override switch)
- Programmed velocity * MD12030 \$MN_OVR_FACTOR_FEEDRATE[30]
(when using a **gray**-coded feed-rate override switch)

The value for MD12100 or the 31st override value for MD12030 defines the dynamic response reserves which the velocity control provides for when the path feed is overshot.

Note

The 31st override value for MD12030 should correspond to the highest override factor which is actually used.

Note

The number of blocks considered by the LookAhead function is limited by the possible number of NC blocks in the IPO buffer.

Velocity profiles

In addition to the fixed, plannable velocity limitations, LookAhead can also take account of the programmed velocity. This makes it possible to achieve a lower velocity by applying LookAhead beyond the current block.

3.3 Continuous-path mode

- **Determination of the following block velocity**

One possible velocity profile contains the determination of the following block velocity.

Using information from the current and the following NC block, a velocity profile is calculated from which, in turn, the required velocity reduction for the current override is derived.

The calculated maximum value of the velocity profile is limited by the maximum path velocity.

With this function it is possible to initiate a speed reduction in the current block taking override into account such that the lower velocity of the following block can be achieved. If the reduction in velocity takes longer than the travel time of the current block, the velocity is further reduced in the following block. Velocity control is only ever considered for the following block.

The function is activated via the machine data:

MD20400 \$MC_LOOKAH_USE_VELO_NEXT_BLOCK

Value	Meaning
TRUE	Function active
FALSE	Function not active

- **Definition of override points**

If the velocity profile of the following block velocity is not sufficient because, for example, very high override values (e.g. 200 %) are used or a constant cutting rate G96/G961 is active, with the result that the velocity must be further reduced in the following block, LookAhead provides a way of reducing the programmed velocity over several NC blocks.

By defining override points, LookAhead calculates a limiting velocity profile for each value. The required velocity reductions for the current override are derived from these profiles.

The calculated maximum value of the velocity profile is limited by the maximum path velocity.

The upper point should cover the velocity range that will be reached by the maximum value set in the machine data:

MD12030 \$MN_OVR_FACTOR_FEEDRATE [n] (evaluation of the path feed rate override switch)

It can also be reached via the value of the machine data:

MD12100 \$MN_OVR_FACTOR_LIMIT_BIN (limit for binary coded override switch)

In this way, a reduction of the velocity continuing into the block in which it is programmed can be avoided.

If velocity reductions across block boundaries are required at a 100 % override, a point should be set in the lower override range as well.

The number of override points used per channel is specified in the machine data:

MD20430 \$MC_LOOKAH_NUM_OVR_POINTS (number of override switch points for LookAhead)

The associated points are stored in the machine data:

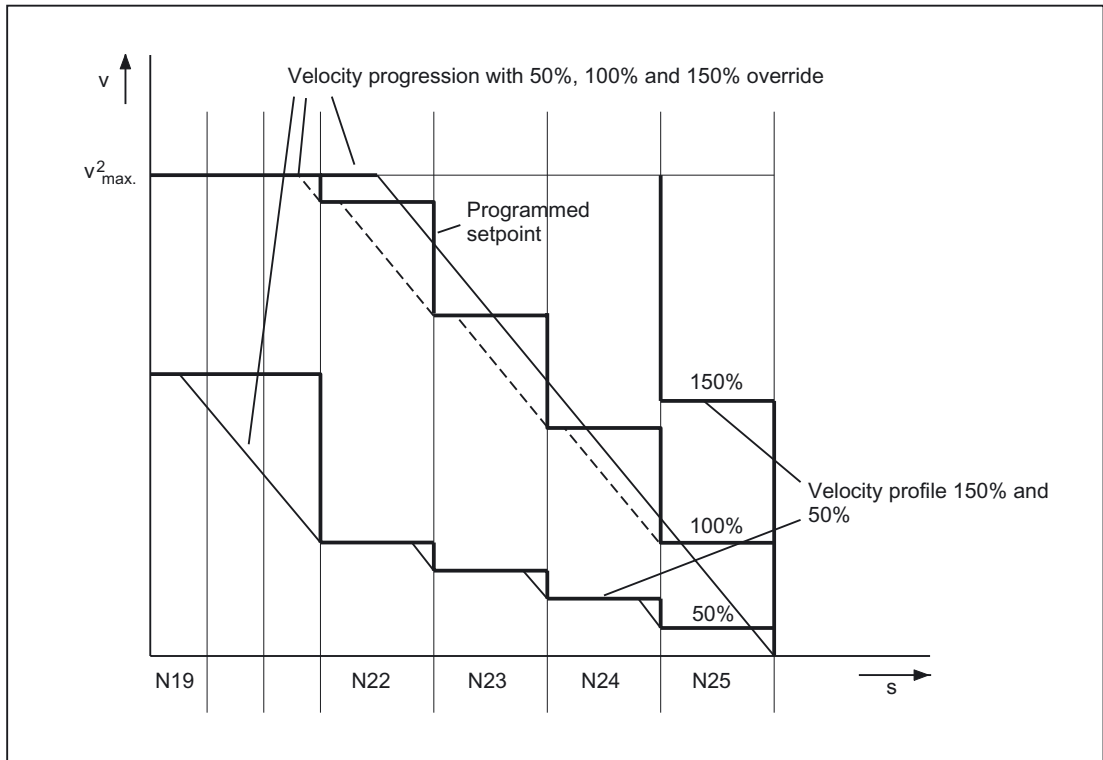

MD20440 \$MC_LOOKAH_OVR_POINTS (prepared override velocity characteristics with LookAhead)

Example:

Limiting velocity characteristics, whereby:

- Override = 50 %, 100 % or 150 %
- Number of LookAhead blocks = 4
- MD20430 \$MC_LOOKAH_NUM_OVR_POINTS = 2
- MD20440 \$MC_LOOKAH_OVR_POINTS = 1.5, 0.5
- MD20400 \$MC_LOOKAH_USE_VELO_NEXT_BLOCK = 1

3.3 Continuous-path mode

A combination of both procedures (determination of following block velocity and determination of override points) can be used to calculate the velocity profiles and is generally advisable because the preset machine data for these functions already takes the widest range of override-dependent velocity limits into account.

Note

If neither of the procedures has been activated, the setpoint velocity is always applied in the current block.

Note

Plannable velocity limits restrict override-specific velocity limits.

Relief factor with block cycle problems

Block cycle problems are encountered in cases where the traversing distances of the NC blocks to be processed are so short that the LookAhead function has to reduce the machine velocity to provide enough time for block processing. In this situation, constant braking and acceleration of path motion may occur.

Velocity fluctuations of this type can be dampened by specifying a relief factor:

MD20450 \$MC_LOOKAH_RELIEVE_BLOCK_CYCLE (relieving factor for the block cycle time)

Limit conditions

Axis-specific feed stop/axis disable

Axis-specific feed stop and axis-specific axis disable are ignored by LookAhead.

If an axis is to be interpolated that should on the other hand be made stationary by axis-specific feed stop or axis disable, LookAhead does not stop path movement before the block in question but decelerates in the block itself.

If this response is not wanted, an **axis**-specific feed stop can be transferred to a **channel** via the PLC to stop the path immediately (see also "Clamping monitoring (Page 84)").

3.3.4.2 Free-form surface mode: Extension function

Function

The "Free-form surface mode: Extension function" is an extension of the LookAhead standard functionality and is used to calculate the path velocity profile during free-form surface processing (see also "Free-form surface mode: Basic functions (Page 196)").

Its use optimizes the continuous-path mode as follows:

- Symmetry between the acceleration and deceleration profiles
- Uniform acceleration process, even with changing jerk or acceleration limits
- Uniform acceleration process of target velocity profiles, irrespective of the degree to which they can or cannot be started with the specified dynamic response limit
- LookAhead braking to lower setpoint velocities

Uniformity and compliance with the dynamic response limit guarantee that the setpoint velocity profiles are smoothed to a homogeneous velocity profile on the part. This serves to minimize the effect of following errors on the quality of the surface.

Therefore, the function offers the following advantages:

- Greater uniformity in the surface of the workpiece
- Lower machine load

Applications

The "Free-form surface mode: Extension function" is used to process workpieces which primarily comprise free-form surfaces.

Note

As better results are not achieved for standard processing applications, standard LookAhead functionality should be used in these cases.

Requirements

- The function is only effective:
 - in AUTOMATIC mode
 - in acceleration mode: acceleration with jerk limit (SOFT)
- Activation is only possible if the requisite memory is configured:

MD28533 \$MC_MM_LOOKAH_FFORM_UNITS = <value>

Sensible value assignment depends upon the part program, the block lengths, the axial dynamic response, as well as upon an active kinematic transformation.

The following setting applies as a guideline for processing free-form surfaces: 18

Note

Due to the additional storage requirements, MD28533 should only be set for the channels in which free-form surfaces are being processed.

Activation/deactivation

The function can be switched on or off independently for every dynamic response mode (see "Dynamic response mode for path interpolation (Page 193)"):

MD20443 \$MC_LOOKAH_FFORM[<n>]= <value>

Index <n>	Dynamic response mode	<value>	Free-form surface mode: Extension function
0	Standard dynamic response settings (DYNNORM)	0	off
		1	on
1	Positioning mode, tapping (DYNPOS)	0	off
		1	on
2	Roughing (DYNROUGH)	0	off
		1	on
3	Finishing (DYNSEMIFIN)	0	off
		1	on
4	Smooth-finishing (DYNFINISH)	0	off
		1	on

The "Free-form surface mode: Extension function" is typically only active if the "Free-form surface mode: Basic functions" are also active. Therefore, the settings in MD20443 \$MC_LOOKAH_FFORM[<n>] should correspond to the settings in MD20606 \$MC_PREPDYN_SMOOTHING_ON[<n>].

The standard LookAhead functionality is active in the dynamic response modes in which the "Free-form surface mode: Extension function" is switched off.

Programming

Generally speaking, the "Free-form surface mode: Extension function" becomes effective as a result of a change in the dynamic response mode in the part program.

Example

The following parameters are assumed:

```
MD20443 $MC_LOOKAH_FFORM[0] = 0
MD20443 $MC_LOOKAH_FFORM[1] = 0
MD20443 $MC_LOOKAH_FFORM[2] = 1
MD20443 $MC_LOOKAH_FFORM[3] = 1
MD20443 $MC_LOOKAH_FFORM[4] = 1
```

Program code	Comment
N10 DYNPOS	; Switch on the DYNPOS dynamic response mode. Standard LookAhead functionality is active in the DYNPOS dynamic response mode.
...

...	
N1009 Z4.994 G01	
N10010 X.520 Y149.679 Z5.000	
N10011 X10.841 Y149.679 Z5.000	
N10012 X11.635 Y149.679 Z5.010	
N10013 X12.032 Y149.679 Z5.031	
M30	

Note

When switching between the standard LookAhead functionality and the "Free-form surface mode: Extension function" or vice versa, continuous-path mode is interrupted by an interpolator stop.

Limit conditions

Automatic function switchover

Applying the following functions when the "Free-form surface mode: Extension function" leads to an automatic switchover to standard LookAhead functionality:

- Feed profile (FLIN, FCUB, FPO)
- Deceleration at corners (G62, G621)
- Thread cutting/tapping (G33, G34, G35, G331, G332, G63)
- Path master-value coupling
- Punching, nibbling
- Acceleration of the path axes with jerk limit (SOFT)
- Cartesian PTP travel

The "Free-form surface mode: Extension function" is then switched on again automatically.

Using the commands of G function group 15 (feed types)

It is not advisable to use the following feed types when the "Free-form surface mode: Extension function" is active:

- Feedrate per revolution (G95, G96, G97, etc.)
- Inverse-time feedrate (G93)

Time response during feedrate overrides

Feedrate overrides (via a machine control panel, \$AC_OVR, ...) can extend the traverse time over standard LookAhead functionality considerably.

Rapid traverse movements (G0)

G0 blocks which are interspersed during free-form surface processing do not switch the LookAhead functionality over (from the "Free-form surface mode: Extension function" to standard LookAhead functionality or vice versa).

This means that even though the standard dynamic response setting (DYNNORM) is effective with G0, the standard LookAhead functionality which is preset for DYNNORM (→ MD20443 \$MC_LOOKAH_FFORM[0]) does not automatically become effective as well as a result.

By retaining the LookAhead functionality which is currently active, a more homogeneous velocity profile is achieved, particularly since G0 and polynomial blocks are usually smoothed and connected by rounding.

Number of NC blocks in the IPO buffer

It is generally advisable to significantly increase the configured number of NC blocks in the interpolation buffer when using the "Free-form surface mode: Extension function":

MD28060 \$MC_MM_IPO_BUFFER_SIZE > 100

If the block memory capacity is too low, this may diminish the uniformity of the path-velocity profile.

3.4 Dynamic adaptations

3.4.1 Smoothing the path velocity

Introduction

The velocity control function utilizes the specified axial dynamic response. If the programmed feedrate cannot be achieved, the path velocity is brought to the parameterized axial limit values and the limit values of the path (velocity, acceleration, jerk). This can lead to repeated braking and acceleration on the path.

If a short acceleration takes place during a machining function with high path velocity, and is thus followed almost immediately by braking, the reduction in the machining time is only minimal. Acceleration of this kind can, however, have undesirable effects if, for example, it results in machine resonance.

In some applications in mold making, especially in the case of high speed cutting, it is desirable to achieve a constant path velocity. In these cases, it can therefore be reasonable to sacrifice transient acceleration processes in favor of a smoother tool path velocity.

Function

If the "smoothing the path velocity" function is active, a smoothing factor, which determines the maximum permissible productivity loss, takes effect with a view to achieving smoother path velocity control: Acceleration processes which contribute less than this factor to a shorter program runtime are not performed. Account is only taken of acceleration processes whose frequencies lie above the configurable limit frequencies of the axes involved.

Benefits:

- Avoidance of excitations of possible machine resonance due to continuous, transient braking and acceleration processes (in the area of less IPO cycles).
- Avoiding of constantly varying cutting rates due to acceleration which brings no significant shortening of the program running time.

Note

The smoothing of the path velocity does not lead to contour errors.

Variations in axis velocity due to curvatures in the contour at constant path velocity may continue to occur and are not reduced with this function.

Variations in path velocity due to the input of a new feedrate are not changed either. This remains the responsibility of the programmer of the subprogram.

Requirements

- The smoothing of the path velocity is only effective in continuous-path mode with LookAhead over multiple blocks with SOFT and BRISK. Smoothing is **not** effective with G0.
- The controller's cycle times must be configured in such a way that preprocessing can prepare sufficient blocks to enable an acceleration process to be analyzed.

Activation/deactivation

The "smoothing of the path velocity" function is activated/deactivated with the machine data: MD20460 \$MC_LOOKAH_SMOOTH_FACTOR (smoothing factor for LookAhead)

Value	Meaning
0.0	Smoothing of the path velocity not active (default)
> 0	Smoothing of the path velocity active

A change in the MD setting is only made effective through NEW CONF.

Parameter assignment

Smoothing factor

The smoothing factor is set via the channel-specific machine data:

MD20460 \$MC_LOOKAH_SMOOTH_FACTOR (smoothing factor for LookAhead)

The percentage value defines how much longer a processing step without accelerations/decelerations may be than the corresponding step with accelerations/decelerations.

This would be a "worst-case" value, if all accelerations within the part program, except the initial approach motion, were smoothed. The actual extension will always be smaller, and may even be 0, if the criterion is not met by any of the accelerations. Values between 50 and 100% may also be entered without significantly increasing the machining time.

Consideration of the programmed feed

The path velocity can be smoothed with or without taking the programmed feedrate into consideration. The selection is made via the machine data:

MD20462 \$MC_LOOKAH_SMOOTH_WITH_FEED (path smoothing with programmed feedrate)

Value	Description
0	Programmed feedrate is not taken into consideration.
1	Programmed feedrate is considered (default setting).

When considering the programmed feedrate, the specified smoothing factor (see MD20460) is maintained better when the override is 100%.

Axis-specific limit frequencies

The axis-specific limit frequencies are defined via the machine data:

MD32440 \$MA_LOOKAH_FREQUENCY (smoothing frequency for LookAhead)

Acceleration and deceleration processes, which run with a high frequency, are smoothed depending upon the parameterization of the following machine data or else are reduced in dynamics:

MD20460 \$MC_LOOKAH_SMOOTH_FACTOR (smoothing factor for LookAhead)

MD20465 \$MC_ADAPT_PATH_DYNAMIC (adaptation of the dynamic path response)

(Refer to "Adaptation of the dynamic path response (Page 184)" for further information about MD20465)

Note

If vibrations are generated in the mechanical system of an axis and if the corresponding frequency is known, MD32440 should be set to a value smaller than this frequency.

The needed resonance frequencies can be calculated using the built-in measuring functions.

Principle

The minimum value for MD32440 is calculated as f_{path} on the basis of the axes involved in the path. For the smoothing only those acceleration processes are taken into consideration, in which the start and the end velocity of this motion are reached within the time given below:

$$t = t_2 - t_1 = 2 / f_{\text{path}}$$

These acceleration processes are dispensed with if the resulting extension in the processing time does not exceed the limit specified in excess of the smoothing factor (MD20460).

Example

The following parameters are assumed:

MD20460 \$MC_LOOKAH_SMOOTH_FACTOR = 10 %

MD32440 \$MA_LOOKAH_FREQUENCY[AX1] = 20 Hz

MD32440 \$MA_LOOKAH_FREQUENCY[AX2] = 20 Hz

MD32440 \$MA_LOOKAH_FREQUENCY[AX3] = 10 Hz

The path involves the 3 axes X = AX1, Y = AX2, Z = AX3.

The minimum value of MD32440 for these 3 axes is thus 10 Hz. This means that any acceleration, which is completed within a period of $t_2 - t_1 = 2/10 \text{ Hz} = 200 \text{ ms}$, is examined. The time t_2 is the time it takes to reach velocity v_1 again following an acceleration process starting from velocity v_1 . The extending of the execution time is also only considered within this range.

If the time $t_2 - t_1$ is greater than 200 ms or if the additional program execution time $t_3 - t_2$ is more than 10% (= MD20460) of $t_2 - t_1$, the following time characteristic applies:

3.4 Dynamic adaptations

Figure 3-7 Characteristic of time-optimum path velocity (without smoothing)

If, however, the time $t_2 - t_1$ is less than 200 ms or if the additional program execution time $t_3 - t_2$ is no more than 10% of $t_2 - t_1$, the following time characteristic applies:

Figure 3-8 Characteristic of the smoothed path velocity

3.4.2 Adaptation of the dynamic path response

Function

Highly dynamic acceleration and deceleration processes during machining can cause excitation of mechanical vibrations of machine elements and consequently a reduction of the surface quality of the workpiece.

The dynamic response of the acceleration and deceleration processes can be adapted to the machine conditions using the "adaptation of the dynamic path response" function.

Note

The "adaptation of the dynamic path response" function only concerns the resulting path and not the deceleration and acceleration processes of the individual axes involved in the path. For this reason, critical deceleration and acceleration processes of the axes with respect to the excitation of mechanical vibrations can occur due to discontinuous contour profiles or kinematic transformations, even with a constant path velocity profile.

Activation

The "adaptation of the dynamic path response" function is only effective during path movements:

- Continuous-path mode (G64, G64x)

In continuous-path mode, the optimal effect of the dynamic response adaptation is attained with an active 100% override. Considerable deviations from this value or functions that cause the path axes to decelerate (e.g. auxiliary function outputs to the PLC) greatly reduce the desired action.

- Exact stop (G60)

In addition, the "adaptation of the dynamic path response" function is **not** active during path movements:

- Programmed rapid traverse (G0)
- Changes in the override value
- Stop requests during motion (e.g. NC-STOP, NC-RESET)
- "Velocity-dependent path acceleration" function (DRIVE) is active

Activation/deactivation

The function is activated/deactivated with the machine data:

MD20465 \$MC_ADAPT_PATH_DYNAMIC (adaptation of the dynamic path response)

Value	Meaning
= 1.0	Dynamic adaptation not active (default setting)
> 1.0	Dynamic adaptation active

When activation takes place, the "**smoothing the path velocity**" function is **always activated** internally in continuous-path mode as well (see "Smoothing the path velocity (Page 181)").

If the smoothing factor (MD20460 \$MC_LOOKAH_SMOOTH_FACTOR) is set to 0% (= function deactivated; default!), a smoothing factor of 100% is used as a substitute. For a smoothing factor other than 0%, the set value takes effect.

Parameter assignment

Adaptation factor of the dynamic path response

Via the adaptation factor of the dynamic path response, temporary changes in the path velocity are executed with smaller dynamic response limit values.

The adaptation factor is to be set on a channel-specific basis:

- For traversing motions with acceleration without jerk limiting (**BRISK**) via:

MD20465 \$MC_ADAPT_PATH_DYNAMIC[0]

→ The adaptation factor acts on the acceleration.

- For traversing motions with acceleration with jerk limiting (**SOFT**) via:

MD20465 \$MC_ADAPT_PATH_DYNAMIC[1]

→ The adaptation factor acts on the jerk.

Axis-specific limit frequencies

The dynamic response limiting should only be active during deceleration and acceleration processes that trigger mechanical vibrations larger than a specific limiting frequency, thus causing excitation of machine resonances.

This limit frequency from which the dynamic response limiting activates, is specified on an axis-specific basis via the machine data:

MD32440 \$MA_LOOKAH_FREQUENCY (smoothing frequency for LookAhead)

(See also "Smoothing the path velocity (Page 181)".)

Principle

During processing and via all the axes involved in the path, the controller cyclically establishes the minimum of all the limit frequencies to be the limit frequency (f) for the adaptation of the dynamic response and calculates the relevant time window (t_{adapt}) from this:

$$t_{\text{adapt}} = 1 / f$$

The size of the relevant time window t_{adapt} determines the further behavior:

1. The time needed to change the velocity is less than t_{adapt} :

The acceleration rates are reduced by a factor > 1 and \leq the value written in machine data:

MD20465 ADAPT_PATH_DYNAMIC (adaptation of the path dynamics)

The reduction in acceleration rate increases the time taken to change the velocity.

The following cases are different:

- The acceleration rate is reduced with a value less than MD20465 so that the process lasts for t_{adapt} [s]. The permitted reduction does not need to be fully utilized.
- The acceleration time is reduced with the value written in MD20465. The process lasts less than t_{adapt} despite the reduced acceleration. The permitted reduction was fully utilized.

2. The time needed to change the velocity is greater than t_{adapt} :

No dynamic response adaptation is required.

Example

The following example is intended to show the effect of the "adaptation of the dynamic path response" function on traversing motions with acceleration and without jerk limiting (BRISK).

The following parameters are assumed:

MD20465 \$MC_ADAPT_PATH_DYNAMIC[0] = 1.5	
MD20460 \$MC_LOOKAH_SMOOTH_FACTOR = 1.0	
MD32440 \$MA_LOOKAH_FREQUENCY[AX1] = 20 Hz	$T_{AX1} = 1/20 \text{ Hz} = 50 \text{ ms}$
MD32440 \$MA_LOOKAH_FREQUENCY[AX2] = 10 Hz	$T_{AX2} = 1/10 \text{ Hz} = 100 \text{ ms}$
MD32440 \$MA_LOOKAH_FREQUENCY[AX3] = 20 Hz	$T_{AX3} = 1/20 \text{ Hz} = 50 \text{ ms}$

Note

To illustrate the effect of dynamic response adaptation, the value for the smoothing factor (MD20460) is set to "1", whereby the "smoothing of the path velocity" function is practically deactivated.

The path involves the 3 axes X = AX1, Y = AX2, Z = AX3.

For path motions in which axis AX2 is involved, all deceleration and acceleration processes that would last less than T_{AX2} are adapted.

If only axes AX1 and/or AX3 are involved in path motions, all deceleration and acceleration processes that would last less than $T_{AX1} = T_{AX3}$ are adapted.

The relevant time window is marked $t_{\text{adapt}...}$ in the figures below.

Figure 3-9 Path velocity profile optimized for time without smoothing or dynamic adaptation response

Figure 3-10 Path velocity profile with adaptation of dynamic path response

Intervals $t_0 - t_1$ and $t_2 - t_3$:

The acceleration process between $t_0 - t_1$ and the deceleration process between $t_2 - t_3$ are extended in terms of time to $t_{adapt01}$ or $t_{adapt23}$ as a result of the acceleration being adapted.

Interval $t_4 - t_5$:

The acceleration process between $t_4 - t_5$ is executed with an acceleration reduced by the maximum adaptation factor of 1.5. However, the acceleration process is completed before time $t_{adapt45}$.

Interval $t_6 - t_7$:

The deceleration process between $t_6 - t_7$ remains unchanged as it lasts longer than $t_{adapt67}$.

3.4.3 Determination of the dynamic response limiting values

In addition to determining the natural frequency of the path axes for assigning parameters to the axis-specific limit frequencies (MD32440 \$MA_LOOKAH_FREQUENCY), the implementation of the "adaptation of the dynamic path response" function also requires dynamic response limits to be determined for velocity, acceleration and jerk.

Procedure

The determination of the dynamic response limits for the traversing of path axes by means of acceleration with jerk limiting (SOFT) is described below. This procedure can be applied by analogy to the case of acceleration without jerk limiting (BRISK).

1. Deactivate the "adaptation of the dynamic path response" function:
MD20465 \$MC_ADAPT_PATH_DYNAMIC[1] = 1
2. Observe the positioning behavior of each path axis at different traversing velocities. When doing so, set the jerk such that the desired positioning tolerance is maintained.

Note

The higher the traversing velocity from which the positioning process is started, the higher in general the jerk can be set.

3. Use the maximum permissible jerk determined for the least critical traversing velocity:
MD32431 \$MA_MAX_AX_JERK (maximum jerk)
4. Determine the F_{APD} factor for all of the path axes using:
 $F_{APD} = (\text{largest determined jerk}) / (\text{smallest determined jerk})$

Note

The smallest determined jerk is the value for the jerk during the most critical traversing velocity.

5. Enter the largest F_{APD} factor that was determined via all the path axes as the value for the adaptation factor for the path dynamic response:
MD20465 \$MC_ADAPT_PATH_DYNAMIC[1] = F_{APD}

3.4.4 Interaction between the "smoothing of the path velocity" and "adaptation of the path dynamic response" functions

The following examples serve to illustrate the interaction between the "smoothing of the path velocity" and "adaptation of the path dynamic response" functions in continuous-path mode.

Example 1

Acceleration mode: BRISK

The path involves the 3 axes X = AX1, Y = AX2, Z = AX3.

The following parameters are assumed:

```
MD20465 $MC_ADAPT_PATH_DYNAMIC[0] = 3
MD20460 $MC_LOOKAH_SMOOTH_FACTOR = 80.0
MD32440 $MA_LOOKAH_FREQUENCY[AX1] = 20      TAX1 = 1/20 Hz = 50 ms
MD32440 $MA_LOOKAH_FREQUENCY[AX2] = 20      TAX2 = 1/20 Hz = 50 ms
MD32440 $MA_LOOKAH_FREQUENCY[AX3] = 20      TAX3 = 1/20 Hz = 50 ms
```

3.4 Dynamic adaptations

Figure 3-11 Path velocity profile optimized for time without smoothing or dynamic adaptation response

Figure 3-12 Path velocity profile with smoothing of the path velocity and adaptation of dynamic path response

Effects of smoothing on path velocity:

- Interval $t_1 - t_2$: The acceleration and deceleration process between t_1 and t_2 does not take place because the lengthening of the machining time without the acceleration process to v_{12} is less than the resulting time if a smoothing factor of 80 % is applied.
- Interval $t_3 - t_5$: The acceleration and braking profile between t_3 and t_5 does not fulfill this condition or takes longer than the parameterized smoothing time $T_{Axn} = 2/20 \text{ Hz} = 100 \text{ ms}$.

Effects of the dynamic response adaptation:

- Interval $t_3 - t_4$: The acceleration process between t_3 and t_4 is shorter than $\text{MIN}(T_{AXn}) = 1/20 \text{ Hz} = 50 \text{ ms}$ and is, therefore, executed with an acceleration reduced by an adaptation factor of 3.
- Interval up to t_1 : The acceleration up to t_1 left over after path smoothing is stretched to the time period up to t_1' by the dynamic response adaptation.

Note

The example shows that those acceleration or deceleration processes that are not eliminated by the smoothing of the path velocity can be subsequently optimized by adapting the dynamic path response. For this reason, both functions should always be activated, if possible.

Example 2

Acceleration mode: SOFT

The path involves the 3 axes $X = AX1$, $Y = AX2$, $Z = AX3$.

The following parameters are assumed:

MD20465 \$MC_ADAPT_PATH_DYNAMIC[1] = 1
MD20460 \$MC_LOOKAH_SMOOTH_FACTOR = 0.0
MD32440 \$MA_LOOKAH_FREQUENCY[AX1] = 10 $T_{AX1} = 1/20 \text{ Hz} = 100 \text{ ms}$
MD32440 \$MA_LOOKAH_FREQUENCY[AX2] = 10 $T_{AX2} = 1/20 \text{ Hz} = 100 \text{ ms}$
MD32440 \$MA_LOOKAH_FREQUENCY[AX3] = 20 $T_{AX3} = 1/20 \text{ Hz} = 50 \text{ ms}$

This leads to a path velocity profile which is optimized in terms of time without smoothing the path velocity or adapting the dynamic path response:

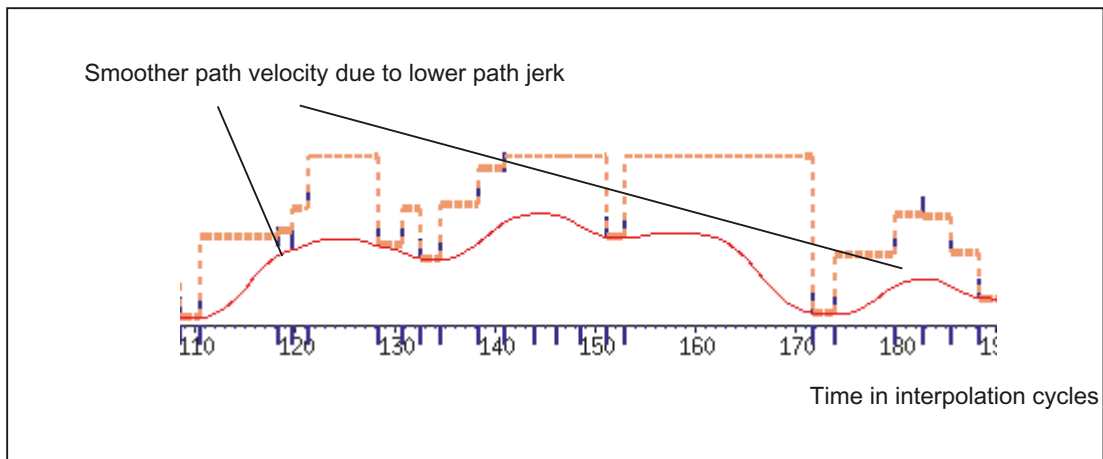

3.4 Dynamic adaptations

The parameter assignment is changed as follows:

```
MD20465 $MC_ADAPT_PATH_DYNAMIC[1] = 4  
MD20460 $MC_LOOKAH_SMOOTH_FACTOR = 1.0
```

This results in a path velocity profile with adaptation of the dynamic path response and with minimum, and thus virtually deactivated, smoothing of the path velocity:

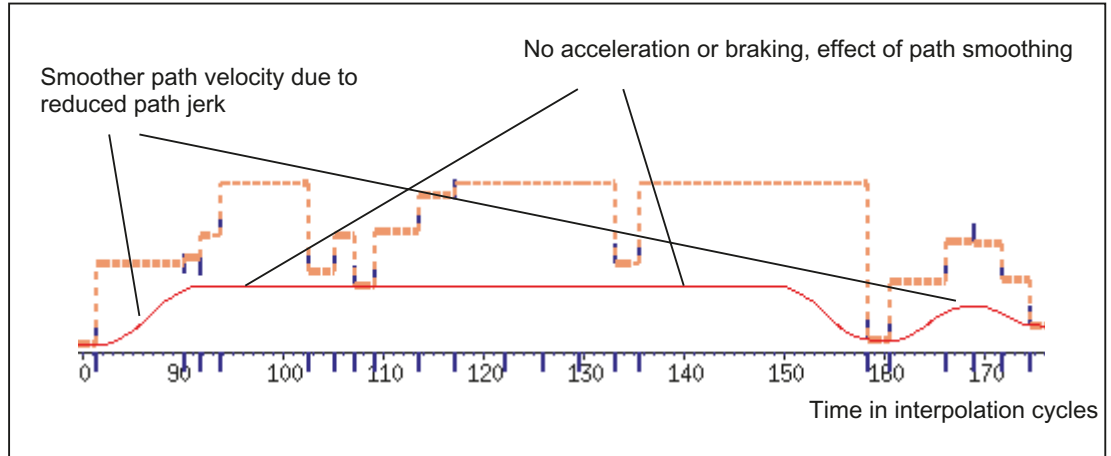

The smoothing factor is set to 0% instead of 1% (in accordance with the default!):

```
MD20460 $MC_LOOKAH_SMOOTH_FACTOR = 0.0
```

A smoothing factor of 100% comes into effect with this parameter assignment.

This gives rise to a path velocity profile with smoothing of the path velocity and adaptation of dynamic path response:

3.4.5 Dynamic response mode for path interpolation

Function

Technology-specific, dynamic response settings can be saved in machine data and can be activated in the part program via the commands from G function group 59 (dynamic response mode for path interpolation).

Command	Activates the dynamic response settings for:
DYNNORM	Standard dynamic response settings
DYNPOS	Positioning mode, tapping
DYNROUGH	Roughing
DYNSEMIFIN	Finishing
DYNFINISH	Smooth finishing

Note

The dynamic response of the path axes alone is determined by the commands from G function group 59 (dynamic response mode for path interpolation). They have no effect on:

- Positioning axes
- PLC axes
- Command axes
- Movements based on axis coupling
- Overlaid movements with handwheel
- JOG movements
- Reference point approach (G74)
- Fixed point travel (G75)
- Rapid traverse movements (G0)

The standard dynamic response setting (DYNNORM) always takes effect for these axis movements.

Application

By switching the dynamic response settings, roughing a workpiece can be optimized in terms of time and smoothing it can be optimized in terms of the surface, for example.

Parameter assignment

Parameters are assigned to the specific dynamic response settings:

- For the axis in question via the machine data:
 - MD32300 \$MA_MAX_AX_ACCEL[<n>] (axis acceleration)
 - MD32431 \$MA_MAX_AX_JERK[<n>] (maximum axial jerk for path motion)
 - MD32432 \$MA_PATH_TRANS_JERK_LIM[<n>] (max. axial jerk at the block transition in continuous-path mode)
 - MD32310 \$MA_MAX_ACCEL_OVL_FACTOR[<n>] (overload factor for axial jumps in velocity)
 - MD32433 \$MA_SOFT_ACCEL_FACTOR[<n>] (scaling of the acceleration limitation with SOFT)
- For the axis via the machine data:
 - MD20600 \$MA_MAX_PATH_JERK[<n>] (path-related maximum jerk)
 - MD20602 \$MC_CURV_EFFECT_ON_PATH_ACCEL[<n>] (influence of path curvature on dynamic path response)
 - MD20603 \$MC_CURV_EFFECT_ON_PATH_JERK[<n>] (influence of path curvature on path jerk)

Value range for index n:

Index <n>	Meaning
0	Value for DYNNORM
1	Value for DYNPOS
2	Value for DYNROUGH
3	Value for DYNSEMIFIN
4	Value for DYNFINISH

NOTICE
<p>Writing the machine data without an index places the same value in all field elements of the machine data in question.</p> <p>Reading the machine data without an index always supplies the value of the field with index 0.</p>

Suppressing G commands

G commands from G function group 59 (dynamic response mode for path interpolation) which are not intended for use should be suppressed by the machine manufacturer via the following machine data:

MD10712 \$MN_NC_USER_CODE_CONF_NAME_TAB[<n>] (list of reconfigured NC commands)

The programming of a suppressed G command leads to an alarm signal. This prevents machine data which has not been configured with the G command taking effect.

Example:

The G commands `DYNPOS` and `DYNSEMIFIN` can be suppressed with the following settings:

MD10712 \$MN_NC_USER_CODE_CONF_NAME_TAB[0]="DYNPOS"

MD10712 \$MN_NC_USER_CODE_CONF_NAME_TAB[1]=" "

MD10712 \$MN_NC_USER_CODE_CONF_NAME_TAB[2]="DYNSEMIFIN"

MD10712 \$MN_NC_USER_CODE_CONF_NAME_TAB[3]=" "

References

You can find further information about programming the G commands from G function group 59 (dynamic response mode for path interpolation) in:

Programming Manual, Fundamentals; chapter: "Path traversing behavior"

3.4.6 Free-form surface mode: Basic functions

Introduction

In applications in tool and mold making, it is important that the surfaces on the workpiece are as uniform as possible. This requirement is generally more important than the precision of the surface of the workpiece.

Workpiece surfaces which lack uniformity can be attributable to the following causes, for example:

- The part program for manufacturing the workpiece contains a non-uniform geometry. This, most notably, affects the profile of the curvature and torsion.

Note

The curvature k of a contour is the inverse of radius r of the nestling circle in a contour point ($k = 1/r$). The torsion is the change in curvature (first derivative).

As a result of the lack of uniformity in geometry, the machine's dynamic response limits are reached during processing of the part program, and needless deceleration and acceleration processes occur. Depending on the extent of the effective over-travel of the axes, this leads to different deviations in contours.

- Needless deceleration and acceleration processes can trigger machine vibrations which result in unwelcome marks on the workpiece.

There are various options available for eliminating these causes:

- The part programs generated by the CAD/CAM system contain a very uniform curvature and torsion profile, preventing needless reductions in path velocity.
- The maximum path velocity is determined in such a way that unwanted geometric fluctuations in the curvature and torsion profile have no effect.

Function

"Free-form surface mode: Basic functions" can be used to make the definition of path velocity limits insensitive to small geometric fluctuations in curvature and torsion without exceeding the machine's dynamic limits in terms of the acceleration and jerk of the axes.

This results in the following advantages:

- Greater uniformity in the profile of the path velocity
- Greater uniformity in the surface of the workpiece
- Reduction in the processing time (if the dynamic response of the machine permits it)

Applications

The function is used to process workpieces which primarily comprise free-form surfaces.

Requirements

The function can only be activated if the requisite memory capacity is reserved during memory configuration:

MD28610 \$MC_MM_PREPDYN_BLOCKS = 10

The value entered prescribes the number of blocks which have to be taken into consideration in the determination of the path velocity (velocity preparation). A sensible value is "10".

If MD28610 has a value of "0", only the movements of the axes in a particular block are taken into consideration when determining the maximum velocity of the path for that block. If the geometry of neighboring blocks is also taken into consideration when determining the velocity of the path (value > 0), a more uniform profile in path velocity is achieved.

Activation/deactivation

The function can be switched on or off independently for every dynamic response mode (see "Dynamic response mode for path interpolation (Page 193)"):

MD20606 \$MC_PREPDYN_SMOOTHING_ON[<n>] = <value>

Index <n>	Dynamic response mode	<value>	Free-form surface mode: Basic functions
0	Standard dynamic response settings (DYNNORM)	0	off
		1	on
1	Positioning mode, tapping (DYNPOS)	0	off
		1	on
2	Roughing (DYNROUGH)	0	off
		1	on
3	Finishing (DYNSEMIFIN)	0	off
		1	on
4	Smooth-finishing (DYNFINISH)	0	off
		1	on

Note

Due to the additional storage requirements, the function should only be activated in the relevant processing channels.

Parameter assignment

Change in the contour sampling factor

The secant error which occurs during the interpolation of curved contours is dependent on the following factors:

- Curvature
- Interpolation cycle (display in the MD10071 \$MN_IPO_CYCLE_TIME)
- Velocity with which the relevant contour is traversed

The max. possible secant error is defined for each axis in the machine data:

MD33100 \$MA_COMPRESS_POS_TOL (maximum tolerance with compression)

If the set interpolation cycle is not sufficiently small, the max. path velocity may be reduced in the case of contours with greater curvature. This is necessary for ensuring that the surface of the workpiece is also produced with an adequate degree of precision in this case.

By changing the contour sampling factor, the time interval with which a curved contour is sampled in the interpolator (contour sampling time) can be set at variance with the interpolation cycle. A contour sampling time which is shorter than the interpolation cycle can prevent a reduction in path velocity in the case of contours with greater curvature.

The contour sampling factor is set with the machine data:

MD10682 \$MN_CONTOUR_SAMPLING_FACTOR

The effective contour sampling time is calculated as follows:

$$T_s = f * T_1$$

- where:
- T_s = effective contour sampling time
 - T_1 = Interpolation cycle time
 - f = Contour sampling factor (value from MD10682)

The default contour sampling factor is "1", i.e. the contour sampling time equals the interpolation cycle.

The contour sampling factor can be both greater or less than "1".

If a value less than "1" is set, monitoring of contour sampling precision is disabled.

The set sampling time may not be below the configured minimum contour sampling time:

MD10680 \$MN_MIN_CONTOUR_SAMPLING_TIME

Note

MD10680 is specifically set for every controller model and cannot be changed.

Programming

Depending on the setting in machine data MD20606 \$MC_PREPDYN_SMOOTHING_ON, "Free-form surface mode: Basic functions" can be switched on and off in the part program by changing the active dynamic response mode.

Example:

By assigning the parameters MD20606 \$MC_PREPDYN_SMOOTHING_ON[2-4] = 1 and MD20606 \$MC_PREPDYN_SMOOTHING_ON[0-1] = 0, the function can be switched on via the commands `DYNROUGH`, `DYNSEMIFIN`, and `DYNFINISH` and switched off via the commands `DYNNORM` and `DYNPOS`.

3.5 Compressor functions

3.5.1 NC block compression

Function

COMPON, COMPCURV

The compressor functions COMPON and COMPCURV generate one polynomial block from up to 10 consecutive linear blocks. The polynomial blocks of the compressor functions have the following properties:

- COMPON: Continuous velocity block transitions.
- COMPCURV: Continuous velocity and acceleration block transitions

COMPCAD

The compressor functions COMPCAD can generate one polynomial block from theoretically as many linear blocks as required. The polynomial blocks have constant velocity and acceleration at the block transitions. Corners that are desirable are identified as such and taken into account.

The maximum tolerable deviation of the calculated path to the programmed points can be specified using machine data for all compressor functions. Different than for COMPON and COMPCURV, for COMPCAD, the specified tolerances are not utilized in different directions in neighboring paths. In fact, COMPCAD attempts to achieve - under similar conditions - also similar deviations from the programmed points.

The common objective of compressor functions is to optimize the surface quality and machining speed by achieving continuous block transitions and increasing the path length for each block.

COMPCAD is very processor and memory-intensive. It is recommended that COMCAD is only used there where surface improvements were not successful using measures in the CAD/CAM program.

Availability

For SINUMERIK 828D, NC block compression is only available for the milling versions.

Rated conditions

- The compressor functions COMPON, COMPCURV and COMPCAD compress straight blocks of the form: N... G01 X... Y... Z... F...
The COMPCAD compressor function also compresses all types of circular blocks.
- When orientation transformation (TRAORI) is active, and under certain preconditions, the compressor functions COMPON, COMPCURV and COMPCAD can also compress motion blocks for tool orientation and tool rotation.

References:

Function Manual Special Functions; 3 to 5-Axis Transformation (F2),
Chapter: "Compression of the orientation (COMPON, COMPCURV and COMPCAD)"

- The position data in the blocks to be compressed can be realized as required, e.g. X100, X=AC(100), X=R1*(R2+R3)
- The compression operation is then interrupted by every other command, e.g. auxiliary function output, in and between the blocks to be compressed.

Parameter assignment

Maximum path length

The maximum distance up to which a block is still compressed, is set using machine data:

MD20170 \$MC_COMPRESS_BLOCK_PATH_LIMIT

Longer blocks are not compressed, but are traversed normally.

Recommended setting: 20 [mm]

Maximum deviation of the path feedrate FLIN and FCUB

The maximum permissible deviation of the path feedrate for active compressor function COMPON or COMPCURV is specified in the machine data in conjunction with FLIN and FCUB:

MD20172 \$MC_COMPRESS_VELO_TOL

The higher the permissible deviation, the more short blocks that can be compressed into a long block.

Recommended setting: 100 [mm/min]

Axial deviation

For each axis involved in the compression, a maximum tolerable deviation of the generated path from the program points can be specified. The setting is done on an axis-for-axis basis using the machine data:

MD33100 \$MA_COMPRESS_POS_TOL

The higher the permissible deviation, the more short blocks that can be compressed into a long block.

Recommended setting: 0.01 [mm]

Contour accuracy

The maximum tolerable deviation of the generated path from the programmed points is specified using the following setting data for each channel:

SD42475 \$SC_COMPRESS_CONTUR_TOL

3.5 Compressor functions

Compression mode

The manner in which the maximum tolerable deviation from MD33100 and SD42475 is taken into account is set via the **units position** in the machine data:

MD20482 \$MC_COMPRESSOR_MODE (mode of compression)

Value	Meaning
xx0	The tolerances specified with MD33100 \$MA_COMPRESS_POS_TOL are maintained for all the axes (geo and orientation axes).
xx1	The tolerances specified with SD42475 \$SC_COMPRESS_CONTUR_TOL are maintained for the geometry axes. The tolerances specified with MD33100 \$MA_COMPRESS_POS_TOL are maintained for the orientation axes.
xx2	The tolerances specified with MD33100 \$MA_COMPRESS_POS_TOL are maintained for the geometry axes. The tolerances specified with - SD42476 \$SC_COMPRESS_ORI_TOL - SD42477 \$SC_COMPRESS_ORI_ROT_TOL are maintained for the axes of orientation motion (TRAORI).
xx3	The tolerances specified with SD42475 \$SC_COMPRESS_CONTUR_TOL are maintained for the geometry axes. The tolerances specified with - SD42476 \$SC_COMPRESS_ORI_TOL - SD42477 \$SC_COMPRESS_ORI_ROT_TOL are maintained for the axes of orientation motion (TRAORI).

The **tens position** in MD20482 is used to set whether blocks with value assignments (e.g. X=100 ...) should be compressed:

Value	Meaning
x0x / x2x	Blocks with value assignments are compressed (default setting). Notice: This behavior is incompatible with earlier releases of the software!
x1x / x3x	Blocks with value assignments are not compressed. This behavior is compatible with earlier releases of the software.

The type of traversing blocks that are compressed is set with the **hundreds position** of MD20482:

Value	Meaning
0xx	Circular blocks and G0 blocks are not compressed.
1xx	Circular blocks are compressed. Only COMPCAD
2xx	G0 blocks are compressed (see "Tolerance and compression of G0 blocks (Page 210)").
3xx	Circular blocks and G0 blocks are compressed.

An additional description of MD20482 can be found in:

References:

Function Manual Special Functions; Multi-Axis Transformations (F2),
Chapter: "Compression of the orientation"

Corner limit angle for COMPCAD

A limit angle can be defined for COMPCAD using the following setting data, from which a block transition is interpreted as corner:

SD42470 \$SC_CRIT_SPLINE_ANGLE (corner limit angle for compressor)

Values between 10 and 40 degrees are useful. The recommended setting is 36 degrees.

Note

The corner limit angle for COMPCAD is only used as an approximate measure for corner detection. By evaluating the plausibility, the compressor can also identify flatter block transitions as corners and larger angles as outliers.

Corresponding machine data

The machine data listed in the following table influence the compressor function. The following values are recommended for these:

Machine data	Recommended value
MD18360 \$MN_MM_EXT_PROG_BUFFER_SIZE (FIFO buffer size for processing from external)	100
MD28520 \$MC_MM_MAX_AXISPOLY_PER_BLOCK (maximum number of axis polynomials per block)	3
MD28530 \$MC_MM_PATH_VELO_SEGMENTS (Number of memory elements for limiting the path velocity)	5
MD28540 \$MC_MM_ARCLENGTH_SEGMENTS (number of memory elements for displaying the arc length function)	10
MD28070 \$MC_MM_NUM_BLOCKS_IN_PREP (number of blocks for block preparation)	60
MD28060 \$MC_MM_IPO_BUFFER_SIZE (number of NC blocks for block preparation)	100
MD32310 \$MA_MAX_ACCEL_OVL_FACTOR[AX1] (overload factor for axial jumps in velocity)	<Value for G64 operation>
MD32310 \$MA_MAX_ACCEL_OVL_FACTOR[AX2]	<Value for G64 operation>
MD32310 \$MA_MAX_ACCEL_OVL_FACTOR[AX3]	<Value for G64 operation>
MD20490 \$MC_IGNORE_OVL_FACTOR_FOR_ADIS (G641/G642 irrespective of the overload factor).	1

3.5 Compressor functions

Programming

Compressor functions are activated using the modal G commands `COMPON`, `COMPCURV` or `COMPCAD`.

When the compressor function is enabled, to further improve the surface quality, the functions `G642` (rounding function) and `SOFT` (jerk limiting) can be used. The commands must be written together at the beginning of the program.

The compressor functions are deactivated using the `COMPOF` command.

Program code	Comment
PROC ...	
N10 COMPCAD SOFT G642	; Activating the COMPCAD compressor
N20 G01 X... Y... Z... F...	; linear traversing blocks 1 ... n
N30 ...	
N1000 COMPOF	; Deactivating the COMPCAD compressor
N1010 RET	

References

The programming of the compressor functions is described in: Programming Manual Job Planning

The use of the compressor function with active orientation transformation is described in: Function Manual Special Functions; Multi-Axis Transformations (F2), Chapter: "Compression of the orientation"

3.5.2 Combining short spline blocks (option for 828D)

Function

During the processing of splines short blocks can so occur, that the path velocity for the interpolation of these spline blocks must be reduced. This is also the case, when the spline actually has a long, smooth curve.

The "Combine short spline blocks" function allows you to combine these spline blocks such that the resulting block length is sufficient and does not reduce the path velocity.

Note

NC block compressor

The NC block compressor (`COMPON`, `COMPCURV` or `COMPCAD`) cannot be employed while compressing spline blocks since it can only be used to compress linear blocks.

Activation

The function "overview of short spline blocks" can be activated for following cases independent of each other:

- BSPLINE active
- BSPLINE/ORICURVE active
- CSPLINE active

The activation is done using machine data:

MD20488 \$MC_SPLINE_MODE (setting for spline interpolation).

Bit	Value	Meaning
Function "Combining shorter spline blocks":		
0	0	for BSPLINE not active
	1	for BSPLINE active
1	0	for BSPLINE/ORICURVE not active
	1	for BSPLINE/ORICURVE active
2	0	for CSPLINE not active
	1	for CSPLINE active

Boundary conditions

- NC-blocks can be combined only if no other details have been programmed except the axial motions and the feed rate. If, for example, auxiliary functions are programmed, which must be given to the PLC, then this block cannot be omitted, since it must be active in the interpolator. This is analogous to the possible compression of G1 blocks with the compressors COMPON, COMPCURV and COMPCAD.
- The maximum number of blocks, which can be combined into a program part one after the other, depends on the size of the available memory for blocks in the block processing.

This memory is established by the machine data:

MD28070 \$MC_MM_NUM_BLOCKS_IN_PREP (number of blocks for block preparation)

Example

In order to attain a higher path velocity when processing the following program, the "combine short spline blocks" function is activated for BSPLINE interpolation via MD20488:

MD20488 \$MC_SPLINE_MODE, bit 0 = 1

Program code	Comment
N10 G1 G64 X0 Y0 Z0 F10000	
N20 G91 BSPLINE	; BSPLINE-interpolation with a combination of short spline blocks is effective from here.

3.6 Contour/Orientation tolerance

Program code	Comment
N30 X0.001 Y0.001 Z0.001	
N40 X0.001 Y0.001 Z0.001	
N50 X0.001 Y0.001 Z0.001	
N60 X0.001 Y0.001 Z0.001	
N70 X0.001 Y0.001 Z0.001	
N80 X0.001 Y0.001 Z0.001	
...	
N1000 M30	

3.6 Contour/Orientation tolerance

Parameter assignment for the contour/orientation tolerance

The maximum permissible contour deviation (contour tolerance) and the maximum permissible angular deviation for the tool orientation (orientation tolerance) are defined in the machine data for every axis:

MD33100 \$MA_COMPRESS_POS_TOL (maximum tolerance with compression)

The value set is valid both for the compressor functions and for the rounding functions with the exception of G641 (in this case, the distance to the block transition programmed with ADIS/ADISPOS applies).

Tolerance values from the following setting data may also be effective instead of MD33100:

SD42475 \$SC_SMOOTH_CONTUR_TOL (maximum contour deviation)

SD42466 \$SC_SMOOTH_ORI_TOL (maximum angular deviation of the tool orientation)

The manner in which the tolerance values from MD33100 and from the SD42465 and SD42466 setting data are to be taken into consideration is set as follows:

- For the rounding functions - via the decimal places in the machine data:
MD20480 \$MC_SMOOTHING_MODE (rounding behavior with G64x)
- For the compressor functions - via the ones position in the machine data:
MD20482 \$MC_COMPRESSOR_MODE (mode of compression)

Further machine and setting data which are of relevance in contour and orientation tolerance settings are:

- MD33120 \$MA_PATH_TRANS_POS_TOL (max. deviation when rounding with G645)
 The value from MD33120 is effective when rounding block transitions with uniform tangents and non-uniform curvature (e.g. circle/straight line transition) with G645.
- SD42676 \$SC_ORI_SMOOTH_TOL
 This setting data determines the tolerance when rounding the surface with OST.
- SD42678 \$SC_ORISON_TOL
 This setting data determines the tolerance when smoothing the orientation with ORISON.

Programming the contour/orientation tolerance

The machine and setting data described here take effect when the program is started and determine the tolerances for all compressor functions, the rounding functions G642, G643, G645, OST, and the ORISON orientation smoothing.

However, the NC program can overwrite these configured tolerances. The NC programmer has the following commands at his/her disposal for this purpose:

Command	Syntax	Meaning
CTOL	CTOL=<value>	Contour tolerance
OTOL	OTOL=<value>	Orientation tolerance
ATOL[<axis>]	ATOL[<axis>]=<value>	Axis-specific tolerance

CTOL and OTOL have priority over ATOL.

Programming does not trigger a preprocessing stop. If possible, it does not interrupt NC block compression either.

The programmed values are valid until they are reprogrammed or deleted by being written with a negative value. They are also deleted at the end of a program, in the event of a channel reset, a mode group reset, an NCK reset (warm restart), and POWER ON (cold restart). On deletion of these values, the values from the machine and setting data are restored.

New values can be programmed and become effective in any block.

Note

The programmed tolerance also acts upon functions which are only implicitly dependent upon the tolerance. These are currently:

- Limiting the chord error in the setpoint value calculation
 - The basic functions of the free-form surface mode
-

Note

The following rounding functions are not affected by the programming of `CTOL`, `OTOL`, and `ATOL`:

- rounding orientation with OSD
Reason: OSD does not use a tolerance, it uses a distance from the block transition.
 - Rounding with G644
Reason: G644 is not used for processing, it is used for optimizing tool changes and other movements in air.
 - Rounding block transitions with uniform tangents and non-uniform curvature with G645
G645 virtually always behaves like G642 and, thus, uses the programmed tolerances. The tolerance value from machine data MD33120 `$MA_PATH_TRANS_POS_TOL` is only used in uniformly tangential block transitions with a jump in curvature, e.g. a tangential circle/straight line transition. The rounding path at these points may also be located outside the programmed contour, where many applications are less tolerant. Furthermore, it generally takes a small, fixed tolerance to compensate for the sort of changes in curvature which need not concern the NC programmer.
-

Read tolerance values

For more advanced applications or for diagnostics, the currently valid tolerances for the compressor functions (`COMPON`, `COMPCURV`, `COMPCAD`), the smoothing types G642, G643, G645, `OST`, and the orientation smoothing `ORISON` can be read via system variables irrespective of how they might have come about.

- For the display in the user interface, in synchronized actions or with a preprocessing stop in the part program via the system variables:

\$AC_CTOL	Contour tolerance effective when the current main run record was preprocessed. If no contour tolerance is effective, \$AC_CTOL will return the root from the sum of the squares of the tolerances of the geometry axes.
\$AC_OTOL	Orientation tolerance effective when the current main run record was preprocessed. If no orientation tolerance is effective, \$AC_OTOL will return the root from the sum of the squares of the tolerances of the orientation axes during active orientation transformation. Otherwise, it will return the value "-1".
\$AA_ATOL[<axis>]	Axis tolerance effective when the current main run record was preprocessed. If no contour tolerance is active, \$AA_ATOL[<geometry axis>] returns the contour tolerance divided by the root of the number of geometry axes. If an orientation tolerance and an orientation transformation are active \$AA_ATOL[<orientation axis>] will return the orientation tolerance divided by the root of the number of orientation axes.

Note

If no tolerance values have been programmed, the \$A variables will not be differentiated sufficiently to distinguish potential differences in the tolerances of the individual functions, since they can only declare one value.

Circumstances like this can occur if the machine data and the setting data set different tolerances for compressor functions, smoothing and orientation smoothing. The variables then return the greatest value prevailing with regard to the currently active functions.

if, for example, a compressor function is active with an orientation tolerance of 0.1° and ORISON orientation smoothing with 1°, the \$AC_OTOL variable will return the value "1". If orientation smoothing is deactivated, only the value "0.1" will remain to be read.

- Without preprocessing stop in the parts program via system variables:

\$P_CTOL	Programmed contour tolerance
\$P_OTOL	Programmed orientation tolerance
\$PA_ATOL	Programmed axis tolerance

Note

If no tolerance values have been programmed, the \$P variables return the value "-1".

3.7 Tolerance and compression of G0 blocks

Function

The function "Tolerance and compression of G0 blocks" allows rapid traverse motion to be executed faster.

It consists of the following components:

1. **Configuring/programming an independent tolerance factor for G0 motion**

Using this factor, the tolerances for G0 motion can be set differently to the workpiece machining tolerances.

2. **Compressing G0 blocks**

If this functionality is selected, for active NC block compression, in addition to traversing blocks with G1 (straight line interpolation), traversing blocks with G0 (rapid traverse) are compressed.

Effectiveness

1. The G0 tolerance factor is only effective, if:

- One of the following functions is active:
 - Compressor functions: COMPON, COMPCURV and COMPCAD
 - Smoothing functions: G642 and G645
 - Orientation smoothing: OST
 - Orientation smoothing: ORISON
 - Smoothing for path-relevant orientation: ORIPATH
- Several (≥ 2) consecutive G0 blocks in the part program.

For a single G0 block, the G0 tolerance factor is not effective, as **at the transition** from a non G0 motion to a G0 motion (and vice versa), the "**lower tolerance**" always applies (workpiece machining tolerance)!

2. The compression of G0 blocks becomes effective:

- For NC block compression (COMPON, COMPCURV or COMPCAD).

Configuration

G0 tolerance factor

The G0 tolerance factor is set channel-specific with the machine data:

MD20560 \$MC_G0_TOLERANCE_FACTOR (tolerance factor for G0)

The G0 tolerance factor can be both greater or less than 1.0. If the factor equals 1.0 (default value), then the same tolerances for G0 blocks are effective as for non-G0 blocks. Normally, the G0 tolerance factor is set to ≥ 1.0 .

Compressing G0 blocks

The compression of G0 blocks is set for specific channels using the **hundreds position** in the machine data:

MD20482 \$MC_COMPRESSOR_MODE (mode of compression)

Value	Meaning
0xx	Circular blocks and G0 blocks are not compressed.
1xx	Circular blocks are compressed. Only COMPCAD.
2xx	G0 blocks are compressed. See also MD20560 \$MC_G0_TOLERANCE_FACTOR or NC command STOLF
3xx	Circular blocks and G0 blocks are compressed.

A more detailed description of MD20482 can be found in:

References:

Function Manual Special Functions; Multi-Axis Transformations (F2),
 Chapter: "Compression of the orientation"

Programming

The tolerance factor set using MD20560 \$MC_G0_TOLERANCE_FACTOR can be temporarily overwritten by programming STOLF in the part program:

Syntax: STOLF=<...>

Example:

Program code	Comment
COMPCAD G645 G1 F10000	; Compressor function COMPCAD
X... Y... Z...	; The machine and setting data apply here.
X... Y... Z...	
X... Y... Z...	
G0 X... Y... Z...	
G0 X... Y... Z...	; Machine data \$MC_G0_TOLERANCE_FACTOR (e.g. =3), is effective here, i.e. a smoothing tolerance of \$MC_G0_TOLERANCE_FACTOR*\$MA_COMPRESS_POS_TOL.
CTOL=0.02	
STOLF=4	
G1 X... Y... Z...	; A contour tolerance of 0.02mm is applied starting from here.
X... Y... Z...	
X... Y... Z...	
G0 X... Y... Z...	
X... Y... Z...	; From here, a G0 tolerance factor of 4 applies, i.e. a contour tolerance of 0.08mm.

The value in MD20560 is not changed by programming the tolerance factor. After a reset or end of part program, the value set using MD20560 is effective again.

Reading the tolerance factor

The G0 tolerance factor, effective in the part program or in the actual IPO block, can be read using system variables.

- For the display in the user interface, in synchronized actions or with a preprocessing stop in the part program via the system variables:

\$AC_STOLF	Active G0 tolerance factor
	G0 tolerance factor, which was effective when processing the actual main run block.

- Without preprocessing stop in the part program via system variable:

\$P_STOLF	Programmed G0 tolerance factor
-----------	--------------------------------

If no value with `STOLF` is programmed in the active part program, then these two system variables supply the value set using MD20560 `$MC_G0_TOLERANCE_FACTOR`.

If no rapid traverse (G0) is active in a block, then these system variables always supply a value of 1.

3.8 RESET response

MD20150

The channel-specific initial state is activated via a RESET for G function groups:

MD20150 \$MC_GCODE_RESET_VALUES (RESET position of G groups)

The following G function groups are of relevance to "continuous-path mode, exact stop, LookAhead":

- Group 10: Exact stop - continuous-path mode
- Group 12: Block-change criterion for exact stop
- Group 21: Acceleration profile
- Group 30: NC block compression
- Group 59: Dynamic response mode for path interpolation

References

For detailed information about setting initial states, see the section titled "Mode Group, Channel, Program Operation, Reset Behavior (K1)."

3.9 Supplementary conditions

3.9.1 Block change and positioning axes

If path axes are traversed in continuous path mode in a part program, traversing positioning axes can also simultaneously affect both the response of the path axes and the block change.

A detailed description of the positioning axes can be found in:

References:

Function Manual, Extended Functions; Positioning axes (P2)

3.9.2 Block change delay

Even if all path axes and special axes traversing in the part program block have satisfied their specific block transition criteria, the block change can still be delayed due to other unsatisfied conditions and/or active functions:

Examples:

- Missing auxiliary function acknowledgement by the PLC
- Non-existent following blocks
- Active function "Empty buffer"

Effects

If a block change cannot be executed in continuous path mode, all axes programmed in this part program block (except cross-block traversing special axes) are stopped. In this case, contour errors do not occur.

The stopping of path axes **during machining** can cause undercuts on the workpiece surface.

3.9.3 Rounding and repositioning (REPOS)

Repositioning within the rounding area

If the traversing motion of the path axes within the rounding area is interrupted for traversing blocks with programmed rounding (part program command G641, G642, G643, G644 or G645), repositioning occurs as follows in the event of a subsequent REPOS operation, depending on the current REPOS mode:

REPOS mode	REPOS end point
RMB	Block start of interrupted traversing block
RMI	Block end of interrupted traversing block
RME	Block end of interrupted traversing block
RMN	Block end of interrupted traversing block

Example

Two traversing blocks N10 and N20 with programmed rounding G641. In the rounding area, the traversing motion is interrupted and the axes are subsequently traversed, e.g., manually to the REPOS starting point. Repositioning on the contour takes place differently, depending on the active REPOS mode.

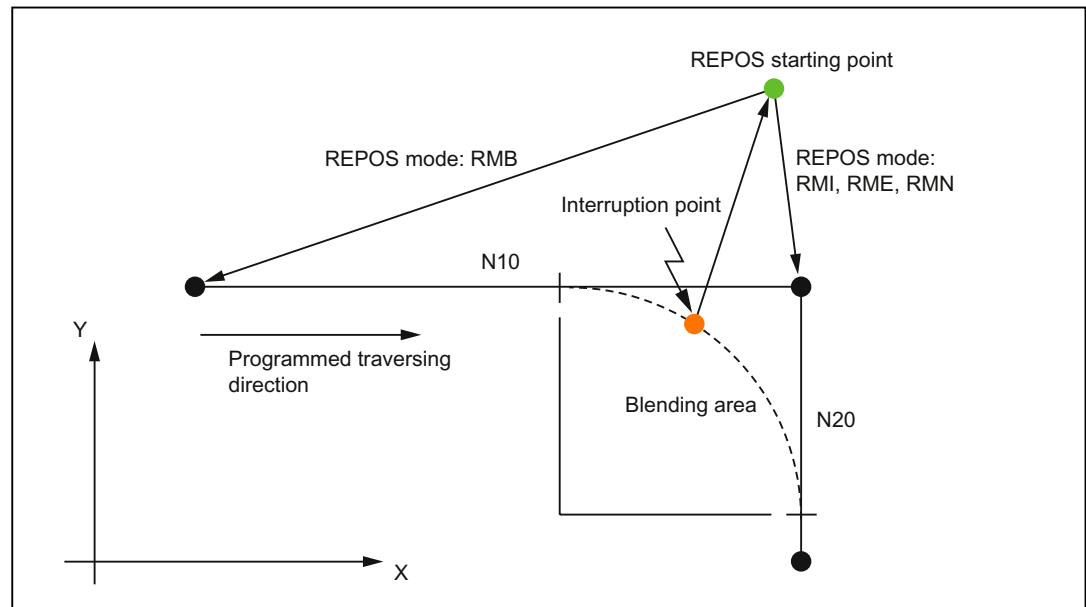

Figure 3-13 Example of rounding and repositioning

3.10 Data lists

3.10 Data lists

3.10.1 Machine data

3.10.1.1 General machine data

Number	Identifier: \$MN_	Description
10110	PLC_CYCLE_TIME_AVERAGE	Average PLC acknowledgment time
10680	MIN_CONTOUR_SAMPLING_TIME	Minimum contour sampling time
10682	CONTOUR_SAMPLING_FACTOR	Contour sampling factor
10712	NC_USER_CODE_CONF_NAME_TAB	List of reconfigured NC commands
12030	OVR_FACTOR_FEEDRATE	Evaluation of the path feed override switch
12100	OVR_FACTOR_LIMIT_BIN	Limit for binary-coded override switch
18360	MM_EXT_PROG_BUFFER_SIZE	FIFO buffer size for execution from external source (DRAM)

3.10.1.2 Channel-specific machine data

Number	Identifier: \$MC_	Description
20150	GCODE_RESET_VALUES	Initial setting of the groups
20170	COMPRESS_BLOCK_PATH_LIMIT	Maximum traversing length of NC block for compression
20172	COMPRESS_VELO_TOL	Maximum permissible deviation from path feed for compression
20400	LOOKAH_USE_VELO_NEXT_BLOCK	LookAhead following block velocity
20430	LOOKAH_NUM_OVR_POINTS	Number of override switch points for LookAhead
20440	LOOKAH_OVR_POINTS	Override switch points for LookAhead
20443	LOOKAH_FFORM	Activating the extended LookAhead
20450	LOOKAH_RELIEVE_BLOCK_CYCLE	Relief factor for the block cycle time
20460	LOOKAH_SMOOTH_FACTOR	Smoothing factor for LookAhead
20462	LOOKAH_SMOOTH_WITH_FEED	Smoothing with programmed feed
20465	ADAPT_PATH_DYNAMIC	Adaptation of path dynamic response
20480	SMOOTHING_MODE	Rounding behavior with G64x
20482	COMPRESSOR_MODE	Compressor mode
20488	SPLINE_MODE	Setting for spline interpolation
20490	IGNORE_OVL_FACTOR_FOR_ADIS	G641/G642 independent of the overload factor
20550	EXACT_POS_MODE	Exact-stop conditions with G0/G1
20560	G0_TOLERANCE_FACTOR	G0 tolerance factor
20600	MAX_PATH_JERK	Path-related maximum jerk

Number	Identifier: \$MC_	Description
20602	CURV_EFFECT_ON_PATH_ACCEL	Influence of path curvature on path dynamic response
20603	CURV_EFFECT_ON_PATH_JERK	Influence of path curvature on path jerk
20606	PREPDYN_SMOOTHING_ON	Activation of the curvature smoothing
28060	MM_IPO_BUFFER_SIZE	Number of NC blocks in IPO buffer (DRAM)
28070	MM_NUM_BLOCKS_IN_PREP	Number of NC blocks for block preparation (DRAM)
28520	MM_MAX_AXISPOLY_PER_BLOCK	Maximum number of axis polynomials per block
28530	MM_PATH_VELO_SEGMENTS	Number of storage elements for limiting path velocity in block
28533	MM_LOOKAH_FFORM_UNITS	Storage for the extended LookAhead
28540	MM_ARCLENGTH_SEGMENTS	Number of storage elements for arc length function representation per block
28610	MM_PREPDYN_BLOCKS	Number of blocks for velocity preparation

3.10.1.3 Axis/spindle-specific machine data

Number	Identifier: \$MA_	Description
32310	MAX_ACCEL_OVL_FACTOR	Overload factor for axial velocity jumps
32431	MAX_AX_JERK	Maximum axial jerk when traversing along the path
32432	PATH_TRANS_JERK_LIM	Maximum axial jerk at the block transition in continuous-path mode
32433	SOFT_ACCEL_FACTOR	Scaling of acceleration limitation for SOFT
32434	G00_ACCEL_FACTOR	Scaling of acceleration limitation for G00
32435	G00_JERK_FACTOR	Scaling of axial jerk limitation for G00
32440	LOOKAH_FREQUENCY	Smoothing limit frequency for LookAhead
33100	COMPRESS_POS_TOL	Maximum deviation with compensation
33120	PATH_TRANS_POS_TOL	Maximum deviation when rounding with G645
35240	ACCEL_TYPE_DRIVE	DRIVE acceleration characteristic for axes on/off
36000	STOP_LIMIT_COARSE	Exact stop coarse
36010	STOP_LIMIT_FINE	Exact stop fine
36012	STOP_LIMIT_FACTOR	Exact stop coarse/fine factor and zero speed monitoring
36020	POSITIONING_TIME	Delay time exact stop fine

B2: Acceleration

4.1 Brief description

4.1.1 General

Scope of functions

The Description of Functions covers the following sub-functions:

- Acceleration
- Jerk
- Knee-shaped acceleration characteristic

Acceleration and jerk

The effective acceleration and jerk can be optimally matched to the machine and machining situation concerned using axis- and channel-specific programmable maximum values, programmable acceleration profiles in part programs and synchronized actions, and dynamic adaptations and limitations.

Knee-shaped acceleration characteristic

The knee-shaped acceleration characteristic means that, in the case of machine axes featuring a motor (in particular stepper motors) with a torque characteristic that is highly dependent upon speed, acceleration can be set at the level required to ensure optimum utilization of the motor whilst at the same time protecting it against overload.

4.1.2 Features

Acceleration

Axis-specific functions:

- Programmable maximum acceleration value
- Acceleration profile that can be selected via part-program instruction:
Acceleration without jerk limitation (`BRISKA`)
- Setting of maximum value using part-program instruction (`ACC`)
- Specific maximum value for programmed rapid traverse (`G00`).
- Specific maximum value for traverse with active jerk limitation
- Excessive acceleration for non-tangential block transitions

Channel-specific functions:

- Acceleration profile that can be selected via part-program instruction:
Acceleration without jerk limitation (BRISK)
- Programmable constant travel time for the purpose of avoiding extreme sudden acceleration
- Programmable acceleration margin for overlaid traversing
- Adjustable acceleration limitation
- Adjustable acceleration for specific real-time events
- Programmable acceleration margin for radial acceleration

Jerk

Axis-specific functions:

- Acceleration profile that can be selected via part-program instruction:
Acceleration with jerk limitation (SOFTA)
- Programmable maximum jerk value for single-axis interpolation
- Programmable maximum jerk value for path interpolation

Channel-specific functions:

- Acceleration profile that can be selected via part-program instruction:
Acceleration with jerk limitation (SOFT)
- Adjustable jerk limitation
- Adjustable path jerk for specific real-time events
- Specific maximum value for programmed rapid traverse (G00)
- Excessive jerk for block transitions without constant curvature

Knee-shaped acceleration characteristic

A knee-shaped acceleration characteristic is parameterized using the following characteristic data:

- Maximum velocity v_{max}
- Maximum acceleration a_{max}
- Creep velocity v_{red}
- Creep acceleration a_{red}
- Nature of the acceleration reduction (constant, hyperbolic, linear)

4.2 Functions

4.2.1 Acceleration without jerk limitation (BRISK/BRISKA) (channel/axis-specific)

4.2.1.1 General information

General information

In the case of acceleration without jerk limitation (jerk = infinite) the maximum value is applied for acceleration immediately. As regards acceleration with jerk limitation, it differs in the following respects:

- **Advantages**

Shorter processing times with the same maximum values for velocity and acceleration.

- **Disadvantages**

Increased load on the machine's mechanical components and risk of inducing high-frequency and difficult-to-control mechanical vibrations.

Acceleration profile

a_{max} : Maximum acceleration value

v_{max} : Maximum velocity value

t: Time

Figure 4-1 Velocity and acceleration schematic for stepped acceleration profile

The following features of the acceleration profile can be identified from the figure above:

- Time: t_0
Sudden acceleration from 0 to $+a_{max}$
- Interval: $t_0 - t_1$
Constant acceleration with $+a_{max}$; linear increase in velocity
- Time: t_1
Sudden acceleration from $2 * a_{max}$ with immediate switchover from acceleration to braking

Note

The sudden acceleration can normally be avoided by specifying a constant velocity time (see Section: "Sudden acceleration with constant velocity phase").

- Interval: $t_1 - t_2$
Constant acceleration with $-a_{max}$; linear decrease in velocity

4.2.1.2 Programmable maximum value (axis-specific)

Function

The maximum acceleration value can be set for each specific machine axis:

MD32300 \$MA_MAX_AX_ACCEL (maximum axis acceleration)

The path parameters are calculated by the path planning component during preprocessing so that the programmed maximum values of the machine axes that are of relevance for the path are not exceeded.

Exceeding of maximum value

It is possible for the maximum value to be exceeded in connection with specific machining situations (see Section: Acceleration matching (ACC) and System variable (\$AC_PATHACC)).

4.2.1.3 Parameterization

Programming

The maximum values are parameterized for specific axes using machine data:

MD32300 \$MA_MAX_AX_ACCEL (maximum axis acceleration)

4.2.1.4 Programming

Path acceleration without jerk limitation (BRISK)

Syntax

BRISK

Functionality

The BRISK part-program instruction is used to select the "without jerk limitation" acceleration profile for the purpose of path acceleration.

G group: 21

Effective: Modal

Reset response

The channel-specific initial setting is activated via a reset:

MD20150 \$MC_GCODE_RESET_VALUES[20]

Supplementary conditions

If the acceleration profile is changed in a part program during machining (BRISK/SOFT) an exact stop is performed at the end of the block.

Single-axis acceleration without jerk limitation (BRISKA)

Syntax

BRISKA (*axis{,axis}*)

Function

The BRISKA part-program instruction is used to select the "without jerk limitation" acceleration profile for single-axis movements (JOG, JOG/INC, positioning axis, reciprocating axis, etc.).

G group: -

Effective: Modal

Axis:

- Value range: Axis identifier for channel axes

Axis-specific initial setting

Acceleration without jerk limitation can be set as the axis-specific initial setting for single-axis movements:

MD32420 \$MA_JOG_AND_POS_JERK_ENABLE = FALSE

Reset response

The axis-specific initial setting is activated via a reset:

MD32420 \$MA_JOG_AND_POS_ENABLE

4.2.2 Constant travel time (channel-specific)

4.2.2.1 General information

Overview

In the case of acceleration without jerk limitation, sudden acceleration of $2 * a_{max}$ occurs on switchover between acceleration and braking. In order to avoid this sudden acceleration, a channel-specific constant travel time can be programmed. The constant travel time defines the time taken to traverse between the acceleration and braking phases at constant velocity:

MD20500 \$MC_CONST_VELO_MIN_TIME (minimum time with constant velocity)

Note

The constant travel time is ineffective:

- Active function: Look Ahead
 - In traversing blocks with a travel time that is less or equal to the interpolation cycle time.
-

- 1: Characteristic with constant travel time
- 2: Characteristic without constant travel time
- a_{max} : Maximum acceleration value
- v_{max} : Maximum velocity value
- t: Time

Figure 4-2 Schematic for abrupt acceleration

The effect of the constant travel time can be seen from the figure above:

- Time: t_1
End of acceleration phase with sudden acceleration $1 * a_{max}$
- Interval: $t_1 - t_2$
Acceleration 0; constant velocity using the parameterized constant travel time
- Time: t_2
Start of braking phase with sudden acceleration $1 * a_{max}$

The times t_0 , t_1' and t_2' indicate the characteristic that would have been produced had no constant travel time been defined.

4.2.2.2 Parameterization

Function

The constant travel time is parameterized for specific channels using machine data:

MD20500 \$MC_CONST_VELO_MIN_TIME
(minimum time with constant velocity)

4.2.3 Acceleration matching (ACC) (axis-specific)

4.2.3.1 General information

Function

A part-program instruction (`ACC`) can be used to match the acceleration of specific axes to the current machining situation. The range used for this purpose is anywhere between greater than 0% and less than or equal to 200% of the maximum value programmed in the machine data.

Effective

Effective	Acceleration matching is effective for all types of interpolation in AUTOMATIC and MDA operating modes as well as with dry-run feed.
Ineffective	Acceleration matching is ineffective in JOG and JOG/REF (reference point approach) operating modes. Acceleration matching is also ineffective if the machine axes have been brought to a standstill via a quick stop due to the detection of a fault (setpoint = 0).

4.2.3.2 Programming

Syntax

`ACC[axis] = adjustment factor`

Functionality

The `ACC` part-program instruction is used to adjust the maximum acceleration value of a machine axis.

Axis:

- Value range: Axis identifier for the channel's machine axes

Adjustment factor:

- Value range: $0 < \text{adjustment factor} \leq 200$
- Unit: Per cent

Deactivate: `ACC[axis] = 100`

Effective: Modal

Reset response

The behavior during channel RESET or M30 can be controlled via MD32320 `$MA_DYN_LIMIT_RESET_MASK`:

Bit 0: 0 The programmed ACC value is reduced to 100 % with channel RESET/M30.

Bit 0: 1 The programmed ACC value is retained beyond channel RESET/M30.

4.2.4 Acceleration margin (channel-specific)

4.2.4.1 General information

General information

Under normal circumstances, preprocessing makes maximum use of the parameterized maximum values of the machine axes for the purpose of path acceleration. In order that an acceleration margin may be set aside for overlaid movements, e.g., within the context of the "Rapid lift away from the contour" function, path acceleration can be reduced by a programmable factor. When, for example, a factor of 0.2 is applied, preprocessing will only use 80% of the maximum possible path acceleration. 20% is set aside as an acceleration margin for overlaid movements.

4.2.4.2 Parameterization

Parameterization

Parameters for the acceleration margin are assigned for each channel by means of machine datum:
MD20610 \$MC_ADD_MOVE_ACCEL_RESERVE
(acceleration margin for overlaid motions)

4.2.5 Path-acceleration limitation (channel-specific)

4.2.5.1 General information

General information

To enable a flexible response to the machining situations concerned, setting data can be used to limit the path acceleration calculated during preprocessing for specific channels:

SD42500 \$SC_SD_MAX_PATH_ACCEL (maximum path acceleration)

The value specified in the setting data is only taken into account if it is smaller than the path acceleration calculated during preprocessing.

The limitation must be activated for specific channels using setting data:

SD42502 \$SC_IS_SD_MAX_PATH_ACCEL = TRUE

4.2.5.2 Parameterization

Parameterization

Parameterization is carried out for specific channels using setting data:

SD42500 \$SC_SD_MAX_PATH_ACCEL (maximum path acceleration)

SD42502 \$SC_IS_SD_MAX_PATH_ACCEL (activation of path-acceleration limitation)

4.2.5.3 Programming

Limit value

Syntax

`$SC_SD_MAX_PATH_ACCEL = limit value`

Functionality

The path-acceleration limitation can be adjusted for the situation by programming the setting data.

Limit value:

- Value range: ≥ 0
- Unit: m/s²

Application:

- Part program
- Static synchronized action

Switch ON/OFF

Syntax

`$SC_IS_SD_MAX_PATH_ACCEL = value`

Functionality

The path-acceleration limitation can be activated/deactivated by programming the setting data.

Parameter: *Value*

- Value range: TRUE, FALSE

Application:

- Part program
- Static synchronized action

4.2.6 Path acceleration for real-time events (channel-specific)

4.2.6.1 General information

General information

So that no compromise has to be made between machining-optimized acceleration on the one hand and time-optimized acceleration in connection with the following real-time events on the other:

- NC-STOP/NC-START
- Feedrate override modifications
- Modification of the velocity default for "safely reduced velocity" within the context of the "Safely Integrated" function

the path acceleration can be set for the real-time events specified above using a channel-specific system variable:

$\$AC_PATHACC = \textit{path acceleration}$

Real-time event acceleration will only be active for the duration of the change in velocity in respect of one of the real-time events specified above.

Limitation

If the specified path acceleration exceeds the capabilities of the machine axes that are of relevance for the path, a limit will be imposed on the path acceleration within the control so that the resulting axial acceleration (a_{res}) is restricted to less than 2x the parameterized maximum axial value (a_{max}).

$a_{res} = 2 * a_{max}$, with $a_{max} = MD32300 \$MA_MAX_AX_ACCEL$

Note

Real-time-event path acceleration is enabled, irrespective of the radial acceleration.

Effective

Effective	Real-time event acceleration is only enabled in AUTOMATIC and MDA operating modes in conjunction with the following real-time events: <ul style="list-style-type: none"> • NC-STOP/NC-START • Override modifications • Modification of the velocity default for "safely reduced velocity" within the context of the "Safely Integrated" function
Ineffective	Path acceleration for real-time events is ineffective for changes in path velocity that are attributable to path planning during preprocessing for the channel, such as contour curvatures, corners, kinematic transformation limitations, etc. Real-time-event path acceleration is ineffective if the programmed value is smaller than the path acceleration calculated during preprocessing for the path section concerned.

Programming

For information about programming system variables in the part program or synchronized actions, see Chapter: Programming.

4.2.6.2 Programming

Syntax

`$AC_PATHACC = path acceleration`

Functionality

Real-time-event path acceleration is set via the channel-specific system variables.

Parameter: *Path acceleration*

- Value range: Path acceleration ≥ 0
- Unit: m/s²

Deactivation: `$AC_PATHACC = 0`

Application:

- Part program
- Static synchronized action

Reset response

Real-time-event path acceleration is deactivated on reset.

Supplementary conditions

Programming `$AC_PATHACC` in the part program automatically triggers a preprocessing stop with REORG (STOPRE).

4.2.7 Acceleration with programmed rapid traverse (G00) (axis-specific)

4.2.7.1 General information

Frequently, the acceleration for the machine axes involved in the machining process must be set lower than the machine's performance capability officially allows because of the supplementary conditions associated with the specific process concerned.

For time-optimized traversing of the machine axes with programmed rapid traverse (part-program instruction G00), a specific maximum value can be programmed for the axis-specific acceleration.

JOG setup mode

This function does not affect acceleration in respect of a rapid traverse override in JOG setup mode.

4.2.7.2 Parameterization

The maximum value for axis-specific acceleration with programmed rapid traverse is parameterized (G00) using the axis-specific machine data:

MD32434 \$MA_G00_ACCEL_FACTOR
(scaling of the acceleration limitation with G00)

This is used to generate the maximum value for axis-specific acceleration with programmed rapid traverse (G00) that is taken into account by the path planning component during preprocessing:

$$\text{Acceleration[axis]} = \text{MD32300 \$MA_MAX_AX_ACCEL} * \text{MD32434 \$MA_G00_ACCEL_FACTOR}$$

4.2.8 Acceleration with active jerk limitation (SOFT/SOFTA) (axis-specific)

4.2.8.1 General information

Function

Compared with acceleration without jerk limitation, acceleration with jerk limitation results in a certain degree of time loss, even when the same maximum acceleration value is used. To compensate for this time loss, a specific maximum value can be programmed for the axis-specific acceleration as far as traversing of the machine axes with active jerk limitation (SOFT/SOFTA) is concerned.

The maximum value for acceleration with active jerk limitation is parameterized using a factor calculated in relation to the axis-specific maximum value. This is used to generate the maximum value for axis-specific acceleration with active jerk limitation that is taken into account by the path planning component during preprocessing:

$$\text{Acceleration}[\text{axis}] = \text{MD32300 } \$\text{MA_MAX_AX_ACCEL} * \text{MD32433 } \$\text{MA_SOFT_ACCEL_FACTOR}$$

4.2.8.2 Parameterization

Function

The maximum value for acceleration with active jerk limitation (SOFT/SOFTA) is parameterized using the axis-specific machine data:

MD32434 \$MA_SOFT_ACCEL_FACTOR
(scaling of the acceleration limitation with SOFT)

4.2.9 Excessive acceleration for non-tangential block transitions (axis-specific)

4.2.9.1 General information

Function

In the case of non-tangential block transitions (corners), the programmable controller may have to decelerate the geometry axes significantly in order to ensure compliance with the parameterized axis dynamics. For the purpose of reducing/avoiding deceleration in connection with non-tangential block transitions, a higher level of axis-specific acceleration can be enabled.

Excessive acceleration is parameterized using a factor calculated in relation to the axis-specific maximum value. This is used to generate the maximum value for axis-specific acceleration with non-tangential block transitions that is taken into account by the path planning component during preprocessing:

$$\text{Acceleration[axis]} = \text{MD32300 \$MA_MAX_AX_ACCEL} * \text{MD32310 \$MA_MAX_ACCEL_OVL_FACTOR}$$

4.2.9.2 Parameterization

Function

Excessive acceleration for non-tangential block transitions is parameterized using the axis-specific machine data:

MD32310 \$MA_MAX_ACCEL_OVL_FACTOR
(overload factor for velocity jumps)

4.2.10 Acceleration margin for radial acceleration (channel-specific)

4.2.10.1 General information

Overview

In addition to the path acceleration (tangential acceleration), radial acceleration also has an effect on curved contours. If this is not taken into account during parameterization of the path parameters, the effective axial acceleration during acceleration and deceleration on the curved contour can, for a short time, reach 2x the maximum value.

$$\begin{aligned} \text{Effective axial acceleration} &= \\ \text{Path acceleration} + \text{radial acceleration} &= \\ 2 * (\text{MD32300 \$MA_MAX_AX_ACCEL}) & \end{aligned}$$

Figure 4-3 Radial and path acceleration on curved contours

The channel-specific machine data:
 MD20602 \$MC_CURV_EFFECT_ON_PATH_ACCEL
 (influence of path curvature on dynamic path response)
 can be used to set the proportion of the axis-specific acceleration that is to be taken into account for radial acceleration.

When, for example, a value of 0.75 is applied, 75% of the axis-specific acceleration will be made available for radial acceleration and 25% for path acceleration.

The corresponding maximum values are generally calculated as follows:

Radial acceleration =
 MD20602 \$MC_CURV_EFFECT_ON_PATH_ACCEL * MD32300 \$MA_MAX_AX_ACCEL

Path acceleration =
 (1 - MD20602 \$MC_CURV_EFFECT_ON_PATH_ACCEL) * MD32300
 \$MA_MAX_AX_ACCEL

Example

The following machine parameters apply:

- MD32300 \$MA_MAX_AX_ACCEL for all geometry axes: 3 m/s
- Maximum path velocity with a path radius of 10 mm due to mechanical constraints of the machine: 5 m/min.

The radial acceleration is calculated as follows:

$$a_{\text{radial}} = \frac{v_{\text{path}}^2 \text{ [m/min]}}{r \text{ [mm]} * 3.6 \text{ [m/s}^2\text{]}} = \frac{5^2}{10 * 3.6} = 0.694 \text{ m/s}^2$$

The acceleration margin is set as follows:

$$\text{MD20602 } \$MC_CURV_EFFECT_ON_PATH_ACCEL = \frac{a_{\text{radial}} \text{ [m/s}^2\text{]}}{\text{MD32300 } \$MA_MAX_AX_ACCEL \text{ [m/s}^2\text{]}} = \frac{0.694}{3} \approx 0.23$$

Linear motions

The acceleration margin referred to above is ineffective in the case of linear motions (linear interpolation) without active kinematic transformation.

4.2.10.2 Parameterization

Function

The proportion of maximum available axis acceleration to be taken into account as an acceleration margin for radial acceleration on curved contours is parameterized using the channel-specific machine data:

MD20602 \$MC_CURV_EFFECT_ON_PATH_ACCEL
(influence of path curvature on dynamic path response)

4.2.11 Jerk limitation with path interpolation (SOFT) (channel-specific)

4.2.11.1 General information

Overview

As far as the functionality described in the rest of this document is concerned, constant acceleration, i.e., acceleration with jerk limitation (jerk = infinite value), is the assumed acceleration profile. In the case of acceleration with jerk limitation, linear interpolation is applied in respect of acceleration from 0 to the maximum value.

Advantages

Minimal load on the machine's mechanical components and low risk of high-frequency and difficult-to-control mechanical vibrations thanks to constant excessive acceleration.

Disadvantages

Longer machining times compared with stepped acceleration profile when the same maximum velocity and acceleration values are used.

Acceleration profile

r_{max}: Maximum jerk value
 a_{max}: Maximum acceleration value
 v_{max}: Maximum velocity value
 t: Time

Figure 4-4 Jerk, acceleration and velocity schematic with jerk limitation acceleration profile

The following features of the acceleration profile can be identified from the figure above:

- Interval: t₀ - t₁
 Constant jerk with +r_{max}; linear increase in acceleration; quadratic increase in velocity
- Interval: t₁ - t₂
 Constant acceleration with +a_{max}; linear increase in velocity
- Interval: t₂ - t₃
 Constant jerk with -r_{max}; linear decrease in acceleration; quadratic decrease in excessive velocity until maximum value +v_{max} is reached
- Interval: t₃ - t₄
 Constant jerk with +r_{max}; linear increase in braking acceleration; quadratic decrease in velocity

- Interval: $t_4 - t_5$
Constant braking acceleration with $-a_{\max}$; linear decrease in velocity
- Interval: $t_5 - t_6$
Constant jerk with $-j_{\max}$; linear decrease in braking acceleration; quadratic decrease in velocity reduction until zero velocity is reached $v = 0$

4.2.11.2 Maximum jerk value (axis-specific)

Function

The maximum jerk value can be set for each specific machine axis using the following machine data:

MD32431 \$MA_MAX_AX_JERK (maximum axis jerk)

The path parameters are calculated by the path planning component during preprocessing so that the programmed maximum values of the machine axes that are of relevance for the path are not exceeded.

Exceeding of maximum value

It is possible for the maximum value to be exceeded in connection with specific machining situations (see following Section: System variable (\$AC_PATHJERK)).

4.2.11.3 Maximum jerk value (channel-specific)

Function

As well as it being possible to set the maximum jerk value for specific axes, it can also be assigned as a channel-specific path parameter using the following machine data:

MD20600 \$MC_MAX_PATH_JERK (path-related maximum jerk)

To prevent the axis and channel-specific maximum jerk values interfering with one another, the channel-specific value must be set to a value greater than the maximum axial values.

4.2.11.4 Parameterization

Function

The axis- and channel-specific maximum values are parameterized using the following machine data:

MD32431 \$MA_MAX_AX_JERK (maximum axis jerk)

MD20600 \$MC_MAX_PATH_JERK (path-related maximum jerk)

4.2.11.5 Programming

Syntax

SOFT

Functionality

The `SOFT` part-program instruction is used to select the acceleration profile with jerk limitation for the traversing operations of geometry axes in the channel.

G group: 21

Effective: Modal

Reset response

The channel-specific initial setting is activated via a reset:

MD20150 \$MC_GCODE_RESET_VALUES[20]

Boundary conditions

If the acceleration mode is changed in a part program during machining (`BRISK` ↔ `SOFT`), a block change is performed at the point of transition with an exact stop at the end of the block, even in continuous-path mode.

4.2.12 Jerk limitation with single-axis interpolation (SOFTA) (axis-specific)

4.2.12.1 General information

Overview

The maximum jerk value can be set for each specific machine axis for single-axis movements (setup modes e.g. JOG, JOG/INC, positioning axis, reciprocating axis, etc.):

MD32430 \$MA_JOG_AND_POS_MAX_JERK (maximum axis jerk)

Initial setting

Acceleration with jerk limitation can be set as the axial initial setting:

MD32420 \$MA_JOG_AND_POS_JERK_ENABLE
(initial setting of axial jerk limitation)

4.2.12.2 Parameterization

Function

The function's initial setting and the maximum values are parameterized for specific axes using machine data:

MD32420 \$MA_JOG_AND_POS_JERK_ENABLE
(initial setting of axial jerk limitation)

MD32430 \$MA_JOG_AND_POS_MAX_JERK (maximum axis jerk)

4.2.12.3 Programming

Syntax

`SOFTA (Axis {Axis})`

Functionality

The `SOFTA` part-program instruction is used to select acceleration with jerk limitation for single-axis movements (positioning axis, reciprocating axis, etc.)

G group: -

Effective: modal

Axis:

- Value range: Axis identifier for channel axes

Axis-specific initial setting

Acceleration with jerk limitation can be set as the axis-specific initial setting for single-axis movements:

MD32420 \$MA_JOG_AND_POS_JERK_ENABLE = TRUE

Reset response

The axis-specific initial setting is activated via a reset:

MD32420 \$MA_JOG_AND_POS_ENABLE

4.2.13 Path-jerk limitation (channel-specific)

4.2.13.1 General information

Overview

To enable a flexible response to the machining situations concerned, setting data can be used to limit the path jerk calculated during preprocessing for specific channels:

SD42510 \$SC_SD_MAX_PATH_JERK (maximum path jerk)

The value specified in the setting data is only taken into account in the channel if it is smaller than the path jerk calculated during preprocessing.

The limitation must be activated for specific channels using setting data:

SD42512 \$SC_IS_SD_MAX_PATH_JERK = TRUE

4.2.13.2 Parameterization

Function

Parameterization is carried out for specific channels using setting data:

SD42510 \$SC_SD_MAX_PATH_JERK (maximum path jerk)

SD42512 \$SC_IS_SD_MAX_PATH_JERK
(activation of path-jerk limitation)

4.2.13.3 Programming

Maximum path jerk

Syntax

$\$SC_SD_MAX_PATH_JERK = \text{jerk value}$

Functionality

The path-jerk limitation can be adjusted for the situation by programming the setting data.

Jerk value:

- Value range: ≥ 0
- Unit: m/s^3

Application:

- Part program
- Static synchronized action

Switch ON/OFF

Syntax

`$SC_IS_SD_MAX_PATH_JERK = value`

Functionality

The path-jerk limitation can be activated/deactivated by programming the setting data.

Parameter: *Value*

- Value range: TRUE, FALSE

Application:

- Part program
- Static synchronized action

4.2.14 Path jerk for real-time events (channel-specific)

4.2.14.1 General information

Overview

So that no compromise has to be made between machining-optimized jerk on the one hand and time-optimized jerk in connection with the following real-time events on the other:

- NC-STOP/NC-START
- Feedrate override modifications
- Modification of the velocity default for "safely reduced velocity" within the context of the "Safely Integrated" function

the path jerk can be set for the real-time events specified above using a channel-specific system variable:

`$AC_PATHJERK = path jerk`

Path jerk for real-time events will only be active for the duration of the change in velocity in respect of one of the real-time events specified above.

Limitation

As the jerk is not a physical variable of any relevance to the drive, **no** limit is imposed on the jerk set.

Effective

Effective	Path jerk for real-time events is only enabled in AUTOMATIC and MDA operating modes in conjunction with the following real-time events: <ul style="list-style-type: none"> • NC-STOP/NC-START • Override modifications • Modification of the velocity default for "safely reduced velocity" within the context of the "Safely Integrated" function
Ineffective	Path jerk for real-time events is ineffective for changes in the path velocity that are attributable to path planning during preprocessing for the channel, such as contour curvatures, corners, kinematic transformation limitations, etc. Path jerk for real-time events is ineffective if the programmed value is smaller than the path jerk calculated during preprocessing for the path section concerned.

Programming

For the purpose of setting the jerk for real-time events in accordance with the acceleration, the system variables can be set as follows:

$\$AC_PATHJERK = \$AC_PATHACC / \text{smoothing time}$

- $\$AC_PATHACC$: Path acceleration [m/s²]

Smoothing time: Freely selectable, e.g., 0.02 s

For information about programming system variables in the part program or synchronized actions, see Chapter: Programming.

4.2.14.2 Programming

Syntax

$\$AC_PATHJERK = \textit{path jerk}$

Functionality

The path jerk for real-time events is set via the channel-specific system variables.

Jerk value:

- Value range: Path jerk ≥ 0
- Unit: m/s³

Application:

- Part program
- Static synchronized action

Reset response

The function is deactivated on reset.

Supplementary conditions

Programming \$AC_PATHJERK in the part program automatically triggers a preprocessing stop with REORG (STOPRE).

4.2.15 Jerk with programmed rapid traverse (G00) (axis-specific)**4.2.15.1 General information****Overview**

Frequently, the maximum jerk for the machine axes involved in the machining process must be set lower than the machine's performance capability officially allows because of the supplementary conditions associated with the specific process concerned.

For time-optimized traversing of the machine axes with programmed rapid traverse (part-program instruction G00), a specific maximum value can be programmed for the axis-specific jerk.

JOG setup mode

This function does not affect jerk in respect of a rapid traverse override in JOG setup mode.

4.2.15.2 Parameterization**Function**

The maximum value for axis-specific jerk with programmed rapid traverse is parameterized (G00) using the axis-specific machine data:

MD32434 \$MA_G00_ACCEL_FACTOR
(scaling of the acceleration limitation with G00)

This is used to generate the maximum value for axis-specific jerk with programmed rapid traverse (G00) that is taken into account by the path planning component during preprocessing:

Jerk[axis] =
MD32431 \$MA_MAX_AX_JERK * MD32435 \$MA_G00_JERK_FACTOR

4.2.16 Excessive jerk for block transitions without constant curvature (axis-specific)

4.2.16.1 General information

Overview

In the case of block transitions without constant curvature (e.g. straight line > circle), the programmable controller has to decelerate movement of the geometry axes significantly in order to ensure compliance with the parameterized axis dynamics. For the purpose of reducing/avoiding deceleration in connection with block transitions without constant curvature, a higher level of axis-specific jerk can be enabled.

The excessive jerk is parameterized using a dedicated axis-specific maximum value.

4.2.16.2 Parameterization

Function

The excessive jerk for block transitions without constant curvature is parameterized using the axis-specific machine data:

MD32432 \$MA_PATH_TRANS_JERK_LIM
(excessive jerk for block transitions without constant curvature)

4.2.17 Velocity-dependent jerk adaptation (axis-specific)

Function

When machining workpieces with free form surfaces, jerk limiting of an access frequently plays an important role: As a result of fluctuations in the change of curvature of the workpiece to be machined, limiting the jerk of all of the axes involved can cause fluctuations in the machining rate in the upper velocity range. These fluctuations in the path velocity can have a negative impact on the quality of the surface being machined. These effects can be avoided using the "velocity-dependent jerk adaptation" function.

Availability

The "velocity-dependent jerk adaptation" function is available independent of the function "Free-form surface mode: Basic functions (Page 196)".

Parameter assignment

The "Velocity-dependent jerk adaptation" function is activated and configured for each specific axis using machine data:

- **MD32437 \$MA_AX_JERK_VELO[<n>]**

Velocity threshold for the linear increase in the jerk adaptation.

The velocity threshold \$MA_AX_JERK_VELO can be separately set for each dynamic mode (see "Dynamic response mode for path interpolation (Page 193)"):

Index <n>:	Velocity threshold for the dynamic mode:
0	Standard dynamic response settings (DYNNORM)
1	Positioning mode, tapping (DYNPOS)
2	Roughing (DYNROUGH)
3	Finishing (DYNSEMIFIN)
4	Smooth-finishing (DYNFINISH)

- **MD32438 \$MA_AX_JERK_VEL1[<n>]**

Velocity threshold, from which the maximum jerk of an axis reaches the maximum value defined using factor MD32439 \$MA_MAX_AX_JERK_FACTOR.

The velocity threshold \$MA_AX_JERK_VEL1 can be separately set for every dynamic mode analog to \$MA_AX_JERK_VELO.

- **MD32439 \$MA_MAX_AX_JERK_FACTOR**

Factor to set the maximum jerk at higher velocities, i.e. for axis velocities, which are higher than the value set using \$MA_AX_JERK_VEL1. The maximum permissible jerk (j_{max}) of an axis at higher velocities is calculated as follows:

$$j_{max} = \$MA_MAX_AX_JERK_FACTOR * MD32431 \$MA_MAX_AX_JERK$$

For axis velocities in the range between the threshold values set using \$MA_AX_JERK_VELO and \$MA_AX_JERK_VEL1, the maximum jerk is linearly increased from \$MA_MAX_AX_JERK to \$MA_MAX_AX_JERK_FACTOR * \$MA_MAX_AX_JERK.

The factor that is set must be ≥ 1 . If a value of 1 is set for this factor, then velocity-dependent jerk adaptation is not active (basic setting).

v₀: MD32437 \$MA_AX_JERK_VELO
 v₁: MD32438 \$MA_AX_JERK_VEL1
 j₀: MD32431 \$MA_MAX_AX_JERK
 j₁: MD32439 \$MA_MAX_AX_JERK_FACTOR * MD32431 \$MA_MAX_AX_JERK

Figure 4-5 Dependency of the maximum jerk of an axis on the axis velocity

Note

The velocity-dependent jerk adaptation is only active, if:
 MD32439 \$MA_MAX_AX_JERK_FACTOR > 1.0

Example

Example of parameter assignment:

MD32437 \$MA_AX_JERK_VELO = 3000 mm/min

MD32438 \$MA_AX_JERK_VEL1 = 6000 mm/min

MD32439 \$MA_MAX_AX_JERK_FACTOR[AX1] = 2.0

MD32439 \$MA_MAX_AX_JERK_FACTOR[AX2] = 3.0

MD32439 \$MA_MAX_AX_JERK_FACTOR[AX3] = 1.0

Effect:

The velocity-dependent jerk adaptation becomes active for the 1st and 2nd axis, while the function for the 3rd axis is not active.

The maximum permitted jerk of the 1st axis is, for axis velocities greater than 6000 mm/min, increased by a factor of 2 - for the 2nd axis, by factor of 3.

The maximum jerk is linearly increased for axis velocities in the range 3000 mm/min to 6000 mm/min.

4.2.18 Jerk filter (axis-specific)

4.2.18.1 General information

Overview

In certain application scenarios, e.g., when milling free-form surfaces, it may be beneficial to smooth the position setpoint characteristics of the machine axes. This enables surface quality to be improved by reducing the mechanical vibrations generated in the machine.

For the purpose of smoothing the position setpoint characteristic of a machine axis, a jerk filter can be activated at position controller level, independently of the channel- and axis-specific jerk limitations taken into account at interpolator level.

The effect of the jerk filter must be as strong as possible without having an unacceptable impact on contour accuracy. The filter should also have as "balanced" a smoothing effect as possible, i.e., if the same contour is traversed forwards and backwards, the contour smoothed by the filter should be as similar as possible in both directions.

To enable the jerk filter to be optimally matched to the machine conditions, various filter modes are available:

- 2nd-order filter (PT2)
- Sliding mean value generation
- Bandstop filter

Mode: 2nd-order filter

Owing to the fact that it is a simple low-pass filter, "2nd-order filter" mode can only meet the requirements specified above where relatively small filter time constants (around 10 ms) are concerned. When used in conjunction with larger time constants, impermissible contour deviations are soon manifest. The effect of the filter is relatively limited.

This filter mode offers advantages if very large filter time constants are needed and contour accuracy is only of secondary importance (e.g. positioning axes).

For historical reasons, this filter mode is set as the default.

Mode: Sliding mean value generation

Where minimal contour deviations are required, filter time constants within the range of 20-40 ms can be set using the "sliding mean value generation" filter mode. The smoothing effect is largely symmetrical.

The display of the calculated servo gain factor (KV factor), e.g. in the HMI Advanced "Axis" service screen, shows smaller values than would normally be expected for the filter. The contour accuracy is in fact higher than the displayed KV filter appears to suggest.

When changing from "2nd-order filter" to "sliding mean value generation" filter mode, the displayed KV factor may, therefore, drop (with identical filter time constant), even though there is an improvement in contour accuracy.

Mode: Bandstop filter

The bandstop filter is a 2nd-order filter in terms of numerator and denominator:

$$H(s) = \frac{\frac{s^2}{(2 * \pi * f_Z)^2} + \frac{2 * s * D_Z}{(2 * \pi * f_Z)}}{\frac{s^2}{(2 * \pi * f_N)^2} + \frac{2 * s * D_N}{2 * \pi * f_N}}$$

where:

- f_Z: Numerator natural freq.
- f_N: Denominator natural freq.
- D_Z: Numerator damping
- D_N: Denominator damping

Since a vibration-capable filter setting is not expected to yield useful results in any case, as with the jerk filter's "2nd-order filter" (PT2) low-pass filter (PT2) mode there is no setting option for the denominator damping D_N. The denominator damping D_N is permanently set to 1.

The bandstop filter can be parameterized in 2 different ways:

- Real bandstop filter
- Bandstop filter with additional amplitude response increase/decrease at high frequencies

Real bandstop filter

The real bandstop filter is applied when identical numerator and denominator natural frequencies are selected:

- f_Z = f_N = f_{block} (blocking frequency)

If numerator damping setting = 0 is selected, the blocking frequency is equivalent to complete attenuation. In this case the 3 dB bandwidth is calculated as follows:

- f_{3 dB bandwidth} = 2 * f_{block}

If instead of complete attenuation, a reduction by a factor of k is all that is required, then numerator damping should be selected in accordance with k. In this case the above formula for calculating the 3 dB bandwidth no longer applies.

Bandstop filter with additional amplitude response increase/decrease at high frequencies

In this case, the numerator and denominator natural frequencies are set to different values. The numerator natural frequency determines the blocking frequency.

By selecting a lower/higher denominator natural frequency than the numerator natural frequency, you can increase/decrease the amplitude response at high frequencies. An amplitude response increase at high frequencies can be justified in most cases, as the controlled system generally possesses a low-pass characteristic itself, i.e., the amplitude response drops at high frequencies anyway.

Supplementary conditions

If too high a numerator natural frequency is selected, the filter is disabled. In this case the limiting frequency f_{Zmax} depends on the position-control cycle:

$$f_{Zmax} = \frac{1}{2 * \pi * T_{Zmin}} = \frac{1}{2 * \pi * T_{Position-control\ cycle}} \quad (\text{Shannon Theorem})$$

The limitation is enabled for specific axes using machine data:
MD32400 \$MA_AX_JERK_ENABLE (axial jerk limitation)

and set with time specifications for the smoothing filter using machine data:
MD32410 \$MA_AX_JERK_TIME (time constants for the axial return filter).

With **SW 5.1** and higher, it is also possible to control the jerk limitation in the position controller with a new filter based on a smoothing method that incurs few contour errors:

MD32402 AX_JERK_MODE = 1	;	2nd-order filter (default)
		corresponds to SW 1 to SW 4.4
MD32402 AX_JERK_MODE = 2	;	Sliding mean value generation
		(New jerk filter with SW 5.1 and higher).
MD32402 AX_JERK_MODE = 3	;	Bandstop filter with SW 6.3 and higher

Modus 2 requires a bit more computation time, but with the same smoothing effect, it results in lower contour errors or, with the same accuracy, in a smoother contour with smoother movements. Mode 2 is recommended. Mode 1 is the default mode in SW 1 to SW 4.4 for compatibility reasons.

For more information about how the jerk filter available with SW 5.1 and higher works (balancing filter for improving the position setpoints of the position controller), please refer to:

References:

/FB1/ Manual of Functions, Basic Functions; Velocities, Setpoint/Actual-Value Systems, Regulatory Control (G2), Chapter: "Control Optimization"

Mode 3

There are 2 parameterization options for the bandstop filter:

- "Real bandstop filter":

When identical numerator and denominator natural frequencies are selected (=blocking frequency). If you select (numerator) damping setting zero, the blocking frequency is equivalent to complete attenuation.

In this case the 3 dB bandwidth is determined on the following basis:

$$f_{bandwidth} = 2 * f_{block}.$$

If instead of complete attenuation, a reduction by a factor of k is all that is required, then the numerator damping should be selected in accordance with k.

- "Bandstop filter with additional amplitude response increase/decrease at high frequencies":

In this case, the numerator and denominator natural frequencies are set to different values. The numerator natural frequency determines the blocking frequency. By selecting a lower (higher) denominator natural frequency than the numerator natural frequency, you can increase (decrease) the amplitude response at high frequencies. An amplitude response increase at high frequencies can be justified in most cases, as the controlled system generally possesses a low-pass characteristic itself, i.e., the amplitude response drops at high frequencies anyway.

4.2.18.2 Parameterization

Activation

The jerk filter is activated using the machine data:

MD32400 \$MA_AX_JERK_ENABLE = TRUE

The jerk filter is active in all operating modes and with all types of interpolation.

Filter mode

The mode is selected using the machine data:

MD32402 \$MA_AX_JERK_MODE = *mode*

Mode = 1	(2nd-order filter)
Mode = 2	(Sliding mean value generation)
Mode = 3	(Bandstop filter)

4.2.19 Knee-shaped acceleration characteristic curve

4.2.19.1 Adaptation to the motor characteristic curve

Function

Various types of motor, particularly stepper motors, have a torque characteristic that is highly dependent upon speed and shows a steep decrease in torque in the upper speed range. To ensure optimum utilization of the motor characteristic curve, it is necessary to reduce the acceleration once a certain speed is reached.

- 1: Torque decrease zone
- n_{red} : Speed above which reduced torque has to be assumed
- n_{max} : Maximum speed
- M_{max} : Max. torque
- M_{red} : Torque at n_{max} (corresponds to creep acceleration)

Figure 4-6 Torque characteristic curve of a motor with torque characteristic that is highly dependent upon speed

Simulation of torque characteristic

For the purpose of simulating the torque characteristic of the motor characteristic curve, the machine data:

MD35242 \$MA_ACCEL_REDUCTION_TYPE = *characteristic*
can be used to select various types of characteristic curve:

0	= Constant characteristic
1	= Hyperbolic characteristic
2	= Linear characteristic

The following figures show typical velocity and acceleration characteristic curves for the respective types of characteristic:

Constant characteristic

Figure 4-7 Acceleration and velocity characteristic with acceleration reduction: 0 = constant

Hyperbolic characteristic

Figure 4-8 Acceleration and velocity characteristic with acceleration reduction: 1 = hyperbolic

Linear characteristic

Figure 4-9 Acceleration and velocity characteristic with acceleration reduction: 2 = linear

The key data for the characteristic curves equate to:

$$\begin{aligned}
 v_{\max} &= \$MA_MAX_AX_VELO \\
 v_{\text{red}} &= \$MA_ACCEL_REDUCTION_SPEED_POINT * \$MA_MAX_AX_VELO \\
 a_{\max} &= \$MA_MAX_AX_ACCEL \\
 a_{\text{red}} &= (1 - \$MA_ACCEL_REDUCTION_FACTOR) * \$MA_MAX_AX_ACCEL
 \end{aligned}$$

4.2.19.2 Effects on path acceleration

Function

The path acceleration characteristic curve is generated on the basis of the types of characteristic for the axes that are of relevance for the path. If axes with different types of characteristic curve are interpolated together, the acceleration profile for the path acceleration will be determined on the basis of the reduction type that is most restrictive.

The following order of priorities applies, whereby 1 = top priority:

1. Acceleration reduction: 0 = constant characteristic
2. Acceleration reduction: 1 = hyperbolic characteristic
3. Acceleration reduction: 2 = linear characteristic
4. No acceleration reduction effective

A situation, whereby no acceleration reduction is active, arises for example when:

MD35220 \$MA_ACCEL_REDUCTION_SPEED_POINT = 1

and/or

MD35230 \$MA_ACCEL_REDUCTION_FACTOR = 0

Note

Machine axes featuring stepper motor and DC drive can be interpolated together.

4.2.19.3 Substitute characteristic curve

Function

If the programmed path cannot be traversed using the parameterized acceleration characteristic curve (e.g., active kinematic transformation), a substitute characteristic curve is generated by reducing the dynamic limit values. The dynamic limit values are calculated to ensure that the substitute characteristic curve provides the best possible compromise between maximum velocity and constant acceleration.

Substitute characteristic curve with linear path sections

Limitation to this value is applied if the programmed path velocity is greater than that at which 15 % of the maximum acceleration capacity is still available ($v_{15\%a}$). Consequently, 15 % of the maximum acceleration capacity/motor torque always remains available, whatever the machining situation.

a_{ers} : Substitute characteristic curve constant acceleration

$a_{15\%}$: Minimal constant acceleration
 $a_{15\%} = 0.15 * (a_{max} - a_{red}) + a_{red}$

v_{ers} : Substitute characteristic curve velocity

v_{prog} : Programmed velocity

$v_{15\%a}$: Velocity at $a_{15\%}$

Figure 4-10 Substitute path characteristic curve: Linear path

Substitute characteristic curve with curved path sections

In the case of curved path sections, normal and tangential acceleration are considered together. The path velocity is reduced so that only up to 25 % of the speed-dependent acceleration capacity of the axes is required for normal acceleration. The remaining 75 % of the acceleration capacity is set aside for the tangential acceleration, i.e., deceleration/acceleration on the path.

- a_N: Normal acceleration
- a_{ers}: Substitute characteristic curve constant acceleration
- v_{ers}: Substitute characteristic curve velocity
- r: Path radius

Figure 4-11 Substitute path characteristic curve: Curved path

Block transitions with continuous-path mode

If continuous-path mode is active, non-tangential block transitions result in axial velocity jumps when the programmed path velocity is used for traversing.

As a result, the path velocity is controlled in such a way that prevents any axial velocity proportion from exceeding the creep velocity v_{red} at the time of the block transition.

Deceleration ramp with continuous-path mode and LookAhead

In the case of consecutive part program blocks with short paths, an acceleration or deceleration operation may be spread over several part program blocks.

In such a situation LookAhead also takes into account the parameterized speed-dependent acceleration characteristic.

- 1: Brake application point
- 2: Torque decrease zone
- 3: Maximum torque zone
- v_{red}: Creep velocity
- v_{max}: Maximum velocity
- N_{xy}: Part program block with block number N_{xy}

Figure 4-12 Deceleration with LookAhead

4.2.19.4 Parameterization

Activating

The knee-shaped acceleration characteristics can be activated specific to the machine axis via the machine data:

```
MD35240 $MA_ACCEL_TYPE_DRIVE = TRUE
```

Function

The knee-shaped acceleration characteristic curve is parameterized for specific axes using the following machine data:

- MD32000 \$MA_MAX_AX_VELO (maximum axis velocity)
- MD35220 \$MA_ACCEL_REDUCTION_SPEED_POINT (speed for reduced acceleration)
- MD35230 \$MA_ACCEL_REDUCTION_FACTOR (reduced acceleration)
- MD32300 \$MA_MAX_AX_ACCEL (Maximum axis acceleration)
- MD35242 \$MA_ACCEL_REDUCTION_TYPE (type of acceleration reduction: 0 = constant, 1 = hyperbolic, 2 = linear)

4.2.19.5 Programming

Channel-specific activation (DRIVE)

Syntax

DRIVE

Functionality

The knee-shaped characteristic curve is activated for path acceleration using the `DRIVE` part-program instruction.

G group: 21

Effective: Modal

Reset response

The channel-specific default setting is activated via a reset:

MD20150 \$MC_GCODE_RESET_VALUES[20]

Dependencies

If the knee-shaped acceleration characteristic curve is parameterized for a machine axis, then this becomes the default acceleration profile for all traversing operations.

If the effective acceleration profile is changed for a specific path section using the `SOFT` or `BRISK` part-program instructions, then an appropriate substitute characteristic curve with lower dynamic limit values is used in place of the knee-shaped acceleration characteristic curve.

The knee-shaped acceleration characteristic curve can be reactivated by reprogramming `DRIVE`.

Axis-specific activation (DRIVEA)

Syntax

DRIVEA (*Axis* {*Axis*})

Functionality

The knee-shaped characteristic curve is activated for all single-axis interpolations (positioning axis, reciprocating axis, etc.) for specific axes using the part-program instruction.

G group: -

Effective: modal

Axis:

- Value range: Axis identifier for channel axes

Reset response

The channel-specific default setting is activated via a reset:

MD20150 \$MC_GCODE_RESET_VALUES[20]

Dependencies

If the knee-shaped acceleration characteristic curve is parameterized for a machine axis, then this becomes the default acceleration profile for all traversing operations.

If the effective acceleration profile is changed for a specific axis using the `SOFTA` or `BRISKA` part-program instructions, then an appropriate substitute characteristic curve is used in place of the knee-shaped acceleration characteristic curve.

It is possible to switch back to the knee-shaped acceleration characteristic curve for a specific axis by programming `DRIVEA`.

4.2.19.6 Boundary conditions

Single axis interpolation

After activating the knee-shaped acceleration characteristics in case of single-axis interpolations (positioning axis, oscillating axis, manual motion, etc.), the machine axis is traversed exclusively in the mode `DRIVEA`.

It is not possible to switch over the acceleration profile via the following part program instructions:

- Abrupt acceleration changes (`BRISKA`)
- Acceleration with jerk limitation (`SOFTA`)

Path interpolation

If for a machine axis involved in a programmed path the knee-shaped acceleration characteristic parameterized without the part program instruction `DRIVE` is active, then a substitute characteristic curve with reduced dynamic limiting values is determined for the path.

Kinematic transformation

The knee-shaped acceleration characteristic is not considered in an active kinematic transformation. With internal control, a switchover is done to acceleration without jerk limitation (BRISK) and a substitute characteristic curve becomes active for the path acceleration.

4.3 Examples

4.3.1 Acceleration

4.3.1.1 Path velocity characteristic

Key statement

An excerpt from a part program is provided below, together with the associated acceleration characteristic, by way of an example. These are used to illustrate how the path velocity can be adapted to take account of various events and the resulting change in acceleration.

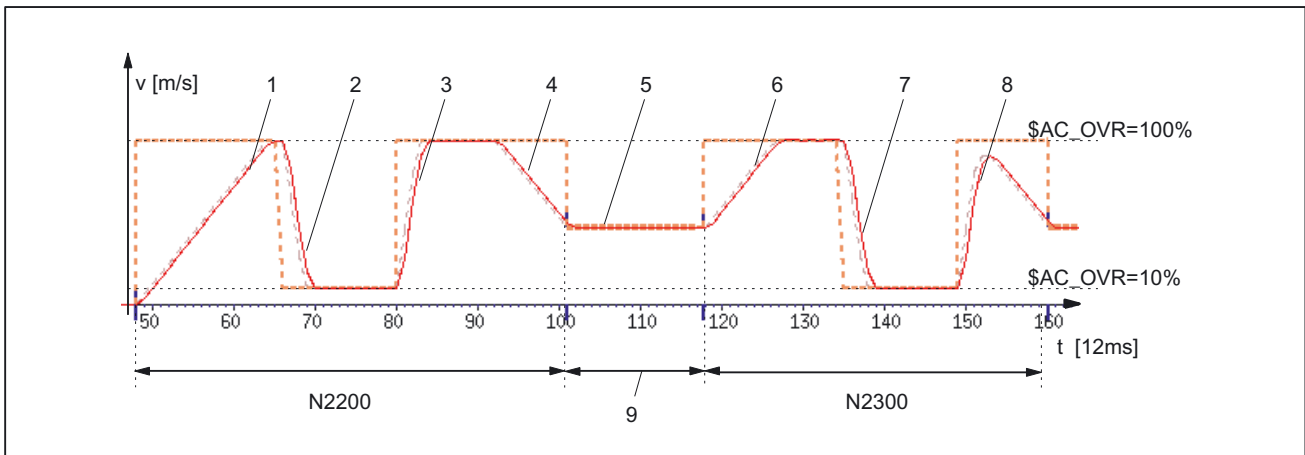

Part program (excerpt, schematic)

```
; Acceleration selection in accordance with fast input 1 ($A_IN[1]):
N53 ID=1 WHEN $A_IN[1] == 1 DO $AC_PATHACC = 2.*$MA_MAX_AX_ACCEL[X]

; Test override profile (simulates external intervention):
N54 ID=2 WHENEVER ($AC_TIMEC > 16) DO $AC_OVR=10
N55 ID=3 WHENEVER ($AC_TIMEC > 30) DO $AC_OVR=100

;Approach
N1000 GO X0 Y0 BRISK
N1100 TRANS Y=-50
N1200 AROT Z=30 G642

; Contour
N2100 X0 Y0
N2200 X = 70 G1 F10000 RNDM=10 ACC[X]=30 ACC[Y]=30
N2300 Y = 70
N2400 X0
N2500 Y0
M30
```

Acceleration profile: BRISK

- 1: Accelerate to 100% of path velocity (F10000) in accordance with acceleration default: ACC (N2200...)
- 2: Brake to 10% of path velocity as a result of override modification (\$AC_OVR) in accordance with real-time acceleration \$AC_PATHACC (N53/N54...)
- 3: Accelerate to 100% of path velocity as a result of override modification (\$AC_OVR) in accordance with real-time acceleration \$AC_PATHACC (N53/N55...)
- 4: Brake to block end velocity for intermediate smoothing block in accordance with acceleration default: ACC (N2200...)
- 5: Speed limitation as a result of smoothing (see 9)
- 6: Accelerate to 100% of path velocity (\$AC_OVR) in accordance with acceleration default: ACC (N2300...)
- 7: Decelerate as a result of override modification at a rate of acceleration that is in accordance with real-time acceleration \$AC_PATHACC (N53/N54...)
- 8: Accelerate to 100% of path velocity as a result of override modification (\$AC_OVR) in accordance with real-time acceleration \$AC_PATHACC (N53/N55...)
- 9: Intermediate block inserted within the control as a result of the programmed smoothing (RNDM) (N2200...)

- 2: Jerk according to \$AC_PATHJERK
- 3: Jerk according to \$MA_MAX_AX_JERK[.] (approach block end velocity)
- 4: Velocity limit due to arc
- 5: Jerk according to \$AC_PATHJERK

Figure 4-14 Switching between path jerk specified during preprocessing and \$AC_PATHJERK

4.3.3 Acceleration and jerk

Key statement

In the following example a short part program is used to illustrate the velocity and acceleration characteristic for the X-axis. It also shows the connection between specific velocity and acceleration-related machine data and the contour sections they influence.

Part program

```

N90 F5000 SOFT G64           ; Continuous-path mode, acceleration with jerk
                             ; limitation
N100 G0 X0 Y0 Z0           ; Rapid traverse
N110 G1 X10                 ; Straight line
N120 G3 CR=5 X15 Y5         ; Circular arc, radius 5 mm, block transition:
                             ; tangential
N130 G3 CR=10 X5 Y15        ; Circular arc, radius 10 mm, block transition:
                             ; tangential
N140 G1 X-5 Y17.679         ; straight, 15° bend
N200 M30
    
```

Figure 4-15 Part program contour

Figure 4-16 X axis: Velocity and acceleration characteristic

4.3.4 Knee-shaped acceleration characteristic curve

4.3.4.1 Activation

Key statement

The example given illustrates how the knee-shaped acceleration characteristic curve is activated on the basis of:

- Machine data
- Part program instruction

Machine data

- Parameterizing the characteristic curve (example only)

```
X axis
MD35220 $MA_ACCEL_REDUCTION_SPEED_POINT[X] = 0.4
MD35230 $MA_ACCEL_REDUCTION_FACTOR[X] = 0.85
MD35242 $MA_ACCEL_REDUCTION_TYPE[X] = 2
MD35240 $MA_ACCEL_TYPE_DRIVE[X] = TRUE

Y axis
MD35220 $MA_ACCEL_REDUCTION_SPEED_POINT[Y] = 0.0
MD35230 $MA_ACCEL_REDUCTION_FACTOR[Y] = 0.6
MD35242 $MA_ACCEL_REDUCTION_TYPE[Y] = 1
MD35240 $MA_ACCEL_TYPE_DRIVE[Y] = TRUE

Z axis
MD35220 $MA_ACCEL_REDUCTION_SPEED_POINT[Z] = 0.6
MD35230 $MA_ACCEL_REDUCTION_FACTOR[Z] = 0.4
MD35242 $MA_ACCEL_REDUCTION_TYPE[Z] = 0
MD35240 $MA_ACCEL_TYPE_DRIVE[Z] = FALSE
```

- Activation by setting as the channel-specific default setting
MC_GCODE_RESET_VALUE[20] = 3 (DRIVE)

4.4 Data lists

4.4.1 Machine data

4.4.1.1 Channel-specific machine data

Number	Identifier: \$MC_	Description
20150	GCODE_RESET_VALUES	Initial setting of the G groups
20500	CONST_VELO_MIN_TIME	Minimum time with constant velocity
20600	MAX_PATH_JERK	Path-related maximum jerk
20602	CURV_EFFECT_ON_PATH_ACCEL	Influence of path curvature on path dynamic response
20610	ADD_MOVE_ACCEL_RESERVE	Acceleration reserve for overlaid movements

4.4.1.2 Axis/spindle-specific machine data

Number	Identifier: \$MA_	Description
32000	MAX_AX_VELO	Maximum axis velocity
32300	MAX_AX_ACCEL	Maximum axis acceleration
32310	MAX_ACCEL_OVL_FACTOR	Overload factor for velocity jump
32320	DYN_LIMIT_RESET_MASK	Reset behavior of dynamic limits
32400	AX_JERK_ENABLE	Axial jerk limitation
32402	AX_JERK_MODE	Filter type for axial jerk limitation
32410	AX_JERK_TIME	Time constant for axial jerk filter
32420	JOG_AND_POS_JERK_ENABLE	Initial setting for axial jerk limitation
32430	JOG_AND_POS_MAX_JERK	Axial jerk
32431	MAX_AX_JERK	Maximum axial jerk at the block transition in continuous-path mode
32432	PATH_TRANS_JERK_LIM	Max. axial jerk of a geometry axis at block boundary
32433	SOFT_ACCEL_FACTOR	Scaling of acceleration limitation for <code>SOFT</code>
32434	G00_ACCEL_FACTOR	Scaling of acceleration limitation for <code>G00</code>
32435	G00_JERK_FACTOR	Scaling of axial jerk limitation for <code>G00</code>
32436	JOG_MAX_JERK	Maximum axial jerk for JOG motion
32437	AX_JERK_VELO	First velocity threshold for velocity-dependent jerk adaptation
32438	AX_JERK_VEL1	Second velocity threshold for the velocity-dependent jerk adaptation

4.4 Data lists

Number	Identifier: \$MA_	Description
32439	MAX_AX_JERK_FACTOR	Factor to set the maximum jerk for higher velocities (velocity-dependent jerk adaptation)
35220	ACCEL_REDUCTION_SPEED_POINT	Speed for reduced acceleration
35230	ACCEL_REDUCTION_FACTOR	Reduced acceleration
35240	ACCEL_TYPE_DRIVE	DRIVE acceleration characteristic for axes on/off
35242	ACCEL_REDUCTION_TYPE	Type of acceleration reduction

4.4.2 Setting data

4.4.2.1 Channel-specific setting data

Number	Identifier: \$SC_	Description
42500	SD_MAX_PATH_ACCEL	Max. path acceleration
42502	IS_SD_MAX_PATH_ACCEL	Analysis of SD 42500: ON/OFF
42510	SD_MAX_PATH_JERK	Max. path-related jerk
42512	IS_SD_MAX_PATH_JERK	Analysis of SD 42510: ON/OFF

4.4.3 System variables

Identifier	Description
\$AC_PATHACC	Path acceleration for real-time events
\$AC_PATHJERK	Path jerk for real-time events

D1: Diagnostics tools

5.1 Brief description

Diagnostic tools

Integrated and external diagnostic tools are available for operating the SINUMERIK control. Further, the NC provides support when localizing drive faults by providing the option of simulating the drive interface of machine axes.

Integrated diagnostic tools

The following information is displayed at the operator interface:

- Display of alarms and messages from the control system or drives in plain text
- Status displays for:
 - Interface signals from NC, HMI, PLC and I/O modules
 - Data blocks
 - PLC flags, timers and counters
 - Inputs and outputs of the PLC.
- Service displays:
 - Nominal values, actual values and status data for axes/spindles
 - Logbook
 - Display showing version of system software installed

External diagnostic tools

The software to be installed on an external computer is used to commission the NC and to commission the SINAMICS drives. The diagnostic functions support commissioning and service personnel during commissioning, troubleshooting, diagnostics and service activities.

The following diagnostic functions are available in the STARTER commissioning software for the SINAMICS S drive system:

- Specifying signals with the ramp-function generator
- Signal recording with the trace function
- Analyzing the control response with the measuring function
- Output of voltage signals for external measuring devices via test sockets

References:

SINAMICS S120 Commissioning Manual

5.2 Description of diagnostic tools

Scope

The Function Manual deals with displays of the user interface, system functions, procedures for determining system statuses and, if necessary, measures for avoiding undesirable conditions for the NC control, PLC and drives.

General

Alarm and signal status displays

The currently active or not yet acknowledged alarms and messages are displayed in the "Diagnostics" operating area.

Alarm log

The alarm log contains the alarms that have occurred and the time. Detailed information on the individual alarms can be found in:

References:

Diagnostics Manual

Note

For alarms and messages, which the machine tool OEM issues (value range), the corresponding descriptions should be taken from the documentation of the machine tool OEM.

Alarm handler

Application

The alarm handler provides an infrastructure for activating and managing alarms on the NCK.

Functions

- Buffering of a maximum of 16 alarms that have been activated since system power-up and which have not yet been reset.
- Alarm reactions can be programmed as channel-specific, mode-group-specific or NCK-specific reactions.
- The "NoReady" alarm reaction can also be programmed as a channel-specific reaction.

Activation

The alarm handler is activated when an error status is detected in the NCK, causing an alarm to be output.

It is possible to trigger an alarm in a part program using the `SETAL` language command.

References:

Programming Manual, Job Planning

Note

The currently active alarms in the NCK are read via the operator panel interface.
It is not possible to set alarms externally in the NCK.

Alarms with an alarm ID in the 60000 ... 60999 range can be activated in a part program.

Data backup

On POWER ON, the alarm-handler data are reinitialized completely, since they are not stored in the solid state NC memory.

Compatibility (only 840D sl)

When alarms occur, it is possible to set the channel-specified signal CHANNEL_NOREADY at the PLC.

The use of this function is controlled via the machine data:

MD11412 \$MN_ALARM_REACTION_CHAN_NOREADY (alarm reaction CHAN_NOREADY permissible)

Value	Meaning
0	The CHANNEL_NOREADY signal is not used (basic setting). Alarms that have specified a channel-specific NOREADY signal are reconfigured by the alarm handler to the mode group specific NOREADY signal. This ensures that earlier PLC software versions remain compatible.
1	The CHANNEL_NOREADY signal is used. The alarm handler reconfigures BAG_NOREADY to CHAN_NOREADY.

Clearing criterion

For each alarm, you must specify how the alarm can be cleared again.

The following clearing criteria are possible:

POWERONCLEAR	The alarm is cleared by switching the control off and then on again.
RESETCLEAR	When the Reset key is pressed, the alarm is cleared in the channel in which it occurred.
CANCELCLEAR	The alarm is cleared in any channel when the Cancel key is pressed. The alarm can also be cleared by means of an NC start or Reset.
NCSTARTCLEAR	The alarm is cleared in the channel in which the alarm occurred by starting a program. The alarm can also be cleared by means of a Reset.
CLEARHIMSELF	The alarm is not cleared by an operator input or action, but explicitly by a "clearAlarm" programmed in the NCK source code.
BAGRESETCLEAR	The alarm is cleared by a "BAGRESETCLEAR" command or by executing a Reset in every channel of this mode group.
NCKRESETCLEAR	The alarm is cleared by an "NCKRESETCLEAR" command or by executing a Reset in every channel.

Alarm display control

The scope of the alarm outputs can be modified using machine data.

- MD11410 \$MN_SUPPRESS_ALARM_MASK (mask for suppressing special alarm outputs)
- MD11411 \$MN_ENABLE_ALARM_MASK (mask for enabling special alarm outputs)
- MD13150 \$MN_SINAMICS_ALARM_MASK (activates the fault and alarm buffer for Sinamics)

References:

Detailed machine-data description

5.3 Service overview

In principle, the following service displays are available:

- Axis/spindle service displays
- Drive service displays
- Profibus-DP service displays

Note

System dependencies

The availability of individual service displays depends on the particular system, e.g.:

- Drive service displays: for digital drives only
 - Profibus-DP service displays: for SINUMERIK 840Di only
-

Operation

To select and use the service displays, see:

Reference:
Operating Manual

5.3.1 Axis/spindle service display

The display of values and states on the control's user interface allows the operating state of the axes and spindles to be evaluated.

Accessing the diagnostic options

The information relevant when commissioning and troubleshooting (diagnostics) axes and spindles is displayed on the operator panel front in the operating area "Diagnosis" in the service display "Axis/spindle" for each axis/spindle:

Schleppabstand	0.000	mm
Regeldifferenz	0.000	mm
Konturabweichung (axial)	0.000	mm
Kv-Faktor (errechnet)	0.000	1000/min
aktives Meßsystem	1	
Lageistwert Meßsystem1	14.664	mm
Lageistwert Meßsystem2	14.664	mm
Lagesollwert	14.664	mm
abs. Kompensationswert Meßsystem1	0.000	mm
abs. Kompensationswert Meßsystem2	0.000	mm
Kompensation Durchhang + Temperatur	0.000	mm
Geschwindigkeitsistwert aktiver Geber	0.000	%
Geschwindigkeitssollwert Antrieb	0.000	%
Positionsoffset zum Leitachse/spindel-Istwert	0.000	mm
Positionsoffset zum Leitachse/spindel-Sollwert	0.000	mm
Override	100.000	%

This information is used for:

- Checking the setpoint branch
(e.g. position setpoint, speed setpoint, spindle speed setpoint prog.)
- Checking the actual value branch
(e.g. position actual value, measuring system 1/2, actual speed)
- Optimizing the position control loop
(e.g. following error, system deviation, servo gain factor)
- Checking the complete control loop of the axis
(e.g. by comparing the position setpoint and position actual position value, speed setpoint and actual speed)
- Checking for hardware faults
(e.g. checking the encoder: If the axis is mechanically moved, then the position actual value must change)
- Setting and checking axis monitoring functions.

Following error	The difference between the position setpoint and position actual position value of active measuring system 1 or 2. Unit: mm, inch or degrees
Error signal	The difference between the position setpoint at the position controller input and the actual position value of active measuring system 1 or 2. Unit: mm, inch or degrees

Contour deviation	<p>The actual contour deviation is displayed with this value (variations of the following error caused by equalization operations on the speed controller due to load changes).</p> <p>The contour deviation results from the difference between an actual position pre-calculated from the position setpoint and the actual position value of active measuring system 1 or 2.</p> <p>Unit: mm, inch or degrees</p>
Servo gain factor (calculated)	<p>The servo gain factor in the display is calculated by the NC according to the following equation:</p> <div style="border: 1px solid black; padding: 10px; margin: 10px 0;"> $K_v \text{ factor} = \frac{\text{Velocity setpoint}}{\text{Following error}} ;$ <p>Unit (for the standard setting): $\frac{[\text{m/min}]}{[\text{mm}]} ;$</p> </div> <p>Velocity setpoint = setpoint currently being output to the axis/spindle.</p> <p>References: Function Manual Basic Functions; Velocities, Setpoint/Actual Value Systems, Closed-Loop Control (G2)</p>
Active meas. system	Here, it is displayed whether measuring system 1 or 2 is active.
Position actual value measuring system 1/2	<p>The actual position of the axis as measured via measuring system 1/2. The position is displayed in the machine coordinate system (no work offsets or tool offsets included).</p> <p>Unit: mm, inch or degrees</p>
Position reference value	<p>Specified position transferred from the interpolator to the position control.</p> <p>Unit: mm, inch or degrees</p>
compensation value meas. system 1 or 2	<p>Display of absolute compensation value for measuring system 1 or 2.</p> <p>The compensation value consists of the sum of backlash and leadscrew error compensation for the actual axis position</p> <p>Unit: mm, inch or degrees</p>
Sag and temperature compensation	<p>Display of the compensation value calculated for the current axis position based on the total of the sag and temperature compensations.</p> <p>Unit: mm, inch or degrees</p>
Velocity actual value of active encoder (only 840Di)	Display of velocity actual value of the currently active encoder.
Velocity setpoint of drive (only 840Di)	Display of velocity setpoint of drive.
Speed actual value	<p>The pulses supplied by the encoder are evaluated by the NC and displayed.</p> <p>Unit: % 100% means maximum speed.</p>

Speed setpoint	Speed setpoint transferred to the drive (= speed setpoint from position controller and feed forward control). Unit: % 100% means maximum speed setpoint	
Spindle speed setpoint prog.	Speed setpoint programmed by the user. Unit: rpm e.g.: Input: S1000; display: 1000 rpm Display applies to spindles only.	
Spindle speed setpoint current	Current active speed setpoint with correct sign, including calculated compensation value and any operative speed limitation (programmed by means of setting or machine data). Unit: rpm Display applies to spindles only.	
Override	The effective correction factor of the feed or spindle correction switch is displayed. Unit: %	
Position offset for master axis/spindle actual value	The currently applicable position offset value is displayed here (relative to the actual value) if such a position offset (angular offset between master and slave axes) has been programmed for the "Synchronous spindle" function. Unit: mm, inches, degrees References: Function Manual Extended Functions, Synchronous Spindle (S3)	
Position offset for master axis/spindle setpoint value	The currently applicable position offset value is displayed here (relative to the setpoint) if such a position offset (angular offset between master and slave axes) has been programmed for the "Synchronous spindle" function. Unit: mm, inches, degrees References: Function Manual Extended Functions, Synchronous Spindle (S3)	
Current gear stage	The current actual gear stage is displayed here. With axes, this is only displayed if a spindle is assigned to the axis. The display corresponds to the NC/PLC interface signal: DB31, ... DBX16.0 to 16.2 (actual gear stage) References: Function Manual Basic Functions; Spindles (S1) Displays which of the 6 parameter sets of the position controller is active. A parameter set switchover takes place, for example, when a gear stage is changed. References: Function Manual Basic Functions; Velocities, Setpoint/Actual Value Systems, Closed-Loop Control (G2)	
Controller mode	Displays the current controller modes.	
	0:	Position Control
	1:	Speed Control
	2:	Hold
	3:	Parking
	4:	Follow-up
5:	Braking	

	For a more detailed description of the controller states, see: References: Function Manual Basic Functions; Various Interface Signals and Functions (A2)
"Referenced" status display	Status display for reference point approach (axis).
	Bit0=Status 0: The machine axis is not referenced with the position measurement system 1 or 2.
	Bit0=Status 1: The machine axis has reached the reference point (incremental measuring system) and/or target point (length measuring system with distance coded reference marks) during reference point approach.
	Bit1=Status 0: No obligation to cross-reference (NC start possible without cross-referencing this axis)
	Bit1=Status 1: There is no obligation to cross-reference for the NC start.
	Dependent on the machine data: MD34110 \$MA_REFP_CYCLE_NR and MD20700 \$MC_REFP_NC_START_LOCK The display corresponds to the NC/PLC interface signal: DB31, ... DBX60.4 and 60.5 (referenced/synchronized 1 or 2) References: Function Manual Basic Functions; Reference Point Approach (R1)
QEC learning active	Indicates whether or not the learning process for quadrant error compensation for the axis is active.
Fixed stop reached	Indicates whether or not the axis has fulfilled the conditions for "Fixed stop reached" when the "Travel to fixed stop" function is active (IS DB31, ... DBX62.5). References: Function Manual Basic Functions; Travel to Fixed Stop (F1)
Torque limitation value	Indicates the value programmed by means of <code>FXST[x]</code> or SD43510 \$SA_FIXED_STOP_TORQUE or the value defined using MD37010 \$MA_FIXED_STOP_TORQUE_DEF for the clamping torque for "Travel to fixed stop". Unit: % of maximum torque References: Function Manual Basic Functions; Travel to Fixed Stop (F1)
Safe actual position of the axis	Displays the actual axis position that has been measured via the NC. This actual position should correspond in value to "Safe actual position of drive". References: Function Manual Safety Integrated

Safe actual position of drive	<p>Displays the actual axis position that has been measured via the drive. This actual position should correspond in value to "Safe actual position of axis".</p> <p>References: Function Manual Safety Integrated</p>
Safe input signals of the axis	<p>Displays the safety input signals of the PLC defined for the "Safety Integrated" function. The status of these input signals should correspond to the "Safe input signals of drive" status.</p> <p>References: Function Manual Safety Integrated</p>
Safe input signals of the drive	<p>Displays the safety input signals of the drive (DMP on drive bus) defined for the "Safety Integrated" function. The status of these input signals should correspond to the "Safe input signals of axis" status.</p> <p>References: Function Manual Safety Integrated</p>
Safe output signals of the axis	<p>Displays the safety output signals of the PLC defined for the "Safety Integrated" function. The status of these output signals should correspond to the "Safe output signals of drive" status.</p> <p>References: Function Manual Safety Integrated</p>
Safe output signals of the drive	<p>Displays the safety output signals of the drive (DMP on drive bus) defined for the "Safety Integrated" function. The status of these output signals should correspond to the "Safe output signals of axis" status.</p> <p>References: Function Manual Safety Integrated</p>

Control technology concept

The figure below shows at which points in the control-loop the axis and spindle information is read off.

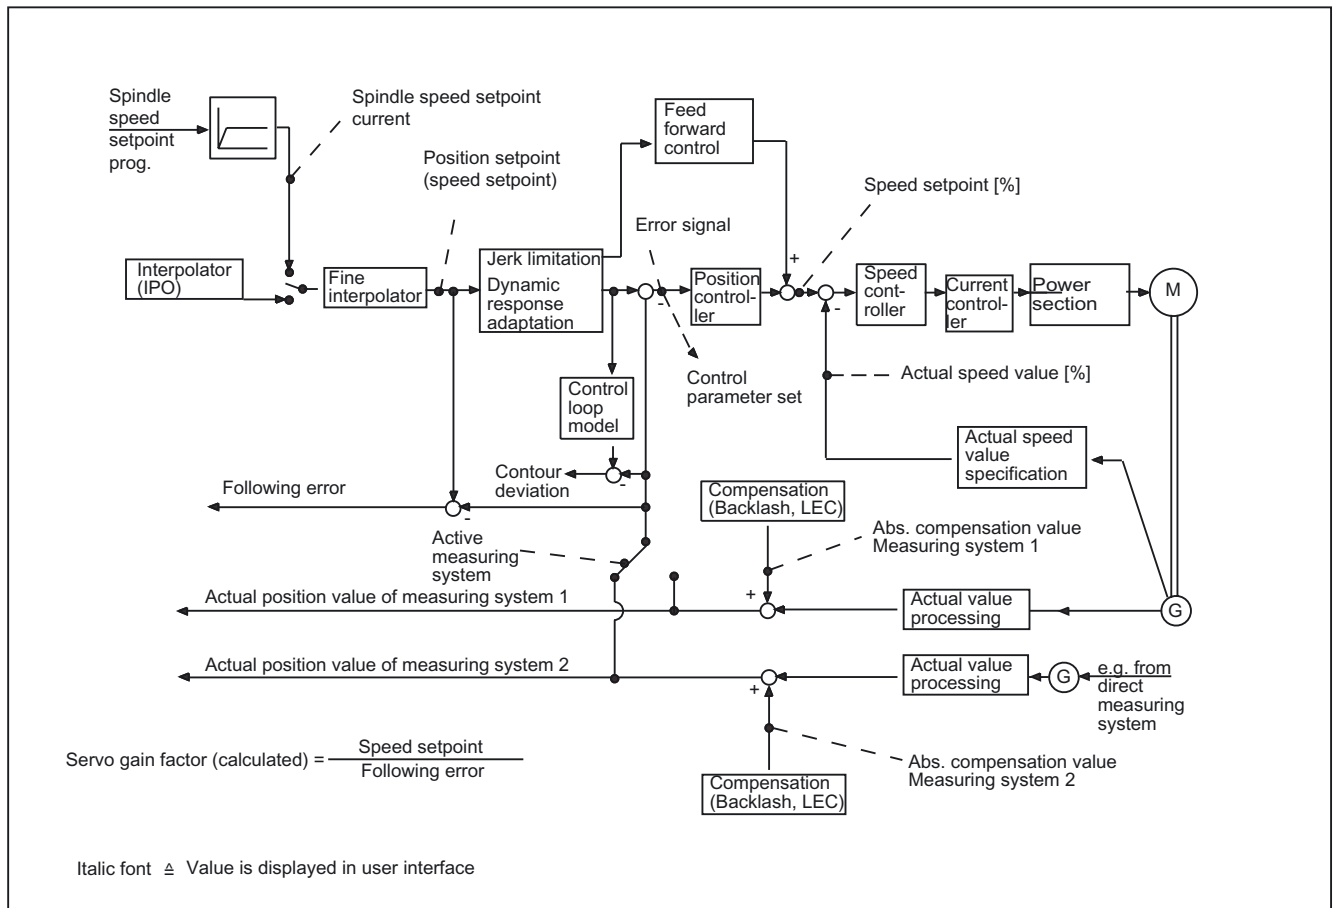

Figure 5-1 Overview diagram of axis and spindle information

Check of the position controller setting

The position controller settings can be easily monitored via the service display "axis/spindle". The number 1 (corresponds to servo gain = 1) should be entered in machine data:

MD32200 \$MA_POSCTRL_GAIN [n] (servo gain factor)

The change takes effect immediately.

For a feedrate of 1 m/mm, a **following error** of 1 mm must be obtained (for servo gain factor = 1 and constant velocity travel), as the servo gain factor is defined as follows:

$$K_v \text{ factor} = \frac{\text{Velocity setpoint}}{\text{Following error}} ;$$

$$\text{Unit (for the standard setting): } \frac{[\text{m/min}]}{[\text{mm}]} ;$$

If the desired servo gain factor (Kv) does not correspond to the actual factor, the possible causes and remedial optimization options are as follows.

- Speed or torque feedforward control is activated. In this case, a higher servo gain factor is set than displayed with MD32200:
- Filter for jerk limitation or dynamic response adaptation is activated. In this case, a lower servo gain factor is set than displayed with MD32200.

Diagnostics for alarms

This information of the service display "Axis/spindle" is also used as diagnostics help when alarms occur, e.g.:

- "Zero speed monitoring"
⇒ **Following error** > MD36030 \$MA_STANDSTILL_POS_TOL (standstill tolerance)
- "Contour monitoring"
⇒ **Contour deviation** > MD36400 \$MA_CONTOUR_TOL (contour monitoring tolerance range)
- "Speed setpoint limitation"
⇒ **Speed setpoint** > MD36210 \$MA_CTRLLOUT_LIMIT (maximum speed setpoint)
- "Position monitoring"
⇒ **Following error** > MD36010 \$MA_STOP_LIMIT_FINE (exact stop fine)
- "Measuring system cannot be switched over"
⇒ Difference between **Position actual value measuring system 1 and 2** > MD36500 \$MA_ENC_CHANGE_TOL (max. tolerance for position actual value sensing)
- "Clamping monitoring"
⇒ **Following error** > MD36050 \$MA_CLAMP_POS_TOL (clamping tolerance with interface signal "Clamping active")

The behavior of the NC control in response to individual alarms, and remedial action is described in:

References:

Diagnostic Manual

Diagnostics of operational state errors

Further, information of the service display "Axis/spindle" can be used to investigate incorrect operating states such as e.g.:

- Although there is a travel command, the axis does not traverse.
⇒ Check whether the controller has been enabled. In **controller mode** position control or speed control (with spindle control) must be activated.
- When feedrate fluctuations occur:
⇒ Detected using **following error** or **speed actual value**.
- Incorrect positioning
⇒ Compare **position setpoint** with **actual value, measuring system 1/2** and **abs. compensation value, measuring system 1/2**.
- The cam is not detected by the PLC during referencing.
⇒ Check **status display "referenced"**
- An incorrect reference point value is displayed.
⇒ Referencing was possibly performed with the incorrect measuring system.
- For a main spindle drive, significant fluctuations occur in the **speed actual value**.
⇒ Speed range for the encoder has been selected too high or the machine data MD36300 \$MA_ENC_FREQ_LIMIT [n] (encoder limit frequency) is set higher than is specified in the encoder data sheet.
- Incorrect spindle positioning occurs.
⇒ An incorrect measuring system is possibly selected or synchronization with the incorrect zero mark.

5.3.2 Drive service display (for digital drives only)

Displays

Displays on the control's user interface that show values and statuses allow for evaluation of the operating statuses of the digital drives.

Access

For the purposes of commissioning and diagnosing

- feed drives (FDD) and
- main spindle drives (MSD)

"Diagnostic" information are displayed for each axis/spindle via the operator panel front in the operating area.

Note

The parameters in the "Drive" service display are not necessary for connecting drives via the PROFIBUS-DP. For SINUMERIK 840Di, the drives are defined as PROFIBUS nodes. The appropriate service data is displayed in 840Di-Start-up in the menu Diagnostics --> PROFIBUS.

Application

The diagnostic options are used for:

- checking the status of enabling and control signals (e.g. **pulse enable**, **drive enable**, **motor selection**, **setpoint parameter set**)
- checking the status of FDD/MSD operating modes (e.g. **setup mode**, **parking axis**)
- displaying temperature warnings
- checking the current setpoint/actual value display (e.g. **actual position value measuring system 1/2**, **speed setpoint**, **actual speed value**)
- checking the drive status (drive ready)
- displaying the current ramp-up phase
- displaying the group error message (**message status class 1**)
- displaying the drive status messages (e.g. **threshold torque not reached**, **minimum speed not reached**, **actual speed = set speed**)

Explanations/Terms

The individual status displays, warnings, messages, etc., are explained in the following sections. For HMI SW 6 and higher, the status is shown in plain text as "yes" or "no" instead of "0" and "1".

For additional information, see:

References:

//IAD/ Commissioning Manual

Drive enable (terminal 64/63)

The display corresponds to the status of terminal 64/63 on the SIMODRIVE611 digital infeed/regenerative feedback unit.

State 1: Central drive enable
State 0 : Central drive disable

Display corresponds to machine datum:
MD1700 \$MD_TERMINAL_STATE
(status of binary inputs).

Pulse enable (terminal 63/48)

The display corresponds to the status of terminal 63/48 on the SIMODRIVE611 digital infeed/regenerative feedback unit.

State 1: Central pulse enable
State 0 : Central pulse disable

Display corresponds to machine data:

MD1700 \$MD_TERMINAL_STATE

(Status of binary inputs).

Pulse enable (terminal 663)

The display corresponds to the status of terminal 663 (relay: safe operational stop) on the drive module.

State 1: Module-specific pulse enable
State 0 : module-specific pulse disable

Display corresponds to machine datum:

MD1700 \$MD_TERMINAL_STATE

(status of binary inputs).

Setup mode (terminal 112) HMI SW 6.3 and later

The display corresponds to the status of terminal 112 on the SIMODRIVE 611 digital infeed/regenerative feedback unit.

State 1: Central drive disable for setup mode
State 0 : Central drive enable, no setup mode

Display corresponds to machine datum:

MD1700 \$MD_TERMINAL_STATE

(status of binary inputs).

PLC pulse enable

Indicates whether the pulse enable from the PLC is available for the drive.

State 1: The pulses for the drive module have been disabled by the PLC.
State 0: Pulse enable for this drive is activated by the PLC.

Display corresponds to IS DB31, ... DBX21.7 ("Pulse enable")

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Speed controller enable NC

This display indicates whether the speed controller for the drive has been enabled by the NC.

State 1: Speed controller enable = OFF
State 0: Speed controller enable = ON

Ramp-up function generator quick stop

Status display for ramp-up function generator quick stop.

State 1: Ramp-up function generator quick stop is not active for the drive.

State 0: Ramp-up function generator quick stop is active. The drive is stopped without a ramp function with speed setpoint = 0 and without pulse suppression.

Display corresponds to IS DB31, ... DBX92.1 ("Ramp-function generator rapid stop").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

DC link state (on/off)

The display contains the following drive warning:

State 0: DC link voltage = ON

State 1: DC link voltage is below warning threshold.

The warning threshold corresponds to machine datum:

MD1604 \$MD_LINK_VOLTAGE_WARN_LIMIT (DC link undervoltage warning threshold).

Enable pulses

Message indicating whether the drive pulses have been enabled.

State 0: The drive module pulses are suppressed. The axis/spindle can therefore not be traversed.

State 1: The drive module pulses are enabled. The axis/spindle can now be traversed.

Display corresponds to IS DB31, ... DBX93.7 ("Enable pulses").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2).

Drive ready

Display of the current status of the selected drive.

State 0: The drive is not ready.

State 1: The drive is ready.

Display corresponds to IS DB31, ... DBX93.5 ("Drive Ready").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Display indicating the current ramp-up phase of the selected drive.

Meaning:

CRC error

Display of communications errors detected in hardware between NC and drive.

Note

If the display shows a value other than "0", please contact your SIEMENS Regional Office!

ZK1 Messages

Display indicates whether messages of status class 1 are active.

State 0: There is no pending ZK1 message.

State 1: One or several status class 1 messages are active.

Status class 1 messages are alarms with the following characteristics:

- They lead to internal responses (e.g. regenerative braking, immediate pulse suppression)
- They are modal.

DC link voltage

indicates the current DC link voltage level within the drive grouping.

Unit: Volts

Speed setpoint

The displayed speed setpoint represents the unfiltered total setpoint value. It consists of the position controller output component and the speed feedforward branch.

Unit: rpm

Display corresponds to machine data:

MD1706 \$MD_DESIRED_SPEED (speed setpoint value).

Speed actual value

The displayed real value represents the unfiltered actual speed value.

Unit: rpm

Display corresponds to machine data:

MD1707 \$MD_ACTUAL_SPEED (actual speed value).

Smoothed actual current value

Display of the smoothed actual current value. The torque-generating actual current value is smoothed by a PT1 element with parameterizable time constants.

Unit: %

100 % corresponds to the maximum current of the power section.

Display corresponds to machine data:

MD1708 \$MD_ACTUAL_CURRENT (smoothed actual current value).

Motor temperature

Display of motor temperature measured via temperature sensors.

Unit: Degrees Celsius

Display corresponds to machine datum:

MD1702 \$MD_MOTOR_TEMPERATURE (motor temperature).

Speed setpoint filter 1

Status display of speed setpoint smoothing function.

State 0: No speed setpoint smoothing is active.

State 1: Smoothing of the speed setpoint as requested by the PLC using IS DB31, ... DBX20.3 ("Speed setpoint smoothing") takes effect because speed setpoint filter 1 is configured as the low pass.

Display corresponds to IS DB31, ... DBX92.3 ("Speed setpoint smoothing active") and is shown in an updated form as of software version 6.3 and later.

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

2nd torque limit

Display of active torque limit

State 0: Torque limit 1 is active.

State 1: Torque limit 2 is active.

Display corresponds to IS DB31, ... DBX92.2 ("Torque limit 2 active").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Integrator disabling

This display indicates whether the speed controller integrator is active.

State 0: The integrator of the speed controller is enabled. The speed controller functions as a PI controller.

State 1: Deactivation of the speed-controller integrator as requested by the PLC using IS DB 31, ... DBX 21.6 ("Integrator disable speed controller") is active for the drive module. The speed controller has therefore switched from a PI to a P controller.

Display corresponds to IS DB31, ... DBX93.6 ("Speed-controller integrator disabled").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Setup mode

Mode display of the SIMODRIVE 611 digital.

State 0: Normal operation is active for the drive.

State 1: Setup mode is active for the drive.

Display corresponds to NST DB31, ... DBX92.0 ("Setup mode active").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Parking axis

Mode display of the SIMODRIVE 611 digital.

State 0: Axis/spindle in normal mode

State 1: Axis/spindle in parking position, i.e. all encoder-specific monitoring and evaluating functions are disabled. This allows the encoder to be withdrawn without initiating an alarm.

Setpoint parameter set (drive)

Indicates which of the 8 drive parameter sets of the SIMODRIVE 611 digital are to be activated by the PLC.

Display corresponds to IS DB31, ... DBX21.0 to 21. ("2Parameter set selection A,B,C").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Actual parameter set (drive)

Display indicating which of the 8 drive parameter sets of the SIMODRIVE 611 digital is currently active.

Display corresponds to IS DB31, ... DBX93.0 to 93.2 ("Active parameter set A,B,C").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals

Operating mode

Display indicating whether the motor is operating as a feed drive or main spindle drive.

Motor selection (star/delta)

Display indicating which motor data set is to be activated by the PLC. At the moment the motor data record is used for the star/delta switchover on main spindle drives.

The following assignment applies:

Motor selection	Application	Coding	
Motor 1	MSD: Star	0	0
Motor 2	MSD: Delta mode	0	1
Motor 3	reserved	1	0
Motor 4	reserved	1	1

The display applies only to main spindle drives.

Display corresponds to NST DB31, ... DBX21.3 to 21.4

("Motor selection A,B").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Actual motor (star/delta)

Display indicating which of the motor data sets is currently active. At the moment the motor data record is used for the star/delta switchover on main spindle drives.

The following assignment applies:

Motor selection	Application	Coding	
Motor 1	MSD: Star	0	0
Motor 2	MSD: Delta mode	0	1
Motor 3	reserved	1	0
Motor 4	reserved	1	1

Display is valid only for main spindle drives.

Display corresponds to NST DB31, ... DBX93.3 to 93.4

("active motor A,B").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Position actual value measuring system 1/2

The actual position of the axis as measured via measuring system 1/2. The position is displayed in the machine coordinate system (no work offsets or tool offsets included).

Unit: mm, inch or degrees

Power section in i²t limitation HMI SW 6.3 and later

Limitation for protecting the power section against continuous overloading of the SIMODRIVE 611 drives.

State 1: i²t-power section limitation has responded

State 0: i²t power section limitation has not responded

Display is valid for SIMODRIVE universal and SIMODRIVE digital.

Display corresponds to NST DB31, ... DBX95.7

("i²t monitoring").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Heatsink temperature warning

Warning signal output by drive:

State 0: The heat sink temperature monitoring has not responded.

State 1: The heatsink temperature monitoring has responded.

Display corresponds to IS DB31, ... DBX94.1

("Heatsink temperature prewarning").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Motor temperature warning

Warning signal output by drive:

State 0: The motor temperature is below the warning threshold.

State 1: The motor temperature has exceeded the defined warning threshold.

The warning threshold corresponds to the machine data:

MD1602 \$MD_MOTOR_TEMP_WARN_LIMIT (maximum motor temperature).

Display corresponds to NST DB31, ... DBX94.0 ("Motor temperature prewarning").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Ramp-up function completed

Status display of drive.

State 0: The ramp-up function has not yet been completed after a new speed setpoint was defined.

State 1: The actual speed value has reached the speed tolerance band after a new speed setpoint was defined.

The speed tolerance band corresponds to machine datum:

MD1426 \$MD_SPEED_DES_EQ_ACT_TOL (tolerance band for 'n_{set}-n_{actual}' message).

Display corresponds to NST DB31, ... DBX94.2 ("Ramp-up function completed").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Torque lower than threshold setting

Status display of drive.

State 0: In the stationary condition (i.e. ramp-up procedure completed), the torque setpoint is greater than the threshold torque.

State 1: In the stationary condition, the torque setpoint has not reached the threshold torque.

The threshold torque corresponds to the machine data:

MD1428 \$MD_TORQUE_THRESHOLD_X (threshold torque).

Display corresponds to IS DB31, ... DBX94.3 ("M_d < M_{dx}").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Speed lower than minimum setting

Status display of drive.

State 0: The speed actual value is higher than the minimum speed.

State 1: The actual speed value is smaller than the minimum speed.

The minimum speed corresponds to the machine data:

MD1418 \$MD_SPEED_THRESHOLD_MIN (n_{min} for 'n_{is} < n_{min}' message).

Display corresponds to IS DB31, ... DBX94.4

"|n_{actual}| < n_{min}").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Speed lower than threshold setting

Status display of drive.

State 0: The actual speed value is greater than the threshold speed.

Status 1: The actual speed value is smaller than the threshold speed.

The threshold speed corresponds to machine datum:

MD1417 \$MD_SPEED_THRESHOLD_X

(n_x for 'n_{actual} < n_x' message).

Display corresponds to NST DB31, ... DBX94.5 ("|n_{actual}| < n_x").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Actual speed = set speed

Status display of drive.

- State 0: The actual speed value is outside the speed tolerance band after a new speed setpoint was defined.
- State 1: The actual speed value has reached the speed tolerance band after a new speed setpoint was defined.

The speed tolerance band corresponds to machine datum:

MD1426 \$MD_SPEED_DES_EQ_ACT_TOL (tolerance band for 'nset-nactual' message).

Display corresponds to NST DB31, ... DBX94.6 (" $|n_{actual}| = n_{set}$ ").

References:

/FB1/ Function Manual Basic Functions; Various Interface Signals (A2)

Variable signal 1

Status display of 611D variable signaling function.

With the variable signaling function, any memory location can be monitored to see whether a definable threshold is exceeded. In addition to the threshold, a tolerance band can be defined which is also taken into account when scanning for violation of the threshold value. The signal can be combined with an ON delay or OFF delay time.

State 0: Threshold value not reached

State 1: Threshold value exceeded

Parameters for the variable signal function are set using the following 611D machine data:

MD1620 \$MD_PROG_SIGNAL_FLAGS	(Bits variable signal function)
MD1621 \$MD_PROG_SIGNAL_NR	(Signal number variable signal function)
MD1622 \$MD_PROG_SIGNAL_ADDRESS	(Address variable signal function)
MD1623 \$MD_PROG_SIGNAL_THRESHOLD	(Threshold variable signal function)
MD1624 \$MD_PROG_SIGNAL_HYSTERESIS	(Hysteresis variable signal function)
MD1625 \$MD_PROG_SIGNAL_ON_DELAY	(ON Delay variable signal function)
MD1626 \$MD_PROG_SIGNAL_OFF_DELAY	(OFF Delay variable signal function)

Diagnostics for alarms

This information is also provided as a diagnostic tool for diagnosing the causes of alarms such as:

- "Ramp-up error"
⇒ Check the **ramp-up phase** to see which ramp-up phase the drive has reached.
- "Drive malfunction"
⇒ **Message ZK1** is set.
⇒ check **specified parameter set, motor selection, DC link status**.
Check following alarms 300500 to 300515.
- "Zero speed monitoring",
25050 "Contour monitoring",
25060 "Speed setpoint limitation"
25080 "Positioning monitoring"
⇒ The enabling for the drive may have been omitted (e.g. **pulse enable, drive enable, pulse enable for PLC** not available); this leads to display **pulses enabled = off**.
- "Motor temperature exceeded"
⇒ Check the current motor temperature.

For details on the behavior of the NC control in response to individual alarms, and remedial action, please refer to:

/DA/ Diagnostic Manual

5.3.3 Service display PROFIBUS DP 840Di

The user interface 840Di Start-Up provides diagnostic screen forms for PROFIBUS-DP and its nodes. . These diagnostic screens are only intended for information. You cannot modify them.

The following detailed information is displayed:

- PROFIBUS configuration
- Information on the slaves regarding their assignment to PLC/NC
- Detailed information on the slaves and the corresponding slots
- Information on the axes.

To obtain a quick overview, the current states of certain functions are represented by colored lamps. The following general conventions are used for the meaning of the individual colors:

- Green: Function is OK.
- Red: Failure or no communication at the moment
- Gray: Function is not available for the present communication.

Diagnostic screen PROFIBUS-DP Configuration

The diagnostic screen PROFIBUS-Configuration provides general information about the PROFIBUS-DP.

The following parameters are displayed:

Table 5- 1 Diagnostic screen Profibus-Configuration

Function/Part function	Explanation/Meaning
Bus-configuration	
Baudrate in MBd	Transmission rate
Cycle time in msec	Configured bus-cycle time; also defines the position controller cycle at the same time
Synchronous part (TDX) in msec	configured time span for the cyclic data exchange within a PROFIBUS-DP cycle
Status	
Configuration ok	Status of the configuration. <ul style="list-style-type: none"> Green lamp: DP-Master is powered up. Red lamp: Error function/no communication
Bus status	Current bus status is shown in this field. Each bus status is explained briefly in the screen. Possible states are: <ul style="list-style-type: none"> POWER_ON OFFLINE CLEAR OPERATE ERROR

Diagnostics screen of the DP slaves

This diagnostic screen provides an overview of the configured slaves and the slaves identified on the bus.

The following information is offered:

Table 5- 2 Diagnostic screen Information about slaves

Function/Part function	Explanation/Meaning
Slave no. (DP address)	Configured DP address of the DP slave
Assignment	It is shown, whether the DP slave is assigned to the NC or to the PLC. <ul style="list-style-type: none"> NC: e.g. one or more drives controlled by the NC. PLC: e.g. I/O peripherals or an axis controlled by the PLC.
active on the bus	Shows, whether the DP slave has been identified on the bus. <ul style="list-style-type: none"> Green lamp: DP slave was identified at the PROFIBUS-DP and the data exchange is working with the assigned component (NC or PLC) Red lamp: Error function/no communication

Function/Part function	Explanation/Meaning
Synchr. with NC	It is shown, whether the DP slave is running synchronously to NC on the bus. <ul style="list-style-type: none"> • Green lamp: DP slave runs synchronously to NC at PROFIBUS-DP i.e. the equidistant data exchange takes place. • Gray lamp: DP slave is not assigned to NC but instead to PLC. • Red lamp: Error function/no communication
Number of slots	Number of configured slots within the DP slave
Details	By pressing the button another diagnostic screen is opened, which contains the detailed information for the respective DP slave.

Detailed information of the slots within a slave

Via the button **Details** the diagnostic screen of detailed information for the slave is opened. This screen shows you detailed information about the slots assigned to the DP slave.

The field Slave shows you the most important information for the currently selected DP slave.

The following information is offered for the slots:

Table 5- 3 Diagnostic screen Detailed information for slave

Function/Part function	Explanation/Meaning
Slave	
Slave no. (DP address)	Configured DP address of the DP slave
Assignment	It is shown, whether the DP slave is assigned to the NC or to the PLC. <ul style="list-style-type: none"> • NC: e.g. one or more drives controlled by the NC. • PLC: e.g. I/O peripherals or an axis controlled by the PLC.
Active on the bus	Shows, whether the DP slave has been identified on the bus. <ul style="list-style-type: none"> • Green lamp: DP slave was identified at the PROFIBUS-DP and the data exchange is working with the assigned component (NC or PLC) • Red lamp: Error function/no communication
Synchronous	It is shown, whether the DP slave is running synchronously to NC on the bus. <ul style="list-style-type: none"> • Green lamp: DP slave runs synchronously to NC at PROFIBUS-DP i.e. the equidistant data exchange takes place. • Gray lamp: DP slave is not assigned to NC but instead to PLC. • Red lamp: Error function/no communication
Slots	
No.	Slot number within the DP slave
I/O address	I/O address in the I/O address area of the PLC assigned to this slot. For NC axes, the set and the actual value must always be configured on the same I/O address.
logical drive no.	Drive number specified in the NC machine data for the axis.
Length [byte]	Length of the I/O area reserved for the slot in step 7 I/O address area
Type	Specification, whether the slot is input, output or diagnostic slot. If the slot is assigned to an NC axis, then the output is always denoted as setpoint value and the input always as actual value.
Machine axis	Display of the name defined in the machine data for this slot. If the slot is not assigned to any NC axis, <No NC-axis> is shown.

Function/Part function	Explanation/Meaning
Telegram type	The telegram type of the NC axis configured in the NC machine data. If the slot is not assigned to any NC axis, the telegram type is not filled (-).
State	Current state of slot. Displayed only for NC axes. <ul style="list-style-type: none"> • Green: Slot used by NC, communication active • Gray: No NC axis • Red: Slot used by NC, communication currently not active

Diagnostic screen for the axes

The diagnostic screen AxisInfo shows the axis-specific detailed information. The diagnostic screen enables an NC-oriented view of the axis information.

The following information is offered for the slots:

Table 5-4 Diagnostic screen Axis Info

Function/Part function	Explanation/Meaning
Machine axis	Name of the axis defined in the NC-machine data
Output	
Slave/Slot	Configured routing
State	Current state of slot. Green lamp: Cyclic communication Red lamp: (still) no cyclic communication
Telegram failures	It is shown, how many telegram failures have occurred since the NC-power up. This value is an indication of the quality (susceptibility to faults) of the PROFIBUS-DP strand.
Encoder 1	
Slave/Slot	Configurable routing
State	Current state of slot. Green lamp: Cyclic communication Red lamp: (still) no cyclic communication
Telegram failures	It is shown, how many telegram failures have occurred since the NC-power up. This value is an indication of the quality (susceptibility to faults) of the PROFIBUS-DP strand.
Type	Display of the encoder type configured in the NC-machine data. ABS: Absolute encoder INC: Incremental value encoder
Encoder 2	(If configured, the same display as for encoder 1)

5.4 Communication log

Log assistance

In event of a fault and when developing OEM applications, control logs may assist with the analysis.

Logs and version

Communication log

The communication errors which have occurred between the HMI and NC are displayed in chronological order via the soft key **Comm. log** in the "Diagnostics" operating area. This error list assists developers of OEM applications in localizing sporadic errors. The list has no relevance for normal operation.

Logbook

The logbook display selected by means of soft key **Logbook** in the "Diagnostics" operating area automatically lists details of all alterations to the control that are relevant for the system (e.g., changes in access level).

For SINUMERIK 840Di, the logbook is displayed in 840Di Start-Up.

Version

in case of service, the integrated HMI or NC software version can be read (Operating area "Diagnosis" under the **Version**) softkey.

The software version of each software module is recorded additionally in a list.

5.5 PLC status

PLC status signals can be checked and altered via the operator panel in the "Diagnostics" operating area.

Application

The end customer or service personnel can use this function on site without a programming device to do the following:

- Check the input and output signals of the PLC I/Os.
- Carry out limited troubleshooting
- Check the interface signals for diagnostic purposes.

Operation

For information about status display operation and changing PLC signals, refer to the Operating Manual for the relevant HMI software.

Status display

The status of the following data can be displayed on the operator panel.

- Interface signals from the machine control panel
- Interface signals to the machine control panel
- Interface signals between the NCK and PLC
- Interface signals between the HMI and PLC
- Data blocks (DB 0-127)
- Flags (FB 0-255)
- Timers (T 0-127)
- Counters (C 0-63)
- Inputs (IB 0-127)
- Outputs (QB 0-127)

For a breakdown of the interface signals (DBx, DBBy), refer to:

References:

/LIS2/ Lists (Volume 2)

Change in status

The status of the above signals can be changed for test purposes. Signal combinations are also possible. A maximum of ten operands can be altered at any one time.

5.6 Identifying defective drive modules

Deactivate drives

Drives can be removed from the NC configuration using a piece of machine data.

Troubleshooting may involve a situation where a drive module (SIMODRIVE 611 digital) displayed in an alarm text needs to be removed from the bus in order to determine whether this module has caused the displayed error.

With machine datum:

MD13030 \$MN_DRIVE_MODULE_TYPE,

individual modules can be removed from the NC-side drive bus configuration (the affected axes are switched to simulation).

Note

You must remove the desired module from the drive bus configuration (SIMODRIVE 611 digital) before you activate the function. To do this, connect the drive so as to exclude the module.

Since this internal modification to the machine configuration can result in damage to the machine if implemented incorrectly, the axes are prevented from moving.

If Safety Integrated has been activated for the modules concerned, you must disable it manually (safety, logged, EMERGENCY STOP scheme).

Remove drive module at NC end

A drive module (SIMODRIVE 611 digital) specified in an alarm text must be removed from the bus:

1. Remove the module from the drive bus network
2. Set entries of the drive module in machine datum:
MD13030 \$MN_DRIVE_MODULE_TYPE
to zero (zero-axis module).
3. Perform an NC RESET.

The axes which were controlled by the removed drive modules are now replaced by simulated axes. The 611D bus with its drive modules is now in a state in which it could normally move axes, but axis traversal has been disabled internally.

Alarm 300020 "Drive %1 removed for diagnostics" displays this status to the operator.

Restoring the initial configuration

After completing the diagnostics, the initial configuration on the drive bus must be restored:

1. Replace or re-install the removed drive module.
2. Change entries of the drive module in machine datum:
MD13030 \$MN_DRIVE_MODULE_TYPE
back to the original values.
3. Perform an NC RESET.

Example

The 2-axis module with drive numbers "1" and "2" must be removed from a drive grouping.

Note

Before activating the function, the module in question must be removed from the drive bus configuration

(SIMODRIVE 611 digital). To do this, connect the drive bus so as to exclude the module.

If Safety Integrated has been activated for the modules concerned, you must disable it manually (safety, logged, EMERGENCY STOP scheme).

Table 5- 5 Bus configuration example

Module	Drive no.	Active	Type	Module type	Power section code
1	10	1	ARM/MSD	Axis	6
Left	1	1	SRM/FDD	Axis	14
Right	2	1	SRM/FDD	Axis	14
Left	4	1	HLA	Axis	
Right	5	1	ANA	Axis	
4	12	1	SLM	Axis	11
5	11	1	PER	DMP-C	

Module "2" must now be removed:

- Machine datum:
MD13030 \$MN_DRIVE_MODULE_TYPE
is to be selected on the "General MD" MD screen.
- DRIVE_MODULE_TYPE[0] = 1
DRIVE_MODULE_TYPE[1] = 2 <- set this entry to zero
DRIVE_MODULE_TYPE[2] = 2 <- set this entry to zero
DRIVE_MODULE_TYPE[3] = 2
DRIVE_MODULE_TYPE[4] = 2
DRIVE_MODULE_TYPE[5] = 1
DRIVE_MODULE_TYPE[6] = 9

- After the changes, the table looks like this:
DRIVE_MODULE_TYPE[0] = 1
DRIVE_MODULE_TYPE[1] = 0
DRIVE_MODULE_TYPE[2] = 0
DRIVE_MODULE_TYPE[3] = 2
DRIVE_MODULE_TYPE[4] = 2
DRIVE_MODULE_TYPE[5] = 1
DRIVE_MODULE_TYPE[6] = 9
- Alarms 300020 "Drive 1 removed for diagnostics" and 300020 "Drive 2 removed for diagnostics" are displayed.

Internally simulated drives are used for all axes which had settings on the removed drive numbers. If the controller is engaged for the drives that are still installed, these drives operate in the normal way. Interpolative traversal of all axes is disabled.

Note

If alarm 300003 "Axis xx drive yy incorrect module type zz" appears, then you have removed only one part of a 2-axis module. In this case, you should check the module type in the drive configuration display. "NO" axis type is shown for removed modules.

5.7 Data lists

5.7.1 Machine data

F1: Travel to fixed stop

6.1 Brief description

Customer benefit

The "Travel to fixed stop" function can be used for operations such as traversing tailstocks or sleeves to an end limit position in order to clamp workpieces.

Features

- The clamping torque and a fixed stop monitoring window can be programmed in the parts program and can also be altered via setting data once the fixed stop has been reached.
- The "travel to fixed stop" function can be implemented for axes as well as for spindles with axis-traversing capability.
- The function can be implemented for several axes simultaneously and parallel to the motion of other axes.
- Torques or the power can be adjusted to a specific setting.
- Travel with limited torque/power (Force Control, `FOC`) can be activated.
- The "travel to fixed stop" functions can be enabled from synchronized actions.
- Block search with calculation, multi-channel (SERUPRO).
Move axes with `FXS` and `FOC` in simulation mode.
- Vertical axes can also be moved with `FXS` to a fixed stop.
- With SW 6.4 and higher, VDI signals can be used to set a `REPOS` offset for each axis and display the `FXS` status currently active on the machine after the search target has been located.

6.2 General functionality

6.2.1 Functional sequence, programming, parameterization

Programming

Travel to fixed stop is selected or deselected with the following commands:

`FXS[<axis>]=1 (select)`

`FXS[<axis>]=0 (deselect)`

The commands are modal.

The clamping torque is set with command:

`FXST[<axis>] = <torque>`

The torque is specified as a percentage referred to the reference torque of the drive (SINAMICS: p2003).

The command is used for setting the width of the fixed stop monitoring window.

`FXSW[<axis>] = <window width>`

The unit is dependent on the default setting: mm, inch or degrees.

Channel axis identifier

Instead of the machine axis identifiers, it is also possible to use channel axis identifiers if the channel axis is precisely assigned to one machine axis.

Restrictions:

Channel axis identifiers may not be used (option disabled) for machine axes which have an active transformation or frame.

If the machine axis is a coupled axis (e.g. following axis), programming is prevented and alarm 14092 "Incorrect axis type" is displayed.

The movement to the destination point can be described as a path or positioning axis movement. With positioning axes, the function `FXS` can be performed across block boundaries. The function may also be selected for several machine axes simultaneously.

The `FXST` and `FXSW` commands are optional.

The travel path and the command which activates that function **must be programmed in one block** (exception: Synchronized actions).

Examples

With machine axis identifiers:

```
X250 Y100 F100 FXS[X1]=1
X250 Y100 F100 FXS[X1]=1 FXST[X1]=12.3
X250 Y100 F100 FXS[X1]=1 FXST[X1]=12.3 FXSW[X1]=2 ; mm
X250 Y100 F100 FXS[X1]=1 FXSW[X1]=2 ; mm
```

References:

/PG/ Programming Manual Fundamentals

Channel axis identifier with unambiguous machine axis assignment:

For the purpose of illustrating the differences in programming, channel axis X is programmed as the image of machine axis AX1 [or X1 (Name in machine parameter: MD10000 \$MN_AXCONF_MACHAX_NAME_TAB)].

```
Programming with machine axis identifiers
FXS[X1] = 1 ; Selecting X1
FXST[X1] = 10 ; New torque for X1
FXSW[X1] = 5 ; New window for X1
```

```
Programming with channel axis identifiers
FXS[X] = 1 ; Selecting X ->X1
FXST[X] = 10 ; New torque X ->X1
FXSW[X] = 5 ; New window for X -> X1
```

All four of the following programming lines have the same effect when the channel axis X is imaged on the machine axis AX1, X1:

```
Z250 F100 FXS[AX1]=1 FXST[AX1]=12.3 FXSW[AX1]=2000
Z250 F100 FXS[X1]=1 FXST[X1]=12.3 FXSW[X1]=2000
Z250 F100 FXS[X]=1 FXST[X]=12.3 FXSW[X]=2000
Z250 F100 FXS[X]=1 FXST[X1]=12.3 FXSW[AX1]=2000
```

Functional sequence

The function is explained by the example below (sleeve is pressed onto workpiece).

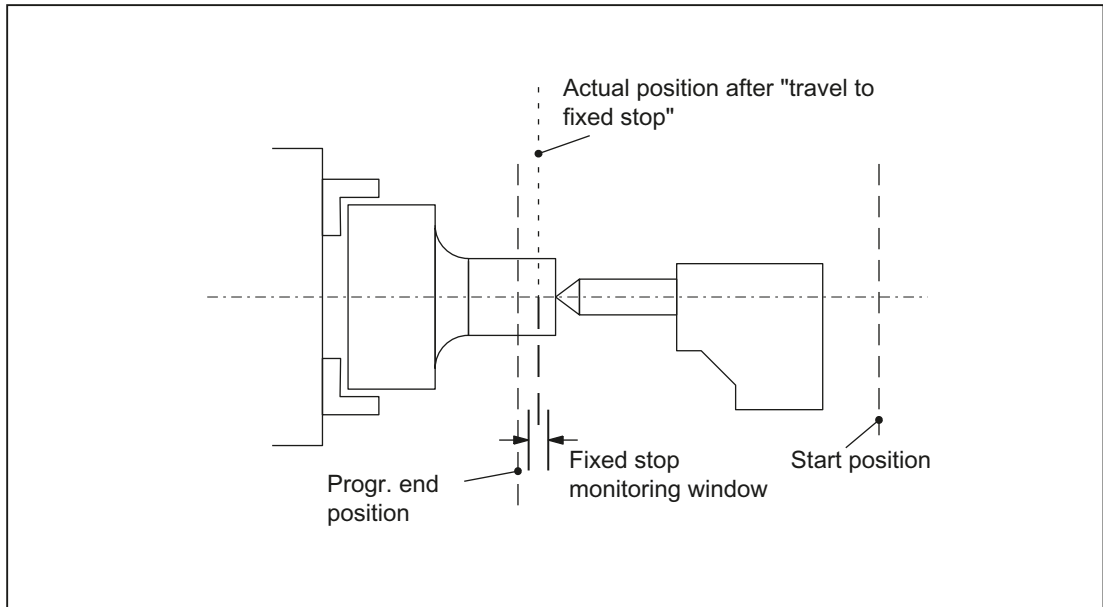

Figure 6-1 Example of travel to fixed stop

Selection

The NC detects that the function "Travel to fixed stop" is selected via the command `FXS[x]=1` and signals the PLC using the IS DB31, ... DBX62.4 ("Activate travel to fixed stop") that the function has been selected.

If the machine data:

`MD37060 $MA_FIXED_STOP_ACKN_MASK`

(Monitoring of PLC acknowledgments for travel to fixed stop)

is set correspondingly, the system waits for the acknowledgement of the PLC using the IS DB31, ... DBX3.1 ("Enable travel to fixed stop").

The programmed target position is then approached from the start position at the programmed velocity. The fixed stop must be located between the start and target positions of the axis/spindle. A programmed torque limit is effective from the start of the block, i.e. the fixed stop is also approached with reduced torque. Allowance for this limitation is made in the NC through an automatic reduction in the acceleration rate.

If no torque has been programmed in the block or since the start of the program, then the value is valid in the axis-specific machine data:

`MD37010 $MA_FIXED_STOP_TORQUE_DEF`

(Fixed stop clamping torque default setting)

Fixed stop reached

As soon as the axis comes into contact with the mechanical fixed stop (workpiece), the closed-loop control in the drive raises the torque so that the axis can move on. The torque rises up to the programmed limit value and then remains constant.

The "Fixed point reached" status can be calculated as follows depending on the machine data MD37040 \$MA_FIXED_STOP_BY_SENSOR (fixed stop recognition by sensor):

- FIXED_STOP_BY_SENSOR = 0

The "Fixed stop reached" status is achieved when the axial contour deviation (= difference between actual and expected following error) has exceeded the value set in machine data:

MD37030 \$MA_FIXED_STOP_THRESHOLD (Threshold for fixed stop detection)

- FIXED_STOP_BY_SENSOR = 1

External sensor transmits the "Fixed stop reached" state to the NC via the PLC using the IS DB31, ... DBX1.2 ("Sensor fixed stop").

- FIXED_STOP_BY_SENSOR = 2

The "Fixed stop reached" status is active either when the status has been detected by the contour monitoring function or when the external sensor signals this status by a signal change from 0 " 1 to (DB31,...DBX 1.2).

The axis contour deviation is explained in:

References:

/FB1/ Function Manual Basic Function; Diagnostics tool (D1)

Internal processes

Once the NC has detected the "Fixed stop reached" status, it deletes the distance-to-go and the position setpoint is made to follow. The controller enabling command remains active.

The PLC is then informed of the state using IS DB31, ... DBX62.5 ("Fixed stop reached").

If the machine data:

MD37060 \$MA_FIXED_STOP_ACKN_MASK

is set correspondingly, then the system waits for the acknowledgement of the PLC using the IS DB31, ... DBX1.1 ("Acknowledge fixed stop reached").

The NC then executes a block change or considers the positioning motion to be completed, but still leaves a setpoint applied to the drive actuator to allow the clamping torque to take effect.

The fixed stop monitoring function is activated as soon as the stop position is reached.

Monitoring window

If no fixed stop monitoring window was programmed in the block or from program start, then the value set in the machine data:

MD37020 \$MA_FIXED_STOP_WINDOW_DEF

(Default for fixed stop-monitoring window)

is valid.

If the axis leaves the position it was in when the fixed stop was detected, then alarm 20093 "Fixed stop monitoring has responded" is displayed and the "Travel to fixed stop" function deselected.

The window must be selected by the user such that the alarm is activated only when the axis leaves the fixed stop position.

Enabling the fixed stop alarms

With the machine data:

MD37050 \$MA_FIXED_STOP_ALARM_MASK

enabling the fixed stop alarms can be established as follows:

MD37050 = 0	Fixed stop not reached (suppress Alarm 20091)
MD 37050 = 2	Fixed stop not reached (suppress alarm 20091) and fixed stop aborted (suppress alarm 20094)
MD 37050 = 3	Fixed stop aborted (suppress alarm 20094)

All other permissible values of 7 or less do not suppress any alarms.

Using the parts program command `NEWCONF` a new setting can be activated.

Fixed stop is not reached

If the programmed end position is reached, without detecting the state "fixed stop reached", then depending on the state of the machine data:

MD37050 \$MA_FIXED_STOP_ALARM_MASK (Release of fixed stop alarms)

the alarm 20091 "Fixed stop not reached" is output.

Function abort

If the "Travel to fixed stop" function is aborted owing to a pulse cancellation command, cancelation of PLC acknowledgments or a Reset in the approach block, the display or suppression of alarm 20094 can be controlled via machine data:

MD37050m \$MA_FIXED_STOP_ALARM_MASK

Abort without alarm

The travel to fixed stop can be aborted by the PLC in the approach block without triggering an alarm (for example, when the operator actuates a key), if in the machine data:

MD37050 \$MA_FIXED_STOP_ALARM_MASK

the alarm 20094 is suppressed.

The Travel to fixed stop function is deselected in response to both "Fixed stop not reached" and "Fixed stop aborted".

Interrupts

If the fixed stop position is not reached when the function is active, alarm 20091 "Fixed stop not reached" is output and a block change executed.

If a travel request (e.g. from the part program, the PLC, from compile cycles or from the operator panel front) is provided for an axis after the fixed stop has been reached, the alarm 20092 "Travel to fixed stop still active" is output and the axis is not moved.

If an axis has reached the fixed stop and is then moved out of this position by more than the value specified in

SD FIXED_STOP_WINDOW (Fixed stop monitoring window)

from the position, then the alarm 20093 "Standstill monitoring has triggered at the stop" is given, the function "Travel to fixed stop" for this axis is deselected and the system variable is set \$AA_FXS[x]=2.

No termination during alarm

"Travel to fixed stop" remains active from now on for alarms,
if the bit values in the machine data:

MD37052 \$MA_FIXED_STOP_ALARM_REACTION

were set.

IS "Mode group ready" (DB11, ... DBX6.3) remains active.

Alarm suppression after new programming

Travel to fixed stop can be used for simple measuring processes.

For example, it is possible to carry out a check for tool breakage by measuring the tool length by traversing onto a defined obstacle. To do so, the fixed stop alarm must be suppressed. When the function for clamping workpieces is then used "normally," the alarm can be activated using parts program commands.

Sequence in case of a fault or abnormal termination

The IS DB31, ... DBX62.4 ("Activate travel to fixed stop") is reset.
Depending on the machine data:
MD37060 \$MA_FIXED_STOP_ACKN_MASK
the acknowledgement of the PLC is awaited through resetting of the NST
DB31, ... DBX3.1 ("Enable travel to fixed stop").
The torque limitation is then canceled and a block change executed.

Deselection

The NC recognizes the function deselection via programming of the command $FXS[x]=0$.
Then an advance stop (STOPRE) is internally released, since it can't be foreseen where the axis will be after deselection.
The torque limitation and monitoring of the fixed stop monitoring window are canceled.
The IS DB31, ... DBX62.4 ("Activate travel to fixed stop") and DB31, ... DBX62.5 ("Fixed stop reached") are reset.
Depending on the machine data:
MD37060 \$MA_FIXED_STOP_ACKN_MASK
the acknowledgement of the PLC is awaited through resetting of the NST
DB31, ... DBX3.1 ("Enable travel to fixed stop") and/or
DB31, ... DBX1.1 ("Acknowledge fixed stop reached").
The axis will then change to position control. The follow-up mode of the position setpoints is ended and a synchronization to the new actual position is carried out.
A programmed traverse motion can then be executed. This motion must lead away from the fixed stop or else the stop or even the machine may sustain damage.
A block change is executed after the target position has been reached.

Multiple selection

A selection may only be carried out once. If the function is called once more due to faulty programming ($FXS[Axis]=1$) the alarm 20092 "Travel to fixed stop still active" is initiated.

Block-related synchronized actions

By programming a block-related synchronized action, travel to fixed stop can be connected during an approach motion.

Programming example:

```
N10 G0 G90 X0 Y0
N20 WHEN $AA_IW[X]>17 DO FXS[X]=1           ; If X reaches a position greater
N30 G1 F200 X100 Y110                       ; 17mm FXS is activated
```

Changing the clamping torque and fixed stop monitoring window

The clamping torque and the monitoring window can be changed with the commands `FXST[x]` and `FXSW[x]`. The changes take effect before traversing movements in the same block.

Programming of a new fixed stop monitoring window causes a change not only in the window width but also in the reference point for the center of the window if the axis has moved prior to reprogramming. The actual position of the machine axis when the window is changed is the new window center point.

Terminal EP (Enable Pulses) can be controlled using MD37002

With the machine data:

MD37002 \$MA_FIXED_STOP_CONTROL

the response in the case of pulse inhibit at the stop is controlled.

Deleting the pulses using terminal EP or using IS DBX31, ...DBX21.7 ("Pulse enable") does not cancel the function. As a result, the drive will press against the fixed stop again without any further operating action when the machine is restarted.

The rise time of the torque corresponds to the time needed by the current controller of the drive to reach the limitation again.

If the pulses are deleted when a deselection is active (waiting for PLC acknowledgments), the torque limit will be reduced to zero. If the pulses are reactivated during this phase, torque is no longer built up. Once the deselection has been completed, you can continue traversing as normally.

FXS commands programmable in synchronized actions

The parts program commands `FXS`, `FXST` and `FXSW` can be programmed in synchronized actions/technology cycles.

The function `FXS[x]=1` can also be activated without movement; the torque is limited immediately. As soon as the axis is moved via a setpoint, the limit stop monitor is activated.

In static and block related synchronized actions, the same commands `FXS`, `FXST`, `FXSW` can be used as in the normal parts program run. The values assigned can result from a calculation.

Ramp for torque limitation with MD37012

A ramp has been implemented so that the setting of a torque limit is not too jerky.

For this in the machine data:

MD37012 \$MA_FIXED_STOP_TORQUE_RAMP_TIME

defining the length of the ramp until the new torque limit is reached.

6.2.2 Response to RESET and function abort

Response to RESET

During selection (fixed stop not yet reached) the function `FXS` can be aborted with `RESET`. The termination is carried out such that an "almost achieved" fixed stop (setpoint already beyond the fixed stop, but still within the threshold for the fixed stop detection) will not result in damage.

This is achieved by synchronizing the position setpoint to the new actual position. As soon as the fixed stop is reached, the function remains operative even after `RESET`.

Function abort

A function abort can be triggered by the following events:

- Emergency stop:
 - With an 840D control, the NC and drive are brought into a no-current condition for "Emergency Stop", i.e. the PLC must react.
 - With an 840Di control, the NC and drive are brought into a no-current condition for Emergency Stop, i.e. the PLC must react.

