| 16 | mixing_time     | Bit    | 2#0           |           |
| 17 | cycle_counter   | Signed | +0            |           |
| 18 |                 | Signed |               |           |

Figure 14-6 Example of a status chart

### "Single read" function

If you use the function "Single read" (this is only available when the chart status is disabled) to evaluate a status chart, the actual values of the target system are accepted and displayed in the column "Actual value". However, the values are not updated while the target system executes the program.

### "Chart status" function

If you enable the chart status (in the menu "Test" or in the function bar), the actual values of the target system are regularly updated. If changes are received from the target system, then the column "Actual value" is updated.

### "New value" column

You can assign (write) certain values in the target system using the column (new value).

### 14.4.3.2 Open status chart

Open a status chart to evaluate or change the contents of the chart.

#### Procedure

- Click on the button "Status chart" in the navigation bar.
- or
- Select the menu command "View" > "Status chart".
- or
- Open the directory of the status chart in the operation tree and double click on the symbol of a chart.
- 
- If your project includes more than one status chart, using the tab for the status charts at the lower edge of the window, you can switch over between the individual charts:

---

#### Note

If you open a status chart, then the status is still not displayed. You must enable the status chart so that the status information is updated (see "Enabling the status table (Page 1169)").

---

### 14.4.3.3 Working with several status charts

#### Inserting additional additional status charts

To insert additional status charts:

- In the operation tree, right click on the "Status chart" folder and in the pop-up menu, select the command "Insert status chart".
- or
- Open the window "Status chart" and call the "Edit" menu of right click and select the command "Insert contents" > "Table".

#### Switching between the status charts

After you have inserted a new status chart, a new tab is displayed at the lower edge of the window "Status chart":

If you wish to switch between the status tables:

- Click on the tab of the required status chart.

### Displaying hidden tabs

Sometimes, a tab is hidden by the buttons on the righthand side that are used to scroll. If a tab cannot be seen, proceed as follows:

- Drag the demarcation line between the tab area and the scroll buttons to display additional tabs.

#### 14.4.3.4 Creating a status chart

You can enter addresses in a status chart in order to monitor and control values from your program. Values of timers and counters can be displayed as bits or words. If you wish to display the value of a timer or a counter, then the state of the output is displayed (on or off). If you wish to display the value of a timer or a counter as word, then the actual value used.

### Procedure

To create a status chart, proceed as follows:

1. Enter the addresses of the required value in the "Address" column.

All memory types are valid with the exception of accumulators and data constants.

To edit an address field:

- Select the required field using the cursor keys or the mouse.
- If you enter data, existing data are deleted and the new characters are entered.
- The field is selected if you double click with the mouse or press key <F2>. You can then move the cursor using the cursor keys to the position that you wish to edit.

| Address |      |
|---------|------|
| 1       | 10.0 |

2. If the element involves a bit (e.g. I, Q or M), then the bit format is displayed in the second column. If the element involves a byte, word or double word, select the field in the column "Format" and double click or press the space bar or ENTER in order to scroll through the valid formats until the correct format is displayed.

| Format |
|--------|
| Signed |

---

### Note

You can select addresses in the symbol table and copy these into the status chart in order to more quickly generate your table.

You can display the status a multiple number of times. You can classify the elements in logical groups to display each group in an individual table. In this way, you avoid having to scroll through extremely long lists.

---

### 14.4.3.5 Editing the status chart

#### Displays

To scroll through the possible data formats for a specific address:

- Select the field "Data format" and repeatedly press the enter key.

To display all available data formats:

- Open the drop-down list field.

#### Changing

To set the width of a column:

- Position the mouse pointer at the edge of a column until the appearance of the cursor changes and then drag to increase or decrease the width of the column.

#### Selecting

To select a complete row (to cut or copy):

- Click the number of the row once.

To select the complete status chart:

- Click the upper lefthand corner once above the row numbers.

#### Inserting

To insert a new row:

1. Select a field or a row in the status chart
2. Open the menu "Edit" or click with the right mouse button on the field (in order that the context menu is displayed).
3. Select the command "Insert contents" > "Row".

The new row is inserted in the status chart above the cursor position. The subsequent rows are shifted downwards by one row.

To insert a new row with the following address and the same data format:

- Select an address field and press the enter key.

To insert a row at the lower end of the status chart:

- Locate the cursor in a field in the last row and press the <arrow downwards> key.

### Delete

To delete a field or a row:

1. Select the field or the row and click with the right mouse button.
2. Select the menu command "Delete" > "Selection"

If you delete a row, then the following rows shift upwards by one row.

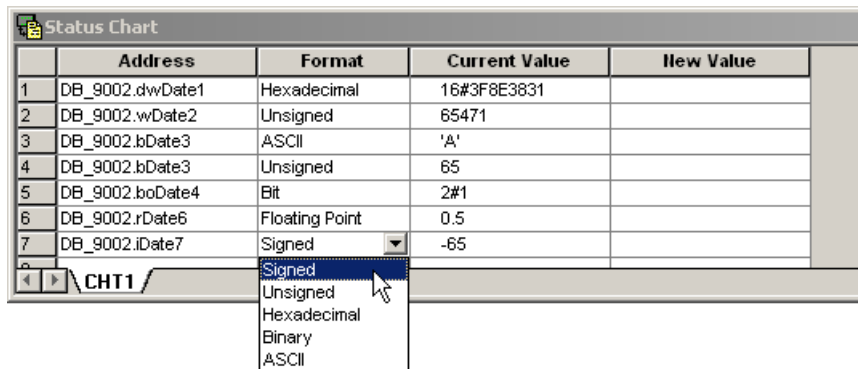

### Navigating

To jump into the next field of the table:

- Press the <TAB> key.

#### 14.4.3.6 Data formats

The data format that you assign to a value defines how the value can be represented in the status chart.

DB9002 is shown symbolically addressed in the diagram. The possible display formats for variables, type INTEGER or WORD are shown using an example of block variable iData7.

#### Note

Bit and binary values are both introduced by the number 2 and the # symbol.

Hexadecimal values are introduced by the number 16 and the # symbol.

Bit values have one digit. Binary values have eight digits.

Signed and unsigned values use the basis 10 (decimal).

### 14.4.3.7 Enabling the status table

Enable the status chart so that the status information can be updated.

#### Procedure

If you wish to continually update the status information in the status chart, enable the chart status:

- To do this, select the menu command "Test" > "Chart status".

or

- Click on the appropriate button in the function bar.

If you only require a "snapshot" of the values, execute the function "Single read":

- Select the menu command "Test" > "Single read".

or

- Click on the appropriate button in the function bar.

---

#### Note

When the chart status is enabled, then the "Single read" function is deactivated.

---

#### Note

If the chart is still empty, then enabling the status chart has not effect: You must first create your status chart by entering program values (addresses) in the "Address" column and you must enter a data type in the "Format" column for each address (see "Creating a status chart (Page 1166)" and "Data formats (Page 1168)").

---

### 14.4.3.8 Working with test functions in the status chart

You access the test functions (Single read, Write all,) using the menu "Test" or using the function bar with the test functions.

#### Single read

Use single read if you require a "snapshot", i.e. a single update of the program status of all values.

As default, the chart status continually interrogates the target system for status updates. If you click on a status chart and the chart status is disabled, then the button for single read is activated.

#### Write all

After you have entered the values in the column "New value" in the status chart, write the required changes to the target system using the command "Write all".

### 14.4.4 Execute cycles

You can specify that the target system should process a certain number of cycles of your program (from 1 cycle up to 65535 cycles). If you specify that the target system should execute a certain number of cycles, then you can monitor the processing of the process variables.

In the first cycle, the value of SM0.1 = 1 (ON).

#### Executing a single cycle

1. The target system must be in STOP operating state. If it is not already in STOP, switch the target system into the STOP operating state.
2. Select the menu command "Test" > "First cycle".

#### Executing several cycles

1. The target system must be in STOP operating state. If it is not already in STOP, switch the target system into the STOP operating state.
2. To execute several cycles, select the menu command "Test" > "Several cycles".

This opens the dialog box "Execute cycles":

3. Specify how many cycles should be executed, and confirm with "OK".

---

#### Note

Ensure that you switch the target system back into the RUN operating state if you wish to return to normal program processing:

- To do this, press the button "RUN" in the function bar.

or

- Select the menu command "Target system" > "RUN" window.
-

## 14.5 Data interface

Data is cyclically exchanged on one hand between the PLC and NC and on the other hand between the PLC and HMI. This especially means that the data received from HMI and destined for the NC must be marshaled by the user program in order that these become effective.

**Data to the PLC** are provided by the firmware at the start of the user program cycle. This ensures, for example, that the signals from the NCK remain constant throughout a cycle.

**Data from the PLC** are transferred by the firmware to the NCK or HMI at the end of the user program cycle.

All data of this interface are listed in the Equipment Manual for SINUMERIK 828D, PPU.

### 14.5.1 PLC-NCK interface

These cyclic data include, e.g. status signals ("Program running", "Program interrupted"), control signals (Start, Stop) and auxiliary and G functions.

Data are structured in signals for:

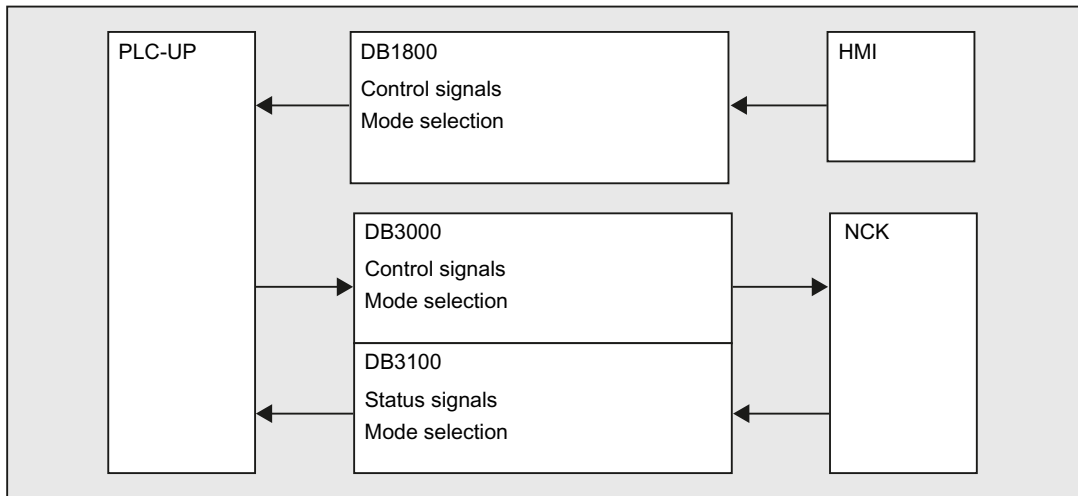

- Mode signals
- NC channel signals
- Axis and spindle signals
- General NCK signals
- Fast data exchange PLC-NCK

#### 14.5.1.1 Mode signals

##### DB3000, 3100

The mode signals specified by the machine control panel or the HMI are transferred to the NCK.

There actual states are signaled to the PLC from the NCK.

### 14.5.1.2 NC channel signals

#### DB2500, 3200, 3300, 3500

The signals are structured as follows:

- Control/status signals with normal cyclic transfer, see "Mode signals (Page 1171)".
- Auxiliary and G functions

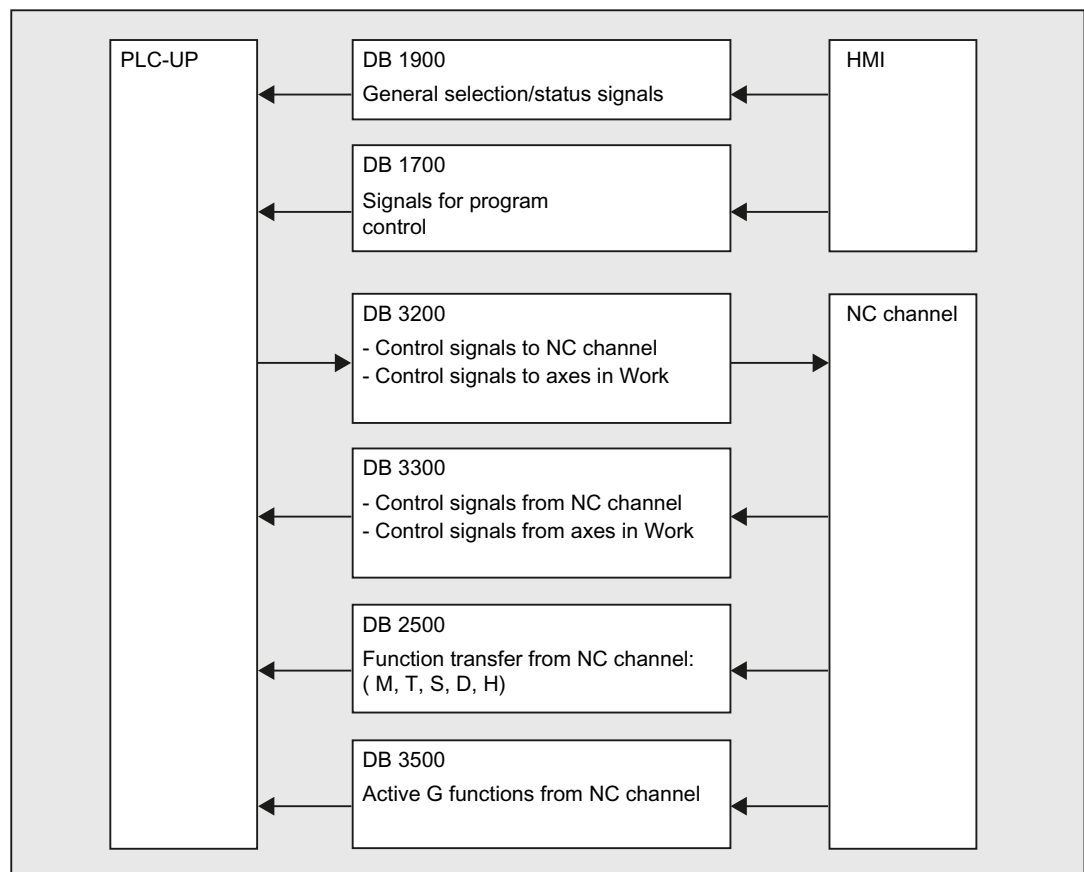

These are entered in the interface DBs in two ways.

First, they are entered with the change signals.

The M signals M0 to M99 are additionally decoded and the associated interface bits are set for one cycle.

For G commands, only the groups selected via machine data are entered in the interface data block.

The S values are also entered together with the related M signals (M03, M04, M05) in the spindle-specific interface. The axis-specific feedrates are also entered in the appropriate axis-specific interface.

### 14.5.1.3 Axis and spindle signals

#### DB3200, 3300, 3700, 3800, 3900

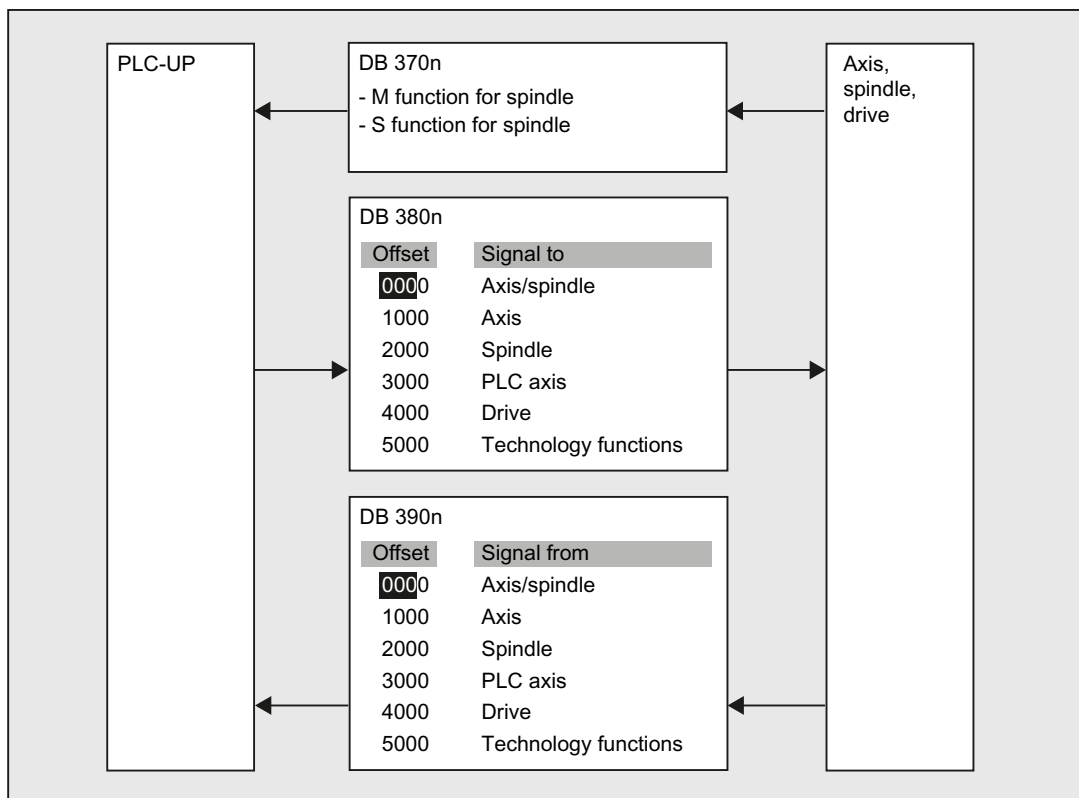

The axis-specific and spindle-specific signals are divided into the following groups:

- Shared axis/spindle signals
- Axis signals
- Spindle signals
- Drive signals

The signals are transferred cyclically with the following exceptions. The exceptions include axial F value, M and S value.

An axial F value is entered via the M, S, F distributor if it is transferred to the PLC during the NC machining process.

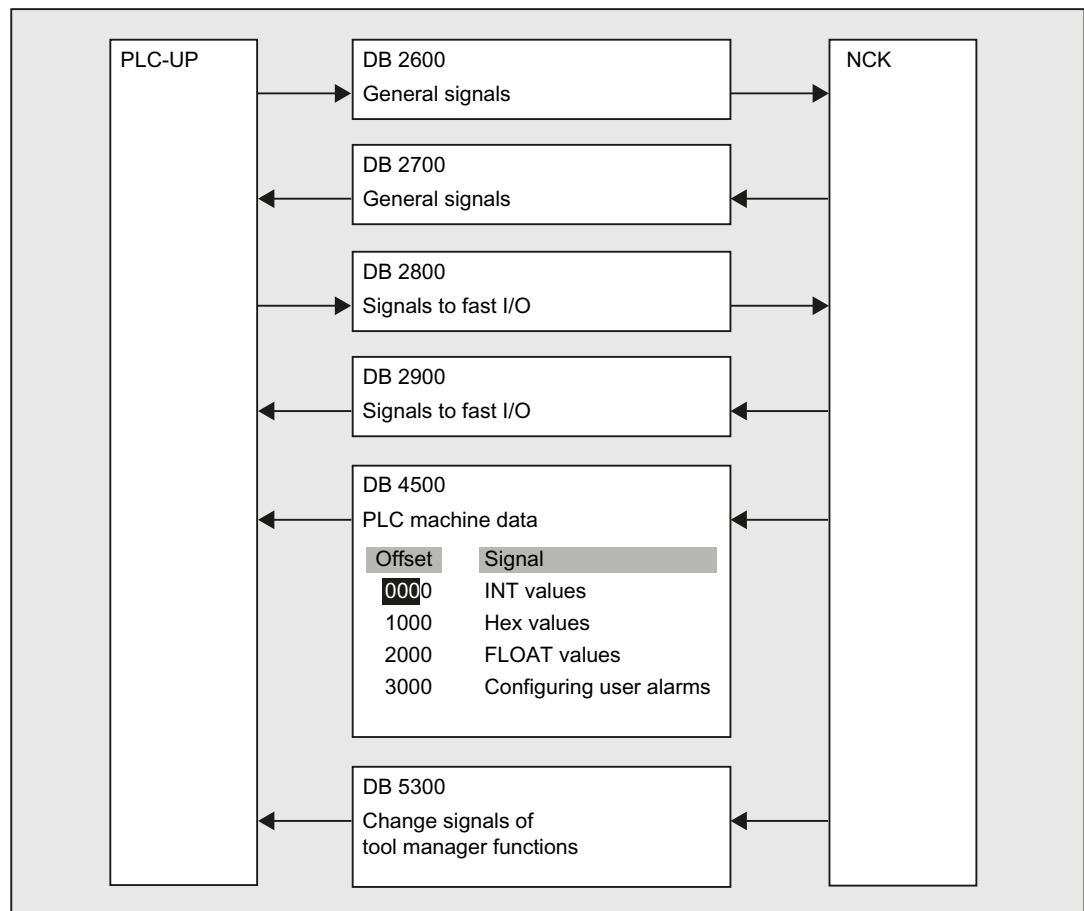

The M and S value are also entered via the M, S, F distributor if one or both values requires processing.

#### 14.5.1.4 General NCK signals

##### DB2600, 2700, 2800, 2900, 4500, 5300

- Setpoints to digital/analog inputs/outputs of the NCK
- Actual values from the digital/analog inputs/outputs of the NCK
- Keyswitch and Emergency Stop signals
- Ready and status signals of the NCK

#### 14.5.1.5 Fast data exchange PLC-NCK

##### DB4900

Data block DB4900 with a size of 1024 bytes is used for fast information exchange between the PLC and NCK.

The assignment of the area (structure) must be identically negotiated in the NC part program and PLC user user program.

This data can be accessed from the NC part program using the commands `$A_DBB[x]`, `$A_DBW[x]`, `$A_DBD[x]` and `$A_DBR[x]`;  $0 \leq x \leq 1023$  (see List Manual, System variables).

In this case, the alignment of the data must be selected corresponding to its format, i.e. a Dword starts at a 4-byte limit and a word at a 2-byte limit. Bytes can be located at any offset within the data field.