 CAUTION
--

Make sure that after canceling the function "Travel to fixed stop" by "Emergency Stop," no dangerous machine situation (MD37002 \$MA_FIXED_STOP_CONTROL e.g. canceling pulse disable) can occur.
--

- The fixed stop monitoring function responds in the case of:
 - Exit from fixed stop position by axis
 - Tool breakage
 - Pulse disable

6.2.3 Block search response

Block search with calculation

The response is as follows:

- If the target block is located in a program section in which the axis must stop at a fixed limit, then the fixed stop is approached if it has not yet been reached.
- If the target block is located in the program section in which the axis must not stop at a fixed limit, then the axis leaves the fixed stop if it is still positioned there.
- If the desired fixed stop status is reached, alarm message 10208 "press NC Start to continue the program" is output. The program can be continued after pressing NC Start to acknowledge.
- At the start of the target block, `FXST[x]` and `FXSW[x]` are set to the same value as they would have during normal program processing.

Block search without calculation

The commands `FXS`, `FXST` and `FXSW` are ignored.

FOC

`FOCON/FOCOF` is activated modally. It is already active in the approach block.

SERUPRO

Block search with calculation, multi-channel

The block search in program test mode is designated SERUPRO and is derived from the "Search-Run by Program test." This search mode allows the user a multi-channel block search with calculation of all required status data from the previous history.

The PLC interface is updated in this block search and matching processes, which cover the interaction of several channels executed within the framework of this block search correctly.

Search process with FXS and FOC

The user selects `FXS` or `FOC` in a program area of the searched target block in order to acquire all states and functions of this machining last valid. The NC will start the selected program in Program test mode automatically. After the target block has been found, the NC stops at the beginning of the target block, deselects Program test internally again and displays the Stop condition "Search target found" in its block display.

If `FXS` "travel to fixed stop" is located between the beginning of the program and the search target, the instruction is not really executed by the NC. The motion is only simulated up to the programmed end point.

 CAUTION
SERUPRO approach does not really take the statement <code>FXS</code> into account. The approach to the programmed end position of the <code>FXS</code> block is only simulated without torque limitation .

The user can log the turning on and turning off of `FXS` in the parts program. If necessary, the user can start an ASUB in order to activate or deactivate `FXS` in this SERUPRO-ASUP.

`$AA_FXS` and `$VA_FXS`

The meaning of system variable `$AA_FXS` is redefined for SERUPRO only and completely replaced by variable `$VA_FXS`. Variables `$AA_FXS` and `$VA_FXS` have the same values continuously outside the SERUPRO function.

Description	NCK Variables
Axis not at fixed stop	<code>\$AA_FXS = 0</code> and <code>\$VA_FXS = 0</code>
Fixed stop successfully approached	<code>\$AA_FXS = 1</code> and <code>\$VA_FXS = 1</code>
Approach to fixed stop failed	<code>\$AA_FXS = 2</code> and <code>\$VA_FXS = 2</code>
Travel to fixed stop selection active	<code>\$AA_FXS = 3</code> and <code>\$VA_FXS = 3</code>
Fixed stop detected	<code>\$AA_FXS = 4</code> and <code>\$VA_FXS = 4</code>
Travel to fixed stop deselection active	<code>\$AA_FXS = 5</code> and <code>\$VA_FXS = 5</code>

`$AA_FXS` Simulate axis traversal

System variable `$AA_FXS` displays the current status of program simulation "program-sensitive system variable."

Example:

If in the SERUPRO process axis Y traversal is simulated with `FXS[Y]=1`, then `$AA_FXS` has a value of 3.

If in the SERUPRO process axis Y traversal is simulated with `FXS[Y]=0`, then `$AA_FXS` has a value of 0.

During simulation with SERUPRO, `$AA_FXS` cannot have the values 1, 2, 4, 5, since the actual status of `$VA_FXS` "travel to fixed stop" can never be detected.

Note

The state `$AA_FXS = 1` is never reached during the SERUPRO operation. This means that other program branches can be executed and as a result the simulation can provide different results - compared with the normal program execution.

If after the SERUPRO process axis Y is traversed again, then variables `$AA_FXS` and `$VA_FXS` are assigned the same values again.

\$VA_FXS Real machine status

Variable \$VA_FXS always describes the real machine status.

In this way, the actual existing machine status of the corresponding axis with \$VA_FXS is displayed.

Setpoint/actual status comparison

The two system variables \$AA_FXS and \$VA_FXS can be used to compare the setpoint and actual states in the parts program. The SERUPRO ASUB routine is then as follows:

SERUPRO ASUB

Asup fxsSeruproAsup.mpf

;The setpoint and actual states are compared for the
;REPOSA block FXS to correspondingly activate or deactivate.

```
N100 WHEN ($AA_FXS[X]==3) AND ($VA_FXS[X]==0 DO FXS[X]=1  
N200 WHEN ($AA_FXS[X]==0) AND ($VA_FXS[X]==1 DO FXS[X]=0  
N1020 REPOSA
```

REPOS display Offset

Once the search target has been found, for each axis of the FXS state prevailing on the machine through the axis VDI-signals:

IS DB31, ... DBX62.4 ("Activate travel to fixed stop")

and

IS DB31, ... DBX62.5 ("Fixed stop reached")

displayed.

Example:

If the machine is at the fixed stop and the block search has reached a block after deselection of FXS, the new target position is displayed via IS DB31, ... DBX62.5 ("Fixed stop reached") is displayed as REPOS offset.

FXS fully automatically in REPOS

With REPOS the functionality of FXS is repeated automatically and designated FXS-REPOS below. This sequence is comparable to the program "fxsSeruproAsup.mpf." Every axis is taken into account and the torque last programmed before the search target is applied.

The user can treat FXS separately in a SERUPRO-ASUP.

The following then applies:

Every FXS action executed in SERUPRO-ASUP automatically takes care of

`$AA_FXS[X] == $VA_FXS[X]`.

This deactivates FXS-REPOS for axis X.

Deactivate FXS REPOS

FXS-REPOS is deactivated by:

- an FXS synchronous action which refers to REPOSA
- Or
- \$AA_FXS[X] == \$VA_FXS[X] in SERUPRO_ASUP.

Note

A SERUPRO-ASUP **without** FXS handling or no SERUPRO-ASUP results in fully automatic FXS-REPOS.

 CAUTION
--

<p>FXS-REPOS moves all path axes in a path grouping to the target position. Axes with and without FXS treatment thus traverse together with the G code and feedrate valid at the time the target block is processed. As a result, the fixed stop may be approached in rapid traverse(G0) or higher velocity.</p>
--

FOC fully automatically in REPOS

The FOC-REPOS function behaves analogously to the FXS-REPOS function.

Note

A continuously changing torque characteristic cannot be implemented with FOC-REPOS.

Example:

A program moves axis X from 0 to 100 and activates FOC every 20 millimeters for 10 millimeters at a time. This torque characteristic is generated with nonmodal FOC and therefore cannot be traced by FOC-REPOS. FOC-REPOS will traverse axis X from 0 to 100 with or without FOC.

For programming examples of FXS "travel to fixed stop," please see:

References:

/FB1/ Function Manual Basic Functions; Mode Group, Channel, Program Operation (K1);
Section: Program test

6.2.4 Miscellaneous

Setting data

The following axis-specific setting data are provided for the "Travel to fixed stop" function:

SD43500 \$SA_FIXED_STOP_SWITCH (selection of travel to fixed stop)

SD43510 \$SA_FIXED_STOP_TORQUE (clamping torque for travel to fixed stop)

SD43520 \$SA_FIXED_STOP_WINDOW (fixed stop monitoring window)

The setting data are effective only when the axis has reached the fixed stop.

The status of the setting data is displayed via the operator panel front in the "Parameters" area.

The commands `FXS[x]`, `FXST[x]` and `FXSW[x]` effect a block synchronous change in these setting data.

If `FXST[x]` and `FXSW[x]` are not programmed, then, if "Travel to fixed stop" is activated, the defaults from the following machine data is copied to the corresponding setting data:

MD37010 \$MA_FIXED_STOP_TORQUE_DEF (default for fixed stop clamping torque)

MD37020 \$MA_FIXED_STOP_WINDOW_DEF (default for fixed stop monitoring window)

The setting data for clamping torque and fixed stop monitoring window can be changed by the operator and via the PLC. It is thus possible to specify a higher or lower clamping torque or a modified fixed stop monitoring window after the fixed stop has been reached.

Changing the clamping torque using the ramp and values greater than 100%

A clamping torque change is transferred to the drive step-like. It is possible to specify a ramp to always ensure that a modified torque limit is reached: The setting is done via the following machine data:

MD37012 \$MA_FIXED_STOP_TORQUE_RAMP_TIME

Clamping torque greater than 100%

Values greater than 100% are only practical for a short time for SD43510 \$SA_FIXED_STOP_TORQUE.

Irrespectively, the maximum torque is limited by the drive.

For example, the following drive machine data have a limiting effect:

p1520/p1521 upper torque limit/force limit / lower torque limit/force limit

p1522/p1523 upper torque limit/force limit / lower torque limit/force limit

p1530/p1531 power limit, motoring / power limit, regenerating

p0640 current limit

p0326 motor stall force correction factor

Additional information can be found in the SINAMICS S120 Function Manual.

Status query in the parts program

System variable \$AA_FXS[x] indicates the status of the "travel to fixed stop" function.
 It has the following coding:

\$AA_FXS=0	Axis not located at the fixed stop.
\$AA_FXS=1	Fixed stop has been approached successfully (axis is within fixed stop monitoring window).
\$AA_FXS=2	Approach to fixed stop has failed (axis is not at fixed stop).
\$AA_FXS=3	Travel to fixed stop activated.
\$AA_FXS=4	Fixed stop detected.
\$AA_FXS=5	Travel to fixed stop is deselected. The deselection is not yet completed.

Query of the system variables in the part programs initiates a preprocessing stop.

As a result of the status query in the parts program, it is possible, for example, to react to an erroneous operational sequence of the "Travel to fixed stop" function.

Example:

MD37050 \$MA_FIXED_STOP_ALARM_MASK = 0

⇒ No alarm is generated in response to an error. A block change therefore takes place and the error scenario can be evaluated via the system variable

```

Program code
X300 Y500 F200 FXS[X1]=1 FXST[X1]=25 FXSW[X1]=5
IF $AA_FXS[X1]=2 GOTOF FXS_ERROR
G01 X400 Y200
  
```

Inoperative IS signals

The following NC/PLC interface signals (PLC → NCK) have no effect for axes at end stop until deselected (incl. traversing motion):

- DB31, ... DBX1.3 (axis/spindle disable)
- DB31, ... DBX2.1 (controller enable)

Actual position at fixed stop

System variable \$AA_IM[x] can determine the actual position of the machine axis, e.g. for test purposes after successful "Travel to fixed stop."

Combination with other functions

"Measure with deletion of distance to go" (command `MEAS`) and "travel to fixed stop" cannot be programmed at the same time in one block.

Exception:

One function is acting on a path axis while the other is acting on a positioning axis or both functions are acting on positioning axes.

Contour monitoring

The axis contour monitoring function is inoperative while "Travel to fixed stop" is active.

Positioning axes

When "Travel to fixed stop" is applied to `POSA` axes, block changes are made independently of the fixed stop motion.

Vertical axes

The "Travel to fixed stop" function can be used for vertical axes even when alarms are active.

Should the traversal of vertical axes be aborted as a result of an `FXS` alarm when "Travel to fixed stop" is active, the relevant drives are not disconnected from the supply via the VDI interface.

This functionality has the same effect on vertical axes as an electronic weight compensation and can be configured via machine data:

MD37052 \$MA_FIXED_STOP_ALARM_REACTION

Note

Additional description regarding the adaptation for SINAMICS, please refer to the SINAMICS S120 Function Manual and the Function Manual Extended Functions; Compensation (K3); Chapter: Electronic counterweight.

MD37052

With the machine data MD37052 \$MA_FIXED_STOP_ALARM_REACTION, the drive is not disconnected from the power supply by setting the bits, even when an alarm is generated, as the NC/PLC interface signal DB11 DBX6.3 (mode group ready) remains active.

Bit value=0:

The alarms have an effect on `FXS` (drive becomes disconnected as previously).

NST DB11 DBX6.3 (mode group ready) is deleted.

Bit value=1:

The alarms have no effect on `FXS`.

NST DB11 DBX6.3 (mode group ready) remains active.

Bit	Alarm	Meaning
0	20090	Travel to fixed stop cannot be programmed
1	20091	Fixed stop is not reached.
2	20092	Travel to a fixed stop active.
3	20093	Standstill monitoring on fixed stop is triggered.
4	20094	Travel to fixed stop aborted.

6.2.5 Supplementary conditions for expansions

Response to pulse blocking

The cancellation of the pulse enable, either using terminal EP (Enable Pulses) or using IS DB31, ... DBX21.7 ("Pulse enable") is known as pulse blocking in the following.

The machine data:

MD37002 \$MA_FIXED_STOP_CONTROL

can be used to influence the interaction of travel to fixed stop and pulse blocking.

Bit 0: Response in case of pulse blocking at stop as follows:

Bit 0 = 0	Travel to fixed stop aborted.
Bit 0 = 1	Travel to fixed stop is interrupted, i.e., the drive becomes powerless.

Once the pulse blocking is canceled again, the drive will press at the limited torque again. The torque is actuated step-like.

Programming FXS in synchronized actions

The function is **not** available for analog axes (PLC acknowledgment cannot be awaited).

Select FXS[]=1:

The following signal interfaces are set:

Message to PLC:

IS DB31, ... DBX62.4 ("Activate travel to fixed stop")

The `FXS` selection command can **only** be used in systems with digital drives (VSA, HSA, HLA).

Following condition **must** be observed:

MD37060 \$MA_FIXED_STOP_ACKN_MASK, Bit 0 = 0

Bit 0 = 1 (waiting for PLC acknowledgement) must **not** be set, otherwise, an interpolator stop would be required to acknowledge the signal, interrupting the movement.

Deselect FXS[]=0:

The following signal interfaces are reset:

Message to PLC:

IS DB31, ... DBX62.4 ("Activate travel to fixed stop")

The machine data:

MD37060 \$MA_FIXED_STOP_ACKN_MASK

must contain the value zero for signal deselection **without** motion stop.

Without ramp

The torque limit is changed without taking into account the ramp if:

- `FXS` is activated with (`FXS[]=1`), to make sure that the reduction is activated immediately (especially for synchronized actions).
- The drive needs to be de-energized as quickly as possible in the event of a fault.

Selection of FXS with G64

In the machine data:

MD37060 \$MA_FIXED_STOP_ACKN_MASK

Bit 0 must be = 0 (Do not wait for PLC-input signal "Enable travel to fixed stop"), since the selection of `FXS` may not initiate a motion stop.

Modify the torque FXST

The clamping torque can already be modified when approaching the stop.

The torque limit `FXST` acts in addition to the acceleration limitation with `ACC`.

The new torque taking into account the ramp

(MD37012 \$MA_FIXED_STOP_TORQUE_RAMP_TIME)

becomes active one interpolation cycle after the change in the drive.

A change of the effective torque can be checked by reading the synchronized action variable `$VA_TORQUE[axis]`.

6.2.6 Travel with limited torque/force FOC (option for 828D)

Function

For applications in which torque or force are to be changed dynamically depending on the travel or on the time or on other parameters (e.g. pressing), the following functionality_{FOC} (Force Control) is provided.

Force/travel or force/time profiles are thus possible using the "Interpolation cycle" resolution.

The function allows torque/force to be modified at any time using synchronized actions.

The function can be activated modally or block-related.

Modal activation (FOCON/FOCOF)

The activation of the function after `POWER_ON` and `RESET` is determined by the machine data: MD37080 \$MA_FOC_ACTIVATION_MODE

Table 6- 1 Controlling the initial setting of the modal limitation of torque/force

	After	Value	Effect
Bit 0	Power On	0	FOCOF
		1	FOCON
Bit 1	RESET	0	FOCOF
		1	FOCON

`FOCON`: Activation of the modally effective torque/force limitation

`FOCOF`: Disable torque/force limitation

The modal activation acts beyond the program end.

If already programmed, it is effective with `FXST` set torque/force.

`FXST` can be programmed irrespectively of `FOCON`; it comes into effect, however, only after the function has been activated.

Programming

The programming of the axis is carried out in square brackets.

The following are permissible:

- Geometry axis identifiers
- Channel axis identifiers
- Machine axis identifiers

Example:

```

N10 FOCON[X] ; Modal activation of the torque limit
N20 X100 Y200 FXST[X]=15 ; X travels with reduced torque (15%)
N30 FXST[X]=75 X20 ; Changing the torque to 75%.
; X travels with this reduced torque.
N40 FOCOF[X] ; Disable torque limit
  
```

Block-related limit (FOC)

The parts program command `FOC` activates the torque limit for a block.

An activation from a synchronized action takes effect up to the end of the current parts program block.

Priority FXS/FOC

An activation of FXS with `FOC` active has priority, i.e. `FXS` is executed.

A deselection of FXS will cancel the clamping.

A modal torque/force limitation remains active.

After `PowerOn` the activation takes effect with the machine data:

`MD37010 $MA_FIXED_STOP_TORQUE_DEF.`

This torque can be modified at any time by programming `FXST.`

Synchronized actions

The language commands `FOC`, `FOCON`, `FOCOF` can also be programmed in synchronized actions as the commands for "travel to fixed stop."

Determine FOC status

The activation status can be read at any time via the status variable `$AA_FOC`.

If `FXS` is also activated, the status is not changed.

- 0: `FOC` not active
- 1: `FOC` modal active
- 2: `FOC` block-related active

Determine torque limit status

The system variables `$VA_TORQUE_AT_LIMIT` can be used at any time to read in systems whether the currently active torque corresponds to the given torque limit.

- 0: Effective torque less than torque limit value
- 1: Effective torque has reached the torque limit value

Restrictions

The function `FOC` is subject to the following restrictions:

- The change of the torque/force limitation representing itself as an acceleration limitation is **only taken into account in the traversing movement at block limits** (see command `ACC`).
- Only `FOC`:
No monitoring is possible from the VDI interface to check that the active torque limit has been reached.
- If the acceleration limitation is not adapted accordingly, an increase of the drag distance during the traversing motion occurs.
- If the acceleration limitation is not adapted accordingly, the end-of-block position is possibly reached later than specified in:
`MD36040 $MA_STANDSTILL_DELAY_TIME`.

The machine data:

`MD36042 $MA_FOC_STANDSTILL_DELAY_TIME`
is introduced for this and monitored in this status.

Possible application link and container axes

All axes that can be traversed in a channel, i.e. also link axes and container axes, can be traversed to fixed stop.

References:

/FB2/ Function Manual Extended Functions; Several Control Panels on Multiple NCUs, Decentralized Systems (B3)

The status of the machine axis is kept in the case of a container switch, i.e. a clamped machine axis remains at the stop.

If a modal torque limitation has been activated with `FOCON`, this is kept for the machine axis even after a container switch.

6.3 Travel to fixed stop

Preconditions

The functions "Travel to fixed stop" and "Force Control" can only be activated for PROFIBUS drives that support a SINAMICS-compatible telegram structure. Please observe the notes in the SINUMERIK 840Di Manual in the chapter "Extended telegram configuration".

Selection

The NC detects that that function "Travel to fixed stop" is selected (using the command `FXS[x]=1` and signals the PLC using the interface signal DB31, ... DBX62.4 ("Activate travel to fixed stop") that the function has been selected.

The axis now traverses to the target position at the programmed velocity. At the same time, the clamping torque (specified via `FXST[x]`) is transferred to the drive via the interface, and this limits its effective torque. In addition, the acceleration is reduced accordingly in the NC automatically acc. to `FXST[x]`).

Fixed stop reached

As soon as the axis reaches the fixed stop, the axial contour deviation increases.

If the threshold entered in the machine data:

MD37030 FIXED_STOP_THRESHOLD

is exceeded or the IS signal DB31, ... DBX1.2 ("Sensor fixed stop") is set, then the control identifies that the fixed stop has been reached.

The NC will then delete the distance to go and will synchronize the position setpoint to the current actual position value. The controller enabling command remains active.

Then the NC issues IS DB31, ... DBX62.5 ("Fixed stop reached") to the PLC.

Then a block change is executed. The clamping torque continues to be applied.

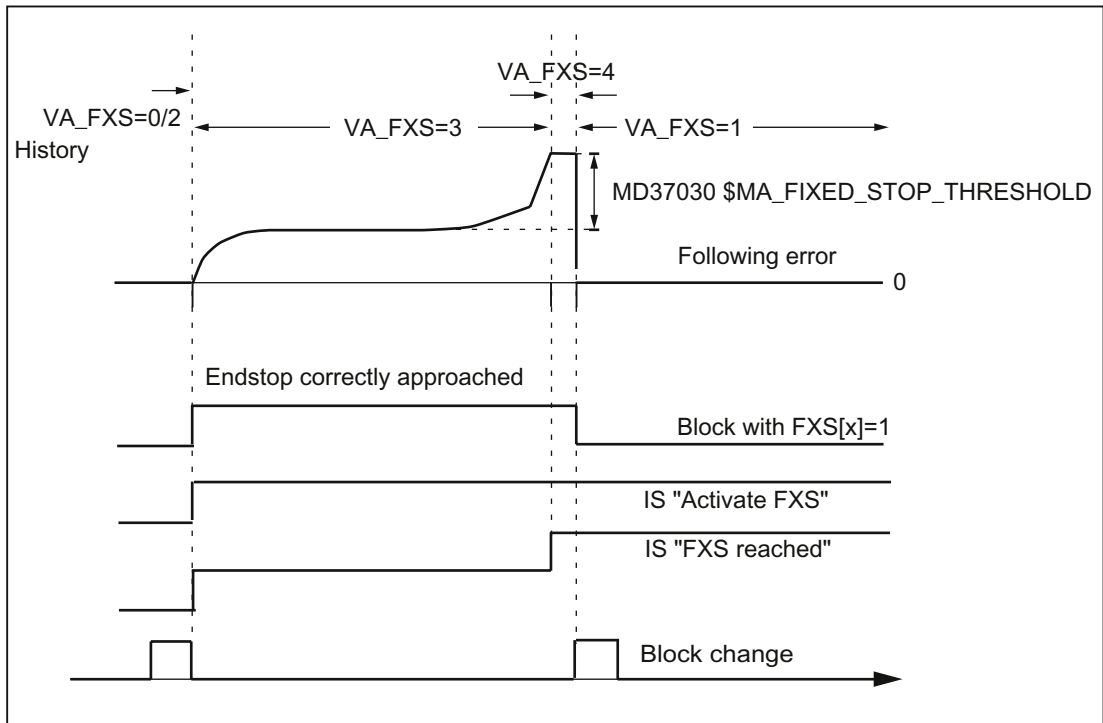

Figure 6-2 Fixed stop reached

Fixed stop is not reached

If the programmed end position is reached without the "Fixed stop reached" status being recognized, then the torque limitation in the drive is canceled via the digital interface and IS DB31, ... DBX62.4 ("Activate travel to fixed stop") is reset.

Then a block change is executed.

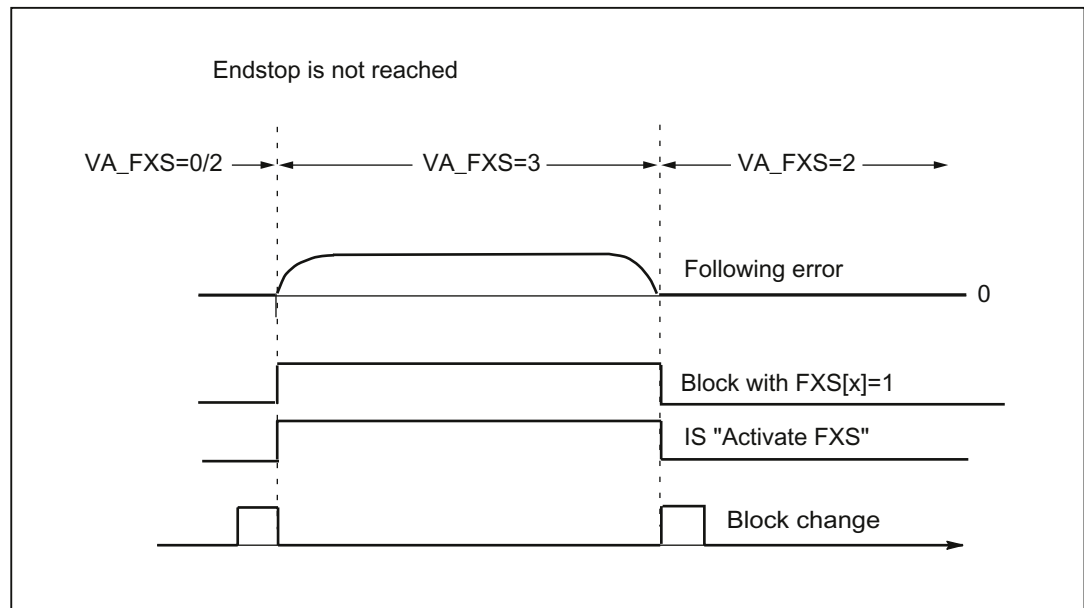

Figure 6-3 Fixed stop is not reached

Deselection

The NC recognizes the function deselection via programming of the command $FXS[x]=0$. Then an advance stop ($STOPRE$) is internally released, since it can't be foreseen where the axis will be after deselection.

The torque limitation and monitoring of the fixed stop monitoring window are canceled.

The IS DB31, ... DBX62.4 ("Activate travel to fixed stop") and DB31, ... DBX62.5 ("Fixed stop reached") are reset.

The axis will then change to position control. The follow-up mode of the position setpoints is ended and a synchronization to the new actual position is carried out.

A programmed traverse motion can then be executed. This motion must lead away from the fixed stop or else the stop or even the machine may sustain damage.

A block change is executed after the target position has been reached.

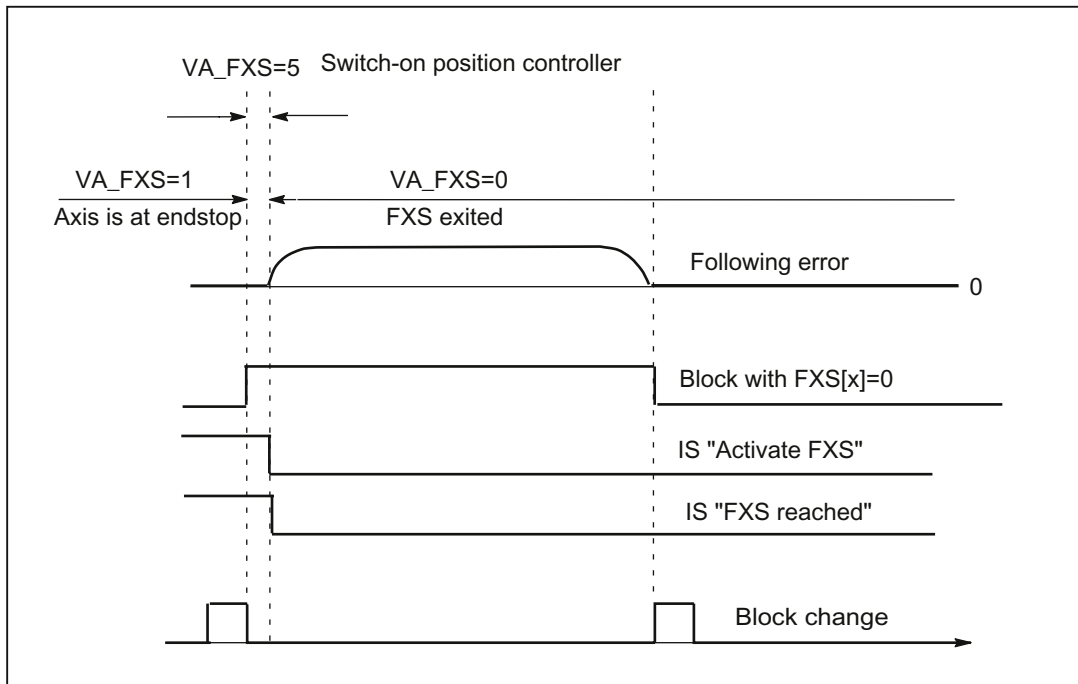

Figure 6-4 Fixed stop deselection

Enabling the fixed stop alarms

With the machine data:

MD37050 \$MA_FIXED_STOP_ALARM_MASK

enabling the fixed stop alarms can be established as follows:

MD 37050 = 0	Fixed stop not reached (suppress Alarm 20091)
MD 37050 = 2	Fixed stop not reached (suppress alarm 20091) and fixed stop aborted (suppress alarm 20094)
MD 37050 = 3	Fixed stop aborted (suppress alarm 20094)

All other values ≤ 7 do not suppress any alarms.

Using the parts program command `NEWCONF` a new setting can be activated.

Terminal EP (Enable Pulses) can be controlled with MD37002

With the machine data:

MD37002 \$MA_FIXED_STOP_CONTROL

the response in the case of pulse inhibit at the stop is controlled.

Deleting the pulses by terminal 663 or the "Pulse enable" IS DBX31, ...DBX21.7 will not abort the function. As a result, the drive will press against the fixed stop again without any further operating action when the machine is restarted.

The rise time of the torque corresponds to the time needed by the current controller of the drive to reach the limitation again.

If the pulses are deleted when a deselection is active (waiting for PLC acknowledgments), the torque limit will be reduced to zero. If the pulses are reactivated during this phase, torque is no longer built up. Once the deselection has been completed, you can continue traversing as normally.

6.4 Examples

Static synchronized actions

Travel to fixed stop (FXS), initiated by a synchronized action.

```

N10 IDS=1 WHENEVER                ; Activate static synchronized action:
  (($R1==1) AND                    ; By the setting of $R1=1
  ($AA_FXS[Y]==0)) DO              ; for
  $R1=0 FXS[Y]=1                    ; the axis Y FXS is activated
  FXST[Y]=10                        ; the active torque is reduced to 10%
  FA[Y]=200                          ; and a travel motion to
  POS[Y]=150                          ; direction of the stop started

N11 IDS=2 WHENEVER                ; once the stop has been recognized
  ($AA_FXS[Y]==4) DO                ; ($AA_FXS[Y]==4), the torque is
  FXST[Y]=30                          ; increased to 30%

N12 IDS=3 WHENEVER                ; after reaching the stop
  ($AA_FXS[Y]==1) DO                ; the torque becomes dependent
  FXST[Y]=$R0                          ; on R0 controlled

N13 IDS=4 WHENEVER                ; deselection in dependence
  (($R3==1) AND                      ; on R3 and
  ($AA_FXS[Y]==1)) DO                ; reverse
  FXS[Y]=0
  FA[Y]=1000 POS[Y]=0

N20 FXS[Y]= 0                        ; normal program run:
G0 G90 X0 Y0

N30 RELEASE(Y)                       ; axis Y for the movement to
                                       ; activate synchronized action

N40 G1 F1000 X100                     ; Movement of another axis
N50 .....

N60 GET(Y)                             ; Include axis Y again in the
                                       ; pathgroup

```

Multiple selection

A selection may only be carried out once. If the function is called once more due to faulty programming ($FXS[Axis]=1$) the alarm 20092 "Travel to fixed stop still active" is initiated.

Programming code that scans $\$AA_FXS[]$ or a separate flag (here R1) in the condition will ensure that the function is not activated more than once.

Programming example (parts program fragment):

```
N10 R1=0
N20 IDS=1 WHENEVER ($R1 == 0 AND $AA_IW[AX3]>7) DO R1=1 FXS[AX1]=1
FXST[AX1] = 12
```

Block-related synchronized actions

By programming a block-related synchronized action, travel to fixed stop can be connected during an approach motion.

Programming example:

```
N10 GO G90 X0 Y0
N20 WHEN $AA_IW[X]>17 DO FXS[X]=1 ; If X reaches a position greater
N30 G1 F200 X100 Y110 ; 17mm FXS is activated
```

6.5 Data lists

6.5.1 Machine data

6.5.1.1 Axis/spindle-specific machine data

Number	Identifier: \$MA_	Description
36042	FOC_STANDSTILL_DELAY_TIME	Delay time, standstill monitoring for active torque/force limiting
37000	FIXED_STOP_MODE	Travel to fixed stop mode
37002	FIXED_STOP_CONTROL	Sequence monitoring for travel to fixed stop
37010	FIXED_STOP_TORQUE_DEF	Fixed stop clamping torque default setting
37012	FIXED_STOP_TORQUE_RAMP_TIME	Time until the modified torque limit is reached
37020	FIXED_STOP_WINDOW_DEF	Default for fixed stop monitoring window
37030	FIXED_STOP_THRESHOLD	Threshold for fixed stop detection
37040	FIXED_STOP_BY_SENSOR	Fixed stop detection via sensor
37050	FIXED_STOP_ALARM_MASK	Enabling the fixed stop alarms
37052	FIXED_STOP_ALARM_REACTION	Reaction to fixed stop alarms
37060	FIXED_STOP_ACKN_MASK	Monitoring of PLC acknowledgments for travel to fixed stop
37070	FIXED_STOP_ANA_TORQUE	Torque limit on fixed stop approach for analog drives
37080	FOC_ACTIVATION_MODE.	Initial setting of the modal torque/force limiting

6.5.2 Setting data

6.5.2.1 Axis/spindle-specific setting data

Number	Identifier: \$SA_	Description
43500	FIXED_STOP_SWITCH	Selection of travel to fixed stop
43510	FIXED_STOP_WINDOW	Fixed stop clamping torque
43520	FIXED_STOP_TORQUE	Fixed stop monitoring window

6.5.3 Signals

6.5.3.1 Signals to axis/spindle

Signal name	SINUMERIK 840D sl	SINUMERIK 828D
Acknowledge fixed stop reached	DB31,DBX1.1	DB380x.DBX1.1
Sensor for fixed stop	DB31,DBX1.2	DB380x.DBX1.2
Axis/spindle disable	DB31,DBX1.3	DB380x.DBX1.3
Controller enable	DB31,DBX2.1	DB380x.DBX2.1
Enable travel to fixed stop	DB31,DBX3.1	DB380x.DBX3.1

6.5.3.2 Signals from axis/spindle

Signal name	SINUMERIK 840D sl	SINUMERIK 828D
Activate travel to fixed stop	DB31,DBX62.4	DB390x.DBX2.4
Fixed stop reached	DB31,DBX62.5	DB390x.DBX2.5

G2: Velocities, setpoint / actual value systems, closed-loop control

7

7.1 Brief description

The description of functions explains how to parameterize a machine axis in relation to:

- Actual-value/measuring systems
- Setpoint system
- Operating accuracy
- Travel ranges
- Axis velocities
- Control parameters

7.2 Velocities, traversing ranges, accuracies

7.2.1 Velocities

Maximum path and axis velocities and spindle speed

The maximum path and axis velocities and spindle speed are influenced by the machine design, the dynamic response of the drive and the limit frequency of the actual-value acquisition (encoder limit frequency).

The maximum axis velocity is defined in machine data:

MD32000 \$MA_MAX_AX_VELO (maximum axis velocity)

The maximum permissible spindle speed is specified using machine data:

MD35100 \$MA_SPIND_VELO_LIMIT (maximum spindle speed)

For an explanation, please refer to:

References:

/FB1/ Function Manual Basic Functions; Spindles (S1)

With a high feedrate (resulting from programmed feedrates and feedrate override), the maximum path velocity is limited to V_{max} .

This automatic feedrate limiting can lead to a drop in velocity over several blocks with programs generated by CAD systems with extremely short blocks.

Example

Interpolation cycle = 12 ms

N10 G0 X0 Y0; [mm]

N20 G0 X100 Y100; [mm]

⇒ Path length programmed in block = 141.42 mm

⇒ $V_{max} = (141.42 \text{ mm}/12 \text{ ms}) \cdot 0.9 = 10606.6 \text{ mm/s} = 636.39 \text{ m/min}$

Minimum path, axis velocity

The following restriction applies to the minimum path or axis velocity:

$$V_{min} \geq \frac{10^{-3}}{\text{Computational resolution} \left[\frac{\text{Incr.}}{\text{mm or degrees}} \right] \cdot \text{interpolation cycle [s]}}$$

The computational resolution is defined using machine data:

MD10200 \$MN_INT_INCR_PER_MM (computational resolution for linear positions)

or

MD10210 \$MN_INT_INCR_PER_DEG (computational resolution for angular positions)

If V_{min} is not reached, no traversing is carried out.

Example

MD10200 \$MN_INT_INCR_PER_MM = 1000 [incr./mm];

Interpolation cycle = 12 ms;

⇒ $V_{min} = 10^{-3}/(1000 \text{ incr./mm} \times 12 \text{ ms}) = 0.005 \text{ mm/min};$

The value range of the feedrates depends on the computational resolution selected.

For the standard assignment of machine data:

MD10200 \$MN_INT_INCR_PER_MM

(computational resolution for linear positions) (1000 incr./mm)

or

MD10210 \$MN_INT_INCR_PER_DEG

(computational resolution for angular positions) (1000 incr./deg.)

The following value range can be programmed with the specified resolution:

Range of values for path feed F and geometry axes:	
Metric system:	Inch system:
$0.001 \leq F \leq 999,999.999$ [mm/min, mm/rev, degrees/min, degrees/rev]	$0.001 \leq F \leq 399,999.999$ [inch/min, inch/rev]

Range of values for feedrate for positioning axes:	
Metric system:	Inch system:
$0.001 \leq FA \leq 999,999.999$ [mm/min, mm/rev, degrees/min, degrees/rev]	$0.001 \leq FA \leq 399,999.999$ [inch/min, inch/rev]

Range of values for spindle speed S:
$0.001 \leq S \leq 999,999.999$ [rpm]

If the computational resolution is increased/decreased, by a factor, then the value ranges change accordingly.

7.2.2 Traversing ranges

Range of values of the traversing ranges

The range of values of the traversing range depends on the computational resolution selected.

If machine data:

MD10200 \$MN_INT_INCR_PER_MM
 (computational resolution for linear positions) (1000 incr./mm)

or

MD10210 \$MN_INT_INCR_PER_DEG
 (computational resolution for angular positions) (1000 incr./degree)

are assigned their default values, the following range of values can be programmed with the input resolution:

Table 7- 1 Traversing ranges of axes

	G71 [mm, degrees]	G70 [inch, degrees]
	Range	Range
Linear axes X, Y, Z, etc.	± 999,999.999	± 399,999.999
Rotary axes A, B, C, etc.	± 999,999.999	± 999,999.999
Interpolation parameters I, J, K	± 999,999.999	± 399,999.999

The unit of measurement of rotary axes is always degrees.

If the computational resolution is increased/decreased by a factor of 10, the ranges of values change accordingly.

The traversing range can be limited by software limit switches and working areas.

References:

/FB1/ Function Manual, Basic Functions; Axis Monitoring, Protection Zones (A3)

The traversing range for rotary axes can be limited via machine data.

References:

/FB2/ Function Manual, Extended Functions; Rotary Axes (R2)

For special features of linear and rotary axes with a large traversing range, see:

References:

/FB1/ Function Manual, Basic Functions; Reference Point Approach (R1)

7.2.3 Positioning accuracy of the control system

Actual-value resolution and computational resolution

The positioning accuracy of the control depends on the actual-value resolution (=encoder increments/(mm or degrees)) and the computational resolution (=internal increments/(mm or degrees)).

The coarse resolution of these two values determines the positioning accuracy of the control.

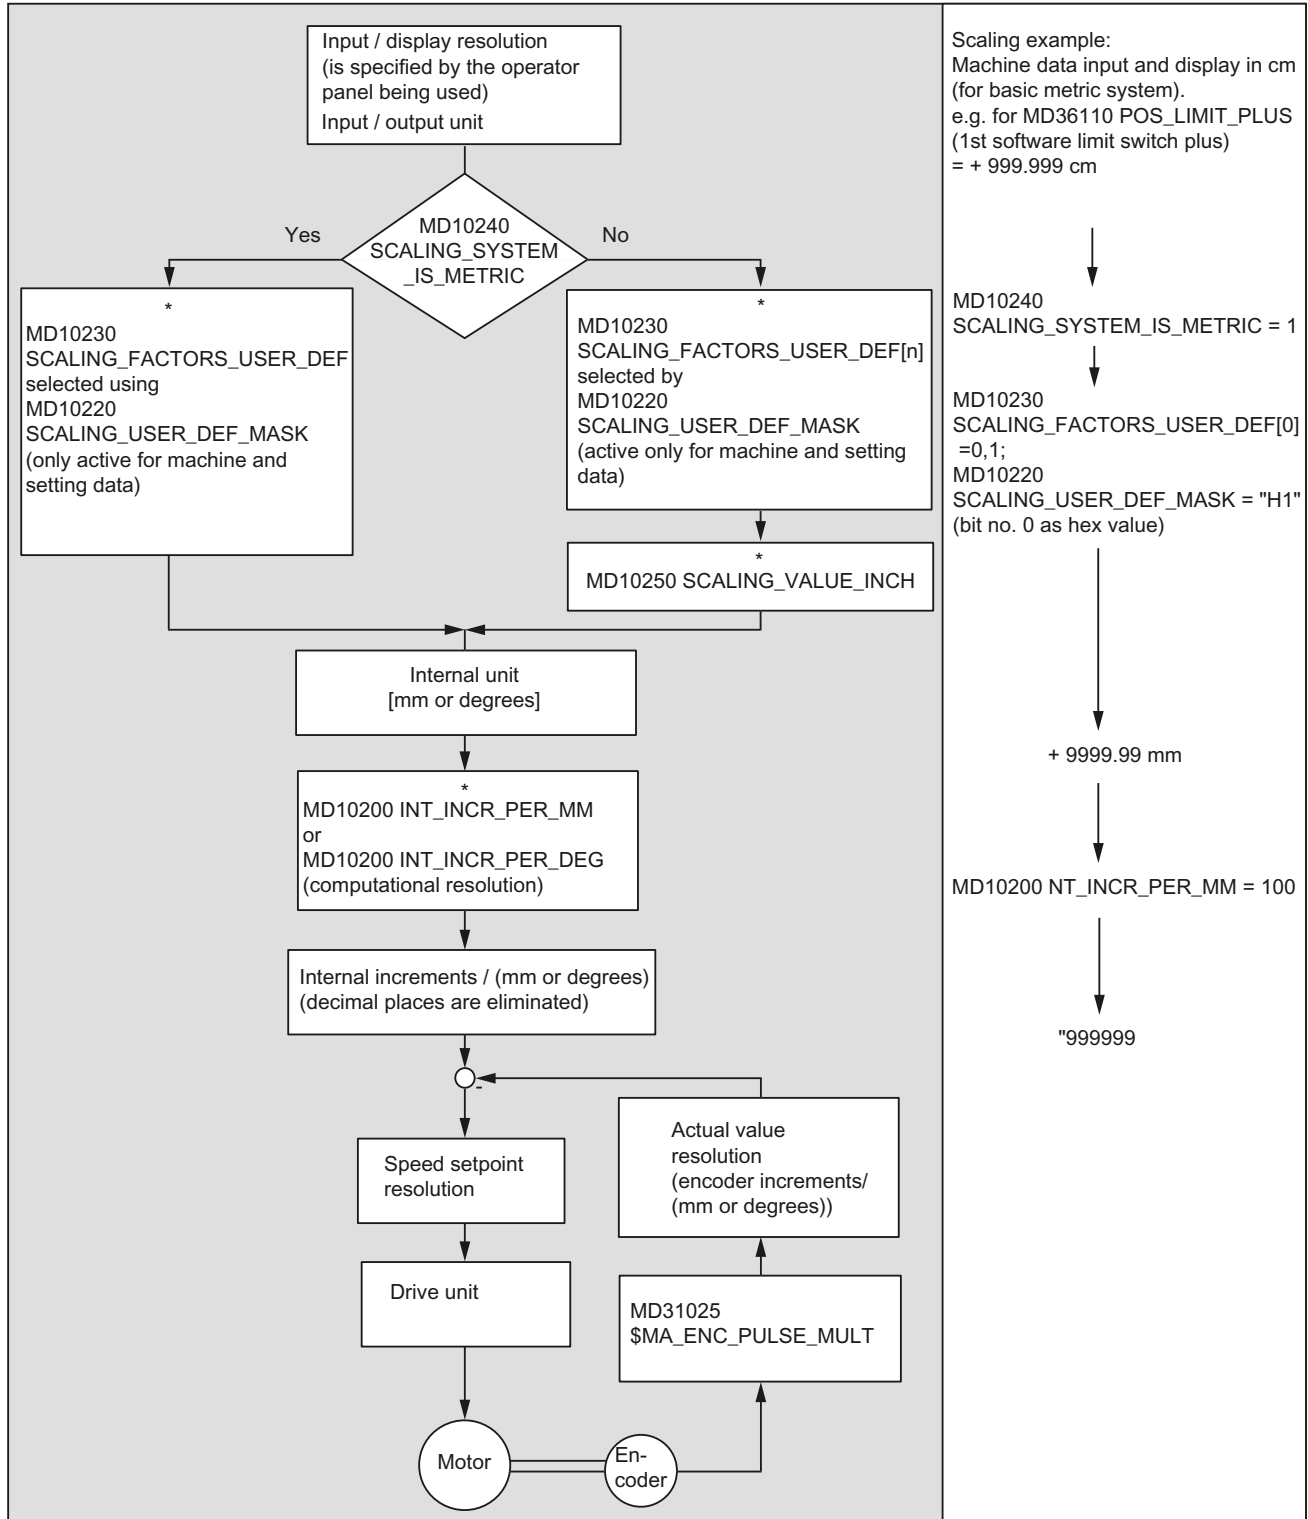

The input resolution, interpolator and position-control cycle selections have no effect on this accuracy.

As well as limiting using MD32000, the control limits the maximum path velocity in relation to the situation and according to the following formula:

$$\frac{\text{Internal increments / mm}}{\text{Encoder increments / mm}} = \frac{1}{\text{ENC_RESOL [n]} * \text{ENC_PULSE_MULT[n]} * \frac{\text{DRIVE_ENC_RATIO_NUMERA [n]}}{\text{DRIVE_ENC_RATIO_DENOM [n]}} * \frac{\text{DRIVE_AX_RATIO_DENOM [n]}}{\text{DRIVE_AX_RATIO_NUMERA [n]}} * \text{LEADSCREW_PITCH} * \text{INT_INCR_PER_MM}}$$

7.2.4 Block diagram of resolutions and scaling values

Block diagram of units and resolutions

This diagram shows how input values are converted into internal units.

It also shows the following conversion to internal increments/(mm or degrees), which can cause loss of decimal places if the computational resolution was selected to be coarser than the input resolution.

In addition, it provides an overview of the following topics:

- Selection of measuring system (metric/inch)
- Scaling of physical quantities of machine and setting data
- Conversion of basic system
- Setting of computational resolution

7.2.5 Input/display resolution, computational resolution

Resolutions: Differences

Resolutions, e.g. resolutions of linear and angular positions, velocities, accelerations and jerk, must be differentiated as follows:

- Input resolution

Data is input via the control panel or parts programs.

- Display resolution

Data is displayed via the control panel.

- Computational resolution

Data input via the control panel or parts program is displayed internally.

The input and display resolution is defined via the control panel being used, whereby the display resolution of position values can be changed with machine data:

MD9004 \$MM_DISPLAY_RESOLUTION.

Machine data:

MD9011 \$MM_DISPLAY_RESOLUTION_INCH

can be used to configure the display resolution of position values using the inch system. This allows you to display up to six decimal places with the inch setting.

For the programming of parts programs, the input resolutions listed in the Programming Manual apply.

The desired computational resolution is defined via machine data:

MD10200 \$MN_INT_INCR_PER_MM (computational resolution for linear positions)

or

MD10210 \$MN_INT_INCR_PER_DEG (computational resolution for angular positions).

It is independent of the input/display resolution but should have at least the same resolution.

The maximum number of places after the decimal point for position values, velocities, etc., in the parts program and the number of places after the decimal point for tool offsets, zero offsets, etc. (and therefore also for the maximum possible accuracy). is defined by the computational resolution.

The accuracy of angle and linear positions is limited to the computational resolution by rounding the product of the programmed value with the computational resolution to an integer number.

To make the rounding clear, powers of 10 should be used for the computational resolution.

Example of rounding

Computational resolution: 1000 increments/mm

Programmed path: 97.3786 mm

Effective value = 97.379 mm

Example of programming in the $1/10 \mu\text{m}$ range

All the linear axes of a machine are to be programmed and traversed within the range of values 0.1 to 1000 μm .

⇒ In order to position accurately to 0.1 μm , the computational resolution must be set to $\geq 10^4$ incr./mm.

⇒ MD10200 \$MN_INT_INCR_PER_MM = 10000 [incr./mm]:

⇒ Example of related parts program:

```
N20 G0 X 1.0000 Y 1.0000      ; Traverse axes to position
                               X=1.0000 mm, Y=1.0000 mm
N25 G0 X 5.0002 Y 2.0003      ; Traverse axes to position
                               X=5.0002 mm, Y=2.0003 mm
```

7.2.6 Scaling of physical quantities of machine and setting data

Input/output units

Machine and setting data that possess a physical quantity are interpreted in the input/output units below depending on whether the metric or inch system is selected:

Physical quantity:	Input/output units for standard basic system:	
	Metric	Inch
Linear position	1 mm	1 inch
Angular position	1 degree	1 degree
Linear velocity	1 mm/min	1 inch/min

7.2 Velocities, traversing ranges, accuracies

Physical quantity:	Input/output units for standard basic system:	
	Metric	Inch
Angular velocity	1 rpm	1 rpm
Linear acceleration	1 m/s ²	1 inch/s ²
Angular acceleration	1 rev./s ²	1 rev./s ²
Linear jerk	1 m/s ³	1 inch/s ³
Angular jerk	1 rev./s ³	1 rev./s ³
Time	1 s	1 s
Position controller servo gain	1/s	1/s
Rev. feedrate	1 mm/rev	inch/rev
Compensation value linear position	1 mm	1 inch
Compensation value angular position	1 degree	1 degree

The units listed below are used for storage. The control always uses these units internally irrespective of the basic system selected.

Physical quantity:	Internal unit:
Linear position	1 mm
Angular position	1 degree
Linear velocity	1 mm/s
Angular velocity	1 deg./s
Linear acceleration	1 mm/s ²
Angular acceleration	1 degree/s ²
Linear jerk	1 mm/s ³
Angular jerk	1 degree/s ³
Time	1 s
Position controller servo gain	1/s
Rev. feedrate	1 mm/degree
Compensation value linear position	1 mm
Compensation value angular position	1 degree

The user can define different input/output units for machine and setting data.

For this, the machine data:

MD10220 \$MN_SCALING_USER_DEF_MASK

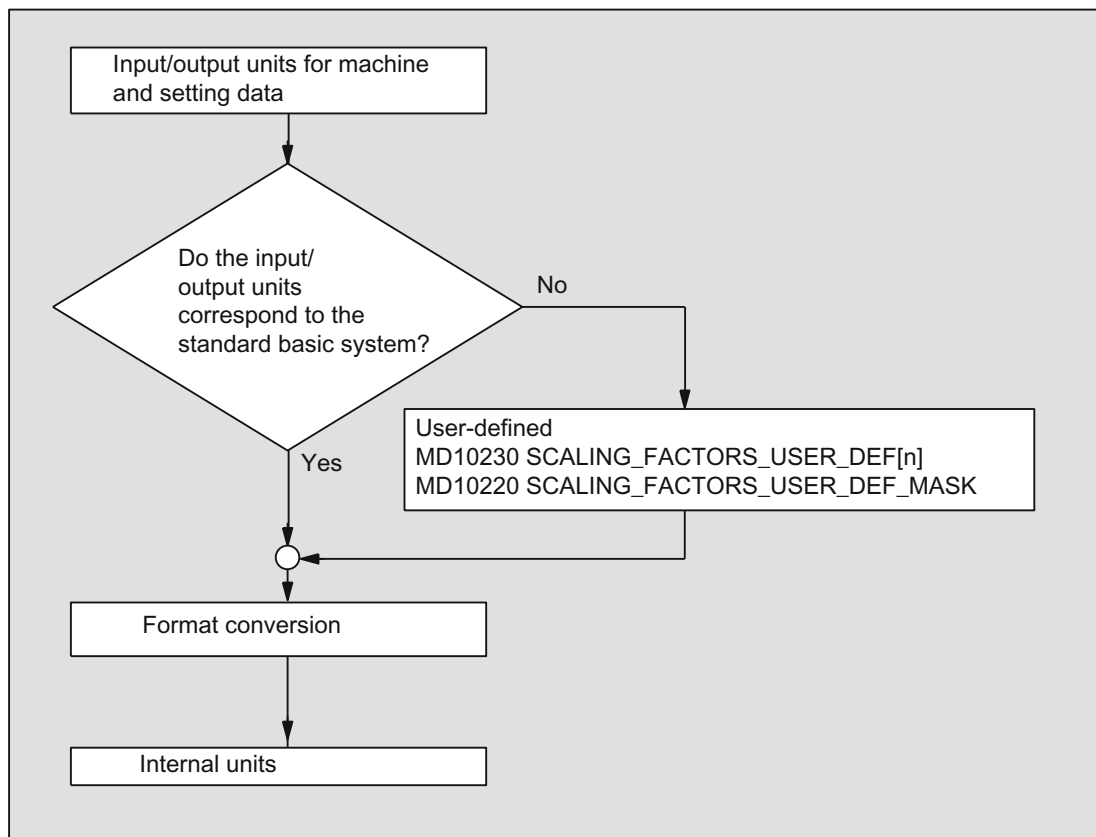

(activation of scaling factors)

and

MD10230 \$MN_SCALING_FACTORS_USER_DEF[n]

(Scaling factors of physical quantities)

allow you to set the adaptation between the newly selected input/output units and the internal units.

The following applies:

Selected input/output unit = MD10230 * internal unit

In the machine data:

MD10230 \$MN_SCALING_FACTORS_USER_DEF[n]

the selected input/output unit printed in each case in the internal units 1mm, 1 degree and 1 s must be input.

Example 1

Machine data input/output of the linear velocities is to be in m/min instead of mm/min (initial state).

(The internal unit is mm/s)

⇒ The scaling factor for the linear velocities is to differ from the standard setting. For this in the machine data:

MD10220 \$MN_SCALING_USER_DEF_MASK

the bit number 2 must be set.

⇒ MD10220 \$MN_SCALING_USER_DEF_MASK = 'H4'; (bit no. 2 as hex value)

⇒ The scaling factor for the linear velocities is to differ from the standard setting. For this in the machine data:

MD10220 \$MN_SCALING_USER_DEF_MASK

the bit number 2 must be set.

⇒ MD10220 \$MN_SCALING_USER_DEF_MASK = 'H4'; (bit no. 2 as hex value)

⇒ The scaling factor is calculated using the following formula:

$$\text{MD10230 SCALING_FACTORS_USER_DEF}[n] = \frac{\text{Input/output unit selected}}{\text{Internal unit}}$$

$$\text{MD10230 SCALING_FACTORS_USER_DEF}[n] = \frac{1 \frac{\text{m}}{\text{min}}}{1 \frac{\text{mm}}{\text{s}}} = \frac{\frac{1000 \text{ mm}}{60 \text{ s}}}{1 \frac{\text{mm}}{\text{s}}} = \frac{1000}{60} = 16.667;$$

⇒ MD10230 SCALING_FACTORS_USER_DEF[n] = 16.667

Index n defines the "linear velocity" in the "Scaling factors of physical quantities" list.

Example 2

In addition to the change in Example 1, the machine data input/output of linear accelerations must be in ft/s² instead of m/s² (initial state). (The internal unit is mm/s².)

⇒ MD10220 SCALING_USER_DEF_MASK = H14 ; (Bit No. 4 and Bit No. 2 from example 1 as hex value)

$$\Rightarrow \text{MD10220 SCALING_FACTORS_USER_DEF}[4] = \frac{1 \frac{\text{ft}}{\text{s}^2}}{1 \frac{\text{mm}}{\text{s}^2}} = \frac{12 \cdot 25,4 \frac{\text{mm}}{\text{s}^2}}{1 \frac{\text{mm}}{\text{s}^2}} = 304,8 ;$$

⇒ MD10230 SCALING_FACTORS_USER_DEF[4] = 304,8

Index 4 defines the "linear acceleration" in the "Scaling factors of physical quantities" list.

7.3 Metric/inch measuring system

7.3.1 Conversion of basic system by parts program

Programmable switchover in the measuring system

The basic system can be switched over within a part program via the G functions *G70/G71/G700/G710* (G group 13). The programmed measuring system (*G70/G71/G700/G710*) and the basic system may be identical or different at any time. When the measuring system is switched over within a particular section of the part program, this would enable an inch thread to be processed on a workpiece within a metric basic system, for example.

The following section of the part program is executed in "metric" in the basic system:
MD10240 \$MN_SCALING_SYSTEM_IS_METRIC = 1

Program code	Comment
N100 G71	; Switchover to metric processing
	; The conversion factor does not come into effect because the
	; programmed
	measuring system does not differ from the basic system.
....	; Metric processing
N200 G70	; Switchover to processing in inches
	; The conversion factor comes into effect.
...	; Machining in inches
N300	; Switchover to metric processing
...	; Metric processing

Initial state of the G functions

The initial state for the G functions can be set via the following machine data on a channel-specific basis:

MD20150 \$MC_GCODE_RESET_VALUES[12] (reset position for G group 13)

When changing the measuring system via the HMI user interface, the reset position is automatically preconfigured for compatibility with the new measuring system via *G700* or *G710*.

Displaying length-related data on the HMI

Length-related data is displayed on the HMI in the configured basic system
MD10240 \$MN_SCALING_SYSTEM_IS_METRIC (metric basic system).

The following length-related data is displayed in the configured basic system:

- Machine data
- Data in the machine coordinate system
- Tool data
- Work offsets

The following length-related data is displayed in the programmed measuring system:

- Data in the workpiece coordinate system

Reading in part programs from external sources

If part programs, including data sets (work offsets, tool offsets, etc.), programmed in a different measuring system from the basic system are read in from an external source, the initial state must first be changed via machine data MD10240.

NC/PLC interface signals

In the case of NC/PLC interface signals containing dimension information, e.g. feedrate for path and positioning axes, data exchange is carried out with the PLC in the configured basic system.

G functions G700/G710

The G functions G700/G710 extend the functionality of G70/G71 as follows:

1. The feedrate is interpreted in the programmed measuring system:
 - G700: length parameters [inch]; feedrates [inch/min]
 - G710: length parameters [mm]; feedrates [mm/min]

The programmed feedrate is modal and therefore remains active after subsequent G70/G71/G700/G710 commands. If the feedrate is to apply in the new G70/G71/G700/G710 context, it must be re-programmed.

2. System variables and machine data specifying lengths in the parts program are read and written in the programmed measuring system.

Differences during the reading and writing of machine data and system variables

The following differences exist between G70/G71 and G700/G710 in terms of reading and writing machine data and system variables in the part program:

- G70/G71: Reading and writing takes place in the configured basic system.
- G700/G710: Reading and writing takes place in the configured measuring system.

Example

The following parts program is executed with an initial metric state:
MD10240 \$MN_SCALING_SYSTEM_IS_METRIC = 1

Program code	Comment
N100 R1=0 R2=0	;
N120 G01 G70 X1 F1000	; Prog. meas. system: inch
N130 \$MA_LUBRICATION_DIST[X]=10	; MD = 10 [mm] (basic system)
N150 IF (\$AA_IW[X]>\$MA_LUBRICATION_DIST[X])	; SYS [mm] > MD [mm] (both basic system)
N160 R1=1	;
N170 ENDIF	;

Program code	Comment
N180 IF (\$AA_IW[X]>10)	; SYS [mm] (basic system) > 10 [inch]
	; (prog. meas. system)
N190 R2=1	;
N200 ENDIF	;
N210 IF ((R1+R2) = 1)	; Alarm if only one of the two
	; conditions (N150, N180) is TRUE
N220 SETAL(61000)	;
N230 ENDIF	;
N240 M30	;

N120: if G70 is replaced by G700, alarm 61000 (N220) does not occur.

Synchronized actions

To ensure in the case of synchronized actions that the current part program context does not determine the measuring system used in the condition and/or action part, the measuring system must be defined within the synchronized action (condition and/or action parts). This is the only way of achieving defined, reproducible behavior in the use of length-related data within a synchronized action.

Example 1

The measuring system is not specified within the synchronized action. Therefore, the traversing motion of the X axis takes place in the measuring system of the configured initial state:

Program code	Comment
N100 R1=0	;
N110 G0 X0 Z0	;
N120 WAITP(X)	;
N130 ID=1 WHENEVER \$R1==1 DO POS[X]=10	; X = 10 inch or mm, depending on the
	; rest of the parts program
N140 R1=1	;
N150 G71 Z10 F10	; Z = 10 mm X = 10 mm
N160 G70 Z10 F10	; Z = 10 inch X = 10 inch
N170 G71 Z10 F10	; Z = 10 mm X = 10 mm
N180 M30	;

Example 2

The "metric" measuring system is explicitly programmed with G71 within the synchronized action. This means the traversing motion of the X axis takes place in the metric measuring system:

Program code	Comment
N100 R1=0	;
N110 G0 X0 Z0	;
N120 WAITP(X)	;
N130 ID=1 WHENEVER \$R1==1 DO G71 POS[X]=10	; X = 10 mm, independent of the
	; rest of the parts program

7.3 Metric/inch measuring system

Program code	Comment
N140 R1=1	;
N150 G71 Z10 F10	; Z = 10 mm X = 10 mm
N160 G70 Z10 F10	; Z = 10 inch X = 10 mm
N170 G71 Z10 F10	; Z = 10 mm X = 10 mm
N180 M30	;

Reading and writing of data in the case of G70/G71 and G700/G710 in the part program

Data area	G70/G71		G700/G710	
	Read	Write	Read	Write

NOTICE

Read position data in synchronized actions

If a measuring system has not been explicitly programmed in the synchronized action (condition component and/or action component) **length-related position data** in the synchronized action are always read in the **parameterized basic system**.

Reference:

/PG/ Programming Manual, Fundamentals; List of Addresses

NC-specific conversion factor

The default conversion factor in the machine data is:

MD10250 \$MN_SCALING_VALUE_INCH (conversion factor for switchover to inch system)

set to 25.4 for converting from the metric to the inch measuring system. By changing the conversion factor, the control system can also be adapted to customer-specific measuring systems.

Axis-specific conversion factor

The default conversion factor in the axis-specific machine data is:

MD31200 \$MA_SCALING_FACTOR_G70_G71 (conversion factor when G70/G71 is active)

set to 25.4 for converting from the metric to the inch measuring system. By changing the conversion factor, the control system can also be adapted to customer-specific measuring systems on an axis-specific basis.

7.3.2 Manual switchover of the basic system

General

The control system can operate with the metric or inch measuring system. The initial setting of the measuring system (basic system) is defined using the following machine data:

MD10240 \$MN_SCALING_SYSTEM_IS_METRIC (basic system metric).

Depending on the basic system, all length-related data is interpreted either as metric or inch measurements.

The relevant softkey on the HMI in the "Machine" operating area is used to change the measuring system of the controller.

The change in the measuring system occurs only under the following boundary conditions:

- MD10260 \$MN_CONVERT_SCALING_SYSTEM=1
- Bit 0 of MD20110 \$MC_RESET_MODE_MASK is set in every channel.

- All channels are in the Reset state.
- Axes do not traverse with JOG, DRF or PLC.
- Constant grinding wheel peripheral speed (GWPS) is not active.

Actions such as part program start or mode change are disabled for the duration of the measuring system changeover.

If the measuring system cannot be changed, this is indicated by a message to that effect on the user interface. These measures ensure that a consistent set of data is always used for a running program with reference to the measuring system.

The actual change in the measuring system is made by writing all the necessary machine data and subsequently activating them with a `RESET`.

The machine data:

`MD10240 $MN_SCALING_SYSTEM_IS_METRIC`

and the corresponding `G70/G71/G700/G710` settings in the machine data:

`MD20150 $MN_GCODE_RESET_VALUES`

are automatically switched over consistently for all configured channels.

During this process, the value in machine data:

`MD20150 $MC_GCODE_RESET_VALUES[12]`

changes between G700 and G710.

This process takes place independently of the protection level currently set.

Note

The availability of the softkey and, therefore, its functionality, can be configured using the compatibility machine data:

`MD10260 $MN_CONVERT_SCALING_SYSTEM`

If several NCUs are linked by NCU-link, the switchover has the same effect on all linked NCUs. If the prerequisites for a switchover are not fulfilled on one of the NCUs linked, no switchover will take place on none of the NCUs. It is assumed that interpolations between several NCUs will take place on the existing NCUs, whereby the interpolations can provide correct results only if the same unit systems are used.

References:

/FB2/ Function Manual, Extended Functions; Several Control Panels on Multiple NCUs, Decentralized Systems (B3)

System data

When changing over the measuring system, from the view of the user, all length-related specifications are converted to the new measuring system automatically.

This includes:

- Positions
- Feedrates
- Acceleration rates
- Jerk
- Tool offsets
- Programmable, settable and work offsets external and DRF offsets
- Compensation values
- Protection zones
- Machine data
- Jog and handwheel factors

After the changeover, all of the above data is available in physical quantities.

Data, for which no unique physical units are defined, is **not** converted automatically.

This includes:

- R parameters
- GUDs (**G**lobal **U**ser **D**ata)
- LUDs (**L**ocal **U**ser **D**ata)
- PUDs (**P**rogram global **U**ser **D**ata)
- Analog inputs/outputs
- Data exchange via FC21

In this case, the user is requested to take into account the currently valid system of units:

MD10240 \$MN_SCALING_SYSTEM_IS_METRIC

The current system of units setting can be read using the signal:

DB10 DBX107.7 (inch measuring system)

Using the signal:

DB10 DBB71 (change counter, system of units inch/metric)

the "system of units change counter" can be read out

- The system of units for sag compensation is configured using:
MD32711 \$MA_CEC_SCALING_SYSTEM_METRIC
References:
/FB2/ Function Manual Extended Functions; Compensations (K3)
- The measuring system for positional data of the indexing axis tables and switching points for software cams is configured in machine data element:
MD10270 \$MN_POS_TAB_SCALING_SYSTEM.
References:
/FB2/ Function Manual, Extended Functions; Software Cams, Limit Switching Signals (N3)/Indexing Axes (T1)

User tool data

For user-defined tool data:

MD18094 \$MN_MM_NUM_CC_TDA_PARAM

and tool cutting edge data:

MD18096 \$MN_MM_NUM_CC_TOA_PARAM

additional machine data sets are introduced:

MD10290 \$MN_CC_TDA_PARAM_UNIT [MM_NUM_CC_TDA_PARAM]

MD10292 \$MN_CC_TOA_PARAM_UNIT [MM_NUM_CC_TOA_PARAM]

A physical unit can be configured using these machine data. All length-related user-defined tool data are automatically converted to the new measuring system according to the input on switchover.

Reference point

The reference point is retained. It is not necessary to repeat referencing.

Input resolution and computational resolution

The input/computational resolution is set in the control using machine data:

MD10200 \$MN_INT_INCR_PER_MM

Default settings:

Metric system	Inch system
1000 (0.001 mm)	0.0001

Example:

1 inch = 25.4 mm ⇒ 0.0001 inch = 0.00254 mm = 2.54 μm

To be able to program and display the last 40 mm, MD10200 must be assigned a value of 100000.

Only with this identical setting for both measuring systems is it possible to change the measuring system without a significant loss of accuracy. Once MD10200 has been set to this value, it will not need to be changed each time the measuring system is switched over.

JOG and handwheel factor

The machine data:

MD31090 \$MA_JOG_INCR_WEIGHT

consists of two values containing axis-specific increment weighting factors for each of the two measuring systems.

Depending on the actual setting in machine data:

MD10240 \$MN_SCALING_SYSTEM_IS_METRIC

the control automatically sets the appropriate value.

The user defines the two increment factors, e.g., for the first axis, during the installation and startup phase:

- Metric:
MD31090 \$MA_JOG_INCR_WEIGHT[0;AX1]=0.001 mm
- Inch:
MD31090 \$MA_JOG_INCR_WEIGHT[1;AX1]=0.00254 mm ≙ 0.0001 inch

In this way, MD31090 does not have to be written on every inch/metric switchover.

Remaining distances are not accumulated during incremental traversing with JOG when the measuring system is changed, since all internal positions always refer to mm.

Data backup

Data sets which can be separately read out of the control and have data where the system of units is relevant, receive - when reading - as a function of machine data:

MD10260 \$MN_CONVERT_SCALING_SYSTEM

an INCH or METRIC identification corresponding to machine data:

MD10240 \$MN_SCALING_SYSTEM_IS_METRIC

This specifies the measuring system in which the data were originally read out.

This information is intended to prevent data sets from being read into the control system with a measuring system, which is different from the active system. In this case, alarm 15030 is triggered and the write process is interrupted.

Since the language instruction is also evaluated in parts programs, these can also be "protected" against operator errors as described above. You can, therefore, prevent parts programs containing only metric data, for example, from running on an inch measuring system.

Archive and machine data sets are downwards compatible for a setting:

MD11220 \$MN_INI_FILE_MODE = 2

Note

The INCH/METRIC operation is only generated if the compatibility machine data:

MD10260 \$MN_CONVERT_SCALING_SYSTEM

is set.

Rounding machine data

All length-related machine data are rounded to the nearest 1 pm when writing in the inch measuring system (MD10240 \$MN_SCALING_SYSTEM_IS_METRIC=0 and MD10260 \$MN_CONVERT_SCALING_SYSTEM=1), in order to avoid rounding problems.

The disturbing loss of accuracy, which occurs as a result of conversion to ASCII when reading out a data backup in the inch system of measurement, is corrected by this procedure when the data is read back into the system.

7.3.3 FGROUP and FGMEM

Programming

It should be possible to program the effective machining feedrate in the usual way as a path feedrate via the F value in processing procedures where the tool, the workpiece or both are moved by a rotary axis (e.g., laser machining of rotating tubes).

In order to achieve this, it is necessary to specify an effective radius (reference radius) for each of the rotary axes involved. You can do this by programming the modal NC address: FGMEM[<rotary axis>]=<reference radius>

The unit of the reference radius depends on the G70/G71/G700/G710 setting.

In order to include the axes in the calculation of the path feedrate, they must all be specified in the FGROUP command.

In order to ensure compatibility with the behavior with no FGMEM programming, the evaluation 1 degree = 1 mm is activated on system power-up and RESET.

This corresponds to a reference radius of:

$$FGMEM = 360 \text{ mm} / (2\pi) = 57.296 \text{ mm}$$

This default is independent of the active basic system (MD10240 \$MN_SCALING_SYSTEM_IS_METRIC) and the currently active G70/G71/G700/G710 setting.

Special features of the feedrate weighting for rotary axes in FGROUP:

Program code

```
N100 FGROUP(X,Y,Z,A)
N110 G1 G91 A10 F100
N120 G1 G91 A10 X0.0001 F100
```

The programmed F value in block N110 is evaluated as a rotary axis feedrate in degrees/min, while the feedrate weighting in block N120 is either 100 inch/min or 100 mm/min, depending on the current inch/metric setting.

CAUTION

The FGMEM factor also works if only rotary axes are programmed in the block. The normal F value interpretation as degree/min applies in this case only if the radius reference corresponds to the FGMEM default:

- For G71/G710: FGMEM[A]=57.296
- For G70/G700: FGMEM[A]=57.296/25.4

Example

The following example is intended to demonstrate the effect of FGROUP on the path and path feedrate. The variable \$AC_TIME contains the time of the block start in seconds. It can only be used in synchronized actions.

7.3 Metric/inch measuring system

Program code	Comment
N100 G0 X0 A0	
N110 FGROUP(X,A)	
N120 G91 G1 G710 F100	; Feedrate = 100mm/min or 100 degrees/min
N130 DO \$R1=\$AC_TIME	
N140 X10	; Feedrate = 100 mm/min, path = 10 mm, R1 = approx. 6 s
N150 DO \$R2=\$AC_TIME	
N160 X10 A10	; Feedrate = 100 mm/min, path = 14.14 mm, R2 = approx. 8 s
N170 DO \$R3=\$AC_TIME	
N180 A10	; Feedrate = 100 degrees/min, path = 10 degrees, R3 = approx. 6 s
N190 DO \$R4=\$AC_TIME	
N200 X0.001 A10	; Feedrate = 100 mm/min, path = 10 mm, R4 = approx. 6 s
N210 G700 F100	; Feedrate = 2540 mm/min or 100 degrees/min
N220 DO \$R5=\$AC_TIME	
N230 X10	; Feedrate = 2540 mm/min, path = 254 mm, R5 = approx. 6 s
N240 DO \$R6=\$AC_TIME	
N250 X10 A10	; Feedrate = 2540 mm/min, path = 254.2 mm, R6 = approx. 6 s
N260 DO \$R7=\$AC_TIME	
N270 A10	; Feedrate = 100 degrees/min, path = 10 degrees, R7 = approx. 6 s
N280 DO \$R8=\$AC_TIME	
N290 X0.001 A10	; Feedrate = 2540 mm/min, path = 10 mm, R8 = approx. 0.288 s
N300 FGREF[A]=360/(2*\$PI)	; Set 1 degree = 1 inch via the effective radius.
N310 DO \$R9=\$AC_TIME	
N320 X0.001 A10	; Feedrate = 2540 mm/min, path = 254 mm, R9 = approx. 6 s
N330 M30	

Diagnostics

Read reference radius

The value of the reference radius of a rotary axis can be read using system variables:

- For the display in the user interface, in synchronized actions or with a preprocessing stop in the part program via the system variables:

\$AA_FGREF[<axis>] Current main run value

- Without preprocessing stop in the part program via system variable:

\$PA_FGREF[<axis>] Programmed value

If no values are programmed, the default $360 \text{ mm}/(2\pi) = 57.296 \text{ mm}$ (corresponding to 1 mm per degree) will be read in both variables.

For linear axes, the value in both variables is always 1 mm.

Read path axes affecting velocity

The axes involved in path interpolation can be read using system variables:

- For the display in the user interface, in synchronized actions or with a preprocessing stop in the part program via the system variables:

\$AA_FGROUP[<axis>]	Returns the value "1" if the specified axis affects the path velocity in the current main run record by means of the basic setting or through FGROUP programming. Otherwise, the variable returns the value "0".
\$AC_FGROUP_MASK	Returns a bit key of the channel axes programmed with FGROUP which are to affect the path velocity.

- Without preprocessing stop in the part program via system variables:

\$PA_FGROUP[<axis>]	Returns the value "1" if the specified axis affects the path velocity by means of the basic setting or through FGROUP programming. Otherwise, the variable returns the value "0".
\$P_FGROUP_MASK	Returns a bit key of the channel axes programmed with FGROUP which are to affect the path velocity.

7.4 Setpoint/actual-value system

7.4.1 General

Control loop

A control loop with the following structure can be configured for every closed-loop controlled axis/spindle:

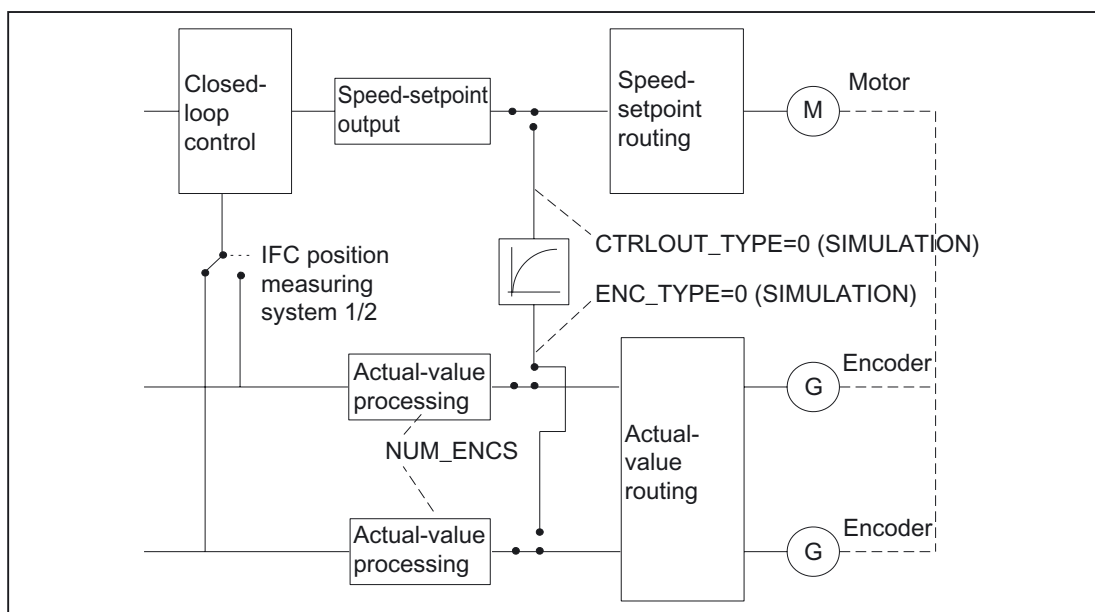

Figure 7-1 Block diagram of a control loop

Setpoint output

A setpoint telegram can be output for each axis/spindle. The setpoint output to the actuator is realized from the SINUMERIK 840D sl.

Actual-value acquisition

A maximum of two measuring systems can be connected for each axis/spindle, e.g. a direct measuring system for machining processes with high accuracy requirements and an indirect measuring system for high-speed positioning tasks.

The number of encoders used is recorded in the machine data:

MD30200 \$MA_NUM_ENCS (number of encoders)

In the case of two actual-value branches, the actual value is acquired for both branches.

The active measuring system is always used for position control, absolute value calculation and display. If both measuring systems are activated at the same time by the PLC interface, positioning measuring system 1 is chosen internally by the control.

Reference point approach is executed by the selected measuring system.

Each position measuring system must be referenced separately.

For an explanation of actual-value acquisition compensation functions, see:

References:

/FB2/ Function Manual, Extended Functions; Compensations (K3)

For an explanation of encoder monitoring, see:

References:

/FB1/ Function Manual, Basic Functions; Axis Monitoring, Protection Zones (A3)

Switching between measuring systems

One can switch between the two measuring systems through the following NC/PLC interface signals:

DB31, ... DBX1.5 (position measuring system 1)

DB31, ... DBX1.6 (position measuring system 2)

References

/FB1/ Function Manual, Basic Functions; Various Interface Signals (A2)

It is possible to switch over measuring systems at any time, the axes do not have to be stationary to do this. Switchover only takes place if a permissible deviation between the actual values and the two measuring systems has not been violated.

The associated tolerance is entered in the machine data:

MD36500 \$MA_ENC_CHANGE_TOL (Max. tolerance on position actual value switchover)

On switchover, the current difference between position measuring system 1 and 2 is traversed immediately.

Monitoring

The permissible deviation between the actual values of the two measuring systems is to be entered in the machine data:

MD36510 \$MA_ENC_DIFF_TOL

For the cyclic comparison of the two measuring systems used, this difference must not be exceeded, as otherwise Alarm 25105 "Measuring systems deviate" is generated.

If the axis is not referenced (at least in the current control measuring system) then the related monitoring is not active if MD36510 = 0 or if neither of the two measuring systems in the axis is active/available).

Types of actual-value acquisition

The used encoder type must be defined through the following machine data:

MD30240 \$MA_ENC_TYPE (type of actual-value acquisition (actual position value))

Simulation axes

The speed control loop of an axis can be simulated for test purposes.

The axis "traverses" with a following error, similar to a real axis.

A simulation axis is defined by setting the two following machine data to "0":

MD30130 \$MA_CTRL_OUT_TYPE[n] (output value of setpoint)

MD30240 \$MA_ENC_TYPE[n] (type of actual-value acquisition)

As soon as the standard machine data have been loaded, the axes become simulation axes.

The setpoint and actual value can be set to the reference point value with reference point approach.

The machine data:

MD30350 \$MA_SIMU_AX_VDI_OUTPUT (output of axis signals with simulation axes)

can be used to define whether the axis-specific interface signals are to be output on the PLC during the simulation.

Actual-value correction

If actual-value corrections performed by the NC on the encoder selected for position control do not influence the actual value of another encoder defined in the same axis, then this encoder is to be declared as "independent" via the following machine data:

MD30242 \$MA_ENC_IS_INDEPENDENT

Actual-value corrections include the following:

- Modulo treatment
- Reference point approach
- Measuring system comparison
- PRESET

7.4.2 Setpoint and encoder assignment

Setpoint marshalling

The following machine data are relevant for the setpoint assignment of a machine axis.

MD30100		\$MA_CTRL_OUT_SEGMENT_NR[n]
Setpoint assignment, bus segment		
System	Value	Meaning
840D sl	5	PROFIBUS-DP / PROFINET (default)

MD30110		\$MA_CTRLOUT_MODULE_NR[n]
Setpoint assignment: Drive number / module number		
System	Value	Meaning
840D sl	x	Index x of MD13050 \$MN_DRIVE_LOGIC_ADDRESS[x] should be entered, which refers to the connected drive. MD30110 \$MA_CTRLOUT_MODULE_NR[n] = x, refers to: MD13050 \$MN_DRIVE_LOGIC_ADDRESS[x] Note The machine data is of no significance if the drive is simulated (MD30130 \$MA_CTRLOUT_TYPE[n] = 0).

MD30120		\$MA_CTRLOUT_NR[n]
Setpoint assignment: Setpoint output on drive module/module		
System	Value	Meaning
840D sl	1	Modular drive at PROFIBUS / PROFINET with PROFIdrive profile (default)

MD30130		\$MA_CTRLOUT_TYPE[n]
Setpoint output type		
System	Value	Meaning
840D sl	0	Simulation (operation without drive)
	1	Setpoint output active

Encoder assignment

The following machine data are relevant for assigning the encoder information of the drive - transferred in the PROFIdrive telegram - to the encoder inputs of the machine axis:

MD30210		\$MA_ENC_SEGMENT_NR[n]
Actual value assignment, bus segment		
System	Value	Meaning
840D sl	5	PROFIBUS-DP / PROFINET

MD30220		\$MA_ENC_MODULE_NR[n]
Actual value assignment: Drive module number/measuring circuit number		
System	Value	Meaning
840D sl	x	The number of the drive assigned using MD13050 \$MN_DRIVE_LOGIC_ADDRESS[x] should be entered. MD30220 \$MA_ENC_MODULE_NR[n] = x, refers to: MD13050 \$MN_DRIVE_LOGIC_ADDRESS[x]

7.4 Setpoint/actual-value system

MD30230		\$MA_ENC_INPUT_NR[n]
Actual value assignment: Input on drive module/measuring circuit module		
System	Value	Meaning
840D sl	x	Number of the encoder interface within the PROFIdrive telegram Examples PROFIdrive telegram 103 x = 1 → 1st encoder interface (G1_ZSW, G1_XIST1, G1_XIST2) x = 2 → 2nd encoder interface (G2_ZSW, G2_XIST1, G2_XIST2) PROFIdrive telegram 118 x = 1 → 1st encoder interface (G2_ZSW, G2_XIST1, G2_XIST2) x = 2 → 2nd encoder interface (G3_ZSW, G3_XIST1, G3_XIST2) Note For SINAMICS S120: - encoder 1 (G1...): Motor encoder - encoder 2 (G2...): Direct measuring system - encoder 3 (G3...): Additional measuring system

MD30240		\$MA_ENC_TYPE[n]
Encoder type of the actual value sensing (position actual value)		
System	Value	Meaning
840D sl	0	Simulation (operation without encoder)
	1	Incremental encoder
	4	Absolute encoder
Note Corresponds with PROFIdrive parameter p979		

MD30242		\$MA_ENC_IS_INDEPENDENT[n, axis]
Encoder is independent		
System	Value	Meaning
840D sl	0	The encoder is not independent.
	1	<p>The encoder is independent.</p> <p>If the actual-value corrections, which are made for the encoder selected for the position control, are not to influence the actual value of the second encoder defined in the same axis, then this should be declared as independent.</p> <p>Actual value corrections are:</p> <ul style="list-style-type: none"> • Modulo handling • Reference point approach • Measuring system alignment • PRESET <p>Example: One axis, 2 encoders, the 2nd encoder is independent MD30200 \$MA_NUM_ENC[AX1] = 2 MD30242 \$MA_ENC_IS_INDEPENDENT[0, AX1] = 0 MD30242 \$MA_ENC_IS_INDEPENDENT[1, AX1] = 1 Selection, position measuring system 1 / 2: DB31.DBX1.5 / 1.6</p> <p>If encoder 1 is selected for closed-loop position control, then the actual value corrections are only performed on this encoder, as encoder 2 is independent.</p> <p>If encoder 2 is selected for position control, then the actual value corrections are performed on both encoders, as encoder 1 is not independent.</p> <p>This means that the machine data only has an effect on the passive encoder of a machine axis.</p>
	2	<p>The passive encoder is dependent.</p> <p>The encoder actual value is changed by the active encoder. In combination with MD35102 \$MA_REFP_SYNC_ENC[1], for reference point approach, the passive encoder is aligned to the active encoder - but is NOT referenced.</p> <p>In the referencing mode MD34200 \$MA_ENC_REFP_MODE = 3 (distance-coded reference marks) the passive encoder is automatically referenced with the next traversing motion after passing the zero mark distance. This is done independent of the actual operating mode setting.</p>
	3	<p>The encoder is independent.</p> <p>For modulo rotary axes, modulo actual value corrections are also performed in the passive encoder.</p>

7.4 Setpoint/actual-value system

Note

Machine data index [n]

The machine data index [n] for encoder assignment has the following meaning:

- n = 0: The first encoder assigned to the machine axis
- n = 1: Second encoder assigned to the machine axis

The assignment is made using machine data:

- MD30220\$MA_ENC_MODULE_NR[n]
- MD30230\$MA_ENC_INPUT_NR[n]

7.4.3 Adapting the motor/load ratios

Gear types

The following gear types are available for adapting the mechanical ratios:

Gear type	Activation	Adaptation	Installation location
Motor/load gear	Parameter set	Fixed configuration	Gear unit
Measuring gear encoder	Power ON	Sensor-dependent	Sensor-side
Load intermediate gear unit	NewConfig	Load-dependent	Tool-side

Local position of gear unit/encoder

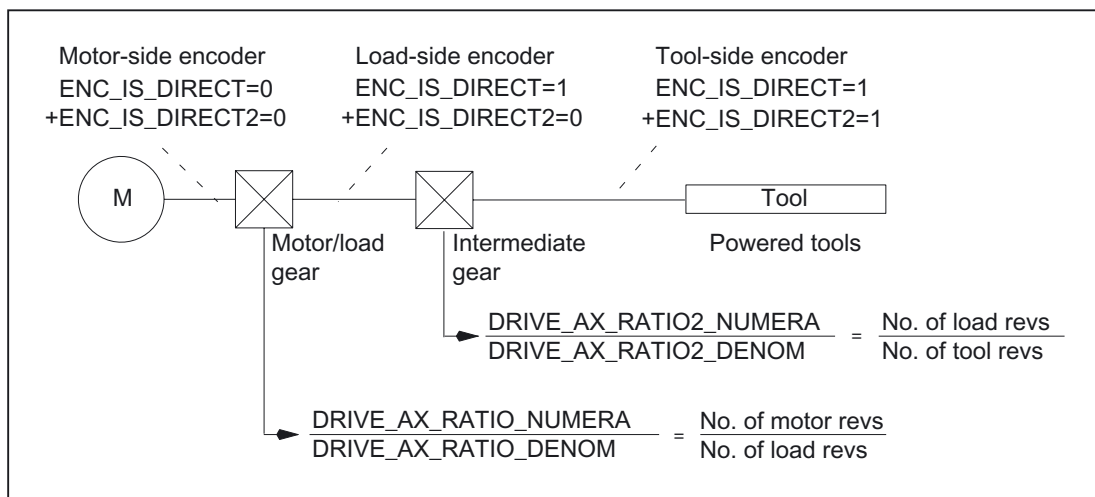

Figure 7-2 Gear unit types and encoder locations

Motor/load gear

The motor/load gear supported by SINUMERIK is configured via the following machine data:

MD31060 \$MA_DRIVE_AX_RATIO_NUMERA (Numerator load gearbox)

MD31050 \$MA_DRIVE_AX_RATIO_DENOM (Denominator load gearbox)

The transmission ratio is obtained from the numerator/denominator ratio of both machine data. The associated parameter sets are used automatically as default by the control to synchronize the position controller with the relevant transmission ratios.

Since a gear stage change is not always carried out automatically, and there are also several ways to request a gear stage change, the position controller is not always incorporated via parameter sets.

Note

For further information about the parameter sets for gear stage change, see:

References:

/FB1/ Function Manual Basic Functions; Spindles (S1)

Intermediate gear

Additional, configurable load intermediate gears are also supported by the control:

MD31066 \$MA_DRIVE_AX_RATIO2_NUMERA (intermediate gear numerator)

MD31064 \$MA_DRIVE_AX_RATIO2_DENOM (intermediate gear denominator)

Power tools generally have their "own" intermediate gear. Such variable mechanics can be configured by multiplying the active intermediate gearbox and the motor/load gearbox.

 CAUTION
--

<p>Unlike the motor/load gear, there is no parameter set for the intermediate gear and, therefore, no way of controlling the time-synchronized switchover to parts program or PLC (VDI interface). Part programming during gear change is, therefore, ruled out. It remains the task of the user to match the synchronization of the relevant changed machine data to the corresponding mechanical switchover and activate it. On switchover during a movement, compensations cannot be ruled out due to jumps in the scaling factors. These are not monitored for violation of the maximum acceleration.</p>
--

Encoder directly at the tool

Another connection option is possible for a "tool-side encoder" on the intermediate gear, by configuring machine data:

MD31044 \$MA_ENC_IS_DIRECT2

Encoder not directly at the tool

The following supplementary conditions apply to a gear change of the intermediate gear in position-control mode:

- The gear ratio to be changed is incorporated in a re-scaling of the encoder information in this case.

In this case, the following applies to axes/spindles in positioning mode:

- A non-abrupt gear change is **only possible at zero speed**.

To do this, the tool-side position before and after a gear change are set equal for a change in the ratio, since the mechanical position does not (or hardly) changes during a gear stage change.

Recommendation:

To avoid 21612 "Controller enable reset during motion", changeover should be carried out "only at zero speed". It is still permissible and expedient to switch the axis or spindle to speed-control or follow-up mode before or during a gear change.

Boundary conditions

If the encoder to be used for position control is **connected directly at the tool**, the gear stage change only affects the physical quantities at the speed interface between the NC and the drive of the motor/load gear. The internal parameter sets are not changed.

Reference point and position reference

In the case of gear changes, it is not possible to make a statement about the effect of the reference point or machine position reference on the encoder scaling. In such cases, the control partially cancels the status "Axis referenced/synchronized".

If the position reference to the machine, tool, etc., has been lost, it must first be restored through appropriate adjustment or referencing of the lost reference point. This is especially important for the functions Travel to fixed stop, Referencing to Bero, Cam and Zero marker.

 CAUTION
The control cannot detect all possible situations that can lead to loss of the machine position reference. Therefore, it is the responsibility of the commissioning engineer or user to initiate explicit referencing of zero marker synchronization in such cases.

Note

In order to permit new referencing without an interrupting RESET, machine data:

MD34080 \$MA_REFP_MOVE_DIST

and

MD34090 \$MA_REFP_MOVE_DIST_CORR

are changed over to NewConfig effectiveness.

For more detailed information about referencing, please see:

References:

/FB1/ Function Manual Basic Functions; Reference Point Travel (R1)

7.4.4 Speed setpoint output

Control direction and travel direction of the feed axes

You must determine the travel direction of the feed axis before starting work.

Control direction

Before the position control is started up, the speed controller and current controller of the drive must be started up and optimized.

Travel direction

With the machine data:

MD32100 \$MA_AX_MOTION_DIR (travel direction).

the direction of motion of the axis can be reversed,

without affecting the control direction of the position control.

Speed setpoint adjustment

SINUMERIK 840D sl

In the case of speed setpoint comparison, the NC is informed, which speed setpoint corresponds to which motor speed in the drive, for parameterizing the axial control and monitoring. This comparison is carried out automatically.

For PROIBUS-DP drives, alternatively, the manual speed setpoint comparison is also possible.

- **Manual comparison**

In the machine data:

MD32250 \$MA_RATED_OUTVAL

a value not equal to zero is entered.

For more detailed information about motor speed adjustments, please see:

References:

/HBI/ Manual SINUMERIK 840Di; "Axes and Spindles"

Note

Velocity adjustment and maximum speed setpoint

Owing to the automatic speed setpoint comparison a velocity adjustment is not necessary for SINUMERIK 840D sl!

Maximum speed setpoint

For SINUMERIK 840D sl, the maximum speed setpoint is defined as a percentage. 100% means maximum speed setpoint or maximum speed for PROFIdrive drives (manufacturer-specific setting parameters in the drive, e.g. p1082 for SINAMICS).

The output of the spindle speed is implemented in the NC for SINUMERIK 840D sl.

Data for 5 gear stages are realized in the control.

These stages are defined by a minimum and maximum speed for the stage itself and by a minimum and maximum speed for the automatic gear stage changeover. A new set gear stage is output only if the new programmed speed cannot be traversed in the current gear stage.

With the machine data:

MD36210 \$MA_CTRL_OUT_LIMIT[n] (maximum speed setpoint)

the speed setpoint is restricted percentage-wise.

Values up to 200% are possible.

When the speed is exceeded, an alarm is generated.

Figure 7-3 Maximum speed setpoint

However, due to control processes, the axes should not reach their maximum velocity (MD32000 \$MA_MAX_AX_VELO) at 100% of the speed setpoint, but at 80% to 95%.

In case of axes, whose maximum speed is attained at around 80% of the speed setpoint range, the default value (80%) of the machine data:

MD32000 \$MA_MAX_AX_VELO (maximum axis velocity)

7.4.5 Actual-value processing

Actual-value resolution

In order to be able to create a correctly closed position control loop, the control system must be informed of the valid actual-value resolution. The following axis-specific machine data are used for the purpose, which are partially specified from the drive (MD31000, 31010, 31020, 31025).

The control calculates the actual-value resolution from the settings made in the MD. The control parameter sets of the position control are identified as servo parameter sets.

The machining process of the machine forms the basis of the position actual-value acquisition.

Direct measuring system (DM) is on machine directly:	Load-side encoder
Indirect measuring system (IM) is on motor indirectly:	Motor-side encoder

7.4 Setpoint/actual-value system

Depending on the type of axis (linear axis, rotary axis) and the type of actual-value acquisition (directly at the machine, indirectly at the motor), the following machine data must be parameterized to calculate the actual-value resolution:

Machine data	Linear axis	Linear axis		Rotary axis	
	Linear scale/ or as direct measuring system	Encoder on motor	Encoder on machine and/or tool	Encoder on motor	Encoder on machine and/or tool
MD30300 \$MA_IS_ROT_AX	0	0	0	1	1
MD31000 \$MA_ENC_IS_LINEAR[n]	1	0	0	0	0
MD31010 \$MA_ENC_GRID_POINT_DIST[n]	Spacing	-	-	-	-
MD34320 \$MA_ENC_INVERS[n]	◆	-	-	-	-
MD31040 \$MA_ENC_IS_DIRECT[n]	- / 1	0	1	0	1
MD31044 \$MA_ENC_IS_DIRECT2[n]	- / 1	0	1	0	1
MD31020 \$MA_ENC_RESOL[n]	-	Pulses/ rev	Pulses/ rev	Pulses/r ev	Pulses/ rev
MD31025 \$MA_ENC_PULSE_MULT[n]	Encoder multiplication				
MD31030 \$MA_LEADSCREW_PITCH	-	mm/rev.	mm/rev.	-	-
MD31050 \$MA_DRIVE_AX_RATIO_DENOM[n]	-	Load rev.	-/1	Load rev.	●
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA[n]	-	Motor rev. if infeed gear available	-/1	Motor rev.	●
MD31070 \$MA_DRIVE_ENC_RATIO_DENOM[n]	-	Encoder rev.	Encoder rev.	Encoder rev.	Encoder rev.
MD31080 \$MA_DRIVE_ENC_RATIO_NUMERA[n]	-	Motor- side encoder*	Motor rev.	Motor rev.	Load rev.

- = Does not apply to this combination

* The encoder on the motor side is a built-in encoder and, therefore, does **not** have a measuring gear unit.
The transmission ratio is always 1:1.

◆ For distance-coded measuring systems

● These machine data are not required for encoder matching (path evaluation).
However, they must be entered correctly for the setpoint calculation! Otherwise the required servo gain factor (K_V) will not be set. The load revolutions are entered into machine data MD31050 \$MA_DRIVE_AX_RATIO_DENOM and the motor revolutions in machine data MD31060 \$MA_DRIVE_AX_RATIO_NUMERA.

Coding of the machine data

The indices of the following machine data are coded at the encoder [Encoder no.]:

Encoder 0 or 1

Encoder-dependent machine data	Meaning
MD31070 \$MA_DRIVE_ENC_RATIO_DENOM[n]	Measuring gear denominator
MD31080 \$MA_DRIVE_ENC_RATIO_NUMERA[n]	Measuring gear numerator
MD31000 \$MA_ENC_IS_LINEAR[n]	Direct measuring system linear scale
MD31010 \$MA_ENC_GRID_POINT_DIST[n]	Distance between reference marks on linear scales
MD31020 \$MA_ENC_RESOL[n]	Encoder pulses per revolution for rotary encoder
MD31040 \$MA_ENC_IS_DIRECT[n]	Encoder is connected directly at the machine
MD34320 \$MA_ENC_INVERS[n]	Length measuring system is in the opposite sense

Additional machine data without index	Meaning
MD30200 \$MA_NUM_ENC	Number of encoders
MD30300 \$MA_IS_ROT_AX	Rotary axis
MD31030 \$MA_LEADSCREW_PITCH	Leadscrew pitch

Index [n] of the following machine data depend on the servo parameter sets of the position controller, with which the actual-value resolution is calculated automatically in the control:

MD DRIVE_AX...[servo parameter set no.] : 0-5

Parameter-set-dependent machine data	Meaning
MD31050 \$MA_DRIVE_AX_RATIO_DENOM[n]	Denominator load gearbox
MD31060 \$MA_DRIVE_AX_RATIO_NUMERA[n]	Numerator load gearbox

For the following machine data, the control does not consider any parameter set nor any indices for coded encoders.

NewConfig-dependent machine data	
Encoder-dependent machine data	Meaning
MD31044 \$MA_ENC_IS_DIRECT2[n]	Encoder on intermediate gear
MD34080 \$MA_REFP_MOVE_DIST [n]	Reference point approach distance
MD34090 \$MA_REFP_MOVE_DIST_CORR[n]	Reference point offset

7.4 Setpoint/actual-value system

NewConfig-dependent machine data	
Additional machine data without index	Meaning
MD31064 \$MA_DRIVE_AX_RATIO2_DENOM	Intermediate gear denominator
MD31066 \$MA_DRIVE_AX_RATIO2_NUMERA	Intermediate gear numerator
MD32000 \$MA_MAX_AX_VELO	Maximum axis velocity

Note

These machine data can be activated in parts programs with the command `NEWCONF` or via the HMI operator panel using a soft key.

Variants of actual-value acquisition

The relevant machine data and relational calculations for the different methods of actual-value acquisition are described in the following.

7.4.6 Adjustments to actual-value resolution

Calculating the ratio

The calculation of the ratio is obtained from the associated machine data and is defined for encoders as follows:

$$\frac{\text{Computational resolution}}{\text{Actual-value resolution}} = \frac{\text{Internal increments}/(\text{mm})}{\text{Encoder increments}/(\text{mm})}$$

For encoders with rotary axis, the following applies:

$$\frac{\text{Computational resolution}}{\text{Actual-value resolution}} = \frac{\text{Internal increments}/(\text{degrees})}{\text{Encoder increments}/(\text{degrees})}$$

The internal pulse multiplication is defined by MD31025 \$MA_ENC_PULSE_MULT.

Linear axis with linear scale

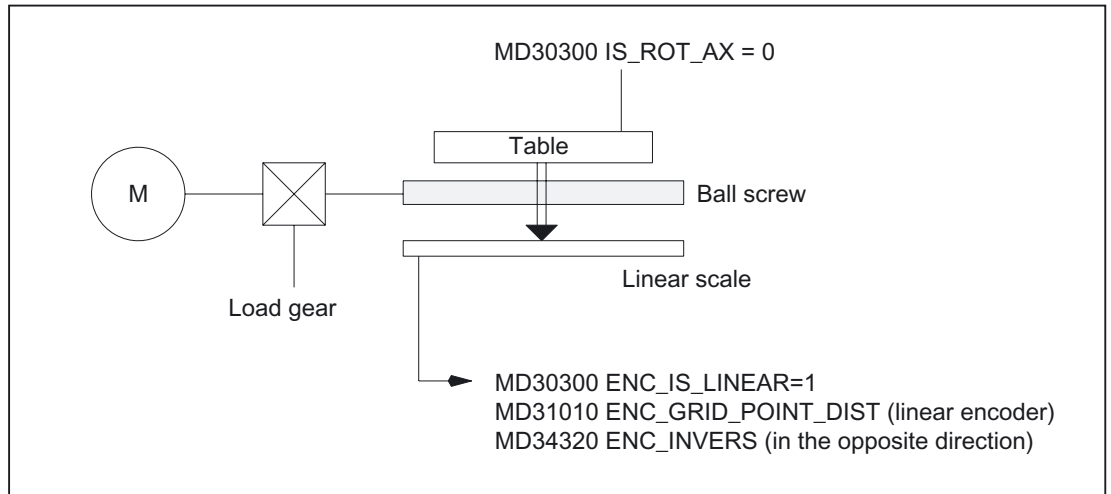

Figure 7-4 Linear axis with linear scale

In order to adapt the actual-value resolution to the calculation resolution, the control calculates the quotients from the "internal increments/mm" and the "encoder increments/mm" as follows:

$$\frac{\text{Internal increments / mm}}{\text{Encoder increments / mm}} = \frac{\text{ENC_GRID_POINT_DIST [n]} * \text{INT_INCR_PER_MM}}{\text{ENC_PULSE_MULT[n]}}$$

The distance for linear encoders is based on the pulse increments.

Linear axis with rotary encoder on motor

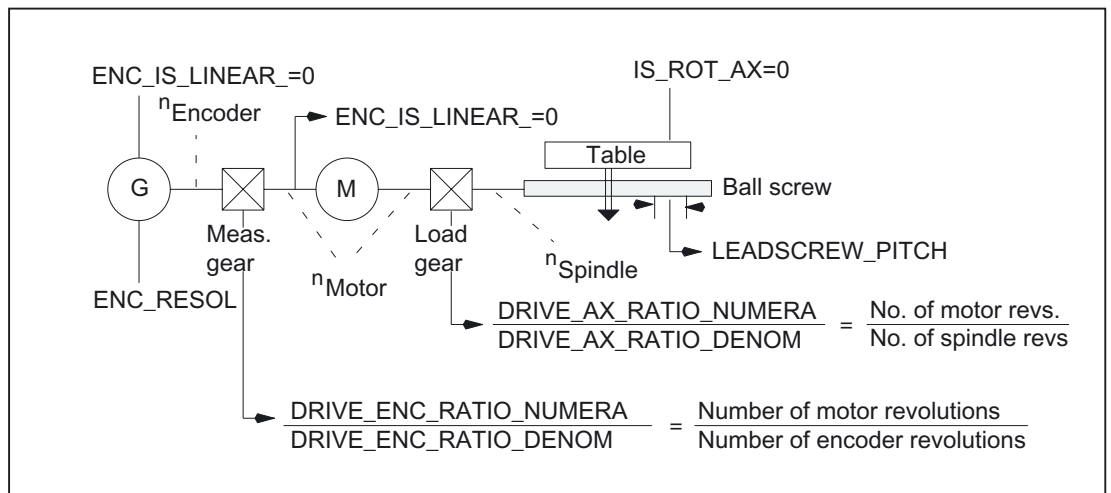

Figure 7-5 Linear axis with rotary encoder on motor

7.4 Setpoint/actual-value system

In order to adapt the actual-value resolution to the calculation resolution, the control calculates the quotients from the "internal increments/mm" and the "encoder increments/mm" as follows:

SINUMERIK example

Linear axis with rotary encoder (2048 Impulse) on motor;

internal multiplication (2048)

Gear: Motor/leadscrew ratio 5:1
 Pitch 10 mm
 10000 increments per mm

$$\frac{\text{Internal increments / mm}}{\text{Encoder increments / mm}} = \frac{1}{\text{ENC_RESOL [n]} * \text{ENC_PULSE_MULT[n]}} * \frac{\text{DRIVE_ENC_RATIO_NUMERA [n]}}{\text{DRIVE_ENC_RATIO_DENOM [n]}} * \frac{\text{DRIVE_AX_RATIO_DENOM [n]}}{\text{DRIVE_AX_RATIO_NUMERA [n]}} * \text{LEADSCREW_PITCH} * \text{INT_INCR_PER_MM}$$

- ⇒ MD30300 \$MA_IS_ROT_AX = 0
- MD31000 \$MA_ENC_IS_LINEAR[0] = 0
- MD31040 \$MA_ENC_IS_DIRECT[0] = 0
- MD31020 \$MA_ENC_RESOL[0] = 2048
- MD31025 \$MA_ENC_PULSE_MULT = 2048
- MD31030 \$MA_LEADSCREW_PITCH = 10
- MD31080 \$MA_DRIVE_ENC_RATIO_NUMERA[0] = 1
- MD31070 \$MA_DRIVE_ENC_RATIO_DENOM[0] = 1
- MD31060 \$MA_DRIVE_AX_RATIO_NUMERA[0] = 5
- MD31050 \$MA_DRIVE_AX_RATIO_DENOM[0] = 1
- MD10200 \$MN_INT_INCR_PER_MM = 10000

$$\Rightarrow \frac{\text{Internal increments/mm}}{\text{Encoder increments/mm}} = \frac{1}{2048 * 2048} * \frac{1}{1} * \frac{1}{5} * 10 \text{ mm} * 10000 \text{ incr./mm} = 0.004768$$

Linear axis with rotary encoder on the machine

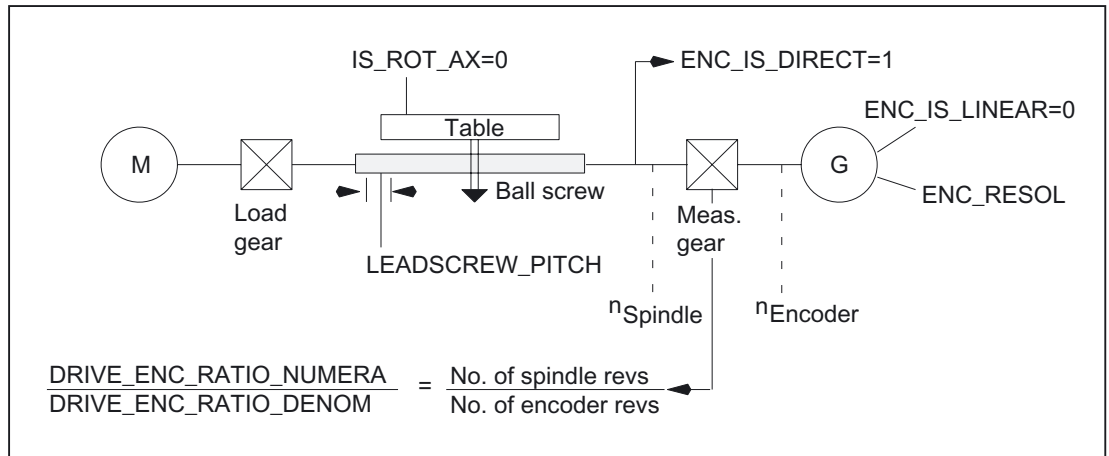

Figure 7-6 Linear axis with rotary encoder on the machine

In order to adapt the actual-value resolution to the calculation resolution, the control calculates the quotients from the "internal increments/mm" and the "encoder increments/mm" as follows:

$$\frac{\text{Internal increments / mm}}{\text{Encoder increments / mm}} = \frac{1}{\text{ENC_RESOL [n]} * \text{ENC_PULSE_MULT[n]}}$$

$$* \frac{\text{DRIVE_ENC_RATIO_NUMERA [n]}}{\text{DRIVE_ENC_RATIO_DENOM [n]}}$$

$$* \text{LEADSCREW_PITCH}$$

$$* \text{INT_INCR_PER_MM}$$

Rotary axis with rotary encoder on motor

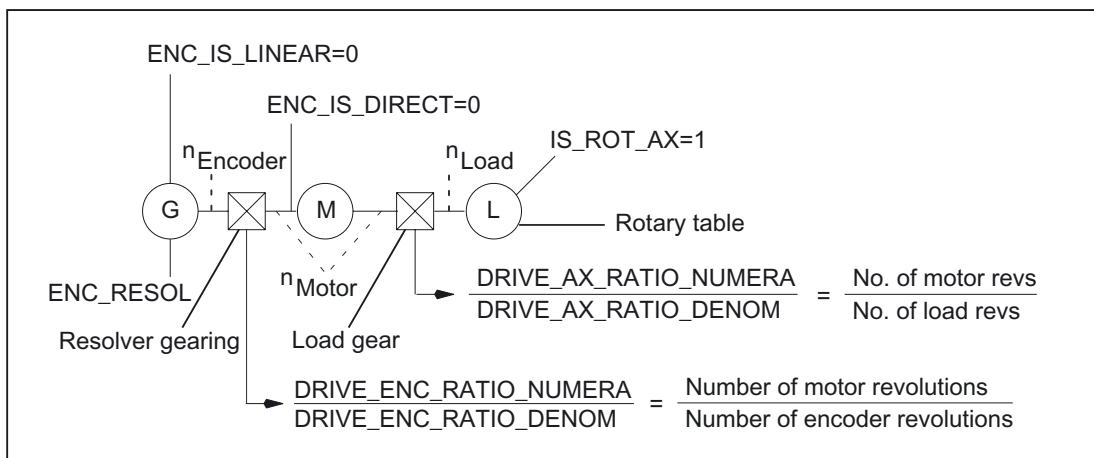

Figure 7-7 Rotary axis with rotary encoder on motor

In order to adapt the actual-value resolution to the calculation resolution, the control calculates the quotients from the "internal increments/degree" and the "encoder increments/degree" as follows:

Example for rotary axis with encoder on motor

Rotary axis with rotary encoder (2048 Impulse) on motor;

internal multiplication (2048)

Gear: Motor/rotary axis ratio 5:1
1000 increments per degree

$$\frac{\text{Internal increments / degrees}}{\text{Encoder increments / degrees}} = \frac{360 \text{ degrees}}{\text{ENC_RESOL [n]} * \text{ENC_PULSE_MULT[n]}}$$

$$* \frac{\text{DRIVE_ENC_RATIO_NUMERA [n]}}{\text{DRIVE_ENC_RATIO_DENOM [n]}}$$

$$* \frac{\text{DRIVE_AX_RATIO_DENOM [n]}}{\text{DRIVE_AX_RATIO_NUMERA [n]}}$$

$$* \text{INT_INCR_PER_DEG}$$

- ⇒ MD30300 \$MA_IS_ROT_AX = 1
- MD31000 \$MA_ENC_IS_LINEAR[0] = 0
- MD31040 \$MA_ENC_IS_DIRECT[0] = 0
- MD31020 \$MA_ENC_RESOL[0] = 2048
- MD31025 \$MA_ENC_PULSE_MULT = 2048
- MD31080 \$MA_DRIVE_ENC_RATIO_NUMERA[0] = 1

MD31070 \$MA_DRIVE_ENC_RATIO_DENOM[0] = 1
 MD31060 \$MA_DRIVE_AX_RATIO_NUMERA[0] = 5
 MD31050 \$MA_DRIVE_AX_RATIO_DENOM[0] = 1
 MD10210 \$MN_INT_INCR_PER_DEG = 1000

$$\Rightarrow \frac{\text{Internal increments/degrees}}{\text{Encoder increments/degrees}} = \frac{360 \text{ degrees}}{2048 * 2048} * \frac{1}{1} * \frac{1}{5}$$

$$* 1000 \text{ incr./degrees} = 0.017166$$

Result:
 1 internal increment corresponds to 0.017166 encoder increments of the internal unit.

Rotary axis with rotary encoder on the machine

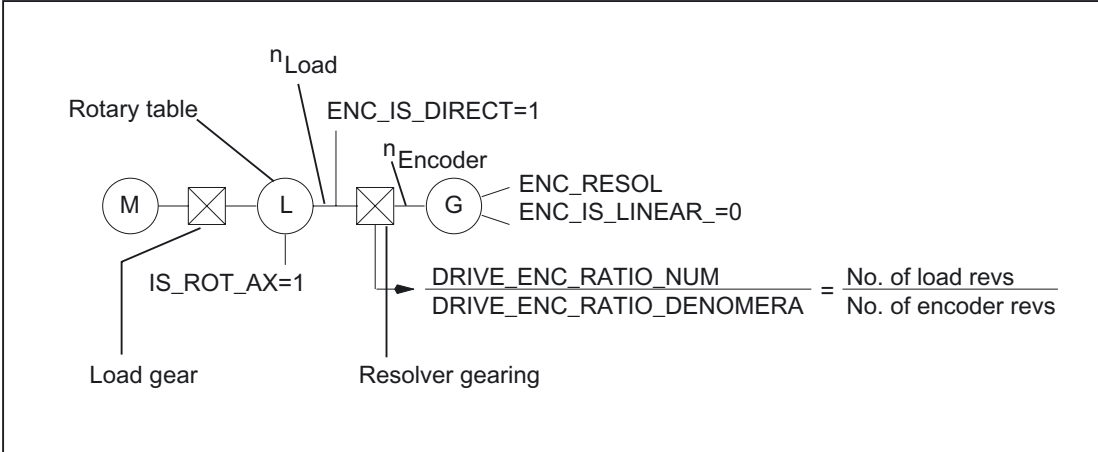

Figure 7-8 Rotary axis with rotary encoder on the machine

In order to adapt the actual-value resolution to the calculation resolution, the control calculates the quotients from the "internal increments/degree" and the "encoder increments/degree" as follows:

$$\frac{\text{Internal increments / degrees}}{\text{Encoder increments / degrees}} = \frac{360 \text{ degrees}}{\text{ENC_RESOL [n]} * \text{ENC_PULSE_MULT[n]}}$$

$$* \frac{\text{DRIVE_ENC_RATIO_NUMERA [n]}}{\text{DRIVE_ENC_RATIO_DENOM [n]}}$$

$$* \text{INT_INCR_PER_DEG}$$

Intermediate gear encoder on tool

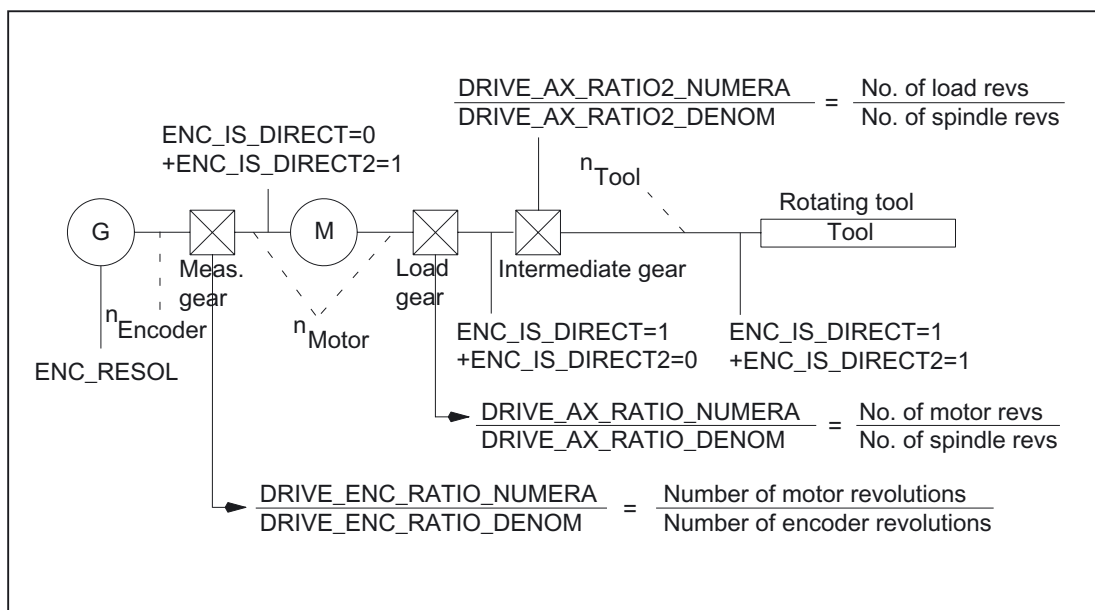

Figure 7-9 Intermediate gear with encoder directly on the rotating tool

In order to adapt the actual-value resolution to the calculation resolution, the control calculates the quotients from the "internal increments/mm" and the "encoder increments/mm" as follows:

$$\frac{\text{Internal increments / degrees}}{\text{Encoder increments / degrees}} = \frac{360 \text{ degrees}}{\text{ENC_RESOL [n]} * \text{ENC_PULSE_MULT[n]}}$$

$$* \frac{\text{DRIVE_ENC_RATIO_NUMERA [n]}}{\text{DRIVE_ENC_RATIO_DENOM [n]}}$$

$$* \text{INT_INCR_PER_DEG}$$

7.5 Closed-loop control

7.5.1 General

Position control of an axis/spindle

The closed-loop control of an axis consists of the current and speed control loop of the drive plus a higher-level position control loop in the NC.

The basic structure of an axis/spindle position control is illustrated below:

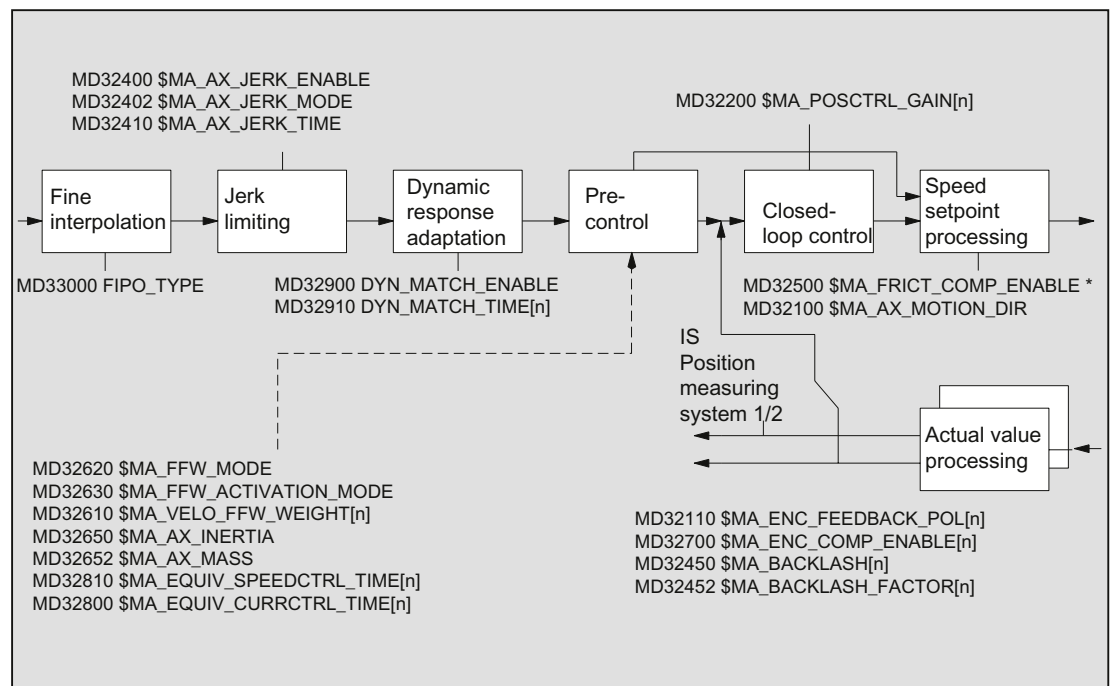

Figure 7-10 Principle representation of the setpoint processing and closed-loop control

For a description of the feedforward control, backlash, friction compensation with further machine data, and leadscrew error compensation, see:

References:

/FB2/ Function Manual Extended Functions; Compensations (K3)

For a description of jerk limitation, see:

References:

/FB1/ Function Manual, Basic Functions; Acceleration (B2).

Fine interpolation

The fine interpolator (FIPO) is used to adjust the setpoint of the (generally slower) interpolator cycle clock to the faster position-control cycle.

Fine interpolation further improves the quality of the contour (decreasing the step effect of the speed setpoint).

There are three types of FIPOs:

1:	Differential FIPO
2:	Cubic FIPO
3:	Cubic FIPO, optimized for operation with feedforward control

The type of fine interpolation can be determined through the following machine data:

MD33000 \$MA_FIPO_TYPE (fine interpolator type)

A differential FIPO not only performs cycle matching but also calculates a mean value (smoothing) from an IPO cycle.

The cubic FIPO, type 3, supplies the best contour accuracy in addition to the cycle adaptation.

Servo gain factor (K_v)

In order that few contour deviations occur in the continuous path mode, a high servo gain factor (K_v) is necessary:

MD32200 \$MA_POSCTRL_GAIN[n]

However, if the servo gain factor (K_v) is too high, instability, overshoot and possibly impermissibly high loads on the machine will result.

The maximum permissible servo gain factor (K_v) depends on the following:

- Design and dynamics of the drive
(rise time, acceleration and braking capacity)
- Machine quality
(elasticity, oscillation damping)
- Position control cycle or speed control cycle for active DSC

The servo gain factor (K_v) is defined as follows:

$$K_v = \frac{\text{Velocity}}{\text{Following error}} ; \frac{[\text{m/min}]}{[\text{mm}]}$$

[m/min]/[mm]: Unit of servo gain factor (K_v) according to VDI standard

Servo gain factor (K_v) setting for SINUMERIK 840D sl

Figure 7-11 Dynamic response adaptation

Dynamic response adaptation

The purpose of dynamic response adaptation is to set an identical following error for axes with different servo gain factors (K_v). The optimum contour accuracy for axes interpolating with each other can thus be achieved without reduced control quality. A high servo gain factor (K_v) for an axis can be maintained, which guarantees optimum disturbance suppression of the axis.

The function is activated with the machine data:

MD32900 \$MA_DYN_MATCH_ENABLE (dynamic response adaptation)

The adaptation of the axes and the difference of the equivalent time constants of the "slowest" control loop to the respective axis is realized using machine data:

MD32910 \$MA_DYN_MATCH_TIME [n] (time constant of dynamic response adaptation)

With this MD the equivalent time constant of the position control loops of the axes with a higher servo gain factor (K_v) is adjusted to the axes with the lowest servo gain factor (K_v).

Example of dynamic response adaptation of axes 1, 2 and 3 (without speed feedforward control):

The equivalent time constant of the position control loop is as follows:	
For axis 1:	30 ms
For axis 2:	20 ms
For axis 3:	24 ms

⇒ Axis 1 is dynamically the slowest axis.

⇒ This results in the following values for the machine data MD32910:

7.5 Closed-loop control

Axis 1:	0 ms
Axis 2:	10 ms
Axis 3:	6 ms

Approximation formulae

The equivalent time constant of the position control loop of an axis is calculated according to the following formula:

- No feedforward control is active

$$T_{\text{Spares}} \approx \frac{1}{\text{MD32200 POSCTRL_GAIN [1/s]}}$$

- Speed feedforward control

$$T_{\text{Spares}} \approx \text{MD32810 EQUIV_SPEEDCTRL_TIME}$$

- Combined torque/speed precontrol

$$T_{\text{Spares}} \approx \text{MD32800 EQUIV_CURRCTRL_TIME}$$

Note

If a dynamic response adaptation is done for a geometry axis, then the same dynamic behavior is necessary for all other geometry axes and is to be activated with the following setting:

MD32900 \$MA_DYN_MATCH_ENABLE= 1

References:

"Commissioning Instructions" SINUMERIK 840D sl, SINAMICS S120

7.5.2 Parameter sets of the position controller

Six different parameters sets

The position control can operate with 6 different servo parameter sets.

They are used as follows

1. Fast adaptation of the position control to altered machine characteristics during operation, e.g. a gear change of the spindle.
2. Matching the dynamics of an axis to another axis, e.g. during tapping.

Parameter set changeover

The following machine data can be changed by switching over the parameter set during operation:	
Denominator load gearbox	MD31050 \$MA_DRIVE_AX_RATIO_DENOM[n]
Numerator load gearbox	MD31060 \$MA_DRIVE_AX_RATIO_NUMERA[n]
Servo gain factor (K _v)	MD32200 \$MA_POSCTRL_GAIN[n]
Backlash compensation	MD32452 \$MA_BACKLASH_FACTOR[n]
Feedforward control factor	MD32610 \$MA_VELO_FFW_WEIGHT[n]
Exact stop limits and zero-speed window	MD36012 \$MA_STOP_LIMIT_FACTOR[n]
	MD36000 \$MA_STOP_LIMIT_COARSE[n]
	MD36010 \$MA_STOP_LIMIT_FINE[n]
	MD36030 \$MA_STANDSTILL_POS_TOL[n]
Equivalent time constant Current control loop for combined torque/speed precontrol	MD32800 \$MA_EQUIV_CURRCTRL_TIME[n]
Equivalent time constant speed control loop for speed feedforward control	MD32810 \$MA_EQUIV_SPEEDCTRL_TIME[n]
Time constant for dynamic response adaptation	MD32910 \$MA_DYN_MATCH_TIME[n]
Threshold value for velocity monitoring	MD36200 \$MA_AX_VELO_LIMIT[n]

Tapping or thread cutting

The following applies to **parameter sets for axes**:

- For machine axes **not** involved in tapping or thread cutting, parameter set 1 (index=0) is always used.

The further parameter sets need not be considered.

- For machine axes involved in tapping or thread cutting, the same parameter set number as for the current gear stage of the spindle is activated.

All parameter sets correspond to the gear stages and must therefore be parameterized.

The current parameter set is displayed in operating area "Diagnostics" in the "Service axis" display. The parameter sets for gear stages 1 to 5 are referred to as interpolation parameters.

Parameter sets during gear stage change

Interpolation parameter sets during gear stage change:

In the case of spindles, each gear stage is assigned its own parameter set.

Dependent on the NC/PLC interface signal:

7.5 Closed-loop control

DB31, ... DBX16.0 - 16.2 (actual gear stage)

the corresponding parameter set is activated.

DB31, ... DBX16.0 - 16.2 (actual gear stage)		Active parameter set	
000	1st gear stage	2	(Index=1)
001	1st gear stage	2	(Index=1)
010	2nd gear stage	3	(Index=2)
011	3rd gear stage	4	(Index=3)
100	4th gear stage	5	(Index=4)
101	5th gear stage	6	(Index=5)
110			
111			

For more information on gear stages for spindles see:

/FB1/ Function Manual Basic Functions; Spindles (S1)

7.6 Optimization of the control

7.6.1 Position controller, position setpoint filter: Balancing filter

Application

For speed and torque feedforward control

With feedforward control active, the position setpoint is sent through a so-called balancing filter before it reaches the controller itself. It is thus possible to control the speed setpoint to 100 % in advance, without resulting in overshoots when positioning.

Filter activation

The filter is activated and the precontrol version selected by changing the axial machine data:

MD32620 \$MA_FFW_MODE

Value	Meaning
3	Speed precontrol
4	Combined torque/speed precontrol

Activation of feedforward control

Parts programs can be used to activate and deactivate the feedforward control for all axes, using instructions `FFWON` and `FFWOF`, which does not affect the following machine data:

MD32630 FFW_ACTIVATION_MODE

Control response with POWER ON, RESET, REPOS, etc.

In the case of POWER ON and RESET, as well as with "Enable machine data", the setting data of the feedforward control are read in anew (see the appropriate values of the machine data).

Mode change, block search and repositioning have **no** influence on the feedforward control.

Recommended setting in case of recommissioning

If recommissioning, or if previous standard values are loaded (switch position 1 on commissioning switch and POWER ON), the following machine data default values apply:

MD32620 \$MA_FFW_MODE = 3

MD32610 \$MA_VELO_FFW_WEIGHT = 1

The balancing time for the speed feedforward control then just has to be adjusted in the following machine data:

MD32810 \$MA_EQUIV_SPEEDCTRL_TIME

Setting the equivalent time constant of the speed control loop

MD32810 speed feedforward control

We recommend that the axis be allowed to move in and out in "AUTOMATIC" mode with a parts program and that travel-in to the target position, i.e., the actual position value of the active measuring system, be monitored with servo trace.

The actual position value can also be output to the drive module's digital-to-analog converter, and an oscilloscope can be used for monitoring.

The initial value for setting is the time constant of the speed control loop. This can be read from the reference frequency characteristic of the speed control loop. In the frequent case of a PI controller with speed setpoint smoothing, an approximate equivalent time can be read from drive machine data p1414, p1415, p1416 and p1421.

Another option would be to trace the speed setpoint and actual value at a constant acceleration using an oscilloscope and to measure the follow-on time of the speed actual value.

This start value (e.g. 1.5 ms) is now entered:

MD32810 \$MA_EQUIV_SPEEDCTRL_TIME = 0.0015

The axis then travels to and fro and the operator monitors a greatly-magnified characteristic of the position actual value at the target position.

The following rules apply to making manual fine adjustments:

Overshoot monitored:	→ magnify MD32810.
Excessively slow approach monitored:	→ reduce MD32810.

Magnifying MD32810

Increasing the value of MD32810 slows the axis down and increases the geometric contour error on curves to some degree.

It has a similar effect to reducing the position controller gain:

MD32200 \$MA_POSCTRL_GAIN

This can also be watched in the Diagnostics area in the screen form "Service Axis" based on the servo gain value calculated.

Reducing MD32810

Reducing the value of MD32810 quickens the axis.

Therefore, MD32810 should be assigned as small a value as possible, with the overshoot setting the limit during positioning.

MD32810 fine adjustment

Experience has shown that the initial value is only modified slightly during fine adjustment, typically by adding or deducting 0.25 ms.

For example, if the initial value is 1.5 ms, the optimum value calculated manually is usually within the range 1.25 ms to 1.75 ms.

In the case of axes equipped with direct measuring systems (load encoders) and strong elasticity, you may possibly accept small overshoots of some micrometers.

These can be reduced with the help of the position setpoint filter for dynamic response adaptation (MD32910 \$MA_DYN_MATCH_TIME) and for jerk (MD32410 \$MA_AX_JERK_TIME), which also reduces the axis speed.

Identical axis data within an interpolation group

All the axes within an interpolation group should have **identical settings** in the following data:

MD32200 \$MA_POSCTRL_GAIN (adapted using MD32910)

MD32620 \$MA_FFW_MODE

MD32610 \$MA_VELO_FFW_WEIGHT

MD32810 \$MA_EQUIV_SPEEDCTRL_TIME (or MD32800 \$MA_EQUIV_CURRCTRL_TIME)
(dependent on the mechanical system and drive)

MD32400 \$MA_AX_JERK_ENABLE

MD32402 \$MA_AX_JERK_MODE

MD32410 \$MA_AX_JERK_TIME

The servo gain display (K_v) in the axis service screen form is used for checking.

Unequal axis data of an interpolation group

If identical values are not possible for the above data, the following machine data can be used to make an adjustment:

MD32910 \$MA_DYN_MATCH_TIME

This allows the same servo gain value (K_v) to be displayed.

Different servo gain display values (K_v) usually point to the following:

- The gear ratios do not match in one or several axes.
- The feedforward control setting data do not match.

Setting the equivalent time constant of the current control loop

MD32800 Equivalent time constant current control loop for precontrol

The same rules and recommendations apply to setting the time constant of the current control loop as to the speed feedforward control.

However, activation of the torque feedforward control filter with:

MD32620 \$MA_FFW_MODE = 4

must, for the purposes of setting the time constant with

MD32800 \$MA_EQUIV_CURRCTRL_TIME

but are enabled as before in the drive.

Limitation to stiff machines

Experience has shown that this expenditure is only worthwhile in the case of very stiff machines, and requires appropriate experience. The elasticities of the machine are often excited due to the injection of the torque so strongly that the existing vibrations neutralize the gain in contour accuracy.

In this case, it would be worth trying the use of Dynamic Stiffness Control (DSC) as an alternative:

MD32640 \$MA_STIFFNESS_CONTROL_ENABLE = 1

Note

If DSC is to be activated (MD32640 = 1), no parameters may be assigned for actual-value inversion in the NC (MD32110 \$MA_ENC_FEEDBACK_POL = -1). Otherwise, error 26017 occurs.

In DSC mode, actual-value inversion may only be undertaken in the drive (SINAMICS parameter p0410).

For more information about the effect of the feedforward control relating to the speed and torque position controller setpoints, please refer to:

References:

Function Manual, Extended Functions; Compensations (K3)

7.6.2 Position controller, position setpoint filter: Jerk filter

Application

In some applications, such as when milling sculptured surfaces, it can be advantageous to smooth the position setpoint curves to obtain better surfaces, due to reduced excitations of machine vibrations.

Functionality

The filter effect of the position setpoints must be as strong as possible without impermissibly affecting contour accuracy.

The smoothing behavior of the filter must also be as "symmetrical" as possible, i.e., if the same contour was to be traveled in both forward and reverse, the characteristic rounded by the filter should be as similar as possible in both directions.

The effect of the filter can be monitored by means of the effective servo gain factor (K_v), which is displayed on the Axis service screen form. The filtering effect rounds the position setpoints slightly, thus reducing the path accuracy so that with increasing filter time a smaller effective servo gain factor (K_v) is displayed.

Filter enable with MD32402

With the machine data:

MD32402 \$MA_AX_JERK_ENABLE

the position setpoint filter is enabled

and determined using the following definitions:

MD32402 \$MA_AX_JERK_MODE	= 2	Filter mode, moving average value
MD32410 \$MA_AX_JERK_TIME	= 0.02	Set the filter time in seconds (e.g. 20 ms)
MD32400 \$MA_AX_JERK_ENABLE	= 1	Enable filter calculation

If no filter mode previously:

MD32402 \$MA_AX_JERK_MODE = 2

was activated, then "Power On" must be initiated once.

Otherwise, "Enable machine data" or "Reset" at the machine control panel are sufficient.

Note

Generally, the filter is set using:

MD32402 \$MA_AX_JERK_MODE = 2

Fine adjustment

The fine adjustment of the jerk filter is carried out as follows:

1. Assess the traversing response of the axis (e.g., based on positioning processes with servo trace).
2. Modify the filter time in MD32410 \$MA_AX_JERK_TIME.
3. Activate the modified time via "Enable machine data" or RESET on the machine control panel.

Disabling

Disabling the jerk filter:

1. Disable filter calculation:
MD32410 \$MA_AX_JERK_ENABLE = 0.
2. Activate the interlock via "Enable machine data" or RESET on the machine control panel.

Boundary conditions

The jerk filter is available in all control versions as follows:

- Effective filter times are limited to a range between a minimum of 1 position-control cycle up to a maximum of 32 position-control cycles (31 position-control cycles are available).

Further supplementary conditions regarding the filter effect:

- The display of the calculated servo gain factor (K_v) in the Axis service screen form displays smaller values than would be appropriate based on the filter effect.
- Path accuracy is better than the displayed servo gain (K_v) suggests.

Therefore, on resetting

MD32400 \$MA_AX_JERK_MODE = 1

to

MD32400 \$MA_AX_JERK_MODE = 2,

the displayed servo gain (K_v) can be reduced while retaining the same filter time, although the path accuracy improves.

Axes that interpolate with each other must be set identically.

Once an optimum value has been identified for these axes, the one with the longest filter time should be used as the setting for all axes within the interpolation group.

For further information about jerk limiting at the interpolator level, please see:

7.6.3 Position control with proportional-plus-integral-action controller

Function

As standard, the core of the position controller is a P controller.

It is possible to switch-in an integral component for special applications (such as an electronic gear). The resulting proportional-plus-integral-action controller then corrects the error between setpoint and actual positions down to zero in a finite, settable time period when the appropriate machine data are set accordingly.

 **CAUTION**

When the proportional-plus-integral-action controller is active, overshoots occur in the actual position. In this instance, you must decide whether this effect is admissible or acceptable for the application in question. Closed-loop control know-how and measurements using the servo trace are absolutely necessary in order to use the function. If the appropriate machine data are incorrectly set, then machines could be damaged due to instability.

Procedure

1. First optimize the position control loop as a proportional-action controller first using the tools described in the previous subsections.
2. Increase the tolerances of the following machine data while measurements are being taken to determine the quality of the position control with proportional-plus-integral-action controller:
 - MD36020 \$MA_POSITIONING_TIME
 - MD36030 \$MA_STANDSTILL_POS_TOL
 - MD36040 \$MA_STANDSTILL_DELAY_TIME
 - MD36400 \$MA_CONTOUR_TOL
3. Activate the position control loop as a proportional-plus-integral-action controller by setting the following machine data:
MD32220 \$MA_POSCTRL_INTEGR_ENABLE ; set value 1
MD32210 \$MA_POSCTRL_INTEGR_TIME ; integral time [sec.]
Effect of integral time:
 - $T_n \rightarrow 0$:
The control error is corrected quickly; however, the control loop can become unstable.
 - $T_n \rightarrow \infty$:
The control error is corrected more slowly.
4. If you search for the optimum compromise for T_n .
 T_n for the application between these two extreme cases, you should not select the value to be too close to the instability limit, as otherwise, instability could occur and in turn damage the machine.
5. Use servo trace to trace the travel-in of an automatic program traveling to and from a target position.
6. Set the servo trace to display the following:
 - Following error
 - Actual velocity
 - Actual position
 - Reference position
7. Reset the tolerance values in the following machine data to the required values, once the optimum value for T_n has been identified:
 - MD36020 \$MA_POSITIONING_TIME
 - MD36030 \$MA_STANDSTILL_POS_TOL
 - MD36040 \$MA_STANDSTILL_DELAY_TIME
 - MD36400 \$MA_CONTOUR_TOL

Example

Setting result after several iterative processes for κ_R and T_n .

Each of the following quantities - following error, actual velocity, actual position, and position setpoint - has been recorded by servo trace. When traversing in JOG mode, the characteristic of the individual data shown in the following figure was then drawn.

Set machine data:

MD32220 \$MA_POSCTRL_INTEGR_ENABLE = 1

MD32210 \$MA_POSCTRL_INTEGR_TIME = 0.003

MD32200 \$MA_POSCTRL_GAIN[1] = 5.0

Parameter set selection 0

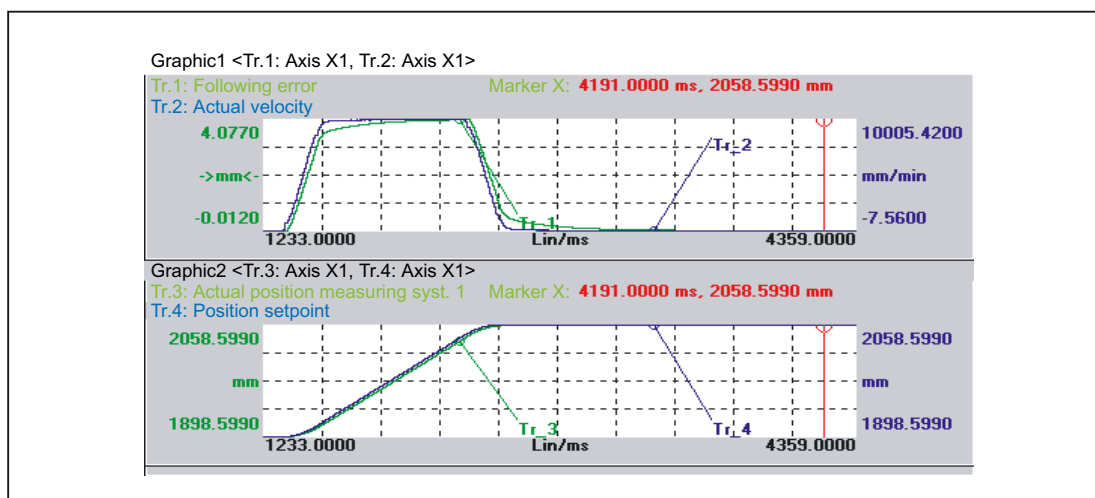

Figure 7-12 Following error (1), actual velocity (2), position actual value (3), position setpoint (4)

7.7 Data lists

7.7.1 Machine data

7.7.1.1 Displaying machine data

Number	Identifier: \$MM_	Description
9004	DISPLAY_RESOLUTION	Display resolution
9010	SPIND_DISPLAY_RESOLUTION	Display resolution for spindles
9011	DISPLAY_RESOLUTION_INCH	Display resolution for INCH system of measurement

7.7.1.2 NC-specific machine data

Number	Identifier: \$MN_	Description
10000	AXCONF_MACHAX_NAME_TAB	Machine axis name
10050	SYSCLOCK_CYCLE_TIME	System basic cycle
10070	IPO_SYSCLOCK_TIME_RATIO	Factor for interpolator cycle
10060	POSCTRL_SYSCLOCK_TIME_RATIO	Factor for position-control cycle
10200	INT_INCR_PER_MM	Computational resolution for linear positions
10210	INT_INCR_PER_DEG	Computational resolution for angular positions
10220	SCALING_USER_DEF_MASK	Activation of scaling factors
10230	SCALING_FACTORS_USER_DEF	Scaling factors of physical quantities
10240	SCALING_SYSTEM_IS_METRIC	Basic system metric
10250	SCALING_VALUE_INCH	Conversion factor for switchover to inch system
10260	CONVERT_SCALING_SYSTEM	Basic system switchover active
10270	POS_TAB_SCALING_SYSTEM	Measuring system of position tables
10290	CC_TDA_PARAM_UNIT	Physical units of the tool data for CC
10292	CC_TOA_PARAM_UNIT	Physical units of the tool edge data for CC
13050	DRIVE_LOGIC_ADDRESS	Logical drive addresses
13060	DRIVE_TELEGRAM_TYPE	Standard message frame type for PROFIBUS DP
13070	DRIVE_FUNCTION_MASK	DP function used
13080	DRIVE_TYPE_DP	Drive type PROFIBUS DP

7.7.1.3 Channel-specific machine data

Number	Identifier: \$MC_	Description
20150	GCODE_RESET_VALUES	Initial setting of the G groups

7.7.1.4 Axis/spindle-specific machine data

Number	Identifier: \$MA_	Description
30110	CTRLOUT_MODULE_NR	Setpoint assignment: Drive number
30120	CTRLOUT_NR	Setpoint assignment: Setpoint output on drive module
30130	CTRLOUT_TYPE	Output type of setpoint
30200	NUM_ENCS	Number of encoders
30220	ENC_MODULE_NR	Actual value assignment: Drive module number
30230	ENC_INPUT_NR	Actual value assignment: Input on the drive module
30240	ENC_TYPE	Type of actual-value acquisition (position actual value)
30242	ENC_IS_INDEPENDENT	Encoder is independent
30300	IS_ROT_AX	Rotary axis
31000	ENC_IS_LINEAR	Direct measuring system (linear scale)
31010	ENC_GRID_POINT_DIST	Distance between reference marks on linear scales
31020	ENC_RESOL	Encoder pulses per revolution
31030	LEADSCREW_PITCH	Leadscrew pitch
31040	ENC_IS_DIRECT	Encoder is connected directly to the machine
31044	ENC_IS_DIRECT2	Encoder on intermediate gear
31050	DRIVE_AX_RATIO_DENOM	Denominator load gearbox
31060	DRIVE_AX_RATIO_NUMERA	Numerator load gearbox
31064	DRIVE_AX_RATIO2_DENOM	Intermediate gear denominator
31066	DRIVE_AX_RATIO2_NUMERA	Intermediate gear numerator
31070	DRIVE_ENC_RATIO_DENOM	Measuring gear denominator
31080	DRIVE_ENC_RATIO_NUMERA	Measuring gear numerator
31090	JOG_INCR_WEIGHT	Weighting of increment for INC/handwheel
31200	SCALING_FACTOR_G70_G71	Factor for converting values when G70/G71 is active
32000	MAX_AX_VELO	Maximum axis velocity
32100	AX_MOTION_DIR	Travel direction
32110	ENC_FEEDBACK_POL	Sign actual value (feedback polarity)
32200	POSCTRL_GAIN	Servo gain factor (Kv)
32210	POSCTRL_INTEGR_TIME	Integrator time position controller
32220	POSCTRL_INTEGR_ENABLE	Activation of integral component of position controller
32250	RATED_OUTVAL	Rated output voltage
32260	RATED_VELO	Rated motor speed
32450	BACKLASH	Backlash
32500	FRICT_COMP_ENABLE	Friction compensation active
32610	VELO_FFW_WEIGHT	Feedforward control factor for speed feedforward control
32620	FFW_MODE	Feedforward control mode
32630	FFW_ACTIVATION_MODE	Activate feedforward control from program
32650	AX_INERTIA	Moment of inertia for torque feedforward control

Number	Identifier: \$MA_	Description
32652	AX_MASS	Axis mass for torque precontrol
32711	CEC_SCALING_SYSTEM_METRIC	System of measurement of sag compensation
32800	EQUIV_CURRCTRL_TIME	Equivalent time constant current control loop for feedforward control
32810	EQUIV_SPEEDCTRL_TIME	Equivalent time constant speed control loop for feedforward control
32900	DYN_MATCH_ENABLE	Dynamics matching
32910	DYN_MATCH_TIME [n]	Time constant for dynamic response adaptation
32930	POSCTRL_OUT_FILTER_ENABLE	Activation of low-pass filter at position controller output
33000	FIPO_TYPE	Fine interpolator type
34320	ENC_INVERS[n]	Length measuring system is inverse
35100	SPIND_VELO_LIMIT	Maximum spindle speed
36200	AX_VELO_LIMIT [n]	Threshold value for velocity monitoring
36210	CTRL_OUT_LIMIT[n]	Maximum speed setpoint
36400	AX_JERK_ENABLE	Axial jerk limitation
36410	AX_JERK_TIME	Time constant for axial jerk filter
36500	ENC_CHANGE_TOL	Max. tolerance for position actual-value switchover
36510	ENC_DIFF_TOL	Measuring system synchronism tolerance
36700	ENC_COMP_ENABLE[n]	Interpolatory compensation

H2: Auxiliary function outputs to PLC

8.1 Brief description

8.1.1 Function

Auxiliary functions permit activation of the system functions of the NCK and PLC user functions. Auxiliary functions can be programmed in:

- Parts programs
- Synchronized actions
- User cycles

References:

For detailed information on using auxiliary function outputs in synchronized actions, refer to the Function Manual, Synchronized Actions.

Predefined auxiliary functions

Predefined auxiliary functions activate system functions. The auxiliary function is also output to the NC/PLC interface.

The following auxiliary functions are predefined:

Type	Function	Example	Meaning
M	Special function	M30	End of program
S	Spindle function	S100	Spindle speed 100 (e.g. rpm)
T	Tool number	T3	Tool number 3
D, DL	Tool offset	D1	Tool cutting edge number 1
F	Feed	F1000	Feedrate 1000 (e.g. mm/min)

User-defined auxiliary functions

User-defined auxiliary functions are either extended predefined auxiliary functions or user-specific auxiliary functions.

Extension of predefined auxiliary functions

Extension of predefined auxiliary functions refers to the "address extensions" parameter. The address extension defines the number of the spindle to which the auxiliary function applies. The spindle function M3 (spindle right) is predefined for the master spindle of a channel. If a 2nd spindle is assigned to a channel, a corresponding user-defined auxiliary function must be defined that extends the predefined auxiliary function.

8.1 Brief description

Type	Function	Example	Meaning
M	Special function	M2=3	2nd spindle: Spindle right
S	Spindle function	S2=100	2nd spindle: Spindle speed = 100 (e.g. rpm)
T	Tool number	T2=3	

User-specific auxiliary functions

User-specific auxiliary functions do not activate system functions. User-specific auxiliary functions are output to the NC/PLC interface only. The functionality of the auxiliary functions must be implemented by the machine manufacturer / user in the PLC user program.

Type	Function	Example	Meaning
H ¹⁾	Auxiliary function	H2=5	User-specific function

1) Recommendation

8.1.2 Definition of an auxiliary function

An auxiliary function is defined by the following parameters:

- **Type, address extension, and value**

The 3 parameters are output to the NC/PLC interface.

- **Output behavior**

The auxiliary function-specific output behavior defines for how long an auxiliary function is output to the NC/PLC interface and when it is output relative to the traversing motion programmed in the same parts program block.

- **Group assignment**

An auxiliary function can be assigned to a particular auxiliary function group. The output behavior can be defined separately for each auxiliary function group. This becomes active if no auxiliary function-specific output behavior has been defined. Group membership also affects output of an auxiliary function after block search.

References:

For more detailed information on auxiliary function output to the NC/PLC interface, see: Function Manual, Basic Functions, Basic PLC Program (P3)

8.1.3 Overview of auxiliary functions

M functions

M (special function)					
Address extension			Value		
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
0 (implicit)	- - -	up to 8 digits	INT	Function	5
Remarks: - - -					
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
1 ... 20	Spindle number	1 ... 99	INT	Function	5
Remarks: Example: "Spindle stop" for 2nd spindle of the channel: M2=5. The master spindle of the channel is addressed if no an address extension is specified.					
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
0 ... 99	Any	2147483647	INT	Function	5
Remarks: User-specific M function					

⁸⁾ See "Meaning of footnotes" at the end of the overview.

Application

Controlling machine functions in synchronism with the part program.

Further information

- The following M functions have a predefined meaning: M0, M1, M2, M17, M30, M3, M4, M5, M6, M19, M70, M40, M41, M42, M43, M44, M45.
- For each M function (M0 - M99), there is a dynamic signal at the NC/PLC interface that indicates the validity (new output) of the M function. In addition, 64 additional signals can be assigned for user M functions.

References:

Function Manual Basic Functions; PLC Basic Program (P3)

- For subprograms, machine data can be used to set whether an output of the M function should be undertaken for the end of the part program M17, M2 and M30 to the PLC:
MD20800 \$MC_SPF_END_TO_VDI (subprogram end to PLC)
- For the predefined M function M40 – M45, only limited redefinition of the output specification is possible.

8.1 Brief description

- The predefined auxiliary functions M0, M1, M17, M30, M6, M4, M5 cannot be redefined.
- M function-specific machine data:
 - MD10800 \$MN_EXTERN_CHAN_SYNC_M_NO_MIN
 - MD10802 \$MN_EXTERN_CHAN_SYNC_M_NO_MAX
 - MD10804 \$MN_EXTERN_M_NO_SET_INT
 - MD10806 \$MN_EXTERN_M_NO_DISABLE_INT
 - MD10814 \$MN_EXTERN_M_NO_MAC_CYCLE
 - MD10815 \$MN_EXTERN_M_NO_MAC_CYCLE_NAME
 - MD20094 \$MC_SPIND_RIGID_TAPPING_M_NR
 - MD20095 \$MC_EXTERN_RIGID_TAPPING_M_NR
 - MD20096 \$MC_T_M_ADDRESS_EXT_IS_SPINO
 - MD22200 \$MC_AUXFU_M_SYNC_TYPE
 - MD22530 \$MC_TOCARR_CHANGE_M_CODE
 - MD22532 \$MC_GEOAX_CHANGE_M_CODE
 - MD22534 \$MC_TRAFO_CHANGE_M_CODE
 - MD22560 \$MC_TOOL_CHANGE_M_CODE

S functions

S (spindle function)					
Address extension			Value		
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
0 ... 20	Spindle number ⁵⁾	0 ... ± 3.4028 exp38 ³⁾	REAL	Spindle speed	3
Remarks:					
The master spindle of the channel is addressed if no an address extension is specified.					

³⁾ , ⁵⁾, ⁸⁾See "Meaning of footnotes" at the end of the overview.

Application

Spindle speed.

Further information

- S functions are assigned to auxiliary function group 3 by default.
- Without an address extension, the S functions refer to the master spindle of the channel.
- S function-specific machine data:
 - MD22210 \$MC_AUXFU_S_SYNC_TYPE (Output time of the S functions)

H functions

H (aux. function)					
Address extension		Value			
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
0 ... 99	Any	- 2147483648 ... + 2147483647	INT	Any	3
		0 ... ± 3.4028 exp38 ^{2) 3) 4)}	REAL		
Remarks: The functionality must be implemented by the user in the PLC user program.					

^{2) 3) 4) 8)} See "Meaning of footnotes" at the end of the overview.

Application

User-specific auxiliary functions.

Further information

- H function-specific machine data:
 - MD22110 \$MC_AUXFU_H_TYPE_INT (type of H-auxiliary function is an integer)
 - MD22230 \$MC_AUXFU_H_SYNC_TYPE (Output time of the H functions)

T functions

T (tool number) ^{5) 6)}					
Address extension		Value			
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
1 ... 12	Spindle number (with active tool management)	0 ... 32000 (also symbolic tool names for active tool management)	INT	Selection of the tool	1
Remarks: Tool names are not output to the PLC. ¹⁾					

^{1) 5) 6) 8)} See "Meaning of footnotes" at the end of the overview.

Application

Tool selection.

8.1 Brief description

Further information

- Identification of the tools, optionally via tool number or location number.

References:

Function Manual, Tool Management
 Function Manual, Basic Functions; Tool Offset (W1)

- When T0 is selected, the current tool is removed from the tool holder but not replaced by a new tool (default setting).
- T function-specific machine data:
 MD22220 \$MC_AUXFU_T_SYNC_TYPE (Output time of the T functions)

D functions

D (tool offset)					
Address extension			Value		
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
---	---	0 ... 9	INT	Selection of the tool offset	1
Remarks: Clearing the tool offset with D0. Default is D1.					

⁸⁾ See "Meaning of footnotes" at the end of the overview.

Application

Selection of the tool offset.

Further information

- Initial setting: D1
- After a tool change, the default tool cut can be parameterized via:
 MD20270 \$MC_CUTTING_EDGE_DEFAULT (Basic position of the tool cut without programming)
- Deselection of the tool offset: D0
- D function-specific machine data:
 MD22250 \$MC_AUXFU_D_SYNC_TYPE (Output time of the D functions)

DL functions

DL (additive tool offset)					
Address extension			Value		
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾

DL (additive tool offset)					
---	---	0 ... 6	INT	Selection of the additive tool offset	1
Remarks: The additive tool offset selected with DL refers to the active D number.					

8) See "Meaning of footnotes" at the end of the overview.

Application

Selection of the additive tool offset with reference to an active tool offset.

Further information

- Initial setting: DL = 0
- DL values cannot be output to the PLC via synchronized actions.
- Default setting of the additive tool offset without an active DL function:
MD20272 \$MC_SUMCORR_DEFAULT (basic setting of the additive offset without a program)
- Deselection of the additive tool offset: DL = 0
- DL function-specific machine data:
MD22252 \$MC_AUXFU_DL_SYNC_TYPE (output time DL functions)

F functions

F (feedrate)					
Address extension		Value			
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
---	---	0.001 ... 999 999.999	REAL	Path feed	6
Remarks: ---					

8) See "Meaning of footnotes" at the end of the overview.

Application

Path velocity.

Further information

- F function-specific machine data:
MD22240 \$MC_AUXFU_F_SYNC_TYPE (output time of F functions)

FA functions

FA (axial feedrate)	
Address extension	Value

8.1 Brief description

FA (axial feedrate)					
Value range	Meaning	Value range	Type	Meaning	Number ⁸⁾
1 - 31	Axis number	0.001 ... 999 999.999	REAL	Axial feedrate	6
Remarks: ---					

8) See "Meaning of footnotes" at the end of the overview.

Application

Axial velocity.

Further information

- F function-specific machine data:
MD22240 \$MC_AUXFU_F_SYNC_TYPE (output time of F functions)

Meaning of footnotes

- 1) If tool management is active, neither a T change signal nor a T word is output to the interface (channel).
- 2) The type for the values can be selected by the user via MD22110 \$MC_AUXFU_H_TYPE_INT.
- 3) Because of the limited display options on the operator panel screens, the REAL type values displayed are restricted to:
-999 999 999.9999 to 999 999 999.9999
The NC calculates internally but with complete accuracy.
- 4) The REAL values are rounded and output to the PLC when setting the machine data:
MD22110 \$MC_AUXFU_H_TYPE_INT = 1 (type of H-auxiliary functions is an integer)
The PLC user program must interpret the value transferred according to the machine data setting.
- 5) If the tool management is active, the meaning of the address extension can be parameterized. Address extension = 0 means the value must be replaced by that of the master spindle number, i.e. it is equivalent to not programming the address extension.
Auxiliary functions M19 "Position spindle" collected during a block search are not output to the PLC.
- 6) M6: Value range of the address extension:
- without tool management: 0 ... 99
- with tool management: 0 ... maximum spindle number
0: to be replaced by the value of the master spindle number or master tool holder
- 7) If tool management is active, the auxiliary function M6 "Tool change" can only be programmed once in a part program block, irrespective the address extensions that are programmed.
- 8) Maximum number of auxiliary functions per part program block.

8.2 Predefined auxiliary functions

Function

Every pre-defined auxiliary function is assigned to a system function and cannot be changed. If a pre-defined auxiliary function is programmed in a part program/cycle, then this is output to the PLC via the NC/PLC interface and the corresponding system function is executed in the NCK.

Definition of a predefined auxiliary function

The parameters of the predefined auxiliary function are stored in machine data and can be changed in some cases. All machine data, which are assigned to an auxiliary function, have the same index <n>.

- MD22040 \$MC_AUXFU_PREDEF_GROUP[<n>] (group assignment of predefined auxiliary functions)
- MD22050 \$MC_AUXFU_PREDEF_TYPE[<n>] (type of predefined auxiliary functions)
- MD22060 \$MC_AUXFU_PREDEF_EXTENSION[<n>] (address extension for predefined auxiliary functions)
- MD22070 \$MC_AUXFU_PREDEF_VALUE[<n>] (value of predefined auxiliary functions)
- MD22080 \$MC_AUXFU_PREDEF_SPEC[<n>] (output behavior of predefined auxiliary functions)

8.2.1 Overview: Predefined auxiliary functions

Significance of the parameters listed in the following tables:

Parameter	Meaning
Index <n>	Machine data index of the parameters of an auxiliary function
Type	MD22050 \$MC_AUXFU_PREDEF_TYPE[<n>]
Address extension	MD22060 \$MC_AUXFU_PREDEF_EXTENSION[<n>]
Value	MD22070 \$MC_AUXFU_PREDEF_VALUE[<n>]
Group	MD22040 \$MC_AUXFU_PREDEF_GROUP[<n>]

Predefined auxiliary functions

General auxiliary functions, Part 1					
System function	Index <n>	Type	Address extension	Value	Group
Stop	0	M	0	0	1

() The value can be changed.

1) The value is depends on the machine data:

MD22560 \$MC_TOOL_CHANGE_M_MODE (M function for tool change)

2) The value can be preset with a different value using the following machine data:

MD20095 \$MC_EXTERN_RIGID_TAPPING_M_NR (M function for switching over to the controlled axis mode (ext. mode))

MD20094 \$MC_SPIND_RIGID_TAPPING_M_NR (M function for switching over to controlled axis mode)

Note

The value 70 is always output to the PLC.

3) The value is set using machine data:

MD22254 \$MC_AUXFU_ASSOC_M0_VALUE (additional M function for program stop)

4) The value is set using machine data:

MD22256 \$MC_AUXFU_ASSOC_M1_VALUE (additional M function for conditional stop)

5) The value is set using machine data:

MD10714 \$MN_M_NO_FCT_EOP (M function for spindle active after reset)

6) The value is set using machine data:

MD26008 \$MC_NIBBLE_PUNCH_CODE (definition of M functions)

8.2.2 Overview: Output behavior

Significance of the parameters listed in the following table:

Parameter	Meaning
Index <n>	Machine data index of the parameters of an auxiliary function
Output behavior	MD22080 \$MC_AUXFU_PREDEF_SPEC[<n>], Bits 0 ... 18 Bits 19 ... 31: Reserved

Output behavior of the predefined auxiliary functions

System function	Index <n>																		
	Output behavior, bit

End of subroutine	24	0	0	0	(0)	0	0	0	(0)	0	0	1	0	0	0	0	0	(0)	(1)
Nibbling	25	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)
Nibbling	26	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)
Nibbling	27	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)

8.2 Predefined auxiliary functions

System function	Index <n>																			
	Output behavior, bit																			
	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Nibbling	28	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)
Nibbling	29	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)
Nibbling	30	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)
Nibbling	31	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)
Nibbling	32	0	0	0	(0)	0	0	0	(0)	(0)	(0)	(0)	(0)	(1)	(0)	0	(0)	(0)	(0)	(1)

() The value can be changed.

Significance of the bits

Bit	Meaning
0	<p>Acknowledgement "normal" after an OB1 cycle</p> <p>An auxiliary function with normal acknowledgment is output to the NC/PLC interface at the beginning of the OB1 cycle. The auxiliary function-specific change signal indicates to the PLC user program that the auxiliary function is valid.</p> <p>The auxiliary function is acknowledged as soon as organization block OB1 has run once. This corresponds to a complete PLC user cycle.</p> <p>The auxiliary function with normal acknowledgment is output in synchronism with the part program block in which it is programmed. If execution of the parts program block, e.g. path and/or positioning axis movements, is completed before acknowledgment of the auxiliary function, the block change is delayed until after acknowledgment by the PLC.</p> <p>In continuous-path mode, a constant path velocity can be maintained in conjunction with an auxiliary function with normal acknowledgment, if the auxiliary function is output by the PLC during the traversing motion and before reaching the end of the block.</p>
1	<p>Acknowledgement "quick" with OB40</p> <p>An auxiliary function with quick acknowledgment is output to the NC/PLC interface before the next OB1 cycle. The auxiliary function-specific change signal indicates to the PLC user program that the auxiliary function is valid.</p> <p>The auxiliary function is acknowledged immediately by the PLC basic program in the next OB40 cycle.</p> <p>Acknowledgment of the auxiliary function is not confirmation that the corresponding PLC user function has been executed. The auxiliary function is still executed in the OB1 cycle. Next output of the auxiliary functions to the PLC is therefore not possible until after this OB1 cycle has run completely. This is noticeable in continuous-path mode (drop in path velocity) especially if auxiliary functions with quick acknowledgment are output in several consecutive part program blocks.</p> <p>With auxiliary functions with quick acknowledgment, it cannot be guaranteed that the PLC user program will respond in synchronism with the block.</p> <p>Note Parameterization of the output behavior of auxiliary functions as "quick auxiliary functions" is only possible in conjunction with user-defined auxiliary functions.</p>

Bit	Meaning
2	No predefined auxiliary function A predefined auxiliary function is treated like a user-defined auxiliary function with this setting. The auxiliary function then no longer triggers the corresponding system function but is only output to the PLC. Example: Reconfiguration of the "Position spindle" auxiliary function (index 9) to a user-defined auxiliary function with normal acknowledgment and output prior to the traversing motion. MD22080 \$MC_AUXFU_PREDEF_SPEC [9] = 'H25' (100101B)
3	No output to the PLC The auxiliary function is not output to the PLC.
4	Spindle response after acknowledgement by the PLC The associated system function is only executed after acknowledgment by the PLC.
5	Output prior to motion The auxiliary function is output to the PLC before the traversing motions programmed in the part program block (path and/or block-related positioning axis movements).
6	Output during motion The auxiliary function is output to the PLC during the traversing motions programmed in the part program block (path and/or block-related positioning axis movements).
7	Output at block end The auxiliary function is output to the PLC after the traversing motions programmed in the part program block have been completed (path and/or block-related positioning axis movements).
8	Not output after block search, types 1, 2, 4 Block search, types 1, 2, 4: The auxiliary function collected during the block search is not output.
9	Collection during block search with program test (type 5, SERUPRO) For a block search with program test, the auxiliary function is collected group-specific in the following system variables: <ul style="list-style-type: none"> • \$AC_AUXFU_M_VALUE[<n>] • \$AC_AUXFU_M_EXT[<n>] • \$AC_AUXFU_M_STATE[<n>]
10	No output during block search with program test (type 5, SERUPRO) For block search with program test, the auxiliary function is not output to the PLC.
11	Cross-channel auxiliary function (SERUPRO) For block search with program test (SERUPRO), the help function is collected on a cross-channel basis in the global list of the auxiliary functions. Note For each auxiliary function group, only the last auxiliary function of the group is always collected.
12	Output performed via synchronized action (read only) The bit is set if the auxiliary function was output to the PLC via a synchronized action.
13	Implicit auxiliary function (read-only) The bit is set if the auxiliary function was implicitly output to the PLC.
14	Active M01 (read only) The bit is set if the auxiliary function, for active M01, was output to the PLC.
15	No output during positioning test run During the run-in test, the auxiliary function is not output to the PLC.
16	Nibbling off

Bit	Meaning
17	Nibbling on
18	Nibbling

Note

In the case of auxiliary functions for which no output behavior has been defined, the following default output behavior is active:

- Bit 0 = 1: Output duration one OB1 cycle
 - Bit 7 = 1: Output at block end
-

8.2.3 Parameter assignment

8.2.3.1 Group assignment

The handling of the auxiliary functions for a block search is defined using the group assignment of an auxiliary function. The 168 auxiliary function groups available are subdivided into predefined and user-definable groups:

Predefined groups: 1 ... 4 10 ... 12 72 ... 168
User-defined groups: 5 ... 9 13 ... 71

Each predefined auxiliary function is assigned, as standard, to an auxiliary function group. For most pre-defined auxiliary functions, this assignment can be changed using the following machine data:

MD22040 \$MC_AUXFU_PREDEF_GROUP[<n>] (group assignment of predefined auxiliary functions)

If an auxiliary function is not assigned to any group, then a value of "0" should be entered into the machine data.

For the pre-defined auxiliary functions with the following indices <n>, the group assignment cannot be changed: 0, 1, 2, 3, 4, 22, 23, 24

Note

1st auxiliary function group and block search

Auxiliary functions of the 1st auxiliary function group are, for a block search, only collected, but not output.

8.2.3.2 Type, address extension and value

An auxiliary function is programmed via the type, address extension, and value parameters (see "Programming an auxiliary function (Page 436)").

Type

The identifier of an auxiliary function is defined via the "type," e.g.:

"M"	For additional function
"S"	for spindle function
"F"	for feed

The setting is done via the following machine data:

MD22050 \$MC_AUXFU_PREDEF_TYPE[<n>] (type of predefined auxiliary functions)

Note

The "type" cannot be changed for predefined auxiliary functions.

Address extension

The "address extension" of an auxiliary function is for addressing different components of the same type. In the case of predefined auxiliary functions, the value of the "address extension" is the spindle number to which the auxiliary function applies.

The setting is done via the following machine data:

MD22060 \$MC_AUXFU_PREDEF_EXTENSION[<n>] (address extension for predefined auxiliary functions)

Grouping together auxiliary functions

To assign an auxiliary function for all spindles of a channel to the same auxiliary function group, the value "-1" is entered for the "address extension" parameter.

Example:

The auxiliary function M3 (machine data index = 6) is assigned to the second auxiliary function group for all the channel's spindles.

```
MD22040 $MC_AUXFU_PREDEF_GROUP[ 6 ]      = 2
MD22050 $MC_AUXFU_PREDEF_TYPE[ 6 ]       = "M"
MD22060 $MC_AUXFU_PREDEF_EXTENSION[ 6 ]   = -1
MD22070 $MC_AUXFU_PREDEF_VALUE[ 6 ]      = 3
```

Value

The parameters "value" and "type" define the meaning of an auxiliary function, i.e. the system function that is activated on the basis of this auxiliary function.

The "value" of an auxiliary function is defined in the machine data:

MD22070 \$MC_AUXFU_PREDEF_VALUE[<n>] (value of predefined auxiliary functions)

Note

The "value" cannot be changed for a predefined auxiliary function. For some predefined auxiliary functions, the "value" can be reconfigured via additional machine data (see "Associated auxiliary functions (Page 431)").

8.2.3.3 Output behavior

Parameter "Output behavior" defines when the predefined auxiliary function is output to the NC/PLC interface and when it is acknowledged by the PLC.

The setting is done via the following machine data:

MD22080 \$MC_AUXFU_PREDEF_SPEC[<n>] (output behavior of predefined auxiliary functions)

Output behavior relative to motion

Output prior to motion

- The traversing motions (path and/or block-related positioning axis movements) of the previous part program block end with an exact stop.
- The auxiliary functions are output at the beginning of the current parts program block.
- The traversing motion of the actual part program block (path and/or positioning axis motion) is only started after acknowledgment of the auxiliary functions by the PLC:
 - Output duration one OB1 cycle (normal acknowledgment): after one OB1 cycle
 - Output duration one OB40 cycle (quick acknowledgment): after one OB40 cycle

Output during motion

- The auxiliary functions are output at the beginning of the traversing motions (path and/or positioning axis movements).
- The path velocity of the current parts program block is reduced so that the time to the end of the block is greater than the time to acknowledgment of the auxiliary functions by the PLC.
 - Output duration one OB1 cycle (normal acknowledgment): one OB1 cycle
 - Output duration one OB40 cycle (quick acknowledgment): one OB40 cycle

Output after motion

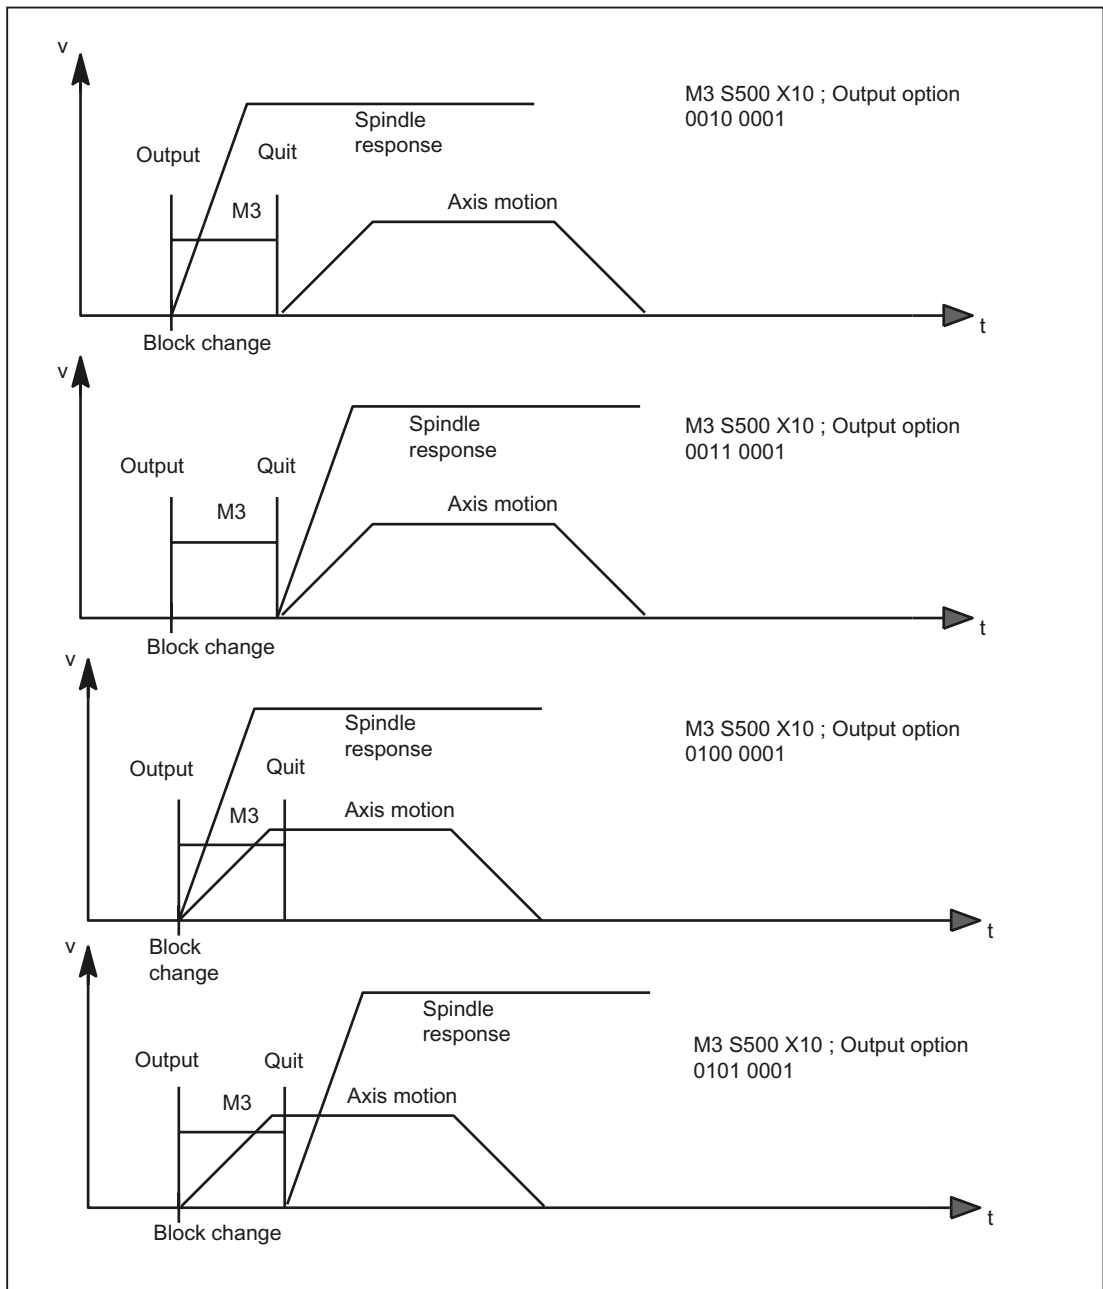

- The traversing motions (path and/or block-related positioning axis movements) of the current part program block end with an exact stop.
- The auxiliary functions are output after completion of the traversing motions.
- The block change is performed after acknowledgment of the auxiliary functions by the PLC:
 - Output duration one OB1 cycle (normal acknowledgment): after one OB1 cycle
 - Output duration one OB40 cycle (quick acknowledgment): after one OB40 cycle

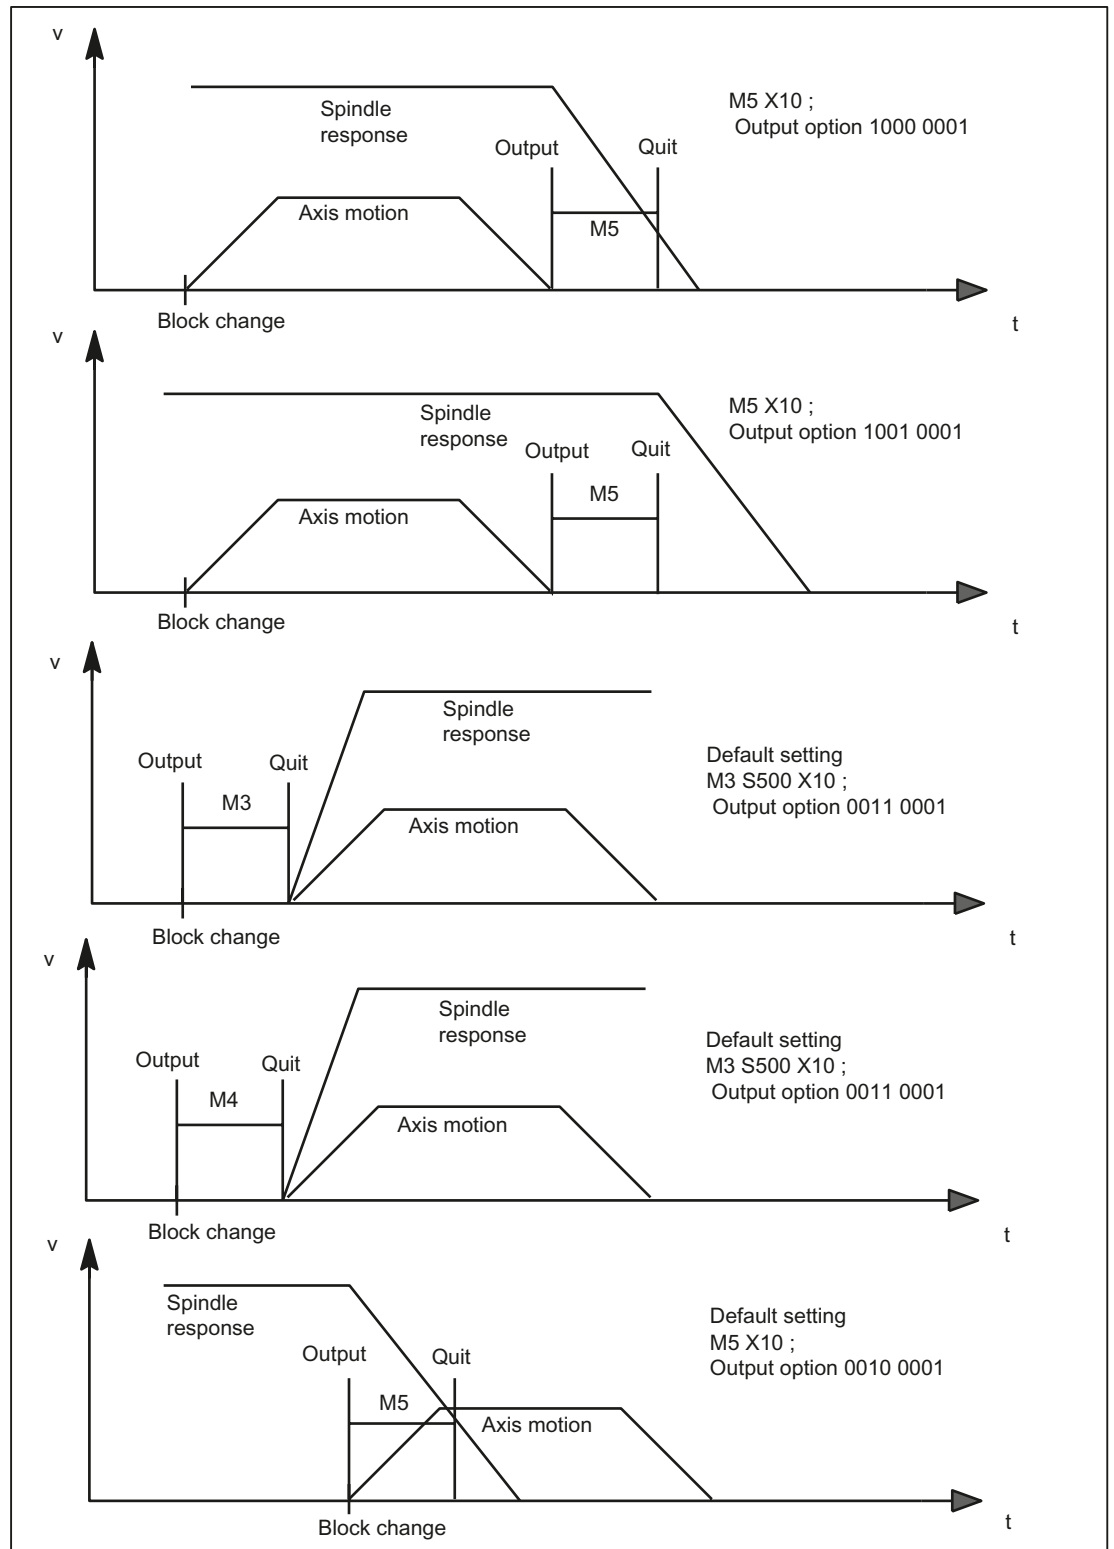

Examples of different output behavior

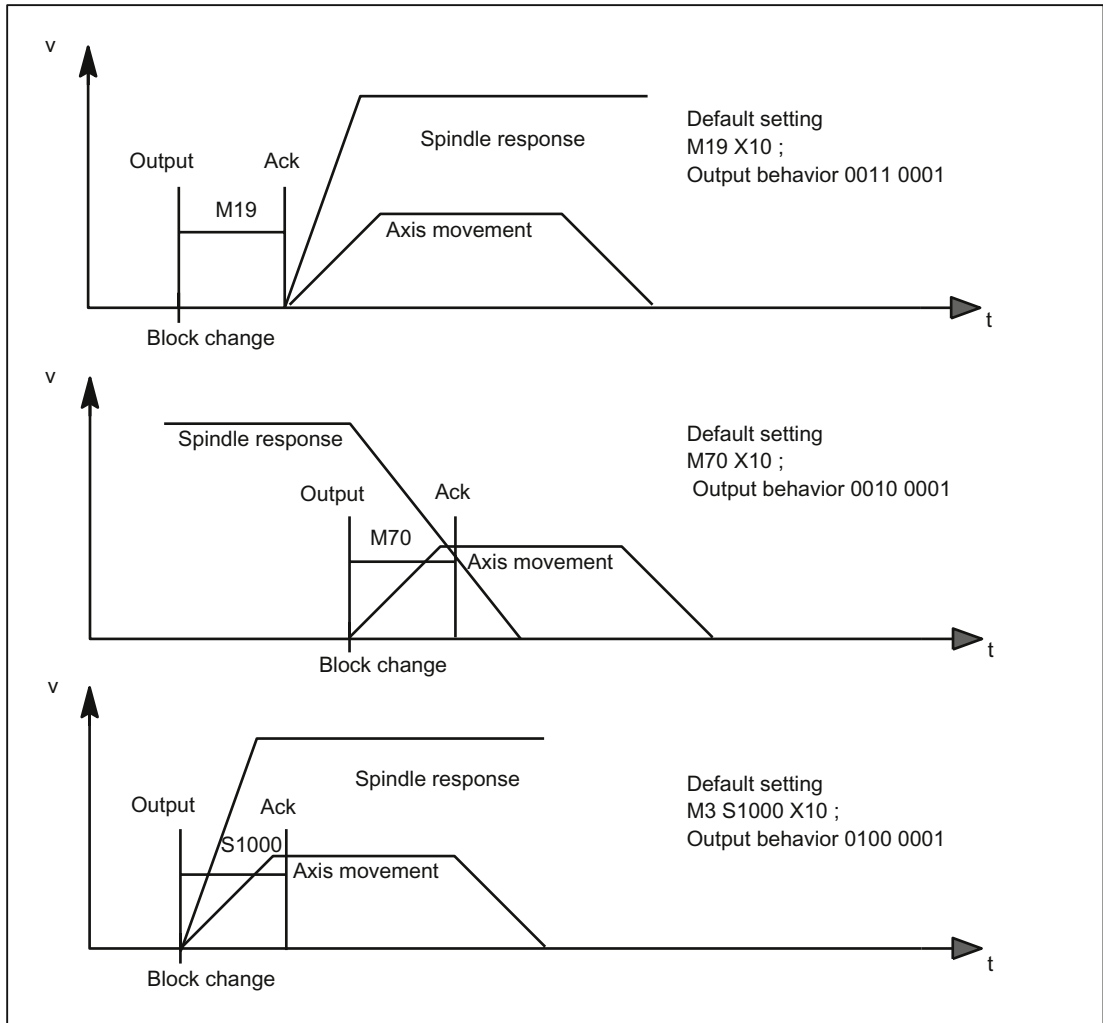

The following figures illustrate the differing behavior regarding:

- Output and acknowledgment of the auxiliary function
- Spindle response (speed change)
- Traverse movement (velocity change)

The binary values specified in the diagrams under "Output behavior" refer to the parameterized output behavior (MD22080).

8.3 User-defined auxiliary functions

There are two uses for user-defined auxiliary functions:

- Extension of predefined auxiliary functions
- User-specific auxiliary functions

Extension of predefined auxiliary functions

Because there is only one set of machine data for the predefined auxiliary functions, they can only ever be used to address one spindle of the channel. To address further spindles, user-defined auxiliary functions must be parameterized to supplement the predefined auxiliary functions.

Extension of predefined auxiliary functions refers to the "address extensions" parameter. The number of the spindle that the auxiliary function refers to is entered in the "address extension" parameter.

The relevant predefined auxiliary functions can be extended for the following system functions:

System function	Type		
		Address extension ¹⁾	
			Value
Tool change	M	1	6
Spindle right	M	1	3
Spindle left	M	1	4
Spindle stop	M	1	5
Position spindle	M	1	19
Axis mode	M	1	70
Automatic gear stage	M	1	40
Gear stage 1	M	1	41
Gear stage 2	M	1	42
Gear stage 3	M	1	43
Gear stage 4	M	1	44
Gear stage 5	M	1	45
Spindle speed	S	1	-1
Tool selection	T	1	-1

¹⁾ Address extension = 1 is the default value used in the auxiliary functions predefined in the machine data

Example:

Extension of the predefined auxiliary function for the system function "spindle right" for the second and third spindle of the channel.

Auxiliary function "spindle right" for the second spindle of the channel:

MD22010 \$MC_AUXFU_ASSIGN_TYPE[n] = "M"
MD22020 \$MC_AUXFU_ASSIGN_EXTENSION[n] = 2
MD22030 \$MC_AUXFU_ASSIGN_VALUE[n] = 3

Auxiliary function "spindle right" for the third spindle of the channel:

MD22010 \$MC_AUXFU_ASSIGN_TYPE[m] = "M"
MD22020 \$MC_AUXFU_ASSIGN_EXTENSION[m] = 3
MD22030 \$MC_AUXFU_ASSIGN_VALUE[m] = 3

User-specific auxiliary functions

User-specific auxiliary functions have the following characteristics:

- User-specific auxiliary functions only activate user functions.
- No system functions can be activated by user-specific auxiliary functions.
- A user-specific auxiliary function is output to the PLC according to the parameterized output behavior.
- The functionality of a user-specific auxiliary function is implemented by the machine manufacturer/user in the PLC user program.

8.3.1 Parameter assignment

8.3.1.1 Maximum number of user-defined auxiliary functions

The maximum number of user-defined auxiliary function per channel can be parameterized via the machine data:

MD11100 \$MN_AUXFU_MAXNUM_GROUP_ASSIGN (maximum number of user-defined auxiliary functions)

8.3.1.2 Group assignment

The handling of the auxiliary functions for a block search is defined using the group assignment of an auxiliary function. The 168 auxiliary function groups available are subdivided into predefined and user-definable groups:

Predefined groups:	1 ... 4	10 ... 12	72 ... 168
User-defined groups:		5 ... 9	13 ... 71

Every user-defined auxiliary function is assigned as standard to the 1st auxiliary function group. The assignment can be changed using the following machine data:

MD22000 \$MC_AUXFU_ASSIGN_GROUP[<n>] (group assignment of user-defined auxiliary functions)

If an auxiliary function is not assigned to any group, then a value of "0" should be entered into the machine data.

Note

1st auxiliary function group and block search

Auxiliary functions of the 1st auxiliary function group are, for a block search, only collected, but not output.

8.3.1.3 Type, address extension and value

An auxiliary function is programmed via the type, address extension, and value parameters (see "Programming an auxiliary function (Page 436)").

Type

The name of an auxiliary function is defined via the "type".

The identifiers for user-defined auxiliary functions are:

Type	Identifier	Meaning
"H"	Auxiliary function	User-specific auxiliary functions
"M"	Special function	Extension of predefined auxiliary functions
"S"	Spindle function	
"T"	Tool number	

The setting is done via the following machine data:

MD22010 \$MC_AUXFU_ASSIGN_TYPE[<n>] (type of user-defined auxiliary functions)

Address extension

MD22020 \$MC_AUXFU_ASSIGN_EXTENSION[<n>] (address extension user-defined auxiliary functions)

The functionality of the address extension is not defined in user-specific auxiliary functions. It is generally used to distinguish between auxiliary functions with the same "value".

Grouping together auxiliary functions

If all the auxiliary functions of the same type and value are assigned to the same auxiliary function group, a value of "-1" must be entered for the "address extension" parameter.

Example:

All user-specific auxiliary functions with the value "= 8" are assigned to the tenth auxiliary function group.

MD22000 \$MC_AUXFU_ASSIGN_GROUP [1]	= 10
MD22010 \$MC_AUXFU_ASSIGN_TYPE [1]	= "H"
MD22020 \$MC_AUXFU_ASSIGN_EXTENSION [1]	= -1
MD22030 \$MC_AUXFU_ASSIGN_VALUE [1]	= 8

Value

MD22030 \$MC_AUXFU_ASSIGN_VALUE[<n>] (value of user-defined auxiliary functions)

The functionality of the "value" parameter is not defined in user-specific auxiliary functions. The value is generally used to activate the corresponding PLC user function.

Grouping together auxiliary functions

If all the auxiliary functions of the same type and address extension are assigned to the same auxiliary function group, a value of "-1" must be entered for the "value" parameter.

Example:

All user-specific auxiliary functions with the address extension "= 2" are assigned to the eleventh auxiliary function group.

MD22000 \$MC_AUXFU_ASSIGN_GROUP [2]	= 11
MD22010 \$MC_AUXFU_ASSIGN_TYPE[2]	= "H"
MD22020 \$MC_AUXFU_ASSIGN_EXTENSION[2]	= 2
MD22030 \$MC_AUXFU_ASSIGN_VALUE[2]	= -1

8.3.1.4 Output behavior

The "output behavior" of user-defined auxiliary functions can be parameterized via the machine data:

MD22035 \$MC_AUXFU_ASSIGN_SPEC[<n>] (output behavior of user-defined auxiliary functions)

For a description of the individual output parameters, see the "Output behavior (Page 422)" section of the predefined auxiliary functions. The information given there can be applied analogously to the output behavior of user-defined auxiliary functions.

8.4 Associated auxiliary functions

Function

Associated auxiliary functions are user-defined auxiliary functions that have the same effect as the corresponding predefined auxiliary functions. User-defined auxiliary functions can be associated for the following predefined auxiliary functions:

- M0 (stop)
- M1 (conditional stop)

Requirements

The precondition for association of a user-defined auxiliary function with one of the predefined auxiliary functions mentioned is parameterization of a user-defined auxiliary function. Only "M" is allowed as a "type" parameter of the user-defined auxiliary function.

Parameter assignment

Association of a user-defined auxiliary function with one of the predefined auxiliary functions mentioned is set in the machine data:

MD22254 \$MC_AUXFU_ASSOC_M0_VALUE (additional M function for program stop)

MD22256 \$MC_AUXFU_ASSOC_M1_VALUE (additional M function for conditional stop)

Group assignment

The group assignment of an associated user-defined auxiliary function is always the group assignment of the corresponding predefined auxiliary function.

Application

Associated auxiliary functions can be used in:

- Main program
- Subroutine
- Cycle

Note

Associated auxiliary functions may not be used in synchronized actions.

NC/PLC interface signals

In the case of an associated user-defined auxiliary function, the same signals are output to the NC/PLC interface as for the corresponding predefined auxiliary function. To distinguish which auxiliary function has actually been programmed, the value of the user-defined auxiliary function ("value" parameter) is output as the value of the auxiliary function. This means it is possible to distinguish between predefined and user-defined auxiliary functions in the PLC user program.

Note

A change in machine data MD22254 and/or MD22256 may require corresponding adjustment of the PLC user program:

Specific NC/PLC interface signals

The following specific NC/PLC interface signals are available:

- DB21, ... DBX318.5 (associated M00/M01 active) feedback signal
- DB21, ... DBX30.5 (activate associated M01) activation signal

Boundary conditions

Please note the following boundary conditions:

- A user-defined auxiliary function may not be multiply associated.
- Predefined auxiliary functions (e.g. M3, M4, M5 etc.) may not be associated.

Example

Associating the user-defined auxiliary function M123 with M0:

```
MD22254 $MC_AUXFU_ASSOC_M0_VALUE = 123
```

The user-defined auxiliary function M123 thus has the same functionality as M0.

8.5 Type-specific output behavior

Function

The output behavior of auxiliary functions relative to a traversing motions programmed in the parts program block can be defined type-specifically.

Parameter assignment

Parameters are assigned to type-specific output behavior via the machine data:

MD22200 \$MC_AUXFU_M_SYNC_TYPE (output time for M functions)

MD22210 \$MC_AUXFU_S_SYNC_TYPE (output time for S functions)

MD22220 \$MC_AUXFU_T_SYNC_TYPE (output time for T functions)

MD22230 \$MC_AUXFU_H_SYNC_TYPE (output time for H functions)

MD22240 \$MC_AUXFU_F_SYNC_TYPE (output time for F functions)

MD22250 \$MC_AUXFU_D_SYNC_TYPE (output time for D functions)

MD22252 \$MC_AUXFU_DL_SYNC_TYPE (output time for DL functions)

The following output behaviors can be parameterized:

MD \$MC_AUXFU_XX_SYNC_TYPE = <value>

Value	Output behavior
0	Output prior to motion
1	Output during motion
2	Output at block end
3	No output to the PLC
4	Output according to the output behavior defined with MD22080

For a description of the various output behaviors, see the section titled "Output behavior (Page 422)".