Data consistency is guaranteed for byte, word and Dword accesses. When transferring several data, the consistency must be guaranteed on the user-side using semaphores, which can be used to detect the validity or consistency of a block.

## 14.5.2 PLC-HMI interface

### DB1700, 1800, 1900

These signals have already been specified in the diagrams of Chapter PLC-NCK interface (Page 1171).

A reference is again made to what has been stated under Data interface (Page 1171):

Data received from the HMI and destined for the NC are not automatically entered into the NC interface range. In fact, these signals and data must be marshaled by the user program.

It involves the following signals:

- Program selection via lists
- Messenger control command
- General signals from/to HMI
- Signals from/to the maintenance planner
- Signals from operator panel (retentive area)
- General selection/status signals from/to HMI (retentive area)

## 14.6 Function interface

### 14.6.1 Read/write NC variables

#### 14.6.1.1 User interface

The PLC user program can read or write a maximum of eight variables from the NCK area via the PLC/NCK interface "Read/write NC variable".

The user interface should be operated as follows:

|   | Action                                                                                                           | See chapter                                                                                   |
|---|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| 1 | Specify each individual variable to be read or written, for a write job: Writing the variables                   | Job specification (Page 1177)                                                                 |
| 2 | Start job                                                                                                        | Job management: Start job (Page 1178)                                                         |
| 3 | Test and wait until "Job completed" or "Error in job"                                                            | Job management: Waiting for end of job (Page 1179)                                            |
| 4 | Evaluate the result interface of each individual variable for validity or error, for read job: Reading variables | Job evaluation (Page 1180)                                                                    |
| 5 | Reset "start"                                                                                                    | Job management: Waiting for end of job (Page 1179), Job management: Cycle diagram (Page 1180) |

#### Job specification

Each of the 1-8 variables that should be processed in a job, must be specified via their parameters in the **variable-specific job interface** (from offset 1000).

The general identifiers are discussed in more detail later for each variable that can be accessed from the interface.

**Convention:** DB120x: The x should be replaced by 0-7 for 1-8 variables.

| DB1200 ...1207 FB2/3 |                                                                         |       | Reading/writing NC data [r/w] |       |       |       |       |       |
|----------------------|-------------------------------------------------------------------------|-------|-------------------------------|-------|-------|-------|-------|-------|
|                      |                                                                         |       | PLC -> NCK interface          |       |       |       |       |       |
| Byte                 | Bit 7                                                                   | Bit 6 | Bit 5                         | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
| DBB 1000             | Variable index                                                          |       |                               |       |       |       |       |       |
| DBB 1001             | Area number                                                             |       |                               |       |       |       |       |       |
| DBW 1002             | Column index for the NCK variable x (WORD)                              |       |                               |       |       |       |       |       |
| DBW 1004             | Line index for the NCK variable x (WORD)                                |       |                               |       |       |       |       |       |
| DBW 1006             |                                                                         |       |                               |       |       |       |       |       |
| DBD 1008             | Write: Data to NCK variable x (data type of the variables: 1...4 bytes) |       |                               |       |       |       |       |       |

**Example, read variable**

As 4th variable to be read, a location type should be read:

- DB1203.DBB1000: 7
- DB1203.DBB1001: -
- DB1203.DBW1002: Location number
- DB1203.DBW1004: Magazine number
- DB1203.DBW1006: -
- DB1203.DBD1008: -

If data are to be written to the NCK area, then their values must be entered into the double word with the offset 1008.

**Write variables**

Values are specified in the double words with offset 1008:

DB120x.DBD1008: Value

**Job management: Start job**

The user should write the following data into the **global job interface** (from offset 0):

| DB1200 FB2/3 |                     | Reading/writing NC data [r/w] |       |       |       |       |                 |       |
|--------------|---------------------|-------------------------------|-------|-------|-------|-------|-----------------|-------|
|              |                     | PLC -> NCK interface          |       |       |       |       |                 |       |
| Byte         | Bit 7               | Bit 6                         | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1           | Bit 0 |
| DBB 0        |                     |                               |       |       |       |       | Write variables | Start |
| DBB 1        | Number of variables |                               |       |       |       |       |                 |       |

**Number of variables**

DB1200.DBB1 = 1 . . . 8: Number of variables to be processed in the job.

**Write variables**

DB1200.DBX0.1 = 0: Read variables from the NCK area

DB1200.DBX0.1 = 1: Write variables into the NCK area

## Start

DB1200.DBX0.1 = 1: Job is started for the specified number of variables.

A new job can only be started if the previous job was completed, see Chapter Job management: Waiting for end of job (Page 1179).

The execution of a job may take several PLC cycles and vary depending on the utilization; thus, this function cannot be specified from time perspective.

## Job management: Waiting for end of job

The job end is signaled in the **global event interface** (offset 2000) using one of two signals for the complete job:

DB1200.DBX2000.0 == 1 or DB1200.DBX2000.1 == 1

The signals are written by the PLC operating system; therefore, they can only be read by the user. A job has been completed if both acknowledgement signals are zero. They become zero if the user resets the signal "Start" (DB1200.DBX0.1) after the end of the job.

| DB1200 FB2/3 |       | Reading/writing NC data [r] |       |       |       |       |              |               |
|--------------|-------|-----------------------------|-------|-------|-------|-------|--------------|---------------|
|              |       | NCK -> PLC interface        |       |       |       |       |              |               |
| Byte         | Bit 7 | Bit 6                       | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1        | Bit 0         |
| DBB 2000     |       |                             |       |       |       |       | Error in job | Job completed |

## Job completed

DB1200.DBX2000.0 = 1 job processing completed without error.

DB1200.DBX2000.0 = 0 otherwise is zero, if the user resets "Start".

## Error in job

DB1200.DBX2000.1 = 1 order had an error, execution terminated.

DB1200.DBX2000.1 = 0 otherwise is zero, if the user resets "Start".

## Possible error causes

- Number of variables (DB1200.DBB1) out of the valid range
- Variable index (DB1200.DBB1000) out of the valid range

**Job management: Cycle diagram**

- ① User sets the signal "Start", job execution starts.
- ② After the PLC firmware signals "Job completed", the user resets the signal "Start".
- ③ By resetting the signal "Start", the PLC firmware resets the signal "Job completed".
- ④ After the PLC firmware signals "Error in job", the user resets the signal "Start".
- ⑤ By resetting the signal "Start", the PLC firmware resets the signal "Error in job".
- ⑥ If the user accidentally resets the signal "Start" before one of the signals "Job completed" or "Error in job" is received, then the result signals for this job are not updated. However, the job is executed.

**Job evaluation**

Both when reading as well as writing variables, the **variable-specific result interface** (from offset 3000 and higher) must evaluate each of the variables processed in the job.

| DB1200...1203 FB2/3 |                                                                          | NC services [r]      |       |       |       |       |                    |                |

**Variable valid**

DB120x.DBX3000.0 = 1 variable valid

DB120x.DBX3000.0 = 0 otherwise.

**Error has occurred**

DB120x.DBX3000.1 = 1 error occurred, → access result

DB120x.DBX3000.1 = 0 otherwise.

**Access result**

Must be evaluated if an error has occurred

DB120x.DBB3001:

0: No error

3: Object access not permitted

5: Invalid address

10: Object does not exist

**Reading variables**

Values are read from the double words with offset 3004:

DB120x.DBD3004: Value

**14.6.1.2 Operable variables****Variable cuttEdgeParam****Compensation value parameters and cutting edge list with D numbers for a tool**

The meanings of the individual parameters depend on the type of the tool in question. Currently, 25 parameters are reserved for each tool edge (but only a part of them is loaded with values). To be able to remain flexible for future extensions, it is not recommended to use a fixed value of 25 parameters for calculation, but the variable value 'numCuttEdgeParams' (variable index 2).

For a detailed description of tool parameters, refer to Chapter W1: Tool offset (Page 1451).

|                | Variable cuttEdgeParam [r/w]                                    |
|----------------|-----------------------------------------------------------------|
| DB120x.DBB1000 | 1                                                               |
| DB120x.DBB1001 | -                                                               |
| DB120x.DBW1002 | (Cutting edge No. - 1) * numCuttEdgeParams + ParameterNr (WORD) |

### Variable `numCuttEdgeParams`

#### Number of P elements of a cutting edge

|                | Variable <code>numCuttEdgeParams</code> [r]                       |
|----------------|-------------------------------------------------------------------|
| DB120x.DBB1000 | 2                                                                 |
| DB120x.DBB1001 | -                                                                 |
| DB120x.DBW1002 | -                                                                 |
| DB120x.DBW1004 | -                                                                 |
| DB120x.DBD1008 | -                                                                 |
| DB120x.DBW3004 | Read: Data from NCK variable x (data type of the variables: WORD) |

### Variable `linShift`

#### Translation of a settable work offset (channel-specific settable frames)

They only exist if MD18601 MM\_NUM\_GLOBAL\_USER\_FRAMES > 0.

There are the frame indices:

- 0: ACTFRAME = actual resulting work offset
- 1: IFRAME = actual settable work offset
- 2: PFRAME = actual programmable work offset
- 3: EXTFRAME = actual external work offset
- 4: TOTFRAME = actual total work offset = total of ACTFRAME and EXTFRAME
- 5: ACTBFRAME = actual total base frame
- 6: SETFRAME = actual 1st system frame (PRESET, scratching)
- 7: EXTFRAME = actual 2nd system frame (PRESET, scratching)
- 8: PARTFRAME = actual 3rd system frame (TCARR and PAROT with orientable tool carrier)
- 9: TOOLFRAME = actual 4th system frame (TOROT and TOFRAME)
- 10: MEASFRAME = result frame for workpiece and tool gauging
- 11: WPFrames = actual 5th system frame (workpiece reference points)
- 12: CYCFrames = actual 6th system frame (cycles)

The max. frame index is 12.

The value of `numMachAxes` is contained in the variable with variable index 4.

|                | Variable linShift [r]                                             |
|----------------|-------------------------------------------------------------------|

| DB120x.DBW1004 | -                                                                 |
| DB120x.DBD1008 | Write: Data to NCK variable x (data type of the variables: REAL)  |
| DB120x.DBW3004 | Read: Data from NCK variable x (data type of the variables: REAL) |

### Variable TEMP\_COMP\_REF\_POSITION (SD43920)

Reference position for position-dependent temperature compensation

|                | Variable TEMP_COMP_REF_POSITION [r/w]                             |
|----------------|-------------------------------------------------------------------|
| DB120x.DBB1000 | 16                                                                |
| DB120x.DBB1001 | No. of the axis (1, 2, ...)                                       |
| DB120x.DBW1002 | -                                                                 |
| DB120x.DBW1004 | -                                                                 |
| DB120x.DBD1008 | Write: Data to NCK variable x (data type of the variables: REAL)  |
| DB120x.DBW3004 | Read: Data from NCK variable x (data type of the variables: REAL) |

### Variable TOOL\_TEMP\_COMP (SD42960[...])

Temperature compensation referred to the tool

|                | Variable TEMP_COMP_REF_POSITION [r/w]                             |
|----------------|-------------------------------------------------------------------|
| DB120x.DBB1000 | 17                                                                |
| DB120x.DBB1001 | -                                                                 |
| DB120x.DBW1002 | Index + 1 (1, 2, 3)                                               |
| DB120x.DBW1004 | -                                                                 |
| DB120x.DBD1008 | Write: Data to NCK variable x (data type of the variables: REAL)  |
| DB120x.DBW3004 | Read: Data from NCK variable x (data type of the variables: REAL) |

## 14.6.2 Program instance services (PI services)

### 14.6.2.1 User interface

#### Job specification

PI services are specified via their **job interface** (DB1200 from offset 4000) via their parameter.

| DB1200 FB2/3 |                 | PI service [r/w]     |       |       |       |       |       |       |
|--------------|-----------------|----------------------|-------|-------|-------|-------|-------|-------|
|              |                 | PLC -> NCK interface |       |       |       |       |       |       |
| Byte         | Bit 7           | Bit 6                | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
| DBB 4000     |                 |                      |       |       |       |       |       | Start |
| DBB 4001     | PI index        |                      |       |       |       |       |       |       |
| DBB 4002     |                 |                      |       |       |       |       |       |       |
| DBB 4003     |                 |                      |       |       |       |       |       |       |
| DBW 4004     | PI parameter 1  |                      |       |       |       |       |       |       |
| DBW 4006     | PI parameter 2  |                      |       |       |       |       |       |       |
| DBW 4008     | PI parameter 3  |                      |       |       |       |       |       |       |
| DBW 4010     | PI parameter 4  |                      |       |       |       |       |       |       |
| DBW 4012     | PI parameter 5  |                      |       |       |       |       |       |       |
| DBW 4014     | PI parameter 6  |                      |       |       |       |       |       |       |
| DBW 4016     | PI parameter 7  |                      |       |       |       |       |       |       |
| DBW 4018     | PI parameter 8  |                      |       |       |       |       |       |       |
| DBW 4020     | PI parameter 9  |                      |       |       |       |       |       |       |
| DBW 4022     | PI parameter 10 |                      |       |       |       |       |       |       |

#### PI index

DB1200.DBB4001 specifies the specific PI service.

#### PI parameter n

From DB1200.DBW4004, PI parameter n must be specified for the specific service.

#### Start

DB1200.DBX4000.1 = 1: Job is started for the specified number of variables.

## Job feedback

The PLC firmware provides feedback as to whether the started PI service was successful or not successful in the **result interface** (DB1200 from offset 5000).

The job end is signaled using one of two signals:

DB1200.DBX5000.0 == 1 or DB1200.DBX5000.1 == 1

The signals are written by the PLC operating system; therefore, they can only be read by the user. A job has been completed if both acknowledgement signals are zero. They become zero if the user resets the signal "Start" (DB1200.DBX4000.1) after the job end.

| DB1200 FB2/3 |       | PI service [r]       |       |       |       |       |              |               |
|--------------|-------|----------------------|-------|-------|-------|-------|--------------|---------------|
|              |       | NCK -> PLC interface |       |       |       |       |              |               |
| Byte         | Bit 7 | Bit 6                | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1        | Bit 0         |
| DBB 5000     |       |                      |       |       |       |       | Error in job | Job completed |
| DBB 5001     |       |                      |       |       |       |       |              |               |
| DBB 5002     |       |                      |       |       |       |       |              |               |

## Job completed

DB1200.DBX5000.0 = 1 job processing completed without error.

DB1200.DBX5000.0 = 0 otherwise is zero, if the user resets "Start".

## Error in job

DB1200.DBX5000.1 = 1 job had an error, execution terminated.

DB1200.DBX5000.1 = 0 otherwise is zero, if the user resets "Start".

## Possible error causes

- Index of the PI service (DB1200.DBB4001) outside the valid range
- Parameter error

PI services: Cycle diagram

- ① User sets the signal "Start", job execution starts.
- ② After the PLC firmware signals "Job completed", the user resets the signal "Start".
- ③ By resetting the signal "Start", the PLC firmware resets the signal "Job completed".
- ④ After the PLC firmware signals "Error in job", the user resets the signal "Start".
- ⑤ By resetting the signal "Start", the PLC firmware resets the signal "Error in job".
- ⑥ If the user accidentally resets the signal "Start" before one of the signals "Job completed" or "Error in job" is received, then the result signals for this job are not updated. However, the job is executed.

14.6.2.2 PI services

PI service ASUB

Initialization

With the ASUB PI service, it is possible to assign the interrupt numbers 1 and 2 fixed program names from the PLC. Precondition for this is the existence of the programs *PLCASUP1\_SPF* or *PLCASUP2\_SPF* in the CMA directory.

| PI index | Function                                                       | Interrupt priority |
|----------|----------------------------------------------------------------|--------------------|
| 1        | Assignment of Interrupt 1 to the CMA_DIR/PLCASUP1_SPF program. | 1                  |
| 2        | Assignment of Interrupt 2 to the CMA_DIR/PLCASUP2_SPF program. | 2                  |

The following must be taken into account during the initialization:

- The PI service ASUB only has to be executed once after a restart and it is then kept.
- An initialization may only be performed when the channel is inactive.
- If a "power up" is configured as the initiating event for the events-triggered program call, initialization must only be started after the end of the event-triggered program.

**Relevant PI parameters for PI services 1 and 2**

| PI parameter | Address        | Signal   | Valid values |
|--------------|----------------|----------|--------------|
| 1            | DB1200.DBW4004 | LIFTFAST | 0/1          |
| 2            | DB1200.DBW4006 | BLSYNC   | 0/1          |

**PI service LOGOUT****Reset password**

The password last transferred to the NCK is reset.

| PI index | Function       |
|----------|----------------|
| 3        | Reset password |

**Relevant PI parameters for PI service 3**

None

**PI service \_N\_DASAVE****Service to save data from SRAM to FLASH**

| PI index | Function                     |
|----------|------------------------------|
| 4        | Data save from SRAM to FLASH |

**Relevant PI parameters for PI service 4**

None

PI service TMMVTL

Function

Using the PI service TMMVTL, it is possible to initiate a task from the PLC to relocate a tool. After an error-free PI start, the TM executes an empty location search in the target magazine for the tool in the specified source location. Subsequently the PLC receives a job for relocating the tool. (in the user interface range 41xx0000). The target magazine must be:

- a real magazine
- the buffer magazine (9998)
- or the loading magazine (9999).

| PI index | Function                        |
|----------|---------------------------------|
| 5        | Initiate job to relocate a tool |

Relevant PI parameter for PI service 5

| PI parameter | Address        | Signal                 | Valid values |
|--------------|----------------|------------------------|--------------|
| 1            | DB1200.DBW4004 | Tool number            | 1 to 31999   |
| 2            | DB1200.DBW4006 | Source location number | 1 to 31999   |
| 3            | DB1200.DBW4008 | Source magazine number | 1 to 9999    |
| 4            | DB1200.DBW4010 | Target location number | 1 to 31999   |
| 5            | DB1200.DBW4012 | Target magazine number | 1 to 9999    |

14.6.3 PLC user alarms

14.6.3.1 User interface

**Note**

Although the name user "*alarms*" is used in the following, it is only defined as to whether it involves a **message** or an **alarm** when entering the particular **cancel criterion** in bits 6 and 7 of machine data MD14516[x].

The user alarms are created in the HMI and are prepared for automatic processing. The user interface of the DB1600 permits:

- these 248 user alarms of numbers 700000 to 700247 to be activated,
- to be provided with an additional numerical parameter, and
- to be activated and acknowledged as well as
- to evaluate the system reactions initiated by it.

### Activation interface of the user alarms

Each user alarm is activated using its assigned activation bit. These bits are set in the **activation interface** (DB1600 from offset 0):

A new user alarm is activated with a 0/1 edge of the particular bit.

| DB1600     |                         | Activating alarm [r/w] |        |        |        |        |        |        |
|------------|-------------------------|------------------------|--------|--------|--------|--------|--------|--------|
| Data block |                         | PLC -> HMI interface   |        |        |        |        |        |        |
| Byte       | Bit 7                   | Bit 6                  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |
|            | Activation of Alarm No. |                        |        |        |        |        |        |        |
| DBB 0      | 700007                  | 700006                 | 700005 | 700004 | 700003 | 700002 | 700001 | 700000 |
|            | Activation of Alarm No. |                        |        |        |        |        |        |        |
| DBB 1      | 700015                  | 700014                 | 700013 | 700012 | 700011 | 700010 | 700009 | 700008 |
|            | Activation of Alarm No. |                        |        |        |        |        |        |        |

### Variables interface of the user alarms

Each user alarm can be given a variable as parameter. One double word each is reserved for this purpose in the **variable interface** from offset 1000. As a consequence, valid offsets must be divisible by 4.

| DB1600     |                           | Variable for alarm [r32/w32] |  |  |  |  |  |  |
|------------|---------------------------|------------------------------|--|--|--|--|--|--|
| Data block |                           | PLC -> HMI interface         |  |  |  |  |  |  |
| DBD 1000   | Variable for alarm 700000 |                              |  |  |  |  |  |  |
| DBD 1004   | Variable for alarm 700001 |                              |  |  |  |  |  |  |
| DBD 1008   | Variable for alarm 700002 |                              |  |  |  |  |  |  |
|            | ...                       |                              |  |  |  |  |  |  |
| DBD 1980   | Variable for alarm 700245 |                              |  |  |  |  |  |  |
| DBD 1984   | Variable for alarm 700246 |                              |  |  |  |  |  |  |
| DBD 1988   | Variable for alarm 700247 |                              |  |  |  |  |  |  |

### Alarm response and cancel criterion

These two terms involve the conception and configuration of user alarms. For each alarm, it can be defined

- as to how the control should respond when it occurs (alarm response),
- what has to be undertaken in order to clear the alarm again, to acknowledge it (clear criterion). The clear criterion simultaneously defines the alarm priority.

Although two different subjects, their setpoints are configured together in one machine data and their actual values are signaled together in one byte of the user interface. This byte is structured as follows:

| Bit 7              | Bit 6                           | Bit 5          | Bit 4    | Bit 3          | Bit 2                         | Bit 1           | Bit 0            |
|--------------------|---------------------------------|----------------|----------|----------------|-------------------------------|-----------------|------------------|
| POWER ON           | Interrupt with DB1600 DBX3000.0 |                | PLC STOP | EMERGENCY STOP | Feedrate disable for all axes | Read-in disable | NC start disable |
| Clearing criterion |                                 | Alarm response |          |                |                               |                 |                  |

The setpoints are configured bit-coded in machine data MD14516[x],  $0 \leq x \leq 247$ ; whereby  $x = \text{user alarm number} - 700000$

**References:**

List Manual SINUMERIK 828D

The codings of the clear criteria and the corresponding priorities are:

| Bit 7 | Bit 6 | User alarm is acknowledged by                     | Type    | Priority |
|-------|-------|---------------------------------------------------|---------|----------|
| 0     | 0     | Resetting of the activation bit                   | Message | Low      |
| 0     | 1     | Acknowledgement in DB1600.DBX3000.0 (refer below) | Alarm   | Medium   |
| 1     | 0     | Power on                                          | Alarm   | High     |
| 1     | 1     | Reserved (internally evaluated as {1, 0})         |         |          |

**Note**

If none of bits 0 to 4 are set for an alarm/message in the machine data, then this defines that it involves a so-called "display message" that has no effect on the system. This especially indicates that also bits 6 and 7 of the corresponding machine data are evaluated.