Note

For the output behavior that can be set for each type of auxiliary function, please refer to the "Detailed Description of Machine Data" List Manual.

Example

Output of auxiliary functions with different output behaviors in a part program block with traverse movement.

Output behavior for which parameters have been assigned:

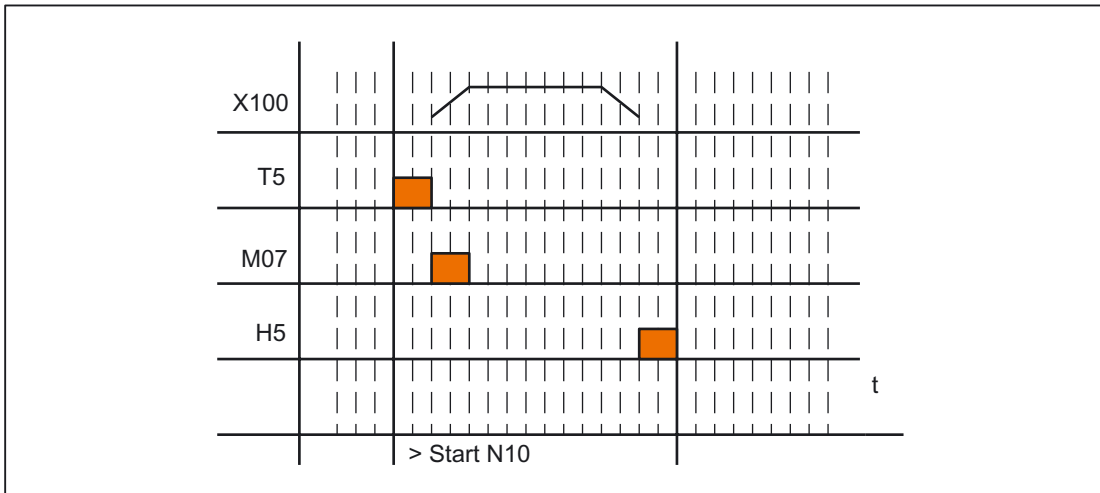

- MD22200 \$MC_AUXFU_M_SYNC_TYPE = 1 ⇒ M function:
Output **during** motion
- MD22220 \$MC_AUXFU_T_SYNC_TYPE = 0 ⇒ T function:
Output **prior to** motion
- MD22230 \$MC_AUXFU_H_SYNC_TYPE = 2 ⇒ H function:
Output **at the end of the block**

Parts program block:

```

Program code
...
N10 G01 X100 M07 H5 T5
...
    
```

Time sequence for auxiliary function output:

8.6 Priorities of the output behavior for which parameters have been assigned

The following priorities must be observed for the following areas in connection with the parameterized output behavior of an auxiliary function:

- Output duration (normal / quick acknowledgment)
- Output relative to motion (prior to / during / after the motion)

As a general rule, the parameterized output behavior with lower priority becomes active if no output behavior with higher priority has been parameterized.

Output duration

The following priorities apply to the output duration:

Priority	Output behavior	Defined via:
Highest	auxiliary function-specific	Part program instruction: QU(...) (see "Programmable output duration (Page 438)")
↓	Auxiliary function-specific	MD22035 \$MC_AUXFU_ASSIGN_SYNC[<n>] MD22080 \$MC_AUXFU_PREDEF_SYNC[<n>]
↓	Group-specific	MD11110 \$MC_AUXFU_GROUP_SPEC[<n>]
Lowest	Not defined	Default output behavior: Output duration one OB1 cycle

Output relative to motion

The following rules apply to output relative to motion:

Priority	Output behavior	Defined via:
Highest	Auxiliary function-specific	MD22035 \$MC_AUXFU_ASSIGN_SYNC[<n>] MD22080 \$MC_AUXFU_PREDEF_SYNC[<n>]
↓	Group-specific	MD11110 \$MC_AUXFU_GROUP_SPEC[<n>]
↓	Type-specific	MD22200 \$MC_AUXFU_M_SYNC_TYPE MD22210 \$MC_AUXFU_S_SYNC_TYPE MD22220 \$MC_AUXFU_T_SYNC_TYPE MD22230 \$MC_AUXFU_H_SYNC_TYPE MD22240 \$MC_AUXFU_F_SYNC_TYPE MD22250 \$MC_AUXFU_D_SYNC_TYPE MD22252 \$MC_AUXFU_DL_SYNC_TYPE
Lowest	Not defined	Default output behavior: Output at block end

Note

Parts program blocks without path motion

In a part program block without a path motion (even those with positioning axes and spindles), the auxiliary functions are all output immediately in a block.

8.7 Programming an auxiliary function

Syntax

An auxiliary function is programmed in a part program block with the following syntax:
<Type> [<Address extension>=] <Value>

Note

If no address extension is programmed, the address extension is implicitly set = 0.

Predefined auxiliary functions with the address extension = 0 always refer to the master spindle of the channel.

Symbolic addressing

The values for the "address extension" and "value" parameters can also be specified symbolically. The symbolic name for the address extension must then be stated in brackets.

Example:

Symbolic programming of the auxiliary function M3 (spindle right) for the first spindle:

Program code	Comment
DEF SPINDEL_NR=1	; First spindle in the channel
DEF DREHRICHTUNG=3	; Clockwise direction of rotation
N100 M[SPINDEL_NR] = DREHRICHTUNG	; corresponding to: M1=3

Note

If you use symbolic names to program an auxiliary function, the symbolic name is not transferred when the auxiliary function is output to the PLC. The corresponding numerical value is transferred instead.

Examples

Example 1: Programming of predefined auxiliary functions

Program code	Comment
N10 M3	; "Spindle right" for the master spindle of the channel.
N20 M0=3	; "Spindle right" for the master spindle of the channel.
N30 M1=3	; "Spindle right" for the 1st spindle of the channel.
N40 M2=3	; "Spindle right" for the 2nd spindle of the channel.

Example 2: Programming examples of auxiliary functions with the corresponding values for output to the PLC

Program code	Comment
DEF Coolant=12	; Output to PLC: - - -
DEF Lubricant=130	; Output to PLC: - - -
H[coolant]=lubricant	; Output to PLC: H12=130
H=coolant	; Output to PLC: H0=12
H5	; Output to PLC: H0=5
H=5.379	; Output to PLC: H0=5.379
H17=3.5	; Output to PLC: H17=3.5
H[coolant]=13.8	; Output to PLC: H12=13.8
H='HFF13'	; Output to PLC: H0=65299
H='B1110'	; Output to PLC: H0=14
H5.3=21	; Error

8.8 Programmable output duration

Function

User-specific auxiliary functions, for which the output behavior "Output duration of an OB1 cycle (slow acknowledgement)" was parameterized, can be defined for individual outputs via the parts program guide *QU* (Quick) for auxiliary functions with quick acknowledgement.

Syntax

An auxiliary function with quick acknowledgment is defined in a part program block with the following syntax:

```
<Type>[<Address extension>]=QU(<Value>)
```

Example

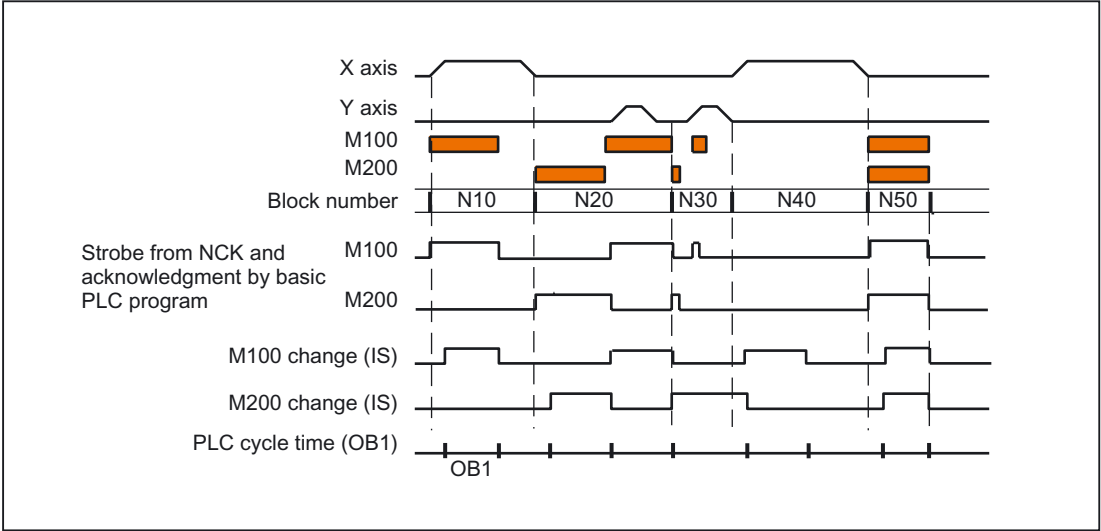

Different behavior for the output of the auxiliary functions M100 and M200 in a parts program. The output behavior of the auxiliary functions is parameterized as follows:

- M100
 - Output duration one OB1 cycle (slow acknowledgment)
 - Output during motion
- M200
 - Output duration one OB1 cycle (slow acknowledgment)
 - Output prior to motion

Program code	Comment
N10 G94 G01 X50 M100	; Output of M100: during the motion ; Acknowledgment: slow
N20 Y5 M100 M200	; Output of M200: prior to the motion ; Output of M100: during the motion ; Acknowledgment: slow
N30 Y0 M=QU(100) M=QU(200)	; Output of M200: prior to the motion ; Output of M100: during the motion ; Acknowledgement: quick
N40 X0	
N50 M100 M200	; Output of M200: immediate 1) ; Output of M100: immediate 1) ; Acknowledgment: slow
M17	

1) Without a traverse movement, auxiliary functions are always output to the PLC immediately.

The following figure shows the time sequence of the part program. Please note the time difference during the processing of parts program blocks N20 and N30.

8.9 Auxiliary function output to the PLC

Function

On output of an auxiliary function to the PLC, the following signals and values are passed to the NC/PLC interface:

- change signals
- "Address extension" parameter
- "Value" parameter

Data areas in the NC/PLC interface

The change signals and values of the auxiliary functions are within the following data areas in the NC/PLC interface:

- Change signals for auxiliary function transfer from NC channel:
DB21, ... DBB58 - DBB67
- Transferred M and S functions:
DB21, ... DBB68 - DBB112
- Transferred T, D and DL functions:
DB21, ... DBB116 - DBB136
- Transferred H and F functions:
DB21, ... DBB140 - DBB190
- Decoded M signals (M0 - M99):
DB21, ... DBB194 - DBB206 (dynamic M functions)

References

- A detailed description of the above data areas in the NC/PLC interface can be found in:
List Manual, Lists, Book 2; chapter: "Signals from/to NCK channel (DB 21 – DB 30)"
- The access methods for the NC/PLC interface are described in:
Function Manual, Basic Functions, Basic PLC Program (P3)

8.10 Auxiliary functions without block change delay

Function

For auxiliary functions with parameterized and/or programmed output behavior, too:

- "Output duration one OB40 cycle (quick acknowledgment)"
- "Output before the motion" or "Output during the motion"

there may be drops in velocity in continuous-path mode (short traverse paths and high velocities). This the system has to wait for acknowledgment of the auxiliary function by the PLC toward the end of the block. To avoid these velocity drops, the block change can be made irrespective of whether such auxiliary functions have been acknowledged:

Parameter assignment

Suppression of the block change delay with quick auxiliary functions is set via the machine data:

MD22100 \$MC_AUXFU_QUICK_BLOCKCHANGE (block change delay with quick auxiliary functions)

Value	Meaning
0	In the case of quick auxiliary function output to the PLC, the block change is delayed until acknowledgment by the PLC (OB40).
1	In the case of quick auxiliary function output to the PLC, the block change is not delayed.

Boundary conditions

Synchronism of auxiliary functions that are output without a block change delay is no longer ensured for the part program block in which they are programmed. In the worst case scenario, acknowledgment comes one OB40 cycle and execution of the auxiliary function comes one OB1 cycle after the change to the next part program block.

8.11 M function with an implicit preprocessing stop

Function

Triggering a preprocessing stop in conjunction with an auxiliary function can be programmed explicitly via the `STOPRE` part program command. Always triggering a preprocessing stop in M function programming can be parameterized for each M function via the following machine data:

MD10713 \$MN_M_NO_FCT_STOPRE[<n>] (M function with preprocessing stop)

Example

The user-defined M function M88 is intended to trigger a preprocessing stop.

Parameter assignment:

MD10713 \$MN_M_NO_FCT_STOPRE [0] = 88

Application:

Parts program (extract)

Program code	Comment
...	
N100 G0 X10 M88	; Traversing motion and implicit preprocessing stop via M88
N110 Y=R1	; N110 is only interpreted after the traversing motion has been completed and the M function has been acknowledged.
...	

Boundary conditions

If a subroutine called indirectly via an M function in a part program in one of the following ways, no preprocessing stop is performed:

- MD10715 \$MN_M_NO_FCT_CYCLE (M function to be replaced by subroutine)
- M98 (ISO dialect T / ISO dialect M)

8.12 Response to overstore

Overstore

On the SINUMERIK operator interface, before starting the following functions:

- NC START of a part program
- NC START to resume an interrupted part program

the auxiliary functions that are output at the start can be changed by the "Overstore" function.

Possible applications include:

- Addition of auxiliary functions after block search
- Restoring the initial state to position a part program

Types of auxiliary functions that can be overstored

The following types of auxiliary functions can be overstored:

- M (special function)
- S (spindle speed)
- T (tool number)
- H (aux. function)
- D (tool offset number)
- DL (additive tool offset)
- F (feed)

Duration of validity

An overstored auxiliary function, e.g. M3 (spindle right), is valid until it is overwritten by another auxiliary function from the same auxiliary function group, by additional overstoreing or by programming in a part program block.

8.13 Block-search response

8.13.1 Auxiliary function output during type 1, 2, and 4 block searches

Output behavior

In the case of type 1, 2, and 4 block searches, the auxiliary functions are collected on the basis of specific groups. The last auxiliary function in each auxiliary function group is output after NC-START in a separate part program block before the actual reentry block, and has the following output behavior:

- Output duration of one OB1 cycle (normal acknowledgment)
- Output prior to motion

Output control

Whether or not the auxiliary function is output to the PLC after a block search can be configured via bit 8 of the machine data:

- MD22080 \$MC_AUXFU_PREDEF_SPEC[<n>]
(output behavior of predefined auxiliary functions)
where <n> = system function index (0 ... 32)
- MD22035 \$MC_AUXFU_ASSIGN_SPEC[<n>]
(output behavior of user-defined auxiliary functions)
where <n> = auxiliary function index (0 ... 254)
- MD11110 \$MN_AUXFU_GROUP_SPEC[<n>]
(output behavior of the auxiliary functions in a group)
where <n> = group index (0 ... 63)

Bit	Value	Meaning
10	0	Output during type 1, 2, and 4 block searches
	1	No output during type 1, 2, and 4 block searches

This behavior does not affect the display and does not affect variables \$AC_AUXFU_STATE[<n>], \$AC_AUXFU_VALUE[<n>], and \$AC_AUXFU_EXT[<n>]. The auxiliary functions are always regarded as collected after a block search, even though they are not output to the PLC.

During collection, an auxiliary function that is not output after a block search also overwrites an auxiliary function whose bit 8 is not set.

The user can scan the collected auxiliary functions after a block search and, under certain circumstances, output them again by means of the subprogram or synchronous actions.

Note

The following auxiliary functions are not collected:

- Auxiliary functions which are not assigned to any auxiliary function group.
 - Auxiliary functions which are assigned to the first auxiliary function group.
-

Overstorage of auxiliary functions

After completion of a block search, the collected auxiliary functions are output on the next NC-START. If it is necessary to output additional auxiliary functions, they can be added via the "Overstore" function (see "Response to overstore (Page 443)").

M19 behavior (position spindle)

After a block search, the last spindle positioning command programmed with M19 is always carried out, even if other spindle-specific auxiliary functions are programmed between the part program with M19 and the target block. Setting the necessary spindle enables must therefore be derived from the interface signals of the traverse commands in the PLC user program:

DB31, ... DBX64.6 / 64.7 (traverse command minus / plus)

In this case, the spindle-specific auxiliary functions M3, M4, and M5 are not suitable because they might not be output to the PLC until after the spindle positioning.

References

For detailed information on the block search, please refer to:

Function Manual, Basic Functions, Mode Group, Channel, Program Operation, Reset Behavior (K1)

8.13.2 Assignment of an auxiliary function to a number of groups

Function

User-defined auxiliary functions can also be assigned to multiple groups via the group assignment (MD22000 \$MC_AUXFU_ASSIGN_GROUP). During the block search these auxiliary functions are collected for all the configured groups.

Note

Predefined auxiliary functions can only be assigned to one group.

Example

The DIN includes the following M-commands for coolant output:

- M7: Coolant 2 ON
- M8: Coolant 1 ON
- M9: Coolants 1 and 2 OFF

Consequently, both coolants can also be active together:

- If M7 and M8 are collected in two separate groups (e.g., groups 5 and 6)
- If M9 has to be assigned to these two groups, e.g.:
 - Group 5: M7, M9
 - Group 6: M8, M9

Parameter assignment:

```
MD11100 $MN_AUXFU_MAXNUM_GROUP_ASSIGN = 4
MD22000 $MC_AUXFU_ASSIGN_GROUP[0] = 5
MD22000 $MC_AUXFU_ASSIGN_GROUP [1] = 5
MD22000 $MC_AUXFU_ASSIGN_GROUP [2] = 6
MD22000 $MC_AUXFU_ASSIGN_GROUP [3] = 6
MD22010 $MC_AUXFU_ASSIGN_TYPE [0] = M
MD22010 $MC_AUXFU_ASSIGN_TYPE [1] = M
MD22010 $MC_AUXFU_ASSIGN_TYPE [2] = M
MD22010 $MC_AUXFU_ASSIGN_TYPE [3] = M
MD22020 $MC_AUXFU_ASSIGN_EXTENSION[0] = 0
MD22020 $MC_AUXFU_ASSIGN_EXTENSION[1] = 0
MD22020 $MC_AUXFU_ASSIGN_EXTENSION[2] = 0
MD22020 $MC_AUXFU_ASSIGN_EXTENSION[3] = 0
MD22030 $MC_AUXFU_ASSIGN_VALUE[0] = 7
```

```
MD22030 $MC_AUXFU_ASSIGN_VALUE[1] = 9
MD22030 $MC_AUXFU_ASSIGN_VALUE[2] = 8
MD22030 $MC_AUXFU_ASSIGN_VALUE [3] = 9
MD22035 $MC_AUXFU_ASSIGN_SPEC [0] = 'H121'
MD22035 $MC_AUXFU_ASSIGN_SPEC [1] = 'H121'
MD22035 $MC_AUXFU_ASSIGN_SPEC [2] = 'H121'
MD22035 $MC_AUXFU_ASSIGN_SPEC [3] = 'H121'
```

Part program (section):

```
Program code
-----
...
N10 ... M8
N20 ... M9
N30 ... M7
...
```

During the block search, the auxiliary function M9 is collected for groups 5 and 6.

Scan of the collected M auxiliary functions:

M function of the fifth group: \$AC_AUXFU_M_VALUE [4] = 7

M function of the sixth group: \$AC_AUXFU_M_VALUE [5] = 9

8.13.3 Time stamp of the active M auxiliary function

When outputting collected auxiliary functions following a block search, attention must be paid to the sequence during collecting. For this reason, each group is assigned a time stamp which can be queried on a group-specific basis by way of the system variable below:

\$AC_AUXFU_M_TICK[<n>] (time stamp of the active M auxiliary function)

8.13.4 Determining the output sequence

Function

The following predefined procedure is provided to simplify the process of determining the output sequence of M auxiliary functions for the programmer:

```
AUXFUMSEQ(VAR INT _NUM_IN, VAR INT _M_IN[], VAR INT _EXT_IN[], VAR
INT _NUM_OUT, VAR INT _M_OUT[], VAR INT _EXT_OUT[])
```

Input parameters:

VAR INT _NUM_IN:	Number of relevant M commands
VAR INT _M_IN[]:	Field of relevant M codes
VAR INT _EXT_IN[]:	Field of relevant M address extensions

Output parameters:

VAR INT _NUM_OUT:	Number of determined M codes
VAR INT _M_OUT[]:	Field of determined M codes
VAR INT _EXT_OUT[]:	Field of determined M address extensions

The function determines the sequence in which the M auxiliary functions, which have been collected on a group-specific basis, are output for the predefined M codes. The sequence is determined from the collection times \$AC_AUXFU_M_TICK[<n>] (see "Time stamp of the active M auxiliary function (Page 447)").

A particular M code is only taken into account once, even if it belongs to more than one group. If the number of relevant M commands is less than or equal to 0, all the collected M codes are output. The number of relevant M commands is limited to 64.

Example

M commands for coolant output:

- M7: Coolant 2 ON
- M8: Coolant 1 ON
- M9: Coolants 1 and 2 OFF

Group assignment:

- Group 5: M7, M9
- Group 6: M8, M9

Part program (section):

```
Program code
...
N10 ... M8
N20 ... M9
N30 ... M7
...
```

During block searches, the auxiliary functions are collected on the basis of specific groups. The last auxiliary function in an auxiliary function group is output to the PLC following a block search:

- Group 5: M7
- Group 6: M9

If they are output in the sequence M7 → M9, no coolant is then active. However, coolant 2 would be active during the execution of the program. Therefore, the correct output sequence for the M auxiliary functions is determined with an ASUP which contains the predefined procedure AUXFUMSEQ (...):

Program code

```

DEF INT _I, _M_IN[3], _EXT_IN[3], _NUM_OUT, _M_OUT[2], _EXT_OUT[2]
_M_IN[0]=7 _EXT_IN[0]=0
_M_IN[1]=8 _EXT_IN[1]=0
_M_IN[2]=9 _EXT_IN[2]=0
AUXFUMSEQ(3, _M_IN, _EXT_IN, _NUM_OUT, _M_OUT, _EXT_OUT)
FOR _I = 0 TO _NUM_OUT-1
    M[_EXT_OUT[_I]]=_M_OUT[_I]
ENDFOR

```

8.13.5 Output suppression of spindle-specific auxiliary functions

Function

In certain situations, such as a tool change, it may be necessary not to output the spindle-specific auxiliary functions collected during the block search in action blocks, but to delay output, for example, until after a tool change. The automatic output of the spindle-specific auxiliary functions after a block search may be suppressed for this purpose. Output can then be performed manually later by overstoreing or by an ASUB.

Parameterization

Suppression of the automatic output of the spindle-specific auxiliary functions after a block search is set via machine data:

MD11450 \$MN_SEARCH_RUN_MODE (behavior after a block search)

Bit	Value	Meaning
2	0	The output of the spindle-specific auxiliary functions is performed in the action blocks.
	1	Output of the auxiliary functions is suppressed in the action blocks.

System variables

The spindle-specific auxiliary functions are always stored in the following system variables during block searches, irrespective of the parameter assignment described above:

System variable	Description
\$P_SEARCH_S [<n>]	Accumulated spindle speed
	Value range: 0 ... Smax
\$P_SEARCH_SDIR [<n>]	Accumulated spindle direction of rotation
	Value range: 3, 4, 5, -5, -19, 70
\$P_SEARCH_SGEAR [<n>]	Accumulated spindle gear level M function
	Value range: 40 ... 45

8.13 Block-search response

System variable	Description	
\$P_SEARCH_SPOS [<n>]	Accumulated spindle position	
	Value range:	0 ... MD30330 \$MA_MODULO_RANGE (size of the module range)
	or	
	Accumulated traversing path	
\$P_SEARCH_SPOSMODE [<n>]	Value range:	-100,000,000 ... 100,000,000
	Accumulated position approach mode	
	Value range:	0 ... 5

For later output of the spindle-specific auxiliary functions, the system variables can be read in an AS, for example, and output after the action blocks are output:

DB21, ... DBX32.6 = 1 (last action block active)

Note

The contents of the system variables \$P_S, \$P_DIR and \$P_SGEAR may be lost after block search due to synchronization operations.

More detailed information on ASUB, block search, and action blocks is to be found in:

References:

Function Manual, Basic Functions; BAG, Channel, Program Operation, Reset Response (K1), Chapter: "Program test"

Example

Block search for contour with suppression of output of the spindle-specific auxiliary functions and start of an ASUB after output of action blocks.

Parameter assignment: MD11450 \$MN_SEARCH_RUN_MODE, bit 2 = 1

After the block search on N55, the ASUB is started.

Parts program:

Program code	Comment
N05 M3 S200	; Spindle 1
N10 G4 F3	
N15 SPOS=111	; Spindle 1 is positioned to 111 degrees in the ASUB
N20 M2=4 S2=300	; Spindle 2
N25 G4 F3	
N30 SPOS[2]=IC(77)	; Spindle 2 traverses incrementally by 77 degrees
N55 X10 G0	; Destination block
N60 G4 F10	
N99 M30	

ASUB:

Program code	Comment
PROC ASUP_SAVE	
MSG ("Output of the spindle functions")	
DEF INT SNR=1	
AUSG_SPI:	
M[SNR]=\$P_SEARCH_SGEAR[SNR]	; Output gear level.
S[SNR]=\$P_SEARCH_S[SNR]	; Output speed (for M40, a suitable gear level is determined).
M[SNR]=\$P_SEARCH_SDIR[SNR]	; Output direction of rotation, positioning or axis mode.
SNR=SNR+1	; Next spindle.
REPEAT AUSG_SPI P=\$P_NUM_SPINDLES-1	; For all spindles.
MSG ("")	
REPOSA	
RET	

Explanation of example

If the number of spindles is known, outputs of the same type can be written in one part program block to reduce program runtime.

Output of \$P_SEARCH_SDIR should be made in a separate part program block because spindle positioning or switchover to axis mode in conjunction with the gear change can cause an alarm.

If the ASUB which has been started is ended with REPOSA, spindle 1 remains at position 111 degrees, while spindle 2 is repositioned at position 77 degrees.

If a different response is required, the program sequence for block search (for example) "N05 M3 S..." and "N30 SPOS[2] = IC(...)" requires special treatment.

Whether block search is active can be ascertained in the ASUB via the system variable \$P_SEARCH.

\$P_SEARCH==1 ; Block search active

In the case of incremental positioning after speed control operation, the path to be traversed is defined but, in some cases, the final position reached only becomes known during positioning. This is the case, for example, during position calibration on crossing the zero mark when switching on position control. For this reason, the distance programmed after the zero position is accepted as the REPOS position (REPOSA in the ASUB).

Boundary conditions

Collected S values

The meaning of an S value in the parts program depends on the feed type that is currently active:

G93, G94, G95, G97, G971:	The S value is interpreted as the speed
G96, G961:	The S value is interpreted as a constant cutting rate

If the feed operation is changed (e.g. for a tool change) before output of the system variable \$P_SEARCH_S, the original setting from the target block in the parts program must be restored to avoid use of the wrong type of feed.

Collected direction of rotation

For output of the direction of rotation, the system variable \$P_SEARCH_SDIR is assigned default value "-5" at the start of the block search. This value has no effect on output.

This ensures that the last spindle operating mode is retained for a block search across program section in which spindles are not programmed with a direction of rotation, positioning or axis mode.

The programming of M19, SPOS, and SPOSA is collected as "M-19" (internal M19) in the system variables \$P_SEARCH_SDIR as an alternative to M3, M4, M5, and M70.

For the output of "M-19", the positioning data is read internally from the system variables \$P_SEARCH_SPOS and \$P_SEARCH_SPOSMODE. Both system variables can also be written to, in order, for example, to make corrections.

Note

Because of the assignments described above (e.g. M[<n>] = \$P_SEARCH_SDIR[<n>]), the values "-5" and "-19" generally remain hidden from the user and only have to be observed in the case of special evaluation of the system variables in the ASUB.

8.13.6 Auxiliary function output with a type 5 block search (SERUPRO)

Output behavior

In the case of type 5 block searches (SERUPRO), an auxiliary function can be output to the PLC during the block search and/or collected on a group-specific basis in the following system variables:

- \$AC_AUXFU_PREDEF_INDEX[<n>] (index of a predefined auxiliary function)
- \$AC_AUXFU_TYPE[<n>] (type of auxiliary function)
- \$AC_AUXFU_STATE[<n>] (output state of the auxiliary function)
- \$AC_AUXFU_EXT[<n>] (address extension of the auxiliary function)
- \$AC_AUXFU_VALUE[<n>] (value of the auxiliary function)

For a description of the system variables, see "Querying system variables (Page 465)".

Output control

Whether an auxiliary function is output to the PLC during a type 5 block search (SERUPRO) and/or collected on a group-specific basis in the following system variables can be configured via bits 9 and 10 of the machine data:

- MD22080 \$MC_AUXFU_PREDEF_SPEC[<n>]
(output behavior of predefined auxiliary functions)
where <n> = system function index (0 ... 32)
- MD22035 \$MC_AUXFU_ASSIGN_SPEC[<n>]
(output behavior of user-defined auxiliary functions)
where <n> = auxiliary function index (0 ... 254)
- MD11110 \$MN_AUXFU_GROUP_SPEC[<n>]
(output behavior of the auxiliary functions in a group)
where <n> = group index (0 ... 63)

Bit	Value	Meaning
9	0	No collection during type 5 block searches (SERUPRO)
	1	Collection during type 5 block searches (SERUPRO)
10	0	Output during type 5 block searches (SERUPRO)
	1	No output during type 5 block searches (SERUPRO)

Output counter

The user can output the collected auxiliary functions to the PLC on a channel-by-channel basis in the block search ASUB. For the purposes of serialized output via multiple channels, the three output counters are changed across all the channels each time an auxiliary function is output:

\$AC_AUXFU_TICK[<n>,<m>] (output counter for the active auxiliary function)

- <n>: Group index (0 to 63)
 <m>: Output counter (0 ... 2)
- 0: Output sequence counter (All outputs within an IPO cycle)
 - 1: Package counter within an output sequence in the IPO cycle
 - 2: Auxiliary function counter within a package

Explanation:

An auxiliary function package comprises a maximum of 10 auxiliary functions.

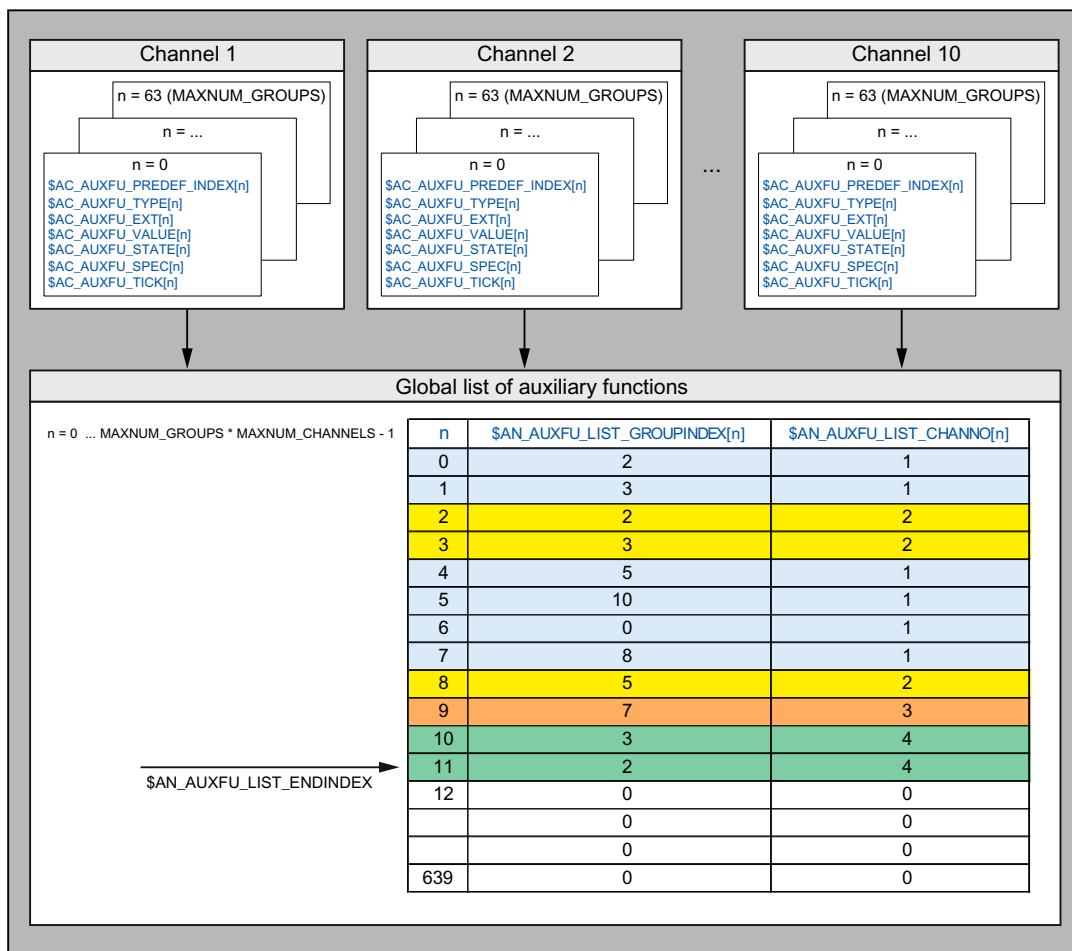

Two packages can be processed per IPO cycle in each channel during SERUPRO because synchronized actions are processed in this cycle.

An output sequence of up to a maximum of 20 packages (2 packages per channel * 10 channels) can be processed within an IPO cycle across all channels.

This encoding defines how many auxiliary function packages and, within these, how many auxiliary functions have been processed during the same IPO cycle: Auxiliary functions which have been collected in one IPO cycle all have the same sequence counter. Auxiliary functions which have been collected in one package (block or synchronized action) all have the same package counter. The total on the auxiliary function counter increases every time an auxiliary function is collected.

Global list of auxiliary functions

At the end of SERUPRO, the auxiliary functions collected on a group-specific basis in the individual channels are entered in a cross-channel (global) list with the channel number (\$AN_AUXFU_LIST_CHANNO[<n>]) and group index (\$AN_AUXFU_LIST_GROUPINDEX[<n>]) according to their counter state (\$SAC_AUXFU_TICK[<n>,<m>]).

The two field variables \$AN_AUXFU_LIST_CHANNO[<n>] and \$AN_AUXFU_LIST_GROUPINDEX[<n>] from the global list are writable and readable. The index <n> has the following range of values: 0 ... MAXNUM_GROUPS * MAXNUM_CHANNELS - 1

The global list is structured on the basis of the sequence in which the search target was found. It is intended to be used as a system proposal for auxiliary functions to be output in the following ASUB at the end of SERUPRO. If an auxiliary function is not to be output, the corresponding group index is to be set to "0".

Behavior regarding spindle auxiliary functions

Following the start of the search, all the channels collect the auxiliary functions in the channel variables on a group-specific basis. In order to perform a far-reaching restoration of the spindle state in the SERUPRO target block using the collected auxiliary functions, the last active auxiliary function in any group of spindle auxiliary functions must characterize the state of the spindle in the target block. In the case of transitions in spindle states, obsolete auxiliary functions are deleted or, if necessary, implicit auxiliary functions are entered.

All the spindle auxiliary functions from the global auxiliary function list must correspond to the spindle states achieved in the target block to enable the auxiliary functions to be processed when the list is output and to ensure that no alarms or unintended spindle states are requested which could prevent the continuation of the part program.

This affects the groups of auxiliary functions for any spindle configured in the system, whereby the spindle number corresponds to an auxiliary function's address extension.

Group a: M3, M4, M5, M19, M70
 Group b: M40, M41, M42, M43, M44, M45
 Group c: S

Deleting obsolete auxiliary functions

In the functions below, the auxiliary functions from group a are deleted for the spindle concerned:

- For the following spindle when a generic coupling, such as COUPON, TRAILON, EGON, etc. is switched on

Generating implicit auxiliary functions from group a

In the functions below, the auxiliary functions from group a are generated implicitly for the spindle concerned:

- For the following spindle when the synchronous spindle coupling is switched off
 - COUPOF generates M3, M4 and S or M5 in the main run depending on the coupling situation.
 - COUPOF(S<n>, S<m>, POS) and COUPOFS(S<n>, S<m>, POS, POS) generate M3, M4 and S.
 - COUPOFS generates M5 in the main run.
 - COUPOFS(S<n>, S<m>, POS) generates M19 in the main run.

The implicit M19 ("SPOS[<address extension>] = IC(0)" in the ASUB) activates the positioning mode without a traversing motion.

- M70 is generated during a traversing motion as an axis or during the transition to axis mode by selecting a transformation during which the spindle enters as an axis.
- M5 is generated during SPCOF.

Note

Within the context of the "axis interchange" and "axis container rotation" functions, the auxiliary functions for programming the spindle must always be specified in a way which ensures compatibility with the actual (motor) state during interchange/rotation. A distinction is made here between the axis interchange and axis container mechanisms.

Example of axis container rotation:

An axis container has four spindles, each assigned to a separate channel (1 - 4). M3 S1000 is always programmed in channel 1, and an axis container rotation is then executed. The other channels do not perform any spindle programming. Following the third axis container rotation and the fourth spindle programming, M3, all four spindles rotate clockwise at a speed of 1,000 rpm. If the end of the SERUPRO now lies within this range, every ASUB for a channel is expected to contain an M3 S1000 for the local spindle.

During interchange however, the collected auxiliary functions may only be assigned to the channel where the spindle is currently located.

Cross-channel auxiliary function

An auxiliary function can also be collected on a cross-channel basis in the global auxiliary function list in the case of type 5 block searches 5 (SERUPRO). Only the last auxiliary function collected from this group (highest counter state) is entered in the global list.

Configuration takes place via bit 11 in the machine data:

- MD22080 \$MC_AUXFU_PREDEF_SPEC[<n>]
(output behavior of predefined auxiliary functions)
where <n> = system function index (0 ... 32)
- MD22035 \$MC_AUXFU_ASSIGN_SPEC[<n>]
(output behavior of user-defined auxiliary functions)
where <n> = auxiliary function index (0 ... 254)
- MD11110 \$MN_AUXFU_GROUP_SPEC[<n>]
(output behavior of the auxiliary functions in a group)
where <n> = group index (0 ... 63)

Bit	Value	Meaning
11	0	Channel-specific collection
	1	Cross-channel collection

The spindle auxiliary functions are filtered out beforehand at the end of the search depending on the spindle state. The channel data is updated accordingly. The global auxiliary function list can be processed in sequence in the ASUBs at the end of the SERUPRO, and the sorted auxiliary functions can be output with channel synchronization.

Querying the last auxiliary function collected

The index of the last auxiliary function collected in the global list can be queried using the system variable \$AN_AUXFU_LIST_ENDINDEX.

8.13.7 ASUB at the end of the SERUPRO

Function

After completing the block search with the program test (SERUPRO), before starting the subsequent processing, the auxiliary functions collected during the search must be output. For this purpose, during the block search, the auxiliary functions are collected in a global list. The SERUPRO end ASUBs generate the corresponding part program blocks channel-specific from this list. This ensures that the collected auxiliary functions can be output both channel-specific as well as cross-channel in the correct sequence. A fully functional SERUPRO end ASUB is a component of the NCK software.

Users/machinery construction OEMs can change the SERUPRO end ASUB. The subsequently described functions support processing the global list of auxiliary functions and generating the part program blocks required for synchronized auxiliary function output.

Function AUXFUSYNC(...)

Function:

The function `AUXFUSYNC` generates a complete part program block as string from the global list of auxiliary functions at each call. The part program block either contains auxiliary functions or commands to synchronize auxiliary function outputs (`WAITM`, `G4`, etc.).

The function triggers a preprocessing stop.

Syntax:

```
PROC AUXFUSYNC (VAR INT <NUM>, VAR INT <GROUPINDEX>[10], VAR
STRING[400] <ASSEMBLED>)
```

Parameters:

<code><NUM></code> :	Contains information about the part program block, supplied in parameter <code><ASSEMBLED></code> or the auxiliary functions contained in it. Value range: -1, 0, 1 ... 10
	Value Meaning
	≥1 Number of auxiliary functions contained in the part program block
	0 Part program block without auxiliary functions, e.g. <code>WAITM</code> , <code>G4</code>
	-1 End identifier. The global list of auxiliary functions has been completely processed for the actual channel.
<code><GROUP INDEX></code> :	Contains the indices of the auxiliary function groups contained in the part program block. With index = number of the auxiliary function group - 1
<code><ASSEMBLED></code> :	Contains the complete part program block for the channel-specific SERUPRO end ASUB as string.

Further information:

If auxiliary functions were collected via a synchronized action, two NC blocks are generated. One NC block to output the auxiliary functions. An executable NC block via which the NC block is transported to the main run to output the auxiliary functions:

1. Output of the auxiliary functions via synchronized action, e.g.: `WHEN TRUE DO M100 M102`
2. Executable NC block, e.g.: `G4 F0.001`

Function AUXFUDEL(...)

Function:

The function AUXFUDEL deletes the specified auxiliary function from the global list of auxiliary functions channel-specific for the calling channel. Deletion is realized by setting the corresponding group index `...GROUPINDEX[n]` to 0.

The function must be called before calling `AUXFUSYNC`.

The function triggers a preprocessing stop.

Syntax:

```
PROC AUXFUDEL(CHAR <TYPE>, INT <EXTENSION>, REAL <VALUE>, INT <GROUP>)
```

Parameters:

<TYPE>:	Type of auxiliary function to be deleted
<EXTENSION>:	Address extension of the auxiliary function to be deleted
<VALUE>:	Value of auxiliary function to be deleted
<GROUP>:	Number of the auxiliary function group

Function AUXFUDELG(...)

Function:

The function AUXFUDELG deletes all auxiliary functions of the specified auxiliary function group from the global list of auxiliary functions channel-specific for the calling channel. Deletion is realized by setting the corresponding group index `...GROUPINDEX[n]` to 0.

The function must be called before calling `AUXFUSYNC`.

The function triggers a preprocessing stop.

Syntax:

```
PROC AUXFUDELG(INT <GROUP>)
```

Parameters:

<GROUP>:	Number of the auxiliary function group
----------	--

Multi-channel block search

CAUTION

Multi-channel block search and AUXFUDEL / AUXFUDELG

If, for a multi-channel block search in the SERUPRO end ASUBs, auxiliary functions with AUXFUDEL / AUXFUDELG are deleted from the global list of auxiliary functions, before calling the AUXFUSYNC function, the channels involved must be synchronized. The synchronization ensures that before calling the AUXFUSYNC, all delete requests are processed and a consistent list is available.

Examples

Two examples for configuring a user-specific SERUPRO end ASUB.

Example 1: Deleting auxiliary functions and generating the auxiliary function output with AUXFUSYNC(...)

Program code	Comment
N10 DEF STRING[400] ASSEMBLED=""	
N20 DEF STRING[31] FILENAME="/_N_CST_DIR/_N_AUXFU_SPF"	
N30 DEF INT GROUPINDEX[10]

8.14 Implicitly output auxiliary functions

Function

Implicitly output auxiliary functions are auxiliary functions which have not been programmed explicitly and which are also output by other system functions (e.g. transformation selection, tool selection, etc.). These implicit auxiliary functions do not lead to any system function; instead, the M codes are collected according to output behavior parameters assigned to them and/or are output to the PLC.

Parameterization

The M codes for auxiliary functions to be output implicitly are defined with the machine data:

- MD22530 \$MC_TOCARR_CHANGE_M_CODE (M code with a toolholder change)

This machine data value indicates the number of the M code which is output when a toolholder is activated at the NC/PLC interface.

If the value is positive, the unchanged M code is always output.

If the value is negative, the number of the toolholder is added to the machine data value, and this number is output.

- MD22532 \$MC_GEOAX_CHANGE_M_CODE (M code when switching the geometry axes)

Number of the M code which is output when the geometry axes on the NC/PLC interface are switched.

- MD22534 \$MC_TRAFO_CHANGE_M_CODE (M code in the case of transformation changes)

Number of the M code which is output during a transformation switch of the geometry axes at the NC/PLC interface.

Note

No M code is output if the number of the M code being output or the MD22530/MD22532/MD22534 value is between 0 and 6, or is either 17 or 30. Whether or not an M code which is generated in this manner leads to conflicts with other functions is not monitored.

Output behavior

In the case of implicitly output auxiliary functions, bit 13 is set in machine data MD22080 or MD22035 (output behavior of predefined or user-defined auxiliary functions).

This bit can be queried via the system variable \$AC_AUXFU_SPEC[<n>].

Implicitly output auxiliary function M19

To achieve uniformity in terms of how M19 and SPOS or SPOSA behave at the NC/PLC interface, auxiliary function M19 can be output to the NC/PLC interface for SPOS and SPOSA (see spindles (S1), "positioning mode" < "General functionality (Page 1285)").

The implicitly output auxiliary function M19 is collected during the block search.

8.15 Information options

Information about auxiliary functions (e.g. about the output status) is possible via:

- The group-specific modal M auxiliary function display on the user interface
- Querying system variables in part programs and synchronized actions

8.15.1 Group-specific modal M auxiliary function display

Function

The output status and acknowledgement status of M auxiliary functions can be displayed on the user interface on a group-specific basis.

Requirements

To implement function-oriented acknowledgement and display of M auxiliary functions, the auxiliary functions must be managed in the PLC and, thus, in the user program itself. Therefore, it is up to the PLC programmer to program the acknowledgement of these auxiliary functions. He has to know which auxiliary functions in which group have to be acknowledged.

Standard

M auxiliary functions that are not managed by means of the PLC are identified by the NC as "transferred" and output to the PLC. There is no functional acknowledgement for these auxiliary functions. All M-auxiliary functions collected after a block search are also displayed so that the operator knows which auxiliary functions will be output after a start following a block search.

PLC activities

In the case of auxiliary function groups that are managed by the PLC itself, the PLC user program must acknowledge all auxiliary functions of this groups when **Apply** and **Function End** are activated. The PLC programmer must know all the auxiliary functions of these groups.

Miscellaneous

Only the **group-specific** M auxiliary functions are displayed. The block-by-block display is also retained. Up to 15 groups can be displayed, whereby **only the last M function of a group** that was either collected or output to the PLC is displayed for each group. The M functions are presented in various display modes depending on their status:

Status	Display mode
Auxiliary function is collected	Inverted with yellow font
Auxiliary function is output from NCK to PLC	Inverted
Auxiliary function has been transferred from NCK to PLC and transport acknowledgement has taken place	Black font on gray background
Auxiliary function is managed by the PLC and has been directly applied by the PLC.	Black font on gray background
Auxiliary function is managed by the PLC, and the function acknowledgement has taken place.	Black font on gray background

Display update

The display is organized in such a way that the collected auxiliary functions are always displayed first, before those that were managed by the PLC and before those that were managed by the NC. A collected auxiliary function is marked as collected until it has been output from the NCK to the PLC. PLC-managed auxiliary functions are retained until they are displaced by another auxiliary function. In the case of a reset, only the collected auxiliary functions and the NC-managed auxiliary functions are deleted.

8.15.2 Querying system variables

Function

Auxiliary functions can be queried on a group-specific basis via system variables in the part program and via synchronized actions:

\$AC_AUXFU_... [<n>] = <value>

System variables	Meaning	
\$AC_AUXFU_PREDEF_INDEX[<n>]	<value>:	Index of the last auxiliary function collected for an auxiliary function group (search) or the last predefined auxiliary function to be output
	Type:	INT
		If no auxiliary function has been output yet for the specified group or if the auxiliary function is a user-defined auxiliary function, the variable supplies the value "-1".
	<n>:	Group index (0 to 63)
	Note: A predefined auxiliary function can be uniquely identified via this variable.	

System variables	Meaning	
\$AC_AUXFU_TYPE[<n>]	<value>:	Type of the last auxiliary function collected for an auxiliary function group (search) or the last auxiliary function to be output
	Type:	CHAR
\$AC_AUXFU_EXT[<n>] or M function specific: \$AC_AUXFU_M_EXT[<n>]	<value>:	Address extension of the last auxiliary function collected for an auxiliary function group (search) or the last auxiliary function to be output
	Type:	INT
\$AC_AUXFU_M_EXT[<n>]	<n>:	Group index (0 to 63)
	<value>:	Value of the last auxiliary function collected for an auxiliary function group (search) or the last auxiliary function to be output
\$AC_AUXFU_M_VALUE[<n>]	Type:	REAL
	<n>:	Group index (0 to 63)
\$AC_AUXFU_SPEC[<n>]	Value:	Bit-encoded output behavior according to MD22080/MD22035 (or QU programming) of the last auxiliary function collected for an auxiliary function group (search) or the last auxiliary function to be output
	Type:	INT
	<n>:	Group index (0 to 63)
Note: This variable can be used to determine whether the auxiliary function should be output with a fast acknowledgement.		
\$AC_AUXFU_STATE[<n>] or M function specific: \$AC_AUXFU_M_STATE[<n>]	<value>:	Output state of the last auxiliary function collected for an auxiliary function group (search) or the last auxiliary function to be output
	Type:	INT
	Value range:	0 ... 5
	0:	No auxiliary function
	1:	M-auxiliary function was collected via a search
	2:	M-auxiliary function has been output to the PLC
	3:	M-auxiliary function has been output to the PLC and the transport acknowledgement has taken place
	4:	M-auxiliary function is managed by the PLC and has been applied by the PLC
5:	M-auxiliary function is managed by the PLC, and the function acknowledgement has taken place	
<n>:	Group index (0 to 63)	

Example

All M-auxiliary functions of the 1st group will be stored in the order they are output

```
id=1 every $AC_AUXFU_M_STATE[0]==2 do
$AC_FIFO[0,0]=$AC_AUXFU_M_VALUE[0]
```

References

For more information on the system variables, refer to:

List Manual, System Variables

8.16 Supplementary conditions

8.16.1 General constraints

Spindle replacement

Because the auxiliary functions are parameterized channel-specifically, if function: "spindle replacement" is used, the spindle-specific auxiliary function must be parameterized immediately in all channels that use the spindles.

Tool management

If tool management is active, the following constraints apply:

- T and M<k> functions are not output to the PLC.
Note
k is the parameterized value of the auxiliary function for the tool change (default: 6):
MD22560 \$MC_TOOL_CHANGE_M_CODE (auxiliary function for tool change)
- If no address extension is programmed, the auxiliary function refers to the master spindle or the master tool holder of the channel.

Definition of the master spindle:

- MD20090 \$MC_SPIND_DEF_MASTER_SPIND
- Part program instruction: SETMS

Definition of the master tool holder

- MD20124 \$MC_TOOL_MANAGEMENT_TOOLHOLDER
- Part program instruction: SETMTH

Maximum number of auxiliary functions per part program block

A maximum of 10 auxiliary functions may be programmed in one part program block.

DL (additive tool offset)

The following restrictions apply to the DL function:

- Only one DL function can be programmed per part program block.
- If DL functions are used in synchronous actions, parameter: "Value" is not output to the PLC.

8.16.2 Output behavior

Thread cutting

During active thread cutting G33, G34 and G35, the following output behavior:

- Output duration one OB40 cycle (quick acknowledgment)
- Output during motion

is always active for the spindle-specific auxiliary functions:

- M3 (spindle right)
- M4 (spindle left)

The spindle-specific auxiliary function M5 (spindle stop) is always output at the end of the block. The parts program block that contains M5 is always ended with exact stop, i.e. even during active continuous path mode.

Synchronized actions

With output auxiliary functions from synchronized actions, the parameterized output behavior is ignored except for the following parameters:

- Bit0: Output duration one OB1 cycle (normal acknowledgment)
- Bit1: Output duration one OB40 cycle (quick acknowledgment)

Auxiliary functions: M17 or M2 / M30 (end of subroutine)

In its own parts program block

If one of the auxiliary functions M17, M2 or M30 is programmed as the only auxiliary function in a part program block and an axis is still in motion, the auxiliary function is not output to the PLC until after the axis has stopped.

Overriding the parameterized output behavior

The parameterized output behavior of the auxiliary functions M17 or M2/M30 is overridden by the output behavior that is determined in the following machine data:

MD20800 \$MC_SPF_END_TO_VDI, Bit 0 (subprogram end / stop to PLC)

Bit	Value	Description
0	0	The auxiliary functions M17 or M2/M30 (subprogram end) are not output to the PLC. Continuous-path mode is not interrupted at the end of the subroutine
	1	The auxiliary functions M17 or M2/M30 (subprogram end) are output to the PLC.

Auxiliary function: M1 (conditional stop)

Overlapping of the parameterized output behavior

The parameterized output behavior of the auxiliary function M1 is overridden by the output behavior defined in the following machine data:

MD20800 \$MC_SPF_END_TO_VDI, Bit 1 (subprogram end / stop to PLC)

8.17 Examples

Bit	Value	Description
1	0	The auxiliary function M01 (conditional stop) is always output to the PLC. A quick acknowledgement is ineffective, because M01 is permanently assigned to the first auxiliary function group and is therefore always output at the end of the block.
	1	The auxiliary function M01 (conditional stop) is only output to the PLC, if the function: "Programmed stop" is activated via the HMI user interface. In the case of a quick acknowledgement, the M1 is output to the PLC during the motion. While the function is not active, this does not interrupt continuous-path mode.

Part program blocks without traverse movement

In a part program block without a traverse movement, all auxiliary functions are output in a block immediately, irrespective of their parameterized output behavior.

8.17 Examples

8.17.1 Extension of predefined auxiliary functions

Task

Parameter assignment of auxiliary functions M3, M4, and M5 for the second spindle of the channel

Parameter assignment: M3

Requirements:

- Machine data index: 0 (first user-defined auxiliary function)
- auxiliary function group: 5
- Type and value: M3 (spindle right)
- Address extension: 2 as appropriate for the 2nd spindle of the channel
- Output behavior:
 - Output duration one OB1 cycle (normal acknowledgment)
 - Output prior to motion

Parameter assignment:

```

MD22000 $MC_AUXFU_ASSIGN_GROUP[ 0 ]      = 5
MD22010 $MC_AUXFU_ASSIGN_TYPE [ 0 ]      = "M"
MD22020 $MC_AUXFU_ASSIGN_EXTENSION [ 0 ] = 2
MD22030 $MC_AUXFU_ASSIGN_VALUE [ 0 ]     = 3
MD22035 $MC_AUXFU_ASSIGN_SPEC [ 0 ]     = 'H21'
    
```

Parameter assignment: M4

Requirements:

- Machine data index: 1 (second user-defined auxiliary function)
- Auxiliary function group: 5
- Type and value: M4 (spindle left)
- Address extension: 2 as appropriate for the 2nd spindle of the channel
- Output behavior:
 - Output duration one OB1 cycle (normal acknowledgment)
 - Spindle response following acknowledgment
 - Output during motion

Parameter assignment:

```
MD22000 $MC_AUXFU_ASSIGN_GROUP [ 1 ]      = 5
MD22010 $MC_AUXFU_ASSIGN_TYPE [ 1 ]       = "M"
MD22020 $MC_AUXFU_ASSIGN_EXTENSION [ 1 ]   = 2
MD22030 $MC_AUXFU_ASSIGN_VALUE [ 1 ]      = 4
MD22035 $MC_AUXFU_ASSIGN_SPEC [ 1 ]       = 'H51'
```

Parameter assignment: M5

Requirements:

- Machine data index: 2 (third user-defined auxiliary function)
- Auxiliary function group: 5
- Type and value: M5 (spindle stop)
- Address extension: 2 as appropriate for the 2nd spindle of the channel
- Output behavior:
 - Output duration one OB1 cycle (normal acknowledgment)
 - Spindle response following acknowledgment
 - Output at block end

Parameter assignment:

MD22000 \$MC_AUXFU_ASSIGN_GROUP [2] = 5
MD22010 \$MC_AUXFU_ASSIGN_TYPE [2] = "M"
MD22020 \$MC_AUXFU_ASSIGN_EXTENSION [2] = 2
MD22030 \$MC_AUXFU_ASSIGN_VALUE [2] = 5
MD22035 \$MC_AUXFU_ASSIGN_SPEC [2] = 'H91'

8.17.2 Defining auxiliary functions

Task

Parameter assignment of the auxiliary function-specific machine data for a machine with the following configuration:

Spindles

- Spindle 1: Master spindle
- Spindle 2: Second spindle

Gear stages

- Spindle 1: 5 gear stages
- Spindle 2: No gear stages

Switching functions for cooling water on/off

- Spindle 1
 - "ON" = M50
 - "OFF" = M51
- Spindle 2
 - "ON" = M52
 - "OFF" = M53

Requirements

Spindle 1 (master spindle)

Note

Default assignments

- The auxiliary functions M3, M4, M5, M70 and M1=3, M1=4, M1=5, M1=70 of spindle 1 (master spindle) are assigned as standard to the second auxiliary function group.
 - All S and S1 values of spindle 1 (master spindle) are assigned to the third auxiliary function group by default.
-

- The gear stage last programmed is to be output after block search. The following auxiliary functions are assigned to the ninth auxiliary function group for this reason:
 - M40, M41, M42, M43, M44, M45
 - M1=40, M1=41, M1=42, M1=43, M1=44, M1=45
- The auxiliary functions M3, M4, M5, M70 and M1=3, M1=4, M1=5, M1=70 (second auxiliary function group) and S and S1 values (third auxiliary function group) should possess the following output behavior:
 - Output duration one OB40 cycle (quick acknowledgment)
 - Output prior to motion
- The auxiliary functions for gear changeover M40 to M45 and M1=40 to M1=45 (ninth auxiliary function group) should have the following output behavior:
 - Output duration one OB1 cycle (normal acknowledgment)
 - Output prior to motion

Spindle 2

- Only one M function for directional reversal may be programmed in one block. The direction of rotation last programmed is to be output after block search. The following auxiliary functions are assigned to the tenth auxiliary function group for this reason:
 - M2=3, M2=4, M2=5, M2=70
- All S2 values are assigned to auxiliary function group 11.
- The auxiliary functions M2=3, M2=4, M2=5, M2=70 (tenth auxiliary function group) and S2 values (auxiliary function group 11) should have the following output behavior:
 - Output duration one OB40 cycle (quick acknowledgment)
 - Output prior to motion

Cooling water

- It is not permissible to switch the cooling water on and off in one part program block. After a block search, the cooling water will be switched on or off. For this purpose, the following auxiliary functions are assigned, for example, to auxiliary function group 12 or 13:
 - Auxiliary function group 12: M50, M51
 - Auxiliary function group 13: M52, M53
- The auxiliary functions M50, M51 (auxiliary function group 12) and M52, M53 (auxiliary function group 13) should have the following output behavior:
 - Output duration one OB1 cycle (normal acknowledgment)
 - Output prior to motion

Parameterization of the machine data

The machine data are parameterized by appropriate programming within a parts program.

K1: Mode group, channel, program operation, reset response

9

9.1 Brief description

Channel

An NC channel represents the smallest unit for manual traversing of axes and automatic processing of part programs. At any one time, a channel will always be in a particular mode, e.g. AUTOMATIC, MDA, or JOG. A channel can be regarded as an independent NC.

Mode group

A channel always belongs to a mode group. A mode group can also consist of several channels.

A mode group can be identified by the fact that all channels of the mode group are always in the same mode at a particular time, e.g. AUTOMATIC, MDA, or JOG. This is ensured through the NC internal mode logic.

A mode group can be regarded as an independent multi-channel NC.

Channel gaps

When channels are configured, placeholder channels can be provided in order to create as uniform a configuration as possible over machines in a series. Only the channels that are actually used are then activated.

Program test

The following options are available for testing or moving in position a new part program.

- Program execution without setpoint outputs
- Program execution in single-block mode
- Program execution with dry run feedrate
- Skip part program blocks
- Block search with or without calculation.

Block search

The block search function enables the following program simulations for locating specific program points:

- Type 1 without calculation at contour
- Type 2 with calculation at contour

9.1 Brief description

- Type 4 with calculation at block end point
- Type 5 automatic start of the selected program point with calculation of all required data from history
- Automatic start of an ASUB after a block search
- Cascaded block search
- Cross-channel block search in "Program test" mode

Program operation

The execution of part programs or part program blocks in AUTOMATIC or MDA modes is referred to as program operation. During execution, the program sequence can be controlled by PLC interface signals and commands.

For each channel, basic settings or channel-specific machine data can be specified. These initial settings affect, for example, G groups and auxiliary function output.

A part program can be selected only if the relevant channel is in the Reset state.

Furthermore, all further program runs are handled by PLC interface signals and the corresponding commands.

- Start of part program or part program block
- Part program calculation and program control
- RESET command, program status, and channel status
- Responses to operator and program actions
- Event-driven program calls

Asynchronous subroutines (ASUBs), interrupt routines

Interrupt inputs allow the NC to interrupt the the current part program execution so that it can react to more urgent events in interrupt routines or ASUBs.

Single block

With the single-block function, the user can execute a part program block-by-block.

There are 3 types of setting for the single-block function:

- SLB1: = IPO single block
- SLB2: = Decode single block
- SLB3: = Stop in cycle

Basic block display

A second basic block display can be used with the existing block display to display all blocks that produce an action on the machine.

The actually approached end positions are shown as an absolute position. The position values refer either to the workpiece coordinate system (WCS) or the settable zero system (SZS).

Program execution from external source

When complex workpieces are machined, the NC may not have enough memory for the programs. The "Execution from external source" function enables subroutines to be called (`EXTCALL`) and executed from an external memory (e.g. from the HMI Advanced hard disk).

Behavior after POWER ON, Reset, ...

The control-system response after:

- Power up (POWER ON)
- Reset/part program end
- Part program start

can be modified for functions, such as G codes, tool length compensation, transformation, coupled axis groupings, tangential follow-up, programmable synchronous spindle for certain system settings through machine data.

Subroutine call with M, T and D functions

For certain applications, it may be advantageous to replace M, T or D functions as well as a few NC language commands `SPOS`, `SPOSA`, by a subroutine call. This can be used, for example, to call the tool change routine.

Relevant machine data can be used to define and control subroutines having M, T or D functions. For example, for a gear stage change.

Program runtime/part counter

Information on the program runtime and the part count is provided to assist the machine tool operator.

The functions defined for this purpose are **not identical to the functions of tool management** and are intended primarily for systems without tool management.

9.2 Mode group (MG)

Mode group

A mode group combines NC channels with axes and spindles to form a machining unit.

A mode group contains the channels that are required to run simultaneously in the same mode from the point of view of the machining sequence.

The configuration of a mode group defines which channels are to be included in the group.

Note

This description assumes one mode group and one channel.

Functions that need several channels (e.g. "Axis replacement" function), are described in:

References:

Function Manual Extended Functions; Mode Groups, Channels, Axis replacement (K5)

Assignment: Channel - Mode group

Axes and/or spindles are assigned to one channel.

The channel, in turn, is assigned to a mode group with the following machine data:

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP (channel valid in mode group)

If the same mode group is addressed in several channels, these channels together form a mode group.

Note

The control system does not recognize mode group-specific data. However, it is possible to make some channel-specific settings that pertain to the mode group.

Channel-specific assignments

Axes can be assigned to multiple channels that, in turn, are allocated to different mode groups. The axes can then be interchanged between these channels (axis replacement). Axis replacement functions independently of the mode group.

Machine axes and spindles are assigned to a channel. They differ as follows:

- Geometry axes can be operated in the path grouping.

Using the master spindle, they can perform functions such as G96, G961, G331, G332, etc.

- Channel axes that are not defined as geometry axes can be moved as path axes, synchronous axes, positioning axes, PLC axes, and command axes.
- Special axes have no geometric relationship with one another.

- Master spindle geometry axes can perform functions using the master spindle.
- Auxiliary spindles are all other spindles/axes in the channel apart from the master spindle.

The `GEOAX` replacement command can be programmed to declare a channel axis as a geometry axis and define its geometry axis number. It is defined with `SETMS`, which spindle in the channel should be the master spindle.

Any axis in the channel can be configured as a spindle. The number of axes per channel depends on the control version. In order to optimize the performance utilization, the available channel and axis configurations are limited depending on the hardware.

With SINUMERIK 840D sl, the following configurations are permissible depending on the HW/SW version:

- Up to 12 axes/spindles per channel
- Maximum of 31 axes or 20 spindles per NCU

For information about other axis configurations such as axis containers, link axes, reciprocating axes, main run, rotary, linear, master and slave axes and the various implementations, see K2: Axis Types, Coordinate Systems, Frames (Page 695) and S1: Spindles (Page 1279).

Mode group-specific interface signals

The exchange of mode group-specific signals to/from the mode group is transferred to DB11 in the user interface. In this way, the mode group can be monitored and controlled from the PLC or NCK.

The following table represents all the mode group-specific interface signals.

Signals from PLC to NCK
Mode group Reset
Mode group Stop axes plus spindles
Mode group Stop
Mode change
Operating mode: JOG, MDA, AUTOM.
Single block: Type A, Type B
Machine function REF, REPOS, TEACH IN,

Signals from NCK to PLC
Mode strobe: JOG, MDA, AUTOMATIC
Machine function strobe: REF, REPOS, TEACH IN
All channels (1 to 10, max.) in Reset state
Mode group Ready
Active mode: JOG, MDA, AUTOMATIC
Digitizing
Active machine function: REF, REPOS, TEACH IN var. INC, 10000 INC 1 INC

Change in mode group

A configuration change of a mode group with respect to its assigned channels requires a subsequent POWER ON.

The change is made using machine data:

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP.

Mode group numbers must be assigned contiguously starting with 1.

Machine data

There are no mode group-specific machine data.

Channel gaps

The channels to which a mode group is assigned with MD10010 are regarded as activated.

Instead of a mode group number, the number "0" can be assigned to channels. The result is as follows:

- The non-activated channel does not take up memory space in the control.
- Series machines with similar designs can be kept uniform during configuration. Only the channels that can actually be used by the machine tool are activated (channels with mode group number greater than 0).

Special case:

Channel 1 must always be available!

⇒ If:

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP [0] = 0

is specified, the control automatically sets

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP [0] = 1 (mode group 1).

Example configurations:

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP[0] = 1

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP[1] = 2

...

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP[3] = 0 ; gap

...

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP[8] = 1

MD10010 \$MN_ASSIGN_CHAN_TO_MODE_GROUP[9] = 2

9.2.1 Mode group Stop

Function

The following NC/PLC interface signals are used to stop the traversing motions of the axes or of the axes and spindles in all mode group channels and to interrupt part program execution:

DB11 DBX0.5 (mode group Stop)

DB11 DBX0.6 (mode group Stop axes plus spindles)

9.2.2 Mode group RESET

Function

A mode group Reset is requested via a mode group-specific NC/PLC interface signal:

DB11 DBX0.7 = 1 (mode group reset)

Effect

Effect on the channels of mode group:

- Part program preparation (preprocessing) is stopped.
- All axes and spindles are decelerated to zero speed according to their acceleration curves without contour violation.
- Any auxiliary functions not yet output to the PLC are no longer output.
- The preprocessing pointers are set to the interruption point, and the block pointers are set to the beginning of the appropriate part programs.
- All initial settings, (e.g. the G functions), are set to the parameterized values.
- All alarms with "Channel reset" criterion are canceled.

If all the channels of the mode group are in reset state, then:

- All alarms with "Mode group reset" cancel criterion are canceled.
- The NC/PLC interface indicates completion of the mode group Reset and the mode group's readiness to operate:

DB11 DBX6.7 (all channels in the reset state)

DB11 DBX6.3 = 1 (mode group ready)

9.3 Mode types and mode type change

Unique mode

The channels of a mode group operate in one mode.

A mode group is either in **AUTOMATIC**, **JOG**, or **MDA** mode.

Several channels of the same mode group **cannot** be in different modes at the same time. If individual channels are assigned to different mode groups, a channel switchover activates the corresponding mode group. This allows mode changes to be initiated via a channel switchover.

Modes in the mode group

The following operating modes are available:

- **AUTOMATIC**

Automatic processing of part programs.

- Part program test
- All channels of the mode group can be active at the same time.

- **JOG in Automatic**

JOG in AUTOMATIC is an extension of AUTOMATIC mode intended to simplify use. JOG can be executed without leaving AUTOMATIC mode if boundary conditions so permit.

- **JOG**

Jogging (manual axis traversal)

- The axes can be traversed manually with the handwheel or the traversing keys.
- Channel-specific signals and interlocks are effective in ASUBs and when a movement is activated via IDS synchronized actions. Links are also taken into account.
- Every channel in the mode group can be active.

- **MDA**

Manual Data Automatic (the NC blocks are entered via the operator panel)

- Restricted automatic execution of part programs and sections of part programs (can be only one block or a sequence of blocks).
- Part program test
- A maximum of 1 channel per mode group can be active (applies only to TEACH IN)
- Axes can be manually traversed only in subordinate machine functions such as JOG, REPOS or TEACH IN.

Applies to all modes

Cross-mode synchronized actions

Modal synchronized actions can be executed per IDS in all modes for the following functions in parallel to the channel:

- Command axis functions
- Spindle functions
- Technology cycles

Selection

The user can select the desired operating mode by means of soft keys on the operator interface.

This selection (AUTOMATIC, MDA, or JOG) is transferred to interface signals: DB11 DBX4.0-2 (strobe mode) in the PLC, but is not activated at this point.

Activation and priorities

The desired mode of the mode group is activated via the interface signals:

DB11 DBX0.0-2 (mode type)

If several modes are selected at the same time, the following priority is in effect:

Priority	Mode	Mode-group signal (NCK → PLC)
1st priority, high	JOG	DB11 DBX0.2
2nd priority, medium	MDA	DB11 DBX0.1
3rd priority, low	AUTOMATIC	DB11 DBX0.0

Display

The current mode of the mode group is displayed via the interface signals:

DB11 DBX6.0-2 (active mode)

Mode-group signal (NCK → PLC)	Active operating mode
DB11 DBX6.2	JOG
DB11 DBX6.1	MDA
DB11 DBX6.0	AUTOMATIC

Global machine function for mode group

After mode selection, a machine function can be selected, which is then valid globally for the whole mode group.

Within JOG mode

Within JOG mode, one of the following machine functions can be selected:

- REF (reference point approach)
- REPOS (repositioning)

Within MDA mode

Within MDA mode, one of the following machine functions can be selected:

- REF (reference point approach)
- REPOS (repositioning)
- TEACHIN (teach-in of axis positions)

TEACH IN, REPOS or REF

The selection of the machine functions TEACH IN, REPOS or REF from the user interface is stored under the interface signal:

DB11 DBX5.0-2 (strobe machine function)

The desired machine functions TEACHIN, REPOS or REF are activated with the interface signals:

DB11 DBX1.0-2 (machine function)

The display of the active machine function TEACHIN, REPOS or REF can be seen in the interface signal:

DB11 DBX7.0-2 (active machine function)

Operating statuses

The following three channel statuses can occur in each mode:

1. Channel reset

The machine is in its initial state. This is defined by the machine manufacturer's PLC program, e.g. after POWER ON or at the end of the program.

2. Channel active

A program has been started, and the program is being executed or a reference point approach is in progress.

3. Channel interrupted

The running program or reference point approach has been interrupted.

Functions in the modes

Modes are supplemented through user-specific functions. These functions are not related to any particular technology or machine. A subset of the available functions can be selected in each mode, depending on the operating state.

These functions are categorized as follows:

- NCK-specific functions
- Mode group-specific functions
- Channel-specific functions

The individual functions can be started and/or executed from the three individual channel statuses: "channel reset", "channel active", or "channel interrupted". The channel states and program states can be checked on the operator panel.

Boundary condition for submode TEACH IN

TEACH IN is not permissible for leading or following axes of an active axis grouping, e.g. for:

- gantry axis grouping or a gantry axis pair
- Coupled-axis grouping of master and slave axis

JOG in AUTOMATIC details

JOG in AUTOMATIC mode is permitted if the mode group is in RESET state and the axis is jog-capable.

RESET for the mode group means:

- All channels in RESET state.
- All programs interrupted.
- No DRF channel active.

Jog-capable axis means:

- The axis is **not**:
 - A PLC axis (as a concurrent positioning axis), i.e. the PLC has fetched the axis via axis replacement (e.g. via FC18).
 - A command axis, i.e. the axis was programmed by a synchronous action and the motion has not yet been completed.
 - A rotating spindle, e.g. a spindle rotating despite RESET.
 - An asynchronous reciprocating axis.

Comment: The "jog-capable" property is independent of the "JOG in AUTOMATIC" function.

Activation

The function "JOG in AUTOMATIC" can be activated with the machine data:

MD10735 \$MN_JOG_MODE_MASK

1. Before POWER ON, the following machine data must be set:
MD10735 \$MN_JOG_MODE_MASK, Bit 0
2. The user switches to AUTO (PLC user interface DB11 DBX0.0 = 0→1 edge). "JOG in AUTOMATIC" is then active if the NCK previously had channel status "RESET" and program status "Aborted" in all mode group channels. The axis in question must also be "jog-capable". DRF must be deactivated (if not already deactivated).
3. RESET is initiated or the running program is finished with M30/M2 in all mode group channels that do not have channel status "Reset" and program status "Aborted".
4. The relevant axis is made "Jog-capable" (e.g. axis replacement PLC→NCK).

Comment: In most applications, the axes to be traversed are "JOG-capable" and switching to AUTO will also activate "JOG in AUTOMATIC"!

Features of JOG in AUTOMATIC

- The +/- keys cause a JOG movement, and the mode group is switched **internally** to JOG. (i.e. "Internal JOG").
- Moving the handwheels causes a JOG movement, and the mode group is switched **internally** to JOG, unless DRF is active.
- An ongoing JOG movement is not complete until the end position of the increment has been reached (if this has been set) or the movement has been aborted with "Delete distance-to-go".

In this way an increment can be stopped using Stop and then moved to the end using Start. The NCK remains in "Internal JOG" during this time. A partial increment is possible, but it must not be interrupted using Stop. There is a mode in which releasing the travel key causes interruption within an increment.

- Without any JOG movement, "JOG in AUTOMATIC" responds in the same way as "Automatic". In particular, the Start key starts the selected part program and the appropriate HMI softkey initiates a block search.
- If JOG movement is active, the NCK is internally in JOG mode, and, thus, a block search request is refused and a Start cannot start the part program. Start starts any remaining increment or has no effect.
- While a mode group axis is being traversed in JOG mode, the mode group remains internally in JOG mode.
Comment: This phase can begin with the JOG movement of an axis and end with the end of the JOG movement of *another* axis.
- Axis replacement is not possible for an axis with active JOG movement. (The axis might change mode group). The NCK blocks any axis replacement attempt.

- The PLC user interface indicates "Automatic" mode:
 - DB11 DBX6.0=1
 - DB11 DBX6.1=0
 - DB11 DBX6.2=0
 - DB11 DBX7.0=0
 - DB11 DBX7.1=0
 - DB11 DBX7.2=0
- In "JOG in AUTOMATIC", the PLC user interface displays whether the mode group is in "Mode group RESET". This enables the NCK to now automatically switch internally to JOG, if required.
 - DB11 DBX6.4
 - DB11 DBX26.4; For mode group 2
 - DB11 DBX46.4; For mode group 3
- In "JOG in AUTOMATIC", the PLC user interface displays whether the NCK has automatically switched to "Internal JOG".
 - DB11 DBX6.5
 - DB11 DBX26.5; For mode group 2
 - DB11 DBX46.5; For mode group 3

Boundary conditions

"JOG in AUTOMATIC" can only switch internally to JOG if the mode group is in "Mode group RESET" state, i.e. it is not possible to jog immediately in the middle of a stopped program. The user can jog in this situation by pressing the JOG key or the Reset key *in all channels* of the mode group.

Selecting AUTOMATIC disables the INC keys and the user can/must press the INC keys again to select the desired increment. If the NCK switches to "Internal JOG", the selected increment is retained.

If the user attempts to jog the geometry or orientation axes, the NCK switches to "Internal JOG" and the motion is executed. Several axes can be physically moved in this way; they must all be "JOG-capable".

Following the JOG movement, the NCK deactivates "Internal JOG" again and selects AUTO mode again. The internal mode change is delayed until the movement is complete. This avoids unnecessary multiple switching operations, e.g. when using the handwheel. The PLC can only rely on the "Internal JOG active" PLC signal.

The NCK will then switch to "Internal JOG" if the axis is not enabled.

9.3.1 Monitoring functions and interlocks of the individual modes

Channel status determines monitoring functions

Monitoring functions in operating modes

Different monitoring functions are active in individual operating modes. These monitoring functions are not related to any particular technology or machine.

In a particular mode only some of the monitoring functions are active depending on the operating status. The channel status determines which monitoring functions are active in which mode and in which operating state.

Interlocking functions in operating modes

Different interlocks can be active in the different operating modes. These interlocking functions are not related to any particular technology or machine.

Almost all the interlocks can be activated in every mode, depending on the operating status.

9.3.2 Mode change

Introduction

A mode change is requested and activated via the mode group interface (DB11, ...). A mode group will either be in AUTOMATIC, JOG, or MDA mode, i.e. it is not possible for several channels of a mode group to take on different modes at the same time.

What mode transitions are possible and how these are executed can be configured in the PLC program on a machine-specific basis.

Note

The mode is not changed internally until the signal "Channel status active" is no longer pending. For error-free mode change however, all channels must assume a permissible operating mode.

Possible mode changes

The following table shows possible mode changes for one channel.

	AUTOMATIC		JOG			MDA			
			Reset	Interrupt	Interrupt	Reset	JOG without handwheel		AUTO
	Reset	Interrupt	Reset	Interrupt	Interrupt	Reset	Interrupt	active	Interrupt
AUTOMATIC			X	X		X			
JOG	X	X				X	X		X
MDA	X	X	X		X				

Possible mode changes are shown by an "X".

Special cases

- **Errors during mode change**

If a mode change request is rejected by the system, the error message "Operating mode cannot be changed until after NC Stop" is output. This error message can be cleared without changing the channel status.

- **Mode change disable**

A mode change can be prevented by means of interface signal:
DB11, DBX0.4 (Mode change disable).

This suppresses the mode change request.

The user must configure a message to the operator indicating that mode change is disabled. No signal is set by the system.

- **Mode change from MDA to JOG**

If all channels of the mode group are in Reset state after a mode change from MDA to JOG, the NC switches from JOG to AUTO. In this state, part program commands `START` or `INIT` can be executed.

If a channel of the mode group is no longer in Reset state after a mode change, the part program command `START` is rejected and Alarm 16952 is issued.

9.4 Channel

Assignment part program - channel

Part programs are assigned to channels.

Part programs of different channels are largely independent of each other.

Channel properties

A channel constitutes an "NC" in which one part program can be executed at a time. Machine axes, geometry axes and positioning axes are assigned to the channels according to the machine configuration and the current program status (AXIS CHANGE, GEO AXIS CHANGE, SETMS).

The system assigns each channel its own path interpolator with associated programming. Each channel can run its own machining program, which is controlled from the PLC.

The following channel-specific functions make it possible for the channels to process part programs independently:

- Each channel has its own NC Start, NC Stop, RESET.
- One feedrate override and one rapid traverse override per channel.
- Dedicated interpreter for each channel.
- Dedicated path interpolator for each channel, which calculates the path points such that all the machining axes of the channel are controlled simultaneously from path axes.
- Selection and deselection of tool cutting edges and their length and radius compensations for a tool in a specific channel.

For more information on tool offset, refer to:

References:

/FB1/ Function Manual, Basic Functions; Tool Offset (W1)

- Channel-specific frames and frames active in the channel for transforming closed calculation rules into Cartesian coordinate systems. Offsets, rotations, scalings, and mirrorings for geometry axes and special axes are programmed in a frame.

For more information on frames, refer to:

References:

/FB1/ Function Manual, Basic Functionse; Axes, Coordinate Systems, Frames (K2), Chap: "External work offset"

- Display of channel-specific alarm responses.
- Display of current machining sequence (axis position, current G functions, current auxiliary functions, current program block) for each channel.
- Separate program control functions for each channel.

These functions (with the exception of the display functions) are controlled and checked by the PLC with interface signals.

Channels in the same mode group always have to be operated in the same mode (AUTOMATIC, JOG, MDA).

Channel configuration

Channels can be filled with their own channel name via the following machine data:

MD20000 \$MC_CHAN_NAME (channel name)

The various axes are then assigned to the available channels via machine data. There can be only one setpoint-issuing channel at a time for an axis/spindle. The axis/spindle actual value can be read by several channels at the same time. The axis/spindle must be registered with the relevant channel.

Moreover, the following channel-specific settings can also be defined via machine data:

- Position of deletions or the basic program settings of G groups via the machine data:
MD20150 \$MC_GCODE_RESET_VALUES (RESET position of G groups)
- Auxiliary function groups regarding the combination and the output time.
- Transformation conditions between machine axes and geometry axes
- Other settings for the execution of a part program

Change in the channel assignment

An online change in the channel configuration cannot be programmed in a part program or PLC user program. Changes in the configuration must be made via the machine data. The changes become effective only after a new POWER ON.

Container axes and link axes

An axis container combines a group of axes in a container. These axes are referred to as container axes. This involves assigning a pointer to a container slot (ring buffer location within the relevant container) to a channel axis. One of the axes in the container is located temporarily in this slot.

Each machine axis in the axis container must be assigned at all times to exactly **one** channel axis.

Link axes can be assigned permanently to one channel or dynamically (by means of an axis container switch) to several channels of the local NCU or the other NCU. A link axis is a non-local axis from the perspective of one of the channels belonging to the NCU to which the axis is not physically connected.

The assignment between the link axes and a channel is implemented as follows:

- For permanent assignment using machine data:
Allow the direct logic machine axis image to show link axes.
- For dynamic assignment:
Allow the axis container slot machine data to show link axes.

For more information on link axes and container axes, refer to

References:

/FB2/ Function Manual, Extended Functions; Several Operator Panel Fronts and NCUs, Distributed Systems (B3)

Interface signals

NCK channel 1 signals lie in DB21 of the user interface, those of channel 2 in DB22. The channel or channels can be monitored and controlled from the PLC or NCK.

Technology in channel

The machine data can be used to relate the technology specification for the machine to specific channels:

MD27800 \$MC_TECHNOLOGY_MODE

Among other functions, this information is used for evaluation in HMI, PLC, and standard cycles.

Siemens supplies standard MD for milling. If the machine tool is not a milling machine, but some other type, a different data/program block can be loaded by the HMI or PLC depending on the technology mode set in the machine data.

Spindle functions using a PLC

It is possible to control special spindle motions via an axial PLC interface as an alternative to FC18 and to start and stop them using VDI interface signals without executing a part program.

This option is available only if the channel status is in "Interrupted" or "RESET" mode and the program status is in "Interrupted" or "Aborted" mode. This acceptance state will occur in case of RESET and in JOG mode.

A separate spindle start can be set for each spindle. The following spindle functions can be controlled by PLC via interface signals:

- Spindle Stop (corresponds to M5)
- Spindle Start clockwise (corresponds to M3)
- Spindle Start counterclockwise" (corresponds to M4)
- Select gear stage
- Spindle positioning (corresponds to M19)

In the case of multi-channel operation, the spindle started by the PLC becomes active in the channel that is handling the spindle when the start command is received.

For more information about the special spindle interface, see:

References:

/FB1/ Function Manual, Basic Functions; Spindles (S1)

Autonomous single-axis operations

It is possible to decouple a particular axis/spindle in the main run from the channel behavior triggered by the NC program run.

The PLC identifies the corresponding axis/spindle from the axial NC/PLC interface signal:

DB31, ... DBB28.7 (PLC controlled axis) = 1 → assume control

DB31, ... DBB28.7 (PLC controlled axis) = 0 → relinquish control

The following functions can be controlled from the PLC:

- Cancel axis/spindle sequence (equivalent to delete distance-to-go)
- Stop or interrupt axis/spindle
- Resume axis/spindle operation (continue the motion sequence)
- Reset axis/spindle to the initial state

For a detailed description of these stand-alone single axis operations, refer to:

References:

/FB2/ Function Manual, Basic Functions; Positioning axes (P2)

For additional information on the channel-specific signal exchange (PLC → NCK), see:

References:

/FB1/ Function Manual Basic Functions; PLC Basic Program (P3)

9.4.1 Global start disable for channel

User/PLC

A global Start disable can be set for the selected channel via the HMI or from the PLC.

Function

When Start disable is set, no new program starts are accepted for the selected channel. Start attempts are counted internally.

If a start is executed by the PLC before a global block disable is sent from the HMI to the NCK, the program is not stopped by the Start disable and its status is transmitted to the HMI.

NC Start disable and global Start disable have the same effect on the internal counter for starts that have been sent but not executed. (OPI variable startRejectCount).

Bypassing global Start disable

The interface signal:

DB21, ... DBX7.5 (PLC → NCK)

allows the PLC to temporarily bypass a global Start disable.

- 0: Global Start disable is effective
- 1: Global Start disable is temporarily canceled.

Messages

If desired, a message can be issued when a Start attempt occurs while a global block disable is active.

The control is exercised using machine data:

MD11411 \$MN_ENABLE_ALARM_MASK Bit 6

- 1: Alarm 16956 appears: Channel %1, Program %2 cannot be started because of "Global Start disable".
- 0: Start attempts when a global block disable is set are not signaled by an alarm.

9.5 Program test

Several control functions are available for testing a new part program. These functions are provided to reduce danger at the machine and time required for the test phase. Several program functions can be activated at the same time to achieve a better result.

Test options

The following test options are described below:

- Program execution without setpoint outputs
- Program execution in single-block mode
- Program execution with dry run feedrate
- Skip part program blocks
- Block search with or without calculation.

9.5.1 Program execution without setpoint outputs

Function

In the "Program test" status, a part program is executed without the output of axis or spindle setpoints.

The user can use this to check the programmed axis positions and auxiliary function outputs of a part program. This program simulation can also be used as an extended syntax check.

Selection

This function is selected via the operator interface in the "Program control" menu.

The selection sets the following interface signal:

DB21, ... DBX25.7 (program test selected)

This does not activate the function.

Activation

The function is activated via interface signal:

DB21, ... DBX1.7 (activate program test)

Display

The corresponding field on the operator interface is reversed and the interface signal in the PLC as a checkback of the active program test:

DB21, ... DBX33.7 (program test active)

Program start and program run

When the program test function is active, the part program can be started and executed (incl. auxiliary function outputs, wait times, G function outputs etc.) via the interface signal:

DB21, ... DBX7.1 (NC-Start)

The safety functions such as software limit switch, working area limits continue to be valid.

The only difference compared to normal program operation is that an internal **axis disable** is set for all axes (including spindles). The machine axes do not move, the actual values are generated internally from the setpoints that are not output. The programmed velocities remain unchanged. This means that the position and velocity information on the operator interface is exactly the same as that output during normal part program execution. The position control is not interrupted when this function is active, so the axes do not have to be referenced when the function is switched off.

CAUTION

The signals for exact stop:
DB31, ... DBX60.6/60.7 (exact stop coarse/fine)
mirror the actual status on the machine.

They are only canceled during program testing if the axis is pushed out of its set position (the set position remains constant during program testing).

With signal:

DB21, ... DBX33.7 (program test active)
both the PLC program and the part program can use variable \$P_ISTEST to decide how to react or branch in response to these signals during testing.

Note

Dry run feedrate

"Program execution without axis motion" can also be activated with the function "Dry run feedrate". With this function, part program sections with a small programmed feedrate can be processed in a shorter time.

Note

Tool management

Because of the axis disable, the assignment of a tool magazine is not changed during program testing. A PLC application must be used to ensure that the integrity of the data in the tool management system and the magazine is not corrupted. The toolbox diskettes contain an example of the basic PLC program.

9.5.2 Program execution in single-block mode

Function

In case of "Program execution in single block mode" the part program execution stops after every program block. If tool cutter radius compensation or a tool nose radius correction is selected, processing stops after every intermediate block inserted by the control.

The program status switches to "Program status stopped".

The channel status remains active.

The next part program block is processed on NC Start.

Application

The user can execute a part program block-by-block to check the individual machining steps. Once the user decides that an executed part program block is functioning correctly, he can call the next block.

Single block types

The following different types of single block are provided:

- Decoding single block

With this type of single block, all blocks of the part program (even the pure computation blocks without traversing motions) are processed sequentially by "NC Start".

- Action single block (initial setting)

With this type of single block, the blocks that initiate actions (traversing motions, auxiliary function outputs, etc.) are processed individually.

Blocks that were generated additionally during decoding (e.g. for cutter radius compensation at acute angles) are also processed individually in single-block mode.

Processing is however not stopped at calculation blocks as these do not trigger actions.

The single block types are determined via the user interface in the menu "Program controls".

 **CAUTION**

In a series of G33/G34/G35 blocks, a single block is only operative if "dry run feed" is selected. Calculation blocks are not processed in single step mode (only if single decoding block is active).
SBL2 is also ineffective with G33/G34/G35.

Selection

It is possible to select the single block mode:

- via the machine control panel (key "Single Block")
- via the user interface

For an exact procedure see:

References:

Operating Manual of the installed HMI Application

Activation

The function is activated through the PLC basic program via the interface signal:

DB21, ... DBX0.4 (activate single block)

Display

Active single block mode is indicated by a reversal in the relevant field in the status line on the operator interface.

Because of the single block mode, as soon as the part program processing has processed a part program block, the following interface signal is set:

DB21, ... DBX35.3 (program status interrupted)

Processing without single block stop

Despite the selected single block mode, a processing without the single block stop can be set for specific program runs, e.g. for:

- internal ASUBs
- User ASUBs
- Intermediate blocks
- Block search group blocks (action blocks)
- Init blocks
- Subroutines with `DISPLOF`

- Non-reorganizable blocks
- Non-repositionable blocks
- Reposition block without travel information
- Tool approach block.

The setting is done via the following machine data:

MD10702 \$MN_IGNORE_SINGLEBLOCK_MASK (Prevent single block stop)

References:

Detailed machine-data description

9.5.3 Program execution with dry run feedrate

Function

During "Program execution with dry run feedrate" the traversing speeds, which have been programmed together with G01, G02, G03, G33, G34 and G35, are replaced by a parameterized feedrate value:

SD42100 \$SC_DRY_RUN_FEED (dry run feed rate)

The dry run feedrate also replaces the programmed revolutional feedrate in program blocks with G95.

The exact way of working of the parameterized dry run feedrate (SD42100) depends on the setting of another setting data:

SD42101 \$SC_DRY_RUN_FEED_MODE (Mode for test run speed)

Value	Meaning
0	Dry run feedrate is the maximum of the programmed feedrate and setting data SD42100. (Default setting!) ⇒ SD42100 becomes effective only when the stored value is greater than the programmed feedrate.
1	Dry run feedrate is the minimum of the programmed feedrate and SD42100. ⇒ SD42100 becomes effective only when the stored value is less than the programmed feedrate.
2	The value in SD42100 acts as the dry run feed rate, regardless of the programmed feedrate.
10	As in the case of "0", except thread cutting (G33, G34, G35) and thread boring (G331, G332, G63). These functions are executed as programmed.
11	As in the case of "1", except thread cutting (G33, G34, G35) and thread boring (G331, G332, G63). These functions are executed as programmed.
12	As in the case of "2", except thread cutting (G33, G34, G35) and thread boring (G331, G332, G63). These functions are executed as programmed.

A dry run feedrate can be selected in the automatic modes and activated on interruption of an automatic mode or end of a block.

For more information on influencing the feedrate, see "V1: Feedrates (Page 1389)".

Application

Workpieces may not be machined when "dry run feedrate" is active because the altered feedrates might cause the permissible tool cutting rates to be exceeded and the workpiece or machine tool could be damaged.

Selection

This function is selected via the operator interface in the "Program control" menu.

The selection sets the following interface signal:

DB21, ... DBX24.6 (dry run feed rate selected)

This does not activate the function.

Activation

The function is activated via interface signal:

DB21, ... DBX0.6 (activate dry run feed)

Display

Active dry run feedrate mode is indicated by a reversal in the relevant field in the status line on the operator interface.

9.5.4 Skip part-program blocks

Function

When testing or breaking in new programs, it is useful to be able to disable or skip certain part program blocks during program execution. For this, the respective records must be marked with a slash.

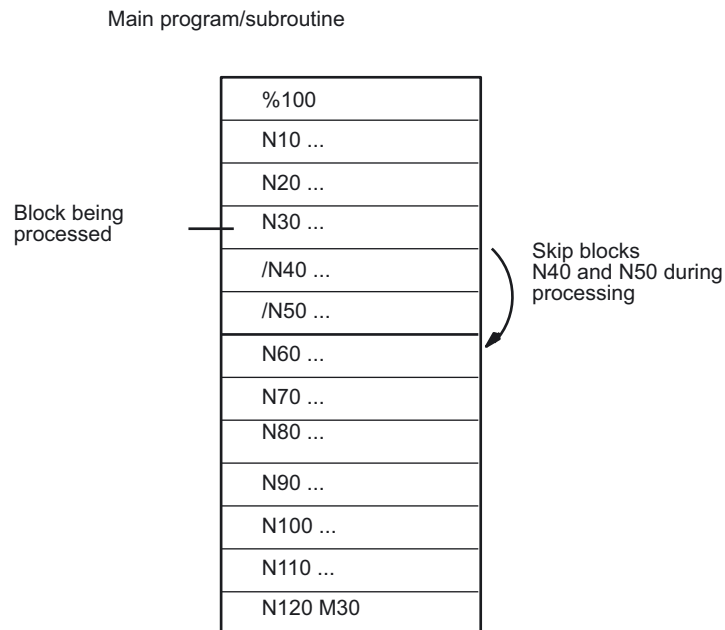

Figure 9-1 Skipping part program blocks

Selection

This function is selected via the operator interface in the "Program control" menu.

The selection sets the following interface signal:

DB21, ... DBX26.0 (skip block selected)

This does not activate the function.

Activation

The function is activated via the interface signal:

DB21, ... DBX2.0 (activate skip block)

Note

The "Skip part programs" function remains active during block searches.

Display

Activated "Skip block" function is indicated by a reversal of the relevant field on the operator interface.

9.6 Block search

Function

Block search offers the possibility of starting part program execution from almost any part program block.

This involves the NC rapidly performing an internal run through the part program (without traversing motions) to the selected target block during block search. Here, every effort is made to achieve to the exact same control status as would result at the target block during normal part program execution (e.g. with respect to axis positions, spindle speeds, loaded tools, NC/PLC interface signals, variable values) in order to be able to resume automatic part program execution from the target block with minimum manual intervention.

Block search types

- **Type 1: Block search without calculation**

Block search without calculation is used to find a part program block in the quickest possible way. No calculation of any type is performed. The control status at the target block remains unchanged compared to the status before the start of the block search.

- **Type 2: Block search with calculation at contour**

Block search with calculation at contour is used to enable the programmed contour to be approached in any situation. On NC Start, the start position of the target block or the end position of the block before the target block is approached. This is traversed up to the end position. Processing is true to contour.

- **Type 4: Block search with calculation at block end point**

Block search with calculation at block end point is used to enable a target position (e.g. tool change position) to be approached in any situation. The end position of the target block or the next programmed position is approached using the type of interpolation valid in the target block. This is not true to contour.

Only the axes programmed in the target block are moved. If necessary, a collision-free initial situation must be created manually on the machine in "JOG REPOS" mode before the start of further automatic part program execution.

- **Type 5: Block search with calculation in "Program test" (SERUPRO) mode**

SERUPRO (**search run by programtest**) is a cross-channel block search with calculation. Here, the NC starts the selected part program in "Program test" mode. On reaching the target block, the program test is automatically deselected. This type of block search also enables interactions between the channel in which the block search is being performed and synchronized actions as well as with other NC channels.

Note

For more information on block searches, refer to:

References:

/FB1/ Function Manual Basic Functions; Auxiliary Function Output to PLC (H2), Chapter: "Behavior on block search"

Subsequent actions

After completion of a block search, the following subsequent actions may occur:

- Type 1 - Type 5: Automatic Start of an ASUB

When the last action block is activated, a user program can be started as an ASUB.

- Type 1 - Type 4: Cascaded block search

A further block search with a different target specification can be started from "Search target found".

9.6.1 Sequence for block search of Type 1, 2 and 4

Time sequence

The block search (Types 1, 2, and 4) proceeds as follows:

1. Activate search via input in HMI Advanced or HMI Embedded
2. Search target found, or alarm if target cannot be found

3. NC Start for output of action blocks

4. NC Start for program continuation.

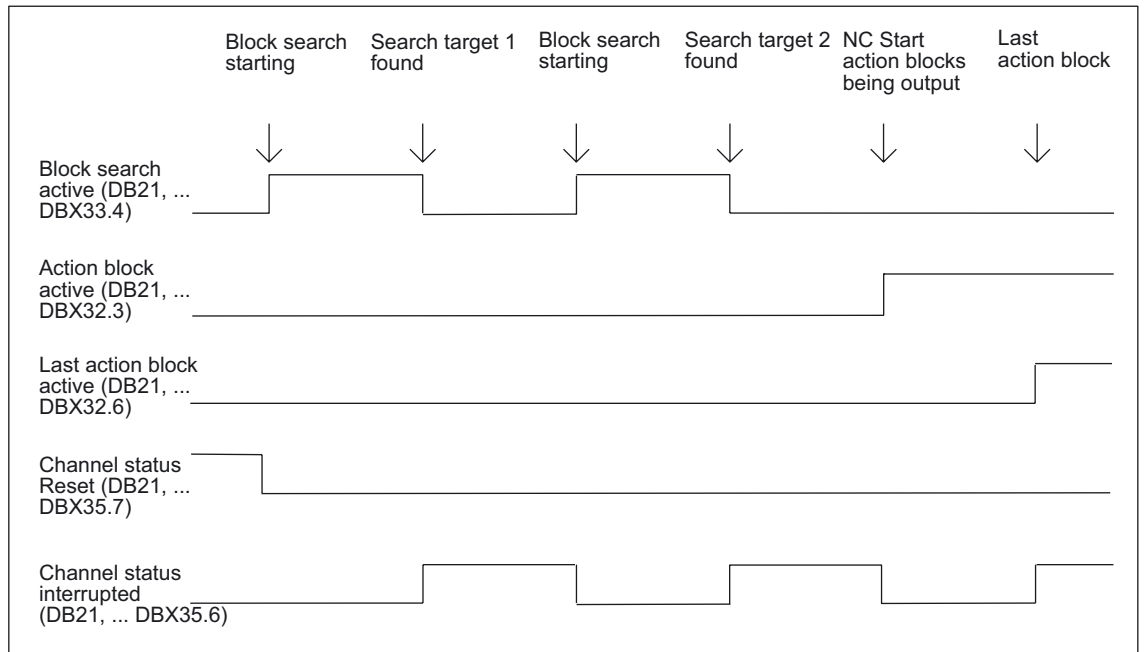

Figure 9-2 Time sequence of interface signals

Interface signals

In the PLC, the following interface signals are set according to the time sequence shown in the figure:

DB21, ... DBX33.4 (block search active)

DB21, ... DBX32.3 (action block active)

DB21, ... DBX32.4 (approach block active)

DB21, ... DBX32.6 (last action block active)

DB21, ... DBX1.6 (PLC action complete)

Continuation mode after block search

Following the block search, the program can be resumed via interface signal: DB21, ... DBX7.1 (NC Start).

If an axis is first programmed after "Block search with calculation at block end point", the incremental value can be added to the value accumulated up to the search target using setting data SD42444 \$SSC_TARGET_BLOCK_INCR_PROG.

Action blocks

Action blocks contain the actions accumulated during "Block search with calculation", such as auxiliary function outputs and tool (T, D), spindle (S), and feedrate programming commands. During "block search with calculation" (contour or block end point), actions such as M function outputs are accumulated in so-called action blocks. These blocks are output on an NC Start after "Search target found".

Note

With the action blocks, the accumulated spindle programming (S value, M3/M4/M5/M19, SPOS) also becomes active.

The PLC user program must ensure that the tool can be operated and that, if necessary, the spindle programming is reset via PLC signal:
DB31, ... DBX2.2(spindle reset)
or the spindle programming is not output.

Single-block processing: MD10702 \$MN_IGNORE_SINGLEBLOCK_MASK ()

By setting bit 3 = 1, it is possible to prevent a stop after every action block in single-block mode.

Boundary conditions for approach block/target block

Block search type 2

Interface signal:

DB21, ... DBX32.4 (approach block active)

is **only** set with "Block search with calculation at contour" because a separate approach block is not generated with "Block search with calculation at block end point" (the approach block is the same as the target block).

Block search type 4

The approach movement "Search with calculation to block end point" is performed using the type of interpolation valid in the target block. This should be G0 or G1, as appropriate. With other types of interpolation, the approach movement can be aborted with an alarm (e.g. circle end point error on G2/G3).

9.6.2 Block search in connection with other NCK functions

9.6.2.1 ASUB after and during block search

Synchronization of the channel axes

With the start of an ASUB after "block search with calculation", the actual positions of all channel axes are synchronized during preprocessing.

Effects:

- System variable: \$P_EP (programmed end position)

In the ASUB, the system variable provides: \$P_EP (programmed end position) the current actual position of a channel axes in the work piece coordinate system.

\$P_EP == "current actual position of the channel axis"

- System variable: \$AC_RETPOINT (repositioning point in the ASUB)

In the ASUB, the system variable provides: \$AC_RETPOINT (repositioning point in the ASUB) the actual position of a channel axis in the workpiece coordinate system accumulated with a block search.

\$AC_RETPOINT == "collected search position of the channel axis (WCS)"

Block search type 2

For block search type 2 (block search with calculation on contour) the following part program command must be programmed at the conclusion of the ASUB:

`REPOSA` (repositioning on the contour; linear; all channel axes)

Effect:

- All channel axes are moved to their search position that was collected during the block search.
- \$P_EP == "accumulated search position of the channel axis (WCS)"

Block search type 4 and part program command `REPOS`

After block search type 4 (block search with calculation at block end point) no automatic repositioning is initiated during the following period of time by the part program command

`REPOS`:

- Start: NC/PLC interface signals: DB21,... DBB32, Bit6 (last action block active) == 1
- End: Continuing the part program processing per NC START,.

The start point of the approach movement is represented by the current axis positions of the channel axes at the time of the NC start command. The end point results from the other transversing movements programmed in the part program.

For block search type 4, no approach movement is generated by the NC.

Effect:

- After exiting the ASUB, the system variable \$P_EP thus provides the actual position, on which the channel axes of the ASUB were positioned (or manual (mode: JOG)).

\$P_EP == "current actual position of the channel axis"

9.6.2.2 PLC actions after block search

To allow activation of PLC actions (starting of ASUBs, call-up of PLC functions) after the end of the block search at a defined point, there is the NCK/PLC interface signal:

DB21, ... DB32.6 (last action block active) == 1

9.6 Block search

This means that all action blocks are processed and that actions are possible by the PLC (ASUB, FC) or the operator (overstoring, mode change after JOG/REPOS). This allows the PLC to perform another tool change, for example, before the start of the transversing movement.

By default, alarm 10208 is output at this moment to notify the operator that another NC START is needed to continue program execution.

In combination with alarm 10208, the following interface signals are set:

DB21, ... DBX36.7 (NCK alarm with processing stop)

DB21, ... DBX36.6 (channel-specific NCK alarm is present)

PLC-controlled alarm triggering

The setting by which alarm 10208 is only triggered after ending the PLC action, is done via machine data:

MD11450 \$MN_SEARCH_RUN_MODE, Bit 0 = 1

Bit	Value	Meaning
0	1	With the change of the last action block after a block search, the following takes place: <ul style="list-style-type: none"> • Execution of the part program is stopped • DB21, ... DBB32.6 (last action block active) = 1 • Alarm display: Alarm 10208 only if the following applies: DB21, ... DBX1.6 (PLC action ended) == 1

9.6.2.3 Spindle functions after block search

Control system response and output

The behavior with regard to the spindle functions after ending the block search can be set via machine data:

MD11450 \$MN_SEARCH_RUN_MODE, Bit 2

Bit	Value	Meaning
2	0	Output of spindle auxiliary functions (M3, M4, M5, M19, M70) in action blocks.
	1	Output of the auxiliary functions is suppressed in the action blocks. The spindle programmings that accumulated during the block search can be output at a later point in time (e.g. via ASUB). The program data for this is stored in the following system variables: <ul style="list-style-type: none"> • \$P_SEARCH_S • \$P_SEARCH_SDIR • \$P_SEARCH_SGEAR • \$P_SEARCH_SPOS • \$P_SEARCH_SPOSMODE

System variables

The spindle-specific auxiliary functions are always stored in the following system variables on block search, irrespective of the programming described above:

System variables	Description
\$P_SEARCH_S[n]	Collected spindle speed, value range = { 0 ... Smax }
\$P_SEARCH_SDIR[n]	Collected spindle rotation direction, value range = { 3, 4, 5, -5, -19, 70 }
\$P_SEARCH_SGEAR[n]	Collected spindle gear stage M function, value range = { 40 ... 45 }
\$P_SEARCH_SPOS[n]	Collected spindle position, value range = { 0 ... MD30330 \$MA_MODULO_RANGE } Collected traverse path, value range = { -100.000.000 ... 100.000.000 }
\$P_SEARCH_SPOSMODE[n]	Collected position approach mode, value range = { 0 ... 5 }

For later output of the spindle-specific auxiliary functions, the system variables can be read, for example in an ASUB, and output after output of the action blocks:
DB21, ... DBX32.6 == 1 (last action block active)

Note

The contents of the system variables \$P_S, \$P_DIR and \$P_SGEAR may be lost after block search due to synchronization operations.

More detailed information on ASUB, block search, and action blocks is to be found in:

- /FB1/ Function Manual, Basic Functions; Auxiliary Function Output to PLC (H2),
Section: Output suppression of spindle-specific auxiliary functions
- /FB1/ Function Manual, Basic Functions; Mode Group, Channel, Program Operation (K1)
Section: Program test
- /FB1/ Function Manual, Basic Functions; Spindles (S1),
Section: Auxiliary spindle functions after block search

9.6.3 Automatic start of an ASUB after a block search

Parameter assignment

Making the function effective

The automatic ASUB start after a block search is activated by the following MD setting:

MD11450 \$MN_SEARCH_RUN_MODE, bit 1 = 1

9.6 Block search

Program to be activated

In the default setting, the program `_N_PROG_EVENT_SPF` is activated from the directory `_N_CMA_DIR` as ASUB after the block search by changing the last action block. If another program is to be activated, then the name of this user program must be entered in the following machine data:

MD11620 \$MN_PROG_EVENT_NAME

Behavior when the single block processing is set

Via the following channel-specific machine data it can be set, whether the activated ASUB are processed without interruption despite a set single block processing or whether the single block processing is to be made active:

MD20106 \$MC_PROG_EVENT_IGN_SINGLEBLOCK

Bit	Value	Description
4	0	Single block execution is active.
	1	Single block processing is suppressed.

Behavior when the read-in disable is set

Via the following channel-specific machine data it can be set, whether the activated ASUB are processed without interruption despite a set read-in disable (`DB21, ... DBX6.1 = 1`), or whether the read-in disable is to be made active:

MD20107 \$MC_PROG_EVENT_IGN_INHIBIT

Bit	Value	Description
4	0	Read-in disable is active.
	1	Read-in disable is suppressed.

Note

For more information on parameterization of MD11620, MD20108 and MD20107 see "Event-driven Program calls > Parameterization (Page 586)".

Programming

The event that has started this ASUB can be determined by scanning the system variable `$P_PROG_EVENT`. In case of an automatic activation after a block search `$P_PROG_EVENT` returns the value "5".

Sequence

Sequence of automatic start of an ASUB after a block search

1. Start block search (with/without calculation, at contour, at end-of-block point).
2. Stop after "Search target found".
3. NC Start for output of action blocks.
4. Last action block is activated.

5. Automatic start of /_N_CMA_DIR/_N_PROG_EVENT_SPF (default) as an ASUB.
6. The NC will stop after changing the last ASUB block (REPOSA command) and the following NC/PLC interface signal is set:

DB21, ... DBX32.6 (last action block active)

The alarm 10208 "Enter NC-start for program continuation" is generated.

Note

If bit 0 is set to "1" in MD11450 \$MN_SEARCH_RUN_MODE, then the alarm 10208 is generated only when the PLC requests this by setting the following NC/PLC interface signal:

DB21, ... DBX1.6 (PLC action complete)

9.6.4 Cascaded block search

Functionality

The "Cascaded block search" function can be used to start another block search from the status "Search target found". The cascading can be continued after each located search target as often as you want and is applicable to the following block search functions:

- Type 1 block search without calculation
- Type 2 block search with calculation at contour
- Type 3 block search with calculation at block end point

Note

Another "cascaded block search" can be started from the stopped program execution only if the search target has been found.

Activation

The "cascaded block search" is configured in the existing machine data:
MD11450 \$MN_SEARCH_RUN_MODE

- Cascaded block search is enabled (i.e., several search targets can be specified) with Bit 3 = 0 (FALSE).
- For compatibility reasons, the cascaded block search can be disabled with Bit 3 = 1 (TRUE). By default, the cascaded block search is set with Bit 3 = 0.

Execution behavior

Search target found, restart search

When the search target is reached, the program execution stops and the search target is displayed as a current block. After each located search target, a new block search can be repeated as often as you want.

Change search target specifications

You can change the search target specifications and block search function prior to each block search start.

Example: Sequence with cascaded block search

- RESET
- Block search up to search target 1
- Block search up to search target 2 → "Cascaded block search"
- NC Start for output of the action blocks → Alarm 10208
- NC Start → Continue program execution

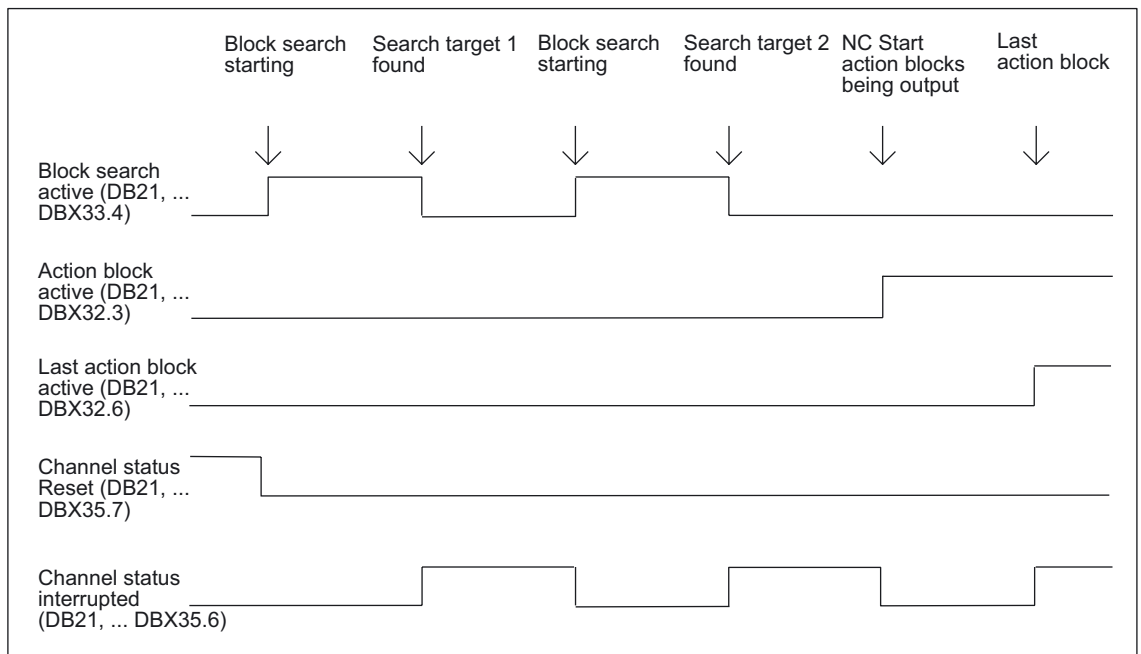

Figure 9-3 Chronological order of interface signals

9.6.5 Examples of block search with calculation

Selection

From the following examples, select the type of block search that corresponds to your task.

Type 4 block search with calculation at block end point

Example with automatic tool change after block search with active tool management:

1. Set machine data:
MD11450 \$MN_SEARCH_RUN_MODE to 1
MD11602 \$MN_ASUP_START_MASK Bit 0 = 1 (ASUB Start from stopped state)
2. Select ASUB "BLOCK_SEARCH_END" from PLC via FB4.

Reference:

/FB1/ Function Manual, Basic Functions, Basic PLC Program (P3)

3. Load and select part program "WORKPIECE_1".
4. Search to block end point, block number $N220$.
5. HMI signals "Search target found".
6. NC Start for output of action blocks.
7. With the PLC signal:
DB21... DB32.6 (last action block active)
the PLC starts ASUB "BLOCK_SEARCH_END" via FC9.
8. After the end of the ASUB (can be evaluated, e.g., via M function $M90$ to be defined, see example for block $N1110$), the PLC sets signal:
DB21, ... DBX1.6 (PLC action ended).

References:

/FB1/ Function Manual, Basic Function, Basic PLC Program (P3)
Alternatively, the VDI interface signal:
DB21-DB30 DBB318 Bit 0 (ASUB is stopped)
can also be scanned.

As a result, Alarm 10208 is displayed, i.e., other actions can now be performed by the operator.

9. Manual operator actions (JOG, JOG-REPOS, overstoring)

10. Continue part program with NC Start.

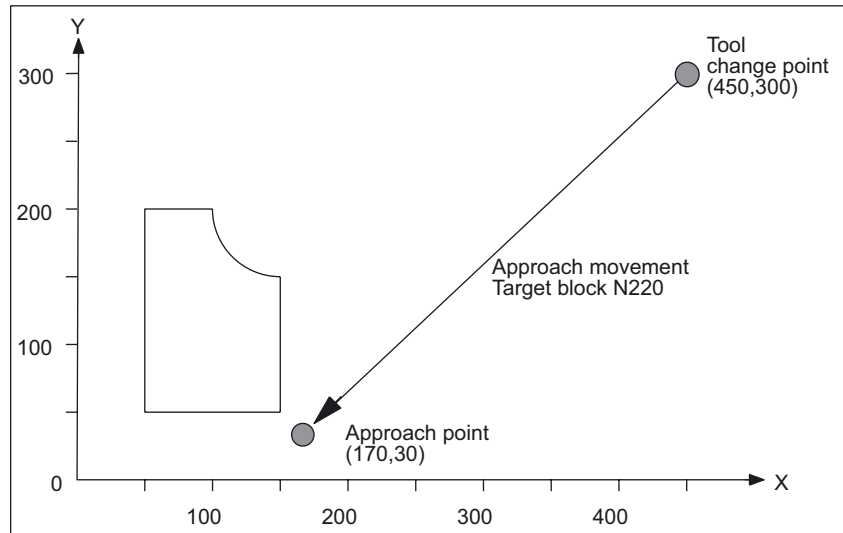

Figure 9-4 Approach movement for search to block end point (target block N220)

Note

"Search to contour" with target block N220 would generate an approach movement to the tool change point (start point of the target block).

Type 2 block search with calculation at contour

Example with automatic tool change after block search with active tool management:

- 1. to 3. Same as example for Type 4 block search
- 4. Search to contour, block number N260
- 5. to 10. Same as example for Type 4 block search

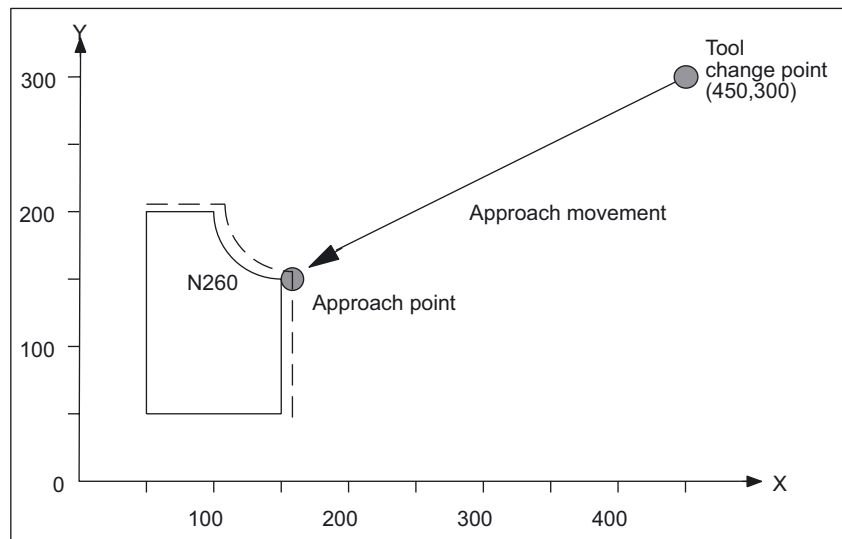

Figure 9-5 Approach movement for search to contour (target block N260)

Note

"Search to block end point" with target block N260 would result in Alarm 14040 (circle end point error).

9.7 Block search Type 5 SERUPRO

SERUPRO

The "search via program test" is from now on referred to as **SERUPRO**. This acronym has been derived from "**SE**arch **RU**n by **PRO**gram test".

Function

SERUPRO can be used for a cross-channel block search.

This search permits a block search with calculation of **all** necessary data from the previous history, so as to acquire all previously valid status data for a particular overall NC status. The **PLC** is hereby updated to the **current status**.

The NC is operated in "Program test" mode during this block search so that interactions between a channel and synchronized actions or between several channels, can take place within an NCU.

Channels

In combination with the HMI, SERUPRO is provided for the following channels:

- For the current SERUPRO channel only (1)
- For all channels with the same workpiece name as the SERUPRO channel (2)
- For all channels with the same mode group as the SERUPRO channel (3)
- For all channels of the NCU (4)

The scope of channels for SERUPRO is selected by means of configuration file **maschine.ini**, in Section [BlockSearch]:

Section [BlockSearch]	Enable search function for HMI and select search configuration
SeruproEnabled=1	;SERUPRO softkey available for HMI. Default value is (1)
SeruproConfig=1	;Number (1) to (4) of above indicated channel grouping. Default value is (1)

All other channels started with SERUPRO are operated in "Self-Acting SERUPRO" mode. Only the channel in which a target block has been selected can be started with a block search in SERUPRO mode.

Supported functions

Supported NC functions during **SERUPRO**:

- Gear stage change
- Setpoint and actual value linkages for drives such as "master-slave" as well as "electronic gear" and "axial master value coupling"
- Coupled motion in axis grouping
- Gantry axes
- Tangential follow-up of individual axes

- Superimposed motion interpolation
- Travel to fixed stop
- Synchronous spindle grouping

On reaching the beginning of the target block (see "Time sequence of SERUPRO" below), the user can activate a SERUPRO ASUB.

Special points should be noted during **SERUPRO ASUB** with regard to:

- Reference point approach
- Tool management
- Spindle ramp-up

Other functions after search target was found, such as:

- Continue machining after SERUPRO search target found (REPOS offset)
- Repositioning on contour with controlled REPOS
- Part program expansions for SERUPRO

Activation

SERUPRO is activated via the HMI. SERUPRO is operated using the "Prog.Test Contour" softkey.

SERUPRO uses REPOS to approach the target block.

Chronological sequence of SERUPRO

1. Via HMI, softkey "Prog. test contour" and the search target are operated.
2. The NC now automatically starts the selected program in "Program test" mode.
 - In this mode, axes are not traversed.
 - Auxiliary functions \$A_OUT and the direct PLC IO are output.
 - The auxiliary functions of the target block are not output.
3. Numerous operator actions are permitted during this phase:
 - Start, Stop
 - Axis replacement
 - Deletion of distance-to-go
 - Mode change, ASUBs, etc.

The program and channel statuses of interface signal:

DB21, ... DBB35

or system variable:

\$AC_PROG

is supplied analogous to real operation.

4. The part program command `WAITM/WAITE/WAITMC` will wait for the partner channels involved.
This waiting occurs if the partner channels are:
 - In SERUPRO mode
 - In Program test mode or are actually running
5. Selection of program test and dry run feedrate is rejected with corresponding Alarm 16935.
6. The NC stops at the beginning of the target block, deselects "Program test" internally, and displays the Stop condition "Search target found" in its block display.
7. As required, the user can start an ASUB that is traversed really. This ASUB is referred to below as the **SERUPRO-ASUB**.
8. The user presses Start:
The spindles are started. Then, the path axes start a **REPOS operation** that guides them to the block starting point of the target block.
The REPOS operation is implemented by a system ASUB and can be expanded using the "Editable ASUB" function.

SERUPRO operation

The sequence of operations in items 2. to 6. corresponds to one **SERUPRO operation**.

SERUPRO ASUB

An ASUB that can be called optionally when the target block is reached. It is actually executed.

SERUPRO approach

Approach to the starting point of the target block during a block search in SERUPRO test mode.

Boundary conditions for block search SERUPRO

The SERUPRO function may only be activated in "AUTOMATIC" mode and may only be aborted in program status (channel status RESET).

If in normal mode **only** the PLC starts commonly several channels, then this can be simulated by SERUPRO in each channel.

If machine data setting:

MD10708 \$MN_SERUPRO_MASK Bit 1 = 0

Alarm 16942: "Channel %1 Start program command action %2<ALNX> not possible" aborts the simulation if part program command `START` is used.

9.7 Block search Type 5 SERUPRO

Machine data:

MD10707 \$MN_SERUPRO_TEST_MASK

allows program testing to be deactivated in the stopped state without the SERUPRO operation being affected. The default setting allows program testing to be deactivated only in the RESET state.

Note

After program testing has been deactivated, a REPOS operation is initiated that is subject to the same restrictions as a SERUPRO approach operation. Any adverse effects can be inhibited using an ASUB.

Controlling SERUPRO behavior

Machine data:

MD10708 \$MN_SERUPRO_MASK

can be used to control the SERUPRO behavior as follows:

Bit	Value	Meaning
0	0	The search stops at M0.
	1	The search is not stopped for M0.
1	0	The search is interrupted for command START with alarm 16942.
	1	Command START starts the specified channel. Caution! Without any special measures, the axes physically traverse (move) in the started channel. The user is solely responsible in preventing the axes from undesirably traversing, e.g. by activating "Program test".
2	0	The SERUPRO function group is disabled.
	1	The SERUPRO function group is enabled. The START command starts the specified channel in the "Program test" mode.
3	0	All channels that find the search target (also for self-acting SERUPRO) end SERUPRO at the same time.
	1	SERUPRO ends as soon as the search target has been found. No further synchronization operations take place in the channels started by SERUPRO.
4	0	The overrides (channel, axis, spindle) specified via the NC/PLC interface are active during SERUPRO.
	1	The overrides (channel, axis, spindle) specified via the NC/PLC interface are not active during SERUPRO. Note The programmable overrides, e.g. OVR, are active during SERUPRO.
5	0	The "Single block" function is active during SERUPRO.
	1	The "Single block" function is not active during SERUPRO.

Basic G function settings for SERUPRO

Machine data:

MD20112 \$MC_START_MODE_MASK

is used to define the channel-specific basic settings after a program start for various G functions, e.g. the actual plane, adjustable work offset, active tool length compensation, active kinematic transformation etc.

For SERUPRO, using machine data:

MD22620 \$MC_START_MODE_MASK_PRT

you can enter your own basic setting. The structure of machine data MD22620 is identical with that of MD20112.

The SERUPRO-specific G function initial settings are enabled using machine data:

MD22621 \$MC_ENABLE_START_MODE_MASK_PRT

Bit	Value	Meaning
0	0	After the part program start, MD20112 \$MC_START_MODE_MASK becomes active
	1	After the part program start, MD22620 \$MC_START_MODE_MASK_PRT becomes active

NC/PLC interface signal "Block search via program test is active"

The block search via program test is displayed using the NC/PLC interface signal:
DB21, ... DBX318.1 = 1

The interface signal is set from the start of the block search until the target block is inserted into the main run.

For user-defined ASUB after the SERUPRO operation

Note

If the machine manufacturer decides to start an ASUB after the SERUPRO operation as described in item 7, the following must be observed:

Stopped status acc. to point 6.:

Machine data:

MD11602 \$MN_ASUP_START_MASK

and

MD11604 \$MN_ASUP_START_PRIO_LEVEL

allow the NCK to start the ASUB from stopped status automatically via the FC9 block.

Acknowledgement of FC9 only after completion of REPOS block:

The ASUB can only be signaled as complete from the FC9 block with "ASUB Done" if the REPOS block has also been completed.

Deselection of assigned REPOS operation after Item 8:

The start of the ASUB deselects the assigned REPOS operation!

Therefore, the ASUB should be ended with REPOSA in order to retain the REPOS operation.

Deleting an unwanted REPOS operation:

The unwanted REPOS operation is deleted by completing the ASUB with `M17` or `RET`.

Special handling of ASUB:

As a basic rule, an ASUB that ends with REPOS and is started from stopped status receives special treatment.

The ASUB stops automatically before the REPOS block and indicates this via:

DB21, ... DBX318.0 (ASUB is stopped)

Automatic ASUB start

The ASUB in path:

`/_N_CMA_DIR/_N_PROG_EVENT_SPF`

is started automatically in SERUPRO approach with machine data:

MD11450 \$MN_SEARCH_RUN_MODE, Bit1 = 1

according to the following sequence:

1. The SERUPRO operation has been performed completely.
2. The user presses "Start".
3. Automatic ASUB start.
4. The NCK stops automatically **before** the `REPOS` part program command and Alarm 10208 "Press NC Start to continue the program" appears.

5. The user presses "Start" again.
6. The NCK executes the REPOS movement and continues the part program at the target block.

Note

The automatic ASUB start with MD11450 requires **Starts** to continue the program.

The procedure is in this respect similar to other search types.

9.7.1 REPOS

MD11470

REPOS occurs according to machine data:

MD11470 \$MN_REPOS_MODE_MASK

Case A:

The REPOS operation moves all axes from the current position to the start of the target block in a single block.

MD11470 \$MN_REPOS_MODE_MASK Bit 3 = 1

Case B:

The path axes are repositioned together in one block. The SPOS and POS axes are repositioned in the residual block.

MD11470 \$MN_REPOS_MODE_MASK Bit 3 = 0

9.7.1.1 Continue machining after SERUPRO search target found

User information regarding the REPOS operation

REPOS is generally used to interrupt an ongoing machining operation and to continue machining after the interruption.

In the SERUPRO approach, on the other hand, a program section must be "executed" later. This is the case, when SERUPRO has finished the simulation and is to be moved again to the target block. SERUPRO refers to the existing REPOS function, which the user can adapt as necessary.

SERUPRO approach

The user can change the REPOS behavior of individual axes at specific times to reposition certain axis types either earlier, later, or not at all. This affects SERUPRO approach in particular. Repositioning movements of some axes can also be controlled independently of SERUPRO approach during the REPOS operation.

 CAUTION
The REPOS operation moves all axes from the current position to the start of the target block in a single block with the appropriate setting of machine data: MD11470 \$MN_REPOS_MODE_MASK Bit 3.
During this process, the NC cannot detect any possible collisions with the machine or the workpiece!
Protection zones and software limits are monitored.

Set REPOS response

Machine data:
MD11470 \$MN_REPOS_MODE_MASK
can be used to set bits that specify the behavior of the NC during repositioning.

- Bit 0 = 1 The dwell time is resumed at the point of interruption in the residual repositioning block.
- Bit 1 = 1 Reserved
- Bit 2 = 1 Prevent repositioning of individual axes using VDI signals.
- Bit 3 = 1 Reposition positioning axes in the approach block during block search via program test (SERUPRO).
- Bit 4 = 1 Positioning axes in approach block on every REPOS.
- Bit 5 = 1 Modified feedrates and spindle speeds are valid immediately in the residual block. Otherwise, not until the next block.
- Bit 6 = 1 After SERUPRO, neutral axes and positioning spindles in the approach block are repositioned as command axis.
- Bit 7 = 1 The level of interface signal:
DB31, ... DBX10.0 (REPOSDELAY)
is read if REPOSA is interpreted.

Axes, which are neither geometry nor orientation axes, are then excluded by REPOS and are not moved.

Repositioning with controlled REPOS

At any point during processing, a part program can be interrupted and an ASUB started with a REPOS.

For path axes, the REPOS mode can be controlled by the PLC via VDI signals to reposition on the contour. This mode is programmed in the part program and defines the approach behavior. See "Repositioning to contour with controlled REPOS".

The REPOS behavior of individual axes can also be controlled via VDI signals and is enabled with machine data:
MD11470 \$MN_REPOS_MODE_MASK BIT 2==1.

Path axes cannot be influenced individually. For all other axes that are not geometry axes, repositioning of individual axes can be prevented temporarily and also delayed. VDI signals can be used to subsequently reenable or to continue blocking individual channel axes that REPOS would like to traverse.

 DANGER
Signal: DB31, ... DBX2.2 (Delete distance-to-go, axis-specific) produces the following dangerous behavior with "Prevent repositioning of individual axes" via: MD11470 \$MN_REPOS_MODE_MASK (Bit 2==1). As long as an axis is programmed incrementally after the interruption, the NC approaches different positions than those approached with no interruption (see example below).

Example: Axis is programmed incrementally

Axis A is positioned at 11° before the REPOS operation; the programmed operation in the interruption block (target block for SERUPRO) specifies 27°.

Any number of blocks later, this axis is programmed to move incrementally through 5° with:
N1010 POS[A]=IC(5) FA[A]=1000.

With interface signal:

DB31, ... DBX10.0 (REPOSDELAY)

the axis does not traverse in the REPOS operation and is moved to 32° with N1010.

(The user may have to deliberately acknowledge the travel from 11° to 27°.)

Caution:

The axis is programmed incrementally after the interruption.

In the example, the NC moves to 16° (instead of 32°).

A) Start axes individually

The REPOS behavior for SERUPRO approach with several axes is selected with:

MD11470 \$MN_REPOS_MODE_MASK BIT 3 == 1

The NC commences SERUPRO approach with a block that moves **all** positioning axes to the programmed end and the path axis to the target block.

The user starts the individual axes by selecting the appropriate feedrate enables. The target block motion is then executed.

B) Reposition positioning axes in the repositioning block

Positioning axes are not repositioned in the residual block but rather in the repositioning block, and their effect is not limited to the block search via program test on SERUPRO approach.

MD11470 \$MN_REPOS_MODE_MASK	
Bit 3=1	for block search via program test (SERUPRO)
Bit 4=1	for each REPOS

Note

If neither bit 3 nor bit 4 is set, "non-path axes" are repositioned in the residual block in this phase.

Prefer or ignore REPOS

Further REPOS adaptations can be made by setting the bits in:

MD11470 \$MN_REPOS_MODE_MASK

- Bit 5 = 1 Modified feedrates and spindle speeds are valid immediately in the residual block and are given priority. This behavior relates to every REPOS operation.
- Bit 6 = 1 Neutral axes and positioning spindles are repositioned after SERUPRO.
Neutral axes that are not allowed to be further repositioned must receive interface signal:
DB31, ... DBX10.0 (REPOSDELAY)
This cancels the REPOS movement.
- Bit 7 = 1 The level of interface signal:
DB31, ... DBX10.0 (REPOSDELAY)
is read if REPOSA is interpreted.
Axes, which are neither geometry nor orientation axes, are then excluded by REPOS and are not moved.
Note: REPOSDELAY is changed from edge to level evaluation.

Delayed approach of axis with REPOS offset

With the axial level-triggered VDI signal axis/spindle (PLC→NCK):
DB31, ... DBX10.0 (REPOSDELAY)

with the edge of NST:
DB21, ... DBX31.4 (REPOSMODEEDGE)
the REPOS offset for this axis is traversed only after the next time it is programmed.

Whether this axis is currently subject to a REPOS offset can be scanned via synchronized actions with \$AA_REPOS_DELAY.

 CAUTION
Interface signal: DB31, ... DBX10.0 (REPOSDELAY) has no effect on machine axes that form a path. Whether an axis is a path axis can be determined with: DB31, ... DBX76.4 (path axis).

Acceptance timing of REPOS VDI signals

With the 0/1 edge of the channel-specific VDI signal (PLC→NCK):
DB21, ... DBX31.4 (REPOSMODEEDGE)

the level signals of:
DB21, ... DBX31.0-31.2 (REPOSPATHMODE0 till 2)

and
DB31, ... DBX10.0 (REPOSDELAY)

are transferred to the NC.

The levels relate to the current block in the main run. There are two different cases:

Case A:

One repositioning block of a currently active REPOS operation is contained in the main run.

The active REPOS operation is aborted, restarted and the REPOS offsets controlled via the signals:

DB21, ... DBX31.0-31.2 (REPOSPATHMODE0 till 2)

and
DB31, ... DBX10.0 (REPOSDELAY).

Case B:

No repositioning block of a currently active REPOS operation is contained in the main run.

Each future REPOS operation wishing to reapproach the current main program block is controlled by the level of interface signal:

DB21, ... DBX31.0-31.2 (REPOSPATHMODE0 till 2)

and
DB31, ... DBX10.0 (REPOSDELAY).

Note

In the running ASUB affects the NST:
DB21, ... DBX31.4 (REPOSMODEEDGE)
does not affect the final REPOS, unless this signal applies to the REPOS blocks.

In Case A, the signal is only allowed in the stopped state.

Response to RESET:

NCK has acknowledged the PLC signal

If the level of the signals:
DB21, ... DBX31.4 (REPOSMODEEDGE) = 1
and
DB21, ... DBX319.0 (REPOSMODEEDGEACKN) = 1
and
a RESET occurs in this situation, then the interface signal of the NCK:
DB21, ... DBX319.1–319.3 (Repos Path Mode Ackn0 to 2)
is deleted.

NCK has not yet acknowledged the PLC signal:

If the level of the signals:
DB21, ... DBX31.4 (REPOSMODEEDGE 4) = 1
and
DB21, ... DBX319.0 (REPOSMODEEDGEACKN) = 0
and a RESET occurs in this situation, the NCK cancels interface signal:
DB21, ... DBX319.0 (REPOSMODEEDGEACKN) = 0
and
DB21, ... DBX319.1–319.3 (Repos Path Mode Ackn0 to 2).

Controlling SERUPRO approach with VDI signals

The SERUPRO approach can be used with:
DB21, ... DBX31.4 (REPOSMODEEDGE)
and the associated signals in the following phases:

- Between "Search target found" and "Start SERUPRO ASUB"
- From "SERUPO-ASUB stops automatically before REPOS" to "Target block is executed"

While the SERUPRO ASUB is being executed, e.g. in the program section before the REPOS operation, interface signal:
DB21, ... DBX31.4 (REPOSMODEEDGE)
does not affect the SERUPRO approach.

REPOS operations with VDI signals

Control REPOS with VDI interface signals

REPOS offsets can be positively influenced with the following channel-specific VDI interface signals **from the PLC**:

DB21, ... DBX31.0-31.2 (REPOSPATHMODE0 to 2) channel-specific *

DB21, ... DBX31.4 (REPOSMODEEDGE) channel-specific

DB31, ... DBX10.0 (REPOSDELAY) *axis/spindle
(This axial interface does **not** affect machine axes that form a path.)

DB31, ... DBX72.0 (REPOSDELAY) axis/spindle

* These signals are available in the respective DB of the HMI or PLC.

REPOS acknowledgement signals

The following VDI signals can be used to acknowledge **from the NCK** functions that control the REPOS response via PLC:

DB21, ... DBX319.0 (REPOSMODEEDGEACKN) channel-specific

DB21, ... DBX319.1-319.3 (Repos Path Mode Ackn0 to 2) channel-specific

DB21, ... DBX319.5 (Repos DEFERRAL Chan) channel-specific

DB31, ... DBX70.0 (Repos offset) axis/spindle

DB31, ... DBX70.1 (Repos offset valid) axis/spindle

DB31, ... DBX70.2 (Repos Delay Ackn) axis/spindle

DB31, ... DBX76.4 (path axis) axis/spindle

For further information, see "REPOS offset in the interface"

REPOS acknowledgement operations

With the channel-specific VDI signal:

DB21, ... DBX319.0 (REPOSMODEEDGEACKN)

if a "handshake" is established by the interface signal:

DB21, ... DBX31.4 (REPOSMODEEDGE)

recognized by the NC and acknowledged with DB21, ... DBX319.0 to the PLC.

Note

If the NCK has not yet acknowledged interface signal:

DB21, ... DBX31.4 (REPOSMODEEDGE)

with interface signal:

DB21, ... DBX319.0 (REPOSMODEEDGEACKN)

a RESET in this situation causes the program to abort, and the REPOS that is to be used to control the REPOSPATHMODE can no longer take place.

A REPOS MODE specified by the PLC from NCK with the interface signals:
 DB21, ... DBX319.1-319.3 (Repos Path Mode Ackn0 to 2)

and
 DB31, ... DBX10.0 (Repos Delay)

with:
 DB31, ... DBX70.2 (Repos Delay Ackn)

in the following way:

A part program is stopped at N20 (→ time (2) in figure). The NCK stops according to the braking ramp. After the PLC has specified the REPOSPATHMODE, the NCK accepts the REPOSPATHMODE with the 0/1 edge of REPOS MODEEDGE at → Time (3). Repos Path Mode Ackn remains set until the ASUB is initiated (→ Time (4)). The REPOS command is started in the ASUB (→ Time (5)). The ASUB RESET block is activated again (→ Time (6)):

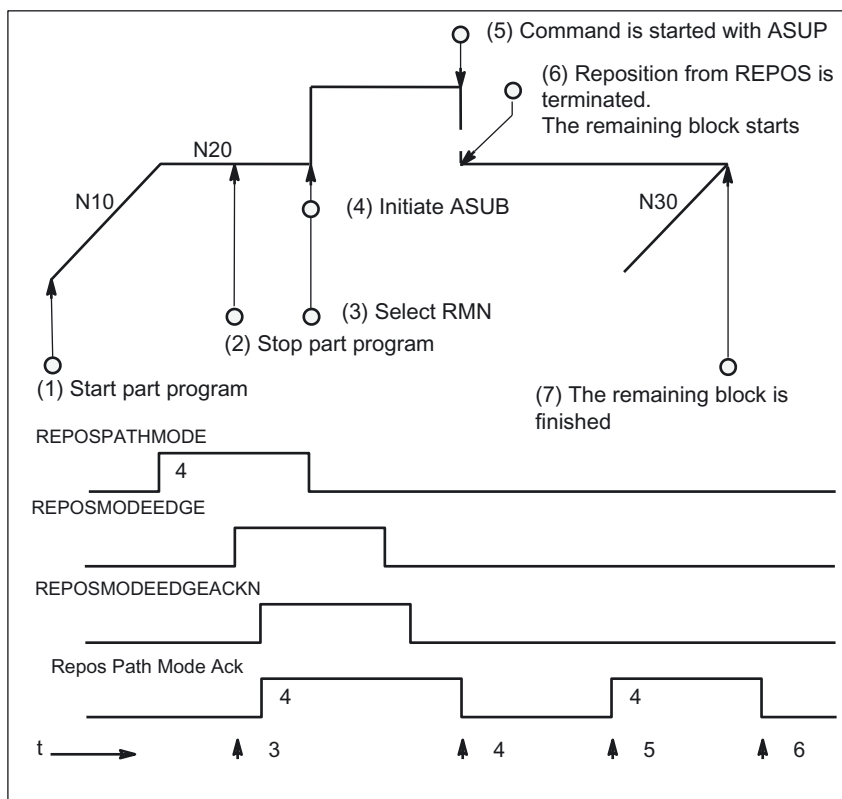

Figure 9-6 REPOS sequence in part program with timed acknowledgement signals from NCK

NCK sets acknowledgement again

Phase with REPOSPATHMODE still active (residual block of the program stopped at → Time (2) is not yet completely executed).

As soon as the REPOS repositioning motion of the ASUB is executed, the NCK sets the "Repos Path Mode Ackn" again (→ Time (5)). If no REPOSPATHMODE has been preselected via a VDI signal, the programmed REPOS mode is displayed.

"Repos Path Mode Ackn" is canceled when the residual block is activated (→ Time (6)). The part program block N30 following the block at → Time (2) is resumed.

Interface signal:

DB31, ... DBX70.2 (Repos Delay Ackn) is defined in the same way.

DB31, ... DBX70.1 (Repos offset valid) = 1, if:

DB21, ... DBX319.1-319.3 (Repos Path Mode Ackn0 to 2) = 4 (RMN).

Valid REPOS offset

When the SERUPRO operation is complete, the user can read out the REPOS offset via the axis/spindle VDI signal (NCK→PLC):

DB31, ... DBX70.0 (REPOS offset).

The effects of this signal on the relevant axis are as follows:

Value 0: No REPOS offset is applied.

Value 1: REPOS offset is applied.

Range of validity

Interface signal:

DB31, ... DBX70.0 (REPOS offset)

is supplied at the end of the SERUPRO operation.

The REPOS offset is invalidated at the start of a SERUPRO ASUB or the automatic ASUB start.

Updating the REPOS offset within the scope

Between the SERUPRO end and SERUPRO start, the axis can be moved in JOG mode with a mode change.

In JOG mode, the user manually moves the axis over the REPOS offset path in order to set interface signal:

DB31, ... DBX70.0 (REPOS offset) to the value 0.

Within the range of validity, the axis can also be traversed using FC18, whereby the IS DB31, ... DBX70.0 (REPOS offset) is continuously updated.

Displaying the range of validity

The range of validity of the REPOS offset is indicated with interface signal:

DB31, ... DBX70.1 (REPOS offset valid)

It is indicated whether the REPOS offset calculation was valid or invalid:

Value 0: The REPOS offset of this axis is calculated correctly.

Value 1: The REPOS offset of this axis cannot be calculated, as the REPOS has not yet occurred, e.g. it is at the end of the ASUB, or no REPOS is active.

REPOS offset after an axis replacement

The group signal:

DB21, ... DBX319.5 (Repos DEFERRAL Chan)

can be used to determine whether a valid REPOS offset has taken place:

Value 0: All axes currently controlled by this channel have either no REPOS offset or their REPOS offsets are invalid.

Value 1: Miscellaneous.

REPOS offset with synchronized synchronous spindle coupling

When repositioning with SERUPRO, processing continues at the point of interruption. If a synchronous spindle coupling was already synchronized, there is no REPOS offset of the following spindle and no synchronization path is present. The synchronization signals remain set.

Search target found on block change

The axial VDI signal:

DB31, ... DBX76.4 (path axis)

is 1 if the axis is part of the path grouping.

This signal shows the status of the current block to be executed during block change. Subsequent status changes are ignored.

If the SERUPRO operation is ended with "Search target found", DB31, ... DBX76.4 (path axis) refers to the target block.

9.7.1.2 Repositioning on contour with controlled REPOS

Approach modes

Influence path axes individually

During SERUPRO approach, a REPOS operation is initiated in order to reposition to the contour. A large number of axes, which the user can control by means of interface signals, is frequently moved. The operator panel interface supplies the offsets per channel axis, which REPOS intends to traverse.

Repositioning of the individual path axes can be controlled by the PLC with the interface signals and it therefore has priority over the actual commands `RMI`, `RMB` and `RME` in the part program.

`RMI` Repositioning to interruption point

`RMB` Repositioning to start of block

`RME` Repositioning to end-of-block position

`RMN` Repositioning to next point on path

Repositioning with RMN

Like RMI , RMB and RME , RMN (REPOS Mode Next) is **redefined** for SUREPRO approach. After an interruption, RMN is used not to complete an already started repositioning, but to process from the next path point:

At the time REPOSA is interpreted, position (B) is referenced in order to find point C at the interruption block with the shortest distance to B. The repositioning block moves from B to C to the end position.

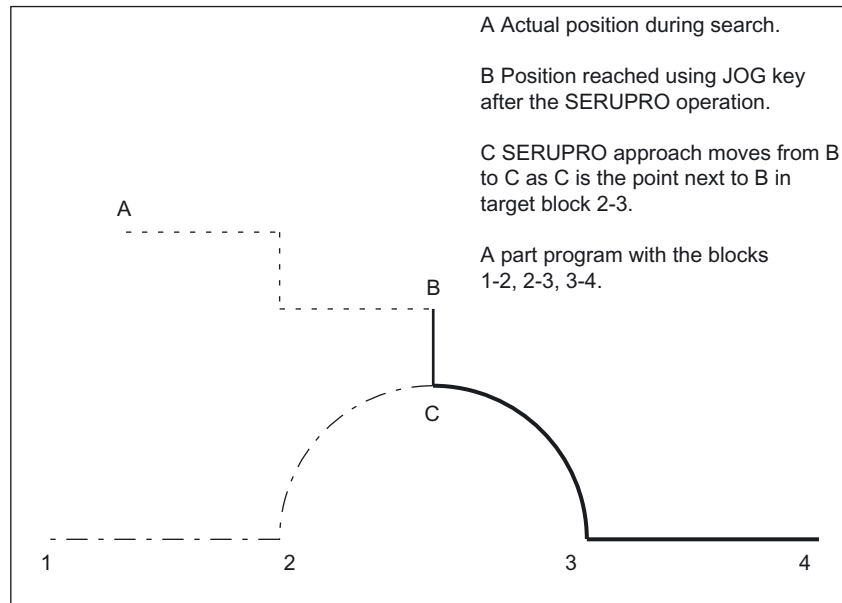

Figure 9-7 SUREPRO approach under RMN

Application and procedure

SUREPRO approach with RMN offers the opportunity of using the application shown in the figure: If a program abort is forced by RESET at any point when the program is advancing from block 2 to 3,

- RMN is used to approach the abort location by the shortest route in order to process just the distance to go from C-3 and 3-4. The user starts a SERUPRO operation at the interruption block and uses the JOG keys to move in front of the problem component of the target block.
- RMI and RMB are always approached with RMI and RMB and the target block thus repeated once completely.

Selecting REPOS mode

With the channel-specific VDI signal (PLC→NCK) DB21, ... DBX31.0-31.2 (REPOSPATHMODE0-2) the concerned function **RMB**, **RMI**, **RME** or **RMN** can be selected with the 3 bits.

Repositioning point

RMNOTDEF REPOS Mode is not redefined

RMB Repositioning of block start point or last end point

RMI Repositioning interruption point

RME Repositioning end-of-block point

RMN Repositioning to next path point

DB21, ... DBX31.0-31.2 (REPOSPATHMODE)=0 corresponds to **RMNOTDEF**

DB21, ... DBX31.0-31.2 (REPOSPATHMODE)=1 corresponds to **RMB**

DB21, ... DBX31.0-31.2 (REPOSPATHMODE)=2 corresponds to **RMI**

DB21, ... DBX31.0-31.2 (REPOSPATHMODE)=3 corresponds to **RME**

DB21, ... DBX31.0-31.2 (REPOSPATHMODE)=4 corresponds to **RMN**

With DB21, ... DBX31.0-31.2 (REPOSPATHMODE0 to 2) = 0, no settings are overwritten and the current program is valid. The interface signal responds to the level of the corresponding mode.

Note

RMN is a general REPOS extension and it is not restricted to SERUPRO. For SERUPRO **RMI** and **RMB** are identical.

With DB21, ... DBX31.0–31.2 (REPOSPATHMODE0 to 2), the path as a whole is controlled. The path axes cannot be changed individually.

The behavior of the other axis types can be changed individually using interface signal DB31, ... DBX10.0 (REPOSDELAY). This REPOS offset is not applied immediately, but only when it is next programmed.

For further information on the programming of repositioning point, please refer to

References:

/PGA/ Programming Manual Job Planning; "Path Behavior" repositioning on Contour

Read REPOS mode in synchronized actions

The valid REPOS mode of the interrupted block can be read via synchronized actions using system variable \$AC_REPOS_PATH_MODE=

0: not defined	Repositioning not defined
1: RMB	Repositioning to beginning
2: RMI	Repositioning to point of interruption
3: RME	Repositioning to block end point
4: RMN	Repositioning to next geometric path point of interrupted block

9.7.2 Acceleration measures via MD

Machine data settings

The processing speed of the entire SERUPRO operation can be accelerated using the following machine data.

MD22600 \$MC_SERUPRO_SPEED_MODE and

MD22601 \$MC_SERUPRO_SPEED_FACTOR

With MD22600 \$MC_SERUPRO_SPEED_MODE == 1, the SERUPRO operation will run at the usual "dry run feedrate".

Through MD22600 \$MC_SERUPRO_SPEED_MODE == 0

MD22601 \$MC_SERUPRO_SPEED_FACTOR is evaluated,

and a further acceleration is permitted. Dynamic monitoring functions are disabled in this mode.

SPEED factor for channel axes during ramp-up

Machine data MD22600 \$MC_SERUPRO_SPEED_MODE is effective for the following channel axes in the main run throughout the entire SERUPRO operation:

- PLC axes
- Command axes
- Positioning axes
- Reciprocating axes

The functions of MD22600 \$MC_SERUPRO_SPEED_MODE and MD22601 \$MC_SERUPRO_SPEED_FACTOR apply only to SERUPRO and not to program testing. In this case **no axes/spindles are moved**.

CAUTION

The NC as a discrete system generates a sequence of interpolation points.

It is possible that a synchronized action that was triggered in normal operation will no longer be triggered in SERUPRO.

Mode of functioning with DryRun

An active SERUPRO SPEED-FACTOR has the following effect on DryRun:

- DryRun is activated simultaneously.

This causes a switch from G95/G96/G961/G97/G971 to G94 in order to execute G95/G96/G961/G97/G971 as quickly as you wish.

- Tapping and thread cutting are performed at the usual velocity for DryRun.

DryRun and SERUPRO affect the spindle/axis with the following G codes:

- G331/G332 causes the spindle to be interpolated as an axis in a path grouping. In the case of tapping, the drilling depth (e.g. axis X) and the pitch and speed (e.g. spindle S) are specified.

In the case of DryRun, the velocity of X is specified, the speed remains constant, and the pitch is adjusted.

Following the SERUPRO simulation, the position for spindle S deviates from the normal position because the spindle S has rotated less during simulation.

9.7.3 SERUPRO ASUP

SERUPRO ASUB special points

Special points should be noted for SERUPRO ASUB with regard to:

- Reference point approach: Referencing via part program G74
- Tool management: Tool change and magazine data
- Spindle ramp-up On starting a SERUPRO ASUB

G74 reference point approach

If statement G74 (reference point approach) is programmed between the program start and the search target, this will be ignored by the NC.

SERUPRO approach does not take this G74 statement into account!

Tool management

If tool management is active, the following setting is recommended:

Set MD18080 \$MA_TOOL_MANAGEMENT_MASK BIT 20 = 0.

The tool management command generated during the SERUPRO operation is thus **not** output to the PLC!

The tool management command has the following effect:

- The NC acknowledges the commands automatically.
- No magazine data are changed.
- Tool data are not changed.

Exception:

The tool enabled during the test mode can assume 'active' status. As a result, the spindle may contain the incorrect tool after the SERUPRO operation.

Remedy:

The user starts a SERUPRO ASUB that is actually traversed. Prior to the start, the user can start an ASUB that loads the correct tool.

SERUPRO operation: Functionality: In sequence steps 2. to 6.

SERUPRO ASUB: Functionality: The sequence of point 7.

In addition, machine data setting MD18080 \$MA_TOOL_MANAGEMENT_MASK Bit 11 = 1 is required because the ASUB may have to repeat a T selection.

Systems with tool management and auxiliary spindle are not supported by SERUPRO!

Example

Tool change subroutine

```

PROC L6                                ; Tool change routine
N500 DEF INT TNR_AKTUELL                ; Variable for active T number
N510 DEF INT TNR_VORWAHL                ; Variable for preselected T number

                                        ; Determine current tool
N520 STOPRE                             ; In program testing
N530 IF $P_ISTEST                        ; from the program context
N540 TNR_AKTUELL = $P_TOOLNO            ; the "current" tool is read.
N550 ELSE                                ; Otherwise, the tool of the spindle
                                        ; is read out.
N560 TNR_AKTUELL = $TC_MPP6[9998,1]     ; Read tool T number on the spindle
N570 ENDIF

N580 GETSELT(TNR_VORWAHL)               ; Read T number of preselected tool
                                        ; of the master spindle. Execute tool
                                        ; change only if tool not yet
                                        ; current.
N590 IF TNR_AKTUELL <> TNR_VORWAHL     ; Approach tool change position
N600 G0 G40 G60 G90 SUPA X450 Y300 Z300 D0
N610 M206                                ; Execute tool change
N620 ENDIF
N630 M17

```

ASUB for calling the tool change routine after block search type 5

```

PROC ASUPWZV2
N1000 DEF INT TNR_SPINDEL                ; Variable for active T number
N1010 DEF INT TNR_VORWAHL                ; Variable for preselected T number
N1020 DEF INT TNR_SUCHLAUF               ; Variable for T number determined in
                                        ; block search
N1030 TNR_SPINDEL = $TC_MPP6[9998,1]     ; Read tool T number on the spindle
N1040 TNR_SUCHLAUF = $P_TOOLNO           ; read T number determined by search
                                        ; run, i.e., that tool determines the
                                        ; current tool offset.
N1050 GETSELT(TNR_VORWAHL)               ; Read T number of preselected tool

```

```
N1060 IF TNR_SPINDEL ==TNR_SUCHLAUF GOTOF      ;  
ASUP_ENDE1  
N1070 T = $TC_TP2[TNR_SUCHLAUF]              ; T selection by tool name  
N1080 L6                                       ; Call tool change routine  
  
                                           ;  
N1085 ASUP_ENDE1:                               ;  
N1090 IF TNR_VORWAHL == TNR_SUCHLAUF GOTOF    ;  
ASUP_ENDE  
N1100 T = $TC_TP2[TNR_VORWAHL]                ; Restore T preselection by tool name  
  
                                           ;  
N1110 ASUP_ENDE:                               ;  
N1110 M90                                       ; Feedback to PLC  
N1120 REPOSA                                   ; ASUB end
```

In both of the programs PROC L6 and PROC ASUPWZV2, the tool change is programmed with M206 instead of M6.

ASUB program "ASUPWZV2" uses different system variables to detect the progress of the program (\$P_TOOLNO) and represent the current status of the machine (\$TC_MPP6[9998,1]).

Spindle ramp-up

When the SERUPRO ASUB is started, the spindle is not accelerated to the speed specified in the program because the SERUPRO ASUB is intended to move the new tool into the correct position at the workpiece after the tool change.

A spindle ramp-up is performed with SERUPRO ASUB as follows:

- SERUPRO operation has finished completely.
- The user starts the SERUPRO ASUB via function block FC 9 in order to ramp up the spindle.
- The start after M0 in the ASUB does not change the spindle status.
- SERUPRO ASUB automatically stops before the REPOS part program block.
- The user presses START.
- The spindle accelerates to the target block state if the spindle was not programmed differently in the ASUB.

Note

Modifications for REPOS of spindles:

The transitions of speed control mode and positioning mode must be taken into consideration in the event of modifications in SERUPRO approach and spindle functionality.

For further information about operating mode switchover of spindles, see

References: /FB1/ Function Manual, Basic Functions; Spindles (S1), 2.1 Spindle Modes.

9.7.4 Self-acting SERUPRO

Self-acting SERUPRO

The channel-specific function "Self-acting SERUPRO" allows a SERUPRO sequence **without** having to previously define a search target in a program of the associated SERUPRO channels.

In addition, a special channel, the "serurpoMasterChan", can be defined for **each** "Self-acting SERUPRO". A search target can be defined in this channel.

The "Self-acting SERUPRO" function supports the SERUPRO cross-channel block search.

Function

The "Self-Acting SERUPRO" operation cannot be used to find a search target. If the search target is not reached, no channel is stopped. In certain situations, however, the channel is nevertheless stopped temporarily. In this case, the channel will wait for another channel. Examples are: Wait marks, couplings, or axis replacement.

Wait phase occurs:

During this wait phase, the NC checks whether the channel "seruproMasterChan" has reached a search target. If no search target is reached, the Wait phase is left.

If the search target is reached, the SERUPRO operation is also ended in the channel. The "serupro-MasterChan" channel must have been started in normal SERUPRO mode.

No wait phase occurs:

"Self-Acting SERUPRO" is ended by M30 of the part program.
The channel is now in Reset state again.
A SERUPRO approach does not take place.

Starting a group of channels

If a group of channels is only started with "Self-Acting SERUPRO", then all channels are ended with "RESET".

Exceptions:

A channel waits for a partner channel that has not been started at all.

A cross-channel block search can be carried out as follows:

- Via the HMI, the user selects the channels that must work together (channel group).
- The user chooses an especially important channel from the channel group for which he wants to select a search target explicitly (target channel).
- The HMI will then start SERUPRO on the target channel and "Self-Acting SERUPRO" in the remaining channels of the channel group.

The operation is complete if **each** channel concerned has deleted "seruproActive".

"Self-acting SERUPRO" accepts no master channel on another NCU.

Activation

"Self-acting SERUPRO" is activated via the HMI as a block search start for the Type 5 block search for target channel "seruproMasterChan".

No search target is specified for dependent channels started from the target channel.

9.7.5 Inhibit specific part of the program in the part program for SERUPRO

Programmed interrupt pointer

As a general rule, only the user of the machine knows the mechanical situation that is currently being executed in the program. The user can use a "**programmable interrupt pointer**" to suppress SERUPRO at a particular point in the program where complex mechanical conditions prevail to enable user intervention.

Through suitable manipulation of the interrupt pointer, it is possible, with "search for interrupt point", to resume processing to the search-suppressed location **prior** to the **search-suppressed location**. Search-suppressed areas can also be defined in areas of the part program in which the NCK is not allowed to resume processing.

The last block processed before the search-suppressed target area is used as a search pointer.

Input program section

The `IPTRLOCK` and `IPTRUNLOCK` language commands mark search-suppressed sections of the program. These language commands cannot be used in synchronized actions.

<code>IPTRLOCK</code>	Start of search-suppressed program section
<code>IPTRUNLOCK</code>	End of search-suppressed program section

`IPTRLOCK`

Freezes the interrupt pointer at the next "machine function block". This block is referred to below as the **Hold block**. If a program abort occurs after `IPTRLOCK`, then the hold block is used as a search pointer.

Machine function block

Is a single block (SBL1) that can be executed in the main run with a stop after each function block.

`IPTRUNLOCK`

The interrupt pointer is repositioned at the current block at the time of the interrupt for the subsequent program section.

Note

When a search target is found, the interrupt pointer is set to the hold block. The block search can be repeated for a new search target with the same hold block.

A search-suppressed area in the part program can be detected using the **\$P_IPRTLOCK** variable.

Nesting rules

The following features regulate the interaction between NC commands `IPTRLOCK` and `IPTRUNLOCK` with nesting and end of subroutine:

1. `IPTRLOCK` is activated implicitly at the end of the subroutine in which `IPTRUNLOCK` is called.
2. `IPTRLOCK` in an untraceable section has no effect.
3. If subprogram1 calls subprogram2 in a search-suppressed area, subprogram2 remains search-suppressed. `IPTRUNLOCK` in particular has no effect in subroutine 2.

Examples of nesting with two program levels

Nesting of search-suppressed program sections in **2 program levels**.

```

; Interpretation of the blocks in an illustrative
; sequence.
; Subprogram1 is prepared for the block search:
N10010 IPTRLOCK() ; Program level 1
N10020 R1 = R1 + 1 ;
N10030 G4 F1 ; hold block
; of the search-suppressed program section starts
... ;
N10040 Subprogram2 ; Interpretation of subprogram2
... ; Program level 2
N20010 IPTRLOCK () ; is ineffective
... ;
N20020 IPTRUNLOCK () ; is ineffective
... ;
N20030 RET ;
... ;
N10050 IPTRLOCK() ;
N10060 R2 = R2 + 2 ;
N10070 G4 F1 ; End of search-suppressed program section
```

An interruption in a search-suppressed program section of the above program always returns `N10030 G4 F1` block.

With implicit IPTRUNLOCK

Nesting of search-suppressed program sections in **two program levels with implicit IPTRUNLOCK**. The implicit IPTRUNLOCK in subprogram 1 ends the search-suppressed area.

```

; Interpretation of the blocks in an illustrative
; sequence.
; Subprogram1 is prepared for the block search:
N10010 IPTRLOCK() ; Program level 1
N10020 R1 = R1 + 1 ;
N10030 G4 F1 ; Hold block
... ; of the search-suppressed program section starts
as in previous example ;
N20030 RET ;
... ;
N10060 R2 = R2 + 2 ;
N10070 RET ; End of search-suppressed program section
N100 G4 F1 ; Main program is continued
    
```

An interruption in a search-suppressed program section of the above program always returns N10030 G4 F1 block.

An interruption at N100 provides N100 again in SPARPRI

On one program level

Nesting of IPTRLOCK and IPTRUNLOCK on one program level

```

; Interpretation of the blocks in an illustrative
; sequence
; Subprogram1 is prepared for the block search:
N10010 IPTRLOCK() ; Program level 1
N10020 R1 = R1 + 1 ;
N10030 G4 F1 ; hold block
; of the search-suppressed program section starts
... ;
N10050 IPTRLOCK() ; is ineffective
... ;
N10060 IPTRUNLOCK() ; is ineffective
N10070 R2 = R2 + 2 ; End of search-suppressed program section
N100 IPTRLOCK() ; is ineffective
... ;
    
```

An interruption in a search-suppressed program section of the above program always returns the N10030 G4 F1 block in SPARPI.

An interruption on N100 then provides N100 again.

Automatic interrupt pointer

In certain applications it can be useful to automatically define a prespecified type of coupling as a search-suppressed area. The automatic interrupt pointer function is activated with machine data

MD 22680 \$MC_AUTO_IPTR_LOCK.

- Bit 0 = 1: Electronic gearbox with EGON
- Bit 1 = 1: Axial leading value coupling with LEADON

This program section begins with the last executable block **before** the activation and ends with the deactivation.

The automatic interrupt pointer is not active for couplings that were activated or deactivated via synchronized actions.

Example: To declare axial master value coupling as search-suppressed:

```
N100 G0 X100 ;
N200 EGON(Y, "NOC", X, 1, ; search-suppressed program section starts
1)
N300 LEADON(A, B, 1) ;
... ;
N400 EGOFS(Y) ;
... ;
N500 LEADOF(A, B) ; search-suppressed program section ends
N600 G0 X200 ;
```

A program abort within search-suppressed program section (N200 - N500) always provides the interrupt pointer with N100.

CAUTION

Using an overlap of the "programmable interrupt pointer" and "automatic interrupt pointer" via machine data, the NC selects the largest possible search-suppressed area.

A program may need a coupling for almost all of the runtime. In this case, the automatic interrupt pointer would always point to the start of the program and the SERUPRO function would in fact be useless.

9.7.6 Special features in the part-program target block

9.7.6.1 STOPRE in the part-program target block

STOPRE block

The STOPRE block receives all modal settings from the preceding block and can, therefore, apply conditions in advance in relation to the following actions:

- Synchronize program line currently processing with the main run.
- Derive modal settings for SERUPRO in order, for example, to influence this REPOS motion on approach of SERUPRO.

Example 1

Position a Z axis by specifying an X axis setpoint.

When block "G1 F100 Z=\$AA_IM[X]" is interpreted, the preceding STOPRE block ensures synchronization with the main run. The correct setpoint of the X axis is thus read via \$AA_IM to move the Z axis to the same position.

Example 2

Read and correctly calculate external zero offset.

```
N10 G1 X1000 F100 ;
N20 G1 X1000 F500 ;
N30 G1 X1000 F1000 ;
N40 G1 X1000 F5000 ;
N50 SUPA G1 F100 X200 ; move external zero offset after 200
N60 G0 X1000 ;
N70 ... ;
```

Via an implicit STOPRE before N50, the NCK can read and correctly and correctly compute the current zero offset.

For a SERUPRO operation on the search target N50 repositioning occurs in the SERUPRO approach to the implicit STOPRE and the speed is determined from N40 with F5000.

Implicit preprocessing stop

Situations in which interpreter issues an implicit preprocessing stop:

1. In all blocks in which one of the following variable access operations occurs: -
Programming of a system variable beginning with \$A...
- Redefined variable with attribute SYN/R/SYNRW
2. On the following part program commands:
- Part program command MEACALC, MEASURE
- Programming of SUPA (suppress frames and online offsets)
- Programming of CTABDEF (start of curve table definition)
- Part program command WRITE/DELETE (write/delete file)
- Before the first WRITE/DELETE command in a sequence of such commands
- Part program command EXTCALL
- Part program command GETSELT, GETEXET
- Tool change and active fine tool offset FTOCON
3. On the following commands executions:
- Finishing of Type 1 search ("Search without calculation") and
Type 2 search with calculation ("Search at contour end point")

Note: Type 2 search "Block search at contour start point" has the same behavior.

9.7.6.2 SPOS in target block

SPOS

If a spindle is programmed with M3/M4 and the target block contains an SPOS command, the spindle is switched over to SPOS on completion of the SERUPRO process (search target located). This is indicated on the VDI interface.

9.7.7 Behavior during POWER ON, mode change and RESET

SERUPRO is inactive during POWER ON. The mode change is permitted during SERUPRO. RESET will cancel SERUPRO and deselects the internally selected program test. SERUPRO cannot be combined with other block search types.

9.7.8 Special features of functions supported during SERUPRO

SERUPRO supports the following NC functions:

- Traversing to fixed stop: FXS and FOC automatically
- Force Control
- Synchronous spindle: Synchronous spindle grouping with COUPON
- Autonomous single-axis operations: the PLC-controlled axes

- Linkages: Setpoint and actual value couplings can be simulated
Master/slave for drives. These functions are closely simulated by electronic gears. The relevant Axial master value coupling restrictions must be considered in each case!
 - Axis couplings
Coupled motion: Axis grouping with TRAILON and TRAILOF,
Traverse gantry axis couplings
Tangential control: Tangential follow-up of individual axes
 - Axis functions
Axis enable,
Autonomous axis operations,
Axis transfer
 - Gear stage change: During program test (not fully automatically)
 - Overlaid movements: Superimposed motion interpolation
- For more information about these functions, see the following subsections.

9.7.8.1 Travel to fixed stop (FXS)

FXS

The functionality of FOC is repeated automatically with REPOS and designated **FXS-REPOS** below. Every axis is taken into account and the torque last programmed before the search target is applied.

Furthermore, the meaning of system variable \$AA_FXS is redefined for SERUPRO as follows:

- \$AA_FXS displays the current status of program simulation.
- \$VA_FXS always describes the real machine status.

The two system variables \$AA_FXS and \$VA_FXS have the same values continuously **outside** the SERUPRO function.

The user can treat FXS and FOC as special commands in a SERUPRO ASUB.

9.7.8.2 Force Control (FOC)

System variables \$AA_FOC, \$VA_FOC

The meaning of system variable \$AA_FOC is redefined for SERUPRO as follows:

- \$AA_FOC represents the current status of program simulation.
- \$VA_FOC always describes the real machine status.

The FOC-REPOS function behaves analogously to the FXS-REPOS function. The functionality of FOC is repeated automatically with REPOS and is designated FOC-REPOS. Every axis is taken into account and the torque last programmed before the search target is applied.

Boundary condition

A continuously changing torque characteristic **cannot** be implemented with FOC-REPOS.

Example

A program moves axis X from 0 to 100 and activates FOC every 20 increments for 10 increments at a time. This torque characteristic is usually generated with non-modal FOC and cannot, therefore, be traced by FOC-REPOS. FOC-REPOS will traverse axis X from 0 to 100, with or without FOC, according to the last programming.

Note

For further information about the SERUPRO block search in relation to FXS or FOC, see

References: /FB1/ Function Manual Basic Functions; Traversing to Fixed Stop (F1), General Functions

9.7.8.3 Synchronous spindle

The synchronous spindle can be simulated.

The synchronous spindle operation with main spindle and any number of following spindles can be simulated in all existing channels with SERUPRO.

For further information about synchronous spindles, see:

References: /FB2/ Function Manual, Extended Functions; Synchronous Spindle (S3)

9.7.8.4 Couplings and master-slave

Setpoint and actual value couplings

The SERUPRO operation is a program simulation in Program Test mode with which setpoint and actual value couplings can be simulated.

Specifications for EG simulation

For simulation of EG, the following definitions apply:

1. Simulation always takes place with setpoint coupling.
2. If under SERUPRO there are only some, i.e. not all, leading axes, the simulation is aborted with Alarm 16952 "Reset Clear/No Start". This can occur with cross-channel couplings.
3. Axes that have only one encoder from the point of view of the NCK and are operated with external data cannot be simulated correctly. These axes must not be integrated in couplings.

 CAUTION
In order to be able to simulate couplings correctly, the couplings must have been switched off previously.
This can occur with machine data MD10708 \$MA_SERUPRO_MASK.

Specifications for coupled axes

The SERUPRO operation simulates coupled axes always assuming that they are setpoint couplings. In this way, the end points are calculated for **all** axes that are used as target points for SERUPRO approach. The coupling is also active with "Search target found". The path from the current point to the end point is carried out for SERUPRO approach with the active coupling.

LEADON

The following specifications apply for the simulation of axial master value couplings:

1. Simulation always takes place with setpoint coupling.
2. SERUPRO approach takes place with active coupling and an overlaid motion of the following axis in order to reach the simulated target point.

The following axis that is moved solely by the coupling cannot always reach the target point. In SERUPRO approach, an overlaid linear motion is calculated for the following axis to approach the simulated point!

Reaching simulated target point for LEAD with JOG

At the time of "Search target found", the coupling is already active, especially for the JOG movements. If the target point is not reached, SERUPRO approach can be used to traverse the following axis with active coupling and an overlaid motion to the target point.

Note

For further information about the repositioning of coupled axes, see

"Continue machining after SERUPRO search target found".

Master-slave

During the block search, only the link status should be updated without calculating the associated positions of the coupled axis.

A system ASUB can be started automatically after the block search is finished. In this subroutine, the user can control the link status and the associated axis positions subsequently. The information needed can be read from additional block search system variables.

System variable for master/slave

The following system variables are needed for the position offset between the axes to be coupled with the desired link status:

NCK variables	Description
\$P_SEARCH_MASLD[X] Slave*	Position offset between slave and master axis when the link is closed.
\$P_SEARCH_MASLC[X] Slave*	Current status of a master/slave link was changed during block search.
\$AA_MASL_STAT[X] Slave*	Current status of a master/slave link active.

Slave* for slave axis identifier

Note

This block search for the master/slave link is effective only if the position offset between the axes can be determined.

In order to determine the programmed positions, the axes to be linked must be in the same channel at the time of the block search. If this is not the case, the block search is aborted with alarm 15395.

Variables \$P_SEARCH_MASLD, \$P_SEARCH_MASLC and \$AA_MASL_STAT are cleared on MASLON.

For further information about the master/slave link, see:

References:

/FB3/ Function Manual Special Function; Speed/Torque Coupling (TE3), Master-Slave

The system ASUB is called progevent.spf and must be available in the /_N_CMA_DIR directory. The contents might be as follows:

progevent.spf
X=Master axis, Y=Slave axis

```

Programming
N10 IF (($S_SEARCH_MASLC[Y] < >0) AND ($AA_MASL_STAT[Y] < >0))
N20 MASLOF(Y)
N30 SUPA Y=$AA_IM[X]-$P_SEARCH_MASLD[Y]
N40 MASLON(Y)
N50 ENDIF
N60 REPOSA
    
```

To ensure that the ASUB can be automatically started, the following machine data must be set:

MD11602 \$MN_ASUB_START_MASK = 'H03'

MD11604 \$MN_ASUP_START_PRIO_LEVEL = 100

MD11450 \$MN_SEARCH_RUN_MODE = 'H02'

Coupled axes

The following coupled axes links are compatible with the SERUPRO operation:

- Coupled motion `TRAILON` and `TRAILOF`
- Gantry axes
- Tangential control
- The activatable and deactivatable "master/slave" link as long as activation and deactivation is not selective

Note

In case of the leading axis, whose following axes are in another channel, with:
MD22601 \$MC_SERUPRO_SPEED_FACTOR = positive
the measure for acceleration of the processing speed does not work.

Coupled motion

The motion-synchronous action for coupled motion of an axis grouping with `TRAILON`, `TRAILOF` is supported by SERUPRO.

For further information about coupled motion with `TRAILON`, `TRAILOF` please refer to

References:

/FB3/ Function Manual, Special Functions; M3, "Axis Couplings and ESR"

/PGA/ Programming Manual Job Planning; "Path Behavior" and "Motion-Synchronous Actions"

Gantry axes

Mechanically linked machine axes can be moved without a mechanical offset using the gantry axis function. This operation is simulated correctly with SERUPRO.

For further information about the functionality of gantry axes, refer to

References:

/FB3/ Function Manual Special Functions; G1, "Gantry Axes"

Tangential control

Tangential follow-up of individual axes is supported by SERUPRO.

For further information about tangential control, see:

References:

/FB3/ Function Manual Special Functions; T3, "Tangential Control"

If "overlaid movements" are used, only the block search via program test (SERUPRO) can be used, since the overlaid movements are interpolated accordingly in the main run. This applies in particular to `$AA_OFF`.

9.7.8.5 Axis functions

SERUPRO conditions

The special conditions for SERUPRO must be observed with axis enable, autonomous axis operations, and axis replacement.

Axis enable

The axial IS DB31, ... DBX3.7 ("Program test axis/spindle enable") controls the axis enables if no closed-loop controller enable is to (or can) be issued at the machine and is active only during the program test or when SERUPRO is active.

It is possible, via the interface signal PLC → NCK

DB31, ... DBX3.7 (program test axis/spindle enable) to do this enabling. If the real servo enable is missing during program testing or SERUPRO, the effect on the axes/spindles is as follows:

- As soon as the simulated program run intends to move an axis/spindle, the message "Waiting for axis enable" or "Waiting for spindle enable" is displayed and the simulation is stopped.
- If, during a simulated movement, the VDI signal DB31, ... DBX3.7 (program test axis/spindle enable) is canceled again, the alarm 21612: "Channel %1 axis %2 VDI signal 'servo enable' reset during motion" is activated.

Autonomous axis operations

Autonomous single-axis operations are axes controlled by the PLC that can also be simulated on SERUPRO. During SERUPRO operation, as in normal operation, the PLC can take over or give up control of an axis. If required, this axis can also be traversed using FC18. The PLC takes over control of the axis **before** the approach block and is responsible for positioning this axis. This is valid for all block search types.

For further information about autonomous single-axis operations, see:

References:

/FB2/ Function Manual Extended Functions; P2, "Positioning axes"

Axis replacement

Problem: A program moves an axis and gives up control before the target block with WAITP(X). X is thus not subject to REPOS and the axis is not taken into account in SERUPRO approach.

Via the machine data MD11470 \$MN_REPOS_MODE_MASK, the following behavior can be achieved for SERUPRO-REPOS:

The neutral axes are moved as "command axes" in the SERUPRO-REPOS. The axis interpolates without a path context even it was last programmed as a path axis. In this scenario, the velocity results from MD32060 \$MA_POS_AX_VELO. After SERUPRO approach, this axis is again neutral.

Neutral axes that are however not allowed to be repositioned must receive the axial VDI signal "REPOSDELAY". This deletes the REPOS movement.

Example:

After SERUPRO, one axis is deliberately moved in the synchronized action via technology cycles. The command axes are always moved in the approach block, never in the target block. The target block can only be changed if all command axes have been moved to the end.

 CAUTION
The PLC-controlled axis is not repositioned! Axes enabled by RELEASE(X) before the target block are not repositioned.

9.7.8.6 Gear stage change

Operational sequences

The gear stage change (GSW) requires physical movements from the NCK in order to shift into a new gear.

In the SERUPRO operation, no gear stage change is required and is carried out as follows:

Some gears can only be changed when controlled by the NC, since either the axis must oscillate or a certain position must be approached beforehand.

The gear stage change can be suppressed selectively for DryRun, program test, and SERUPRO using bits 0 to 2 in MD35035 \$MA_SPIND_FUNCTION_MASK.

The gear stage change must then be performed in REPOS; this will work even if the axis involved is to be in "speed control mode" at the target block. In other cases, the automatic gear stage change is denied with an alarm if, for example, the axis was involved in a transformation or coupling between the gear stage change and the target block.

Note

For further information about gear stage changes in DryRun, Program test and SERUPRO, see

References: /FB1/ Function Manual Basic Functions; Spindle Programming (S1)

9.7.8.7 Superimposed motion

Only SERUPRO

If "overlaid movements" are used, only the block search via program test (SERUPRO) can be used, since the overlaid movements are interpolated accordingly in the main run. This applies in particular to \$AA_OFF.

Velocity profile instead of maximum axis velocity

During Program test, a velocity profile must be used, which allows "superimposed movements" to be interpolated during the main run. It is thus not possible to interpolate at the maximum axis velocity.

The axis velocity is set in "Dry run feedrate" mode using SD42100 \$SC_DRY_RUN_FEED.

The velocity of the SERUPRO operation is selected using MD22600 \$MC_SERUPRO_SPEED_MODE.

9.7.8.8 REPOS offset in the interface

REPOS offset provided or valid

When the SERUPRO operation is finished, the user can use the OPI to read off the REPOS offset applied via the REPOS process.

An axial interface bit is offered for this DB31, ...DBX70.0 (REPOS offset).

Value 0 No REPOS offset has to be applied to this axis

Value 1 A REPOS offset has to be applied to this axis.

Scope: The axis-VDI-interface bit "REPOS offset" is provided when the SERUPRO operation is finished. The "REPOS offset" is invalid when a SERUPRO ASUB starts or continues. The axis can be moved in JOG mode with a mode change between the SERUPRO end and start and the "REPOS offset" bit is continuously updated (i.e., the user traverses the REPOS offset by hand and the bit changes to 0). In the scope, the axis can also be traversed using FC18, with the "REPOS offset" continuously being updated.

The scope of "REPOS offset" is displayed with the axial VDI interface bit DB31, ...DBX70.1 (REPOS offset valid):

Value 0 DB31, ... DBX70.0 (REPOS offset) has not been calculated as valid

Value 1 DB31, ... DBX70.0 (REPOS offset) has been calculated as valid

9.7.8.9 Making the initial settings more flexible

Initial setting/initial SERUPRO setting

Machine data MD20112 \$MC_START_MODE_MASK defines the initial setting of the control for part program start with respect to the G codes (especially the current plane and settable zero offset), tool length compensation, transformation, and axis couplings. The special option exists for the SERUPRO operation of using MD22620 \$MC_ENABLE_START_MODE_MASK_PRT to select an initial setting that differs from the normal part program start. The new setting must therefore be stored in: MD22620 \$MC_START_MODE_MASK_PRT

The meaning of the bits of MD22620 is identical to those of: MD20112 \$MC_START_MODE_MASK.

Example

The synchronous spindle coupling at the beginning of the SERUPRO operation is retained for the part program start.

```

; synchronous spindle coupling not
; configured
$MC_START_MODE_MASK = 'H400' ; is switched off
$MC_START_MODE_MASK_PRT = 'H00' ; remains active
$MC_ENABLE_START_MODE_MASK_PRT = 'H01' ; $MC_START_MODE_MASK_PRT is evaluated
; in SERUPRO instead of
; $MC_START_MODE_MASK
```

9.7.9 System variables and variables for SERUPRO sequence

SERUPRO detection

The SERUPRO sequence can be detected using the following system variables:

\$P_ISTEST is TRUE (valid also for program test)

\$P_SEARCH is set to 5 (search in extended program test)

\$AC_ASUP Bit 20 in system ASUB is set after the search target is found (SERUPRO operation step 8.)

\$P_ISTEST AND (5 == \$P_SEARCHL) reliably detects SERUPRO.

\$AC_SEARCH is **not** supplied by the SERUPRO operation.

Note

\$P_SEARCHL is set at the beginning of the SERUPRO operation and

reset on RESET. As a result, \$P_SEARCHL continues to be set in the SERUPRO ASUB and in the residual part program and can continue to be evaluated.

In contrast, the \$P_ISTEST variable is set only in the SERUPRO operation and is thus suitable for search-specific adaptation of programs.

Synchronized action

SERUPRO can be scanned in a synchronized action using system variable

\$AC_SERUPRO = TRUE.

SERUPRO Updated REPOS acknowledgements can be scanned via:

"Program-sensitive system variable"	Description
\$AC_REPOS_PATH_MODE	Type of REPOS MODE
\$AA_REPOS_DELAY	REPOS suppression is currently active for this axis

\$AC_SERUPRO and \$P_ISTEST, if SERUPRO is still active in the main run

Note

During interpretation of system variables \$P_ISTEST and \$AC_SERUPRO, a check is made to determine whether the SERUPRO target block has already been found.

If so, an implicit preprocessing stop is inserted before the two system variables are evaluated.

As a result, interpretation is halted and not continued again until SERUPRO is deactivated in the main run as well. The decision as to whether SERUPRO must be active or inactive is then made correctly.

Additional variable for interpretation during simulation search

In JOG and MDA modes, NC variable "selectedWorkPProg" can be used to select whether the previously selected program or the program to be simulated is to be displayed in the HMI during the simulation, e.g., with SERUPRO. For more information, refer to

References: /LIS2/ Lists (Book 2), Section "Variables".

9.7.10 Restrictions

Conditional use

SERUPRO supports the following NC functions subject to certain restrictions:

NCK functionality	Restrictions
Master/slave for drives and SERUPRO	Selective enabling and disabling of the master/slave link with MASLON active
Axis enables and SERUPRO	Real servo enable missing during program testing
Axis replacement and SERUPRO	Axes traversing as path axes before RELEASE are ignored on REPOS

9.8 Program operation mode

PLC, MD, operation

The execution of part programs can be controlled via the HMI in many ways using PLC inputs, machine data settings and operator inputs.

Definition

The execution of part programs or part program blocks in AUTOMATIC or MDA modes is referred to as program operation.

Channel control

Every channel can be manipulated by means of interface signals from the PLC. The control is exercised via mode group-specific or channel-specific interface signals. An overview of these signals is given under data lists in this Function Manual.

Status messages

Each channel reports its current program operation status to the PLC with interface signals. These signals are, in turn, divided up into mode group-specific and channel-specific signals.

9.8.1 Initial settings

Machine data

Defined conditions can be set via machine data for the program operation or certain implementations of the NC language scope.

MD settings

Initial settings

Initial settings can be programmed in channel-specific machine data for each channel. These initial settings affect, for example, G groups and auxiliary function output.

Auxiliary function output

The timing for output of auxiliary functions can be predefined via machine data AUXFU_x_SYNC_TYPE (MD22200, 22210, 22220, 22230, 22240, 22250, 22260), (output timing for M, S, T, H, F, D, E functions). For further information, see:

References:

/FB1/ Function Manual Basic Functions; Auxiliary Function Outputs to PLC (H2)

G groups

An initial programming setting can be specified for each of the available G groups using MD20150 \$MC_GCODE_RESET_VALUES (reset state of G groups). This initial setting is automatically active during program start or in Reset until it is deselected by a G command from the same G group.

Via the MD22510 \$MC_GCODE_GROUPS_TO_PLC (G codes, which are output to interface NCK-PLC after block change/RESET), the output of the G codes to the PLC interface can be activated.

A list of G groups with the associated G functions is available in:

References:

/PG/ Programming Manual Fundamentals

Basic configurations of the NC language scope for SINUMERIK solution line

For SINUMERIK 840D sl, certain basic configurations of the NC language scope can be generated (configurable) via machine data. The options and functions of the NC language scope is specially tailored (configured) to the needs of the user.

NC language scope

The way that non-active options and functions should be moved with NC language commands can be set via the machine data MD10711 \$MN_NC_LANGUAGE_CONFIGURATION:

0: All available language commands can be programmed. Whether or not the needed function is activated can only be recognized upon execution. This corresponds to the default setting for previous controls such as SINUMERIK 840D and 840Di.

If only **certain options** are enabled and **not all operations** are available:

1: All **the language commands are known**. Language commands for non-enabled options are already recognized at the beginning of the program interpretation and lead to the alarm 12553 "option/function is not active."

2: Only those language commands are known, which correspond to the **current scope of enabled options** of the NCK software. All commands for non-enabled options are not recognized and trigger the alarm 12550 "Name not defined or option/function not available".

Note

Option-free functions also have the status "enable option"

If only **certain functions activated** are:

3: All the language commands are known. Non-activated functions are already recognized at the beginning of the program interpretation and result in the alarm 12553 "Option/function is not active". For example, if the option date is set for the cylinder coat transformation, but the transformation is not activated in machine data MD24100 \$MC_TRAOF_TYPE_1, then the programming of TRACYL triggers the alarm 12553.

4: Only those NC language commands are known, which correspond to the current scope of active functions of the NCK software. All commands for non-active functions are not recognized and trigger the alarm 12550 "Name not defined or option/function not available". Whether the command in question is generally unavailable in the Siemens NC language or whether this is true only on the corresponding system cannot be distinguished in this scenario.

Whether the current NC language scope of enabled options and active functions is also truly programmable can be checked using the STRINGIS program command, see example.

Check sample application for NC language scope on cylinder jacket transformation TRACYL

The cylinder jacket transformation is optional and must be enabled beforehand. In order to check this, the following initial conditions are assumed:

The cylinder coat transformation option is **not** enabled and the machine data \$MN_NC_LANGUAGE_CONFIGURATION = 2; NC language command TRACYL is unknown

The following program is started

```
N1 R1=STRINGIS("TRACYL")           ;R1 is 0 (TRACYL is an unknown name)
N2 IF STRINGIS("TRACYL") ==204
N3 TRACYL(1, 2, 3)                 ;block is not interpreted
N4 ELSE
N5 G00
N6 ENDIF
N7 M30
```

Example of whether STRINGIS result is programmable or not

The result of STRINGIS = number-coded return value (three-digit)

Number coding of the basic information (1st digit from the left):

000 Name is unknown, programming is denied with Alarm 12550

100: Name is known but cannot be programmed, triggers alarm 12533

200: Name/symbol is known, but interpretation is not possible

2xx: Name/symbol is known, the **command can be programmed**, if xx > 0

Definition for name/symbol:

Name: Any STRING that is checked to see whether it is a component of the NC language in the existing NCK version or configuration.

Symbol: contains the description or significance of an NC language command that is needed for the NC program and cycle interpretation.

9.8 Program operation mode

Dependent on machine data MD10711

\$MN_NC_LANGUAGE_CONFIGURATION = (set value) results in the following interpretations of the option and function relative to their programmability 2xx:

Table 9- 1 Setting options

MD10711 =		0	1	2	3	4
Option	Function	Return value as the basic information (1st digit from the left)				
0	0	2	1	0	1	0
1	0	2	2	2	1	0
1	1	2	2	2	2	2
0	1	2	1	0	1	0

Definition for option/function:

0 corresponds to option not activated or function deactivated
 1 corresponds to option/activated or function activated

For more detailed information on the value ranges of 2xx programmable functions, see

References:

/PGA/ Programming Manual Job Planning; Other Functions, "STRINGIS"

9.8.2 Selection and start of part program or part-program block

Reset status

Channel status

A part program can be selected only if the relevant channel is in the Reset state.

Start command, channel status

There are two possible START commands for initiating processing of a part program or part program block:

- The channel-specific interface DB21, ... DBX7.1 (NC Start), which is usually controlled from the machine control panel key NC Start, starts program execution in the same channel.
- With the NC instruction START, program execution in the first channel can be started from the second channel, for example (for further information, see Section on Channel synchronization).

The START command can only be executed in AUTOMATIC and MDA modes. For this, the channel concerned must be in the following state:

DB21, ... DBX35.7(channel status reset) or

DB21, ... DBX35.6 (channel status interrupted).

Signals, Alarms

Required signal states

The part program can now be enabled for execution in the channel with the START command on the condition that certain signal states exist on the machine.

The following enable signals are relevant on the VDI interface:

- DB11 DBX4.4 (mode group ready) must be present
- DB11 DBX0.7 (mode group reset) must not be present
- DB21, ... DBX1.7 (activate program test) must not be present
- DB21, ... DBX7.0 (NC start disable) must not be present
- DB21, ... DBX7.2 (NC stop at the block limit) must not be present
- DB21, ... DBX7.3 (NC Stop) must not be present
- DB21, ... DBX7.4 (NC Stop axes plus spindle) must not be present
- DB21, ... DBX7.7 (Reset) must not be present
- DB10 DBX56.1 (Emergency stop) may not be present
- No axis or NCK alarm must be active

For a further explanation of the individual signals see Chapter 5.

Execution of command

The parts program or the parts program block is automatically executed and the the following interface signals are set:

DB21, ... DBX35.5 (channel status reset)

DB21, ... DBX35.0 (program status running)

The program is processed until the end of the program has been reached or the channel is interrupted or aborted by a STOP or RESET command.

Alarms

Under certain conditions the START command will have no effect and one of the following alarms will be triggered:

- 10200 "No NC Start permitted with active alarm"
- 10202 "No NC Start permitted with active command" (see /DA/)
- 10203 "No NC Start permitted for non-referenced axes"

9.8.3 Part-program interruption

"Interrupted" status

Channel status

The STOP command is executed only if the channel concerned has the status IS DB21, ... DB35.5 ("Channel active").

STOP commands

There are various commands that stop the program execution and set the channel status to "interrupted". These are in particular the interface signals:

- DB21, ... DBX7.2 ("NC stop at the block limit")
- DB21, ... DBX7.3 ("NC stop")
- DB21, ... DBX7.4 ("NC stop, axes plus spindles")
- DB21, ... DBX2.0 ("Single block")
- Programming command "M00" or "M01".

For a further explanation of the individual interface signals, please see

References: /FB1/ Function Manual Basic Functions; NC/PLC interface signals (Z1), for explanations of the individual part program instructions, see:

References: /PG/ Programming Manual Fundamentals; see "List of Instructions"

Execution of command

After execution of the STOP command, the IS DB21, ... DBX35.3 ("Program status interrupted") is set. Processing of the interrupted program can continue from the point of interruption with the command START.

The following actions are executed when the STOP command is triggered:

- Part program execution is stopped at the next block limit (with NC stop at block limit, M00/M01 or single block), processing is stopped immediately with the other STOP commands.
- Any auxiliary functions of the current block not yet output, are no longer output.
- The axes of each channel are brought to a standstill along a braking ramp and part program execution is then stopped.
- The block indicator stops at the point of interruption.

Possible actions in the interrupt state

The following actions can be executed when the part program has been interrupted (program status stopped, channel interrupted):

- Overstoring
References:
/BEM/, Operating Manual HMI Embedded
- Block search
References:
/BEM/ Operating Manual HMI Embedded
- Repositioning at contour (machine function REPOS)
References:
/BEM/ Operating Manual HMI Embedded
- Oriented tool retraction
References:
/PGA/ Programming Manual, Job Planning
- Interrupt routine
- DRF-Function, Displacement of the workpiece zero
References:
/FB2/ Function Manual, Extended Functions; Manual and Handwheel Travel (H1)
- Starting the interrupted program with the interface signal:
DB21, ... DBX7.1 (NC start) or
via NC instruction START from another channel.

9.8.4 RESET command

Command priority

Channel status

The RESET command can be executed in every channel state. This command is aborted by another command.

Commands

RESET command

The following Reset commands are available:

- DB11, ... DBX0.7 ("mode group reset")
- DB21, ... DBX7.7 ("Reset")

For a further explanation of the individual interface signals, please see

References: /FB1/ Function Manual Basic Functions; NC/PLC interface signals (Z1)

A RESET command can be used to interrupt an active part program or a part program block (in MDA).

9.8 Program operation mode

After execution of the Reset command, the interface signal DB21, ... DBX35.7 ("Channel status Reset") is set.

The part program cannot be continued at the point of interruption. All the axes of the channel go into exact stop unless they are in follow-up mode. The same applies to the spindles configured in the channel.

The following actions are executed when the RESET command is triggered:

- Part program preparation is stopped immediately.
- Axes and, if they exist, spindles in the channel are decelerated along a braking ramp.
- Any auxiliary functions of the current block not yet output, are no longer output.
- The block indicator is reset to the beginning of the part program.
- All Reset alarms (channel-specific, axis-specific, spindle-specific) are cleared from the display.

9.8.5 Program status

Interface information

The status of the selected program is displayed in the interface for each channel. The PLC can then trigger certain responses and interlocks configured by the manufacturer depending on the status.

The program status is only displayed in the AUTOMATIC and MDA modes. In all other modes the program status is aborted or interrupted.