### Active alarm responses and clear criteria of the user alarms

The present **active alarm responses** (i.e. the actual responses) and the **active clear criteria** can be globally read-out of the interface.

| DB1600     | Active alarm response [r] |       |       |       |       |       |       |       |
|------------|---------------------------|-------|-------|-------|-------|-------|-------|-------|
| Data block |                           |       |       |       |       |       |       |       |
| Byte       | Bit 7                     | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |

| DB1600   |          | Active alarm response [r]       |  |          |                |                               |                 |                  |
|----------|----------|---------------------------------|--|----------|----------------|-------------------------------|-----------------|------------------|
| DBB 2000 | POWER ON | Interrupt with DB1600 DBX3000.0 |  | PLC STOP | EMERGENCY STOP | Feedrate disable for all axes | Read-in disable | NC start disable |
| DBB 2001 |          |                                 |  |          |                |                               |                 |                  |
| DBB 2002 |          |                                 |  |          |                |                               |                 |                  |
| DBB 2003 |          |                                 |  |          |                |                               |                 |                  |

One bit is set if for at least one active alarm the corresponding response or the corresponding clear criterion is configured. It is cleared, if this response/clear criterion is no longer configured for any of the alarms present.

## Acknowledgement interface of the user alarms

### Precondition

Precondition to acknowledge a user alarm is that the corresponding activation bit is reset.

- Messages with clear criterion {0,0} then disappear automatically from the display.
- Alarms with clear criterion {0,1} are cleared by the acknowledgement bit *Ack*.
- Alarms with clear criterion {1,0} are not influenced when the acknowledgement bit is set and can only be cleared by a power on.

| DB1600     |       | Alarm acknowledgement [r/w] |       |       |       |       |       |       |
|------------|-------|-----------------------------|-------|-------|-------|-------|-------|-------|
| Data block |       |                             |       |       |       |       |       |       |
| Byte       | Bit 7 | Bit 6                       | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
| DBB 3000   |       |                             |       |       |       |       |       | Ack   |
| DBB 3001   |       |                             |       |       |       |       |       |       |
| DBB 3002   |       |                             |       |       |       |       |       |       |
| DBB 3003   |       |                             |       |       |       |       |       |       |

### Interface to HMI.

The PLC can transfer eight messages or alarms for display on the HMI, which are displayed in the sequence that they occur.

When additional messages/alarms occur, the first seven are kept in the HMI, and the latest message or the latest alarm is displaced from one that has just occurred according to the following rules:

- System message/alarm displaces user message/alarm
- Messages/alarms with a higher priority displace those of a lower priority.

The first seven messages/alarms are kept in the display because it is very probable that these define the cause of the problem and the following are just of a secondary nature. However, if one or several messages/alarms are acknowledged and therefore cleared, then a corresponding number of alarms/messages that have been received move up in the HMI.

## 14.6.4 PLC axis control

### 14.6.4.1 Overview

#### Target

The PLC can control eight axes or spindles via data blocks of the user interface; the axis/spindle is specified by its DB number:

- **DB380x** PLC → NCK interface
- **DB390x** NCK → PLC interface
- **DB390x** Axis index:  $0 \leq x \leq 7$ , whereby axis index = axis number-1

The following functions are supported:

- Positioning axes
- Spindle positioning
- Rotate spindle
- Oscillate spindle
- Indexing axes

#### References:

- Function Manual, Extended Functions; Positioning Axes (P2) and Indexing axes (T1)
- Function Manual, Basic Functions; Spindles (S1)

#### Precondition

The axis to be controlled must be assigned to the PLC. An axis can be interchanged between NC and PLC using the user interface "*Axis interchange*" (DB3800.DBB8/DB3900.DBB8).

#### Function start

Each function is activated by the positive edge of the corresponding "Start" signal. This signal must remain a logical "1" until the function has been positively or negatively acknowledged (e.g. using *Position reached* = "1" or *Error* = "1"). The signal "Positioning axis active" = "1" indicates that the function is active and that the output signals are valid.

#### Interrupt

It is **not** possible to **interrupt** the function by resetting the start signal, but only via other interface signals (using the axis-specific signal *Delete distance to go/spindle reset*, DB380x DBX2.2).

The axis interface returns axis status signals that may need to be evaluated (e.g. *exact stop, travel command*, → DB390x).

If the axis/spindle is being traversed via the NC program when the PLC axis control is called (travel command present), then the function is only started after this movement has ended. No error code is output in this situation.

**Axis disable**

With the **axis disable** set, an axis controlled via PLC axis control will not move. Only a simulated actual value is generated. (Behavior as with NC programming).

**14.6.4.2 User interface****Preparing the NC axis as PLC axis (axis interchange)**

Firstly, the axis/spindle must be requested from the PLC. This is realized via the following user interface:

**Common signals to axis/spindle (excerpt)**

Request axis or spindle:

| DB3800...3807 |                          | Signals to axis/spindle [r/w] |       |                                             |       |       |       |                         |
|---------------|--------------------------|-------------------------------|-------|---------------------------------------------|-------|-------|-------|-------------------------|
| Data block    |                          | PLC -> NCK interface          |       |                                             |       |       |       |                         |
| Byte          | Bit 7                    | Bit 6                         | Bit 5 | Bit 4                                       | Bit 3 | Bit 2 | Bit 1 | Bit 0                   |
| DBB 0008      | Request PLC axis/spindle |                               |       | Activation signal when this byte is changed |       |       |       | Request NC axis/spindle |

Every change to a request bit at the interface (DB380x.DBX0008.7 or bit DB380x.DBX0008.0) must be signaled to the NC using a 0→1 edge of the activation signal (bit DB380x.DBX0008.4). This activation signal should be reset again after one cycle.

**General signals from axis/spindle (excerpt)**

State interrogation is possible via the interface DB390x.DBB8. However, for simulation, the axis machine data MD30350 MA\_SIMU\_AX\_VDI\_OUTPUT must be set.

| DB3900...3907 |                  | Signals from axis/spindle [r] |                           |                             |       |       |       |                 |
|---------------|------------------|-------------------------------|---------------------------|-----------------------------|-------|-------|-------|-----------------|

|                                                                                     | 0 0 0 0 0 0 0 1 | 0 0 1 0 0 0 0 1   | PLC resets activation signal; Status "NC axis" and "Axis interchange possible".                         |
| .....  Axis is assigned to the PLC, can be used and is then enabled:                |                 |                   |                                                                                                         |
|                                                                                     | 0 0 0 1 0 0 0 0 | 0 1 0 0 0 0 0 1   | PLC enables axis                                                                                        |
|                                                                                     | 0 0 0 0 0 0 0 0 | 0 1 1 0 0 0 0 1   | PLC resets activation signal; Status "neutral axis/spindle", "NC axis" and "axis interchange possible". |

**Functional interface**

The two tables provide an overview of the available interface signals. The precise description of the signals and the explanation of what signals are relevant for the individual functions are explained in the following.

**Signals to PLC axis**

| DB3800...3807 |                          |                           | Signals to PLC axis [r/w]       |                           |                    |                                           |                                            |                                      |
|---------------|--------------------------|---------------------------|---------------------------------|---------------------------|--------------------|-------------------------------------------|--------------------------------------------|--------------------------------------|
| Data block    |                          |                           | PLC -> NCK interface            |                           |                    |                                           |                                            |                                      |

| DBB 3000      | Start positioning axis   | Start spindle positioning | Start spindle rotation          | Start spindle oscillation |                    |                                           |                                            |                                      |
| DBB 3001      |                          |                           | Stop spindle rotation           | Stop spindle oscillation  |                    |                                           |                                            |                                      |
| DBB 3002      | Automatic gear selection | Constant cutting rate     | Direction of rotation as for M4 |                           | Handwheel override | Traversing dimension, inches (not metric) | Distance condition, shortest distance (DC) | Distance condition, incremental (IC) |

| DB3800...3807 |                                                                                    | Signals to PLC axis [r/w] |  |  |  |  |                                               |                                               |
|---------------|------------------------------------------------------------------------------------|---------------------------|--|--|--|--|-----------------------------------------------|-----------------------------------------------|
| DBB 3003      | Indexing position                                                                  |                           |  |  |  |  | Distance condition, abs. pos. direction (ACP) | Distance condition, abs. neg. direction (ACN) |
| DBD 3004      | Position (REAL, with indexing axis: DINT)                                          |                           |  |  |  |  |                                               |                                               |
| DBD 3008      | Feedrate velocity (REAL), if < 0, the value is taken from machine data POS_AX_VELO |                           |  |  |  |  |                                               |                                               |

The bits of the distance conditions and the direction of rotation definition define the particular positioning or traversing mode, only one of the bits must be set:

| Meaning                                            | Distance condition to be set |
|----------------------------------------------------|------------------------------|
| Positioning absolute                               | No mode bit set              |
| Positioning incremental                            | DBB3002.0 = 1                |
| Positioning, shortest distance                     | DBB3002.1 = 1                |
| Positioning, absolute, positive approach direction | DBB3003.1 = 1                |
| Positioning, absolute, negative approach direction | DBB3003.0 = 1                |
| Direction of rotation as for M4                    | DBB3002.5 = 1                |

The remaining bits are used to specify and start the particular function, these function bits as well as position and velocity are explained in more detail for the individual functions.

### Signals from PLC axis

| 3900...3907 |                         | Signals from PLC axis [r] |       |       |       |       |                        |                        |
|-------------|-------------------------|---------------------------|-------|-------|-------|-------|------------------------|------------------------|
| Data block  |                         | PLC -> NCK interface      |       |       |       |       |                        |                        |
| Byte        | Bit 7                   | Bit 6                     | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1                  | Bit 0                  |
| 3000        | Positioning axes active | Position reached          |       |       |       |       | Error while traversing | Axis cannot be started |
| 3001        |                         |                           |       |       |       |       |                        |                        |
| 3002        |                         |                           |       |       |       |       |                        |                        |
| 3003        | Error number            |                           |       |       |       |       |                        |                        |

#### 14.6.4.3 Functions

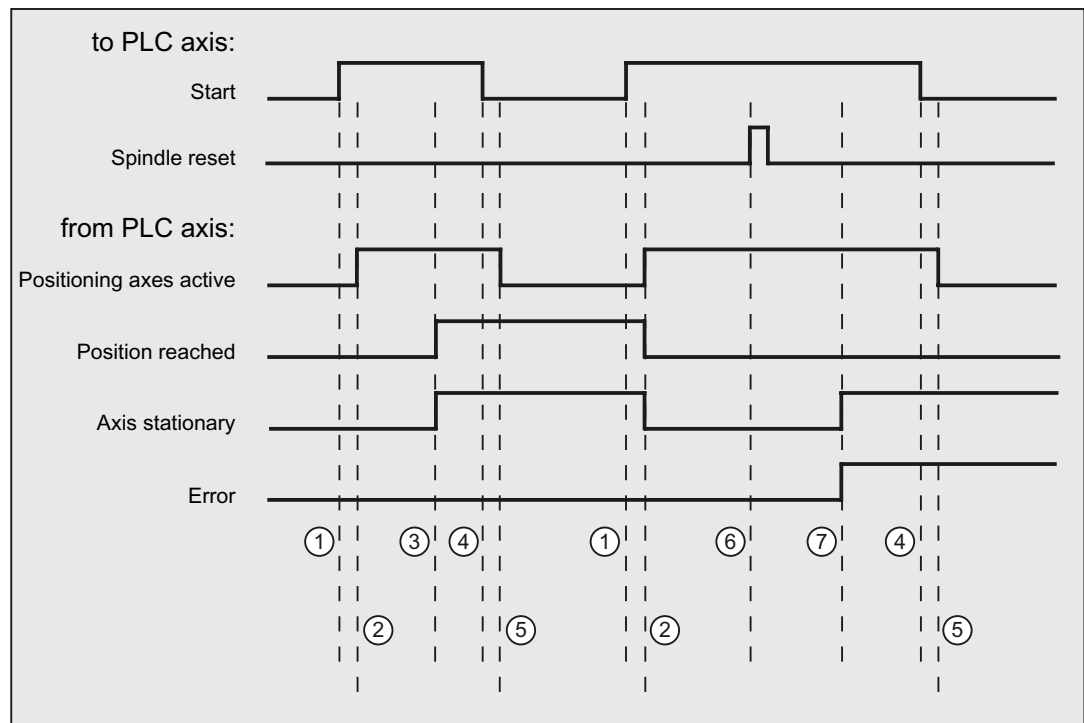

In the following, it is assumed, that

- the axis or spindle was correctly assigned to the PLC,
- controller and pulse enable are set,
- after setting all of the control signals, only one of the start signals is set in DB380x.DBB3000.

**Spindle positioning**

| DB380x    | PLC → NCK control signals            | Valid values | Remark                                                                                              |
|-----------|--------------------------------------|--------------|-----------------------------------------------------------------------------------------------------|
| DBX3002.0 | Incremental                          | 0 1          | Only one of the bits must be set, if all bits are 0, then this means absolute positioning.          |
| DBX3002.1 | Shortest distance                    | 0 1          |                                                                                                     |
| DBX3002.5 | Direction of rotation as for M4      | 0            |                                                                                                     |
| DBX3003.0 | Absolute, negative direction         | 0 1          |                                                                                                     |
| DBX3003.1 | Absolute, positive direction         | 0 1          |                                                                                                     |
| DBD3004   | Setpoint position/setpoint distance  | REAL         | for "incremental": Setpoint distance                                                                |
| DBD3008   | Feedrate velocity                    | REAL         | If = 0, the value from MD35300 \$MA_SPIND_POSCTRL_VELO (position control activation speed) is taken |
| DBX3000.7 | Start                                | 0 1          | Reset does not result in a stop!                                                                    |
| DBX2.2    | Delete distance-to-go, spindle reset | 0 1          | Interrupt signal, exits the function                                                                |

| DB390x    | NCK → PLC status signals | Remark                                                      |
|-----------|--------------------------|-------------------------------------------------------------|
| DBX3000.7 | Positioning axes active  | Also 1, if override = 0 or setpoint position reached.       |
| DBX3000.6 | Position reached         | 1: Setpoint position reached with "Exact stop fine".        |
| DBX3000.1 | Error                    | 1: Error when traversing, evaluate error number in DBB3003! |
| DBB3003   | Error number             |                                                             |
| DBX1.4    | Axis/spindle stationary  | 1: if $n < n_{min}$                                         |

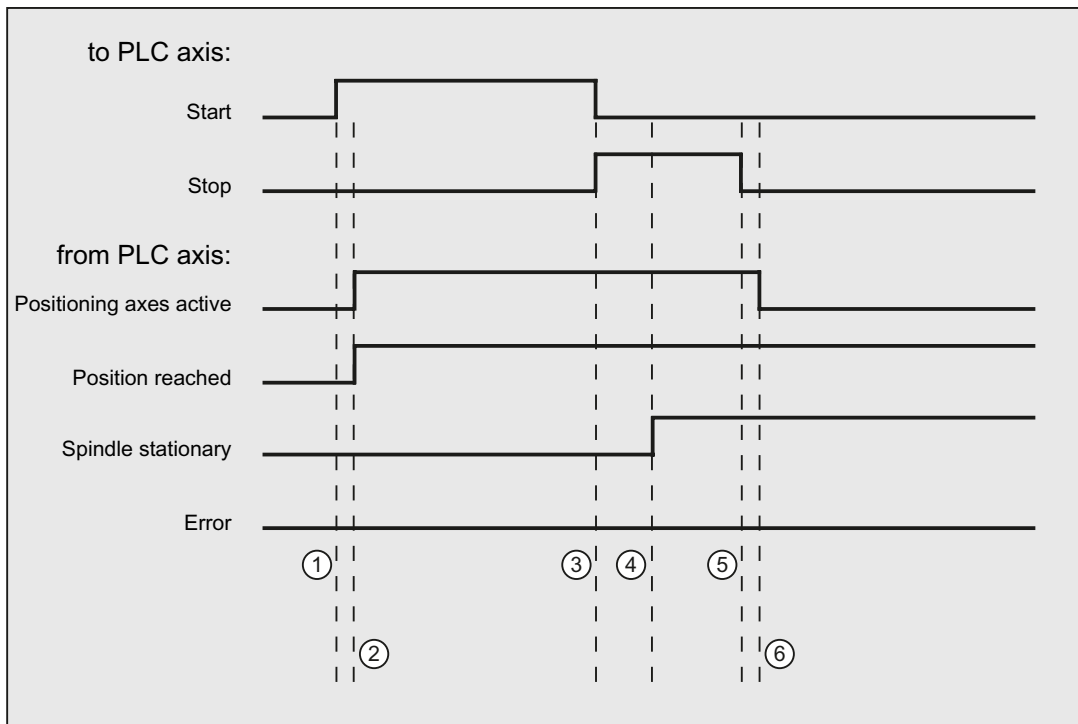

- ① Function activated by user with a positive edge of *Start*.
- ② Signal *Positioning axes active*.
- ③ When the position is reached this is signaled (*Position reached*), *Spindle stationary* is set.
- ④ The user then withdraws *Start*.
- ⑤ The signal *Position reached* is then reset.
- ⑥ Positioning is interrupted by setting *Spindle reset*. This signal must be present for at least 1 PLC cycle.
- ⑦ The spindle comes to a standstill (*Spindle stationary*), the *Fault* signal is set. (In this case, fault number 115 is output.)

### Rotate spindle

| DBX380x   | PLC → NCK control signals       | Valid values | Remark                                                                                                                          |
|-----------|---------------------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------|
| DBX3002.0 | Incremental                     | 0            | <i>Direction of rotation as for M4:</i><br>1: Direction of rotation specified by M4<br>0: Direction of rotation specified by M3 |
| DBX3002.1 | Shortest distance               | 0            |                                                                                                                                 |
| DBX3002.5 | Direction of rotation as for M4 | 0 1          |                                                                                                                                 |
| DBX3003.0 | Absolute, negative direction    | 0            |                                                                                                                                 |
| DBX3003.1 | Absolute, positive direction    | 0            |                                                                                                                                 |
| DBD3008   | Feedrate velocity               | REAL         | Spindle speed                                                                                                                   |
| DBX3000.5 | Start spindle rotation          | 0 1          |                                                                                                                                 |
| DBX3001.5 | Stop spindle rotation           | 0 1          |                                                                                                                                 |

| DB390x    | NCK → PLC status signals | Remark                                                      |
|-----------|--------------------------|-------------------------------------------------------------|
| DBX3000.7 | Positioning axes active  | 1: for start or stop == 1                                   |
| DBX3000.6 | Position reached         | 1: Function was started without an error                    |
| DBX3000.1 | Error                    | 1: Error when traversing, evaluate error number in DBB3003! |
| DBB3003   | Error number             |                                                             |
| DBX1.4    | Axis/spindle stationary  |                                                             |

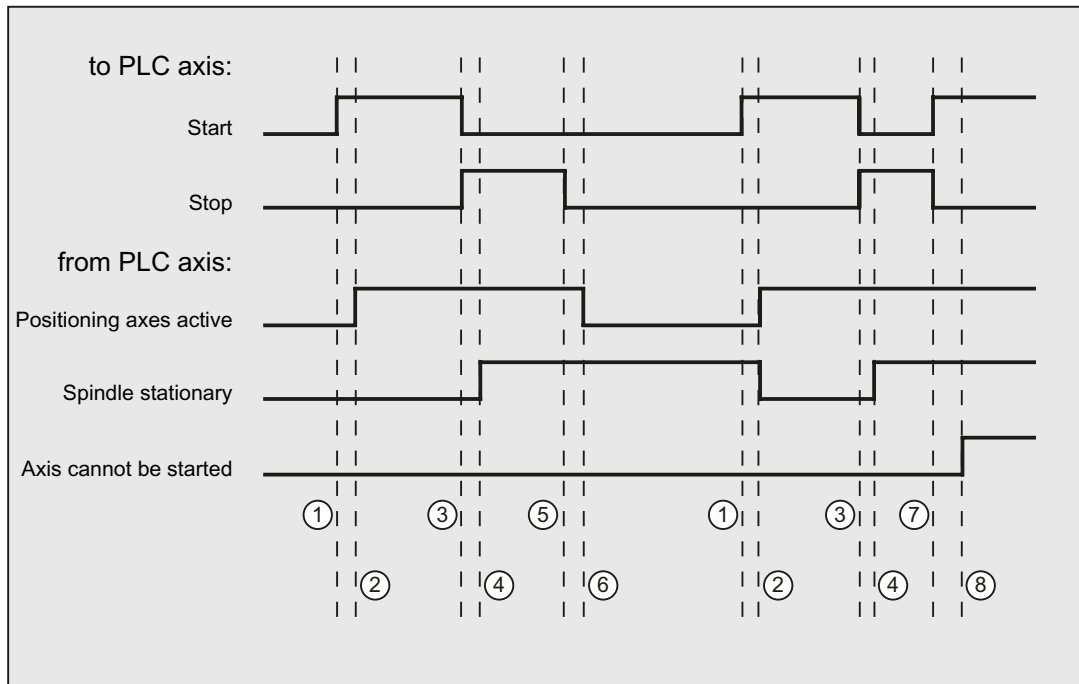

- ① Function activated by user with a positive edge of *Start*.
- ② Signals *Positioning axis active* and *Position reached* are signaled back, *Position reached* is in this case irrelevant.
- ③ The user stops spindle rotation by resetting *Start* and setting *Stop*.
- ④ The spindle stops and the *Spindle stationary* signal is set.
- ⑤ The user then resets *Stop*.
- ⑥ Reset of *Stop* causes *Positioning axis active* to be reset.

## Oscillate spindle

| DB380x    | PLC → NCK control signals                       | Valid values | Remark                                                                                                                                                                                                                                                                                                                                                                    |

| DBX3000.0 | Axis cannot be started   | 1: Error when starting, evaluate error number in DBB3003!   |
| DBB3003   | Error number             |                                                             |
| DBX1.4    | Axis/spindle stationary  |                                                             |

- ① Function activated by user with a positive edge of *Start*.  
**Note:** This is only possible when the *Positioning axis active* signal is reset!
- ② Signals *Positioning axis active* and *Position reached* are signaled back, *Position reached* is in this case irrelevant and is therefore not shown.
- ③ The user stops spindle oscillation by resetting *Start* and setting *Stop*.
- ④ The spindle stops and the *Spindle stationary* signal is set.
- ⑤ The user then resets *Stop*.
- ⑥ Reset of *Stop* causes *Positioning axis active* to be reset.
- ⑦ *Stop* is reset in the user program and *Start* is again set, incorrectly, in the same PLC cycle. This means that *Positioning axis active* is not reset, but...
- ⑧ ...the *Axis cannot be started* signal is set (error number 106).

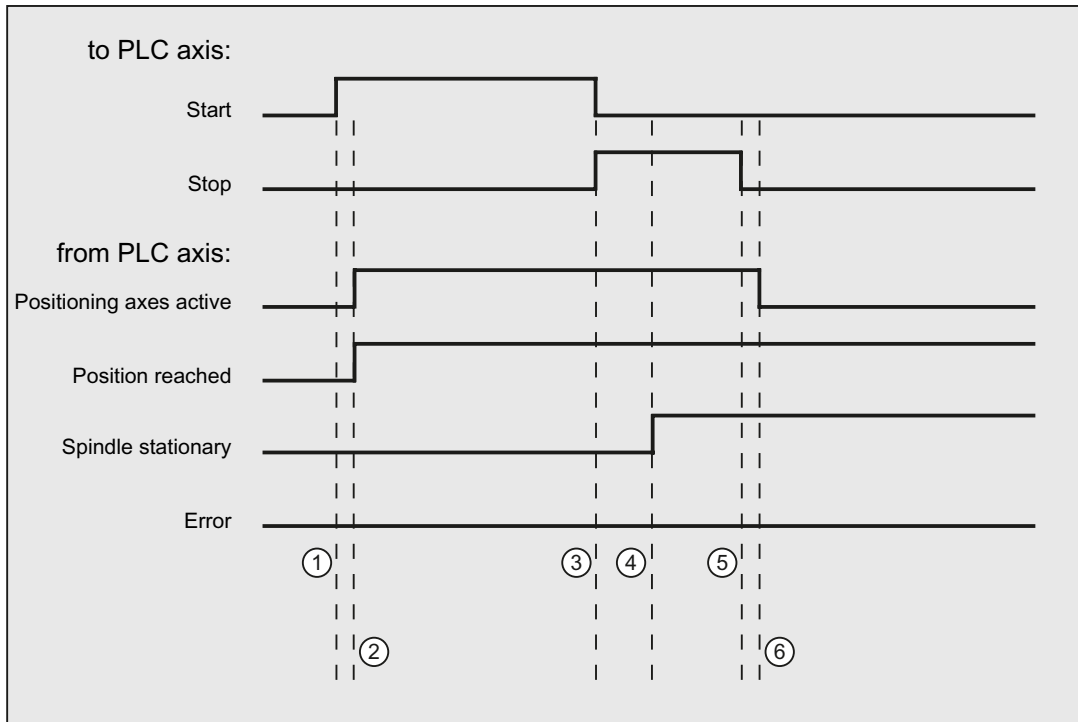

### Indexing axis

| DBX380x   | PLC → NCK control signals           | Valid values | Remark                                                                                     |

- ① Function activated by user with a positive edge of *Start*.
- ② Signals *Positioning axis active* and *Position reached* are signaled back, *Position reached* is in this case irrelevant.
- ③ The user stops spindle rotation by resetting *Start* and setting *Stop*.
- ④ The spindle stops and the *Spindle stationary* signal is set.
- ⑤ The user then resets *Stop*.
- ⑥ Reset of *Stop* causes *Positioning axis active* to be reset.

- ① Function activated by user with a positive edge of *Start*.
- ② Signals *Positioning axis active* and *Position reached* are signaled back, *Position reached* is in this case irrelevant.
- ③ The user stops spindle rotation by resetting *Start* and setting *Stop*.
- ④ The spindle stops and the *Spindle stationary* signal is set.
- ⑤ The user then resets *Stop*.
- ⑥ Reset of *Stop* causes *Positioning axis active* to be reset.

**Rotate spindle with constant cutting rate [feet/min]**

- ① Function activated by user with a positive edge of *Start*.
- ② Signals *Positioning axis active* and *Position reached* are signaled back, *Position reached* is in this case irrelevant.
- ③ The user stops spindle rotation by resetting *Start* and setting *Stop*.
- ④ The spindle stops and the *Spindle stationary* signal is set.
- ⑤ The user then resets *Stop*.
- ⑥ Reset of *Stop* causes *Positioning axis active* to be reset.

#### 14.6.4.4 Error messages

If a function could not be executed, this is indicated by the signal *Error* (DB390x.DBX3000.1 or DB390x.DBX3000.0) with a 'logical 1'. The cause of the error is coded as an error number:

### 14.6.5 Starting ASUBs

ASUBs (asynchronous subprograms) are NC programs that can be started at any time from the PLC. In this sense, regarding the NC, they are interrupt programs, as the NC program being executed is interrupted by the ASUB.

Precondition is that the ASUB is selected and parameterized using an NC program or using the → PI service ASUB. (By executing the PI service ASUB with the appropriate PI index, one of the two interrupts 1 or 2 is assigned the ASUB intended for the purpose.)

Only one ASUB can be started at one time. If, in a PLC cycle, both start signals of the function interface described below are set to a logical 1, then the ASUBs are started in the sequence in which they are called. The user must set the start signal to a logical 0 if an acknowledgement was set in the interface for the job result.

#### Note

It is not permissible that a start signal is set:

- If the PI service ASUB has not been completed.
- if DB2600.DBX0.1 (Emergency Stop) is set.
- During a request for a channel reset by the PLC.

The ASUB can only be restarted if the channel is in the reset state and IS DB3300.DBX3.7 (channel state reset) is set.

#### 14.6.5.1 The ASUB UP interface

##### Job start

| DB3400   |       | ASUB: Job [r/w]      |       |       |       |       |       |            |
|----------|-------|----------------------|-------|-------|-------|-------|-------|------------|
|          |       | PLC -> NCK interface |       |       |       |       |       |            |
| Byte     | Bit 7 | Bit 6                | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0      |
| DBB 0000 |       |                      |       |       |       |       |       | INT1 start |
| DBB 0001 |       |                      |       |       |       |       |       | INT2 start |
| DBB 0002 |       |                      |       |       |       |       |       |            |
| DBB 0003 |       |                      |       |       |       |       |       |            |

##### INT1 start, INT2 start

1: Starts the execution of the ASUB, which is assigned to the INT in question.

0: Reset to 0 for acknowledgement input in the result interface

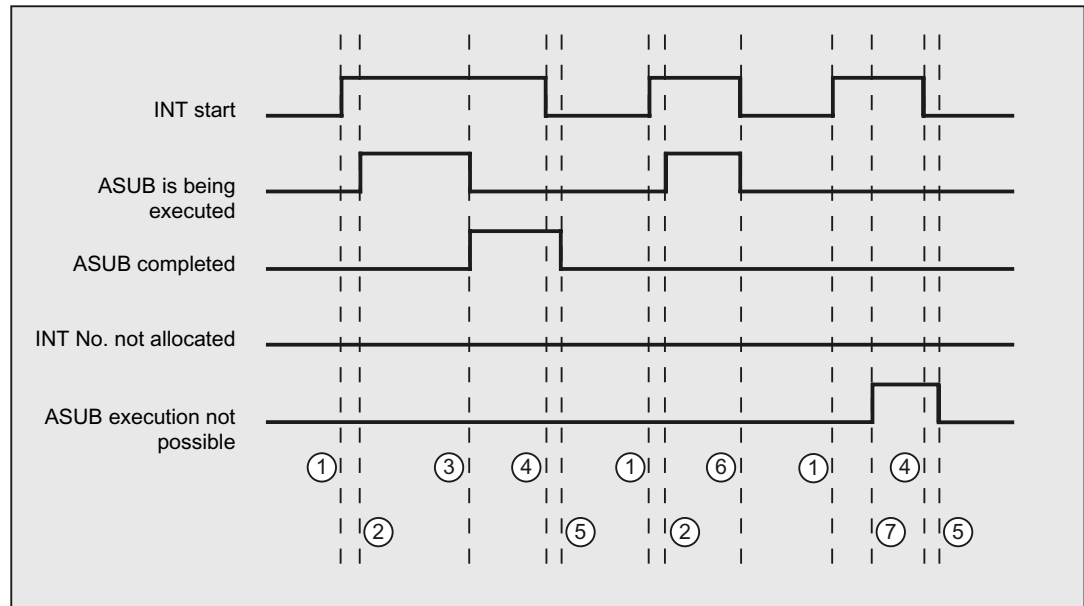

**Job result**

| DB3400   |       | ASUB: Result [r]     |       |       |                         |                             |                        |                |
|----------|-------|----------------------|-------|-------|-------------------------|-----------------------------|------------------------|----------------|
|          |       | PLC -> NCK interface |       |       |                         |                             |                        |                |
| Byte     | Bit 7 | Bit 6                | Bit 5 | Bit 4 | Bit 3                   | Bit 2                       | Bit 1                  | Bit 0          |
| DBB 1000 | INT1  |                      |       |       |                         |                             |                        |                |
|          |       |                      |       |       | ASUB cannot be executed | Interrupt No. not allocated | ASUB is being executed | ASUB completed |
| DBB 1001 | INT2  |                      |       |       |                         |                             |                        |                |
|          |       |                      |       |       | ASUB cannot be executed | Interrupt No. not allocated | ASUB is being executed | ASUB completed |
| DBB 1002 |       |                      |       |       |                         |                             |                        |                |
| DBB 2003 |       |                      |       |       |                         |                             |                        |                |

- **ASUB cannot be executed**  
**Negative acknowledgment:** (e.g. for Emergency Stop or channel reset request).
- **Interrupt No. not allocated**  
**Negative acknowledgment:** Number has still not been allocated. → Execute PI service ASUB?!
- **ASUB is being executed**  
ASUB in progress.
- **ASUB completed**  
**Positive acknowledgment:** ASUB successfully completed. The start signal can not be reset.

## 14.6.5.2 Signal flow

- ① Function activated by user with a positive edge of *Start*.
- ② *ASUB is being executed* is signaled back.
- ③ The acknowledgement *ASUB completed* indicates the successful execution, *ASUB is being executed* is withdrawn.
- ④ The signal to initiate the function is reset after receiving the acknowledgement from the user.
- ⑤ Signal change by the firmware
- ⑥ Not permitted! If function activation is reset prior to receipt of acknowledgment, the output signals are not updated – without the operational sequence of the activated function being affected.
- ⑦ *ASUB cannot be executed*: Negative acknowledgement, error occurred.

## R1: Reference point approach

### 15.1 Brief description

#### Function

The "Reference Point Approach" function is used to synchronize the measuring system of a machine axis with machine zero. The machine axis is traversed to machine zero and the measuring system set to zero.

If it is not possible to approach machine zero directly, a reference point within the traversing range of the machine axis is used whose position with reference to machine zero precisely known.

After the reference point approach, the measuring system of the machine axis is not set to zero but to the corresponding reference point value.

#### Measuring systems and referencing methods

The "Reference point approach" function enables machine axes to be referenced using the following measuring systems and referencing methods:

- Measuring systems
  - Incremental rotary measuring system with at least one zero mark
  - Incremental linear measuring system
  - Rotary measuring system with distance-coded reference marks (supplied by Heidenhain)
  - Linear measuring system with distance-coded reference marks (supplied by Heidenhain)
  - Absolute rotary measuring system
  - Absolute linear measuring system
- Referencing methods
  - Referencing with incremental measuring systems with BERO and one-edge and two-edge detection
  - Referencing with incremental measuring systems with replacement of homing cam with BERO
  - Referencing with incremental measuring systems with BERO with configured approach velocity for spindle applications
  - Referencing with measuring systems with distance-coded reference marks by overtravelling 2 or 4 zero marks
  - Referencing of passive measuring systems using measuring system adjustment
  - Referencing in follow-up mode
  - Referencing with cam switch at the drive

### Start

The reference point approach of a machine axis can be started manually or via the part program:

- Manual: Operation mode JOG and MDA, machine function REF
- Part program: Part program command *G74*

## 15.2 Axis-specific referencing

In axis-specific reference point approach, reference point approach must be initiated individually for each machine axis that is to be referenced.

### Selecting mode and machine function

Before starting reference point approach of the machine axes, you must first place the relevant mode group in JOG or MDA mode:

DB11, ... DBX0.2 (active JOG mode)

DB11, ... DBX0.1 (active JOG mode)

Then machine function REF (reference point approach) must be selected:

DB11, ... DBX1.2 (REF machine function)

### Start of reference point approach

In axis-specific reference point approach, each machine axis must be started individually.

Reference point approach is started with the axis-specific traversing keys:

DB31, ... DBX4.6 (Traversing key minus)

DB31, ... DBX4.7 (Traversing key minus)

### Direction enable

To avoid faulty operation, the direction release must be parameterized:

MD34010 \$MA\_REFP\_CAM\_DIR\_IS\_MINUS (approach reference point in minus direction)

The direction enable specifies which traversing key starts the reference point approach:

| Value | Description                                 |
|-------|---------------------------------------------|
| 0     | Reference point approach in plus direction  |
| 1     | Reference point approach in minus direction |

## Jog mode

The following machine data element can be used to specify whether reference point approach is completed when the direction key is pressed once or whether the operator is required to keep the direction key pressed (jogging) for safety reasons:

MD11300 \$MN\_JOG\_INC\_MODE\_LEVELTRIGGRD (INC and REF in jog mode)

If the machine operator releases the direction key, the machine axis is decelerated to zero speed. Reference point approach is not aborted. Reference point approach is continued the next time the direction key is pressed.

## Referencing status

The referencing status of the machine axis is reset with the start of the reference point approach:

DB31, ... DBX60.4 (referenced / synchronized 1)

DB31, ... DBX60.5 (referenced / synchronized 2)

DB21, ... DBX36.2 (all axes with obligatory reference point are referenced)

## Distance-coded measuring systems

In distance-coded measuring systems, reference point approach can be started with any traversing key.

## Sequence

The machine operator or machine manufacturer (via the PLC user program) is responsible for ensuring that the machine axes are referenced in the proper order.

- Machine operator

The machine axes must be started by the machine operator in the specified order.

- Machine manufacturer

The PLC user program of the machine manufacturer allows machine axes to be started only in the proper order.

## Simultaneous reference point approach of several machine axes

Several machine axes can be referenced simultaneously, depending on the control:

|                 |                     |
|-----------------|---------------------|
| SINUMERIK 840D: | max. 8 machine axes |
|-----------------|---------------------|

## Completion of reference point approach

Acknowledgment that reference point approach of a machine axis has been successfully completed is given by setting the referencing status:

DB31, ... DBX60.4 (referenced / synchronized 1)

DB31, ... DBX60.5 (referenced / synchronized 2)

### Cancellation of reference point approach

In axis-specific reference point approach, the machine axis is traversed in the channel that was assigned as the master channel of the machine axis.

MD30550 \$MA\_AXCONF\_ASSIGN\_MASTER\_CHAN

For aborting the reference point approach, either mode group reset or channel reset for the master channel of the machine axis must be activated:

DB11, ... DBX0.7 (mode group reset)

DB21, ... DBX7.7 (channel reset)

All machine axes that have not yet successfully completed reference point approach when the action is cancelled remain in status "Not referenced":

DB31, ... DBX60.4 (referenced / synchronized 1)

DB31, ... DBX60.5 (referenced / synchronized 2)

## 15.3 Channel-specific referencing

In channel-specific reference point approach, all machine axes of the channel are referenced in the parameterized sequence when reference point approach is initiated.

### Selecting mode and machine function

Before starting reference point approach of the machine axes, you must first set the mode group to JOG or MDA mode:

DB11, ... DBX0.2 (active JOG mode)

DB11, ... DBX0.1 (active MDA mode)

Then machine function REF (reference point approach) must be selected:

DB11, ... DBX1.2 (REF machine function)

### Parameterizing the axis sequence

The following machine data element is used to specify the sequence in which the machine axes of the channel are referenced:

MD34110 \$MA\_REFP\_CYCLE\_NR = *Number*

| Number | Description                                                                         |
|--------|-------------------------------------------------------------------------------------|
| -1     | The machine axis does not have to be referenced for NC START in the channel.        |
| 0      | The machine axis does not participate in channel-specific reference point approach. |
| 1 - 15 | Sequence number in channel-specific reference point approach.                       |

The machine axes are referenced in ascending order of numbers.

Machine axes with the same number will be referenced simultaneously.

### Simultaneous reference point approach of several machine axes

Several machine axes can be referenced simultaneously, depending on the control:

|                 |                     |
|-----------------|---------------------|
| SINUMERIK 840D: | Max. 8 machine axes |
| SINUMERIK 810D: | Max. 5 machine axes |

### Start of reference point approach

Channel-specific reference point approach is started with:

DB21, ... DBX1.0 (activate referencing)

The status of channel-specific reference point approach is indicated by the channel with:

DB21, ... DBX33.0 (activate referencing)

### Referencing status

The referencing status of the machine axis is reset with the start of the reference point approach:

DB31, ... DBX60.4 (referenced / synchronized 1)

DB31, ... DBX60.5 (referenced / synchronized 2)

### Completion of reference point approach

As soon as channel-specific reference approach has been successfully completed for all machine axes involved, this is acknowledged with:

DB21, ... DBX36.2 (all axes with obligatory reference point are referenced)

### Cancellation of reference point approach

In channel-specific reference point approach the machine axis is traversed in the channel to which that axis is currently assigned as channel axis.

For aborting the reference point approach either mode group reset or channel reset for the corresponding channel must be activated:

DB11, ... DBX0.7 (mode group reset)

DB21, ... DBX7.7 (channel reset)

All machine axes for which the reference point approach is not yet successfully completed when the action is cancelled remain in status "Not referenced":

DB31, ... DBX60.4 (referenced / synchronized 1)

DB31, ... DBX60.5 (referenced / synchronized 2)

## 15.4 Reference point approach from part program (G74)

Referencing of machine axes can be activated for the first time or repeated from the part program

Referencing must be repeated, for example, after:

- Converting the actual value of the machine axis: `PRESETON` function
- Machine axis is parked:  
DB31, ... DBX1.5 (position measuring system 1) = 0  
DB31, ... DBX1.6 (position measuring system 2) = 0
- DB31, ... DBX2.1 (servo enable) = 0
- Exceeding the encoder limit frequency of the position measuring system

### Programming

#### Syntax

`G74 Machine axis { Machine axis }`

#### Function

Machine axes can be referenced from a part program with part program instruction `G74`

Parameter: *Machine axes*

The name of the machine axis must be specified. The machine axis must be a channel axis of the channel in which the part program is processed.

Effective:

`G74` is non-modal.

#### Special features

`G74` must be programmed in a separate part program block.

### Reset response

Mode group reset or channel reset aborts the reference point approach for all programmed machine axes:

DB11, ... DBX0.7 (mode group reset)

DB21, ... DBX7.7 (channel reset)

All machine axes for which the reference point approach is not yet successfully completed when the action is cancelled remain in status "Not referenced":

DB31, ... DBX60.4 (referenced / synchronized 1)

DB31, ... DBX60.5 (referenced / synchronized 2)

## 15.5 Referencing with incremental measurement systems

### 15.5.1 Zero mark selection with BERO

#### Function

Referencing of incremental measuring systems is based on the unique position of the encoder zero mark relative to the overall traversing range of the machine axis. If several encoder zero marks are detected in the traversing range of the machine axis due to machine-specific factors, e.g., reduction gear between encoder and load, a BERO must be mounted on the machine and connected to the relevant drive module (SIMODRIVE 611D) via a BERO input in order to uniquely specify the reference point. The position of the reference point is then derived from the combination of BERO signal and encoder zero mark.

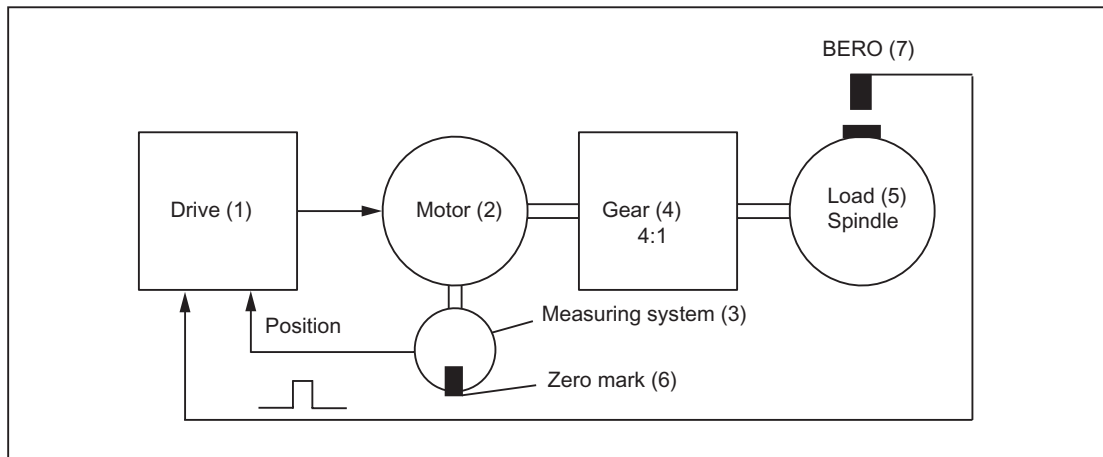

Figure 15-1 Zero mark selection with BERO

Zero mark evaluation with BERO must be parameterized as the referencing mode:

MD34200 \$MA\_ENC\_REFP\_MODE = 5

#### Negative edge evaluation

In the case of a referencing operation with a negative edge evaluation of the BERO signal:

MD34120 \$MA\_REFP\_BERO\_LOW\_ACTIVE = FALSE

synchronization is with the next encoder zero mark encountered after the BERO is exited.