Program statuses

The following program statuses are available at the interface:

- DB21, ... DBX35.4 ("Program status aborted")
- DB21, ... DBX35.3 ("program status interrupted")
- DB21, ... DBX35.2 ("Program status stopped")
- DB21, ... DBX35.1 ("Program status wait")
- DB21, ... DBX35.0 ("Program status running")

For a further explanation of the individual interface signals, please see

References: /FB1/ Function Manual Basic Functions; NC/PLC interface signals (Z1)

The effect of commands/signals

The program status can be controlled by activating different commands or interface signals. The following table shows the resulting program status when these signals are set (assumption: status before the signal is set -> Program status running).

Table 9- 2 Effect on program status

Commands	Program execution statuses				
	Aborted	Interrupted	Stopped	Wait	Running
IS "Reset"	X				
IS "NC Stop"			X		
IS "NC stop at block limit"			X		
IS "NC stop axes and spindles"			X		
IS "Read-in disable"					X
IS "Feed stop, channelsp."					X
IS "Feed stop, axisp."					X
Feed override = 0%					X
IS "Spindle stop"					X
M02/M30 in a block	X				
M00/M01 in a block			X		
IS "Single block"			X		
IS "Delete distance-to-go"					X
Auxiliary functions output to PLC but not yet acknowledged			X		
Wait instruction in program				X	

9.8.6 Channel status

Interface representation

The current channel status is displayed in the interface. The PLC can then trigger certain responses and interlocks configured by the manufacturer depending on the status at the interface.

The channel status is displayed in all operating modes.

Channel statuses

The following channel statuses are available at the interface:

- DB21, ... DBX35.7 ("channel status reset")
- DB21, ... DBX35.6 ("channel status interrupted")
- DB21, ... DBX35.5 ("channel status reset")

For a further explanation of the individual signals see Chapter 5.

The effect of commands/signals

The channel status can be modified through the activation of various commands or interface signals. The following table shows the resulting channel status when these signals are set (assumed status before the signal is set - > Channel status active).

The "Channel status active" signal is obtained when a part program or part program block is being executed or when the axes are traversed in JOG mode.

9.8 Program operation mode

Commands	Resulting channel status		
	Reset	Interrupted	active
IS "Reset"	X		
IS "NC Stop"		X	
IS "NC stop at block limit"		X	
IS "NC stop axes and spindles"		X	
IS "Read-in disable"			X
IS "Feed stop, channelsp."			X
IS "Feed stop, axisssp."			X
Feed override = 0%			
IS "Spindle stop"			X
M02/M30 in a block	X		
M00/M01 in a block		X	
IS "Single block"		X	
IS "Delete distance-to-go"			X
Auxiliary functions output to PLC but not yet acknowledged			X
Wait instruction in program			X

9.8.7 Responses to operator or program actions

Status transitions

The following table shows the channel and program statuses that result after certain operator and program actions.

The left-hand side of the table shows the channel and program statuses and the mode groups from which the initial situation can be selected. Various operator/program actions are listed on the right-hand side of the table, the number of the situation after the action has been carried out is shown in brackets after each action.

Table 9-3 Responses to operator or program actions

Situation	Channel status			Program status					Active mode			Operator or program action (Situation after the action)
	R	U	A	N	U	S	W	A	A	M	J	
1		x						x	x			RESET (4)
2		x						x		x		RESET (5)
3		x						x			x	RESET (6)
4	x			x					x			NC Start (13); Mode change (5 or 6)
5	x			x						x		NC Start (14); Mode change (4 or 6)
6	x			x							x	Direction key (15); Mode change (4 or 5)
7		x		x						x		NC Start (14)

Situation	Channel status			Program status					Active mode			Operator or program action (Situation after the action)
	R	U	A	N	U	S	W	A	A	M	J	
8		x		x							x	NC Start (15)
9		x			x				x			NC Start (13); Mode change (10 or 11)
10		x			x					x		NC Start (16); Mode change (9 or 11)
11		x			x						x	Direction key (17); Mode change (9 or 10)
12		x				x			x			NC Start (13); Mode change (10 or 11)
13			x					x	x			NC Stop (12)
14			x	x						x		NC Stop (7); at block end (5)
15			x	x							x	NC Stop (8); at JOG end (6)
16			x		x					x		NC Stop (10); at block end (10)
17			x		x						x	NC Stop (11); at JOG end (11)
18			x				x		x			Reset (4); wait for other channel (18)

Channel status

R --> aborted

U --> interrupted

A --> running

Program status

N --> aborted

U --> interrupted

S --> stopped

W --> waiting

A --> running

Operating modes

A --> aborted

M --> aborted

J --> aborted

9.8.8 Part-Program Start

Start handling

Table 9- 4 Typical program sequence

Sequence	Command	Conditions (must be satisfied before the command)	Comments
1	Load program (via the operator interface or part program)		
2	Select AUTOMATIC mode		
3	Program preselection	Channel preselected Preselected channel in RESET state User ID sufficient for program preselection	
4	NC start for preselected channel	NC start disable not available Reference point approached in all axes	
5			Program execution
6	M02/M30/RESET	None	End of program

9.8.9 Example of timing diagram for a program run

Signal sequences

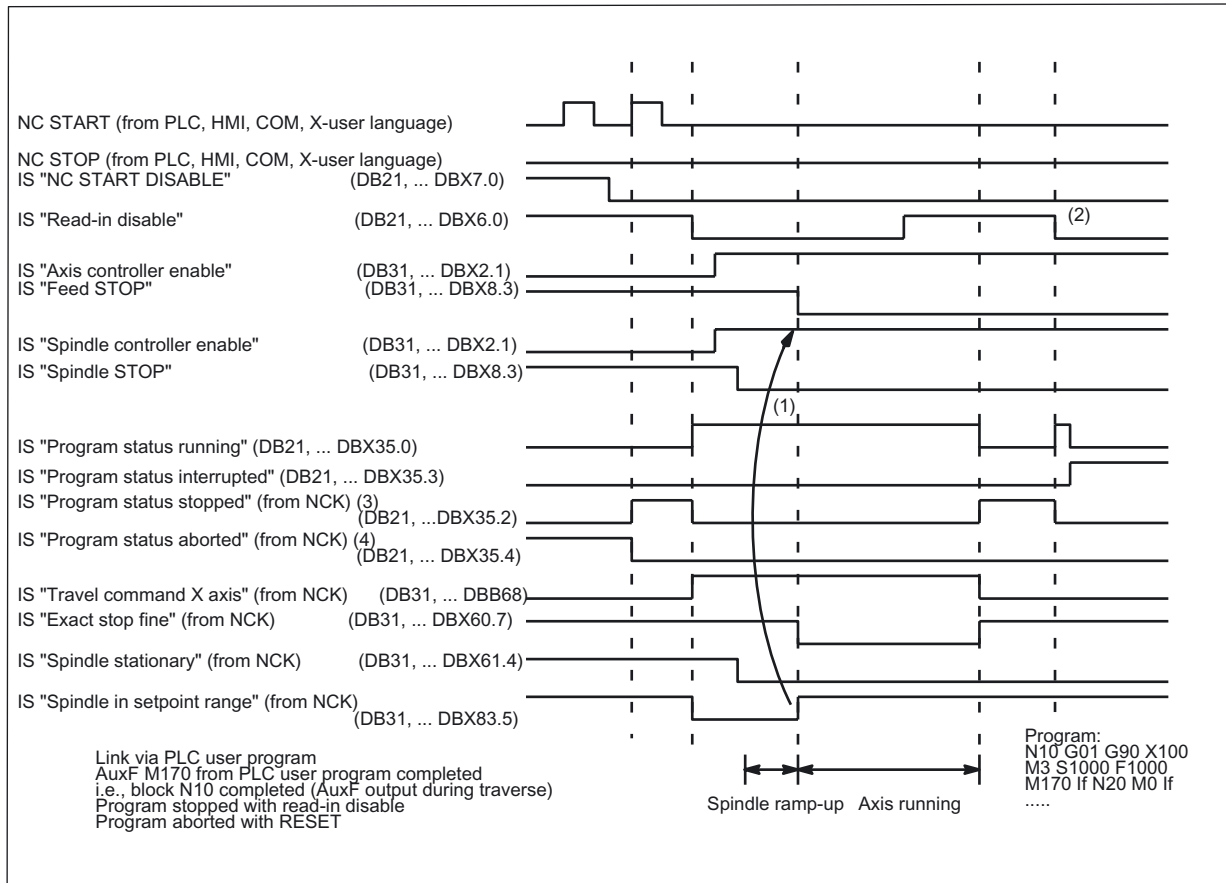

Figure 9-8 Examples of signals during a program run

9.8.10 Program jumps

9.8.10.1 Jump back to start of program

Function

With the function "Jump back to start of the program" the control jumps back from a part program to the beginning of the program. The program is then processed again.

As compared to the function "Program jumps to jump marks", with which a repeated processing of the program can also be implemented, the function "Jump back to the start of the program" offers the following advantages:

- The programming of a jump mark at the start of the program is not necessary.
- The program restart can be controlled through the NC/PLC interface signal:
DB21, ... DBX384.0 (control program branching)
- The timer for the program runtime can be reset to "0" at the restart of the program.
- The timer for workpiece counting can be incremented by "1" at program restart.

Application

The function is used, if the processing of subsequent workpieces is to be done through an automatic program restart e.g. in case of turning machine with bar loader/-changer.

Activation

The jump back takes place only when the following NC/PLC interface signal is set:

DB21, ... DBX384.0 (control program branching) = 1

If the signal is at "0", then no jump back is executed and the program processing is continued with the next part program block after the function call.

Parameter assignment

Program runtime

The runtime of the selected NC program is stored in the system variable \$AC_CYCLE_TIME. When starting a new program, the system variable is automatically reset to "0"(see Chapter "Program runtime (Page 675)")

Via the following machine data it can be set that the system variable \$AC_CYCLE_TIME is reset to "0" even in case of a program restart through the function "jump back to start of program":

MD27860 \$MC_PROCESSTIMER_MODE (Activation of the program runtime measurement)

9.8 Program operation mode

Bit	Value	Description
8	0	\$AC_CYCLE_TIME is not reset to "0" by the function "jump back to start of program".
	1	\$AC_CYCLE_TIME is reset to "0" by the function "jump back to start of program".

Note

In order that the setting of bit 8 can become effective, the measurement of the current program runtime must be active (MD27860 bit 1 = 1).

Workpiece count

After the part program end (M02 / M30) has been attained, the activated workpiece counters (\$AC_TOTAL_PARTS / \$AC_ACTUAL_PARTS / \$AC_SPECIAL_PARTS) are incremented by "1" (see Chapter "Workpiece Counter (Page 681)").

Via the following machine data it can be set that the activated workpiece counter is incremented even in case of a program restart through the function "jump back to start of program":

MD27880 \$MC_PART_COUNTER (activation of workpiece counters)

Bit	Value	Description
		In case of a program restart through the function "jump back to start of program", the workpiece counter:
7	0	\$AC_TOTAL_PARTS is not incremented.
	1	\$AC_TOTAL_PARTS is incremented.
11	0	\$AC_ACTUAL_PARTS is not incremented.
	1	\$AC_ACTUAL_PARTS is incremented.
15	0	\$AC_SPECIAL_PARTS is not incremented.
	1	\$AC_SPECIAL_PARTS is incremented.

Programming

The function is called in the main or the part program via the command GOTOS.

Syntax: GOTOS

Parameters: none

Application in synchronized actions: not possible

Note

GOTOS internally initiates a STOPRE (pre-processing stop).

Example

Programming	Comment
N10 ...	; Beginning of the program
...	
N90 GOTOS	; Jump to beginning of the program
...	

9.8.11 Program section repetitions

9.8.11.1 Overview

Function

The program section repetition allows the repetition of any labeled section of a part program. For more information on labels, please see:

References:

/PG/ Programming Manual Fundamentals; Program Jumps and Program Repetitions

Definition options of part program sections

The program repetition offers various options for defining a part program section that is supposed to be repeated:

- A single part program block
- A part program section after a start label
- A part program section between a start label and end label
- A part program section between a start label and the key word: ENDLABEL

References:

/PGA/ Programming Manual Job Planning; Chapter "Program Coordination"

9.8.11.2 Individual part program block

Functionality

Via `REPEATB` (B=Block) in part program block N150, the part program processing branches to the part program block N120 that is labeled `START_1`. This is repeated x number of times. If P is not specified, the program section is repeated exactly once. After the last repetition, the part program is continued with the part program block N160 following the `REPEATB` instruction.

```
:  
N100 ...  
N120 START_1: ... ; Label: START_1  
N130 ...  
N140 ...  
N150 REPEATB START_1 P=n ; Repetition after: START_1  
N160 ...  
:
```

Note

Label search direction

The part program block identified by the label can appear before or after the `REPEATB` statement. The search initially commences toward the start of the program. If the label is not found, a search is made in the direction of the program end.

Programming

Syntax: `REPEATB <Label> [P=n]`

Label	Start label to which the instruction: <code>REPEAT</code> branches Type: String
P	Number of repetitions
n	Number of repetitions Type: Integer

9.8.11.3 A part program section after a start label

Functionality

Via `REPEAT` in part program block N150, the part program processing branches to the part program block N120 that is labeled `START_1`. This part program block and all of the following part program blocks (N130 and N140) are repeated x number of times up to the part program block that contains the `REPEAT` instruction (N150). If P is not specified, the part program section (N120 - N140) is repeated exactly once. After the last repetition, the part program is continued with the part program block N160 following the `REPEAT` instruction.

```
:  
N100 ...  
N120 START_1: ... ; Start label: START_1  
N130 ...  
N140 ...  
N150 REPEAT START_1 P=n ; Repetition after: START_1  
N160 ...  
:
```

Note

Label search direction

The part program block marked with the Start label **must** come before the `REPEAT` instruction.

Programming

Syntax: `REPEAT <Label> [P=n]`

Label	Start label to which the instruction: <code>REPEAT</code> branches Type: String
P	Number of repetitions
n	Number of repetitions Type: Integer

9.8.11.4 A part program section between a start label and end label

Functionality

Via `REPEAT` in part program block N160, the part program processing branches to the part program block N120 that is labeled `START_1` with a start label. This part program block and all the part program blocks up to and including the part program block marked with the end label `END_1` (N140) are repeated x number of times. If P is not specified, the part program section (N120 - N140) is repeated exactly once. After the last repetition, the part program is continued with the part program block N170 following the `REPEAT` instruction.

```
:  
N100 ...  
N120 START_1: ... ; Start label: START__1  
N130 ...  
N140 END_1 ... ; End label: END_1  
N150 ...  
N160 REPEAT START_1 END_1 P=n ; Repetition: START_1 until END_1  
N170 ...  
:
```

Note

Label search direction

The program section marked with the Start and End labels can come before or after the `REPEAT` instruction. The search initially commences toward the start of the program. If the Start label is not found, a search is made in the direction of the program end.

If the `REPEAT` instruction is between the Start and End label, only the part program section from the Start label to the `REPEAT` instruction is repeated.

`REPEAT` instruction repeated.

Programming

Syntax:	<code>REPEAT <Start_Label> <End_Label> [P=n]</code>
<code>Start_Label</code>	Start label to which the instruction: <code>REPEAT</code> branches. Beginning of the part program section that is repeated. Type: String
<code>End_Label</code>	End of the part program section that is repeated. Type: String
<code>P</code>	Number of repetitions
<code>n</code>	Number of repetitions Type: Integer

9.8.11.5 A part program section between a Start label and the key word: ENDLABEL

Functionality

Via `REPEAT` in part program block N150, the part program processing branches to the part program block N120 that is labeled `START_1` with a start label. This part program block and all the part program blocks up to and including the part program block marked with the key word `ENDLABEL` (N140) are repeated x number of times. If P is not specified, the part program section (N120 - N140) is repeated exactly once. After the last repetition, the part program is continued with the part program block N170 following the `REPEAT` instruction.

```
:  
N100 ...  
N120 START_1: ... ; Start label: START__1  
N130 ...  
N140 ENDLABEL: ... ; End label: Keyword ENDLABEL  
N150 ...  
N160 REPEAT START_1 END_1 P=n ; Repetition: START_1 until END_1  
N170 ...  
:
```

Note

Label search direction

The program section marked with the Start and End labels can come before or after the `REPEAT` instruction. The search initially commences toward the start of the program. If the Start label is not found, a search is made in the direction of the program end.

If no keyword `ENDLABEL` is located between the Start label and the `REPEAT` instruction, the part program section from the Start label to the `REPEAT` instruction is repeated.

Programming

Syntax:	<code>REPEAT <Label> [P=n]</code>
	<code>Label</code> Start label to which the instruction: <code>REPEAT</code> branches. Beginning of the part program section that is repeated. Type: String
	<code>P</code> Number of repetitions
	<code>n</code> Number of repetitions Type: Integer

9.8.12 Event-driven program calls

9.8.12.1 Function

What is the purpose of the function?

The function "Event-driven program calls" offers the possibility of letting an application program run implicitly during certain events, such as for doing the default settings of functions of initializations.

Events

Triggering events can be:

- Part program start
- Part program end
- Operator panel reset
- Power-up of the NC control

The triggering events are selected with the machine data MD20108 \$MC_PROG_EVENT_MASK (see chapter "Parameterization").

User program

In the default setting the program `_N_PROG_EVENT_SPF` is activated after the triggering event occurs. If a different application program is to be activated, then it must be entered in the machine data MD11620 \$MN_PROG_EVENT_NAME (see chapter "Parameterization").

The application program activated by the event is basically processed in the channel, in which the respective event occurred.

The application program is executed with the lowest priority and so can be interrupted by the user ASUB.

Processing sequence

Sequence during activation through part program start

Initial state:

Channel:	in the Reset-state
Mode:	AUTO
	AUTO + oversteering or MDA
	TEACHIN

1. NC Start
2. Initialization sequence with evaluation of:
MD20112 \$MC_START_MODE_MASK (Definition of the control default settings in case of NC START)
3. Implicit call of _N_PROG_EVENT_SPF as part program
4. Processing of the data part of the main program
5. Processing of the program part of the main program

Sequence during activation through part program end

Initial state:

Channel: in active status
Mode: AUTO
AUTO + overstring or MDA
TEACHIN

1. Block with end of part program is changed
2. Control activates reset-sequence with evaluation of machine data:
MD \$MC_RESET_MODE_MASK
\$MC_GCODE_RESET_VALUES
\$MC_GCODE_RESET_MODE
3. Implicit call of _N_PROG_EVENT_SPF as ASUB
4. Control activates reset-sequence with evaluation of machine data:
\$MC_RESET_MODE_MASK
\$MC_GCODE_RESET_VALUES
\$MC_GCODE_RESET_MODE
⇒ The G code reset position continues to be set with machine data!

Sequence during activation through operator panel reset

Initial state:

Channel: any
Mode: any

1. Control activates reset-sequence with evaluation of machine data:

MD \$MC_RESET_MODE_MASK

\$MC_GCODE_RESET_VALUES

\$MC_GCODE_RESET_MODE

2. Implicit call of `_N_PROG_EVENT_SPF` as ASUB

3. Control activates reset-sequence with evaluation of machine data:

\$MC_RESET_MODE_MASK

\$MC_GCODE_RESET_VALUES

\$MC_GCODE_RESET_MODE

⇒ The G code reset position continues to be set with machine data!

Sequence during activation through power-up

1. Control activates after power-up reset-sequence with evaluation of machine data:

MD \$MC_RESET_MODE_MASK

\$MC_GCODE_RESET_VALUES

\$MC_GCODE_RESET_MODE

2. Implicit call of `_N_PROG_EVENT_SPF` as ASUB

3. Control activates reset-sequence with evaluation of machine data:

\$MC_RESET_MODE_MASK

\$MC_GCODE_RESET_VALUES

\$MC_GCODE_RESET_MODE

⇒ The G code reset position continues to be set with machine data!

Signal chart

The following diagrams show the signal chart of the NC/PLC interface signals DB21, ... DBB35 ("Program status" and "Channel status") in case of event-driven program call:

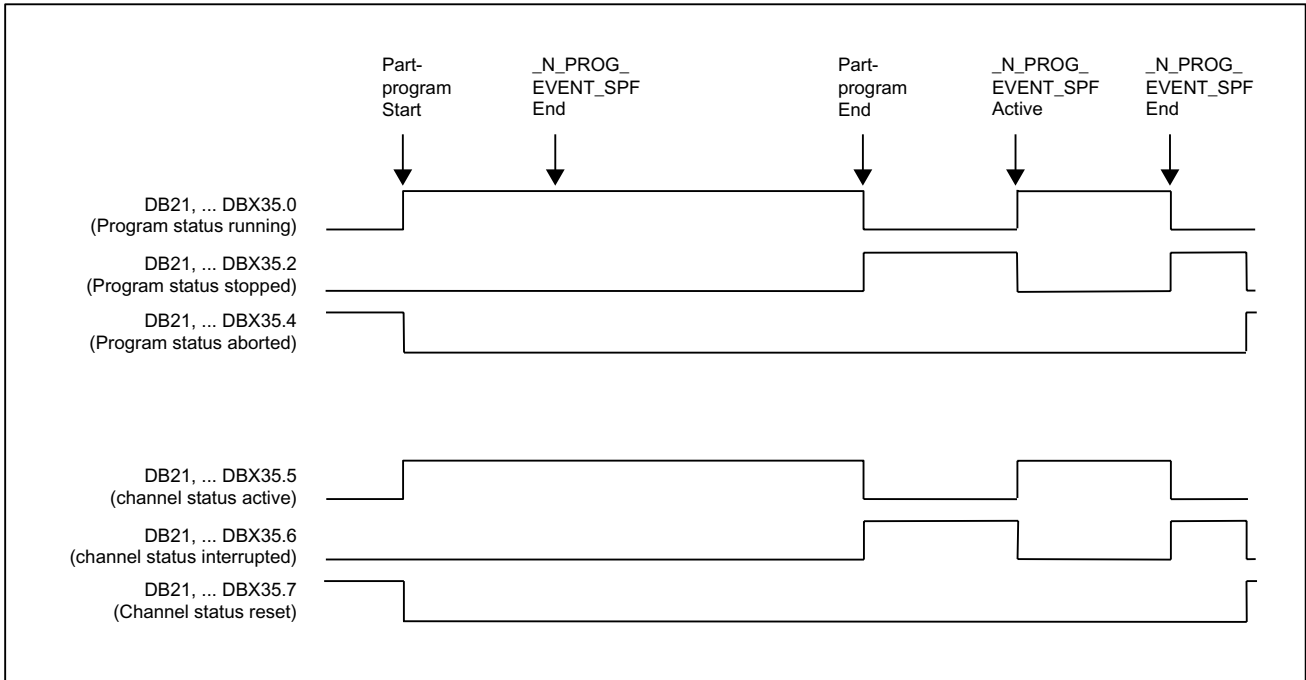

Figure 9-9 Signal chart in case of activation through part program start and part program end

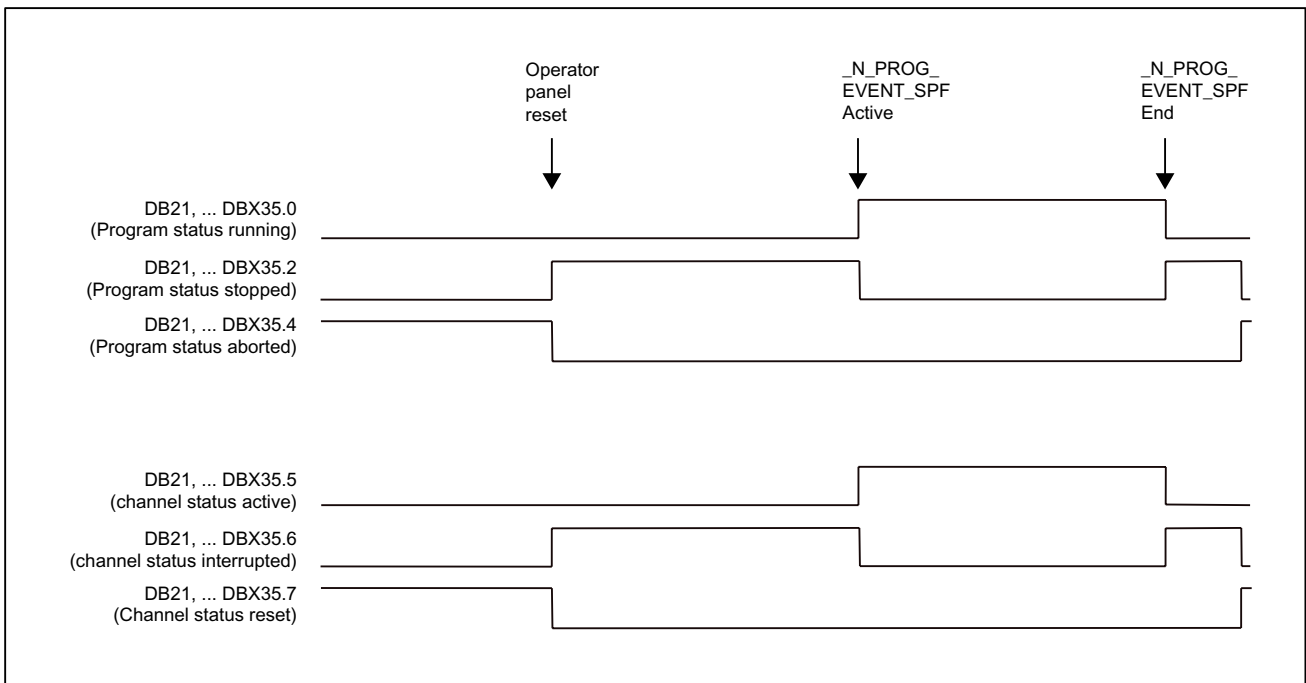

Figure 9-10 Signal chart during activation through operator panel reset

Note

DB21, ... DBX35.4 ("Program status aborted") and DB21, ... DBX35.7 ("Channel status reset") are only received if event-driven use program is complete. Between program end and the start of the event-driven application program these states are not imported. This is also the case between an operator panel reset and the start of the application program.

Display

The information about the triggering event is provided to the PLC via the NC/PLC interface byte DB21, ... DBB376.

Bit	Value	Description
0	1	Part program start from the channel status reset
1	1	Part program end
2	1	Operator panel reset
3	1	Ramp-Up
4	1	1st start after block search (see "Automatic Start of an ASUB after block search (Page 515)")

The global query of DB21, ... DBB376 on 0 enables the determination, whether an event-driven application program is active at all.

If the event-driven application program has expired or has been interrupted with RESET, then the related display bit is deleted in the interface. For a very brief program, the corresponding bit remains for at least the duration of a complete PLC cycle.

9.8.12.2 Parameter assignment

Triggering event

Which events the application program should activate, is set channel-specific in the machine data:

MD20108 \$MC_PROG_EVENT_MASK (event-controlled program call)

Bit	Value	Description
0	1	Activation through part program start
1	1	Activation through part program end
2	1	Activation through Operator panel reset
3	1	Activation through Power up of the NC control

Prerequisite for the activation:

The application program (default setting: `_N_PROG_EVENT_SPF`) must be loaded and cleared.

Note

MD20108 `$MC_PROG_EVENT_MASK` is ignored during the simulation.

User program

In the default setting after an event set with MD20108 occurs, the program `_N_PROG_EVENT_SPF` is activated from the directory `_N_CMA_DIR`.

If another program is to be activated, then the name of this user program must be entered in the following machine data:

MD11620 `$MN_PROG_EVENT_NAME`

The specified program must be present in one of the cycle directories.

The following search path is run when an event set with MD20108 occurs.

1. `/_N_CUS_DIR/` for user cycles
2. `/_N_CMA_DIR/` for manufacturer cycles
3. `/_N_CUS_DIR/` for standard cycles

The first found program with the given name is called.

Note

The specified name is checked syntactically as in case of a subroutine identifier i.e. the first two characters must be alphabets or underscores (no digits). Prefix (`_N_`) and suffix (`_SPF`) of the program names are added automatically, if not specified.

Note

The same protection mechanisms that can be activated for cycles (protection levels for writing, reading etc.) are activated.

Behavior when starting a user ASUB

The behavior of the function "event-driven program call" upon start of a user ASUB from the channel status reset can be set channel-specific with the machine data:

MD20109 `$MC_PROG_EVENT_MASK_PROPERTIES`

Bit	Value	Description
0	0	The occurrence of an event set with MD20108 (part program start, part program end and/or operator panel reset) leads to the activation of the event-driven user program.
	1	The occurrence of an event set with MD20108 does not lead to the activation of the event-driven user program.

Behavior when the single block processing is set

The behavior of the function "event-driven program call" in case of set single block processing can be set channel-specific with the machine data:

MD20106 \$MC_PROG_EVENT_IGN_SINGLEBLOCK

Bit	Value	Description
		In the event-driven user program:
0		• after an activation through part program start
	0	the single block processing is effective.
	1	the single block processing is suppressed.
1		• after an activation through part program end
	0	the single block processing is effective.
	1	the single block processing is suppressed.
2		• after an activation through operator panel reset:
	0	the single block processing is effective.
	1	the single block processing is suppressed.
3		• after an activation through power-up
	0	the single block processing is effective.
	1	the single block processing is suppressed.

If the single block processing is suppressed, then the event-driven user program is processed without interruption.

Note

MD20106 \$MC_PROG_EVENT_IGN_SINGLEBLOCK affects all single block processing types.

Note

The single block processing in the event-driven user program can be switched-off through the following configuration:

MD10702 \$MN_IGNORE_SINGLEBLOCK_MASK (Prevent single block stop) bit 0 = 1

The differentiated settings in MD20106 \$MC_PROG_EVENT_IGN_SINGLEBLOCK are then ineffective.

Behavior when the read-in disable is set

The behavior of the function "event-driven program call" in case of set read-in disable (DB21, ... DBX6.1 = 1) can be set channel-specific with the machine data:

MD20107 \$MC_PROG_EVENT_IGN_INHIBIT

Bit	Value	Description
0		In the event-driven user program:
		• after an activation through part program start
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.
1		• after an activation through part program end
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.
2		• after an activation through operator panel reset:
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.
3		• after an activation through power-up
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.

Note

For bit 0 = 1 (user program is activated after part program start) the following constraint is applicable:

If the user program is ended with the part program command `RET`, then `RET` always leads to an executable block (similar to `M17`).

In case of bit 0 = 0, `RET` interpretation is done in the interpreter and leads to an executable block.

Suppress updating of the display of the program and channel statuses.

In order to avoid a flickering of the display of the program and the channel statuses in the operator panel, the updating of the display can be suppressed for the execution of the normally very brief event-driven user program. In the display then, the program and channel status remains visible before activation of the event-driven user program (e.g. "program status cancelled" and "channel state reset").

The parameterization of this function is done with the channel-specific machine data:

MD20192 \$MC_PROG_EVENT_IGN_PROG_STATE

9.8 Program operation mode

Bit	Value	Description
		During execution of an event-driven user program the updating of the display of the program and channel status
1		<ul style="list-style-type: none"> upon an activation through part program end
	0	is not suppressed.
	1	suppressed.
2		<ul style="list-style-type: none"> upon an activation through operator panel reset:
	0	is not suppressed.
	1	suppressed.
3		<ul style="list-style-type: none"> upon an activation through power-up
	0	is not suppressed.
	1	suppressed.

Note

The system variables \$AC_STAT and \$AC_PROG are not affected by this function, i.e. in the running event-driven user program \$AC_STAT is set to "active" and \$AC_PROG to "running".

NC/PLC interface signals DB21, ... DBX35.0-7 ("Program status ..." and "Channel status ...") also remain unaffected.

Behavior for NC Stop

The behavior of the function "event-driven program call" for NC-Stop (i.e. NC/PLC interface signal DB21, ... DBX7.2, 7.3 or 7.4 is set) can be set channel-specific for the triggering event part program end, operator panel reset and power up with the machine data:

MD20193 \$MC_PROG_EVENT_IGN_STOP

Bit	Value	Description
		The event-driven user program is:
1		<ul style="list-style-type: none"> upon an activation through part program end
	0	stopped/prevented at NC stop
	1	despite NC Stop been completely processed.
2		<ul style="list-style-type: none"> upon an activation through operator panel reset:
	0	stopped/prevented at NC stop
	1	despite NC Stop been completely processed.
3		<ul style="list-style-type: none"> upon an activation through power-up
	0	stopped/prevented at NC stop
	1	despite NC Stop been completely processed.

In this way, an edge change of the interface signal DB21, ... DBX7.3 (NC-Stop) initiated by the user by activating the NC Stop key in case of reset or power-up is ignored during the execution of the event-driven user program and an undesired stop behavior at the machine is prevented.

Note

A programming of `DELAYFSTON`/`DELAYFSTOF` in the event-driven user program cannot be provided with the behavior set with MD20193, because the NC Stop can cause an interruption before the execution of the first command `DELAYFSTON`.

9.8.12.3 Programming

User program

End of program

The following must be kept in mind, if the user program is to be activated through the part program start.

- The user program must be ended with `M17` or `RET`.
- A jump back by means of `REPOS` command is not permitted and leads to an alarm.

Block display

The display can be suppressed in the current block display using the `DISPLOF` attribute in the `PROC` statement.

Processing status

Via the user M function the PLC can be informed about the processing status of the event-driven user program.

Scan for triggering event

The event, which causes the activation of the user program, can be queried in the user program with the following system variable:

`$P_PROG_EVENT` (event-driven program call active)

Value	Description
1	Activation through part program start
2	Activation through part program end
3	Activation through Operator panel reset
4	Activation through Power up
5	Activation after output of the last action block after Block search (see "Automatic Start of an ASUB after block search (Page 515)")

Query of the current channel

The application program is basically processed in the channel, in which the corresponding event has occurred. The current channel is queried in the user program with the following system variables:

\$P_CHANNO (query of the current channel number)

Note

Power up is an event that takes place in all channels.

9.8.12.4 Boundary conditions

Emergency stop / error message

If an error is present when the operator panel is reset or after power-up EMERGENCY STOP or Mode group/NCK-Continue, then the event-driven user program will only be processed after EMERGENCY STOP or the error has been acknowledged in all channels.

Note

The power up event occurs in all channels at the same time.

9.8.12.5 Examples

Example 1: Call of all events set with MD20108

Parameter assignment:

MD20108 \$MC_PROG_EVENT_MASK = 'H0F'

Call of _N_PROG_EVENT_SPF for:

- Part program start
- Part program end
- Operator panel reset
- Ramp-Up

Programming:

Program code	Comment
PROC PROG_EVENT DISPLOF	
IF (\$P_PROG_EVENT==1)	; Processing for part program start.
MY_GUD_VAR=0	; Initialize GUD variable
RET	
ENDIF	
IF (\$P_PROG_EVENT==2) OR (\$P_PROG_EVENT==3)	; Processing for part program end and operator panel reset.
DRFOF	; Deactivate DRF offsets
IF \$MC_CHAN_NAME=="CHAN1"	
CANCEL(2)	; Delete modal synchronized action 2
ENDIF	
RET	
ENDIF	
IF (\$P_PROG_EVENT==4)	; Sequence for power-up
IF \$MC_CHAN_NAME=="CHAN1"	
IDS=1 EVERY \$A_INA[1]>5.0 DO \$A_OUT[1]=1	
ENDIF	
RET	
ENDIF	
RET	

Example 2: Call through Operator panel reset

Parameter assignment:

MD20108 \$MC_PROG_EVENT_MASK = 'H04'

Call of _N_PROG_EVENT_SPF for:

- Operator panel reset

Programming:

Program code	Comment
PROC PROG_EVENT DISPLOF	
N10 DRFOF	; Deactivate DRF offsets
N20 M17	

Example 3: Initialization of the function

Section of the startup file (_N_INITIAL_INI):

Program code	Comment
...	
CHANDATA (3)	; Initialization for channel 3
\$MC_PROG_EVENT_IGN_INHIBIT='H04F'	
\$MC_PROG_EVENT_MASK='H04'	
...	

Meaning:

The part program _N_PROG_EVENT_SPF from the directory _N_CMA_DIR should be started automatically with the RESET key and processed till the end, regardless of whether the read-in disable is activated or deactivated.

9.8.13 Influencing the Stop events through Stop delay area

Stop Delay Area

The reaction to a stop event can be influenced by conditioned interruptible area in the current part program. Such a program area is called stop delay area.

Within the stop delay areas there should be no stop and the feed should not be changed. Stops do not take effect until the program section has been completed (Example: making of a thread).

A stop delay area is defined with the part program commands:

DELAYFSTON	Start a Stop Delay Area
DELAYFSTOF	End a Stop Delay Area

References:

Programming Manual, Job Planning

Stop events

Overview of the NCK events that cause a stop:

NCK events	Response	Stop criteria
Reset and mode group RESET	immediate	IS: DB21, ... DBX7.7 and DB11 DBX20.7
PROG_END	Alarm 16954	NC prog.: M30
Interrupt	delayed	IS: "FC-9" and ASUP DB10 DBB1
DELDISTOGO_SYNC	immediate	IS: "Delete distance-to-go" DB21, ... DBX6.2 and axial
PROGRESETREPEAT	delayed	IS: "Clear number of subprogram passes" DB21, ... DBX6.3
PROGCANCELSUB	delayed	IS: "Program level abort" DB21, ... DBX6.4

NCK events	Response	Stop criteria
SINGLEBLOCKSTOP	delayed	In the stop delay area: NC stops at the end of the 1st block outside the stop delay area. Single block is active before the stop delay area: IS: "NC Stop at block limit" DB21, ... DBX7.2
SINGLEBLOCK_IPO	delayed	IS: "Activate single-block type 1" DB11 DBX21.7
SINGLEBLOCK_DECODIER	delayed	IS: "Activate single-block type 2" DB11 DBX21.6
STOPALL	immediate	IS: DB21, ... DBX7.4 and DB11 DBX20.6
STOPPROG	delayed	IS: DB21, ... DBX7.3 and DB11 DBX20.5
OVERSTORE_BUFFER_END_REACHED	Alarm 16954	NC prog.: Stop because of empty overstore buffer
PREP_STOP	Alarm 16954	NC prog.: STOPRE and all implicit Stopres
PROG_STOP	Alarm 16954	NC prog.: M0 and M1
STOPPROGATBLOCKEND	delayed	IS: "NC Stop at block limit" DB21, ... DBX7.2
STOPPROGATSUPEND	System fault	SR end should always deselect the stop delay section.
WAITM	Alarm 16954	NC prog.: WAITM
WAITE	Alarm 16954	NC prog.: WAITE
INIT_SYNC	Alarm 16954	NC prog.: INIT with parameter "S"
MMCCMD	Alarm 16954	NC prog.: MMC(STRING, CHAR)
PROGMODESLASHON	delayed	IS: DB21, ... DBB26 Activate/switch over skip block
PROGMODESLASHOFF	delayed	IS: DB21, ... DBB26 deactivate skip block
PROGMODEDRYRUNON	delayed	IS: DB21, ... DBX0.6 Activate DryRun
PROGMODEDRYRUNOFF	delayed	IS: DB21, ... DBX0.6 Deactivate DryRun
BLOCKREADINHIBIT_ON	delayed	IS: DB21, ... DBX6.1 Activate read-in disable
STOPATEND_ALARM	immediate	Alarm: Alarm configuration STOPATENDBYALARM
STOP_ALARM	immediate	Alarm: Alarm configuration STOPBYALARM
STOPATIPOBUFFER_ISEMPY_ALARM	immediate	Internal: Stop after alarm on empty IPO buffer
STOPATIPOBUF_EMPTY_ALARM_REORG	immediate	Internal: Stop after alarm on empty IPO buffer
RETREAT_MOVE_THREAD	Alarm 16954	NC prog.: Alarm 16954 at LFON (Stop & fast lift in G33 not possible)
WAITMC	Alarm 16954	NC prog.: WAITMC
NEWCONF_PREP_STOP	Alarm 16954	NC prog.: NEWCONF
BLOCKSEARCHRUN_NEWCONF	Alarm 16954	NC prog.: NEWCONF
SET_USER_DATA	delayed	OPI: PI "_N_SETUDT"
SYSTEM_SHUTDOWN	immediate	System shutdown for SINUMERIK 840Di
ESR	delayed	Extended stop and retract
EXT_ZERO_POINT	delayed	External work offset
STOPRUN	Alarm 16955	OPI: PI "_N_FINDST" STOPRUN

Reaction

The reaction to a stop event can be:

- **immediate**
Stops immediately even in stop delay section. Is known as a "hard stop event".
- **delayed**
Does not stop (even short-term) until after stop delay section. Is known as a "soft stop event".
- **Alarm 16954**
Program is aborted because illegal program commands have been used in stop delay section.
- **Alarm 16955**
Program is continued, an illegal action has taken place in the stop delay section.
- **Alarm 16957**
The program section (stop delay section) enclosed by `DELAYFSTON` and `DELAYFSTOF` could not be activated. As a result, every stop will take effect immediately and is not subject to a delay! This will always occur when the deceleration begins before the stop delay area but ends within the stop delay area. Likewise, if the stop delay area is entered with an override of 0, the stop delay area also cannot be activated. (example: a `G4` before the stop delay section allows the user to reduce the override to 0. The next block in the stop delay section then begins with override 0 and the described alarm situation occurs.)

Note

MD11411 \$MN_ENABLE_ALARM_MASK (activation of warnings) Bit 7 activates this alarm.

Stop criteria

A stop event can be triggered by the following:

- VDI interface signals from the PLC → "Hard" stop event
- Alarms with NOREADY response → "Hard" stop event
- Stop key → "Soft" stop event
- Read-in disable → "Soft" stop event
- Single BLock → "Soft" stop event

Note

Some NCK events are stopped for a short time, in order to perform a switching operation, and restart immediately. These include e.g. the ASUB that stops the contour briefly in order to then start the ASUB program immediately. These events are also allowed in the stop delay area, however they are pushed back to its end and are thus considered "soft stop events".

Conditions

The following conditions apply while a stop delay area is being processed:

- A change in the **feed** is ignored while in the stop delay area. A **feed disable** is thus not effective until the program area has been exited, and is stopped.
- None of the main run axes, such as command axes and positioning axes, which are traversed with `POSA`, is stopped.
- Part program command `G4` is permitted in the stop delay area.

Other part program commands that cause a stop in the meantime (e.g. `WAITM`), are not permitted and trigger the alarm 16954.

- A stop delay section entered with an override of 0% will not be accepted!

9.9 Asynchronous subroutines (ASUBs), interrupt routines

9.9.1 Function

9.9.1.1 General functionality

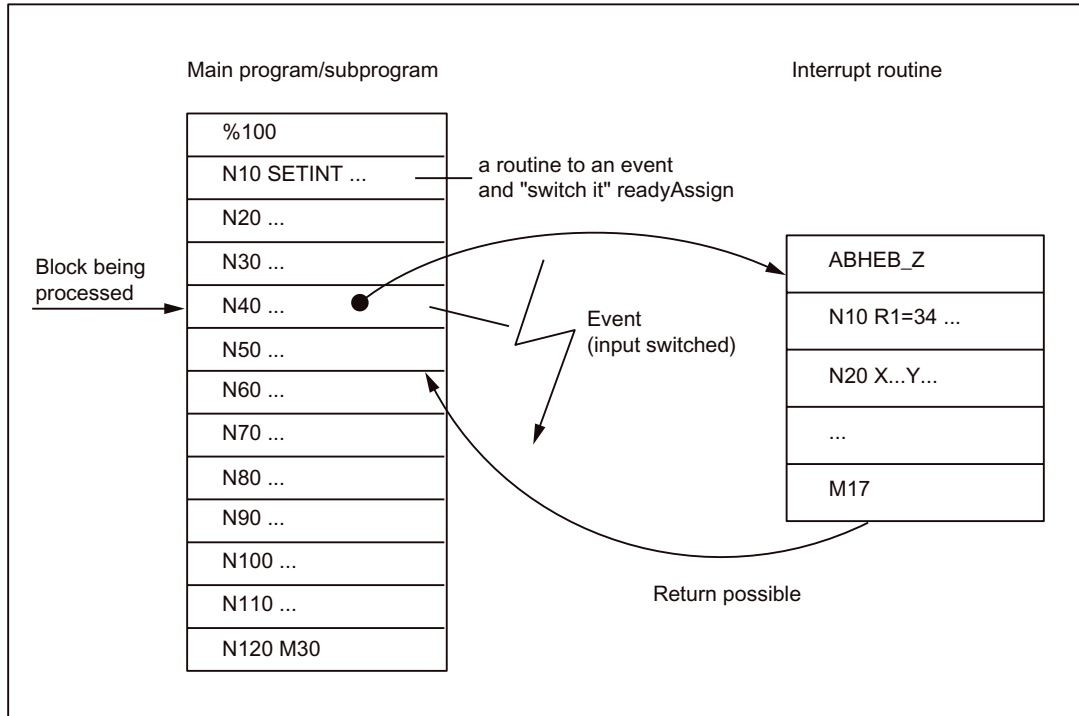

Note

The terms "asynchronous subroutines (ASUB)" and "interrupt routines" used alternatively in the description below refer to the same functionality.

Interrupt routines

Interrupt routines are normal part programs, which are started by interrupt events (interrupt inputs, process or machine status) related to the machining process or the relevant machine status.

Any part program block currently being executed will be interrupted by the routine if it is not specifically declared to be locked against interruption. It is possible to continue the subroutine at the point of interruption at a later stage.

Definition of interrupt routines

The command `SETINT` or an interrupt signal via the PI service "ASUB" must be assigned to a part program, which is supposed to act as interrupt routine. This turns the part program into an interrupt routine.

Interrupt signals

- A total of 8 interrupt signals (inputs) are available.
- All inputs can be controlled via the PLC.
- The first four interrupt signals are also controlled via the 4 rapid NC inputs of the NCU module.
- The signal status of the rapid NC inputs can be read out via the PLC interface (DB10).
- The transmission of the rapid NC input signals to the interrupt signals can be disabled via the PLC interface (DB10).

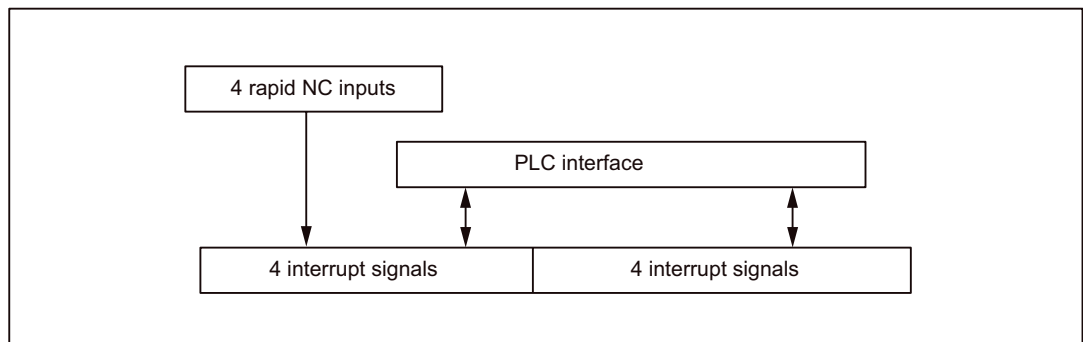

Figure 9-11 Interrupt signals

For more information on PLC control of the rapid NC inputs (interrupt signals) see:

References:

Function Manual Basic Functions; PLC Basic program (P3)

Function Manual, Extended Functions; Digital and analog NCK I/Os (A4)

Call of interrupt routines

During program operation

It is possible to call the interrupt routines, when the mode groups are present in program operation. This means that the processing is done either in the mode type AUTOMATIC or MDA part program blocks.

Outside the program operation

Interrupt routines can also be activated in the following program statuses or mode types:

- JOG, JOG REF
- MDA Teach In, MDA Teach In REF, MDA Teach In JOG, MDA REF, MDA JOG

- AUTOMATIC, stopped, ready
- Not referenced

If an interrupt routine is activated in JOG or REF mode, it will interrupt any jogging and referencing operations in progress.

Activating

The activation of an interrupt routine can be done:

- By a 0/1 transition of the interrupt signal, triggered by a 0/1 transition at the rapid NC input
- by the call of the "Function Call ASUB"

References:

Function Manual Basic Functions; PLC Basic Program (P3)

- an exit is set via the synchronous action, which indirectly sets an interrupt entry via short-circuit (see "Examples (Page 611)").

References:

Function Manual, Synchronized Actions

Display

The activation of an interrupt routine is shown with the following NC/PLC interface signal:

DB21, ... DBX378.0 (ASUB active)

9.9.1.2 Sequence of an interrupt routine in program operation

Decelerating the axes

Upon activation, all machine axes are decelerated to a standstill according to the acceleration ramp(MD32300 \$MA_MAX_AX_ACCEL), and the axis positions are stored.

Reorganization

In addition to decelerating the axes, the previously decoded calculation blocks are calculated back to the interruption block. i.e. all the variables, frames and G codes are assigned the value that they would have at the point of interruption if the part program had not been previously decoded. These values are put in the buffer so that they can be called up again when the interrupt routine is completed.

Exceptions, where no reorganization is possible:

- In thread cutting blocks
- With complex geometries (e.g. spline or radius compensation)

Processing of interrupt routine

The Interrupt routine is automatically started on completion of reorganization.

The system handles the interrupt routine like a normal part program (nesting depth, etc.)

End of interrupt routine

After the end identifier ($M02$, $M30$, $M17$) of the Interrupt routine has been processed, the axis traverses by default to the end position programmed in the part program block following the interruption block.

A `REPOS` instruction must have been programmed at the end of the interrupt routine if return positioning to the point of interruption is required, e.g.

N104 REPOS L M17

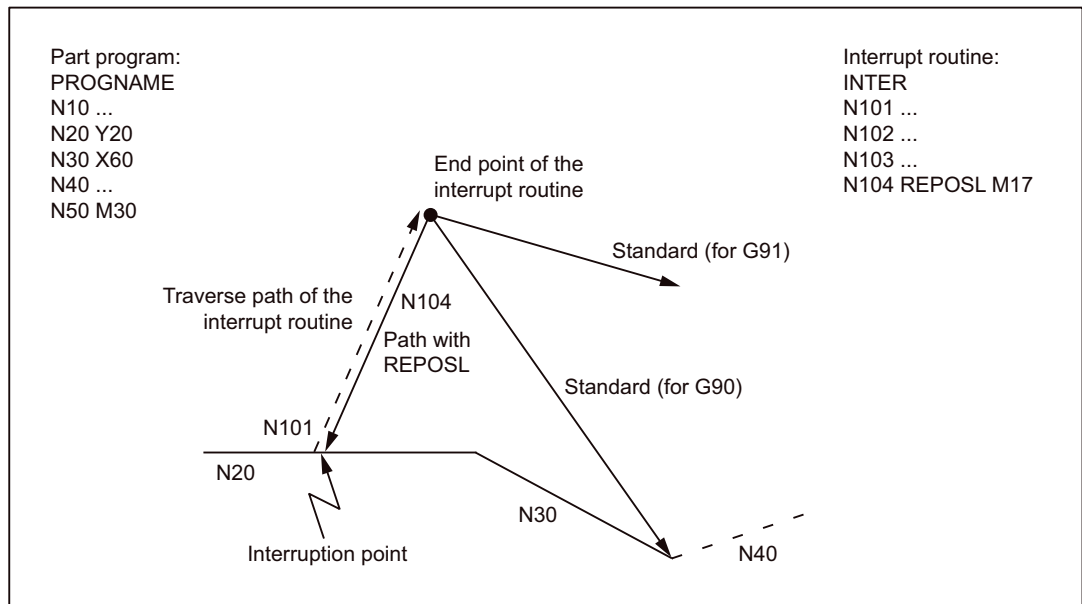

Figure 9-12 End of interrupt routine

9.9.1.3 Interrupt routine with REPOSA

If an interrupt routine with REPOSA triggered by the PLC (block FC9) "interrupted" in channel status in program operation is completed, then the following sequence is typical:

1. Before the re-approach to the contour, the controller stops and goes to program status "Stopped". The following NC/PLC-interface signal is set:
DB21, ... DBX318.0 (ASUB is stopped)
2. The operator presses the START key. Thereupon, the signal DB21, ... DBX318.0 is reset and the re-approach motion starts.
3. At the end of the re-approach motion, the FC9 signal "ASUB done" is set and the path of the interrupted part program is continued.

Note

The NC/PLC-interface signal DB21, ... DBX318.0 (ASUB is stopped) is available only for the following case: Interrupt "interrupted" in program operation in the channel status.

Note

In case of interrupt routines that close without REPOS, the signals "Asub-Done" and DB21, ... DBX318.0 (ASUB is stopped) occur at the same time.

9.9.1.4 NC response

The different reactions of the control to an activated interrupt routine in the various operating states are given in the following table:

Status of NC	ASUB start	Control system reaction
Program is active	Interrupt, (PLC)	<ol style="list-style-type: none"> 1. Fast retraction or stop axes 2. Interrupt the program for the duration of the ASUB 3. Approach of the interruption point, if REPOS in ASUB 4. Continuation of the part program
RESET	Interrupt, (PLC)	<p>The ASUB is executed like a main program. RESET (without M30) is executed at the end of the ASUB. The next control system status depends on the following machine data:</p> <p>MD20110 \$MC_RESET_MODE_MASK MD20112 \$MC_START_MODE_MASK</p> <p>References: Function Manual Basic Functions; Axes, Coordinate Systems, Frames (K2), Chapter: "Workpiece-related actual-value system"</p>
Program operation (AUTOMATC or MDA) + channel stopped	Interrupt, (PLC)	<p>ASUB is executed. At the end of the ASUB the STOP state is reapplied.</p> <p>If REPOS in the ASUB:</p> <ul style="list-style-type: none"> • The ASUB processing is stopped before the approach block. • The approach movement can be initiated with the Start key.
	Start key	Once the ASUB has been executed, processing of the interrupted program is resumed.

Status of NC	ASUB start	Control system reaction
Manual mode + channel stopped	Interrupt, (PLC)	Control system assumes the status "internal program execution mode" for the addressed channel (not evident externally) and then activates the ASUB. The selected operating mode remains valid. The original status is resumed after execution of the ASUB (M17).
JOG AUTO Teach-In AUTO Teach reference pnt.	Interrupt, (PLC)	Stop processing, evaluate: MD11602 \$MN_ASUP_START_MASK MD11604 \$MN_ASUP_START_PRIO_LEVEL
MDA JOG, MDA Teach-In, MDA Teach reference pnt.	Interrupt, (PLC)	Internal switchover to "internal program execution mode" if appropriate, activate ASUB, restore status prior to ASUB start. Any LIFTFAST defined with SETINT is not activated in JOG mode.
Manual mode + channel running	Interrupt, (PLC)	The current active motion is stopped. The distance-to-go is deleted. The remaining sequence of operations is the same as for "Manual mode, channel stopped".
Processing of INITIAL.INI	not possible	The signal "Interrupt request not possible" is generated.
Block search		
Alarm that cannot be removed by NC start.		
Digitalizing active		
Channel in fault condition		

9.9.2 Parameter assignment

Effect of mode group signals

The effect of the mode group signals (mode group reset, mode group Stop axes plus spindle, mode change disable, ...) on channels of mode group, which are currently processing the interrupt routines, is set in the machine data:

MD11600 \$MN_BAG_MASK

Bit	Value	Description
0	0	Mode group signals are applicable.
	1	Mode group signals are not applicable.

MD11600 also controls, whether the internal program execution mode is imported only for the channel, in which the interrupt routine has been activated, or to all channels in the mode group.

Bit	Value	Description
1	0	The mode switchover is done to all channels in the mode group.
	1	An internal mode switchover takes place only in the channel, in which the interrupt routine was activated (possible only if bit 0 is set to "1").

If, via MD 11600, the channel in which the interrupt is running has left the mode group, the mode group signals Mode Group RESET, Mode Group STOP, ... have **no** effect on this channel. In this way the interrupt routines can run without being disturbed by the mode group signals.

Ignore stop conditions

In the default setting an ASUB start is prevented under the following conditions:

- Stop by means of Stop key, M0, M01
- Not all axes are referenced yet
- read-in disable is active (DB21, ... DBX6.1 = 1)

Via the following machine data the ASUP Start can also be enabled for these conditions:

MD11602 \$MN_ASUP_START_MASK (ignore stop conditions for ASUB)

Bit	Value	Description
0		Stop reason: Stop key, M0 or M1
	0	Stop reason prevented ASUB start.
	1	An ASUB is started immediately, if the NCK is in the reset status or in the JOG mode. Tip: Without this bit setting, no ASUB can be started in the reset status /JOG mode. Note: <ul style="list-style-type: none"> • This bit is set implicitly, if the machine data MD20108 \$MC_PROG_EVENT_MASK in a channel deviates from zero! • This bit is set implicitly, if in the machine data MD11450 \$MN_SEARCH_RUN_MODE the bit 1 is set!
1		Stop reason: Not all axes are referenced yet
	0	Stop reason prevented ASUB start.
	1	ASUB start also permitted, if all axes are not yet referenced.
2		Stop reason: Read-in disable is active
	0	The ASUB is selected internally, but processed only when the read-in disable is cancelled. The value of the machine data MD20116 \$MC_IGNORE_INHIBIT_ASUP is evaluated. In case MD20116=0, then an ASUB is triggered internally immediately, the blocks of the ASUB Program are changed only with the cancellation of the read-in disable. With the triggering of ASUB the path is decelerated immediately (except with the option of BLSYNC). A resetting of the read-in disable is done in the ASUP program.
	1	ASUB start also permitted, when the read-in disable is active. That is, the blocks of the ASUB program are changed and processed immediately. In this way, the machine data MD20116 \$MC_IGNORE_INHIBIT_ASUP becomes ineffective. The NCK behavior corresponds to the machine data allocation: MD20116 \$MC_IGNORE_INHIBIT_ASUP= FFFFFFFF.

Note

Explicit ASUB start

If MD11602 is set such that the ASUB may not be started automatically, the routine can still be activated by the **Start key**. Any rapid retraction that may be parameterized is always started.

Jogging during interruption of a JOG ASUB

In case of single or multi-channel systems the ASUB started automatically in the mode type JOG can be jogged during interruption.

This functionality is enabled via the bit 3 in the machine data:

MD11602 \$MN_ASUP_START_MASK

Bit	Value	Description
3	0	Jogging during interruption of a JOG ASUB is not possible.
	1	Jogging during interruption of a JOG ASUB is possible.

In case of multi-channel systems, the bit 1 must also be set in the machine data MD11600 \$MN_BAG_MASK.

After jogging, a REPOS is triggered with the START key and the ASUB is continued at the interruption point.

Application example:

In case of a single-slide turning machine a stock removal cycle is started as ASUB in the mode type JOG and with this a shaft several meters long is processed. During processing it is necessary to change the cutting edge of the tool. The machine operator stops the ASUB and jogs away for changing the cutting edge of the tool. After changing the cutting edge, he activates the START key. The interruption point is approached through REPOS. Thereafter, the ASUB is continued.

Note

The function "Jogging during interruption of a JOG ASUB" acts only for those ASUB, which have been activated from the program status "cancelled" (channel status reset).

The function does not work in multi-channel systems without MD11600 \$MN_BAG_MASK Bit1=1.

Effectiveness of MD11602

Priorities are assigned to the interrupt routines, which define the ranking during the processing (see also "Programming"). There are priorities from 1 to 128. Priority 1 corresponds to the highest priority.

Starting from which priority the ASUB start conditions parameterized with MD11602 \$MN_ASUP_START_MASK are to be effective, is determined with the machine data:

MD11604 \$MN_ASUP_START_PRIO_LEVEL

MD11602 is considered from the priority given here till the highest priority.

Behavior when the read-in disable is set

Via the following channel-specific machine data it can be set for each interrupt signal, whether the assigned interrupt routines are processed without interruption despite a set read-in disable (DB21, ... DBX6.1 = 1), or whether the read-in disable is to be made active:

MD20116 \$MC_IGNORE_INHIBIT_ASUP

Bit	Value	Description
		In case of a set read-in disable:
0		• after an activation the interrupt routine is assigned to the interrupt signal 1 :
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.
1		• after an activation the interrupt routine is assigned to the interrupt signal 2 :
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.
2		• after an activation the interrupt routine is assigned to the interrupt signal 3 :
	0	the read-in disable is effective.
	1	the read-in disable is suppressed.
...		

Note

The settings in MD20116 \$MC_IGNORE_INHIBIT_ASUP are ineffective, if the read-in disable in the interrupt routines is ignored through the following configuration:

MD11602 \$MN_ASUP_START_MASK (ignore stop conditions for ASUB) Bit 2 = 1

Behavior when the single block processing is set

Via the following channel-specific machine data it can be set for each interrupt signal, whether the assigned interrupt routines are processed without interruption despite a set single block processing or whether the single block processing is to be made active:

MD20117 \$MC_IGNORE_SINGLEBLOCK_ASUP

Bit	Value	Description
		In case of a single block processing:
0		• after an activation the interrupt routine is assigned to the interrupt signal 1 :
	0	the single block processing is effective.
	1	the single block processing is suppressed.
1		• after an activation the interrupt routine is assigned to the interrupt signal 2 :
	0	the single block processing is effective.
	1	the single block processing is suppressed.
2		• after an activation the interrupt routine is assigned to the interrupt signal 3 :
	0	the single block processing is effective.
	1	the single block processing is suppressed.
...		

Note

MD20117 \$MC_IGNORE_SINGLEBLOCK_ASUP is effective only for the single block processing type 1 (SBL1).

Note

The settings in MD20117 \$MC_IGNORE_SINGLEBLOCK_ASUB are ineffective, if the single block processing in the interrupt routines is ignored through the following configuration:

MD10702 \$MN_IGNORE_SINGLEBLOCK_MASK (Prevent single block stop) bit 1 = 1

Suppress updating of the display of the program and channel statuses.

In order to avoid a flickering of the display of the program and the channel statuses in the operator panel, the updating of the display can be suppressed for the execution of the normally very brief interrupt routines. The program and the channel status before the activation of the interrupt routine then remain visible in the display.

The parameterization of this function is done with the channel-specific machine data:

MD20191 \$MC_IGN_PROG_STATE_ASUP

Bit	Value	Description
		The updating of the display of the program and channel statuses is:
0		• during execution the interrupt routine is assigned to the interrupt signal 1 :
	0	is not suppressed.
	1	suppressed.
1		• during execution the interrupt routine is assigned to the interrupt signal 2 :
	0	is not suppressed.
	1	suppressed.
2		• during execution the interrupt routine is assigned to the interrupt signal 3 :
	0	is not suppressed.
	1	suppressed.
...		

The activation of an interrupt routine with suppressed display updating is shown with the following NC/PLC interface signal:

DB21, ... DBX378.1 (stopped ASUB active)

Note

The system variables \$AC_STAT and \$AC_PROG are not affected by this function, i.e. in the running interrupt routine \$AC_STAT is set to "active" and \$AC_PROG to "running".

NC/PLC interface signals DB21, ... DBX35.0-7 ("Program status ..." and "Channel status ...") also remain unaffected.

Fast retraction from contour (LIFTFAST)

If mirroring is active for execution via frames, then the following machine data can be used to set whether during "fast retraction from the contour" the retraction direction is also to be mirrored:

MD21202 \$MC_LIFTFAST_WITH_MIRROR (fast retraction with mirroring)

The distance for the fast retraction is stored for the 3 geometry axes in the machine data:

MD21200 \$MC_LIFTFAST_DIST (Traversing path for fast retraction from the contour)

The maximum axis acceleration (MD32300 \$MA_MAX_AX_ACCEL) effective during the LIFTFAST motion is reduced by a factor, which is specified in the following machine data:

MD20610 \$MC_ADD_MOVE_ACCEL_RESERVE

This creates an acceleration reserve for an overlaid motion.

9.9.3 Programming

Assignment Interrupt signal ↔ part program

The assignment interrupt signal ↔ part program is done with the command SETINT.

Example:

Program code	Comment
...	
N20 SETINT(3) ABHEBEN_Z	; If input 3 switches, then interrupt routine "ABHEB_Z" should start.
...	

Together with `SETINT` additionally the following commands can be programmed:

- `LIFTFAST`
When the interrupt signal arrives, a "Fast retraction of the tool from the contour" is executed before the interrupt routine starts. The motion direction for the fast retraction is specified by the program instruction `ALF`.
- `BLSYNC`
Upon receiving the interrupt signal, the current program block is processed and only then is the interrupt routine started.

Note

The assignment interrupt signal ↔ part program is cleared when the following happens:

- Channel in Reset state
 - `CLRINT` instruction in part program
-

Priorities

If several `SETINT` instructions are in the part program and therefore several signals can be simultaneously received, the assigned interrupt routines must be allocated priorities that define the sequence in which the interrupt routines are executed:

`PRIO=<value>`

There are priorities from 1 to 128. Priority 1 corresponds to the highest priority.

Example:

Program code	Comment
...	
N20 <code>SETINT(3) PRIO=2 ABHEBEN_Z</code>	; If input 3 switches, then interrupt routine "ABHEB_Z" should start.
N30 <code>SETINT(2) PRIO=2 ABHEBEN_X</code>	; If input 2 switches, then interrupt routine "ABHEB_X" should start.
...	

The interrupt routines are executed in the sequence of the priority values if the inputs become available simultaneously (are energized simultaneously): First "ABHEBEN_Z", then "ABHEBEN_X".

REPOS-query

Interrupt routines sequences may be generated for which there is no unambiguous return to an interruption point in the block processing sequence (REPOS).

The system variable `$P_REPINF` can be used to scan the ASUB to determine whether a REPOS is possible.

Value	Description
0	Repositioning with REPOS not possible because: <ul style="list-style-type: none"> • not called in ASUB • ASUB ran from reset status • ASUB ran from JOG
1	Repositioning with REPOS possible in ASUB

Determine cause of activation

With the system variable \$AC_ASUP the cause leading to the activation of an interrupt routine, is specified bit-coded and can be read in the part program and in synchronous actions (see "User-specific ASUB for RET and REPOS > Programming (Page 613)").

Flexible programming

The following commands help in the flexible programming of interrupt routines:

Command	Description
SAVE	If the SAVE command has been used to define the interrupt routine, the G codes, frames and transformations previously active in the interrupted part program become operative again as soon as the interrupt routine is ended.
DISABLE	The DISABLE command can be set to protect part program sections from being interrupted by an interrupt routine. The assignment interrupt signal ↔ part program is maintained but the interrupt routine no longer respond to the 0/1 signal transition.
ENABLE	The DISABLE command can be reset with the ENABLE command. Interrupt routines are not activated until the next 0/1 transition of the interrupt signal.
CLRINT	Clear assignment Interrupt signal ↔ part program

References

Programming Manual, Job Planning; Chapter: "Flexible NC Programming" > "Interrupt routine (ASUB)"

9.9.4 Restrictions

Cross-mode start of interrupt routines

Requirements:

- Option: Cross-mode actions
- MD11602 \$MN_ASUP_START_MASK, at least Bit 0 = 1

For error-free execution of the function, the following settings in particular must be noted:

- MD11600 \$MN_BAG_MASK
- MD11604 \$MN_ASUP_START_PRIO_LEVEL
- Interrupt assignment priority

Recommended settings:

- MD11600 \$MN_BAG_MASK = H11
- MD11602 \$MN_ASUP_START_MASK = H111
- MD11604 \$MN_ASUP_START_PRIO_LEVEL = 7

9.9.5 Examples

Activation of an interrupt routine via synchronous action

1. Define number of active digital inputs/outputs:
MD10350 \$MN_FASTIO_DIG_NUM_INPUTS=3
MD10360 \$MN_FASTIO_DIG_NUM_OUTPUTS=3
2. Generate short-circuit with the following MD setting:
MD10361 \$MN_FASTIO_DIG_SHORT_CIRCUIT[0]='H0102B102'
MD10361 \$MN_FASTIO_DIG_SHORT_CIRCUIT[1]='H0202B202'
3. HW assignment of the external NC input byte for NC program interrupt:
MD21210 \$MC_SETINT_ASSIGN_FASTIN=2 ; better 1 byte more than needed
4. Define input as ASUB trigger:
SETINT(1) PRIO=1 SYNCASUP
5. IDS=1 EVERY \$\$AC_PATHN>=0.5 DO \$A_OUT_[9]=1

9.10 User-specific ASUB for RET and REPOS

9.10.1 Function

Function

The NCK software supplied contains preprogrammed processes (internal ASUBs) for implementation of the RET and REPOS functions. They can be replaced by user-specific ASUBs written by the machine tool manufacturer.

DANGER

The machine manufacturer is responsible for the contents of ASUB routines used to replace ASUP.SYF supplied by Siemens.

Installation

In the manufacturer directory `_N_CMA_DIR` or in the user directory `_N_CUS_DIR` a routine with the name "`_N_ASUP_SPF`" can be loaded. These must implement the actions desired by the user for the functions RET and REPOS.

9.10.2 Parameter assignment

Activating

The parameters for the activation of the user-specific routine "`_N_ASUP_SPF`" are set with the machine data:

MD11610 \$MN_ASUP_EDITABLE (activation of a user-specific ASUP program).

Bit 0 and bit 1 specify, which of the internal system routines are to be replaced by the user-specific ASUB:

Binary value	Description
0	Neither in case RET nor in case of REPOS the user-specific routine <code>_N_ASUP_SPF</code> is activated.
1	The user-defined routine is activated for RET , the routine provided in the system is activated for REPOS.
2	The user-defined routine is activated for REPOS , the routine provided in the system is activated for RET.
3	As in case RET and also in case of REPOS the user-specific routine is activated.

Bit 2 defines in which directory the user-specific routine is to be searched first in case of activation.

Bit	Value	Description
2	0	The user-specific routine is searched first in the user directory <code>_N_CUS_DIR</code> .
	1	The user-specific routine is searched first in the manufacturer directory <code>_N_CMA_DIR</code> .

Defining a level of protection

If a user-specific ASUB is to be used for RET and/or REPOS, i.e. when:
`MD11610 $MN_ASUP_EDITABLE ≠ 0`
then a level of protection can be defined for the user-specific routine "`_N_ASUP_SPF`". The level of protection can have values in the range 0 - 7.

The setting is done via the following machine data:

`MD11612 $MN_ASUP_EDIT_PROTECTION_LEVEL` (level of protection of the user-specific ASUB)

For further information about protection levels, refer to:

References:

Commissioning Manual; Level of protection concept

Behavior when the single block processing is set

Via the following machine data it can be set, that despite a set single block processing the internal ASUB or the user-specific "`_N_ASUP_SPF`" is processed without interruption:

`MD10702 $MN_IGNORE_SINGLEBLOCK_MASK` (Prevent single block stop)

Bit	Value	Description
0	0	A stop is done in each ASUB block.
	1	The ASUB is processed without interruption.

9.10.3 Programming

Determine cause of ASUB activation

The reason that led to the activation is specified in bit code through the `$AC_ASUP` system variable, and can be read in part program and synchronized actions.

	Bit																			
	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RET							1			1	*		1							
REPOS	1	1	1	1	1	1		1	1		*	1		1	1					

*: If bit 9 is set, then the behavior depends on MD20114 (see table below)

9.10 User-specific ASUB for RET and REPOS

The significance of the bits of system variable \$AC_ASUP is as follows:

Bit	Description
0	User interrupt "ASUB with BLSYNC" Continuation: Freely selectable REORG or RET
1	User interrupt "ASUP"; The position at which it was stopped is stored for continuation with REPOS. Continuation: Freely selectable REORG or RET
2	User interrupt "ASUB from channel status Ready" Continuation: Freely selectable REORG or RET
3	User interrupt "ASUB in a manual mode and in channel status not Ready" Continuation: Freely selectable REORG or RET
4	User interrupt "ASUP"; The current position is stored when the interrupt occurs, for continuation with REPOS. Continuation: Freely selectable REORG or RET
5	Abort of the subroutine repeat Continuation: With system ASUB REPOS
6	Activation of decoder single block Continuation: With system ASUB REPOS
7	Activation of delete distance-to-go Continuation: With system ASUB RET
8	Activation of axis synchronization Continuation: With system ASUB REPOS
9	Mode change Continuation: in case of system ASUP, REPOS or RET depending upon MD20114 \$MC_MODESWITCH_MASK (interruption of MDA through mode change):
	Bit 0 = 0: → RET
	Bit 0 = 1: → REPOS
10	Program continuation during TEACHIN or after TEACHIN deactivation Continuation: With system ASUB RET
11	Overstore selection Continuation: With system ASUB REPOS
12	Alarm with reaction correction block with REPOS Continuation: With system ASUB REPOS
13	Retraction motion in case of G33 and Stop Continuation: With system ASUB RET
14	Activation of dry run feedrate Continuation: With system ASUB REPOS
15	Deactivation of dry run feedrate Continuation: With system ASUB REPOS
16	Activation of skip block Continuation: With system ASUB REPOS

Bit	Description
17	Deactivation of skip block Continuation: With system ASUB REPOS
18	Activate machine data Continuation: With system ASUB REPOS
19	Make user data effective Continuation: With system ASUB REPOS
20	Activation of system ASUB, after search type SERUPRO has reached the search target Continuation: With system ASUB REPOS

9.11 Single block

Block-by-block processing

With the single-block function, the user can execute a part program block-by-block.

Single-block types

There are 3 types of setting for the single-block function:

- SBL1 := IPO single block
When the SLB1 function is active, machining stops or pauses after each machine action block (Ipo block).
- SBL2 := Decode single block
When the SLB2 function is active, machining always stops or pauses after each part program block. If a part program block is processed in several IPO blocks, machining stops after every Ipo block. Thread cutting is an exception.
- SBL3 := Decode single block
As for SLB2, but machining also stops in the part program blocks of the cycles.

1. Stopping after every block is undesirable in many situations and/or with certain blocks.

– 1st example:

Change after jog operation, if reorganization and/or repositioning is not possible, MD10702, bits 6 and 7.

If a stop occurs in a block at the end of block, which cannot be reorganized and/or repositioned, in this situation Jog mode cannot be selected.

– 2nd example:

Change after JOG operation to a STOPRE block, MD10702, bits 6 and 7

If AUTO mode is changed to Jog mode while a STOPRE block is active, in addition to system ASUB2, a continuation start will be followed by one residual block and one or possibly (with decoder single block) two more STOPRE blocks. A logic operation, which always triggers a part program start in single block and then always changes to Jog mode, remains at the STOPRE block indefinitely.

– 3rd example:

DISPOF: Deactivate block display, MD10702, bits 6 and 7

If DISPOF is programmed in a subroutine, the block display is suppressed. The operator must continuously press Start blindly in the single block up to the end of the subroutine.

2. When single block is deactivated there is no stop at end of block.

3. When STOPRE blocks are displayed, the main run and preprocessing are synchronized in the decoding single block.

The following sections describe how to control the behavior of single blocks and prevent stops in particular situations.

9.11.1 Decoding single block SBL2 with implicit preprocessing stop

Asynchronicity

As a result of preprocessing of part program blocks, the reference between the current block display relative to the main run status of the NCK and the variable values displayed on the HMI can be lost. The operator display then shows implausible variable values.

Preprocessing stop for each block

A preprocessing stop is executed for active SBL2 with each block with the channel-specific setting data SD42200 \$SC_SINGLEBLOCK2_STOPRE (activate debug mode for SBL2). This suppresses preprocessing of part program blocks and maintains the relationship between the current block display and the variable values display.

Note

This variant of SBL2 does not maintain an accurate contour. In other words, as a result of the preprocessing stop, a different contour may be generated from the one created without single-block mode or with SBL1.

Application: Debug mode for testing part programs.

9.11.2 Single block stop: Suppression using SBLOF

Single block off

Programs characterized by the `SBLOF` language command are executed completely in one block as with every type of single block.

`SBLOF` is also valid in the called subroutines.

SBLOF

Example for subroutine without stop in single block:

```
PROC EXAMPLE SBLOF
G1 X10
RET
```

At the return command, the decision is made whether to stop at the end of the subprogram:

Return jump with M17
Return jump with RET

Stop at the end of the subprogram
No stop at end of subroutine

SBLOF in the program

SBLOF alone must remain in the block. Single-block stop is deactivated from this block onwards up to the next programmed SBLON or up to the end of the active subroutine level.

If SBLOF is active, then this definition is also valid in the called subroutines. SBLON

Example for an area in single block mode

The area between N20 and N60 is executed as one step in single-block mode.

```
N10 G1 X100 F1000
N20 SBLOF ; Deactivate single block
N30 Y20
N40 M100
N50 R10=90
N60 SBLON ; Reactivate single block
N70 M110
N80 ...
```

Asynchronous subprograms

The asynchronous subroutines ASUP1.SYF and ASUP2.SYF started system-internally in REORG/REPOS can process the system ASUP in one step through the programming of SBLOF.

Example: ASUP.SPF:

```
N10 SBLOF
N20 IF $AC_ASUP=='H200'
N30 RET ; No REPOS on mode change
N40 ELSE
N50 REPOSA ; REPOS in all other cases
N60 ENDIF
N70 RET
```

Constraints

- The current block display can be suppressed in cycles with DISPLOF.
- If DISPLOF is programmed together with SBLOF, then the cycle call continues to be displayed on single-block stops within the cycle.
- The preset behavior of asynchronous subroutines in single block mode specified in MD20117 MC_IGNORE_SINGLEBLOCK_ASUP (process interrupt program fully despite single block) can be overwritten on a program-specific basis using SBLOF.

Cycle

Example 1: A cycle is to act like a command for a user.

Main program:

```
N10 G1 X10 G90 F200
N20 X-4 Y6
N30 CYCLE1
N40 G1 X0
N50 M30
```

Program cycle:1

```
N100 PROC CYCLE1 DISPLOF SBLOF          ; Suppress single block
N110 R10=3*SIN(R20)+5
N120 IF (R11 <= 0)
N130 SETAL(61000)
N140 ENDIF
N150 G1 G91 Z=R10 F=R11
N160 M17
```

CYCLE1 is processed for an active single block, i.e., the Start key must be pressed once to process CYCLE1.

Example 2: An ASUB, which is started by the PLC in order to activate a modified zero offset and tool offsets, is to be executed invisibly.

```
N100 PROC ZO SBLOF DISPLOF
N110 CASE $P_UIFRNUM OF 0 GOTOF
_G500 1 GOTOF _G54 2 GOTOF _G55 3 GOTOF _G56 4
GOTOF _G57 DEFAULT GOTOF END
N120 _G54: G54 D=$P_TOOL T=$P_TOOLNO
N130 RET
N140 _G54: G55 D=$P_TOOL T=$P_TOOLNO
N150 RET
N160 _G56: G56 D=$P_TOOL T=$P_TOOLNO
N170 RET
N180 _G57: G57 D=$P_TOOL T=$P_TOOLNO
N190 RET
N200 END: D=$P_TOOL T=$P_TOOLNO
N210 RET
```

9.11.3 Single block stop: inhibit according to situation

Suppress stopping in single cases

Depending on

MD10702 \$MN_IGNORE_SINGLEBLOCK_MASK (Prevent single block stop)

setting bits 0 to 12 = 1 can suppress stopping at the end of the block during the following machining processes.

Program execution must not stop after single blocks in the case of the following even if block-by-block processing is selected:

1. An internal ASUB
2. During a user ASUP
3. Subroutines with the attribute DISPLOF
4. Intermediate blocks
5. Block search group blocks
6. Init blocks
7. Blocks, which cannot be reorganized
8. Blocks, which are not repositionable
9. A repositioning block, which contains no traversing information
10. A prerun/main run/synchronization block, due to REORG
11. At a Tool selection block.
12. At a GET block
13. During a single block type 2

Sequence

If an ASUB is activated during the single block, for example, execution of the ASUB is completed. The deceleration movement does not take place until after the end of the ASUB or the first IPO block in which single-block suppression is not activated. If the velocity is too large for the deceleration to be performed in this block (with continuous-path mode G64 active), G_{64} , further block changes are allowed.

For decoding single block, MD10702 is only effective with "internal ASUB", "user ASUB" and "subroutines with the attribute DISPLOF". In these cases, it is already clear at the time of interpretation that the block belongs to one of the above categories. In these cases, further blocks can be generated.

SBLON in ASUB

The single block stop of an internal ASUP or user ASUP that is suppressed with MD10702 \$MN_IGNORE_SINGLEBLOCK_MASK can be reactivated in ASUP by programming SBLON.

This functionality can be suppressed again with MD20117

\$MC_IGNORE_SINGLEBLOCK_ASUB. The SBLON command then becomes ineffective.

Boundary conditions

The following restriction applies to decoding single block SBL2:

- Block search approach blocks
- Block not in ASUB; DISPLOF, SBLOF
- Non-reorganizable and non-repositionable blocks
- Blocks that are not generated in the interpreter, e.g., intermediate blocks

9.11.4 Single-block behavior in mode group with type A/B

Classifying channels

One mode group channel must be classified as a single-block control channel (KS), while the other mode group channels must be classified as dependent channels (KA) via interface signal. Type A or type B single-block behavior can be selected for KA channels.

Type A determines Stop (analogous to STOP key).

Type B determines Stop (analogous to stop at block limit).

Channel classification

In **one** channel (**KS**) in a mode group, the user should select single-block (NST DB21 ... DBX0.4 (activate single block)). Single-block type A or B refers to **other** channels (**KA**) of a mode group.

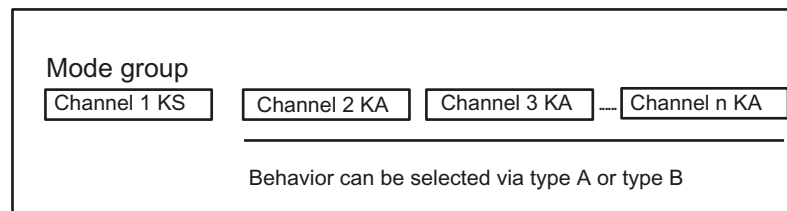

Figure 9-13 Channel classification for single block in mode group 1

Type A, NST DB11, ... DBX1.7=1 (single block type A)

- all channels are stopped.
- All channels receive a start (Start key).
- Channel KS stops at the end of the block (due to single-block)
- Channels KA receive a **STOP**. (analogous to STOP key).
- All channels are stopped. (deceleration phase of all KAs)

Type B, NST DB11, ... DBX1.6=1 (single block type B)

- All channels are stopped.
- All channels receive a start
- Channel KS stops at the end of the block

- Channels KA receive a **STOPATEND**.
(analogous with NST DB21, ... DBX7.2 ("NC stop at the block limit)).
- All channels are stopped at a block limit (at some point in time).

9.12 Program control

Options

1. Function selection (via operator interface or PLC)
2. Activation of skip levels
3. Adapting the size of the interpolation buffer
4. Program display modes via an additional basic block display
5. Execution from external source (buffer size and number)
6. Execution from external subroutines

9.12.1 Function selection (via operator panel front or PLC)

Operator interface or PLC

The user can control part program execution via the operator panel front or PLC.

Selection, activation, feedback

Selection

Different functions are available under the Program control soft key. Selection affects an interface signal in the PLC. These signals are to be understood as selection signals from the operator interface, and do not activate the selected function.

Activation

These signal states must be transferred to another area of the data block to activate the selected function. With program control by the PLC the signals are to be set directly.

Feedback

The activated functions are partly signaled back to the PLC from the NCK.

Table 9- 5 Program control: Interface signals

Function	Selection signal	Activation signal	Feedback signal
SKP skip block 0 to 7	DB21, ... DBX26.0 - 26.7	DB21, ... DBX2.0 - 2.7	---
SKP skip block 8 to 9	DB21, ... DBX27.0 - 27.1	DB21, ... DBX31.6 - 31.7	---
DRY dry run feedrate	DB21, ... DBX24.6	DB21, ... DBX0.6	DB21, ... DBX318.6
ROV Rapid traverse override	DB21, ... DBX25.3	DB21, ... DBX6.6	---
Single block:	Preselection of SBL1, SBL2 or SBL3 via program control display of HMI		
SBL1: Action single block	HMI operator panel	DB21, ... DBX0.4	---
SBL2: Decoding single block			
SBL3: In cycle			
M01 (Programmed stop)	DB21, ... DBX24.5	DB21, ... DBX0.5	DB21, ... DBX32.5
Associated M01	DB21, ... DBX24.4	DB21, ... DBX30.5	DB21, ... DBX318.5
DRF selection	DB21, ... DBX24.3	DB21, ... DBX0.3	DB21, ... DBX33.3
PRT program test	DB21, ... DBX25.7	DB21, ... DBX1.7	DB21, ... DBX33.7

References:

/FB1/ Function Manual Basic Functions; NC/PLC Interface Signals (Z1)

/BAD/ Operating Manual HMI Advanced "Operating Area, Machine"

9.12.2 Activation of skip levels**Function**

It is possible to skip blocks, which are not to be executed every time the program runs. Blocks to be skipped are indicated in the part program by an oblique "/" before the block number.

The skip levels in the parts program are specified by "/0" to "/9".

Only one skip level can be specified for each part program block.

Parameter assignment

The number of skip levels is defined using machine data:

MD51029 \$MM_MAX_SKP_LEVEL (max. number of skip levels in the NC program)

Programming

Blocks, which are not to be executed in every program pass (e.g., program test blocks) can be skipped according to the following schematic.

Program code	Comment
/N005	; Block skipped, (DB21, ... DBX2.0) 1st skip level
/0 N005	; Block skipped, (DB21, ... DBX2.0) 1st skip level
/1 N010	; Block skipped, (DB21, ... DBX2.1) 2nd skip level
/2 N020	; Block skipped, (DB21, ... DBX2.2) 3rd skip level
/3 N030	; Block skipped, (DB21, ... DBX2.3) 4th skip level
/4 N040	; Block skipped, (DB21, ... DBX2.4) 5th skip level
/5 N050	; Block skipped, (DB21, ... DBX2.5) 6th skip level
/6 N060	; Block skipped, (DB21, ... DBX2.6) 7th skip level
/7 N070	; Block skipped, (DB21, ... DBX2.7) 8th skip level
/8 N080	; Block skipped, (DB21, ... DBX31.6) 9th skip level
/9 N090	; Block skipped, (DB21, ... DBX31.7) 10th skip level

Activation

The 10 skip levels "/0" to "/9" are activated by the PLC setting the PLC → NCK interface signals.

The function is activated from the HMI via the "Program control" menu in the "Machine" operating area:

- for skip levels "/0" to "/7":
via the interface HMI → PLC DB21, ... DBB26 (skip block selected).
- for skip levels "/8" to "/9":
via interface HMI → PLC DB21, ... DBX27.0 to DBX27.1.

References:

Operating Manual

Note

The levels to be skipped can only be changed when the control is in the STOP/RESET state.

9.12.3 Adapting the size of the interpolation buffer

MD28060

The channel-specific interpolator executes prepared blocks from the interpolation buffer during the part program run. The maximum number of blocks requiring space in the interpolation buffer at any given point in time is defined by the memory configuring MD28060 \$MM_IPO_BUFFER_SIZE (number of NC blocks in the IPO buffer (DRAM)). For some applications it may be meaningful not to use the full buffer capacity in order to minimize the "interval" between preparation and interpolation.

SD42990

The number of blocks in the interpolation buffer can be restricted dynamically to a **smaller** value than in MD28060 \$MC_MM_IPO_BUFFER_SIZE (number of NC blocks in the IPO buffer (DRAM)), minimum 2 blocks, with the setting data SD42990 \$SC_MAX_BLOCKS_IN_IPOBUFFER (max. number of blocks in the IPO buffer).

Values of setting data SD42990 \$SC_MAX_BLOCKS_IN_IPOBUFFER:

Value	Effect
< 0	No interpolation buffer limit active. The max. possible interpolation buffer as set in MD 28060: MM_IPO_BUFFER_SIZE is activated.
or 1	The minimum permissible interpolation buffer with 2 blocks is activated.
< < MM_IPO_BUFFER_SIZE	The interpolation buffer is activated with no more than the maximum specified number of blocks.
>= MM_IPO_BUFFER_SIZE	The interpolation buffer is activated with the number of blocks specified in MD 28060: MM_IPO_BUFFER_SIZE.

Note

If SD42990 \$SC_MAX_BLOCKS_IN_IPOBUFFER is set in the part program, the interpolation buffer limitation takes effect immediately if the block with the SD is being preprocessed by the interpreter.

This means that the limitation of the IPO buffer may take effect a few blocks before the intended limitation (see also MD 28070 \$MC_MM_NUM_BLOCKS_IN_PREP).

To avoid premature activation and to make the limitation of the IPO buffer take effect in synchronism with the block, a STOPRE (preprocessing stop) must be programmed before the SD is set in the part program.

Validity

SD42990 \$SC_MAX_BLOCK_IN_IPOBUFFER has global, channel-specific validity and can also be modified in a part program. This modified value is maintained at program end. If this setting data is to be reset again on defined events, a so-called event-driven program must be created to do this. For example, this setting data could always be set to a predefined value on RESET.

Application

The IPO buffer limitation can be used whenever the number of blocks between block preparation and interpolation must be minimized, e.g., when actual positions in the part program must be read and processed for other purposes.

Example

```
N10 ...
N20 ...
.....
N100 $SC_MAX_BLOCKS_IN_IPOBUFFER = 5           ; Limitation of IPO buffer to 5 NC
                                                blocks
N110 ...
N120 ...
.....
N200 $SC_MAX_BLOCKS_IN_IPOBUFFER = -1         ; Cancellation of the IPO buffer
                                                limitation
N210 ...
.....
```

9.12.4 Program display modes via an additional basic block display

Basic block display (only for ShopMill/ShopTurn)

A second so-called basic block display can be used with the existing block display to show all blocks that produce an **action on the machine**.

Look Ahead basic block display

The actually approached end positions are shown as an absolute position. The position values refer either to the workpiece coordinate system (WCS) or the settable zero system (SZS).

The number of Look Ahead display blocks stored in the display buffer depends on the number of prepared blocks in the NCK preprocessing buffer in the relevant processing state. If a preprocessing stop is processed, the number of display blocks is reduced to zero and increases again after the stop is acknowledged. In the case of REORG events (e.g., mode change, ASUB start), the display blocks stored for Look Ahead are deleted and preprocessed again afterwards.

Processed values

Values processed in the basic block display coincide with the:

- selected tools
- feed and spindle speed
- actually approached position values

exceptions:

With active tool radius compensation, deviations can occur.

For modulo axes, the programmed value is displayed in the basic block display. This value can also lie outside the modulo range.

Note

As a basic rule the positions are represented in the WCS or the SZS.

The basic block display can be activated or deactivated with setting data

SD42750 \$SC_ABSBLOCK_ENABLE.

9.12.5 Basic block display for ShopMill/ShopTurn

Configure basic block display

The basic block display can be configured via the following machine data:

NCK machine data for basic block display	Significance:
MD28400 \$MC_MM_ABSBLOCK	Activate basic block display
MD28402 \$MC_MM_ABSBLOCK_BUFFER_CONF[2]	Size of display buffer
Display machine data	Position values to be set:
MD9004 \$MM_DISPLAY_RESOLUTION	For metric measurements
MD9011 \$MM_DISPLAY_RESOLUTION_INCH	For inch measurements
MD9010 \$MM_SPIND_DISPLAY_RESOLUTION	Settable coordinate system for spindle display resolution
MD9424 \$MM_MA_COORDINATE_SYSTEM	For actual value display in WCS or SZS

These display machine data are copied to NCK machine data MD17200 \$MN_GMMC_INFO_UNIT[0] to MD17200 \$MN_GMMC_INFO_UNIT[3]. allowing them to be accessed from the NCK.

Activating

The basic block display is activated by MD 28400 \$MC_MM_ABSBLOCK by means of Power On. If MD28400 \$MC_MM_ABSBLOCK is set to 1, a channel-specific display buffer (FIFO) is created during power-up.

Size of display buffer (FIFO) = (MD28060 \$MC_MM_IPO_BUFFER_SIZE + MD28070 \$MC_MM_NUM_BLOCKS_IN_PREP) multiplied by 128 bytes. This corresponds to a size of 6KB in the machine data default setting.

Optimize size of display buffer:

The memory requirement can be optimized by entering a value between 128 and 512. The display blocks preprocessed in the display buffer are transferred to the HMI via a configurable upload buffer.

Maximum size of upload buffer is obtained by multiplying (MD28402 \$MC_MM_ABSBLOCK_BUFFER_CONF[0] + MD28402 \$MC_MM_ABSBLOCK_BUFFER_CONF[1] + 1) by the block length configured in MD28400 \$MC_MM_ABSBLOCK.

The number of blocks **before** the current block is configured in MD28402 \$MC_MM_ABSBLOCK_BUFFER_CONF[0] and the number of blocks **after** the current block is configured in MD28402 \$MC_MM_ABSBLOCK_BUFFER_CONF[1].

Constraints

If the length of a display block configured in MD28400 \$MC_MM_ABSBLOCK is exceeded, this display block is truncated accordingly. This is represented by string "..." at the end of the block.

For preprocessed cycles (MD10700 \$MN_PREPROCESSING_LEVEL > 1), the display block contains **only** axis positions.

Additional boundary conditions for the basic block display:

- Modal synchronized action blocks with absolute values are not taken into account.
- The basic block display is deactivated during block search with or without computation.
- Polar coordinate programming is not shown in Cartesian system.

Radius / diameter values

Diameter values shown in the basic block display and position display may be needed as a radius for internal calculation. These values for measurements in radius/diameter according to G code group 29 can be manipulated using the following options:

- G code DIAMCYCOF (expansion of channel-specific diameter programming)
This G code deactivates the channel-specific diameter programming during the cycle execution. In this way, computations in the cycle can always be done in the radius. The position display and the basic block display are continued according to the state of the diameter programming before DIAMCYCOF.
In the basic block display, the last displayed value is retained.
- G code DIACYCOFA[AX] (axis-specific diameter programming)
This G code deactivates the axis-specific diameter programming during the cycle execution. In this way, computations in the cycle can always be done in the radius. In the position display and in the basic block display, this continues according to the state of the diameter programming before DIACYCOFA[AX].
In the basic block display, the last displayed value is retained.
- MD27100 \$MC_ABSBLOCK_FUNCTION_MASK

Bit0 = 1 Transverse axis setpoints are always shown as diameter values in the basic block display.

Behavior while the compressor is active

With active compressor and G/Code group 30 not equal to COMPOF, two display blocks are generated:

- The first contains the G/Code of the active compressor.
- The second contains the string "..." as character for missing display blocks.

Example

```
G0 X10 Y10 Z10                      ; Block to be preprocessed for the basic block display
COMPCAD                              ; Compressor for optimized surface quality (CAD prog.) A
...                                   ; string as character for missing display blocks
```

To avoid bottlenecks in the NCK performance, the basic block display is deactivated automatically. As a sign that the display blocks are missing, a display block with the string "..." is generated.

All display blocks are always generated in the single block.

9.12.6 Structure for a DIN block

Structure of display block for a DIN block

Basic structure of display block for a DIN block

- Block number/label
- G-functions of the first G-group
(only if changed as compared to the last machine function block).
- Axis position
(sequence corresponding to MD20070 \$MC_AXCONF_MACHAX_USED (machine axis number valid in the channel)).
- Further modal G functions
(only if changed as compared to the last machine function block).
- Other addresses as programmed.

The display block for the basic block display is directly derived from the programmed part program blocks according to the following rules:

- Macros are expanded.
- Skip identifiers and comments are omitted.
- Block number and labels are transferred from the original block, but omitted if DISPLOF is active.
- The number of decimal places is defined in display machine data MD 9004, MD 9010 and MD 9011 via the HMI.

HMI display machine data	Access in NCK machine data
MD9004 \$MM_DISPLAY_RESOLUTION	MD17200 \$MN_GMMC_INFO_NO_UNIT[0]
MD9011 \$MM_DISPLAY_RESOLUTION_INCH	MD17200 \$MN_GMMC_INFO_NO_UNIT[1]
MD9010 \$MM_SPIND_DISPLAY_RESOLUTION	MD17200 \$MN_GMMC_INFO_NO_UNIT[2]
MD9424 \$MM_MA_COORDINATE_SYSTEM	MD17200 \$MN_GMMC_INFO_NO_UNIT[3]

- Programmed axis positions are represented as absolute positions in the coordinate system (WCS / ENS) specified in MD9424 \$MM_MA_COORDINATE_SYSTEM (coordinate system for actual value display)

Note

The modulo correction is omitted for modulo axes, which means that positions outside the modulo range can be displayed. It also means that the basic block display differs from the position display in which values are always modulo-converted.

Examples

Comparisons between display block (original block) and basic block display:

- **Programmed positions** are displayed as absolute.
 The addresses AP/RP are displayed with their programmed values.

Original block:	Display block:
N10 G90 X10.123	N10 X10.123
N20 G91 X1	N20 X11.123

- **Address assignments** (non-DIN addresses) are displayed in the form <address> = <constant>.

Original block:	Display block:
N110 R1 = -67.5 R2 = 7.5	
N130 Z = R1 RND = R2	N130 Z-67.5 RND = 7.5

- **Address indices** (address extensions) are displayed as constants <address> [<constant>] = <constant>.

Original block:	Display block:
N220 DEF AXIS AXIS_VAR = X	
N240 FA[AXIS_VAR] = R2	N240 FA[X] = 1000

- **DIN addresses without address extension** are displayed in the form <din_address> <constant>.

Original block:	Display block:
N410 DEF REAL FEED = 1.5	
N420 F = FEED	N420 F1.5

The following applies for **H functions**: Each programmed value is displayed irrespective of the output type to PLC (MD22110 \$MC_AUXFU_H_TYPE_INT (type of H auxiliary function is integer)).

9.12 Program control

- For **Tool selection by tool command** display information is generated in the form T<value> or T=<string>. If an address extension has been programmed, this is displayed as well.
If several spindles have been configured or the "Tool change via master tool holder" function (MD20124 \$MC_TOOL_MANAGEMENT_TOOLHOLDER (tool holder number)) is active, the T number is always output with address extension.
If no address extension has been programmed, the number of the master spindle or the master toolholder is used instead (T<spindle_number/tool_holder>=).
- For the **Spindle programming** via S, M3, M4, M5, M19, M40 - M45 and M70 (or MD 20094 \$MC_SPIND_RIGID_TAPPING_M_NR (M function for switching over in the controlled axis operation)) the following regulation applies regarding the address extension:
If an address extension has been programmed, then this is also resolved.
If several spindles have been configured, then the address extension is also output.
If no address extension has been programmed, the number of the master spindle is used (S<spindle_number>=).
- **Indirect G code programming** in form G[<group>] = <printout> is substituted by the corresponding G code.

Original block:	Display block:
N510 R1=2	
N520 G[8]= R1	N520 G54

- **Modal G codes** that do not generate an executable block are collected and output with the display block of the next executable block if permitted by the syntax (DIN block). If this is not the case (e.g. predefined subroutine call TRANSMIT), a separate display block containing the modified G codes is placed in front of the next executable block.

Original block:	Display block:
N610 G64	G64
N620 TRANSMIT	N620 TRANSMIT

- A display block is always generated for **part program lines** in which the addresses **F** and **FA** appear (including for MD22240 \$MC_AUXFU_F_SYNC_TYPE = 3 (output time of the F functions)).

Original block:	Display block:
N630 F1000	N630 F1000
N640 X100	N640 X100

- The **display blocks generated for the block display** are derived **directly** from the programmed part program blocks. If intermediate blocks (e.g. tool radius compensation G41/G42, radius/chamfer RNDM, RND, CHF, CHR) are generated in the course of contour preprocessing, these are assigned the display information from the part program block on which the motion is based.

Original block:	Display block:
N710 Y157.5 G42	N710 Y157.5 G42
N720 Z-67.5 RND=7.5	N720 Z-67.5 RND=7.5

- With the **EXECTAB command** (processing a table of contour elements), the block generated by EXECTAB is shown in the display block.

Original block:	Display block:
N810 EXECTAB (KTAB[5])	N810 G01 X46.147 Z-25.38

- For the **EXECSTRING command**, the block generated via EXECSTRING is displayed in the display block.

Original block:
N910 DEF STRING[40] PROGSTRING = "N905 M3 S1000 G94 Z100 F1000 G55"
N920 EXECSTRING (PROGSTRING)

Display block:
N905 Z100 G55 G94 M3 S1000 F1000

9.12.7 Execution from external

Function

The "Execution from external" function can be used to execute programs that cannot be saved directly in the NC memory due to memory shortage from an external program memory.

Note

Protected cycles (_CPF files) cannot be processed with this function.

External program memory

External program memory can be found on the following data carriers:

- Local drive
- Network drive
- USB drive

Note

Execution from external source via USB interface

If external programs are to be transferred from an external USB drive via a USB interface, only the interface via X203 (named "TCU_1") can be used.

A USB FlashDrive cannot be recommended as a persistent storage medium.

Applications

- **Direct execution from external programs**

In principle, any program that is accessible via the directory structure of the interface in the "Execution from external" HMI mode can be selected and executed.

- **Execution of external sub-programs from the part program**

The external subroutine is called through the part program command `EXTCALL` with specification of a call path (optional) and the subroutine identifier (→ see "Execution from external subroutines (Page 635)").

Parameter assignment

A reloading memory (FIFO buffer) must be reserved in the dynamic NC memory for executing a program in the "Executing from external" mode (main program or subroutine).

Size of FIFO buffer

The size of the FIFO buffer is set in the machine data:

MD18360 \$MN_MM_EXT_PROG_BUFFER_SIZE (FIFO buffer size for processing from external)

Default: 30 kbyte

Number of the FIFO buffer

One FIFO buffer must be provided each for all programs (main run or subroutine) that are executed simultaneously in the "Execution from external source" mode.

The number of the FIFO buffer is set in the machine data:

MD18362 \$MN_MM_EXT_PROG_NUM (number of externally executed program levels executable simultaneously)

Behavior during RESET, POWER ON

External program calls are aborted through RESET and POWER ON and the concerned FIFO buffers are erased.

A program selected for "Execution from external source" remains selected for "Execution from external source" even after RESET / part program end. A POWER ON deletes the selection.

9.12.8 Execution from external subroutines

Function

Individual machining steps for producing complex workpieces may involve program sequences that require so much memory they cannot be stored in the NC memory.

In such cases, the user has the option of executing the program sequences as subroutines from an external program memory in the "Execution from external source" mode with the help of the `EXTCALL` part program instruction.

Preconditions

The following preconditions are applicable to the execution from external subroutines:

- The subroutines must be accessible via the directory structure of the operator interface.
- A reloading memory (FIFO buffer) must be reserved for each subprogram in the dynamic NC memory.

Parameter assignment

The path for the external subprogram directory can be preset using setting data:

SD42700 \$SC_EXT_PROG_PATH (Program path for the `EXTCALL` external subprogram call)

The entire path of the program to be called along with the subprogram path or identifier specified during programming is derived therefrom.

Programming

An external subroutine is called by means of parts program command `EXTCALL`.

Syntax: `EXTCALL("<path/><program name>")`

Parameter:

`<path>`: Absolute or relative path data (**optional**)
Type: STRING

<program name>: The program name is specified without prefix "_N_".
 The file extension ("MPF", "SPF") can be attached to program
 names using the "_" or "." character (**optional**).
 Type: STRING

Note

Path specification: Short designations

The following short designations can be used to specify the path:

- **LOCAL_DRIVE**: for local drive
- **CF_CARD**: for CompactFlash Card
- **USB**: for USB front connection

CF_CARD: and **LOCAL_DRIVE**: can be alternatively used.

EXTCALL call with absolute path name

If the subprogram exists at the specified path, it will be executed following the **EXTCALL** call. If it does not exist, program execution is cancelled.

EXTCALL call with relative path name/without path name

In the event of an **EXTCALL** call with a relative path name or without a path name, the available program memories are searched as follows:

- If a path name is preset in SD42700 \$SC_EXT_PROG_PATH, the data specified in the **EXTCALL** call (program name or with relative path name) is searched for first, starting from this path. The absolute path results from linking the following characters:
 - The path name preset in SD42700
 - The "/" character as a separator
 - The subprogram path or identifier programmed in **EXTCALL**
- If the called subprogram is not found at the preset path, the data specified in the **EXTCALL** call is then searched for in the user-memory directories.
- The search ends when the subprogram is found for the first time. If the search does not produce any hits, the program is canceled.

Example

Execute from local drive

Main program:

```
Program code  
-----  
N010 PROC MAIN  
N020 ...  
N030 EXTCALL ("ROUGHING")  
N040 ...  
N050 M30
```

External subprogram:

```
Program code  
-----  
N010 PROC ROUGHING  
N020 G1 F1000  
N030 X= ... Y= ... Z= ...  
N040 ...  
...  
...  
N999999 M17
```

The "MAIN.MPF" main program is stored in NC memory and is selected for execution.

The "SCHRUPPEN.SPF" or "SCHRUPPEN.MPF" subprogram to subsequently loaded is on the local drive in the directory "/user/sinumerik/data/prog/WKS.DIR/WST1.WPD".

The subprogram path is preset in SD42700:

```
SD42700 $SC_EXT_PROG_PATH = "LOCAL_DRIVE:WKS.DIR/WST1.WPD"
```

Note

Without the path being specified in the SD42700, the EXTCALL operation for this example would have to be programmed as follows:

```
EXTCALL ("LOCAL_DRIVE:WKS.DIR/WST1.WPD/SCHRUPPEN")
```

9.13 System settings for power-up, RESET/part-program end and part-program start

Concept

The control-system response after:

- Power up (POWER ON)
- Reset/part program end
- Part program start

can be modified for functions, such as G codes, tool length compensation, transformation, coupled axis groupings, tangential follow-up, programmable synchronous spindle via machine data.

The control-system response after:	can be set with:
Power-up (POWER ON) *)	MD20110 \$MC_RESET_MODE_MASK (Definition of control default settings after reset/parts program end) MD20144 \$MC_TRAFO_MODE_MASK (Selection of the kinematic transformation function) MD20150 \$MC_GCODE_RESET_VALUES (initial setting of the G groups)
RESET/part program end	MD20110 \$MC_RESET_MODE_MASK (Definition of control default settings after reset/parts program end) MD20150 \$MC_GCODE_RESET_VALUES (initial setting of the G groups) MD20152 \$MC_GCODE_RESET_MODE (Definition of control initial setting after reset)
Part program start	MD20112 \$MC_START_MODE_MASK (definition of initial control system settings after part program start) MD20110 \$MC_RESET_MODE_MASK (Definition of control default settings after reset/parts program end)
*) see also POWER ON (Page 814)	

Example:

For certain applications (e.g. grinding) it is advisable not to apply the reset position of individual functions until the part program start. This is possible through the appropriate setting of machine data MD20110, MD20150, MD20152 and MD20112.

System settings after power-up

MD20110 \$MC_RESET_MODE_MASK, bit 0 = 0 or 1

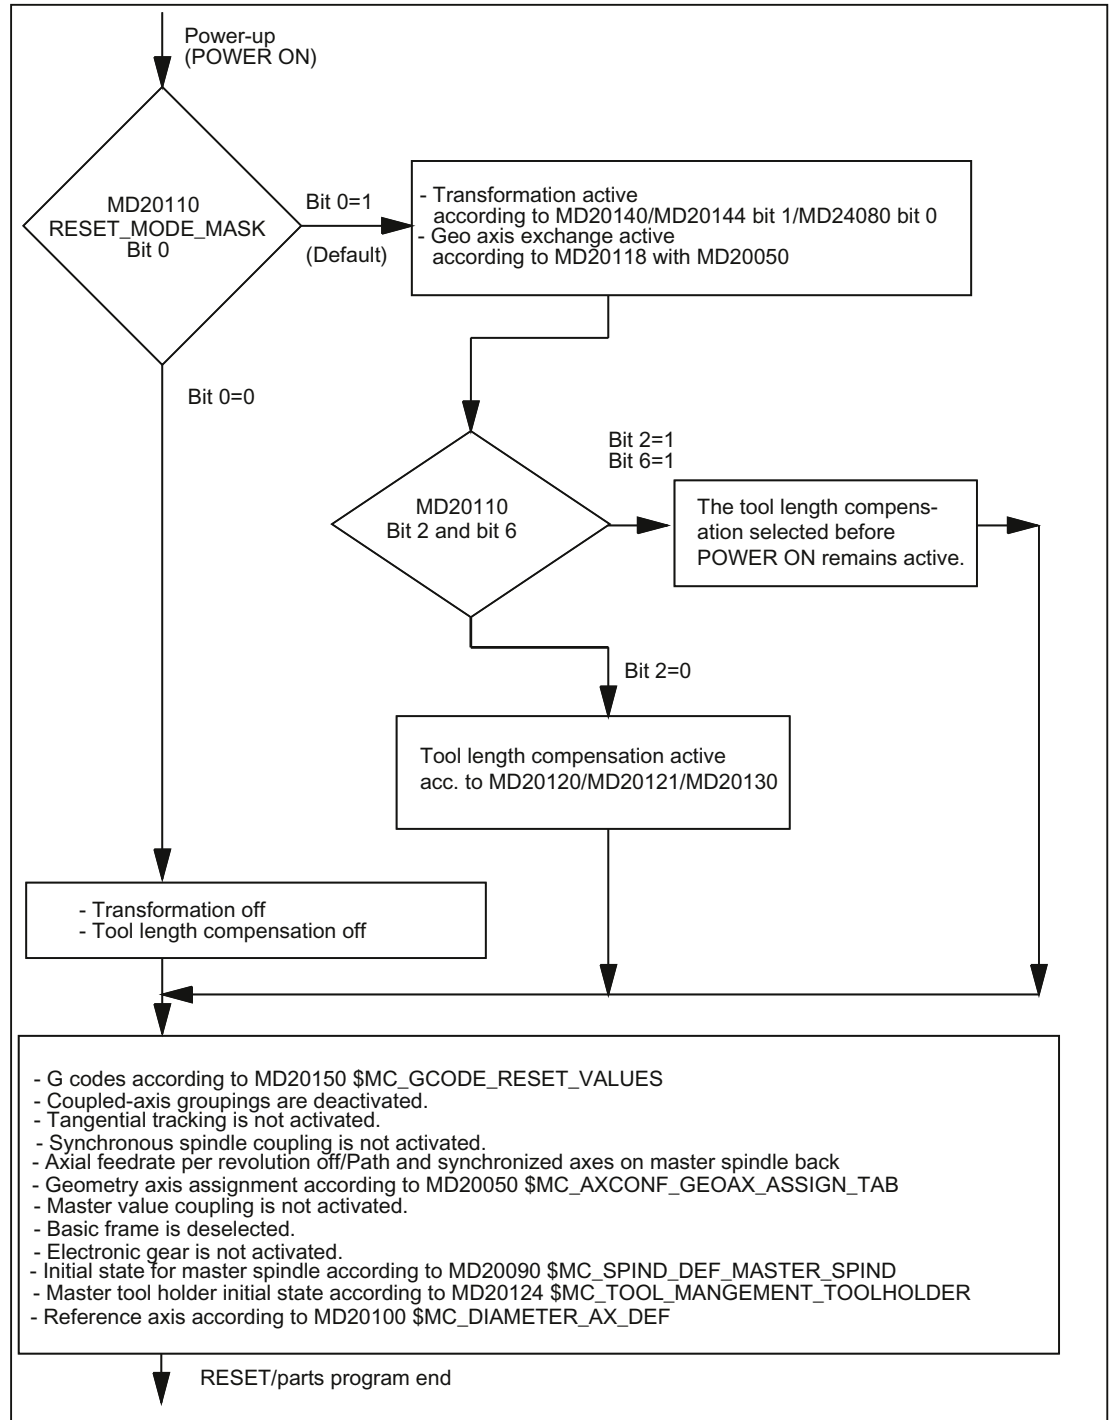

Figure 9-14 System settings after power-up

System settings after RESET/part program end and part program start

MD20110 \$MC_RESET_MODE_MASK, bit 0 = 0 or 1

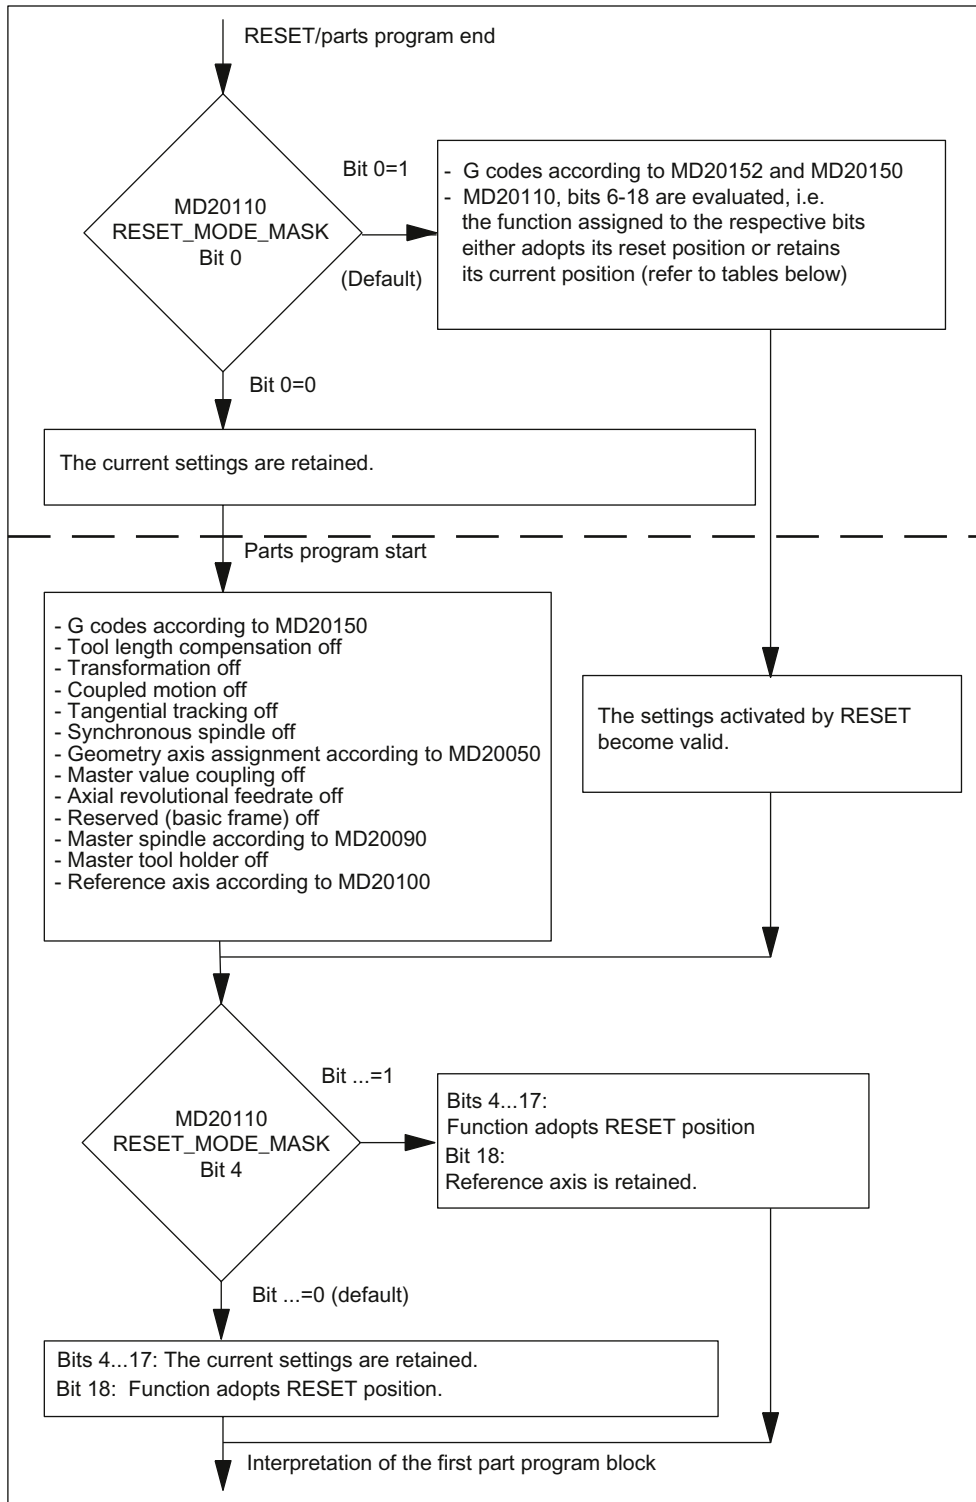

Figure 9-15 System settings after RESET/part program end and part program start

MD20152 \$MC_GCODE_RESET_MODE

Each G code group controlled in MD20150 \$MC_GCODE_RESET_VALUES[i] can be selectively controlled with MD20152 \$MC_GCODE_RESET_MODE[i].

MD20152 \$MC_GCODE_RESET_MODE[i] (i = G code group -1)	0	1
MD20150 \$MC_GCODE_RESET_VALUES[i]	The value stored in MD20150 is active	The last active/ current value is active

Part program start

The initial setting of the control system at part program start, e.g. G codes (especially active plane and active settable zero offset), active tool length compensation, transformation, and axis coupling, is determined using machine data:

MD20112 \$MC_START_MODE_MASK (definition of the basic setting of the control after part program start)

Bit assignment, see:

References:

Detailed machine-data description

Application

If a bit is set in MD20112 \$MC_START_MODE_MASK, the reset action of the relevant function can be delayed until the start of the parts program.

Note

In MD20110 bits set to 1 cause settings to be retained,
in MD20112 bits set to 0 cause settings to be retained.

Significance of the machine data

The channel-specific machine data in the table "Selection of RESET and power-up response" has the following significance:

Machine data	Meaning
MD20120 \$MC_TOOL_RESET_VALUE	Tool length compensation on power-up Definition of the tool (T No.) whose tool length compensation values must be considered during RESET and power-up according to MD20110 \$MC_RESET_MODE_MASK
MD20121 \$MC_TOOL_PRESEL_RESET_VALUE	Preselected tool on RESET Definition of the tool (T-No.) as a preselected tool whose tool length compensation values must be considered during RESET and power-up according to MD20110 \$MC_RESET_MODE_MASK

Machine data	Meaning
MD20130 \$MC_CUTTING_EDGE_RESET_VALUE	Tool cutting-edge length compensation on power-up Definition of the cutting-edge number (D number) of the tool in MD20120 \$MC_TOOL_RESET_VALUE
MD20140 \$MC_TRAFO_RESET_VALUE	Power-up transformation data block Definition of the transformation data block (TRAORI, TRAANG, TRANSMIT)
MD20144 \$MC_TRAFO_MODE_MASK	Selection of the kinematic transformation function Setting bit 1 causes the last active transformation to be retained on POWER ON.
MD20150 \$MC_GCODE_RESET_VALUES	Initial setting of the G groups
MD20152 \$MC_GCODE_RESET_MODE	Reset behavior of G groups G code initial state on RESET MD20152 specifies for each entry in MD20150 \$MC_GCODE_RESET_VALUES whether the setting in accordance with MD20150 \$MC_GCODE_RESET_VALUES is adopted again (MD20152=0) or the current setting is retained (MD20152=1) on reset/part program end.
MD21330 \$MC_COUPLE_RESET_MODE_1	Coupling cancellation response Cancellation of an axis coupling
MD20050 \$MC_AXCONF_GEOAX_ASSIGN_TAB	Assignment of geometry axis to channel axis Acts upon bit 12 in MD20110/20112
MD20118 \$MC_GEOAX_CHANGE_RESET	Allow automatic geometry axis change Acts upon bit 12 in MD20110/20112

Example

1. Activate RESET setting on RESET:
MD20110 = 'H01' (bit 0)
MD20112 = '0'
2. Transformation remains active on RESET/parts program start:
MD20110 = 'H81' (bit 0 + bit 7)
MD20112 = '0'

3. Tool length compensation remains active on RESET/part program start:
MD20110 = 'H41' (bit 0 + bit 6)
MD20112 = '0'
4. Active level (bit 4) and settable frame (bit 5) remain active after RESET and are reset on parts program start:
MD20110 = 'H31' (bit 4 + bit 5)
MD20112 = '30'

Note

For bit 5 and bit 6:

If MD20110/MD20112 are parameterized so that tool length compensation or a frame is active on a parts program start/MDA start, the first programming of the axes must use absolute measurements (because of the offsetting process).

Exception: With MD42442/MD42440 the offsetting process for G91 is suppressed.

9.13.1 Tool withdrawal after POWER OFF with orientation transformation

Function

If processing with tool orientation is interrupted (e.g. as a result of power failure), the transformation which was previously active can be reselected after POWER ON to generate a frame towards the tool axis. The tool can then be retracted in JOG mode by means of a retraction movement towards the tool axis.

Precondition

This procedure requires valid axis positions after POWER ON which are either delivered by absolute encoders or by the function "Position restoration on POWER ON (Page 1245)".

Parameter assignment

Last active transformation should be kept after POWER ON

This functionality is activated using the MD setting:

MD20144 \$MC_TRAFO_MODE_MASK, Bit 1 = 1

In addition, the following bits must be set:

MD20110 \$MC_RESET_MODE_MASK, bit 0 = 1 and bit 7 = 1

For the significance of MD20144 and 20110, see "System settings for power-up, RESET/part-program end and part-program start (Page 638)".

NC language command WAITENC

For axes, which should be taken into account with `WAITENC` (see section "Programming") the following axis-specific machine data must be set to "1":

`MD34800 $MA_WAIT_ENC_VALID = 1`

Programming

In the user program (.../_N_CMA_DIR/_N_PROG_EVENT_SPF) to be called event-controlled when powering up (precondition: MD20108 bit 3 = 1), the system must wait using the NC language command `WAITENC` until the valid axis positions are available.

A frame that positions the tool axis in the direction of the X, Y or Z axis can then be generated using the NC language command `TOROTX/TOROTY/TOROTZ`.

Example

Orientation transformation and orientation axes with incremental encoders.

Configuration:	Meaning:
<code>MD10720 \$MN_OPERATING_MODE_DEFAULT [0] = 6</code>	Power-up in JOG mode
<code>MD30240 \$MA_ENC_TYPE [0, <axis>] = 1</code>	Incremental measuring system
<code>MD34210 \$MA_ENC_REFP_STATE [0, <axis>] = 3</code>	Enable the restoration of axis positions for incremental encoders.
<code>MD20108 \$MC_PROG_EVENT_MASK = 'H9'</code>	Activate event-controlled using program <code>PROG_EVENT</code> during power-up and at the start of the part program.
<code>MD20152 \$MC_GCODE_RESET_MODE [52] = 1</code>	Obtain TOFRAME via reset.
<code>MD20110 \$MC_RESET_MODE_MASK = 'HC1'</code>	Obtain transformation and tool offset via reset.
<code>MD20144 \$MC_TRAFO_MODE_MASK = 'H02'</code>	Obtain transformation via POWER OFF.

Event-controlled user program (.../_N_CMA_DIR/_N_PROG_EVENT_SPF):

Program code	Comment
<code>; Example with activation of the frame, which aligns the WCS in the tool direction, when powering-up and resetting with part program start.</code>	
<code>IF \$P_PROG_EVENT == 4</code>	<code>; Powering-up.</code>
<code> IF \$P_TRAFO <> 0</code>	<code>; Transformation has been selected.</code>
<code> WAITENC</code>	<code>; Wait for valid axis positions of the orientation axes.</code>
<code> TOROTZ</code>	<code>; Rotate the Z axis of the WCS towards the tool axis.</code>
<code> ENDIF</code>	
<code> M17</code>	
<code>ENDIF</code>	
<code>IF \$P_PROG_EVENT == 1</code>	<code>; Start of the part program.</code>
<code> TOROTOF</code>	<code>; Reset the tool frame.</code>
<code> RET</code>	
<code>ENDIF</code>	

The `WAITENC` command essentially corresponds to the following NC program sequence (example for 5-axis machine with AB kinematics):

Program code	Comment
<code>WHILE TRUE</code>	<code>; Wait for a measuring system.</code>
<code> IF ((<code>\$AA_ENC_ACTIVE[X]==TRUE</code>) AND (<code>\$AA_ENC_ACTIVE[Y]==TRUE</code>) AND (<code>\$AA_ENC_ACTIVE[Z]==TRUE</code>) AND (<code>\$AA_ENC_ACTIVE[A]==TRUE</code>) AND (<code>\$AA_ENC_ACTIVE[B]==TRUE</code>)) GOTOF GET_LABEL</code>	
<code> ENDIF</code>	
<code> G4 F0.5</code>	<code>; 0.5 s wait time</code>
<code>ENDWHILE</code>	
<code>:Position synchronization</code>	
<code>GET_LABEL: GET(X,Y,Z,A,B,)</code>	

Boundary conditions

Retracting the tool in JOG mode

Once the tool has been retracted in the JOG mode, axes whose positions have been restored are referenced. For further details, see also machine data:

- MD20700 \$MC_REFP_NC_START_LOCK
- MD34110 \$MA_REFP_CYCLE_NR

Note

If machine data MD20700 \$MC_REFP_NC_START_LOCK is set to a value of "2", then an NC start is also possible with "restored" axis positions (in the MDA mode or when overstoring).

Axes with incremental encoders and without actual value buffering

It is to be assumed that axes with incremental encoders and without actual-value buffering are clamped with sufficient speed in the event of a power failure to prevent them drifting from their last position setpoint.

9.14 Replacement of NC functions by subprograms

9.14.1 General

Function

The NC-language offers the option of structuring more complex processing sequences through subprograms. Normally these subprograms are started from the part programs with explicitly programmed subprogram calls. Along with this, there is also the possibility of hiding a subprogram call behind another NC -command (e.g. call of an M function) and thus of replacing the actual command function by the subprogram.

Example: Call of the tool change cycle by the auxiliary function `M6`

The reasons for this are as follows:

- Existing part programs can be adapted to the changed environmental conditions without correcting the part programs themselves.
- An introduced programming style can be maintained.

Replaceable NC functions

The following NC functions can be replaced by subprograms:

- M, T, and D/DL auxiliary functions:
 - M Functions for switching operations
 - T Functions for tool selection
 - D/DL-Functions for tool compensation selection
- Spindle-related functions during active synchronous spindle coupling:
 - Gear stage change (automatic change or direct gear stage)
 - Spindle positioning with `SPOS`, `SPOSA` and `M19`

9.14.2 Replacement of M functions

Conditions

The following conditions are applicable for replacing the M functions:

- A maximum of one function replacement is active for each block.
- The block with the function replacement may **not** contain the following elements:
 - M98
 - Modal subroutine call
 - Subprogram return
 - Part program end
- A subroutine call must not be superimposed on M functions with predetermined significance (see Section "Non-configurable M functions").

Configuration

The numbers of the M functions to be replaced by the subprograms are specified in the machine data:

MD10715 \$MC_M_NO_FCT_CYCLE[<n>]

The names of the subprograms that are to replace the M functions specified in MD10715 are entered in the machine data:

MD10716 \$MC_M_NO_FCT_CYCLE_NAME[<n>]

Example

MD10715 \$MC_M_NO_FCT_CYCLE[0] = 101

MD10716 \$MC_M_NO_FCT_CYCLE_NAME[0] = "SUB_M101"

⇒ Call of the subprogram SUB_M101 through M101

MD10715 \$MC_M_NO_FCT_CYCLE[1] = 102

MD10716 \$MC_M_NO_FCT_CYCLE_NAME[1] = "SUB_M102"

⇒ Call of the subprogram SUB_M102 through M102

Programming

If the M function configured with MD10715 is programmed in a part program block, the appropriate subroutine is called at the end of the part program block.

If the M function is programmed again within the called subroutine, the M function is not replaced again. In addition, other M function replacements configured with MD10715 or MD10716 are not executed.

Exception:

The M function is also replaced in an ASUB if the ASUB was started in a subroutine that was called via an M function.

System variables for the transfer parameters

Information about the programmed M function can be read in the replacement subroutine via the following system variables:

System variable	Meaning
\$C_M_PROG	= TRUE if the M function has been replaced
\$C_M	Value of the replaced address M (type: INT)
\$C_AUX_VALUE[0]	Value of the replaced address M (type: REAL)
\$C_ME	Address extension of the replaced M function
\$C_AUX_EXT[0]	Address extension of the replaced M function (identical to \$C_ME)
\$C_AUX_IS_QUICK[0]	= TRUE if M function was programmed with quick output to PLC

M functions that cannot be configured

M Functions that trigger system functions as pre-defined auxiliary functions should not be used to call subroutines. The following M functions have standard predetermined significance:

M function	Remarks
M0 ... M5, M17, M30, M19, M40 ... M45	Predefined auxiliary functions that trigger system functions
M98, M99	with activated external NC language: MD18800 \$MN_MM_EXTERN_LANGUAGE == TRUE

M functions can be defined for specific tasks using the following machine data. Through this, they receive a fixed meaning and, therefore, must not be used to call subroutines:

Machine data	Significance
MD10714 \$MN_M_NO_FCT_EOP	M function for spindle active after RESET
MD10804 \$MN_EXTERN_CHAN_M_NO_SET_INT	M function for ASUB activation (external mode)
MD10806 \$MN_EXTERN_CHAN_M_NO_DISABLE_INT	M function for ASUB deactivation (external mode)
MD10814 \$MN_EXTERN_M_NO_MAC_CYCLE	Macro call via M function
MD20094 \$MC_SPIND_RIGID_TAPPING_M_NR	M function for switchover to controlled axis mode
MD20095 \$MC_EXTERN_RIGID_TAPPING_M_NR	M function for switchover to controlled axis mode (external mode)
MD22254 \$MC_AUXFU_ASSOC_M0_VALUE	Additional M function for program stop
MD22256 \$MC_AUXFU_ASSOC_M1_VALUE	Additional M function for conditional stop

Machine data	Significance
MD26008 \$MC_NIBBLE_PUNCH_CODE	Definition of M functions (for nibble-specific)
MD26012 \$MC_PUNCHNIB_ACTIVATION	Activation of punching and nibbling functions

Note

An exception here is the M function for the tool change configured via the following machine data:

MD22560 \$MC_TOOL_CHANGE_M_CODE (Tool change with M Function)

This M function is permitted to be replaced by a subroutine (see "Replacement of the M function for the tool change (Page 652)").

9.14.3 Replacement of T and D/DL functions

9.14.3.1 General

Conditions

The following conditions are applicable for the replacement of T or D or DL functions:

- A maximum of one function replacement is active for each block.
- The block with the function replacement may **not** contain the following elements:
 - M98
 - Modal subroutine call
 - Subprogram return
 - Part program end

Configuration

Specification of the replacement subroutine

The name of the subroutine, which is to become effective in case of **T-Function replacement**, is entered in the machine data:

MD10717 \$MN_T_NO_FCT_CYCLE_NAME

The name of the subroutine, which is to become effective in case of **D/DL function replacement**, is entered in the machine data:

MD11717 \$MN_D_NO_FCT_CYCLE_NAME

Note

The same subroutine should be configured for the T and D/DL replacement subroutine.

Specification of the D or DL number to the replacement subroutine

For a simultaneous programming of D or DL and T in a block, D or DL can **either** be specified as parameter to the replacement subroutine **or** executed before calling the replacement subroutine.

The behavior depends on the setting of bit 0 in the machine data:

MD10719 \$MN_T_NO_FCT_CYCLE_MODE (Parameterization of the T function replacement)

Bit	Value	Description
0	0	The D or the DL number is specified to the replacement subroutine via the system variable (default setting).
	1	The D or DL number is calculated directly in the block. Note: This function is only active if the tool change was configured with M function: MD22550 \$MC_TOOL_CHANGE_MODE = 1 otherwise the D or DL values are always transferred.

Call time of the replacement subroutine

The call time of the replacement subroutine is defined by the setting of bit 1 and bit 2 in the machine data:

MD10719 \$MN_D_NO_FCT_CYCLE_MODE

Value of bit 1	Value of bit 2	Call time of the replacement subroutine
0	0	At block end (default) After the replacement subroutine has been executed, the interpretation is resumed with the subprogram line following the line that triggered the replacement operation.
1	0	At block start After the replacement subroutine has been executed, the part program line that controlled the call of the subroutine is interpreted. The T address and the D or DL address and the M function for the tool change are no longer processed.
0/1	1	At block start and block end The replacement program is called twice.

Note

Which replacements are to be performed at the block start and which are to be performed at the block end is up to the user.

Programming

Read activation time of the replacement subroutine

The \$P_SUB_STAT system variables can be used to define the time (block start / block end) when the replacement operation is executed:

Value	Description
0	Replacement subroutine is not active
1	Replacement subroutine is active, call at block start
2	Replacement subroutine is active, call at block end

Example: T function replacement

Project design:

MD22550 \$MC_TOOL_CHANGE_MODE = 0

MD10717 \$MN_T_NO_FCT_CYCLE_NAME = "MY_T_CYCLE" T replacement subroutine

MD10719 \$MN_T_NO_FCT_CYCLE_MODE = 0

Meaning:

Tool change with
T function

Programming	Comment
...	
N110 D1	
N120 G90 G0 X100 Y100 Z50	; D1 is active
N130 D2 X110 Z0 T5	; D1 remains active, programmed D2 is provided to the T replacement cycle as a variable.
...	

A comprehensive example for the T function replacement is given in "Examples of M/T function replacement during tool change (Page 657)".

9.14.3.2 Replacement of the M function for the tool change

Tool change with M function

MD22550 \$MC_TOOL_CHANGE_MODE = 1

For certain machine types (e.g. milling machine with tool magazine) the T function is not used for the actual tool change, but instead for its preparation i.e. with the T function the new tool is brought to the tool change position parallel to the machining time (without interruption of the processing).

The actual tool change is then called with the M function, which is configured in the following machine data:

MD22560 \$MC_TOOL_CHANGE_M_CODE (M function for tool change)

References:

Function Manual Extended Functions; Tool Change (W3)

Replacement of the M function for the tool change

The M function for the tool change configured via MD22560 is replaced by a subroutine, if a corresponding replacement subroutine is configured via both the following machine data:

MD10715 \$MN_M_NO_FCT_CYCLE[n] (M function to be replaced by a subroutine)

MD10716 \$MN_M_NO_FCT_CYCLE_NAME[n] (Name of subroutine for M function)

For more information, see "Replacement of M functions (Page 647)".

Note

The configuration of a replacement subroutine for the tool change with M code is dependent on whether the tool change with M code was actually configured with MD22550 \$MC_TOOL_CHANGE_MODE.

M function replacement with parameter transfer

If an M function replacement is configured with MD10715[n] and MD10716[n], then for this M function replacement a parameter transfer can be set (similar to the parameter transfer for the T function replacement):

MD10718 \$MN_M_NO_FCT_CYCLE_PAR = n

The data (parameters) needed for the tool offset or the tool offset selection is passed to the subroutine via the system variables. The parameters stored in the system variables always refer to the part program line in which the M function to be replaced is programmed.

Note

The address extension and function value of the M function must be explicitly, i.e. constantly, programmed for M function replacements with parameter transfer. An indirection definition via variables is not allowed.

Permissible programming:

```
M<function value>  
M=<function value>  
M[<address extension>] = <function value>
```

Impermissible programming:

```
M=<Variable1>  
M[<variable2>] = <variable1>
```

Conflict case: M and T functions for tool change in a block

If, in addition to the M function replacement with parameter transfer, a T function replacement was configured, the following behavior is applicable in case of a conflict, i.e. T and M function for tool change are in one block:

- The T function replacement does not take place. Instead, the T value is made available to the M function replacement via the appropriate \$C_T... system variables.
- The programming of the address T in the M function subroutine does not result in another replacement.

9.14.3.3 Function replacement with parameter transfer

Rules for parameter transfer

The following rules are applicable for the parameter transfer to the replacement subroutines:

- If one of the above-mentioned replacements is active, then all the information required for the tool offset selection (T, D or DL numbers, M function for tool change, address extensions) is transferred to the replacement subroutine.

Exception:

MD10719 \$MN_T_NO_FCT_CYCLE_MODE Bit 0 = 1

With this configuration the D or the DL numbers are not transferred to the replacement subroutines.

- In a block, only one replacement subroutine can be processed at a time.

In case of multiple replacements of the T, D/DL addresses and the M Function for the tool change, only one of the replacement subroutines is always active even under different names. As described above, all the required parameters for the tool offset selection are then made available to it. If configured accordingly, the subroutine is called before and/or after execution of the part program line.

- **One and the same subroutine** can be configured for the replacement of the T, D/DL addresses and the M Function for the tool change. The function to be replaced can then be determined by querying the system variables.

 CAUTION
The values passed to the replacement subroutine have not yet been executed and must, therefore, be programmed again in this subroutine.

System variables

The programmed values (T, D or DI numbers, M function for tool change, address extensions) can be transferred to the replacement subroutine via the following system variables:

System variable	Description
\$C_T_PROG	Returns the value "1", if address T has been programmed.
\$C_T	Value of the programmed address T
\$C_TE	Address extension of address T
\$C_TS_PROG	Returns the value "1", if the address T has been programmed with a tool identifier of type STRING (only in case of active tool monitoring).
\$C_TS	Returns the string of the tool identifier programmed under address T (only in case of active tool monitoring)
\$C_D_PROG	Returns the value "1", if address D has been programmed.
\$C_D	Value of the programmed address D
\$C_DL_PROG	Returns the value "1", if address DL has been programmed.

System variable	Description
\$C_DL	Value of the programmed address DL
\$C_M_PROG	Returns the value '1', if an M function has been programmed for the tool change.
\$C_M	Value of the programmed address M There are two different cases: 1. For the tool change with M function, a replacement subroutine is programmed with parameter transfer. \$C_M then returns the value: MD10715 \$MN_M_NO_FCT_CYCLE 2. Only one replacement subroutine was configured for the addresses T and/or D/DL and in the program the M function for the tool change is programmed with the addresses to be replaced. \$C_M then returns the value: MD22560 \$MC_TOOL_CHANGE_M_CODE
\$C_ME	Address extension of the M function for the tool change

Sample parameter transfers

Example 1:

Tool change with M6 should be active. The D/DL number is to be transferred to the replacement subroutine.

Project design:

MD22550 \$MC_TOOL_CHANGE_MODE = 1

MD10717 \$MN_T_NO_FCT_CYCLE_NAME = "MY_T_CYCLE"

MD10719 \$MN_T_NO_FCT_CYCLE_MODE = 0

Meaning:

Tool change with M function

T replacement subroutine

Transfer of the D/DL number

Programming	Comment
...	
N210 D1	
N220 G90 G0 X100 Y100 Z50	; D1 is active
N230 D2 X110 Z0 T5	; D1 remains active, programmed D2 is provided to the T replacement subroutine as a variable.
N240 M6	; Execute tool change
...	

Example 2:

Tool change with M6 should be active. The D/DL number is **not** to be transferred to the replacement subroutine.

9.14 Replacement of NC functions by subprograms

Project design:

MD22550 \$MC_TOOL_CHANGE_MODE = 1

MD10717 \$MN_T_NO_FCT_CYCLE_NAME = "MY_T_CYCLE"

MD10719 \$MN_T_NO_FCT_CYCLE_MODE = 1

Meaning:

Tool change with M function

Replacement subroutine for T function

No transfer of the D/DL number

Programming	Comment
...	
N310 D1	
N320 G90 G0 X100 Y100 Z50	; D1 is active
N330 D2 X110 Z0 T5	; D2 is activated, D2 is not transferred to the T replacement subroutine as a variable
N340 M6	; Execute tool change
...	

Example 3:

A replacement subroutine (MY_T_CYCLE) is configured for T and M6.

In addition, MD10718 \$MN_M_NO_FCT_CYCLE_PAR (M Function replacement with parameters) was used to configure the parameter transfer to M6 replacement subroutine.

If M6 is now programmed in the block with D or DL, then the D or the DL number is also transferred as parameter to the M6 replacement subroutine, when:

MD10719 \$MN_T_NO_FCT_CYCLE_MODE = 1

Project design:

MD22550 \$MC_TOOL_CHANGE_MODE = 1

MD22560 \$MC_TOOL_CHANGE_M_CODE = 6

MD10715 \$MC_M_NO_FCT_CYCLE[3] = 6

MD10716 \$MC_M_NO_FCT_CYCLE_NAME[3] = "MY_T_CYCLE"

MD10717 \$MN_T_NO_FCT_CYCLE_NAME = "MY_T_CYCLE"

MD10718 \$MN_M_NO_FCT_CYCLE_PAR = 3

MD10719 \$MN_T_NO_FCT_CYCLE_MODE = 1

Meaning:

Tool change with M function

M code for tool change

M function to be replaced

Replacement subroutine for M function

Replacement subroutine for T function

Parameter-transfer to the replacement subroutine for M6

No transfer of the D/DL number

Programming	Comment
...	
N410 D1	
N420 G90 G0 X100 Y100 Z50	; D1 is active
N330 D2 X110 Z0 T5 M6	; D1 remains active, D2 and T5 are transferred to the M6 replacement subroutine as a variable
...	

9.14.3.4 Example of M/T function replacement for tool change

Example 1: Call of subroutine SUB_M6 through M6 with parameter transfer

Project design:

MD10715 \$MN_M_NO_FCT_CYCLE[2] = 6

MD10716 \$MN_M_NO_FCT_CYCLE_NAME[2] = "SUB_M6"

MD10718 \$MN_M_NO_FCT_CYCLE_PAR = 2

Meaning:

M code for tool change

Replacement subroutine for M function

M function replacement with parameter transfer

Main program:

Programming
PROC MAIN
...
N10 T1 D1 M6
...
N90 M30

Replacement subroutine:

Programming	Comment
PROC SUB_M6	
N110 IF \$C_T_PROG==TRUE	; Scan whether address T has been programmed
N120 T[\$C_TE] = \$C_T	; Execute T selection
N130 ENDIF	
N140 M[\$C_ME] = 6	; Execute tool change
N150 IF \$C_D_PROG==TRUE	Scan whether address D has been programmed.
N160 D=\$C_D	Execute D selection
N170 ENDIF	
N190 M17	

Example 2: Replacement of T address and D or DL addresses at block start

The following should be true for the example:

- Tool change is done with the address T.
- Tool management not active.
- B axis as indexing axis with Hirth tooth system.

Project design:

MD11717 \$MN_D_NO_FCT_CYCLE_NAME = "D_T_SUB_PROG"

MD10717 \$MN_T_NO_FCT_CYCLE_NAME = "D_T_SUB_PROG"

MD10719 \$MN_T_NO_FCT_CYCLE_MODE = 'H2'

MD22550 \$MC_TOOL_CHANGE_MODE = 0

Meaning:

Replacement subroutine for D function

Replacement subroutine for M function

Call at block start

Tool change with T function

Main program:

Programming
...
N410 G01 F1000 X10 T1=5 D1
...

Replacement subroutine:

Programming	Comment
N1000 PROC D_T_SUB_PROG DISPLOF SBLOF	
...	
N4100 IF \$C_T_PROG==TRUE	; Scan whether address T has been programmed
N4110	; Replacement for address T with tool no.
N4120 POS[B] = CAC(\$C_T)	; Move revolver to indexing position
N4130 T[\$C_TE] = \$C_T	; Select tool (T selection)
N4140 ENDIF	
N4300 IF \$C_T_PROG==TRUE	; Scan whether address D has been programmed.
N4310	; Replacement for address D
N4320 D=\$C_D	; Select offset (D selection)
N4330 ENDIF	
N4400 IF \$C_DL_PROG==TRUE	; Scan whether address DL has been programmed.
N4410	; Replacement for address DL
N4420 D=\$C_DL	; Select insert offset
N4430 ENDIF	
...	
N9999 RET	

This causes the part program line
N410 G01 F1000 X10 T1=5 D1
to execute the following program:

Program	Comment
N1000 PROC D_T_SUB_PROG DISPLOF SBLOF	
...	
N4100 IF \$C_T_PROG==TRUE	; Scan whether address T has been programmed
N4110	; Replacement for address T with tool no.
N4120 POS[B] = CAC(\$C_T)	; Move revolver to indexing position
N4130 T[\$C_TE] = \$C_T	; Select tool (T selection)
N4140 ENDIF	
N4300 IF \$C_T_PROG==TRUE	; Scan whether address D has been programmed.
N4310	; Replacement for address D

9.14 Replacement of NC functions by subprograms

Program	Comment
N4320 D=\$C_D	; Select offset (D selection)
N4330 ENDIF	
N4400 IF \$C_DL_PROG==TRUE	; Scan whether address DL has been programmed.
N4430 ENDIF	
...	
N9999 RET	
N410 G01 F1000 X10	; Rest of N410 without tool programming

9.14.3.5 Conflict resolution in case of multiple replacements

Multiple replacements

Multiple replacements mean that several replacement subroutines with different names have been configured, e.g.:

- For Address D and DL:
MD11717 \$MN_FCT_CYCLE_NAME = "D_SUB_PROG"
- For Address T:
MD10717 \$MN_FCT_CYCLE_NAME = "T_SUB_PROG"
- For the M function for the tool change
MD10715 \$MN_M_NO_FCT_CYCLE[0] = 6
MD10716 \$MN_M_NO_FCT_CYCLE_NAME[0] = "M6_SUB_PROG"
MD10718 \$MN_M_NO_FCT_CYCLE_PAR = 0
MD22550 \$MC_TOOL_CHANGE_MODE = 1
MD22560 \$MC_TOOL_CHANGE_M_CODE = 6

Conflict resolution

The following table illustrates how the control system resolves the conflicts in case of multiple replacements:

The following are programmed in one part program line:			Called replacement subroutine:
D and/or DL	T	M6	
-	-	X	M6_SUB_PROG
-	X	-	T_SUB_PROG
-	X	X	M6_SUB_PROG
X	-	-	D_SUB_PROG
X	-	X	M6_SUB_PROG

The following are programmed in one part program line:			Called replacement subroutine:
D and/or DL	T	M6	
X	X	–	T_SUB_PROG
X	X	X	M6_SUB_PROG

9.14.4 Replacement of spindle-related functions

9.14.4.1 General

Function

In case of active synchronous spindle coupling, the following spindle-related functions can be replaced by a subroutine for the leading spindle of this coupling:

- Direct gear stage change with M41 to M45 and automatic gear stage change in case of speed programming with M40
- Spindle positioning with SPOS, SPOSA and M19

Conditions

- The replacement of a spindle-related function is executed only when:
 - the programmed spindle is active as leading spindle of a synchronous spindle coupling.
 - Leading and following spindle are present in the same channel.
 - in case of a gear-stage change actually a gear-stage change is present.
- Only one of the possible spindle-related function replacements can be executed in a part program line. Multiple replacements lead to the termination of the part program processing. If still several spindle-related functions have to be replaced, then the respective function calls must be distributed to several part program lines.

Configuration

Functions to be replaced

The spindle-related functions to be replaced through the subprogram are selected in the machine data:

MD30465 \$MA_AXIS_LANG_SUB_MASK

Bit	Description
0	Gear-stage change automatic (M40) and directly (M41-M45)
	= 0 No replacement
	= 1 Replacement through the subroutine set in MD15700 and MD15702
1	Spindle positioning with SPOS / SPOSA / M19
	= 0 No replacement
	= 1 Replacement through the subroutine set in MD15700 and MD15702

9.14 Replacement of NC functions by subprograms

Name of subprogram

The name of the subroutine, which is to replace the spindle-related function selected in MD30465, is to be entered in the machine data:

MD15700 \$MN_LANG_SUB_NAME (Name for the substitution subroutine)

Path to the subroutine

The path to the subroutine is set with the machine data:

MD15700 \$MN_LANG_SUB_NAME (call path for the substitution subroutine)

Value	Description
0	Path to the directory with the Manufacturer cycles: /_N_CMA_DIR (default setting)
1	Path to the directory with the User cycles: /_N_CUS_DIR
2	Path to the directory with the Siemens cycles: /_N_CST_DIR

Call time of the replacement subroutine

Call at block start

If the replacement subroutine is called at block start, then the part program line that led to the calling of the subroutine is processed after the subroutine is processed. The parts to be replaced from the replacement subroutine are not processed any more.

Call at block end

During call at block end, the part program line that lead to the calling of the subroutine is called first. The parts to be replaced in the replacement subroutine are processed. The subroutine is called finally.

Read activation time of the replacement subroutine

The \$P_SUB_STAT system variables can be used to define the time (block start / block end) when the replacement operation is executed:

Value	Description
0	Replacement subroutine is not active
1	Replacement subroutine is active, call at block start
2	Replacement subroutine is active, call at block end

9.14.4.2 Function replacement during gear-stage change

Function

If a gear-stage change is to be done for the leading spindle of an active synchronous spindle coupling and the replacement is configured through a subroutine (MD30465 \$MA_AXIS_LANG_SUB_MASK, Bit 0 = 1), then a replacement subroutine is called for the implementation of the gear-stage change.

The replacement subroutine handles the following tasks:

1. Resolve coupling
2. The gear stage change of the spindles involved in the coupling is executed
3. Close coupling again

Call time of the replacement subroutine

The call always takes place at the block start during automatic gear stage change with M40.

In case of programmed gear-stage change with M41 to M45 the time of the call depends on the output response of this auxiliary function to the PLC:

MD22080 \$MC_AUXFU_PREDEF_SPEC[12] (output specification for M41)

...

MD22080 \$MC_AUXFU_PREDEF_SPEC[16] (output specification for M45)

Bit	Value	Description
5	1	Output of the auxiliary function before the motion
6	1	Output of the auxiliary function during the motion
7	1	Output of the auxiliary function after the motion

In case of output **before or during** the motion the subroutine call is made at the **block start**. In case of output **after** the motion the subroutine call is made at the **block end**.

Data transfer to the replacement subroutine

The data required for the replacement can be read in the replacement subroutine through the following system variables:

System variable	Description
\$P_SUB_AXFCT	scan for replacement type Returns the value "1", if the replacement for the gear-stage change (M40, M41-M45) is used.
\$P_SUB_GEAR	Programmed gear stage Returns for each spindle the programmed or the calculated gear stage. Outside the replacement program, these variables deliver the gear stage of the leading spindle.

9.14 Replacement of NC functions by subprograms

System variable	Description
\$P_SUB_AUTOGEAR	Automatic gear stage change is active Delivery to a spindle-specific replacement the information whether an automatic gear stage change with M40 was active in the part program line that triggered the replacement operation. Outside the replacement operation, this variable delivers the current setting in the interpreter.
\$P_SUB_LA	Leading spindle of the active coupling Returns the axis identifier of the leading spindle of the active coupling, which had triggered the replacement operation. Tip: If the variable is called outside the replacement operation, the program processing is cancelled with an alarm.
\$P_SUB_CA	Following spindle of the active coupling Returns the axis identifier of the following spindle of the active coupling, which had triggered the replacement operation. Tip: If the variable is called outside the replacement operation, the program processing is cancelled with an alarm.

Example

Configuration

The replacement subroutine for the gear-stage change is activated:

MD30465 \$MA_AXIS_LANG_SUB_MASK[AX5] = 'H0001'

For the output of M41 to M45 to the PLC an output before the motion is configured:

MD22080 \$MC_AUXFU_PREDEF_SPEC[12] = 'H21'

MD22080 \$MC_AUXFU_PREDEF_SPEC[13] = 'H21'

MD22080 \$MC_AUXFU_PREDEF_SPEC[14] = 'H21'

MD22080 \$MC_AUXFU_PREDEF_SPEC[15] = 'H21'

MD22080 \$MC_AUXFU_PREDEF_SPEC[16] = 'H21'

Main program:

Programming	Comment
PROC MAIN	
...	
N110 COUPON(S2,S1)	; Activate synchronous spindle coupling

...	
N9999 RET	

9.14.4.3 Function replacement during spindle positioning

Function

When the leading spindle of an active synchronous coupling with SPOS, SPOSA or M19 is to be positioned and the replacement is configured through a subroutine (MD30465 \$MA_AXIS_LANG_SUB_MASK, Bit 1 = 1), then a replacement subroutine is called for the implementation of the positioning.

The replacement subroutine handles the following tasks:

1. Resolve coupling
2. The spindles involved in the coupling are positioned separately at the position specified by the leading spindle
3. Close coupling again

Application

Parallel processing of workpieces, e.g. in double-spindle machine. The spindles in such a machine are coupled with the help of a coupling factor not equal to one and must, e.g. be positioned at the same position due to a tool change. If the coupling is separated earlier, then each spindle can be positioned at the tool change position separately.

Call time of the replacement subroutine

The call of the replacement subroutine during spindle positioning with SPOS or SPOSA always takes place at the block start.

In the programming of M19 the call time depends on the output response of this auxiliary function to the PLC:

MD22080 \$MC_AUXFU_PREDEF_SPEC[9] (output specification for M19)

Bit	Value	Description
5	1	Output of the auxiliary function before the motion
6	1	Output of the auxiliary function during the motion
7	1	Output of the auxiliary function after the motion

In case of output **before or during** the motion the subroutine call is made at the **block start**. In case of output **after** the motion the subroutine call is made at the **block end**.

Data transfer to the replacement subroutine

The data required for the replacement can be read in the replacement subroutine through the following system variables:

System variable	Description
\$P_SUB_AXFCT	scan for replacement type Returns the value "2", when the replacement for spindle positioning is active.
\$P_SUB_SPOS	Scan whether spindle positioning with SPOS is active Returns TRUE, when the replacement is activated through SPOS.
\$P_SUB_SPOSA	San whether spindle positioning with SPOSA is active Returns TRUE, when the replacement is activated through SPOSA.
\$P_SUB_M19	Scan whether spindle positioning with M19 is active Returns TRUE, when the replacement is activated through M19.
\$P_SUB_SPOSIT	SPOS / SPOSA -Position Returns the programmed position. Tip: If the variable is called outside the replacement operation, the program processing is cancelled with an alarm.
\$P_SUB_SPOSMODE	position approach mode Returns the position approach mode for the spindle position returned by \$P_SUB_SPOSIT:
	= 0 No change of the position approach mode
	= 1 AC
	= 2 IC
	= 3 DC
	= 4 ACP
	= 5 ACN
	= 6 OC
	= 7 PC
Tip: If the variable is called outside the replacement operation, the program processing is cancelled with an alarm.	
\$P_SUB_LA	Leading spindle of the active coupling Returns the axis identifier of the leading spindle of the active coupling, which had triggered the replacement operation. Tip: If the variable is called outside the replacement operation, the program processing is cancelled with an alarm.
\$P_SUB_CA	Following spindle of the active coupling Returns the axis identifier of the following spindle of the active coupling, which had triggered the replacement operation. Tip: If the variable is called outside the replacement operation, the program processing is cancelled with an alarm.

Example

Configuration

The replacement subroutine for the spindle positioning is activated:

```
MD30465 $MA_AXIS_LANG_SUB_MASK[AX5]='H0002'
```

For the output of M19 to the PLC an output before the motion is configured:

```
MD22080 $MC_AUXFU_PREDEF_SPEC[9]='H0021'
```

For spindle positioning with M19 the spindle position "260" is configured:

```
SD43240 $SA_M19_SPOS[AX5]=260
```

For the position approach mode during spindle positioning with M19 "Approach in positive direction (ACP)" is configured:

```
SD43250 $SA_M19_SPOSMODE[AX5]=4
```

Main program:

Programming	Comment
PROC MAIN	
...	
N110 COUPON(S2,S1)	; Activate synchronous spindle coupling
N220 SPOS[1]=100	; Position leading spindle with SPOS
...	
N310 G01 F1000 X100 M19	; Position leading spindle with M19

Replacement subroutine _N_LANG_SUB_SPF, Variant 1:

This programming example is optimized for simplicity and speed. The spindles are thus addressed directly (typically the machine manufacturer would know, which following Spindle(s) are affected during spindle positioning and address these spindles directly). In the example S1 is the leading spindle and S2 is the following spindle.

The SPOS and SPOSA commands are handled in common in the replacement subroutine. In other words SPOSA is mapped to the SPOS command.

N9999 RET	

9.14.4.4 Sequence

The sequence of replacement of a spindle-related function depends on the replacement type (gear-stage change or spindle positioning) and on the time of call of the replacement subroutine (block start or block end).

The most important options are described in more detail below:

Sequence of a replacement program for a gear stage change at block start

The leading spindle is located in an active synchronous spindle coupling and an automatic (M40 S...) or a gear stage change programmed with M41 to M45 is determined during the interpretation of a part program line.

1. Call the replacement subroutine

The replacement subroutine set using MD15702 \$MN_LANG_SUB_PATH (call path) MD15700 \$MN_LANG_SUB_NAME is called.

The system variable \$P_SUB_AXFCT returns the value "1":

⇒ Replacement for gear-stage change is active.

The system variable \$P_SUB_STAT returns the value "1":

⇒ Replacement subroutine is active, call at block start.

2. Transfer of the required data in the replacement subroutine

With the system variable \$P_SUB_GEAR the programmed gear stage M41 to M45 or during automatic gear-stage change (M40 S...) the calculated gear-stage is scanned in the replacement subroutine.

The system variable \$P_SUB_LA delivers the axis identifier of the leading spindle and \$P_SUB_CA delivers the axis identifier of the first following spindle involved in the coupling.

3. Resolve coupling, gear-stage change of the spindles involved in the coupling

The coupling is disabled and the gear-stage change is done separately for the leading and following spindles involved in the coupling.

4. Close coupling again and continue the part program

Then the coupling is closed again.

After the replacement subroutine has been executed, the part program line that controlled the call of the subroutine is interpreted. Thus, the *s* value that lead to calling the replacement subroutine during automatic gear stage change is now active too. In this case, the automatic gear stage change *M40* too is restored again. The gear stage request *M41-M45* is no longer processed.

Sequence of a replacement program for a gear stage change at block end

The part program line that leads to calling the replacement subroutine is executed first, **without** the gear stage change. The replacement subroutine is called finally.

The system variable `$P_SUB_STAT` returns the value "2":

⇒ Replacement subroutine is active, call at block end.

The further sequence corresponds to the sequence of a replacement program for a gear-stage change at block start.

Sequence of a replacement program for spindle positioning at the block start

The leading spindle is located in an active synchronous spindle coupling and the leading spindle is positioned while interpreting a part program line with *SPOS*, *SPOSA* or *M19*.

1. Call the replacement subroutine

The replacement subroutine set using MD15702 `$MN_LANG_SUB_PATH` (call path) MD15700 `$MN_LANG_SUB_NAME` is called.

The system variable `$P_SUB_AXFCT` returns the value "2":

⇒ Replacement for spindle-positioning is active.

The system variable `$P_SUB_STAT` returns the value "1":

⇒ Replacement subroutine is active, call at block start.

2. Transfer of the required data in the replacement subroutine

With the system variables `$P_SUB_SPOS`, `$P_SUB_SPOSA` or `$P_SUB_M19` the positioning command to be replaced can be determined.

The system variables `$P_SUBPOSIT` and `$P_SUBPOS MODE` are used to query the travel position and the position approach mode that must be used.

The system variable `$P_SUB_LA` delivers the axis identifier of the leading spindle and `$P_SUB_CA` delivers the axis identifier of the first following spindle involved in the coupling.

3. Resolve coupling, positioning of the spindles involved in the coupling

The coupling is disabled and the leading and the following spindles involved in the coupling are positioned accordingly.

4. Close coupling again and continue the part program

Then the coupling is closed again.

After the replacement subroutine has been executed, the part program line that controlled the call of the subroutine is interpreted. In this case the `SPOS`, `SPOSA` or `M19` command used to trigger the replacement is no longer processed.

Sequence of a replacement program for a spindle positioning with M19 at block end

The part program line that leads to calling the replacement subroutine is executed first, **without** the spindle positioning.

The system variable `$P_SUB_STAT` returns the value "2":

⇒ Replacement subroutine is active, call at block end.

The further sequence corresponds to the sequence of a replacement program for spindle positioning at block start.

9.14.5 Properties of replacement subroutines

General rules

- Like any other subroutine, a replacement subroutine can contain a `PROC` statement.
- Replacement subroutines can also be called from the ISO-Dialect mode. The processing of the replacement subroutine is basically done in Siemens standard mode. The return shifts the control back to the language mode.
- No transfer parameters can be defined. The transfer of data to the replacement subroutine always occurs via a system variable.
- The `PROC` statement enables program attributes such as `SBLOF` and `DISPLOF` to be programmed.

- The behavior in case of active single block and programmed `SBLOF` attribute depends on the setting of bit 14 in the machine data:

MD10702 IGNORE_SINGLEBLOCK_MASK (Prevent single block stop)

Bit 14 = 0:

The replacement subroutine behaves like any other subroutine:

- Return jump with `M17`: Stop at the end of the subprogram

Note:

The output of the M function at the PLC depends on the setting of bit 0 in the machine data:

MD20800 \$MC_SPF_END_TO_VDI (subprogram end to PLC)

Bit 0 = 0: no output

Bit 0 = 1: `M17` is output to the PLC.

- Return jump with `RET`: No stop at end of subprogram

Bit 14 = 1:

In a part program line, in which a replacement subroutine is called, **stop is done only once**. Thereby it is not important, whether:

- the replacement subroutine was called at the block start and/or at the block end.
- from the replacement subroutine further subroutines were called.
- the replacement subroutine was exited with `M17` or `RET`.

The single block stop takes place for the replacement of M functions at the end of the replacement subroutine. For the replacement of T functions and D/DL functions the time of the single block stop depends on the call time of the replacement subroutine:

Call at block start ⇒ single block stop at the end of the part program line

Call at block end ⇒ single block stop at the end of the replacement subroutine

- If the replacement subroutine has the `DISPLOF` attribute, the program line that has resulted in the replacement subroutine call is displayed as the current block in the block display.
- With `DELAYFSTON` and `DELAYFSTOF` areas or even the entire replacement subroutine can be protected against interruptions, such as NC stop, read-in disable, etc.
- Replacements do not occur recursively, i.e. the function that has led to the replacement subroutine call is no longer replaced if it is programmed again in the replacement subroutine.

Output of auxiliary functions to PLC

In the case of replacements that are called due to programmed auxiliary functions, the replacement subroutine call does not result in any output of the auxiliary function to the PLC. The auxiliary function is only output if it is programmed again in the replacement cycle.

Block-search response

The replacement subroutines are executed as in the normal program mode in case of block search with calculation and SERUPRO.

9.14.6 Restrictions

For using the function "Replacement of NC functions through subroutines" the following boundary conditions must be noted:

- Replacements in synchronized actions are not permitted
- Replacements in technology cycles are not permitted
- A part program line that contains language constructs to be replaced at the block start may not be placed in front of any block-wise synchronized actions.
- Spindle-related replacements are executed only if the programmed spindle is the leading spindle of an active synchronous spindle coupling. It is detected by the system only if the leading spindle is located in the channel in which the coupling was closed. If the leading spindle is changed to another channel, then a gear stage change or a repositioning of this spindle does not lead to the desired call in the replacement cycle.
- Only the actions required for the respective replacements can be performed in the replacement cycle.
- in a part program block in which a replacement subroutine is called at the block end, no:
 - modular subroutine call should be active
 - subroutine return should be programmed.
 - part program end should be programmed.

 CAUTION
--

The system does not monitor whether the user actually replaces the respective function in the replacement cycle. Therefore, if the user fails to implement this correctly, the actual intended function can be omitted.

9.15 Program runtime / Part counter

Information on the program runtime and workpiece counter are provided to support the machine tool operator.

This information can be processed as system variables in the NC and/or PLC program. This information is also available to be displayed on the operator interface.

9.15.1 Program runtime

Function

The "program runtime" function provides internal NC timers to monitor technological processes, which can be read into the part program and into synchronized actions via the NC and channel-specific system variables.

Time since the last control power-up

The timers for measuring the time since the last control power-up are always active and can be read via NC-specific system variables:

System variable	Meaning
\$AN_SETUP_TIME	Time since the last control power-up with default values ("cold restart") in minutes. Is automatically reset to "0" in each control power-up with default values.
\$AN_POWERON_TIME	Time since the last normal control power-up ("warm restart") in minutes. Is automatically reset to "0" in each normal control power-up.

Program runtimes

The timers for measuring the program runtimes are:

- only available in the AUTOMATIC operating mode.
- can be read via channel-specific system variables.

Some of the timers are always active, others can be activated / deactivated through MD parameterization.

The following system variables are available for the timers that are always active:

System variable	Meaning
\$AC_ACT_PROG_NET_TIME	<p>Actual net runtime of the current program in seconds</p> <p>Net runtime means that the time, in which the program was stopped, has been deducted.</p> <p>If, in the AUTOMATIC operating mode, a part program is restarted from the RESET channel state, then \$AC_ACT_PROG_NET_TIME is automatically reset to "0".</p> <p>Additional properties:</p> <ul style="list-style-type: none"> • The reset button does not reset \$AC_ACT_PROG_NET_TIME back to "0" but only stops the timer. • When starting an ASUB, \$AC_ACT_PROG_NET_TIME is set to "0" and also counts the runtime of the ASUB. At the end of an ASUB, it behaves just the same as for the RESET button: The timer is only held, but is not set to "0". • \$AC_ACT_PROG_NET_TIME is not reset when starting an event-controlled program (PROG_EVENT). <p>The program runtime is only counted further if it involves a start, M30 or a search PROG_EVENT.</p> <ul style="list-style-type: none"> • The behavior of \$AC_ACT_PROG_NET_TIME for GOTOS and override = 0% can be parameterized using MD27850 (refer to Section "Parameter assignment") <p>Tip: With \$AC_PROG_NET_TIME_TRIGGER, \$AC_ACT_PROG_NET_TIME can be manipulated further.</p>
\$AC_OLD_PROG_NET_TIME	<p>Net runtime in seconds of the program that has just been correctly ended "Correctly ended" means that the program was not interrupted with RESET, but instead ended properly with M30.)</p> <p>If a new program is started, \$AC_OLD_PROG_NET_TIME remains unscanned, till M30 is reached again.</p> <p>Additional properties:</p> <ul style="list-style-type: none"> • \$AC_OLD_PROG_NET_TIME is set to "0" if the currently selected program is edited. • \$AC_OLD_PROG_NET_TIME is not changed at the end of an ASUB or an event-controlled program (PROG_EVENT). <p>Tip: The implied copying process of \$AC_ACT_PROG_NET_TIME after \$AC_OLD_PROG_NET_TIME takes place only when \$AC_PROG_NET_TIME_TRIGGER is not written.</p>
\$AC_OLD_PROG_NET_TIME_COUNT	<p>Changes to \$AC_OLD_PROG_NET_TIME</p> <p>After POWER ON, \$AC_OLD_PROG_NET_TIME_COUNT is at "0".</p> <p>\$AC_OLD_PROG_NET_TIME_COUNT is always increased if the control has newly written to \$AC_OLD_PROG_NET_TIME.</p> <p>If the user terminates the running program with RESET, \$AC_OLD_PROG_NET_TIME and \$AC_OLD_PROG_NET_TIME_COUNT remain unchanged.</p> <p>With \$AC_OLD_PROG_NET_TIME_COUNT it can thus be ascertained, whether \$AC_OLD_PROG_NET_TIME was written.</p> <p>Example: If two programs running consecutively have the same runtime and were ended correctly, then the user can identify this via the changed value in \$AC_OLD_PROG_NET_TIME_COUNT.</p>

System variable	Meaning
\$AC_PROG_NET_TIME_TRIGGER	<p>Trigger for the runtime measurement</p> <p>Used for selective measurement of program sections i.e. by writing \$AC_PROG_NET_TIME_TRIGGER in the NC program the time measurement can be enabled and disabled again:</p> <ol style="list-style-type: none"> 1. \$AC_PROG_NET_TIME_TRIGGER = 2 starts the measurement and in so doing sets \$AC_ACT_PROG_NET_TIME to "0". 2. \$AC_PROG_NET_TIME_TRIGGER = 1 ends the measurement and copies the value from \$AC_ACT_PROG_NET_TIME into \$AC_OLD_PROG_NET_TIME. <p>In order to exploit all trigger options, specific values for \$AC_PROG_NET_TIME_TRIGGER are filled with special functions:</p>
0	<p>Neutral state</p> <p>The trigger is not active.</p>
1	<p>Exit</p> <p>Ends the measurement and copies the value from \$AC_ACT_PROG_NET_TIME into \$AC_OLD_PROG_NET_TIME. \$AC_ACT_PROG_NET_TIME is set to "0" and then continues to run.</p>
2	<p>Start</p> <p>Starts the measurement and in so doing sets \$AC_ACT_PROG_NET_TIME to "0". \$AC_OLD_PROG_NET_TIME is not changed.</p>
3	<p>Stop</p> <p>Stops the measurement. Does not change \$AC_OLD_PROG_NET_TIME and keeps \$AC_ACT_PROG_NET_TIME constant until it resumes</p>
4	<p>Resume</p> <p>The measurement is resumed, i.e. a measurement that was previously stopped is continued. \$AC_ACT_PROG_NET_TIME continues to run. \$AC_OLD_PROG_NET_TIME is not changed.</p>
All system variables are reset to 0 as a result of POWER ON!	

Note**Residual time for a workpiece**

If the same workpieces are produced one after the other, then from the timer values:

- Processing time for the last workpiece produced (see \$AC_OLD_PROG_NET_TIME)
- and
- current processing time (see \$AC_ACT_PROG_NET_TIME)

the remaining residual time for a workpiece can be determined.

The residual time is displayed on the operator interface in addition to the current processing time.

NOTICE

Using STOPRE

The system variables \$AC_OLD_PROG_NET_TIME and \$AC_OLD_PROG_NET_TIME_COUNT do not generate any implicit preprocessing stop. This is uncritical when used in the part program if the value of the system variables comes from the previous program run. However, if the trigger for the runtime measurement (\$AC_PROG_NET_TIME_TRIGGER) is written very frequently and as a result \$AC_OLD_PROG_NET_TIME changes very frequently, then an explicit STOPRE should be used in the part program.

The following system variables are available for the timers that are activated / deactivated through MD parameterization:

System variable	Meaning
\$AC_OPERATING_TIME	<p>Total runtime of NC programs in Automatic mode (in s)</p> <p>In the automatic mode, the runtimes of all programs between NC start and end of program / reset are summed up.</p> <p>The default is not to count in NC STOP and override = 0%. Continued counting can be activated at an override of 0% via MD27860.</p> <p>The value is automatically reset to "0" every time the control powers up.</p>
\$AC_CYCLE_TIME	<p>Runtime of the selected NC program (in seconds)</p> <p>The runtime between NC Start and End of program / NC-Reset is measured in the selected NC program.</p> <p>The default is not to count in NC STOP and override = 0%. Continued counting can be activated at an override of 0% via MD27860.</p> <p>The value is automatically reset to "0" every time a new NC program starts up. MD27860 can be set to ensure that this value will be deleted even if there is a jump to the beginning of the program with GOTOS or in the event of ASUBs and PROG_EVENTS starting.</p>
\$AC_CUTTING_TIME	<p>Processing time in seconds</p> <p>The runtime of the path axes (at least one is active) is measured in all NC programs between NC start and end of program/NC reset without rapid traverse active. MD27860 can be used to set whether measuring should only be conducted when the tool is active or independent of the tool state.</p> <p>The measurement is interrupted when a dwell time is active.</p> <p>The value is automatically reset to "0" every time the control powers up with default values.</p>

Activation/deactivation

The timer that can be activated is switched-in/switched-out using machine data:

MD27860 \$MC_PROCESSTIMER_MODE, Bit 0-2

Bit	Value	Meaning
0	0	Timer for \$AC_OPERATING_TIME not active.
	1	Timer for \$AC_OPERATING_TIME active.
1	0	Timer for \$AC_CYCLE_TIME not active.
	1	Timer for \$AC_CYCLE_TIME active.
2	0	Timer for \$AC_CUTTING_TIME not active.
	1	Timer for \$AC_CUTTING_TIME active.

Parameter assignment

Behavior of the timer that is always active

The behavior of the timer that is always active for GOTOS and override = 0% is set using machine data:

MD27850 \$MC_PROG_NET_TIMER_MODE

Bit	Value	Meaning
0	0	\$AC_ACT_PROG_NET_TIME is not reset to "0" in case of a jump with GOTOS to the program start (initial setting).
	1	With a jump with GOTOS to the start of the program, \$AC_ACT_PROG_NET_TIME is reset to "0", the value is first saved in \$AC_OLD_PROG_NET_TIME and the program counter \$AC_OLD_PROG_NET_TIME_COUNT is incremented.
1	0	For override = 0%, \$AC_ACT_PROG_NET_TIME is not increased. This means that the program runtime is measured without the time for which the override was set to "0" (basic setting).
	1	Also for override = 0%, \$AC_ACT_PROG_NET_TIME is increased. This means that the program runtime is measured with the time for which the override was set to "0".

Behavior of the timer that can be activated

The behavior of the timer that can be activated for certain functions (e.g. test run feedrate, program test) is set using machine data:

MD27860 \$MC_PROCESSTIMER_MODE

Bit	Value	Meaning
4	0	No measurement during active dry run feedrate.
	1	Measurement during active dry run feedrate.
5	0	No measurement during program test.
	1	Measurement during program test.
6	Only for bit 1 = 1 (timer for \$AC_CYCLE_TIME is active)	
	0	\$AC_CYCLE_TIME is reset to "0" also in case of Start through ASUB and PROG_EVENTS.
	1	\$AC_CYCLE_TIME is not reset to "0" in case of Start through ASUB and PROG_EVENTS.

Bit	Value	Meaning
7		Only for bit 2 = 1 (timer for \$AC_CUTTING_TIME is active)
	0	Timer for \$AC_CUTTING_TIME counts only for the active tool.
	1	Timer for \$AC_CUTTING_TIME counts independent of the tool.
8		Only for bit 1 = 1 (timer for \$AC_CYCLE_TIME is active)
	0	\$AC_CYCLE_TIME is not reset to "0" in case of a jump with GOTOS to the program start.
	1	\$AC_CYCLE_TIME is reset to "0" in case of a jump with GOTOS to the program start.
9		Only for bit 0, 1 = 1 (timer for \$AC_OPERATING_TIME and \$AC_CYCLE_TIME are active)
	0	Counting of the program runtime is not continued at an override of 0%.
	1	Counting of the program runtime continues at an override of 0%.

Boundary conditions

- **Block search**
No program runtimes are determined through block searches.
- **REPOS**
The duration of a REPOS process is added to the current processing time (\$AC_ACT_PROG_NET_TIME).

Examples

Example 1: Parameterization of the runtime measurement via MD27860

- Activating the runtime measurement for the active NC program and hence no measurement in case of active dry run feedrate and program test:
MD27860 \$MC_PROCESSTIMER_MODE = 'H2'
- Activating the measurement for the tool action time and measurement also with active dry run feedrate and program test.
MD27860 \$MC_PROCESSTIMER_MODE = 'H34'
- Activating the measurement for the total runtime and the processing time with an active tool, including measurement with a program test:
MD27860 \$MC_PROCESSTIMER_MODE = 'H25'
- Activating the measurement for the total runtime and the machining time (independent of the tool), including measurement with a program test:
MD27860 \$MC_PROCESSTIMER_MODE = 'Ha5'
- Activating the measurement for the processing time with an active tool, including measurements at an override = 0%, but not with a trial run feed active:
MD27860 \$MC_PROCESSTIMER_MODE = 'H22'

Example 2: Measuring the duration of "mySubProgrammA"

Program code

```
...  
N50 DO $AC_PROG_NET_TIME_TRIGGER=2  
N60 FOR ii= 0 TO 300  
N70 mySubProgrammA  
N80 DO $AC_PROG_NET_TIME_TRIGGER=1  
N95 ENDFOR  
N97 mySubProgrammB  
N98 M30
```

After the program has processed line N80, the net runtime of "mySubProgrammA" is located in \$AC_OLD_PROG_NET_TIME.

The value from \$AC_OLD_PROG_NET_TIME:

- is kept beyond M30.
- is updated each time the loop is run through.

Example 3: Measuring the duration of "mySubProgrammA" and "mySubProgrammC"

Program code

```
N10 DO $AC_PROG_NET_TIME_TRIGGER=2  
N20 mySubProgrammA  
N30 DO $AC_PROG_NET_TIME_TRIGGER=3  
N40 mySubProgrammB  
N50 DO $AC_PROG_NET_TIME_TRIGGER=4  
N60 mySubProgrammC  
N70 DO $AC_PROG_NET_TIME_TRIGGER=1  
N80 mySubProgrammD  
N90 M30
```

9.15.2 Workpiece counter

Function

The "Workpiece counter" function makes available various counters which can be used in particular internally in the control to count workpieces.

The counters exist as channel-specific system variables with read and write access in a range of values from 0 to 999,999.999.

Channel-specific machine data can be used to control counter activation, counter reset timing and the counting algorithm.

System variables for workpiece counting

System variable	Description
\$AC_REQUIRED_PARTS	Number of the workpieces to be produced (setpoint number of workpieces) In this counter the number of workpieces at which the actual workpiece count (\$AC_ACTUAL_PARTS) will be reset to "0" can be defined. MD27880 can be used to activate the generation of the display alarm: "Channel %1 workpiece target = %2 reached" and of the channel-specific NC/PLC interface signal: DB21, DBX317.2 (workpiece target reached).
\$AC_TOTAL_PARTS	Number of completed workpieces in total (actual workpiece total) This counter specifies the total number of all workpieces produced since the start time. The value is only automatically reset to "0" when the control powers up with default values.
\$AC_ACTUAL_PARTS	Number of completed workpieces (actual workpiece total) This counter registers the total number of all workpieces produced since the start time. On condition that \$AC_REQUIRED_PARTS > 0, the counter is automatically reset to "0" when the required number of workpieces (\$AC_REQUIRED_PARTS) is reached.
\$AC_SPECIAL_PARTS	Number of workpieces selected by the user This counter supports user-specific workpiece counts. An alarm can be defined to be output when the setpoint number of workpieces is reached (\$AC_REQUIRED_PARTS). Users must reset the counter themselves.

Note

All workpiece counters are set to "0" when the control powers up with default values and can be read and written independent of their activation.

Activation

The workpiece counter is activated with the machine data:

MD27880 \$MC_PART_COUNTER (activation of workpiece counters)

Bit	Value	Significance
0	1	\$AC_REQUIRED_PARTS is active
1	0	Alarm / signal output in case of: \$AC_ACTUAL_PARTS = \$AC_REQUIRED_PARTS
	1	Alarm / signal output in case of: \$AC_SPECIAL_PARTS = \$AC_REQUIRED_PARTS
4	1	\$AC_TOTAL_PARTS is active.
5	0	\$AC_TOTAL_PARTS is increased by the value "1" through M02 / M30.
	1	\$AC_TOTAL_PARTS is incremented by the value "1" through the M command defined with MD27882[0].
6	0	\$AC_TOTAL_PARTS is also active for program test / block search.

Bit	Value	Significance
7	1	\$AC_TOTAL_PARTS is incremented by the value "1" upon a jump back with GOTOS.
8	1	\$AC_ACTUAL_PARTS is active
9	0	\$AC_ACTUAL_PARTS is increased by the value "1" through M02 / M30.
	1	\$AC_ACTUAL_PARTS is incremented by the value "1" through the M command defined with MD27882[1].
10	0	\$AC_ACTUAL_PARTS is also active for program test / block search.
11	1	\$AC_ACTUAL_PARTS is incremented by the value "1" upon a jump back with GOTOS.
12	1	\$AC_SPECIAL_PARTS is active.
13	0	\$AC_SPECIAL_PARTS is increased by the value "1" through M02 / M30.
	1	\$AC_SPECIAL_PARTS is incremented by the value 1 through the M command defined with MD27882[2].
14	0	\$AC_SPECIAL_PARTS is also active for program test / block search.
15	1	\$AC_SPECIAL_PARTS is incremented by the value "1" upon a jump back with GOTOS.

Workpiece counting with user-defined M command

If the corresponding bit is set in MD27880, then the count pulse can be triggered via a user-defined M command instead of via the end of program M2/M30.

The M command code is defined with the machine data:

MD27882 \$MC_PART_COUNTER_MCODE[<n>] (workpiece counting with user-defined M command)

<n>	Significance
0	MD27882[0] defines the M command code, in which \$AC_TOTAL_PARTS is incremented.
1	MD27882[1] defines the M command code, in which \$AC_ACTUAL_PARTS is incremented.
2	MD27882[2] defines the M command code, in which \$AC_SPECIAL_PARTS is incremented.

The respective workpiece counter is incremented by "1", when a user-defined M command is called.

Boundary conditions

- **Mode change / NC RESET**

The counters are not affected by a mode change or NC RESET.

- **\$AC_REQUIRED_PARTS ≤ 0**

Where $\$AC_REQUIRED_PARTS \leq 0$ and MD27880 \$MC_PART_COUNTER bit 0 = 1, the counting procedure and the identity comparison set with MD27880 are **not** conducted for all the activated counters.

Examples

- **Activation of the workpiece counter \$AC_REQUIRED_PARTS:**
MD27880 \$MC_PART_COUNTER = 'H3'
 - \$AC_REQUIRED_PARTS is active
 - Display alarm at: \$AC_REQUIRED_PARTS == \$AC_SPECIAL_PARTS
- **Activation of the workpiece counter \$AC_TOTAL_PARTS:**
MD27880 \$MC_PART_COUNTER = 'H10'
MD27882 \$MC_PART_COUNTER_MCODE[0] = 80
 - \$AC_TOTAL_PARTS is active; the counter is incremented by the value 1 with each M02.
 - \$MC_PART_COUNTER_MCODE[0] has no significance.
- **Activation of the workpiece counter \$AC_ACTUAL_PARTS:**
MD27880 \$MC_PART_COUNTER = 'H300'
MD27882 \$MC_PART_COUNTER_MCODE[1] = 17
 - \$AC_ACTUAL_PARTS is active; the counter is incremented by a value of "1" with each M17.
- **Activation of the workpiece counter \$AC_SPECIAL_PARTS:**
MD27880 \$MC_PART_COUNTER = 'H3000'
MD27882 \$MC_PART_COUNTER_MCODE[2] = 77
 - \$AC_SPECIAL_PARTS is active.
 - The following takes place with every M77: \$AC_SPECIAL_PARTS + 1
- **Deactivation of the workpiece counter \$AC_ACTUAL_PARTS:**
MD27880 \$MC_PART_COUNTER = 'H200'
MD27882 \$MC_PART_COUNTER_MCODE[1] = 50
 - \$AC_ACTUAL_PARTS is inactive

- **Activation of all counters:**

- ```
MD27880 $MC_PART_COUNTER = 'H3313'
```
- ```
MD27882 $MC_PART_COUNTER_MCODE[0] = 80
```
- ```
MD27882 $MC_PART_COUNTER_MCODE[1] = 17
```
- ```
MD27882 $MC_PART_COUNTER_MCODE[2] = 77
```
- \$AC_REQUIRED_PARTS is active
 - Display alarm at: \$AC_REQUIRED_PARTS == \$AC_SPECIAL_PARTS
 - \$AC_TOTAL_PARTS is active; the counter is incremented by the value 1 with each M02.
 - \$MC_PART_COUNTER_MCODE[0] has no significance.
 - \$AC_ACTUAL_PARTS is active; the counter is incremented by a value of "1" with each M17.
 - \$AC_SPECIAL_PARTS is active; the counter is incremented by a value of "1" with each M77.

- **Workpiece counter \$AC_ACTUAL_PARTS is not processed during the program test/block search:**

- ```
MD27880 $MC_PART_COUNTER = 'H700'
```
- ```
MD27882 $MC_PART_COUNTER_MCODE[1] = 75
```
- \$AC_ACTUAL_PARTS is active; the counter is incremented by a value of "1" with each M75, apart from during the program test and search.

- **Cancellation of the count modes in the MD27880 \$MC_PART_COUNTER with bit 0 = 1:**

- ```
MD27882 $MC_PART_COUNTER_MCODE[0] = 41
```
- ```
MD27882 $MC_PART_COUNTER_MCODE[1] = 42
```
- ```
MD27882 $MC_PART_COUNTER_MCODE[2] = 43
```

## 9.16 Data lists

### 9.16.1 Machine data

#### 9.16.1.1 General machine data

##### Displaying machine data

| Number                   | Identifier: \$MM_      | Description                       |
|--------------------------|------------------------|-----------------------------------|
| <b>SINUMERIK Operate</b> |                        |                                   |
| 9421                     | MA_AXES_SHOW_GEO_FIRST | Display geo axes of channel first |
| 9422                     | MA_PRESET_MODE         | PRESET / basic offset in JOG.     |
| 9423                     | MA_MAX_SKP_LEVEL       | Maximum number of skip levels     |

##### NC-specific machine data

| Number | Identifier: \$MN_         | Description                                                                          |
|--------|---------------------------|--------------------------------------------------------------------------------------|
| 10010  | ASSIGN_CHAN_TO_MODE_GROUP | Channel valid in mode group                                                          |
| 10280  | PROG_FUNCTION_MASK        | Comparison commands ">" and "<"                                                      |
| 10700  | PREPROCESSING_LEVEL       | Program preprocessing level                                                          |
| 10702  | IGNORE_SINGLEBLOCK_MASK   | Prevent single-block stop                                                            |
| 10707  | PROG_TEST_MASK            | Program test modes                                                                   |
| 10708  | SERUPRO_MASK              | Block change modes                                                                   |
| 10710  | PROG_SD_RESET_SAVE_TAB    | Setting data to be updated                                                           |
| 10711  | NC_LANGUAGE_CONFIGURATION | Manner of handling the languages, whose related option or function is not activated. |
| 10713  | M_NO_FCT_STOPRE           | M function with preprocessing stop                                                   |
| 10715  | M_NO_FCT_CYCLE            | M function to be replaced by subroutine                                              |
| 10716  | M_NO_FCT_CYCLE_NAME       | Subroutine name for M function replacement                                           |
| 10717  | T_NO_FCT_CYCLE_NAME       | Name of the tool change cycle for T function replacement                             |
| 10718  | M_NO_FCT_CYCLE_PAR        | M function replacement with parameters                                               |
| 10719  | T_NO_FCT_CYCLE_MODE       | Parameter assignment for T function replacement                                      |
| 11450  | SEARCH_RUN_MODE           | Block search parameter settings                                                      |
| 11470  | REPOS_MODE_MASK           | Repositioning properties                                                             |
| 11600  | BAG_MASK                  | Mode group response to ASUB                                                          |
| 11602  | ASUP_START_MASK           | Ignore stop conditions for ASUB                                                      |
| 11604  | ASUP_START_PRIO_LEVEL     | Priorities, starting from which \$MN_ASUP_START_MASK is effective                    |

| Number | Identifier: \$MN_          | Description                                                                 |
|--------|----------------------------|-----------------------------------------------------------------------------|
| 11610  | ASUP_EDITABLE              | Activating a user-specific ASUB program                                     |
| 11612  | ASUP_EDIT_PROTECTION_LEVEL | Protection level of user-specific ASUB program                              |
| 11620  | PROG_EVENT_NAME            | Program name for PROG_EVENT                                                 |
| 11717  | D_NO_FCT_CYCLE_NAME        | Subroutine name for D function replacement                                  |
| 15700  | LANG_SUB_NAME              | Name for replacement subroutine                                             |
| 15702  | LANG_SUB_PATH              | Call path for replacement subroutine                                        |
| 17200  | GMMC_INFO_NO_UNIT          | Global HMI info (without physical unit)                                     |
| 17201  | GMMC_INFO_NO_UNIT_STATUS   | Global HMI status info (without physical unit)                              |
| 18360  | MM_EXT_PROG_BUFFER_SIZE    | FIFO buffer size for execution from external source (DRAM)                  |
| 18362  | MM_EXT_PROG_NUM            | Number of program levels that can be processed simultaneously from external |

### 9.16.1.2 Channel-specific machine data

#### Basic machine data

| Number | Identifier: \$MC_          | Description                                                                 |
|--------|----------------------------|-----------------------------------------------------------------------------|
| 20000  | CHAN_NAME                  | Channel name                                                                |
| 20050  | AXCONF_GEOAX_ASSIGN_TAB    | Assignment of geometry axis to channel axis                                 |
| 20060  | AXCONF_GEOAX_NAME_TAB      | Geometry axis name in channel                                               |
| 20070  | AXCONF_MACHAX_USED         | Machine axis number valid in channel                                        |
| 20080  | AXCONF_CHANAX_NAME_TAB     | Channel axis name in channel [channel axis no.]: 0...7                      |
| 20090  | SPIND_DEF_MASTER_SPIND     | Initial setting of master spindle in channel                                |
| 20100  | DIAMETER_AX_DEF            | Geometry axis with transverse axis function                                 |
| 20106  | PROG_EVENT_IGN_SINGLEBLOCK | Prog events ignore the single block                                         |
| 20107  | PROG_EVENT_IGN_INHIBIT     | Prog events ignore the read-in disable                                      |
| 20108  | PROG_EVENT_MASK            | Event-driven program calls                                                  |
| 20109  | PROG_EVENT_MASK_PROPERTIES | Prog events properties                                                      |
| 20114  | MODESWITCH_MASK            | Setting for REPOS                                                           |
| 20116  | IGNORE_INHIBIT_ASUP        | Execute user ASUBs completely in spite of read-in disable                   |
| 20117  | IGNORE_SINGLEBLOCK_ASUP    | Process user ASUBs completely in spite of single-block processing           |
| 20160  | CUBIC_SPLINE_BLOCKS        | Number of blocks for C spline                                               |
| 20170  | COMPRESS_BLOCK_PATH_LIMIT  | Maximum traversing length of NC block for compression                       |
| 20191  | IGN_PROG_STATE_ASUP        | Do not display the execution of the interrupt routine on the operator panel |
| 20192  | PROG_EVENT_IGN_PROG_STATE  | Do not display the execution of the program events on the operator panel    |

9.16 Data lists

| Number | Identifier: \$MC_          | Description                                                              |
|--------|----------------------------|--------------------------------------------------------------------------|
| 20193  | PROG_EVENT_IGN_STOP        | Prog events ignore the Stop key                                          |
| 20210  | CUTCOM_CORNER_LIMIT        | Max. angle for intersection calculation with tool radius compensation    |
| 20220  | CUTCOM_MAX_DISC            | Maximum value for DISC                                                   |
| 20230  | CUTCOM_CURVE_INSERT_LIMIT  | Maximum angle for intersection calculation with tool radius compensation |
| 20240  | CUTCOM_MAXNUM_CHECK_BLOCKS | Blocks for predictive contour calculation with tool radius compensation  |
| 20250  | CUTCOM_MAXNUM_DUMMY_BLOCKS | Maximum number of blocks without traversing motion for TRC               |
| 20270  | CUTTING_EDGE_DEFAULT       | Basic setting of tool cutting edge without programming                   |
| 20400  | LOOKAH_USE_VELO_NEXT_BLOCK | Look Ahead to programmed following block velocity                        |
| 20430  | LOOKAH_NUM_OVR_POINTS      | Number of override corner values for Look Ahead                          |
| 20440  | LOOKAH_OVR_POINTS          | Override switch points for LookAhead                                     |
| 20500  | CONST_VELO_MIN_TIME        | Minimum time with constant velocity                                      |
| 20600  | MAX_PATH_JERK              | Path-related maximum jerk                                                |
| 20610  | ADD_MOVE_ACCEL_RESERVE     | Acceleration reserve for overlaid movements                              |
| 20700  | REFP_NC_START_LOCK         | NC start disable without reference point                                 |
| 20750  | ALLOW_GO_IN_G96            | G0 logic for G96, G961                                                   |
| 20800  | SPF_END_TO_VDI             | Subprogram end to PLC                                                    |
| 21000  | CIRCLE_ERROR_CONST         | Circle end point monitoring constant                                     |
| 21010  | CIRCLE_ERROR_FACTOR        | Circle end point monitoring factor                                       |
| 21100  | ORIENTATION_IS_EULER       | Angle definition for orientation programming                             |
| 21110  | X_AXIS_IN_OLD_X_Z_PLANE    | Coordinate system for automatic Frame definition                         |
| 21200  | LIFTFAST_DIST              | Traversing path for fast retraction from the contour                     |
| 21210  | SETINT_ASSIGN_FASTIN       | HW assignment of the ext. NCK input byte for NC program interrupt:       |
| 21202  | LIFTFAST_WITH_MIRROR       | Lift fast with mirror                                                    |

**Block search**

| Number | Identifier: \$MC_          | Description                                                  |
|--------|----------------------------|--------------------------------------------------------------|
| 20128  | COLLECT_TOOL_CHANGE        | Tool change commands to the PLC after block search           |
| 22600  | SERUPRO_SPEED_MODE         | Velocity with block search type 5                            |
| 22601  | SERUPRO_SPEED_FACTOR       | Velocity factor for block search type 5                      |
| 22621  | ENABLE_START_MODE_MASK_PRT | Switches MD22620: START_MODE_MASK_PRT for SERUPRO search run |
| 22622  | DISABLE_PLC_START          | Allow part program start via PLC                             |
| 22680  | AUTO_IPTR_LOCK             | Disable interrupt pointer                                    |

**Reset response**

| Number | Identifier: \$MC_        | Description                                                                       |
|--------|--------------------------|-----------------------------------------------------------------------------------|
| 20110  | RESET_MODE_MASK          | Initial setting after RESET / parts program end                                   |
| 20112  | START_MODE_MASK          | Basic setting for NC start after part program start                               |
| 20118  | GEOAX_CHANGE_RESET       | Allow automatic geometry axis change                                              |
| 20120  | TOOL_RESET_VALUE         | Tool length compensation when powering-up (RESET / part program end)              |
| 20121  | TOOL_PRESEL_RESET_VALUE  | Preselected tool on RESET                                                         |
| 20130  | CUTTING_EDGE_RESET_VALUE | Tool cutting edge length compensation when powering-up (RESET / part program end) |
| 20140  | TRAFO_RESET_VALUE        | Transformation data set when powering-up (RESET / part program end)               |
| 20150  | GCODE_RESET_VALUES       | Initial setting of the G groups                                                   |
| 20152  | GCODE_RESET_MODE         | Reset behavior of G groups                                                        |
| 20156  | MAXNUM_GCODES_EXT        | Reset behavior of the external G groups                                           |
| 22620  | START_MODE_MASK_PRT      | Initial setting at special NC Start after power-up and at RESET                   |

**Auxiliary function settings**

| Number | Identifier: \$MC_           | Description                                                            |
|--------|-----------------------------|------------------------------------------------------------------------|
| 22000  | AUXFU_ASSIGN_GROUP          | Auxiliary function group                                               |
| 22010  | AUXFU_ASSIGN_TYPE           | Auxiliary function type                                                |
| 22020  | AUXFU_ASSIGN_EXTENSION      | Auxiliary function extension                                           |
| 22030  | AUXFU_ASSIGN_VALUE          | Auxiliary function value                                               |
| 22200  | AUXFU_M_SYNC_TYPE           | Output timing of M functions                                           |
| 22210  | AUXFU_S_SYNC_TYPE           | Output timing of S functions                                           |
| 22220  | AUXFU_T_SYNC_TYPE           | Output timing of T functions                                           |
| 22230  | AUXFU_H_SYNC_TYPE           | Output timing of H functions                                           |
| 22240  | AUXFU_F_SYNC_TYPE           | Output timing of F functions                                           |
| 22250  | AUXFU_D_SYNC_TYPE           | Output timing of D functions                                           |
| 22400  | S_VALUES_ACTIVE_AFTER_RESET | S function active after RESET                                          |
| 22410  | F_VALUES_ACTIVE_AFTER_RESET | F function active after RESET                                          |
| 22510  | GCODE_GROUPS_TO_PLC         | G codes that are output to the NCK/PLC interface on block change/RESET |
| 22550  | TOOL_CHANGE_MODE            | New tool offset for M function                                         |
| 22560  | TOOL_CHANGE_M_CODE          | M function for tool change                                             |

**Memory settings**

| Number | Identifier: \$MC_        | Description                                         |
|--------|--------------------------|-----------------------------------------------------|
| 27900  | REORG_LOG_LIMIT          | Percentage of IPO buffer for log file enable        |
| 28000  | MM_REORG_LOG_FILE_MEM    | Memory size for REORG (DRAM)                        |
| 28010  | MM_NUM_REORG_LUD_MODULES | Number of blocks for local user variables for REORG |
| 28020  | MM_NUM_LUD_NAMES_TOTAL   | Number of local user variables (DRAM)               |
| 28040  | MM_LUD_VALUES_MEM        | Memory size for local user variables (DRAM)         |
| 28050  | MM_NUM_R_PARAM           | Number of channel-specific R parameters (SRAM)      |
| 28060  | MM_IPO_BUFFER_SIZE       | Number of NC blocks in IPO buffer (DRAM)            |
| 28070  | MM_NUM_BLOCKS_IN_PREP    | Number of blocks for block preparation (DRAM)       |
| 28080  | MM_NUM_USER_FRAMES       | Number of settable Frames (SRAM)                    |
| 28090  | MM_NUM_CC_BLOCK_ELEMENTS | Number of block elements for compile cycles (DRAM)  |
| 28100  | MM_NUM_CC_BLOCK_USER_MEM | Size of block memory for compile cycles (DRAM)      |
| 28400  | MM_ABSBLOCK              | Activating basis blocks with absolute values        |
| 28402  | MM_ABSBLOCK_BUFFER_CONF  | Dimension size of upload buffer                     |
| 28500  | MM_PREP_TASK_STACK_SIZE  | Stack size of preparation task (DRAM)               |

**Program runtime and workpiece counter**

| Number | Identifier: \$MC_     | Description                      |
|--------|-----------------------|----------------------------------|
| 27860  | PROCESSTIMER_MODE     | Activate the runtime measurement |
| 27880  | PART_COUNTER          | Activate the workpiece counter   |
| 27882  | PART_COUNTER_MCODE[ ] | Workpiece counting via M command |

**9.16.1.3 Axis/spindle-specific machine data**

| Number | Identifier: \$MA_         | Description                               |
|--------|---------------------------|-------------------------------------------|
| 30465  | AXIS_LANG_SUB_MASK        | Substitution of NC language commands      |
| 30550  | AXCONF_ASSIGN_MASTER_CHAN | Reset position of channel for axis change |
| 30600  | FIX_POINT_POS             | Fixed value positions of axes with G75    |
| 33100  | COMPRESS_POS_TOL          | Maximum deviation with compensation       |

## 9.16.2 Setting data

### 9.16.2.1 Channel-specific setting data

| Number | Identifier: \$SC_       | Description                                           |
|--------|-------------------------|-------------------------------------------------------|
| 42000  | THREAD_START_ANGLE      | Start angle for thread                                |
| 42010  | THREAD_RAMP_DISP        | Acceleration behavior of axis when thread cutting     |
| 42100  | DRY_RUN_FEED            | Dry run feedrate                                      |
| 42200  | SINGLEBLOCK2_STOPRE     | Activate debug mode for SBL2                          |
| 42444  | TARGET_BLOCK_INCR_PROG  | Continuation mode after block search with calculation |
| 42700  | EXT_PROG_PATH           | Program path for external subroutine call EXTCALL     |
| 42750  | ABSBLOCK_ENABLE         | Enable basic block display                            |
| 42990  | MAX_BLOCKS_IN_IPOBUFFER | Maximum number of blocks in the interpolation buffer  |

## 9.16.3 Signals

### 9.16.3.1 Signals to NC

| Signal name    | SINUMERIK 840D sl | SINUMERIK 828D |
|----------------|-------------------|----------------|
| Emergency stop | DB10.DBX56.1      | DB2600.DBX0.1  |

### 9.16.3.2 Signals to mode group

| Signal name                        | SINUMERIK 840D sl | SINUMERIK 828D |
|------------------------------------|-------------------|----------------|
| AUTOMATIC mode                     | DB11.DBX0.0       | DB3000.DBX0.0  |
| MDA mode                           | DB11.DBX0.1       | DB3000.DBX0.1  |
| JOG mode                           | DB11.DBX0.2       | DB3000.DBX0.2  |
| Mode change disable                | DB11.DBX0.4       | DB3000.DBX0.4  |
| Mode group stop                    | DB11.DBX0.5       | -              |
| Mode group stop axes plus spindles | DB11.DBX0.6       | -              |
| Mode group RESET                   | DB11.DBX0.7       | DB3000.DBX0.7  |
| Machine function teach in          | DB11.DBX1.0       | DB3000.DBX1.0  |
| Machine function REPOS             | DB11.DBX1.1       | -              |
| Machine function REF               | DB11.DBX1.2       | DB3000.DBX1.2  |

## 9.16.3.3 Signals from mode group

| Signal name                        | SINUMERIK 840D sl | SINUMERIK 828D |
|------------------------------------|-------------------|----------------|
| Selected mode AUTOMATIC            | DB11.DBX4.0       | -              |
| Selected mode MDA                  | DB11.DBX4.1       | -              |
| Selected JOG mode                  | DB11.DBX4.2       | -              |
| Selected machine function teach in | DB11.DBX5.0       | -              |
| Selected machine function REPOS    | DB11.DBX5.1       | -              |
| Selected machine function REF      | DB11.DBX5.2       | -              |
| Active mode AUTOMATIC              | DB11.DBX6.0       | DB3100.DBX0.0  |
| Active mode MDA                    | DB11.DBX6.1       | DB3100.DBX0.1  |
| Active mode JOG                    | DB11.DBX6.2       | DB3100.DBX0.2  |

## K2: Axis types, coordinate systems, frames

### 10.1 Brief description

#### 10.1.1 Axes

##### Machine axes

Machine axes are the axes that actually exist on a machine tool.