#### Positive edge evaluation

In the case of a referencing operation with a positive edge evaluation of the BERO signal:

MD34120 \$MA\_REFP\_BERO\_LOW\_ACTIVE = TRUE

synchronization is with the next encoder zero mark encountered after the BERO is approached.

If, mechanically, the BERO is sized in such a way that the positive BERO signal covers the entire width of the encoder zero mark, the encoder zero mark will be reliably detected in both traversing directions.

## 15.5.2 Chronological sequence

Reference point approach with incremental measuring systems can be divided into three phases:

- Phase 1: Traversing to the reference cam
- Phase 2: Synchronization with the zero mark of the position measuring system (encoder zero mark)
- Phase 3: Traversing to the reference point

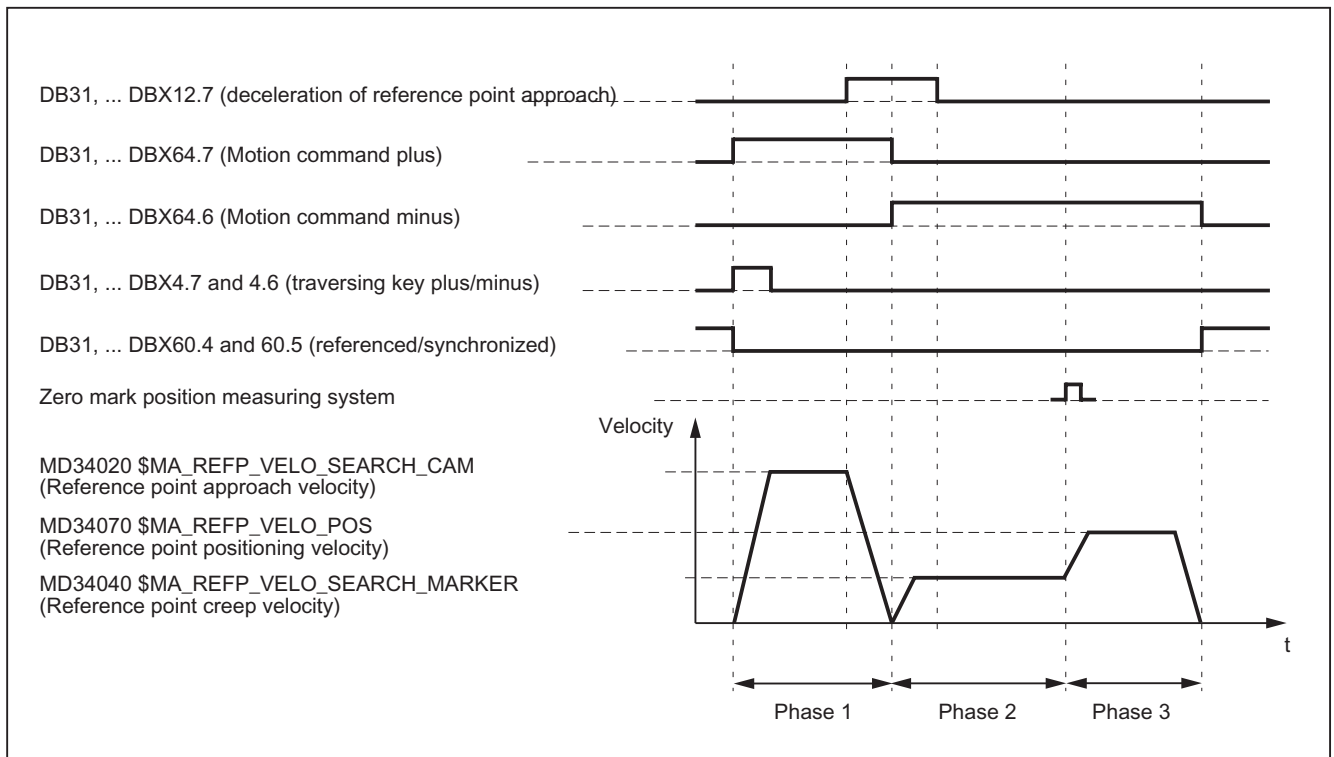

Figure 15-2 Time sequence when referencing with incremental measuring systems (example)

### 15.5.3 Phase 1: Traversing to the reference cam

#### Phase 1: Graphic representation

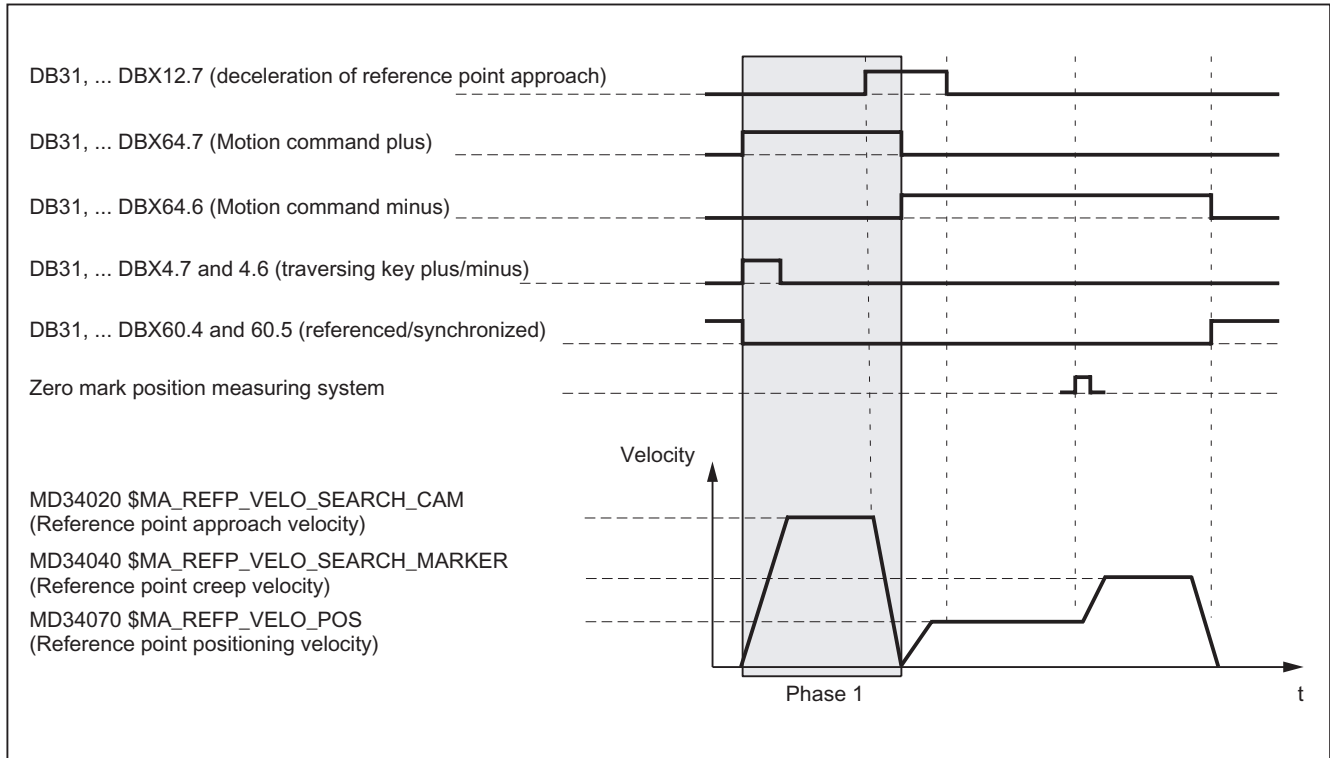

Figure 15-3 Phase 1: Traversing to the reference cam

#### Phase 1: Start

For information on starting reference point approach, refer to "Axis-specific referencing" and "Channel-specific referencing."

#### Phase 1: Sequence

In phase 1, depending on the position of the machine axis with reference to the homing cam, we distinguish between three cases:

1. The machine axis is positioned before the reference cam
2. The machine axis is positioned on the reference cam
3. The machine axis has no reference cam

#### Case 1: The machine axis is positioned before the reference cam

After the start of reference point approach, the machine axis is accelerated in the parameterized direction and to the parameterized reference point approach velocity:

MD34010 \$MA\_REFP\_CAM\_DIR\_IS\_MINUS (Reference point approach in minus direction)

MD34020 \$MA\_REFP\_VELO\_SEARCH\_CAM (Reference point approach velocity)

The PLC user program communicates to the NC that the reference cam has been reached via the following interface signal:

DB31, ... DBX12.7 (reference point approach deceleration)

As a result the NC decelerates to zero speed. The following distance  $s_{min}$  is still minimally back tracked:

$$S_{MIN} = \frac{(MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER)^2}{2 * MD32300 \$MA\_MAX\_AX\_ACCEL}$$

This minimum distance is required to ensure that the machine axis exits the reference cam in Phase 2 at the parameterized reference point creep velocity.

Phase 1 is now complete. Reference point approach is continued with Phase 2.

Figure 15-4 Minimum distance for deceleration

### Case 2: The machine axis is positioned on the reference cam

The machine axis remains at its starting position.

Phase 1 is now complete. Reference point approach is continued with Phase 2.

### Case 3: The machine axis has no reference cam

Machine axes without reference point cams remain at their starting position.

These include, for example:

- Machine axes that only have one zero mark along their entire traversing range
- Rotary axes that only have one zero mark per revolution

Zero must be entered in the following machine data for machine axes without a reference point cam:

MD34000 \$MA\_REFP\_CAM\_IS\_ACTIVE (Axis with reference cam) = 0

Phase 1 is now complete. Reference point approach is continued with Phase 2.

**Phase 1: Features**

- Feed override active.
- Feed stop (channel-specific and axis-specific) is active.
- NC-STOP and NC-START are active.
- The machine axis is stopped if the reference cam does not arrive within the parameterized distance:

MD34030 \$MA\_REFP\_MAX\_CAM\_DIST (max. distance to reference cam)

DB31, ... DBX12.7 (reference point approach delay) = 1

**15.5.4 Phase 2: Synchronization with the zero mark**

**Phase 2: Graphic representation**

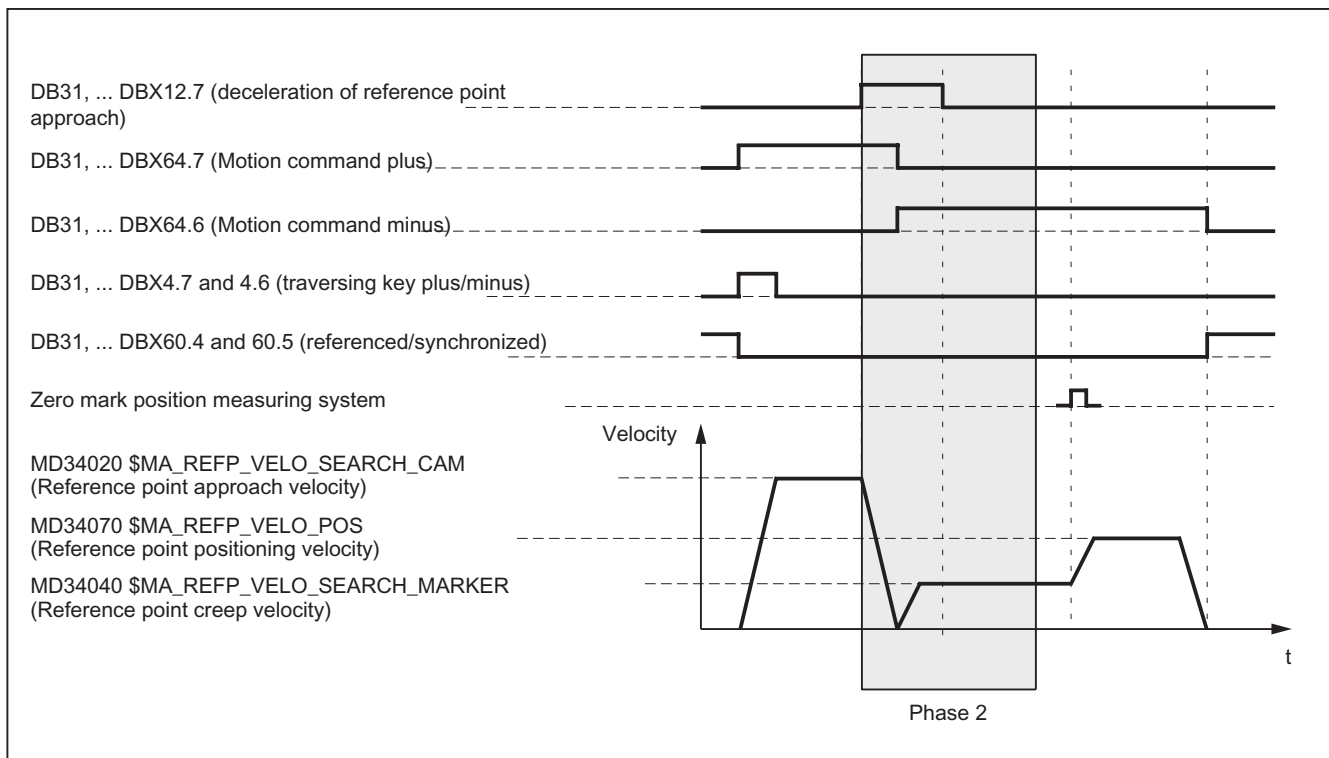

Figure 15-5 Phase 2: Synchronization with the zero mark

**Phase 2: Start**

Phase 2 is automatically started when phase 1 has been completed without an alarm.

**Initial situation:**

The machine axis is positioned on the reference cam.

**Zero mark search direction:**

The zero mark is searched for in the parameterized direction and approached:

MD34050 \$MA\_REFP\_SEARCH\_MARKER\_REVERSE (direction reversal on reference cam)

**Phase 2: Sequence**

Synchronization in Phase 2 can occur in two ways:

- Synchronization with falling reference cam signal edge
- Synchronization with rising reference cam signal edge

The type of synchronization is determined with the machine data:

MD34050 \$MA\_REFP\_SEARCH\_MARKER\_REVERSE (direction reversal on reference cam)

| Value | Meaning                                                |
|-------|--------------------------------------------------------|
| 0     | Synchronization with falling reference cam signal edge |
| 1     | Synchronization with rising reference cam signal edge  |

**Note**

If the actual velocity of the machine axis at approach of the reference cam has not yet reached the target velocity of Phase 2 within the parameterized tolerance limits, Phase 1 will be re-started:

MD35150 \$MA\_SPIND\_DES\_VELO\_TOL (spindle speed tolerance)

This will be the case, for example, if the machine axes are positioned at the reference cam when reference point approach starts.

**Case 1: Synchronization with falling reference cam signal edge**

During synchronization with falling reference cam signal edge, the machine axis accelerates to the parameterized reference point creep velocity against the parameterized reference point approach direction (traversing direction of Phase 1):

MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER (reference point creep velocity)

MD34010 \$MA\_REFP\_CAM\_DIR\_IS\_MINUS (Reference point approach in minus direction)

After the reference cam is exited (DB31, ... DBX12.7 = 0), the next encoder zero mark is awaited.

As soon as the encoder zero mark is detected, Phase 2 comes to an end. The machine axis continues at constant velocity and reference point approach is continued with phase 3.

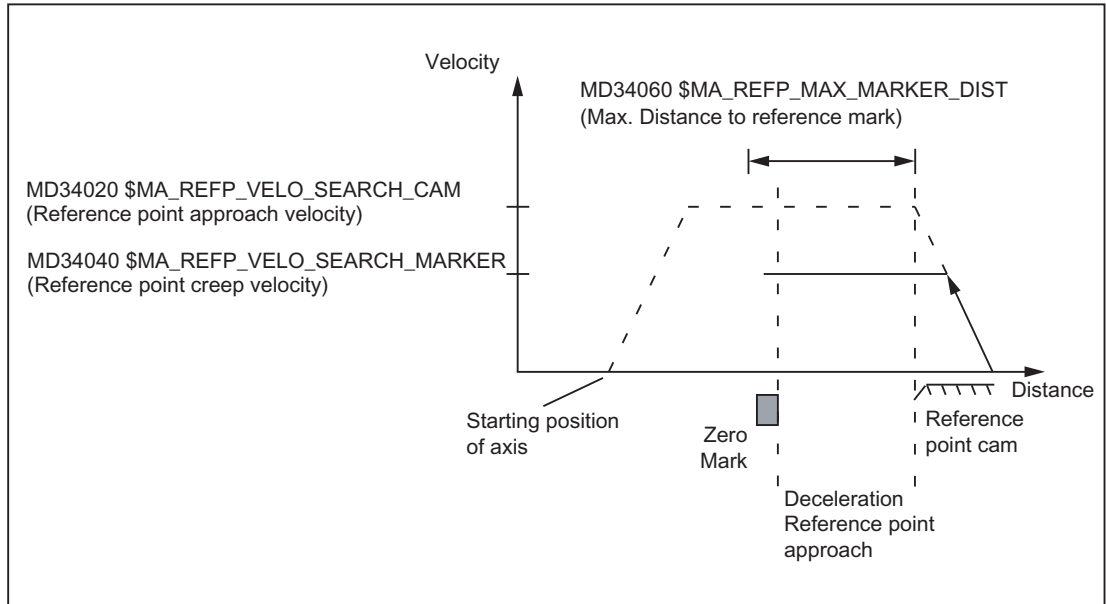

Figure 15-6 Synchronization with falling reference cam signal edge

### Case 2: Synchronization with rising reference cam edge

During synchronization with rising reference cam signal edge, the machine axis accelerates to the parameterized reference point approach velocity against the parameterized reference point approach direction (traversing direction of the phase 1):

MD34020 \$MA\_REFP\_VELO\_SEARCH\_CAM (Reference point approach velocity)

MD34010 \$MA\_REFP\_CAM\_DIR\_IS\_MINUS (Reference point approach in minus direction)

After the reference cam is exited (DB31, ... DBX12.7 = 0), the machine axis is decelerated to stillstand.

The machine axis then travels back to the reference cam at the parameterized reference point creep velocity:

MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER (reference point creep velocity)

After the reference cam is reached (DB31, ... DBX12.7 = 1), the next encoder zero mark is awaited.

As soon as the encoder zero mark is detected, Phase 2 comes to an end. The machine axis continues at constant velocity and reference point approach is continued with phase 3.

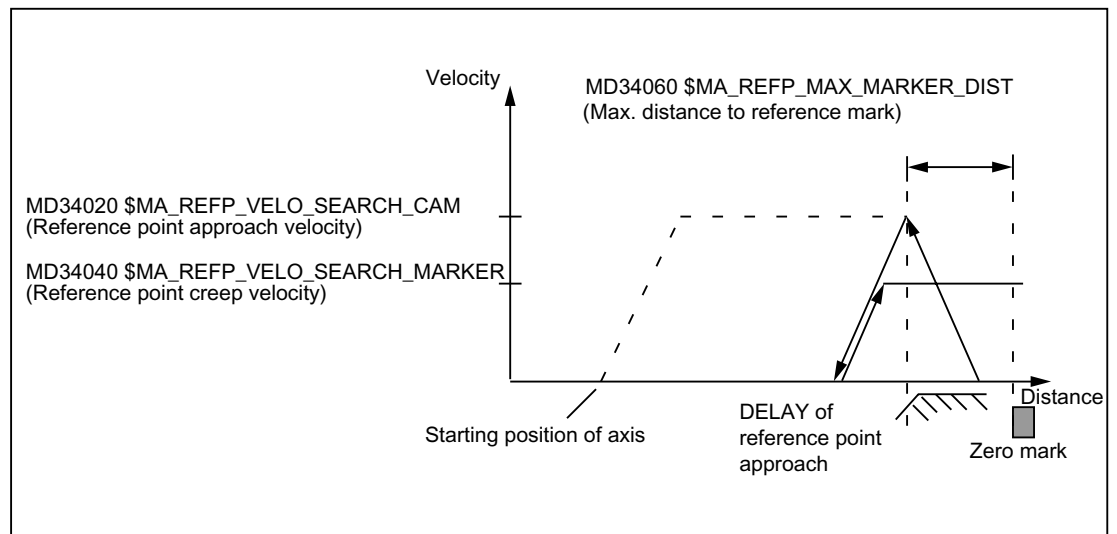

Figure 15-7 Synchronization with rising reference cam signal edge

### Electronic reference cam offset

Electronic reference cam offset is used for compensating reference cam length increases caused by temperature:

MD34092 \$MA\_REFP\_CAM\_SHIFT (electronic reference cam offset for incremental measuring systems with equidistant zero marks)

After a rising or falling reference cam edge is detected the axis is synchronized for the next encoder zero mark only after the cyclically calculated offset path has been covered.

Because the offset path  $s_{\text{shift}}$  is calculated by the NC in IPO cycles, the following minimum and maximum offset paths  $s_{\text{shift\_min}}$  and  $s_{\text{shift\_max}}$  will result:

$$s_{\text{shift\_min}} = \text{MD34092 } \$\text{MA\_REFP\_CAM\_SHIFT}$$

$$s_{\text{shift\_max}} = \text{MD34092 } \$\text{MA\_REFP\_CAM\_SHIFT} + \text{MD34040 } \$\text{MA\_REFP\_VELO\_SEARCH\_MARKER} * \text{interpolation cycle}$$

The reference cam offset acts in the direction of zero mark search.

#### Prerequisite

The reference cam offset is only active for machine axes for which a reference cam has been parameterized:

$$\text{MD34000 } \$\text{MA\_REFP\_CAM\_IS\_ACTIVE} = 1$$

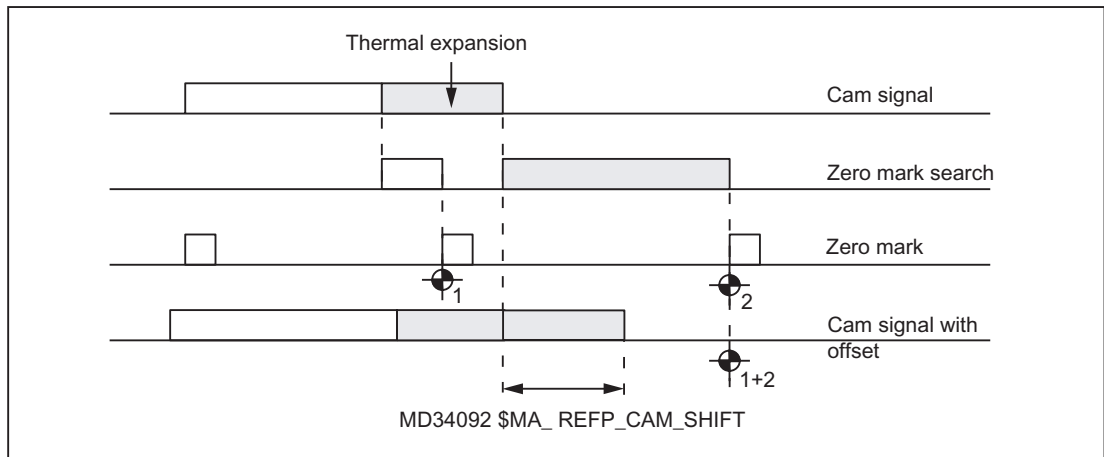

Figure 15-8 Electronic reference cam offset

## Reference cam adjustment

### Encoder with equidistant zero marks

Always ensure that the reference cam of encoders that supply zero marks at equidistances is accurately adjusted so that the correct zero mark is always detected during reference point approach.

### Dynamic response

The following factors influence the dynamic response from the arrival of the reference cam to the machine up to the detection of reference cam signals transferred from the PLC user program to the NC:

- Switching accuracy of the reference cam switch
- Delay of the reference cam switch (NC contact)
- Delay at the PLC input
- PLC cycle time
- Cycle time for updating the VDI interface
- Interpolation cycle
- Position control cycle

**Setting notes**

- Reference cam

Aligning the signal edge of the reference cam directly between two zero marks has proven to be the most practical method.

- Electronic reference cam offset

Information needed for parameterizing the electronic reference cam offset is to be found in the read-only machine data:

MD34093 \$MA\_REFP\_CAM\_MARKER\_DIST (distance between reference cam/reference mark)

The indicated value is equivalent to the distance between departure from the reference cam and detection of the reference mark. If the values are too small, there is a risk that the determination of the reference point will be non-deterministic, due to temperature effects or fluctuations in the operating time of the cam signal.

**WARNING**

If the reference cam adjustment is faulty or inaccurate, an incorrect zero mark can be evaluated. The control then calculates an incorrect machine zero. As a result, the machine axis will approach the wrong positions. Software limit switches, protected areas and working area limitations act on incorrect positions and are therefore incapable of protecting the machine. The path difference is +/- of the path covered by the machine axis between 2 zero marks.

**Phase 2: Features**

- Feedrate override is **not** active.

Internal motion with feedrate override = 100%.

If a feedrate override of 0% is specified, motion is aborted.

- Feed stop (channel-specific and axis-specific) is active.
- NC-STOP and NC-START are **not** active.
- If the machine axis does not arrive at Phase 2 within the parameterized distance of the reference mark (encoder zero mark), the machine axis will be stopped:

MD34060 \$MA\_REFP\_MAX\_MARKER\_DIST (max. distance to the reference mark)

### 15.5.5 Phase 3: Traversing to the reference point

#### Phase 3: Graphic representation

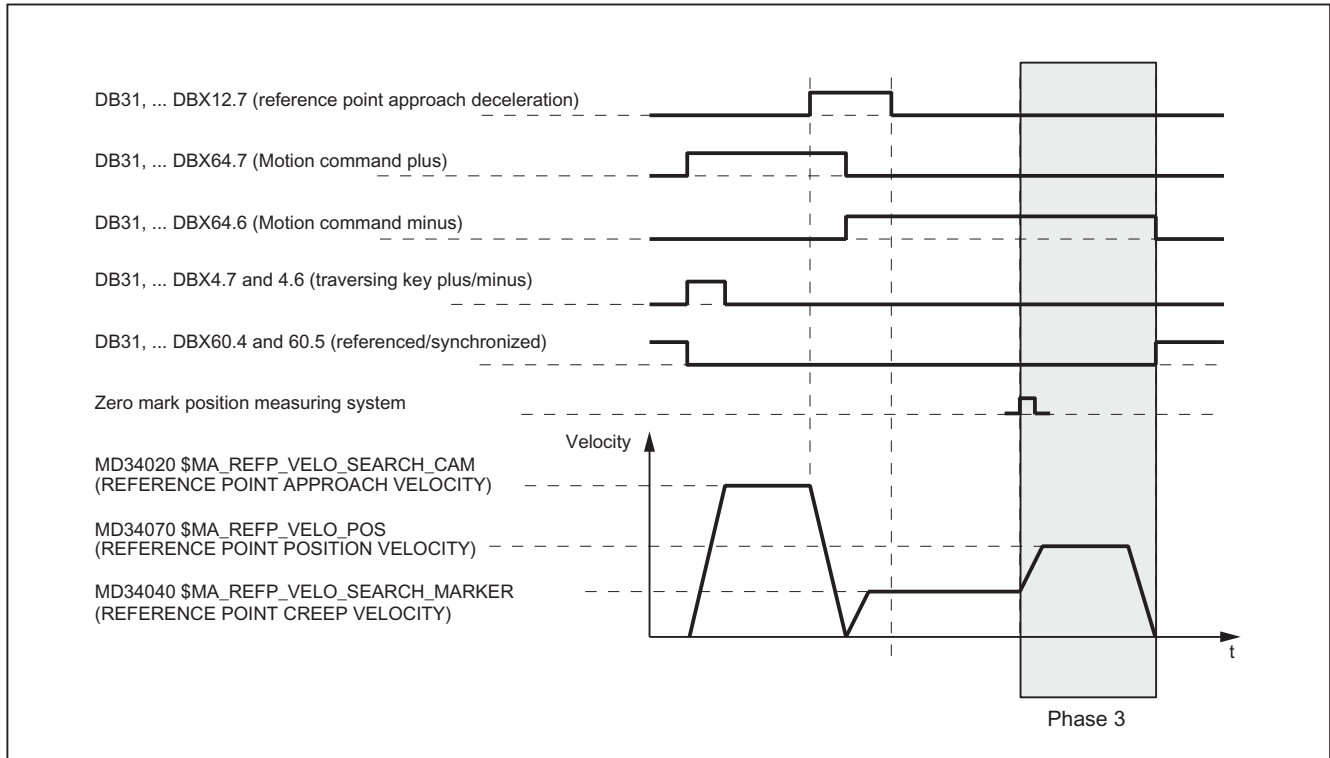

Figure 15-9 Phase 3: Traversing to the reference point

#### Phase 3: Start

At the end of phase 2 the machine axis travels at reference point creep velocity. Therefore, as soon as phase 2 is completed successfully without an alarm, phase 3 is started without interruption.

##### Initial situation

The encoder zero mark has been detected.

#### Phase 3: Sequence

The machine axis moves at the assigned reference point positioning velocity:  
 MD34070 \$MA\_REFP\_VELO\_POS (reference point positioning velocity)  
 from the encoder zero mark detected in Phase 2 to the reference point.

The path  $s_{ref}$  to be covered is calculated from the sum of the reference point distance plus reference point offset:

MD34080 \$MA\_REFP\_MOVE\_DIST (reference point distance)

MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR (reference point offset)

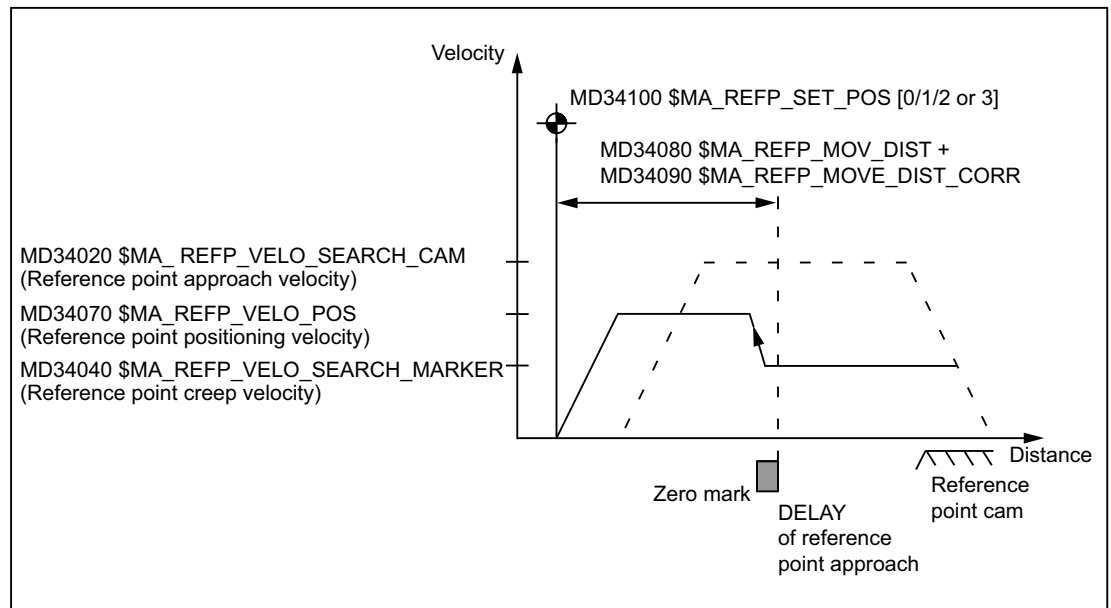

Figure 15-10 Reference point position

When the reference point is reached the machine axis is stopped and the actual value system of the machine axis is synchronized with the reference point value specified by the PLC user program.

MD34100 \$MA\_REFP\_SET\_POS [ n ] (Reference point value)

The reference point value is specified by the PLC user program via:

DB31, ... DBX2.4 / .5 / .6 / .7 (reference point value 1 / 2 / 3 / 4)

The reference point value, which was selected by the PLC user program at the time of the arrival of the reference cam in Phase 1 (DB31, ... DBX12.7 = 1), is taken over by the NC.

The machine axis is now referenced. As identification, the NC sets the appropriate interface signal depending on the active measuring system:

DB31, ... DBX60.4 / .5 (Referenced/Synchronized 1 / 2) = 1

### Features of phase 3

- Feed override active.
- Feed stop (channel-specific and axis-specific) is active.
- NC STOP and NC START are active.

**Special feature of phase 3**

If the parameterized distance from the encoder zero mark to the reference point, i.e. the sum of reference point distance and reference point offset (MD34080 + MD34090) is smaller than the required braking distance for stopping from the reference point positioning velocity (MD34070), the machine axis initially stops "behind" the reference point and then travels back to it.

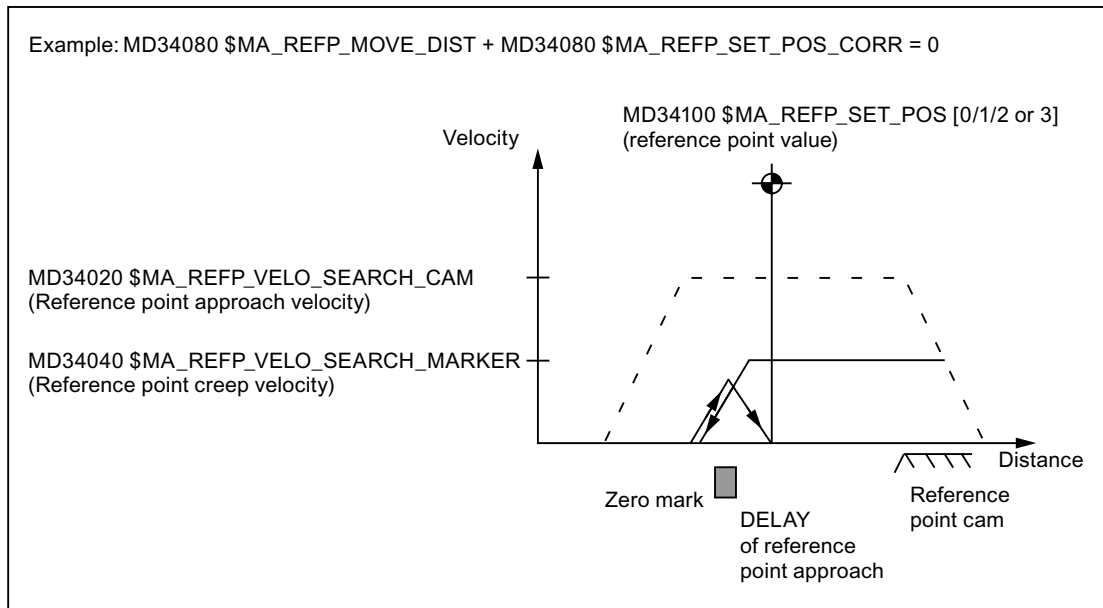

Figure 15-11 Reference point distance plus reference point offset smaller than braking distance

**15.5.6 Restoration of position after POWER OFF**

**General information**

In the case of incremental encoders, actual values can be buffered even after POWER OFF. This gives rise to the following functionalities:

- "Buffered actual value" followed by automatic referencing.
- "Position restoration with POWER ON":

The buffered actual values are adopted as automatic reference values.

 **WARNING**

During the time in which the measuring system (encoder) of the machine axis is switched off (POWER OFF, "parking" the axis, etc.), the machine axis may not be moved any further by mechanical means (e.g. "coasting" axes). This must be supported by the machine manufacturer with such measures as holding brakes, etc., and ensured by the user. Otherwise the actual value system of the machine axis will no longer be synchronized resulting in danger to personnel and machine. If this situation cannot be prevented mechanically, it would be better to use absolute encoders.

### 15.5.6.1 Buffered actual value

#### Automatic referencing

By buffering the actual value, "automatic referencing" is enabled, which does not require machine axes with incremental measuring systems, after situations in which they are in the "Not referenced" condition, to traverse back to the reference point for referencing of the measuring system. For example, this is the case after:

- POWER OFF/ON
- "Parking" selected:

DB31, ... DBX1.5 / 1.6 (position measuring system 1/2) = 0

DB31, ... DBX2.1 (servo enable) = 0

If the function is active, referencing is performed without axis motion by synchronizing the actual value system of the machine axis to the last valid actual value. The actual value is buffered in a retentive memory area of the control even after POWER OFF.

#### Precondition for automatic referencing

At the time of automatic referencing (e.g. after POWER ON, "Parking" of the machine axis is again deselected, etc.), the encoder status of the active measuring system of the machine axis must have the value 2.

MD34210 \$MA\_ENC\_REFP\_STATE = 2

That is, the encoder is referenced, an exact stop is reached, and automatic referencing is active the next time the encoder is activated.

The following conditions must be fulfilled:

- "Automatic referencing" is assigned for the measuring system (encoder):  
MD34210 \$MA\_ENC\_REFP\_STATE = 1 (Encoder status = 1)  
Automatic referencing enabled, but encoder not yet referenced or exact stop not reached.
- The measuring system has already been successfully referenced with reference point approach.  
This is identified by the NC by changing the encoder status from 1 to 2:  
MD34210 \$MA\_ENC\_REFP\_STATE = 2 (Encoder status = 2)  
Encoder is referenced, an exact stop is reached, and automatic referencing is active the next time the encoder is activated.
- The machine axis was disabled in "Exact stop fine" status.

---

**Note**

Within the scope of actual value buffering, the following axis specific interface signal is evaluated:

DB31, ... DBX60.7 (Position reached with fine exact stop)

The actual values of machine axes that do not use the signal cannot be buffered.

---

## Functional sequence

Two different cases apply for automatic referencing, which depend on the encoder status:

- **Case 1: Encoder status = 2**

Automatic referencing in parameterized, the measuring system has been referenced and the machine axis was switched off in status "exact stop fine".

As a result:

- The actual value system of the machine axis is synchronized with the buffered actual value.
- The status of the machine axis is set to "Referenced".

DB31, ... DBX60.4 / 60.5 (Referenced/Synchronized 1/2) = 1

- **Case 2: Encoder status = 1**

Automatic referencing in parameterized but the measuring system has either not yet been referenced or the machine axis was not switched off in status "exact stop fine".

As a result:

- The actual value system of the machine axis is synchronized with zero.
- The status of the machine axis is set to "Not referenced":

DB31, ... DBX60.4 / 60.5 (Referenced/Synchronized 1/2) = 0

### 15.5.6.2 Position restoration with POWER ON

#### Function

In addition to the axis position, incremental encoder buffering also sets the referenced status. However, the restored incremental encoder position is actually not the same as "real" re-referencing. In order to assess the quality of the restored position, a "restored" status is delivered instead of the "referenced" status.

#### Parameter assignment

In order to restore the last axis position buffered before switching off, the encoder status must be set to the value "3":

```
MD34210 $MA_ENC_REFP_STATE = 3
```

Referencing does not take place automatically. The encoder state is "Position restored". Monitoring for the software limit switches is already activated in this state.

This state is indicated by the following signals in the NCK PLC interface:

DB31, ... DBX71.4 ("restored 1") for encoder 1

DB31, ... DBX71.5 ("restored 2") for encoder 2

The "Position restored" state can only be exited by referencing the axis. As a consequence, IS DB31, .... DBX71.4/5 ("restored 1/2") is deleted and IS DB31, .... DBX60.4/5 ("referenced/synchronized 1/2") is set.

---

#### Note

In the case of spindles, the states "Position restored" and "Referenced/Synchronized" can also be deleted by exceeding the encoder limit frequency.

---

#### Retracting the tool in JOG mode

Once the tool has been retracted in JOG mode, axes whose positions have been restored are referenced. For further details, see also machine data:

- MD20700 \$MC\_REFP\_NC\_START\_LOCK (NC start lock without a home position).
- MD34110 \$MA\_REFP\_CYCLE\_NR (Axis sequence for channel-specific referencing)

The PLC prompts the display of this state with the output of a corresponding PLC message by evaluating the above NC/PLC interface signals.

---

#### Note

If machine data MD20700 \$MC\_REFP\_NC\_START\_LOCK is set to a value of "2", then an NC start is also possible with "restored" axis positions (in the MDA mode or when overstoring).

---

## 15.6 Referencing with distance-coded reference marks

### 15.6.1 General overview

#### Distance-coded reference marks

Measuring systems with distance-coded reference marks consist of two parallel scale tracks:

- Incremental grating
- Reference mark track

The distance between any two consecutive reference marks is defined. This makes it possible to determine the absolute position of the machine axis when two consecutive reference marks are crossed. For example, if the distance between the reference marks is approx. 10 mm, a traverse path of approx. 20 mm is all that is required to reference the machine axis.

Referencing can be performed from any axis position in the positive or negative direction (exception: end of travel range).

## 15.6.2 Basic parameter assignment

### Linear measuring systems

The following data must be set to parameterize linear measuring systems:

- The absolute offset between the machine zero point and the position of the first reference mark of the linear measuring system:

MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR (reference point/absolute offset)

See also below: Determining the absolute offset

- Orientation of the length measuring system (equidirectional or inverse) relative to the machine system coordinate system:

MD34320 \$MA\_ENC\_INVERS (length measuring system inverse to the machine system)

Figure 15-12 DIADUR graduated glass scale with distance-coded reference marks (dimensions in mm for 20 mm scale division)

### Rotary measuring system

For rotary measuring systems, the same applies as for linear measuring systems (see above).

### Determining the absolute offset

The following procedure is recommended for the determination of the absolute offset between the machine zero point and the position of the first reference mark of a machine axis:

1. Enter the value zero for the absolute offset:

MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR = 0

2. Perform reference point approach.

**Note:** Reference point approach should be performed at a point in the machine where the exact position of the machine axis relative to machine zero can be determined easily with a laser interferometer, for example.

3. Determine the actual position of the machine axis via the operator interface screen.

4. Measure the current position of the machine axis with reference to the machine zero point.
5. Calculate absolute offset and enter in MD34090.