##### Channel axes

Every geometry axis and every special axis is assigned to a channel and, therefore, a channel axis. Geometry axes and additional axes are always traversed in "their" channel.

##### Geometry axes

The three geometry axes always make up a fictitious rectangular coordinate system, the basic coordinate system (BCS).

By using FRAMES (offset, rotation, scaling, mirroring), it is possible to image geometry axes of the workpiece coordinate system (WCS) on the BCS.

##### Special axes

In contrast to geometry axes, no geometrical relationship is defined between the special axes.

##### Path axes

Path axes are interpolated together (all the path axes of a channel have a common path interpolator).

All the path axes of one channel have the same acceleration phase, constant travel phase and delay phase.

##### Positioning axes

Positioning axes are interpolated separately (each positioning axis has its own axis interpolator). Each positioning axis has its own feedrate and acceleration characteristic.

## Synchronized axes

Synchronous axes are interpolated together with path axes (all path axes and synchronous axes of one channel have a common path interpolator).

All path axes and all synchronous axes of a channel have the same acceleration phase, constant travel phase and deceleration phase.

## Axis configuration

The machine data below are used to assign the geometry axes, special axes, channel axes and machine axes as well as the names of the individual axis types:

MD20050 \$MC\_AXCONF\_GEOAX\_ASSIGN\_TAB (assignment of geometry axis to channel axis)

MD20060 \$MC\_AXCONF\_GEOAX\_NAME\_TAB (name of the geometry axis in the channel)

MD20070 \$MC\_AXCONF\_MACHAX\_USED (machine axis number valid in channel)

MD20080 \$MC\_AXCONF\_CHANAX\_NAME\_TAB (name of the channel axis in the channel)

MD10000 \$MN\_AXCONF\_MACHAX\_NAME\_TAB (machine axis name)

MD35000 \$MA\_SPIND\_ASSIGN\_TO\_MACHAX (assignment of spindle to machine axis)

## Replaceable geometry axes

The "Replaceable geometry axes" function allows the geometry axes in a grouping to be replaced by other channel axes.

Axes that are initially configured as synchronous special axes in a channel can replace any selected geometry axis in response to a program command.

## Link axis

Link axes are axes, which are physically connected to another NCU and whose position is controlled from this NCU. Link axes can be assigned dynamically to channels of **another** NCU. Link axes are not local axes from the perspective of a particular NCU.

The **axis container** concept is used for the dynamic modification of the assignment to an NCU. Axis replacement with `GET` and `RELEASE` from the part program is not available for link axes across NCU boundaries.

The link axes are described in

### References:

/FB2/ Function Manual, Extended Functions; Multiple Operator Panels on Multiple NCUs, Distributed Systems (B3)

## Axis container

An axis container is a circular buffer data structure, in which local axes and/or link axes are assigned to channels. The entries in the circular buffer can be **shifted cyclically**.

In addition to the direct reference to local axes or link axes, the link axis configuration in the logical machine axis image also allows references to axis containers.

This type of reference consists of:

- Axis container number
- A slot (circular buffer location within the corresponding container)

The entry in a circular buffer location contains:

- A local axis

Or

- A link axis

The axis container function is described in

### References:

/FB2/ Function Manual, Extended Functions; Multiple Operator Panels on Multiple NCUs, Distributed Systems (B3)

## 10.1.2 Coordinate systems

### MCS

The machine coordinate system (MCS) has the following properties:

- It is defined by the machine axes.
- The machine axes can be perpendicular to each other to form Cartesian system or arranged in any other way.
- The names of the machine axes can be defined.
- The machine axes can be linear or rotary axes.

### BCS

The basic coordinates system (BKS) has the following properties:

- The geometry axes form a perpendicular Cartesian coordinate system.
- The BCS is derived from a kinematic transformation of the MCS.

### BZS

The basic zero system (BZS) is the basic coordinate system with a basic offset.

## SZS

The settable zero system (SZS) is the workpiece coordinate system with a programmable frame from the viewpoint of the WCS. The workpiece zero is defined by the settable frames G54 to G599.

## WCS

The workpiece coordinate system (WCS) has the following properties:

- In the workpiece coordinate system all the axes coordinates are programmed (parts program).
- It is made up of geometry axes and special axes.
- Geometry axes always form a perpendicular Cartesian coordinate system
- Special axes form a coordinate system without any geometrical relation between the special axes.
- The names of the geometry axes and special axes can be defined.
- The workpiece coordinate system can be translated, rotated, scaled or mirrored with `FRAMES (TRANS, ROT, SCALE, MIRROR)`.

Multiple translations, rotational movements, etc., are also possible.

## Zero offset external

The zero offset external has the following properties:

- At a time defined in the PLC, a predefined additional zero offset between the basic and the workpiece coordinate systems is activated.
- The magnitudes of the offsets can be set by the following for each of the axes involved:
  - PLC
  - Operator Panel
  - Part program
- Activated offsets take effect at the instant the first motion block of the relevant axes is processed after offset activation. The offsets are superimposed on the programmed path (no interpolation).

The velocity, at which the zero offset external is applied, is as follows:

Programmed `F` value plus +1/2 JOG velocity

The zero offset external is traversed at the end of `G0` blocks.

- The activated offsets are retained after `RESET` and end of program.
- After `POWER ON`, the last active offset is still stored in the control but must be reactivated by the PLC.

### 10.1.3 Frames

#### Frame

A frame is a closed calculation rule (algorithm) that translates one Cartesian coordinate system into another.

#### Frame components

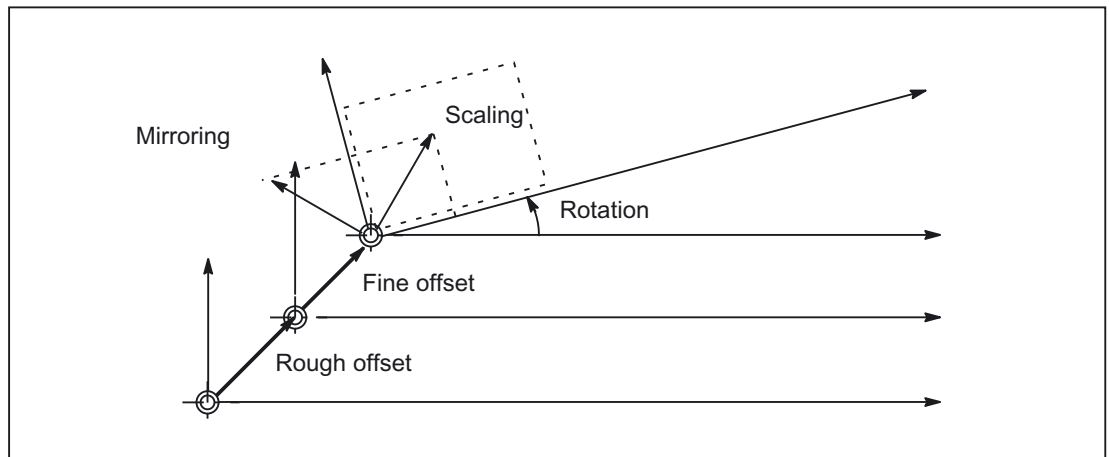

Figure 10-1 Frame components

A frame consists of the following components:

| Frame components |              | Programmable with:                                                                                                    |
|------------------|--------------|-----------------------------------------------------------------------------------------------------------------------|
| Offset           | Rough offset | TRANS<br>ATRANS (additive translation component)<br>CTRANS (zero offset for multiple axes)<br>G58 (axial zero offset) |
|                  | Fine offset  | CFINE<br>G59 (axial zero offset)                                                                                      |
| Rotation         |              | ROT / ROTs<br>AROT / AROTS<br>CROTS                                                                                   |
| Scaling          |              | SCALE<br>ASCALE                                                                                                       |
| Mirroring        |              | MIRROR<br>AMIRROR                                                                                                     |

#### Features in relation to axes

The rough and fine offsets, scaling and mirroring can be programmed for geometry and special axes. A rotation can also be programmed for geometry axes.

### Rough and fine offsets

The translation component of frames comprises:

- Rough offset with `TRANS`, `ATRANS` and `CTRANS`

The rough offset is normally specified by the machine setter.

The programmable offsets for all geometry axes and special axes are specified with `TRANS`.

- Fine offset with `CFINE`

This can be defined by the machine operator, within certain input limits.

### G58, G59

`G58` and `G59` can be programmed to replace the rough and fine offsets of the programmable frame on an axial basis. These functions can only be used when the fine offset is configured.

- Rough offset with `G58`

`G58` changes only the absolute translation component (rough offset) for the specified axis; the total of additively programmed translations (fine offset) is retained.

- Fine offset with `G59`

`G59` is used for axial overwriting of the additively programmed translations for the specified axes that were programmed with `ATRANS`.

### Frame rotations

Orientations in space are defined via frame rotations as follows:

- Rotation with `ROT` defines the individual rotations for all geometry axes.
- Solid angles with `ROTS`, `AROTS`, `CROTS` define the orientation of a plane in space.
- Frame rotation with `TOFRAME` defines a frame with a Z axis pointing in the tool direction.

### Scaling

`SCALE` is used to program the programmable scale factors for all geometry axes and special axes.

If a new scaling is to be based on a previous scaling, rotation, translation or mirroring, then `ASCALE` must be programmed.

### Mirroring

The axis to be mirrored can be set via the following machine data:

MD10610 MIRROR\_REF\_AX (reference axis for the mirroring)

| Value     | Meaning                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | Mirroring is performed around the programmed axis.                                                                                         |
| 1, 2 or 3 | Depending on the input value, mirroring is mapped onto the mirroring of a specific reference axis and rotation of two other geometry axes. |

## Frame chaining

Frame components or complete frames can be combined to form a complete frame using the chain operator ":" For instance, the actual frame `$P_ACTFRAME` comprises chaining the complete basic frame, adjustable frame, the systems frames and the programmable frame:

```
$P_ACTFRAME = $P_PARTFRAME : $P_SETFRAME : $P_EXTFRAME :
 $P_ISO1FRAME : $P_ISO2FRAME : $P_ISO3FRAME :
 $P_ACTBFRAME : $P_IFRAME : $P_TOOLFRAME :
 $P_WPFRAME : $P_TRAFRAME : $P_PFRAME
 $P_ISO4FRAME : $P_CYCFRAME
```

## Frames with G91

Incremental programming with `G91` is defined such that the compensation value is traversed additively to the incrementally programmed value when a zero offset is selected.

The behavior depends on the setting in the setting data:

SD42440 `$SC_FRAME_OFFSET_INCR_PROG` (zero offset in frames)

| Value | Meaning                                                                                                  |
|-------|----------------------------------------------------------------------------------------------------------|
| 1     | Zero offset is applied on <code>FRAME</code> and incremental programming of an axis (= default setting). |
| 0     | Only the programmed path is traversed.                                                                   |

## Suppression of frames

The actual frames can be suppressed with the following operations:

| Command | Meaning                                                                                                                                              |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| G53     | Suppression of the actual work offset (non-modal)                                                                                                    |
| G153    | Suppression of the actual frame including basic frame                                                                                                |
| SUPA    | Suppression of actual work offset, including programmed offsets, system frames, handwheel offsets (DRF), external work offset, and overlaid movement |

### NCU global basic frames

Using NCU global basic frames, frames for other channels can be **pre-assigned** from a channel.

Properties of the NCU global basic frames:

- Can be read and written from all channels.
- Can be activated only in the channels
- Offsets, scaling and mirroring for channel and machine axes

All global and channel-specific basic frames are chained and therefore a complete basic frame is obtained. As standard, there is at least one basic frame available per channel.

### Settable frames

Settable frames can be defined as either global NCU or channel-specific frames.

### Consistency

When writing, reading and activating frames, e.g. using channel coordination, the user is solely responsible for achieving consistent behavior within the channels. Cross-channel activation of frames is not supported.

## 10.2 Axes

### 10.2.1 Overview

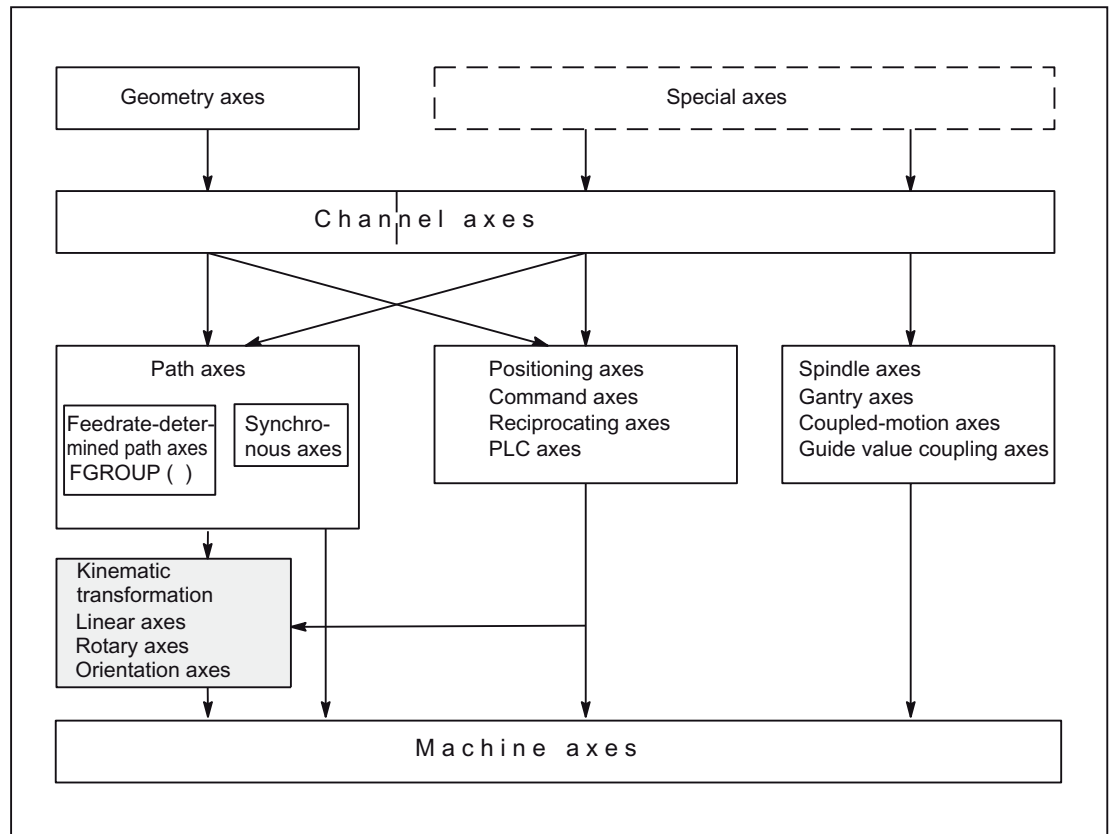

Figure 10-2 Relationship between geometry axes, special axes and machine axes

Figure 10-3 Local and external machine axes (link axes)

### 10.2.2 Machine axes

#### Meaning

Machine axes are the axes that actually exist on a machine tool.

Figure 10-4 Machine axes X, Y, Z, B, S on a Cartesian machine

## Application

The following can be machine axes:

- Geometry axes X, Y, Z
- Orientation axes A, B, C
- Loader axes
- Tool turrets
- Axes for tool magazine
- Axes for automatic tool changer
- Spindle sleeves
- Axes for pallet changers
- etc.

### 10.2.3 Channel axes

#### Meaning

Each geometry axis and each special axis is assigned to a channel. Geometry axes and additional axes are always traversed in "their" channel.

### 10.2.4 Geometry axes

#### Meaning

The three geometry axes always make up a fictitious rectangular coordinate system.

By using FRAMES (offset, rotation, scaling, mirroring), it is possible to image geometry axes of the workpiece coordinate system (WCS) on the BCS.

#### Application

Geometry axes are used to program the workpiece geometry (the contour).

Plane selection  $G17$ ,  $G18$  and  $G19$  (DIN 66217) always refers to the three geometry axes. That is why it is advantageous to name the three geometry axes X, Y and Z.

## 10.2.5 Replaceable geometry axes

### Significance

The "Replaceable geometry axes" function allows the geometry axes in a grouping to be replaced by other channel axes.

Axes that are initially configured as synchronous special axes in a channel can replace any selected geometry axis in response to a program command.

### Example

On a machine with two Z axes, Z1 and Z2, either of the Z axes can be programmed as the geometry axis in response to an instruction in the part program.

### Activation

Axis replacement is activated by the program command:

```
GEOAX([n, channel axis name]...)
```

n=0: Removes an axis from the geometry axis grouping.

n=1, 2, 3: Index of the geometry axis

GEOAX( ): Establishes the basic setting defined via MD for the assignment of channel axes to geometry axes.

Channel axis name: Name of channel axis, which is to operate as a geometry axis.

A channel axis, which has been designated a geometry axis, can only be addressed under its geometry axis name. The geometry axes names themselves remain unchanged.

Geometry axes can be replaced either individually or as a group in one command.

### Supplementary conditions

As a basic rule, any channel axis designated as a geometry axis can be replaced by another channel axis.

In this case, the following restrictions apply:

- Rotary axes may not be programmed as geometry axes.
- A geometry axis, which has the same name as a channel axis, cannot be replaced by another channel axis (alarm message). Nor can an axis of this type be removed from the geometry axis grouping. It cannot change its position within the geometry axis grouping.
- Both axes in each of the axis pairs involved in the replacement operation must be block-synchronized.

- The following functions may not be active when geometry axes are replaced:
  - Transformation
  - Spline interpolation
  - Tool radius compensation
  - Tool fine compensation
- Any active DRF offset or zero offset external will remain operative. They both act on channel axes. The channel axis assignment is not affected by the replacement of geometry axes.

### Replacement of geometry axes

All frames, protection zones and working area limitations are deleted. They may need to be reprogrammed after the replacement operation.

The system response to replacement of geometry axes is, therefore, identical to its response to a change (switch on/off, switchover) in a kinematic transformation.

### Tool Length Compensation

Any active tool length compensation remains operative and is applied to the new geometry axes after replacement.

The system treats tool length compensations as not yet applied for the following geometry axes:

- All geometry axes, which have been newly added to the geometry axis grouping
- All geometry axes, which have changed their positioning within the geometry axis grouping

Geometry axes, which retain their position within the geometry axis grouping after a replacement operation, also retain their status with respect to tool length compensation.

### RESET

The reset behavior of the changed geometry axis assignment is defined with the following machine data:

MD20110 \$MC\_RESET\_MODE\_MASK (definition of initial control system settings after RESET/TP-End)

MD20118 \$MC\_GEOAX\_CHANGE\_RESET (allow automatic geometry axis change)

**MD20110 \$MC\_RESET\_MODE\_MASK**

| Bit | Value | Significance                                                                                                                                                                                                                                                                            |
|-----|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12  | 0     | In case of set machine data MD20118 \$MC_GEOAX_CHANGE_RESET (allow automatic geometry axis change) a changed geometry axis assignment is deleted during reset or parts program end.<br>The initial setting defined in the machine data for the geometry axis assignment becomes active. |
|     | 1     | A modified geometry axis assignment remains active after a reset/part-program end.                                                                                                                                                                                                      |

**MD20118 \$MC\_GEOAX\_CHANGE\_RESET**

| Value | Significance                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | The current configuration of the geometry axes remains unchanged on reset and program start. With this setting, the response is identical to older software versions without geometry axis replacement.                                                                                                                                                                                                                                                        |
| 1     | The configuration of the geometry axis remains unchanged during reset or parts program end as a function of machine data MD20110 \$MC_RESET_MODE_MASK and during parts program start as a function of machine data MD20112 \$MC_START_MODE_MASK (definition of initial control system settings with NC START) or brought to the initial status defined in the machine data MD20050 \$MC_AXCONF_GEOAX_ASSIGN_TAB (assignment of geometry axis to channel axis). |

**Program start**

Analogously to the Reset response, the behavior during program start is based on the setting in the machine data:

MD20112 \$MC\_START\_MODE\_MASK (definition of initial control system settings with NC-START)

| Bit | Value | Significance                                                              |
|-----|-------|---------------------------------------------------------------------------|
| 12  | 0     | A modified geometry axis assignment remains active on part-program start. |
|     | 1     | A modified geometry axis assignment is cleared on part-program start.     |

**Approaching a reference point**

When the "Reference point approach" mode is selected, the geometry axis configuration defined by the machine data is automatically set.

## M code

A changeover of the geometry axis with `GEOAX( )` can be communicated to the PLC through the output of an M code:

`MD22532 $MC_GEOAX_CHANGE_M_CODE` (M-Code during tool holder change)

---

### Note

If this machine data is set to one of the values 0 to 6, 17, 30, then no M code is output.

---

## Transformation changeover

The following interrelationships must be noted with respect to kinematic transformation and geometry axis replacement:

- Geometry axis assignments cannot be modified when the transformation is active.
- Activation of a transformation deletes the programmed geometry axis configuration and replaces it by the geometry axis assignment stored in the machine data of the activated transformation.
- The initial setting defined through MD for the geometry axis configuration becomes effective after deactivating the transformation.

Should it be necessary to modify the geometry axis assignment in connection with transformations, then another new transformation must be configured. The total number of the transformations simultaneously available in the channel is equal to 8.

A maximum of two transformations per channel can be available simultaneously from the transformation groups below:

- Orientation transformations  
(3-axis, 4-axis, 5-axis and nutation transformation)
- `TRAANG` (oblique axis)
- `TRANSMIT`
- `TRACYL`

### References:

/FB3/ Function Manual, Special Functions; 3-Axis to 5-Axis Transformation (F2)

/FB2/ Function Manual, Extended Functions; Kinematic Transformation (M1)

## Example

In the example below, it is assumed that there are 6 channel axes with channel axis names XX, YY, ZZ, U, V, W and three geometry axes with names X, Y, Z. The basic setting is defined in machine data such that the geometry axes are imaged on the first three channel axes, i.e., on XX, YY and ZZ.

```

GEOAX() ; The geometry axis assignment defined via the machine
 data
 MD AXCONF_GEOAX_ASSIGN_TAB
 is effective,
 i.e., XX, YY and ZZ become geometry axes.

G0 X0 Y0 Z0 U0 V0 W0 ; All the axes in rapid traverse to position 0.
GEOAX (1, U, 2, V, 3, W) ; Channel axis U becomes the first, V the second and W
 the third geometry axis.

GEOAX(1, XX, 3, ZZ) ; Channel axis XX becomes the first, ZZ the third
 geometry axis. The second geometry axis remains
 unchanged.

G17 G2 X20 I10 F1000 ; Semicircle in the X, Y plane. Channel axes XX and V
 traverse.

GEOAX(2,W) ; Channel axis W becomes the second geometry axis. The
 first and third geometry axes remain unchanged.

G17 G2 X20 I10 F1000 ; Full circle in the X, Y plane. Channel axes XX and W
 traverse.

GEOAX() ; The geometry axis assignment defined via the machine
 data
 MD AXCONF_GEOAX_ASSIGN_TAB
 is effective,
 i.e., XX, YY and ZZ become geometry axes.

GEOAX (1, U, 2, V, 3, W) ; U, V and W become the first, second and third
 geometry axes.

G1 X10 Y10 Z10 XX=25 ; Channel axes U, V, W each traverse to position 10,
 XX traverses to position 25.

GEOAX(0,V) ; V is again removed from the geometry axis grouping.
 U and W remain geometry axes. The second geometry
 axis is no longer assigned.

GEOAX (1, U, 2, V, 3, W) ; U, V and W become the first, second and third
 geometry axes, i.e., U and W remain unchanged.

GEOAX(3,V) ; V becomes the third geometry axis. This means that
 W, which was previously the third geometry axis, is
 removed from the geometry axis grouping. The second
 geometry axis is no longer assigned.

```

## 10.2.6 Special axes

### Significance

In contrast to geometry axes, no geometrical relationship is defined between the special axes.

---

#### Note

Geometry axes have an exactly defined relationship in the form of a right-angled coordinate system.

---

Special axes are part of the basic coordinate system (BCS). With FRAMES (translation, scaling, mirroring), special axes of the workpiece coordinate system can be mapped on the basic coordinate system.

### Application

Typical special axes are:

- Rotary axes
- Machine tool axes
- Tool revolver axes
- Loader axes

## 10.2.7 Path axes

### Meaning

Path axes are interpolated together (all the path axes of a channel have a common path interpolator).

All the path axes of one channel have the same acceleration phase, constant travel phase and delay phase.

The feedrate programmed under address  $F$  (path feedrate) applies to all the path axes programmed in a block, with the following exceptions:

- An axis has been programmed that has been defined as having no control over the path velocity with instruction  $FGROUP$ .
- Axes programmed with instructions  $POS$  or  $POSA$  have an individual feedrate setting (axis interpolator).

### Application

Path axes are used to machine the workpiece with the programmed contour.

## 10.2.8 Positioning axes

### Significance

Positioning axes are interpolated separately (each positioning axis has its own axis interpolator). Each positioning axis has its own feedrate and acceleration characteristic. Positioning axes can be programmed in addition to path axes (even in the same block). Path axis interpolation (path interpolator) is not affected by the positioning axes. Path axes and the individual positioning axes do not necessarily reach their block end points at the same time.

Instructions `POS` and `POSA` are used to program positioning axes and define block change criteria:

- `POS`  
Block change takes place when the path axes and positioning axes have reached their block end points.
- `POSA`  
Block change takes place when the path axes have reached their end of block position. Positioning axes continue to traverse beyond block limits to their block end point.

Concurrent positioning axes differ from positioning axes in that they:

- Only receive their block end points from the PLC
- Can be started at any time (not at block limits)
- Do not affect the execution of current part programs.

### Application

Typical positioning axes are:

- Loaders for moving workpieces away from machine
- Tool magazine/turret

/FB1/ Function Manual, Basic Functions; Basic PLC Program (P3)  
/FB2/ Function Manual, Extended Functions; Oscillation (P5)  
/FBSY/ Function Manual Synchronized Actions

## 10.2.9 Main axes

### Significance

A main axis is an axis that is interpolated by the main run.

This interpolation can be started as follows:

- From synchronized actions  
(as command axes due to an event via block-related, modal or static synchronized actions)
- From the PLC via special function blocks in the PLC basic program  
(named as a concurrent positioning axis or a PLC axis)
- Via the setting data or from the part program  
(as an asynchronous or block-synchronous oscillating axis)

### Channel control

An axis interpolated by the main axis reacts in terms of:

- NC STOP
- Alarm handling
- Program control
- End of program
- RESET

---

#### Note

The response at the end of the program varies. The axis movement need not always be completed and, therefore, may carry on beyond the end of the program.

---

### Application

Certain axes in the main run can be decoupled at the channel response triggered by the NC program sequence and controlled from the PLC. These axes are also interpolated in the main run and respond independently for the channel and program sequence.

A PLC-controlled axis can then be controlled independently by the NC. This concerns the following actions:

- The sequence for canceling the axis (equivalent to delete distance-to-go)
- Stopping or interrupting the axis
- Continuing the axis (continue sequence of motion)
- Resetting the axis to its basic status

## 10.2.10 Synchronized axes

### Significance

Synchronous axes are components of the path axes, which are not referenced in order to calculate the tool path velocity. They are interpolated together with path axes (all path axes and synchronous axes of one channel have a common path interpolator).

All path axes and all synchronous axes of a channel have the same acceleration phase, constant travel phase and deceleration phase.

The feedrate (path feedrate) programmed under address `F` applies to all the path axes programmed in a block but not to the synchronous axes.

Synchronous axes take the same time to cover the programmed path as the path axes.

### FGROUP command

The command `FGROUP` specifies whether the axis is a feed-defining **path axis** (used to calculate the path velocity) or a **synchronous axis** (not used to calculate the path velocity).

### Example

```

N05 G00 G94 G90 M3 S1000 X0 Y0 Z0 ;
N10 FGROUP(X,Y) ; Axes X/Y are path axes,
 Z is a synchronous axis.
N20 G01 X100 Y100 F1000 ; Progr. feedrate 1000 mm/min.
 Feedrate of axis X = 707 mm/min.
 Feedrate of axis Y = 707 mm/min.
N30 FGROUP (X) ; Axis X is a path axis,
 axis Y is a synchronous axis
N20 X200 Y150 ; progr. Feedrate 1000 mm/min
 Feedrate of Axis X = 1000 mm/min
 Feedrate of Axis Y is set to 500 mm/min,
 because only half the distance is to be
 traversed.

```

---

**Note**

The channel axis name must be used for the `FGROUP` command.

This is defined by the machine data:

MD20080 \$MC\_AXCONF\_CHANAX\_NAME\_TAB (name of the channel axis in the channel)

---

**Application**

In the case of helical interpolation `FGROUP` can be programmed to determine whether:

- The programmed feedrate should be valid on the path  
(all 3 programmed axes are path axes)
- The programmed feedrate should be valid on the circuit  
(2 axes are path axes and the infeed axis is a synchronous axis)

### 10.2.11 Axis configuration

#### Assigning geometry, special, channel and machine axes.

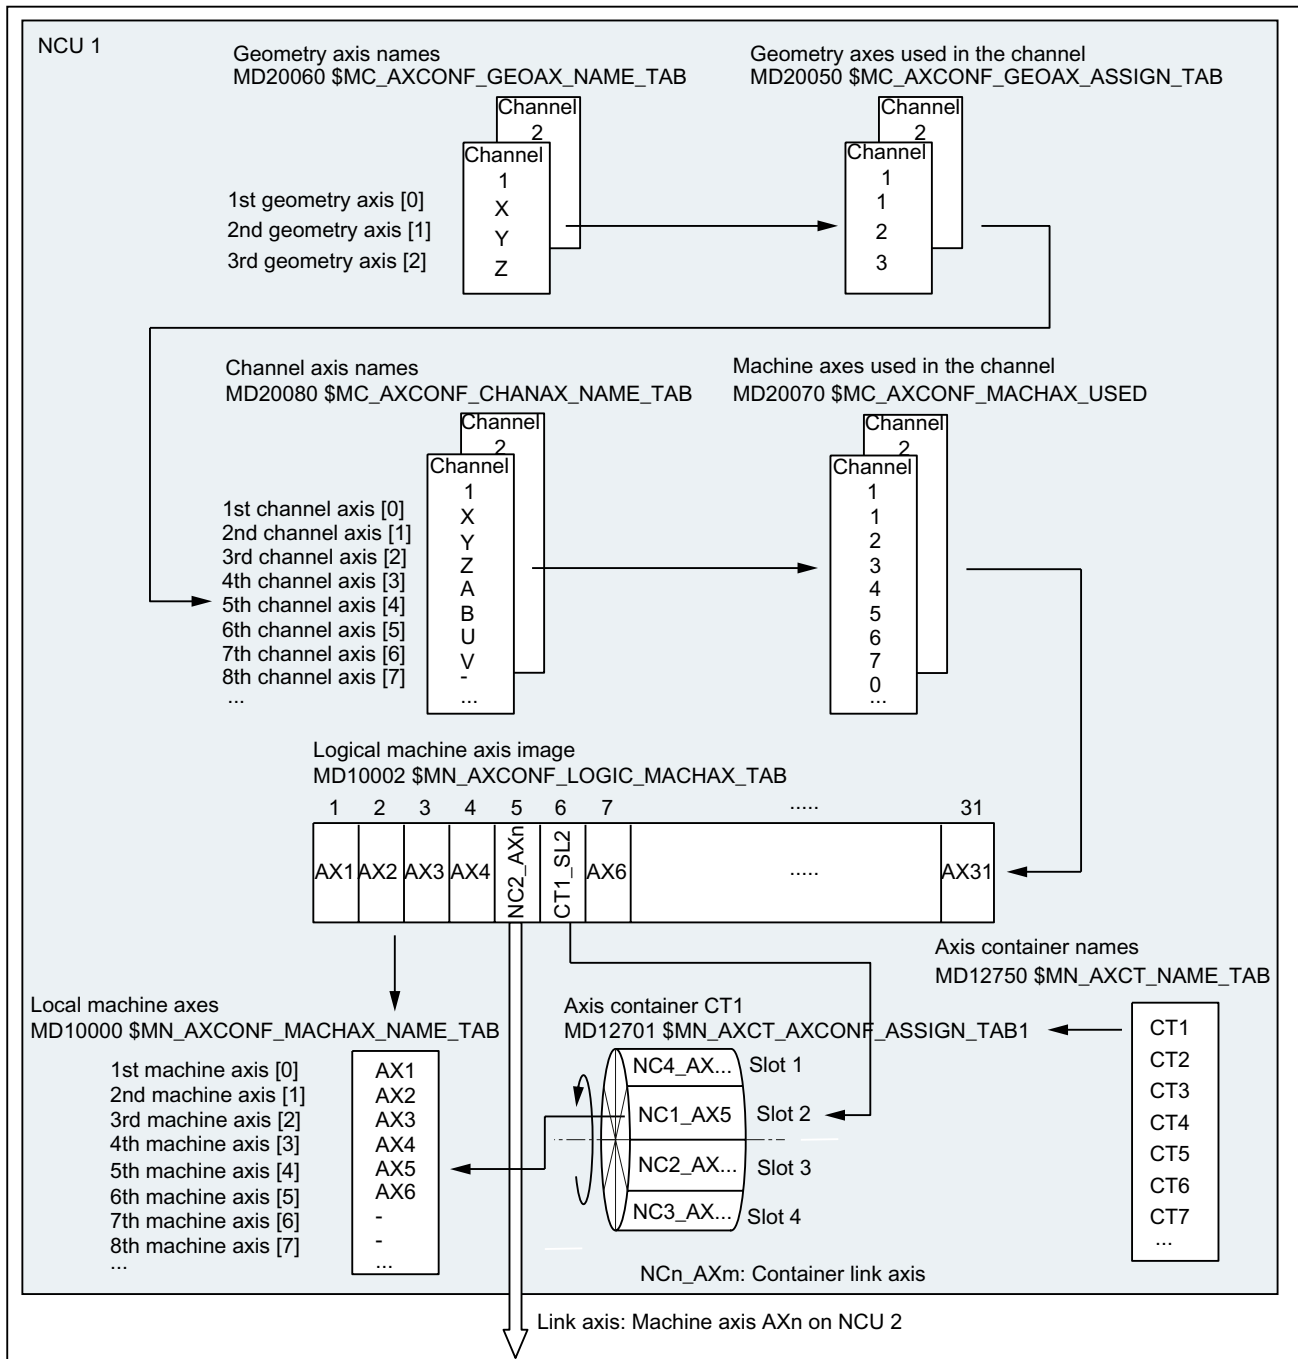

Figure 10-5 Axis configuration

## Special features

- Leading zeros for user-defined axis identifiers are ignored:  
MD10000 ` \$MN\_AXCONF\_MACHAX\_NAME\_TAB[0] = X01 corresponds to X1
- The geometry axes must be assigned to the channel axes in ascending order without any gaps.
- All channel axes that are not geometry axes are special axes.

## Channel axis gaps

Normally, each channel axis defined in machine data MD20080 \$MC\_AXCONF\_CHANAX\_NAME\_TAB must be assigned a machine axis.

In order to simplify commissioning series of machines with a different number of machine axes, channel axes may also be defined, which are not assigned to any machine axis. As a result, gaps can occur in the numbering sequence of the channel axes.

Any channel axis gaps must be explicitly enabled:

MD11640 \$MN\_ENABLE\_CHAN\_AX\_GAP = 1

Without being enabled, a value of 0 in machine data:

MD20070 \$MC\_AXCONF\_MACHAX\_USED

ends the assignment of possibly existing additional machine axes to channel axes.

### References:

/FB2/ Function Manual Extended Functions; Several Control Panels on Multiple NCUs, Decentralized Systems (B3)

---

### Note

Channel axes without assigned machine axes (channel axis gaps) are, regarding the number and indexing of the channel axes, treated just like normal channel axes with associated machine axes.

If a channel axis without assigned machine axis (channel axis gap) is defined as geometry axis, then this is rejected without an alarm.

---

**Example: Channel axis gap**

Channel axis B is not assigned a machine axis in the following example.

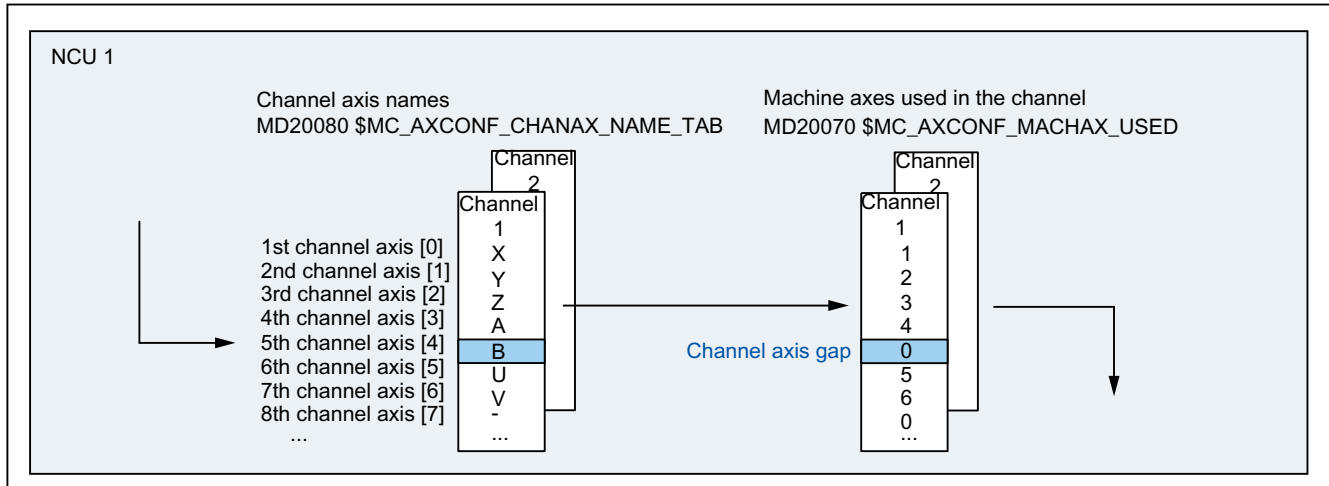

Figure 10-6 Axis configuration with channel axis gap (excerpt)

**Special situations: Channel axis gaps**

Regarding channel axis gaps, the following also have to be taken into account:

- Channel axes without assigned machine axes (channel axis gaps) are, regarding the number and indexing of the channel axes, treated just like normal channel axes with associated machine axes.
- If a channel axis without assigned machine axis (channel axis gap) is defined as geometry axis, then this is rejected without an alarm.

**10.2.12 Link axes**

**Meaning**

A link axis is a machine axis that is not on the NCU from which it is traversed. The identifier of a local machine axis is not entered in the machine data for the logical machine axis image of the traversing NCU, but the NCU and machine axis identifier of the NCU to which it is physically connected.

As an example, machine axis AX1 of NCU2 should be traversed from NCU1:

- NCU1: MD10002 \$MN\_AXCONF\_LOGIC\_MACHAX\_TAB[n] = NC2\_AX1

**Precondition**

The NCUs involved must be connected using link communication as precondition for using link axes. The link axes and link communication functions are described in detail in:

**References:**

/FB2/ Function Manual Extended Functions; Several Control Panels on Multiple NCUs, Decentralized Systems (B3)

## 10.3 Zeros and reference points

### 10.3.1 Reference points in working space

#### Zeros and reference points

The neutral position of the machine is obtained from the coordinate axes and the constructive characteristics of the machine. The zero of the coordinate system is obtained by defining a suitable reference point on the machine in its neutral position.

The position of the coordinate systems (MCS, BCS, BZS, SZS, WCS) is determined by means of zeros.

| Zero points                                                                         |                           | Reference points                                                                    |                                       |
|-------------------------------------------------------------------------------------|---------------------------|-------------------------------------------------------------------------------------|---------------------------------------|
|  | <b>M</b> = Machine zero   |  | <b>R</b> = Reference point            |
|  | <b>W</b> = Workpiece zero |  | <b>T</b> = Toolholder reference point |

#### Machine zero M

The machine zero M defines the machine coordinate system MCS. All other reference points refer to the machine zero.

#### Workpiece zero W

The workpiece zero W defines the workpiece coordinate system in relation to the machine zero M. The programmed part-program blocks are executed in the workpiece coordinate system WCS.

#### Reference point R

The position of the reference point R is defined by cam switches. Reference point R calibrates the position measuring system.

With incremental encoders, the reference point must be approached every time the control power is switched on. The control can only then work with the measuring system and transfer all position values to the coordinate systems.

### Toolholder reference point T

The toolholder reference point T is located on the toolholder locator. By entering the tool lengths, the control calculates the distance between the tool tip (TCP Tool Center Position) and the toolholder reference point.

### Example: Zeros and reference points on a turning machine

### 10.3.2 Position of coordinate systems and reference points

#### Control POWER ON

For incremental measuring probes, the reference point must be approached each time the control is activated so that the control can transfer all position values to the coordinate system.

Figure 10-7 Position of coordinate systems by machine zero M and workpiece zero W

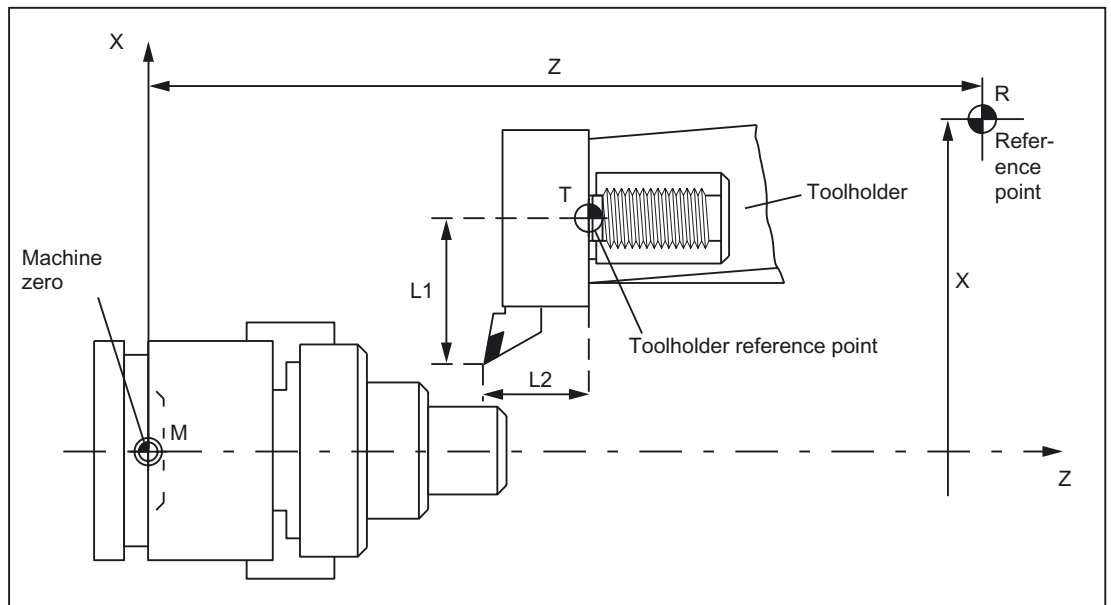

Figure 10-8 Position of reference point in relation to machine zero

## 10.4 Coordinate systems

### 10.4.1 Overview

#### Cartesian coordinate systems

DIN 66217 stipulates that machine tools must use right-angled, rectangular (Cartesian) coordinate systems. The positive directions of the coordinate axes are determined using the "Right Hand Rule". The coordinate system is related to the workpiece and programming takes place independently of whether the tool or the workpiece is being traversed. When programming, it is always assumed that the tool traverses relative to the coordinate system of the workpiece, which is intended to be stationary.

Figure 10-9 Right-hand rule

Figure 10-10 Clockwise, rectangular Cartesian coordinate system

The following coordinate systems are defined:

|     |                                                     |
|-----|-----------------------------------------------------|
| MCS | <b>M</b> achine <b>C</b> oordinat <b>S</b> ystem    |
| BCS | <b>B</b> asic <b>C</b> oordinate <b>S</b> ystem     |
| BZS | <b>B</b> asic <b>Z</b> ero <b>S</b> ystem           |
| SZS | <b>S</b> ettable <b>Z</b> ero <b>S</b> ystem        |
| WCS | <b>W</b> orkpiece <b>C</b> oordinate <b>S</b> ystem |

### Interrelationships between coordinate systems

The coordinate systems are determined by the kinematic transformation and the FRAMES.

A kinematic transformation is used to derive the BCS from the MCS. If no kinematic transformation is active, the BCS is the same as the MCS.

The basic frame maps the BCS onto the BKS.

An activated adjustable FRAME G54...G599 ENS is derived from the BNS.

The WCS, which is the basis for programming, is defined by the programmable FRAME.

Figure 10-11 Interrelationships between coordinate systems

## 10.4.2 Machine coordinate system (MCS)

### Machine coordinate system (MCS)

The machine coordinate system (MCS) is made up of all physically available machine axes.

Figure 10-12 MCS with machine axes X, Y, Z, B, C (5-axis milling machine)

Figure 10-13 MCS with machine axes X, Z (turning machine)

### Axial preset offset

The "Preset" function can be used to redefine the control zero in the machine coordinate system. The preset values act on machine axes. Axes do not move when "Preset" is active.

---

#### Note

After Preset, the reference points are invalid!

If possible do not use this function.

---

## 10.4.3 Basic coordinate system (BCS)

### Basic coordinate system (BCS)

The basic coordinate system (BCS) consists of three mutually perpendicular axes (geometry axes) as well as other special axes, which are not interrelated geometrically.

### Machine tools without kinematic transformation

BCS and MKS always coincide when the BCS can be mapped onto the MCS without kinematic transformation (e.g., TRANSMIT / face transformation, 5-axis transformation and up to three machine axes).

On such machines, machine axes and geometry axes can have the same names.

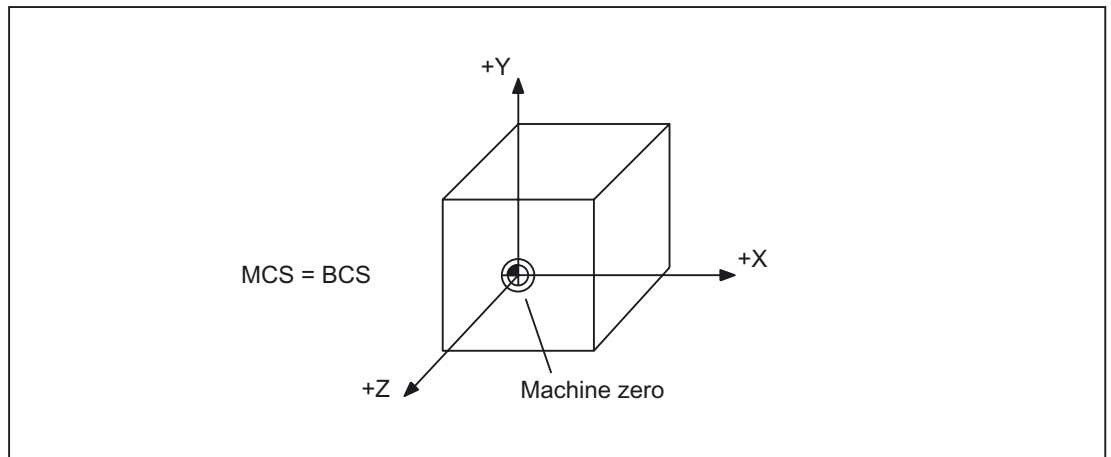

Figure 10-14 MCS=BCS without kinematic transformation

### Machine tools with kinematic transformation

The BCS and MCS do not coincide when the BCS is mapped onto the MCS with kinematic transformation (e.g., `TRANSMIT` / face transformation, 5-axis transformation or more than three axes).

On such machines the machine axes and geometry axes must have different names.

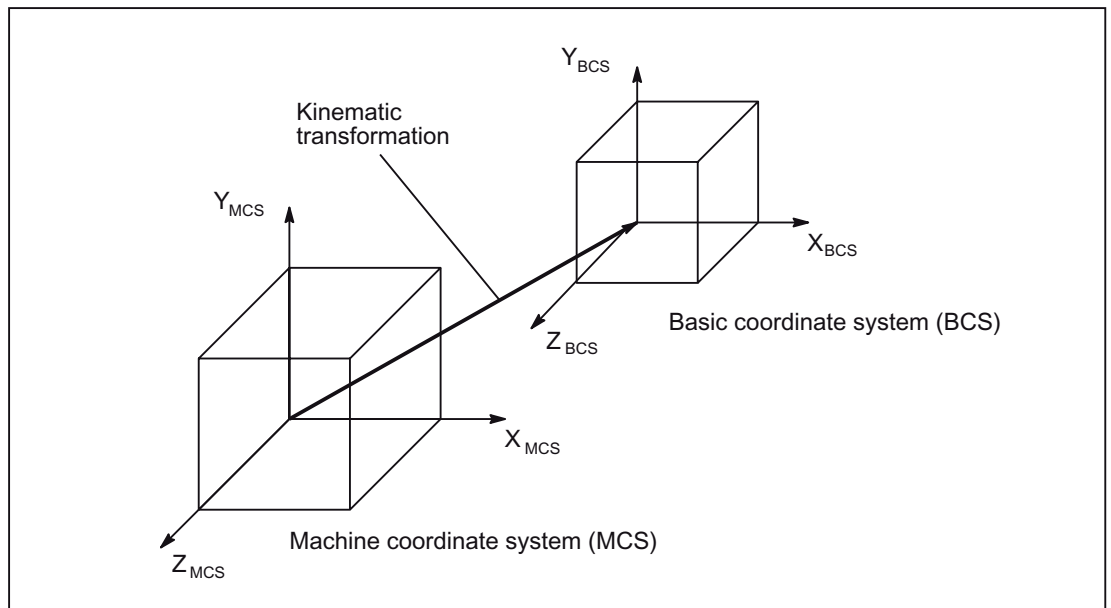

Figure 10-15 Kinematic transformation between the MCS and BCS

### Machine kinematics

The workpiece is always programmed in a two- or three-dimensional, right-angled coordinate system (WCS). However, such workpieces are being programmed ever more frequently on machine tools with rotary axes or linear axes not perpendicular to one another. Kinematic transformation is used to represent coordinates programmed in the workpiece coordinate system (rectangular) in real machine movements.

### 10.4.4 Additive offsets

#### Zero offsets external

The "zero offset external" is an axial offset. Unlike with frames, no components for rotation, scaling and mirroring are possible.

Figure 10-16 Zero offset external between BCS and BZS

## Setting the offset values

The offset values are set:

- PLC  
By describing system variables
- Via the operator panel  
From menu "Current zero offsets"
- NC Program  
By assigning to system variable \$AA\_ETRANS[axis]

## Activation of the offset values

The 0/1 edge of the following PLC signal activates the previously defined offset values:

DB31, ... DBX3.0 (accept external zero offset)

The 0/1 edge change is only evaluated in Automatic operating mode.

## Effect of activation

The offset for an axis becomes active when the first motion block for this axis is executed after the offset is activated.

### Example of possible chronological sequence:

```
G0 X100
X150 ; A new "Zero offset external" is activated by the PLC during this
 motion.
X200 ; The new "Zero offset external" is applied due to G0 programming at the
 end of the block (X200), if no velocity reserve is available (100%).
```

The "Zero offset external via system frame" is applied immediately.

Channel-specific system frames can be configured through the following machine data:

MD28082 \$MC\_MM\_SYSTEM\_FRAME\_MASK (System frames SRAM)

## Programming

Setting a new offset via the axis-specific system variables:

`$AA_ETRANS[axis]=Ri`

The instruction below reads the axis-specific active offset value:

`Ri=$AA_ETRANS[axis]`

---

### Note

The read value can then differ from the previously set value, if the set value has not yet been activated.

The read value corresponds to a value set previously, if the most recently set value has not yet been activated. The system frame for the "Zero offset external" exists only if it has been configured.

---

## DRF offset

The DRF offset enables the adjustment of an additional incremental zero offset for geometry and additional axes in the basic coordinate system **through handwheel**.

The DRF offset can be read via the axis-specific system variable:

`$AC_DRF[<Axis>]`

### References:

/FB2/ Function Manual Extended Functions; Jog with/without Handwheel (H1),  
Section: DRF offset

## Overlaid movements

The "Superimposed motion" for the programmed axis can only be accessed from synchronized actions via the system variable `$AA_OFF[axis]`.

## Run-up

After run-up (POWER ON) the last used offset values for the "Zero offset external" are stored and do not become effective again until there is a renewed activation signal.

System frames are retained during Power ON, depending on the following machine data:

MD24008 `$MC_CHSFRAME_POWERON_MASK` (reset system frames after Power On)

## RESET/end of program

The activated values remain active after RESET and program end.

Reset response of channel-specific system frames as follows:

The system frame for the "external zero offset" is active after RESET with the following machine data setting:

MD24006 \$MC\_CHSFRAME\_RESET\_MASK, Bit 1 = 1

The "external zero offset" in the active system frame is deleted in the data management through the following machine data setting:

MD24006 \$MC\_CHSFRAME\_RESET\_MASK, Bit 1 = 0

The following frames are active after RESET:

- System frame for:
  - MD24006 \$MC\_CHSFRAME\_RESET\_MASK, Bit 4 = 1 (workpiece reference point)
  - MD24006 \$MC\_CHSFRAME\_RESET\_MASK, Bit 5 = 1 (cycles)

## Suppression

The NC program instruction `SUPA` suppresses the "Zero offset external" while the block is being processed.

The command `G74` (reference point approach) and the equivalent operator actions in "Reference point approach" mode suppress the "Zero offset external" for the duration of the reference point approach.

With `G74`, i.e., "Automatic" or "MDA" mode, the previously active "Zero offset external" automatically becomes active again with the next traverse motion in the block.

After a mode change from "Reference point approach" mode, the VDI signal for the referenced axes must be set for reactivation.

### 10.4.5 Basic zero system (BZS)

#### Basic zero system (BZS)

The basic zero system (BZS) is the basic coordinate system with a basic offset.

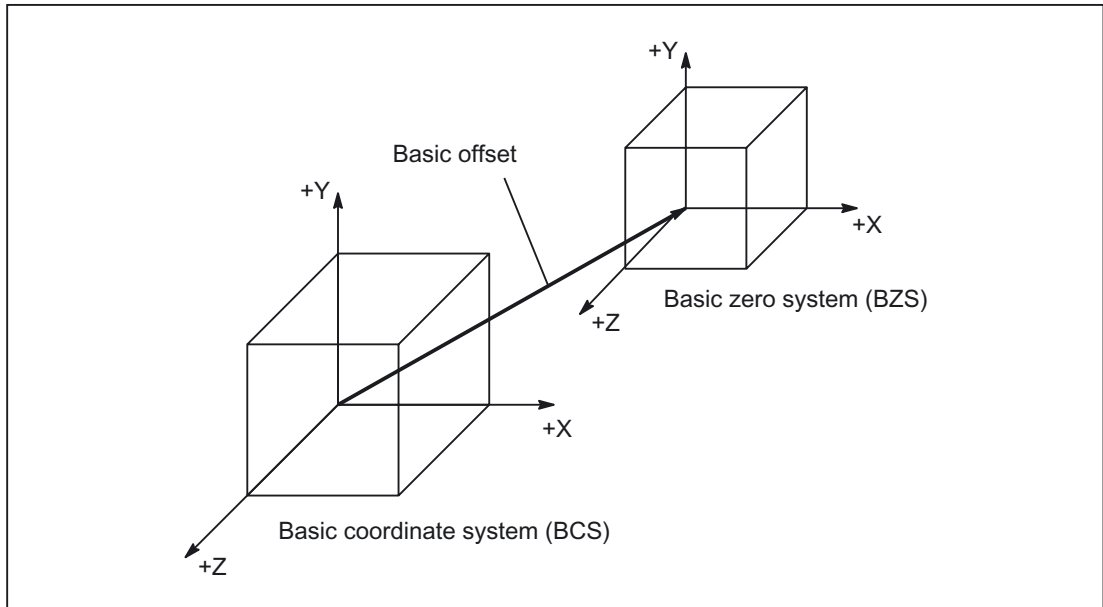

Figure 10-17 Basic offset between BCS and BZS

#### Basic offset

The basic offset describes the coordinate transformation between BCS and BZS. It can be used, for example, to define the palette window zero.

The basic offset comprises:

- Zero offset external
- DRF offset
- Superimposed motion

- Chained system frames
- Chained basic frames

Figure 10-18 Example of the use of the basic offset

The following settings apply:

- The user can change the basic offset from the part program by means of an operator action and from the PLC.
- If the basic offset is to take effect immediately, an ASUB can be started via the PLC using FC9 in order to execute the appropriate G code.

---

#### Note

##### Recommendation to the machine manufacturer

Use the 3rd basic offset onwards for your own applications.

The 1st and 2nd basic offset are reserved for PRESET and the "Zero offset external".

---

### 10.4.6 Settable zero system (SZS)

#### Settable zero system (SZS)

The "settable zero system" (SZS) is the workpiece coordinate system WCS with a programmable frame (viewed from the perspective of the WCS). The workpiece zero is defined by the settable FRAMES G54 to G599.

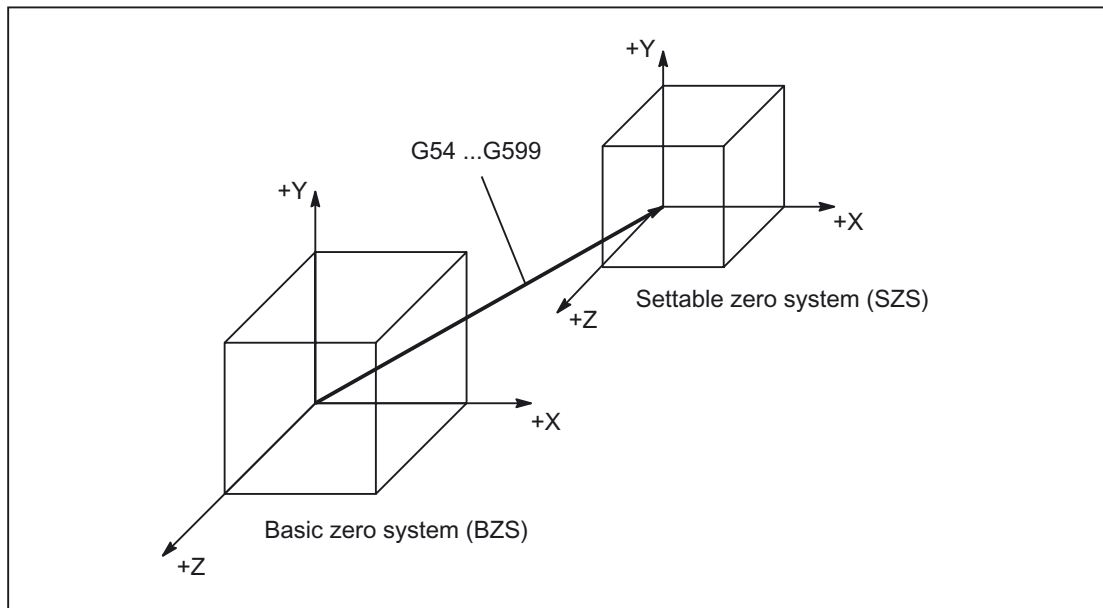

Figure 10-19 Settable FRAME G54 ... G599 between BNS and ENS

Programmable offsets act on the "settable zero system". All programmable offsets refer to the "settable zero system".

#### WCS actual-value display in WCS or SZS

The actual values of the axes in the machine coordinate system (MCS) or the WCS can be displayed on the HMI operator interface. For displays in WCS, the actual values can also be displayed in relation to the SZS. The corresponding parameterization takes place through the machine data:

MD9424 \$MM\_MA\_COORDINATE\_SYSTEM (coordinate system for actual value display)

| Value | Significance                                |
|-------|---------------------------------------------|
| 0     | Actual-value display in relation to the WCS |
| 1     | Actual-value display in relation to the SZS |

**Note**

**Display of the current coordinate system**

When "Actual-value display in relation to the SZS" is active, the WCS is still displayed on the HMI operator interface as the coordinate system to which the actual-value display relates.

**Example**

Actual-value display in relation to the WCS or SZS

| Code (excerpt)                | Actual value display:<br>Axis X (WCS) | Actual value display:<br>Axis X (SZS) |
|-------------------------------|---------------------------------------|---------------------------------------|
| N10 X100                      | 100                                   | 100                                   |
| N20 X0                        | 0                                     | 0                                     |
| N30 \$P_PFRAME = CTRANS(X,10) | 0                                     | 10                                    |
| N40 X100                      | 100                                   | 110                                   |

**10.4.7 Workpiece coordinate system (WCS)**

**Workpiece coordinate system (WCS)**

The workpiece coordinate system (WCS) is the programming basis.

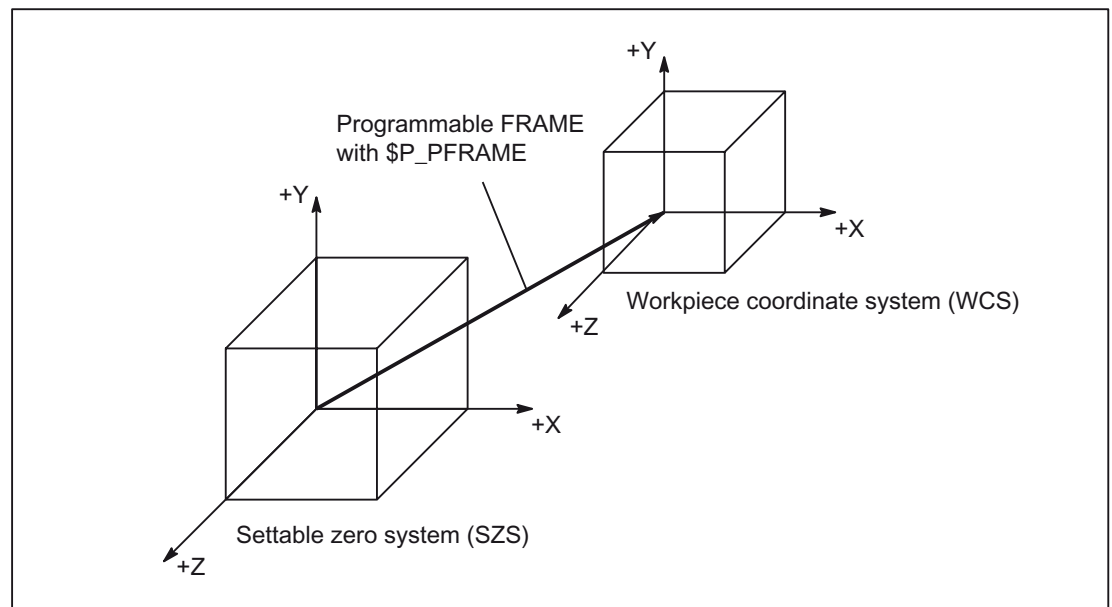

Figure 10-20 Programmable FRAME between SZS and WCS

## 10.5 Frames

### 10.5.1 Frame types

#### Frame

A frame is a data structure that contains values for offset (TRANS), fine offset (FINE), rotation (ROT), mirroring (MIRROR) and scaling (SCALE) for axes.

#### Axial frame

An axial frame contains the frame values of an axis.

Example of the data structure of an axial frame:

| Axis | TRANS | FINE | ROT | MIRROR | SCALE |
|------|-------|------|-----|--------|-------|
| X    | 10.0  | 0.1  | 0.0 | 0      | 1     |

#### Channel-specific frame

A channel-specific frame contains frame values for all channel axes (geometry, special and machine axes).

Rotations (ROT) are only included in the calculation for geometry axes.

A channel-specific frame is only active in the channel in which the frame is defined.

Example of the data structure of a channel-specific frame:

- Geometry axes: X, Y, Z
- Special axes: A
- Machine axes: AX1

| Axis | TRANS | FINE | ROT  | MIRROR | SCALE |
|------|-------|------|------|--------|-------|
| X    | 10.0  | 0.1  | 0.0  | 0      | 1     |
| Y    | 0.0   | 0.0  | 0.0  | 1      | 1     |
| Z    | 0.0   | 0.0  | 45.0 | 0      | 1     |
| A    | 2.0   | 0.1  | 0.0  | 0      | 2     |
| AX1  | 0.0   | 0.0  | 0.0  | 0      | 0     |

#### Global frame

A global frame contains the frame values for all machine axes.

A global frame is active in all channels of the NC.

Example of the data structure of a channel-specific frame:

- Machine axes: AX1, ... AX5

| Axis | TRANS | FINE | ROT | MIRROR | SCALE |
|------|-------|------|-----|--------|-------|
| AX1  | 10.0  | 0.1  | -   | 0      | 1     |
| AX2  | 0.0   | 0.0  | -   | 1      | 1     |
| AX3  | 0.0   | 0.0  | -   | 0      | 1     |
| AX4  | 2.0   | 0.1  | -   | 0      | 2     |
| AX5  | 0.0   | 0.0  | -   | 1      | 1     |

## Effect

When activating a frame, using the frame values, a static coordinate transformation for the axes contained in the frame is performed using a defined algorithm.

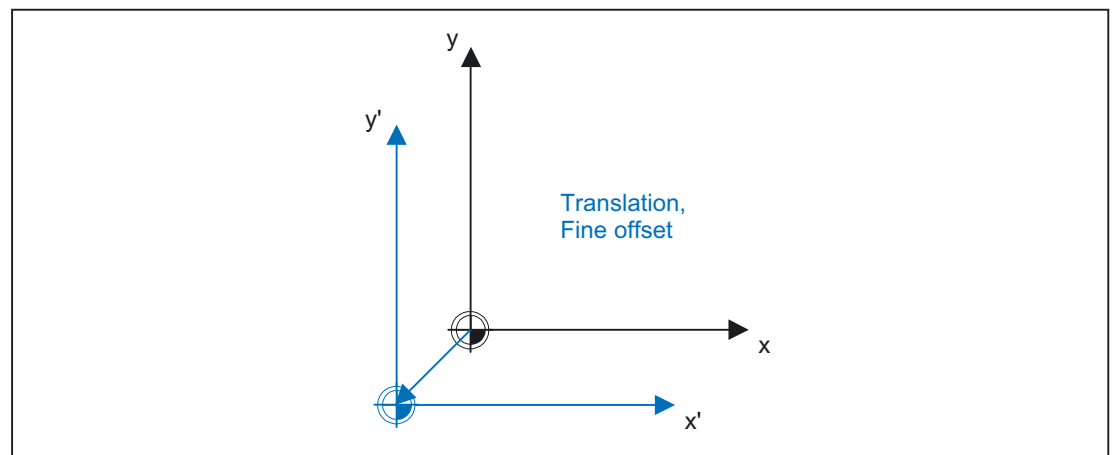

## 10.5.2 Frame components

### 10.5.2.1 Translation

## Programming

The program commands below are used to program the translation:

| Command                                      | Comment          |
|----------------------------------------------|------------------|
| <code>\$P_UIFR[1] = CTRANS(x,10,y,10)</code> |                  |
| <code>\$P_UIFR[1,x,tr] = 10</code>           | Frame components |
| <code>TRANS x=10 y=10</code>                 | Prog. frame only |

### 10.5.2.2 Fine offset

#### Parameterization

The corresponding fine offset parameterization takes place through the machine data:  
 MD18600 \$MN\_MM\_FRAME\_FINE\_TRANS (fine offset in FRAME (SRAM))

| Value | Significance                                                                                       |
|-------|----------------------------------------------------------------------------------------------------|
| 0     | The fine offset cannot be entered or programmed.                                                   |
| 1     | Fine offset possible for settable frames, basic frames and the prog. frame via command or program. |

#### Programming

The fine offset can be programmed in the program using command `CFINE (x, .., y, ...)`.  
 The coarse offset is defined with `CTRANS(...)`. Coarse and fine offset add up to the total offset.

`$P_UBFR = CTRANS(x, 10) : CFINE(x, 0.1) : CROT(x, 45)`

`$P_UIFR[1]=CFINE(x, 0.5, y, 1.0, z, 0.1)`

Access to the individual components of the fine offset is achieved through component specification **FI**.

`finex = $P_UIFR[ $P_UIFRNUM, x, FI ]`

Fine offsetting can be programmed only if:

`MD18600 $MN_FRAME_FINE_TRANS = 1`

if this is not the case, then each assignment of a fine offset to a settable frame and to the basic frame with the alarm "FRAME: fine offset not possible".

A fine offset changed by the operator does not apply until after activation of the corresponding frame, i.e., activation via `G500, G54 to G599`.

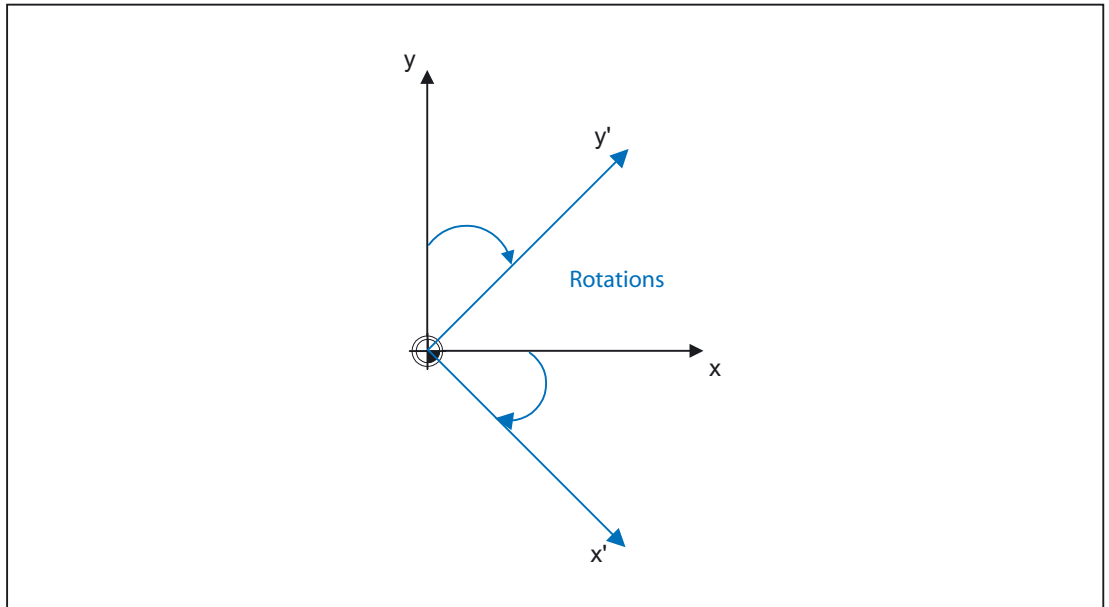

Once activated, a fine offset of a frame remains active the whole time the frame is active.

When the offset of the current frame is displayed, the total offset (coarse offset and fine offset) is output.

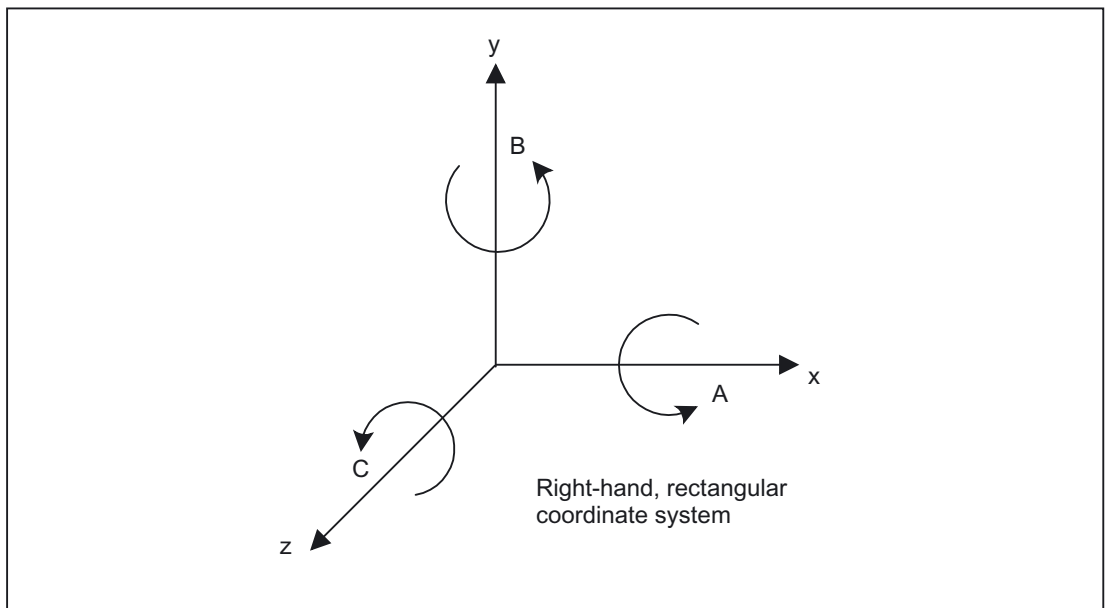

### 10.5.2.3 Rotations for geometry axes

#### Function

The direction of rotation about the coordinate axes is determined by means of a right-hand, rectangular coordinate system with axes X, Y and Z.

If the rotary motion is in a clockwise direction when looking in the positive direction of the coordinate axis, the direction of rotation is positive. A, B and C identify rotations whose axes are parallel to X, Y and Z.

**Parameter assignment**

The corresponding rotation in frame is parameterized through the machine data:  
 MD10600 \$MN\_FRAME\_ANGLE\_INPUT\_MODE (rotation sequence in FRAME)

| Value | Meaning      |
|-------|--------------|
| 1     | RPY notation |
| 2     | Euler angle  |

**RPY**

Rotations with a RPY angle are carried out in the order Z, Y', X''.

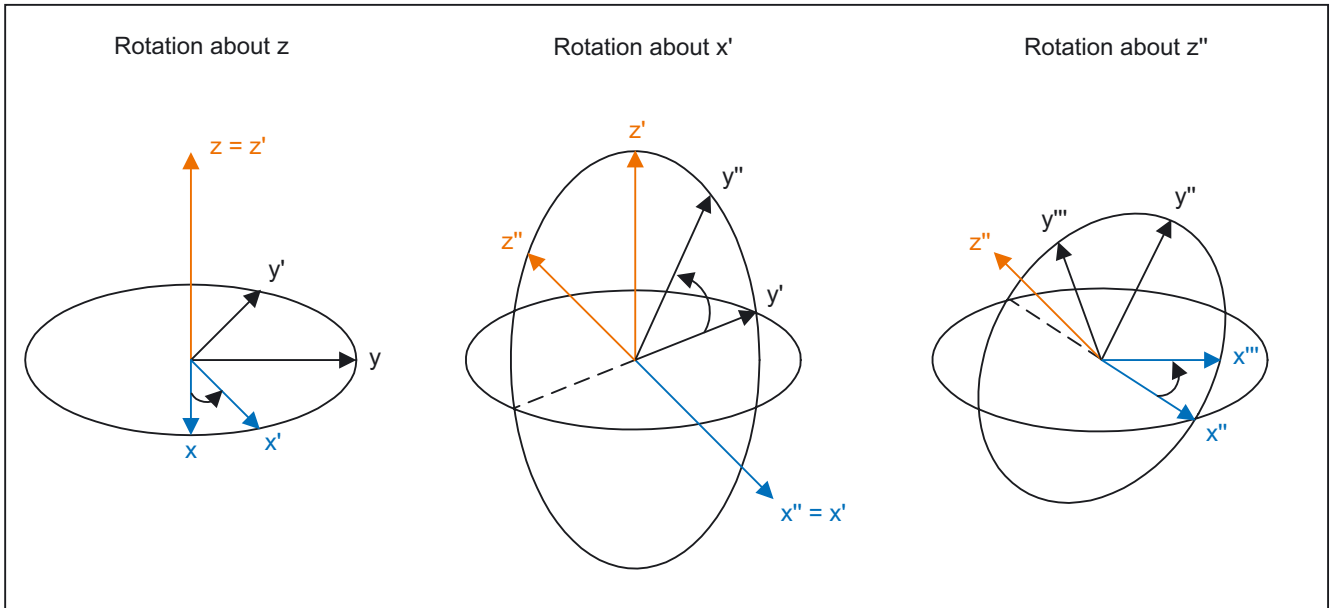

The angles are only clearly and uniquely defined in the following ranges:

$$\begin{aligned}
 -180 &\leq x \leq 180 \\
 -90 &< y < 90 \\
 -180 &\leq z \leq 180
 \end{aligned}$$

**Euler angle**

Rotations with a **Euler angle** are carried out in the order Z, X', Z''.

The angles are only clearly and uniquely defined in the following ranges:

$$\begin{aligned} 0 &\leq x < 180 \\ -180 &\leq y \leq 180 \\ -180 &\leq z \leq 180 \end{aligned}$$

The written angles can be uniquely read back again in these areas. When rotations that are larger than the specified angles are entered, these are converted to a mode of representation that does not exceed the specified range limits.

| RPY example                                     |                            |                                                 |
|-------------------------------------------------|----------------------------|-------------------------------------------------|
| <code>\$P_UIFR[1]=crot(x,10,y,90,z,40)</code>   | returns when reading back: | <code>\$P_UIFR[1]=crot(x,0,y,90,z,30)</code>    |
| <code>\$P_UIFR[1]=crot(x,190,y,0,z,-200)</code> | supplies when reading:     | <code>\$P_UIFR[1]=crot(x,-170,y,0,z,160)</code> |

On writing and reading frame rotation components, these limits should be observed so the same results are achieved on writing and reading, or on repeated writing.

## Programming

The program commands below are used to program the rotation:

```
$P_UIFR[1]=CROT(x,10,y,10)
ROT x=10 y=10
$P_UIFR[1,x,rt]=10
```

## CRPL - Constant Rotation Plane

The predefined function "Constant Rotation Plane", allows a rotation to be programmed in any plane for each frame:

```
FRAME CRPL(INT,REAL)
```

This method offers the advantage that no axis identifier, around which a rotation should be executed, has to be specified for a geometry coordinate axis.

As a rule, turning machines have only two geo axes, meaning that, up to now, a rotation in the plane could not be programmed.

**Parameter:**

|      |                              |                                                                                                                                                                                                         |
|------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INT  | 0:                           | Rotation in the active plane                                                                                                                                                                            |
|      | 1:                           | Rotation about z                                                                                                                                                                                        |
|      | 2:                           | Rotation about y                                                                                                                                                                                        |
|      | 3:                           | Rotation about x                                                                                                                                                                                        |
|      |                              |                                                                                                                                                                                                         |
| REAL | Angle of rotation in degrees |                                                                                                                                                                                                         |
|      | RPY:                         | -180 <= x <= 180                                                                                                                                                                                        |
|      |                              | -90 <= y <= 90                                                                                                                                                                                          |
|      |                              | -180 <= z <= 180                                                                                                                                                                                        |
|      | Euler:                       | -180 <= x <= 180                                                                                                                                                                                        |
|      |                              | 0 <= y <= 180                                                                                                                                                                                           |
|      |                              | -180 <= z <= 180                                                                                                                                                                                        |
|      |                              | The user must keep to the named angles, in the interests of a unique backward calculation. If the limits are violated, a unique backward calculation is impossible. Entry is not aborted with an alarm. |

**Chaining with frames**

CRPL () can be chained with frames and known frame functions such as CTRANS (), CROT (), CMIRROR (), CSCALE (), CFINE ().

**Examples:**

```

$P_PFRAME = $P_PFRAME : CRPL(0,30)
$P_PFRAME = CTRANS(x,10) : CRPL(1,30)
$P_PFRAME = CROT(x,10) : CRPL(2,30)
$P_PFRAME = CRPL(3,30) : CMIRROR(y)

```

### 10.5.2.4 Scaling

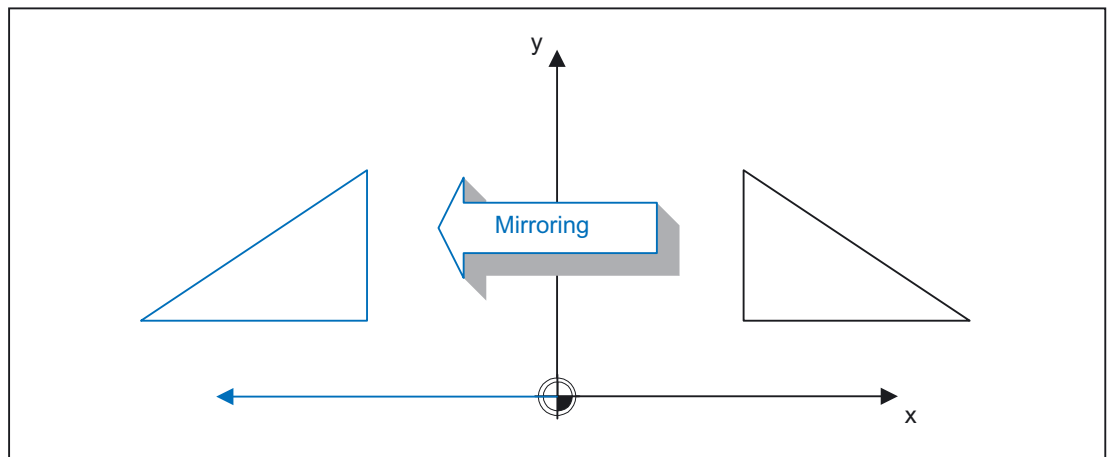

#### Programming

The program commands below are used to program the scaling:

```
$P_UIFR[1] = CSCALE(x,1,y,1)
SCALE x = 1 y = 1
$P_UIFR[1,x,sc] = 1
```

### 10.5.2.5 Mirroring

#### Programming

The program commands below are used to program a mirroring:

```
$P_UIFR[1] = CMIRROR(x,1,y,1)
MIRROR x = 1 y = 1
$P_UIFR[1,x,mi] = 1
```

### 10.5.2.6 Chain operator

Frame components or complete frames can be combined into a complete frame using the chain operator ( : ).

### 10.5.2.7 Programmable axis identifiers

Geo, channel and machine axis identifiers can be used in the frame commands. The programmed axis must be known to the channel-specific frames in the channel.

## SPI

When programming frame instructions, the `SPI(<spindle number>)` axis function can be used in place of an axis identifier.

`SPI(<spindle number>)` forms the reference of the spindle to the channel axis.  
→ refer to MD35000 \$MA\_SPIND\_ASSIGN\_TO\_MACHAX[ ] (assignment of spindle to machine axis)

The following frame instructions can be programmed with `SPI(spino)`:

```
CTRANS ()
CFINE ()
CMIRROR ()
CSCALE ()
```

A spindle can only be assigned to one rotary axis at a time. The `CROT(...)` function can therefore not be programmed with `SPI()`, as only geometry axes are permitted for `CROT()`.

The channel axis identifier or machine axis identifier of the axis belonging to the spindle is always output when decompiling frames, even when axis identifiers have been programmed in the part program with `SPI(...)`.

If the spindle is assigned e.g., to the Channel Axis A then the programming:

```
N10 $P_UIFR[1] = CTRANS (SPI (1) , 33.33, X, 1) : CSCALE (SPI (1) , 33.33) : CMIRROR (SPI (1))
```

during recompilation:

```
$P_UIFR[1]=CTRANS (X, 1, A, 33.33) : CSCALE (A, 33.33) : CMIRROR (A)
```

If a spindle and an assigned axis are programmed in a frame instruction, then Alarm 16420 "Axis % multiply programmed" is output.

#### Example:

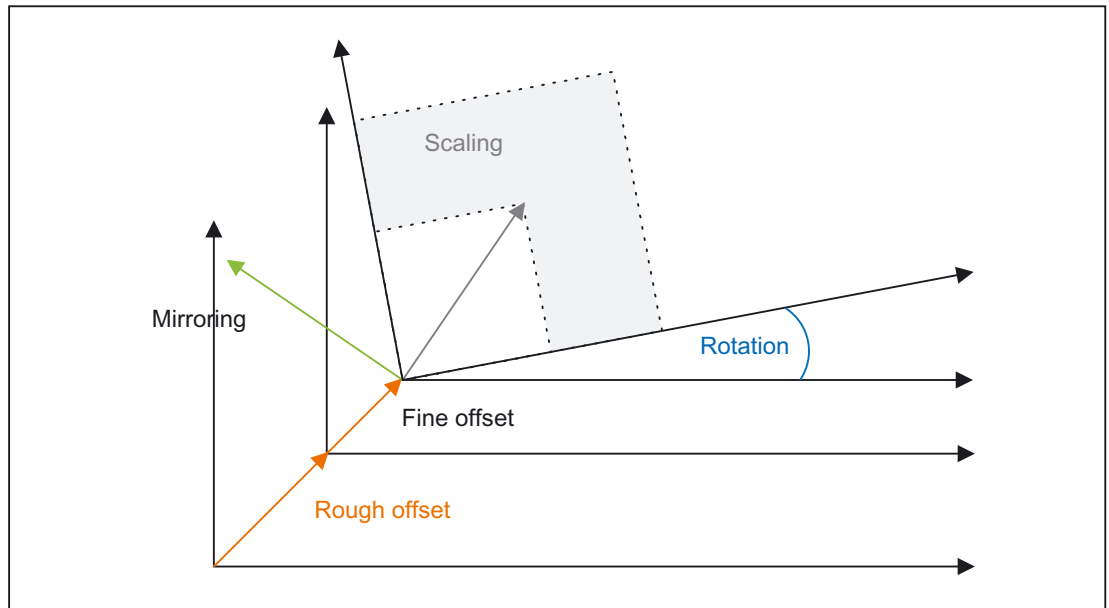

```
$P_UIFR[1] = CTRANS (SPI (1) , 33.33, X, 1, A, 44)
```

(The spindle is assigned to Axis A.)

## Programming examples

```
$P_PFRAME[SPI(1),TR]=22.22
$P_PFRAME=CTRANS(X, axis value,Y,axis value,SPI(1),axis value)
$P_PFRAME=CSCALE(X,Scale,Y,scale,SPI(2),scale)
$P_PFRAME=CMIRROR(S1,Y,Z)
$P_UBFR=CTRANS(A,10):CFINE(SPI(1),0.1)
```

### 10.5.2.8 Coordinate transformation

The formulae below are used to discover the coordinate transformation for geometry axes:

$$\begin{array}{ll} \text{WCS} \rightarrow \text{BCS} & \vec{v} = \underline{R} * \underline{S} * \underline{M} * \vec{v}' + \vec{t} \\ \text{BCS} \rightarrow \text{WCS} & \vec{v}' = \text{inv}(\underline{M}) * \text{inv}(\underline{S}) * \text{inv}(\underline{R}) + (\vec{v} - \vec{t}) \end{array}$$

V: Position vector in BCS

V': Position vector in WCS

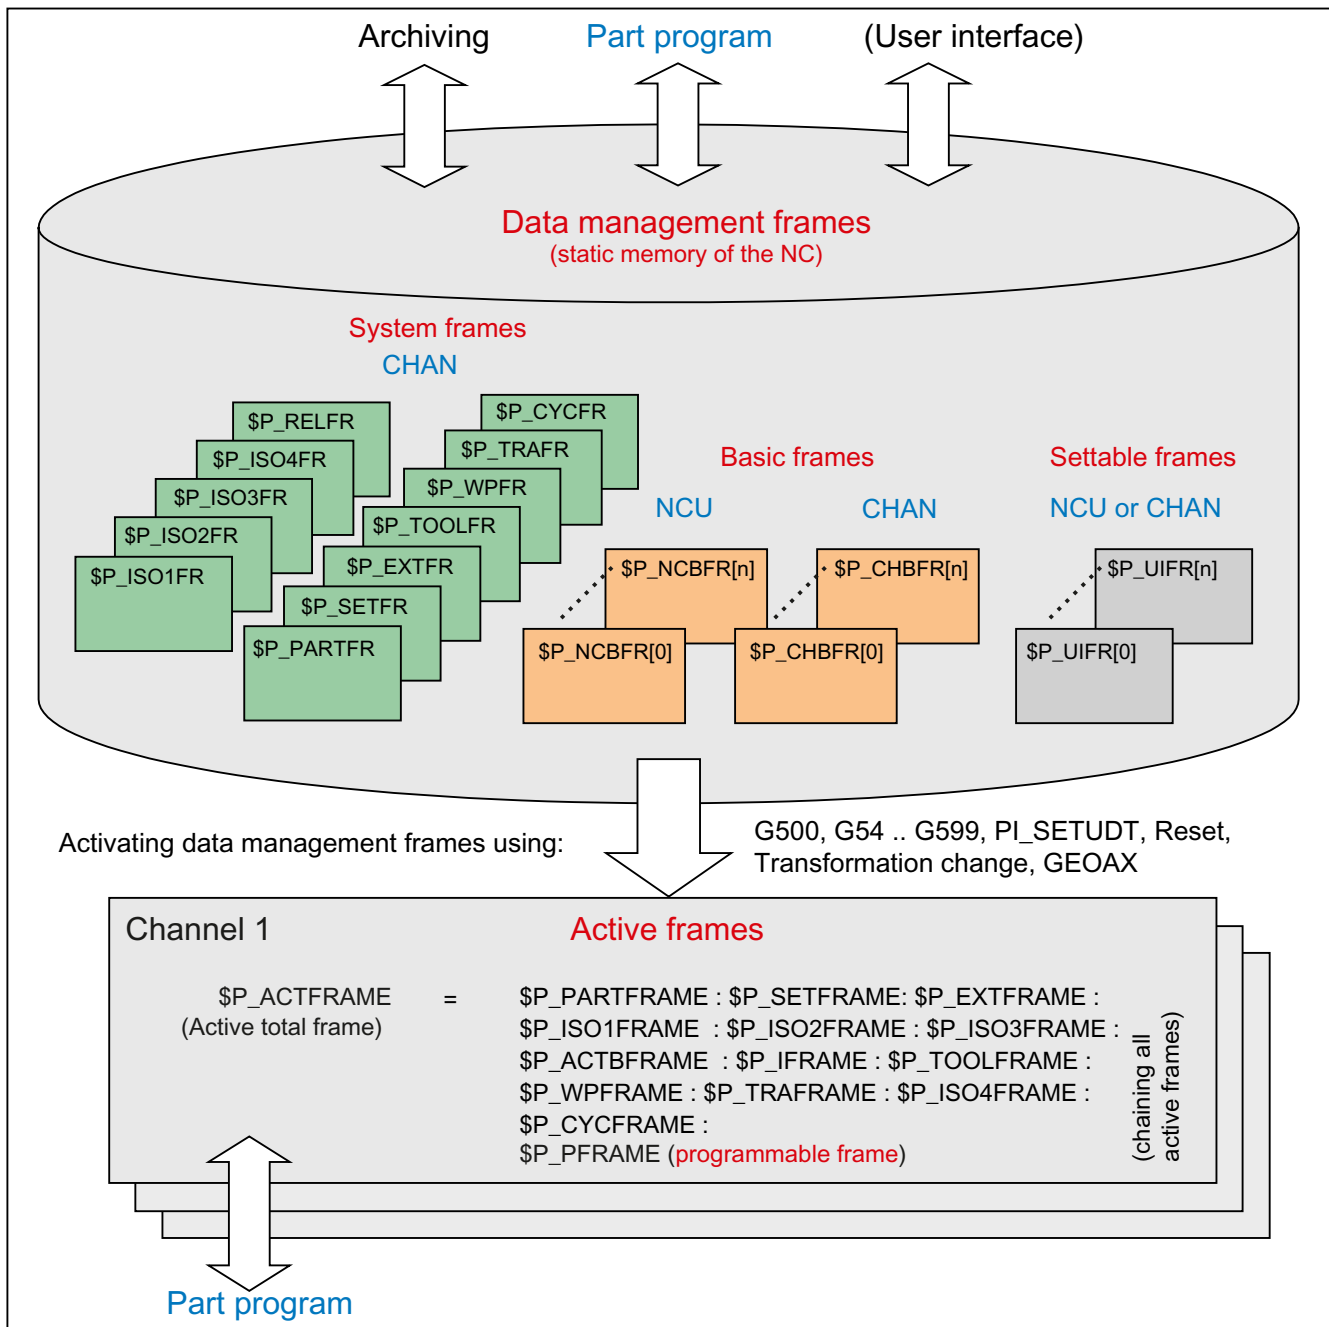

## 10.5.3 Frames in data management and active frames

### 10.5.3.1 Overview

The following frame types are available:

- System frames (see diagram)
- Basic frames ( $\$P\_NCBFR[n]$ ,  $\$P\_CHBFR[n]$ )
- Adjustable frames ( $\$P\_UIFR[n]$ )
- Programmable frame ( $\$P\_PFRAME[n]$ )

Apart from the programmable frame, all types have a frame in the data management (data management frame) and an active frame. For a programmable frame, there is only one active frame.

**Writing frames**

Data management frames and active frames can be written from the part program. Only data management frames can be written via the user interface.

**Archiving frames**

Only data management frames can be archived.

### 10.5.3.2 Activating data management frames

Data management frames become active frames as a result of the following actions:

- Part program commands to activate/deactivate offsets: G54...G599, G500
- RESET and MD20110 \$MC\_RESET\_MODE\_MASK, Bit14 = 1
- Transformation changeover
- Changing the geometry axis assignment `GEOAX`
- via SINUMERIK Operate with PI service "\_N\_SETUDT"

#### Activating via SINUMERIK Operate

The activation of a data management frame with PI service "\_N\_SETUDT" only becomes active in the channel after a hot restart for the selected part program. The activation is effective in the reset state if the following machine data is set:

MD9440 \$MM\_ACTIVATE\_SEL\_USER\_DATA (set active offset immediately)

#### Activating system frames

System frames are activated by:

- programming the corresponding system function in the part program
- Operator control at SINUMERIK Operate

---

#### Note

##### Modifying system frames of the data management

Although in principle, system frames of the data management can be modified by the cycle programmer and activated using a G500, G54...G599 operation. However, this option should only be used with reservation.

---

### Activating data management frames

The behavior when activating data management frames can be set using the following machine data:

MD24050 \$MC\_FRAME\_SAA\_MODE (save and activate data management frames)

| Bit | Value | Meaning                                                                                                                                                                                                                                    |
|-----|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 0     | Data management frames are activated <b>only</b> by programming the \$P_CHBFRMASK, \$P_NCBFRMASK and \$P_CHSFRMASK bit masks.<br>G500...G599 activate only the corresponding settable frame.<br>The reset response is independent of this. |
|     | 1     | Data management frames are not implicitly described by system functions, such as TOROT, PAROT, zero offset external and transformations.                                                                                                   |

#### System variable \$P\_CHSFRMASK

The system frames of the data management can be activated using system variable **\$P\_CHSFRMASK**. The value of the variables is specified as bit coded according to the machine data:

MD28082 \$MC\_MM\_SYSTEM\_FRAME\_MASK (system frames of the data management)

The corresponding system frame of the data management in the channel is activated by setting a bit of the system variable **\$P\_CHSFRMASK** to a value of 1. For a value of 0, the currently active system frame in the channel remains active.

#### Activating system frames after RESET

After RESET, the system frames in the channel are activated whose bits are set in the following machine data:

MD24006 \$MC\_CHSFRAME\_RESET\_MASK (active system frames after Reset)

#### Activating system frames for TCARR, PAROT and TOROT, TOFRAME

The system frames for TCARR, PAROT and TOROT, TOFRAME are activated according to the setting in the following machine data:

MD20150 \$MC\_GCODE\_RESET\_VALUES (initial setting of the G groups)

When changing over geometry axes using transformation selection/deselection or the GEOAX command, the actual total frame \$P\_ACTFRAME is either deleted or is re-calculated using the new geometry axis constellation and activated. The system frames and all other frames are conditioned again in relation to the geometry axes.

### 10.5.3.3 NCU global frames

All settable frames  $G_{54}$  to  $G_{599}$  and all basic frames can be configured NCU globally or channel-specifically. A combination of these is also possible with basic frames. Global frames affect all channels on an NCU. All channels have read and write access to the NCU. Global frames only have axial frame components, such as translations, scales and mirrors of individual axes. Each channel can read or modify global frames for any machine axis.

A characteristic of global frames is that they are calculated in all channels of an NCU. As the assignment of machine axes to channel axes and, in particular, to geometry axes, can be different in all channels, there is no geometric relationship. Global frames describe offsets, scales and mirrors of machine axes. Rotations cannot be used on global frames.

All settable frames can be reconfigured to global frames with the following machine data:

MD18601 \$MN\_MM\_NUM\_GLOBAL\_USER\_FRAMES (number of global, pre-defined user frames (SRAM))

If the value of this machine data is greater than zero, there are no channel-specific settable frames.

The following machine data becomes irrelevant then, and is not evaluated:

MD28080 \$MC\_MM\_NUM\_USER\_FRAMES (number of settable frames (SRAM))

The number of global basic frames is parameterized through the following machine data:

MD18602 \$MN\_MM\_NUM\_GLOBAL\_BASE\_FRAMES (number of global, basic frames (SRAM))

Channel-specific basic frames can also exist simultaneously through the following machine data:

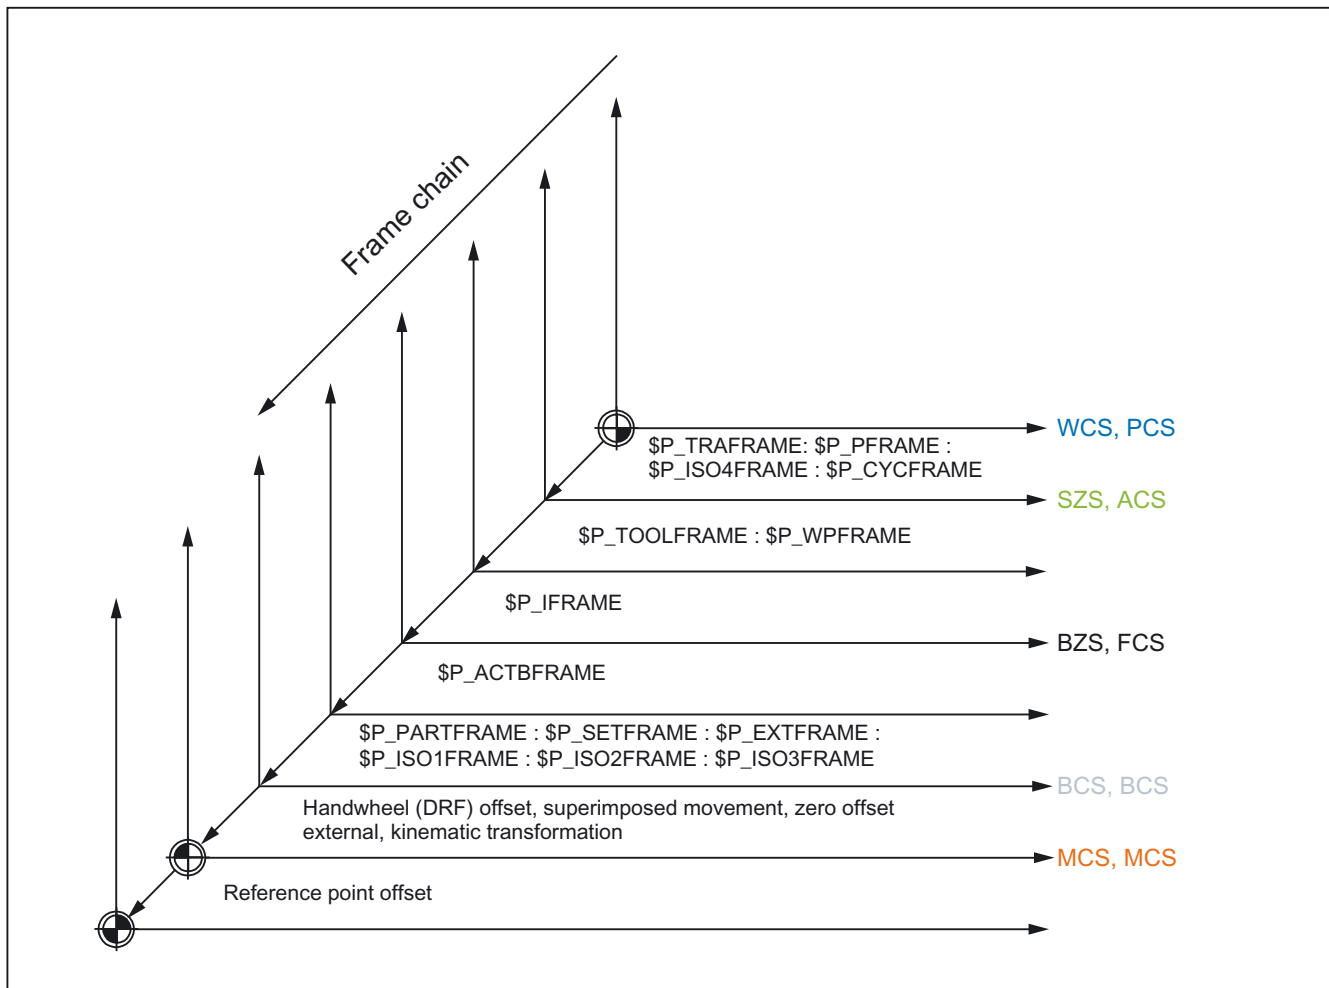

MD28081 \$MC\_MM\_NUM\_BASE\_FRAMES (number of basic frames (SRAM))

Global frames can be read and written from all channels of an NCU. When writing global frames, the user must ensure channel coordination. This can be achieved through e.g., wait markers.

### 10.5.4 Frame chain and coordinate systems

#### 10.5.4.1 Overview

The figure below shows the frame chain for the current complete frame. The frame chain is stored between the BCS and WCS. The SZS (**Settable Zero System**) corresponds to the WCS, transformed by the programmable frame. The BZS (**Basic Zero System**) still includes the current settable frame. The system frame for the zero offset external is only available if it has been configured, otherwise the zero offset external is interpolated as a superimposed motion of the axis, as it has been up to this point.

- WCS: **W**orkpiece **C**oordinate **S**ystem
- SZS: **S**ettable **Z**ero **S**ystem
- BZS: **B**asic **Z**ero **S**ystem
- BCS: **B**asic **C**oordinate **S**ystem
- MCS: **M**achine **C**oordinate **S**ystem
- PCS: **P**art **C**oordinate **S**ystem
- ACS: **A**ddjustable **C**oordinate **S**ystem
- FCS: **F**oot **C**oordinate **S**ystem
- BCS: **B**asic **C**oordinate **S**ystem
- MCS: **M**achine **C**oordinate **S**ystem

The current complete frame is calculated according to the formula below:

$$\begin{aligned} \$P\_ACTFRAME = & \$P\_PARTFRAME : \$P\_SETFRAME : \$P\_EXTFRAME : \\ & \$P\_ISO1FRAME : \$P\_ISO2FRAME : \$P\_ISO3FRAME : \\ & \$P\_ACTBFRAME : \$P\_IFRAME : \\ & \$P\_TOOLFRAME : \$P\_WPFRAME : \$P\_TRAFRAME : \\ & \$P\_PFRAME : \$P\_ISO4FRAME : \$P\_CYCFRAME \end{aligned}$$

### 10.5.4.2 Relative coordinate systems

Relative coordinate systems display the current setpoint positions of the axes, which lie relative to a specified reference point in the active displayed coordinate system. No programming can be done regarding the relative coordinate systems. Only the axis positions in these systems can be read via the system variables.

The new display coordinate systems lie relative to WCS and ENS coordinate system and result through transformation of the WCS or ENS axis positions with the active system frame  $\$P\_RELF RAME$ . The relative coordinate systems can not only be displaced linearly, but also rotated, mirrored, compressed or expanded.

The position indicator for axis setpoints is done in WCS or in ENS. The configuring is done via HMI machine data. Always only one display-coordinate system is active in the channel. For this reason only one relative frame is provided, which generates both the relative coordinate systems in the same ratio. The HMI displays the relative coordinates according to the configuring.

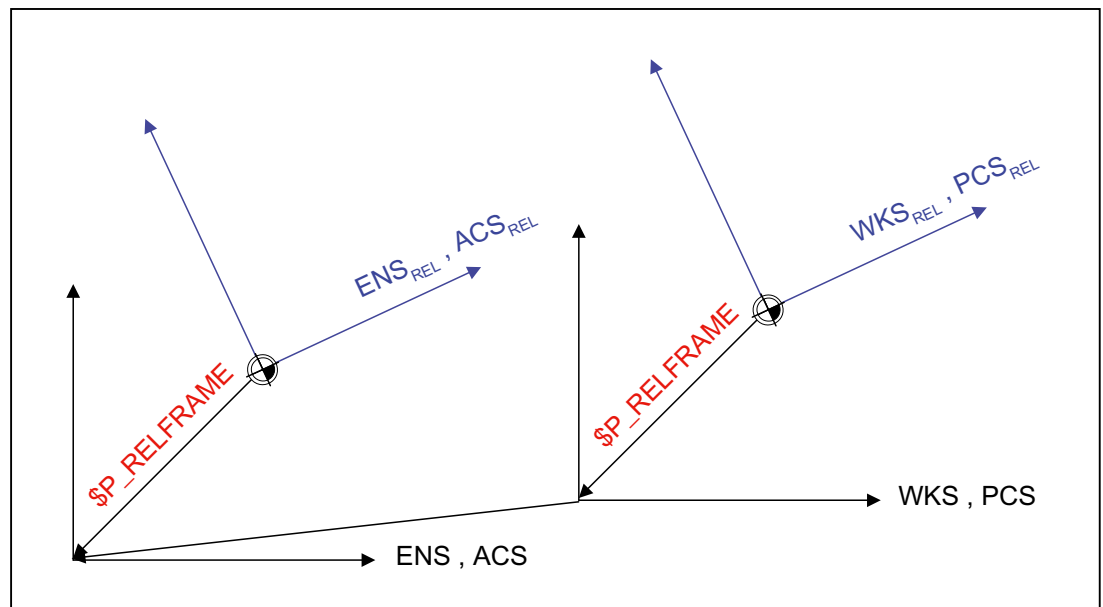

Figure 10-21 Relative coordinate systems

The data maintenance frame \$P\_RELFR can be written in the part program and via BTSS. All the frame components can be modified.

The active system frame \$P\_RELFRAME can be written in the part program and via BTSS.

The configuring of the system frame \$P\_RELFR is done via the following machine data:

| Machine data                           | Bit | Description                                                                    |
|----------------------------------------|-----|--------------------------------------------------------------------------------|
| MD28082 \$MC_MM_SYSTEM_FRAME_MASK      | 11  | Creation of \$P_RELFR; with this, relative coordinate systems become existent. |
| MD28083 \$MC_MM_SYSTEM_DATAFRAME_MASK  | 11  | Data maintenance frame \$P_RELFR                                               |
| MD24006 \$MC_CHSFRAME_RESET_MASK.      | 11  | \$P_RELFR becomes active at Reset                                              |
| MD24007 \$MC_CHSFRAME_RESET_CLEAR_MASK | 11  | \$P_RELFR is deleted at Reset                                                  |
| MD24008 \$MC_CHSFRAME_POWERON_MASK     | 11  | \$P_RELFR is deleted at PowerOn                                                |

The axis position in the relative coordinate system  $WCS_{Rel}$  can be read via the variable \$AA\_PCS\_REL[ax]. The variable can be read in part program, BTSS and via synchronous actions.

The axis position in the relative coordinate system  $ENS_{Rel}$  can be read via the variable \$AA\_ACS\_REL[ax]. The variable can be read in part program, BTSS and via synchronous actions.

The setting of a relative reference point via the operator panel is done via the general command interface for the workpiece and tool measuring. The system frame \$P\_RELFR for relative coordinate systems is calculated and activated as follows:

- \$AC\_MEAS\_TYPE = 14
- PI-services \_N\_SETUDT(6, 7)

An example for setting the relative axis positions is given in:

**References:**

/FB2/ Function Manual Extended Functions; Measurement (M5), Chapter "Measurement of Geo- and special axes (Meas Type 14, 15)"

### 10.5.4.3 Configurable SZS

The function of the SZS coordinate system is to display actual values and move the axes during a cycle interruption. Cycles utilize frames in the frame chain to perform their functions. They input translations or rotations into either the programmable frame or the cycle system frame. The WCS is, therefore, modified by cycles. A user who uses Stop to interrupt a cycle, however, does not wish to traverse in the "cycle coordinate system", but in the programmed WCS. This is why the SZS is used for the display. For reasons of compatibility, the SZS is made configurable.

The following machine data can be used to set whether the ENS is with or without the programmable frame, the transformation frame and  $\$P\_ISO4FRAME$ :

MD24030  $\$MC\_FRAME\_ACS\_SET$  (setting of the ENS coordinate system)

As default, the value 1 is set.

Reconfiguring the SZS affects all SZS actual-value displays and the \$AA\_IEN[axis] system variables. Traversing geometry axes in JOG mode in the SZS also depends on the configuration.

#### 10.5.4.4 Manual traverse in the SZS coordinate system

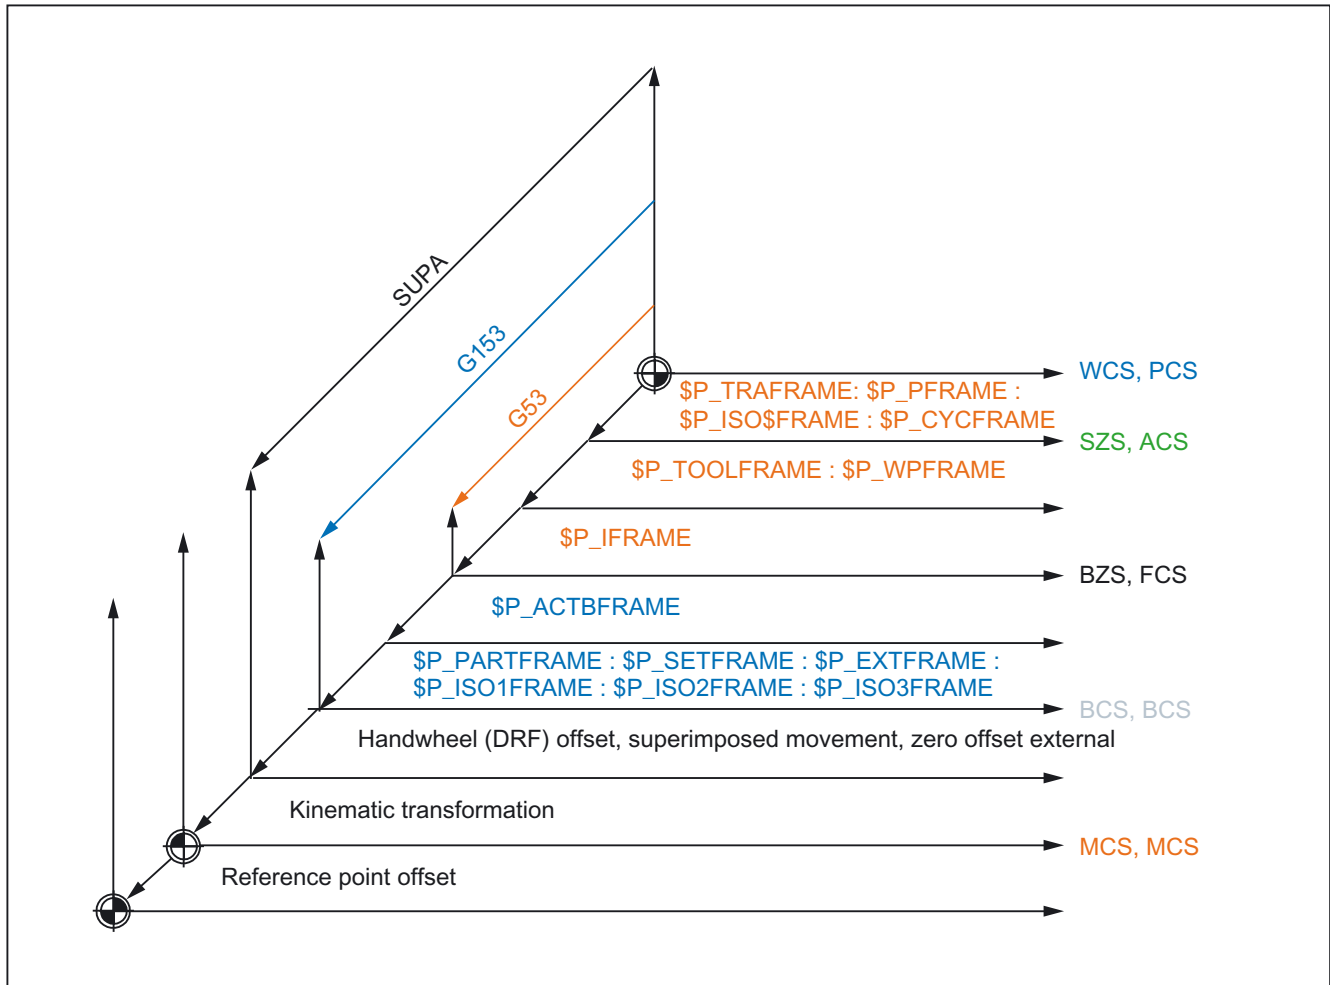

Previously, geometry axes have been traversed manually in JOG mode in the WCS. In addition, there is also the option to carry out this manual operation in the SZS coordinate system. The \$AC\_JOG\_COORD variable enables the user to switch between manual traversing in the WCS and SZS. The user can now select if he wants to traverse in the SZS or the WCS.

### 10.5.4.5 Suppression of frames

#### Programming

| Command | Significance                                                                                                                                                                                                                                                                                                                                                                    |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| G53     | Non-modal suppression of the following frames: <ul style="list-style-type: none"> <li>• System frame for cycles</li> <li>• Programmable frame</li> <li>• System frame for transformations, workpieces, TOROT and TOFRAME</li> <li>• Active settable frame</li> </ul>                                                                                                            |
| G153    | Non-modal suppression of the following frames: <ul style="list-style-type: none"> <li>• System frame for cycles</li> <li>• Programmable frame</li> <li>• System frame for TOROT and TOFRAME, workpieces</li> <li>• Active settable frame</li> <li>• All channel-specific and NCU global basic frames</li> <li>• System frames for PAROT, PRESET, scratching, ext. ZO</li> </ul> |
| SUPA    | Implicit preprocessing stop and non-modal suppression of frames analog G153 and additional <ul style="list-style-type: none"> <li>• Handwheel offsets (DRF)</li> <li>• [ext. zero offset]</li> <li>• Overlaid motion</li> </ul>                                                                                                                                                 |
| G500    | Modal activation of the G500 frame. The G500 frame should be a zero frame.                                                                                                                                                                                                                                                                                                      |
| DRFOF   | Deactivate (clear) the handwheel offsets (DRF)                                                                                                                                                                                                                                                                                                                                  |

**Parameterization**

Frame suppressions `SUPA`, `G153` and `G53` lead to the `WCS`, `SZS` and possibly the `BZS` jumping when frame suppression is active. This characteristic for position display and pre-defined position variables can be changed through the following machine data:

MD24020 `$MC_FRAME_SUPPRESS_MODE` (Positions during frame suppression)

| Bit | Significance                                                |
|-----|-------------------------------------------------------------|
| 0   | Positions for display (BTSS) are without frame suppression. |
| 1   | Position variables are without frame suppression.           |

When the bit is set, the position for the display or the variables is calculated without frame suppression so that no further jumps in the position occur.

## 10.5.5 Frame chain frames

### 10.5.5.1 Overview

There are up to four frame variants:

- Settable frames ( $G_{500, G54}$  to  $G_{599}$ )
- Basic frames
- Programmable frame
- System frames

### 10.5.5.2 Settable frames $\$P\_UIFR[n]$

The number of NCU global settable frames is set through the following machine data:

MD18601  $\$MN\_MM\_NUM\_GLOBAL\_USER\_FRAMES$  (number of global, pre-defined user frames (SRAM))

The number can be between 0 and 100. If the MD has a value greater than zero, there are only NCU global settable frames, otherwise the following machine data specifies the number of channel-specific settable frames:

MD28080  $\$MC\_MM\_NUM\_USER\_FRAMES$  (number of settable frames (SRAM))

System variable  $\$P\_UIFR[n]$  can be used to read and write the frame field elements. The frame is not activated simultaneously when writing a field element, but rather activation only takes place on execution of a  $G_{500, G54}$ , to  $G_{599}$  instruction. For NCU global frames, the changed frame only becomes active in those channels of the NCU, which execute a  $G_{500, G54}$  to  $G_{599}$  instruction. The variable is used primarily for storing write operations from HMI or PLC. These frame variables are saved by the data backup.

### Current settable frame $\$P\_IFRAME$

The predefined frame variable  $\$P\_IFRAME$  can be used to read and write the current settable frame, which is valid in the channel, in the part program. The written settable frame is immediately included in the calculation. In the case of NCU global settable frames, the modified frame acts only in the channel in which the frame was programmed. If the frame is to be modified for all channels of an NCU,  $\$P\_UIFR[n]$  and  $\$P\_IFRAME$  must be written simultaneously. The other channels must then activate the corresponding frame, e.g., with  $G_{54}$ .

### Programming of settable frames

Settable frames can be read and written via the part program and via the OPI by operator actions and by the PLC. However, only data management frames can be written by the OPI. The index of the active settable frame can be ascertained via the  $\$P\_UIFRNUM$  system variable.

### 10.5.5.3 Channel basic frames \$P\_CHBFR[n]

The number of basic frames in the channel can be configured via the machine data:

MD28081 \$MC\_MM\_NUM\_BASE\_FRAMES (number of basic frames (SRAM))

The minimum configuration is designed for at least one basic frame per channel. A maximum of 16 basic frames per channel is possible. In addition to the 16 basic frames, there can also be 16 NCU-global basic frames in the channel.

System variable \$P\_CHBFR[n] can be used to read and write the basic frame field elements. While writing a basic frame field element, the chained total frame is not activated. Instead, the activation takes place only after a G500, G54..G599 instruction is executed. The variable is used primarily for storing write operations to the basic frame on HMI or PLC. These frame variables are saved by the data backup.

#### Current channel basic frames \$P\_CHBFRAME[n]

System variable \$P\_CHBFRAME[n] can be used to read and write the current channel basic frame field elements. The resulting total basic frame is calculated by means of the write process in the channel. Whenever a basic frame is written, the complete basic frame is calculated again.

#### Basic frame in channel \$P\_UBFR

The system variable is retained for reasons of compatibility, although it is redundant for the \$P\_CHBFR[0] variables.

The basic frame with field device 0 is not activated simultaneously when writing to the predefined \$P\_UBFR variable, but rather activation only takes place on execution of a G500, G54..G599 instruction. For NCU global frames, the changed frame only becomes active in those channels of the NCU, which execute a G500, G54..G599 instruction. The variable is used primarily for storing write operations to the basic frame on HMI or PLC. The variable can also be read and written in the program.

\$P\_UBFR is identical to \$P\_CHBFR[0]. One basic frame always exists in the channel by default, so that the system variable is compatible with older versions. If there is no channel-specific basic frame, an alarm is issued at read/write: "Frame: Instruction not allowed" is output on a read or write access.

#### Current first basic frame in the channel \$P\_BFRAME

The system variable is retained for reasons of compatibility, although it is redundant for the \$P\_CHBFRAME[0] variables.

The predefined frame variable \$P\_BFRAME can be used to read and write the current basic frame with the field device of 0, which is valid in the channel, in the part program. The written basic frame is immediately included in the calculation. In the case of NCU global settable frames, the modified frame acts only in the channel in which the frame was programmed. If the frame is to be modified for all channels of an NCU, \$P\_UBFR and \$P\_BFRAME must be written simultaneously. The other channels must then activate the corresponding frame, e.g., with G54.

\$P\_BFRAME is identical to \$P\_CHBFRAME[0]. The system variable always has a valid default value. If there is no channel-specific basic frame, an alarm is issued at read/write: "Frame: Instruction not allowed" is output on a read or write access.

#### Programming basic frames

Basic frames can be read and written via the part program and via the OPI by operator actions and by the PLC. However, only data management frames can be written by the OPI.

#### 10.5.5.4 NCU global basic frames \$P\_NCBFR[n]

The number of global basic frames can be configured via the machine data:

MD18602 \$MN\_MM\_NUM\_GLOBAL\_BASE\_FRAMES (number of global, basic frames (SRAM))

There are a maximum of 16 global basic frames. All basic frames are stored as fields.

System variable \$P\_NCBFR[n] can be used to read and write the basic frame field elements. While writing a basic frame field element, the chained total frame is not activated. Instead, the activation takes place only after a G500, G54..G599 instruction is executed. If the modified frame is to be active in every channel of the NCU, every channel must execute a G500, G54..G599 instruction. The variable is used primarily for storing write operations to the basic frame on HMI or PLC. These frame variables are saved by the data backup.

##### Current NCU global basic frames \$P\_NCBFRAME[n]

System variable \$P\_NCBFRAME[n] can be used to read and write the current global basic frame field elements. The resulting total basic frame is calculated by means of the write process in the channel. The modified frame is activated only in the channel in which the frame was programmed. If the frame is to be modified for all channels of an NCU, \$P\_NCBFR[n] and \$P\_NCBFRAME[n] must be written simultaneously. The other channels must then activate the frame, e.g., with G54. Whenever a basic frame is written, the complete basic frame is calculated again.

##### Programming global frames

Global frames are programmed analogously, as are channel-specific frames, i.e., global basic frames are programmed with \$P\_NCBFR[n] and global settable frames with \$P\_UIFR[n].

Geometry axis, channel axis and machine axis identifiers can be used as axis identifiers for frame program commands. If there is no machine axis for the channel axis on the NCU, programming with channel axis identifiers is rejected with the alarm 18314 "Frame: Type conflict". Channel-specific frames can be programmed with geometry axis, channel axis and machine axis identifiers. If there is no corresponding channel axis for the machine axis on the NCU, programming with machine axis identifiers is rejected with the alarm 18314 "Frame: Type conflict". If frame components are applied to a machine axis or a channel axis, which is also a geometry axis, the corresponding geometry axis components will also be simultaneously modified.

Example:

```
$P_NCBFR[0] = CTRANS(ax1, 10)
$P_NCBFR[0] = CTRANS(x, 10)
$P_NCBFR[0, ax1, FI] = 0.1
$P_NCBFR[0, x, FI] = 0.1
```

Rotations cannot be used on global frames. The programming of a rotation is denied with alarm: "18310 Channel %1 Block %2 Frame: rotation not allowed" is displayed.

It is not possible to program chaining of global frames and channel-specific frames, and any attempt at this is rejected with the alarm 18314 "Frame: Type conflict". All global frames and channel-specific frames are internally chained to the complete frame. This takes place in the channel and only with all channel axes known in the channel. The assignment of a frame with rotation components to a global frame is denied with alarm "Frame: Rotation not allowed".

Example:

```
$P_NCBFR[0] = CTRANS(x, 10):CROT(y, 45) ; Faulty assignment on the global basic
frame
```

The following frames are channel-specific:

\$P\_UBFR, \$P\_BFRAME, \$P\_CHBFR[n],

\$P\_CHBFRAME[n], \$P\_NCBFRAME[n],

\$P\_ACTBFRAME and \$P\_ACTFRAME

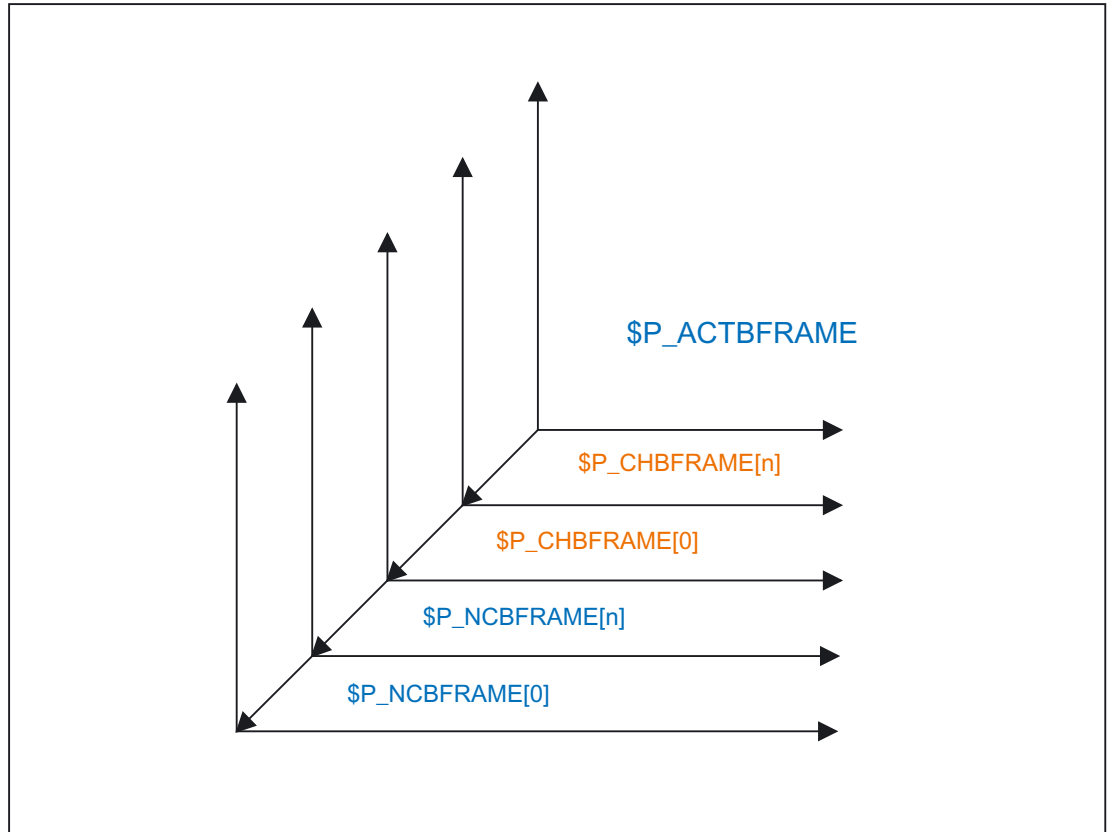

These frames can contain rotation components.

These frames only affect the channel that has been set.

With SW 5.1, attempts to program a channel axis, which is also a link axis, is rejected with alarm "14092 Channel %1 block %2 axis %3 is wrong axis type". An axis can be programmed only if it physically exists on the NCU.

### 10.5.5.5 Complete basic frame \$P\_ACTBFRAME

The chained complete basic frame is determined by the variable. The variable is read-only.

\$P\_ACTBFRAME  
corresponds to  
\$P\_NCBFRAME[0] : ... : \$P\_NCBFRAME[n] : \$P\_CHBFRAME[0] : ... : \$P\_CHBFRAME[n].

#### Programmability of the complete basic frame

System variables \$P\_CHBFRMASK and \$P\_NCBFRMASK can be used to select, which basic frames to include in the calculation of the "complete" basic frame. The variables can only be programmed in the program and read via the operator panel interface. The value of the variables is interpreted as a bit mask and specifies, which basic frame array element of \$P\_ACTBFRAME is included in the calculation. \$P\_CHBFRMASK can be used to define, which channel-specific basic frames are included, and \$P\_NCBFRMASK can be used to define, which NCU global basic frames are included in the calculation. When the variables are programmed, the complete basic frame and the complete frame are calculated again. After `RESET` and in the default setting, the value of \$P\_CHBFRMASK equals \$MC\_CHBFRAME\_RESET\_MASK and the value of \$P\_NCBFRMASK equals \$MN\_NCBFRAME\_RESET\_MASK.

```
$P_NCBFRMASK = 'H81' ; $P_NCBFRAME[0] : $P_NCBFRAME[7]
$P_CHBFRMASK = 'H11' ; $P_CHBFRAME[0] : $P_CHBFRAME[4]
```

### 10.5.5.6 Programmable frame \$P\_PFRAME

Programmable frames are available only as active frames.  
 This frame is reserved for the programmer.

The programmable frame can be maintained with the machine data:  
 MD24010 \$MC\_PFRAME\_RESET\_MODE = 1 ("Reset mode for programmable frame")  
 during RESET.

This functionality is important, most of all if after a RESET one still wants to retract out of an oblique hole.

#### MIRROR

Mirrorings of a geometry axis were thus far (up to SW-P4) related to a defined reference axis only using the machine data:

MD10610 \$MN\_MIRROR\_REF\_AX ("reference axis for the mirroring").

From the user's point of view, this definition is hard to follow. When mirroring the z axis, the display showed that the x axis was mirrored and the y axis had been rotated about 180 degrees. When mirroring two axes this became even more complex and it was no longer easy to understand, which axes had been mirrored and, which had not.

With SW P5 and higher, there is the option to clearly display the mirroring of an axis. A mirroring is then not mapped to the mirroring of a reference axis and rotation of other axes. This setting can be configured through the machine data setting:

MD10610 \$MN\_MIRROR\_REF\_AX = 0.

MIRROR and AMIRROR are used to expand the programming of the programmable frame. Previously, the specified value of the coordinate axis, e.g., the value 0 for MIRROR X0, is not evaluated, but the AMIRROR has a toggle function, i.e., MIRROR X0 activates the mirror and a further AMIRROR X0 deactivates it. MIRROR always has an absolute effect and AMIRROR an additive effect.

The

MD10612 \$MN\_MIRROR\_TOGGLE = 0 ("Mirror Toggle")

machine data setting can be used to define that the programmed values are evaluated.

A value of 0, as in AMIRROR X0, deactivates the mirroring of the axis, and values not equal to 0 cause the axis to be mirrored if it is not already mirrored.

It is possible to read or write mirrors component by component independent of machine data MD10612 \$MN\_MIRROR\_TOGGLE.

A value = 0 means that the axis is not mirrored and a value = 1 means that the axis will always be mirrored, irrespective of whether it has already been mirrored or not.

```
$P_NCBFR[0,x,mi] = 1 ; x axis is always mirrored.
$P_NCBFR[0,x,mi] = 0 ; x axis mirror is OFF.
```

### Axial replacement G58, G59

The translation component of the programmable frame is split into an absolute component and a component for the total of all additively programmed translations. The absolute component can be changed using `TRANS`, `CTRANS` or by writing the translation components, in which the additive component is set to zero. `G58` changes only the absolute translation component for the specified axis; the total of additively programmed translations is retained.

```
G58 X... Y... Z... A... ...
```

`G59` is used for axial overwriting of the additively programmed translations for the specified axes, which were programmed with `ATRANS`.

```
G59 X... Y... Z... A... ...
```

Example:

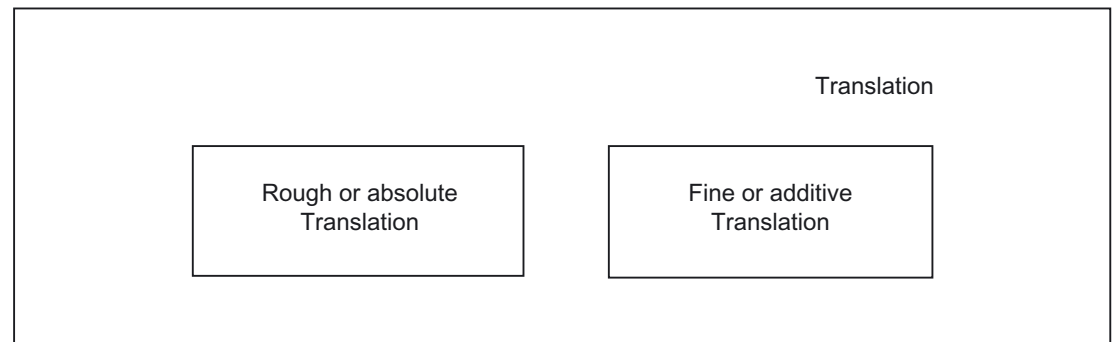

```
TRANS X10 Y10 Z10
ATRANS X5 Y5 ; Total translations X15 Y15 Z10
G58 X20 ; Total translations X25 Y15 Z10
G59 X10 Y10 ; Total translations X30 Y20 Z10
```

`G58` and `G59` can be used only if machine data:

`MD24000 $MC_FRAME_ADD_COMPONENTS` ("Frame components for `G58` / `G59`") is `TRUE`, otherwise Alarm "18311 Channel %1 Block %2 Frame: instruction not permissible" is output.

The function can also only be used in conjunction with a configured fine offset for the programmable frame. If `G58` or `G59` is used without a configured fine offset, alarm "18312 channel %1 block %2 frame: Fine offset not configured" is output.

The absolute component of the translation is stored in the rough offset component and the additive translation component is stored in the fine offset component. To this end, the programmable frame or the fine offset is expanded.

The fine component is transferred on saving the programmable frame in a local frame variable (LUD or GUD) and on rewriting.

The table below shows the effect of various program commands on the absolute and additive translation.

|                         | Coarse or absolute translation | Fine or additive translation |
|-------------------------|--------------------------------|------------------------------|
| TRANS X10               | 10                             | 0                            |
| ATRANS X10              | Unchanged                      | alt_fine + 10                |
| CTRANS (X, 10)          | 10                             | 0                            |
| CTRANS ( )              | 0                              | 0                            |
| CFINE (X, 10)           | 0                              | 10                           |
| \$P_PFRAME [X, TR] = 10 | 10                             | Unchanged                    |
| \$P_PFRAME [X, FI] = 10 | Unchanged                      | 10                           |
| G58 X10                 | 10                             | Unchanged                    |
| G59 X10                 | Unchanged                      | 10                           |

### 10.5.5.7 Channel-specific system frames

#### Channel-specific system frames

System frames are only described by system functions, such as PRESET, scratching, zero offset external and oblique processing. There are up to seven system frames per channel.

The valid system frames in the channel can be defined via machine data:

MD28082 \$MC\_MM\_SYSTEM\_FRAME\_MASK (System frames SRAM)

Only system frames required for system functions should be configured, in the interests of memory space. Per channel, each system frame occupies approx. 1 KB SRAM and approx. 6 KB DRAM. The system frame for PRESET and scratching and the system frame for cycles are the default. Channel-specific system frames are configured as bit codes, in accordance with the table below:

| Bit | Default | System frame                                           |
|-----|---------|--------------------------------------------------------|
| 0   | 1       | PRESET and scratching                                  |
| 1   | 0       | Zero offset external via system frames                 |
| 2   | 0       | TCARR and PAROT with an orientational toolholder       |
| 3   | 0       | TOROT and TOFRAME                                      |
| 4   | 0       | Frame for workpiece reference points                   |
| 5   | 1       | Frame for cycles                                       |
| 6   | 0       | Frame for selection and deselection of transformations |
| 7   | 0       | \$P_ISO1FRAME : Frame for G51.1 mirroring (ISO)        |
| 8   | 0       | \$P_ISO2FRAME : Frame for G68 2DROT (ISO)              |
| 9   | 0       | \$P_ISO3FRAME : Frame for G68 3DROT (ISO)              |
| 10  | 0       | \$P_ISO4FRAME: Frame for G51 scale (ISO)               |
| 11  | 0       | \$P_RELFR: Frame for relative coordinate systems       |

Example:

\$MC\_MM\_SYSTEM\_FRAME\_MASK = 'B001101' means that there are three system frames; one for PRESET, one for PAROT and one for TOROT and TOFRAME.

The system frame mask is used to define if the corresponding function has a system frame. With non-configured frames, in certain circumstances the function will be rejected with an alarm.

### System frames in data management

The system frames are stored in the static NC memory and can, therefore, be archived and reloaded. System frames in data management can be read and written in the program using the following variables:

| System variables | Significance                                                            |
|------------------|-------------------------------------------------------------------------|
| \$P_SETFR        | System frame for PRESET and scratching ( <b>SetFrame</b> )              |
| \$P_EXTFR        | System frame for zero offset external ( <b>ExtFrame</b> )               |
| \$P_PARTFR       | System frame for TCARR and PAROT ( <b>PartFrame</b> )                   |
| \$P_TOOLFR       | System frame for TOROT and TOFRAME ( <b>ToolFrame</b> )                 |
| \$P_WPFR         | System frame for workpiece reference points ( <b>Work-Piece-Frame</b> ) |
| \$P_CYCFR        | System frame for cycles ( <b>Cycle-Frame</b> )                          |
| \$P_TRAFRAME     | System frame for transformations ( <b>Transformation Frame</b> )        |
| \$P_ISO1FR       | Frame for G51 .1 mirroring (ISO)                                        |
| \$P_ISO2FR       | Frame for G68 2DROT (ISO)                                               |
| \$P_ISO3FR       | Frame for G68 3DROT (ISO)                                               |
| \$P_ISO4FR       | System frame for G51 scale (ISO)                                        |
| \$P_RELFR        | System frame for relative coordinate systems                            |

All write operations to these frames must be executed using system functions. For cycle programmers, it has been made possible to write the frames using the above variables. Attempts to write to a non-configured system frame are rejected with the alarm "Channel %1 block %2 name %3 not defined or option not available".

System frames in the data management are either activated directly with the system function (TOROT, PAROT, etc.), or with a G500, G54 to G599 instruction.

### Active system frames

The active system frames are the frames, which are active in the main run. An appropriate current system frame exists for each current system frame in the data management. Only with the activation of the data management frame are the values taken into account with regard to the preprocessing.

The following current system frames exist:

- **\$P\_SETFRAME**

In the part program, the variable `$P_SETFRAME` can be used to read and write the current system frame for PRESET and scratching. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_EXTFRAME**

In the part program, the variable `$P_EXTFRAME` can be used to read and write the current system frame for the zero offset external. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_PARTFRAME**

In the part program, the variable `$P_PARTFRAME` can be used to read and write the current system frame for `TCARR` and `PAROT` for toolholders with orientation capability. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_TOOLFRAME**

In the part program, the variable `$P_TOOLFRAME` can be used to read and write the current system frame for `TOROT` and `TOFRAME`. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_WPFRAME**

In the part program, the variable `$P_WPFRAME` can be used to read and write the current system frame for setting workpiece reference points. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_CYCFRAME**

In the part program, the variable `$P_CYCFRAME` can be used to read and write the current system frame for cycles. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_TRAFRAME**

In the part program, the variable `$P_TRAFRAME` can be used to read and write the current system frame for transformations. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_ISO1FRAME, \$P\_ISO2FRAME, \$P\_ISO3FRAME, \$P\_ISO4FRAME**

One can read and write the current system frames for special ISO language commands in the parts program through the variables. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_RELFRAME**

In the part program, the variable `$P_RELFRAME` can be used to read and write the current system frame for relative coordinate systems. The variable returns a zero frame if the system frame is not configured through MD28082.

- **\$P\_ACSFRAME**

The currently resulting frame that is defined by the ENS-(ACS) coordinate system, can be read and written through the `$P_ACSFRAME` variable.

For MD24030 \$MC\_FRAME\_ACS\_SET = 0, the frame is calculated as follows:

```
$P_ACSFRAME = $P_PARTFRAME : $P_SETFRAME : $P_EXTFRAME :
 $P_ISO1FRAME : $P_ISO2FRAME : $P_ISO3FRAME :
 $P_ACTBFRAME : $P_IFRAME :
 $P_TOOLFRAME : $P_WPFRAME
```

For MD24030 \$MC\_FRAME\_ACS\_SET = 1, the frame is calculated as follows:

```
$P_ACSFRAME = $P_PARTFRAME : $P_SETFRAME : $P_EXTFRAME :
 $P_ISO1FRAME : $P_ISO2FRAME : $P_ISO3FRAME :
 $P_ACTBFRAME : $P_IFRAME :
 $P_TOOLFRAME : $P_WPFRAME : $P_TRAFRAME:
 $P_PFRAME : $P_ISO4FRAME
```

- \$P\_ACTFRAME

The resulting current complete frame \$P\_ACTFRAME is now a chain of all system frames, basic frames, the current settable frame and the programmable frame. The current frame is always updated whenever a frame component is changed.

The current complete frame is calculated according to the formula below:

```
$P_ACTFRAME = $P_PARTFRAME : $P_SETFRAME : $P_EXTFRAME :
 $P_ISO1FRAME : $P_ISO2FRAME : $P_ISO3FRAME :
 $P_ACTBFRAME : $P_IFRAME :
 $P_TOOLFRAME : $P_WPFRAME : $P_TRAFRAME:
 $P_PFRAME : $P_ISO4FRAME : $P_CYCFRAME
```

## 10.5.6 Implicit frame changes

### 10.5.6.1 Frames and switchover of geometry axes

In the channel, the geometry axis configuration can be changed by switching a transformation on and off and with the `GEOAX()` command (R3).

Machine data

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE

can be used to configure, for all channels of the system, whether the current complete frame is calculated again on the basis of the new geometry axes or whether the complete frame is deleted.

Four modes can be set via machine data:

- MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 0

The current complete frame is deleted when geometry axes are switched over, when transformations are selected and deselected, and on `GEOAX()`.  
The modified geometry axis configuration is not used until a new frame is activated.

- MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 1

The current complete frame is calculated again when the geometry axes are switched over, and the translations, scales and mirrors of the new geometry axes are effective. The rotations of the geometry axes, which were programmed before the switchover, remain effective for the new geometry axes.  
The aspects described in the chapter "Frames for selection and deselection of transformations" are relevant to `TRANSMIT`, `TRACYL` and `TRAANG`.

**References:**

/FB1/ Function Manual, Basic Functions; Axes, Coordinate System, Frames (K2);  
Chapter: Frame for selection and deselection of transformations

- MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 2

The current complete frame is calculated again when the geometry axes are switched over, and the translations, scales and mirrors of the new geometry axes are effective. If rotations are active in the current basic frames, the current settable frame or the programmable frame before the switchover, it is aborted with the alarm "Frame: Geometry axis switchover not allowed".

The aspects described in the chapter "Frames for selection and deselection of transformations" are relevant to `TRANSMIT`, `TRACYL` and `TRAANG`.

**References:**

/FB1/ Function Manual, Basic Functions; Axes, Coordinate System, Frames (K2);  
Chapter: Frame for selection and deselection of transformations

- MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 3

The current frame is deleted when selecting and deselecting transformations.

With `GEOAX()`, the current complete frame is calculated again and the translations, scales and mirrors of the new geometry axes come into effect.

The rotations of the geometry axes, which were programmed before the switchover, remain effective for the new geometry axes.

The workpiece geometry is described by a coordinate system that is formed by the geometry axes. A channel axis is assigned to each geometry axis and a machine axis is assigned to each channel axis. An axial frame exists for each machine axis and for each frame (system frame, basic frame, settable frame, programmable frame). When a new machine axis is assigned to a geometry axis, the axial frame components of the machine axis, such as translations (coarse and fine), scales and mirrors of the appropriate frame, are also applied. The new geometry in the channel is then generated by the new contour frames resulting from the new geometry axes (up to three in number).

The current valid frames are calculated again on the geometry axis switchover and a resulting complete frame is generated. The data management frames are not included unless they are activated.

Example:

The channel axis is to become a geometry axis x through `geo axis` substitution. The substitution is to give the programmable frame a translation component of 10 in the x axis. The current settable frame is to be retained.

```
MD10602 $MN_FRAME_GEOAX_CHANGE_MODE = 1
```

```
$P_UIFR[1] = CROT(x,10,y,20,z,30) ; Frame is retained after geo axis
 substitution.
G54 ; Settable frame becomes active.
TRANS a10 ; Axial offset of a is also substituted.
GEOAX(1, a) ; a becomes x axis;
 $P_ACTFRAME=CROT(x,10,
 y,20,z,30):CTRANS(x10).
```

Several channel axes can become geometry axes on a transformation change.

Example:

Channel axes 4, 5 and 6 become the geometry axes of a 5-axis transformation. The geometry axes are thus all substituted before the transformation. The current frames are changed when the transformation is activated. The axial frame components of the channel axes, which become geometry axes, are taken into account when calculating the new WCS. Rotations programmed before the transformation are retained. The old WCS is restored when the transformation is deactivated. The most common application will be that the geometry axes do not change before and after the transformation and that the frames are to stay as they were before the transformation.

Machine data:

```
$MN_FRAME_GEOAX_CHANGE_MODE = 1
```

```
$MC_AXCONF_CHANAX_NAME_TAB[0] = "CAX"
$MC_AXCONF_CHANAX_NAME_TAB[1] = "CAY"
$MC_AXCONF_CHANAX_NAME_TAB[2] = "CAZ"
$MC_AXCONF_CHANAX_NAME_TAB[3] = "A"
$MC_AXCONF_CHANAX_NAME_TAB[4] = "B"
$MC_AXCONF_CHANAX_NAME_TAB[5] = "C"
```

```
$MC_AXCONF_GEOAX_ASSIGN_TAB[0] = 1
$MC_AXCONF_GEOAX_ASSIGN_TAB[1] = 2
$MC_AXCONF_GEOAX_ASSIGN_TAB[2] = 3

$MC_TRAFO_GEOAX_ASSIGN_TAB_1[0]=4
$MC_TRAFO_GEOAX_ASSIGN_TAB_1[1]=5
$MC_TRAFO_GEOAX_ASSIGN_TAB_1[2]=6
```

```
$MC_TRAFO_AXES_IN_1[0] = 4
$MC_TRAFO_AXES_IN_1[1] = 5
$MC_TRAFO_AXES_IN_1[2] = 6
$MC_TRAFO_AXES_IN_1[3] = 1
$MC_TRAFO_AXES_IN_1[4] = 2
```

Program:

```
$P_NCBFRAME[0] = ctrans(x,1,y,2,z,3,a,4,b,5,c,6)
$P_CHBFRAME[0] = ctrans(x,1,y,2,z,3,a,4,b,5,c,6)
$P_IFRAME = ctrans(x,1,y,2,z,3,a,4,b,5,c,6):crot(z,45)
$P_PFRAME = ctrans(x,1,y,2,z,3,a,4,b,5,c,6):crot(x,10,y,20,z,30)
```

```
TRAORI ; Geo axis (4,5,6) sets transformer
 ; $P_NCBFRAME[0] = ctrans(x,4,y,5,z,6,cax,1,cay,2,caz,3)
 ; $P_ACTBFRAME =ctrans(x,8,y,10,z,12,cax,2,cay,4,caz,6)
 ; $P_PFRAME =
 ctrans(x,4,y,5,z,6,cax,1,cay,2,caz,3):crot(x,10,y,20,z,30)
 ; $P_IFRAME = ctrans(x,4,y,5,z,6,cax,1,cay,2,caz,3):crot(z,45)

TRAFOOF ; Geo axis (1,2,3) sets transformation deactivation
 ; $P_NCBFRAME[0] = ctrans(x,1,y,2,z,3,a,4,b,5,c,6)
 ; $P_CHBFRAME[0] = ctrans(x,1,y,2,z,3,a,4,b,5,c,6)
 ; $P_IFRAME = ctrans(x,1,y,2,z,3,a,4,b,5,c,6):crot(z,45)
 ; $P_PFRAME = ctrans(x,1,y,2,z,3,a,4,b,5,c,6):crot(x,10,y,20,z,30)
```

### 10.5.6.2 Frame for selection and deselection of transformations

This function is available with NCK 51.00.00 and higher. Transformations TRANSMIT, TRACYL and TRAANG are supported.

As a rule, the assignment of geometry axes to channel axes changes when selecting and deselecting transformations. It is not possible to uniquely assign axial frame components to geometric contour frame components when carrying out transformations, in which rotary axes become linear axes and vice versa. The contour frame must be conditioned using special treatment for such non-linear transformations.

The mode, set with MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 1 and 2, is expanded in such a way as to take the above transformations into account.

When selecting transformations, the contour frame is connected to the axial frames. With transformations TRANSMIT, TRACYL and TRAANG, the virtual geometry axis is subject to special treatment.

#### NOTICE

##### Transformations with virtual axes

When selecting TRANSMIT or TRACYL, offsets, scaling and mirroring of the real Y axis are not transferred and accepted in the virtual Y axis. Offsets, scaling and mirroring of the virtual Y axis are deleted for TRAFOOF.

## TRANSMIT

#### Transmit expansions:

The machine data below can be used to take the axial complete frame of the TRANSMIT rotary axis, i.e., the translation, fine offset, mirroring and scaling, into account in the transformation:

MD24905 \$MC\_TRANSMIT\_ROT\_AX\_FRAME\_1 = 1

MD24955 \$MC\_TRANSMIT\_ROT\_AX\_FRAME\_2 = 1

A rotary axis offset can, for example, be entered by compensating the oblique position of a workpiece in a frame within a frame chain. As a rule, this offset can also be included in the transformation as an offset in the rotary axis. A c axis offset, as in the figure above, then leads to corresponding x and y values.

MD24905 \$MC\_TRANSMIT\_ROT\_AX\_FRAME\_1 = 2

MD24955 \$MC\_TRANSMIT\_ROT\_AX\_FRAME\_2 = 2

With this setting, the axial offset of the rotary axis is taken account of in the transformation up to the SZS. The axial offsets of the rotary axis included in the SZS frames are entered into the transformation frame as rotation. This setting is only effective if the transformation frame has been configured.

#### Frame expansions:

The expansions described below are only valid for the following machine data settings:

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 1

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 2

The selection of transformation TRANSMIT produces a virtual geometry axis, coupled by way of the rotary axis, which is merely included in the contour frame but does not have a reference to an axial frame. The geometric value results from the rotation of a rotary axis. All other geometry axes accept their axial components when the transformation is selected.

#### Translations:

When selecting TRANSMIT, translations of the virtual axis are deleted. Translations of the rotary axis can be taken into account in the transformation.

#### Rotations:

Rotation before the transformation is taken over.

#### Mirroring:

Mirroring of the virtual axis is deleted. Mirroring of the rotary axis can be taken into account in the transformation.

#### Scaling:

Scaling of the virtual axis is deleted. Scaling of the rotary axis can be taken into account in the transformation.

#### Example:

**TRACYL**

**TRACYL expansions:**

The machine data below can be used to take the axial complete frame of the TRACYL rotary axis, i.e., the translation, fine offset, mirroring and scaling, into account in the transformation:

MD24805 \$MC\_TRACYL\_ROT\_AX\_FRAME\_1 = 1

MD24855 \$MC\_TRACYL\_ROT\_AX\_FRAME\_2 = 1

A rotary axis offset can, for example, be entered by compensating the oblique position of a workpiece in a frame within a frame chain. As a rule, this offset can also be included in the transformation as an offset in the rotary axis or as a y offset. A c axis offset, as in the figure above, then leads to corresponding x and y values.

MD24805 \$MC\_TRACYL\_ROT\_AX\_FRAME\_1 = 2

MD24855 \$MC\_TRACYL\_ROT\_AX\_FRAME\_2 = 2

With this setting, the axial offset of the rotary axis is taken account of in the transformation up to the SZS. The axial offsets of the rotary axis included in the SZS frames are entered into the transformation frame as offsets on the peripheral surface. This setting is only effective if the transformation frame has been configured.

**Frame expansions:**

The expansions described below are only valid for the following machine data settings:

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 1

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 2

The selection of transformation TRACYL produces a virtual geometry axis on the peripheral surface, coupled via the rotary axis, which is only taken into account in the contour frame but does not have a reference to an axial frame. All components of the virtual geometry axis are deleted. All other geometry axes accept their axial components when the transformation is selected.

**Translations:**

When selecting TRACYL, translations of the virtual axis are deleted. Translations of the rotary axis can be taken into account in the transformation.

**Rotations:**

Rotation before the transformation is taken over.

**Mirroring:**

Mirroring of the virtual axis is deleted. Mirroring of the rotary axis can be taken into account in the transformation.

**Scaling:**

Scaling of the virtual axis is deleted. Scaling of the rotary axis can be taken into account in the transformation.

**Example:****Machine data for TRACYL:**

```

## TRAANG

### Frame expansions:

The expansions described below are only valid for the following machine data settings:

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 1

MD10602 \$MN\_FRAME\_GEOAX\_CHANGE\_MODE = 2

### Translations:

When selecting TRAANG, translations of the virtual axis are deleted.

### Rotations:

Rotation before the transformation is taken over.

### Mirroring:

Mirrorings of the virtual axis are taken over.

### Scaling:

Scalings of the virtual axis are taken over.

**Example:****Machine data for TRAANG:**

```

; FRAME configurations

$MC_MM_SYSTEM_FRAME_MASK = 'H1' ; SETFRAME
$MC_CHSFRAME_RESET_MASK = 'H41' ; Frames are active after RESET.
$MC_CHSFRAME_POWERON_MASK = 'H41' ; Frames are deleted for "Power On".

$MN_FRAME_GEOAX_CHANGE_MODE = 1 ; Frames are calculated after switchover
 of the geo axis.

$MC_RESET_MODE_MASK = 'H4041' ; Basic frame is not deselected after
 RESET.
;$MC_RESET_MODE_MASK = 'H41' ; Basic frame is deselected after RESET.

### 10.5.6.3 Adapting active frames

The geometry axis configuration can change during program execution or on `RESET`. The number of available geometry axes can vary from zero to three. With unavailable geometry axes, components in the active frames (e.g., rotations) can lead to the active frames for this axis configuration becoming invalid. This is indicated by the alarms below:

Channel %1 block %2 rotation programmed for non-existent geometry axis

This alarm remains present until the frames have been changed accordingly.

The machine data below can be used to switch on the automatic adaptation of active frames, thus preventing alarm 16440:

MD24040 \$MC\_FRAME\_ADAPT\_MODE

Bitmask for adapting the active frames with reference to the axis constellation.

The following settings apply:

- Bit 0: Rotations in active frames, which rotate coordinate axes with no geometry axes, are deleted from the active frames.
- Bit 1: Shear angles in the active frames are orthogonalized.
- Bit 2: Scalings of all geometry axes in the active frames are set to value 1.

With machine data setting

MD24040 \$MC\_FRAME\_ADAPT\_MODE = 1,

all rotations in the active frames, which could produce coordinate axis movements for non-existent geometry axes, are deleted.

The data management frames are not changed. Only the possible rotations are applied when the data management frames are activated.

Example:

No y axis exists:

MD20050 \$MC\_AXCONF\_GEOAX\_ASSIGN\_TAB[0] = 1

MD20050 \$MC\_AXCONF\_GEOAX\_ASSIGN\_TAB[1] = 0

MD20050 \$MC\_AXCONF\_GEOAX\_ASSIGN\_TAB[2] = 3

\$P\_UIFR[1] = crot(x,45,y,45,z,45)

```
N390 G54 G0 X10 z10 f10000

if $P_IFRAME <> crot(y,45) ; Only the rotation about y is taken over.
setal(61000)
endif
```

#### 10.5.6.4 Mapped frames

##### Overview

The "Mapped frames" function supports the cross-channel consistent change of axial frames, which are performed in channel-specific or global data management frames.

For instance, if the frame mapping is active for machine axes AX1 and AX4, and the axial frame for AX1 is written in the data management in the channel-specific basic frame \$P\_CHBFR[0], then this frame data is also accepted for AX4 in all channels in which the axis is parameterized as channel axis.

## Preconditions

The following preconditions must be fulfilled for frame mapping:

- The data management frames relevant for mapping must be configured:  
MD28083 \$MC\_MM\_SYSTEM\_DATAFRAME\_MASK (system frames)
- The relevant channel-specific data management frames must be enabled for mapping:  
MD10616 \$MN\_MAPPED\_FRAME\_MASK (enable frame mapping)

### Note

Mapping is always performed for global data management frames. They do not have to be explicitly enabled for this purpose.

## Parameter assignment

The parameterization of the mapping relationships is realized in the axis-specific machine data:

MD32075 \$MA\_MAPPED\_FRAME[<AXn>] = "AXm"

AXn, AXm: Machine axis identifier with n, m = 1, 2, ... max. number of machine axes

## Mapping rules

The following rules apply for frame mapping:

- The mapping is bidirectional.  
An axial frame can be written for AXn or AXm. The frame data are always accepted and taken for the other axis.
- All parameterized mapping relationships are always evaluated.  
When writing an axial frame of axes AXn, all mapping relationships are evaluated and the frame data accepted for all directly and indirectly involved axes.
- The mapping is global across all channels.  
When writing an axial frame of axis AXn or AXm for a channel-specific frame, the frame data are accepted for all channels in which AXn or AXm are parameterized as channel axes.
- Circular relationships are not permissible.  
The mapping relationships must not be parameterized so that when writing an axial frame of axes AXn in an NC channel, two axes are simultaneously changed.

- When writing an axial frame, if the geometry or special axis identifier is used, the currently assigned machine axis identifier is used to evaluate the mapping relationships.
- Mapping is frame-specific.  
When writing an axial frame, the frame data is only mapped within the same channel-specific or global data management frame.

**NOTICE****Data consistency**

The user/machine manufacturer is solely responsible for ensuring that after a frame is written, consistent frame data is subsequently used in all channels - e.g. by using channel synchronization.

**Permissible mapping**

|   | Description                                                                                                                                                        | Parameter assignment: \$MA_                                |

| ② | Chained mapping relationships where axes AX4 and AX5 are always simultaneously written and these are channel axes in the same channel. | MAPPED_FRAME[<AX4>] = "AX7"<br>MAPPED_FRAME[<AX5>] = "AX8" |

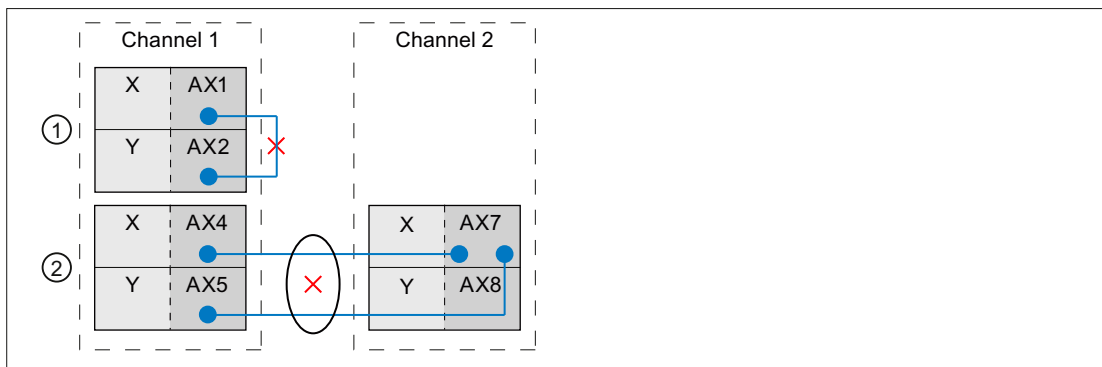

Figure 10-23 Examples: Mapping that is not permissible

## Activating the data management frame

Data management frames can be written in the part program and via the user interface of SINUMERIK Operate. The following should be noted when activating the data management frames in the channels written directly and via frame mapping:

- Writing in the part program  
The data management frames must be explicitly activated in each channel (G500, G54 ... G599)
- Writing via user interface  
Data management frames are written via the user interface – e.g. by entering new work offsets. A modified data management frame is immediately active in all of the involved channels if none of these channels is in the "Channel active" state. The data management frame is not active in any channel if one of the channels involved is in the "Channel active" state. The activation must then be explicitly programmed in each channel in the part program (G500, G54 ... G599). Or, the next time that the channel state changes, it becomes active after "Channel reset".

## Example

The following channels and channel axes are parameterized at a control:

- Channel 1
  - Z: Geometry axis
  - AX1: Machine axis
- Channel 2
  - Z: Geometry axis
  - AX4: Machine axis

The zero point of the Z axis should always be the same in both channels:

- Mapping relationship: \$MA\_MAPPED\_FRAME[AX1] = "AX4"

### Programming in the part program

#### Channel 1

```
...
N100 WAIT (10,1,2)
N110 $P_UIFR[1] = CTRANS(Z, 10)
N120 WAIT (20,1,2)
N130 G54
N140 IF ($P_IFRAME[0, Z, TR] <> 10)
N150 SETAL(61000)
N160 ENDIF
...
```

#### Channel 2

```
...
N200 WAIT (10,1,2)
N220 WAIT (20,1,2)
N230 G54
N230 IF ($P_IFRAME[0, Z, TR] <> 10)
N250 SETAL(61000)
N260 ENDIF
...
```

## 10.5.7 Predefined frame functions

### 10.5.7.1 Inverse frame

To round off the frame arithmetic, the part program provides a function which calculates the inverse frame from another frame. The chaining between a frame and its inverse frame always produces a zero frame.

FRAME INVFRAME( FRAME )

Frame inversion is an aid for coordinate transformations. Measuring frames are usually calculated in the WCS. If you should wish to transform this calculated frame into another coordinate system, i.e., the calculated frame should be entered into any desired frame within the frame chain, the calculations below should be used.

The new complete frame is a chain of the old complete frame and the calculated frame.