The absolute offset is calculated with respect to the machine coordinate system and depending on the orientation of the measuring system (equidirectional or inverse) as:

| Orientation of the measuring system | Absolute offset                               |
|-------------------------------------|-----------------------------------------------|
| equidirectional                     | Measured position + displayed actual position |
| Opposite direction                  | Measured position - displayed actual position |

|                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------|
|  <b>WARNING</b>                                                   |
| After determining the absolute offset and the entry in MD34090, the reference point traversing for the machine axis must be carried out once more. |

### Referencing methods

Referencing with distance-coded reference marks can be performed in one of two ways:

- Evaluation of **two** consecutive reference marks:  
MD34200 \$MA\_ENC\_REFP\_MODE (referencing mode) = 3  
Advantage:
  - Short travel path
- Evaluation of **four** consecutive reference marks:  
MD34200 \$MA\_ENC\_REFP\_MODE = 8  
Advantage:
  - Plausibility check by NC is possible
  - Increase in reliability of referencing result

### 15.6.3 Chronological sequence

#### Chronological sequence

Referencing with distance-coded reference marks can be divided into two phases:

- Phase 1: Travel across the reference marks with synchronization
- Phase 2: Traveling to a fixed destination point

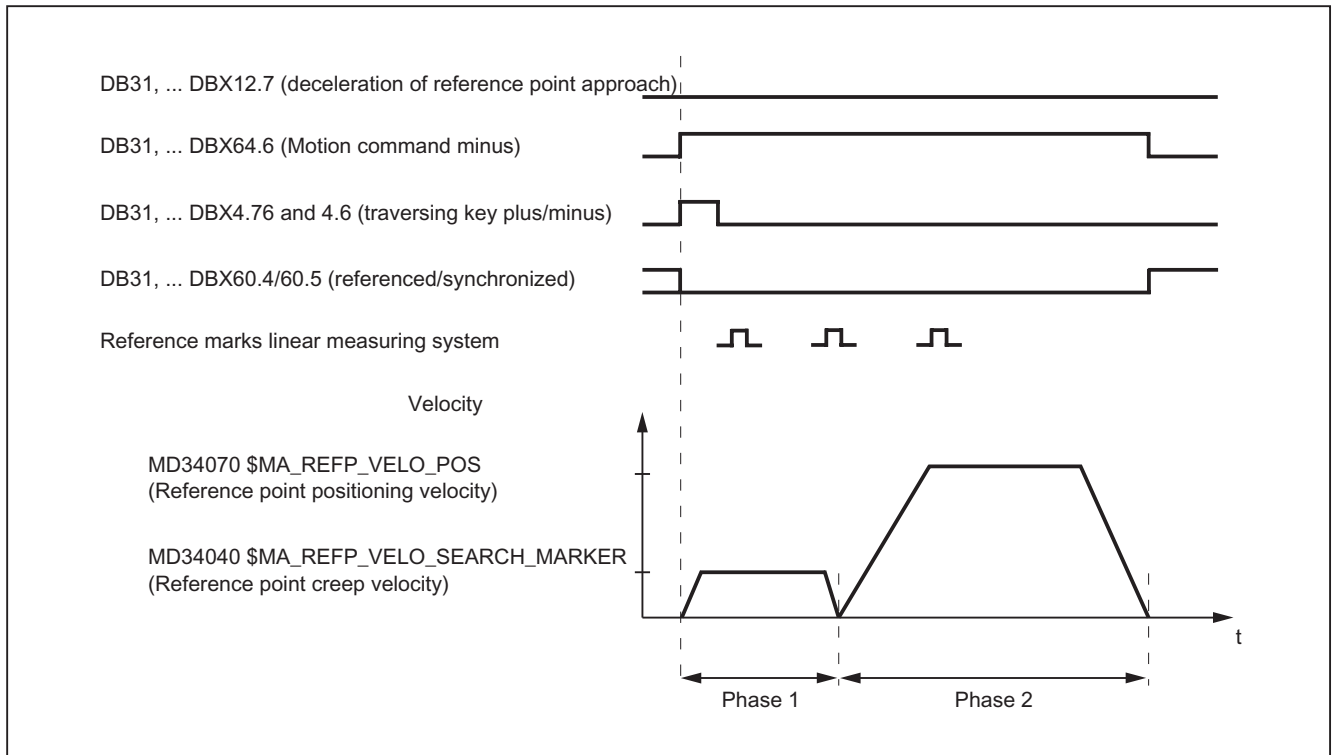

Figure 15-13 Distance-coded reference marks

### 15.6.4 Phase 1: Travel across the reference marks with synchronization

#### Phase 1: Start

For information on starting reference point approach, refer to "Axis-specific referencing" and "Channel-specific referencing."

## Reference cam

In measuring systems with distance-coded reference marks, reference cams are not required for the actual referencing action. For functional reasons, however, a reference cam is required for channel-specific reference point approach and reference point approach from the part program (G74) before the traversing range end of the machine axis.

## Phase 1: Sequence

### Sequence without touching a reference cam

Once reference point approach is started, the machine axis accelerates to the assigned reference point creep velocity:

MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER (reference point creep velocity)

Once the parameterized number of reference marks has been crossed, the machine axis is stopped again and the actual value system of the machine axis is synchronized to the absolute position calculated by the NC.

### Sequence when starting from the reference cam

If the machine axis is at the reference cam at the start of the reference point traversing, it accelerates to the parameterized reference point creep velocity against the parameterized reference point approach direction:

MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER (reference point creep velocity)

MD34010 \$MA\_CAM\_DIR\_IS\_MINUS (Reference point approach in minus direction)

That ensures that the machine axis does not reach the travel range limit before it has crossed the parameterized number of reference marks.

Once the parameterized number of reference marks has been crossed, the machine axis is stopped again and the actual value system of the machine axis is synchronized to the absolute position calculated by the NC.

### Sequence when contact is made with reference cam during referencing

Once reference point approach is started, the machine axis accelerates to the assigned reference point creep velocity:

MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER (reference point creep velocity)

Before the machine axis travels over the parameterized number of reference marks, it touches the reference cam. It is then reversed and reference mark search is restarted in the opposite direction.

Once the parameterized number of reference marks has been crossed, the machine axis is stopped again and the actual value system of the machine axis is synchronized to the absolute position calculated by the NC.

### Plausibility check of the reference mark distance

An error occurs if, during reference point traversing for two subsequent reference marks, the NC determines a distance greater than twice the parameterized reference mark distance.

MD34300 \$MA\_ENC\_REFP\_MARKER\_DIST (Reference mark distance)

The machine axis will then traverse in opposite direction at half the parameterized reference point creep velocity (MD34040) and the search for reference mark is restarted.

If a faulty reference mark distance is detected again, the machine axis is stopped and the reference point traversing is aborted (alarm 20003 "fault in the measuring system").

### Abort criterion

If the parameterized number of reference marks is not detected within the parameterized distance, the machine axis is stopped and reference point traversing is aborted.

MD34060 \$MA\_REFP\_MAX\_MARKER\_DIST (max. distance to the reference mark)

### Features of phase 1

After phase 1 is successfully completed, the actual value system of the machine axis is synchronized.

## 15.6.5 Phase 2: Travel to fixed stop

### Phase 2: Start

Phase 2 is automatically started when phase 1 has been completed without an alarm.

#### Initial situation:

- The machine axis is positioned directly behind the last of the parameterized number of reference marks.
- The actual value system of the machine axis is synchronized.

**Phase 2: Sequence**

In Phase 2, the machine axis completes reference point approach by traversing to a defined target position (reference point). This action can be suppressed in order to shorten the reference point approach:

MD34330 \$MA\_STOP\_AT\_ABS\_MARKER

| Value | Meaning                      |
|-------|------------------------------|
| 0     | Travel to target position    |
| 1     | No travel to target position |

**Travel to target position (normal case)**

The machine axis accelerates to the parameterized reference point position velocity and travels to the parameterized target point (reference point):

MD34070 \$MA\_REFP\_VELO\_POS (Reference point positioning velocity)

MD34100 \$MA\_REFP\_SET\_POS (reference point value)

The machine axis is referenced. To identify this, the NC sets an interface signal for the measuring system that is currently active:

DB31, ... DBX60.4 / 60.5 (Referenced/Synchronized 1/2) = 1

**No travel to target position**

The machine axis is now referenced. To identify this, the NC sets an interface signal for the measuring system that is currently active:

DB31, ... DBX60.4 / 60.5 (Referenced/Synchronized 1/2) = 1

**Features of phase 2**

Phase 2 will display different characteristics, depending on whether a reference point cam is parameterized for the machine axis.

**Machine axis without reference point cam**

MD34000 \$MA\_REFP\_CAM\_IS\_ACTIVE (Axis with reference point cam) = 0

Properties:

- Feed override active.
- The feed stop (channel-specific and axis-specific) is active.
- NC STOP and NC START are active.

**Machine axis with reference point cam**

MD34000 \$MA\_REFP\_CAM\_IS\_ACTIVE (Axis with reference point cam) = 1

Properties:

- Feedrate override is **not** active.  
Machine axis moves internally when feedrate override = 100%.  
If a feedrate override of 0% is specified, an abort occurs.
- The feed stop (channel-specific and axis-specific) is active.
- NC-STOP and NC-START are **not** active.
- If the parameterized number of reference marks is not detected within the parameterized distance after the exit of the reference cam, the machine axis will be stopped.  
MD34060 \$MA\_REFP\_MAX\_MARKER\_DIST (max. distance to the reference mark)

### Special features of rotary measuring systems

On rotary distance-coded measuring systems, the absolute position can only be determined uniquely within one revolution. Depending on the mechanical mounting of the encoder, the overtravel of the absolute position in the hardware does not always coincide with the traversing range of the rotary axis.

### Special features of modulo rotary axes

With modulo rotary axes, the reference point position is mapped on the parameterized modulo range:

MD30330 \$MA\_MODULO\_RANGE (extent of modulo range)

MD30340 \$MA\_MODULO\_RANGE\_START (starting position of modulo range)

---

#### Note

The reference point position is mapped onto the assigned (ghost) modulo range even with axis function "Determination of reference point position rotary, distance-coded encoder within the configured modulo range":

MD30455 \$MA\_MISC\_FUNCTION\_MASK (axis functions), BIT1 = 1

---

## 15.7 Referencing by means of actual value adjustment

### 15.7.1 Actual value adjustment to the referencing measurement system

#### Function

When actual value adjustment to the referencing measuring system is performed, the resulting absolute actual position after successful referencing of the measuring system of a machine axis is transferred directly to all other measuring systems of the machine axis, and the machine axis is designated as referenced:

DB31, ... DBB60.4 / 60.5 (referenced/synchronized 1/2) = 1

#### Advantage

When the machine axis switches from an explicitly referenced measuring system to the measuring system referenced by actual value adjustment, continuous servo control is assured (servo enable active) because the matched actual position prevents a sudden change in actual value.

---

#### Note

In order to improve positioning precision by determining the measuring-system-specific encoder fine information, we recommend explicitly re-referencing the measuring system previously referenced by actual value adjustment after switching over.

---

#### Activation

The activation of the actual value adjustment to the referencing measuring system is machine-specifically carried out via:

MD34102 \$MA\_REFP\_SYNC\_ENCS = 1

### 15.7.2 Actual value adjustment to the referenced measurement system

#### Function

If a machine axis has several measuring systems and one of them is referenced, the remaining measuring systems can be referenced by actual value adjustment to the measuring system already referenced.

#### Advantage

Referencing does not take as long because the path to be traversed only has to be sufficiently long to allow elimination of the backlash in both measuring systems.

If the distance to the traversing range limits is large enough, referencing can be started at any point along the traversing range of the machine axis in any direction because no zero mark, reference point cam, etc., is required.

## Parameter assignment

The following machine data must be parameterized for actual value adjustment to a referenced measuring system:

- Homing mode: Actual value adjustment to a referenced measuring system  
MD34200 \$MA\_ENC\_REFP\_MODE[*measuring system*] = 6
- Traverse path for backlash recovery:  
MD34080 \$MA\_REFP\_MOVE\_DIST[*measuring system*] (reference point distance)

---

### Note

#### Reference point distance greater than zero

To ensure reliable backlash recovery, the assigned value for the reference point distance must be greater than the maximum backlash of both measuring systems.

#### Reference point distance equal to zero

The reference point distance can also equal zero. In this case, actual value adjustment is performed without a traversing movement as soon as reference point approach starts. In this case, the active backlash should be less than half the increment of the measuring system whose actual value is taken.

---

## 15.7.3 Actual value adjustment for measuring systems with distance-coded reference marks

### Function

In order to improve positioning precision by determining the measuring-system-specific encoder fine information, we recommend explicitly re-referencing the measuring system previously referenced by actual value adjustment after switching over the measuring system.

If an encoder with distance-coded reference marks is used for the passive measuring system, referencing can be avoided if the following conditions are met:

1. Active measuring system: indirect measuring system (motor measuring system) with absolute encoder, for example
2. Passive measuring system: Direct measuring system with distance-coded reference marks
3. Travel movement of the machine axis with the referenced indirect measuring system before measuring system switchover in which the number of reference marks required for referencing are crossed. This automatically references the passive direct measuring system.

## Parameterization

In addition to the specific machine data required to reference the individual measuring systems, the following machine data must be set:

- Enable actual value adjustment:  
MD34102 \$MA\_REFP\_SYNC\_ENCS = 1
- Direct measuring system with distance-coded reference marks:
  - MD34200 \$MA\_ENC\_REFP\_MODE[*measuring system*] = 3  
Distance-coded reference marks
  - MD30242 \$MA\_ENC\_IS\_INDEPENDENT[*measuring system*] = 2

During actual value adjustment, the passive direct measuring system is adjusted to the actual position of the active indirect measuring system, but is not marked as referenced. After the parameterized number of reference marks have been crossed, the passive direct measuring system is automatically referenced. Referencing is performed in every operating mode.

## Sequence

1. Initial situation: Neither of the measuring systems are referenced:  
DB31, ... DBX60.4 = 0 (referenced / synchronized 1)  
DB31, ... DBX60.5 = 0 (referenced / synchronized 2)
2. Reference the indirect measuring system according to the measuring system type:  
DB31, ... DBX60.4 = 1 (referenced / synchronized 1)  
DB31, ... DBX60.5 = 0 (referenced / synchronized 2)
3. Traverse the machine axis across the parameterized number of reference marks.  
This automatically references the direct measuring system:  
DB31, ... DBX60.4 = 1 (referenced / synchronized 1)  
DB31, ... DBX60.5 = 1 (referenced / synchronized 2)

## 15.8 Referencing in follow-up mode

### Function

Incremental measuring systems and measuring systems with distance-coded reference marks can be referenced even when the machine axis is in follow-up mode. This requires that reference point approach be properly parameterized according to the measuring system in use (see "Referencing with incremental measuring systems" and "Referencing with distance-coded reference marks").

When referencing in follow-up mode the machine axis is moved not by the NC but by means of an external travel movement over the encoder zero mark and the parameterized number of distance-coded reference marks. The measuring system is referenced when the encoder zero mark or parameterized number of distance-coded reference marks are detected.

---

### Note

#### Reproducibility of the referencing result

In NC-guided reference point approach, reproducibility of the referencing result is ensured through adherence to the assigned traverse velocities during the referencing operation. During referencing in follow-up mode, responsibility for achieving reproducibility of the referencing results lies with the machine manufacturer / user.

---

### Unique zero mark

Referencing of an incremental measuring system is based on the explicit position of the encoder zero mark relative to the overall traversing range of the machine axis.

Because the reference cam signal is not evaluated by the NC during referencing in follow-up mode, unique identification of the reference point when referencing in follow-up mode will only result with:

- Only one encoder zero mark in the traversing range of the machine axis
- Linear measuring systems with distance-coded reference marks
- Modulo rotary axes (absolute position within one revolution)

### Zero mark selection when several zero marker signals occur

If several encoder zero marks are detected in the traversing range of the machine axis due to machine-specific factors, e.g., reduction gear between encoder and load, a BERO must be mounted on the machine and connected to the relevant drive module (SIMODRIVE 611D) via a BERO input in order to uniquely specify the reference point. The position of the reference point is then derived from the combination of BERO signal and encoder zero mark.

Zero mark evaluation with BERO must be parameterized as the referencing mode:

MD34200 \$MA\_ENC\_REFP\_MODE = 5

### Negative edge evaluation

In the case of a referencing operation with a negative edge evaluation of the BERO signal:  
MD34120 \$MA\_REFP\_BERO\_LOW\_ACTIVE = FALSE  
synchronization is with the next encoder zero mark encountered after the BERO is exited.

### Positive edge evaluation

In the case of a referencing operation with a positive edge evaluation of the BERO signal:  
MD34120 \$MA\_REFP\_BERO\_LOW\_ACTIVE = TRUE  
synchronization is with the next encoder zero mark encountered after the BERO is approached.

Mechanically, the BERO must be sized in such a way that the positive BERO signal covers the entire width of the encoder zero mark.

## Enable

The "Referencing in follow-up mode" function is enabled with:

MD34104 \$MA\_REFP\_PERMITTED\_IN\_FOLLOWUP = TRUE

## Starting the referencing operation

If the machine axis is operating in the follow-up mode at the start of reference point traversing, (DB31,... DBX61.3 == TRUE) the measuring system will be referenced in the follow-up mode.

If the machine axis is not operating in the follow-up mode at the start of reference point traversing, the "normal" from the NC controlled reference point travels is carried out.

Referencing in follow-up mode can be started in the following modes:

- JOG-REF: Traversing keys
- AUTOMATIC: Part program command <sup>G74</sup>

## Sequence of referencing operation (JOG-REF mode)

1. Activate follow-up mode of machine axis:  
DB31, ... DBX1.4 (follow-up mode) = 0  
DB31, ... DBX2.1 (servo enable) = 0
2. Take into account activation of follow-up mode:  
DB31, ... DBX61.3 (follow-up mode active) = 1
3. Switch to JOG-REF mode.
4. External movement of machine axis across encoder zero mark or parameterized number of distance-coded reference marks. The referencing operation is started internally in the NC as soon as the machine axis is moved:  
DB31, ... DBX61.4 (axis/spindle stationary) = 0
5. The measuring system is referenced after the encoder zero mark or the assigned number of distance-coded reference marks have been successfully detected:  
DB31, ... DBX60.4/60.5 (referenced/synchronized 1 / 2) = 1

### Aborting the reference operation

An active referencing operation can be aborted by:

- Deselecting follow-up mode
- NCK Reset

### Response when measuring systems are already referenced

A measuring system that has already been referenced can only be re-referenced in AUTOMATIC mode using part program instruction G74.

### Sequence of referencing operation (AUTOMATIC mode)

1. Switch to AUTOMATIC mode.
2. Start the part program.
3. Activate follow-up mode of machine axis:  
DB31, ... DBX1.4 (follow-up mode) = 0  
DB31, ... DBX2.1 (servo enable) = 0
4. Take into account activation of follow-up mode:  
DB31, ... DBX61.3 (follow-up mode active) = 1
5. The referencing operation is started internally in the NC as soon as part program instruction G74 is processed.
6. External movement of machine axis across encoder zero mark or parameterized number of distance-coded reference marks.
7. The measuring system is referenced after the encoder zero mark or the assigned number of distance-coded reference marks have been successfully detected:  
DB31, ... DBX60.4 / 60.5 (referenced/synchronized 1/2) = 1
8. The block change occurs after the referencing operation has been successfully completed.

### Aborting the reference operation

An active referencing operation can be aborted by:

- Deselecting follow-up mode
- NCK Reset

### Response when measuring systems are already referenced

A measuring system that you have already referenced can be referenced again.

## 15.9 Referencing with absolute value encoders

### 15.9.1 Information about calibration

#### Machine axes with absolute encoder

The advantage of machine axes with absolute value encoder is that after a one time adjustment procedure, the necessary reference point traversing with incremental measuring systems (e.g. build-up of control, de-selection of "Parking" of machine axes etc.) can be skipped and the actual value system of the machine axis can be immediately synchronized to the determined absolute position.

#### Adjustment

Adjustment of an absolute encoder involves matching the actual value of the encoder with the machine zero once and then setting it to valid.

The current adjustment status of an absolute value encoder is displayed in the following axis specific machine data of the machine axis, to which it is connected:

MD34210 \$MA\_ENC\_REFP\_STATE (status of absolute encoder)

| Value | Meaning                    |
|-------|----------------------------|
| 0     | Encoder not calibrated     |
| 1     | Encoder adjustment enabled |
| 2     | Encoder is calibrated      |

#### Adjustment methods

The following adjustment methods are supported:

- Adjustment by entering a reference point offset
- Adjustment by entering a reference point value
- Automatic adjustment with probe
- Adjustment with BERO

#### Readjustment

Readjustment of the absolute encoder is required after:

- Gear change between load and absolute encoder
- Removal/installation of the absolute value encoder
- Removal/installation of the motor with the absolute value encoder
- Data loss in the static NC memory

- Battery failure
- Setting actual value (PRESETON)

#### NOTICE

The NCK can only detect a required readjustment during the following events:

- Gear change with change of gear ratio
- Addressing the zero-mark monitoring
- New encoder serial number after change of the absolute value encoder

Thereupon, the status of the absolute encoder is automatically reset by NCK to 0 (encoder not calibrated) (MD34210 = 0) and the following alarm is displayed:

Alarm 25022 "Axis <Axis identifier> Encoder <Number> Warning 0"

or when addressing the zero-mark monitoring (only systems with SIMODRIVE 611D):  
Alarm 25020 "Axis <Axis identifier> Zero-mark monitoring of the active encoder"

In all other cases (e.g. PRESETON) it is the sole responsibility of the user, by resetting the status to 0 (encoder not adjusted), to show the misalignment of the absolute value encoder and to carry out a readjustment.

#### WARNING

##### Data backup

During the back-up of machine data of a machine A, the encoder status of the machine axis (MD34210) is also backed up.

During loading of this data record into a machine B of the same type, e.g. in the context of a serial start-up or after a case of maintenance, the referenced machine axes will be automatically regarded as adjusted / referenced by the NC. It is the special responsibility of the machine manufacturer / user to undertake a readjustment in such cases.

See also explanations regarding machine data:

MD30250 \$MA\_ACT\_POS\_ABS (Absolute encoder position at the time of switch-off)

## 15.9.2 Calibration by entering a reference point offset

### Function

During adjustment by entering the reference point offset, the difference between the position displayed on the operator interface and the true actual position in the machine is determined and made known to the NC as reference point offset.

## Procedure

1. Determining the position of the machine axis with reference to the machine zero point via e.g.:
  - Position measurement (e.g. laser interferometer)
  - Moving the machine axis to a known position (e.g., fixed stop)
2. Reading the displayed actual position of the machine axis on the operator interface.
3. Calculating the reference point offset (difference between the actual positions determined under point 1 and 2) and entering in machine data:

MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR (reference point offset)

4. Marking the absolute value encoder as adjusted:

MD34210 \$MA\_ENC\_REFP\_STATE = 2

---

### Note

The encoder adjustment does not become active until the next time the encoder is activated (e.g., when the controller is powered up).

---

5. Initiate POWER ON reset.
  6. Controlling the position of the machine axis displayed on the operator interface.
- 

### Note

#### Backlash compensation

If backlash compensation is parameterized for a measuring system with absolute value encoder, the following must be observed:

No backlash is permitted during machine axis travel to the adjusted machine position.