\$P\_ACTFRAME = \$P\_ACTFRAME : \$AC\_MEAS\_FRAME

The new frame in the frame chain is therefore:

Target frame is \$P\_SETFRAME:

\$P\_SETFRAME = \$P\_ACTFRAME : \$AC\_MEAS\_FRAME : INVFRAME(\$P\_ACTFRAME) : \$P\_SETFRAME

Target frame is nth channel basic frame \$P\_CHBFRAME[n]:

n = 0: TMP = \$P\_PARTFRAME : \$P\_SETFRAME : \$P\_EXTFRAME : \$P\_NCBFRAME[0..k]

n <> 0: TMP = \$P\_PARTFRAME : \$P\_SETFRAME : \$P\_EXTFRAME : \$P\_NCBFRAME[0..k] : \$P\_CHBFRAME[0..n-1]

k = \$MN\_MM\_NUM\_GLOBAL\_BASE\_FRAMES

\$P\_CHBFRAME[n] = INVFRAME(TMP) : \$P\_ACTFRAME : \$AC\_MEAS\_FRAME : INVFRAME(\$P\_ACTFRAME) : TMP : \$P\_CHBFRAME[n]

Target frame is \$P\_IFRAME:

```
TMP = $P_PARTFRAME : $P_SETFRAME : $P_EXTFRAME : $P_BFRAME
$P_IFRAME = INVFRAME(TMP) : $P_ACTFRAME : $AC_MEAS_FRAME :
INVFRAME($P_ACTFRAME) : TMP : $P_IFRAME
```

Application example:

A frame calculated, for example, via a measuring function, must be entered in the current `SETFRAME` such that the new complete frame is a chain of the old complete frame and the measurement frame. The `SETFRAME` is calculated accordingly by means of frame inversions.

```

### 10.5.7.2 Additive frame in frame chain

Measurements on the workpiece or calculations in the part program and cycles generally produce a frame that is applied additively to the current complete frame. The WCS and thus the programming zero must, therefore, be displaced and possibly rotated. This measured frame is available as a temporary frame and not yet actively included in the frame chain. This function is used to calculate and possibly activate this frame:

```
INT ADDFRAME (FRAME, STRING)
```

#### Programming

Parameter 1:      Type: `FRAME`      Additively measured or calculated frame

Parameter 2:      Type: `STRING`      Strings for current frames:  
 "\$P\_CYCFRAME", "\$P\_ISO4FRAME",  
 "\$P\_PFRAME", "\$P\_WPFRAME",  
 "\$P\_TOOLFRAME", "\$P\_IFRAME",  
 "\$P\_CHBFRAME[0..16]", "\$P\_NCBFRAME[0..16]",  
 "\$P\_ISO1FRAME", "\$P\_ISO2FRAME",  
 "\$P\_ISO3FRAME",  
 "\$P\_EXTFRAME", "\$P\_SETFRAME"  
 "\$P\_PARTFRAME"

Strings for data management frames:  
 "\$P\_CYCFR", "\$P\_ISO4FR", "\$P\_TRAFR",  
 "\$P\_WPFR",  
 "\$P\_TOOLFR", "\$P\_UIFR[0..99]",  
 "\$P\_CHBFR[0..16]", "\$P\_NCBFR[0..16]",  
 "\$P\_ISO1FR", "\$P\_ISO2FR", "\$P\_ISO3FR",  
 "\$P\_EXTFR", "\$P\_SETFR", "\$P\_PARTFR"

|                 |                        |        |                                    |
|-----------------|------------------------|--------|------------------------------------|
| Function value: | Type: <code>INT</code> | Value: | Significance:                      |
|                 |                        | 0      | OK                                 |
|                 |                        | 1      | Specified target (string) is wrong |
|                 |                        | 2      | Target frame is not configured     |
|                 |                        | 3      | Rotation in frame is not permitted |

The `ADDFRAME ()` function calculates the target frame, which is specified by the `STRING`. The target frame is calculated in such a way that the new complete frame appears as a chain of the old complete frame and the transferred frame, e.g.:

```
ERG = ADDFRAME (TMPFRAME, "$P_SETFRAME")
```

The new complete frame is calculated to be:

$$\$P\_ACTFRAME_{new} = \$P\_ACTFRAME_{old} : TMPFRAME$$

If a current frame has been specified as a target frame, then the new complete frame becomes active at the preprocessing stage. If the target frame is a data management frame, then the frame is not operative until it is explicitly activated in the part program.

The function does not set any alarms, but returns the error codes via the return value. The cycle can react according to the error codes.

## 10.5.8 Functions

### 10.5.8.1 Setting zeros, workpiece measuring and tool measuring

PRESET is achieved using HMI operator actions or measuring cycles. The calculated frame can be written to system frame `SETFRAME`. The position setpoint of an axis in the WCS can be altered when the actual-value memory is preset.

"Scratching" means workpiece and tool measuring. The position of the workpiece in relation to an edge, a corner or a hole can be measured. To determine the zero position of the workpiece or the hole, position setpoints can be added to the measured positions in the WCS. The resultant offsets can be entered in a selected frame. In tool measuring, the length or radius of a tool can be measured using a measured reference part.

Measurements can be taken via operator actions or measuring cycles. Communication with the NCK takes place via predefined system variables. In the NCK, the calculation is made by using a HMI operator action to activate a PI service, or by using a part-program command from the measuring cycles. A tool and a plane can be selected as a basis for the calculation. The calculated frame is entered in the result frame.

### 10.5.8.2 Zero offset external via system frames

#### Zero offset via PLC or part program

The amount of the external zero offset can be specified through HMI and PLC via BTSS or programmed in the part program via the axis-specific system variable `$AA_ETRANS`  
[<Axis>] = <Value>.

#### Activation

The activation of the external zero offset takes place through the interface signal: DB31, ... DBX3.0 (accept external zero offset)

#### Behavior

After the activation the respective specified axis-specific amount of the external zero offset is traversed outside for each axis with the next possible traversing block.

Next possible means that enough dynamic reserves must be available for the respective axis for traversing the zero offset. If the axis is traversed in the next traversing block after activation owing to its programming with the maximum speed, dynamic reserve is no longer available for traversing the external zero offset.

Together with the continuous path mode `G64` the traversing of the offset can stretch over several part program blocks.

### Zero offset via system frame

The external zero offset can then also be managed and activated by the functionality described above via the system frame \$P\_EXTFRAME .

#### Configuring

The configuring of the external zero offset is done via the system frame \$P\_EXTFRAME via bit1 = 1 in the machine data: MD28082 \$MC\_MM\_SYSTEM\_FRAME\_MASK = 'B0010'  
The amount for the external zero offset can be specified manually via the HMI user interface and the PLC user program via BTSS or programmed in the part program via the axial system variable \$AA\_ETRANS[<Axis>].

#### Activation

The activation of the external zero offset takes place through the interface signal: DB31, ... DBX3.0 (accept external zero offset)

#### Behavior

Upon activation of the external zero offset the traversing movements of all axes, except command and PLC axes, are stopped immediately and the advance is reorganized. The rough offset of the current system frame and of the system frame in data management is set to the value of the axial system variable \$AA\_ETRANS[<axis>]. Thereafter, the offset is traversed first and then the interrupted movement is continued.

#### Behavior for incremental dimension

In case of active incremental dimension G91 and machine data:  
MD42440 \$MC\_FRAME\_OFFSET\_INCR\_PROG (zero offset in frames) = 0  
traversing the offset is done in the scope of the external zero offset via system frame, despite opposite configuring of the machine data, with the approach block, although it is specified by a frame.

---

#### Note

The external zero offset always acts absolutely.

---

### 10.5.8.3 Toolholder

#### Translations

With kinematics of type P and M the selection of a toolholder activates an additive frame (table offset of the orientational toolholder), which takes into account the zero point offset as a result of the rotation of the table. The zero offset is entered in a system frame (\$P\_PARTFR). In this case the translatory component of this frame is overwritten. Other contents of this frame remain intact.

To be able to use this system frame, the bit 2 must be set in the machine data: MD28082 \$MC\_MM\_SYSTEM\_FRAME\_MASK.

Alternatively, there is the option to enter this offset into the basic frame identified by machine data

MD20184 \$MC\_TOCARR\_BASE\_FRAME\_NUMBER.

This option is available in the interests of compatibility with older software versions.

It is not recommended for use with new systems.

A frame offset as a result of a toolholder change becomes effective immediately on selection of `TCARR=...`. A change in the tool length, on the other hand, only becomes effective immediately if a tool is active.

A frame rotation does not take place on activation and a rotation which is already active is not changed. As in case T (only the tool can be rotated), the position of the rotary axes used for the calculation is dependent on the G code `TCOFR / TCOABS` and determined from the rotation component of an active frame or from the entries `$TC_CARRn`. Activation of a frame changes the position in the workpiece coordinate system accordingly, without compensating movement by the machine itself.

The ratios are shown in the figure below:

Figure 10-24 Frame on activation of a rotary table with TCARR

With kinematics of type M (tool and table are each rotary around one axis), the activation of a toolholder with `TCARR` simultaneously produces a corresponding change in the effective tool length (if a tool is active) and the zero offset.

## Rotations

Depending on the machining task, it is necessary to take into account not only a zero offset (whether as frame or as tool length) when using a rotary toolholder or table, but also a rotation. However, the activation of an orientational toolholder never leads directly to a rotation of the coordinate system.

If only the tool can be rotated, a frame can be defined for it using `TOFRAME` or `TOROT`.

With rotary tables (kinematics types P and M), activation with `TCARR` similarly does not lead to an immediate rotation of the coordinate system, i.e. even though the zero point of the coordinate system is offset relative to the machine, while remaining fixed relative to the zero point of the workpiece, the orientation remains unchanged in space.

If the coordinate system needs to be fixed relative to the workpiece, i.e. not only offset relative to the original position but also rotated according to the rotation of the table, then `PAROT` can be used to activate such a rotation in a similar manner to the situation with a rotary tool.

With `PAROT`, the translations, scalings and mirroring in the active frame are retained, but the rotation component is rotated by the rotation component of an orientational toolholder corresponding to the table.

Up to and including SW P6.1, the rotation activated by `PAROT` is calculated in the programmable frame (`$P_PFRAME`), thus changing its rotation component.

With SW P6.2 and higher, the entire programmable frame remains unchanged, including its rotation component.

The rotation component, which describes the rotation of the tool table, is then entered into system frame `$PARTFR`, if bit 2 of machine data `MD28082 $MC_MM_SYSTEM_FRAME_MASK` is set.

Alternatively, the basic frame described in machine data `MD20184 $MC_TOCARR_BASE_FRAME_NUMBER` can also be used.

As with the note made in the description of the table offset, the second alternative here is not recommended for use with new systems.

The rotation component of the part frame can be deleted with `PAROTOF`, independently of whether this frame is found in a basic or a system frame.

The translation component is deleted when a toolholder, which does not produce an offset, is activated or a possibly active orientational toolholder is deselected with `TCARR=0`.

`PAROT` or `TOROT` take into account the overall orientation change in cases where the table or the tool are oriented with two rotary axes. With mixed kinematics only the corresponding component caused by a rotary axis is considered. It is thus possible, for example, when using `TOROT`, to rotate a workpiece such that an oblique plane lies parallel to the X-Y plane fixed in space, whereby rotation of the tool must be taken into account in machining where any holes to be drilled, for example, are not perpendicular to this plane.

**Example:**

On a machine, the rotary axis of the table points in the positive Y direction. The table is rotated by +45 degrees. `PAROT` defines a frame, which similarly describes a rotation of 45 degrees about the Y axis. The coordinate system is not rotated relative to the actual environment (marked in the figure with "Position of the coordinate system after TCARR"), but is rotated by -45 degrees relative to the defined coordinate system (position after PAROT). If this coordinate system is defined with `ROT Y-45`, for example, and if the toolholder is then selected with active `TCOFR`, an angle of +45 degrees will be determined for the rotary axis of the toolholder.

Language command `PAROT` is not rejected if no orientational toolholder is active. However, such a call then produces no frame changes.

**Machining in direction of tool orientation**

Particularly on machines with tools that can be oriented, traversing should take place in the tool direction (typically, when drilling) without activating a frame (e.g. using `TOFRAME` or `TOROT`), on which one of the axes points in the direction of the tool. This is also a problem if, when carrying out oblique machining operations, a frame defining the oblique plane is active, but the tool cannot be set exactly perpendicularly because an indexed toolholder (Hirth tooth system) prevents free setting of the tool orientation. In these cases it is then necessary - contrary to the actually requested motion perpendicular to the plane - to drill in tool direction, as the drill would otherwise not be guided in the direction of its longitudinal axis, which among other things would lead to breaking of the drill.

The end point of such a motion is programmed with `MOV T= . . . .`

The programmed value is effective incrementally in the tool direction as standard.

The positive direction is defined from the tool tip to the tool adapter. The content of `MOV T` is thus generally negative for the infeed motion (when drilling), and positive for the retraction motion.

This corresponds to the situation with normal paraxial machining, e.g. with `G91 Z . . . .`

Instead of `MOV T= . . .` it is also possible to write `MOV T=IC ( . . . )` if it is to be plainly visible that `MOV T` is to function incrementally. There is no functional difference between the two forms.

If the motion is programmed in the form `MOV T=AC ( . . . )`, `MOV T` functions absolutely.

In this case a plane is defined, which runs through the current zero point, and whose surface normal vector is parallel to the tool orientation. `MOV T` then gives the position relative to this plane (see figure). The reference plane is only used to calculate the end position. Active frames are not affected by this internal calculation.

Programming with `MOV T` is independent of the existence of a toolholder that can be oriented. The direction of the motion is dependent on the active plane.

It runs in the directions of the vertical axes, i.e. with `G17` in Z direction, with `G18` in Y direction and with `G19` in X direction. This applies both where no orientational toolholder is active and for the case of an orientational toolholder without rotary tool or with a rotary tool in its basic setting.

`MOV T` acts similarly for active orientation transformation (3-4-5-axis transformation).

If in a block with `MOV T` the tool orientation is changed simultaneously (e.g. active 5-axis transformation by means of simultaneous interpolation of the rotary axes), the orientation at the start of the block is decisive for the direction of movement of `MOV T`.

With an active 5-axis transformation, the path of the tool center point (TCP) is not affected by the change of orientation, i.e. the path remains a straight line and its direction is determined by the tool orientation at the start of the block.

If `MOV T` is programmed, linear or spline interpolation must be active (`G0`, `G1`, `ASPLINE`, `BSPLINE`, `CSPLINE`). Otherwise, an alarm is produced.

If a spline interpolation is active, the resultant path is generally not a straight line, since the end point calculated by `MOV T` is treated as if it had been programmed explicitly with X, Y, Z.

A block with `MOV T` must not contain any programming of geometry axes (alarm 14157).

### Definition of frame rotations with solid angles

Where a frame is to be defined to describe a rotation around more than one axis, this is achieved through chaining individual rotations. A new rotation is hereby always performed in the already rotated coordinate system.

This also applies to programming in a block e.g. with `ROT X... Y... Z...`,

(the sequence of rotations is defined by machine data:

`MD10600 $MN_FRAME_ANGLE_INPUT_MODE`

and is independent of the sequence of the axis letters in the block)

and when constructing a frame in multiple blocks, e.g. in the format:

```
N10 ROT Y...
N20 AROT X...
N30 AROT Z...
```

In workpiece drawings, oblique surfaces are frequently described by way of solid angles, i.e. the angles, which the intersection lines of the oblique plane form with the main planes (X-Y, Y-Z, Z-X planes) (see figure). The machine operator is not expected to convert these solid angles into the angles of rotation of a chaining of individual rotations.

For this reason, the language commands `ROTS`, `AROTS` and `CROTS` are used, with which the rotations can be immediately described as solid angles.

The orientation of a plane in space is defined unambiguously by specifying two solid angles. The third solid angle is derived from the first two. Therefore, a maximum of 2 solid angles may be programmed, e.g. in the form `ROTS X10 Y15`. If a third solid angle is specified, an alarm will be triggered.

It is permissible to specify a single solid angle. The rotations which are performed with `ROTS` or `AROTS` in this case are identical to those for `ROT` and `AROT`.

An expansion of the existing functionality arises only in cases where exactly two solid angles are programmed.

The two programmed axes define a plane, the non-programmed axis defines the related third axis of a right-hand coordinate system. Which axis is first and which second is then unambiguously defined for both programmed axes (the definition corresponds to those found in the plane definition of `G17/G18/G19`). The angle programmed with the axis letter of an axis of the plane then specifies the axis, around which the other axis of the plane must be rotated in order to move this into the line of intersection, which the rotated plane forms with the plane surrounded by the other and the third axis. This definition ensures that, in the case that one of the two programmed angles is towards zero, the defined plane enters the plane, which is created if only one axis is programmed (e.g. with `ROT` or `AROT`).

The diagram shows an example where X and Y are programmed. Y here gives the angle, by which the X axis must rotate around the Y axis to bring the X axis to the line of intersection formed by the oblique plane and the X-Z plane. The same principle applies for the programmed value of X.

---

**Note**

In the shown position of the oblique plane the value of Y is positive, that of X on the other hand negative.

---

The specification of the solid angle does not define the orientation of the two-dimensional coordinate system within the plane (i.e. the angle of rotation around the surface normal vector). The position of the coordinate system is thus determined so that the rotated first axis lies in the plane, which is surrounded by the first and third axes of the non-rotated coordinate system.

This means that

- When programming X and Y the new X axis lies in the old Z-X plane.
- When programming Z and X the new Z axis lies in the old Y-Z plane.
- When programming Y and Z the new Y axis lies in the old X-Y plane.

If the required coordinate system does not correspond to this basic setting, then an additional rotation must be performed with `AROT...`

On programming the solid angles, they are converted into the equivalent RPY or Euler angles, depending on machine data:

`MD10600 $MN_FRAME_ANGLE_INPUT_MODE.`

These then appear also in the display.

## Frame rotation in tool direction

With the language command `TOFRAME`, which also existed in older software versions, it is possible to define a frame whose Z axis points in the tool direction.

An already programmed frame is then overwritten by a frame, which describes a pure rotation. Any zero offsets, mirrorings or scalings existing in the previously active frame are deleted.

This response is sometimes interfering. It is often particularly practical to retain a zero offset, with which the reference point in the workpiece is defined.

The language command `TOROT` is then also used. This command overwrites only the rotation component in the programmed frame and leaves the remaining components unchanged.

The rotation defined with `TOROT` is the same as that defined with `TOFRAME`.

`TOROT` is, like `TOFRAME`, independent of the availability of an orientational toolholder. This language command is also especially useful for 5-axis transformations.

The new language command `TOROT` ensures consistent programming with active orientational toolholders for each kinematics type.

`TOFRAME` or `TOROT` defines frames whose Z direction points in the tool direction. This definition is suitable for milling, where `G17` is usually active. However, particularly with turning or, more generally, when `G18` or `G19` is active, it is desirable that frames, which will be aligned on the X or Y axis, can be defined. As a result of this, the G codes below are newly introduced into G code group 53:

```
TOFRAMEX
TOFRMAEY
TOFRAMEZ
TOROTX
TOROTY
TOROTZ
```

These G codes enable corresponding frames to be defined. The functions of `TOFRAME` and `TOFRAMEZ` or of `TOROT` and `TOROTZ` are identical to one another.

With software version P6 and higher, there is the option to write frames produced by `TOROT` or `TOFRAME` into their own system frame (`$P_TOOLFR`).

For this, bit 3 must be set in machine data:

```
MD28082 $MC_MM_SYSTEM_FRAME_MASK.
```

The programmable frame is then retained unchanged.

When programming `TOROT` or `TOFRAME`, etc. response is identical, with or without a system frame. Differences occur when the programmable frame is processed further elsewhere.

In new systems, it is recommended that only the intended system frame is used for frames produced by G codes in group 53.

Example:

`TRANS` is programmed after `TOROT`. `TRANS` without specified parameters deletes the programmable frame. In the variant without a system frame, this also deletes the frame component of the programmable frame produced by `TOROT`, but if the `TOROT` component is in the system frame, it is retained.

`TOROT` or `TOFRAME`, etc. are disabled with language command `TOROTOF`. `TOROTOF` deletes the entire system frame `$P_TOOLFR`. If the programmable frame (old variant) and not the system frame is described by commands `TOFRAME`, etc. `TOROT` only deletes the rotation component and leaves the remaining frame components unchanged.

If a rotating frame is already active before language command `TOFRAME` or `TOROT` is activated, a request is often made that the newly defined frame should deviate as little as possible from the old frame. This is the case, for example, if a frame definition needs to be modified slightly because the tool orientation cannot be set freely on account of Hirth-toothed rotary axes. The language commands uniquely define the Z direction of the new frame.

In previous software versions, machine data:

```
MD21110 $MC_X_AXIS_IN_OLD_X_Z_PLANE
```

can be used to choose between two variants for the position of the X-axis and Y-axis.

However, in both cases there is no reference to the previously active frame.

Setting data

```
SD42980 $SC_TOFRAME_MODE
```

is, therefore, introduced, which can be used to control the response of `TOFRAME` and `TOROT`.

It can accept values of 0 (inactive) to 3. If the value of the setting data is not zero, the effect of machine data:

```
MD21110 $MC_X_AXIS_IN_OLD_X_Z_PLANE
```

is overwritten.

The values 1 to 3 have the following meanings:

- 1: The new X direction is chosen to lie in the X-Z plane of the old coordinate system. In this setting the angle difference between the old and new Y axis will be minimal.
- 2: The new Y direction is chosen to lie in the Y-Z plane of the old coordinate system. In this setting the angle difference between the old and new Y axis will be minimal.
- 3: The value chosen is the mean value of the two settings, which would have been chosen with 1 and 2.

**Characteristics and expansions:**

Settings 1 and 2 are reached by rotating the coordinate system around the Z axis, starting from any position on the X and Y axis, until the desired setting is reached. Setting 3 is achieved by executing a rotation whose value is the exact mean of these two angles. However, this only applies for the case that the old and new Z direction enclose an angle of less than 90 degrees. With variant 1, both the old and new X axes form an angle of under 90 degrees, with variant 2 the same is true of the Y axis (the relevant axes point in "approximately" the same direction). If the two Z directions form an angle of more than 90 degrees, however, the conditions of an angle < 90 degrees between the old and new axes can no longer be met simultaneously for both X and Y. In this case, priority is given to the X direction, i.e. a mean value is taken from the direction for 1 and the negative direction for 2.

If one of the G codes `TOFRAMEX`, `TOFRAMEY`, `TOROTX`, `TOROTY` is programmed in place of `TOFRAME(Z)` or `TOROT(Z)`, the descriptions for adapting the axis directions perpendicular to the main direction are also valid for the cyclically exchanged axes. The assignments in the table below are then valid:

|                                     | <code>TOFRAME</code> , <code>TOFRAMEZ</code><br><code>TOROT</code> , <code>TOROTZ</code> | <code>TOFRAMEY</code><br><code>TOROTY</code> | <code>TOFRAMEX</code><br><code>TOROTX</code> |
|-------------------------------------|------------------------------------------------------------------------------------------|----------------------------------------------|----------------------------------------------|
| Tool direction<br>(vertical axis)   | Z                                                                                        | Y                                            | X                                            |
| Secondary axis<br>(horizontal axis) | X                                                                                        | Z                                            | Y                                            |
| Secondary axis<br>(ordinate)        | Y                                                                                        | X                                            | Z                                            |

**Example:**

```

...
...
N90 $SC_TOFRAME_MODE=1
N100 ROT Z45
N110 TCARR=1 TCOABS T1 D1
N120 TOROT
...
...

```

N100 describes a rotation by 45 degrees in the X-Y plane. It is assumed that the toolholder activated in N110 rotates the tool by 30 degrees around the X axis, i.e. the tool lies in the Y-Z plane and is rotated by 30 degrees relative to the Z axis. As a result the Z axis of the frame newly defined in N120 also points in this direction (independently of the value in setting data SD42980 \$SC\_TOFRAME\_MODE in N90).

In the figure below, the situation for setting data setting: SD42980 \$SC\_TOFRAME\_MODE=1 is shown:

The old and new X axes X and X' coincide in the projection in the direction of the old Z axis. The old and new Y axes Y and Y' form an angle of 8.13 degrees (right angles are generally not retained in the projection).

For setting data setting: SD42980 \$SC\_TOFRAME\_MODE=2, Y and Y' would coincide accordingly and X and X' would form an angle of 8.13 degrees.

For setting data setting: SD42980 \$SC\_TOFRAME\_MODE=3, X and X', as well as Y and Y', would each form an angle of 4.11 degrees.

#### Note

The named angles (8.13 and 4.11 degrees) are the angles, which the projections of the axes form in the X-Y plane. They are not the spatial angles of these axes.

## TCARR and PAROT

Previously, TCARR has used the basic frame identified by machine data: MD20184 \$MC\_TOCARR\_BASE\_FRAME\_NUMBER.

A system frame can be created for TCARR and PAROT alone, in order to avoid conflicts with systems, which already use all the basic frames.

`PAROT`, `TOROT` and `TOFRAME` have previously changed the rotation component of the programmable frame. In this case, it is not possible to shut down `PAROT` or `TOROT` separately. On `RESET`, the programmable frame is deleted, which means the after changing the operating mode to `JOG`, the rotation component of `PAROT` and `TOROT` is no longer available. The user must also have unrestricted access to the programmable frame. Frames produced by `PAROT` and `TOROT` must be able to be archived and reloaded via data backup.

The system frame for `TCARR` and `PAROT` is configured with bit 2 in machine data: `MD28082 $MC_MM_SYSTEM_FRAME_MASK`.

Machine data:  
`MD20184 $MC_TOCARR_BASE_FRAME_NUMBER`  
is then no longer evaluated.

If the system frame for `TCARR` is configured, `TCARR` and `PAROT` describe that system frame; otherwise the basic frame identified by machine data: `MD20184 $MC_TOCARR_BASE_FRAME_NUMBER` is described.

With kinematics systems of the types P and M, `TCARR` will enter the table offset of the orientational toolholder (zero offset resulting from the rotation of the table) as a translation into the system frame. `PAROT` converts the system frame such, that a part-oriented WCS results.

The system frames are stored in the SRAM and, therefore, remain stored after Reset. The system frames also remain active in the case of a mode change.

For the display, the G codes `PAROT` and `TOROT`, `TOFRAME` are each assigned to a separate G code group.

## PAROTOF

`PAROTOF` is the switch off command for `PAROT`. This command deletes the rotations in the system frame for `PAROT`. In so doing, the rotations in the current `$P_PARTFRAME` and in the data management frame `$P_PARTFR` are deleted. The position of the coordinate system is then recreated according to `TCARR`. `PAROTOF` is in the same G code group as `PAROT` and appears, therefore, in the G code display.

## TOROT and TOFRAME

The system frame for `TOROT` and `TOFRAME` is configured with bit 3 in machine data: `MD28082 $MC_MM_SYSTEM_FRAME_MASK`.

This system frame is located before the programmable frame in the frame chain. The SZS coordinate system is located before the programmable frame.

## TOROTOF

`TOROTOF` is the switch off command for `TOROT` and `TOFRAME`. This command deletes the system frame for `TOROT` and `TOFRAME`. The current `$P_TOOLFRAME` and the data management frame `$P_TOOLFR` are also deleted. `TOROTOF` is in the same G code group as `TOROT` and `TOFRAME` and appears, therefore, in the G code display.

## Example

Example of using an orientational toolholder with deactivated kinematics:

```

N10 $TC_DP1[1,1]= 120
N20 $TC_DP3[1,1]=13 ; Tool length 13 mm
; Definition of toolholder 1:
N30 $TC_CARR1[1] = 0 ; X components of 1st offset vector
N40 $TC_CARR2[1] = 0 ; Y components of 1st offset vector
N50 $TC_CARR3[1] = 0 ; Z components of 1st offset vector
N60 $TC_CARR4[1] = 0 ; X components of 2nd offset vector
N70 $TC_CARR5[1] = 0. ; Y components of 2nd offset vector
N80 $TC_CARR6[1] = -15. ; Z components of 2nd offset vector
N90 $TC_CARR7[1] = 1 ; X components of 1st axis
N100 $TC_CARR8[1] = 0 ; Y components of 1st axis
N110 $TC_CARR9[1] = 0 ; Z components of 1st axis
N120 $TC_CARR10[1] = 0 ; X components of 2nd axis
N130 $TC_CARR11[1] = 1 ; Y components of 2nd axis
N140 $TC_CARR12[1] = 0 ; Z components of 2nd axis
N150 $TC_CARR13[1] = 30. ; Angle of rotation of 1st axis
N160 $TC_CARR14[1] = -30. ; Angle of rotation of 2nd axis
N170 $TC_CARR15[1] = 0 ; X components of 3rd offset vector
N180 $TC_CARR16[1] = 0 ; Y components of 3rd offset vector
N190 $TC_CARR17[1] = 0 ; Z components of 3rd offset vector
N200 $TC_CARR18[1] = 0 ; X components of 4th offset vector
N210 $TC_CARR19[1] = 0 ; Y component of 4th offset vector
N220 $TC_CARR20[1] = 15. ; Z components of 4th offset vector
N230 $TC_CARR21[1] = A ; Reference for 1st axis
N240 $TC_CARR22[1] = B ; Reference for 2nd axis
N250 $TC_CARR23[1] = "M" ; Toolholder type
N260 X0 Y0 Z0 A0 B45 F2000
N270 TCARR=1 X0 Y10 Z0 T1 TCOABS ; Selection of orient. toolholder
N280 PAROT ; Rotation of table
N290 TOROT ; Rotation of z axis in tool orient.
N290 X0 Y0 Z0
N300 G18 MOV=AC(20) ; Processing in G18 plane
N310 G17 X10 Y0 Z0 ; Processing in G17 plane
N320 MOV=-10
N330 PAROTOF ; Deactivate rotation of table
N340 TOROTOF ; No longer align WCS with tool
N400M30

```

### 10.5.9 Subprograms with SAVE attribute (SAVE)

For various frames, the behavior regarding subprograms can be set using the SAVE attribute.

#### Settable frames G54 to G599

The behavior of the adjustable frames can be set using MD10617 \$MN\_FRAME\_SAVE\_MASK.BIT0:

- BIT0 = 0

Using the subprogram, if only the values of the active adjustable frame are changed using the system variable \$P\_IFRAME, but the G functions are kept, then the change is also kept after the end of the subprogram.

- BIT0 = 1

With the end of the subprogram, the adjustable frame, G function and values, active before the subprogram call, are reactivated.

#### Basic frames \$P\_CHBFR[ ] and \$P\_NCBFR[ ]

The behavior of the basic frame can be set using MD10617 \$MN\_FRAME\_SAVE\_MASK.BIT1:

- BIT1 = 0

If the active basic frame is changed by the subprogram, the change remains effective even after the end of the subprogram.

- BIT1 = 1

With the end of the subprogram the basic frame which is active before the subroutine call is reactivated.

#### Programmable frame

With the end of the subprogram the programmable frame active before the subroutine call is reactivated.

#### System frames

If the system frames are changed by the subprogram, the change remains effective even after the end of the subprogram.

### 10.5.10 Data backup

Data block `_N_CHANx_UFR` is used to archive the system frames.

Machine data

`MD28082 $MC_MM_SYSTEM_FRAME_MASK`

should not have changed between saving and reintroducing the saved system frames. If it has changed then it is possible that saved system frames could no longer be loaded. In this case, the loading process triggers an alarm.

Data backup always takes place in accordance with the currently valid geometry axis assignment, not in accordance with the axis configurations set in the machine data.

The machine data

`$MC_MM_SYSTEM_DATAFRAME_MASK`

can be used to configure data management frames for the system frames.

If you do not want a data management frame for a system frame, the frame does not have to be saved. With `G500`, `G54` to `G599`, the active frame is retained.

A separate data block `_N_NC_UFR` is used to archive global frames.

The block requested by the HMI is created if the machine data

`MD18601 $MN_MM_NUM_GLOBAL_USER_FRAMES`

or

`MD18602 $MN_MM_NUM_GLOBAL_BASE_FRAMES`

has a value greater than zero.

Channel-specific frames are saved in data block `_N_CHANx_UFR`.

In certain circumstances, alarms could be triggered when reintroducing saved data, if the frame affiliates, be they NCU global or channel-specific, have been changed using machine data.

Data backup always takes place in accordance with the axis configuration set in the machine data, not in accordance with the currently valid geometry axis assignment.

### 10.5.11 Positions in the coordinate system

The setpoint positions in the coordinate system can be read via the following system variables. The actual values can be displayed in the WCS, SZS, BZS or MCS via the PLC. There is a softkey for actual-value display in MCS/WCS. Machine manufacturers can define on the PLC side, which coordinate system corresponds to the workpiece coordinate system on their machines. The HMI requests the appropriate actual values from the NCK.

#### **\$AA\_IM[axis]**

The setpoints in the machine coordinate system can be read for each axis using the variables `$AA_IM[axis]`.

#### **\$AA\_IEN[axis]**

The setpoints in the settable zero system (SZS) can be read for each axis using the variables `$AA_IEN[axis]`.

#### **\$AA\_IBN[axis]**

The setpoints in the basic zero system (BZS) can be read using the variable `$AA_IBN[axis]`.

#### **\$AA\_IW[axis]**

The setpoints in the workpiece coordinate system (WCS) can be read using the variable `$AA_IW[axis]`.

## 10.5.12 Control system response

### 10.5.12.1 POWER ON

#### Frame conditions after POWER ON

| Frame                | Frame conditions after POWER ON                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Programmable frame   | Deleted.                                                                                                                                                                                                      |
| Settable frames      | Are retained, depending on:<br>MD24080 \$MC_USER_FRAME_POWERON_MASK Bit 0 = 1<br>MD20152 \$MC_GCODE_RESET_MODE[7] = 1                                                                                         |
| Complete basic frame | Retained, depending on<br>MD20110 \$MC_RESET_MODE_MASK bit 0 and bit 14<br>Individual basic frames can be deleted with<br>MD10615 \$MN_NCBFRAME_POWERON_MASK<br>and<br>MD24004 \$MC_CHBFRAME_POWERON_MASK.    |
| System frames        | Retained<br>Depending on:<br>MD24008 \$MC_CHSFRAME_POWERON_MASK,<br>individual system frames can be deleted on POWER ON.<br>Deletion of system frame is executed in the data management<br>on first priority. |
| Zero offset external | Permanent, but has to be activated again.<br>The system frame is retained.                                                                                                                                    |
| DRF offset           | Deleted.                                                                                                                                                                                                      |

### 10.5.12.2 Mode change

#### System frames

System frames are retained and remain active when the operating mode is changed.

#### JOG mode

In JOG mode, the frame components of the current frame are only taken into account for the geometry axes if a rotation is active. No other axial frames are taken into account.

#### PLC and command axes

The response for PLC and command axes can be set via machine data:

MD32074 \$MA\_FRAME\_OR\_CORRPOS\_NOTALLOWED (Frame or HL correction is not permissible)

### 10.5.12.3 RESET, end of part program

#### RESET responses of basic frames

The RESET response of basic frames is set via the machine data:

MD20110 \$MC\_RESET\_MODE\_MASK (definition of initial control settings after RESET/TP-End)

#### RESET responses of system frames

The system frames are retained in the data management after a Reset.

The machine data below can be used to configure the activation of individual system frames:

MD24006 \$MC\_CHSFRAME\_RESET\_MASK (active system frames after Reset)

| Bit | Significance                                                                |
|-----|-----------------------------------------------------------------------------|
| 0   | System frame for actual value setting and scratching is active after RESET. |
| 1   | System frame for zero offset external is active after RESET.                |
| 2   | Is not evaluated.                                                           |
| 3   | Is not evaluated.                                                           |
| 4   | System frame for workpiece reference point is active after RESET.           |
| 5   | System frame for cycles is active after RESET.                              |
| 6   | Reserved, RESET response depends on MD20110 \$MC_RESET_MODE_MASK.           |
| 7   | System frame \$P_ISO1FR is active after RESET.                              |
| 8   | System frame \$P_ISO2FR is active after RESET.                              |
| 9   | System frame \$P_ISO3FR is active after RESET.                              |
| 10  | System frame \$P_ISO4FR is active after RESET.                              |
| 11  | System frame \$P_RELFR is active after RESET.                               |

#### RESET response of the system frames of TCARR, PAROT, TOROT and TOFRAME

The RESET response of the system frames of `TCARR`, `PAROT`, `TOROT` and `TOFRAME` depends on the G-Code RESET setting.

The setting is made with machine data:

MD20110 \$MC\_RESET\_MODE\_MASK (definition of initial control settings after RESET/TP-End)

MD20152 \$MC\_GCODE\_RESET\_MODE[ ] (RESET response of G groups)

MD20150 \$MC\_GCODE\_RESET\_VALUES (RESET position of G groups)

| MD20110                                                           | Significance                                                    |         |
|-------------------------------------------------------------------|-----------------------------------------------------------------|---------|
| Bit 0 = 0                                                         | TCARR and PAROT system frames are retained as before the RESET. |         |
| Bit 0 = 1                                                         | MD20152 \$MC_GCODE_RESET_MODE[51] = 0                           |         |
|                                                                   | MD20150 \$MC_GCODE_RESET_VALUES[51] = 1                         | PAROTOF |
|                                                                   | MD20150 \$MC_GCODE_RESET_VALUES[51] = 2                         | PAROT   |
|                                                                   | MD20152 \$MC_GCODE_RESET_MODE[51] = 1                           |         |
|                                                                   | TCARR and PAROT system frames are retained as before the RESET. |         |
|                                                                   | MD20152 \$MC_GCODE_RESET_MODE[52] = 0                           |         |
|                                                                   | MD20150 \$MC_GCODE_RESET_VALUES[52] = 1                         | TOROTOF |
|                                                                   | MD20150 \$MC_GCODE_RESET_VALUES[52] = 2                         | TOROT   |
|                                                                   | MD20150 \$MC_GCODE_RESET_VALUES[52] = 3                         | TOFRAME |
|                                                                   | MD20152 \$MC_GCODE_RESET_MODE[52] = 1                           |         |
| TOROT and TOFRAME system frames are retained as before the RESET. |                                                                 |         |

TCARR and PAROT are two independent functions, which describe the same frame. With PAROTOF, the component of TCARR is not activated on RESET.

### Frame conditions after RESET / parts program end

| Frame                | Condition after RESET / part program end                                                                                                      |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Programmable frame   | Deleted.                                                                                                                                      |
| Settable frames      | Retained, depending on MD20110 \$MC_RESET_MODE_MASK and MD20152 \$MC_GCODE_RESET_MODE.                                                        |
| Complete basic frame | Retained, depending on: MD20110 \$MC_RESET_MODE_MASK Bit 0 and Bit 14, MD10613 \$MN_NCBFRAME_RESET_MASK and MD24002 \$MC_CHBFRAME_RESET_MASK. |
| System frames        | Retained, depending on MD24006 \$MC_CHSFRAME_RESET_MASK and MD20150 \$MC_GCODE_RESET_VALUES[ ].                                               |
| External zero offset | Retained                                                                                                                                      |
| DRF offset           | Retained                                                                                                                                      |

### Deletion of system frames

The system frames in the data management can be deleted during RESET using machine data:

MD24007 \$MC\_CHSFRAME\_RESET\_CLEAR\_MASK (deletion of system frames during RESET)

| Bit | Significance                                                                  |
|-----|-------------------------------------------------------------------------------|
| 0   | System frame for actual value setting and scratching is deleted during RESET. |
| 1   | System frame for zero offset external is deleted during RESET.                |
| 2   | Reserved, for TCARR and PAROT see MD20150 \$MC_GCODE_RESET_VALUES[ ].         |
| 3   | Reserved, for TOROT and TOFRAME see MD20150 \$MC_GCODE_RESET_VALUES[ ].       |
| 4   | System frame for workpiece reference points is deleted during RESET.          |
| 5   | System frame for cycles is deleted during RESET.                              |
| 6   | Reserved, RESET response depends on MD20110 \$MC_RESET_MODE_MASK.             |
| 7   | System frame for \$P_ISO1FR is deleted during RESET.                          |
| 8   | System frame for \$P_ISO2FR is deleted during RESET.                          |
| 9   | System frame for \$P_ISO3FR is deleted during RESET.                          |
| 10  | System frame for \$P_ISO4FR is deleted during RESET.                          |
| 11  | System frame \$P_RELFR is deleted during RESET.                               |

**10.5.12.4 Part program start**

**Frame conditions after part program start**

| Frame                | Condition after parts program start                     |
|----------------------|---------------------------------------------------------|
| Programmable frame   | Deleted.                                                |
| Settable frames      | Retained, depending on:<br>MD20112 \$MC_START_MODE_MASK |
| Complete basic frame | Retained                                                |
| System frames        | Retained                                                |
| External zero offset | Retained                                                |
| DRF offset           | Retained                                                |

**10.5.12.5 Block search**

**Block search**

Data management frames are also modified when carrying out a block search with calculation.

**Cancellation of block search**

If the block search is aborted with RESET, then the machine data:  
MD28560 \$MC\_MM\_SEARCH\_RUN\_RESTORE\_MODE  
can be used to configure that all data management frames are set to the value they had before the block search:

| Bit | Significance                                    |
|-----|-------------------------------------------------|
| 0   | All frames in the data management are restored. |

In case of cascaded block searches, the frames are set to the status of the previous block search.

**SERUPRO**

The "SERUPRO" function is not supported.

**10.5.12.6 REPOS**

There is no special treatment for frames. If a frame is modified in an ASUB, it is retained in the program. On repositioning with REPOS, a modified frame is included, provided the modification was activated in the ASUB.

## 10.6 Workpiece-related actual-value system

### 10.6.1 Overview

#### Definition

The term "workpiece-related actual-value system" designates a series of functions that permit the user:

- To use a workpiece coordinate system defined in machine data after power-up.  
Features:
  - No additional operations are necessary.
  - Effective in JOG and AUTOMATIC modes
- To retain the valid settings for the following after end of program for the next part program:
  - Active plane
  - Settable frame (G54-G57)
  - Kinematic transformation
  - Active tool offset
- To change between work coordinate system and machine coordinate system via the user interface.
- To change the work coordinate system by operator action (e.g., changing the settable frame or the tool offset).

### 10.6.2 Use of workpiece-related actual-value system

#### Requirements, basic settings

The settings described in the previous Section have been made for the system.  
The predefined setting after power-up of the HMI software is MCS.

#### Switchover to WCS

The change to the WCS via the user interface causes the axis positions relative to the origin of the WCS to be displayed.

#### Switchover to MCS

The change to the MCS via the user interface causes the axis positions relative to the origin of the MCS to be displayed.

**Interrelationships between coordinate systems**

The figure below shows the interrelationships between the machine coordinate system (MCS) and the workpiece coordinate system (WCS).

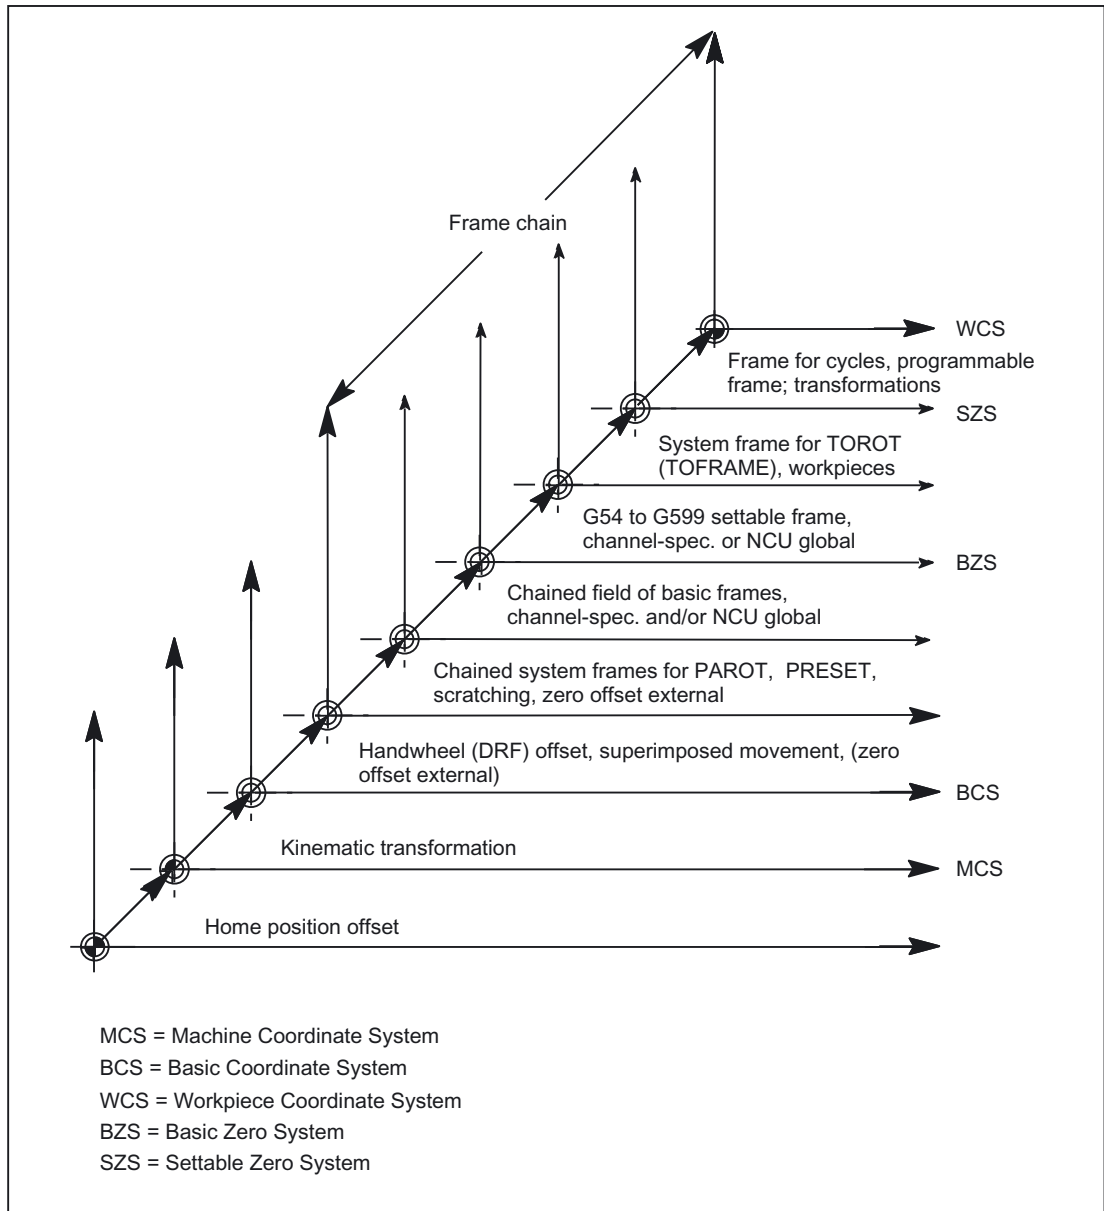

Figure 10-25 Interrelationship between coordinate systems

### 10.6.3 Special reactions

#### Overstore

Overstoring in `RESET` state of:

- Frames (zero offsets)
- Active plane
- Activated transformation
- Tool offset

immediately affects the actual-value display of all axes in the channel.

#### Entry via operator panel front

If operations on the operator panel are used to change the values for "Active frame" (zero offsets, "Parameters" operating area) and "Active tool length compensation" ("Parameters" operating area), one of the following actions is used to activate these changes in the display:

- Press the `RESET` key.
- Reselect:
  - Zero offset by the part program
  - Tool offset by the part program
- Reset:
  - Zero offset by overstoreing
  - Tool offset by overstoreing
- Part-program start

#### MD9440

If the HMI machine data `MD9440 ACTIVATE_SEL_USER_DATA` for the operator panel front is set, the entered values become active immediately in `RESET` state.

When values are entered in the part-program execution stop state, they become effective when program execution continues.

#### Actual-value reading

If the actual value of `$AA_IW` is read in the WCS after activation of a frame (zero offset) or a tool offset, the activated changes are already contained in the result read even if the axes have not yet been traversed with the activated changes.

The actual values in the settable zero system (SZS) can be read from the part program for each axis using the variable `$AA_IEN[axis]`.

The actual values in the basic zero system (BZS) can be read from the part program for each axis using the variable `$AA_IBN[axis]`.

### Actual-value display

The programmed contour is always displayed in the WCS.

The following offsets are added to the MCS:

- Kinematic transformation
- DRF offset/zero offset external
- Active frame
- Active tool offset of the current tool

### Switchover by PLC

The actual values can be displayed in the WCS, SZS, BZS or MCS via the PLC. The PLC can define, which coordinate system corresponds to the workpiece coordinate system on a machine.

On MMC power-on the MCS is preset.

With the signal DB19 DBB0.7 "MCS/WCS switchover", it is also possible to switch from the PLC to the WCS.

### Transfer to PLC

Depending on machine data

MD20110 / MD20112, bit 1,

the auxiliary functions (D, T, M) are output to the PLC (or not) on selection of the tool length compensation.

---

#### Note

If the WCS is selected from the PLC, an operator action can still be used to switch between the WCS and MCS for the relevant mode.

However, when the mode and or area is changed, the WCS selected by the PLC is evaluated and activated.

### 10.8.2 Coordinate systems

#### Configuring a global basic frame

An NC with 2 channels is required. The following applies:

- The global basic frame can then be written by either channel.
- The other channel recognizes this change when the global basic frame is reactivated.
- The global basic frame can be read by either channel.
- Either channel can activate the global basic frame for that channel.

## 10.8.3 Frames

### Example 1

The channel axis is to become a geometry axis through geometry axis substitution.

The substitution is to give the programmable frame a translation component of 10 in the X axis.

The current settable frame is to be retained:

FRAME\_GEOX\_CHANGE\_MODE = 1

|                      |                                                  |
|----------------------|--------------------------------------------------|
| \$P_UIFR[1] =        | ; Frame is retained after geo axis substitution. |
| CROT(x,10,y,20,z,30) |                                                  |
| G54                  | ; Settable frame becomes active.                 |
| TRANS a10            | ; Axial offset of a is also substituted.         |
| GEOAX(1, a)          | ; a becomes x axis.                              |
|                      | ; \$P_ACTFRAME= CROT(x,10,y,20,z,30):CTRANS(x10) |

Several channel axes can become geometry axes on a transformation change.

## Example 2

Channel axes 4, 5 and 6 become the geometry axes of a 5-axis orientation transformation. The geometry axes are thus all substituted before the transformation.

The current frames are changed when the transformation is activated.

The axial frame components of the channel axes, which become geometry axes, are taken into account when calculating the new WCS. Rotations programmed before the transformation are retained. The old WCS is restored when the transformation is deactivated.

The most common application will be that the geometry axes do not change before and after the transformation and that the frames are to stay as they were before the transformation.

## N2: Emergency stop

### 11.1 Brief description

#### Function

The control system supports the machine manufacturer in implementing an emergency stop function on the basis of the following functions:

- An emergency stop button is installed in a location easily accessible to the machine operator on all SINUMERIK machine control panels. The functionality of the emergency stop button includes the positive opening of electrical switching contacts and a mechanical self-activating latching/locking.
- The emergency stop request to the NC is transmitted via the NC/PLC interface on the PLC.
- In response to an emergency stop command, the NC decelerates all axes and spindles as quickly as possible (with setpoint value 0), i.e. braking at the current limit of the drives.
- In the case of an emergency stop, all machine functions controlled by the PLC can be brought to a safe state that can be set by the machine manufacturer.
- Unlatching the emergency stop button does not cancel the emergency stop state nor does it initiate a restart.
- After the emergency stop state has been canceled, it is not necessary to reference the machine axes or synchronize the spindles. The actual positions of the machine axes are continuously tracked during the emergency stop sequence.

### 11.2 Relevant standards

#### Relevant standards

Compliance with the following standards is essential for the emergency stop function:

- EN ISO 12000-1
- EN ISO 12000-2
- EN 418
- EN 60204

## EMERGENCY STOP

In accordance with EN 418, an emergency stop is a function that:

- Is intended to prevent or diminish developing or existing risks to operating personnel, and damage to the machine or machined materials.
- is triggered by a single action of a person, if the normal stop function is not suitable for it.

## Hazards

In the terms of EN 418, risks may arise from:

- Functional irregularities (machine malfunctions, unacceptable properties of the material to be machined, human error, etc.).
- Normal operation.

## Standard EN ISO 12000-2

In accordance with the basic safety requirement of the EC Machinery Directive regarding emergency stop, machines must be equipped with an emergency stop device.

### Exceptions

No emergency stop device is required on machines:

- Where an emergency stop device would not reduce the risk, either because the shutdown time would not be reduced or because the measures to be taken would not be suitable for controlling the risk.
- that are held and operated manually.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NOTICE</b>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| The machine manufacturer is expressly directed to comply with the national and international standards. The SINUMERIK controllers support the machine manufacturer in the implementation of the emergency stop function according to the specifications in the following function description. But the responsibility for the emergency stop function (its triggering, sequence, and acknowledgment) rests exclusively with the machine manufacturer. |

## 11.3 Emergency stop control elements

### Emergency stop control elements

In accordance with EN 418, emergency stop control elements must be designed so that they latch mechanically on their own and are easy for the operator and others to actuate in the event of an emergency.

The following list includes some possible types of control elements:

- Mushroom-head pushbutton switches
- Wires/cables, cords, rods
- Puller grips
- In special cases: Foot-operated switches without protective covers

### Emergency stop button and control

Actuation of the emergency stop button or a signal derived directly from the button must be routed to the controller (PLC) as a PLC input. In the PLC user program, this PLC input must be forwarded to the NC on the interface signal:

DB10 DBX56.1 (Emergency stop)

Resetting of the emergency stop button or a signal derived directly from the button must be routed to the controller (PLC) as a PLC input. In the PLC user program, this PLC input must be forwarded to the NC on the interface signal:

DB10 DBX56.2 (Acknowledge emergency stop)

### Connection conditions

For connecting the emergency stop button see:

**References:**

/BH/ Equipment Manual Operator Components

## 11.4 Emergency stop sequence

After actuation of the emergency stop control element, the emergency stop device must operate in the best possible way to prevent or minimize the danger.

"In the best possible way" means that the most favorable delay rate can be selected and the correct stop category (defined in EN 60204) can be determined according to a risk assessment.

### Emergency stop sequence in the NC

The predefined (in EN 418) sequence of internal functions implemented to obtain the emergency stop state is as follows in the control system:

1. Part program execution is interrupted.

All machine axes are braked in the relevant axis-specific parameterized time:

MD36610 \$MA\_AX\_EMERGENCY\_STOP\_TIME (time of braking ramp in event of errors)

The maximum braking ramp that can be achieved thereby, is defined by the maximum brake current of the respective drive. The maximum brake current is achieved by setting a setpoint = 0 (fast braking).

2. Reset interface signal:

DB11 DBX6.3 (Mode group ready)

3. Set the interface signal:

DB10 DBX106.1 (Emergency stop active)

4. Alarm 3000 "emergency off" is shown.

5. After the expiry of a parameterized delay time, the servo enables of machine axes are reset.

The setting of the delay time is programmed in machine data:

MD36620 \$MA\_SERVO\_DISABLE\_DELAY\_TIME (switch-off delay servo enable)

The following setting rule must be observed: MD36620 ≥ MD36610

6. All machine axes are switched in the follow-up mode within the controller.

The machine axes are no longer in position control during this.

## Emergency stop sequence at the machine

The emergency stop sequence on the machine is determined solely by the machine manufacturer.

Attention should be paid to the following points in connection to the sequence on the NC:

- The process in the NC is started using the interface signal:

DB10 DBX56.1 (Emergency stop)

After the machine axes have come to a standstill, the power supply must be interrupted, in compliance with EN 418.

---

### Note

The responsibility for interrupting the power supply rests with the machine manufacturer.

---

- The digital and analog outputs of the PLC I/O are not influenced by the emergency stop sequence in the NC.

If individual outputs are required to attain a particular state or voltage level in the event of an emergency stop, the machine manufacturer must implement this in the PLC user program.

- The fast digital outputs of the NCK I/O system are not influenced by the emergency stop sequence in the NC.

If individual outputs must assume a specific state in the case of emergency stop, the machine manufacturer must transmit the desired state to the NC in the PLC user program via interface signals:

DB10 DBB4-7

---

### Note

If the sequence in the NC is not to be executed as described above, then the interface signal DB10 DBX56.1 (emergency stop) must not be set until an emergency stop state defined by the machine manufacturer in the PLC user program is reached.

As long as the interface signal is not set and no other alarm is pending, all interface signals are operative in the NC. Any emergency stop state defined by the manufacturer (including axis-, spindle-, and channel-specific emergency stop states) can therefore be assumed.

---

## 11.5 Emergency stop acknowledgement

The emergency stop control element may only be reset as a result of manual manipulation of the emergency stop control element according to EN 418.

Resetting of the emergency stop control element alone must not trigger a restart command.

A machine restart must be impossible until all of the actuated emergency stop control elements have been deliberately reset by hand.

### Emergency stop acknowledgement

The EMERGENCY STOP state is only reset if the interface signal:DB10 DBX56.2 (acknowledge EMERGENCY STOP) is set followed by the interface signal:DB11, ... DBX0.7 (mode group reset).

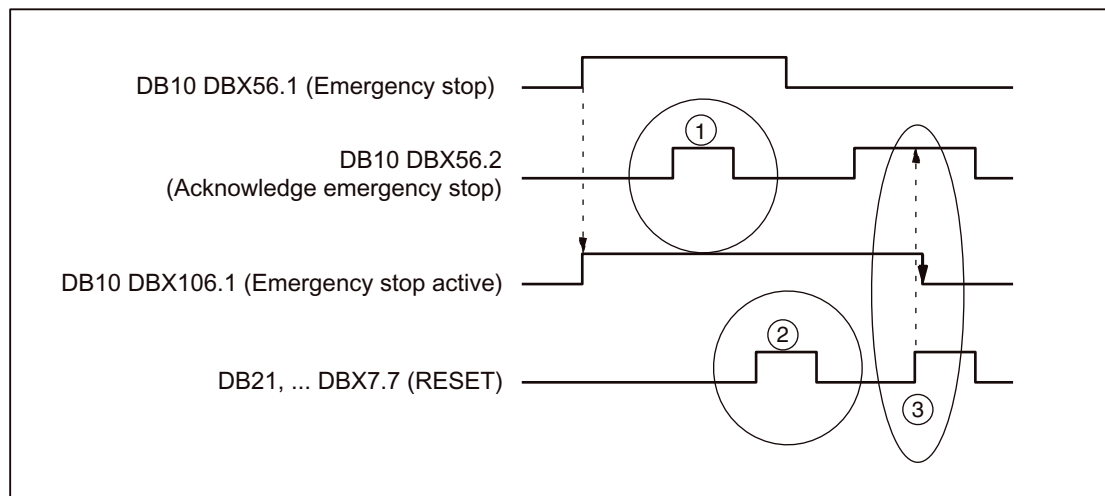

Hence it can be noted that the interface signal DB10 DBX56.2 (acknowledge emergency stop) and the interface signal DB21, ... DBX7.7 (Reset) together are set at least for so long, till the interface signal DB10 DBX106.1(emergency stop active) is reset.

---

#### Note

The emergency stop state cannot be reset with the interface signal DB21, ... DBX7.7 (Reset) alone.

---

- (1) DB10 DBX56.2 (acknowledge emergency stop) is inoperative
- (2) DB21, ... DBX7.7 (Reset) is inoperative
- (3) DB10 DBX56.2 and DB21, ... DBX7.7 reset DB10 DBX106.1(emergency stop active)

Figure 11-1 Resetting the emergency stop state

## Effects

Resetting the emergency stop state has the following effects:

- within the controller for all machine axes:
  - the servo enables are set.
  - the follow-up mode is cancelled.
  - the position control is activated.
- the following interface signals are set:  
DB31, ... DBX60.5 (position control active)  
DB11 DBX6.3 (Mode group ready).
- the following interface signal is reset:  
DB10 DBX106.1 (Emergency stop active)
- the alarm 3000 "emergency off" is deleted.
- Part program processing is interrupted in all channels of the NC.

## PLC and NCK I/Os

The PLC user program must switch the PLC and NCK I/Os back to the state for operation of the machine.

## POWER OFF / ON (supply off / on)

The emergency stop state can also be reset by switching the controller off and back on (POWER OFF / ON).

### **Requirement:**

During power-up of the control the interface signal DB10 DBX56.1 (emergency stop) may not be set.

## 11.6 Data lists

### 11.6.1 Machine data

## P1: Transverse axes

### 12.1 Brief description

#### Transverse axis

Within the framework of "turning" technology, the transverse axis refers to the machine axis that travels perpendicular to the axis of symmetry of the spindle, in other words, to longitudinal axis Z.

#### Properties

- Every geometry axis of a channel can be defined as a transverse axis.
- Only one transverse axis can be defined per channel.
- A transverse axis is a linear axis for the following functions, which can be permitted and activated at the same time or separately:
  - Programming and display in the diameter
  - Reference axis for constant cutting speed G96 / G961 / G962

#### Several transverse axes in the channel

Diameter programming and reference axis for G96 / G961 / G962 can be active for different transverse axes.

#### Transverse axis functions (overview)

|                                                             | Programming and display in the diameter                        |                                 |                     | Reference axis for G96/G961/G962                                       |          |

---

**Note**

Rotary axes are not permitted to serve as transverse axes.

---

### Programming the transversing paths

The traverse paths of a transverse axis programmed in the part program may be either radius- or diameter-based. It is possible to switch between the two reference types with the part program commands `DIAMON` (DIAMeter ON = diameter) and `DIAMOF` (DIAMeter OF = radius). In this way, dimensional information can be taken directly from the technical drawing without conversion.

#### Active parts program

When the part program `DIAMON` (dimensional information as diameter) is active, the following is true for the transverse axis:

- The setpoint and actual values that refer to the workpiece coordinate system are displayed as diameter values.
- System variables for setpoints and actual values that refer to the workpiece coordinate system contain diameter values.
- Offsets are entered, programmed and displayed in radius format.
- Programmed end positions are converted to radius values internally.
- The absolute interpolation parameters (e.g. I, J, K) for circular interpolation (G2 and G3) are converted to radius values internally.
- Measurement results that were determined by touch trigger probe in the workpiece coordinate system are stored as diameter measurements.
- Setpoints and actual values can be read in diameter format in the WCS with the aid of system variables.

When the part program command `DIAMOF` (dimensional information as radius) is active, the above-mentioned data is always entered, programmed, internally stored, read or displayed as radius data.

## 12.2 Defining a geometry axis as transverse axis

### Transverse axis

Within the framework of "turning" technology, the transverse axis refers to the machine axis that travels perpendicular to the axis of symmetry of the spindle, in other words, to longitudinal axis Z.

Figure 12-1 Position of the transverse axis in the machine coordinate system

### Definition

#### Definition of a transversing axis in the channel

The definition of a geometry axis as a transverse axis is done using machine data:

MD20100 \$MC\_DIAMETER\_AX\_DEF (geometry axis with transverse axis function).

For this axis, diameter programming and assigning a constant cutting speed with G96/G961/G962 are both permitted.

#### Definition of several transversing axes in the channel

The machine data MD30460 \$MA\_BASE\_FUNCTION\_MASK allows the definition of additional transverse axes, for which axis-specific diameter programming with bit2=1 is possible.

An axis can be simultaneously defined in MD20100 and in MD30460 with bit2. For this, the channel-specific MD20100 has a higher priority than the axis-specific MD30460.

With:

- MD20100, the function G96/G961/G962 is assigned to the transverse axis during power up.
- MD20100, the channel-specific diameter programming DIAMON, DIAMOF, DIAM90, DIAMCYCOF is assigned to the transverse axis during power up. This axis occupies the axis-specific basic position DIAMCHANA[AX] after power up.
- MD30460 bit2 the additional enabling of the axis-specific statements DIAMONA[AX], DIAMOFA[AX], DIAM90A[AX], DIACYCOFA[AX], DIMCHANA[AX].

### Example for defining a transverse axis in the channel

```
MD20100 $MC_DIAMETER_AX_DEF="X" ;the geometry axis X is the transverse axis
in the channel
```

### Restrictions

However, only exactly one geometry axis can be defined as transverse axis per channel.  
With MD30460 \$MA\_BASE\_FUNCTION\_MASK bit2=1 is only permitted for linear axes.

### Channel-specific basic position after power up, RESET

The channel-specific basic position after power up or RESET or end of parts program of the G group 29: DIAMON, DIAM90, DIAMOF, DIAMCYCOF define the

MD20150 \$MC\_GCODE\_RESET\_VALUE  
and independently of  
MD20110 \$MC\_RESET\_MODE\_MASK / bit0 the MD20152 \$MC\_GCODE\_RESET\_MODE.

The user can set the respective desired status via an event-controlled program call (prog-event).

If G96/G961/G962 is the basic position after power up, a transverse axis must be defined using MD20100 \$MC\_DIAMETER\_AX\_DEF, otherwise the alarm message 10870 is output.

Reference axis for G96/G961/G962 retained:

MD20110 \$MC\_RESET\_MODE\_MASK, bit 18=1 for RESET or end of parts program

MD20112 \$MC\_START\_MODE\_MASK, bit 18=1 for start of parts program

A reference axis for G96/G961/G962 can also be assigned without application of a transverse axis in MD20100 via SCC[AX]. For this scenario, the constant cutting speed cannot be activated with G96. For further information refer to

#### Reference

/PG/ Programming Manual Fundamentals, Feedrate Control and Spindle Motion  
"Constant Cutting Speed (G96, G961, G962, G97, G971, LIMS, ACC[AX])"

## 12.3 Dimensional information for transverse axes

Transverse axes can be programmed with respect to both diameter and radius. Generally, they are diameter-related, i.e. programmed with doubled path dimension so that the corresponding dimensional information can be transferred to the part program directly from the technical drawings.

Figure 12-2 Transverse axis with diameter information (D1, D2)

### Switching the diameter programming on/off

#### Channel-specific diameter programming

The activating or deactivating of the diameter programming is done via the modally active parts program statements of the G group 29:

- `DIAMON`: Diameter programming ON
- `DIAMOF`: Diameter programming OFF, in other words, radius programming ON
- `DIAM90`: Diameter or radius programming depending on the reference mode:
  - Diameter programming ON in connection with absolute dimensioning `G90`
  - Radius programming ON in connection with incremental dimensioning `G91`
- `DIAMCYCOF`: Radius programming for `G90` and `G91` ON, for the HMI, the last active G code of this group remains active

Reference is made exclusively to the transverse axis of the channel.

#### Axis-specific diameter programming for several transverse axes in one channel

##### Note

The additionally specified axis must be activated via MD30460 `$MA_BASE_FUNCTION_MASK` with bit2=1.

The axis specified must be a known axis in the channel. Geometry, channel or machine axes are permitted.

Programming is not permitted in synchronized actions.

The following axis-specific modal statements can be programmed several times in a parts program block:

- `DIAMONA[Axis]`: Diameter programming for `G90`, `G91 AC` and `IC ON`
- `DIAMOFA[Axis]`: Diameter programming OFF, in other words, radius programming ON
- `DIAM90A[axis]`: Diameter or radius programming depending on the reference mode:
  - Diameter programming ON in connection with absolute dimensioning `G90` and `AC`
  - Radius programming ON in connection with incremental dimensioning `G91` and `IC`
- `DIACYCOFA[axis]`: Radius programming for `G90` and `G91 ON`, for the HMI, the last active G code of this group remains active
- `DIAMCHANA[axis]`: Acceptance of diameter programming channel status
- `DIAMCHAN`: all axes with MD30460, bit2=1 accept the diameter programming channel status

Axis-specific modal statements have priority over the channel setting.

### Acceptance of the additional transverse axis in the channel

Due to a GET request from the parts program, the diameter programming status for an additional transverse axis is accepted in the new channel during axis replacement using `RELEASE[axis]`.

#### Axis replacement in synchronized actions

For axis replacement in synchronized actions, a transverse axis takes the status of the axis-specific diameter programming with it into the new channel if the following applies to the transverse axis:

- with MD30460, bit2=1 axis-specific diameter programming is permitted.
- it is not subordinated to the channel-specific diameter programming in the releasing channel.

The active dimension can be queried via the system variable `$AA_DIAM_STAT[AX]`.

#### Axis replacement via axis container rotation

By rotating the axis container, the assignment of a channel axis can change to assignment of a machine axis. The current diameter programming status is retained however for the channel axis after the rotation. This also applies to the current channel status and axis status, because the status is the same for all axes of the axis container at the time of the machine data "putting into effect" the status from MD30460 `$MA_BASE_FUNCTION_MASK`.

### Initial setting

The following machine data is used to parameterize the initial setting:

MD20150 `$MC_GCODE_RESET_VALUES [28]` (initial setting of the G groups)  
and independently of MD20110 `$MC_RESET_MODE_MASK` for bit0 the  
MD20152 `$MC_GCODE_RESET_MODE`

## Diameter-related data

After activation of the diameter programming, the following data refer to diameter dimensions:

### DIAMON/DIAMONA[AX]

- Display data of transverse axis in the workpiece coordinate system:
  - Setpoint and actual position
  - Distance-to-go
  - REPOS offset
- "JOG" mode:
  - Increments for incremental dimension (INC) and handwheel travel (dependent upon active MD)
- Part program programming:
  - End positions, independent of reference mode (G90 / G91)
  - Interpolation parameters of circular-path programming (G2 / G3) if these are programmed with part program instruction: AC absolute.
- Actual values read with reference to the workpiece coordinate system (WCS):
  - \$AA\_MW[*Transverse axis*]
    - System variable of the measuring functions MEAS (measuring with delete distance-to-go) and MEAW (measuring without delete distance-to-go)
  - \$P\_EP[*Transverse axis*]
  - \$AA\_IW[*Transverse axis*]

### DIAM90/DIAM90A[AX]

After activation of the reference-mode-dependent diameter programming, the following data are always displayed in relation to diameter regardless of the operating mode (G90 / G91):

- Actual value
- Actual values read with reference to the workpiece coordinate system (WCS):
  - \$AA\_MW[*Transverse axis*]
    - System variable of the measuring functions MEAS (measuring with delete distance-to-go) and MEAW (measuring without delete distance-to-go)
  - \$P\_EP[*Transverse axis*]
  - \$AA\_IW[*Transverse axis*]

### DIAMCYCOF/DIACYCOFA[AX]

Just as for DIAMCYCOF, a changeover to radius programming takes place within the controller for DIACYCOFA[AX]. The diameter programming status that was active before DIAMCYCOF or DIACYCOFA[AX] continues to be displayed to the HMI.

**Permanently radius-related data**

For transverse axes, the following data is **always** entered, programmed and displayed in relation to radius:

- Offsets:
  - Tool offsets
  - Programmable and configurable frames
  - External work offset
  - DRF and preset offset
  - etc.
- Working area limitation
- Software limit switch
- Feed
- Display data with reference to the machine coordinate system
- Display data of the service images for axis, FSD and MSD

**Extended functions for data that is always radius-related:**

The following applies for PLC axes, via FC18 or axes controlled exclusively from the PLC:

- The dimension for PLC axes in the radius also applies to several transverse axes with diameter function and is independent of channel-specific or axis-specific diameter programming.
- In the JOG mode (Inc) a PLC axis is subordinate to the channel status. If diameter programming is active and MD20624 \$MC\_HANDWH\_CHAN\_STOP\_COND bit 15 = 0, only half the path of the specified increment is traversed.

**Radius programming** from MD20100 \$MC\_DIAMETER\_AX\_DEF and MD30460 \$MA\_BASE\_FUNCTION\_MASK bit 2 is taken into account as follows depending on MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK:

| MD20360 \$MC_TOOL_PARAMETER_DEF_MASK |       |                                                                                                                                                         |
|--------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit                                  | Value | Meaning                                                                                                                                                 |
| 3                                    | 0     | Work offset \$P_EXTFRAME and frames<br>For transverse axes, work offsets in frames are always calculated as radius values.                              |
| 5                                    | 0     | External work office (axis overlay)<br>For transverse axes, the external work offset is always calculated as radius value.                              |
| 8                                    | 1     | Display of remaining path in WCS always as a radius                                                                                                     |
| 9                                    |       | For all transverse axes, with MD11346 \$MN_HANDWH_TRUE_DISTANCE==1                                                                                      |
|                                      | 0     | • half of the path of the specified handwheel increment is traveled, if channel-specific or axis-specific diameter programming is active for this axis. |
|                                      | 1     | • half of the path of the specified handwheel increment is always traveled.                                                                             |

### Displaying position values in the diameter

Position values of the transverse axis are always displayed as a diameter value, if bit 0 = 1 is set by MD27100 \$MC\_ABSBLOCK\_FUNCTION\_MASK.

### Dimension on several transverse axes permanent diameter-related data

Several transverse axes permitted by MD30460 \$MA\_BASE\_FUNCTION\_MASK, bit 2 = 1 do not behave differently in comparison to a transverse axis defined using MD20100 \$MC\_DIAMETER\_AX\_DEF. Diameter values continue to be converted into radius values.

According to MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK, for all of the transverse axes defined in the channel, the following functions can be activated as diameter:

| MD20360 \$MC_TOOL_PARAMETER_DEF_MASK |       |                                                                                  |
|--------------------------------------|-------|----------------------------------------------------------------------------------|
| Bit                                  | Value | Meaning                                                                          |
| 1                                    | 1     | Transverse axis tool length as a diameter                                        |
| 2                                    | 1     | Alarm for wear or tool length as a diameter and plane change                     |
| 3                                    | 1     | Work offset in frames of the transverse axis as a diameter                       |
| 4                                    | 1     | Preset value as a diameter                                                       |
| 5                                    | 1     | External work offset of transverse as a diameter                                 |
| 6                                    | 1     | Actual values of the transverse axis as a diameter                               |
| 7                                    | 1     | Display of actual values of the transverse axis as a diameter value              |
| 10                                   | 1     | Tool portion of an active tool carrier that can be oriented if no tool is active |
| 11                                   | 1     | Evaluation of \$TC_DP6 as a diameter                                             |
| 12                                   | 1     | Evaluation of \$TC_DP15 as wear of the tool diameter                             |
| 15                                   | 1     | Incremental values of the transverse axis for cycle masks as diameter            |

#### Work offset \$P\_EXTFRAME and frames

Bit 3 = 1: For all transverse axes, work offsets in frames are always calculated as diameter values. The frame stores the work offsets internally as a radius value. There is no conversion during a change of diameter, to radius programming or vice versa.

#### External work offset

Bit 5 = 1: For all transverse axes, external work offsets are always calculated as diameter values. There is no conversion during a change of diameter, to radius programming or vice versa.

### Settable response of geometry axes for traveling with handwheel

If the geometry axis is traveled as a transverse axis in the channel for handwheel traveling MD11346 \$MN\_HANDWH\_TRUE\_DISTANCE == 1, the response of the handwheel traveling can be changed via MD20624 \$MC\_HANDWH\_CHAN\_STOP\_COND, bit15:

Bit 15 = 0: Only the half path of the specified increment is traveled.

Bit 15 = 1: The specified increment is traveled completely.

### Application examples

X is a transverse axis defined via MD20100 \$MC\_DIAMETER\_AX\_DEF.  
 Y is a geometry axis and U is an additional axis. These two axes are transverse axes with specified diameter further defined in MD30460 \$MA\_BASE\_FUNCTION\_MASK with bit2=1.  
 DIAMON is not active after power up.

```

N10 G0 G90 X100 Y50 ;no diameter programming is active
N20 DIAMON ;Channel-specific diameter programming, in effect for X
N30 Y200 X200 ;Dimensions: X in the diameter, Y in the radius
N40 DIAMONA[Y] ;axis-specific modal diameter programming,
 ;in effect for Y
N50 Y250 X300 ;Dimensions: X and Y in diameter
N60 DIAM90 ;Dimensions: X G90/AC in the diameter, G91/IC in the
 radius
N70 Y200 ;Y: continuing, axis-specific modal diameter programming
N75 G91 Y20 U=DIC(40) ;Dimensions: Y in the diameter, U non-modally IC in
 the diameter
N80 X50 Y100 ;Dimensions: X in the radius (G91), Y in the diameter
N85 G90 X100 U200 ;Dimensions: X in the diameter, U in the radius
N90 DIAMCHANA[Y] ;Y accepts the channel status DIAM90
N95 G91 X100 Y100 ;Dimensions: X and Y in the radius(G91)
N100 G90 X200 Y200 ;Dimensions: X and Y in diameter

```

### Example with axle replacement

Transverse axes with diameter specification applied as in the previous example.  
 X and Y are located in channel 1 and are also known in channel 2, i.e. permitted for axis replacement.

```

Channel 1
N10 G0 G90 X100 Y50 ;no diameter programming is active
N20 DIAMON ;Channel-specific diameter programming for X
N30 Y200 X200 ;Dimensions: X in the diameter, Y in the radius
N40 DIAMONA[Y] ;Y axis-specific modal diameter programming
N50 Y250 X300 ;Dimensions: X and Y in diameter
N60 SETM(1) ;Synchronous marker 1
N70 WAIT(1,2) ;wait for synchronous marker 1 in channel 2
Channel 2
...
N50 DIAMOF ;channel 2 no diameter programming active
...
N100 WAIT(1,1) ;wait for synchronous marker 1 in channel 1
N110 GETD(Y) ;Axis replacement direct Y
N120 Y100 ;Y the channel-specific diameter programming
 ;subordinated in channel 2, i.e. dimension in the radius

```

## 13.1 Brief description

### General

The PLC basic program organizes the exchange of signals and data between the PLC user program and the NCK (Numerical Control Kernel), HMI (Human Machine Interface) and MCP (Machine Control Panel). In the case of signals and data, a distinction is made between the following groups:

- Cyclic signal exchange
- Event-driven signal exchange
- Messages

### Cyclic signal exchange

The cyclically-exchanged signals consist primarily of bit arrays.

- They contain **commands** transmitted from the PLC to the NCK (such as start or stop) and **status information** from the NCK (such as program running, interrupted, etc.).
- The bit fields are organized into signals for:
  - Mode group
  - Channels
  - Axes/spindles
  - General NCK signals

The cyclic exchange of data is performed by the basic program at the start of the PLC cycle (OB1). This ensures, for example, that the signals from the NCK remain constant throughout a cycle.

### Event-driven signal exchange NCK → PLC

PLC functions that have to be executed as a function of the workpiece program are triggered by auxiliary functions in the workpiece program. If a block with auxiliary functions is executed, the type of auxiliary function determines whether the NCK has to wait for this function to execute (e.g. tool change) or whether the function will be executed together with the workpiece machining process (e.g. tool loading on milling machines with chain magazine).

Data transfer must be as fast and yet as reliable as possible, in order to minimize the effect on the NCK machining process. Data transfer is, therefore, interrupt- and acknowledgment-driven. The basic program evaluates the signals and data, acknowledges this to the NCK and transfers the data to the application interface at the start of the cycle. If the data do not require user acknowledgment, this does not affect NC processing.

### Event-driven signal exchange PLC → NCK

An "event-driven signal exchange PLC → NCK" takes place whenever the PLC passes a request to the NCK (e.g. traversal of an auxiliary axis). In this case, data transfer is also acknowledgment-driven. When performed from the user program, this type of signal exchange is triggered using a function block (FB) or function call (FC).

The associated FBs (Function Blocks) and FCs (Function Calls) are supplied together with the basic program.

### Messages

User messages are acquired and conditioned by the basic program. A defined bit field is used to transfer the message signals to the basic program, where they are evaluated and, if message events occur, entered in the PLC's interrupt buffer by means of the ALARM S/SQ functions. If an HMI (e.g. SINUMERIK Operate) is being used, the messages are transferred to the HMI and displayed.

### PLC/HMI data exchange

In this type of data exchange, the HMI takes the initiative, being referred to as the "client" on the bus system. The HMI polls or writes data. The PLC processes these requests at the cycle control point via the operating system. The PLC basic program is not involved in these exchanges.

---

#### Note

The function of the machine is largely determined by the PLC program. Every PLC program in the RAM can be edited with the programming device.

---

## 13.2 Key data of the PLC-CPU's for 840D sl and 840Di sl

### Scope of performance

The table given below shows the performance range of the PLC CPU's and the scope of the basic PLC program with reference to various types of control.

| PLC CPU:                                                                         | Type of control                                                              |                                                                              |
|----------------------------------------------------------------------------------|------------------------------------------------------------------------------|------------------------------------------------------------------------------|
|                                                                                  | 840Di sl                                                                     | 840D sl                                                                      |
|                                                                                  | Integrated CPU317-2DP                                                        | Integrated CPU317-2DP                                                        |
| <sup>1)</sup> Firmware release:                                                  | FW 2.1                                                                       | FW 2.1                                                                       |

- <sup>1)</sup> Firmware release: Release of the SIMATIC CPU, from which the SINUMERIK PLC CPU is derived.
- <sup>2)</sup> The memory is also on the CompactFlash Card of the NCU.
- <sup>3)</sup> Although there are four ports on the front panel, ports PN-P3 and PN-P4 have not been released for use, and are, from FW 2.6 and higher, permanently deactivated in the configuration.

**Note**

**Number of PROFIBUS slaves**

The content of the SDB2000 and related further SDBs is stored by the PLC operating system in internal data structures, which the PROFIBUS ASIC can also access. Furthermore, information from SDB2000 is also conditioned (CPI interface) and transmitted to the NCK and the PLC basic program. This is necessary in order to control drives and PROFIsafe modules on the PROFIBUS. A memory area defined by the PLC is available for these data structures. Its size is limited by the maximum number of slots. This means that during loading, SDBs with fewer slaves than listed above may be refused. A slot is usually a slave module or the slave itself. Only on a module with both I and O areas does one module count as 2 slots. It is, therefore, not possible to specify the size of SDB 2000 exactly. It cannot be determined whether the configuration is legal until the SDB container has been loaded to the CPU. The values shown above must be taken as guide values only. If the configuration is not permissible, the alarm 410160 is set. If the configuration does not fit in the internal data range, no PROFIsafe and no SFC 15 functions work.

**PLC versions**

- PLC 317-2DP release, based on SIMATIC version 2.1 (version ID 20.70.xx) is integrated.
- PLC 319-3PN/DP release, based on SIMATIC version 2.4 (version ID 24.90.xx) is integrated.

These versions are compatible with the corresponding SIMATIC CPU 300, which means that all modules and software packages that are approved for these versions and CPUs on SIMATIC are, therefore, suitable. Centralized I/O modules are the exception. The version ID in the version screen comprises the following:

- SIMATIC CPU PLC primary version identifier
- Internal increment

### Version screen on HMI

In the version screen the currently used PLC and the associated version of the PLC operating system are displayed under PLC (e.g. PLC317-2DP 20.70.40). In the column after that the module ID of the PLC module used can be read.

The following PLC module codes are currently in use:

| Module code           | PLC module             | Firmware release <sup>1)</sup> | Operating system SW version ID |
|-----------------------|------------------------|--------------------------------|--------------------------------|
| 201x                  | PLC 317-2DP with IBC32 | FW 2.1                         | 20.70.40                       |
| MCI 2 (840Di)<br>211x | PLC 317-2DP with IBC32 | FW 2.1                         | 20.70.40                       |
| 2308                  | PLC 319-3PN/DP         | FW 2.4                         | 24.90.xx <sup>2)</sup>         |
|                       |                        | FW 2.6                         | 26.90.xx                       |
|                       |                        | FW 2.7                         | 27.90.xx                       |

<sup>1)</sup> Firmware release: Release of the SIMATIC CPU, from which the SINUMERIK PLC CPU is derived.

<sup>2)</sup> xx: Placeholder for a SINUMERIK internal version assignment of the PLC version

### Version screen according to the module state in STEP 7 Online

If, using STEP 7 Online, you connect to a PLC integrated in SINUMERIK, there, under the "General" tab, you can determine the hardware version of the PLC module as well as the PLC firmware version.

The following versions are available:

| Hardware Product version        | PLC module             | Firmware version <sup>1)</sup> | Designation SW version operating system <sup>2)</sup> |
|---------------------------------|------------------------|--------------------------------|-------------------------------------------------------|
| 20xx<br>PLC317 HW of 840Dsl     | PLC 317-2DP with IBC32 | V 2.1.10                       | 20.70.41                                              |
| 21xx<br>MCI 2 Board (840Di)     | PLC 317-2DP with IBC32 | V 2.1.10                       | 20.72.41                                              |
| 23xx<br>PLC319 HW of the 840Dsl | PLC 319-3PN/DP         | V 2.4.2                        | 24.90.13                                              |
|                                 |                        | V 2.6.5                        | 26.90.13                                              |
|                                 |                        | V 2.7.2                        | 27.90.06                                              |

<sup>1)</sup> Firmware release: Version of the SIMATIC CPU and specification of the SIMATIC hotfix, from which the SINUMERIK PLC CPU is derived (e.g. V-2.1, HF10; or V-2.7, HF2).

<sup>2)</sup> The last two positions of the software version are used within SINUMERIK to assign a PLC version

**PLC basic program functions**

|                                          | Type of control |         |
|------------------------------------------|-----------------|---------|
|                                          | 840Di           | 840D sl |
| <b>Scope</b>                             |                 |         |

| <b>Safety Integrated</b>                 |                 | +       |
| <b>Program diagnostics</b>               | +               | +       |

**Mode switch for the PLC CPU's**

On the NCU component, the right-hand twist button labeled "PLC" is used to set the PLC operating mode.

The switch settings are listed in the following table.

| Switch setting | Meaning | Comment             |
|----------------|---------|---------------------|
| 0              | RUN-P   |                     |
| 1              | RUN     | Cannot load program |
| 2              | STOP    |                     |
| 3              | MRES    |                     |

## 13.3 Reserve resources (timers, counters, FC, FB, DB, I/O)

### Reserve resources (timers, counters, FC, FB, DB, I/O)

The components below are reserved for the basic program:

- **Timers**

No reservation

- **Counter**

No reservation

- **FC, FB, DB**

FC 0 to FC 29 and FB 0 to FB 29 are reserved for the basic program. The number range between 1000 and 1023 is also reserved for FCs and FBs. Data blocks DB 1 to DB 62 and DB 71 to DB 80 are reserved. The number range 1000 to 1099 is also reserved in addition for DB. The data blocks of channels, axes/spindles and tool management functions that are not activated may be assigned as desired by the user.

- **I/O range**

The PLC has an I/O address volume of 8192 bytes each for inputs and outputs. The address ranges starting at 4096 / 4096 are reserved for/occupied by integrated drives. However, diagnostic addresses for modules can be assigned to the highest address range as proposed by STEP 7. Furthermore, the address range between 256 and 287 is assigned for the NCK, CP and HMI in rack 0 on the SIMATIC 300 station.

## 13.4 Startup hardware configuration of the PLC-CPUs

### General procedure

The hardware configuration for the PLC CPUs used in the NCU7x0, including other components of the NCU (NCK, CP, HMI, drive), must be defined via STEP 7. Proceed as follows in STEP7:

1. Create a new project (File, New, Project)
2. Insert, Hardware, SIMATIC 300 station
3. Select the SIMATIC 300 station with the mouse
4. Right mouse button, open object

The HW-Config is now started.

5. A suitable SINUMERIK component is selected from the hardware catalog "SIMATIC 300 \ SINUMERIK \ 840D sl".
6. I/Os are to be extended from the hardware catalog of STEP 7  
 The addresses for the I/O modules can be changed, if needed.

### Preconditions

In order to be able to select SINUMERIK components from the hardware catalog, you must run the Toolbox setup program first ("Hardware expansions for STEP7" and "Starter"). The current version of hardware expansions for STEP 7 can also be found under eSupport.

### Example of current hardware allocations PLC to NCU

Table 13- 1 Hardware expansions

| NCU                         | MLFB                | Comparable SIMATIC CPU MLFB included | Selecting from STEP 7 hardware catalog                                  |
|-----------------------------|---------------------|--------------------------------------|-------------------------------------------------------------------------|
| SINUMERIK 840D<br>NCU 710.1 | 6FC5 371-0AA00-0AA0 | 6ES7 317-2AJ00-0AB0                  | NCU710.1<br>STEP 7 V5.3 SP2 and higher<br>and Toolbox 840D sl 01.01.00) |
| SINUMERIK 840D<br>NCU 720.1 | 6FC5 372-0AA00-0AA0 | 6ES7 317-2AJ00-0AB0                  | NCU720.1<br>STEP 7 V5.3 SP2 and higher<br>and Toolbox 840D sl 01.01.00) |
| SINUMERIK 840D<br>NCU 730.1 | 6FC5 373-0AA00-0AA0 | 6ES7 317-2AJ00-0AB0                  | NCU730.1<br>STEP 7 V5.3 SP2 and higher<br>and Toolbox 840D sl 01.01.00) |

| NCU                             | MLFB                | Comparable<br>SIMATIC CPU MLFB<br>included | Selecting from STEP 7 hardware<br>catalog                                             |
|---------------------------------|---------------------|--------------------------------------------|---------------------------------------------------------------------------------------|
| SINUMERIK 840D<br>NCU 740.1     | 6FC5 374-0AA01-?AA0 | 6ES7 318-3EL00-0AB0                        | NCU740.1<br>STEP 7 V5.4 or later<br>and Toolbox 840D sl 01.04.02)                     |
| SINUMERIK 840Di sl<br>with MC12 | 6FC5 222-0AA02-1AA0 | 6ES7 317-2AJ00-0AB0                        | 840Di with PLC317-2 DP<br>STEP 7 V5.3 SP2 and higher<br>and Toolbox 840D sl 01.02.00) |

**Note**

On SINUMERIK 840D, SIMATIC line 0 is allocated for the SINUMERIK components.

In this line stretches to:

- **Slot 2:** the integrated PLC with the different bus systems
- **Slot 3,** empty
- **Slot 4:** the NCK 840D sl. The properties (I/O-address 256, process alarm) of the NCK must not be changed, as process interrupts (e.g. auxiliary functions) of the NCK to PLC may, in this case, no longer function.
- **Slot 5:** the integrated Ethernet CP 840D sl
- **Slot 6:** the integrated HMI 840D sl

The integrated drive is linked on the internal PCI bus (PROFIBUS protocol).

Currently, this bus does not support I/O access, and SFCs are not supported for this bus.

If you are using a different NCU, you can change the NCU using "drag & drop". The settings remain unaffected. When using the program "Starter" the icon "SINAMICS\_in\_NCUxyz" is also to be deleted and created again after the exchange of the NCU in the SIMATIC Manager.

P3: Basic PLC program for SINUMERIK 840D sl  
 13.4 Startup hardware configuration of the PLC-CPU's

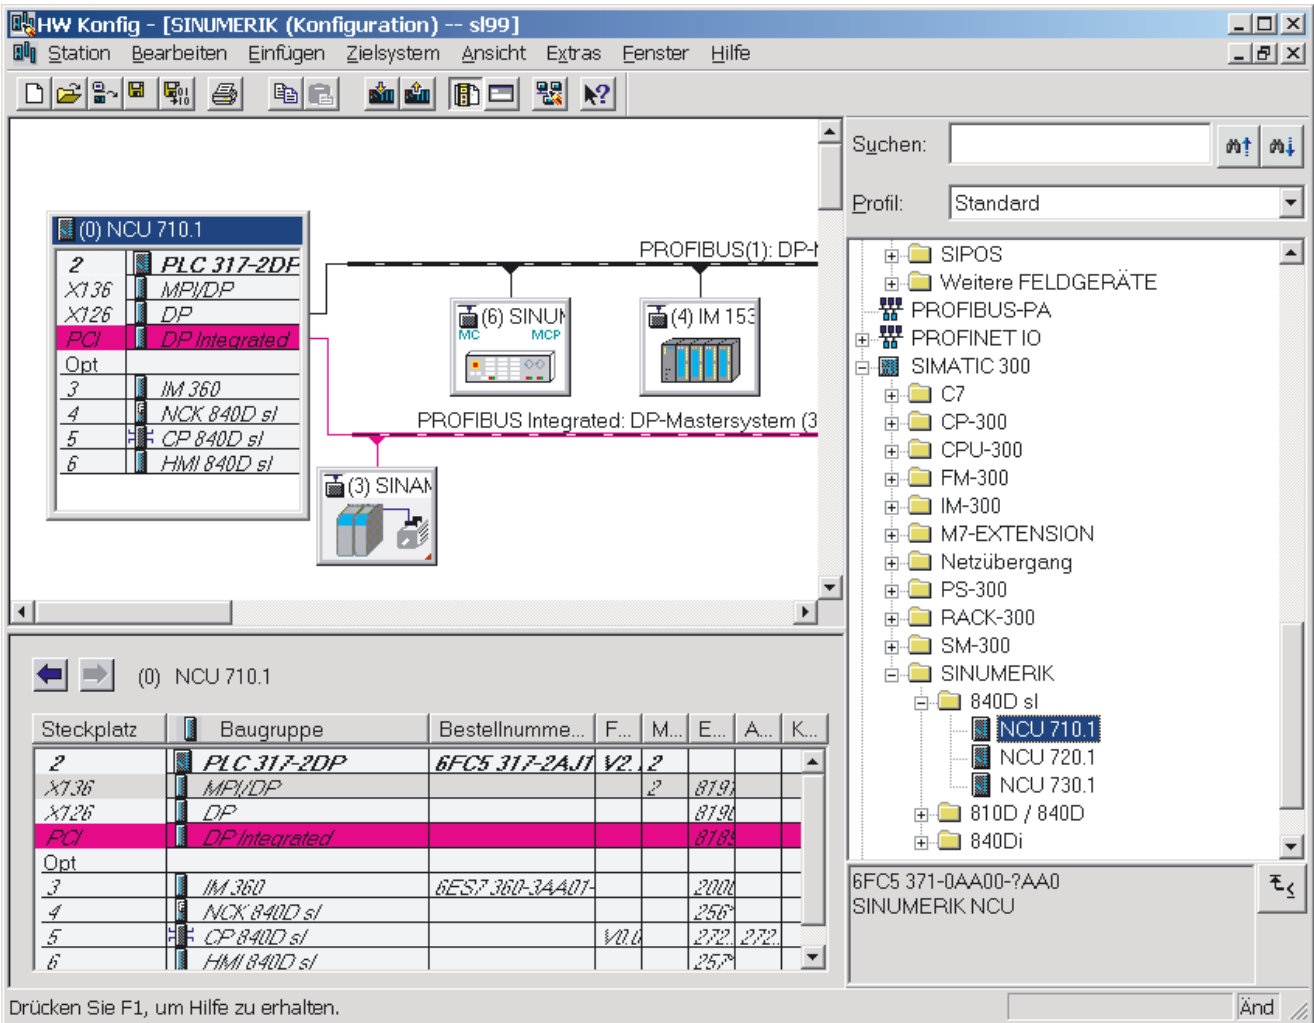

Figure 13-1 Hardware configuration on the SINUMERIK 840D sl and SINAMICS Properties dialog box

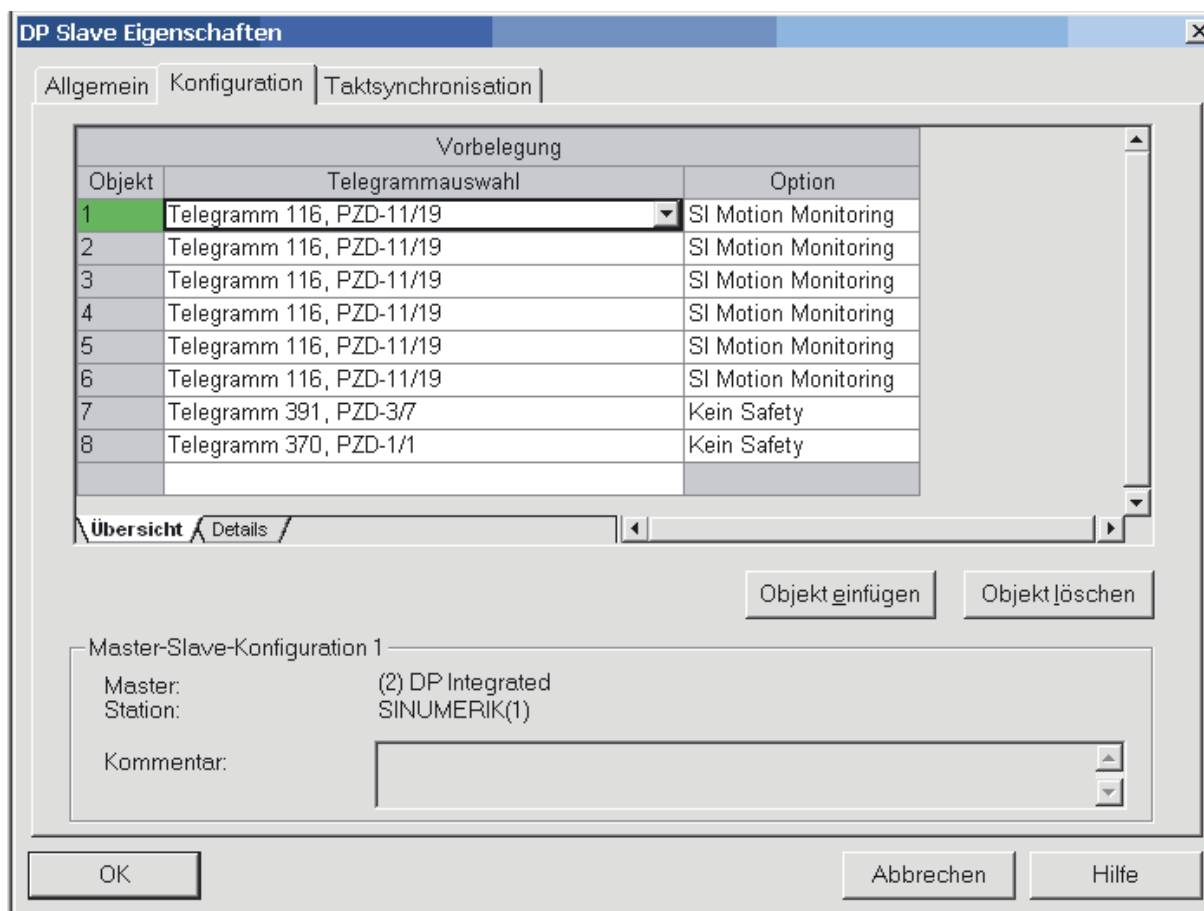

Figure 13-2 DP slave properties

In the Properties dialog box for the integrated SINAMICS drive, object codes 1 to 6 are used to identify axes 1 to 6. The axes are set for the largest possible message frame type 106 and Safety Motion Monitoring as standard. This is the default setting. Telegram type 106 features the longest possible user data length of an NC axis. The message frame type in the NC machine data may not tally at all with this setting. In the context of an NC axis, message frame type 106 means: 2 encoders + DSC

Object 8 contains the ALM via which, for example, enables have to be activated by the PLC user program. Object 7 contains the CU (device 0). The Equipment Manual for the NCU7x0 contains a further description of these objects.

Axis expansions with the NX10 and NX15 modules are possible for NCU710, NCU720 and NCU730. You will find NX10 and NX15 in the PROFIBUS-DP\SINAMICS module catalog.

You will find the clock settings for the drives in the dialog box under the "Isochronous Operation" tab. In case the transmission cycles of the drives have to be changed, a change must be made under this tab.

### **Ethernet communication**

In case of CP 840D the Ethernet address is assigned by default for the port X127. As such, the PLC can be reached via this port from a STEP 7 project. If needed, the Ethernet address on the CP 840D can be changed to the Ethernet address of the port X120 or X130. Then a cable connection to the PG of this port is also necessary.

### **Connection of central I/O devices**

The physical connection for a connection to an IM361 does not exist. No central I/O is possible.

## 13.5 Starting up the PLC program

### 13.5.1 Installation of the basic program

A complete general reset of the NCK and the PLC is necessary before starting up the NCU component for the first time. Turn the "SIM/NCK" switch on the left-hand side to position 1 and the "PLC" switch on the right-hand side to position 3. Then restart the controller. This action generates a "hard reset request" on the PLC. The memories of the PLC and NC are then initialized.

#### Installation

The basic program is installed by the Toolbox by means of the execution of a setup program for the basic program, hardware expansion for STEP7 (option package for SINUMERIK 840D sl) and NC-Var selector components, as well as for other tools. To start the installation, run setup.exe in the main CD directory. You can then choose which components to install. After the installation you can select the basic program library directly from STEP7 (bp7x0\_14, 14 is the main basic program version 1.4). The concrete version of the basic program can be scanned for the object properties of the library or the program folder in the comment field.

#### General

The OB source programs, including standard parameterization, interface symbols and data-block templates for the handheld unit and M decoding functions are included in the SIMATIC project or SIMATIC library of the basic program.

STEP 7 must be installed before installing the basic program Toolbox. After an update of STEP 7, it is generally recommended to reinstall the hardware expansion for STEP 7 from the toolbox.

### 13.5.2 Application of basic program

A new CPU program (e.g. "Turnma1") must be set up in a project by means of the STEP 7 software for each installation (machine).

#### Comment

The catalog structures of a project and the procedure for creating projects and user programs are described in the relevant SIMATIC documentation.

#### Procedure

The basic-program blocks are copied using the SIMATIC Manager and "File" > "Open" > "Library".

The following components must be copied from the library:

- From the block container: FCs, FBs, DBs, OBs, SFC, SFB, UDT
- Source\_files (from the source container): GPOB840D
- Possibly MDECLIST, HHU\_DB and others
- The symbols table (from the symbols container)

### Compatibility with STEP 7

There are no dependencies between the basic program and current STEP7 versions.

### 13.5.3 Version codes

#### Basic Program

The version of the basic program is displayed on the HMI version screen along with the controller type.

The controller type is encoded as follows:

| Left-justified decade of DB 17 DBD 0 (byte 0) | Controller type                                   |
|-----------------------------------------------|---------------------------------------------------|
| 03                                            | SINUMERIK 840D (561,571, 572, 573)                |
| 04                                            | SINUMERIK 840Di                                   |
| 03                                            | SINUMERIK 840D sl (NCU 7x0)<br>SINUMERIK 840Di sl |

#### User program

Users can also display their own PLC version codes on the HMI version screen. For this purpose, a data of type STRING containing a maximum of 54 characters must be defined in any data block. The data can contain a text of the user's choice. Parameter assignments for this string are made via a pointer in FB 1. Parameterization requires symbolic definition of the data block.

See also section "block descriptions" > "FB 1: RUN\_UP Basic program, start-up section (Page 946)".

### 13.5.4 Machine program

The machine manufacturer creates the machine program using the library routines supplied with the basic program. The machine program contains the logic operations and sequences on the machine. The interface signals to the NC are also controlled in this program. More complex communication functions with the NCK, e.g. read/write NC data, tool-management acknowledgments, etc., are activated and executed via blocks FCs and FBs of the basic-program).

The machine program can be created in various STEP 7 creation languages, e.g. AWL, KOP, FUP, S7-HIGRAPH, S7GRAPH, SCL. The complete machine program must be generated and compiled in the correct sequence.

This means that blocks that are called by other blocks must generally be compiled **before these** blocks.

If blocks that are called by other blocks are subsequently modified in the interface (VAR\_INPUT, VAR\_OUTPUT, VAR\_IN\_OUT, VAR) as the program is developed, then the call block and all blocks associated with it must be compiled again. This general procedure applies analogously to instance data blocks for FBs. If these sequence of operations is not maintained, time-stamp conflicts occur when the data retranslated into STEP 7. As such, the recompilability of the blocks is not ensured and with the function "Status of block" unnecessary conflicts can also appear. It is, moreover, advisable to generate blocks in ASCII-STL by means of the STEP 7 editor when they have been created in Ladder Diagram or in single statements (incremental mode).

### 13.5.5 Data backup

The PLC-CPU does not save any symbolic names, but instead only the datatype descriptions of the block parameters VAR\_INPUT, VAR\_OUTPUT, VAR\_IN\_OUT, VAR and the datatypes of the global data blocks.

---

#### Note

No sensible recompilation is possible without the related project for this machine. This especially affects, for instance the function status of the block or the necessary changes done in the PLC-CPU programs later. It is, therefore, necessary to keep a backup copy of the STEP 7 project located in the PLC CPU on the machine. This is a great help for the service case and saves unnecessary consumption of time in restoring the original project.

---

If the STEP 7 project exists and has been created according to the instructions given above, then symbols can be processed in the PLC-CPU on this machine. It may also be advisable to store the machine source programs as ".awl" files in case they are required for any future upgrade.

The source programs of all organization blocks and all instance data blocks should always be available.

### 13.5.6 PLC-series startup, PLC archive

Once the blocks have been loaded to the PLC CPU, a series archive can be generated via the HMI operator interface to back up data on the machine. To ensure data consistency, this backup must be created immediately after block loading when the PLC is in the Stop state. It does not replace the SIMATIC project backup as the series archive saves binary data only. For instance, no symbolic information is present here. In addition, no CPU DBs (SFC 22 DBs) or SDBs generated in the CPU are saved.

The PLC series archive can be generated directly from the relevant SIMATIC project as an alternative. To do this, in STEP 7 select the "Archive" tab available under the "Options" > "Settings" menu item. This contains an entry "SINUMERIK (\*.arc)", which must be selected to create a series commissioning file. After selection of the archive, select the "File" > "Archive" menu item. The relevant series archive will then be generated. If the project contains several programs, the program path can be selected. A series archive is set up for the selected program path. All blocks contained in the program path are incorporated into the archive, except for CPU-DBs (SFC 22 DBs). In addition, the "SDB archive" can be activated or deactivated in the function. With this selection the SDB present in the STEP 7 project can be added to the archive or left outside.

## Automation

The process of generating a series archive can be automated (comparable to the command interface in STEP7). In generating this series archive, the command interface is expanded.

The following functions are available for this expansion:

The functions (shown here in VB script) are not available until server instantiations and Magic have been called:

```
Const S7BlockContainer = 1138689, S7PlanContainer = 17829889
```

```
Const S7SourceContainer = 1122308
```

```
set S7 = CreateObject("Simatic.Simatic.1")
```

```
instantiate rem command interface of STEP 7
```

```
Set S7Ext = CreateObject("SimaticExt.S7ContainerExt")
```

```
Call S7Ext.Magic("")
```

Functions:

```
Function Magic(bstrVal As String) As Long
```

```
Function MakeSeriesstart-up (FileName As String, Option As Long, Container As S7Container) As Long
```

## Description

```
Function Magic(bstrVal As String) As Long
```

Call gives access to certain functions. The function must be called once after server instantiation. The value of bstrVal can be empty. This initiates a check of the correct STEP 7 version and path name in Autoexec. The functions are enabled with a return parameter of 0.

Return parameter (-1) = incorrect STEP 7 version

Return parameter (-2) = no entry in Autoexec.bat

```
Function MakeSeriesstart-up(FileName As String, Option As Long, Container As S7Container) As Long
```

**"Option" parameter:**

|            |                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 0:         | Normal series IBN file with general reset.                                                                                                 |
| Bit 0 = 1: | Series IBN file without general reset. When project contains SDBs, this option is inoperative.<br>A general reset is then always executed. |
| Bit 1 = 1: | Series IBN file with PLC restart                                                                                                           |

**Return parameter value:**

|    |                                                                         |
|----|-------------------------------------------------------------------------|
| 0  | = OK                                                                    |
| -1 | = Function unavailable, call Magic function beforehand                  |
| -2 | = File name cannot be generated                                         |
| -4 | = Container parameter invalid or container block empty                  |
| -5 | = Internal error (memory request rejected by Windows)                   |
| -6 | = Internal error (problem in STEP 7 project)                            |
| -7 | = Write error when generating series startup files (e.g. diskette full) |

**Use in script**

```

If S7Ext.Magic("") < 0 Then
 Wscript.Quit(1)
End If
Set Proj1 = s7.Projects("new")
set S7Prog = Nothing
Set s7prog = Proj1.Programs.Item(1) 'if there is only one program'
For Each cont In s7prog.Next
 If (Cont.ConcreteType = S7BlockContainer) Then
 ' Check block container
 Exit For
End if
Cont = Nothing
Next
Error = S7Ext.MakeSerienIB("f:\dh\arc.dir\PLC.arc", 0, Cont)
' Now error analysis

```

The **For Each ... Next** Block programmed above can be programmed in the Delphi programming language as follows (the programming for C, C++ programming languages is similar):

```

Var
 EnumVar: IEnumVariant;
 rgvar: OleVariant;
 fetched: Cardinal;

```

```

//For Each Next
EnumVar := (S7Prog.Next._NewEnum) as IEnumVariant;
While (EnumVar.Next(1,rgvar,fetched) = S_OK) Do Begin
 Cont := IS7Container(IDispatch(rgvar)); //block container
 Check sources
 If (Cont.ConcreteType = S7BlockContainer) Then Break;
 Cont := NIL;
End;

```

## 13.5.7 Software upgrade

### Software upgrade

Whenever you update the PLC or NCK software, always reset the PLC to its initial state first. This initial clear state can be achieved by means of a general PLC reset. In case of this resetting all the available blocks are deleted.

In normal cases, the new basic program is to be linked for a new NCU software version. The basic programs blocks must be loaded into the user project for this purpose. In this case no OB 1, OB 40, OB 82, OB 86, OB 100, the FC 12 and also the DB 4 may not be transmitted, if these blocks are already present in the user project. These blocks may have been modified by the user. The new basic program must be linked with the user program.

To do this, proceed as follows:

1. Generate the text or source file of all user blocks before copying the basic program.
2. Then copy the new basic program blocks to this machine project (for a description, see Subsection "Application of basic program")
3. All user programs "\*.awl" must then be recompiled in the correct order! (see also: "Machine program (Page 870)":
4. This newly compiled machine program must then be loaded to the PLC CPU with STEP 7.

However, it is normally sufficient to recompile the organization blocks (OB) and the instance data blocks of the machine program. This means you only need to generate sources for the organization blocks and the instance data blocks (before upgrading).

### Overall reset

A description of how to perform a general PLC reset appears in the Commissioning Manual. However, a general reset does not delete the contents of the diagnostic buffer nor the node address on the MPI bus. Another possible general reset method is described below. This method must be used when the normal general reset process does not work.

Proceed as follows:

| No. | Action                                                                             | Effect                                     |
|-----|------------------------------------------------------------------------------------|--------------------------------------------|
| 1   | Control system is switched off                                                     |                                            |
| 2   | PLC switch setting 3 (MRES) and switch control on again or perform hardware RESET. | LED labeled PS flashes slowly.             |
| 3   | Set PLC start-up switch to position 2 (STOP) and back to position 3 (MRES).        | The LED labeled PS starts to flash faster. |
| 4   | Set PLC start-up switch to setting 2 or 0.                                         |                                            |

## NC tags

The latest NC VAR selector can be used for each NC software version (even earlier versions). For older NC software versions the variables can also be selected from the latest complete list. The data content in DB 120 (default DB for variables) does not depend on the software status. That is, variables selected in an older software version need not be reselected when the software is upgraded.

## 13.5.8 I/O modules (FM, CP modules)

Special packages for STEP 7 are generally required for more complex I/O modules. Some of these special packages include support blocks (FCs, FBs) stored in a STEP7 library. The blocks contain functions for operating the relevant module which are parameterized and called by the user program. In many cases, the FC numbers for the CP and FM module handling blocks are also included in the number range of the basic program for the 840D.

What can one do in these conflicts?

The block number of the basic program must remain unchanged. The block numbers of required handling blocks can be assigned to free numbers using STEP 7. These new blocks (with new FC numbers) are then called in the user program with the parameter assignments required by the function.

### 13.5.9 Troubleshooting

This section describes problems which may occur, their causes and remedies and should be read carefully before hardware is replaced.

| Errors, cause/description and remedy |                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                        |
|--------------------------------------|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Serial no. error information         | Errors                                                | Cause/description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | To correct or avoid errors                                                                                                                                                                                             |
| 1                                    | No connection via MPI to PLC.                         | The MPI cable is not plugged in or is defective. Possibly, the STEP 7 software is also not correctly configured for the MPI card.                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Test: Create a link with the programmer in the STEP 7 editor by means of connection "Direct_PLC". A number of node addresses must be displayed here. If they do not appear, the MPI cable is defective/not plugged in. |
| 2                                    | PLC cannot be accessed in spite of PLC general reset. | A system data block SDB 0 has been loaded with a modified MPI address. This has caused an MPI bus conflict due to dual assignment of addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                    | Disconnect all MPI cables to other components. Create the link "Direct_PLC" with the programmer. Correct the MPI address.                                                                                              |
| 3                                    | All four LEDs on the PLC flash (DI disaster)          | A system error has occurred in the PLC.<br><b>Measures:</b><br>The diagnostic buffer on the PLC must be read to analyze the system error in detail. To access the buffer, the PLC must be stopped (e.g. set "PLC" switch to position 2). A hardware reset must then be performed. The diagnostic buffer can then be read out with STEP 7. Relay the information from the diagnostic buffer to the Hotline / Development Service. A general reset must be carried out if requested after the hardware RESET. The diagnostic buffer can then be read with the PLC in the Stop state. | Once the PLC program has been RESET or reloaded, the system may return to normal operation. Even in this case, the content of the diagnostic buffer should be sent to the Development Office.                          |

## 13.6 Coupling of the PLC CPUs

### 13.6.1 General

The AS 300 family is used as PLC for SINUMERIK 840D sl / 840Di sl. The PLC-CPU is integrated into the NCU component as a sub-module. The relevant performance data for PLC CPUs can be found in the table in "Key data of the PLC-CPU for 840D sl and 840Di sl (Page 857)" or in the SIMATIC Catalog.

### 13.6.2 Features of PLC CPUs

SINUMERIK 840D sl / 840Di sl PLC CPUs are based on standard SIMATIC CPUs in the S7-300 family. As a result, they generally possess the same functions. The deviations can be taken from the Table in "Key data of the PLC-CPU for 840D sl and 840Di sl (Page 857)". Owing to differences in their memory system as compared to the SIMATIC CPU, certain functions are not available (e.g. save blocks on memory card, save project on memory card).

---

#### Note

With the current SIMATIC CPUs, the PLC is not automatically started after voltage failure and recovery when a PLC Stop is initiated via software operation. In this instance, the PLC remains in the Stop state with an appropriate diagnostic entry for safety reasons. You can start the PLC only via software operation "Execute a restart" or by setting the switch to "Stop" and then "Run". This behavior is also integrated in the current versions of the SINUMERIK PLC.

---

### 13.6.3 Interface with integrated PLC

#### Physical interfaces

As the SINUMERIK 840D sl / 840Di sl system has an integrated PLC, signals can be exchanged between the NCK and PLC directly via a dual-port RAM.

#### Data exchange with the control panel

Data exchange with the operator panel (HMI, OP) usually takes place via the internal software-based C bus. Alternatively, external HMI or OP systems can also be connected on Ethernet or the MPI bus. In the event of connection to the Ethernet bus, the integrated CP provides the link to the PLC.

Data exchange with the machine control panel (MCP) and handheld unit (HHU) is realized depending on the interface version of the MCP or HHU. Possible connection paths include: MPI, PROFIBUS, Ethernet.

Programming devices should preferably be connected directly to the PLC on the Ethernet bus via the internal CP or via the MPI (Multi-Point-Interface).

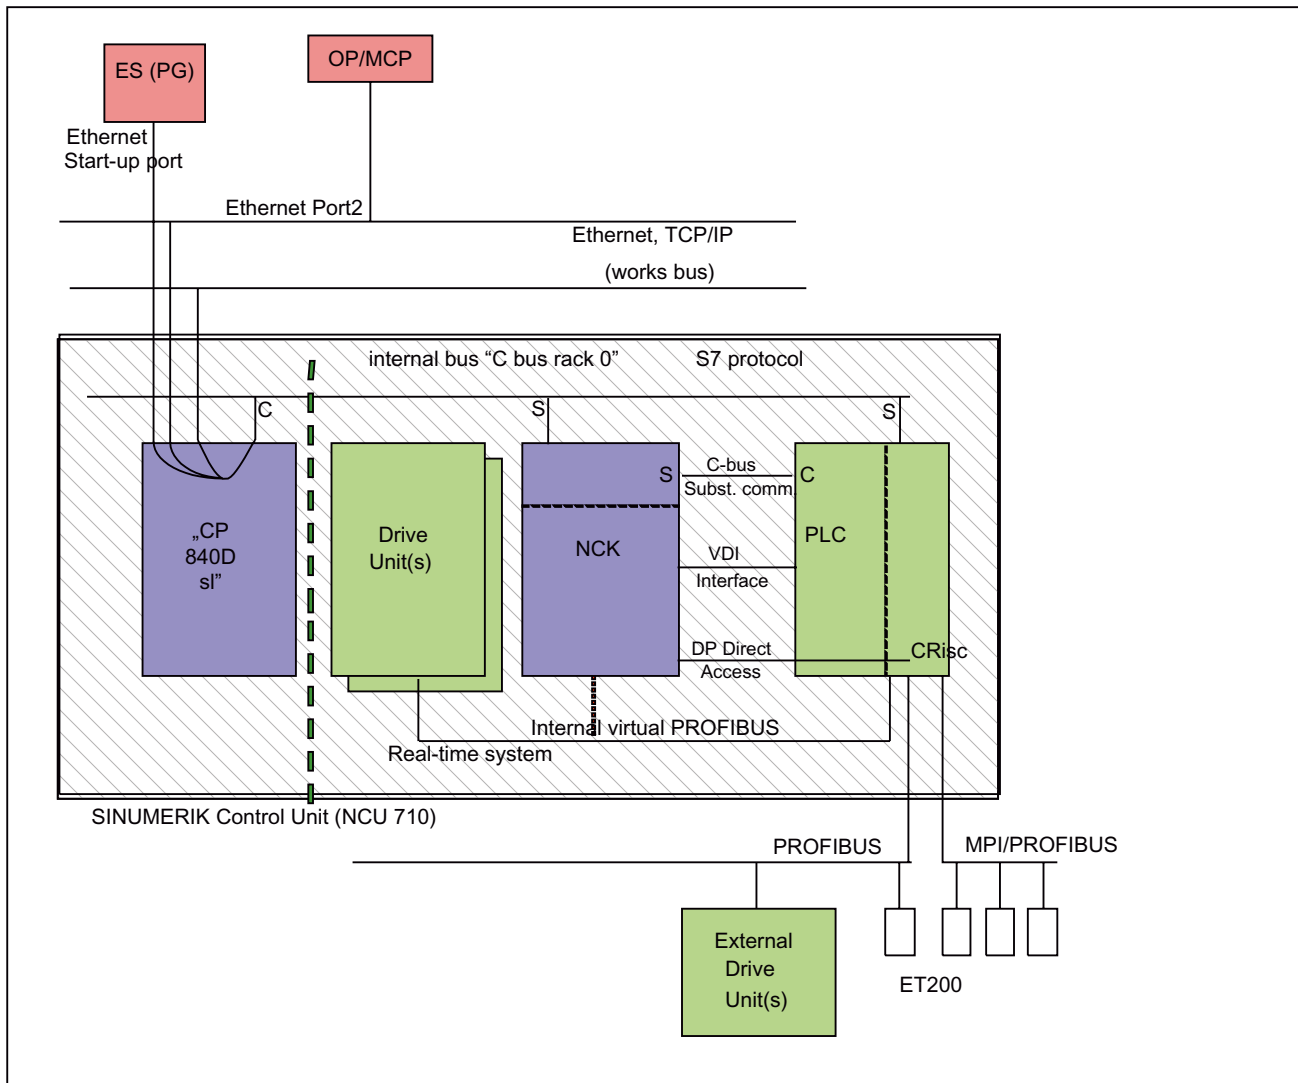

Figure 13-3 NCK/PLC coupling on SINUMERIK 840D (integrated PLC)

### NCK/PLC interface

As illustrated in the figure, NCK/PLC data exchange is organized by the basic program in the PLC. At the beginning of the cycle (OB1), the **status information** (e.g. "Program running") written to the internal DPR (DPR = Dual Port RAM) by the NCK is copied to data blocks by the basic program, which the user can then access (user interface). The **control signals** for the NCK (e.g. NC start) entered in the interface data blocks by the user are also written to the internal DPR and transmitted to the NCK at the start of the cycle.

Workpiece-program-specific **auxiliary functions** transferred to the PLC are first evaluated by the basic program (interrupt-driven) and then transferred to the user interface at the start of OB 1. If the relevant NC block contains auxiliary functions that require that NCK processing is interrupted (e.g. M06 for tool change), the basic program stops the decoding of the NCK block initially for one PLC cycle. The user can then use the "read disable" interface signal to halt the block execution until the tool change has been completed. If, on the other hand, the relevant NC block only contains auxiliary functions, which do not require interruption of the decoding (e.g. M08 for cooling medium on), the transfer of these "fast" auxiliary functions is directly acknowledged in OB 40, so that decoding is only insignificantly influenced by the transfer to the PLC.

The evaluation and enabling of the **G functions** transferred from the NCK are also alarm-driven, however they are transferred directly to the user interface. Where a G function is evaluated at several points in the PLC program, differences in the information of the G function within one PLC cycle may arise.

In the case of **NC actions** triggered and assigned with parameters by the PLC (e.g. traverse concurrent axes), triggering and parameter assignment is performed using FCs and FBs, not interface data blocks. The FCs and FBs belonging to the actions are supplied together with the basic program. The FCs and FBs required must be loaded by the user and called in the PLC program of the machine manufacturer (machine program). For an overview of FC, FB and data blocks, sorted according to basic and extended functions, please refer to the chapter "Start-up of PLC programs".

## Interface HMI/PLC

HMI/PLC data exchange takes place via the software C bus or via the Ethernet, internal CP, control-internal C bus link. The CP transfers the data intact from one bus segment to another. The HMI is always the active partner (client) and the PLC is always the passive partner (server). Data transmitted or requested by the HMI are read from and written to the HMI/PLC interface area by the PLC operating system (timing: cycle control point). From the viewpoint of the PLC application, the data are identical to I/O signals.

## Interface MCP / PLC, interface HHU / PLC (Ethernet link)

MCP/PLC and HHU (HT2) /PLC data exchange takes place via the integrated CP's Ethernet bus. The CP transfers the MCP/HHU signals to and fetches them from the PLC's internal DPR (Dual-Port RAM). On the PLC side, the basic program handles communication with the user interface. The basic program parameters define the operand areas (e.g. I/O) and the start addresses via the parameters of the basic programs (FB 1, DB 7).

### Interface MCP/PLC (PROFIBUS link)

MCP/PLC data exchange takes place via the PLC's PROFIBUS. The MCP's I/O addresses are to be set in the PLC's process image area and via HW configuration in STEP 7. The MCP\*In, MCP\*Out pointer variables must be set to the same addresses. The selected DP slave number must be entered in MCP\*BusAdr.

### Interface MCP/PLC, interface HHU/PLC (MPI link)

is no longer supported

### 13.6.4 Diagnostic buffer on PLC

The diagnostic buffer of the PLC (readable using STEP 7) will enter diagnostic information on the PLC operating system.

## 13.7 Interface structure

### Interface DBs

Mapping in interface data blocks is necessary due to the large number of signals exchanged between the NCK and PLC. These are global data blocks from the viewpoint of the PLC program. During system start-up, the basic program creates these data blocks from current NCK machine data (no. of channels, axes, etc.). The advantage of this approach is that the minimum amount of PLC RAM required for the current machine configuration is used.

### 13.7.1 PLC/NCK interface

#### General

The PLC/NCK interface comprises a data interface on one side and a function interface on the other. The data interface contains status and control signals, auxiliary functions and G functions, while the function interface is used to transfer jobs from the PLC to the NCK.

#### Data interface

The data interface is subdivided into the following groups:

- NCK-specific signals
- Mode-group-specific signals
- Channel-specific signals
- Axis/spindle/drive-specific signals

### Function interface

The function interface is formed by FBs and FCs. The figure below illustrates the general structure of the interface between the PLC and the NCK.

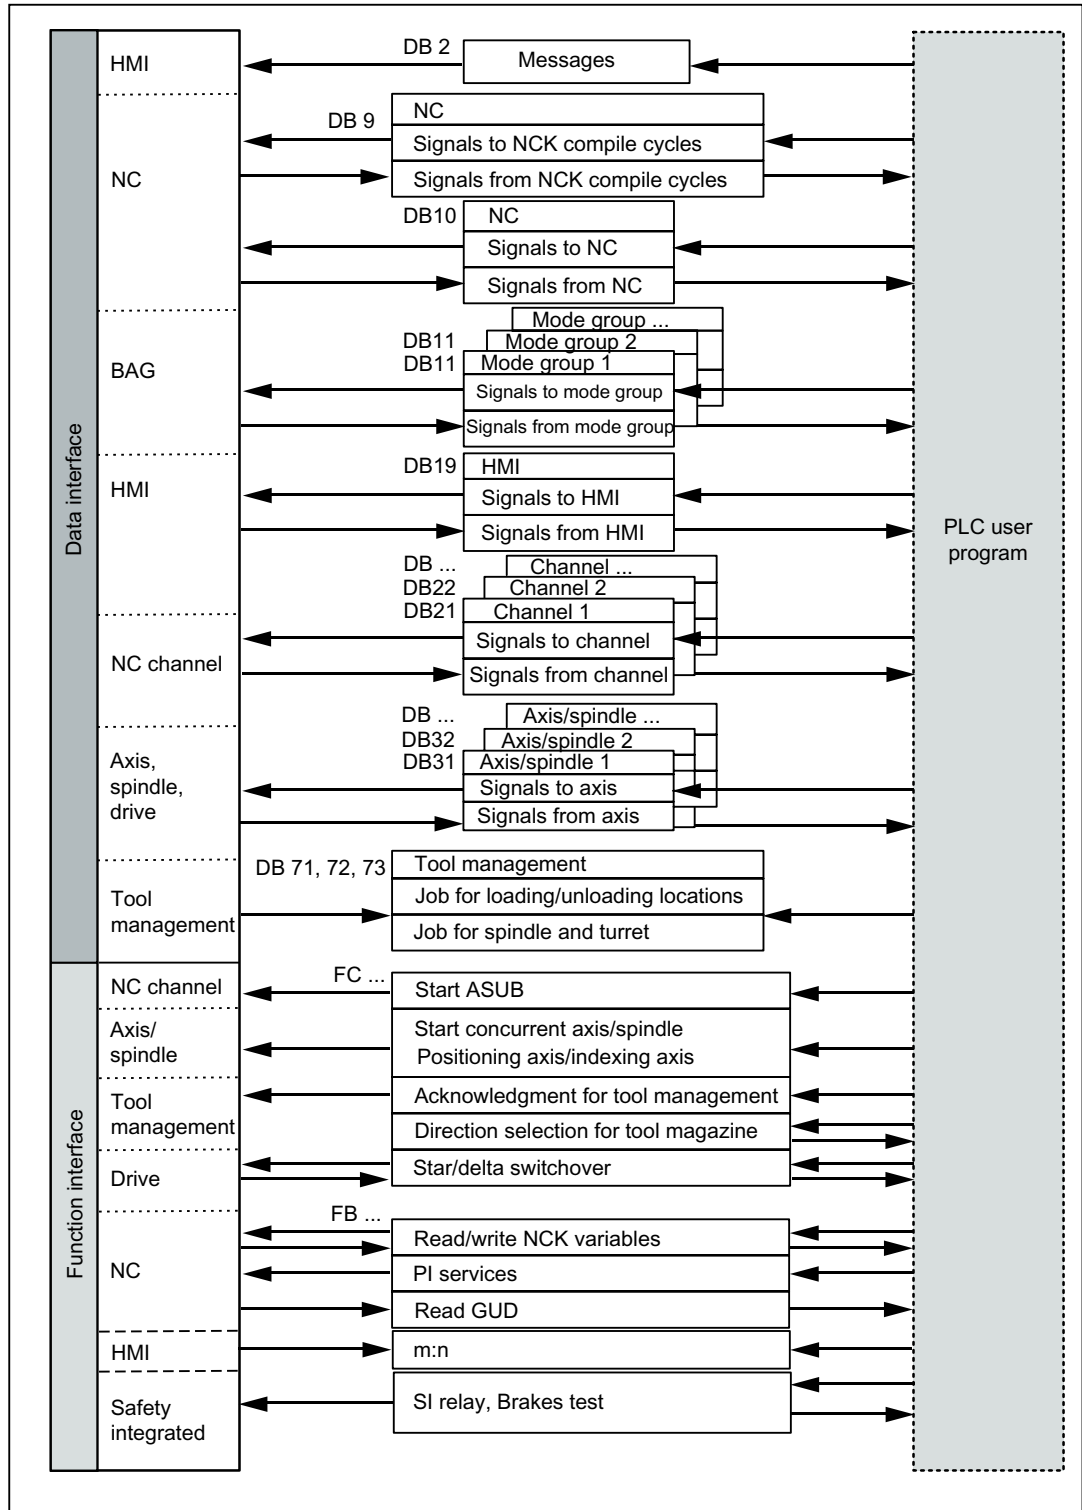

Figure 13-4 PLC/NCK user interface

### Compile-cycle signals

In addition to the standard signals exchanged between the PLC and NCK, an interface data block for compile cycles is also generated if required (DB 9). The associated signals, which are dependent on the compile cycles, are transmitted cyclically at the start of OB 1. The basic program starts transmission at the lowest address and works up to the highest. First, signals are transferred from the PLC to the NCK, then from the NCK to the PLC. The user must synchronize the NCK and PLC as necessary (e.g. using the semaphore technique). Signal transmission is asynchronous between NCK and PLC. This means, for example, that active NCK data transmission can be interrupted by the PLC. This can mean that data is not always consistent.

### PLC/NCK signals

The group of signals from the PLC to NCK includes:

- Signals for modifying the digital and analog I/O signals of the NCK
- Keyswitch and emergency stop signals

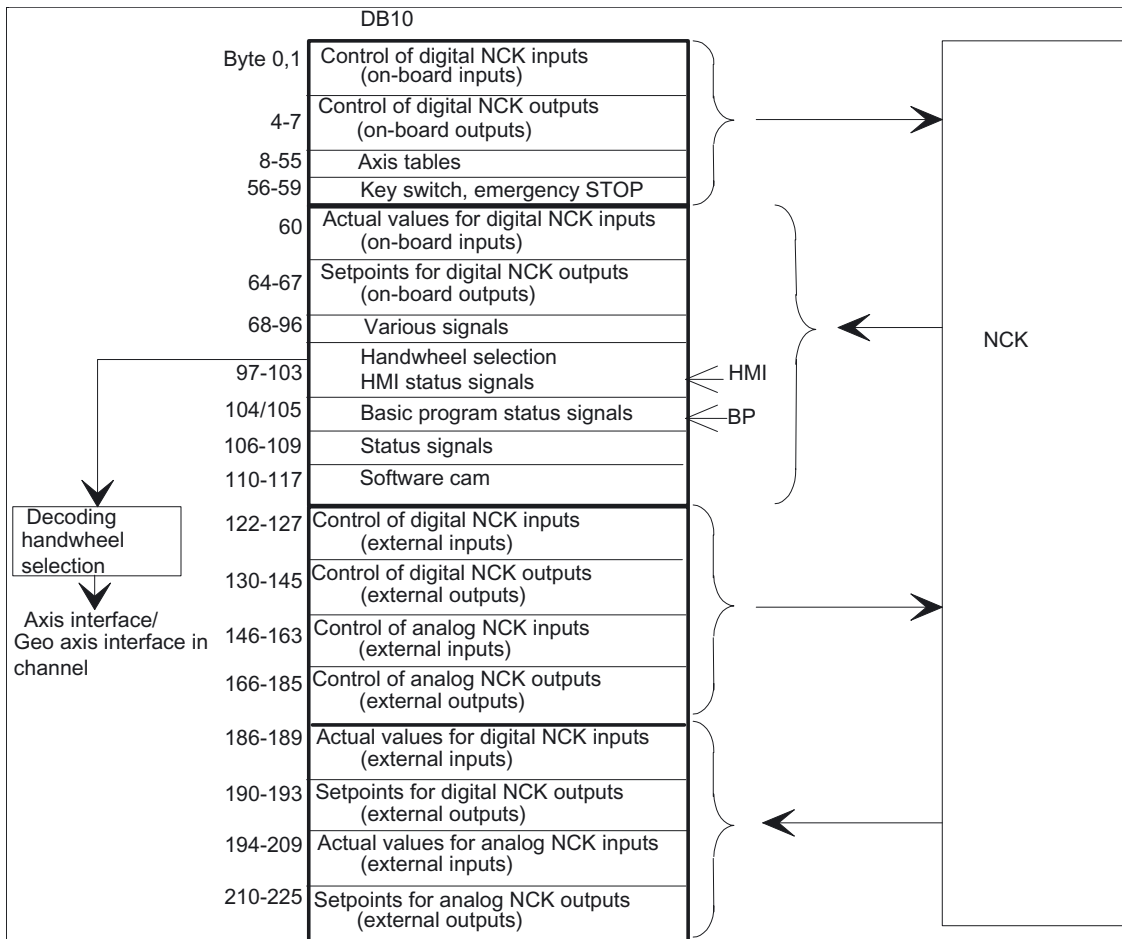

Figure 13-5 PLC/NCK interface

## NCK/PLC signals

The group of signals from the NCK to PLC includes:

- Actual values of the digital and analog I/O signals of the NCK
- Ready and status signals of the NCK

Also output in this group are the HMI handwheel selection signals and the status signals.

The signals for handwheel selection are decoded by the basic program and entered in the machine-/axis-specific interface.

## Digital/analog inputs/outputs of the NCK

The following must be noted with respect to the digital and analog inputs and outputs of the NCK:

### Inputs:

- All input signals or input values of the NCK are also transferred to the PLC.
- The transfer of signals to the NC parts program can be suppressed by the PLC. Instead, a signal or value can be specified by the PLC.
- The PLC can also transfer a signal or value to the NCK even if there is no hardware for this channel on the NCK side.

### Outputs:

- All signals or values to be output are also transferred to the PLC.
- The NCK can also transfer signals or values to the PLC even if there is no hardware for this channel on the NCK side.
- The values transferred by the NCK can be overwritten by the PLC.
- Signals and values from the PLC can also be output directly via the NCK I/O devices.

---

### Note

While realizing the digital and analog NCK I/Os the information contained in the following documentation must be taken into account:

### References:

Function Manual Extended Functions; Digital and analog NCK I/Os (A4)

---

## Signals PLC/Mode group

The operating mode signals set by the machine control panel or the HMI are transferred to the operating mode group (BAG) of the NCK. On the 840D, these are valid for all NCK channels. On 840D systems, several mode groups can optionally be defined in the NCK.

The mode group reports its current status to the PLC.

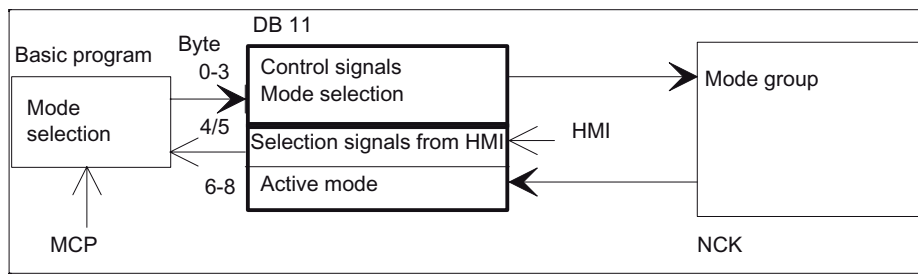

Figure 13-6 PLC/Mode group interface

### Signals PLC/NCK channels

The signal groups below must be considered on the interface:

- Control/status signals
- Auxiliary/G functions
- Tool management signals
- NCK functions

The **control / status functions** are transmitted cyclically at the start of OB1. The signals entered in the channel-specific interface by the HMI (HMI signals are entered by the PLC operating system) are also transferred at this time if they have been defined on the HMI operator panel, not on the MCP.

**Auxiliary functions and G functions** are entered in the interface data blocks in two ways. First, they are entered with the change signals.

- The **M signals** M00 - M99 (they are transferred from the NCK with extended address 0) are also decoded and the associated interface bits set for the duration of one cycle.
- For **G functions**, only the groups selected via machine data are entered in the interface data block.
- The **S values** are also entered together with the related M signals (M03, M04, M05) in the spindle-specific interface. The axis-specific feedrates are also entered in the appropriate axis-specific interface.

When the **tool management (magazine management)** function is activated in the NCK, the assignment of spindle or revolver and the loading/unloading points are entered in separate interface DBs (DB71 - 73)

The triggering and parameter assignment of **NCK functions** is performed by means of PLC function calls. The following function calls are available:

- Position a linear axis or rotary axis
- Position an indexing axis
- Start a prepared asynchronous subprogram (ASUB)
- Reading/writing of NC variables
- Update magazine and tool movement

Some of the above functions are described in their own function documentation.

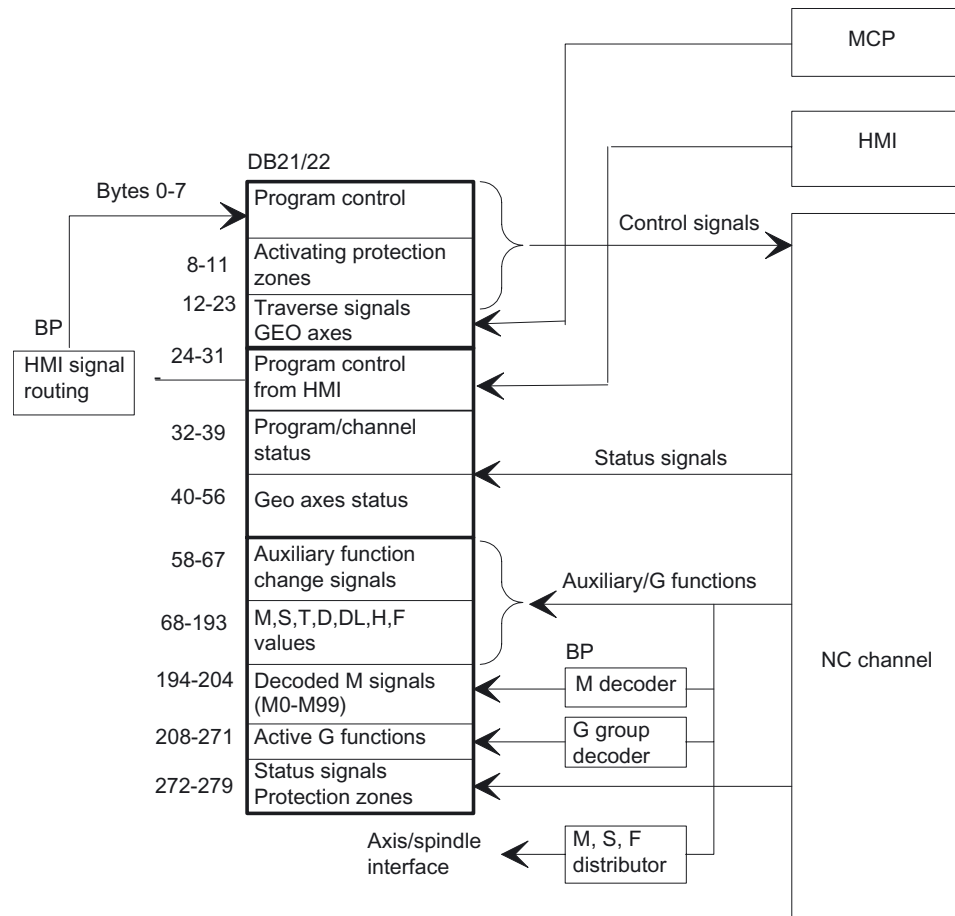

Figure 13-7 PLC/NCK channel interface

### PLC/axis, spindle, drive signals

The axis-specific and spindle-specific signals are divided into the following groups:

- Shared axis/spindle signals
- Axis signals
- Spindle signals
- Drive signals

The signals are transmitted cyclically at the start of OB 1 with the following exceptions:

Exceptions include:

- Axial F value
- M value
- S value

An **axial F value** is entered via the M, S, F distributor of the basic program if it is transferred to the PLC during the NC machining process.

The **M and S value** are also entered via the M, S, F distributor of the basic program if one or both values require processing.

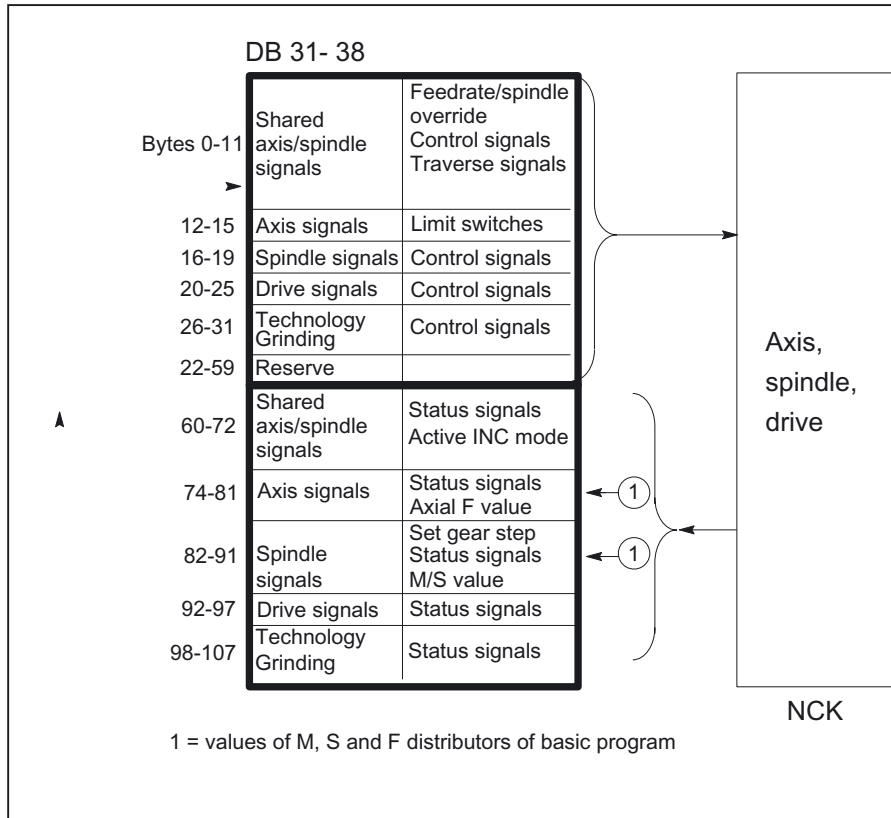

Figure 13-8 Interface between PLC and axes/spindles/drives

### 13.7.2 Interface PLC/HMI

#### General

The following groups of functions are required for the PLC/HMI interface:

- Control signals
- Machine operation
- PLC messages
- PLC status display

#### Control signals

Some control signals are signal inputs, for example, via the machine control panel, which have to be taken into account by the HMI. This group of signals includes, for example, display actual values in MCS or WCS, key disable, etc. These are exchanged with the HMI via a separate interface data block (DB19).

## Machine operation

All operator inputs, which lead to response actions on the machine, are monitored by the PLC. Operator actions are usually performed on the machine control panel (MCP). However, it is also possible to perform some operator actions on the HMI e.g. mode selection.

The PLC operating system enters the operating signals sent by the HMI directly into the interface data blocks. As standard, the basic program routes these operating signals in such a way that, provided equivalent operator actions are available, these can be performed either on the HMI or on the MCP. If required, the user can switch off the operation via HMI through a parameter "MMCToIF" of FB1.

## PLC messages

The signaling functions are based on the system diagnostic functions integrated in the operating system of the AS 300. These have the following characteristics:

- The PLC operating system enters all important system states and state transitions in a **diagnostics status list**. Communication events and I/O module diagnostics data (for modules with diagnostic functions) are also entered.
- Diagnostics events, which lead to a system stop, are also entered with a time stamp in a **diagnostic buffer** (circular buffer) in the chronological order of their occurrence.
- The events entered in the diagnostic buffer are automatically transmitted to human machine interface systems (OP or HMI) via the bus systems once these have issued a ready signal (message service). Transfer to the node ready is a function of the PLC operating system. Receipt and interpretation of the messages are executed by the HMI software.
- The PLC user program can also use SFCs (System Function Calls) to enter messages in the diagnostic buffer or ALARM S/ALARM SQ buffer.
- The events are entered in the interrupt buffer.

The associated message texts must be stored on the OP or HMI.

An FC (FC 10) for message acquisition is prepared in conjunction with the basic program. This FC records events, subdivides them into signal groups and reports them to the HMI via the interrupt buffer.

The message acquisition structure is shown in the figure "Acquisition and signaling of PLC events". The features include:

- Bit fields for events related to the VDI interface are combined in a single data block (DB2) with bit fields for user messages.
- Bit fields are evaluated at several levels by FC10.
  - **Evaluation 1; Acquisition of group signals**

A group signal is generated for each group of signals if at least one bit signal is set to "1". This signal is generally linked to the disable signal of the VDI interface (on modules with diagnostic functions). The group signals are acquired completely in cycles.
  - **Evaluation 2; Acquisition of interrupt messages**

A fixed specification exists to define which signals in a group generate an interrupt message when they change from "0" to "1".
  - **Evaluation 3; Acquisition of operating signals**

A fixed specification exists to define which signals in a group generate an operational message.
- The scope of the user bit fields (user area) is set by default to 10 areas with 8 bytes each, but the number of areas can also be adjusted to suit the requirements of the machine manufacturer via basic program parameters in FB 1.

### Acknowledgment concept

The following acknowledgment procedures are implemented for error and operational messages:

**Operating messages** are intended for the display of normal operating states as information for the user. Acknowledgment signals are, therefore, not required for this type of message. An entry is made in the diagnostic status list for incoming and outgoing messages. The HMI maintains an up-to-date log of existing operating messages using the identifiers "operating message arrived" and "operating message gone".

**Interrupt messages** are used to display error states on the machine, which will usually lead to the machine being stopped. Where several errors occur in rapid succession, it is important to be able to distinguish their order of occurrence for troubleshooting purposes. This is indicated, on the one hand, by the order in which they are entered in the diagnostic buffer and on the other, by the time stamp, which is assigned to every entry.

If the cause of the error disappears, the associated interrupt message is only deleted if the user has acknowledged it (e.g. by pressing a key on the MCP). In response to this signal, the "Message acquisition" FC examines which of the reported errors have disappeared and enters these in the diagnostic buffer with the entry "Interrupt gone". This enables the HMI to also maintain an up-to-date log of pending interrupt messages. The time of day indicating the time at which the error occurred is maintained for messages, which are still pending (in contrast to a received interrogation).

### STEP 7

A tool can be started in the SIMATIC Manager via menu item "Target system" > "CPU messages". Alarms and messages can be displayed by number using this tool. To do this, activate the "Alarm" tab and enter a check mark under "A" in the upper half of the screen.

## User program

The user PLC program merely needs to call the basic program block FC 10 with appropriate parameter settings in the cyclic program section and set or reset the bit fields in DB2. All further necessary measures are implemented by the basic program and HMI.

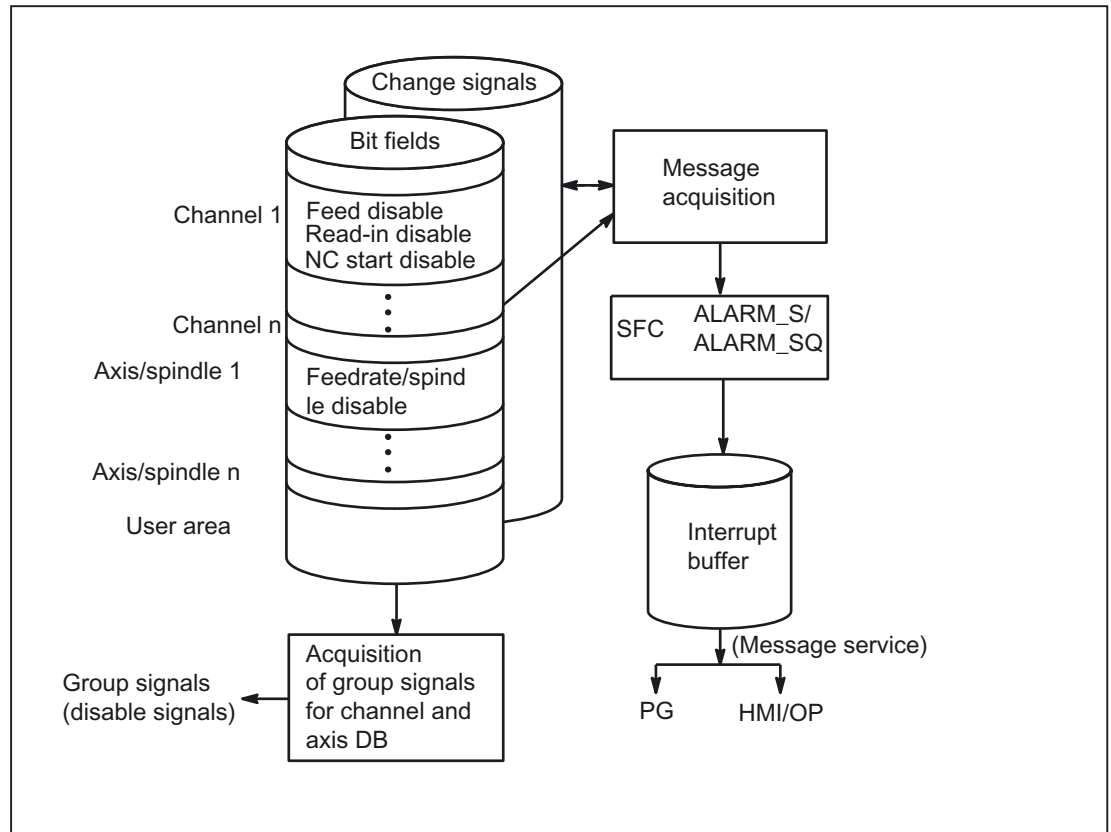

Figure 13-9 Acquisition and signaling of PLC events

## Extensions of the PLC alarms via the block FC 10

The FB 1-parameter "ExtendAIMsg" helps in making a selection of the PLC alarm mechanism.

If "ExtendAIMsg:= FALSE" the earlier process of the FC 10 with the DB 2 is active as bit-field data block. The known restrictions regarding the number of channels and axes are applicable.

On the other hand, in case of "ExtendAIMsg:= TRUE" the extension of the FC 10 becomes active. The DB 2 and DB 3 are created as usual. The user must set or reset the bits in DB 2. The parameter setting via message and alarm and a parameter setting of the numeric value of the 2nd decade of the user alarms are contained in DB 5.

The extensions are:

- Support for 10 channels, 31 axes.
- Areas for feed stop, read-in disable, etc. are available without messages. The information from this area is stored on the interface in DB21, DB31 depending upon the FC 10-parameter "ToUserIF" together with the related message bits as group signals. As such, the previous cumbersome handling of the signals is omitted.
- The alarms / messages also get the 16-bit integer additional value (%Z parameter in the alarm text) in addition to the alarm number for the user area 0. The user must write the 16-bit integer values in the DB 2 in the Array variable ZInfo0 parallel to setting an alarm bit. An integer value is available for each bit in the user area 0, see UDT1002 in the basic program.
- The user messages can be parameteized in the second decade of the message number in the numerical range 0 to 9. The display value of the second decade must be written by the user in the DB5 in the array variable UserDek2No. A number can be defined for each user area, see DB 5 in the basic program.

The value 0 is set by default for second decade.

The structuring of the DB 2 in UDT1002 can be recognized (basic program). In case of new alarm functions, the UDT1002 must be assigned symbolically to the DB2.

At the start of DB 2 there are bit fields for signals without alarm generation. This is followed by an array of size 64 integer for additional info of the user area 0.

Thereafter follow the areas, which also trigger alarms / messages (see List Manual) These areas are extended to 10 channels, 31 axes.

### Simple implementation of a user program on the new alarms

The source container of the basic program contains the file "udt2\_for\_Convert.awl", which has the following structural element from UDT1002:

- ChanA as array of 1 ... 8
- AxisA as array of 1 ... 18
- UserA as array of 1 ... 31

This UDT2 is to be compiled via the KOP/FUP/AWL - Editor. The UDT2 must be assigned to the DB 2 in the symbol table.

Sources must be generated for components, which have assignments on DB 2. Alternatively, sources can naturally be created for all blocks too. The UDT1002 must now be assigned to the DB 2 in the symbol table. Thereafter, the sources must be recompiled.

Now all the alarm allocations are assigned to the new data areas in the DB 2 and now only the parameter "ExtendAlMsg" at FB 1 must be set to True.

After a Power On RESET the alarm behavior is the same as earlier.

### 13.7.3 PLC/MCP/HHU interface

#### General

There are three different connection options for the machine control panel (MCP) and the handheld unit (HHU). This is in part due to the history of the MCP and HHU. This description focuses primarily on the connection of the Ethernet components.

On SINUMERIK 840 D sl, the machine control panel (MCP) or HT8 (MCP) and handheld unit HT1, HT2 (HHU) are connected via the Ethernet bus, which also links the TCU to the NCU. The advantage of this is that only one bus cable is required to connect the operator unit.

#### Topology SINUMERIK 840D sl

On the 840 D, the machine control panel and the handheld unit are connected to the CP 840D sl Ethernet bus (see Figure below). Where the connection of further keys and displays is required for customized operator panels, an additional keyboard interface (machine control panel without operating unit) can be used. For each keyboard interface, 64 pushbuttons, switches, etc. and 64 display elements can be connected via ribbon cable.

The signals sent from the MCP are copied to the PLC's DPR (Dual Port RAM) by the integrated Ethernet CP-840D sl. The basic program of the PLC enters the incoming signals in the input image configured on FB1. The NC-related signals are generally distributed by the basic program to the VDI interface. If required, the signals can be modified by the user.

The signals from the PLC to the MCP (displays) are transferred in the opposite direction.

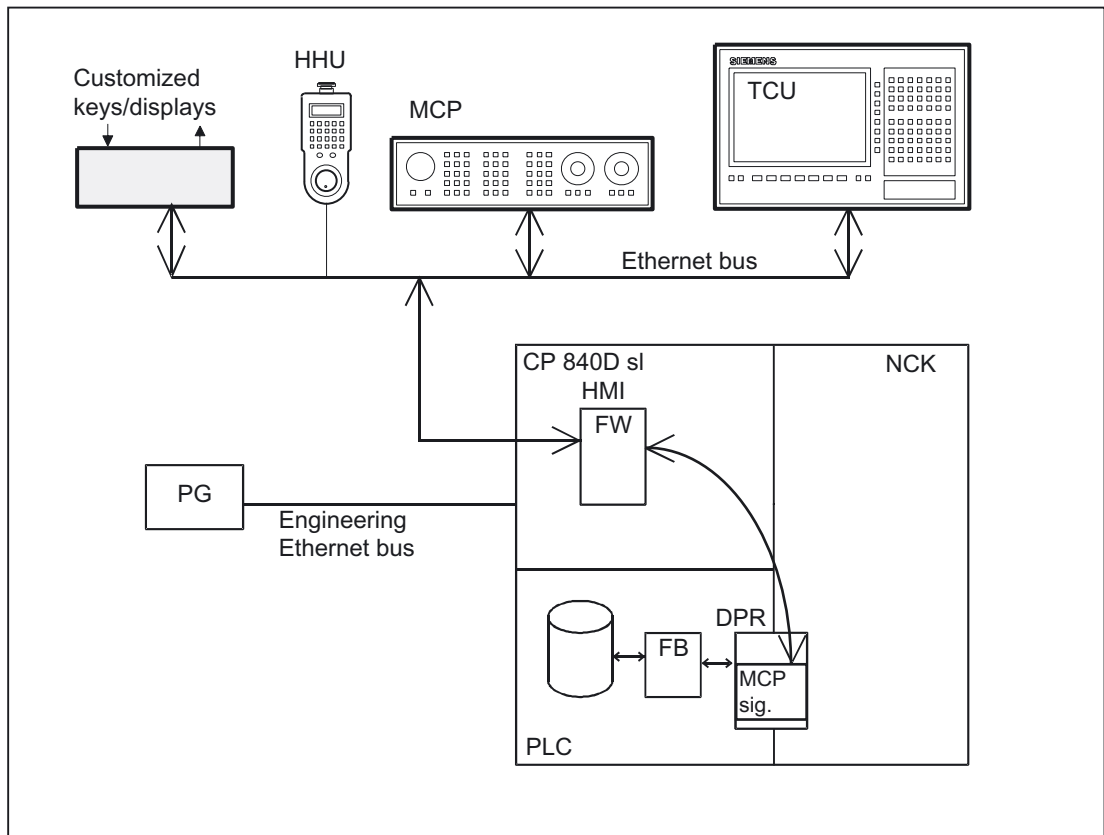

Figure 13-10 Connection of the machine control panel on 840D sl

### Topology SINUMERIK 840Di sl

In case of 840Di sl the machine control panel, the handheld unit are connected via Ethernet or PROFIBUS. The PLC operating system copies the incoming signals straight to the user interface (e.g. input image) at the cycle control point. As on the SINUMERIK 840 D sl, transfer to the VDI interface is performed by the user program or by standard blocks of the basic program (e.g. FC19).

### Bus addresses

On Ethernet components, MAC and IP addresses or logic names are determining factors in respect of communication. The control system's system programs convert logic names into MAC or IP addresses. On the PLC, the numeric component of the logic name is used for communication. This numeric part is specified by the user to the FB 1 via the parameter "MCPxBusAdr".

The logical name of an MCP or HHU always begins with "DIP". This is followed by a number corresponding to the switch position of the MCP component (e.g. DIP 192, DIP 17).

### MCP interface in the PLC

The signals from the machine control panel are routed by default via the I/O interface to the PLC area. A distinction must be made between NC and machine-specific signals. NC-specific key signals are distributed to the relevant mode-group-, NCK-, axis- and spindle-specific interface by FC19 (or FC24, FC25, FC26, depending on the type of MCP) by default. The reverse applies to the associated status signals, which are routed to the MCP interface. For this purpose, FC 19 or the other blocks mentioned above must be called in the **user program**.

Customized keys, which can be used to trigger a wide range of machine functions, must be evaluated directly by the user program. The user program also routes the status signals to the output area for the LEDs.

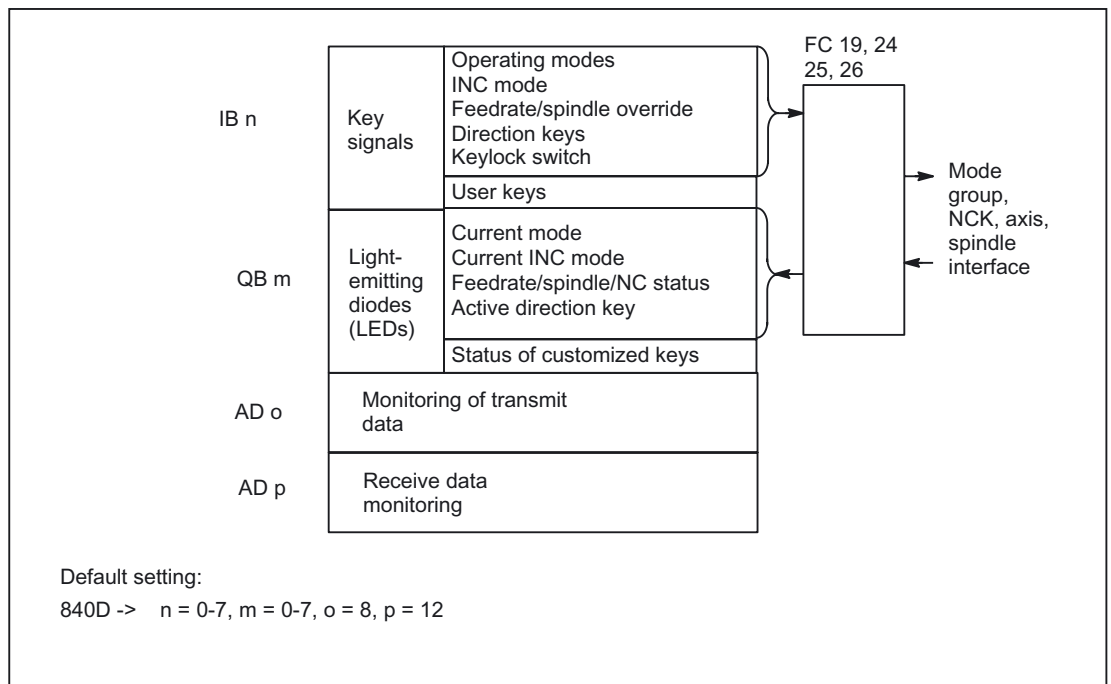

Figure 13-11 Interface to and from machine control panel

## **13.8 Structure and functions of the basic program**

### **General**

The program is modular in design, i.e. it is structured according to NCK functions.

In the operating system, a distinction is made between the following levels of execution:

- Start-up and synchronization (OB 100)
- Cyclic mode (OB 1)
- Process interrupt handling (OB 40)
- Diagnostic interrupt, module failure processing (OB 82, OB 86)

Each section of the basic program - as illustrated in the figure below - must be called by the user in OBs 1, 40 and 100.

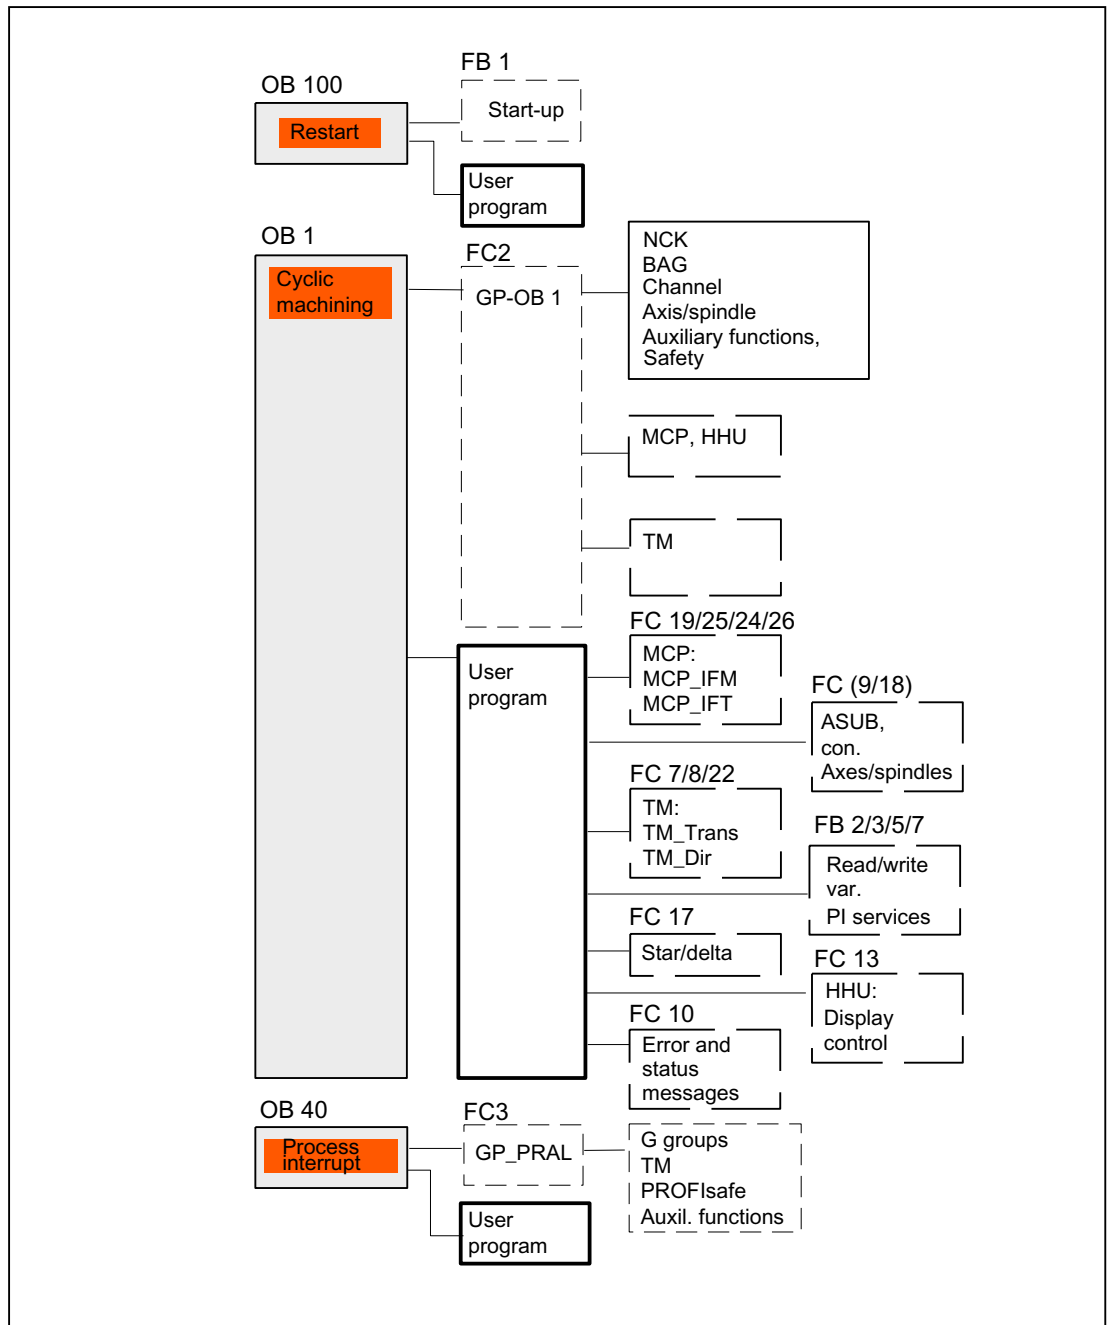

Figure 13-12 Structure of the basic program

## 13.8.1 Start-up and synchronization of NCK PLC

### Loading the basic program

The basic program must be loaded with the S7 tool when the PLC is in the Stop state. This ensures that all blocks in the basic program will be initiated correctly the next time they are called. Otherwise, undefined states can occur in the PLC (e.g. blinking of all PLC LEDs).

### Start-up

The synchronization of NCK and PLC is performed during startup. The system and user data blocks are checked for integrity and the most important basic program parameters are verified for plausibility. In cases of errors, the basic program produces an alarm (visible on HMI) and switches the PLC to the Stop state.

A warm restart is not provided, i.e. following system initialization, the operating system runs organization block OB 100 and always commences cyclic execution at the start of OB 1.

### Synchronization

The PLC is synchronized with the HMI and NCK and CP during power-up.

### Sign-of-life

After a correct initial start and the first complete OB1 cycle (initial setting cycle) the PLC and NCK continuously exchange sign of life signals. If the sign of life from the NCK fails to materialize, the PLC/NCK interface is initialized and the signal "NCK CPU ready" in DB 10 is set to FALSE.

## 13.8.2 Cyclical mode (OB 1)

### General

The NCK PLC interface is processed completely in cyclic mode. From a chronological viewpoint, the basic program runs ahead of the user program. In order to minimize the execution time of the basic program, only the control/status signals are transmitted cyclically; transfer of the auxiliary functions and G functions only takes place on request.

The following functions are performed in the cyclic part of the basic program:

- Transmission of the control/status signals
- Distribution of the auxiliary functions
- M decoding (M00 - M99),
- M, S, F distribution
- Transmission of the MCP signals via the NCK (on the SINUMERIK 840D only)
- Acquisition and conditioning of the user errors and operating messages.

## Control/Status signals

A shared feature of the control and status signals is that they are bit fields. The basic program updates them at the start of OB1.

The signals can be subdivided into the following groups:

- General signals
- Mode group-specific signals (such as mode types)
- Channel-specific signals (such as program and feed modifications)
- Axis- and spindle-specific signals (such as feed disable)

## Auxiliary and G functions

The auxiliary and G functions have the following characteristics:

- Transfer to the PLC is block-synchronous (referred to a parts program block)
- Transfer is acknowledge-driven.
- The acknowledgment times have an immediate effect on the execution time of NC blocks containing auxiliary functions requiring acknowledgment.

The value range is presented in the table below:

| Function   | Structure    |            | Range of values |                              | Data type |           |
|------------|--------------|------------|-----------------|------------------------------|-----------|-----------|
|            | 1st value    | 2nd value  | 1st value       | 2nd value                    | 1st value | 2nd value |
| G function |              | G function |                 | 255 <sup>1)</sup>            |           | Byte      |
| M word     | M group      | M word     | 99              | 99.999.999                   | Word      | DWord     |
| S word     | Spindle no.  | S word     | 6               | Floating point <sup>2)</sup> | Word      | DWord     |
| T word     | Magazine no. | T word     | 99              | 65535                        | Word      | Word      |
| D word     | -            | D word     | 99              | 255                          | Byte      | Byte      |
| H word     | H group      | H word     | 99              | Floating point               | Word      | DWord     |
| F word     | Axis No.     | F word     | 18              | Floating point               | Word      | DWord     |

<sup>1)</sup> relative number, transferred for each G group

The M, S, T, H, D and F values sent by the NCK are output together with the accompanying change signals to the **CHANNEL DB** interface via the auxiliary/G functions (see List Manual). The function value and the extended address are transferred to the appropriate data word. The accompanying modification signal is activated to 1 for one PLC cycle. When the modification signal is reset, the acknowledgment is passed to the NCK. The acknowledgment of high-speed auxiliary functions is given by the basic program immediately the basic program detects the auxiliary function.

In addition to distribution of the auxiliary and G functions, selected signals are processed as described below.

## M decoder

M functions can be used to transfer both switching commands and fixed point values. Decoded dynamic signals are output to the **CHANNEL DB** interface for standard M functions (range M00 - M99) signal length = 1 cycle time).

## G group decoders

In the case of G functions sent by the NCK, the related groups are decoded and the current G number is entered in the corresponding interface byte of the CHANNEL DB, i.e. all active G functions are entered in the channel DBs. The entered G functions are retained even after the NC program has terminated or aborted.

---

### Note

During system startup, all G group bytes are initialized with the value "0".

---

## M, S, F distributor

The M, S, F, distributor is used to enter spindle-specific M words M(1...6)=[3,4,5], S words and F words for axial feeds in the appropriate **spindle and axis data blocks**. The criterion for distribution is the extended address, which is passed to the PLC for M words, S words and axial F words.

## MCP signal transmission

On the SINUMERIK 840 D, depending on the bus connection, MCP signals are transmitted to the parameterized I/O areas either directly to the PLC or indirectly via an internal procedure using the basic program.

## User messages

The acquisition and processing of the user error and operational messages is performed by an FC in the basic program.

### 13.8.3 Time-interrupt processing (OB 35)

The user must program **OB 35** for time-alarm processing. The default time base setting of OB 35 is 100 ms. A different time base can be selected using the STEP7 "HW Config" tools. However, the OB 35 time setting must be at least 3 ms in order to avoid a PLC CPU stop. The stop is caused by reading of the HMI system state list during power-up of the HMI. This reading process blocks priority class control for approx. 2 ms. The OB 35 with a time base set to a rather lower value is then no longer processed correctly.

### 13.8.4 Process interrupt processing (OB 40)

A process interrupt **OB 40** (interrupt) can, for example, be triggered by appropriately configured I/Os or by certain NC functions. Due to the different origin of the interrupt, the PLC user program must first interpret the cause of the interrupt in OB 40. The cause of the interrupt is contained in the local data of OB 40.

**References:**

SIMATIC STEP 7 Description or Online Help of STEP 7

### 13.8.5 Diagnostic interrupt, module failure processing (OB 82, OB 86)

#### General

A module diagnosis or module failure on an I/O module triggers OB 82 / OB 86. These blocks are supplied by the basic program. The basic program block FC5 is called in these OBs. This is wired by default to trigger a PLC stop in the event of an error being detected.

A PLC Stop

- If the cause of the error is removed, a PLC stop will not be triggered.
- does not occur in case of the Profibus-MCPs specified as the FB 1 parameters.

The response can be changed by modifying the FC5 parameter setting.

#### PROFIBUS Diagnosis

The slaves of both the PROFIBUS connections MPI/DP or DP1 are registered by the basic program as group message in the form of a ready signal in the interface signal

DB10 DBX92.0 (MPI/DP Bus Slaves OK) and

DB10 DBX92.1 (DP1 Bus Slaves OK)

The group message is derived from the LED status of the respective PROFIBUS (System state list SZL 0x174).

If an error or a failure of a slave is detected, the alarm 400551 or 400552 is also reported. The alarm is automatically deleted when the error is removed. Detailed information about the error or the failure will be displayed in the alarm messages as exact cause of error in a future HMI software version in the diagnostics. No FC 125, FB 125 is necessary for this diagnostic display, because the information is called directly from the HMI via the corresponding SZL functions of the PLC operating system via the communication channels to the PLC. This saves the relatively large block in the PLC and reduces also the PLC cycle time. Since the FB 125 works under interrupt disable during its processing, OBs with a higher priority can be executed more quickly.

---

#### Note

Till the HMI software version with the diagnostic display for the PROFIBUS becomes available, it is recommended to use FC 125 for PROFIBUS diagnostics. This block has relatively less cycle time and the slave states can be updated via the DB 10 interface signal mentioned earlier by activating the FC 125 block.

---

## 13.8.6 Response to NCK failure

### General

During cyclic operation, the PLC basic program continuously monitors NCK availability by polling the sign-of-life character. If the NCK is no longer reacting, the NCK PLC interface is initialized, and the **NCK CPU ready** signal in the area of the **signals from NC (DB 10.DBX 104.7)** is reset. Furthermore, the signals sent from the NCK to the PLC and vice versa are set to an initial state.

The PLC itself remains active so that it can continue to control machine functions. However, it remains the responsibility of the user program to set the machine to a safe state.

### NCK → PLC signals

The signals sent by the NCK to the PLC are divided into the following groups:

- Status signals from the NCK, channels, axes and spindles
- Modification signals of the auxiliary functions
- Values of the auxiliary functions
- Values of the G functions

#### Status signals:

The status signals from the NCK, channels, axes, and spindles are reset.

#### Auxiliary-function modification signals:

Auxiliary-function modification signals are also reset.

#### Auxiliary-function values:

Auxiliary-function values are retained so that it is possible to trace the last functions triggered by the NCK.

**G-function values:**

G function values are reset (i.e. initialized with the value 0 respectively).

**PLC → NCK signals**

The signals sent by the PLC to the NCK are divided into control signals and tasks that are transferred by FCs to the NCK.

**Control signals:**

The control signals from the PLC to the NCK are frozen; cyclic updating by the basic program is suspended.

**Jobs from PLC to NCK:**

The FCs and FBs, which are used to pass jobs to the NCK, must no longer be processed by the PLC user program, as this could lead to incorrect checkback signals. During power-up of the control, a job (e.g. read NCK data) must not be activated in the user program until the **NCK CPU ready** signal is set.

## 13.8.7 Functions of the basic program called from the user program

### General

In addition to the modules of the basic program, which are called at the start of OBs 1, 40 and 100, functions are also provided, which have to be called and supplied with parameters at a suitable point in the user program.

These functions can be used, for example, to pass the following jobs from the PLC to the NCK:

- Traversing concurrent axes (FC 18)
- Start asynchronous subprograms (ASUBs) (FC 9),
- Selecting NC programs (FB 4)

- Control of spindle (FC 18),
- Read/write variables (FB 2, FB 3).

**Note**

The following note will later help you to check and diagnose a function call (FCs, FBs of basic program). These are FCs and FBs, which are controlled by a trigger signal (e.g. via parameter Req, Start, etc.), and which supply an execution acknowledgment as an output parameter (e.g. via parameter Done, NDR, Error, etc.). A variable compiled of other signals, which produce the trigger for the function call should be set. Start conditions may be reset only as a function of the states of parameters Done, NDR and Error. This control mechanism may be positioned in front of or behind the function call. If the mechanism is placed after the call, the output variables can be defined as local variables (advantage: Reduction of global variables, flags, data variables and time-related advantages over data variables). The trigger parameter must be a global variable (e.g. flag, data variable). In OB 100, jobs still activated by the user program (Parameter Req, Start, etc.:= TRUE) must be set to zero at the named parameters. A POWER OFF/ON could result in a state in which jobs are still active.

**Concurrent axes**

The distinguishing features of concurrent axes are as follows:

- They must be defined as such via the NC machine data.
- They can be traversed either from the PLC or from the NC by means of the JOG keys,
- Starting from the PLC is possible in the NC operating modes MDA and AUTOMATIC via FC.
- The start is independent of NC block boundaries.

Function calls are available for positioning axes, indexing axes and spindles (FC 18).

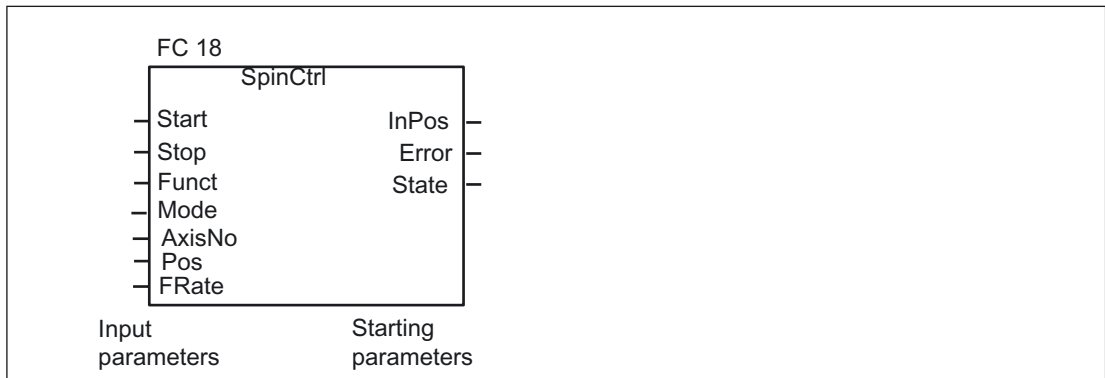

Figure 13-13 FC 18 input/output parameters

## ASUBs

Asynchronous subprograms (ASUBs) can be used to activate any function in the NCK. Before an asynchronous subprogram can be started from the PLC, it must be ensured that it is available and prepared by the NC program or by FB 4 PI services (ASUB).

Once prepared in this way, it can be started at any time from the PLC. The NC program running in one of the parameterized channels of FC 9 is interrupted by the asynchronous subprogram. An ASUB is started by calling FC 9 from the user program by setting the start parameter to 1.

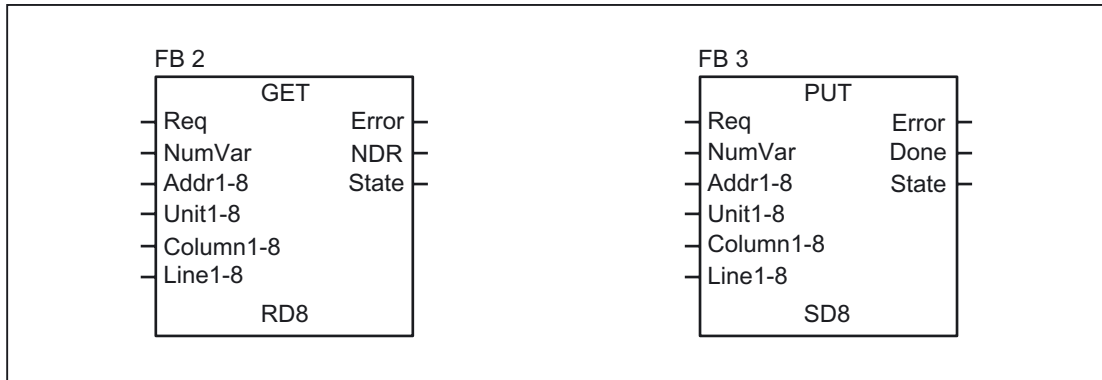

### Note

If an asynchronous subprogram has not been prepared by an NC program or by FB 4 (ASUB) (e.g. if no interrupt no. has been assigned), a start error is output (StartErr = TRUE).

## Read/Write NC variables

NCK variables can be read with FB GET while values can be entered in NCK variables with FB PUT. The NCK variables are addressed via identifiers at inputs Addr1 to Addr8. The identifiers (symbols) point to address data, which must be stored in a global DB. To allow generation of this DB, PC software is supplied with the basic program with which the required variables can be selected from a table, which is also supplied. The selected variables are first collected in a second, project-related list. Command **Generate DB** creates a ".AWL" file, which must be linked to the program file for the machine concerned and compiled together with the machine program.

1 to 8 values can be read or written with a read or write job. If necessary, the values are converted [e.g. NCK floating point values (64 bits) are converted to PLC format (32 bits with 24-bit mantissa and 8-bit exponent) and vice versa]. A loss of accuracy results from the conversion from 64-bit to 32-bit REAL. The maximum precision of 32-bit REAL numbers is approximately 10 to the power of 7.

**Functions AG\_SEND, AG\_RECV**

The named functions correspond to the functions of the library "SIMATIC\_NET\_CP" of the S7-300 CPU in STEP 7. In general, these functions are valid for the online help of these functions. The functions AG\_SEND, AG\_RECV can be used for data exchange with another station via the integrated "CP 840D sl".

There are a total of 5 functions for the "AG Functions"

1. AG\_SEND (SINUMERIK 840D sl)
2. AG\_RECV (SINUMERIK 840D sl)
3. AG\_LOCK (currently not implemented)
4. AG\_UNLOCK (currently not implemented)
5. AG\_CNTRL (currently not implemented)

The 3 functions mentioned last are currently not available for SINUMERIK 840D.

**Note**

For the function AG\_SEND the signal sequence for the parameter ACT is currently displayed wrongly. ACT must be TRUE as long as an event is reported in DONE or ERROR.

When using the functions AG\_SEND, AG\_RECV a data transport to the other point takes place via the Ethernet Bus of the CP. The other point is configured normally in STEP 7 in NetPro. The special feature in the call of the functions lies in the specification of the parameter "LADDR" to the named blocks.

In case of SINUMERIK 840D sl the parameter "LADDR" must be filled with the value W#16#8110. In the basic program, these functions are available under the FC numbers 1005, 1006, 1007, 1008, 1010.

Table 13- 2 Allocation of the FC numbers to the corresponding FC in the library "SIMATIC\_NET\_CP"

| FC number | FC Blocks |
|-----------|-----------|
| 1005      | FC 5      |
| 1006      | FC 6      |
| 1007      | FC 7      |

| FC number | FC Blocks |
|-----------|-----------|
| 1008      | FC 8      |
| 1010      | FC 10     |

These blocks can also be used in a SIMATIC-CPU 3xx with CP343-1.

The protocols TCP and UDP are supported. TCP is to be preferred.

**Note**

Other communication blocks, such as BSEND, USEND, which possess a CP343-1, are not supported in SINUMERIK 840D sl.

## 13.8.8 Symbolic programming of user program with interface DB

### General

**Note**

The basic program library on the CD supplied with the Toolbox for the 840D contains files NST\_UDTB.AWL and TM\_UDTB.AWL.

The compiled UDT blocks from these two files are stored in the CPU program of the basic program.

A UDT is a data type defined by the user that can, for example, be assigned to a data block generated in the CPU.

Symbolic names of virtually all the interface signals are defined in these UDT blocks.

The UDT numbers 2, 10, 11, 19, 21, 31, 71, 72, 73 are used.

The assignments have been made as follows:

| UDT assignments |                            |                                                                |
|-----------------|----------------------------|----------------------------------------------------------------|
| UDT number      | Assignment to interface DB | Significance                                                   |
| UDT 2           | DB 2                       | Interrupts/Messages                                            |
| UDT 10          | DB 10                      | NCK signals                                                    |
| UDT 11          | DB 11                      | Mode group signals                                             |
| UDT 19          | DB 19                      | HMI signals                                                    |
| UDT 21          | DB 21 to DB 30             | Channel signal                                                 |
| UDT 31          | DB 31 to DB 61             | Axis/spindle signals                                           |
| UDT 71          | DB71                       | Tool management: Load/unload locations                         |
| UDT 72          | DB 72                      | Tool management: Change in spindle                             |
| UDT 73          | DB 73                      | Tool management: Change in revolver                            |
| UDT 77          | DB 77                      | MCP and HHU signals with standard SDB 210                      |
| UDT 1002        | DB 2                       | Extended alarms / messages (FB 1-Parameter "ExtendAIMsg:=TRUE" |

To symbolically program the interface signals, the interface data blocks must first be symbolically assigned using the symbol editor.

For example, symbol "AxisX" is assigned to operand DB31 with data type UDT 31 in the symbol file.

After this input, the STEP 7 program can be programmed in symbols for this interface.

---

**Note**

Programs generated with an earlier software version that utilize the interface DBs described above can also be converted into symbol programs. A fully qualified instruction for data access e.g. "U DB31.DBX60.0" is then necessary here for (spindle/ no axis) in the program created till now. This command is converted upon activation of the symbolics in the editor "AxisX.E\_SpKA".

---

## Description

Abbreviated symbolic names of the interface signals are defined in the two STL files NST\_UDTB.AWL and TM\_UDTB.AWL.

In order to create the reference to the names of the interface signals, the name is included in the comment after each signal.

The names are based on the English language. The comments are in English.

The symbolic names, commands and absolute addresses can be viewed by means of a STEP 7 editor command when the UDT block is opened.

---

**Note**

Unused bits and bytes are listed, for example, with the designation "f56\_3".

- "56": Byte address of the relevant data block
  - "3": Bit number in this byte
-

## 13.8.9 M decoding acc. to list

### Description of functions

When the **M decoding according to list** function is activated via the GP parameter of FB1 "ListMDecGrp" (number of M groups for decoding), up to 256 M functions with extended address can be decoded by the basic program.

The assignment of the M function with extended address and the bit to be set in the signal list is defined in the decoding list. The signals are grouped for this purpose.

The signal list contains 16 groups with 16 bits each as decoded signals.

There is only one decoding list and one signal list i.e. this is a cross-channel function.

The M functions are decoded. Once they are entered in the decoding list, then the associated bit in the signal list is set.

When the bit is set in the signal list, the read-in disable in the associated NCK channel is set simultaneously by the basic program.

The read-in disable in the channel is reset once the user has reset all the bits output by this channel and thus acknowledged them.

The output of an M function decoded in the list as a high-speed auxiliary function does not result in a read-in disable.

The figure below shows the structure of the **M decoding according to list**:

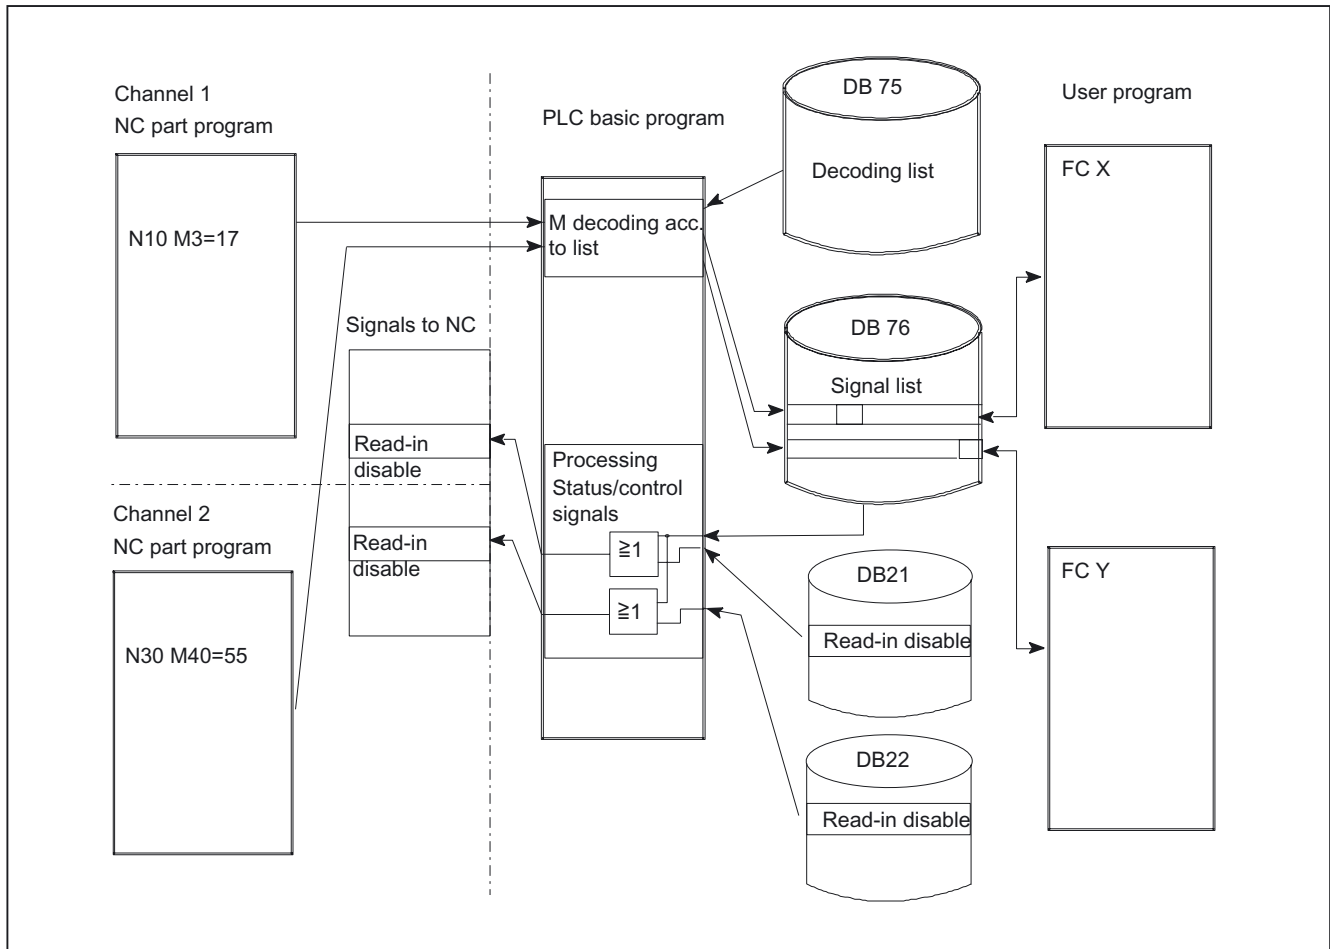

Figure 13-14 M decoding acc. to list

### Activation of the function

The number of groups to be evaluated / decoded is indicated in the basic program parameter "ListMDecGrp" when FB 1 is called in OB 100 (see also "FB 1: RUN\_UP Basic program, start-up section (Page 946)"). M decoding is activated if this value is between 1 and 16. Before the function is activated, the decoding list DB75 must be transferred to the PLC followed by a restart.

### Structure of decoding list

The source file for the decoding list (MDECLIST.AWL) is supplied with the basic program. DB 75 is created when the STL source is compiled.

There must be an entry in decoding list DB 75 for every group of M functions to be decoded.

A maximum of 16 groups can be created.

16 bits are available in each group in the list of decoded signals.

The assignment between the M function with extended DB address and the bit to be set in the signal list is specified via the first and last M functions in the decoding list.

The bit address is generated correspondingly from the first M function ("MFirstAdr") to the last M function ("MLastAdr") from bit 0 up to maximum bit 15 for each group.

Each entry in the decoding lists consists of 3 parameters, each of which is assigned to a group.

| Assignment of groups |                     |                          |                         |
|----------------------|---------------------|--------------------------|-------------------------|
| Group                | Extended M address  | First M address in group | Last M address in group |
| 1                    | MSigGrp[1].MExtAdr  | MSigGrp[1].MFirstAdr     | MSigGrp[1].MLastAdr     |
| 2                    | MSigGrp[2].MExtAdr  | MSigGrp[2].MFirstAdr     | MSigGrp[2].MLastAdr     |
| ...                  | ...                 | ...                      | ...                     |
| 16                   | MSigGrp[16].MExtAdr | MSigGrp[16].MFirstAdr    | MSigGrp[16].MLastAdr    |

| Type and value range for signals |      |                 |                          |
|----------------------------------|------|-----------------|--------------------------|
| Signal                           | Type | Value range     | Remark                   |
| MExtAdr                          | Int  | 0 ... 99        | Extended M address       |
| MFirstAdr                        | DInt | 0 to 99.999.999 | First M address in group |
| MLastAdr                         | Dint | 0 to 99.999.999 | Last M address in group  |

## Signal list

Data block DB 76 is set up when the function is activated.

A bit is set in the appropriate group in DB 76 for an M signal decoded in the list.

At the same time, a read-in disable is set in the channel in which the M function has been output.

## Example

Three groups of M commands are to be decoded in the following example:

- M2 = 1 to M2 = 5
- M3 = 12 to M3 = 23
- M40 = 55

Structure of the decoding list in DB 75:

| Example parameters |                       |                          |                         |                     |
|--------------------|-----------------------|--------------------------|-------------------------|---------------------|
| Group              | Decoding list (DB 75) |                          |                         | Signal list         |
|                    | Extended M address    | First M address in group | Last M address in group | DB 76               |
| 1                  | 2                     | 1                        | 5                       | DBX 0.0 ... DBX 0.4 |
| 2                  | 3                     | 12                       | 23                      | DBX 2.0 ... DBX 3.3 |
| 3                  | 40                    | 55                       | 55                      | DBX 4.0             |

```
DATA_BLOCK DB 75
TITLE =
VERSION : 0.0

```

### Structure of FB 1 in the OB 100

(enter the number of M groups to be decoded in order to activate the function):

```
Call FB 1, DB 7(
...
ListMDecGrp := 3, //M decoding of three groups
...
);
```

The appending of the entry in OB 100 and transfer of DB 75 (decoding list) to the AG must be followed by a restart. During the restart, the basic program sets up DB76 (signal list).

If the NC program is started at this point and the expanded M function (e.g. M3=17) is processed by the NCK, this M function will be decoded and bit 2.5 set in DB 76 (see decoding list DB 75). At the same time, the basic program sets the read-in disable and the processing of the NC program is halted (in the corresponding NC-channel DB the entry "expanded address M function" and "M function no." is made).

The read-in disable in the channel is reset once the user has reset and, therefore, acknowledged, all the bits output by this channel in the signal list (DB 76).

## 13.8.10 PLC machine data

### General

The user has the option of storing PLC-specific machine data in the NCK. The user can then process these machine data after the power-up of the PLC (OB 100). This enables, for example, user options, machine expansion levels, machine configurations, etc., to be implemented.

The interface for reading these data lies in the DB 20. However, DB20 is set up by the basic program during power-up only when user machine data are used i.e. sum of GP parameters "UDInt", "UDHex" and "UDReal" is greater than zero.

The sizes of the individual areas, and hence the total length of the DB 20, is set by the following PLC machine data:

MD14504 \$MN\_MAXNUM\_USER\_DATA\_INT

MD14506 \$MN\_MAXNUM\_USER\_DATA\_HEX

MD14508 \$MN\_MAXNUM\_USER\_DATA\_FLOAT

These settings are specified to the user in the GP parameters "UDInt", "UDHex" and "UDReal".

The data is stored in the DB 20 by the BP in the sequence:

1. Integer MD
2. Hexa-fields MD
3. Real MD

The integer and real values are stored in DB 20 in S7 format.

Hexadecimal data are stored in DB20 in the order in which they are input (use as bit fields).

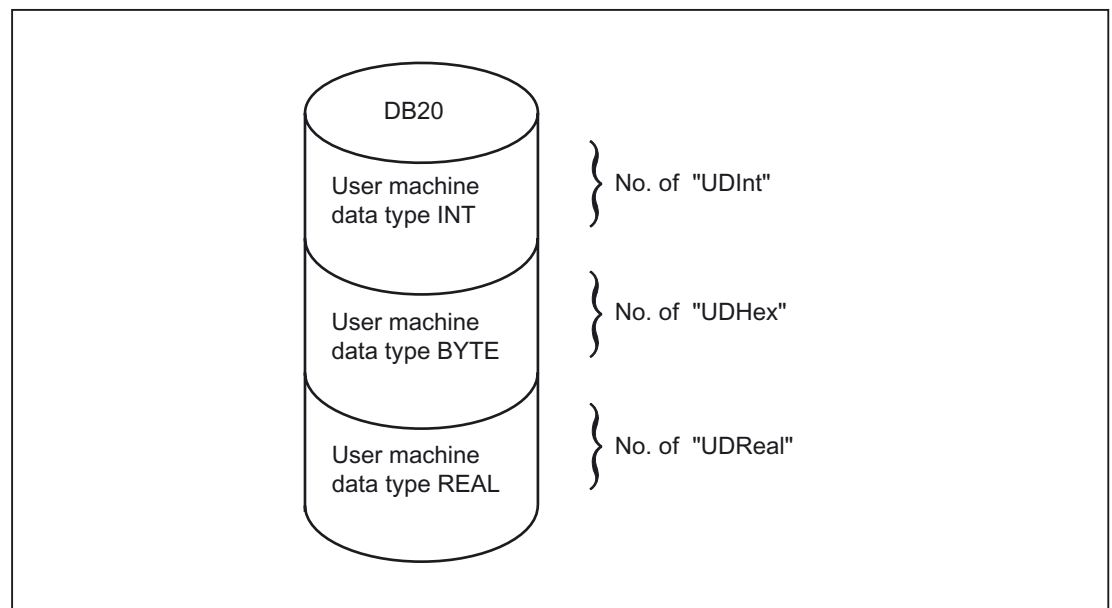

Figure 13-15 DB 20

**Note**

If the number of PLC machine data used is increased later, then DB20 must be deleted beforehand. To prevent such extensions in use having any effect on the existing user program, the data in DB20 should be accessed in symbolic form wherever possible, e.g. by means of a structure definition in the UDT.

| Interrupts                 |                                                     |
|----------------------------|-----------------------------------------------------|
| <b>400120</b>              | <b>Delete DB 20 in PLC and restart</b>              |
| Explanation                | DB length is not the same as the required DB length |
| Response                   | Interrupt display and PLC Stop                      |
| To correct or avoid errors | Delete DB 20 followed by RESET                      |
| Continuation               | After cold restart                                  |

**Example**

The project in the example requires 4 integer values, 2 hexadecimal fields with bit information and 1 real value.

Machine data:

```

MD14510 $MN_USER_DATA_INT[0] 123
MD14510 $MN_USER_DATA_INT[1] 456
MD14510 $MN_USER_DATA_INT[2] 789
MD14510 $MN_USER_DATA_INT[3] 1011
...
MD14512 $MN_USER_DATA_HEX[0] 12
MD14512 $MN_USER_DATA_HEX[1] AC
...
MD14514 $MN_USER_DATA_FLOAT[0] 123.456

```

GP Parameter (OB 100):

```

CALL FB 1, DB 7 (
 MCPNum := 1,
 MCP1In := P#E0.0,
 MCP1Out := P#A0.0,
 MCP1StatSend := P#A8.0,
 MCP1StatRec := P#A12.0,
 MCP1BusAdr := 6,
 MCP1Timeout := S5T#700MS,
 MCP1Cycl := S5T#200MS,
 NCCyclTimeout := S5T#200MS,
 NCRunupTimeout := S5T#50S;

```

BP parameters (to scan runtime):

```

1 gp_par.UDInt; //4,
1 gp_par.UDHex; //2,
1 gp_par.UDReal; //1)

```

During PLC power-up, DB20 was generated with a length of 28 bytes:

| DB 20   |              |
|---------|--------------|
| address | data         |
| 0.0     | 123          |
| 2.0     | 456          |
| 4.0     | 789          |
| 6.0     | 1011         |
| 8.0     | b#16#12      |
| 9.0     | b#16#AC      |
| 10.0    | 1.234560e+02 |

The structure of the machine data used is specified in a UDT:

```

TYPE UDT 20
 STRUCT
 UDInt : ARRAY [0 .. 3] OF INT ;
 UDHex0 : ARRAY [0 .. 15] OF BOOL ;
 UDReal : ARRAY [0 .. 0] OF REAL ; //Description as field, for
 //later expansions
 END_STRUCT;
END_TYPE

```

**Note**

ARRAY OF BOOL are always sent to even-numbered addresses. For this reason, an array range of 0 to 15 must generally be selected in the UDT definition or all Boolean variables specified individually.

Although only a REAL value is used initially in the example, a field (with one element) has been created for the variable. This ensures that extensions can be made easily in the future without the symbolic address being modified.

**Symbolic accesses**

An entry is made in the symbol table to allow data access in symbolic form:

| Symbol | Operand | Data type |
|--------|---------|-----------|
| UData  | DB 20   | UDT 20    |

Access operations in user program (list includes only symbolic read access):

```
...
L "UData".UDInt[0];
L "UData".UDInt[1];
L "UData".UDInt[2];
L "UData".UDInt[3];

U "UData".UDHex0[0];
U "UData".UDHex0[1];
U "UData".UDHex0[2];
U "UData".UDHex0[3];
U "UData".UDHex0[4];
U "UData".UDHex0[5];
U "UData".UDHex0[6];
U "UData".UDHex0[7];
... ...
U "UData".UDHex0[15];

L "UData".UDReal[0];
...
```

### 13.8.11 Configuration machine control panel, handheld unit, direct keys

#### General

Up to two machine control panels and one handheld unit can be in operation at the same time. For the machine control panel or HT8 (MCP) and hand-held unit HT2, HT1 (BHG) there are various connection options (Ethernet, PROFIBUS). It is possible to connect two MCPs to different bus systems (mixed operation is only possible on Ethernet and PROFIBUS). This can be achieved using FB1 parameter "MCPBusType". In this parameter, the right-hand decade is responsible for the first MCP and the left-hand decade for the second MCP.

The components are parameterized by calling basic-program block FB 1 in OB 100. FB 1 stores its parameters in the associated instance DB (DB 7, symbolic name "gp\_par"). Separate parameter sets are provided for each machine control panel and the handheld unit. The input/output addresses of the user must be defined in these parameter sets. These input and output addresses are also used in FC 19, FC 24, FC 25, FC 26 and FC 13. Further, the addresses for status information, Profibus or Ethernet are also to be defined. The default time settings for timeout and cyclic forced retriggering should not be changed. Please refer to the Operator Components Manual for further information on MCPs and HHU (HT2) components.

## Activation

Each component is activated either via the number of machine control panels (MCPNum parameter) or, in the case of the handheld unit, via the HHU parameter. The MCP and HHU connection settings are entered in FB1 parameters "MCPMPi", "MCPBusType" or "BHG", "BHGMPi".

## Handheld unit (HT2)

In the handheld unit the addressing is done via a parameter of the GD parameter set. This was necessary for reasons of compatibility of the parameter names.

## Configuration

Essentially, there are various communication mechanisms for transferring data between the MCP/HHU and PLC. These mechanisms are characterized by the bus connection of the MCP and HHU. In one case (Ethernet), data is transported via the "CP 840D sl".

The mechanism is parameterized completely via the MCP/HHU parameters in FB1.

In the other case the transmission is done through the PLC-operating system through the Profibus configuration

The parameter setting is done via STEP 7 in HW-Config. To enable the basic program to access these data and failure monitoring of MCP/HHU, the addresses set in FB 1-parameters must be made available to the basic program.

An overview of the various coupling mechanisms appears below. Mixed operation can also be configured.

If an error is detected due to a timeout monitor, an entry is made in the alarm buffer of the PLC CPU (interrupts 400260 to 400262). In this case, the input signals from the MCP or from the handheld unit (MCP1In/MCP2In or BHGIn) are reset to 0. If it is possible to resynchronize the PLC and MCP/HHU, communication is resumed automatically and the error message reset by the GP.

---

### Note

In the following tables, "(n.r.)" indicates "not relevant".

---

## 840D sl: Ethernet connection

Without further configuration settings being made, communication takes place directly from the PLC GP via the CP 840D sl. The FB 1 parameters listed below are used for parameterization.

The numeric part of the logical name of the component must be entered in "MCP1 BusAdr", "MCP2 BusAdr" or "BHGRecGDNo" (corresponds to the bus address of node). The logical name is defined via switches on the MCP or terminal box.

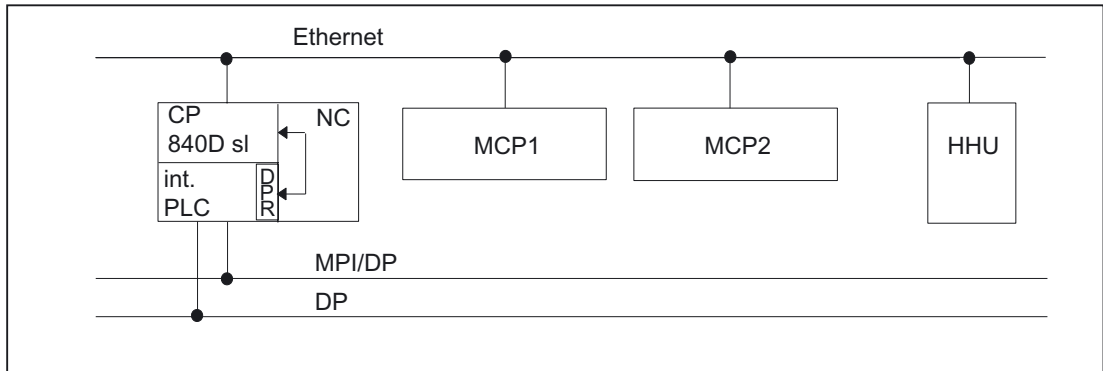

Figure 13-16 840D sl: Ethernet connection

| Relevant parameters (FB 1)            |                    |                          |
|---------------------------------------|--------------------|--------------------------|
| MCP                                   |                    | HHU                      |

|                                       |                    | BHGSendGBZNo (n.r.)      |
| MCPsDB210= FALSE                      |                    | BHGSendObjNo (n.r.)      |
| MCPCopyDB77 = FALSE                   |                    | <b>BHGMPI = FALSE</b>    |
|                                       |                    | BHGStop                  |
|                                       |                    | BHG NotSend              |

An error entry is also made in the PLC alarm buffer for timeouts. As a result, the following error messages are output at the HMI:

- 400260: MCP 1 failure
- or
- 400261: MCP 2 failure
- 400262: HHU failure

An MCP or HHU failure is detected immediately after a cold restart even if no data have yet been exchanged between the MCP/HHU and PLC.

The monitoring function is activated as soon as all components have signaled "Ready" after power-up.

### Example OPs: Direct control key

The direct control keys of the OPs at the Ethernet Bus should be transferred to the PLC. Till now, the direct control keys have been transferred to the PLC via the PROFIBUS or via a special cable connection between OP and MCP.

For connecting the direct control keys via the Ethernet, this concerns e.g. the "OP08T", there is a parameterization in the basic program for activating the data transport. The related parameters lie in the instance DB of the FB 1 (OpKeyNum to OpKeyBusType, see data table). The parameters are provided by the user in the start OB 100 through the switching of the parameter at the FB 1 call. The bus address and Op1/2KeyStop can also be modified in the cyclic operation by writing the FB 1-Instance-DB DB 7.

The transport of the user data of the direct control keys runs in the same way as in the case of Ethernet MCP. The data transport can also be stopped and restarted via writing the DB 7-parameter "Op1/2KeyStop". During the Stop-phase the address of the direct control key module (TCU-index or the MCP-address) can also be changed.

After resetting the Stop-signal a connection to the new address is established.

The status of the respective direct-key interfaces can be read in the interface signal:

DB10.DBX104.3 (OP1Key ready)

or

DB10.DBX104.4 (OP2Key ready)

#### Address direct control keys

For the parameter Op1/2KeyBusAdr the TCU-index is normally to be used. This affects the OPs, such as OP08T, OP12T, which for the direct control keys **do not** have special cable connection to an Ethernet MCP.

If OPs with direct control keys have a special cable connection and these are connected to an Ethernet-MCP, then for the parameter Op1/2KeyBusAdr the address of the MCP (DIP-switch setting of the MCP) is to be used. Only the data stream of the direct control keys (2 bytes) is transferred via the direct control key interface.

#### Alarm direct control keys

An error entry is also made in the PLC alarm buffer for timeouts. As a result, the following error messages are output at the HMI:

- 400274: Direct control key 1 failed
- or
- 400275: Direct control key 2 failed

#### Control unit switching for direct control keys

The user switches Op1/2KeyBusAdr with 0xFF and Stop = TRUE in the startup block OB 100. Via the M to N block FB 9 the direct control key address of the M to N-interface is stored to the parameter "Op1KeyBusAdr".

| Relevant parameters (FB 1)                          |           |                        |

| Op1KeyStop                              | Op2KeyStop    |                        |
| Op1KeyNotSend                           | Op2KeyNotSend |                        |
| OpKeyBusType = b#16#55 (via CP 840D sl) |               |                        |
|                                         |               |                        |

### MCP identification

Via the Identify interface in the DB 7 it is possible to query the type of the Ethernet component (MCP, HT2, HT8 or direct keys) with the relevant parameters at the input/output in cyclic operation:

- Relevant parameters at the input:  
 "IdentMcpBusAdr", "IdentMcpProfilNo", "IdentMcpBusType", "IdentMcpStrobe"
- Relevant parameters at the output:  
 "IdentMcpType", "IdentMcpLengthIn", "IdentMcpLengthOut",

Here the DIP device address or the TCU index at the parameter "IdentMcpBusAdr" is activated by the user program together with setting of the Strobe signal.

The input parameter "IdentMcpProfilNo" is normally to be set to the value 0. This parameter is to be set to the value 1 only in the identification of the direct control keys. The parameter "IdentMcpBusType" currently has no significance for a user program and is to be left in its default value.

After resetting the Strobe signal by the basic program, valid output information becomes available to the user. The resetting of the Strobe signals by the basic program can last for several PLC cycles (up to 2 seconds).

The output parameters should show the user the size of the data areas for the addressed device. Furthermore, it can be defined here, whether an HT2 or an HT8 or no device is connected to the connection box. With this information the MCP channel or the HHU-channel can be activated. In the cyclic operation the parameters can be written symbolically by the user program and read via the symbol names of the DB 7 (gp\_par).

| Relevant parameters (FB 1) |                   |                                 |

|                                           |                             |

#### 840D sl: PROFIBUS connection on the DP port

In case of PROFIBUS connection of the MCP, this component must be considered in the hardware configuration setting of STEP 7. The MCP is connected to the standard DP bus of the PLC (**not to MPI/DP**). The addresses must be stored in the input and output log range. These start addresses must also be stored in the pointer parameters of the FB1. The FB1 parameters listed below are used for further parameterization.

There is no PROFIBUS variant of the HHU. For this reason, an Ethernet connection is shown for the HHU in this figure. The Profibus slave address must be stored in the parameter "MCP1BusAdr" and "MCP2BusAdr". Enter the pointer to the configured diagnostic address (e.g. P#A8190.0) in "MCPxStatRec".

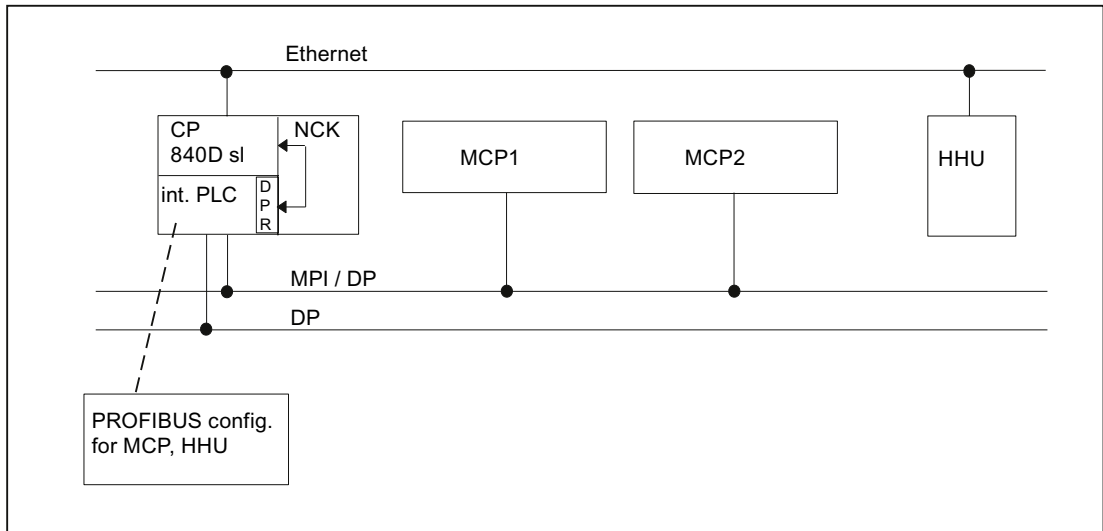

Figure 13-17 840D sl: PROFIBUS connection

| Relevant parameters (FB 1)       |                     |                          |
|----------------------------------|---------------------|--------------------------|
| MCP                              |                     | HHU                      |

| MCP1BusAdr                       | MCP2BusAdr          | BHGInLen                 |
| MCP1Timeout                      | MCP2Timeout         | BHGOutLen                |
| MCP1Cycl (n.r.)                  | MCP2Cycl            | BHGTimeout (n.r.)        |
| <b>MCPMPI = FALSE</b>            |                     | BHGCycl (n.r.)           |
| MCP1Stop                         | MCP2Stop            | BHGRecGDNo               |
| <b>MCPBusType = b#16#33</b>      |                     | BHGRecGBZNo (n.r.)       |
|                                  |                     | BHGRecObjNo (n.r.)       |
| MCPsDB210 = FALSE                |                     | BHGSendGDNo (n.r.)       |
| MCPCopyDB77 = FALSE              |                     | BHGSendGBZNo (n.r.)      |
|                                  |                     | BHGSendObjNo (n.r.)      |
|                                  |                     | <b>BHGMPI = FALSE</b>    |
|                                  |                     | BHGStop                  |

MCP failure normally switches the PLC to the STOP state. If this is undesirable, OB 82, OB 86 can be used to avoid a stop. The basic program has, as standard, the OB 82 and OB 86 call. FC5 is called in these OBs. This FC5 checks whether the failed slave is an MCP. If this is the case, no PLC stop is triggered. Setting "MCPxStop" := TRUE causes the basic program to deactivate the MCP as a slave via SFC 12. If the PLC does not switch to the stop state following the failure of or a fault on the MCP, an alarm message will be generated via the basic program. The interrupt is deleted when the station recovers.

### 840D sl: PROFIBUS connection on the MPI/DP port

With the PROFIBUS connection of the MCP, this component must be considered in the STEP 7 hardware configuration. The MCP is connected on the MPI/DP bus of the PLC.

The addresses must be stored in the input and output log range. These start addresses must also be stored in the pointer parameters of the FB1. The FB1 parameters listed below are used for further parameter assignment. There is no PROFIBUS variant of the HHU. For this reason, an Ethernet connection is shown for the HHU in this diagram. The PROFIBUS slave address must be stored in the MCP1BusAdr and MCP2BusAdr. Enter the pointer to the configured diagnostic address (e.g. P#A8190.0) in MCPxStatRec.

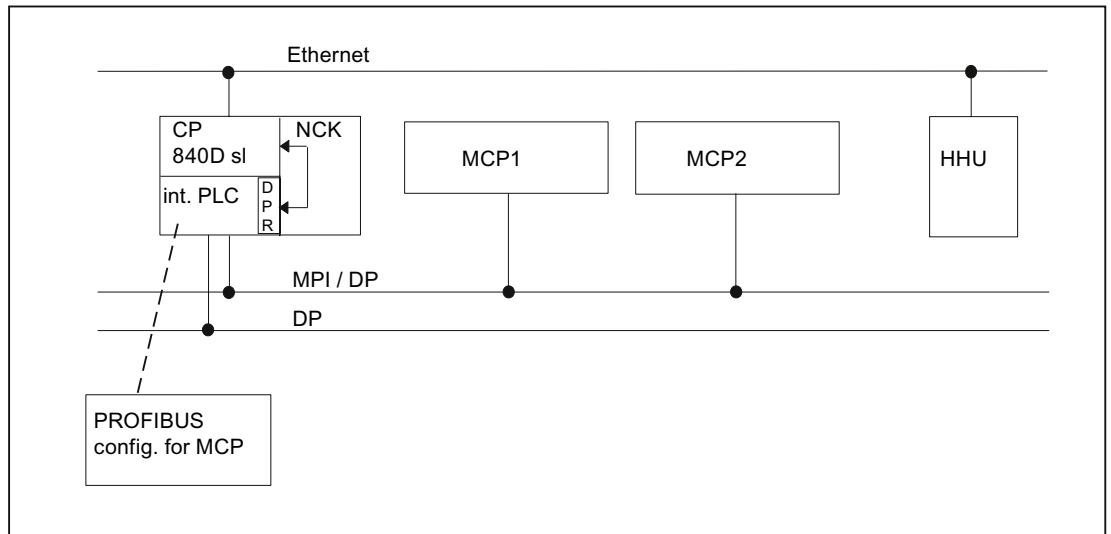

Figure 13-18 840D sl: PROFIBUS connection on the MPI/DP port

| Relevant parameters (FB1)        |                     |                          |
|----------------------------------|---------------------|--------------------------|

| MCP1Stop                         | MCP2Stop            | BHGRecGDNo               |
| <b>MCPBusType = b#16#44</b>      |                     | BHGRecGBZNo (n.r.)       |
|                                  |                     | BHGRecObjNo (n.r.)       |
| MCPsDB210= FALSE                 |                     | BHGSendGDNo (n.r.)       |
| MCPCopyDB77 = FALSE              |                     | BHGSendGBZNo (n.r.)      |
|                                  |                     | BHGSendObjNo (n.r.)      |

| Relevant parameters (FB1) |                |
|---------------------------|----------------|
| MCP                       | HHU            |
|                           | BHGMPI = FALSE |
|                           | BHGStop        |

MCP failure normally switches the PLC to the STOP state. If this is unwanted, OB 82, OB 86 can be used to avoid a PLC stop. The basic program has, as standard, the OB 82 and OB 86 call. FC5 is called in these OBs. This FC5 checks whether the failed slave is an MCP. If this is the case, no PLC stop is triggered. Setting MCPxStop := True causes the basic program to deactivate the MCP as a slave via SFC 12. If the PLC does not switch to the stop state following the failure of or a fault on the MCP, an alarm message will be generated via the basic program. The alarm is deleted when the station returns.

### 840D sl: PROFINET connection

In case of a PROFINET connection of the MCP, this component must be parameterized in the hardware configuration of STEP 7. The MCP is coupled with the PROFINET module of the CPU.

When parameterizing the MCP in HW Config, the addresses should be placed in the input and output mapping area. These start addresses must also be stored in the pointer parameters (MCPxIn and MCPxOut) of FB1. This is because signals are transferred between the MCP and basic program via these parameters. The MCP is also monitored using parameter MCPxIn. This is the reason that parameter MCPxBusAdr is not relevant for this MCP version.

Enter the pointer to the configured diagnostic address (e.g. P#A8190.0) in MCPxStatRec.

The PROFINET-MCP has its own type, which should be applied for parameter MCPBusType.

The FB1 parameters listed below are used for further parameter assignment. There is no Profibus variant of the HHU. An Ethernet port for the HHU is shown in the diagram.

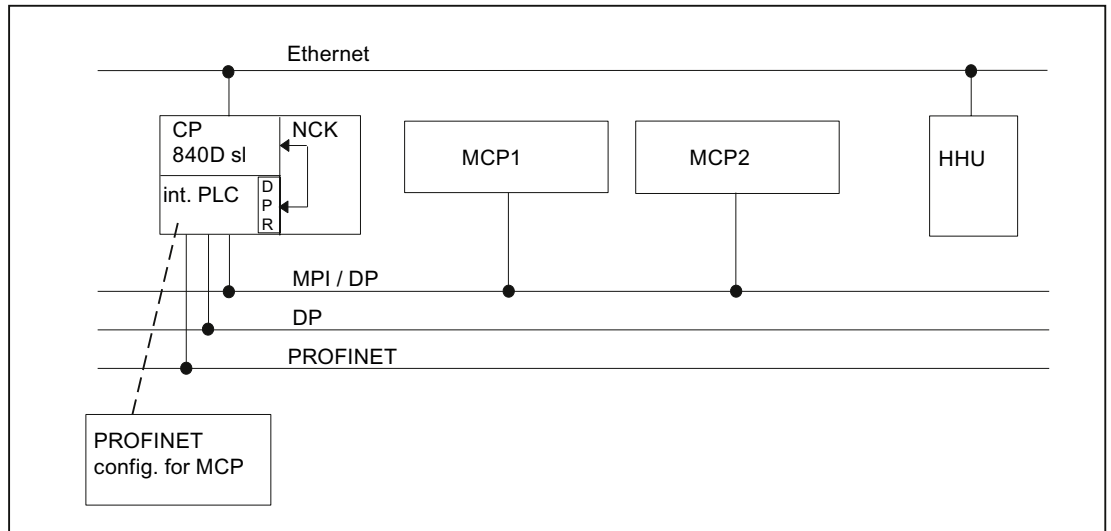

Figure 13-19 840D sl: PROFINET connection

| Relevant parameters (FB1)        |                     |                          |
|----------------------------------|---------------------|--------------------------|
| MCP                              |                     | HHU                      |
| MCPNum = 1 or 2 (number of MCPs) |                     | HHU = 5 (via CP 840D sl) |

|                                  |                     | <b>BHGMPI = FALSE</b>    |
|                                  |                     | BHGStop                  |

MCP failure normally switches the PLC to the STOP state. If this is unwanted, then OB 82, OB 86 can be used to avoid a PLC stop. The basic program has, as standard, the OB 82 and OB 86 call. FC5 is called in these OBs. This FC5 checks whether the failed slave is an MCP. If this is the case, no PLC stop is triggered. The input address at parameter MCPxIn is of significance when monitoring for MCPxIn failure.

Setting MCPxStop := True causes the basic program to deactivate the MCP as a slave via SFC 12. If the PLC does not switch to the stop state following the failure of or a fault on the MCP, an alarm message will be generated via the basic program. The alarm is deleted when the station returns.

### **13.8.12 Switchover of handheld device**

Only Ethernet variants support switchover/deactivation of the machine control panel (MCP) or handheld unit (HHU) as standard. On MPI and PROFIBUS variants, this function is either not supported at all or can only be implemented in restricted format requiring additional effort on the part of the user. For example, with the PROFIBUS variant of the MCP, the DB77 data area specified for MCP1, MCP2 or HHU can be used for the MCP pointer on FB1. The MCP slave bus address must be set correctly under MCPxBusAdr as this is used as the basis for monitoring. A user program copy routine to copy the signals of the active MCP from the I/O area configured in HW Config to DB77. This enables a number of MCPs on the PROFIBUS to be switched via signals. Set the MCPxStop parameter to True for the switchover phase from one MCP to another.

One method will be outlined now with the Ethernet variants of MCP and HHU.

#### **Control signals**

Parameters MCP1Stop, MCP2Stop and BHGStop can be used to stop communication with individual components (parameter setting = 1). This function is available only on Ethernet variants. This stop or activation of communication can be applied in the current cycle. However, the change in value must be implemented through the symbolic notation of the parameters and not by means of another FB 1 call.

Example of stopping transfer from the first machine control panel:

```
SET;
S gp_par.MCP1Stop;
```

Setting parameters MCP1Stop, MCP2Stop, BHGStop also results in a suppression or deletion of interrupts 400260 to 400262.

#### **Switchover of Bus address**

An existing connection with a machine control panel (MCPI) or handheld unit (HHU) can be aborted. Another MCP or HHU component already connected to the bus (different address) can then be activated. Proceed as follows to switch addresses:

1. Stop communication with component to be decoupled via parameter MCP1Stop or MCP2Stop or BHGStop = 1.
2. Following checkback in DB10 byte 104 (relevant bits 0, 1 and 2 are set to 0), the bus address (with MCP, this is the FB1 parameter "MCP1BusAdr" or "MCP2BusAdr") is changed; With HHU Ethernet variant, the bus address is set at FB1 parameter "BHGRcGDNo") of this unit is changed to the new component.
3. In this PLC cycle, communication with the new component can now be activated again by means of parameter MCP1Stop or MCP2Stop or BHGStop = 0.
4. Communication with the new component is taking place when the checkback is in DB 10 byte 104 (relevant bits 0, 1, 2 are set to 1).

## **13.9 SPL for Safety Integrated**

Rather than being a function of the basic program, SPL is a user function. The basic program makes a data block (DB 18) available for Safety SPL signals and runs a data comparison to ensure the consistency of SPL program data in the NCK.

## 13.10 Assignment overview

### 13.10.1 Assignment: NCK/PLC interface

The values of the NC/PLC interface for SINUMERIK 840D sl are described in detail in:

**References:**

Lists sl (Book 2)

### 13.10.2 Assignment: FB/FC

| Number                      | Significance             |
|-----------------------------|--------------------------|
| FB 15                       | Basic program            |
| FB 1, FC 2, FC 3, FC 5      | Basic program            |
| FC 0 ... 29                 | Reserved for Siemens     |
| FB 0 ... 29                 | Reserved for Siemens     |
| FC 30 ... 999 <sup>1)</sup> | Free for user assignment |
| FB 30 ... 999 <sup>1)</sup> | Free for user assignment |
| FC 1000 ... 1023            | Reserved for Siemens     |
| FB 1000 ... 1023            | Reserved for Siemens     |
| FC 1024 ... upper limit     | Free for user assignment |
| FB 1024 ... upper limit     | Free for user assignment |

<sup>1)</sup> The actual upper limit of the block number (FB/FC) depends on the PLC CPU on which the selected NCU is located.

---

**Note**

Values of FC, FB see "Memory requirements of the basic PLC program (Page 928)".

---

### 13.10.3 Assignment: DB

---

**Note**

Only as many data blocks as are required according to the NC machine data configuration are set up.

---

| Overview of data blocks  |                 |                                                             |              |

| 71 ... 74                |                 | Tool management                                             | BP           |
| 75 ... 76                |                 | M group decoding                                            |              |
| 77                       |                 | Data block for MCP signals                                  |              |
| 78 ... 80                |                 | Reserved for Siemens                                        |              |
| 81 ... 999 <sup>1)</sup> |                 | see below: ShopMill, ManualTurn                             |              |
| 1000 ... 1099            |                 | Reserved for Siemens                                        |              |
| 1100 ... High<br>limit   |                 | Free for user assignment                                    |              |

<sup>1)</sup> The actual upper limit of the block number (DB) depends on the PLC CPU on which the selected NCU is located. The data blocks of channels, axes/spindles and tool management functions that are not activated may be assigned as desired by the user.

### Note

The data blocks of channels, axes/spindles and tool management functions that are not activated may be assigned as required by the user.

### 13.10.4 Assignment: Timers

| Timer No.                   | Significance |
|-----------------------------|--------------|
| T 0 ... T 512 <sup>1)</sup> | User area    |

<sup>1)</sup> The actual upper limit of the timer number (DB) depends on the PLC CPU on which the selected NCU is located.

## 13.11 Memory requirements of the basic PLC program

The basic program consists of basic and optional functions. The **basic functions** include cyclic signal exchange between the NC and PLC. The **Options** include e.g. the FCs, which can be used, if needed.

The table below lists the memory requirements for the basic functions and the options. The data quoted represent guide values, the actual values depend on the current software version.

| Memory requirements of blocks for SINUMERIK 840D sl |                               |                                                         |                    |
|-----------------------------------------------------|-------------------------------|---------------------------------------------------------|--------------------|
| Block type no.                                      | Function                      | Remark                                                  | Block size (bytes) |
|                                                     |                               |                                                         | Working memory     |
| <b>Basic functions in basic program</b>             |                               |                                                         |                    |

| FC 17                        | Star/delta switchover of MSD          | Load for star/delta switchover                       | 114 |
| Spindle control              |                                       |                                                      |     |
| FC 18                        | Spindle control                       | Load for spindle control from PLC                    | 132 |
| PLC/NC communication         |                                       |                                                      |     |
| FB 2                         | Read NC variable                      | Load for Read NC variable                            | 76  |
| DB n                         | Read NC variable                      | One instance DB per FB 2 call                        | 270 |
| FB 3                         | Write NC variable                     | Load for Write NC variable                           | 76  |
| DB m                         | Write NC variable                     | One instance DB per FB3 call                         | 270 |
| FB 4                         | PI services                           | Load for PI services                                 | 76  |
| DB o                         | PI services                           | One instance DB per FB 4 call                        | 130 |
| DB 16                        | PI services description               | Load for PI services                                 | 618 |
| FB 5                         | Read GUD variables                    | Load for PI services                                 | 76  |
| DB p                         | Read GUD variables                    | One instance DB per FB 5 call                        | 166 |
| DB 15                        | General communication                 | Global data block for communication                  | 146 |
| FB 7                         | PI services 2                         | Load for PI services                                 | 76  |
| DB o                         | PI services 2                         | One instance DB per FB4 call: every                  | 144 |
| FC 21                        | Transfer                              | Load with dual-port RAM, ...                         | 164 |
| m:n                          |                                       |                                                      |     |
| FB 9                         | Switchover M to N                     | Load with M to N                                     | 58  |

13.11 Memory requirements of the basic PLC program

| <b>Basic program options</b> |                              |                                               |                 |
|------------------------------|------------------------------|-----------------------------------------------|-----------------|
| Safety Integrated            |                              |                                               |                 |
| FB 10                        | Safety relay                 | Load with Safety option                       | 74              |
| FB 11                        | Brake test                   | Load with Safety option                       | 76              |
| DB 18                        | Safety data                  | DB for Safety                                 | 226             |
| Tool management              |                              |                                               |                 |
| FC 7                         | Transfer function turret     | Load for tool management option               | 84              |
| FC 8                         | Transfer function            | Load for tool management option               | 132             |
| FC 22                        | Direction selection          | Load, when direction selection is needed      | 138             |
| DB 71                        | Loading locations            | Generated by BP as a function of NC MD        | 40+30*B         |
| DB 72                        | Spindles                     | Generated by BP as a function of NC MD        | 40+48*Sp        |
| DB 73                        | Revolver                     | Generated by BP as a function of NC MD        | 40+44*R         |
| DB 74                        | Basic function               | Generated by BP as a function of NC MD        | 100+(B+Sp+R)*22 |
| Compile cycles               |                              |                                               |                 |
| DB 9                         | Interface PLC compile cycles | Is generated by BP as a function of NC option | 436             |

**Example**

Based on the memory requirements in the table above, the memory requirements have been determined for two sample configurations (see table below).

| Block type no.                                      | Function            | Remark | Block size (bytes) |
|-----------------------------------------------------|---------------------|--------|--------------------|
|                                                     |                     |        | Working memory     |
| Minimum configuration (1 spindle, 2 axes and T MCP) |                     |        |                    |
| see above                                           | Basic program, base |        | 54688              |
|                                                     | Interface DBs       |        | 1612               |
|                                                     | MCP                 |        | 92                 |
|                                                     |                     | Total  | 56392              |

| Block type no.                                                | Function            | Remark | Block size (bytes) |
|---------------------------------------------------------------|---------------------|--------|--------------------|
|                                                               |                     |        | Working memory     |
| Maximum configuration (2 channels, 4 spindles, 4 axes, T MCP) |                     |        |                    |
| see above                                                     | Basic program, base |        | 54688              |
| see above                                                     | Interface DBs       |        | 2768               |
| see above                                                     | MCP                 |        | 92                 |

| Maximum configuration (2 channels, 4 spindles, 4 axes, T MCP) |                          |                                          |       |
|---------------------------------------------------------------|--------------------------|------------------------------------------|-------|
| see above                                                     | Error/operating messages |                                          | 66    |
| see above                                                     | ASUBs                    | 1 ASUB initiation                        | 128   |
| see above                                                     | Concurrent axis          | For 2 turrets                            | 132   |

| see above                                                     | Tool management          | 2 turrets with one loading point each    | 674   |
| see above                                                     | Compile cycles           |                                          | 436   |
|                                                               |                          | Total                                    | 59822 |

## 13.12 Basic conditions and NC VAR selector

### 13.12.1 Supplementary conditions

#### 13.12.1.1 Programming and parameterizing tools

#### Hardware

For the PLCs used in SINUMERIK 840D sl, the following equipment is required for the programming devices or PCs:

|                               | Minimum                                                        | Recommendation |
|-------------------------------|----------------------------------------------------------------|----------------|
| Processor                     | Pentium                                                        | Pentium        |
| RAM (MB)                      | 256                                                            | 512 or more    |
| Hard disk, free capacity (MB) | 500                                                            | > 500          |
| interfaces                    | MPI, Ethernet incl. cable<br>Memory card                       |                |
| Graphic                       | SVGA (1024*768)                                                |                |
| Mouse                         | Yes                                                            |                |
| Operating system              | Windows 2000 /XP Professional, STEP7 version 5.3 SP2 or higher |                |

The required version of **STEP7** can be installed on equipment meeting the above requirements in cases where the package has not already been supplied with the programming device.

The following functions are possible with this package:

- Programming
  - Editors and compilers for STL (complete scope of the language incl. SFB/SFC calls), LAD, FBD
  - Creation and editing of assignment lists (symbol editor)
  - Data block editor
  - Input and output of blocks ON/OFF line
  - Insertion of modifications and additions ON and OFF line
  - Transfer of blocks from programming device to the PLC and vice versa
- Configuring
  - Parameterizing tool **HW Config** for CPU and I/O device parameterization
  - **NetPro** parameterizing tool for setting the CPU communication parameters
  - Output of system data such as hardware and software version, memory capacity, I/O expansion/assignment

- Testing and diagnostics (ONLINE)
  - Variable status/forcing (I/Os, flags, data block contents, etc.)
  - Status of individual blocks
  - Display of system states (ISTACK, BSTACK, system status list)
  - Display of system messages
  - PLC STOP/complete restart/overall reset triggering from the programming device
  - Compress PLC
- Documentation
  - Printout of individual or all blocks
  - Allocation of symbolic names (also for variables in data blocks)
  - Input and output of comments within each block
  - Printout of test and diagnostics displays
  - Hardcopy function
  - Cross-reference list
  - Program overview
  - Assignment plan I/O/M/T/Z/D
- Archiving of utility routines
  - Allocation of the output statuses of individual blocks
  - Comparison of blocks
  - Rewiring
  - STEP 5 → STEP 7 converter
- Option packages
  - Programming in S7-HIGRAPH, S7-GRAPH, SCL.  
These packages can be ordered from the SIMATIC sales department.
  - Additional packages for configuration modules (e.g. CP3425 → NCM package)

---

**Note**

More information about possible functions can be found in SIMATIC catalogs and STEP 7 documentation.

### 13.12.2 NC VAR selector

#### 13.12.2.1 Overview

#### General

The PC application "NC VAR selector" fetches the addresses of required NC variables and processes them for access in the PLC program (FB 2/FB 3). This enables the programmer to select NC variables from the entire range of NC variables, to store this selection of variables, to edit them by means of a code generator for the STEP7 compiler and finally to store them as an ASCII file (\*.AWL) in the machine CPU program. This process is shown in the figure "NC VAR selector".

For storing the files created by NC-VAR-selector a catalog is to be implemented via the Windows Explorer with any catalog name. The selected data of the NC-VAR selector (data.VAR and data.AWL files) must be stored in this catalog. Thereafter, the AWL file is to be transferred and compiled via the menu option "Code" → "in STEP7 Project" The "Daten.AWL" (STL data) file must then be inserted into the STEP 7 machine project via "Insert", "External Source" in the STEP 7 Manager. The source container must be selected in the manager for this purpose. This action stores this file in the project structure. Once the file has been transferred, these AWL (STL) files must be compiled with STEP 7.

**Note**

The latest NC VAR selector can be used for each NC software version (even earlier versions). For older NC software versions the variables can also be selected from the latest complete list. The data content in DB 120 (default DB for variables) does not depend on the software status. That is, variables selected in an older software version need not be reselected when the software is upgraded.

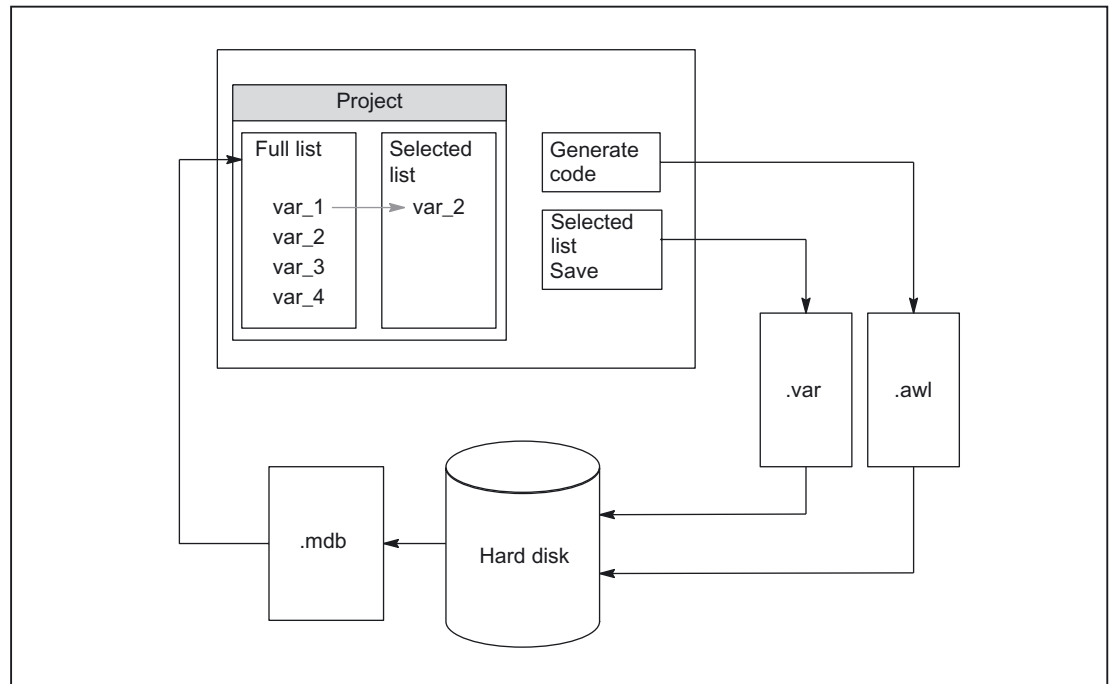

Figure 13-20 NC VAR selector

After the "NC VAR selector" application has been started, select a list of variables of an NC variant (hard disk → file Ncv.mdb) to display all the variables contained in this list in a window.

The variable list ncv\*.mdb is separated on:

| SINUMERIK 840D                                   |                    |
|--------------------------------------------------|--------------------|
| NC variables including machine and setting data: | ncv_NcData.mdb     |
| Machine data for 611D drive:                     | ncv_611d.mdb       |
| Machine data for 611D linear drive:              | ncv_611dLinear.mdb |

| SINUMERIK 840D                                        |                       |
|-------------------------------------------------------|-----------------------|
| Machine data of the 611D drive, Performance 2:        | ncv_611d_P2.mdb       |
| Machine data of the 611D linear drive, Performance 2: | ncv_611d_P2Linear.mdb |
| Machine data of the hydraulic drive:                  | ncv_Hydraulics.mdb    |

| SINUMERIK 840D sl                                |                       |
|--------------------------------------------------|-----------------------|
| NC variables including machine and setting data: | ncv_NcData.mdb        |
| Parameters of the Drive:                         | ncv_SinamicsServo.mdb |

The user can also transfer variables to a second list (separate window). This latter selection of variables can then be stored in an ASCII file or edited as a STEP 7 source file (.awl) and stored.

Once he has generated a PLC data block by means of the STEP 7 compiler, the programmer is able to read or write NCK variables via the basic program function blocks "PUT" and "GET" using the STEP 7 file.

The list of selected variables is also stored as an ASCII file (file extension .var).

The variable list supplied with the "NC VAR selector" tool is adapted to the current NC software version. This list does not contain any variables (GUD variables) defined by the user. These variables are processed by the function block FB 5 in the basic program.

---

#### Note

The latest version of the "NC VAR selector" is capable of processing all previous NC software versions. It is, therefore, not necessary to install different versions of the "NC VAR selector" in parallel.

---

### System features, supplementary conditions

The PC application "NC VAR selector" requires Windows 95 (or later operating system).

The assignment of names to variables is described in:

**References:**

/LIS1/ Lists (Book 1); Chapter: Variables,  
or in the Variables Help file (integrated in NC VAR selector).

### 13.12.2.2 Description of functions

#### Overview

The figure below illustrates how the NC VAR selector is used within the STEP 7 environment.

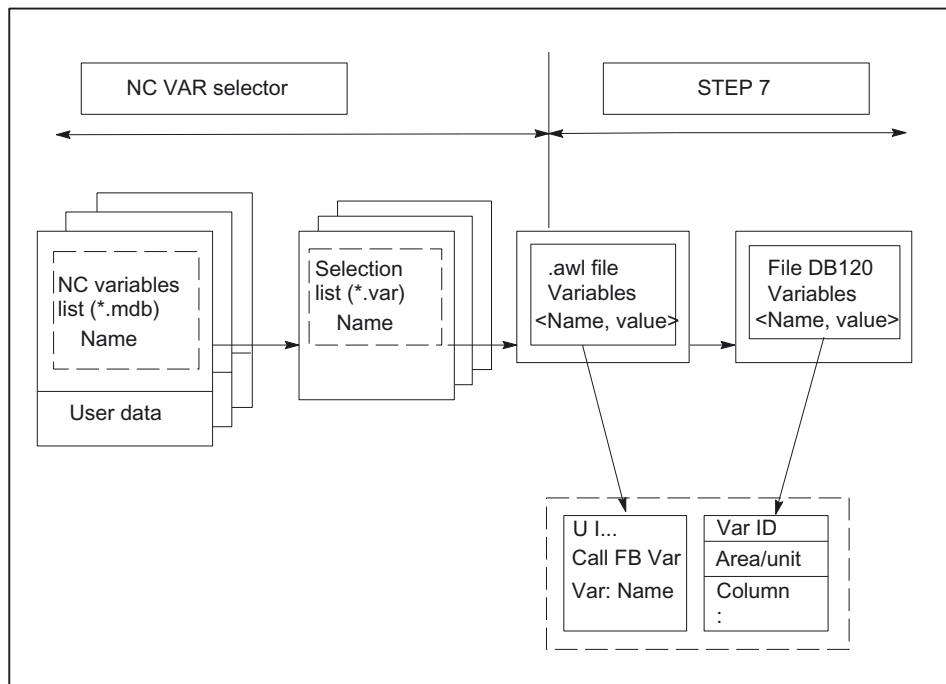

Figure 13-21 Application of NC VAR selector in the STEP 7 environment

The NC VAR selector is used to generate a list of selected variables from a list of variables and then to generate an **.awl** file that can be compiled by the STEP 7 compiler.

- A **.awl** file contains the names and alias names of the NC variables, as well as information about their address parameters. Any data block generated from this file will only contain the address parameters (10 bytes per parameter).
- The generated data blocks must always be stored in the machine-specific file storage according to STEP 7 specifications.
- To ensure that the parameterization of the GET/PUT (FB 2/3) blocks with respect to NC addresses can be implemented with symbols, the freely assignable, symbolic name of the generated data block must be included in the STEP 7 symbol table.

### Basic display/Basic menu

After the NC VAR selector has been selected (started), the basic display with all input options (upper menu bar) appears on the screen. All other displayed windows are placed within the general window.

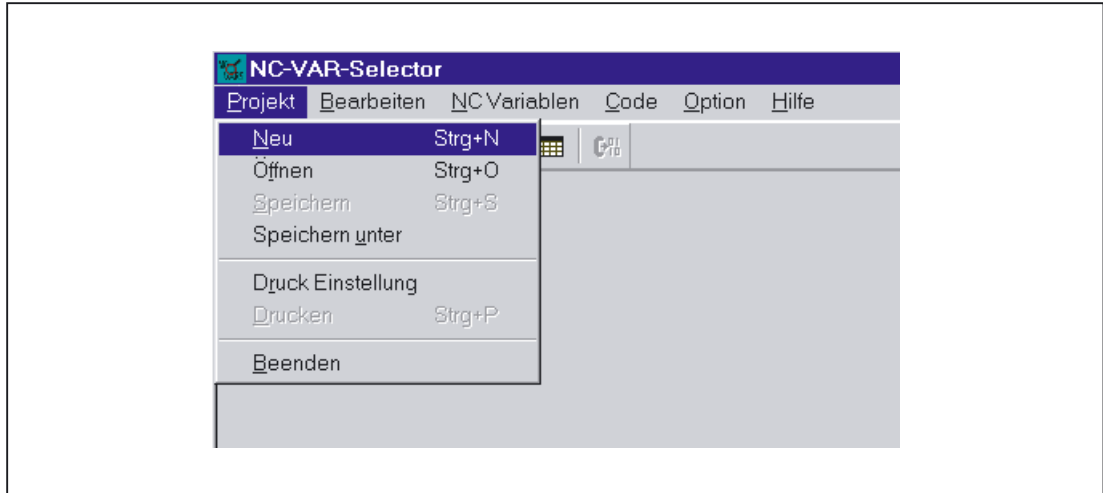

Figure 13-22 Basic display with basic menu

### Project menu item

All operator actions associated with the project file (file of selected variables) are performed under this menu item.

### Terminating the application

The application can be terminated by selecting the "End" option under the "Project" menu item.

### Creating a new project

A new project (new file for selected variables) can be set up under the "Project" menu item.

A window is displayed for the selected variables when "NEW" is selected. The file selection for the NC variable list is then displayed after a prompt (applies only if the NC variable list is not already open).

| Projekt: unknown |          |               |               |
|------------------|----------|---------------|---------------|
| Bereich          | Baustein | VariablenName | S7 Alias Name |
|                  |          |               |               |

Figure 13-23 Window with selected variables for new project

The selected variables are displayed in a window.

### Open an already existing project

Select "Open" under the "Project" menu item to open an existing project (variables already selected). A file selection window is displayed allowing the appropriate project with extension ".var" to be selected.

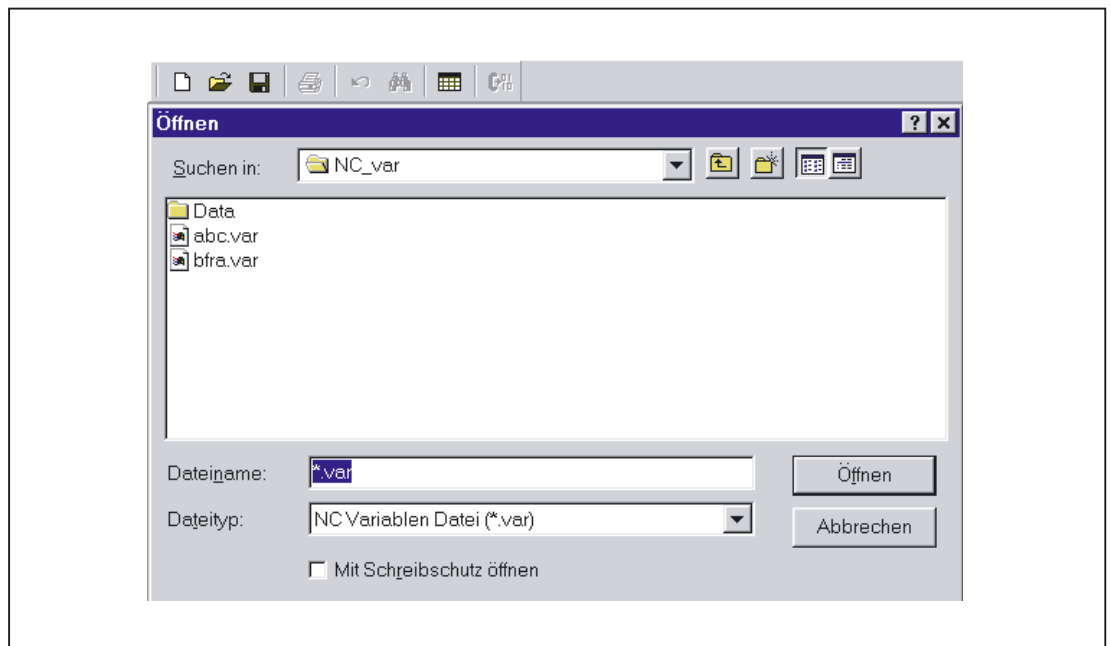

Figure 13-24 Selection window for existing projects

If, after selection of the project, new variables are to be added, a complete list of NC variables must be selected. No complete list need be called if the user only wishes to delete variables from the project.

### Storing a project

The variable list is stored using the "Project" > "Save" or "Save As...." menu items.

"Save" stores the variable list under a path, which is already specified. If the project path is not known, then the procedure is as for "Save As....".

"Save As..." displays a window in which the path for the project to be stored can be specified.

### Printing a project

The "Print" command under the "Project" menu item can be selected to print a project file. The number of lines per page is selected under the "Print Setting" menu item. The default setting is 77 lines.

### Edit menu item

The following operator actions are examples of those, which can be carried out directly with this menu item:

- Transfer variables
- Delete variables
- Change alias names
- Find variables

These actions can also be canceled again under Edit.

### Undoing actions

Operator actions relating to the creation of the project file (transfer variables, delete variables, change alias names) can be undone in this menu.

### NC variables menu item

The basic list of all variables is saved in NC Var Selector path Data\Swxy (xy stands for software version no., e.g. SW 5.3:=xy=53). This list can be selected as an NC variables list. In case of SINUMERIK 840D sl the basic lists are present in the path Data\Swxy\_sl.

### Selecting an NC variable list

A list of all the NC variables for an NC version can now be selected and displayed via the "NC Variable List", "Select" menu item.

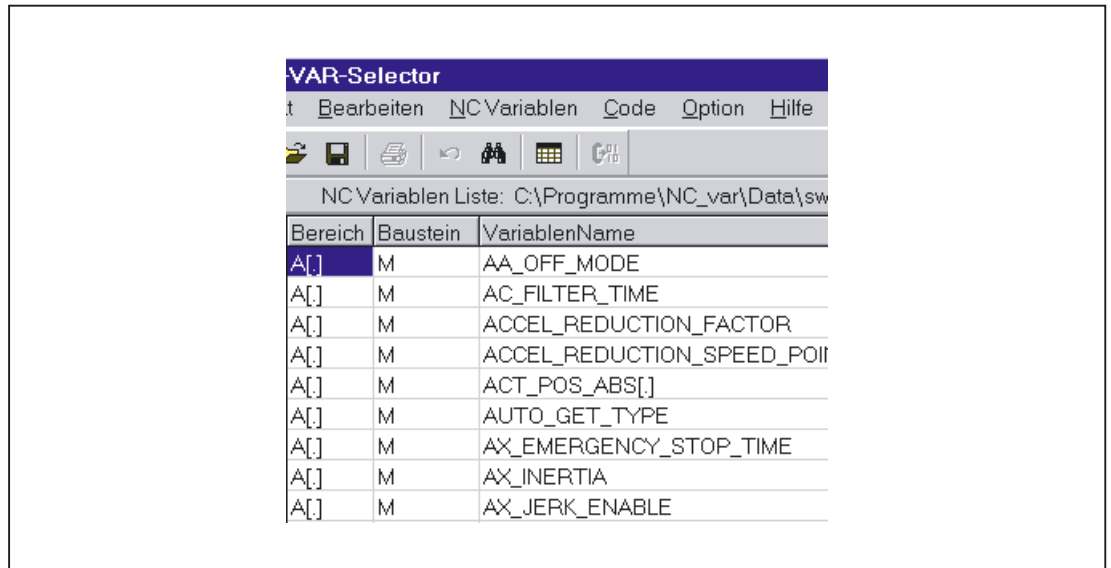

Figure 13-25 Window with selected Complete List

The field variables (e.g. axis area, T area data, etc.) are indicated by means of brackets ([.]). Additional information must be specified here. When the variables are transferred to the project list, the additional information required is requested.

### Displaying subsets

Double-click on any table field (with the exception of variable fields) to display a window in which filter criteria can be preset.

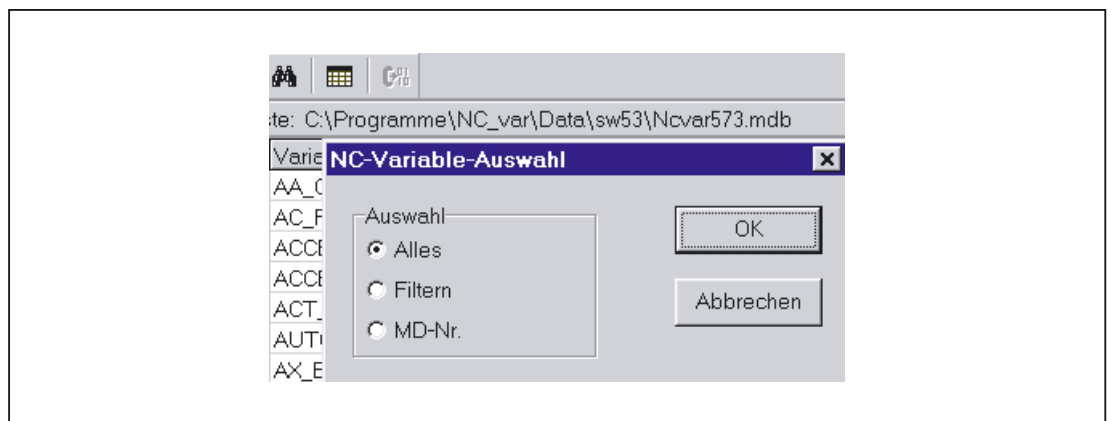

Figure 13-26 Window with filter criteria for displaying list of variables

There are three options:

- Display all data
- Input area, block and name (incl. combinations)
- Display MD/SE data number

The following wildcards can also be used:

|   |                                            |
|---|--------------------------------------------|
| * | To extend the search criterion as required |
|---|--------------------------------------------|

### Example: Search criteria

|                              |        |                |
|------------------------------|--------|----------------|
| Name search criterion: CHAN* | Found: | CHAN_NAME      |
|                              |        | chanAlarm      |
|                              |        | chanStatus     |
|                              |        | channelName    |
|                              |        | chanAssignment |

- Select variable

A variable is selected by means of a simple mouse click and transferred to the window of selected variables by double-clicking. This action can also be undone under the "Edit" menu item.

### Alias name

The variable names provided can be up to 32 characters in length. To make variables clearly identifiable in the data block to be generated, several ASCII characters are added to the selected name. However, the STEP 7 compiler recognizes only 24 ASCII characters as an unambiguous STEP 7 variable. Since it cannot be precluded that variable names can only be differentiated by the last 8 character positions, **ALIAS** names are used for names, which are too long. When a variable is selected, the length of the STEP7 name to be used is, therefore, checked. If the name is longer than 24 characters, the user must enter an additional name, which is then used as the alias.

**In this case, the user must ensure that the alias name is unambiguous.**

Alias input can always be activated by the user in the "Options" menu. An alias name can then be entered every time a variable is transferred.

It is also possible to edit alias names at a later point in time by double-clicking on the S7 variable name field. This action can also be undone under the "Edit" menu item.

|       |         |          |                        |
|-------|---------|----------|------------------------|
| 7     | A[.]    | M        | AX_EMERGENCY_STOP_TIME |
| 8     | A[.]    | M        | AX_INERTIA             |
| 9     | A[.]    | M        | AX_JERK_ENABLE         |
| 10    | A[.]    | M        | AX_JERK_TIME           |
| Proje |         |          |                        |
|       | Bereich | Baustein | VariablenName          |
| 1     | A[.]    | M        | AA_OFF_MODE            |

Figure 13-27 Screen with complete list and selected variables

## Scrolling

A scroll bar is displayed if it is not possible to display all variables in the window. The remaining variables can be reached by scrolling (page up/down).

## Variables in multi-dimensional structures

If variables are selected from multi-dimensional structures, then the column and/or line number as well as the area number must be entered so that the variables can be addressed. The required numbers can be found in the NC variables documentation.

### References:

Lists sl (Book1); Variables

By entering a zero (0) as the block number or the line or column index, it is possible to use the variable in the S7 PLC as a pointer to these data. When reading or writing these data via the functions "PUT" and "GET", the optional parameters "UnitX", "ColumnX" and "LineX" must be filled with the necessary information.

Eingabe von Zeile, Spalte und Bereichsnummer

Bereichs Nr.

Zeile

Variable  
 ACT\_POS\_ABS[.]  
 ergänzen mit: (siehe Hilfe)  
 Bereichs Nr. = Achsnr.  
 Zeile

Figure 13-28 Entry field for line, column and block no.

### Delete variables

Variables are deleted in the window of selected variables by selecting the appropriate variables (single mouse click) and pressing the "Delete" key. No deletion action is taken with the double-click function. It is possible to select several variables for deletion (see "Selecting variables").

This action can also be undone under the "Edit" menu item.

---

#### Note

Deleting of variables results in a change of the absolute addresses of the pointer structures to the variables. When changing the variable selection, it is, therefore, absolutely necessary to **generate** one or several **text files of all user blocks prior to the change**. This is the only way to ensure that the assignment of the variables in FB "GET" or FB "PUT" remains correct, even after recompilation.

---

### Storing a selected list

Once variables have been selected, they can be stored under a project name. The files are stored on a project-specific basis.

A window is displayed for the file to be stored. The project path and name for the file must be selected in the window.

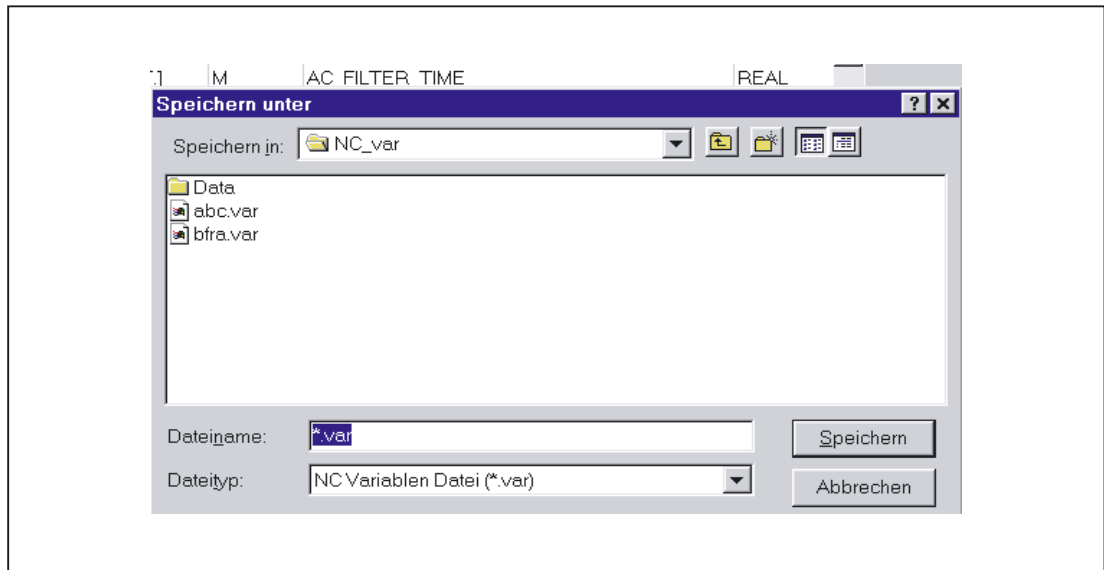

Figure 13-29 Window for project path and name of file to be stored

## Code generation

This menu item contains three selection options:

1. Settings (input of data block number to be generated) and other settings
2. Generate (create data block)
3. In the STEP7 project (transferring the data block to a STEP7 project)

## Settings

Under this menu item, the DB number and the symbol for this DB number for which the code is created is entered.

Under the "Mass System" tab, a selection is made to determine how the unit system variables are calculated in the PLC.

Under the "Generate" tab, the project creation is defined for the relevant target system.

## Generate

Under this menu item, the STEP 7 file from the selected variable list with extension ".awl" is set.

A file is generated when "Select" is clicked:

An **.awl** file that can be used as an input for the STEP 7 compiler.

A window opens, in which path and name for the .awl file to be generated must be specified for the file to be saved.

## In STEP 7 project

The generated AWL file is transferred to a selectable SIMATIC project (program path) and compiled. Furthermore, the symbol can also be transferred. This function is available from STEP 7 version 5.1 onwards. This process takes a longer time owing to the call of STEP 7. Before transferring a new AWL file the file window of the AWL file is to be closed in the KOP/FUP/AWL Editor.

## Option menu item

The following can be selected under the "Option" menu item:

- The current language
- The mode for alias input (always >24 characters)

## Help menu item

The information below can be viewed by selecting the corresponding submenu item:

- The Operator's Guide
- The Description of Variables

The copyright and the version number can also be displayed.

### 13.12.2.3 Start-up, installation

The Windows application "NC Var selector" is installed using the SETUP program supplied with the package.

## 13.13 Block descriptions

### 13.13.1 FB 1: RUN\_UP Basic program, start-up section

#### Function

The synchronization of NCK and PLC is performed during startup. The data blocks for the NC/PLC user interface are created with reference to the NC configuration defined in the machine data and the most important parameters verified for plausibility. In the event of an error, FB 1 passes an error identifier to the diagnostics buffer and switches the PLC to the STOP state.

To enable an orderly start-up of the control, it is vital to synchronize the NCK and PLC, as these systems have their own types of power-up procedure. During startup routine, therefore, the CPUs perform "subsidiary startup functions" and exchange ID information to ensure that the procedure is functioning correctly.

Since the startup procedure is asynchronous, it is unavoidable that one CPU may have to "wait" until the other has "caught up". This is automatically managed by the basic program.

The integrated PLC only supports cold starts. A warm restart is not provided, i.e. following system initialization, the operating system runs organization block OB 100 and always commences cyclic execution at the start of OB 1.

Users need only supply the FB 1 parameters that are relevant to their applications. The preset values in the associated instance DB 7 do not need to be assigned. The block can only be called in OB 100.

#### Output parameters

The output parameters in FB 1 provide the PLC user with information about the control system configuration. These data can also be accessed in the cyclic program section.

There are two access options:

1. Direct access to the DB 7 data block (instance of the FB 1) in symbolic format (e.g. L gp\_par.MaxChan; in this case, gp\_par is the symbolic name of the DB 7)
2. Assignment of a flag; during parameterization of the FB 1, the data element is assigned to the relevant parameter (e.g. MaxChan:=MW 20) Information about the maximum number of channels can then be polled in memory word 20 in the rest of the user program.

---

#### Note

For the values of the parameters of MCP and HHU see "Configuration machine control panel, handheld unit, direct keys (Page 914)".

---

| UDHex             | O    | INT                     |             | Quantity of hexadecimal machine data in DB20 |
| UDReal            | O    | INT                     |             | Quantity of REAL machine data in DB 20       |
| IdentMcpType      | O    | BYTE                    |             | Type (HT2, HT8, ...)                         |
| IdentMcpLengthIn  | O    | BYTE                    |             | Length info input data in PLC                |
| IdentMcpLengthOut | O    | BYTE                    |             | Length info output data in PLC               |

### MCP/HHU monitoring (840D sl)

The following alarms are displayed at HMI in cases of errors for the communication with the machine control panel (MCP):

- 400260: MCP 1 failure or
- 400261: MCP 2 failure
- 400262: HHU failure

In this case, the input signals from the MCP or from the handheld unit (MCP1In/MCP2In or BHGIn) are reset to 0. If it is possible to resynchronize the PLC and MCP/HHU, communication is resumed automatically and the error message reset by the GP.

### Call example for 840D sl

An example call for the FB 1 in OB 100 appears below. This example is part of the diskette with basic program for 840D sl.

```

ORGANIZATION_BLOCK OB 100
VAR_TEMP
 OB100_EV_CLASS : BYTE ;
 OB100_STRTUP : BYTE ;
 OB100_PRIORITY : BYTE ;
 OB100_OB_NUMBR : BYTE ;
 OB100_RESERVED_1 : BYTE ;
 OB100_RESERVED_2 : BYTE ;
 OB100_STOP : WORD ;
 OB100_RESERVED_3 : WORD ;
 OB100_RESERVED_4 : WORD ;
 OB100_DATE_TIME : DATE_AND_TIME;
END_VAR
BEGIN

```

```

CALL FB 1, DB 7 (
 MCPNum := 1,
 MCP1In := P#E0.0,
 MCP1Out := P#A0.0,
 MCP1StatSend := P#A8.0,
 MCP1StatRec := P#A12.0,
 MCP1BusAdr := 6,
 MCP1Timeout := S5T#700MS,
 MCP1Cycl := S5T#200MS,
 NC-CyclTimeout := S5T#200MS,
 NC-RunupTimeout := S5T#50S);
//INSERT USER PROGRAM HERE
END_ORGANIZATION_BLOCK

```

### 13.13.2 FB 2: Read GET NC variable

#### Function

The PLC user program can read variables from the NCK area using FB GET. The FB is multi-instance-capable.

FB 2 also includes an Instance DB from the user area.

When FB 2 is called with a positive signal edge change at control input "Req", a job is started, which reads the NCK variables referenced by ADDR1-ADDR8 and then copies them to the PLC operand areas referenced by RD1 to RD8. Successful completion of the read process is indicated by a logical "1" in status parameter "NDR".

The **read process** lasts for several PLC cycles (normally 1 ... 2). The block can be called up in cyclic mode only.

Any errors are indicated by Error and State.

In order to reference the NC variables, all required variables are first selected with the "NC VAR selector" tool and generated as STL source in a data block. A name must then be assigned to this DB in the symbol table.

"DB name.S7 name" is transferred as the actual parameter of the NCK variable address (Addr1 to Addr8) when FB 2 is called.

## Variable addressing

For some NC variables, it is necessary to select area no. and/or line or column from the NC-VAR selector. For these variables it is possible to select a basic type, i. e. area/column/row is filled with "0" by default. The contents of the area number, line and column specified by the NC VAR selector are checked for a "0" in the FB. If a "0" is present, the value is transferred to the input parameter. The user must supply the required parameters (UnitX/ColumnX/LineX) before calling FB GET.

### NOTICE

FB 2 can read NC variables only if basic program parameter NCKomm ="1" has been set (in OB 100: FB 1, DB 7). The call is permitted only in cyclic program OB1. An assignment for all parameters with Req = 0 is also permitted in OB 100.

When **channel-specific** variables are read, only variables from **one** and the same channel may be addressed via Addr1 to Addr8 in a job (FB 2 call).

In areas V and H, different logic axis numbers must not be assigned in one job. (Failure to observe this rule results in Error:= TRUE, State:= W#16#02).

NCK variables within **one** group can be combined in a job:

|         | Area |      |   |   |   |
|---------|------|------|---|---|---|
| Group 1 | C[1] | N    | B | A | T |
| Group 2 | C[2] | N    | B | A | T |
| Group 3 | V[.] | H[.] |   |   |   |

The same rules apply to channels 3 to 10 as illustrated as examples in the above table in groups 1 and 2.

### Note

Especially when reading several long strings, the number of usable variables can be less than 8.

## Declaration of the function

```

FUNCTION_BLOCK FB 2
VAR_INPUT
 Req : BOOL;
 NumVar : INT ;
 Addr1 : ANY ;
 Unit1 : BYTE ;
 Column1 : WORD ;
 Line1 : WORD ;

```

## Description of formal parameters

The table below list all formal parameters of the GET function.

| Signal             | Type | Type | Range of values                                   | Remark                                                        |
|--------------------|------|------|---------------------------------------------------|---------------------------------------------------------------|
| Req                | I    | BOOL |                                                   | Job start with positive signal edge                           |
| NumVar             | I    | INT  | 1 ... 8<br>(corresponds to use of Addr1 to Addr8) | Number of variables to be read                                |
| Addr1 to Addr8     | I    | ANY  | [DBName].[VarName]                                | Variable identifiers from <b>NC Var selector</b>              |
| Unit1 to Unit8     | I    | BYTE |                                                   | Area address, optional for variable addressing                |
| Column1 to Column8 | I    | WORD |                                                   | Column address, optional for variable addressing              |
| Line1 to Line8     | I    | WORD |                                                   | Line address, optional for variable addressing                |
| Error              | O    | BOOL |                                                   | Negative acknowledgment of job or execution of job impossible |
| NDR                | O    | BOOL |                                                   | Job successfully executed Data are available                  |
| State              | O    | WORD |                                                   | See error identifiers                                         |
| RD1 to RD8         | I/O  | ANY  | P#Mm.n BYTE x...<br>P#DBnr.dbxm.n BYTE x          | Target area for read data                                     |

## Error identifiers

If it was not possible to execute a job, the failure is indicated by "logic 1" on status parameter error. The error cause is coded at the block output State:

| State   |        | Significance                                | Note                                                                                                  |
|---------|--------|---------------------------------------------|-------------------------------------------------------------------------------------------------------|
| WORD H  | WORD L |                                             |                                                                                                       |
| 1 ... 8 | 1      | Access error                                | In high byte number of Var in which error occurred                                                    |
| 0       | 2      | Error in job                                | Incorrect compilation of Var. in a job                                                                |
| 0       | 3      | Negative acknowledgment, job not executable | Internal error, try:<br>NC RESET                                                                      |
| 1 ... 8 | 4      | Insufficient local user memory available    | Read var. is longer than specified in RD1 to RD8; in high byte number of var, in which error occurred |
| 0       | 5      | Format conversion error                     | Error on conversion of var. type double: Var. is not within S7 REAL area                              |
| 0       | 6      | FIFO full                                   | Job must be repeated since queue is full                                                              |

13.13 Block descriptions

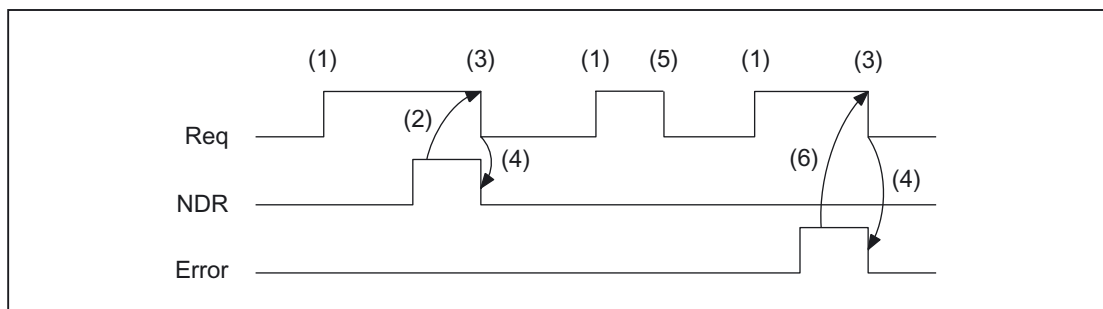

| State   |           | Significance                 | Note                                           |
|---------|-----------|------------------------------|------------------------------------------------|
| WORD H  | WORD L    |                              |                                                |
| 0       | 7         | Option not set               | BP parameter "NCKomm" is not set               |
| 1 ... 8 | 8         | Incorrect target area (RD)   | RD1 to RD8 may not be local data               |
| 0       | 9         | Transmission occupied        | Job must be repeated                           |
| 1 ... 8 | 10        | Error in variable addressing | Unit or column/line contains value 0           |
| 0       | 11        | Address of variable invalid  | Check Addr (or variable name), area, unit      |
| 0       | 12        | NumVar = 0                   | Check parameter NumVar                         |
| 1 ... 8 | 13 (0x0d) | ANY data reference incorrect | NcVar date required has not been parameterized |

**Configuration steps**

Proceed as follows to read NC variables:

- Select variables with the NC VAR selector.
- Save selected variables in a \*.VAR file
- Generate a STEP 7 \*.STL source file.
- Generate a DB with the associated address data.
- Enter the symbol for the generated DB in the symbol table so that it is possible to access the address parameters symbolically in the user program.
- Set FB2 parameters

**Pulse diagram**

- (1) Activation of function
- (2) Positive acknowledgment: Receive new data
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change by means of FB
- (5) Not permissible
- (6) Negative acknowledgment: Error has occurred, error code in the output parameter State

### Call example

Reading of three channel-specific machine data from channel 1, whose address specifications are stored in DB120.

Select data with NC VAR selector and store in file DB120.VAR; then create file DB120.AWL:

| Area | Block | Name                                | Type | No.   | Byte | S7 Name                |
|------|-------|-------------------------------------|------|-------|------|------------------------|
| C[1] | M     | MD20070 \$MC_AXCONF_MACHAX_USED[1]  | char | 20070 | 1    | C1AxConfMachAx Used1   |
| C[1] | M     | MD20070 \$MC_AXCONF_MACHAX_USED[2]  | char | 20070 | 1    | C1AxConfMachAx Used2   |
| C[1] | M     | MD20090 \$MC_SPIND_DEF_MASTER_SPIND | int  | 20090 | 1    | C1SpindDefMaster Spind |

S7 (ALIAS) names have been selected in order to:

- Incorporate the channel designation into the name  
and
- Remove the characters [ ], which are not legal in a STEP 7 symbol.

Entry of the name in the S7 SYMBOL table (e.g. NCVAR for DB120):

| Symbol | Operand | Data type |
|--------|---------|-----------|
| NCVAR  | DB 120  | DB 120    |

File DB120.AWL must be compiled and transferred to the PLC.

Parameterization of FB 2 with instance DB 110:

```

DATA_BLOCK DB 110 //Unassigned user DB, as instance for FB 2
FB 2
BEGIN
END_DATA_BLOCK
Function FC "VariablenCall" : VOID
 U I 7.7; //Unassigned machine control panel key
 S M 100.0; //Activate req.
 U M 100.1; //NDR completed message
 R M 100.0; //Terminate job
 U I 7.6; //Manual error acknowledgment
 U M 102.0; //Error pending
 R M 100.0; //Terminate job
 CALL FB 2, DB 110 (
 Req := M 100.0,
 NumVar := 3, //Read 3 variables
 Addr1 := NCVAR.C1AxConfMachAxUsed1,
 Addr2 := NCVAR.C1AxConfMachAxUsed2,
 Addr3 := NCVAR.C1SpindDefMasterSpind,
 Error := M102.0,
 NDR := M100.1,
 State := MW104,
)

```

13.13 Block descriptions

```
RD1 := P#DB99.DBX0.0 BYTE 1,
RD2 := P#DB99.DBX1.0 BYTE 1,
RD3 := P#M110.0 INT 1);
```

**Example: Variable addressing**

Reading of two R parameters of channel 1, whose address specifications are stored in DB 120 as the basic type. The R parameter number is parameterized via parameter LineX.

```
DATA_BLOCK DB 120
VERSION : 0.0
STRUCT
 C1_RP_rpa0_0:
 STRUCT
 SYNTAX_ID : BYTE := B#16#82;
 area_and_unit : BYTE := B#16#41;
 column : WORD := W#16#1;
 line : WORD := W#16#0;
 block type : BYTE := B#16#15;
 NO. OF LINES : BYTE := B#16#1;
 type : BYTE := B#16#F;
 length : BYTE := B#16#8;
 END_STRUCT;
END_STRUCT;
BEGIN
END_DATA_BLOCK
 CALL FB 2, DB 110 (
 Req := M 0.0,
 NumVar := 2,
 Addr1 := "NCVAR".C1_RP_rpa0_0,
 Line1 := W#16#1,
 Addr2 := "NCVAR".C1_RP_rpa0_0,
 Line2 := W#16#2,
 Error := M 1.0,
 NDR := M 1.1,
 State := MW 2,
 RD1 := P#M 4.0 REAL 1,
 RD2 := P#M 24.0 REAL 1);
```

## Data types

The data types of the NCK are listed in the NC-VAR selector with the variables. The tables below give the assignments to the S7 data types.

| Classification of data types |               |
|------------------------------|---------------|
| NCK data type                | S7 data type  |
| double                       | REAL          |
| double                       | REAL2         |
| float                        | REAL          |
| long                         | DINT          |
| integer                      | DINT          |
| uint_32                      | DWORD         |
| int_16                       | INT           |
| uint_16                      | WORD          |
| unsigned                     | WORD          |
| char                         | CHAR or BYTE  |
| string                       | STRING        |
| bool                         | BOOL          |
| datetime                     | DATE_AND_TIME |

In order to read a double variable from the NCK without adapting the format, an ANY pointer of the REAL 2 type must be specified in the target area for read data (e.g. P#M100.0 REAL 2). If the basic program recognizes REAL 2 as the target type when reading a double variable, the data is applied to the PLC data area as a 64-bit floating point number.

### 13.13.3 FB 3: PUT write NC variables

#### Function

The PLC user program can write variables in the NCK area using FB PUT. The FB is multi-instance-capable.

Every FB 3 call must be assigned a separate instance DB from the user area.

When FB 3 is called with a positive signal edge change at control input Req, a job is started to overwrite the NC variables referenced by Addr1 to Addr8 with the data of the PLC operand areas locally referenced by SD1 to SD8. Successful completion of the write process is indicated by a logical "1" in status parameter "Done".

The **write process** lasts for several PLC cycles (normally 1-2). The block can be called up in cyclic mode only.

Any errors are indicated by Error and State.

In order to reference the NC variables, all required variables are first selected with the "NC VAR selector" tool and generated as STL source in a data block. A name must then be assigned to this DB in the symbol table.

"DB name.S7 name" is transferred as the actual parameter of the NCK variable address (Addr1 to Addr8) when FB 3 is called.

### Variable addressing

For some NC variables, it is necessary to select area no. and/or line or column in the NC VAR selector. For these variables it is possible to select a basic type, i.e. area/column/row is filled with "0" by default.

The contents of the area number, line and column specified by the NC VAR selector are checked for a "0" in the FB. If a "0" is present, the value is transferred to the input parameter. The user must supply the required parameters (UnitX/ColumnX/LineX) before calling Here unit corresponds to area no., column to column and line to row.

### Machine data, GUD

In order to define machine data and GUDs without a password, the protection levels of the data you want to access must be redefined to the lowest level.

**Reference:**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NOTICE</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <p>FB 3 can only write NC variables if basic program parameter "NCKomm" has been set to "1" (in OB 100: FB 1, DB 7). The call is permitted only in cyclic program OB1. An assignment for all parameters with Req = 0 is also permitted in OB 100.</p> <p>When <b>channel-specific</b> variables are written, only variables from <b>one</b> and the same channel may be addressed via Addr1 to Addr8 in a job (FB 3 call).</p> <p>In areas V and H, different logic axis numbers must not be assigned in a single job. (Failure to observe this rule results in Error:= TRUE, State:= W#16#02).</p> |

NCK variables within **one** group can be combined in a job:

|         | Area |      |   |   |   |
|---------|------|------|---|---|---|
| Group 1 | C[1] | N    | B | A | T |
| Group 2 | C[2] | N    | B | A | T |
| Group 3 | V[.] | H[.] |   |   |   |

The same rules apply to channels 3 to 10 as illustrated as examples in the above table in groups 1 and 2.

---

**Note**

Especially when reading several long strings, the number of usable variables can be less than 8.

---

## Declaration of the function

**Description of formal parameters**

The table below lists all formal parameters of the PUT function.

| Signal                  | Type | Type | Range of values                                     | Remark                                                           |
|-------------------------|------|------|-----------------------------------------------------|------------------------------------------------------------------|
| Req                     | I    | BOOL |                                                     | Job start with positive signal edge                              |
| NumVar                  | I    | INT  | 1 to 8<br>(corresponds to use of<br>Addr1 to Addr8) | Number of variables to be written                                |
| Addr1 to Addr8          | I    | ANY  | [DBName].[VarName]                                  | Variable identifiers from<br><b>NC Var selector</b>              |
| Unit 1 to Unit 8        | I    | BYTE |                                                     | Area address, optional for<br>variable addressing                |
| Column 1 to Column<br>8 | I    | WORD |                                                     | Column address, optional for<br>variable addressing              |
| Line 1 to Line 8        | I    | WORD |                                                     | Line address, optional for variable<br>addressing                |
| Error                   | O    | BOOL |                                                     | Negative acknowledgment of job<br>or execution of job impossible |
| Done                    | O    | BOOL |                                                     | Job successfully executed                                        |
| State                   | O    | WORD |                                                     | See error identifiers                                            |
| SD1 to SD8              | I/O  | ANY  | P#Mm.n BYTE x...<br>P#DBnr.dbxm.n BYTE x            | Data to be written                                               |

## Error identifiers

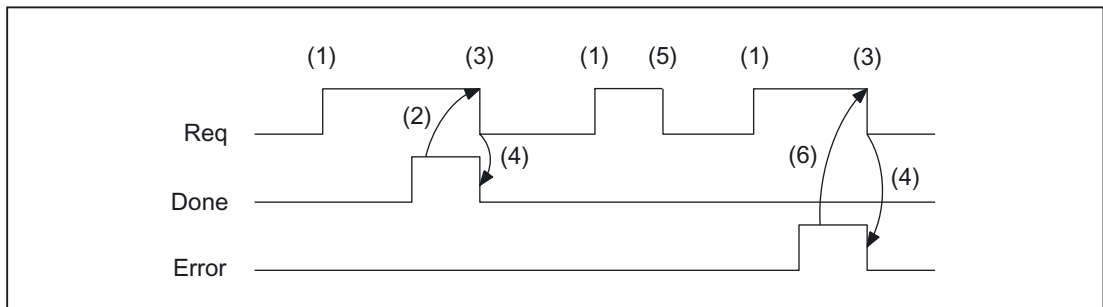

If it was not possible to execute a job, the failure is indicated by "logic 1" on status parameter error. The error cause is coded at the block output State:

| State   |           | Significance                                             | Note                                                                                           |
|---------|-----------|----------------------------------------------------------|------------------------------------------------------------------------------------------------|
| WORD H  | WORD L    |                                                          |                                                                                                |
| 1 to 8  | 1         | Access error                                             | In high byte number of Var in which error occurred                                             |
| 0       | 2         | Error in job                                             | Incorrect compilation of Var in a job                                                          |
| 0       | 3         | Negative acknowledgment, job not executable              | Internal error, try: Check job, NC RESET                                                       |
| 1 ... 8 | 4         | Data areas or data types do not match or string is empty | Check data to be written in SD1 to SD8; in high byte number of the Var in which error occurred |
| 0       | 6         | FIFO full                                                | Job must be repeated since queue is full                                                       |
| 0       | 7         | Option not set                                           | BP parameter "NCKomm" is not set                                                               |
| 1 ... 8 | 8         | Incorrect target area (SD)                               | SD1 to SD8 may not be local data                                                               |
| 0       | 9         | Transmission occupied                                    | Job must be repeated                                                                           |
| 1 ... 8 | 10        | Error in variable addressing                             | Unit or column/line contains value 0                                                           |
| 0       | 11        | Variable addr. invalid or var. is read-only              | Check Addr (or variable name), area, unit                                                      |
| 0       | 12        | NumVar = 0                                               | Check parameter NumVar                                                                         |
| 1 to 8  | 13 (0x0d) | ANY data reference incorrect                             | NcVar date required has not been parameterized                                                 |
| 1 to 8  | 15 (0x0f) | User data too long                                       | Remedy: Pack fewer variables in the job or use shorter string variables                        |

## Configuration steps

To write NC variables, the same configuration steps are required as for reading NC variables. It is useful to store the address data of all NC variables to be read or written in a DB.

**Pulse diagram**

- (1) Activation of function
- (2) Positive acknowledgment: variables have been written
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change by means of FB
- (5) Not permissible
- (6) Negative acknowledgment: Error has occurred, error code in output parameter state

**Call example**

Writing of three channel-specific machine data of channel 1:

**Select the three data with NC VAR selector and store in the file DB120.VAR:**

| Area | Block | Name    | Type   | Byte | S7 Name    |
|------|-------|---------|--------|------|------------|
| C[1] | RP    | rpa[5]  | DOUBLE | 4    | rpa_5C1RP  |
| C[1] | RP    | rpa[11] | DOUBLE | 4    | rpa_11C1RP |
| C[1] | RP    | rpa[14] | DOUBLE | 4    | rpa_14C1RP |

**Entry NCVAR for DB 120 with the S7 SYMBOL Editor:**

| Symbol | Operand | Data type |
|--------|---------|-----------|
| NCVAR  | DB 120  | DB 120    |

File DB120.AWL must be compiled and transferred to the PLC.

**Call and parameterization of FB 3 with instance DB 111:**

```

DATA_BLOCK DB 111 //Unassigned user DB, as instance for FB 3
FB 3
BEGIN
Function FC "VariablenCall": VOID
END_DATA_BLOCK
 U I 7.7; //Unassigned machine control panel key
 I M 100.0; //Activate req.
 U M 100.1; //Done completed message
 R M 100.0; //Terminate job
 U I 7.6; //Manual error acknowledgment

```

```

U M 102.0; //Error pending
R M 100.0; //Terminate job
CALL FB 3, DB 111 (
 Req := M 100.0,
 NumVar := 3, //Write 3 variables
 Addr1 := NCVAR.rpa_5C1RP,
 Addr2 := NCVAR.rpa_11C1RP,
 Addr3 := NCVAR.rpa_14C1RP,
 Error := M102.0,
 Done := M100.1,
 State := MW104,
 SD1 := P#DB99.DBX0.0 REAL 1,
 SD2 := P#DB99.DBX4.0 REAL 1,
 SD3 := P#M110.0 REAL 1);

```

### Example: Variable addressing

Writing of two R parameters of channel 1, whose address specifications are stored in DB 120 as the basic type. The R parameter number is parameterized via parameter LineX.

```

DATA_BLOCK DB 120
VERSION : 0.0
STRUCT
 C1_RP_rpa0_0:
 STRUCT
 SYNTAX_ID : BYTE := B#16#82;
 area_and_unit : BYTE := B#16#41;
 column : WORD := W#16#1;
 line : WORD := W#16#0;

 NO. OF LINES : BYTE := B#16#1;
 type : BYTE := B#16#F;
 length : BYTE := B#16#8;
 END_STRUCT;
END_STRUCT;
BEGIN
END_DATA_BLOCK
CALL FB 3, DB 122 (
 Req := M 10.0,
 NumVar := 2,
 Addr1 := "NCVAR".C1_RP_rpa0_0,
 Line1 := W#16#1,
 Addr2 := "NCVAR".C1_RP_rpa0_0,
 Line3 := W#16#2

```

13.13 Block descriptions

---

```
Error := M 11.0,
Done := M 11.1,
State := MW 12,
SD1 := P#M 4.0 REAL 1,
SD2 := P#M 24.0 REAL 1);
```

### 13.13.4 FB 4: PI\_SERV PI services

#### Function

FB PI\_SERV can be used to start program-instance services in the NCK area.

---

**Note**

Recommendation: Use the extended FB 7 in place of FB 4.

---

A program section, which carries out a particular function (e.g. with tool management, search for empty location in a magazine), is executed in the NCK by making a request via the PI service.

Every FB 4 call must be assigned an instance DB from the user area.

The specified service is referenced via the "PIService" parameter. The selected PI service is supplied via the freely assignable additional input variables with varying data types (Addr1 to Addr4 for strings, WVar1 to WVar 10 for INTEGER or WORD variables).

A job is started when **FB 4 is called** by means of a positive edge change at control input Req. Successful execution of the job is displayed by means of a logical "1" in status parameter "Done". Any errors are indicated by Error and State.

The "PI" data block (DB16) contains internal descriptions of the possible PI services. A name must then be assigned to this DB in the signal list. On calling the FB 4, "DB-Name.PI-Name" is transferred as the actual parameter for "PIService".

The execution of the PI service extends over several PLC cycles (generally 1 to 2). The block can be called up in cyclic mode only.

---

**Note**

FB 4 can start PI services only if the basic program parameter "NCKomm" has been set to "1" (in OB 100: FB 1, DB 7). The call is permitted only in cyclic program OB1. An assignment for all parameters with Req = 0 is also permitted in OB 100.

---

## Declaration of the function

```

FUNCTION_BLOCK FB 4
VAR_INPUT
 Req : BOOL ;
 PIService : ANY ;
 Unit : INT ;
 Addr1 : ANY ;
 Addr2 : ANY ;
 Addr3 : ANY ;
 Addr4 : ANY ;
 WVar1 : WORD ;
 WVar2 : WORD ;
 WVar3 : WORD ;
 WVar4 : WORD ;
 WVar5 : WORD ;
 WVar6 : WORD ;
 WVar7 : WORD ;
 WVar8 : WORD ;
 WVar9 : WORD ;
 WVar10 : WORD ;
END_VAR
VAR_OUTPUT
 Error : BOOL ;
 Done : BOOL ;
 State : WORD ;
END_VAR

```

## Description of formal parameters

The following table shows all formal parameters of the function PI\_SERV.

| Signal          | Type | Type | Range of values                                      | Remark                                                                     |
|-----------------|------|------|------------------------------------------------------|----------------------------------------------------------------------------|
| Req             | I    | BOOL |                                                      | Job request                                                                |
| PIService       | I    | ANY  | [DBName].[VarName]<br>Standard is:<br>"PI".[VarName] | PI service description <sup>1)</sup>                                       |
| Unit            | I    | INT  | 1...                                                 | Area number                                                                |
| Addr1 to Addr4  | I    | ANY  | [DBName].[VarName]                                   | Reference to strings specification according to selected PI service        |
| WVar1 to WVar10 | I    | WORD | 1...                                                 | INTEGER or WORD variables. Specification according to selected PI service, |
| Error           | O    | BOOL |                                                      | Negative acknowledgment of job or execution of job impossible              |

13.13 Block descriptions

| Signal | Type | Type | Range of values | Remark                    |
|--------|------|------|-----------------|---------------------------|
| Done   | O    | BOOL |                 | Job successfully executed |
| State  | O    | WORD |                 | See error identifiers     |

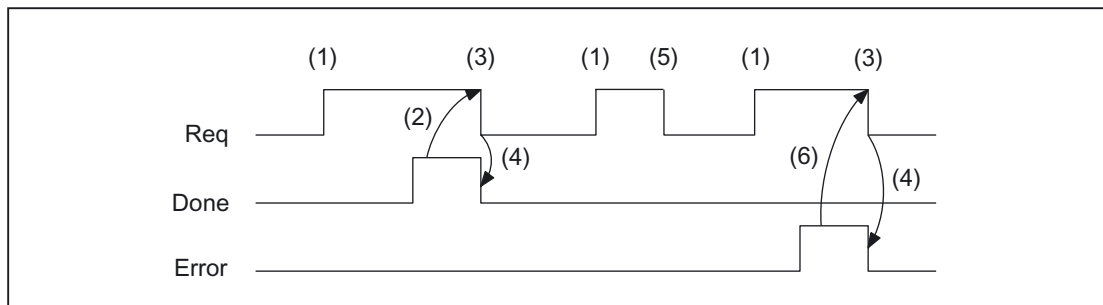

1) See README file on basic program diskette supplied

**Error identifiers**

If it was not possible to execute a job, the failure is indicated by "logic 1" on status parameter error. The error cause is coded at the block output State:

| State     | Significance                                | Note                                            |
|-----------|---------------------------------------------|-------------------------------------------------|
| 3         | Negative acknowledgment, job not executable | Internal error, try:<br>NC RESET                |
| 6         | FIFO full                                   | Job must be repeated since queue is full        |
| 7         | Option not set                              | BP parameter "NCKomm" is not set                |
| 9         | Transmission occupied                       | Job must be repeated                            |
| 13 (0x0d) | ANY data reference incorrect                | String date required has not been parameterized |
| 14 (0x0e) | PIService parameter reference incorrect     | No valid PI description                         |
| 15 (0x0f) | String too long                             | Addr1.. Check Addr4 strings                     |

**Timing diagram**

- (1) Activation of function
- (2) Positive acknowledgment: PI service has been executed
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change by means of FB
- (5) Not permissible
- (6) Negative acknowledgment: Error has occurred, error code in the output parameter State

### 13.13.4.1 Overview of available PI services

The following section provides an overview of the PI services that can be started from the PLC.

The significance and application of the general FB 4 input variables (Unit, Addr ..., WVar ...) depend on the individual PI service concerned.

Table 13- 3 General PI services

| PI service | Function                                      |
|------------|-----------------------------------------------|
| ASUB       | Assign interrupt                              |
| CANCEL     | Execute cancel                                |
| CONFIG     | Reconfiguration of tagged machine data        |
| DIGION     | Digitizing on                                 |
| DIGIOF     | Digitizing off                                |
| FINDBL     | Activate block search                         |
| LOGIN      | Activate password                             |
| LOGOUT     | Reset password                                |
| NCRES      | Trigger NC-RESET                              |
| SELECT     | Select program for processing for one channel |
| SETUDT     | Sets the current user data to active          |
| SETUFR     | Activate user frame                           |

Table 13- 4 PI services of tool management

| PI service | Function                                                     |
|------------|--------------------------------------------------------------|
| CRCEDN     | Create new cutting edge                                      |
| CREACE     | Create cutting edge                                          |
| CREATO     | Generate tool                                                |
| DELECE     | Delete a cutting edge                                        |
| DELETO     | Delete tool                                                  |
| MMCSEM     | Semaphores for various PI services                           |
| TMCRT0     | Create tool                                                  |
| TMFDPL     | Empty location search for loading                            |
| TMFPBP     | Empty location search                                        |
| TMGETT     | T number for the specified tool identifier with duplo number |
| TMMVTL     | Prepare magazine location for loading, unload tool           |
| TMPOSM     | Position magazine location or tool                           |
| TMPCIT     | Set increment value for workpiece counter                    |
| TMRASS     | Reset active status                                          |
| TRESMO     | Reset monitoring values                                      |
| TSEARC     | Complex search using search screen forms                     |

### 13.13.4.2 General PI services

#### PI service: ASUB

**Function: Assign interrupt**

A program stored on the NCK is assigned an interrupt signal for a channel. This is possible only when the program file may be executed. The path names and the program names are to be written in correct notation.

For the correct notation of the path and the program names see:

**References:**

Programming Manual Job Planning; Chapter: "File and Program Management" > "Program Memory".

| Parameterization |        |             |                  |
|------------------|--------|-------------|------------------|
| Signal           | Type   | Value range | Meaning          |
| PIService        | ANY    | PI.ASUP     | Assign interrupt |
| Unit             | INT    | 1 ... 10    | Channel          |
| WVar1            | WORD   | 1 ... 8     | Interrupt number |
| WVar2            | WORD   | 1 ... 8     | Priority         |
| WVar3            | WORD   | 0/1         | LIFTFAST         |
| WVar4            | WORD   | 0/1         | BLSYNC           |
| Addr1            | STRING |             | Path name        |
| Addr2            | STRING |             | Program name     |

**Note**

The SETINT instruction is also used to make the assignment.

The ASUP PI service may only be executed when the channel to be activated is in RESET state.

**References:**

Programming Manual, Job Planning; Chapter: "Flexible NC-Programming" > "Interrupt routine (ASUB)"

#### PI service: CANCEL

**Function: Execute Cancel**

Has the effect that the function "Cancel" (corresponding to the key on HMI) is executed.

| Parameterization |      |             |         |
|------------------|------|-------------|---------|
| Signal           | Type | Value range | Meaning |
| PIService        | ANY  | PI.CANCEL   | Cancel  |

**PI service: CONFIG****Function: Reconfiguration**

The reconfiguration command activates machine data, which have been entered sequentially by the operator or the PLC, almost in parallel.

The command can only be activated when the control is in RESET state or the program is interrupted (NC stop at block limit). An FB 4 error checkback message is output if these conditions are not fulfilled (state = 3).

| Parameterization |      |             |                 |
|------------------|------|-------------|-----------------|
| Signal           | Type | Value range | Meaning         |
| PIService        | ANY  | PI.CONFIG   | Reconfiguration |
| Unit             | INT  | 1           |                 |
| WVar1            | INT  | 1           | Classification  |

**PI service: DIGION****Function: Digitizing on**

Selecting digitizing in the specified channel.

| Parameterization |      |             |               |
|------------------|------|-------------|---------------|
| Signal           | Type | Value range | Meaning       |
| PIService        | ANY  | PI.DIGION   | Digitizing on |
| Unit             | INT  | 1 to 10     | Channel       |

**PI service: DIGIOF****Function: Digitizing off**

Deactivating digitizing in the specified channel.

| Parameterization |      |             |                |
|------------------|------|-------------|----------------|
| Signal           | Type | Value range | Meaning        |
| PIService        | ANY  | PI.DIGIOF   | Digitizing off |
| Unit             | INT  | 1 to 10     | Channel        |

**PI service: FINDBL****Function: Activate block search**

A channel is switched to block search mode and the appropriate acknowledgment then transmitted. The block search is then executed immediately by the NCK. The search pointer must already be in the NCK at this point in time. The search can be interrupted at any time by an NC RESET. Once the search is successfully completed, the normal processing mode is reactivated automatically. NC Start then takes effect from the located search target. The operator is responsible for providing a collision-free approach path.

13.13 Block descriptions

| Parameterization |      |             |                    |
|------------------|------|-------------|--------------------|
| Signal           | Type | Value range | Meaning            |
| PIService        | ANY  | PI.FINDBL   | Block search       |
| Unit             | INT  | 1 to 10     | Channel            |
| WVar1            | WORD | x           | Preprocessing mode |

- x Writes the preprocessing mode
- Value:      Meaning:
- = 1          Without calculation
- = 2          With calculation
- = 3          with main block consideration

**PI service: LOGIN**

**Function: Create password**

Transfers the parameterized password to the NCK. The passwords generally consist of 8 characters. If required, blanks must be added to the string of the password.

**Example:**

Password: STRING[8] := 'SUNRISE';

| Parameterization |        |              |                 |
|------------------|--------|--------------|-----------------|
| Signal           | Type   | Value range  | Meaning         |
| PIService        | ANY    | PI.LOGIN     | Create password |
| Unit             | INT    | 1            | NCK             |
| Addr1            | STRING | 8 characters | Password        |

**PI service: LOGOUT**

**Function: Reset password**

The password last transferred to the NCK is reset.

| Parameterization |      |             |                |
|------------------|------|-------------|----------------|
| Signal           | Type | Value range | Meaning        |
| PIService        | ANY  | PI.LOGOUT   | Reset password |
| Unit             | INT  | 1           | NCK            |

**PI service: NCRES**

**Function: Trigger NC-RESET**

Initiates an NCK RESET. The Unit and WVar1 parameters must be assigned 0.

| Parameterization |      |             |                  |
|------------------|------|-------------|------------------|
| Signal           | Type | Value range | Meaning          |
| PIService        | ANY  | PI.NCRES    | Trigger NC-RESET |
| Unit             | INT  | 0           | 0                |
| WVar1            | WORD | 0           | 0                |

### PI service: SELECT

#### Function: Select processing for a channel

A program stored on the NCK is selected for processing for one channel. This is possible only if the file may be executed. The path name and program name must be entered as described in the Programming Manual Job Planning, File and Program Management, Section "Program Memory". Please also refer to example of FB 4 for notation of path and program names.

#### Possible block types

| Block types              |     |
|--------------------------|-----|
| Workpiece directory      | WPD |
| Main program             | MPF |
| Subroutine               | SPF |
| cycles                   | CYC |
| Asynchronous subprograms | ASP |
| Binary files             | BIN |

| Parameterization |        |             |                   |
|------------------|--------|-------------|-------------------|
| Signal           | Type   | Value range | Meaning           |
| PIService        | ANY    | PI.SELECT   | Program selection |
| Unit             | INT    | 1 ... 10    | Channel           |
| Addr1            | STRING |             | Path name         |
| Addr2            | STRING |             | Program name      |

### PI service: SETUDT

#### Function: Set function current user data active

The current user data, such as tool offsets, basic frames and settable frames are set to active in the next NC block (only in STOP state).

| Parameterization |      |                 |                    |
|------------------|------|-----------------|--------------------|
| Signal           | Type | Range of values | Meaning            |
| PIService        | ANY  | PI.SETUDT       | Activate user data |
| Unit             | INT  | 1 to 10         | Channel            |

13.13 Block descriptions

| Parameterization |      |                 |                                  |
|------------------|------|-----------------|----------------------------------|
| Signal           | Type | Range of values | Meaning                          |
| WVar1            | WORD | 1 to 5          | User Data Type                   |
|                  |      |                 | 1 = active tool offset           |
|                  |      |                 | 2 = active Basic frame           |
|                  |      |                 | 3 = active settable frame        |
|                  |      |                 | 4 = active global Basic frame    |
|                  |      |                 | 5 = active global settable frame |
| WVar2            | WORD | 0               | Standby                          |
| WVar3            | WORD | 0               | Standby                          |

PI service: SETUFR

Function: Activate user frames

User frames are loaded to the NCK. All necessary frame values must be transferred to the NCK beforehand by writing variables with FB 3.

| Parameterization |      |             |                      |
|------------------|------|-------------|----------------------|
| Signal           | Type | Value range | Meaning              |
| PIService        | ANY  | PI.SETUFR   | Activate user frames |
| Unit             | INT  | 1 to 10     | Channel              |

13.13.4.3 PI services of tool management

PI service: CRCEDN

Function: Create new cutting edge

If the T number of an existing tool is specified in parameter "T number" in the PI service, then a cutting edge is set up for this particular tool (in this case, parameter "D number" (number of cutting edge to be created) has a value range of 00001–00009). If a positive T number is specified as a parameter and the tool for the T number entered does not exist, then the PI service is aborted. If a value of 00000 is entered as the T number (model of absolute D numbers), then the D number values can range from 00001–31999. The new cutting edge is set up with the specified D number. If the specified cutting edge already exists, then the PI service is aborted in both cases.

| Parameterization |      |                 |                         |
|------------------|------|-----------------|-------------------------|
| Signal           | Type | Range of values | Significance            |
| PIService        | ANY  | PI.CRCEDN       | Create new cutting edge |
| Unit             | INT  | 1 ... 10        | TOA                     |

| Parameterization |      |                          |                                                                                                                                                                       |
|------------------|------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signal           | Type | Range of values          | Significance                                                                                                                                                          |
| WVar1            | INT  |                          | T number of tool for which cutting edge must be created. A setting of 00000 states that the cutting edge should not refer to any particular tool (absolute D number). |
| WVar2            | INT  | 1 ... 9 or<br>01 - 31999 | Edge number of tool cutting edge                                                                                                                                      |

**PI service: CREACE****Function: Create cutting edge**

Creation of the cutting edge with the next higher/next unassigned D number for the tool with the transferred T number in TO, TS (if present). The cutting edge for the OEM cutting edge data is set up simultaneously in the TUE block - if one is present.

| Parameterization |      |                 |                     |
|------------------|------|-----------------|---------------------|
| Signal           | Type | Range of values | Significance        |
| PIService        | ANY  | PI.CREACE       | Create cutting edge |
| Unit             | INT  | 1 ... 10        | TOA                 |
| WVar1            | INT  |                 | T number            |

**PI service: CREATO****Function: Create tool**

Creation of a tool with specification of a T number. The tool is entered as existing in the tool directory area (TV). The first "cutting edge" D1 (with zero contents) is created for tool offsets in the TO block. D1 (with zero contents) is also created for the OEM "cutting edge" data in the TUE block - if one is present. If a TU block exists, it will contain the data set for the tool.

| Parameterization |      |                 |              |
|------------------|------|-----------------|--------------|
| Signal           | Type | Range of values | Significance |
| PIService        | ANY  | PI.CREATO       | Create tool  |
| Unit             | INT  | 1 ... 10        | TOA          |
| WVar1            | INT  |                 | T number     |

**PI service: DELECE**

**Function: Delete a tool cutting edge**

If the T number of an existing tool is specified in parameter “T number” in the PI service, then a cutting edge is deleted for this particular tool (in this case, parameter “D number” (number of cutting edge to be created) has a value range of 00001–00009). If a positive T number is specified as a parameter and the tool for the T number entered does not exist, then the PI service is aborted. If a value of 00000 is entered as the T number (model of absolute D numbers), then the D number values can range from 00001-31999. If the specified cutting edge does not exist, then the PI service is aborted in both cases.

| Parameterization |      |                               |                                                                                                                                                                       |
|------------------|------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**PI service: MMCSEM**

Semaphores for various PI services

**For use by HMI and PLC**

10 semaphores are provided for each channel. These protect critical functions for the HMI/PLC. By setting the semaphore for the corresponding function number, several HMI/PLC units can be synchronized with it in cases where a function contains a critical section with respect to data to be fetched by the NCK. Semaphores are managed by the HMI/PLC. A semaphore value of 1 stipulates a Test & Set operation for the semaphore of the specified function number. The return value of the PI service represents the result of this operation:

- Checkback value Done := TRUE: Semaphore has been set, critical function can be called
- Checkback value Error := TRUE with state = 3: Semaphore was already set, critical function cannot be called at the present time. The operation must be repeated later.

---

**Note**

On completion of the operation (reading data of this PI service) it is **essential** that the **semaphore is enabled again**.

---

**Parameter:**

WVar1 = FunctionNumber

This function number represents a PI service:

| Function number | PI service                                                  |
|-----------------|-------------------------------------------------------------|
| 1               | TMCRTO (create tool)                                        |
| 2               | TMFDPL (search for empty location for loading):             |
| 3               | TMMVTL (prepare magazine location for loading, unload tool) |
| 4               | TMFPBP (search for location)                                |
| 5               | TMGETT (search for tool number)                             |
| 6               | TSEARC (search for tool)                                    |
| 7 ... 10        | Reserved                                                    |

WVar2=SemaphorValue

| Value | Description            |
|-------|------------------------|
| 0:    | Reset semaphore        |
| 1:    | Test and set semaphore |

| Parameterization |      |                 |                |
|------------------|------|-----------------|----------------|
| Signal           | Type | Range of values | Significance   |
| PIService        | ANY  | PI.MMCSEM       | Set semaphore  |
| Unit             | INT  | 1, 2 to 10      | Channel        |
| WVar1            | INT  | 1 ... 10        | FunctionNumber |
| WVar2            | WORD | 0, 1            | SemaphoreValue |

**PI service: TMCRT0**

**Function Create tool:**

Creating a tool with specification:

- of an identifier, a duplo number, e.g. with:  
 $\$TC\_TP1[y] = \text{duplo number};$   
 $\$TC\_TP2[y] = \text{"tool identifier"};$
- optionally a T number, e.g. with:  
 $y = \text{T number}$

The tool is entered as existing in the tool directory area (TV). The first cutting edge "D1" (with zero contents) is created for tool offsets in the TO block. "D1" (with zero contents) is also set up for the monitoring data in the TS block, and simultaneously with zero contents for the OEM cutting edge data in the TUE block - if one is present. The TD block contains the identifier, duplo number and number of cutting edges (=1) for the T number that is entered optionally or allocated by the NCK.

If a TU block exists, it will contain the data set for the tool. After execution of the PI, the T number of the tool created is available in the TV block under **TnumWZV**.

**Note**

Before and after this PI service, the MMCSEM PI service must be called up with the associated parameter WVar1 for this PI service. See PI service MMCSEM for more information.

| Parameterization                                                                                                                                                             |        |                    |                 |

| T number > 0 means a T number must be specified<br>T number = -1 means that the NCK should allocate a T number<br>The example shows T number = -1 ⇒ T number assigned by NCK |        |                    |                 |

**PI service: TMFDPL**

**Function: Empty location search for loading**

(dependent on parameter assignment):

**Location\_number\_to = -1, Magazine\_number\_to = -1:**

Searches all magazines in the specified area (= channel) for an empty location for the tool specified with a T number. After execution of the PI, the magazine and locations numbers found during the search are listed in the configuration block of the channel (component **magCMCcmdPar1** (magazine number) and **magCMCcmdPar2** (location number)). Location\_number\_ID and magazine\_number\_ID can be set as search criteria or not (= -1). The PI is acknowledged positively or negatively depending on the search result.

**Location\_number\_to = -1, Magazine\_number\_to = Magazine\_number:**

An empty location for the tool specified with a T number is searched for in the specified magazine. Location\_number\_ID and magazine\_number\_ID can be set as search criteria or not (= -1). The PI is acknowledged positively or negatively depending on the search result.

**Location\_number\_to = Location\_number, Magazine\_number\_to = Magazine\_number:**

The specified location is checked, to confirm that it is free to be loaded with the specified tool. Location\_number\_ID and magazine\_number\_ID can be set as search criteria or not (= -1). The PI is acknowledged positively or negatively depending on the search result.

Command parameters 1 and 2 are located at source.

Loading: If source is an internal loading magazine, then the command parameters are located at the target (a real magazine).

Unloading: Source is always a real magazine.

**Note**

Before and after this PI service, the MMCSEM PI service must be called up with the associated parameter WVar1 for this PI service. See PI service MMCSEM for more information.

| Parameterization |      |                 |                            |

**PI service: TMFPBP**

**Function: Empty location search**

(dependent on parameter assignment):

For this see the description of FB 7: PI\_SERV2 General PI services

**PI service: TMGETT**

**Function: Determine T number for the specified tool identifier with duplo number**

Determining the T number for a specified tool identifier with duplo number. The PI-services stores the T number determined for the tool as result in the variable TnumWZV in the block TV. If the specified tool does not exist, then the T number "-0001" is returned. Since the PI-service returns a result in the variable TnumWZV, the service is to be stored with the semaphore mechanism (PI-service \_N\_MMCSSEM) with the function number for \_N\_TMGETT.

**Note**

Before and after this PI service, the MMCSSEM PI service must be called up with the associated parameter WVar1 for this PI service. See PI service MMCSSEM for more information.

| Parameterization |        |                    |                                                              |

| WVar2            | INT    |                    | Duplo number of the tool, for which the T number is searched |

**PI service: TMMVTL**

**Function: Prepare magazine location for loading, unload tool**

This PI service is used both to load and unload tools. Whether the PI initiates a loading or unloading operation depends on the assignment between the real locations and the "from" parameters and "to" parameters: Loading ⇒ 'From' = Loading point/station, unloading ⇒ 'To' = loading point/station

The TMMVTL PI service is used for all movements.

1. Loading and unloading (loading point ↔ magazine)
2. Loading and unloading (loading point ↔ buffer storage, e.g. spindle)
3. Relocation within a magazine
4. Relocation between different magazines
5. Relocation between magazine and buffer storage
6. Relocation within buffer storage

The following variables from the TM block are used to monitor case 1, 3, 4, 5:

magCmd (area no. = TO unit, line = magazine number)

magCmdState <- "acknowledgment"

The following variables from the TMC block are used to monitor case 2, 6):

magCBCmd (area no. = TO unit)

magCBCmdState <- "acknowledgment"

#### Load function

Prepares the specified real magazine for the specified channel for loading, i.e. traverses the magazine to the selected location for loading at the specified loading point/station (location\_number\_from, magazine\_number\_from) and inserts the tool.

When location\_number\_to = -1, an empty location for the tool specified by a T number is first sought in the specified magazine and the magazine then traversed. After execution of the PI, the number of the location found is listed in the TM area in component **magCMCmdPar2** for the **real** magazine of the channel.

With location\_number\_to = -2 and a valid magazine number, loading takes place into the currently queued magazine position of the specified magazine. After execution of the PI, the number of the location for tool loading is listed in the TM area in component **magCMCmdPar2** for the real magazine of the channel.

#### Unload function

The tool specified by the tool number is unloaded at the specified loading point/station (location\_number\_to, magazine\_number\_to), i.e. the magazine is traversed to the position for unloading and the tool is then removed. The magazine location for the tool is marked as being free in the TP block. The tool can be specified either via a T number or by means of the location and magazine numbers. The value -1 is entered at unused specification points.

#### Note

Before and after this PI service, the MMCSEM PI service must be called up with the associated parameter WVar1 for this PI service. See PI service MMCSEM for more information.

| Parameterization |      |                 |                                                       |

**PI service: TMPOSM**

**Function: Position magazine location or tool**

(dependent on parameter assignment):

A magazine location, which has either been specified directly or qualified via a tool located on it, is traversed to a specified position (e.g. in front of a load location) via the PI service.

The PI service makes a magazine location, which can be qualified in various ways, traverse in front of a specified load location. The load location must be specified in the PI parameters "location\_number\_from" and "magazine\_number\_from" (compulsory!).

The magazine location to be traversed can be qualified by the following:

- T number of the tool

The location where the tool is positioned traverses; the "tool identifier", "duplo number", "location\_number\_from" and "magazine\_number\_from" parameters are irrelevant (i.e. values "", "-0001", "-0001", "-0001").

or

- Tool identifier and duplo number

The location where the tool is positioned traverses; the "T number", "location\_number\_from" and "magazine\_number\_from" parameters are irrelevant (i.e. value "-0001" each).

or

- Direct specification of the location in the "location\_number\_from" and "magazine\_number\_from" parameters

The tool-qualifying parameters T number, "tool identifier" and "duplo number" are irrelevant (i.e. values "-0001", "", "-0001").

| Parameterization |        |                    |                                    |

| Signal           | Type | Range of values | Significance                                                                                                                                       |
| PIService        | ANY  | PI.TMPCIT       | Set increment value for workpiece counter                                                                                                          |
| Unit             | INT  | 1 ... 10        | TOA                                                                                                                                                |
| WVar1            | WORD | 0 ... max.      | Spindle number; corresponds to the type index in the location data with spindle location type of the buffer magazine in channel.000 = main spindle |
| WVar2            | WORD | 0 ... max.      | Increment value; indicates the number of spindle revolutions after which the workpiece counter is incremented                                      |

**PI service: TMRASS**

**Function: Reset the active status**

Resetting the active status on worn tools

This PI service is used to search for all tools with the tool status active and disabled. The active status is then canceled for these tools. Potentially appropriate times for this PI service are the negative edge of VDI signal "tool disable ineffective", an end of program, or a channel RESET. This PI service is intended mainly for the PLC, since it knows when the disabled tool is finally no longer to be used.

| Parameterization |      |                 |                     |
|------------------|------|-----------------|---------------------|

| PIService        | ANY  | PI. TMRASS      | Reset active status |
| Unit             | INT  | 1 ... 10        | TO area             |

**PI service: TRESMO**

**Function: Reset monitoring values**

This PI service resets the monitoring values of the designated edges of the designated tools to their setpoint (initial) values.

This only relates to tools with active monitoring.

Compare the NC-Speech Command `RESETMON.`

| Parameter assignment |      |               |                                                         |

|                      |      |             | 0: All active tool-monitoring functions (\$TC_TP9) are reset.                                                   |

**PI service: TSEARCH**

**Function: Complex search using search screen forms**

(dependent on parameter assignment):

The PI service allows you to search for tools with specified properties within a search domain (in one or more magazines starting and ending at a specific location). The specified properties refer only to data of the tools and their cutting edges.

The PI service is only available if tool management is activated.

You can define a search direction and the number of hits for the PI service (e.g. one tool for the next tool with matching properties or all tools with the specified properties).

As a result of this service, the user who made the call receives a list of the internal T numbers of the tools found.

The search criteria can only be specified as AND operation. If an application needs to define an OR operation for the search criteria, it must first execute a series of queries with AND criteria and then combine/evaluate the results of the individual queries.

To assign the parameters of the PI service, the properties of the required tools are first defined via variable service in the TF block. For this in the block TF in the operand masks (parMaskT..) the relevant

- comparison criteria (which tool data is to be compared?) are highlighted,
- comparison operator-data (parDataT..) filled with the corresponding comparison types (==, <, >, <=, >=, &&) to be executed
- and the comparison values are entered in the operand data.

The PI service is then initiated and, after its successful return, the variable service from the TF block is used to read out the number of hits in the variable resultNrOfTools and the result list in the variable resultToolNr (i.e. the list of internal T numbers of the tools found in the search - resultNrOfTools quantity).

The PI service must be encapsulated with a semaphore from its preparation until the successful return of the result. This is the only way to ensure exclusive access and the exclusive use of the TF block in conjunction with the TSEARC PI service. The function number provided for the semaphore feature (PI service MMCSEM) is the function number for TSEARC.

If the service is configured incorrectly, a malfunction occurs. In all other cases, it will return a result, even if no tools are found (resultNrOfTools = 0).

The search domain can be defined as follows in the parameters "MagNrFrom", "PlaceNrFrom", "MagNrTo", "PlaceNrTo":

| MagNr From | PlaceNr From | MagNr To | PlaceNr To | Search area                                                                                       |
|------------|--------------|----------|------------|---------------------------------------------------------------------------------------------------|
| WVar1      | WVar2        | WVar3    | WVar4      |                                                                                                   |
| #M1        | #P1          | #M2      | #P2        | Locations starting at magazine #M1, location #P1 up to magazine #M2, location #P2 are searched    |
| #M1        | -1           | #M1      | -1         | All locations in magazine #M1 - and no others - are searched                                      |
| #M1        | -1           | -1       | -1         | All locations starting at magazine #M1 are searched                                               |
| #M1        | #P1          | -1       | -1         | All locations starting at magazine #M1 and location #P1 are searched                              |
| #M1        | #P1          | #M1      | -1         | Locations in magazine #M1 starting at magazine #M1 and location #P1 in this magazine are searched |
| #M1        | #P1          | #M2      | -1         | Locations starting at magazine #M1, location #P1 up to magazine #M2, location #P2 are searched    |
| #M1        | -1           | #M2      | #P2        | Locations starting at magazine #M1 up to magazine #M2, location #P2 are searched                  |
| #M1        | -1           | #M2      | -1         | Locations starting at magazine #M1 up to and including magazine #M2 are searched                  |
| -1         | -1           | -1       | -1         | All magazine locations are searched                                                               |

For a symmetric search (see parameter "SearchDirection")

- the search area may stretch over only a single magazine (cases 2 and 5 from the above table). If another search domain is specified, the service will malfunction.
- a reference location must be entered in the parameters "MagNrRef" and "PlaceNrRef", with respect to which the symmetric search is done.

13.13 Block descriptions

The reference location is a buffer location (a location from the magazine buffer, i.e. change position, gripper, etc.) or a load point (a location from the internal loading magazine). The search is executed symmetrically with reference to the magazine location in front of the specified reference location. A multiple assignment to the magazine being searched must be configured in the TPM block for the reference location. If this is not the case, a malfunction occurs. If the magazine location in front of the reference location is outside the search domain, the service responds as if it has not found a matching location.

**Note**

Before and after this PI service, the MMCSEM PI service must be called up with the associated parameter WVar1 for this PI service. See PI service MMCSEM for more information.

| Parameter assignment |      |             |                                                                                                                                                                                                       |

|                      |      |             | 3: Browse all tools to search for the first tool found with this property                                                                                                                             |

## Call example

### Program selection in channel 1 (main program and workpiece program)

Entry of PI for DB 16 and STR for DB 124 with the S7 SYMBOL editor:

| Parameterization |         |           |
|------------------|---------|-----------|
| Symbol           | Operand | Data type |
| PI               | DB 16   | DB 16     |
| STR              | DB 124  | DB 124    |

```

DATA_BLOCK DB 126 //Unassigned user DB, as instance for FB 4
FB 4
BEGIN
END_DATA_BLOCK

DATA_BLOCK DB 124
 struct
 PName: string[32]:= '_N_TEST_MPF ';
 Path: string[32]:= '/_N_MPF_DIR/'; //Main program
 PName_WST: string[32]:= '_N_ABC_MPF';
 Path_WST: string[32]:= //Workpiece program
 '/_N_WCS_DIR/_N_ZYL_WPD';
 end_struct
BEGIN
END_DATA_BLOCK

Function FC "PICall" : VOID
 U I 7.7; //Unassigned machine control panel key
 S M 0.0; //Activate req.
 U M 1.1; //Done completed message
 R M 0.0; //Terminate job
 U I 7.6; //Manual error acknowledgment
 U M 1.0; //Error pending
 R M 0.0; //Terminate job

 CALL FB 4, DB 126 (
 Req := M0.0,
 PIService := PI.SELECT,
 Unit := 1, //CHAN 1
 Addr1 := STR.Path,
 Addr2 := STR.PName, //Main-program selection
 //Addr1:=STR.Path_WST,
 //Addr2:=STR.PName_WST, //Workpiece-program selection
 Error := M1.0,
 Done := M1.1,
 State := MW2);

```

### 13.13.5 FB 5: GETGUD read GUD variable

#### Function

The PLC user program can read a GUD variable (GUD = Global User Data) from the NCK or channel area using the FB GETGUD.

The FB has multi-instance capability. The call is permitted only in cyclic program OB1. An assignment for all parameters with Req = 0 is also permitted in OB 100. Capital letters must be used for the names of GUD variables.

Every FB 5 call must be assigned a separate instance DB from the user area.

A job is started when **FB 5 is called** by means of a positive edge change at control input Req. This job includes the name of the GUD variable to be read in parameter "Addr" with data type "STRING". The pointer to the name of the GUD variables is assigned symbolically to the "Addr" parameter with <DataBlockName>.<VariableName>. Additional information about this variable is specified in parameters "Area", "Unit", "Index1" and "Index2" (see table of block parameters).

When parameter "CnvToken" is activated, a variable pointer (token) can be generated for this GUD variable as an option. This pointer is generated via the NC-VAR selector for system variables of the NC. Only this method of generating pointers is available for GUD variables. Once a pointer has been generated for the GUD variable, then it is possible to read and write via FB 2 and FB 3 (GET, PUT) with reference to this variable pointer. This is the only method by which GUD variables can be read. When FB 2 or FB 3 is parameterized, only parameter Addr1 ... Addr8 need to be parameterized for this GUD variable pointer. GUD variable fields are an exception. In these fields Line1 to Line8 must also be parameterized with the field device from these variables. The successful completion of the read process is displayed by the status parameter "Done"=TRUE.

The read process extends over several PLC cycles (generally 1 to 2).

Any errors are displayed via the output parameters "Error" and "State".

---

#### Note

In order to read a double variable from the NCK without adapting the format, an ANY pointer of the REAL 2 type must be specified in the target area for read data (e.g.: P#M100.0 REAL 2). If the basic program recognizes REAL 2 as the target type when reading a "double" variable, the data is applied to the PLC data area as a 64-bit floating point number.

FB 5 can only write GUD variables if basic program parameter "NCKomm" has been set to "TRUE" (in OB 100: FB 1, DB 7; see "FB 1: RUN\_UP Basic program, start-up section (Page 946)").

---

#### Declaration of the function

```
FUNCTION_BLOCK FB 5 //Server name
 KNOW_HOW_PROTECT
 VERSION : 3.0
VAR_INPUT
 Req : BOOL;
 Addr: ANY ; //Variables name string
 Area BYTE ; //Area: NCK = 0, channel = 2
 Unit : BYTE ;
 Index1: INT; //Field index 1
 Index2: INT; //Field index 2
 CnvtToken: BOOL; //Conversion into 10-byte token
 VarToken ANY ; //Struct with 10 bytes for the variable token
END_VAR

VAR_OUTPUT
 Error : BOOL;
 Done : BOOL;
 State : WORD ;
END_VAR

VAR_IN_OUT
 RD: ANY ;
END_VAR

BEGIN
END_FUNCTION_BLOCK
```

### Description of formal parameters

The table below lists all formal parameters of the GETGUD function.

| Signal    | Type | Type | Value range                              | Comment                                                                          |
|-----------|------|------|------------------------------------------|----------------------------------------------------------------------------------|
| Req       | I    | BOOL |                                          | Job start with positive signal edge                                              |
| Addr      | I    | ANY  | [DBName].[VarName]                       | GUD variable name in a variable of data type STRING                              |
| Area      | I    | BYTE |                                          | Area address:                                                                    |
|           |      |      |                                          | 0: NCK variables                                                                 |
|           |      |      |                                          | 2: Channel variables                                                             |
| Unit      | I    | BYTE |                                          | NCK area: Unit:=1<br>Channel area: Channel no.                                   |
| Index1    | I    | INT  |                                          | Field index 1 of variable<br>Variable has the value 0 if no field index is used. |
| Index2    | I    | INT  |                                          | Field index 2 of variable<br>Variable has the value 0 if no field index is used. |
| CnvtToken | I    | BOOL |                                          | Activate generation of a 10 byte variable token                                  |
| VarToken  | I    | ANY  | [DBName].[VarName]                       | Address to a 10-byte token (see example)                                         |
| Error     | O    | BOOL |                                          | Negative acknowledgment of job or execution of job impossible                    |
| Done      | O    | BOOL |                                          | Job successfully executed                                                        |
| State     | O    | WORD |                                          | See error identifiers                                                            |
| RD        | I/O  | ANY  | P#Mm.n BYTE x...<br>P#DBnr.dbxm.n BYTE x | data to be read                                                                  |

### Error identifiers

If it was not possible to execute a job, the failure is indicated by "logic 1" on status parameter error. The error cause is coded at the block output State:

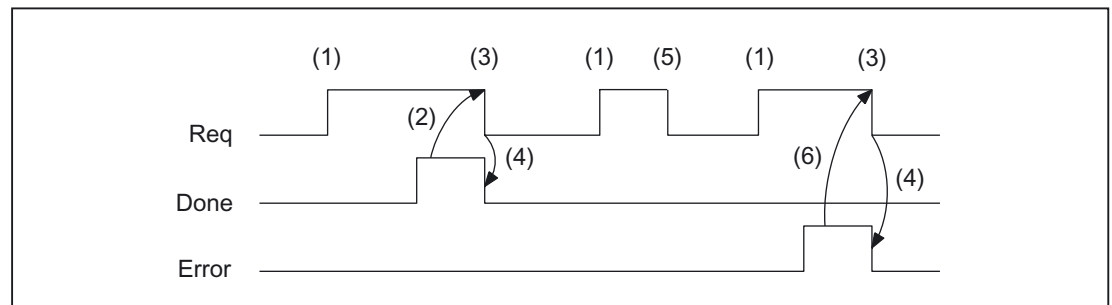

| State  |        | Meaning                                     | Note                                   |
|--------|--------|---------------------------------------------|----------------------------------------|
| WORD H | WORD L |                                             |                                        |
| 0      | 1      | Access error                                |                                        |
| 0      | 2      | Error in job                                | Incorrect compilation of Var. in a job |
| 0      | 3      | Negative acknowledgment, job not executable | Internal error, try:<br>NC RESET       |
| 0      | 4      | Data areas or data types do not tally       | Check data to be read in RD            |

| State   |           | Meaning                                  | Note                                                  |
|---------|-----------|------------------------------------------|-------------------------------------------------------|
| WORD H  | WORD L    |                                          |                                                       |
| 1       | 4         | Insufficient local user memory available | read variable is longer than specified in RD          |
| 0       | 6         | FIFO full                                | Job must be repeated, since queue is full             |
| 0       | 7         | Option not set                           | BP parameter "NCKomm" is not set                      |
| 0       | 8         | Incorrect target area (SD)               | RD may not be local data                              |
| 0       | 9         | Transmission occupied                    | Job must be repeated                                  |
| 0       | 10        | Error in addressing                      | Unit contains value 0                                 |
| 0       | 11        | Address of variable invalid              | Address check (or variable name), area, unit          |
| 1 ... 8 | 13 (0x0d) | ANY data reference incorrect             | String/NcVar data required has not been parameterized |
| 0       | 15 (0x0f) | String more than 32 characters           | GUD variable name too long                            |

### Configuration steps

To be able to read a GUD variable, its name must be stored in a string variable. The data block with this string variable must be defined in the symbol table so that the "Addr" parameter can be assigned symbolically for FB GETGUD. A structure variable can be defined optionally in any data area of the PLC to receive the variable pointer (see specification in following example).

### Pulse diagram

- (1) Activation of function
- (2) Positive acknowledgment: variables have been written
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change by means of FB
- (5) Not permissible
- (6) Negative acknowledgment: Error has occurred, error code in the output parameter "State"

**Call example 1**

Read a GUD variable from channel 1 with the name "GUDVAR1" (type definition of the variables: INTEGER). The user-defined variable should be converted in a 10-byte variable pointer for the subsequent writing with the F3 (see also the table "Assignment of the data types" in "FB 2: Read GET NC variable (Page 954)").

**Call and parameterization of FB 5 with instance DB 111:**

```
//Data block for GUD variable
DATA_BLOCK DB_GUDVAR //Assignment to symbol table

STRUCT
 GUDVar1 : STRING[32] := 'GUDVAR1'; //Name is defined by user
 GUDVar1Token :
 STRUCT
 SYNTAX_ID : BYTE ;
 area_and_unit : BYTE ;
 column : WORD ;
 line : WORD ;
 block type : BYTE ;
 NO. OF LINES : BYTE ;
 type : BYTE ;
 length : BYTE ;
 END_STRUCT;
END_STRUCT;

BEGIN
END_DATA_BLOCK

//Unassigned user DB, as instance for FB 5
DATA_BLOCK DB 111

 FB 5
BEGIN
END_DATA_BLOCK

//Unassigned user DB, as instance for FB 3
DATA_BLOCK DB 112

 FB 3
BEGIN
END_DATA_BLOCK

//A user-defined channel variable from channel 1 must be read
//with conversion into a variable pointer to allow subsequent
//writing of this variable.
```

```

Function FC "VariablenCall" : VOID
U I 7.7; //Unassigned machine control panel key
S M 100.0; //Activate req.
U M 100.1; //Done completed message
R M 100.0; //Terminate job
U I 7.6; //Manual error acknowledgment
U M 102.0; //Error pending
R M 100.0; //Terminate job

CALL FB 5, DB 111 (
 Req := M 100.0, //Starting edge for reading
 Area := B#16#2, //Channel variable
 Unit := B#16#1, //Channel 1
 Index1 := 0, //No field index
 Index2 := 0, //No field index
 CnvtToken := TRUE, //Conversion into 10-byte token
 VarToken := DB_GUDVAR.GUDVar1Token,
 Error := M 102.0,
 Done := M 100.1,
 State := MW 104
 RD := P#DB99.DBX0.0 DINT 1 //free memory area
);

```

After a successful FB-5 call the writing can be done via the returned address of the FB 5 parameter ("VarToken") with the help of FB3.

```

CALL FB 3, DB 112 (
 Req := M 200.0,
 NumVar := 1, //Write 1 GUD variable
 Addr1 := DB_GUDVAR.GUDVar1Token,
 Error := M 102.0,
 Done := M 100.1,
 State := MW 104
 SD1 := P#DB99.DBX0.0 DINT 1);

```

## Call example 2

Read a GUD variable from channel 1 with the name "GUD\_STRING" (type definition of the variables: STRING with length 30 bytes). The user-defined variable should be converted in a 10-byte variable pointer for subsequent writing with the FB 3.

### Call and parameterization of FB 5 with instance DB 111:

```

//Data block for GUD variable
DATA_BLOCK DB_GUDVAR //Assignment to symbol table

```

13.13 Block descriptions

```

STRUCT
 GUDVarS : STRING[32] := 'GUD_STRING'; //Name is defined by user
 GUDVarSToken :
 STRUCT
 SYNTAX_ID : BYTE ;

 VarToken := DB_GUDVAR.GUDVarSToken,
 Error := M 102.0,
 Done := M 100.1,
 State := MW 104
 RD := DB_GUDVAR.string_of_GUD);
```

After a successful FB-5 call the writing can be done via the returned address of the FB 5 parameter ("VarToken") with the help of FB3.

```
CALL FB 3, DB 112 (
 Req := M 200.0,
 NumVar := 1, //Write 1 GUD variable
 Addr1 := DB_GUDVAR.GUDVarSToken,
 Error := M 102.0,
 Done := M 100.1
 State := MW 104
 SD1 := DB_GUDVAR.new_name);
```

### 13.13.6 FB 7: PI\_SERV2 PI-services

#### Function

A detailed description of the FB 7 is contained in the description of FB 4.

The FB is multi-instance-capable. The call is permitted only in cyclic program OB1. An assignment for all parameters with Req = 0 is also permitted in OB 100.

The only difference to FB 4 is the number of WVar1 and subsequent parameters. These are defined in FB 7 from WVar1 to WVar16 (FB 4 in the VAR\_INPUT from WVar1 to WVar10). All the other parameters are identical to FB 4.

This PI server can be used for all PI services that have been implemented with FB 4. In addition, the PI services listed below can only be executed with FB 7.

### Declaration of the function

```

FUNCTION_BLOCK FB 7
Var_INPUT
 Req : BOOL ;
 PIService : ANY ;
 Unit : INT ;

| State           | O    | WORD |                    | See error identifiers                                                      |

### Overview: Additional PI-services supplementary to the FB 4 PI-services

The following section provides an overview of the PI services that can be started from the PLC. The significance and application of the general FB 7 input variables (Unit, Addr ..., WVar ...) depend on the individual PI service concerned.

| PI service | Function              | Available in   |
|------------|-----------------------|----------------|
| TMFPBP     | Empty location search | SINUMERIK 840D |

#### PI service:TMFPBP

##### Function: Empty location search

(dependent on parameter assignment)

This service searches the magazine(s) named in the relevant parameters for an empty location, which meets the specified criteria such as tool size and location type. The result of the empty location search can be fetched from variables magCMCmdPar1 (magazine number) and magCMCmdPar2 (location number) in block TMC when the service has functioned correctly. As the PI service stores a result in variables magCMCmdPar1 and magCMCmdPar2, the service must be protected by the semaphore mechanism (PI service MMCSEM) with the function number for \_N\_TMFDP in cases where several control units or PLCs are operating on one NC. The search area can be predefined in the following way by setting parameters "MagazineNumber\_From", "LocationNumber\_From", "MagazineNumber\_To", "LocationNumber\_To":

| Magazine Number_From | Location Number_From | Magazine Number_To | Location Number_To | Search area                                                                                    |
|----------------------|----------------------|--------------------|--------------------|------------------------------------------------------------------------------------------------|
| WVar1                | WVar2                | WVar3              | WVar4              |                                                                                                |
| #M1                  | #P1                  | #M1                | #P1                | Only location #P1 in magazine #M1 is checked                                                   |
| #M1                  | #P1                  | #M2                | #P2                | Locations starting at magazine #M1, location #P1 up to magazine #M2, location #P2 are searched |
| #M1                  | -1                   | #M1                | -1                 | All locations in magazine #M1 - and no others - are searched                                   |

| -1                       | -1                       | -1                     | -1                     | All magazine locations are searched                                                               |

**Note**

Before and after this PI service, the MMCSEM PI service must be called up with the associated parameter WVar1 for this PI service. See PI service MMCSEM for more information.

### 13.13.7 FB 9: MtoN Control unit switchover

#### Function

This block allows switchover between several **control units** (HMI operator panel fronts and/or MCP machine control panels), which are connected to one or more NCU control modules via a bus system.

#### References:

Function Manual, Extended Functions; Several Control Panels on Multiple NCUs, Decentralized Systems (B3)

The **Interface** between the individual control units and the NCU (PLC) is the M : N interface in the data block DB 19. The FB 9 works with the signals of these interfaces.

Apart from initialization, sign-of-life monitoring and error routines, the following **basic functions** are also performed by the block for control unit switchover:

| Tabulated overview of functions:          |                                                     |

| HMI queuing                               | HMI wants to go online with an NCU                  |
| HMI coming                                | HMI is connecting to an NCU                         |
| HMI going                                 | HMI is disconnecting from an NCU                    |
| Forced break                              | HMI must break connection with an NCU               |
| Operating focus changeover to server mode | Change operating focus from one NCU to the other    |
| Active/passive operating mode:            | Operator control and monitoring/monitoring only     |
| MCP switchover                            | As an option, MCP can be switched over with the HMI |

### Brief description of a few important functions

Active/passive operating mode:

An online HMI can operate in two different modes:

|               |                                        |
|---------------|----------------------------------------|
| Active mode:  | Operator can control and monitor       |
| Passive mode: | Operator can monitor (HMI header only) |

After switchover to an NCU, this initially requests active operating mode in the PLC of the online NCU. If two control units are linked online simultaneously to an NCU, one of the two is always in active mode and the other in passive mode. The operator can request active mode on the passive HMI at the press of a button.

### MCP switchover

As an option, an MCP assigned to the HMI can be switched over at the same time. To achieve this, the MCP address must be entered in the "mstt\_adress" parameter of the NETNAMES.INI configuration file on the HMI and "MCPEnable" must be set to TRUE. The MCP of the passive HMI is deactivated so that there is only ever one active MCP on an NCU at one time.

### Boot condition

To prevent the previously selected MCP being reactivated when the NCU is restarted, input parameters MCP1BusAdr = 255 (address of 1st MCP) and "MCP1STOP" =TRUE (deactivate 1st MCP) must be set when FB1 is called in OB100.

### Approvals

When one MCP is switched over to another, any active feed or axis enables will be retained.

---

#### Note

Keys actuated at the moment of switchover remain operative until the new MCP is activated (by the HMI, which is subsequently activated). The override settings for feedrate and spindle also remain valid. To deactivate actuated keys, the input image of the machine control signals must be switched to non-actuated signal level on a falling edge of DB10.DBX104.0. The override settings should remain unchanged. Measures for deactivating keys must be implemented in the PLC user program (see example "Override Changeover").

The call is permitted only in cyclic program OB1.

---

## Declaration of the function

```

FUNCTION_BLOCK FB 9
VAR_INPUT
 Ack : BOOL ; //Acknowledge interrupts
 OPMixedMode: BOOL:= FALSE; //Mixed operation with non-M-to-N-enabled
 //OP deactivated
 ActivEnable: BOOL:= TRUE; //Not supported
 MCPEnable : BOOL:= TRUE; //Activate MCP switchover
END_VAR
VAR_OUTPUT
 Alarm1 : BOOL ; //Interrupt: Error in HMI bus address, bus
 //type!
 Alarm2 : BOOL ; //Interrupt: No confirmation HMI 1 offline!
 Alarm3 : BOOL ; //Interrupt: HMI 1 is not going offline!
 Alarm4 : BOOL ; //Interrupt: No confirmation HMI 2 offline!
 Alarm5 : BOOL ; //Interrupt: HMI 2 is not going offline!
 Alarm6 : BOOL ; //Interrupt: Queuing HMI is not going
 //online!
 Report : BOOL ; //Message: Sign-of-life monitoring
 ErrorMMC : BOOL ; //Error detection HMI
END_VAR

```

## Description of formal parameters

The table below lists all formal parameters of the M:N function.

| Formal parameters of M:N function |      |      |                                                                                               |                                                                                                                                    |

| Report                            | O    | BOOL | Message: Sign-of-life monitoring HMI                                                          |                                                                                                                                    |
| ErrorMMC                          | O    | BOOL | Error detection HMI                                                                           |                                                                                                                                    |

---

**Note**

The block must be called by the user program. The user must provide an instance DB with any number for this purpose. The call is multi-instance-capable.

---

**Example of a call for FB 9**

```
CALL FB 9, DB 109 (
Ack := Error_ack, //e.g., MCP RESET
OPMixedMode := FALSE,
ActivEnable := TRUE,
MCPEnable := TRUE); //Enable for MCP switchover
```

---

**Note**

Input parameter "MCPEnable" must be set to TRUE to enable the MCP switchover. The default value of these parameters is set in this way and need not be specially assigned when the function is called.

---

**Interrupts, errors**

The output parameters "Alarm1" to "Alarm6" and "Report" exist as information in the PLC and are output in the event of M:N errors visualized on the HMI by the appearance of alarms 410900 - 410906.

If execution of an HMI function has failed (and an appropriate error message cannot be displayed), status parameter "ErrorMMC" is set to 'logical 1' (e.g., booting error, when no connection is made).

**Call example for FB 1 (Call in OB 100)**

```
CALL "RUN_UP", "gp_par" (
MCPNum := 1,
MCP1In := P#I 0.0,
MCP1Out := P#Q 0.0,
MCP1StatSend := P#Q 8.0,
MCP1StatRec := P#Q 12.0,
MCP1BusAdr := 255, //Address of 1st MCP
MCP1Timeout := S5T#700MS,
MCP1Cycl := S5T#200MS,
MCP1Stop := TRUE, //MCP switched off
NCCyclTimeout := S5T#200MS,
NCRunupTimeout := S5T#50S);
```

### Example: Override switchover

```

//Auxiliary flags used M100.0, M100.1, M100.2, M100.3
//Edge positive of MCP1Ready must check the override
//and measures for activation
//Initiate MCP block
//This example applies to the feedrate override.
//The interface and input bytes must be exchanged for spindle override.
U DB10.DBX 104.0; //MCP1Ready
EN M 100.0; //Edge trigger flag 1
JCN smth1;
S M 100.2; //Set auxiliary flag 1
R M 100.3; //Reset auxiliary flag 2

//Save override
 L DB21.DBB 4; //Feed override interface
 T EB 28; //Buffer storage (freely input
 //or flag byte)

smth1:
U M 100.2; //Switchover takes place
O DB10.DBX 104.0; //MCP1Ready
JCN smth2;
U DB10.DBX 104.0; //MCP1Ready
FP M 100.1; //Edge trigger flag 2
JC smth2;
U M 100.2; //Switchover takes place
R M 100.2; //Reset auxiliary flag 1
JC smth2;
U M 100.3; //Comparison has taken place
SPB MCP; //Call MCP program
//Route the stored override to the interface of the switched MCP
//until the override values match
 L EB 28; //Buffer storage open
 T DB21.DBB 4; //Route override interface
 L EB 3; //Override input byte for feed
 <>i; //Match?
JC smth2; //No, jump
S M 100.3; //Yes, set auxiliary flag 2
//When override values match, call the MCP program again
MCP: CALL "MCP_IFM" (//FC 19
 BAGNo := B#16#1,
 ChanNo := B#16#1,
 SpindleIFNo := B#16#0,

```

```
FeedHold := M 101.0,
SpindleHold := M 101.1);
smth2: NOP 0;
```

### 13.13.8 FB 10: Safety relay (SI relay)

#### Function

The SPL block "Safety relay" for "Safety Integrated" is the PLC equivalent of the NC function of the same name. The standard SPL "Safety relay" block is designed to support the implementation of an emergency stop function with safe programmable logic. However, it can also be used to implement other similar safety functions, e.g., control of a protective door. The function contains 3 input parameters (In1, In2, In3). On switchover of one of these parameters to the value 0, the output Out0 is deactivated without delay and outputs Out1, Out2 and Out3 deactivated via the parameterized timer values (parameters TimeValue1, TimeValue2, TimeValue3). The outputs are activated again without delay, if inputs In1 to In3 take the value 1 and a positive edge change is detected at one of the acknowledgement inputs Ack1, Ack2. To bring the outputs to their basic setting (values = 0) after booting, the parameter "FirstRun" must be configured as follows. The parameter "FirstRun" must be switched to the value TRUE via a retentive data (memory bit, bit in data block) on the first run after control booting. This data can be preset, e.g., in OB 100. The parameter is reset to FALSE when FB 10 is executed for the first time. Separate data must be used for parameter "FirstRun" for each call with its own instance.

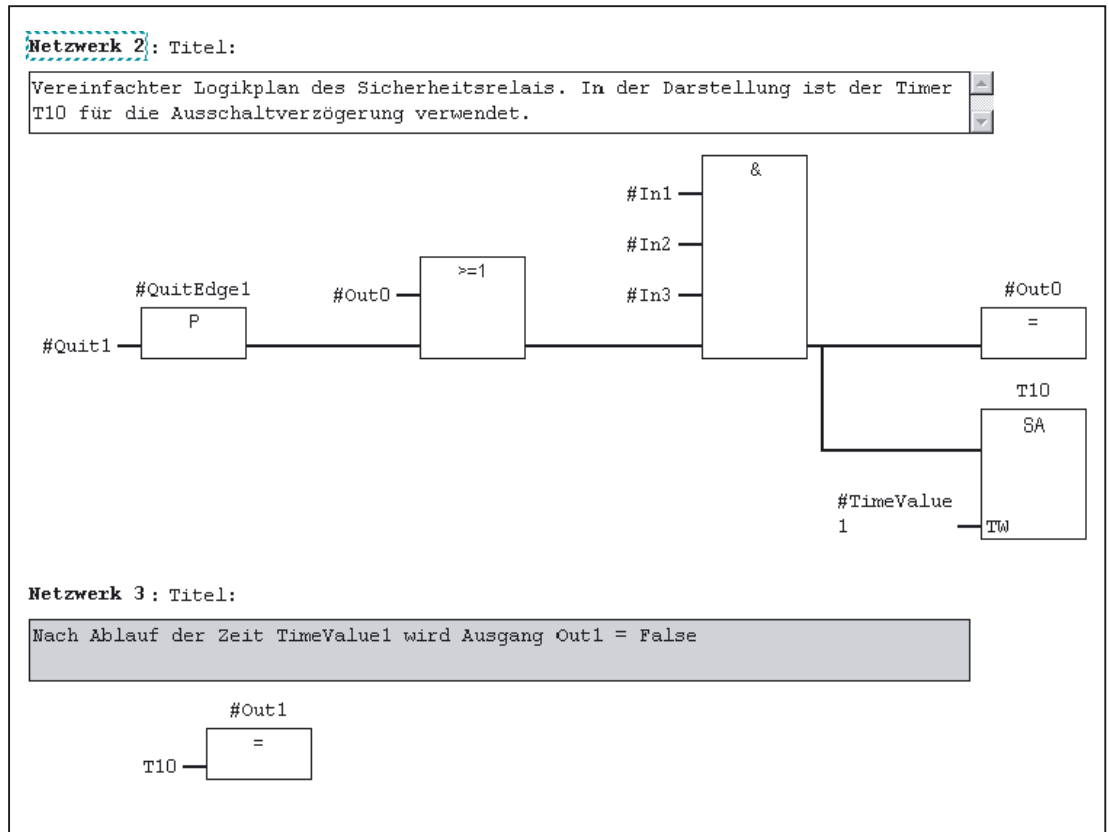

The corresponding NCK-SPL-component is described in:

**References:**

Function Manual Safety Integrated

## Simplified block diagram in CSF

The figure below shows only one acknowledgment input Ack1 and one delayed deactivation output Out1. The circuit for Ack2 and the other delayed outputs are identical. The parameter FirstRun is also missing in the function diagram. The mode of operation is described above.

## Declaration of the function

```

FUNCTION_BLOCK FB 10
VAR_INPUT
 In1 : BOOL := TRUE; //Input 1
 In2 : BOOL := TRUE; //Input 2
 In3 : BOOL := TRUE; //Input 3
 Ackn1 : : BOOL; //Ack 1 signal
 Ackn2 : : BOOL; //Ack 2 signal
 TimeValue1 : TIME := T#0ms ; //TimeValue for output 1
 TimeValue2 : TIME := T#0ms ; //TimeValue for output 2
 TimeValue3 : TIME := T#0ms ; //TimeValue for output 3
END_VAR
VAR_OUTPUT
 Out0 : BOOL; //Output without delay

```

13.13 Block descriptions

```

 Out1 : BOOL; //Delayed output to false by timer 1
 Out2 : BOOL; //Delayed output to false by timer 2
 Out3 : BOOL; //Delayed output to false by timer 3
END_VAR
VAR_INOUT
 FirstRun : BOOL; //TRUE by user after 1st start of SPL
END_VAR

```

**Description of formal parameters**

The following table shows all formal parameters of the SI relay function:

| Formal parameters of SI relay function |      |      |                                  |
|----------------------------------------|------|------|----------------------------------|
| Signal                                 | Type | Type | Comment                          |
| In1                                    | I    | BOOL | Input 1                          |
| In2                                    | I    | BOOL | Input 2                          |
| In3                                    | I    | BOOL | Input 3                          |
| Ackn1                                  | I    | BOOL | Acknowledge input 1              |
| Ackn2                                  | I    | BOOL | Acknowledge input 2              |
| TimeValue1                             | I    | TIME | Time value 1 for OFF delay       |
| TimeValue2                             | I    | TIME | Time value 2 for OFF delay       |
| TimeValue3                             | I    | TIME | Time value 3 for OFF delay       |
| Out0                                   | O    | BOOL | Output, instantaneous (no delay) |
| Out1                                   | O    | BOOL | Output, delayed by TimeValue1    |
| Out2                                   | O    | BOOL | Output, delayed by TimeValue2    |
| Out3                                   | O    | BOOL | Output, delayed by TimeValue3    |
| FirstRun                               | I/O  | BOOL | Activation of basic setting      |

**Note**

The block must be called once by the user program (per SI relay) cyclically in the OB1 cycle from when the SPL program starts. The user must provide an instance DB with any number for this purpose. The call is multi-instance-capable.

**13.13.9 FB 11: Brake test**

**Function**

The braking operation check should be used for all axes, which must be prevented from moving in an uncontrolled manner by a holding brake. This check function is primarily intended for the so-called "vertical axes".

The machine manufacturer can use his PLC user program to close the brake at a suitable moment in time (guide value every 8 hours, similar to the SI test stop) and allow the drive to produce an additional torque / additional force equivalent to the weight of the axis. In error-free operation, the brake can produce the necessary braking torque/braking force and keep the axis at a virtual standstill. When an error occurs, the actual position value exits the parameterizable monitoring window. In this instance, the position controller prevents the axis from sagging and negatively acknowledges the mechanical brake test.

The necessary parameterization of NC and Drive is described in:

**References:**

Function Manual Safety Integrated

The brake test must always be started when the axis is at a standstill. For the entire duration of the brake test, the enable signals of the parameterized axis must be set to enable (e.g. the controller inhibit, feed enable signals). Furthermore, the signal at the axis/spindle DB31, ... .DBX28.7 (PLC-controlled axis) is to be set to status 1 by the user program for the complete duration of the test.

Before activating the signal DB31, ... .DBX28.7 (PLC-controlled axis) the axis is to be switched as "neutral axis", e.g. DB31, ... .DBX8.0 - 8.3 (assign NC axis to channel) is to be set to channel 0 as well as DB31, ... .DBX8.4 (activation signal when using this byte) is to be set.

The return message:

- about the current status can be queried in DB31, ... .DBB68.
- the Nc via the signal DB31, ... .DBX63.1 (PLC controls axis) is to be awaited before the block is started. The direction in which the drive must produce its torque/force is specified by the PLC in the form of a "traversing motion" (e.g., via FC 18).

The axis must be able to reach the destination of this movement without risk of collision if the brake is unable to produce the necessary torque/force.

**Note**

**Instructions for FC 18**

If FC18 is called for the same axis in the remainder of the user program, the calls must be mutually interlocked. For example, this can be achieved via a common call of this function with an interlocked common data interface for the FC 18 parameters. A second option is to call the FC18 repeatedly, in which case the inactive FC18 will not be processed by the program. A multiple-use interlock must be provided.

The brake test is divided into the following steps:

| Brake test sequence              |                      |                       |
|----------------------------------|----------------------|-----------------------|
| Step                             | Expected feedback    | Monitoring time value |
| Start brake test                 | DBX 71.0 = 1         | TV_BTactiv            |
| Close brake                      | Bclosed = 1          | TV_Bclose             |
| Output traversing command        | DBX 64.6 Or DBX 64.7 | TV_FeedCommand        |
| Issue test travel command        | DBX 62.5 = 1         | TV_FXSreached         |
| Wait for the holding time        | DBX 62.5 = 1         | TV_FXShold            |
| Deselect brake test / open brake | DBX 71.0 = 0         | TV_BTactiv            |
| Output test ok                   |                      |                       |

### Declaration of the function

```

Function_BLOCK FB 11
VAR_INPUT
 Start : BOOL ; //Start of brake test
 Ackn : BOOL ; //Acknowledge error
 Bclosed : BOOL ; //Brake closed input (single channel - PLC)
 Axis : INT; //Testing axis no.
 TimerNo : TIMER ; //Timer from user
 TV_BTactiv : S5TIME ; //TimeValue -> brake test active
 TV_Bclose : S5TIM; //TimeValue -> close brake
 TV_FeedCommand : S5TIME ; //TimeValue -> force FeedCommand
 TV_FXSreached : S5TIME ; //TimeValue -> fixed stop reached
 TV_FXShold : S5TIME ; //TimeValue -> test brake
END_VAR
VAR_OUTPUT
 CloseBrake : BOOL ; //Signal close brake
 MoveAxis : BOOL ; //Do move axis
 Done : BOOL ;
 Error : BOOL ;
 State : BYTE ; //Error byte
END_VAR

```

### Description of formal parameters

The following table lists all of the formal parameters of the brake test function

| Formal parameters of brake test function |      |        |                                                                             |
|------------------------------------------|------|--------|-----------------------------------------------------------------------------|
| Signal                                   | Type | Type   | Remark                                                                      |
| Start                                    | I    | BOOL   | Starts the brake test                                                       |
| Ack                                      | I    | BOOL   | Acknowledge fault                                                           |
| Bclosed                                  | I    | BOOL   | Checkback input whether Close Brake is activated (single-channel - PLC)     |
| Axis                                     | I    | INT    | <b>Axis number of axis to be tested</b>                                     |
| TimerNo                                  | I    | TIMER  | Timer from user program                                                     |
| TV_BTactiv                               | I    | S5TIME | Monitoring time value → brake test active, checking of axis signal DBX 71.0 |

| Formal parameters of brake test function |      |        |                                                                                                         |

13.13.10 FB 29: Signal recorder and data trigger diagnostics

Function

**Signal recorder**

The diagnostics FB allows various diagnostic routines to be performed on the PLC user program. A diagnostic routine logs signal states and signal changes. In this diagnostic routine, function number 1 is assigned to the "Func" parameter. Up to 8 signals of the parameters "Signal\_1" to "Signal\_8" are recorded in a ring buffer each time one of the signals changes. The current information of parameters "Var1" as BYTE value, and "Var2" and "Var3" as INTEGER values are also stored in the ring buffer.

The number of past OB 1 cycles is also stored in the buffer as additional information. This information enables the graphical evaluation of signals and values in OB 1 cycle grid. The first time the diagnostics FB is called in a new PLC cycle, the "NewCycle" parameter must be set to TRUE. If the diagnostics FB is called several times in the same OB 1 cycle, the "NewCycle" parameter must be set to FALSE for the second and subsequent calls. This prevents a new number of OB 1 cycles from being calculated.

The ring buffer, specified by the user, must have an ARRAY structure specified as in the source code. The array can have any number of elements. A size of 250 elements is recommended. The "ClearBuf" parameter is used to clear the ring buffer and set the BufAddr pointer (I/O parameter) to the start. The instance DB related to the FB is a DB from the user area and is to be transferred to the FB Diagnostics with the parameter "BufDB".

### Data trigger

The data trigger function is intended to allow triggering on specific values (or bits) at any permissible memory cell. The cell to be triggered is "rounded" with a bit mask ("AndMask" parameter) before the "TestVal" parameter is compared in the diagnostic block.

### Note

The source code for the function is available in the source container of the basic-program library under the name "Diagnose.awl". The instance DB and the ring buffer DB are also defined in this source block. The function call is also described in the function. The DB numbers and the call must be modified.

### Declaration of the function

```
FUNCTION_BLOCK FB 29
VAR_INPUT
Func : INT ; //Function number: 0 = No function,
 //1 = Signal recorder, 2 = Data trigger
 Signal_1 : BOOL ; //Start of brake test
 Signal_2 : BOOL ;

| DataAdr                                   | I    | POINTER |             | Pointer to word to be tested                    |
| TestVal                                   | I    | WORD    |             | Comparison value                                |
| AndMask                                   | I    | WORD    |             | See description                                 |
| TestIsTrue                                | O    | BOOL    |             | Result of comparison                            |

### Configuration steps

- Select function of diagnostics block.
- Define suitable data for the recording as signal recorder or data triggering.
- Find a suitable point or points in the user program for calling the diagnostics FB.
- Create a data block for the ring buffer, see call example.
- Call the diagnostics FB with parameters in the user program.

In function 1, it is advisable to clear the ring buffer with the "ClearBuf" parameter. When the recording phase with function 1 is completed, read out the ring buffer DB in STEP7 with the function "opening the data block in the data view". The content of the ring buffer DB can now be analyzed.

### Call example

```

FUNCTION FC 99: VOID
TITLE =
VERSION : 0.0

BEGIN
NETWORK
TITLE = NETWORK

CALL FB 29, DB 80 (
Func
 Signal_1 := M 100.0,
 Signal_2 := M 100.1,
 Signal_3 := M 100.2,
 Signal_4 := M 100.3,
 Signal_5 := M 10.4,
 Signal_6 := M 100.5,
 Signal_7 := M 100.6,
 Signal_8 := M 100.7,

```

13.13 Block descriptions

```

 NewCycle := TRUE,
 Var1 := MB 100,
 BufDB := 81,
 ClearBuf :=M 50.0);
 END_FUNCTION

```

13.13.11 FC 2: GP\_HP Basic program, cyclic section

Function

The complete processing of the NCK-PLC interface is carried out in cyclic mode. In order to minimize the execution time of the basic program, only the control/status signals are transmitted cyclically; transfer of the auxiliary functions and G functions only takes place when requested by the NCK.

Declaration

```

 FUNCTION FC 2: VOID
 //no parameters

```

Call example

As far as the time is concerned, the basic program must be executed **before** the user program. It is, therefore, called first in OB 1.

The following example contains the standard declarations for OB 1 and the calls for the basic program (FC2), the transfer of the MCP signals (FC19), and the acquisition of error and operating messages (FC10).

```

ORGANIZATION_BLOCK OB 1
VAR_TEMP
 OB1_EV_CLASS : BYTE ;
 OB1_SCAN_1 : BYTE ;
 OB1_PRIORITY : BYTE ;
 OB1_OB_NUMBR : BYTE ;
 OB1_RESERVED_1 : BYTE ;
 OB1_RESERVED_2 : BYTE ;
 OB1_PREV_CYCLE : INT;
 OB1_MIN_CYCLE : INT;
 OB1_MAX_CYCLE : INT;
 OB1_DATE_TIME : DATE_AND_TIME;
END_VAR
BEGIN
CALL FC 2; //Call basic program as first FC

```

```
//INSERT USER PROGRAM HERE
CALL FC 19 (//MCP signals to interface
BAGNo := B#16#1, //Mode group no. 1
ChanNo := B#16#1, //Channel no. 1
SpindleIFNo := B#16#4, //Spindle interface number = 4
FeedHold := m22.0, //Feed stop signal
 //modal
SpindleHold := db2.dbx151.0); //Spindle stop modal
 //in message DB
CALL FC 10 (//Error and operational messages
 ToUserIF := TRUE, //Signals transferred from DB2 to interface
 //to interface
 Ack := I6.1); //Acknowledgment of error messages
 //via I 6.1
END_ORGANIZATION_BLOCK
```

### 13.13.12 FC 3: GP\_PRAL Basic program, interrupt-driven section

#### Function

Block-synchronized transfers from the NCK to the PLC (auxiliary and G functions) are carried out in the interrupt-driven part of the basic program. **Auxiliary functions** are subdivided into normal and high-speed auxiliary functions.

The high-speed functions of an NC block are buffered and the transfer acknowledged to the NC. These are passed to the application interface at the start of the next OB1 cycle.

High-speed auxiliary functions programmed immediately one after the other, are not lost for the user program. This is ensured by a mechanism in the basic program.

Normal auxiliary functions are acknowledged to the NC only after one completed cycle duration. This allows the application to issue a read disable to the NC.

The **G Functions** are evaluated immediately and passed to the application interface.

#### NC process interrupts

If the interrupt is triggered by the NC (possible in each IPO cycle), a bit in the local data of OB 40 ("GP\_IRFromNCK") is set by the basic program, when the FB 1 parameter "UserIR": = TRUE"). This data is not set on other events (process interrupts through I/Os). This information makes it possible to branch into the associated interrupt routine in the user program in order to initiate the necessary action.

To be able to implement high-speed, job-driven processing of the user program for the machine, the following NC functions are available in the interrupt processing routine (OB 40 program section) for the PLC user program:

- Selected **auxiliary functions**
- **Tool-change function** for tool-management option
- **Position reached** for positioning axes, indexing axes and spindles with activation via PLC

The functions listed above can or must be evaluated by the user program in OB 40 in order to initiate reactions on the machine. As an example, the revolver switching mechanism can be activated when a T command is programmed on a turning machine.

For further details on programming hardware interrupts (time delay, interruptibility, etc.) refer to the corresponding SIMATIC documentation.

### Auxiliary functions

Generally, high-speed or acknowledging auxiliary functions are processed with or without interrupt control independently of any assignment.

Basic-program parameters in FB 1 can be set to define which auxiliary functions (T, H, DL) must be processed solely on an interrupt-driven basis by the user program.

Functions which are not assigned via interrupts are only made available by the cyclic basic program as in earlier versions. The change signals of these functions are available in a PLC cycle.

Even if the selection for the auxiliary function groups (T, H, DL) is made using interrupt control, only one interrupt can be processed by the user program for the selected functions.

A bit is set channel-specifically in the local data "GP\_AuxFunction" for the user program (if "GP\_AuxFunction[1]" is set, then an auxiliary function is available for the 1st channel).

In the related channel-DB the change signal and the function value are available for the user. The change signal of this interrupt driven function is reset to zero in the cyclic basic program section after the execution of at least one full OB1 cycle (max. approx. two OB1 cycles).

### Tool change

With the tool-management option, the tool-change command for revolver and the tool change in the spindle is supported by an interrupt. The local data bit "GP\_TM" in OB 40 is set for this purpose. The PLC user program can thus check the tool management DB (DB 72 or DB 73) for the tool change function and initiate the tool change operation.

### Position reached

In the bit structure, "GP\_InPosition" of the local data of OB 40 is specific to the machine axis (each bit corresponds to an axis/spindle, e.g. GP\_InPosition[5] corresponds to axis 5).

If a function has been activated via FC 18 (spindle control, positioning axis, indexing axis) for an axis or spindle, the associated "GP\_InPosition" bit can be used to implement instantaneous evaluation of the "InPos" signal of the FCs listed above. This feature can be used, for example, to obtain immediate activation of clamps for an indexing axis.

## Declaration

```
FUNCTION FC 3 : VOID
//no parameters
```

## Call example

As far as the time is concerned, the basic program must be executed **before** other interrupt-driven user programs. It is, therefore, called first in OB 40.

The following example contains the standard declarations for OB 40 and the call for the basic program.

```
ORGANIZATION_BLOCK OB 40
VAR_TEMP
 OB40_EV_CLASS : BYTE ;
 OB40_STRT_INF : BYTE ;
 OB40_PRIORITY : BYTE ;
 OB40_OB_NUMBR : BYTE ;
 OB40_RESERVED_1 : BYTE ;
 OB40_MDL_ID : BYTE ;
 OB40_MDL_ADDR : INT ;
 OB40_POINT_ADDR : DWORD ;
 OB40_DATE_TIME : DATE_AND_TIME ;

//Assigned to basic program
GP_IRFromNCK : BOOL ; //Interrupt by NCK for user
GP_TM : BOOL ; //Tool management
GP_InPosition : ARRAY [1..3] OF BOOL ; //Axis-oriented for positioning,
//Indexing axes, spindles
GP_AuxFunction : ARRAY [1..10] OF BOOL ; //Channel-oriented for auxiliary functions
GP_FMBlock : ARRAY [1..10] OF BOOL ; //Currently not used
//Further local user data may be defined from this point onwards
END_VAR
BEGIN
 CALL FC 3 ;
 //INSERT USER PROGRAM HERE
END_ORGANIZATION_BLOCK
```

### 13.13.13 FC 5: GP\_DIAG Basic program, diagnostic alarm, and module failure

#### Function

Module defects and module failures are detected in this section of the basic program.

The FC5 block parameter can be used to define whether the PLC is to be placed in Stop mode. The PLC is placed in STOP mode only for incoming events. Exceptions of the parameter "PLC-Stop" are the Profibus-MCPs parameterized at FB 1 (must be connected to the DP1 Bus).

#### Declaration

```
FUNCTION FC 5: VOID
 VAR_INPUT
 PlcStop: BOOL:= TRUE;
 END_VAR
```

#### Call example

As far as timing is concerned, the basic program can be executed after other user programs. This is advisable since the FC5 circuitry will place the PLC in Stop mode.

This example contains the standard declarations for OB 82 and OB 86 and the call of the basic program block.

```
ORGANIZATION_BLOCK OB 82
VAR_TEMP
 OB82_EV_CLASS : BYTE ;
 OB82_FLT_ID : BYTE ;
 OB82_PRIORITY : BYTE ;
 OB82_OB_NUMBR : BYTE ;
 OB82_RESERVED_1 : BYTE ;
 OB82_IO_FLAG : BYTE ;
 OB82_MDL_ADDR : INT ;
 OB82_MDL_DEFECT : BOOL ;
 OB82_INT_FAULT : BOOL ;
 OB82_EXT_FAULT : BOOL ;
 OB82_PNT_INFO : BOOL ;
 OB82_EXT_VOLTAGE : BOOL ;
 OB82_FLD_CONNCTR : BOOL ;
 OB82_NO_CONFIG : BOOL ;
 OB82_CONFIG_ERR : BOOL ;
 OB82_MDL_TYPE : BYTE ;
 OB82_SUB_NDL_ERR : BOOL ;
 OB82_COMM_FAULT : BOOL ;
 OB82_MDL_STOP : BOOL ;
 OB82_WTCH_DOG_FLT : BOOL ;
 OB82_INT_PS_FLT : BOOL ;
 OB82_PRIM_BATT_FLT : BOOL ;
```

```
OB82_BCKUP_BATT_FLT : BOOL ;
OB82_RESERVED_2 : BOOL ;

 OB86_RACKS_FLTD : ARRAY [0 .. 31] OF BOOL;
 OB86_DATE_TIME : DATE_AND_TIME;
END_VAR
BEGIN
 CALL FC 5
 (PlcStop := TRUE) ;
END_ORGANIZATION_BLOCK
```

### 13.13.14 FC 6: TM\_TRANS2 transfer block for tool management and multitool

#### Function

The TM\_TRANS2 block is used for position changes of the tool, status changes and multitool.

The FC 6 block includes the same functionality as for the FC 8, only that in addition the multitool functionality is also integrated. This is the reason that only the parts of the multitool functionality are explained in this chapter. The functionality that is included that goes beyond this is described in "FC 8: TM\_TRANS transfer block for tool management (Page 1027)".

### Declaration of the function

#### STL representation

```

FUNCTION FC 6 : VOID
VAR_INPUT
 Start: BOOL;
 TaskIdent: BYTE ;
 TaskIdentNo: BYTE ;
 NewToolMag: INT;
 NewToolLoc: INT;
 OldToolMag: INT;
 OldToolLoc: INT;
 Status: INT;
 MtoolPlaceNum: INT;
END_VAR
VAR_OUTPUT
 Ready BOOL;
 Error: INT;
END_VAR
BEGIN
END_FUNCTION

```

### Description of formal parameters

The table below lists all formal parameters of the multitool function:

| Signal        | Type | Type | Value range | Comment                |
|---------------|------|------|-------------|------------------------|
| MtoolPlaceNum | I    | INT  |             | Multitool location No. |

### 13.13.15 FC 7: TM\_REV Transfer block for tool change with revolver

#### Function

After a revolver has been changed, the user will call this block FC TM\_REV. The revolver number (corresponding to interface number in DB 73) must be specified in parameter "ChgdRevNo" for this purpose. As this block is called, the associated "Interface active" bit in data block DB 73, word 0 of FC 7 is reset after parameter "Ready" := TRUE is returned.

Block FC TM\_REV may be started (with "Start" parameter = "TRUE") only if an activation signal for the appropriate interface (DB 73, word 0) for this transfer has been supplied by the tool management function.

When this job is executed correctly, the output parameter "Ready" contains the value TRUE. The user must then set the "Start" parameter to FALSE or not call the block again.

If the "Ready" parameter is set to FALSE, the error code in the "Error" parameter must be interpreted.

If the error code = 0, then this job must be repeated in the next PLC cycle (e.g. "Start" remains set to "TRUE"). This means that the transfer job has not yet been completed (see example FC 7 call and timing diagram).

The "Start" parameter does not need a signal edge for a subsequent job.

|                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  <b>WARNING</b>                                                                                                   |
| A cancellation of a transfer (e.g. through an external signal RESET) is not permitted. The "Start" parameter must always retain the 1 signal until the "Ready" and/or "Error" parameters $\neq$ 0. |

An error code  $\neq$  0 indicates incorrect parameterization.

---

#### Note

For further details on tool management (also with regard to PLC) refer to the Description of Functions Tool Management. In addition, PI services for tool management via FB 4, FC 8 and FC 22 are available.

---

## Manual revolver switching

If a manual action is used to rotate the revolver, this information must be forwarded to the tool management. The asynchronous transfer function of FC 8 must be used to transfer the modified positions of the revolver. This must only occur once on the first manual rotation in the sequence. In this case, the following parameterization of the asynchronous transfer is needed via FC 8:

```
TaskIdent = 4
TaskIdentNo = channel
NewToolMag = Magazine number of the revolver
NewToolLoc = Original location of the tool
OldToolMag = Magazine no. buffer storage (spindle) = 9998
OldToolLoc = Buffer storage number of the spindle
Status = 1
```

This action also causes the same T command to be resent to the tool-management interface if the previous T is programmed again.

## Declaration of the function

### STL representation

```
FUNCTION FC 7 : VOID
//NAME :TM_REV
VAR_INPUT
```

13.13 Block descriptions

```

Start: BOOL ;
ChgdRevNo: BYTE ;
END_VAR
VAR_OUTPUT
 Ready: BOOL ;
 Error : INT;
END_VAR
BEGIN
END_FUNCTION

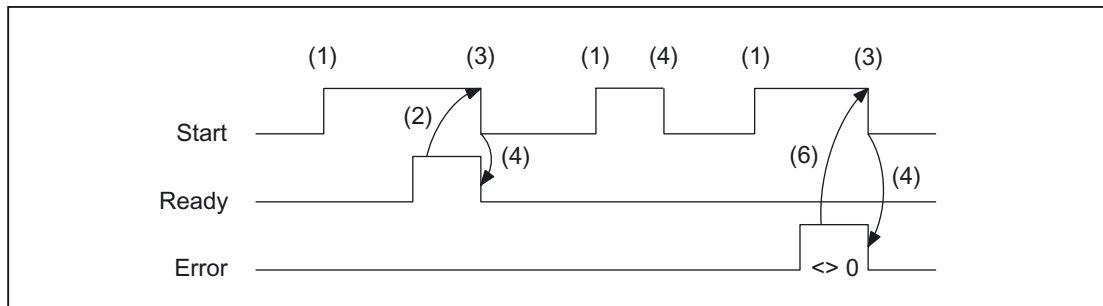

```

**Description of formal parameters**

The table below lists all formal parameters of the TM\_REV function.

| Signal    | Type | Type | Value range | Comment                      |                                                                         |
|-----------|------|------|-------------|------------------------------|-------------------------------------------------------------------------|
| Start     | I    | BOOL |             | 1 = Start of transfer        |                                                                         |
| ChgdRevNo | I    | BYTE | 1...        | Number of revolver interface |                                                                         |
| Ready     | O    | BOOL |             | 1 = Transfer complete        |                                                                         |
| Error     | O    | INT  | 0 ... 3     | Error checkback              |                                                                         |
|           |      |      |             | 0 :                          | No error has occurred                                                   |
|           |      |      |             | 1:                           | No revolver present                                                     |
|           |      |      |             | 2:                           | Illegal revolver number in parameter "ChgdRevNo"                        |
|           |      |      |             | 3:                           | Illegal job ("interface active" signal for selected revolver = "FALSE") |

**Pulse diagram**

- (1) Activation of function by means of a positive edge
- (2) Positive acknowledgment: Tool management has been transferred
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change using FC
- (5) This signal chart is not permissible. The job must generally be terminated since the new tool positions must be conveyed to the tool management in the NCK.
- (6) Negative acknowledgment: Error has occurred, error code in the output parameter Error

## Call example

```
CALL FC 7 (//Tool-management transfer block
 //for Revolver
Start := m 20.5, //Start := "1 " => transfer trigger
ChgdRevNo := DB61.DBB 1,
Ready := m 20.6,
Error := DB61.DBW 12);
u m 20.6; //Poll ready
r m 20.5; //Reset start
spb m001; //Jumps, if everything OK
l db61.dbw 12; //Error information
ow w#16#0; //Evaluate error
JC error; //Jumps to troubleshooting, if <> 0
m001: //Start of another program
error:
r m 20.5; //Reset start, if an error has occurred
```

### 13.13.16 FC 8: TM\_TRANS transfer block for tool management

#### Function

The user calls this block FC TM-TRANS when the position of the tool or the status of the transfer operation changes. The parameter "TaskIdent" specifies the transfer job for the block FC 8 at the tool management interface:

- For loading/unloading positions,
- For spindle change positions,
- For revolver change positions as transfer identifier
- Asynchronous transfer
- Asynchronous transfer with location reservation

The interface number is indicated in parameter "TaskIdentNo".

Example for loading point 5:

Parameter "TaskIdent" := 1 and "TaskIdentNo" := 5.

Furthermore, the **current** tool positions and status data (list of "Status" parameter in the following text) are also transmitted for this transfer function.

---

**Note**

FC8 informs the NCK of the current positions of the old tool.

The NCK knows where the old and the new tool have been located until the position change.

---

In the case of a transfer without a so-called "old tool" (e.g. on loading), the value 0 is assigned to parameters "OldToolMag", "OldToolLoc".

Block FC TM\_TRANS may be started only with "Start" parameter = "TRUE" if an activation signal for the appropriate interface (DB 71, DB 72, DB 73 in word 0) for this transfer has been supplied by the tool management function.

When this job is executed correctly, the output parameter "Ready" contains the value TRUE.

The user must then set the "Start" parameter to FALSE or not call the block again.

If the "Ready" parameter = FALSE, the error code in the "Error" parameter must be interpreted (see Call example FC 8 and timing diagram).

If the error code = 0, then this job must be repeated in the next PLC cycle (e.g. "Start" remains set to "TRUE"). This means that the transfer operation has not yet been completed.

If the user assigns a value of less than 100 to the Parameter "Status", then the associated interface in data block DB 71 or DB 72 or DB 73, word 0 is deactivated (process completed). The appropriate bit for the interface is set to 0 by FC 8.

The "Start" parameter does not need a signal edge for a subsequent job. This means that new parameters can be assigned with "Start = TRUE" immediately when "Ready = TRUE" is received.

### Asynchronous transfer

To ensure that changes in the position of a tool are automatically signaled from PLC to tool management (e.g. power failure during an active command or independent changes in the position by the PLC), block FC 8 TM\_TRANS with "TaskIdent": = 4 or 5 is called. This call does not require interface activation by tool management.

If parameter "TaskIdent" = 5 the tool management reserves the location in addition to changing the position. The location is only reserved if the tool has been transported from a real magazine to a buffer storage.

A relevant NC channel must be parameterized in the "TaskIdentNo" parameter.

The previous position of the tool is specified in parameters "OldToolMag", "OldToolLoc"; the current position of the tool is specified in parameters "NewToolMag", "NewToolLoc". Status = 1 must be specified.

With status 5, the specified tool remains at location "OldToolMag", "OldToolLoc". This location must be a buffer (e.g. spindle). The real magazine and location must be specified in the parameters "NewToolMag", "NewToolLoc"; the location is at the position of the buffer. This procedure must always be used if the tool management is to be informed of the position of a specific magazine location. This procedure is used for alignment in search strategies.

---

**Note**

A cancellation of a transfer (e.g. through an external signal RESET) is not permitted. The "Start" parameter must always retain the 1 signal until the "Ready" and/or "Error" parameters  $\neq 0$ .

---

An error code  $\neq 0$  indicates incorrect parameterization.

---

**Note**

For further details on tool management (also with regard to PLC) refer to the Description of Functions Tool Management. In addition, PI services for tool management via FB 4, FC 7 and FC 22 are available.

---

## Declaration of the function

### STL representation

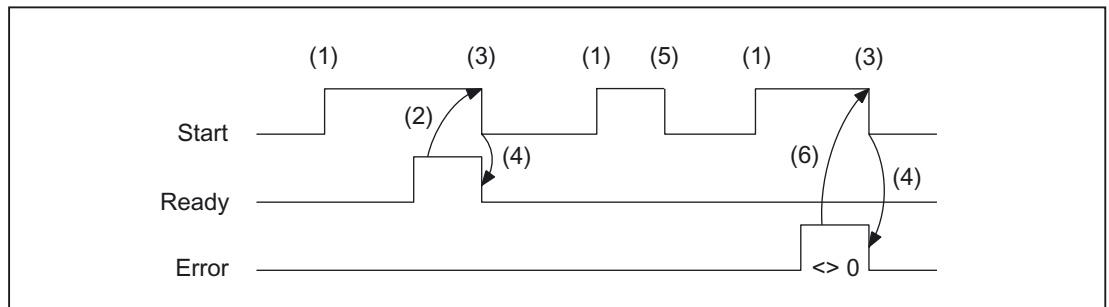

```
FUNCTION FC 8 : VOID
//NAME :TM_TRANS
VAR_INPUT
 Start: BOOL ;
 TaskIdent: BYTE ;
 TaskIdentNo: BYTE ;
 NewToolMag: INT;
 NewToolLoc: INT;
 OldToolMag: INT;
 OldToolLoc: INT;
 Status: INT;
END_VAR
VAR_OUTPUT
 Ready BOOL ;
 Error : INT;
END_VAR
BEGIN
END_FUNCTION
```

**Description of formal parameters**

The table below lists all formal parameters of the TM\_TRANS function:

| Signal                                             | Type                                                                                                            | Type | Value range                | Comment                                                                                                                                                                   |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start                                              | I                                                                                                               | BOOL |                            | 1 = Start of transfer                                                                                                                                                     |
| TaskIdent                                          | I                                                                                                               | BYTE | 1 ... 5                    | Interface or tank identifier                                                                                                                                              |
|                                                    |                                                                                                                 |      |                            | 1: Loading/unloading location                                                                                                                                             |
|                                                    |                                                                                                                 |      |                            | 2: Spindle change position                                                                                                                                                |
|                                                    |                                                                                                                 |      |                            | 3: Revolver change position                                                                                                                                               |
|                                                    |                                                                                                                 |      |                            | 4: Asynchronous transfer                                                                                                                                                  |
| 5: Asynchronous transfer with location reservation |                                                                                                                 |      |                            |                                                                                                                                                                           |
| TaskIdentNo                                        | I                                                                                                               | BYTE | 1 ...                      | Number of associated interface or channel number. The upper nibble can specify the interface number for asynchronous transfer (e.g. B#16#12, 1st interface, 2nd channel). |
| NewToolMag                                         | I                                                                                                               | INT  | 1, 0 ...                   | Current magazine number of tool to be replaced                                                                                                                            |

| Other values:                                      | The number corresponds to the error message of the tool management function in the NCK caused by this transfer. |      |                            |                                                                                                                                                                           |

## Timing diagram

- (1) Activation of function by means of a positive edge
- (2) Positive acknowledgment: Tool management has been transferred
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change using FC
- (5) This signal chart is not permissible. The job must generally be terminated since the new tool positions must be conveyed to the tool management in the NCK.
- (6) Negative acknowledgment: Error occurred, error code in the output parameter Error

## Status list

### Status = 1:

**The WZV operation is completed** (loading/unloading/reloading, prepare change, change).

The parameters "NewToolMag", "NewToolLoc", "OldToolMag", "OldToolLoc" of the FC 8 block are to be parameterized to the actual positions of the tools involved. Except in the case of preparing change these are normally the specified target position of the tools of the associated WZV interface, see also "Explanations of the formal parameters".

1. In the case of loading/unloading/reloading, the tool has arrived at the required target address. If the bit in the interface in DB 71.DBX (n+0).3 "position at loading point" is enabled, status 1 cannot be used for the function termination. Status 5 must be used for correct termination.
2. In the case of "Prepare change", the new tool is now available. The tool may, for example, be positioned in a buffer (grripper). In some cases, the target (magazine, location) of the old tool has been moved to the tool-change position after placement of the new tool in a buffer. However, the old tool still remains in the spindle. The preparations for a tool change are thus complete. After this acknowledgment, the "Change" command can be received. The positions in parameters "NewToolMag", "NewToolLoc", "OldToolMag" and "OldToolLoc" correspond to the current tool positions.
3. In the case of "Change" (spindle or revolver), the tools addressed in the interface have now reached the required target addresses.  
The tool-change operation is thus completed.

### Status = 2: The "new" tool cannot be made available.

This status is only admissible in conjunction with the "Prepare Change" command. When this status is applied, the PLC must be prevented from making a change with the proposed tool. The proposed (new) tool is disabled by the tool management function in the NCK. A new command is then output by the tool management with a duplo tool. The positions in parameters "NewToolMag", "NewToolLoc", "OldToolMag", and "OldToolLoc" correspond to the original tool positions.

**Status = 3: An error occurred.**

The tool positions must not have been changed. Any changes to the magazine positions which have taken place in the meantime must be notified beforehand, for example, with status = 105 via FC 8 transfer block. Only then will the tool positions be taken into account by the tool management function.

**Status = 4: It would be better to position the "old" tool in the magazine position specified in parameters "OldToolMag" and "OldToolLoc".**

This status is permissible only in conjunction with preparation for tool change (change into spindle). After this status has been transferred to the tool management in the NCK, the tool management tries to consider the specified magazine position in the next command. But this is done only when this position is free. Parameters "NewToolMag" and "NewToolLoc" are not taken into account.

**Status = 5: The operation is complete.**

The "new" tool is in the position specified in parameters "NewToolMag", "NewToolLoc". In this case, the specified tool is not really in this position, but is still in the same magazine location. However, this magazine location has been moved to the position set in the parameters (e.g. tool change position). This status may be used only for revolvers, chain-type magazines and disk magazines. Status 5 enables the tool management function to adjust the current position of a magazine and to improve the search strategy for subsequent commands. This status is permissible only in conjunction with loading, unloading, and reloading operations and with preparations for a tool change.

The "OldToolMag" and "OldToolLoc" parameters must be parameterized with the data of a buffer.

- **Loading, reloading:**

On loading or reloading, a location for the tool is already reserved in the NCK. The machine operator must then insert the tool at the target location. Note: The location reservation is canceled when the control system is switched on again.

- **Tool-change preparation:**

Tool motions still to be executed are not carried out until after the tool has been changed.

- **Positioning to load point:**

If the bit in the interface in DB 71.DBX (n+0).3 "position at loading point" is enabled, status 1 cannot be used for the function termination.

**Status = 6: The WZV job has been completed.**

This status has the same function as status 1, but, in addition, a reservation of the source location is carried out. This status is only permitted when reloading. The command is ended and the source location of the tool is reserved if the target location is in a buffer magazine.

**Status = 7: Initiate repetition of the command "Prepare Tool".**

This status is only admissible in conjunction with the "Change tool" command. This status is intended for use when the "new" tool has changed its position (e.g. via an asynchronous command of the "new" tool). After "Ready = 1" has been provided by FC 8, the "Prepare Change" command is repeated automatically with the same tool. For the automatic repetition, a new tool search is carried out. The positions in parameters "NewToolMag", "NewToolLoc", "OldToolMag", and "OldToolLoc" correspond to the original tool positions.

**Status = 103: The "new" tool can be inserted.**

This status is permitted only in the tool change preparation, when the PLC may reject the new tool (e.g. in case of MD20310 \$MC\_TOOL\_MANAGEMENT\_MASK, bit 4=1 for the possibility, request changed parameter from PLC once again). The tool positions have remained unchanged. This status is thus necessary, when the processing is to be continued in the NCK without an unnecessary stop.

**References:**

Function Manual Tool Management

**Status = 104: The "new" tool is in the position specified in parameters "NewToolMag", "NewToolLoc".**

This status is only permissible if the tool is still in the magazine in the same location. The "old" tool is in the position (buffer) specified in parameters "OldToolMag", "OldToolLoc". In this case, however, the new tool is not really in this position, but is still in the same magazine location. However, this magazine location has been moved to the position set in the parameters (e.g. tool change position). This status may be used only in conjunction with revolvers, chain-type magazines and disk magazines for the "Tool change preparation" phase. Status enables the tool management to adjust the current position of a magazine and to improve the search strategy for subsequent commands.

**Status = 105: The specified buffer has been reached by all tools involved**  
(standard case if the operation has not yet been completed).

The tools are in the specified tool positions (parameters "NewToolMag", "NewToolLoc", "OldToolMag", "OldToolLoc").

**Status definition**

A general rule for the acknowledgment status is that the state information 1 to 7 leads to the termination of the command. If FC 8 receives one of the statuses, the "Interface active bit" of the interface specified in FC 8 is reset to "0" (see also interface lists DB 71 to DB 73), thus completing the operation. The response is different in the case of status information 103 to 105. When the FC 8 receives one of these items of status information, the "Interface active bit" of this interface remains at "1". Further processing is required by the user program in the PLC (e.g. continuation of magazine positioning). This item of status information is generally used to transfer changes in position of one or both tools while the operation is still in progress.

**Call example**

```
CALL FC 8 (//Tool-management transfer block
 Start := m 20.5, //Start := "1 " => transfer trigger
 TaskIdent := DB61.DBB 0,
 TaskIdentNo := DB61.DBB 1,
```

13.13 Block descriptions

```

NewToolMag := DB61.DBW 2, //Current position of new tool
NewToolLoc := DB61.DBW 4,
OldToolMag := DB61.DBW 6, //Current position of old tool
OldToolLoc := DB61.DBW 8,
Status := DB61.DBW 10, //Status
Ready := m 20.6,
Error := DB61.DBW 12);
u m 20.6; //Poll ready
r m 20.5; //Reset start
spb m001; //Jumps, if everything OK
l DB61.dbw 12; //Error information
ow w#16#0; //Evaluate error
JC error; //Jumps to troubleshooting

m001: //Normal branch

error: //Troubleshooting
r m 20.5: //Reset start

```

13.13.17 FC 9: ASUB startup of asynchronous subprograms

Function

The FC ASUB can be used to trigger any functions in the NC. Before an ASUB can be started from the PLC, it must have been selected and parameterized by an NC program or by FB 4 (PI service ASUB). The channel and the interrupt numbers for the parameters in FC 9 must match here.

Once prepared in this way, it can be started at any time from the PLC. The NC program running on the channel in question is interrupted by the asynchronous subprogram. Only one ASUB can be started in the same channel at a time. If the start parameter is set to logical 1 for two FC 9s within one PLC cycle, the ASUBs are started in the sequence in which they are called.

The start parameter must be set to logic 0 by the user once the ASUB has been terminated (Done) or if an error has occurred.

For the purpose of job processing, every FC ASUB requires its own WORD parameter "Ref" from the global user memory area. This parameter is for internal use only and must not be changed by the user. The parameter "Ref" is initialized with the value 0 in the first OB 1 cycle and, for this reason, **every FC 9 must be called absolutely**. Alternatively, the user can initialize parameter "Ref" with a value of 0 during startup. This option makes conditional calls possible. When a conditional call is activated by parameter "Start" = 1, it must remain active until parameter "Done" has made the transition from 1 to 0.

---

#### Note

The FB 4 call must be terminated before the FC 9 can be started. FC 9 cannot be started if "Emergency off" is set. Neither can FC 9 be started if the channel reset is active.

---

### Declaration of the function

```

FUNCTION FC 9 : VOID
//NAME :ASUP
VAR_INPUT
 Start: BOOL ;
 ChanNo: INT;
 IntNo: INT;
END_VAR
VAR_OUTPUT
 Active: BOOL ;
 Done : BOOL ;
 Error : BOOL ;
 StartErr: BOOL ;
END_VAR
VAR_IN_OUT
 Ref: WORD ;
END_VAR

```

### Description of formal parameters

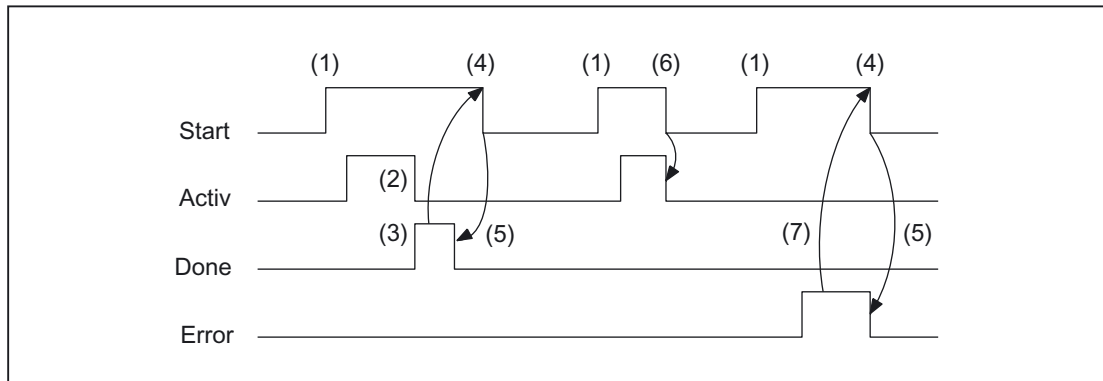

The table below lists all formal parameters of the ASUB function.

| Signal | Type | Type | Value range | Remark                     |
|--------|------|------|-------------|----------------------------|
| Start  | I    | BOOL |             |                            |
| ChanNo | I    | INT  | 1 ... 10    | No. of the NC channel      |
| IntNo  | I    | INT  | 1 ... 8     | Interrupt No.              |
| Active | O    | BOOL |             | 1 = Active                 |
| Done   | O    | BOOL |             | 1 = ASUB completed         |
| Error  | O    | BOOL |             | 1 = Interrupt switched off |

13.13 Block descriptions

| Signal   | Type | Type | Value range                  | Remark                                       |
|----------|------|------|------------------------------|----------------------------------------------|
| StartErr | O    | BOOL |                              | 1 = Interrupt number not assigned or deleted |
| Ref      | I/O  | WORD | Global variable (MW, DBW,..) | 1 word per FC 9 (for internal use)           |

Timing diagram

- (1) Activation of function
- (2) ASUP active
- (3) Positive acknowledgment: ASUB ended
- (4) Reset function activation after receipt of acknowledgment
- (5) Signal change using FC
- (6) Not permitted If function activation is reset prior to receipt of acknowledgment, the output signals are not updated without the operational sequence of the activated function being affected.
- (7) Negative acknowledgment: Error has occurred

Call example

```

CALL FC 9 (//Start an asynchronous subprogram
 //in channel 1 interrupt number 1

 Start := I 45.7,
 ChanNo := 1,
 IntNo := 1,
 Active := M 204.0,
 Done := M204.1,
 Error := M 204.4,
 StartErr := M 204.5,
 Ref := MW 200);

```

### 13.13.18 FC 10: AL\_MSG error and operating messages

#### Function

FC AL\_MSG evaluates the signals entered in DB 2 and displays them as incoming and outgoing error and operational messages on the HMI.

The incoming signals (positive edge) are displayed immediately in the case of both error and operational messages.

Outgoing signals (negative edge) are only canceled immediately in the case of operating messages. Error messages remain stored on the HMI - even if the signals no longer exist - until the "acknowledge" parameter is issued, WCS.e. until the user acknowledges the messages.

The "ToUserIF" parameter can be used to transfer the group signals for the feed, read and NC start disabling signals and feed stop signal to the existing axis, spindle and channel interfaces. The group signals are transferred to the user interface directly from the status information in DB 2 irrespective of an interrupt acknowledgment.

1. If parameter "ToUserIF": is set to FALSE, signals are not transferred to the user interface. In this case, the user must take measures in his PLC program to ensure that these signals are influenced in the interface.
2. If parameter "ToUserIF": is set to TRUE, all signals listed above are sent to the user interface as a group signal in each case. The user PLC program can, therefore, influence these signals only via DB 2 in connection with a message or interrupt output. The appropriate information is overwritten in the user interface.

As an alternative to the procedure described under paragraph 2, the user can influence the disable and stop signals without a message output by applying a disable or stop signal state to the interface signals after FC AL\_MSG has been called.

The following program illustrates this method:

```
CALL FC 10 (
 ToUserIF := TRUE,
 Ack := I 6.1);

u m 50.0; //Feed disable for channel 1
to DB 21;
s dbx 6.0; //Setting the blocking condition,
 //Resetting is done via FC AL_MSG,
 //if M 50.0 outputs the signal "0".
```

### FB 1 parameter "ExtendAlMsg"

With the activation of the parameter a new structuring of the DB 2 becomes effective (see "Interface PLC/HMI (Page 886)"). Upon activation the bit fields are available to the user for the disable and halt signals, which do not generate any alarms, messages. As a result, the user need not implement the aforesaid measures. The desired functionality is given automatically by a simple setting, resetting of signals in the new DB 2 areas.

The error and the operating messages are stored by the user in data block DB 2 (see description of DB 2 in the lists of interface signals).

---

#### Note

In DB 2, a "1" signal must be present for several OB1 cycles to ensure that a message can also be displayed on the HMI. There is an upper limit for the number of interrupts and messages that can be pending at the same time. This upper limit is dependent on the PLC CPU. On PLC 317-2DP, the upper limit for messages pending simultaneously is 60.

---

### Declaration of the function

#### STL representation

```

FUNCTION FC 10 : VOID
 //NAME: AL_MSG
VAR_INPUT
 ToUserIF : BOOL ;
 Ack : BOOL ;
END_VAR
END_FUNCTION

```

### Description of formal parameters

The table below lists all formal parameters of the AL-MSG function.

| Signal   | Type | Type | Range of values | Remark                                                 |
|----------|------|------|-----------------|--------------------------------------------------------|
| ToUserIF | I    | BOOL |                 | 1 = Transfer the signals to user interface every cycle |
| Ack      | I    | BOOL |                 | 1 = Acknowledge error messages.                        |

### Call example

```

CALL FC 10 (//Error and operational messages
 ToUserIF := TRUE, //Signals from DB 2 are transferred to
 //interface
 Ack := I6.1); //Acknowledgement of the error message done via
 //Input E6.1.

```

### 13.13.19 FC 12: AUXFU call interface for user with auxiliary functions

#### Function

FC AUXFU is generally called on an event-driven basis in the basic program if the channel transferred in the input parameter contains new auxiliary functions. The PLC user can extend FC AUXFU with program instructions for processing his auxiliary function to avoid cyclic polling of the channel DBs. This mechanism permits auxiliary functions to be processed on a job-driven basis. FC AUXFU is supplied as a compiled empty block in the basic program. In this case, the basic program supplies parameter "Chan" with the channel number. The PLC user knows which channel has new auxiliary functions available. The new auxiliary functions can be determined by the auxiliary-function change signals in the channel concerned.

#### Declaration of the function

```
FUNCTION FC 12: VOID //Event control of auxiliary functions
VAR_INPUT
 Chan: BYTE ;
END_VAR
BEGIN
 BE;
END_FUNCTION
```

#### Explanation of formal parameters

The table below lists all formal parameters of the AUXFU function:

| Signal | Type | Type | Value range | Remark               |
|--------|------|------|-------------|----------------------|
| Chan   | I    | BYTE | 0 ... 9     | No. of NC channel -1 |

#### Example

```
FUNCTION FC 12: VOID //Event control of auxiliary functions
VAR_INPUT
 Chan: BYTE ; //Parameter is supplied by basic program
END_VAR
VAR_TEMP
 ChanDB: INT;
END_VAR
BEGIN
L Chan; //Channel index no., (0,1,2,..)
+ 21; //Channel DB offset
```

13.13 Block descriptions

```

T ChanDB; //Save channel DB no.
TO DB[ChanDB]; //Channel DB is opened indirectly
//Auxiliary-function change signals are now scanned, etc.
 BE;
END_FUNCTION

```

**13.13.20 FC 13: BHGDisp Display control for handheld unit**

**Function**

This block carries out the display control for the handheld unit (HHU or HT2). The information to be output on the display is stored as 32 characters in string data ChrArray (these are 64 characters when using an HT2). A fixed text assignment of 32 or 64 characters is, therefore, required for this string when the data block is created.

16 characters are sent to BHG/HT2 for each job, which lasts for several OB 1-cycle. The assignment of the characters in ChrArray to each line is unique. For line 1 the characters 1 to 16 and for the line 2 the characters 17 to 32 of the string data ChrArray are transferred. In addition, for HT2 the line 3 with the characters 33 to 48 and line 4 made of characters 49 to 64 are shown.

The block checks, whether the minimum length of the ChrArray is available for operating the BHG or the HT2. If less characters are present in the string data than are to be displayed, then the line is filled with blanks.

By setting parameter Row to 0, it is possible to suppress the display (e.g. if several variables in one or several PLC cycles need to be entered in the string without any display output). If several lines are to be updated "simultaneously" (transfer of the characters to the lines lasts for several OB 1 cycles) (Parameter Row > 1), then the lines are updated one by one each with 16 characters per line.

Variable portions within the string can be inserted by means of the numerical converter functionality (optional). For the numeric converter the parameter "Convert" must be set to TRUE. The variable to be displayed is referenced via the pointer Addr. Parameter "DataType" contains the format description of this parameter (see parameter table). The number of bytes of the variable is linked to the format description. The address justified to the right within the string is specified by parameter "StringAddr". The number of written characters is shown in the parameter table.

**Signals**

Byte 1 is supplied by the output signals of the HHU and the character specifications are supplied by the block. These may not be written by the PLC user program.

## Additional parameters

### HHU

The pointer parameters for the input and output data of the handheld unit must be parameterized in the start OB 100 in FB 1, DB 7. Parameter "BHGIn" corresponds to the input data of the PLC from the handheld unit (data received by PLC). Parameter "BHGOut" corresponds to the output data of the PLC to the handheld unit (data transmitted by PLC). These two pointers must be set to the starting point of the relevant data area (which is also parameterized in SDB 210 with an MPI link).

For operating a BHG a "2" is to be entered at FB 1 parameter BHG.

### HT2

For using a HT2 a "5" is to be entered at FB 1 parameter BHG. The pointer parameter of the input and output data are also to be supplied, as described above.

In the parameters BHGRecGDNo and BHGRecGBZNo the value is to be entered, which is configured at the S2 of the DIP-Fix-switch (rotary coding switch) of the connection module of the HT2.

---

### Note

#### Numerical conversion

If the numerical converter is used to display information, then it is better to avoid performing a conversion in every PLC cycle for the sake of reducing the PLC cycle time.

The conversion routine can be used independently of the display control. This is to be queried in parameter row "0", although the convert parameter should be set. Consequently, only the string is processed, and the converter routine is executed.

#### High display resolution

If, for example, the actual axis value is to be displayed with a higher resolution, the following should be noted:

Variables will continue to be read with FB 2 or FB 5. REAL 2 is used instead of ANY pointer BYTE 8 as the criterion for output as a 64-bit floating point number (e.g.

When specifying the 64-bit floating point number on the HHU/HT2, an output format of up to 14 places, split freely between places before and after the decimal point, can be selected instead of fixed formats.

---

## Declaration of the function

### STL representation

```

DATA_BLOCK "strdat" //DB number defined in the symbol file

STRUCT //32 characters are defined
 disp: STRING [32]:= 'character_line1 character_line2';
END_STRUCT;
BEGIN
END_DATA_BLOCK

```

13.13 Block descriptions

```

FUNCTION FC 13 : VOID
 VAR INPUT
 Row : BYTE ; //Display line (see table)
 ChrArray : STRING ; //Transfer at least string[32/64]
 Convert : BOOL ; //Activate numerical conversion
 Addr: POINTER; //Points to the variable being converted
 DataType : BYTE ; //Data type of the variables
 StringAddr : INT ; //right-justified string address (1...32/64)
 Digits : BYTE ; //Number of decimal places (1 to 3)
 END VAR
 VAR OUTPUT
 Error : BOOL ; //Conversion or string error
 END VAR

```

**Description of formal parameters**

The table below lists all formal parameters of the BHGDisp function:

| Signal   | Type | Type    | Value range                         | Remark                                                                                                    |                                 |
|----------|------|---------|-------------------------------------|-----------------------------------------------------------------------------------------------------------|---------------------------------|
| Row      | I    | BYTE    | 0 ... B#16#F                        | Display-line<br>"binary" evaluation:                                                                      |                                 |
|          |      |         |                                     | 0:                                                                                                        | no display output               |
|          |      |         |                                     | 1:                                                                                                        | Line 1                          |
|          |      |         |                                     | 2:                                                                                                        | Line 2                          |
|          |      |         |                                     | 3:                                                                                                        | Line 1 and line 2 to be changed |
|          |      |         |                                     | 4:                                                                                                        | Line 3                          |
|          |      |         |                                     | 5:                                                                                                        | Line 1 and line 3 to be changed |
|          |      |         |                                     | 8:                                                                                                        | Line 4                          |
|          |      |         | B#16#F                              | automatic change of all 4 lines                                                                           |                                 |
| ChrArray | I    | STRING  | >= string[32]<br>[DBName].[VarName] | This string contains the entire display content<br>For HT2 the string with 64 characters must be created. |                                 |
| Convert  | I    | BOOL    |                                     | Activation of numerical conversion                                                                        |                                 |
| Addr     | I    | Pointer |                                     | Points to the variable to be converted                                                                    |                                 |
| DataType | I    | BYTE    | 1 ... 8, B#16#13                    | Data type of the tag                                                                                      |                                 |
|          |      |         |                                     | 1:                                                                                                        | BOOL, 1 character               |
|          |      |         |                                     | 2:                                                                                                        | BYTE, 3 characters              |
|          |      |         |                                     | 3:                                                                                                        | CHAR, 1 character               |

Call example

//DB with the name strdat is declared in symbol table, data element disp is declared as String[32] (in HT2: //String[64]) and completely assigned with characters

```
CALL FC 13 (
 Row := MB 26,
 ChrArray := "strdat".disp,
 Convert := M 90.1,
 Addr := P#M 20.0, //Number to be converted
 DataType := MB 28, //Data type of the variables
 StringAddr := MW 30,
 Digits := B#16#3, //3 decimal places
 Error := M 90.2);
```

13.13.21 FC 17: YDelta Star-Delta changeover

Function

The block for the star-delta changeover controls the timing of the defined switching logic such that the changeover can be performed in either direction even when the spindle is running. This block may be used only for digital main spindle drives and must be called separately for each spindle.

The changeover operation is implemented via 2 separate contactors in a sequence involving 4 steps:

|         |                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1: | Deleting the interface signal DB31, ... .DBX21.5 (motor selection done) in the related axis-DB and registering the changeover process via A with DB31, ... .DBX21.3 (motor selection).                       |
| Step 2: | As soon as the checkback message IS DB31, ... DBX93.7 (Pulse enabled) = 0 and the acknowledgment of the announced motor selection from the drive have appeared, the currently energized contactor drops out. |
| Step 3: | The other contactor is energized after the time period set by the user in parameter "TimeVal" has elapsed.                                                                                                   |
| Step 4: | After a further delay, the changeover is signaled to the drive with NST DB31, ... DBX21.5 (motor selection done):                                                                                            |

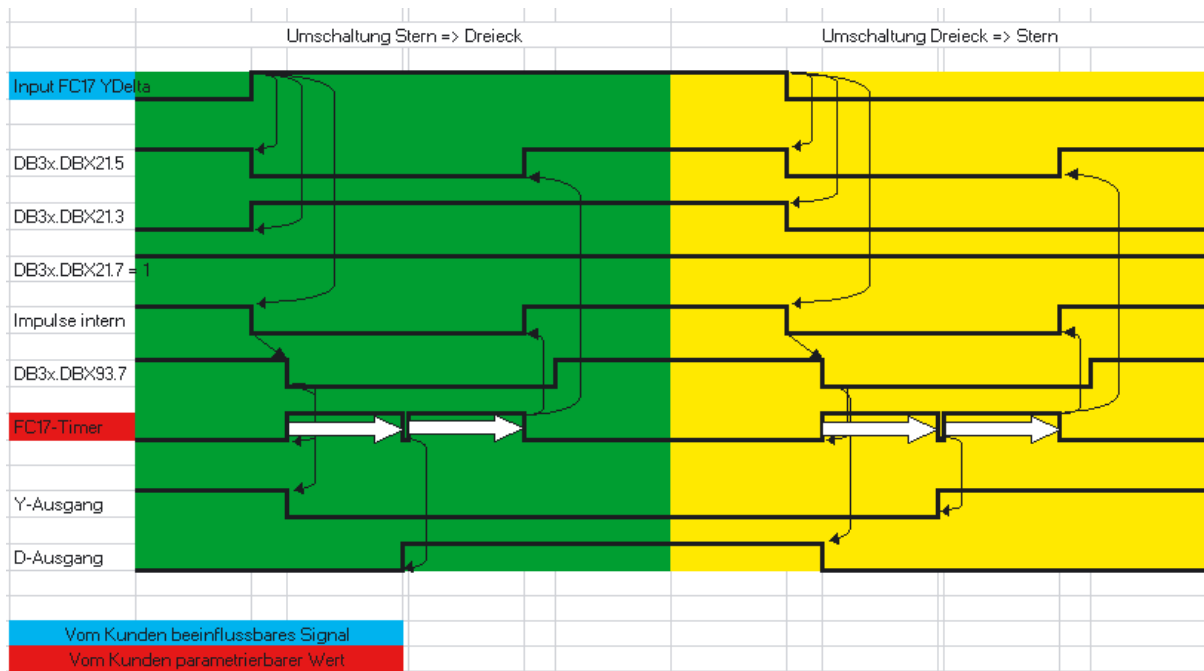

Figure 13-30 Star-delta changeover

For more information on motor speed adjustments see:

**References:**

Function Manual Basic Functions; Spindles (S1); Chapter "Configurable gear adjustments"  
Function Manual Basic Functions; Speeds, Reference/Actual value syst., Regulation (G2)

**Error message**

If the parameter "SpindleIFNo" is not in the permissible range, the PLC is stopped with output of interrupt message number 401702.

**Special features**

When parameterizing "TimeVal" with the value 0, a default value of 100 ms is used. With a value of less than 50 ms, the minimum setting of 50 ms is applied.

The block must be called unconditionally.

**Note**

Switchover does not take place if the spindle is in an axis mode such as M70, SPOS.

### Boundary conditions

Star-delta changeover on digital main spindle drives initiates a process, which contains closed-loop control sequences. Since the closed-loop control system supports automatic star-delta changeover, certain restrictions should be noted:

- Due to the automatic deactivation of the pulse on the drive, the NST DB31, ... .DBX93.7 (Pulse enabled) deactivates simultaneously the IS DB31, ... .DBX61.7 (current controller active) and DB31, ... .DBX61.6 (speed controller active).
- If a changeover from star to delta takes place while the spindle is rotating and the spindle position controller is switched on, IS "Position controller active" (DB31, ... DBX61.5), this triggers alarm 25050 "Contour monitoring".
- Once the star-delta changeover has been initiated with FC 17, it cannot be delayed by the user, e.g. by waiting until the star/delta contactors change over during the course of operation. The user can implement this signal interaction with PLC logic.

### Declaration of the function

#### STL representation

```

VAR_INPUT
 YDelta: BOOL; //Star = 0, delta = 1
 SpindleIFNo: INT; //Machine axis number
 TimeVal: S5TIME ; //Time value
 TimerNo : INT; //User timer for changeover time
END_VAR
VAR_OUTPUT
 Y: BOOL; //Star contactor
 Delta: BOOL; //Delta contactor
END_VAR
VAR_IN_OUT
 Ref: WORD ; //Block status word (instance)
END_VAR

```

### Description of formal parameters

The table below lists all formal parameters of the YDelta function:

| Signal      | Type | Type   | Value range | Comment                                                                                       |
|-------------|------|--------|-------------|-----------------------------------------------------------------------------------------------|
| YDelta      | I    | BOOL   |             | = Star<br>= Triangle<br>The changeover edge of the signal initiates the changeover operation. |
| SpindleIFNo | I    | INT    | 1 ...       | Number of the axis interface declared as a spindle                                            |
| TimeVal     | I    | S5time | 0 ...       | Switchover time                                                                               |

| Signal  | Type | Type | Value range | Comment                                         |
|---------|------|------|-------------|-------------------------------------------------|
| TimerNo | I    | INT  | 10 ...      | Timer for programming the wait time             |
| Y       | O    | BOOL |             | Energizing of star contactor                    |
| Delta   | O    | BOOL |             | Energizing of delta contactor                   |
| Ref     | I/O  | WORD |             | Instance for status information<br>Internal use |

### Call example

```
CALL FC 17 (
 YDelta := I 45.7, //Star delta
 SpindleIFNo := 4,
 TimeVal := S5T#150ms,
 TimerNo := 10, //Timer 10
 Y := Q 52.3, //Star contactor
 Delta := Q 52.4, //Delta contactor
 Ref := mw 50); //Instance
```

## 13.13.22 FC 18: SpinCtrl spindle control

### Function

FC SpinCtrl can be used to control spindles and axes from the PLC.

#### References

/FB1/ Function Manual, Basic Functions; Spindles (S1)  
 Function Manual, Extended Functions; Positioning Axes (P2)  
 Function Manual, Extended Functions; Indexing Axes (T1)

This block supports the following functions:

- Position spindle
- Rotate spindle
- Oscillate spindle
- Indexing axes
- Positioning axes

Each function is activated by the positive edge of the appropriate initiation signal (start, stop). This signal must remain in the logic "1" state until the function has been acknowledged positively or negatively by InPos="1" or Error = "1". The output parameters are deleted when the relevant trigger signal is reset and the function terminated.

To be able to control an axis or spindle via the PLC, it must be activated for the PLC. This can, for example, be achieved by calling the FC "SpinCtrl" with activation of the "Start" or "Stop" parameter. In this case, the FC "SpinCtrl" requests control over the spindle/axis from the NC.

The NC feeds back the status of this spindle/axis in byte 68 in the associated spindle/axis interface (DB31, ...) (see interface lists). Once the axis/spindle is operating under PLC control, the travel command for the active state can be evaluated via the relevant axis interface.

On completion ("InPos" is TRUE, "Start" changes to zero), the axis/spindle check function is switched to a neutral status by FC "SpinCtrl".

Alternatively, the PLC user program can also request the check for the PLC prior to calling FC "SpinCtrl".

By calling this function several times in succession, a better response reaction by the spindle/axis can be obtained as the changeover process in the FC can be omitted.

Activation through the PLC user program is executed in the corresponding spindle interface in byte 8.

After return of the check, the spindle can again be programmed by the NC program.

---

**Note**

**Please note:**

FC 18 must be called cyclically until signal "InPos" or, in the case of an error "Error", produces an edge transition of 1 to 0. Only when the "InPos"/"Error" signal has a 0 state can the axis/spindle concerned be "started" or "stopped" again (the next "start" must be delayed by at least one PLC cycle). This also applies when the assignment in data byte 8 on the axial interface has been changed.

**Abort:**

The function cannot be aborted by means of parameter "Start" or "Stop", but only by means of the axial interface signals (e.g. delete distance-to-go). The axial interface also returns status signals of the axis that may need to be evaluated (e.g. exact stop, traverse command).

**InPos on spindle - rotation/oscillation:**

For the function "Rotate spindle" and also for "Oscillate spindle" the significance of the parameter "InPos" is defined as follows:

Setpoint speed is output → unction started without errors.

Reaching the desired spindle speed must be evaluated via the spindle interface.

**Simultaneity:**

Several axes can be traversed simultaneously or subject to a delay by FC 18 blocks. The upper limit is defined by the maximum number of axes. The NCK handles the PLC function request (FC 18) via independent interfaces for each axis/spindle.

**Axis disable:**

With the axis disabled, an axis controlled via FC 18 will not move. Only a simulated actual value is generated. (Behavior as with NC programming).

---

**! WARNING**

If several block calls (FC 18) have been programmed for the same axis/spindle in the PLC user program, then the functions concerned must be interlocked by conditional calls in the user program. The conditional call of a started block (parameter Start or Stop = TRUE) must be called cyclically until the signal state of output parameter "Active" or "InPos" changes from 1 to 0.

**Functions****1. Position spindle:**

The following signals are relevant:

|          |                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------|

## FRate

The feed rate in FC 18 can also be specified as:

- Cutting rate with unit m/min or feet/min
- Constant grinding wheel surface speed in m/s or feet/s

These alternative velocity settings can be used only if this function is activated by the NC program. Checkback signals for successful activation can be found in byte 84 on the axis interface.

## Error identifiers

If a function could not be executed, this is indicated by the "Error" status parameter being set to 'logic 1'. The error cause is coded at block output "State":

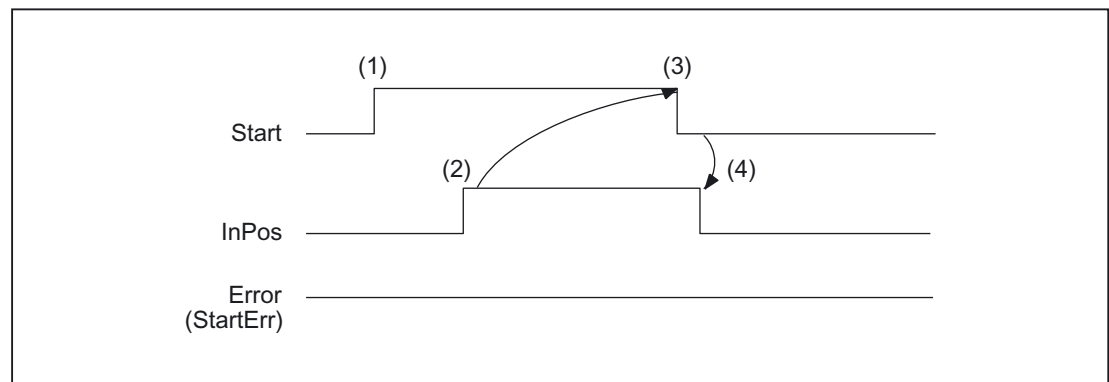

| State                                         | Significance                                                          |

### Pulse diagram

- (1) Activation of function by means of a positive signal edge with start or stop
- (2) Positive acknowledgment: Function executed/Position reached
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change using FC

### Timing diagram (fault scenario)

- (1) Activation of function by means of a positive signal edge with start or stop
- (2) Negative acknowledgment: Error has occurred
- (3) Reset function activation after receipt of acknowledgment
- (4) Signal change using FC

## Call examples

### 1. Position spindle:

```

//Positive acknowledgment resets Start:
U M112.0; //InPos
R M 100.0; //Start

//Negative acknowledgment, after error evaluation (state: MB114) reset with T12
start
U M113.0; //Error
U I 6.4; //Key T12
R M 100.0; //Start

//Start with T13
U I 6.3; //Key T13
AN F 112.0; //Restart only when InPos or Error = 0
AN F 113.0;
S M 100..0;

CALL FC 18 (
 Start := M100.0,
 Stop := FALSE,
 Funct := B#16#1, //Position spindle
 Mode := B#16#2, //Shortest path
 AxisNo := 5,
 Pos := MD104,
 FRate := MD108,
 InPos := M112.0,
 Error := M113.0,
 State := MB114);

```

### 2. Start spindle rotation:

```

CALL FC 18 (
 Start := M100.0,
 Stop := FALSE,
 Funct := B#16q#, //Rotate spindle
 Mode := B#16#5, //Rotational direction as for M4
 AxisNo := 5,
 Pos := 0.0,
 FRate := MD108,
 InPos := M112.0,
 Error := M113.0,
 State := MB114);

```

### 3. Start spindle oscillation

```
CALL FC 18 (
 Start := M100.0,
 Stop := FALSE, //Oscillate spindle
 Funct := B#16#3,
 Mode := B#16#0,
 AxisNo := 5,
 Pos := 0.0,
 FRate := MD108,
 InPos := M112.0,
 Error := M113.0,
 State := MB114);
```

### 4. Traverse indexing axis

```
CALL FC 18 (
 Start := M100.0,
 Stop := FALSE, //Not used
 Funct := B#16#4, //Traverse indexing axis
 Mode := B#16#0, //Position absolutely
 AxisNo := 4,
 Pos := MD104, //Default setting in REAL: 1.0;2.0;..
 FRate := MD108,
 InPos := M112.0,
 Error := M113.0,
 State := MB114);
```

### 5. Position axes

```
CALL FC 18 (
 Start := M100.0,
 Stop := FALSE, //Not used
 Funct := B#16#5, //Position axes
 Mode := B#16#1, //Position incrementally
 AxisNo := 6,
 Pos := MD104,
 FRate := MD108,
 InPos := M112.0,
 Error := M113.0,
 State := MB114);
```

### 13.13.23 FC 19: MCP\_IFM transmission of MCP signals to interface

#### Function

With the FC MCP\_IFM (M-variant) from the machine control panel a range of 19 inch e.g. MCP 483 are transferred to the corresponding signals of the NCK-/PLC-interface:

- Mode Groups
- Axis selections
- WCS/MCS switchover commands
- Traversing keys
- Overrides
- Key-operated switch

In the basic program (FC 2) handwheel selections, modes and other operating signals are transferred from the operator panel front (HMI) to the NCK/PLC interface so that the modes support selection from the MCP or HMI.

Transfer of MMC signals to the interface can be deactivated by setting the value of the parameter "MMCToIF" to "FALSE" in FB 1 (DB 7).

The following specifications apply to the **feed override**, **axis travel keys** and **INC keys** depending on the active mode or on the coordinate system selected:

- **Feed override:**
  - The feed override is transferred to the interface of the selected channel and to the interface of the axes.
  - The feed override signals are transferred to the NC channel in addition to the "Rapid traverse override" (DBB 5) interface byte if the "Feed override for rapid traverse effective" HMI signal is set (exception: Switch setting "Zero"). "Rapid traverse override effective" is also set with this HMI signal.
- **Machine functions for INC and axis travel keys:**
  - When the MCS is selected, the signals are transferred to the interface of the selected machine axis.
  - When the WCS is selected, the signals are transferred to the geo-axis interface of the parameterized channel.
  - When the system is switched between MCS and WCS, the active axes are generally deselected.

The **handwheel selection signals from the HMI** are decoded and activated in the machine-axis or the Geo-axis interface of the handwheel selected (only if parameter "HWheelMMC := TRUE" in FB 1).

The LEDs on the machine control panel derived from the selections in the acknowledgment.

Feedrate and spindle Start/Stop are not transferred to the interface, but output modally as a "FeedHold" or "SpindleHold" signal. The user can link these signals to other signals leading to a feed or spindle stop (this can be implemented, e.g. using the appropriate input signals in FC 10: AL\_MSG). The associated LEDs are activated at the same time.

If the machine control panel fails, the signals it outputs are preset to zero; this also applies to "FeedHold" and "SpindleHold" output signals.

Multiple calls of FC 19 or FC 24, FC 25, FC 26 are permitted in a single PLC cycle. In this case, the first call in the cycle drives the LED displays. Furthermore, all actions of the parameterized block are carried out in the first call. In the following calls, only a reduced level of processing of the channel and mode group interface takes place. The geometry axes are supplied with directional data only in the first block call in the cycle.

Single block processing can be selected/deselected only in the first call in the cycle.

The second machine control panel can be processed if parameter "ModeGroupNo" has been increased by B#16#10. When parameterizing, the HHU number is contained in the lower nibble (lower 4 bits).

"BAGNo" = 0 or B#16#10 means that the mode group signals are not processed.

"ChanNo" = 0 means that the channel signals are not processed.

The INC selections are transferred to the mode group interface. The activation for this specification is done via the DB10.DBX57.0 (INC-inputs in BAG-area active) through this block once after power up.

Machine control panels can still be handled in parallel by this module. The module 2 call for the 2nd machine control panel in OB1 cycle must come after the call of the 1st MCP Support for two MCPs is provided in the control panel blocks up to certain limits (support is not provided as standard for mutual interlocking of axis selections with identical assignments on two MCPs).

## Flexible axis configuration

It is possible to be flexible in the assignment of axis selections or direction keys for machine axis numbers.

Better support is now provided by the MCP blocks for the use of two MCPs, which are to run in parallel, in particular for an application using two channels and two mode groups. Note that the axis numbers are also specified in the parameterized mode group number of the MCP block in the axis tables of the relevant MCP.

To afford this flexibility, tables for axis numbers are stored in DB 10.

For the **first** machine control panel (MCP) the table starts from the byte 8 (symbolic name: MCP1AxisTb[1..22]) and for the **second** Machine control panel (MCP) starting from the byte 32 (symbolic name: MCP2AxisTb[1..22]) for the second MCP. Here the machine axis numbers are to be entered byte-wise.

It is permissible to enter a value of 0 in the axis table. Checks are not made to find illegal axis numbers, meaning that false entries can lead to a PLC Stop.

For **FC 19**, the **maximum possible number of axis selections** can also be restricted. This upper limit is set for the first Machine control panel in DB10.DBW30 (symbolic name: MCP1MaxAxis) or for the second Machine control panel in DB10.DBW54 (symbolic name: MCP2MaxAxis) set.

The default setting is 0, corresponding to the maximum number of configured axes. The axis numbers and the limit can also be adapted dynamically. Afterwards, a new axis must be selected on FC 19. Axis numbers may not be switched over while the axes are traversing the relevant direction keys.

The compatibility mode is preset with axis numbers **1 to 9** for both MCPs and restricted to the configured number of axes.

### Example

More than nine axes are to be controlled with FC19 using a special application. We recommend that you proceed as follows:

- Reserve free key on MCP
- Evaluate this key as a flipflop
- Evaluate the flipflop output as pos. and neg. edge
- For pos. edge write one set of axis numbers in the axis table (DB10) and switch on LED via this key.
- For neg. edge write one set of axis numbers in the axis table (DB10) and switch on LED via this key.

### Declaration of the function

```

FUNCTION FC 19 : VOID //symbolic name: MCP_IFM

 VAR_INPUT
 BAGNo : BYTE ;
 ChanNo: BYTE ;
 SpindleIFNo: BYTE ;
 END_VAR

 VAR_OUTPUT
 FeedHold : BOOL ;
 SpindleHold : BOOL ;
 END_VAR

BEGIN
END_FUNCTION

```

### Description of formal parameters

The table below shows all formal parameters of the "MCP\_IFM" function:

| Signal      | Type | Type | Range of values                         | Remark                                                                                                                             |
|-------------|------|------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| BAGNo       | I    | BYTE | 0 - b#16#0A and<br>b#16#10 -<br>b#16#1A | No. of mode group to which the mode signals are transferred.<br>BAGNo >= b#16#10 means access to the second machine control panel. |
| ChanNo      | I    | BYTE | 0 - B#16#0A                             | Channel no. for the channel signals                                                                                                |
| SpindleIFNo | I    | BYTE | 0 - 31<br>(B#16#1F)                     | Number of the axis interface declared as a spindle                                                                                 |
| FeedHold    | O    | BOOL |                                         | Feed stop from MCP, modal                                                                                                          |
| SpindleHold | O    | BOOL |                                         | Spindle stop from MCP, modal                                                                                                       |

### Channel signals

| Destination:<br>MCP - LED | Source:<br>Interface DB (parameter ChanNo) |
|---------------------------|--------------------------------------------|
| NC start                  | DB21, ... .DBX35.0                         |
| NC stop                   | DB21, ... .DBX35.2 or DB21, ... .DBX35.3   |
| Single block              | DB21, ... .DBX0.4                          |

#### Note

Direction key LEDs are controlled by operating the direction keys.

Axis selection and WCS/MCS LEDs are controlled by operating the relevant pushbutton switch.

### Call example

```
CALL FC 19 (//Machine control panel M variants Signals to interface
 BAGNo := B#16#1, //Mode group no. 1
 ChanNo := B#16#1, //Channel no. 1
 SpindleIFNo := B#16#4, //Spindle interface number = 4
 FeedHold := m22.0, //Feed stop signal modal
 SpindleHold := db2.dbx151.0); //Spindle stop modal in
//message DB
```

With these parameter settings, the signals are sent to the 1st mode group, the 1st channel and all axes. In addition, the spindle override is transferred in the 4th axis/spindle interface. The feed hold signal is passed to bit memory 22.0 and the spindle stop signal to data block DB2, data bit 151.0.

### Reconnecting the axis selections

To ensure a flexible assignment of the axis selection keys to the appropriate axis or spindle, FC 19 **needs not be modified or reprogrammed**. The axis number simply has to be entered in axis table DB10.DBB8 and followed as required: The axis number simply has to be entered in axis table DB10.DBB8 and followed as required:

#### Example:

The spindle is defined as the 4th axis and must be selected via axis key 9.

```
Solution:
The value 4 must be entered in DB10 byte (8+(9-1)) for the 4th axis.

CALL FC 19 (//signals to interface
 BAGNo := B#16#1, //Mode group no. 1
 ChanNo := B#16#1, //Channel no. 1
 SpindleIFNo := B#16#4, //Spindle interface number = 4

 FeedHold := m30.0, //Feed stop signal modal
 SpindleHold := m30.1); //Spindle stop modal
```

### 13.13.24 FC 21: transfer PLC NCK data exchange

#### Function

When the Transfer block is called, data are exchanged between the PLC and NCK according to the selected function code. Data are transferred as soon as FC 21 is called, not only at the start of the cycle.

The "Enable" signal activates the block.  
FC 21 is processed only when "Enable" = "1".

The following functions for the data exchange between PLC and NCK are supported:

1. Signal synchronized actions at the NCK - channel
2. Signals synchronized actions from NCK - channel
3. Fast data exchange PLC-NCK (Read function in NCK)
4. Fast data exchange PLC-NCK (Write function in NCK)
5. Update control signals to NCK - channel
6. Update control signals to axes (data byte 2 of the user interface)
7. Update control signals to axes (data byte 4 of the user interface)

## Declaration of the function

### STL representation

```

VAR_INPUT
 Enable : BOOL ;
 Funct: BYTE ;
 S7Var : ANY ;
 IVar1 : INT ;
 IVar2 : INT ;

END_VAR

VAR_OUTPUT
 Error : BOOL ;
 ErrCode : INT ;

END_VAR

```

## Explanation of formal parameters

The table below shows all formal parameters of the "Transfer" function:

| Signal | Type | Type | Value range          | Comment            |                                   |
|--------|------|------|----------------------|--------------------|-----------------------------------|
| Enable | I    | BOOL |                      | 1 = FC 21 active   |                                   |
| Funct  | I    | BYTE | 1 ... 7              | 1:                 | Synchronized actions at channel   |
|        |      |      |                      | 2:                 | Synchronized actions from channel |
|        |      |      |                      | 3:                 | Read data                         |
|        |      |      |                      | 4:                 | Write data                        |
|        |      |      |                      | 5:                 | Control signals to channel        |
|        |      |      |                      | 6, 7:              | Control signals to axis           |
| S7Var  | I    | ANY  | S7 data storage area | Depends on "Funct" |                                   |
| IVAR1  | I    | INT  | 0 ...                | Depends on "Funct" |                                   |
| IVAR2  | I    | INT  | 1 ...                | Depends on "Funct" |                                   |

13.13 Block descriptions

| Signal  | Type | Type | Value range | Comment            |
|---------|------|------|-------------|--------------------|
| Error   | O    | BOOL |             |                    |
| ErrCode | O    | INT  |             | Depends on "Funct" |

**Function 1, 2: Signals synchronized actions to / from Channel**

Synchronized actions can be disabled or enabled by the PLC.  
 The data area is stored on the user interface in DB21, ... .DBB300 ...307 (to channel) and DB21, ... .DBB308 ...315 (from channel). The parameter "S7Var" is not evaluated for this function, but must be assigned an actual parameter (see call example). The data are transferred to/from the NC as soon as FC 21 is processed.

The following signals are relevant:

| Signal  | Type | Type | Value range          | Comment                              |
|---------|------|------|----------------------|--------------------------------------|
| Enable  | I    | BOOL |                      | 1 = FC 21 active                     |
| Funct   | I    | BYTE | 1, 2                 | 1: Synchronized actions at channel   |
|         |      |      |                      | 2: Synchronized actions from channel |
| S7Var   | I    | ANY  | S7 data storage area | Not used                             |
| IVAR1   | I    | INT  | 1..MaxChannel        | Channel number                       |
| Error   | O    | BOOL |                      |                                      |
| ErrCode | O    | INT  |                      | 1: "Funct" invalid                   |
|         |      |      |                      | 10: Channel no. invalid              |

**Call example:**

```

FUNCTION FC 100 : VOID

VAR_TEMP
 myAny: ANY ;
END_VAR

BEGIN
NETWORK

//Deactivate synchronized actions with ID3, ID10 and ID31 in NC channel 1 :
SYAK: OPEN DB21;
 SET;
 S DBX 300.2; //ID3
 S DBX 301.1; //ID10
 S DBX 303.6; //ID31
 L B#16#1;
 T MB11;
 SPA TRAN;

```

```
//Synchronized actions from NCK channel 1:
SYVK: L B#16#2;
 T MB11;
TRAN: CALL FC 21 (
 Enable := M 10.0, //if TRUE, FC 21 active
 Funct := MB 11,
 S7Var := #myAny, //Not used
 IVAR1 := 1, //Channel no.
 IVAR2 := 0,
 Error := M 10.1,
 ErrCode := MW 12);
END_FUNCTION
```

### Function 3, 4: Rapid data exchange PLC-NCK

#### General

A separate, internal data area is provided to allow the high-speed exchange of data between the PLC and NCK. The size of the internal data field is preset to 4096 bytes. The accesses (read/write) from PLC take place via the FC 21. The occupation of this range (structure) must be defined identically in the NC part program and the PLC user program.

These data can be accessed from the NC parts program by commands \$A\_DBB[x], \$A\_DBW[x], \$A\_DBD[x], \$A\_DBR[x] (see List Manual System variables).

The concrete address in the data field is specified by a byte offset (0 to 4095) in parameter IVAR1. In this case, the alignment must be selected according to the data format, i.e. a Dword starts at a 4-byte limit and a word at a 2-byte limit. Bytes can be positioned on any chosen offset within the data field, single-bit access operations are not supported and converted to a byte access operation by FC 21. Data type information and quantity of data are taken from the ANY parameter, transferred via S7Var.

Without additional programming actions, data consistency is only ensured for 1 and 2 byte access in the NCK and in the PLC. For the 2-byte consistency this is true only for the data type WORD or INT, but not for the data type BYTE.

In the case of longer data types or transfer of fields, which should be transferred consistently, a semaphore byte must be programmed in parameter IVAR2 that can be used by FC 21 to determine the validity or consistency of a block. This handling must be supported by the NC, i.e. in the part program, by writing or deleting the semaphore byte. The semaphore byte is stored in the same data field as the actual user data.

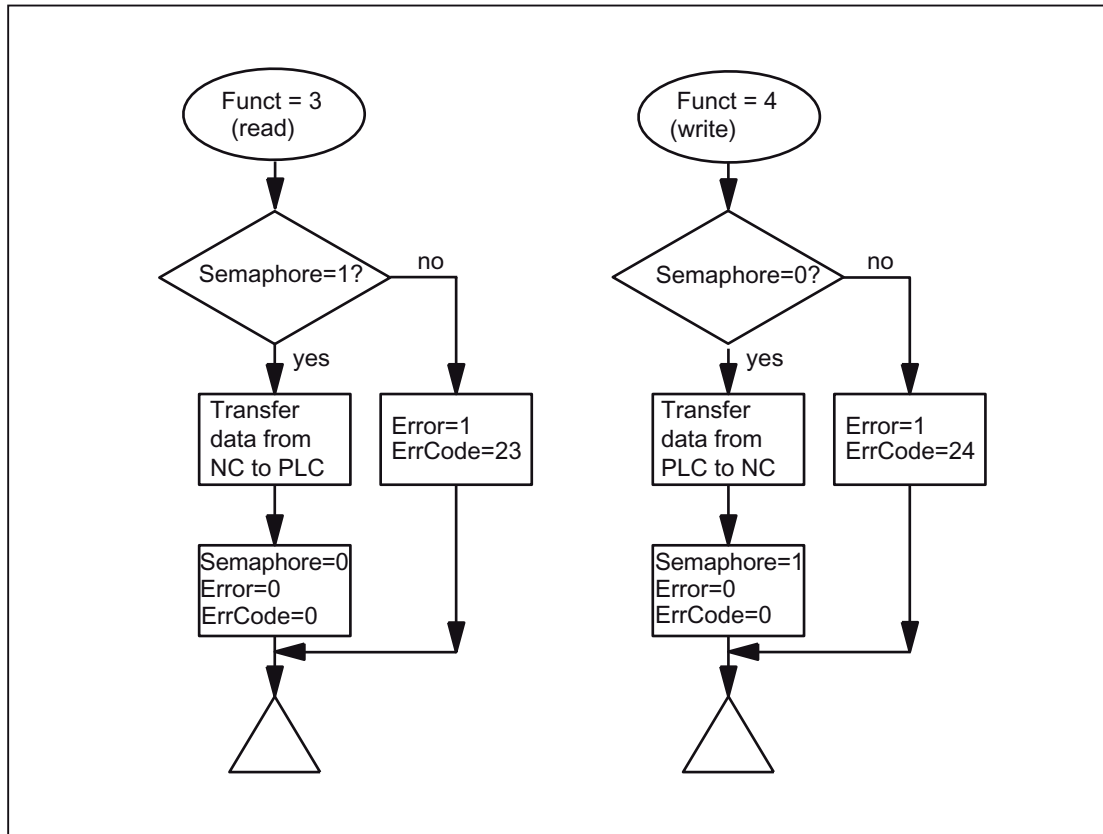

The semaphore byte is identified by a value between 0 and 4095 in IVAR2.

The PLC reads and describes the semaphore byte via FC 21 in the same call, which should transfer the user data. The PLC programmer only needs to set up a semaphore variable. For access from the NC via the parts program, the semaphore feature must be programmed using individual instructions according to the flow chart shown below. The sequence is different for reading and writing variables.

Only individual variables or ARRAYS can be supported directly by the semaphore technique. Structure transfers must be subdivided into individual jobs. The user must ensure data consistency of this structure by programming a semaphore system.

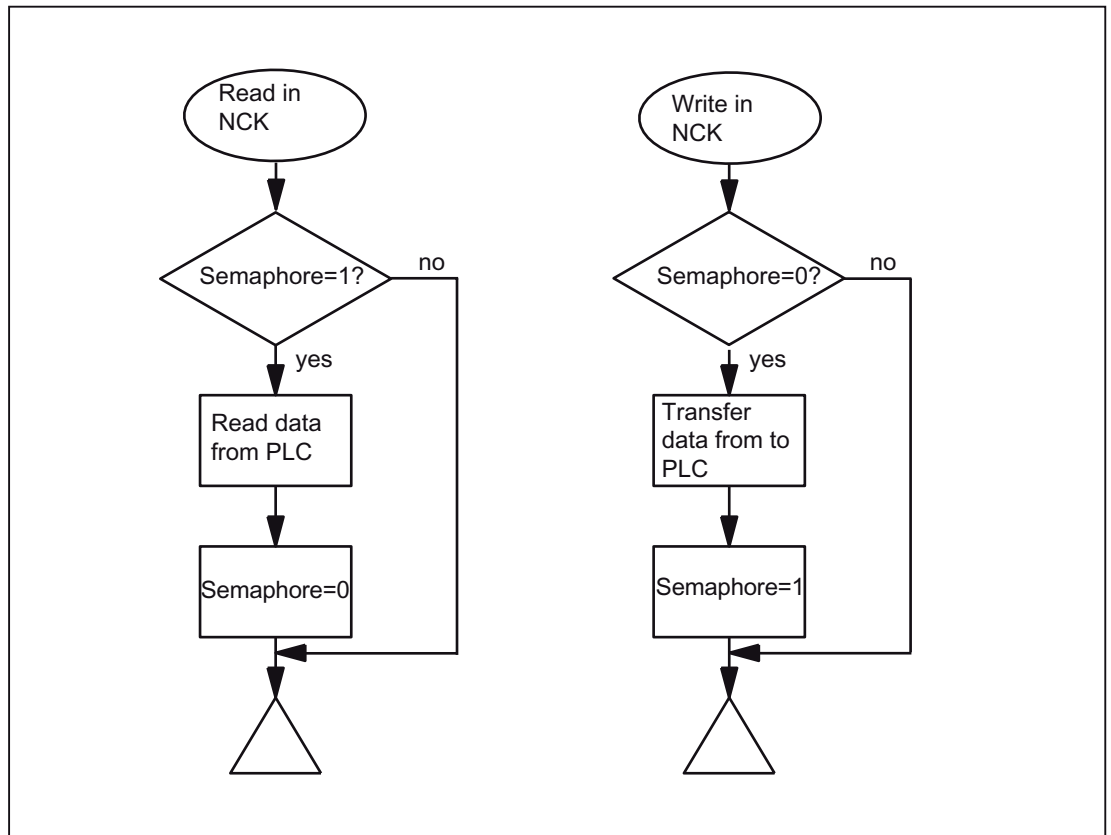

If IVAR2 is set to -1, data are transferred without a semaphore.

**Data exchange with semaphore in PLC (schematic of FC21)**

Basic structure in NCK:

#### Variable value ranges

The following signals are relevant:

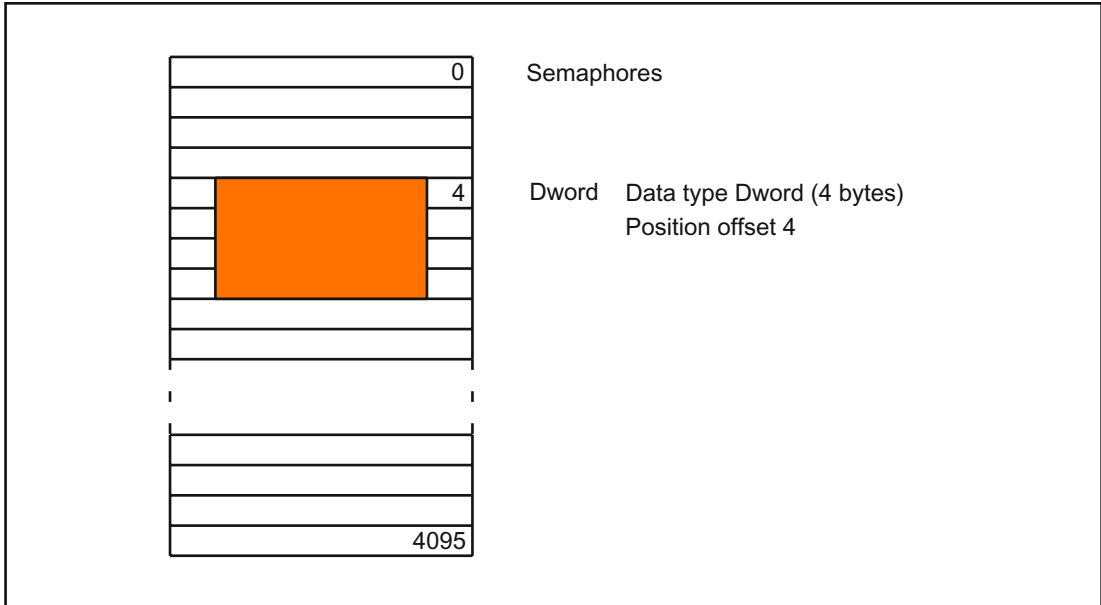

| Signal  | Type | Type | Value range                     | Comment                                          |
|---------|------|------|---------------------------------|--------------------------------------------------|
| Enable  | I    | BOOL |                                 | = FC 21 active                                   |
| Funct   | I    | BYTE | 3, 4                            | 3: Read data                                     |
|         |      |      |                                 | 4: Write data                                    |
| S7Var   | I    | ANY  | S7 data area, except local data | Source/destination data storage area             |
| IVAR1   | I    | INT  | 0 ... 4095                      | Position offset                                  |
| IVAR2   | I    | INT  | -1 ... 4095                     | Semaphore byte<br>Transfer without semaphore: -1 |
| Error   | O    | BOOL |                                 |                                                  |
| ErrCode | O    | INT  |                                 | 20: Alignment error                              |
|         |      |      |                                 | 21: illegal position offset                      |
|         |      |      |                                 | 22: Illegal semaphore byte                       |
|         |      |      |                                 | 23: No new data to be read                       |
|         |      |      |                                 | 24: Cannot write data                            |
|         |      |      |                                 | 25: Local data parameterized for S7Var           |

**Call example:**

**1. Read double word of position offset 4 with semaphore in byte 0 and store in MD100:**

Data type Dword (4 bytes)

Position offset 4

```

CALL FC 21 (
 Enable := M 10.0, //if TRUE, FC 21 active
 Funct := B#16#3, //Read data
 S7Var := P#M 100.0 DWORD 1,
 IVAR1 := 4,
 IVAR2 := 0,
 Error := M 10.1,
 ErrCode := MW12);
UN M10.1; //Enable while 1, until value is read
R M10.0;

```

**Examples: Examples of NCK programming from synchronized actions:**

**Data transfer from NC to PLC, with data written via synchronized actions;**

**Byte 0 serves as the semaphore**

```
ID=1 WHENEVER $A_DBB[0] == 0 DO $A_DBR[4] = $AA_IM[X] $A_DBB[0] = 1
```

**Data transfer from PLC to NC, with data read via synchronized actions;**

**Byte 1 serves as the Semaphore:**

```
ID=2 WHENEVER $A_DBB[1] == 1 DO $R1 = $A_DBR[12] $A_DBB[1] = 0
```

## 2. Read word of position offset 8 without semaphore and store in MW 104:

```

CALL FC 21 (
 Enable :=M 10.0, //if TRUE, FC 21 active
 Funct :=B#16#3, //Read data
 S7Var :=P#M 104.0 WORD 1,
 IVAR1 :=8,
 IVAR2 :=-1,
 Error :=M 10.1,
 ErrCode :=MW12);

```

### Function 5: Update control signals to channel

The purpose of this function is to transmit important control signals at high speed in between cyclic data transfers. Data bytes 6 and 7 of user interfaces DB21, ... are transferred to the NC. The channel is specified in parameter "IVAR1". This enable, for example, the feed disable, read-in disable to be transferred outside of the PLC cycle.

The following signals are relevant:

| Signal  | Type | Type | Value range          | Comment                       |
|---------|------|------|----------------------|-------------------------------|
| Enable  | I    | BOOL |                      | 1= FC 21 active               |
| Funct   | I    | BYTE | 5                    | 5: Control signals to channel |
| S7Var   | I    | ANY  | S7 data storage area | Not used                      |
| IVAR1   | I    | INT  | 1st max. channel     | Channel number                |
| Error   | O    | BOOL |                      |                               |
| ErrCode | O    | INT  |                      | 1: "Funct" invalid            |
|         |      |      |                      | 10: Channel no. invalid       |

### Function 6: Update control signals to axes

The purpose of function 6 is to transmit important control signals at high speed in between cyclic data transfers. The **data byte 2** of application interface DB31, ... is transferred to the NC. The transfer is performed for all activated axes. This allows the controller enable to be transferred outside the PLC cycle, for example.

The following signals are relevant:

| Signal  | Type | Type | Value range          | Comment                    |
|---------|------|------|----------------------|----------------------------|
| Enable  | I    | BOOL |                      | 1= FC 21 active            |
| Funct   | I    | BYTE | 6                    | 6: Control signals to axes |
| S7Var   | I    | ANY  | S7 data storage area | Not used                   |
| IVAR1   | I    | INT  | 0                    |                            |
| Error   | O    | BOOL |                      |                            |
| ErrCode | O    | INT  |                      | 1: "Funct" invalid         |

### Function 7: Update control signals to axes

The purpose of function 7 is to transmit important control signals at high speed in between cyclic data transfers. The **data byte 4** of application interface DB31, ... is transferred to the NC. The transfer is performed for all activated axes. This enables, for example, the feed stop to be transferred outside the PLC cycle.

The following signals are relevant:

| Signal  | Type | Type | Value range          | Comment                    |
|---------|------|------|----------------------|----------------------------|
| Enable  | I    | BOOL |                      | 1= FC 21 active            |
| Funct   | I    | BYTE | 7                    | 7: Control signals to axes |
| S7Var   | I    | ANY  | S7 data storage area | Not used                   |
| IVAR1   | I    | INT  | 0                    |                            |
| Error   | O    | BOOL |                      |                            |
| ErrCode | O    | INT  |                      | 1: "Funct" invalid         |

### 13.13.25 FC 22: TM\_DIR Direction selection for tool management

#### Function

The block TM\_DIR provides the shortest path for positioning a magazine or a revolver based on the actual and setpoint position.

As long as a 1 signal is applied to the **Start** input, all output parameters are updated cyclically. Changes can be made to input parameters (e.g. position values) in subsequent PLC cycles.

The output signals are undefined when the start signal is at 0 level.

In the case of direction selection with special positioning input "Offset" > 0, a new setpoint position is calculated from the setpoint and special positions and the number of magazine locations according to the following formula:

New setpoint position = (setpoint pos. - (special pos. -1)) neg. modulo # locations

The new setpoint position corresponds to the location number at which the magazine must be positioned so that the setpoint position requested by the user corresponds to the location number of the special position. The directional optimization is active both with and without special positioning.

The block must be called once with the appropriate parameter settings for each magazine.

#### WARNING

The block may only be called in conjunction with the tool management.

#### Note

For further details on tool management (also with regard to PLC) refer to the Description of Functions Tool Management. Furthermore, PI services are provided for tool management via the FB 4, FC 7 and FC 8 (see also the corresponding Sections in this documentation).

## Declaration of the function

### STL representation

```

FUNCTION FC 22 : VOID
//NAME: TM_DIR
VAR_INPUT
 MagNo: INT ;
 ReqPos: INT;
 ActPos: INT;
 Offset: BYTE ;
 Start: BOOL ;
END_VAR

VAR_OUTPUT
 Cw: BOOL ;
 Ccw: BOOL ;
 InPos: BOOL ;
 Diff: INT;
 Error : BOOL ;
END_VAR

BEGIN
END_FUNCTION

```

## Description of formal parameters

The table below shows all formal parameters of the "TM\_DIR" function.

| Signal | Type | Type | Range of values | Remark                             |
|--------|------|------|-----------------|------------------------------------|
| MagNo  | I    | INT  | 1 ...           | Magazine number                    |
| ReqPos | I    | INT  | 1 ...           | Setpoint location                  |
| ActPos | I    | INT  | 1 ...           | Actual location                    |
| Offset | I    | BYTE | 0 ...           | Offset for special positioning     |
| Start  | I    | BOOL |                 | Start of calculation               |
| Cw     | O    | BOOL |                 | 1 = Move magazine clockwise        |
| Ccw    | O    | BOOL |                 | 1 = Move magazine counterclockwise |
| InPos  | O    | BOOL |                 | 1 = In position                    |
| Diff   | O    | INT  | 0 ...           | Differential path (shortest path)  |
| Error  | O    | BOOL |                 | 1 = error                          |

### Call example

```
CALL FC 22 (//Tool management direction selection
 MagNo := 2, //Magazine number
 ReqPos := mw 20, //Target position
 ActPos := mw 22, //Current position
 Offset := b#16#0, //Offset for special positioning
 Start := m 30.4, //Start trigger
 ; //Return parameters
 Cw := m 30.0, //Move magazine
 ; //in anticlockwise direction
 Ccw := m 30.1, //Move magazine
 ; //in anticlockwise direction
 InPos := m 30.2, //Magazine in position
 Diff := mw 32, //Differential path
 Error := m30.3 //Error has occurred
);
```

### 13.13.26 FC 24: MCP\_IFM2 transmission of MCP signals to interface

#### Function

With FC MCP\_IFM2 (M variant slim machine control panel e.g. MCP 310), the following are transferred from the machine control panel (MCP) to the corresponding signals of the NCK/PLC interface:

- Mode groups
- Axis selections
- WCS/MCS switchover
- Traversing keys
- Overrides or override simulation signals

In the basic program (FC 2), handwheel selections, modes and other operating signals continue to be transferred from the operator panel front or HMI to the NCK/PLC interface so that the modes support selection from the MCP or HMI.

Transfer of HMI signals to the interface can be deactivated by setting the value of the parameter "MMCToIF" to "FALSE" in FB 1 (DB 7). "MMCToIF" can also be activated/deactivated in the cyclic program by setting and resetting (e.g. R gp\_par.MMCToIF).

The following specifications apply to the **feed override, axis travel keys** and **INC keys** depending on the active mode or on the coordinate system selected:

- **Feed override:**
  - The feed override is transferred to the interface of the selected channel and to the interface of the axes.
  - The feed override signals are transferred to the NC channel in addition to the "Rapid traverse override" (DBB 5) interface byte if the "Feed override for rapid traverse effective" HMI signal is set (exception: Switch setting "Zero"). "Rapid traverse override effective" is also set with this HMI signal.
- **Machine functions for INC and axis travel keys:**
  - When the MCS is selected, the signals are transferred to the interface of the selected machine axis.
  - When the WCS is selected, the signals are transferred to the geo-axis interface of the parameterized channel.
  - When the system is switched between MCS and WCS, the active axes are generally deselected.

The **handwheel selection signals from HMI** are decoded and activated in the machine-axis or the Geo-axis interface of the handwheel selected (only if parameter "HWheelMMC := TRUE" in FB 1).

The associated LEDs of the machine control panel are derived from the acknowledgments from the relevant selections.

Feedrate and spindle Start/Stop are not transferred to the interface, but output modally as a "FeedHold" or "SpindleHold" signal. The user can link these signals to other signals leading to a feed or spindle stop (this can be implemented, e.g. using the appropriate input signals in FC 10: AL\_MSG). The associated LEDs are activated at the same time.

The **spindle direction** (+, -) is not switched directly either, but made available as output parameter "SpindleDir". permitting, for example, FC 18 to be parameterized. A spindle enable signal is also switched via parameter "SpindleHold". One possible method of moving a spindle directly is to preselect it as an axis so that it can be traversed via (axis) direction keys.

If the machine control panel fails, the signals it outputs are preset to zero; this also applies to "FeedHold" and "SpindleHold" output signals.

Multiple calls of FC 24 or FC 19, FC 25, FC 26 are permitted in a single PLC cycle. In this case, the first call in the cycle drives the LED displays. Furthermore, all actions of the parameterized block are carried out in the first call. In the following calls, only a reduced level of processing of the channel and mode group interface takes place. The geometry axes are supplied with directional data only in the first block call in the cycle.

Single block processing can be selected/deselected only in the first call in the cycle.

The second machine control panel can be processed if parameter "ModeGroupNo" has been increased by B#16#10. When parameterizing, the HHU number is contained in the lower nibble (lower 4 bits).

"BAGNo" = 0 or B#16#10 means that the mode group signals are not processed.

ChanNo = 0 means that the channel signals are not processed.

The INC selections are transferred to the mode group interface. The activation for this specification is done via the DB10.DBX57.0 (INC-inputs in BAG-area active) through this block once after power up.

Furthermore, two machine control panels can be handled in parallel by this block. The module 2 call for the 2nd machine control panel in OB1 cycle must come after the call of the 1st MCP. Support for two MCPs is provided in the control panel blocks up to certain limits (support is not provided as standard for mutual interlocking of axis selections with identical assignments on two MCPs).

### Flexible axis configuration

It is possible to be flexible in the assignment of axis selections or direction keys for machine axis numbers.

Better support is now provided by the MCP blocks for the use of two MCPs, which are to run in parallel, in particular for an application using two channels and two mode groups. Note that the axis numbers are also specified in the parameterized mode group number of the MCP block in the axis tables of the relevant MCP.

To afford this flexibility, tables for axis numbers are stored in DB 10.

For the **first** machine control panel (MCP), the table starts at byte 8 (symbolic name: MCP1AxisTbl[1..22]) and for the **second** machine control panel (MCP) starting from the byte 32 (symbolic name: MCP2AxisTbl[1..22]) for the second MCP. The machine axis numbers must be entered byte by byte here. It is permissible to enter a value of 0 in the axis table. Checks are not made to find impermissible axis numbers, meaning that false entries can lead to a PLC Stop.

For **FC 24**, the **maximum possible number of axis selections** can also be restricted.

This upper limit is set for the 1st machine control panel in DB10.DBW30 (symbolic name: MCP1MaxAxis) or for the 2nd machine control panel in DB10.DBW54 (symbolic name: MCP2MaxAxis) for the respective MCP.

The default setting is 0, corresponding to the maximum number of configured axes. The axis numbers and the limit can also be adapted dynamically. Afterwards, a new axis must be selected on FC 24. Axis numbers may not be switched over while the axes are traversing the relevant direction keys. The compatibility mode is preset with axis numbers **1 to 6** for both MCPs and restricted to the configured number of axes.

### Declaration of the function

```

FUNCTION FC 24 : VOID
//NAME: MCP_IFM2

VAR_INPUT
 BAGNo : BYTE ;
 ChanNo: BYTE ;
 SpindleIFNo: BYTE ;
END_VAR

```

```

VAR_OUTPUT
 FeedHold : BOOL ;
 SpindleHold : BOOL ;
 SpindleDir: BOOL ;
END_VAR

BEGIN
END_FUNCTION

```

### Description of formal parameters

The table below shows all formal parameters of the "MCP\_IFM2" function:

| Signal      | Type | Type | Range of values                         | Remark                                                                                                                             |
|-------------|------|------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| BAGNo       | I    | BYTE | 0 - b#16#0A<br>and<br>b#16#10 - b#16#1A | No. of mode group to which the mode signals are transferred.<br>BAGNo >= b#16#10 means access to the second machine control panel. |
| ChanNo      | I    | BYTE | 0 - B#16#0A                             | Channel no. for the channel signals                                                                                                |
| SpindleIFNo | I    | BYTE | 0 - 31<br>(B#16#1F)                     | Number of the axis interface declared as a spindle                                                                                 |
| FeedHold    | O    | BOOL |                                         | Feed stop from MCP, modal                                                                                                          |
| SpindleHold | O    | BOOL |                                         | Spindle stop from MCP, modal                                                                                                       |
| SpindleDir  | O    | BOOL |                                         | Direction of spindle rotation                                                                                                      |
|             |      |      |                                         | 0: corresponds to + (left)                                                                                                         |
|             |      |      |                                         | 1: corresponds to - (right)                                                                                                        |

### Call example

```

CALL FC 24 (
//Slim machine control panel M variants
//signals to interface
 BAGNo := B#16#1, //Mode group no. 1
 ChanNo := B#16#1, //Channel no. 1
 SpindleIFNo := B#16#4, //Spindle interface number = 4
 FeedHold := m22.0, //Feed stop signal modal
 SpindleHold := db2.dbx151.0); //Spindle stop modal in message data block
 SpindleDir:= m22.1); //Spindle direction return

```

With these parameter settings, the signals are sent to the 1st mode group, the 1st channel and all axes. In addition, the spindle override is transferred in the 4th axis/spindle interface. The feed hold signal is passed to bit memory 22.0 and the spindle stop signal to data block DB2, data bit 151.0. The spindle direction feedback signal supplied via parameter "SpindleDir" can be used as a direction input for an additional FC 18 call.

### 13.13.27 FC 25: MCP\_IFT transfer of MCP/OP signals to interface

#### Function

With the FC MCP\_IFM (M-variant) from the machine control panel a range of 19 inch e.g. MCP 483 are transferred to the corresponding signals of the NCK-/PLC interface:

- Mode groups
- Direction keys of four axes
- WCS/MCS switchover commands
- Overrides
- Key-operated switch

In the basic program (FC 2), handwheel selections, modes and other operating signals continue to be transferred from the operator panel front or HMI to the NCK/PLC interface so that the modes support selection from the MCP or BT.

Transfer of HMI signals to the interface can be deactivated by setting the value of the parameter "MMCToIF" to "FALSE" in FB 1 (DB 7).

The following specifications apply to the **feed override, axis travel keys** and **INC keys** depending on the active mode or on the coordinate system selected:

- **Feed override:**
  - The feed override is transferred to the interface of the selected channel and to the interface of the axes.
  - The feed override signals are transferred to the NC channel in addition to the "Rapid traverse override" (DBB 5) interface byte if the "Feed override for rapid traverse effective" HMI signal is set (exception: Switch setting "Zero"). "Rapid traverse override effective" is also set with this HMI signal.
- **Machine functions for INC and axis travel keys:**
  - When the MCS is selected, the signals are transferred to the interface of the selected machine axis.
  - When the WCS is selected, the signals are transferred to the geo-axis interface of the parameterized channel.

The **handwheel selection signals from the MMC** are decoded and activated in the machine-axis or the Geo-axis interface of the handwheel selected (only if parameter "HWheelMMC := TRUE" in FB 1). = TRUE").

The LEDs on the machine control panel derived from the selections in the acknowledgment.

Feedrate and spindle Start/Stop are not transferred to the interface, but output modally as a "FeedHold" or "SpindleHold" signal. The user can link these signals to other signals leading to a feed or spindle stop (this can be implemented, e.g. using the appropriate input signals in FC 10: AL\_MSG). The associated LEDs are activated at the same time.

If the machine control panel fails, the signals it outputs are preset to zero; this also applies to "FeedHold" and "SpindleHold" output signals.

Multiple calls of FC 25 or FC 19, FC 24, FC 26 are permitted in a single PLC cycle. In this case, the first call in the cycle drives the LED displays. Furthermore, all actions of the parameterized block are carried out in the first call. In the following calls, only a reduced level of processing of the channel and mode group interface takes place. The geometry axes are supplied with directional data only in the first block call in the cycle.

Single block processing can be selected/deselected only in the first cycle.

The second machine control panel can be processed if parameter "ModeGroupNo" has been increased by B#16#10. When parameterizing, the HHU number is contained in the lower nibble (lower 4 bits).

"BAGNo" = 0 or B#16#10 means that the mode group signals are not processed.

ChanNo = 0 means that the channel signals are not processed.

### Flexible axis configuration

It is possible to be flexible in the assignment of axis selections or direction keys for machine axis numbers.

Better support is now provided by the MCP blocks for the use of two MCPs, which are to run in parallel, in particular for an application using two channels and two mode groups. The module 2 call for the 2nd machine control panel in OB1 cycle must come after the call of the 1st MCP. Note that the axis numbers are also specified in the parameterized mode group number of the MCP block in the axis tables of the relevant MCP.

To afford this flexibility, tables for axis numbers are stored in DB 10.

For the **first** machine control panel (MCP), the table starts at byte 8 (symbolic name: MCP1AxisTbl[1..22]) and for the **second** Machine control panel (MCP) starting from the byte 32 (symbolic name: MCP2AxisTbl[1..22]) for the second MCP. The machine axis numbers are entered here byte-wise. It is permissible to enter a value of 0 in the axis table. Checks are not made to find impermissible axis numbers, meaning that false entries can lead to a PLC Stop.

The restriction of the **possible number of axes at FC 25** is done via the 0-values in the axis table. The axis numbers can also be adapted dynamically. Axis numbers may not be switched over while the axes are being traversed via the relevant direction keys. The compatibility mode is preset with axis numbers **1 to 4** for both MCPs and restricted to the configured number of axes.

---

#### Note

For further information see "FC 19: MCP\_IFM transmission of MCP signals to interface (Page 1058)".

---

**Declaration of the function**

```

FUNCTION FC 25 : VOID
//NAME: MCP_IFT

VAR_INPUT
 BAGNo : BYTE ;
 ChanNo: BYTE ;
 SpindleIFNo: BYTE ;
END_VAR

VAR_OUTPUT
 FeedHold : BOOL ;
 SpindleHold : BOOL ;
END_VAR

BEGIN
END_FUNCTION

```

**Description of formal parameters**

The table below shows all formal parameters of the "MCP\_IFT" function:

| Signal      | Type | Type | Value range                             | Comment                                                                                                                            |
|-------------|------|------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| BAGNo       | I    | BYTE | 0 - b#16#0A<br>and<br>b#16#10 - b#16#1A | No. of mode group to which the mode signals are transferred.<br>BAGNo >= b#16#10 means access to the second machine control panel. |
| ChanNo      | I    | BYTE | 0 - B#16#0A                             | Channel no. for the channel signals                                                                                                |
| SpindleIFNo | I    | BYTE | 0 - 31<br>(B#16#1F)                     | Number of the axis interface declared as a spindle                                                                                 |
| FeedHold    | O    | BOOL |                                         | Feed stop from MCP, modal                                                                                                          |
| SpindleHold | O    | BOOL |                                         | Spindle stop from MCP, modal                                                                                                       |

## Call example

```
CALL FC 25 (//Machine control panel T variants
 //signals to interface
 BAGNo := B#16#1, //Mode group no. 1
 ChanNo := B#16#1, //Channel no. 1
 SpindleIFNo := B#16#4, //Spindle interface number = 4
 FeedHold := m22.0, //Feed stop signal modal
 SpindleHold := db2.dbx151.0); //Spindle stop modal in message data block
```

With these parameter settings, the signals are sent to the 1st mode group, the 1st channel and all axes. In addition, the spindle override is transferred in the 4th axis/spindle interface. The feed hold signal is passed to bit memory 22.0 and the spindle stop signal to data block DB2, data bit 151.0.

### 13.13.28 FC 26: HPU\_MCP transmission of HT8 signals to interface

Call examples

Call of the FC 26 for the first MCP, the first mode group and the first channel of the NC.

```
CALL FC 26 (
 BAGNo := B#16#01, //Machine control panel of HT8
 ChanNo := B#16#01); //1.MCP, 1.BAG
//Channel 1
```

Call of the FC 26 for the second MCP, the second mode group and the third channel of the NC.

```
CALL FC 26(
 BAGNo := B#16#12, //Machine control panel of HT8
 ChanNo := B#16#03); //2.MCP, 2.BAG
//Channel 3
```

General function description

The function FC 26 "HPU\_MCP (nachine control panel-signals of the hand-held unit HT8" transfers the HT8-specific signals of the following functions between the HT8-input/output data areas parameterized in the function block FB 1 (Parameter: MCPxIn and MCPxOut) and the NC/PLC-interface:

- Mode groups
- Machine function INC
- Coordinate system WCS or MCS
- Axial traverse key
- Axis selection
- Feed override
- Rapid traverse override
- Keyswitch information

**Note**

**Mode switchover through HT 8 and/or HMI**

The function FC 2 "GP\_HP Basic program, cyclic part" transfers the signals of the block-switchover in such a way that an alternative selection of MCP of HT 8 and of the HMI is possible. The transfer of the HMI signals to the NC/PLC interface can also be switched off in the function block FB 1 with the parameter "MMCToIF" = FALSE.

**Active axes:**

Using HT 8 a maximum of 6 axes can be addressed at the same time. The selection of the axes is to be realized by the user/machine manufacturer in the PLC user program.

---

**Flexible axis configuration**

The function FC 26 enables a flexible assignment of the machine axes to the traversing keys or to the axis selection. 2 tables are available in DB 10 for this purpose:

- Machine axis table 1st MCP: DB10.DBB8 to DBB13 (Table of the machine axis number)  
Symbolic name: MCP1AxisTbl[1..22]
- Machine axis table 2nd MCP: DB10.DBB32 to DBB37 (Table of the machine axis number)  
symbolic name: MCP2AxisTbl[1..22]

In the tables the axis numbers n (with n = 1, 2, ...) of the active machine axis are to be entered byte-wise. The value 0 must be entered in the unused table locations.

The table length can be specified to the FC 26:

- 1st MCP: DB10.DBB30 (upper limit of the machine axis table)
- 2nd MCP: DB10.DBB54 (upper limit of the machine axis table)

A value of 4, for example, means that FC 26 takes into account only the first 4 table entries or machine axes. The maximum value for the FC 26 is 6. For value 0 or values greater than 6 the maximum value is taken implicitly.

---

**Note**

Please note the following constraints:

- A check of the permissible machine axis numbers is not done. Invalid machine axis numbers can lead to a PLC Stop.
  - The machine axis numbers can be changed dynamically. The table may not be written, if currently a machine axis is being moved via a traversing key.
-

### Transfer of the traversing key signals depending upon the active coordinate system

The traversing key signals for 6 axes lie in the HT 8 input data area below:

- EB n + 2, Bit 0 - Bit 5 (positive traversing direction)
- EB n + 3, Bit 0 - Bit 5 (negative traversing direction)

The switchover of the coordinate system is done via the input signal:

- EB n + 0, Bit 0 (MCS/WCS)

The input signal is evaluated in FC 26 with the help of the edge trigger flag. The active coordinate system is shown in the following output signal:

- AB n + 0, Bit 0 (MCS/WCKS) with 0 = MCS, 1 = WCS

In case of active MCS the traversing key signals of the axes 1 - 6 are transferred in the axis-specific interfaces (DB31, ... .DBX4.6 and DBX4.7 (traversing key +/-)) of the axes specified in the machine axis tables (DB10.DBB8 to DBB13 or DBB32 to DBB37).

In case of active WCS it is assumed that the axes 1 - 3 of the machine axis table are geometric axes. For this reason the traversing key signals:

- of the axes 1 - 3 (EB n + 2 / 3, Bit 0 - Bit 2) are transferred in the interface of the geometric axes in DB21, ... .DBB 12 + (n \* 4), with n = 0, 1, 2), Bit 6 and Bit 7 (traversing keys +/-) of the channel specified with the parameter "ChanNo" .  
The assignment of the traversing key signals of the axes 1, 2 and 3 to the geometric axes 1, 2 and 3 of the channel is permanent and may not be changed.
- of the axes 4 - 6 (EB n + 2 / 3, Bit 3 - Bit 5) are transferred in the axis-specific interface (DB31, ... .DBX4.6 and DBX4.7 (traversing keys +/-)) of the axes 4 - 6 entered in the machine axis table (DB10.DBB11 to DBB13 or DBB35 to DBB37).

### No traversing of machine axes in WCS

In case of active WCS (AB n + 0, Bit 0 = 1) the traversing of the machine axes can be locked. For this, the following output signals are to be set in the PLC user program:

- AB n + 3, Bit 7 = 1 (For WCS: no machine axes)

Requirement to the FC 26, not to transfer any traversing key signals for the machine axes. The traversing key signals for the axes 1 - 3 of the machine axis table are transferred to the geometric axes 1 - 3 of the specified channel. The traversing key signals for the axes 4 - 6 of the machine axis table are not transferred.

- AB n + 2, Bit 6 (axes 7 - n selected)

Requirement at the FC 26 not to transfer any traversing key signals, since the axes 1 - 6 of the machine axis table are switched over. The axes 1 - 3 are thus not geometric axes, but instead also machine axes.

## Feed override

The value of the HT8 override switch is transferred as feed override in the channel-specific interface DB 21, ... .DBB4 (feedrate override) of the programmed channel (parameter: "ChanNo") and in the axis-specific interfaces DB31, ... .DBB0 (feedrate override) of the axes programmed in the table DB10.DBB8 to DBB13 (machine axis number).

## Rapid traverse override

Is for the programmed channel (parameter: "ChanNo") the signal DB21, ... .DBX25.3 = 1 (feedrate override for rapid traverse) set, the value of the HT8 override switch is set as rapid traverse override in this channel-specific. Interface in DB 21, ... .DBB5 (rapid traverse override) and in addition the signal DB21, ... .DBX6.6 = 1 (rapid traverse override active) is set.

## Machine function INC

The HT8 signals of the machine functions INC are transferred differently depending upon the active coordinate system MCS or WCS:

- Active coordinate system: MCS

The selected machine function INC is transferred for all 6 axes in the axis-specific interfaces in DB31, ... .DBX5.0 to DBX5.5 (machine function) of the axes programmed in the table in DB10.DBB8 to DBB13 (machine axis numbers).

- Active coordinate system: WCS

For the axes 1 to 3 the signals of the machine function INC are transferred in the channel-specific. Interface in DB21, ... .DBX13.0 to DBX13.5 (machine function) of the programmed channel (Parameter: "ChanNo").

For the axes 4 to 6 the signals of the machine function INC are transferred in the channel-specific. interfaces in DB31, ... .DBX5.0 to DBX5.5 (machine function) of the axes programmed in the table in DB10.DBB11 to DBB13 (machine axis numbers).

The selection signals of the INC machine functions are transferred in the mode group-specific interface DB11 DBB 2 + (n \* 20), Bit 0 to Bit 5 (with n = 0, 1, 2, ...). The FC 26 informs the NCK about the activation of the mode group-interface for the INC machine function once after the power-up with DB10.DBX57.0 (INC inputs active in the mode group area).

## Handwheel selection

The hand-wheel selection signals are evaluated by HMI and transferred to the corresponding NC/PLC interface signals of the machine or geometric axes:

- Geometry axes: DB21, ... DBB 12 + (n \* 4), Bit 0 to Bit 2 (with n = 0, 1, 2)
- Machine axes: DB31, ... .DBX4.0 to DBX4.2

Requirement: FB 1-Parameter: "HWheelIMMC" = TRUE

### Multiple call in one PLC cycle

Multiple calls of FC 26 are permitted in a single PLC cycle. Upon the first call in the PLC cycle:

- all actions of the parameterized blocks are executed
- the LED signals are written in the output area
- in case of selected WCS, the traversing key signals of the geometric axes are written
- the signals for the selection and deselection of the individual block are processed

Upon further calls of the FC 26 only a reduced processing of the channel and mode group-interface is done.

### Processing of two MCP

If the function FC 26 is called twice for two MCP in the cyclic sequence of the PLC program (organization block OB 1), the call for the second MCP must be made after the call for the first MCP.

---

#### Note

If an axis can be traversed from two MCP, then the implementation of a mutual interlocking is the responsibility of the user (machine manufacturer).

---

### Failure of the MCP of HT8

In case of failure of the MCP of HT8 all the input signals are set to the value 0.

13.13.29 FC 19, FC 24, FC 25, FC 26 source code description

Task

Machine control panel to application interface (FC 19 M variant, FC 24 slim variant, FC 25 T variant, FC 26 HT8 variant)

Associated blocks

- DB 7, no. of MOGs, channels, axes
- DB 7, pointer of machine control panel
- DB 8, storage for the next cycle

Resources used

None.

General

The blocks FC 19 (M version), FC 24 (slim-line version), FC 25 (T version) and FC 26 (HT8 version) transfer the signals of the machine control panel to and from the application interface. In the input parameters, "ModeGroupNo" selects the mode group to be processed by the block. The "ModeGroupNo" parameter also selects the number of the machine control panel (Bit 4). "ChanNo" selects the channel to be processed.

Not FC 26:

The "SpindleIFNo" parameter defines the axis interface of the spindle. The spindle override is transferred to this spindle interface. The parameters are checked for incorrect parameterization.

Not FC 26:

Output parameters "FeedHold" and "SpindleHold" are generated from the 4 feed/spindle disable and feed/spindle enable keys and are returned with "logical 1" for disable.

Information for the next cycle is stored in DB8, bytes 0 to 3 or bytes 62 to 65, depending on the machine control panel number. This information is the edge trigger flag, feed value and selected axis number. The blocks are provided with user data via the pointer parameters in DB 7 "MCP1In" and "MCP1Out" ("MCP2In" and "MCP2Out"). The pointers are addressed indirectly via a further pointer from the VAR section of DB7 in order to avoid absolute addressing. This additional pointer is determined symbolically in FB1.

## Block description

All 4 components have a similar structure and are classified for the individual subtasks:

**In the Input network**, various parameters are copied to local variables. The machine control signals (user data for input/output area) are also copied between locations using the various pointers in DB 7 (gp\_par). These local variables are handled in the block for reasons of efficiency. Some values are initialized for the start-up.

MCS/WCS switchover with edge evaluation, axis selections, direction keys and rapid traverse overlay is determined in the **Global\_IN network** for further processing in the block. User-specific changes must take place in this part of the program, which are mainly oriented at the axis selection.

Only the keyswitch information is copied in **Network NC**.

The **mode group network** transfers the modes of the keys as dynamic signals to the NCK. The INC checkback signals from the NC are stored temporarily for the corresponding LEDs. If the mode group number is 0, this network is not processed. A too large number generates the message 401901 or 402501 and changes over after stop.

In the **Channel network** the NC Start, Stop, Reset and Single Block functions are activated by corresponding checkback signals. The direction keys of the geometry axes are supplied if a corresponding preselection is made, otherwise they are cleared. If the channel number is 0, this network is not processed. A too large number generates the message 401902 or 402502 and changes over after stop.

The **Spindle network** transfers the spindle override to the interface configured via "SpindleIFNo".

The **Network Axes** transfers the feed override to the selected axis interface. The direction keys are assigned to the selected axis/spindle. If an axis has been selected previously, the direction information is set to 0.

The output parameters are prepared and the LED signals of the INC machine function are generated in the **Global\_OUT network**.

The **Output network** transfers the output signals of the machine control panel from the VAR\_TEMP image to the logical address. The data for the next cycle are also saved.

### Axis selection extension

The Global\_IN network must be modified if more than nine axes are selected. If other keys and LEDs are to be used on the machine control panel here, proceed as follows:

1. The command UD DW#16#Value (comment: Clear all axis LEDs for display) deletes all defined LEDs for axis selections. The bit mask is currently processing the nine axis selection LEDs.
2. The command UW W#16# (comment: "Masking all the axis selection buttons") checks whether the direction has changed. The bit string must be adjusted here.
3. The branch destination list (SPL) must be expanded with new jump labels. The new jump labels should be inserted in descending order before label m009. The selection information should be extended for the new jump labels, as described for labels m009 and m008.

---

#### Note

The blocks are made available as STL sources if required. But they do not match the current status of the block. Some details of the actual implementation in C have been developed further. For this reason we recommend that you specify your additional requirements for the blocks and that you pass these onto project management via the sales department.

---

## 13.14 Signal/data descriptions

### 13.14.1 Interface signals NCK/PLC, HMI/PLC, MCP/PLC

#### References

The NCK/PLC, HMI/PLC and MCP/PLC interface signals are contained in the List Manual: Lists sl (Book 2)

The reference code contained therein (according to the signal names) refer to the respective function description, in which the signal is described.

The NCK signals that are evaluated by the basic program and transferred in conditioned form to the user interface are presented in the following sections.

### 13.14.2 Decoded M signals

The M functions programmed in the part program, ASUB or synchronized actions are channel specifically transferred from the NC to the PLC:

- M functions from channel 1: DB 21
- M functions from channel 2: DB 22
- etc.

The signal length is one PLC cycle.

---

#### Note

The spindle-specific M functions below are not decoded: M3, M4, M5, and M70.

---

| Address in DB 21, ... | Variable          | Type | Comment               |
|-----------------------|-------------------|------|-----------------------|
| DBX 194.0 ... 7       | M_Fkt_M0 ... M7   | BOOL | M signals M0 ... M7   |
| DBX 195.0 ... 7       | M_Fkt_M8 ... M15  | BOOL | M signals M8 ... M15  |
| DBX 196.0 ... 7       | M_Fkt_M16 ... M23 | BOOL | M signals M16 ... M23 |
| DBX 197.0 ... 7       | M_Fkt_M24 ... M31 | BOOL | M signals M24 ... M31 |
| DBX 198.0 ... 7       | M_Fkt_M32 ... M39 | BOOL | M signals M32 ... M39 |
| DBX 199.0 ... 7       | M_Fkt_M40 ... M47 | BOOL | M signals M40 ... M47 |
| DBX 200.0 ... 7       | M_Fkt_M48 ... M55 | BOOL | M signals M48 ... M55 |
| DBX 201.0 ... 7       | M_Fkt_M56 ... M63 | BOOL | M signals M56 ... M63 |
| DBX 202.0 ... 7       | M_Fkt_M64 ... M71 | BOOL | M signals M64 ... M71 |
| DBX 203.0 ... 7       | M_Fkt_M72 ... M79 | BOOL | M signals M72 ... M79 |
| DBX 204.0 ... 7       | M_Fkt_M80 ... M87 | BOOL | M signals M80 ... M87 |

13.14 Signal/data descriptions

| Address in DB 21, ... | Variable          | Type | Comment               |
|-----------------------|-------------------|------|-----------------------|
| DBX 205.0 ... 7       | M_Fkt_M88 ... M95 | BOOL | M signals M88 ... M95 |
| DBX 206.0 ... 3       | M_Fkt_M96 ... M99 | BOOL | M signals M96 ... M99 |

**Note**

The M02/M30 auxiliary function output to the PLC does not state that the part program has been terminated. To determine definitely the end of a part program in the channel, the following interface signal must be evaluated:

DB21, ... .DBX33.5 (M02/M30 active)

The channel status must be RESET. The auxiliary function output could arise from an asynchronous subroutine (ASUB) or a synchronized action and has nothing to do with the real end of the parts program in this case.

**13.14.3 G functions**

The G functions programmed in the part program, ASUB or synchronized actions are channel specifically transferred from the NC to the PLC:

- G functions from channel 1: DB 21
- G functions from channel 2: DB 22
- etc.

The signal length is one PLC cycle.

**POWER ON**

After POWER ON, the value zero, i.e. active G groups undefined, is specified in the NC/PLC interface for all G groups.

**Part program end or abort**

After part program end or abort, the last state of the G group is retained.

**NC START**

After NC-START the values of the 8 G-groups specified in the machine data: MD22510 \$NC\_ GCODE\_GROUPS\_TO\_PLC are overwritten according to the default setting set via the machine data as well as the values programmed in the part program.

| Address in DB 21, ... | Variables  | Type | Basic position | Comment                      |
|-----------------------|------------|------|----------------|------------------------------|
| DBB 208               | G_FKT_GR_1 | BYTE | 0              | Active G function of group 1 |

| DBB 241               | G_FKT_GR_34 | BYTE | 0              | Active G function of group 34 |
| DBB 242               | G_FKT_GR_35 | BYTE | 0              | Active G function of group 35 |
| DBB 243               | G_FKT_GR_36 | BYTE | 0              | Active G function of group 36 |
| DBB 244               | G_FKT_GR_37 | BYTE | 0              | Active G function of group 37 |
| DBB 245               | G_FKT_GR_38 | BYTE | 0              | Active G function of group 38 |
| DBB 246               | G_FKT_GR_39 | BYTE | 0              | Active G function of group 39 |
| ...                   | ...         | ...  | ...            | ...                           |
| DBB 271               | G_FKT_GR_64 | BYTE | 0              | Active G function of group 64 |

A complete listing of all the G functions is given in:

**References:**

Programming Manual Fundamentals; Chapter: "List of G-Functions/Preparatory functions"

#### 13.14.4 Message signals in DB 2

DB 2 allows the user to display the messages for individual signals on the operator panel. As the lists of interface signals show, signals are divided into predefined groups. When a message occurs, disappears or is acknowledged, the number entered in the message number column is transferred to the HMI. Text can be stored in the HMI for each message number.

**References:**

- Lists sl (Book 2), see Section "PLC-Messages (DB 2)".
- Startup Manual; Chapter "Alarm and message texts"

---

**Note**

The number of user areas can be parameterized via FB 1.

After the configuration has been modified (FB 1: MsgUser), DB 2/3 must be deleted.

---

## 13.15 Programming tips with STEP 7

Some useful tips on programming complex machining sequences in STEP7 are given below. This is essentially handling of the data type POINTER or ANY.

Fundamental tips on the structure of the data type POINTER and ANY see:

**References:**

STEP 7 Manual; Chapter: "Designing user programs" > "Register of CPU and saving of data"

### 13.15.1 Copying data

#### Copying variants

For the high-speed copying of data from one DB into another it is recommended

- **for larger data quantities** to use the system function SFC BLKMOV or SFC FILL, because here a high-speed copying takes place.
- the routine given below is **for smaller data quantities**, because the supply of ANY parameter to the SFCs consumes additional time.

#### Example

| Code               | Comment                                     |
|--------------------|---------------------------------------------|
|                    | //DB xx.[AR1] is the source                 |
|                    | //DI yy.[AR2] is the destination            |
| OPEN DB 100;       | //Source DB                                 |
| LAR1 P#20.0;       | //Source start address on data byte 20      |
| OPEN DI 101;       | //Destination DB                            |
| LAR2 P#50.0;       | //Destination start address on data byte 50 |
|                    | //AR1, AR2, DB, DI loaded beforehand        |
| L 4;               | //Transfer 8 bytes                          |
| M001:              |                                             |
| L DBW [AR1,P#0.0]; | //Copy word-oriented                        |
| T DIW [AR2,P#0.0]; |                                             |
| +AR1 P#2.0;        |                                             |
| +AR2 P#2.0;        |                                             |
| TAK;               |                                             |
| LOOP M001;         |                                             |

## 13.15.2 ANY and POINTER

The following programming examples show the programming mechanism. They demonstrate how input/output and transit variables (VAR\_INPUT, VAR\_OUTPUT, VAR\_IN\_OUT) are accessed by data types "POINTER" or "ANY" within an FC or FB. The access operations are described in such a way that a part symbolic method of programming can be used.

### 13.15.2.1 Use of POINTER and ANY in FC

#### Function

FC 99 has inputs parameters that are defined as POINTER or ANY.

The example shows a body program via which the subcomponents of the POINTER or ANY can be accessed. In this case, the DB parameterized with POINTER or ANY is opened and the address offset stored as a cross-area pointer in address register AR1, Thus allowing access to data elements of variables (generally structures and arrays) that are addressed via the POINTER, ANY.

This access operation is described at the end of the relevant program sequence in the example. With data type ANY, it is also possible to execute a check or branch when the variable is accessed based on the data type and the number of elements involved.

#### Example

| Code                            | Comment                         |
|---------------------------------|---------------------------------|
| FUNCTION FC 99: VOID            |                                 |
| VAR_INPUT                       |                                 |
| Row : BYTE ;                    |                                 |
| Convert : BOOL ;                | //Activate numerical conversion |
| Addr: POINTER;                  | //Points to variable            |
| Addr1 : ANY ;                   |                                 |
| END_VAR                         |                                 |
| VAR_TEMP                        |                                 |
| dbchr : WORD ;                  |                                 |
| Number: WORD ;                  |                                 |
| type : BYTE ;                   |                                 |
| END_VAR                         |                                 |
| BEGIN                           |                                 |
| NETWORK                         |                                 |
| TITLE =                         |                                 |
|                                 | //POINTER                       |
| L                P##Addr;       |                                 |
| LAR1 ;                          | //Retrieve pointer              |

### 13.15.2.2 Use of POINTER and ANY in FB

#### Function

FB 99 has inputs parameters that are defined as POINTER or ANY.

The example shows a body program via which the subcomponents of the POINTER or ANY can be accessed. In this case, the DB parameterized with POINTER or ANY is opened and the address offset stored as a cross-area pointer in address register AR1, thus allowing access to data elements of variables (generally structures and arrays) that are addressed via the POINTER, ANY.

This access operation is described at the end of the relevant program sequence in the example. With data type ANY, it is also possible to execute a check or branch when the variable is accessed based on the data type and the number of elements involved.

#### Example

| Code                | Comment                         |
|---------------------|---------------------------------|
| FUNCTIONBLOCK FB 99 |                                 |
| VAR_INPUT           |                                 |
| Row : BYTE ;        |                                 |
| Convert : BOOL ;    | //Activate numerical conversion |
| Addr: POINTER;      | //Points to variable            |
| Addr1 : ANY ;       |                                 |
| END_VAR             |                                 |

| Code                                  | Comment                                  |
|---------------------------------------|------------------------------------------|
| VAR_TEMP                              |                                          |

### 13.15.2.3 POINTER or ANY variable for transfer to FC or FB

#### POINTER or ANY variable

With version 1 or later of STEP 7 it is possible to define a pointer or ANY in VAR\_TEMP.  
 The following two examples show how an ANY can be supplied.

### Example 1: Transfer ANY parameter via a selection list to another FB (FC)

**Several** ANY parameters are defined in an FB (FC). A specific ANY parameter must now be chosen from a selection list for transfer to another FB (FC). This can only be done by means of an ANY in VAR\_TEMP. 1 to 4 can be set in parameter "WhichAny" in order to select Addr1 to Addr4.

#### Note

Address register AR2 is used in the block. However, this address register AR2 is also used for multi-instance DBs. For this reason, this FB should **not** be declared as multi-instance DB.

| Code                      | Comment                                                                      |
|---------------------------|------------------------------------------------------------------------------|

| T        LD [AR1,P#4.0];  |                                                                              |

| Code                    | Comment                   |
|-------------------------|---------------------------|
| L                       | DIW [AR2,P#8.0];          |
| T                       | LW [AR1,P#8.0];           |
| CALL FB 101, DB 100     |                           |
| (ANYPAR := #Temp_addr); | //ANYPAR is data type ANY |

**Example 2: Transfer an ANY parameter constructed earlier to another FB (FC)**

An ANY parameter that has already been compiled must be transferred to another FB (FC). This can be done only by means of an ANY stored in VAR\_TEMP.

| SLD 3;                  | //Offset is a bit offset         |
| T                       | LD [AR1,P#6.0];                  |
| CALL FB 101, DB 100     |                                  |
| (ANYPAR := #Temp_addr); | //ANYPAR is data type ANY        |

### 13.15.3 Multi-instance DB

#### Function

From Version 2 in STEP 7, you can provide multi-instance enabled FBs, i.e. with multi-instance DBs. The primary characteristic of multi-instance DBs is that a data module can be used for various instances of FBs (see STEP 7 documentation), The quantity structure of the DBs can be optimized this way.

Multi-instance DBs should be activated only when they are actually going to be used since they increase the runtime and code size of the FBs.

---

#### Note

When complex programs are implemented in multi-instance enabled FBs that use a pointer and address register, it is important for the programmer to observe certain rules.

With multi-instance DBs, the start address of the variable (VAR\_INPUT, VAR\_OUTPUT, VAR\_IN\_OUT, VAR) is transferred with the DI data block register and address register AR2. When variables are accessed within the multi-instance enabled FB, the compiler independently controls the access operation via address register AR2. However, when complex program sections also have to work with address registers in the same FB (e.g. to copy data), then the old contents of AR2 must be saved before the register is changed. The contents of AR2 must be restored to their original state before an instance variable (VAR\_INPUT, VAR\_OUTPUT, VAR\_IN\_OUT, VAR) is accessed. The AR2 register of the instance is to be saved most usefully in a local variable (VAR\_TEMP).

The command "Load pointer to an instance variable" returns a pointer value from the start of the instance data. To be able to access this variable via a pointer, the offset stored in AR2 must be added.

---

#### Example

| Code                            | Comment                                         |
|---------------------------------|-------------------------------------------------|
| FUNCTION_BLOCK FB 99            |                                                 |
| VAR_INPUT                       |                                                 |
| varin: INT ;                    |                                                 |
| END_VAR                         |                                                 |
| VAR                             |                                                 |
| variable1: ARRAY[[0..9] of INT; |                                                 |
| variable2: INT ;                |                                                 |
| END_VAR                         |                                                 |
| BEGIN                           |                                                 |
| L        P##variable1;          | //Pointer at start of ARRAY                     |
|                                 | //The value 8500 0010 is now in the accumulator |
|                                 | //and a cross-area pointer is in the AR2        |
|                                 | //Pointer. If one is to work across areas       |
|                                 | //then, during the addition of these            |
|                                 | //two pointers, an area is to be disabled.      |

| Code               |                   | Comment                                   |
|--------------------|-------------------|-------------------------------------------|
| AD                 | DW#16#00FF_FFFF,  | //Skipping of an area                     |
| LAR1               |                   | //Load into AR1                           |
| TAR2;              |                   |                                           |

|                    |                   | //You can now indirectly access the ARRAY |
|                    |                   | //of variable 1 via AR1.                  |
| L                  | DIW [AR1, P#0.0]; | //E.g. access to the first element        |
| END_FUNCTION_BLOCK |                   |                                           |

### 13.15.4 Strings

The STRING data type is required by certain services of the basic program. For this reason, some additional facts about the string structure and general handling procedures for parameter assignments are given below.

#### Structure of strings

A data of type STRING is generally stored (defined) in a data block. There are two methods of defining a string:

1. Only the data type STRING is assigned to a variable. The STEP7 compiler automatically generates a length of 254 characters.
2. Data type STRING is assigned to a variable together with a string length in square parenthesis (e.g. [32]). With this method, the STEP7 compiler generates a string length corresponding to the input.

Two bytes more than prescribed by the definition are always stored for variables of the STRING data type. The STEP 7 compiler stores the maximum possible number of characters in the 1st byte. The 2nd byte contains the number of characters actually used. Normally, the useful length of the assigned strings is stored by the STEP 7 compiler. The characters (1 byte per character) are then stored from the 3rd byte onwards.

String parameters are generally assigned to blocks of the basic program by means of a POINTER or ANY. Such assignments must generally be made using symbolic programming methods. The data block, which contains the parameterizing string, must be stored in the symbol list. The assignment to the basic program block is then made by means of the symbolic data block name followed by a full stop and the symbolic name of the string variable.

## 13.15.5 Determining offset addresses for data block structures

### Function

Another task, which occurs frequently, is symbolic determination of an offset address within a structured DB, e.g. an ARRAY or STRUCTURE is stored somewhere within the DB. After loading the address register symbolically with the start address, you might like to access the individual elements of the ARRAY or STRUCTURE via an address register. One way of loading the address register symbolically is to use an FC whose input parameter is a pointer. The address of the ARRAY or STRUCTURE is then assigned symbolically to the input parameter of this FC in the program. The program code in the FC now determines the offset address from the input parameter, and passes the offset address in the address register (AR1) to the calling function. Symbolic addressing is thus possible even with indirect access.

### Example

| Code                    | Comment                              |
|-------------------------|--------------------------------------|
| FUNCTION FC 99: VOID    |                                      |
| VAR_INPUT               |                                      |
| Addr: POINTER;          | //Points to variable                 |
| END_VAR                 |                                      |
| BEGIN                   |                                      |
| NETWORK                 |                                      |
| TITLE =                 |                                      |
| L        P##Addr;       |                                      |
| LAR1 ;                  | //Retrieve pointer from Addr         |
| L        D [AR1,P#2.0]; | //Offset part of pointer of variable |
| LAR1 ;                  |                                      |
| END_FUNCTION            |                                      |

## 13.15.6 FB calls

### Function

For optimizing the flow speeds, it is useful to call all function block calls with many static parameters, such as the blocks FB 2, 3, 4, 5, and 7 provided by the basic program in start-up with the related instance parameters. In the start-up (OB 100), the preassignment of the parameters must be done, which can then no longer be changed in the cyclic part (OB 1). These fixed parameter values are no longer parameterized in the cyclic call, because they have already been written in the Instance DB.

### Example: Parameterization of FB 2 with instance DB 110

The following example shows how a useful distribution in OB 100 and OB 1 portion is to be implemented.

First, the usual call in the cyclic program is displayed.

```
CALL FB 2, DB 110 (
 Req := M 100.0,
 NumVar := 2, //Read 2 variables
 Addr1 := NCVAR.C1_RP_rpa0_0
 Line1 : W#16#1
 Addr2 := NCVAR.C1_RP_rpa0_0
 Line2 . W#16#2
 Error := M1.0,
 NDR := M1.1,
 State := MW 2,
 RD1 := P#M 4.0 REAL 1,
 RD2 := P#M 24.0 REAL 1,
```

The modified version of the program call starts from here.  
Here the call in OB 100 is displayed:

```
CALL FB 2, DB 110 (
 Req := FALSE,
 NumVar := 2, //Read 2 variables
 Addr1 := NCVAR.C1_RP_rpa0_0
 Line1 : W#16#1
 Addr2 := NCVAR.C1_RP_rpa0_0
 Line2 . W#16#2
 RD1 := P#M 4.0 REAL 1,
 RD2 := P#M 24.0 REAL 1,
```

Here the call still remaining in OB 1 is displayed:

```
CALL FB 2, DB 110 (
 Req := M0.0,
 Error := M1.0,
 NDR := M1.1,
 State := MW 2,
```

---

#### Note

Owing to this measure, a shorter cycle time is achieved in OB 1, because the static parameter values need not be copied in the instance DB in each OB-1 cycle.

---

#### The savings of this variant:

The cyclic copying effort of 3 integer values and 4 ANY parameters with respect to the instance DB, which results from 3 time loading of a constant in the instance data block. In case of each ANY transfer, constants are loaded in the data block 4 times with subsequent transfer.

## 13.16 Data lists

### 13.16.1 Machine data

#### 13.16.1.1 NC-specific machine data

| Number | Identifier: \$MN_      | Description                 |
|--------|------------------------|-----------------------------|
| 10100  | PLC_CYCLIC_TIMEOUT     | Cyclic PLC monitoring time  |
| 14504  | MAXNUM_USER_DATA_INT   | Number of user data (INT)   |
| 14506  | MAXNUM_USER_DATA_HEX   | Number of user data (HEX)   |
| 14508  | MAXNUM_USER_DATA_FLOAT | Number of user data (FLOAT) |
| 14510  | USER_DATA_INT          | User data (INT)             |
| 14512  | USER_DATA_HEX          | User data (HEX)             |
| 14514  | USER_DATA_FLOAT[n]     | User data (FLOAT)           |

#### Note

Machine data in integer/hex format is operated in the NC as DWORD. A machine data in floating point format is managed in the NC as FLOAT (8-Byte IEEE) They are stored only in the NC/PLC interface and can be read by the PLC user program from DB 20 even during PLC booting.

#### 13.16.1.2 Channel-specific machine data

| Number | Identifier: \$MC_      | Description                                  |
|--------|------------------------|----------------------------------------------|
| 28150  | MM_NUM_VDIVAR_ELEMENTS | Number of elements for writing PLC variables |

## P4: PLC for SINUMERIK 828D

### 14.1 Overview

#### 14.1.1 PLC firmware

The PLC of the SINUMERIK 828D is an integrated PLC based on the SIMATIC S7-200 command set.

The PLC user program is essentially programmed using a Windows PC with the "Programming Tool PLC828". In addition, the PLC can be diagnosed and edited via the operator interface of the control. A "Ladder-Add-On-Tool" is available in the control for this purpose.

Note the following special features:

- The PLC user program is completely programmed in ladder logic (LAD).
- A subset of the programming language of the S7-200 is supported.
- When loading to the CPU, in addition to the code for execution, the complete project data (including symbols and comments) is loaded into the control. This means that the control always has the project that matches the currently running PLC user program.
- When loading from the CPU, the complete project data (including symbols and comments) is loaded into the Programming Tool PLC828 and can be processed/edited using this.
- The user must manage the data and process information according to type. The declared data type must be used consistently each time that the data is accessed.

#### 14.1.2 PLC user interface

The user interface is set-up by the PLC firmware, which also organizes the exchange of all signals and data between the PLC on one side and the NCK and HMI on the other side.

The user interface comprises the parts:

- Data interface with cyclic exchange (see "Data interface (Page 1171)")
- Function interface with function or task-related data exchange (see "Function interface (Page 1177)").

The structured data of these interfaces (retentive and non-retentive) are made available to the user by the firmware by assigning to data blocks: The NC (NCK, tool manager, NC channel, axes, spindles, ...) and the HMI are "Communication partners" of the PLC user program.

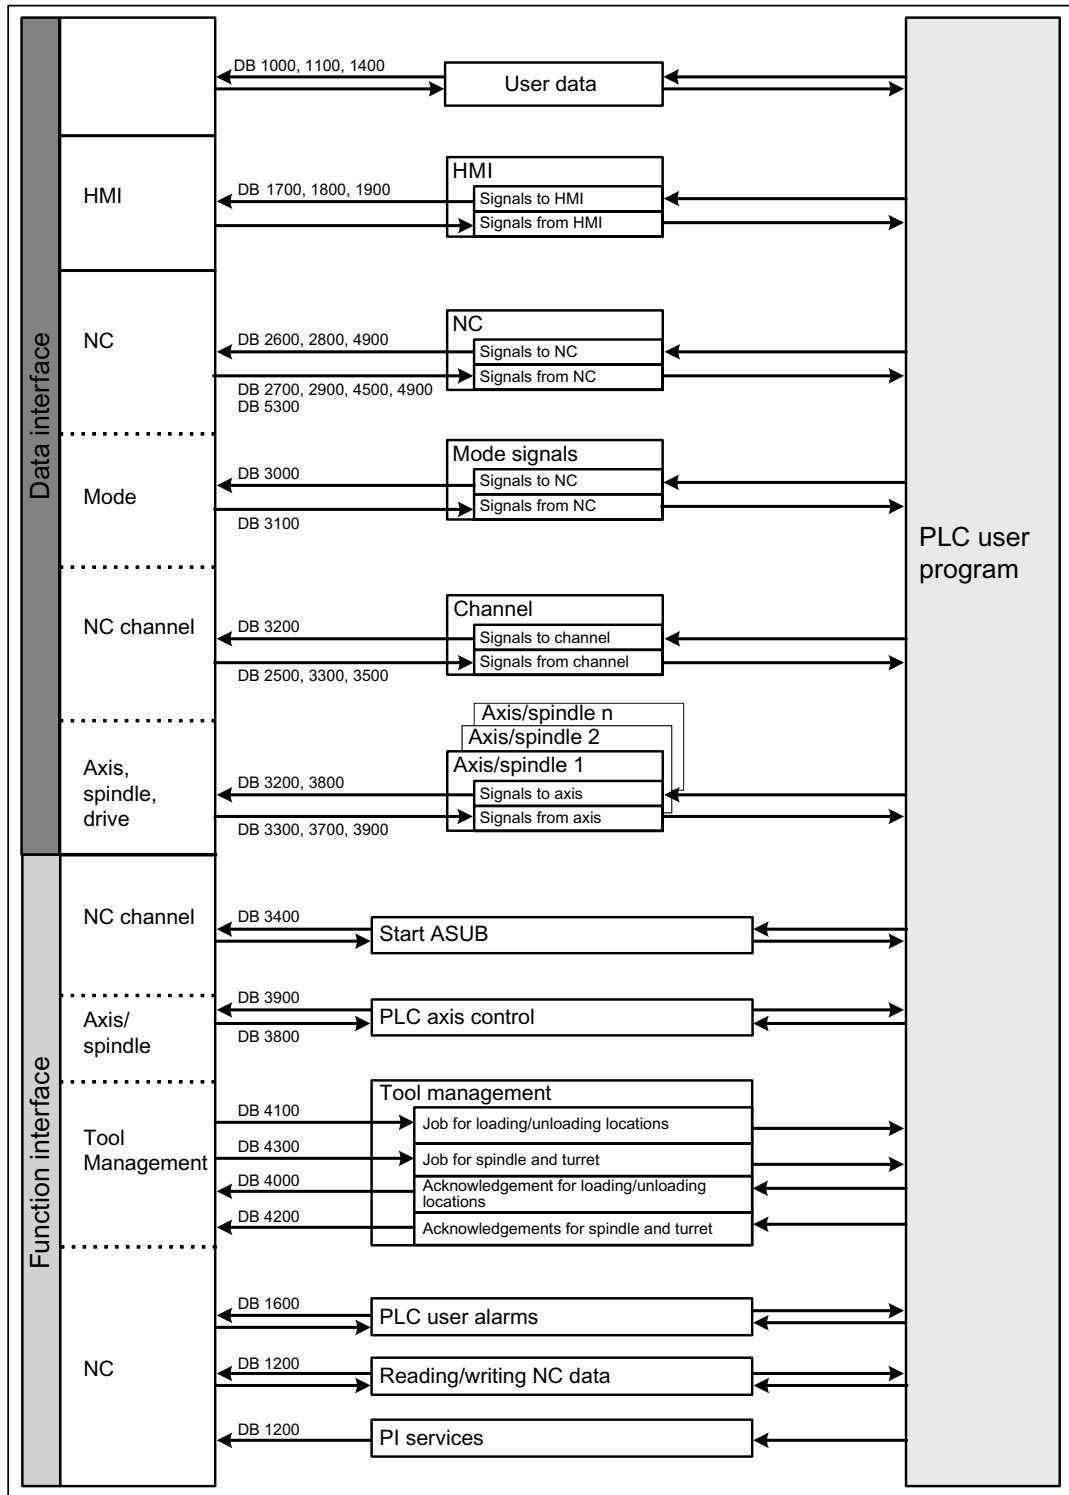

Figure 14-1 Overview of the user interface of the PLC 828D

### 14.1.2.1 Data that are cyclically exchanged

Data which is exchanged between the PLC and NC on one side as well as between the PLC and HMI on the other side.

Data **to** the PLC are provided by the firmware at the cyclic start of the user program. This ensures, for example, that the signals from the NCK remain constant throughout a cycle.

The firmware transfers data **from** the PLC to the NCK or HMI at the cycle end of the user program.

#### Interface PLC ↔ NCK

The cyclic data include e.g. status signals ("program running", "program interrupted") and control signals (start, stop) and auxiliary and G functions.

Data are structured in signals for:

- Modes
- Channels
- Axes/spindles
- General NCK signals

#### Interface PLC ↔ HMI

These are signals for:

- Program selection via lists
- Messenger control command
- General signals from/to HMI
- Signals from/to the maintenance planner
- Signals from operator panel (retentive area)
- General selection/status signals from/to HMI (retentive area)

### 14.1.2.2 Alarms and messages

The user interface in DB1600 offers the option of displaying fault and operating messages on the HMI.

The firmware evaluates the signals that have been entered and sends these as coming and going alarms and messages to the HMI where they are displayed. The HMI manages the fault texts.

### 14.1.2.3 Retentive data

For the retentive data there are the user data blocks DB9000 - DB9063 and the data area DB1400.DBW0 - DBW127. There the user can store all data that should remain valid after POWER OFF/ON. The retentive data is stored in the non-volatile memory, however, not for data backup.

**14.1.2.4 Non-retentive data**

Non-retentive data (e.g. bit memories, timers and counters) are deleted every time the control is booted.

**14.1.2.5 PLC machine data**

The PLC machine data are in the NCK machine data area. At POWER ON, this data is transferred by the PLC firmware into DB4500 of the PLC user interface where it can be evaluated by the PLC user program.

**References**

SINUMERIK 828D List Manual

**14.1.3 PLC key data**

The integrated PLC has a program memory of 24000 PLC operations, which are completely executed in one fixed PLC cycle.

A maximum of 500 operations can be executed in the INT0 interrupt program that can be optionally used. It is executed servo-synchronous and allows the fastest possible reaction to process events. This is the reason that interrupt-capable PLC I/O modules are not required.

| Data                                          | Number | Special features                    |
|-----------------------------------------------|--------|-------------------------------------|
| Main program (MAIN)                           | 1      |                                     |
| Subprograms (SBRx)                            | 256    |                                     |
| Interrupts                                    | 2      |                                     |
| Time controlled interrupt                     | 1      | Servo-synchronous interrupt program |
| Alarms/messages                               | 248    |                                     |
| Bit memory                                    | 4096   | Non-retentive                       |
| Counter                                       | 64     | Non-retentive                       |
| Timers,<br>of which:                          | 128    | Non-retentive                       |
| 10 ms increment interval                      | 112    |                                     |
| 100 ms increment interval                     | 16     |                                     |
| User data block each with a max. of 512 bytes | 64     | Address range DB9000 to DB9063      |
| Data transmission NCK ↔ PLC                   |        | Via fixed parameterizable interface |

#### 14.1.4 PLC I/O, fast onboard inputs/outputs

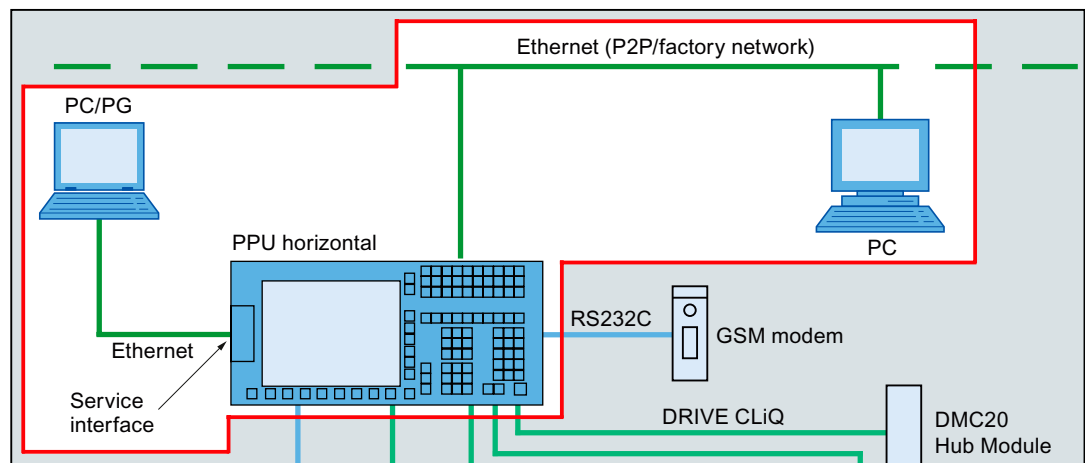

For information on the I/O modules, the machine control panels as well as the assignment of the onboard inputs/outputs to the PLC, see:

Equipment Manual PPU SINUMERIK 828D

## 14.2 Programming Tool PLC828

The "Programming Tool PLC 828" is the tool with which PLC programs can be generated in a user-friendly fashion. This is a Windows program and must be installed on a Windows PC. This PC must be equipped with an Ethernet port for online access to the control and must be connected to the control via the factory network or the service interface.

**References:**

Commissioning Manual SINUMERIK 828D

When calling the Programming Tool PLC828 – without specifying an existing project – then implicitly a new project is created with the "Project1" default name. This project can be immediately used to generate the PLC user program and then saved under any name and loaded into the control system.

Existing projects can be opened in the typical Windows fashion, also typical for Windows, a user-friendly online help is available by pressing F1.

## 14.3 Programming

### 14.3.1 Introduction

#### 14.3.1.1 Important terms

When calling the Programming Tool PLC828, a new project is implicitly created or a specified one is opened.

However, what is project, what is a program, a data block? What are data classes?

The most important terms will now be briefly explained. For additional and more detailed information, see:

- Programming Tool PLC828, online help
- S7-200 System Manual

#### Project

A project is the largest possible organizational unit for the user when working with the PLC. It is comparable with a Container, and can:

- accept program and data blocks, symbol and status tables, cross-references as well as interface and debug settings.
- be saved on a data carrier or loaded from there.
- be loaded into the CPU or retrieved from there.

#### Data classes

Data classes are especially the properties of actual values of such data blocks that the user explicitly brings into the project. (data blocks that are inherent to the system are not meant, e.g. the user interface.)

The data classes "Manufacturer", "Individual" and "User" were introduced into SINUMERIK 828D in order to:

- be able to assign the DB actual values to specific user groups.
- be able to load values belonging to a user group (i.e. data class) into or out of the CPU.
- simplify troubleshooting and maintenance.

All programs (with the exception of the two interrupt programs INT100 and INT101) and all data block structures (i.e. the inner structure, the "Type" of data blocks) and data block initial values have the "Manufacturer" data class.

The interrupt programs INT100 and INT101 are of the "Individual" type.

## Program

A program (also a program organization unit "POU") is a block for a sequence of commands (including comments), that the user assembles one after the other using the LAD Editor to solve his particular task. The user has three types of these POU's at his disposal:

- The main program (MAIN)  
There is only one of these. The system calls this in the PLC cycle.
- 256 optional subprograms (SBR\_xyz)  
Subprograms are used to structure and encapsulate functions.  
Once coded, they can be called a multiple number of times.
- Three optional interrupt programs  
These are executed with a higher priority at a different location in the PLC cycle and are reserved for special tasks.

## Data block

A data block is a block for data (initial values, actual values) and comments with the following properties:

- The data are saved in precisely the same sequence as specified by the user. This means that the inner structure of the data block is defined and if several data blocks are created with the same inner structure (i.e. the same type), then a certain data is always located at a specific location. This location is called offset and is the relative length in bytes from the beginning of the data block (DB) up to the actual piece of data.
- Initial values can be assigned to the data that they assume after being loaded into the PLC for the first time.
- The actual values of the data can also be read online from the control, changed and also saved with the project.

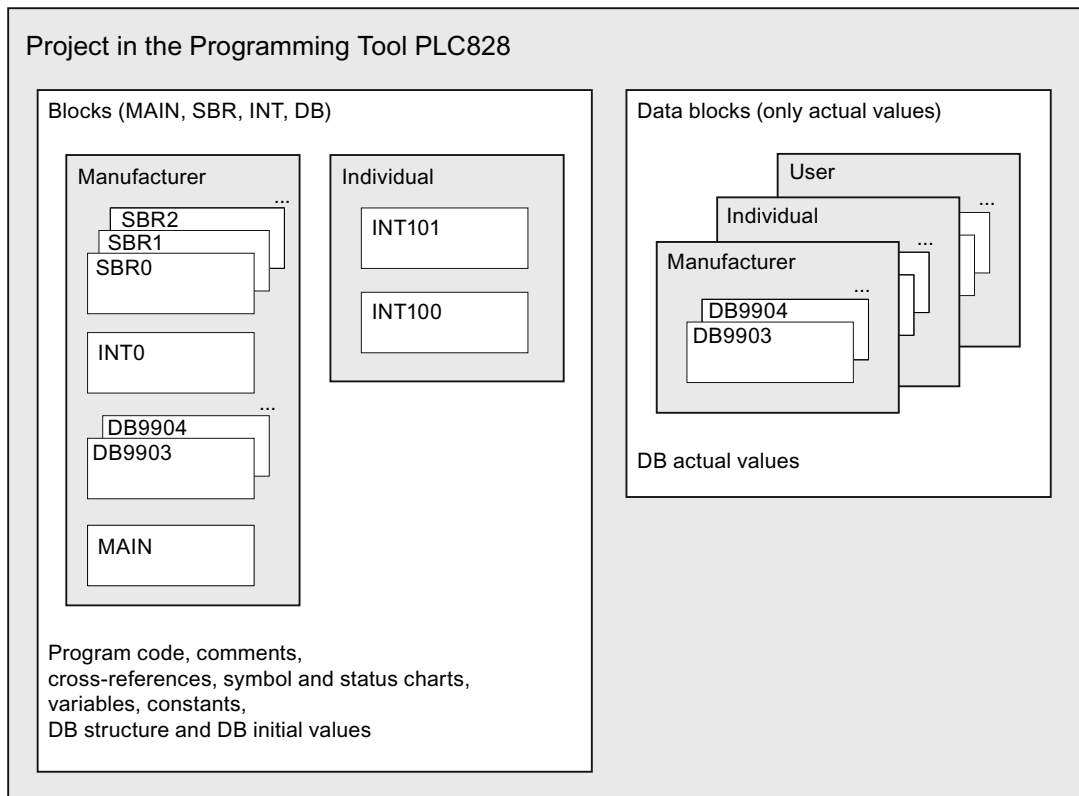

Figure 14-2 Example of a project structure

## Symbol tables

The symbol table is used for symbolic addresses. Frequently, symbols simplify programming and increase the transparency of programs. In the compiled program, which is loaded into the target system, all of the symbols are converted into absolute addresses. The data relating to the symbol table are loaded into the target system.

## Status table

In the status tables, you can observe how the process values change as the program is executed. Status tables are not loaded into the target system. They are only intended to be able to monitor the activities of the target system (or the simulated target system).

## Cross references

The following are displayed in tabular form in the cross reference window:

- the symbolic or absolute addresses and the locations where they are used
- the bytes that are being used
- the bits that are being used

The cross references and the data on the elements used are not loaded into the target system.

### 14.3.1.2 Create/open a project

#### Creating a new project

- Double-click on the "Programming Tool PLC828" button.

or

- In the Windows start menu, select the command "Programming Tool PLC828" > "Programming Tool PLC828".

The Programming Tool PLC828 is started and a new project is opened.

#### Opening an existing project

- In the Programming Tool PLC828, the menu "File", select one of the following commands:
  - "Open"  
Navigate to an existing project and open it.
  - "File name"  
If you just recently worked in a project, this project is listed in the "File" menu and you can directly open it without first having to select it in the dialog box.
- You can also navigate to the required directory in Windows Explorer and directly open the project from there without having to first start the Programming Tool PLC 828. Your project is in a single file with the \*.ptp extension.

---

#### Note

If you have created a project, then you can start to write your program. However, you should have executed the following tasks beforehand:

- **Range check according to the target system**  
You can select the target system type before you write your program so that the Programming Tool PLC828 can check the parameter range corresponding to the target system. (If you have selected a CPU type for your project, the operations that cannot be used for your target system are marked with a red x in the operation tree.)
  - **Setting-up the work environment**  
You can set up your work environment in various ways ("Windows look and feel"). More detailed information is provided in the online help under "Setting-up the Programming Tool display".
-

### 14.3.1.3 Program organization using the the Programming Tool

The Programming Tool PLC828 organizes your program in the Program Editor in individual tabs per POU. As standard, when creating a new project, the main program MAIN and a subprogram SBR\_0 are created. MAIN is always in the first tab, all subprograms and interrupt programs that you have generated then follow.

#### MAIN

MAIN cannot be renamed and is permanently assigned to the "Manufacturer" data class.

#### Subprograms

Subprograms are useful if you wish to execute a function a multiple number of times. In order that you do not have to include the logic in the main program at each location where you wish to execute the function, you write the logic once in a subprogram and you then call this subprogram as often as required while executing the main program. Meaningful names can be assigned to subprograms; these are also assigned to the "Manufacturer" data class.

Advantages:

- The functional sequence in the main program is very transparent.
- Subprograms are easy to port. You can easily demarcate a function and without many resources, call it from other programs with other parameter values.

---

#### Note

The use of global variables restrict the portability of subprograms as the assignment of addresses in the variable memory of a program can always be in conflict with the assignment of addresses in another program. Subprograms, which access local variables for all address assignments, are on the other hand extremely easy to port, because there is no danger of conflicting addresses.

---

## Interrupt programs

Interrupt programs are used to be able to handle special process conditions or requirements. The PLC828 makes a differentiation as follows:

| Condition                                                  | Program | Description                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Shortest response time: Executed in the <b>servo cycle</b> | INT_0   | For extremely fast responses to events, which absolutely required this. In INT_0, the direct access commands, that either access an internal, I/O image updated in the servo cycle or only the hardware of the onboard IO, can be practically used.<br>Data class: "Manufacturer"<br><b>Note:</b><br>The size of block INT_0 is limited to 500 operations. |
| Executed <b>before</b> MAIN, after reading the inputs      | INT_100 | Especially to marshal data that is read accessed in the additional cycle.<br>Data class: "Individual"                                                                                                                                                                                                                                                      |
| Executed <b>after</b> MAIN, before writing to the outputs  | INT_101 | Especially when marshaling data that were previously written in the PLC cycle, but which should be output to other or additional outputs.<br>Data class: "Individual"                                                                                                                                                                                      |

Interrupt programs cannot be renamed, but they can be assigned to data classes.

The interrupt program is inserted in the project by double clicking on the corresponding name in the operation tree: "Libraries" > "Interrupt programs".

The PLC firmware then automatically makes the call.

## Exiting program organizational units

As a result of the described program organization (each POU occupies its own tab), it is quite clear where MAIN and the individual sub and interrupt programs end; this is the reason that they do not require any special end delimiter.

Addressing (Page 1121)

Type of memory (Page 1118)

### 14.3.1.4 Fast onboard inputs and outputs

SINUMERIK 828D provides 4 inputs and 4 outputs "onboard". These are also fed to the outside at connector X142; therefore no I/O modules are required and these I/O can be especially quickly processed ("fast I/O").

As standard, these IO are assigned to the NCK, the assignment to the PLC is described in:

**References:**

Commissioning Manual SINUMERIK 828D

Addressing the onboard **inputs**: I256.0 ... I256.3

Addressing the onboard **outputs**: Q256.0 ... Q256.3

The onboard IO is not assigned to an image memory; reading and writing are always directly made to/from the hardware. This is the reason that direct operation commands must be used when accessing this IO:

- Direct NO contact -| I |-
- Direct NC contact -| / I |-
- Directly set bit value -(SI)-
- Directly reset bit value -(RI)-
- Directly assign bit value -( I )-

It makes sense to use the interrupt program **INT0** for this purpose, because these command can be executed as quickly as possible in the servo cycle.

### 14.3.2 Target system memory

#### 14.3.2.1 Type of memory

| Type | Description                                            | Access in the bit format | Access in the type format | Access in the word format | Access in the double word format | can be retentive |
|------|--------------------------------------------------------|--------------------------|---------------------------|---------------------------|----------------------------------|------------------|
| I    | Digital inputs and process image input                 | read / write             | read / write              | read / write              | read / write                     | no               |
| Q    | Digital outputs and process image output               | read / write             | read / write              | read / write              | read / write                     | no               |
| M    | Internal bit memory                                    | read / write             | read / write              | read / write              | read / write                     | no               |
| SM   | Special bit memory (SM0.0 - SM0.6 are write-protected) | read / write             | read / write              | read / write              | read / write                     | no               |
| V    | Variable memory                                        | read / write             | read / write              | read / write              | read / write                     | yes              |

| Type | Description                                  | Access in the bit format | Access in the type format | Access in the word format                | Access in the double word format | can be retentive |
|------|----------------------------------------------|--------------------------|---------------------------|------------------------------------------|----------------------------------|------------------|
| T    | Actual values of timers and time bits        | Time bit read / write    | no                        | actual value of time read / write        | no                               | no               |
| C    | Actual values of the counters and count bits | Counter bit read / write | no                        | actual value of the counter read / write | no                               | no               |
| AC   | Accumulators                                 | no                       | read / write              | read / write                             | read / write                     | no               |
| L    | Local data memory                            | read / write             | read / write              | read / write                             | read / write                     | no               |

### 14.3.2.2 Addressing range of the target system

Address range of a memory type is the addressing range for this type of memory that spans the lowest and highest possible address numbers. The lowest and highest possible address number depends on the particular memory type.

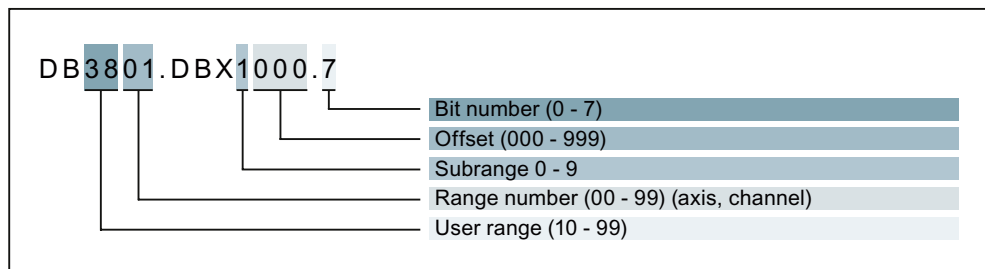

If you execute operations, which communicate with the target system, then the Programming Tool PLC828 recognizes your CPU version. When generating your program, you must ensure that you only use the address range valid for this CPU. If you attempt to load a program that accesses addresses ranges, which are not valid for this CPU, then an error message is output.

### Address ranges

| Access method  | Type of memory | Min. and max. address numbers                            |
|----------------|----------------|----------------------------------------------------------|
| Bit (byte.bit) | I              | 0.0 - 255.7 <sup>1)</sup><br>256.0 - 256.3 <sup>2)</sup> |
|                | Q              | 0.0 - 255.7 <sup>1)</sup><br>256.0 - 256.3 <sup>2)</sup> |
|                | M              | 0.0 - 999.7                                              |
|                | SM             | 0.0 - 0.6                                                |
|                | T              | 0 - 15 (100 ms)<br>16 - 127 (10 ms)                      |
|                | C              | 0 - 63                                                   |
|                | L              | 0.0 - 59.7                                               |
| Byte           | IB             | 0 - 255 <sup>1)</sup>                                    |
|                | QB             | 0 - 255 <sup>1)</sup>                                    |
|                | MB             | 0 - 999                                                  |
|                | SMB            | 0                                                        |
|                | LB             | 0 - 59                                                   |
|                | AC             | 0 - 3                                                    |

| Access method       | Type of memory | Min. and max. address numbers       |
|---------------------|----------------|-------------------------------------|
| Word                | IW             | 0 - 254 <sup>1)</sup>               |
|                     | QW             | 0 - 254 <sup>1)</sup>               |
|                     | MW             | 0 - 998                             |
|                     | T              | 0 - 15 (100 ms)<br>16 - 127 (10 ms) |
|                     | C              | 0 - 63                              |
|                     | LW             | 0 - 58                              |
|                     | AC             | 0 - 3                               |
| Double word         | ID             | 0 - 252 <sup>1)</sup>               |
|                     | QD             | 0 - 252 <sup>1)</sup>               |
|                     | MD             | 0 996                               |
|                     | LD             | 0 - 56                              |
|                     | AC             | 0 - 3                               |
| User interface      | DB             | 1000 - 7999 <sup>3)</sup>           |
| User data blocks    | DB             | 9000 - 9063 <sup>3)</sup>           |
| Special data blocks | DB             | 9900 - 9999 <sup>3)</sup>           |

- 1) Range of the process image variables! The assignment of these variables to the physical inputs and outputs can be taken from the system overview in the SINUMERIK 828D Commissioning Manual.
- 2) These addresses directly serve (i.e. without image memory) the 4 onboard inputs and the 4 onboard outputs if these are assigned to the PLC.
- 3) Only the DB numbers are specified in the table for reasons of simplicity. Their addressing depends on the DB structure and is realized according to the following scheme:

| Access      | Example          | Explanation                                                               |
|-------------|------------------|---------------------------------------------------------------------------|
| Bit         | DB3801.DBX1000.7 | Bit 7 of the byte with offset 0 in subrange 1 for axis 2 in user range 38 |
| Byte        | DB3801.DBB0      | Byte with offset 0 in subrange 0 for axis 2 in user range 38              |
| Word        | DB4500.DBW2      | Word with offset 2 in subrange 0 in range 0 in user range 45              |
| Double Word | DB2500.DBD3004   | Double word with offset 4 in subrange 3 in range 0 in user range 25       |

The access type is part of the address notation and must not be considered to be the same as the data type or confused with this (see "Data types (Page 1124)").

---

#### Note

The permitted **offset** for an address is dependent on the access:

- Bit or byte access: Any offset permitted.  
Byte-size variables are placed one beside another seamlessly in a DB.
- Word access: Offset must be divisible by 2.  
Word-size variables (2 bytes) are always saved on even offsets.
- Double word access: Offset must be divisible by 4.  
Double word-size variables (4 bytes) are always saved on offsets which are divisible by 4.

See also "Data types (Page 1124)".

---

**User interface** is an interface comprising data blocks that the firmware creates on the target system. It is used to exchange data between the PLC on one side and the NCK and HMI on the other side (→ List Manual SINUMERIK 828D).

This DB neither has to be loaded from the CPU nor into the CPU because it is created by the firmware and therefore belongs to the system.

**User data blocks** are exclusively created by the user. If it is intended to indirectly access blocks of the same structure, then these should be located one after the other regarding the numbering.

**Special data blocks** are permanently specified as far as their structure is concerned from the system and can be found in the Programming Tool PLC828 in "Libraries". However, whether they are integrated in the user program, assigned to a data class and loaded into the CPU is the responsibility of the user and his design philosophy (if e.g. a maintenance planner is not used, then these do not have to be integrated as far as the DB is concerned).

### 14.3.2.3 Addressing

#### Direct addressing

For direct addressing, the *memory type* as well as the *address number* must be specified (also refer to "Addressing range of the target system (Page 1119)").

The CPU memory (V, I, Q, M and SM) can be accessed bit by bit as well as in the byte, word and double-word format. The direct address comprises the memory type and a valid address number.

To access a bit in a memory area, enter the byte address and the number of the bits. Separate the byte from the bit using a decimal point.

Examples:

|                |                            |
|----------------|----------------------------|
| DB9900.DBX20.0 | Bit 0 in byte 20 of DB9900 |
| MB21,          | Flag byte 21               |
| QD16,          | Output double word 16      |
| I1.7,          | Bit 7 in input byte 1      |

### Indirect addressing

Indirect addressing can only be used for data blocks with the same structure (the same type). These are used so that when accessing data blocks, the number of the data block can be variably addressed. The data block number must be located in one of the accumulators AC0 ... AC3 (see "Data blocks (Page 1127)").

### Absolute and symbolic addressing

You can specify the addresses in the operations in your program either absolutely or symbolically.

An *absolute address* specifies the memory type and the address number.

A *symbolic address* (briefly: symbol) specifies the address using a name (a combination of alphanumeric characters).

*Global symbols* are assigned in the symbol tables to their absolute address values and are valid throughout the project (global). This assignment can be made at any time.

*Local symbols* are assigned in the local variable table of the particular program and are only valid in this program (local).

Examples for displaying addresses in the program editor:

|         |                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------|
| IO.0    | An absolute address specifies the memory type and address number.                                                                          |
| #Input1 | The # character is located in front of a local symbol.                                                                                     |
| INPUT1  | Global symbol                                                                                                                              |
| ???     | Red question marks designate an address that has still not been defined (you must specify the address before you can compile the program). |

Both addressing types – absolute and symbolic – are coupled to the particular view:

Menu "View" > "Symbolic addressing (Ctrl +Y)"

This setting should always be set using the menu "View > "Symbol table (Ctrl +T)".

Recommendation: Decide on one of the two addressing types and then keep this.

### Global and local range of validity

Symbolic addresses that were assigned in the symbol table are globally valid. Symbolic addresses that were assigned in a local variable table are locally valid.

## Local variables

Local variables are assigned in the local variable table of the particular POU and are limited to the validity range of the POU in which they were set-up. Each program organizational unit has its own local variable table.

Example:

You define a variable with the name INPUT1 in the local variable table of a subprogram with the SBR1 name.

If you refer to INPUT1 from SBR1, then the program editor identifies INPUT1 as a local variable from SBR1.

However, if you refer to INPUT1 at another location in the program (e.g. in MAIN or in a second program), the program editor does not recognize INPUT1 as a local variable and treats INPUT1 as a non-defined global symbol.

---

### Note

#### Assigning names to local and global symbols

If you use the same name for an address at the local and at the global level, then the local use has priority. This means that if the program editor defines a definition for the name in the local variable table of a certain program block, then this definition is used. If a definition is not found, then the program editor checks the symbol table.

Example:

You define the global symbol "PumpOn" You also define "PumpOn" as local variable in SBR2, however, not in SBR1.

If the program is compiled, the local definition for "PumpOn" in SBR2 is used. The global definition is used for "PumpOn" in SBR1.

---

### Note

#### Using local and global symbols

Local variables use the temporary, local memory of the target system. Subprograms that only use local variables and transfer parameters, are easy to port and can be flexibly used.

If you wish to use a parameter in several program organizational units, then it makes sense to define this parameter as global symbol in the symbol table - and not in the local variable table. This reason for this is that then you would have to include the parameter in every local variable table of the individual POUs.

---

### Note

#### Initialization of local variables

As local variables occupy temporary memories, you must initialize the local variables in the POU each time that the POU is called. You **cannot** assume that a local variable keeps a data value from one POU call to the next.

---

### 14.3.2.4 Data types

When defining symbols in the global symbol table, a data type does not have to be explicitly specified, as it is implicitly specified by the data associated with the symbol.

If you assign values in the local variable table, then you must specify a data type for every local variable.

By explicitly specifying a data type for a value, you give the Programming Tool PLC828 clear instructions how much memory must be assigned for the value (e.g. the value 100 can be stored as BYTE, WORD or DWORD) and how the value is to be represented (e.g. should 0 be interpreted as BOOL or as numerical value?).

The operations and parameterized subprograms are recognized using a precise definition. This definition is also called signature. For all standardized operations, the data types permissible for the addresses of the operation are specified in the signature. For parameterized subprograms, the signature of the subprogram is generated by the user in the local variable table.

### Data type check

The Programming Tool PLC828 offers a simple data type check. If a data type is specified for a local or global variable, the software checks that the data type of the address corresponds to the signature of the operation.

| Elementary data types | Description             | Memory area                                     |
|-----------------------|-------------------------|-------------------------------------------------|
| BOOL (bit)            | Boolean                 | 0 ... 1                                         |
| BYTE                  | Byte, unsigned          | 0 ... 255                                       |
| WORD                  | Integer number (16 bit) | -32768 ... +32767                               |
| DWORD (Double Word)   | Integer number (32 bit) | -2147483648 ... +2147483647                     |
| REAL                  | 32-bit floating point   | +/- 10 <sup>-37</sup> ... +/- 10 <sup>+38</sup> |

| Complex data types | Description               | Memory area                         |
|--------------------|---------------------------|-------------------------------------|
| TON                | Switch-on delay           | 100 ms T0 ... T15<br>10 ms from T16 |
| TOF                | Switch-off delay          | 100 ms T0 ... T15<br>10 ms from T16 |
| TONR               | Switch-on delay, latching | 100 ms T0 ... T15<br>10 ms from T16 |
| CTU                | Up counter                | C0 ... C63                          |
| CTD                | Down counter              | C0 ... C63                          |
| CTUD               | Up-down counter           | C0 ... C63                          |

The Programming Tool PLC828 has two data type check stages:

1. Elementary data type check

For the elementary data type check, if a symbol or a variable is assigned a data type, then all data types are automatically assigned, which correspond to the bit size of the user-defined data type. If, for instance, you specify DINT as data type, then the local variable is also automatically assigned the DWORD data type, because both data types are 32-bit types. The REAL data type is not automatically assigned although it also involves a 32-bit data type. The REAL data type is defined so that it does not have any equivalent data types: it is always clear. The elementary data type check is only performed when using local variables.

| User-defined data types | Equivalent data type |
|-------------------------|----------------------|
| BOOL                    | BOOL                 |
| BYTE                    | BYTE                 |
| WORD                    | WORD, INT            |
| INT                     | WORD, INT            |
| DWORD                   | DWORD, INT           |
| DINT                    | DWORD, DINT          |
| REAL                    | REAL                 |

## 2. No data check

This mode is only available for global variables where no data types can be specified. If a data type check is not active, all data types of the same size are automatically assigned to the symbol.

Example:

A symbol, which is assigned to address DB1400.DBD4, then the following data types are automatically assigned by the programming software: DWORD, DINT and REAL.

| User-defined address | Assigned equivalent data type |
|----------------------|-------------------------------|
| DB1400.DBX0.0        | BOOL                          |
| DB1400.DBB0          | BYTE                          |
| DB1400.DBW2          | WORD, INT                     |
| DB1400.DBD4          | DWORD, DINT, REAL             |

## Advantages of the data type check

The data type check helps you to avoid programming errors that have been widely propagated through the program. If an operation supports numbers with signs, the Programming Tool PLC828 designates the use of unsigned numbers in addresses of operations.

Example:

The comparison < I is an operation with sign. -1 is less than 0 for addresses with sign. However, if the operation < I supports unsigned data types, then the programming itself must ensure that the following does not occur: While a program is being executed, an unsigned value of 40.000 is actually smaller than 0 for the operation < I. If it cannot be guaranteed that the unsigned numbers for signed operations do not exceed the positive and negative limit values, then unpredictable events can occur in your program or in the mode of operation of the control.

### Working with operations to convert the data type

Conversion operations convert one data type into another. The Programming Tool PLC828 supports the following conversion operations to transfer values between the elementary data types.

| Conversion of data types | Conversion operations | Complete data type check, permissible addresses | Data check, permissible addresses |
|--------------------------|-----------------------|-------------------------------------------------|-----------------------------------|
| INT in BCD               | I_BCD                 | IN: INT<br>OUT: INT                             | IN: WORD, INT<br>OUT: WORD, INT   |
| BCD in INT               | BCD_I                 | IN: INT<br>OUT: INT                             | IN: WORD, INT<br>OUT: WORD, INT   |
| DINT in REAL             | DI_R                  | IN: DINT<br>OUT: REAL                           | IN: DWORD, DINT<br>OUT: REAL      |
| REAL in DINT (ROUND)     | TRUNC                 | IN: REAL<br>OUT: DINT                           | IN: REAL<br>OUT: DWORD, DINT      |

### 14.3.2.5 Constants

#### Range of constants

| Size of the data | Range without sign              |                 | Range with sign                 |                         |
|------------------|---------------------------------|-----------------|---------------------------------|-------------------------|
|                  | Decimal:                        | Hexadecimal:    | Decimal:                        | Hexadecimal:            |
| B (Byte)         | 0 ... 255                       | 0 ... FF        | -128 ... +127                   | 80 ... 7F               |
| W (Word)         | 0 ... 65535                     | 0 ... FFFF      | -32768 ... +32767               | 8000 ... 7FFF           |
| D (Double word)  | 0 ... 4294967295                | 0 ... FFFF FFFF | -2147483648 ... +2147483647     | 8000 0000 ... 7FFF FFFF |
| Size             | Decimal real number (positive)  |                 | Decimal real number (negative)  |                         |
| D (Double word)  | +1.175495E-38 ... +3.402823E+38 |                 | -1.175495E-38 ... -3.402823E+38 |                         |

#### Format identifier of constants

In many operations, your program can use constants in the byte, word or double word format. Format identifiers specify how a constant value is to be displayed (in the binary, decimal, hexadecimal or ASCII format).

Constants in the program are considered as decimal numbers if a format identifier is not specified:

- 2# for dual numbers
- 16# for hexadecimal numbers

Examples of binary constants:

| Example | Numerical basis | Separator | Constant |
|---------|-----------------|-----------|----------|
| 2#1101  | 2               | #         | 1101     |

Examples of hexadecimal constants:

| Example | Numerical basis | Separator | Constant |
|---------|-----------------|-----------|----------|
| 16#3FB2 | 16              | #         | 3FB2     |

---

#### Note

Underscore characters can increase the readability in imported ASCII files.

Example: 16#A\_B\_C\_D

---

### 14.3.2.6 Data blocks

#### Data block types

A distinction should be made between three types of data blocks (see also "Addressing range of the target system (Page 1119)"):

- Data blocks of the user interface

These are used to communicate from the user program with the individual control components and are created by the system. The user accesses the interface using read and write access operations.

---

#### Note

According to the notation type and addressing, although they are data blocks, these DBs do not make a distinction between initial and actual values and they are also not part of the PLC user project. The information provided in the section "Properties of data blocks" does not apply to these DBs.

---

- Special data blocks

They are used for special tasks (e.g. tool manager, service planner) and are available pre-configured in the Programming Tool PLC828. If the particular functionality is to be used, the corresponding DBs must be incorporated in the user program.

- User data blocks

Users define their structure and incorporate them in the user program.

### Data block properties

A data block is a block for data (initial values, actual values) and comments with the following properties:

- The data are saved in precisely the same sequence as specified by the user. This means that the inner structure of the data block is defined and if several data blocks are created with the same inner structure (i.e. the same type), then a certain data is always located at a specific location. This location is called offset and is the relative length in bytes from the beginning of the data block (DB) up to the actual piece of data.
- Initial values can be assigned to the data. When loaded into the CPU for the first time, the actual values of the DB are initialized with these initial values. The initial values are also stored in the CPU.
- The actual values of the data can also be read online from the control, changed and also saved with the project.

The data block structures are, just like the POU's, part of the project. They are compiled, saved, imported or exported with the project. Further, they are loaded with the project into or out of the target system. Data blocks only contain actual values. These can be loaded into or out of the target system independent of the project. It is absolutely necessary that the structure of the data block to be loaded into the target system matches the project opened in the Programming Tool PLC828. Data blocks are listed like POU's in their own symbol table.

If you change the CPU type for your project, then the existing data blocks are not lost. However, if you select a CPU in which the data blocks are not available, then you must observe that the variables from the data block are now displayed in their absolute address (e.g. DB9000.DBB0). Only when the target system is started is a check made as to whether this address is valid and the program is then possibly not executed.

You can rename your data blocks and change their properties, by clicking with the right mouse button in the operation tree on the corresponding data block. Select "Properties". The "Properties data block" dialog box opens. Here, you can change the name, block number and data class as well as add an author and comments.

---

#### Note

If you just want to rename your data block, click the right mouse button in the instruction tree on the object you want to rename and chose "Rename".

You can also easily edit your data block in another program (e.g. Microsoft Excel).

---

## Editing data blocks in the Programming Tool PLC828

To edit data blocks in the Programming Tool PLC828:

- In the navigation bar, click on the button "Data block".
- Select the "View" > "Data block" menu command.
- In the operation tree, double click on the button "Data block" and then on the data block to be edited:

## Assigning addresses and initial values in the data block

You define the structure of the DB (the sequence of the individual DB variables) in the declaration view. Initial values can be assigned to the variables of the data block that are saved with the data class or the project and with which the actual values of the DBs are initialized when loaded into the CPU for the first time.

When you define a variable, you assign its name and data type. The default initial value is set to zero/OFF, however, this can also be changed. You can optionally insert comments. The Programming Tool PLC828 automatically assigns the address. Each address is aligned by its size which means that gaps can occur.

Example:

|   | Address | Name    | Data Type | Format         | Initial Value |    |
|---|---------|---------|-----------|----------------|---------------|----|
| 1 | 0.0     | dwDate1 | DWORD     | Hexadecimal    | 16#00000000   | K1 |
| 2 | 4.0     | wDate2  | WORD      | Unsigned       | 0             | K2 |
| 3 | 6.0     | bDate3  | BYTE      | Unsigned       | 0             | K3 |
| 4 | 7.0     | boDate4 | BOOL      | Bit            | OFF           | K4 |
| 5 | 7.1     | boDate5 | BOOL      | Bit            | OFF           | K5 |
| 6 | 8.0     | rDate6  | REAL      | Floating Point | 0.5           | K6 |
| 7 | 12.0    | iDate7  | INT       | Signed         | +0            | K7 |

The maximum size of a data block is limited (512 bytes), if it is exceeded the Programming Tool PLC828 marks the excess variable addresses using a red wavy line. The Programming Tool PLC828 returns an error when compiling the project.

## Assigning actual values

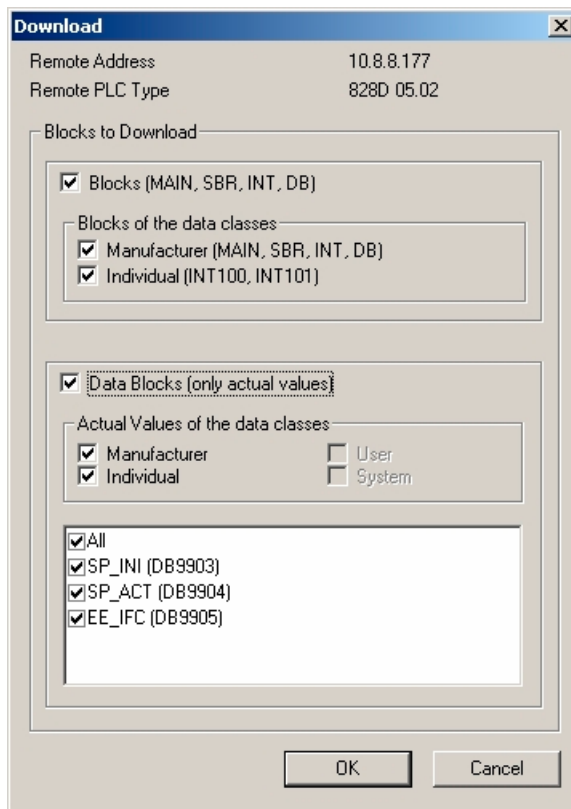

Actual values are saved with their data class (Manufacturer, Individual or User). They are only displayed and can be changed in the data view, while on the other hand, the structure of the variables (name, data type, initial value and comment) is write-protected in the data view.

After loading the actual values of the data block (not the complete project), these values become effective in the target system.

Example:

|   | Address | Name    | Data Type | Format         | Initial Value | Actual Value |    |
|---|---------|---------|-----------|----------------|---------------|--------------|----|
| 1 | 0.0     | dwDate1 | DWORD     | Hexadecimal    | 16#00000000   | 16#01234567  | K1 |
| 2 | 4.0     | wDate2  | WORD      | Unsigned       | 0             | 0            | K2 |
| 3 | 6.0     | bDate3  | BYTE      | Unsigned       | 0             | 0            | K3 |
| 4 | 7.0     | boDate4 | BOOL      | Bit            | OFF           | OFF          | K4 |
| 5 | 7.1     | boDate5 | BOOL      | Bit            | OFF           | OFF          | K5 |
| 6 | 8.0     | rDate6  | REAL      | Floating Point | 0.5           | 0.0          | K6 |
| 7 | 12.0    | iDate7  | INT       | Signed         | +0            | +0           | K7 |

DB\_9000 DB\_9001 **DB\_9002** DB\_9003 TM\_CTS TM\_VTS TM\_ACK MP\_INI MP\_ACT

The structure of the data block in the project must match the structure of the data block in the target system. If you have modified the structure of the data block, or re-created the DB, then the complete project has to be loaded again.

You can access the data view in the following ways:

- Click in the standard function bar on the symbol "Display data block values".
- or
- Select the menu command "View" > "Display data block values".

### Accepting initial values

If you accept the initial values, then all of the actual values of a data block are overwritten. If you hadn't selected an initial value for a variable, then the Programming Tool PLC828 sets it to zero/OFF. Other data blocks are not changed in the process.

In order to reset all actual values in the actual data block to the initial values:

- In the table, click on the right mouse button and in the context menu select "Accept initial values".

or

- Select the menu command "Edit" > "Accept initial values".

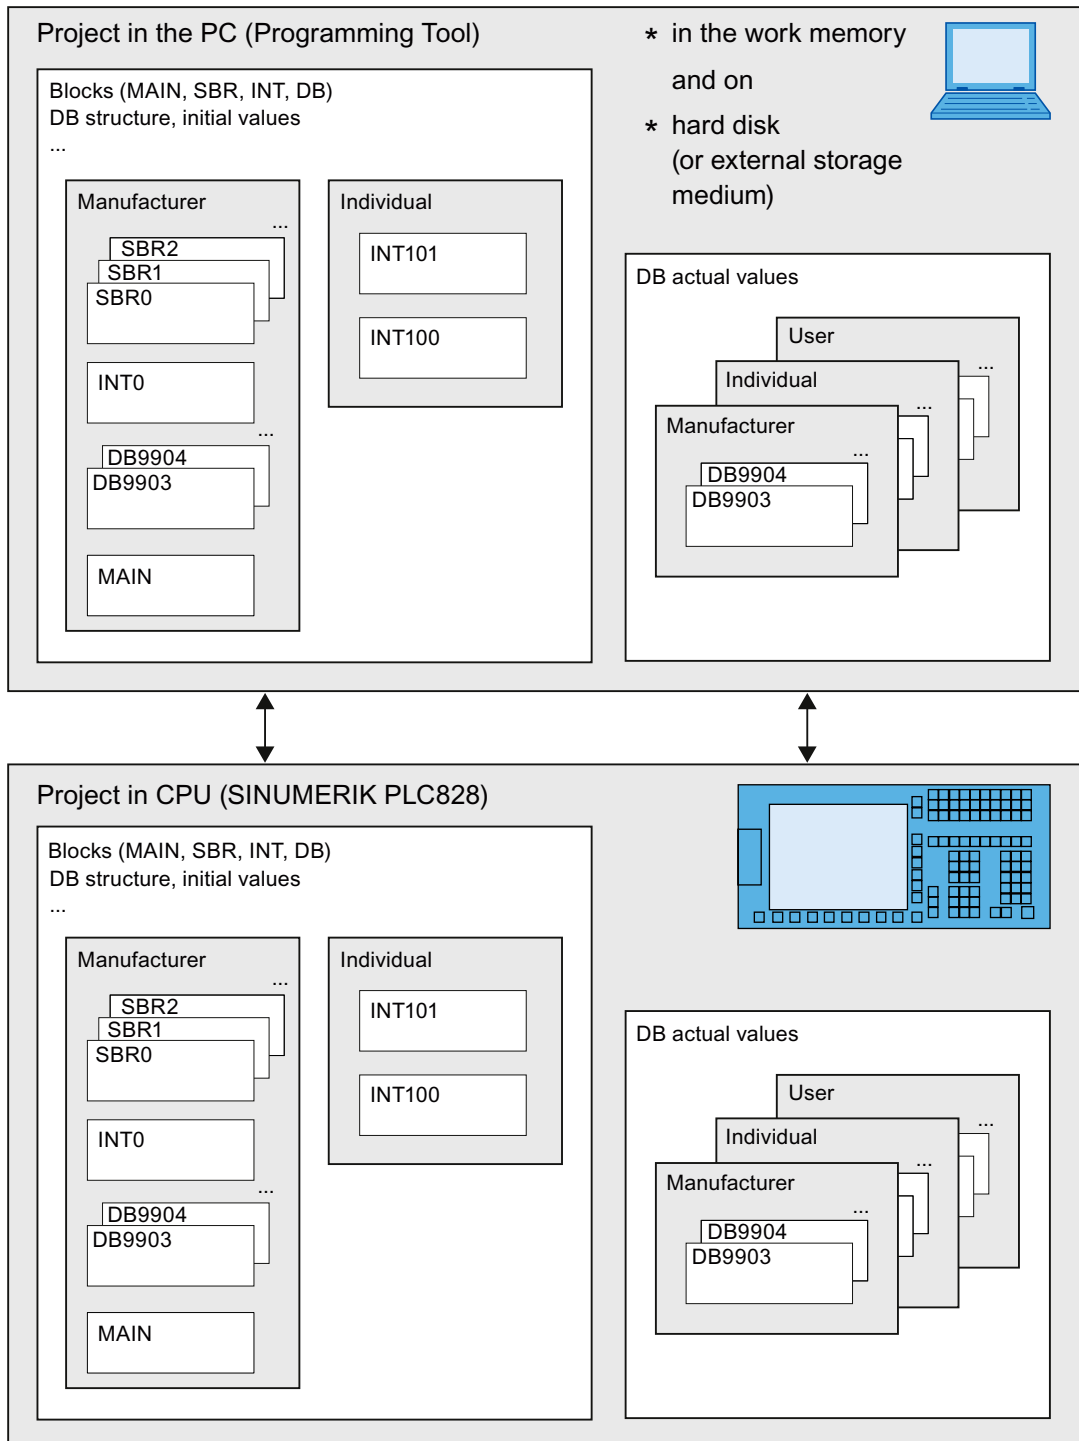

### Loading and saving the data blocks

**Save** involves writing the DB (depending on the selection, structure + initial values + additional blocks and tables or actual values or both together) from the PC work memory to the hard disk or to another external storage medium. After the project has been opened, these values are again available.

**Load into CPU** involves writing the DB (depending on the selection, structure + initial values + additional blocks and tables or actual values or both together) from the PC work memory into the PLC828.

**Load from CPU** is the inverse operation.

Load operations are selected from the data class perspective.

## Direct addressing for data blocks

- Absolute addressing

The direct, absolute address of the variables in their data block number comprises the absolute input from the number of the data block (e.g. DB9000) a period and the address of the variables.

The selection is made using the menu command "View" > "DB address representation (Ctrl+B)":

Example:

DB9000.DBB0

- Symbolic addressing

The variables of the data blocks can be assigned names in the symbol table. When using the variable it is sufficient to specify this name from the symbol table.

If no name is assigned to the DB variable in the symbol table, then the symbolic address comprises the DB name (e.g. myDB\_9000) and the name of the variables in the data block (e.g. Vcorrection1).

| Address       | Name of the variables in the data block | Entry in the symbol table | Absolute representation | Symbolic representation |
|---------------|-----------------------------------------|---------------------------|-------------------------|-------------------------|
| DB9000.DBX0.0 | Vcorrection1                            | FeedCorrAx1               | DB9000.DBX0.0           | FeedCorrAx1             |
| DB9000.DBX0.0 | Vcorrection1                            |                           | DB9000.DBX0.0           | myDB_9000.Vcorrection1  |

Figure 14-3 Symbolic address representation

The menu command "View" > "Symbolic addressing" (Ctrl+Y)" is used to switch over between absolute and symbolic representation.

## Indirect addressing for data blocks

You may be able to simplify the programming if data blocks with the same structure are used in your program. You can indirectly address the data blocks using the accumulators AC0 to AC3. The accumulators are used to tell the program which data block is to be handled. The value in the AC is then treated as index.

For example, for axis DBs, the program text can be somewhat reduced by not having to write a dedicated program for each axis, but instead access the appropriate axis via the various data blocks and the index (AC). The value in AC is treated as an index. This is the reason that it starts at 0 for the first axis. Indirect addressing is only possible using ACs. It is not possible to display the actual data value in the program status of the Programming Tool PLC828. The absolute address cannot be determined. V addresses cannot be used for indirect addressing.

Figure 14-4 Indirect addressing

**Absolute input**

DB3800[AC1].DBX2.1  
 DB9000[AC0].DBW0

**Symbolic input**

ToAxis[AC1].ControlEnable  
 Prototyp1[AC0].MyWord1

It is not permissible to use constants for indexing:

DB3800[1].DBX2.1                                      ToAxis[5].ControlEnable

Indirect addressing using V addresses is also not permitted:

|                  |                |
|------------------|----------------|
| V3800[5]0002.1   | V380[5]0002.1  |
| V3800[AC0]0002.1 | V38[AC0]0002.1 |

**Using Cut, Copy and Paste in the data block editor**

You can save data (rows, columns and cells) of your data block in the Microsoft clipboard to edit them in a different program. You can proceed as follows:

- In the context menu (right mouse button) using the commands "Cut"/"Copy" and "Paste".
- Using the keyboard by pressing the shortcut keys <Ctrl+X>/<Ctrl+C> and <Ctrl+V>.
- In the main menu using the "Edit" > "Cut"/"Copy" and "Edit" > "Paste".

|         |                                                                           |
|---------|---------------------------------------------------------------------------|
| Cut:    | Selected data is copied into the clipboard and is deleted                 |
| Copy:   | Selected data is copied into the clipboard and is not deleted             |
| Paste:  | If data is in the clipboard, then this data is pasted.                    |
| Delete: | Selected data block/section is deleted, it is not saved in the clipboard. |

You can easily edit your data block in this way, e.g. in Microsoft Excel:

|    | A      | B        | C     | D              | E   | F   | G              |
|----|--------|----------|-------|----------------|-----|-----|----------------|
| 1  | DBB0   | mybyte1  | BYTE  | Unsigned       | 0   | 0   | Comment for Df |
| 2  | DBB1   | mybyte2  | BYTE  | Unsigned       | 0   | 0   | Comment for Df |
| 3  | DBW2   | myword1  | WORD  | Unsigned       | 0   | 0   | Comment for Df |
| 4  | DBW4   | myint1   | INT   | Signed         | 0   | 0   | Comment for Df |
| 5  | DBX6.0 | mybit1   | BOOL  | Bit            | OFF | OFF | Comment for Df |

### Using special data blocks

The Programming Tool PLC828 offers you the possibility of using special data blocks for tool change, maintenance planning and the device manager. You will find these in the operation tree under "Libraries" > "Special data blocks".

These data blocks have a fixed structure. They can be used with a double click or using Copy and Paste (in the operation tree).

The following special data blocks are available:

|        |          |                                              |
|--------|----------|----------------------------------------------|
| TM_CTS | (DB9900) | Constant transfer step table for tool change |
| TM_VTS | (DB9901) | Variable transfer step table for tool change |
| TM_ACK | (DB9902) | Acknowledgment step table for tool change    |
| SP_INI | (DB9903) | Start data for maintenance planner           |
| SP_ACT | (DB9904) | Actual data for maintenance planner          |
| EE_IFC | (DB9905) | Interface for device manager                 |

## Resolving errors

The Programming Tool PLC828 marks errors made when data is being entered (e.g. in the LAD Editor or the symbol table). For example, an illegal syntax or the use of invalid values can result in input errors. You must correct all errors that have occurred before you can compile error-free and load the program into the CPU.

Every data block is involved in the compilation run of the project.

Compilation is started:

- Using the menu command "Target system" > "Compile"

or

- by clicking on the symbol.

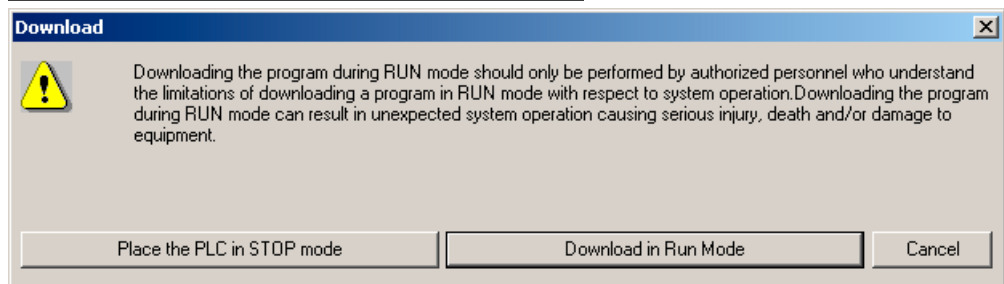

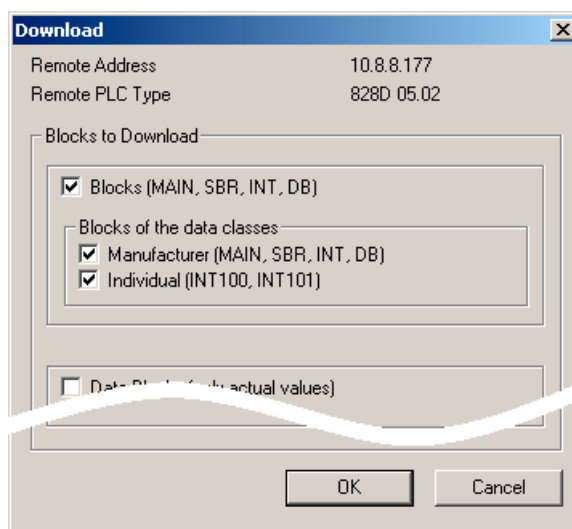

If any errors occur during compilation, then they are displayed in the output window. Position the cursor to an error message in the output window and double click on it so that you see the line in the data block with the error.

## Loading the data block into the target system

Here, reference is made to Chapter "Data classes (Page 1141)" in which loading and saving (not only data blocks) is explained in detail.

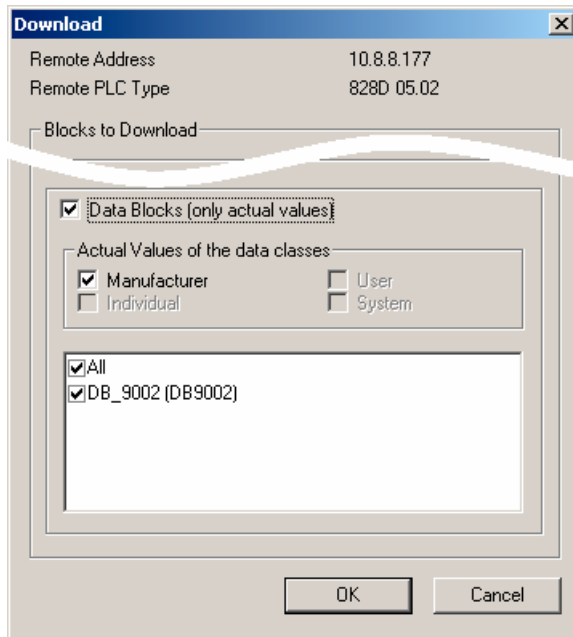

- After making structural changes to a data block, this must be loaded into the target system with the PLC in the stop state. The changes only become effective when subsequently going into the RUN operating state. If the target system identifies that a data block is new or has been changed, then it sets the initial values for this data block as the first actual values.

Under all circumstances, you should activate the three check boxes of the data classes. Why? If the modified DB is also called from the data class "Individual", then program errors occur as a result of the fact that it is deselected: Namely then, INT100 or INT101 access the "old" structure of the DB.

- After making changes to the actual values of a data block, these must then be subsequently loaded into the target system. (The structure of the data block in the target system must match the structure of the data block in the project). There are two ways of loading the actual values into the CPU:
  - By clicking on the "Write all" symbol.
  - By loading the DB in the RUN operating state:

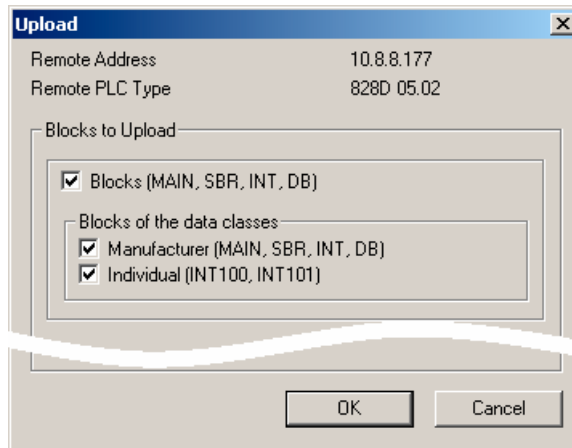

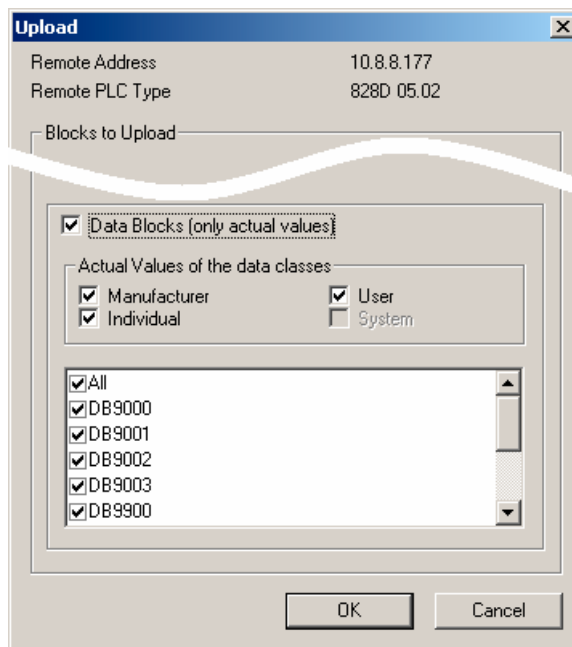

### Loading a data block from the target system

Here, reference is made to Chapter "Data classes (Page 1141)" in which loading and saving (not only data blocks) is explained in detail.

- You must first open a project in the Programming Tool PLC828 before you can load the program block (project) and therefore its structure from the target system. As the structure and initial values of the data blocks are permanently assigned the "Manufacturer" data class, then only the check box of this data class has to be activated.

- If you only want to load the actual values of a data block from the target system, then first open the corresponding project in the Programming Tool PLC828 or load it from the target system. You can now load the actual values. You cannot load the data block if the structure of the data block in the target system does not match that of the data block of the project that has been opened, or if the project that has been opened does not have a data block.

**14.3.2.7 Special bit memories and their functions**

Special bit memories SMB0 (SM0.0 ... SM0.6) include seven bits that are updated by the PLC firmware at the end of each cycle. You can realize various functions in your program.

| Special bit memories<br>(write protected) | Description                                                                                                                                                                                                                                                                  |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SM0.0                                     | This bit is always switched on.                                                                                                                                                                                                                                              |
| SM0.1                                     | This bit is switched on in the first cycle. It is used, for example, to call an initialization subprogram.                                                                                                                                                                   |
| SM0.2                                     | This bit is switched on for the length of a cycle, if retentive data has been lost. It can be used either as an error bit memory or as a mechanism for calling up special startup sequences.                                                                                 |
| SM0.3                                     | This bit is switched on for the length of a cycle if the RUN operating mode has been set after switching on (power on). This permits a warm-up time for the system before starting operation.                                                                                |
| SM0.4                                     | This bit ensures a cycle that is switched-on for 30 seconds and switched-out 30 seconds. And more precisely for a cycle time of 1 minute. This way you have an easy to program delay or a cycle time of 1 minute.                                                            |
| SM0.5                                     | This bit ensures a cycle that is switched-on for 0.5 seconds and switched-out for 0.5 seconds. And more precisely for a cycle time of 1 second. This means that you have an easy way of programming a delay time or a cycle time of 1 second.                                |
| SM0.6                                     | This bit represents a clock cycle. It is switched-on for one cycle and switched-out for the next cycle. So you can use this bit as a cycle counter input.                                                                                                                    |
| SM0.7                                     | This bit indicates the position of the mode switch (TERM - off, RUN - on). If this bit is used to enable freely programmable communication, if the switch is set to RUN, then you can enable normal communication with the programming device by setting the switch to TERM. |

### **14.3.3 Operation set**

The PLC of SINUMERIK 828D provides the following operation groups:

- Bit logic operations
- Fixed-point arithmetic
- Interrupt operations
- Floating-point arithmetic
- Program control operations
- Shift/rotate operations
- Transfer operations
- Conversion operations
- Comparison operations
- Logical operations
- Counters
- Timers
- Subprograms

You can take details from the online help of the Programming Tool PLC828 and the S7-200 System Manual.

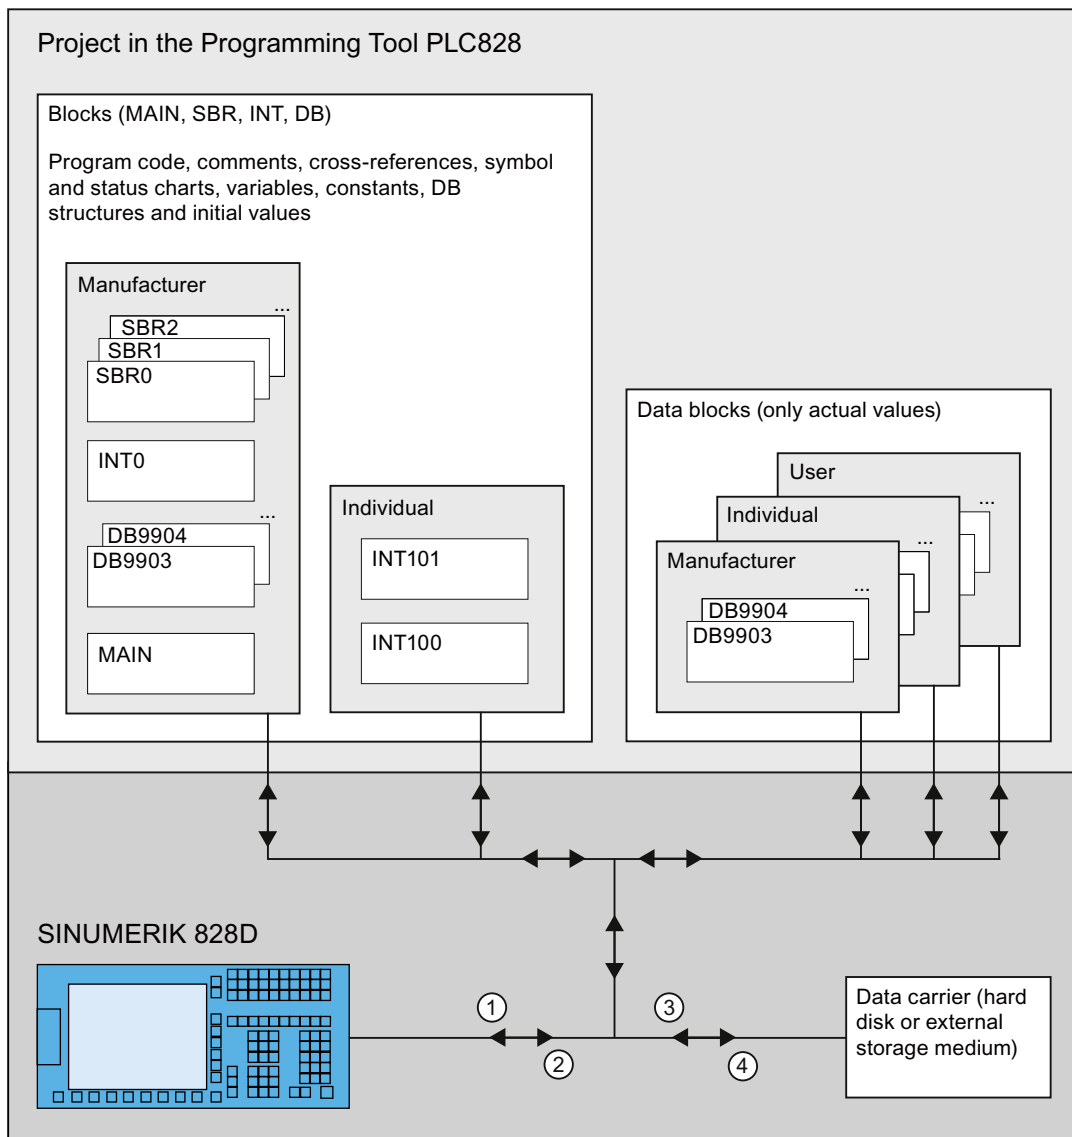

### **14.3.4 Data classes**

#### **14.3.4.1 Defining data classes**

#### **Overview**

Data classes are user-related organizational units for programs and data blocks as project subcontainer.

They are special in so much that they mutually demarcate the contents: The data and programs assigned to them can be handled as group - i.e. as data class. This applies when loading into the control and from the control as well as for data backup using export and import.

- ① Load into CPU
- ② Load from CPU
- ③ Open Project
- ④ Save project (under)

Figure 14-5 Project structure in the Programming Tool PLC828 and the structure of the data class transport paths

From the user's perspective, there are three data classes:

- Manufacturer:
  - POU's (MAIN, all subprograms and the interrupt program INT0);
  - The data blocks: internal structure (type information) plus initial values;
  - The data blocks: Actual values, if assigned by the user;
- Individual:
  - the interrupt programs INT100 and INT101
  - The data blocks: Actual values, if assigned by the user;
- User:
  - The data blocks: Actual values, if assigned by the user;

All of the existing data classes are always automatically selected in the dialog box for loading. This means that all of the data and blocks belonging to the project are always loaded, if they have not been deselected by the user.

## Example

With a standard (series) machine, where the machinery OEM also commissioned the PLC user program, a PLC input (IO module) fails. The input is rewired to a free input. The INT100 interrupt program can be used so that the service/erection technician doesn't have to change the PLC user program of the machine manufacturer due to the rewiring, which is a complex and tedious task: This runs in front of the main program (MAIN) and writes the rewired input to the original input in the image. INT100 is assigned to data class "Individual" and is loaded into the CPU with this data class.

The project block of the machinery construction OEM has the data class "Manufacturer" and is loaded into the CPU with this data class.

If the machine manufacturer updates his PLC user program, the correction program is not influenced. The corrections remain independent of this and are still effective.

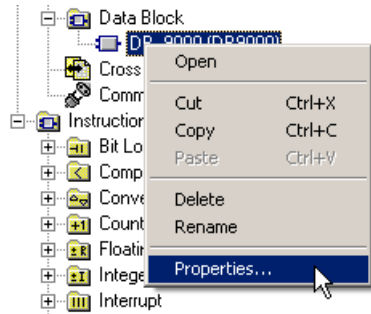

The interrupt program INT100 can be independently loaded in its data class and the correction function described above executed.

### 14.3.4.2 Assigning a block to a data class

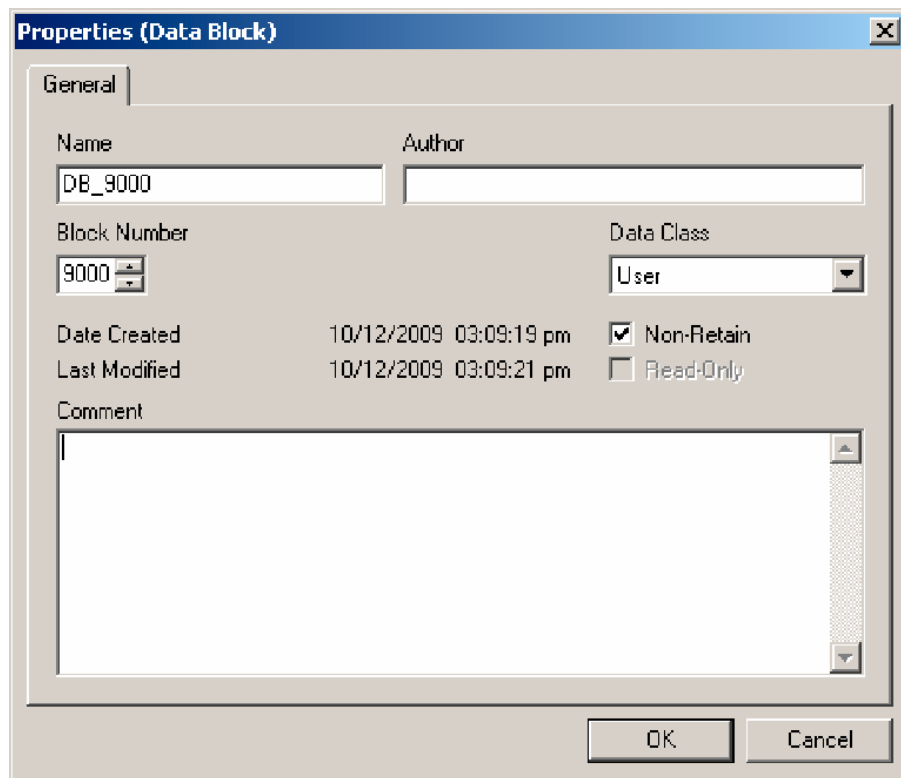

A data block is assigned to a data class in its property dialog box.

#### Procedure

1. In the operation tree, right click on the corresponding block and select "Properties":

2. Assign the block to one of the three possible data classes:

Here, for DB9000, in addition to the data class "User", the "Non-Retain" property was also selected. Data blocks with this attribute are reset to the initial values after each power off and power on.

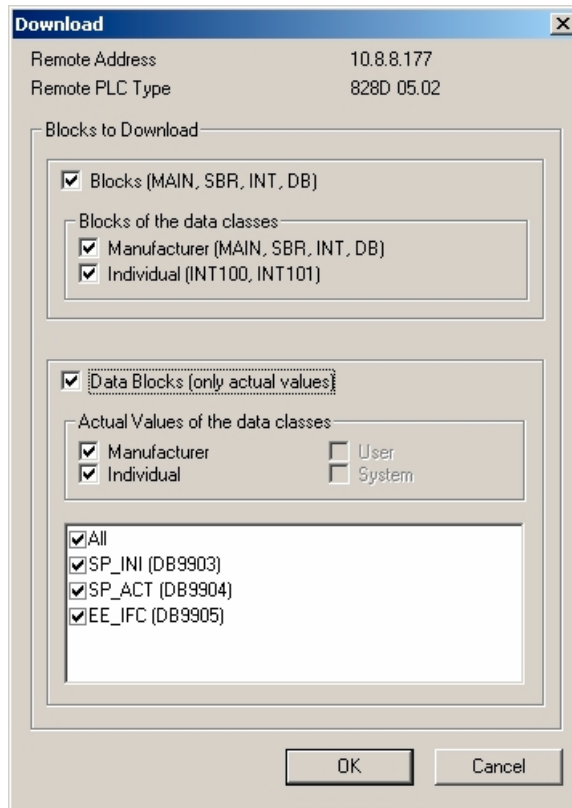

#### See also

Defining data classes (Page 1141)

### 14.3.4.3 Load data class(es) into the CPU

#### Procedure

1. In the window "Load into CPU", select the data class(es) whose blocks are to be loaded:

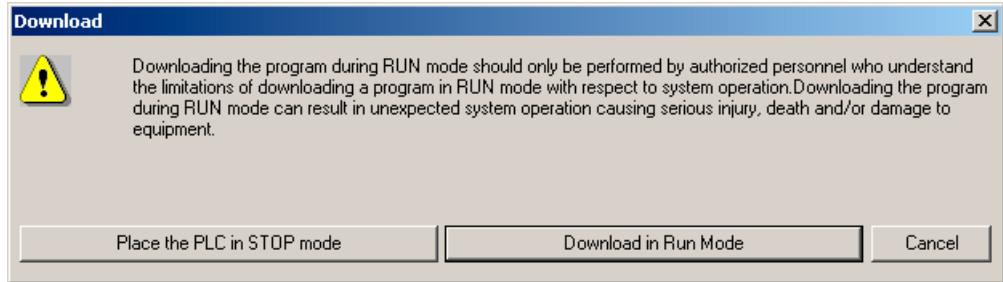

2. Select the option "Blocks (MAIN, SUBR, INT, DB)", if program or data block changes are to be loaded into the target system.
3. Select the option "Data blocks (only actual values)" if actual values of one or several data blocks are to be loaded into the target system.

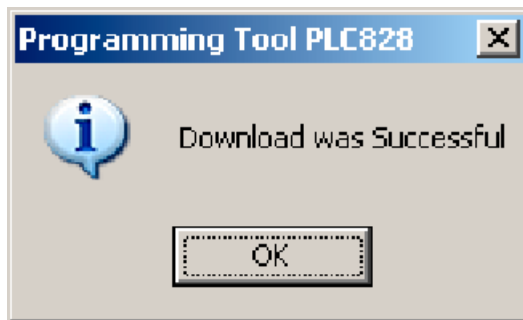

4. Select one of the following options in the message window "Load into CPU":
  - "Bring target system into the stop condition"
    - If structurally modified programs or initial values of data blocks are to be loaded into the target system.

or

  - "Load in the RUN operating state"
    - If neither program nor data block structures have changed.

The following message must be output after loading:

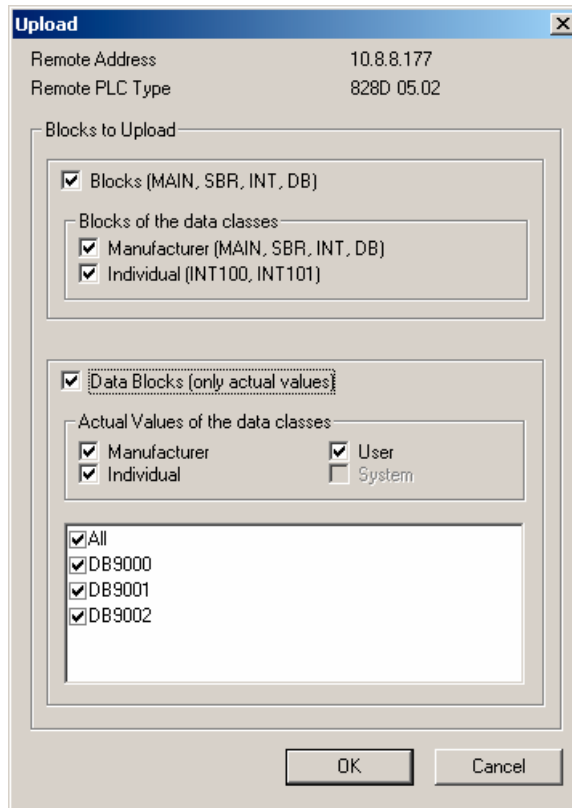

5. Confirm this message.
6. After "Loading in stop condition" – if required – switch the control back to RUN.

#### 14.3.4.4 Load data class(es) from CPU

##### Procedure

1. In the window "Load from CPU", select the data class(es) whose blocks are to be loaded:

2. Select the option "Blocks (MAIN, SUBR, INT, DB)", if program or data block changes are to be loaded into the target system.
3. Select the option "Data blocks (only actual values)" if actual values of one or several data blocks are to be loaded into the target system.

4. If required, save the opened project in the Programming Tool PLC828, it is then overwritten when "Load from CPU":

A new project with the name of the project located in the target system is created.

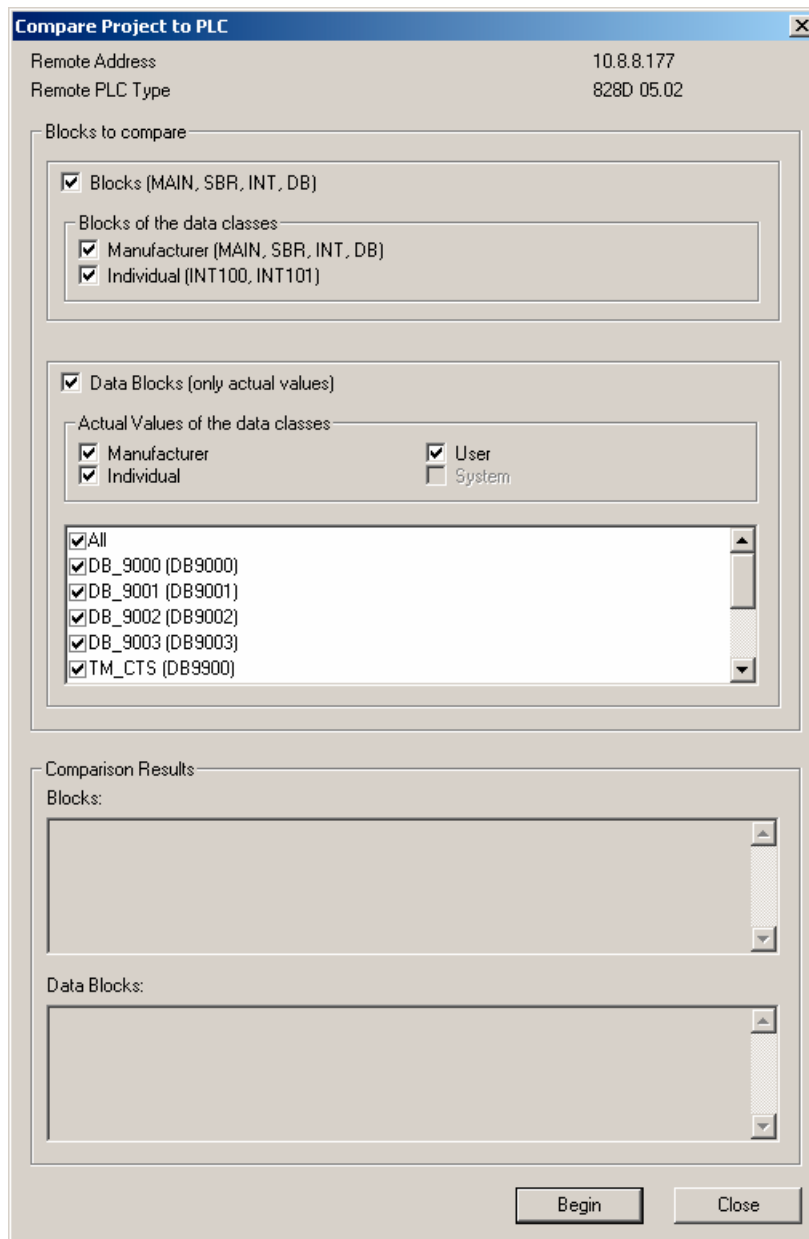

5. After a warning that the existing project will be possibly changed as a result of "Load from CPU", the requested data are loaded from the target system (also refer to the diagram "Project structure in the Programming Tool PLC828 and the structure of the data classes transport paths" in Defining data classes (Page 1141)).

#### 14.3.4.5 Comparison between online and offline projects

The data classes, whose blocks are to be compared, can be selected in the dialog box "Compare..."(menu "Target system" > "Compare...").

If data classes only exist in the offline project or only in the CPU (online project), these are correspondingly marked. The differences that exist between the offline and online existing program blocks (SBRs, INTs) or data blocks (DBs) are shown as a result of the comparison:

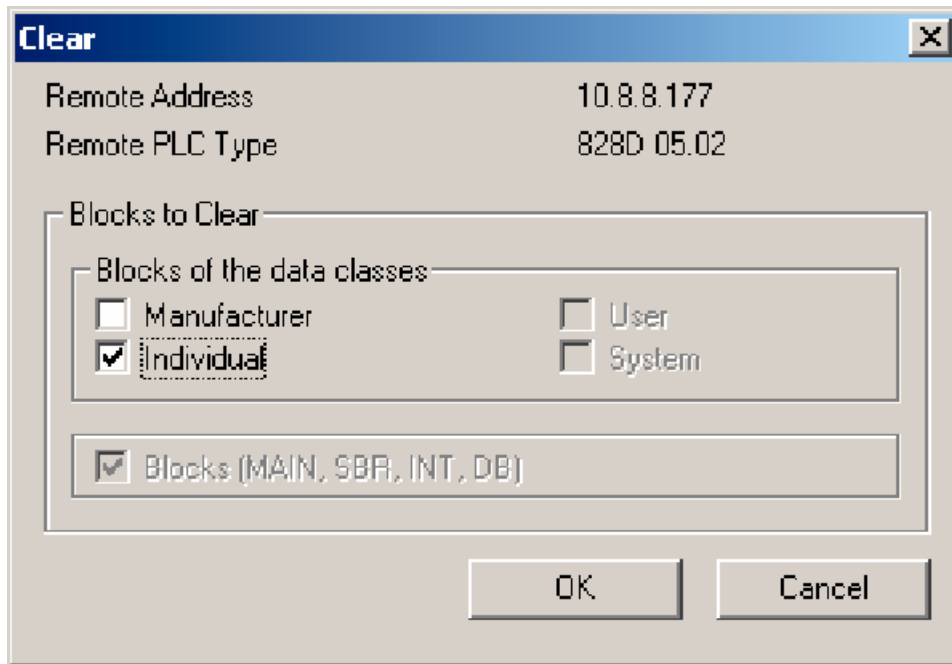

**Example:**

The differences between the actual values saved (offline) in the project (e.g. +22) and the actual values available in the target system (online) (e.g. +11) are displayed in the lower field "data blocks".

### 14.3.4.6 Delete in the target system

Delete is only permitted in the "STOP" operating state.

Deleting "Manufacturer" results in a start error at the transition into the "RUN" operating state. The target system then returns into the safe "STOP" operating state.

#### See also

Defining data classes (Page 1141)

### 14.3.5 Rewire addresses

#### Function

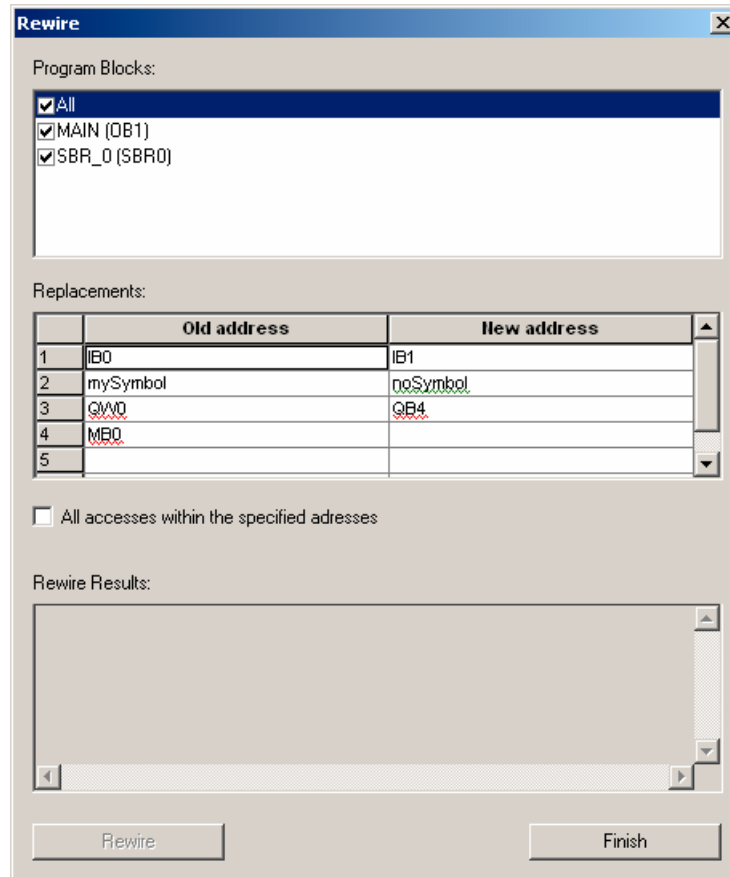

Addresses in the PLC user program can be centrally changed - e.g. IW0 to IW8 - using the "rewire" function. This means that user programs can be quickly adapted to the modified I/O expansion stage.

#### Example:

The customer writes a PLC user program for a series of machines. Due to the different machine expansion stage, the I/O expansion stage of several machines differs, which is the reason that addresses must be individually changed in the user program. Under certain circumstances, this can involve several hundred addresses. Using the "rewire" dialog box, for these machines, it is now possible to enter a list of the addresses to be changed, e.g. inputs and outputs. This is executed using the "rewire" function, and the addresses are changed in the user program.

## Procedure

Use the dialog box "rewire", to rewire addresses:

Please proceed as follows:

1. Open the dialog box "Rewire" in the LAD editor using the context menu ("Rewire ...") or using the menu bar ("Edit > Rewire ...").
2. In the list "Program blocks" (list of all of the POU's available in the project), select the POU's in which the rewire operation is to be executed.

3. Enter the old and the new addresses for rewiring in the "Replacements" list.

**Permitted addresses include:**

- Inputs
- Outputs
- Bit memory
- Special bit memory
- Variable memory / data blocks
- Timers
- Counters

**Editing the list of addresses**

The following functions are supported using the context menu (right mouse button):

- Cut (Ctrl+X)
- Copy (Ctrl+C)
- Paste (Ctrl+V)
- Select all (Ctrl+A)
- Paste row (Ctrl+I)
- Delete selection

This means that it is possible to copy the list or parts of the list from other or into other applications, e.g. Microsoft Excel.

**"Old address"**

In this column, enter the name or the address which you wish to rewire.

**"New address"**

In this column, enter the new name or the new address. Please ensure that the type of the new address corresponds to that of the old address, e.g. old address IW0 and new address IW4, not IB4, or old address DB9000.DBB0 and new address MB0, not MW0.

**Checking the validity of addresses**

If the name of the address (symbol) does not exist in the open project, then this is marked with a green wavy line.

If the type of the old address does not match that of the new address, or if only one address was entered (old or new address), then this address is marked using a red wavy line.

4. Select or deselect the option "All accesses within the specified addresses".

If the option is enabled, then the addresses ranges (BYTE, WORD, DWORD) are rewired.

Example:

You specify IW0 and IW4 as address ranges. The, addresses I0.0 ... I1.7 are rewired to addresses I4.0 ... I5.7. Addresses from the rewired range (e.g. I0.1) can then no longer be individually entered into the table.

5. Click on the button "Rewire" to start the function.

---

**Note**

If you wish to exit the dialog box, without activating the function "Rewire", then use the "Exit" button.

---

After executing the rewire function, the results are displayed in the list "Results of rewiring". The list contains the address list with the columns "Old address" and "New address". These list the individual blocks and the number of wiring operations that were carried out in each block. Using the context menu (right mouse button), the results can be copied into other applications, e.g. Microsoft Word.

---

**Note**

**The following must be taken into account when rewiring:**

- Name or number of a POU cannot be changed using the "Rewire" function. For this purpose, in the operation tree in the POU context menu (click with the right mouse button, e.g. on SBR\_0) using the functions "Rename" or "Properties ...".
  - Timers can only be rewired to remain timers (e.g. old address T0, new address T16) and counters can only be rewired to remain counters (e.g. old address C0, new address C1).
-

## 14.4 Test and diagnostic functions

### 14.4.1 Program status

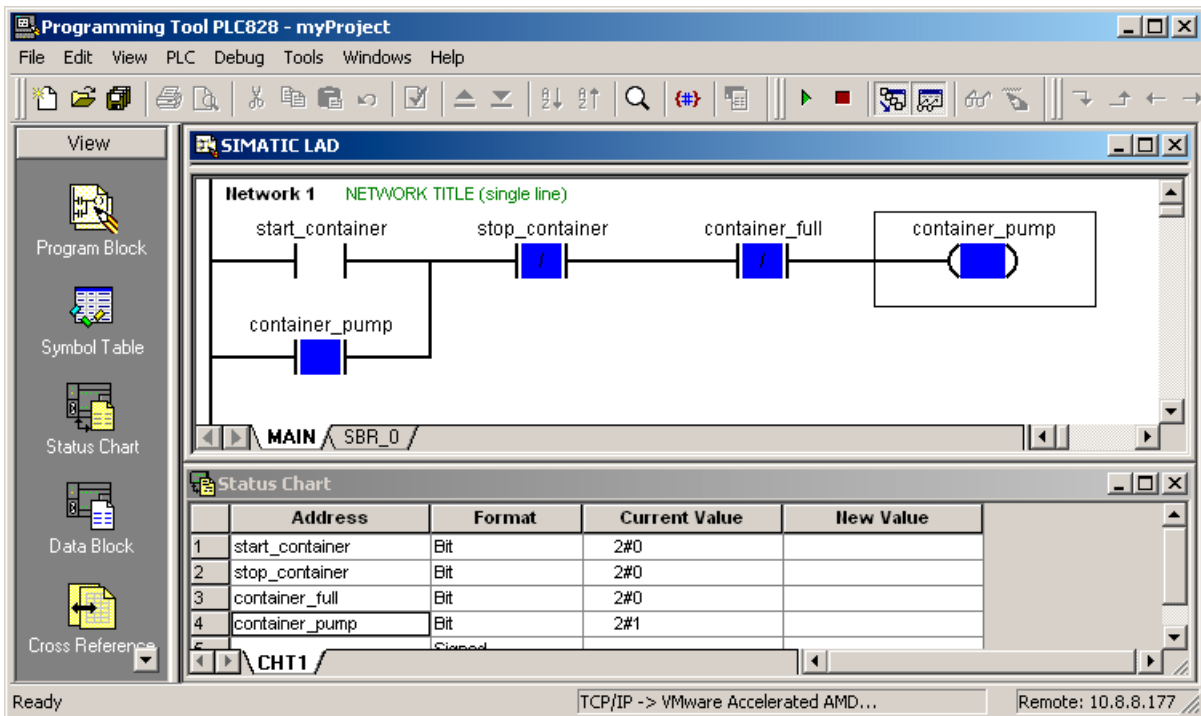

Once you have established communication between your programming device, on which the Programming Tool PLC828 is installed, and a target system and have loaded a program into the target system, you can work with the diagnostic functions of the Programming Tool PLC828 and test new programs as well as monitor programs that are already being processed.

These help topics are subsequently described.

#### 14.4.1.1 Status definition

"Status" refers to the display of the actual values of addresses while executing the program in the target system. You can display status information in a status chart or by switching-on the program status in the program editor.

An example for status information in the status chart and in the program editor of the Programming Tool PLC828 is shown in the following diagram:

### Note

Please note that unnecessary project components (e.g. the operation tree and the output window) have been omitted, in order to provide more space to display the required components (LAD program editor, status chart, function bar to test and symbol for the status chart in the navigation bar). Using the menu "View", you can set-up the environment in the Programming Tool PLC828 corresponding to your particular tasks, i.e. you can display just the project components that you require.

#### 14.4.1.2 Preconditions of the status update

Before you can update the status to monitor and test your program, you must execute the following tasks:

- Your program must be able to be compiled error-free.
- You must have set-up the communication between the Programming Tool PLC828 and the target system.
- Your program must have been loaded error-free into the target system.
- After you have loaded the program into the target system, then you should again bring this into the RUN operating state. Otherwise, the address status is displayed, however, the target system cannot execute the program so that you are not shown the logic operations that you expect.

### 14.4.1.3 Influence of the operating state on the target system

The type of monitoring and test functions that you execute depends on the operating state of your target system.

Even if your program is not executed in the STOP operating state, the operating system of the target system still monitors the target system (status of RAM and I/O, and transfers the data status to the Programming Tool PLC828. If the target system is in the STOP operating state, then you can execute the following functions:

- You can display the actual values of the addresses in the table status or in the program status. (This is the same as the function "Single read", as the program is not executed.)
- You can write values in the table status.
- You can execute a certain number of cycles and display the effect in a status chart and/or in the program status.

If the target system is in the RUN operating state, you cannot execute the functions "First cycle" or "Several cycles". You can write values into a status chart, you can also execute the following functions (not in the STOP operating state):

- In the table status, you can carry out the continuous updates. (If you wish to only execute an update, you must switch-off the table status so that you can execute the command "Single read".)
- You can execute continuous updates in the program status.

### 14.4.1.4 Communication and cycle

In a continuous cycle, the target system reads the inputs, it executes the program, writes to the outputs and executes system functions as well as the communication. This cycle runs with an extremely high speed of many times per second. Even if the Programming Tool PLC828 issues status requests in a fast sequence, it is important that you clearly understand that you cannot monitor each individual event that takes place in the target system. When using the program status or the table status, if you read data values from a target system program, the interrogate the data by taking samples (spot check). The update rate of the status values read from the target system depends on the communication baud rate.

#### 14.4.1.5 Status update

##### Program status in LAD

If you monitor the program status in the program editor in LAD, the status is updated at the end of each cycle. If an address is processed by several operations, the intermediate values of the addresses are not displayed by the status. Only the values of the addresses at the end of each program cycle are displayed in the LAD program status.

##### Update status (procedure)

You can update the status in various ways:

- Open the program editor window and enable the program status (menu "Test" > "Program status") in order to view the continuous status update in the RUN operating status of the target system.

Bear in mind that "continuous" does not mean in real time; instead, it means that the programming device quickly polls the PLC for status information and displays it on your screen, updating the display as quickly as your communications permit. Some rapidly fluctuating values may not be identified and displayed on your screen. It is also possible that the values change too quickly for you to read them. You can update the status once if you switch the target system to the STOP operating state. Even if the target system is in the STOP operating state, you can use the "Multiple cycles" command to view one or more cycles. Using the "First cycle" function, you can view a single cycle - whereby the bit memory of the first cycle is activated.

- Open the status chart window and enable the chart status to view continuous updates when the target system is in the RUN operating status.
- Disable the chart status and use the "Single read" function if you wish to update the status and you do not want to switch the target system into the STOP mode.

If you switch the target system into the STOP operating state and enable chart status, then this also enables you to update the status. Furthermore, you can use the "Multiple cycles" and "First cycle" functions while you are viewing a status chart.

#### 14.4.1.6 Simulating process conditions

You can simulate process conditions by writing new values to addresses. To do so, use the status chart.

#### 14.4.1.7 Checking cross references and the elements used

If you test your program, it is possible that you wish to supplement, delete or change the parameters.

In the window "Cross-references", you can determine how the parameters are presently assigned in your program. This helps you to avoid assigning values twice.

## 14.4.2 Program status in the LAD program editor

### 14.4.2.1 Display program status

---

#### Note

If, in the STOP operating state, you have loaded a program into the target system, you must switch the target system back into the RUN operating state before you can display continuous updates of the program status!

---

#### Procedure

To enable the program status, proceed in one of the following ways:

- Select the menu command "Test" > "Program status".

or

- To test, click in the function bar on the "Program status" button.

The program status is displayed in the program editor.

Boolean operations (contacts, coils) are displayed as colored blocks if the address value is 1 (the bit is enabled).

The value of non-boolean addresses is displayed and updated as quickly as the communication permits it.

---

#### Note

If you enable the program status, many other functions in the programming tool are deactivated. For instance, you cannot change your program, unless you disable the program status again. Other functions, e.g. switching the display from one program editor to another, mean that the program status is automatically disabled. If you wish to display the status gain, you must reselect the command "Program status".

---

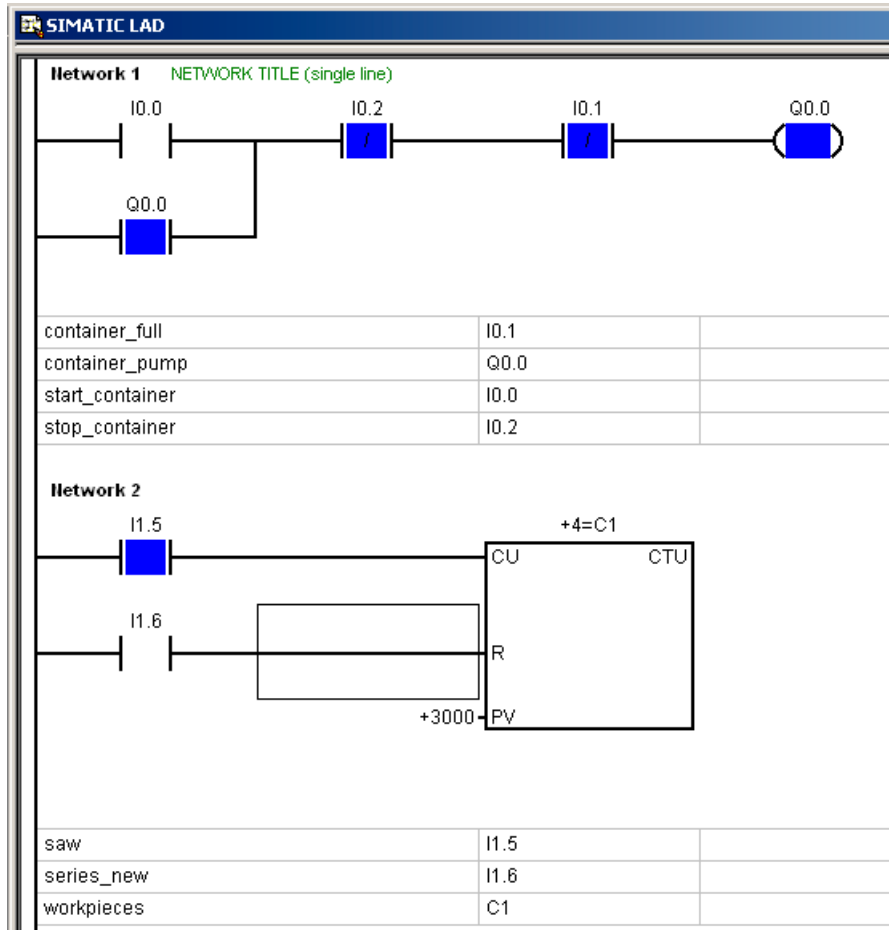

**Note**

If you have problems when enabling the program status, please consider the following prerequisites:

- You must have set-up the communication (so that you can load your program into the target system).
  - You must have selected the correct CPU version so that you can load the program into the target system.
  - Your program must be able to be compiled error-free.
  - Your program must be able to be loaded error-free into the target system.
  - Your target system must be in the RUN operating state in order that the status update can be continuously displayed. Otherwise, only changes at the inputs and outputs (if they are available) are displayed. As the program is not executed in the target system, changes at the inputs and outputs do not have the same effects as you would expect at the program logic in the displayed program status.
  - If you display another program area, which is not executed (e.g. an interrupt program or subprogram or an area, which was skipped due to a jump operation), the status is not displayed as the code is not interrogated.
-

### 14.4.2.2 Display properties

If you display the program status in LAD, the boolean operations are displayed as colored blocks, if the value of the address is 1 (bit is enabled). The actual data value from other addresses is displayed next to the address (or instead of the address). The display is updated, if changes are read from the target system.

### 14.4.2.3 Restrictions

The advantage of displaying the status in the program editor is due to the fact that you obtain a graphic display of the events in your program. However, not all of the tools are available as in the status chart (e.g. the function "Single read", "Write all").

It is important that you know the restrictions of the program status if you test and monitor your program.

## Signal flow

**The color marking for "Signal flow" does not mean that there is always a signal flow!**

In the program status in LAD, the values are only displayed at the end of the cycle. This means that it can be sometimes difficult to evaluate just what the "signal flow" display really means. Boolean contacts and coils are shown color coded in the program status in LAD corresponding to the value of the bit addresses. If the bit value is 1 (bit is enabled), then the operation is marked in color. However, this does not necessarily mean that the operation was actually executed. There are several conditions that can result in an unclear signal flow display:

- If, when evaluating the status, the target system is in the STOP operating state, contacts can be activated, however, coils and boxes are not switched-on because the program is not being executed.
- If the program contains a jump operation, then it is possible that the networks that you are investigating, do not display the expected results because the target system skipped these operations while executing the program.
- It is a similar situation if you consider a subprogram. The boolean addresses can be activated, however, the subprogram logic can only be executed if the subprogram is activated. If the subprogram was not called from the main program, then no logic of the networks was executed regardless of what the bit values of the operations display.

## Status at the end of the cycle in LAD

If you display the program status in the program editor in LAD, the status is updated at the end of every cycle. Displaying your program in another programming language has no effects at all on the actual program.

### 14.4.2.4 Adapting the program status display

#### Adapting the program status display in the program editor

Procedure:

1. Select the menu command "Tools > Options".
2. Open the "Status" tab.

You can now edit the following settings:

- **Zoom factor**

To edit the scaling.

Shortcut key: You can use the shortcut key to quickly set the zoom factor in the program status:

- Press the Ctrl key and the plus key in the numerical block of the keyboard to increase the display size.
- Press the Ctrl key and the minus key in the numerical block of the keyboard to reduce the display size.

- **Field width and height**

To edit the grid settings.

You can increase the field width so that information can be displayed which otherwise would be cut-off. You can reduce the field height so that there is sufficient space so that your networks can be shown on the screen.

- **Signal flow**

You can change the color, which shows that boolean addresses are activated (bit value is 1).

- **Address display**

You can display the addresses either within or outside the operations. You can also display the status value without changing the name or the address.

## Adapting the arrangement of the window in the Programming Tool PLC828

In order to create more space for the window of the program editor, or to be able to display it with another window, e.g. the status chart, the symbol table or the cross references, you can adapt the arrangement and size of all of the windows shown in the Programming Tool PLC828 as follows:

1. Select the window whose display you wish to adapt.
2. Reduce/increase the size and position the window using the mouse or using the appropriate key combinations of your keyboard.

-or-

Use the commands from the menus "View" and "Window" that are available for the window display.

### 14.4.3 Displaying the status in a status chart

#### 14.4.3.1 Properties of a status chart

##### Application

After you have loaded your program into the target system, you can generate one or several status charts to monitor and test program execution.

The program is continuously executed if the target system is in the RUN operating state. You can enable the chart status so that the status values in the chart are continuously updated (not interrupted). As an alternative, using the "Single read" function, you can generate a "Snapshot" of the status values in the table without having to enable the status chart.

While you look at a status chart, you can also switch the target system into the STOP operating state and only execute the first or a certain number of cycles in which you monitor program execution.

---

##### Note

Please note that you cannot change your chart if the chart status is enabled! Disable the chart status if you wish to edit the chart.

---

### Opening / enabling a status chart

Opening a status chart is not the same as enabling a status chart. You can open and evaluate or change a status chart: However, if you do not execute the command "Single read" (in the menu "Test" or in the function bar) or enable the chart status (in the menu "Test" or in the function bar) no status information will be displayed in the "Actual value" column.

|    | Address         | Format | Current Value | New Value |
|----|-----------------|--------|---------------|-----------|