#### Activate reference point offset permanently

The entered reference point offset (MD34090) will be permanently active only after initial POWER ON - Reset. If the machine axis is moved after the absolute encoder adjustment without an interim POWER ON - Reset, the reference point offset entered in the machine data can be overwritten, for example, as part of internal overrun offset.

#### Checking the actual position

Following adjustment of the absolute encoder, we recommend that you verify the actual position of the machine axis the next time you power up the controller (POWER ON).

---

### 15.9.3 Adjustment by entering a reference point value

#### Function

During adjustment by entering the reference point value, the absolute position of the machine axis with reference to the machine zero point is determined by e.g.:

- Position measurement (e.g. laser interferometer)
- Moving the machine axis to a known position (e.g. fixed stop)

This determined position value will be made known to the NC as the reference point value. The NC then calculates the reference point offset from the difference between the encoder absolute value and the reference point value.

#### Procedure

1. Set reference mode to "Take over of the reference point value"  
MD34200 \$MA\_ENC\_REFP\_MODE = 0
2. Traversing machine axis in the JOG mode to the (e.g. Laser interferometer) position to be measured or already known (e.g. fixed stop).

---

#### Note

The machine axis can only be traversed in the direction enabled for referencing with the travel keys:

MD34010 \$MA\_REFP\_CAM\_DIR\_IS\_MINUS (approach reference point in minus direction)

To avoid an invalid position because of backlash in the drive train, the known position must be approached at low velocity.

---

3. Communicate the position of the machine axis relative to machine zero to the NC as the reference point value:  
MD34100 \$MA\_REFP\_SET\_POS = *Position*
4. Releasing encoder adjustment:  
MD34210 \$MA\_ENC\_REFP\_STATE = 1
5. Activate NCK-Reset for acceptance of the entered machine data values.
6. Switch to JOG-REF mode.

7. Operate the travel key used for referencing in step 2.

The machine axis does not move when the traversing key is actuated!

The NC calculates the reference point offset from the entered reference point value and that given by the absolute value encoder. The result is entered into the machine data:

MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR (reference point offset)

The status of the absolute value encoder is set to "Encoder is adjusted":

MD34210 \$MA\_ENC\_REFP\_STATE = 2

The actual value system of the machine axis is synchronized.

The machine axis is now referenced. As identification, the NC sets the appropriate interface signal based on which measuring system is currently active:

DB31, ... DBB60.4 / 60.5 (referenced/synchronized 1 / 2) = 1

8. Initiate POWER ON reset.

---

### Note

#### Activate reference point offset permanently

The entered reference point offset (MD34090) will only be permanently active after POWER ON - Reset.

If the machine axis is moved after the absolute encoder adjustment without an interim POWER ON - Reset, the reference point offset entered in the machine data can be overwritten, for example, within internal overrun corrections.

#### Checking the actual position

Following adjustment of the absolute encoder, we recommend that you verify the actual position of the machine axis the next time you power up the controller (POWER ON).

---

## 15.9.4 Automatic calibration with probe

### Function

In automatic adjustment with a probe, a known position in the machine is approached with the machine axis from a part program. The position value is stored in the NC as a reference point value. The position is reached when the probe switches, and the NC then calculates the reference point offset from the difference between the encoder value and reference point value.

---

#### Note

##### Part program for automatic adjustment

The part program for automatic adjustment using a probe must be created by the machine manufacturer / user for the specific requirements of the machine.

##### Freedom from collision

Because actual-value-related monitoring is not active for the machine axes being referenced, the machine operator must take special care to ensure that collisions do not occur in the machine while the machine axes are being moved!

---

### Part program

The part program for automatic adjustment of absolute encoders with probe must perform the points listed below for each axis in the order indicated:

1. Approach the adjustment position of machine axis, which is detected from the probe response.

The position must be approached several times from the same direction, but at a velocity which is gradually reduced on each approach, to ensure that the measured value obtained is as accurate as possible. The measured value is stored in system variable \$AA\_IM.

2. Calculating and writing the reference point offset:

```
MD34090 $MA_REFP_MOVE_DIST_CORR = MD34100 $MA_REFP_SET_POS - $AA_IM
```

3. Set the absolute encoder status to "Encoder is adjusted":

```
MD34210 $MA_ENC_REFP_STATE = 2
```

## Sequence

Proceed as follows for automatic adjustment with probe:

1. Enable part program start even for non-referenced machine axes:

MD20700 \$MC\_REFP\_NC\_START\_LOCK = 0

2. Enter the machine axis position relative to machine zero when probe is switched as the reference point value for all relevant machine axes:

MD34100 \$MA\_REFP\_SET\_POS = reference point value

3. Activate NCK-Reset for the acceptance of the entered machine data values.

4. Start part program.

5. After completion of the part program, re-secure the partial program start for machine axes which are not referenced:

MD20700 \$MC\_REFP\_NC\_START\_LOCK = 1

6. Initiate POWER ON - Reset so that the reference point offset written by the part program is permanently active:

MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR (reference point offset)

---

### Note

#### Activate reference point offset permanently

The entered reference point offset (MD34090) will only be permanently active after POWER ON - Reset.

If the machine axis is moved after the absolute encoder adjustment without an interim POWER ON - Reset, the reference point offset entered in the machine data can be overwritten, for example, as part of internal overrun offset.

#### Checking the actual position

Following adjustment of the absolute encoder, we recommend that you verify the actual position of the machine axis the next time you power up the controller (POWER ON).

---

## 15.9.5 Calibration with BERO

### Function

For adjustment using BERO, a reference point approach to a defined machine position is performed the same as for incremental measuring systems. In this case the BERO replaces the encoder zero mark that the absolute encoder does not have. After successful completion of reference point approach, the NC automatically calculates the reference point offset from the difference between the encoder absolute value and the parameterized reference point value.

## Procedure

Proceed as follows for adjustment with BERO:

1. Set referencing mode to "Referencing with BERO":

MD34200 \$MA\_ENC\_REFP\_MODE = 2

2. Assign reference point value:

MD34100 \$MA\_REFP\_SET\_POS = *Reference point value*

3. Start reference point approach.

Reference point approach can be started manually in JOG-REF mode or in AUTOMATIC or MDA mode from a part program (G74).

After a successful reference point approach, the absolute encoder is calibrated, the actual value system of the machine axis is synchronized, and the machine axis is referenced.

To identify this, the NC sets an interface signal for the measuring system that is currently active:

DB31, ... DBB60.4 / 60.5 (referenced/synchronized 1 / 2) = 1

---

### Note

If the BERO is removed after adjustment of the absolute encoder, the referencing mode must be assigned to "Referencing with absolute encoder".

MD34200 \$MA\_ENC\_REFP\_MODE = 0

---

## Signal propagation delay compensation

The signal propagation time can cause corruption of the absolute position detected by the NC. The signal propagation time can be compensated for in any direction:

MD31122 \$MA\_BERO\_DELAY\_TIME\_PLUS (BERO delay time plus)

MD31123 \$MA\_BERO\_DELAY\_TIME\_MINUS (BERO delay time minus)

---

### Note

Prerequisite for a correct compensation of signal propagation time is drives of type SIMODRIVE 611 digital. The compensation times are pre-set in delivery condition in such a way that changes are usually not required.

---

## Creep velocity

If with the approach of BERO, it is to be proceeded with the parameterized reference point creep velocity (MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER) then "BERO with projected start velocity with spindles" must be parameterized as reference mode:

MD34200 \$MA\_ENC\_REFP\_MODE = 7

### 15.9.6 Reference point approach with absolute encoders

#### Traversing movement release

If for a machine axis with adjusted absolute value encoder as active measuring system, reference point traversing is activated (manual in the mode JOG-REF or automatic according to part program instruction G74), the machine axis travels depending on the parameterized release traversing movement.

MD34330 \$MA\_REFP\_STOP\_AT\_ABS\_MARKER = <Value>

| Value | Meaning                                                                                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | Traversing is enabled.<br>When reference point approach is initiated, the machine axis moves to the reference point position. Reference point approach is completed when the reference point position is reached. |
| 1     | Traversing is <b>not</b> enabled.<br>After the activation of the reference point travel, the machine axis does not travel and the reference point travel is immediately completed.                                |

### 15.9.7 Reference point approach in rotary absolute encoders with external zero mark

#### Function

To be able to use the reference point approach with a zero mark, as is usual in incremental encoders (refer to Chapter "Referencing in incremental measuring systems") even with absolute encoders, the missing HW zero marks are created in software form once every encoder revolution, always at the same position within the rotation.

#### Difference compared to referencing with incremental encoders

An absolute encoder with replacement zero mark should not be considered as a complete equivalent of an incremental encoder. All the properties of the absolute encoder are retained. The following table lists the different properties of incremental and absolute encoders:

Table 15- 1 Properties of incremental and absolute encoders

| Feature                    | Incremental encoder                  | Absolute encoders                    |
|----------------------------|--------------------------------------|--------------------------------------|

## Requirement

The function can be used only with rotary absolute encoders:

- MD31000 \$MA\_ENC\_IS\_LINEAR = 0
- MD30240 \$MA\_ENC\_TYPE = 4

## Parameter assignment

- Reference point approach with zero marks:  
MD34200 \$MA\_ENC\_REFP\_MODE = 1
- A reference point offset should not be input in the following MD:  
MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR

This MD describes, in connection with absolute encoders, the offset between machine and absolute encoder zero, and it therefore has a different meaning.

- The load-side zero mark search rate MD34040 \$MA\_REFP\_VELO\_SEARCH\_MARKER should not exceed the limiting frequency of the absolute trace of the encoder MD36302 \$MA\_ENC\_FREQ\_LIMIT\_LOW.

If the speed is too high, absolute information cannot be read any more, and thus, no equivalent zero marks are generated.

- If no zero marks are found within:

MD34060 \$MA\_REFP\_MAX\_MARKER\_DIST

otherwise, an alarm will be triggered.

- A start of the zero mark search with the override of a BERO (MD34200 = 5) is not supported. MD34200 = 0 is to be used as a equivalent.
- The following MD must be set if the absolute encoder retains even the referenced status through POWER OFF, besides the last position:

MD34210 \$MA\_ENC\_REFP\_STATE = 2

### Data backup and standard commissioning

Some properties of an absolute encoder restrict the transfer of series startup files to other machines. The following machine data must be checked and corrected if necessary after loading the series startup:

- MD30250 \$MA\_ACT\_POS\_ABS (internal encoder position)
- MD30270 \$MA\_ENC\_ABS\_BUFFERING (traversing range extension)
- MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR (absolute offset)
- MD34210 \$MA\_ENC\_REFP\_STATE (adjustment status)
- MD34220 \$MA\_ENC\_ABS\_TURNS\_MODULO (Modulo range)
- MD34230 \$MA\_ENC\_SERIAL\_NUMBER (encoder serial number)

## 15.9.8 Automatic encoder replacement detection

### Function

Automatic encoder replacement detection is required for absolute encoders in order to detect if the encoder has been replaced and therefore needs to be readjusted.

The NC reads the encoder-specific serial number of the encoder from the drive every time the control is powered up. If the serial number has changed the NC resets the encoder status to "Encoder not calibrated".

MD34210 \$MA\_ENC\_REFP\_STATE = 0

The status of the measuring system is indicated as "Not referenced":

DB31, ... DBB60.4 / 60.5 (referenced/synchronized 1/2) = 0

## Serial number display

The NC stores the serial numbers read in the build-up specific to the machine in the machine data:

MD34230 \$MA\_ENC\_SERIAL\_NUMBER (encoder serial number)

---

### Note

Currently, only the serial numbers of absolute encoders with an EnDat interface can be read. For all other encoders the display shows that no serial number has been read.

Automatic encoder replacement detection can therefore only be used with the specified encoder types.

---

## Avoiding readjustments

In some special cases, for example, when a machine axis (built-on rotary axes) is removed and then mounted again, readjustment is not necessary / desirable.

To avoid readjustment, zero must be parameterized as a serial number to be ignored for the measuring system of the machine axis in question.

MD34232 \$MA\_EVERY\_ENC\_SERIAL\_NUMBER = 0

If the NC now reads zero as the serial number, the encoder status is not reset and the serial number indicated in the machine data is kept.

### Example sequence of operation:

1. The NC reads the serial number of the absolute encoder for the measuring system of the machine axis in question and the serial number is not equal to zero.
2. The absolute encoder is calibrated in the correct manner.
3. When the controller is powered up subsequently, the NC reads "zero" as the serial number of the absolute encoder.

Serial number "zero" is ignored and the encoder status remains the same, that is "calibrated".

4. When the controller is powered up, the NC again reads the serial number it read under Item 1 and that is still indicated in the machine data. The encoder status continues to be "Adjusted".

---

### Note

#### PROFIBUS drives

As not every drive connected via PROFIBUS-DP is able to deliver the encoder serial number in time for build-up of control or at all, the range of the encoder serial number with PROFIBUS drives is pre-set with zero to avoid unnecessary new NC internal adjustments:

MD34232 \$MA\_EVERY\_ENC\_SERIAL\_NUMBER = 0

A manual parameterizing to 1 is ineffective.

---

### 15.9.9 Enabling the measurement system

The measuring system of a machine axis is activated in the following cases:

- Power up of the control (POWER ON)
- Activation of the measuring system via interface signal (deselection of "parking"):  
DB31, ... DBB1.5 / 1.6 (position measuring system 1/2)  
DB31, ... DBB2.1 (servo enable)
- Violation of the assigned encoder limit frequency (spindles):  
MD36300 \$MA\_ENC\_FREQ\_LIMIT

When the measuring system is activated, the NC synchronizes the actual value system of the machine axis with the current absolute value. Traversing is disabled during synchronization for axes but not for spindles.

#### Parameterizing the encoder limit frequency (spindles)

The EQN 1325 absolute encoder made by Heidenhain has an incremental track and an absolute track.

If a spindle is driven at a speed above the encoder limit frequency of the incremental track, the substantially lower limit frequency of absolute track must be parameterized as the encoder limit frequency.

MD36300 \$MA\_ENC\_FREQ\_LIMIT

Otherwise an incorrect absolute position would be read because the parameterized encoder limit frequency is not reached when the measuring system is activated. This would cause a position offset in the actual value system of the machine axis.

#### Determining the encoder limit frequency

The encoder limit frequency to be parameterized is derived from the smaller of the two following limit speeds:

- Encoder

The limit speed or encoder limit frequency is listed in the data sheet of the encoder (e.g., limit speed = 2000 [rpm])

- NC

Due to the NC-internal evaluation process, the maximum limit speed for which error-free calculation of the absolute value by the NC is possible is 4 encoder revolutions per interpolation cycle.

For an interpolation cycle of, for example, 12 ms: Limit speed = 4 / 12 ms = 20,000 rpm

The limiting frequency corresponding to the limiting speed is calculated to be:

$$MD36300 = \frac{4 * MD31020}{MD10050 * MD10070}$$

MD31020 \$MA\_ENC\_RESOL (Encoder lines per revolution)  
MD10050 \$MN\_SYSCLOCK\_CYCLE\_TIME (System clock cycle)  
MD10070 \$MN\_IPO\_SYSCLOCK\_TIME\_RATIO (Factor for interpolator cycle)

---

**Note**

The position control switching speed relevant for spindles is set according to the encoder limiting frequency of the absolute value encoder of the spindle:

MD35300 \$MA\_SPIND\_POSCTRL\_VELO (position control switching speed)

MD36300 \$MA\_ENC\_FREQ\_LIMIT (Encoder limit frequency)

---

## 15.9.10 Referencing variants that are not supported

The following referencing variants are not supported when used with absolute encoders:

- Referencing / calibrating with encoder zero mark
- Distance-coded reference marks
- BERO with two-edge evaluation

## 15.10 Supplementary conditions

### 15.10.1 Large traverse range

#### Notes on uniqueness of encoder position

##### Linear absolute encoder

The absolute value of linear position encoders, e.g. Heidenhain LC181, is always unique for the scale lengths available.

##### Rotary absolute encoder

The absolute value of rotary absolute encoders is only unique within the range of the specific maximum encoder revolutions.

For example, the EQN 1325 rotary absolute encoder by Heidenhain supplies a unique absolute value in the range of 0 to 4,096 encoder revolutions.

Depending on how the encoder is connected that will result in:

- Rotary axis with encoder on load: 4096 load revolutions
- Rotary axis with encoder on motor: 4096 motor revolutions
- Linear axis with encoder on motor: 4096 motor revolutions

Example:

An EQN 1325 rotary absolute encoder is connected to the motor of a linear axis. For an effective leadscrew pitch of 10 mm this will result in a unique absolute value within the travel range -20.48 to +20.48 m.

### Supplementary conditions

- Linear axes with a traversing range > 4096 encoder revolutions, rotatory absolute value encoder EQN 1325 and a parameterized absolute value encoder range of MD34220 \$MA\_ENC\_ABS\_TURNS\_MODULO = 4096:
  - The maximum possible travel range corresponds to that of incremental encoders.
- Endlessly turning rotary axes with absolute encoders:
  - Any number of integer transmission ratios are permitted.
  - We recommend that you parameterize endlessly turning rotary axes with absolute encoders as modulo rotary axes (traversing range 0...360 degrees).  
MD34220 \$MA\_ENC\_ABS\_TURNS\_MODULO  
Otherwise, the machine axis may require a very long traverse path to reach absolute zero when the measuring system is activated.
- Machine axes with absolute encoders:
  - To ensure that the NC correctly determines the current actual position when the measuring system is reactivated, the machine manufacturer / user must ensure that the machine axis is moved less than half the assigned traversing range when the measuring system is deactivated (POWER OFF, "parking" selected).  
MD34220 \$MA\_ENC\_ABS\_TURNS\_MODULO

## 15.11 Data lists

### 15.11.1 Machine data

#### 15.11.1.1 NC-specific machine data

| Number | Identifier: \$MN_         | Description                    |
|--------|---------------------------|--------------------------------|

## S1: Spindles

### 16.1 Brief description

The primary function of a spindle is to set a tool or workpiece in rotary motion in order to facilitate machining.

Depending on the type of machine, the spindle must support the following functions in order to achieve this:

- Input of a direction of rotation for the spindle (M3, M4)
- Input of a spindle speed (S, SVC)
- Spindle stop, without orientation (M5)
- Spindle stop with orientation / Spindle positioning (SPOS, M19 and SPOSA)
- Gear change (M40 to M45)
- Spindle-axis functionality (spindle becomes rotary axis and vice versa)
- Thread cutting (G33, G34, G35)
- Tapping without compensating chuck (G331, G332)
- Tapping with compensating chuck (G63)
- Revolutional feedrate (G95)
- Constant cutting rate (G96, G961, G97, G971)
- Programmable spindle speed limits (G25, G26, LIMS=)
- Position encoder assembly on the spindle or on the spindle motor
- Spindle monitoring for min. and max. speed as well as max. encoder limit frequency and end point monitoring of spindle
- Switching the position control (SPCON, SPCOF, M70) on/off
- Programming of spindle functions:
  - From the part program
  - Via synchronized actions
  - Via PLC with FC18 or via special spindle interfaces for simple spindle activation

## 16.2 Operating modes

### 16.2.1 Overview

#### Spindle modes

The spindle can have the following modes:

- Control mode
- Oscillation mode
- Positioning mode
- Synchronous mode, synchronous spindle

**References:**

Function Manual, Extended Functions, Synchronous Spindle (S3)

- Rigid tapping

**References:**

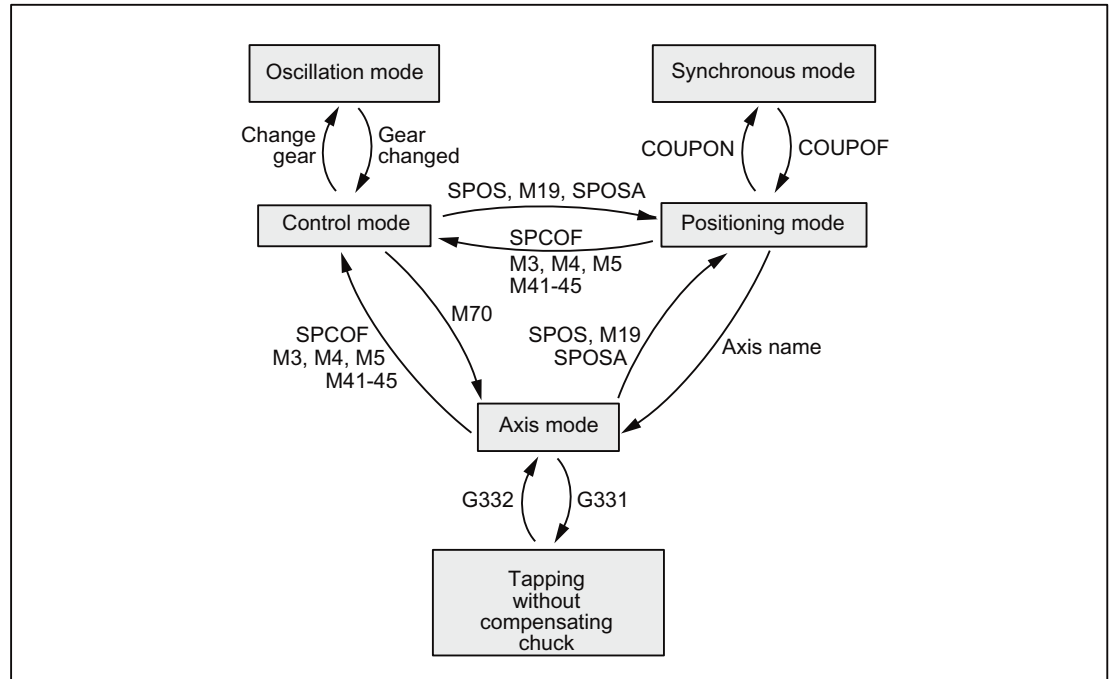

Programming Manual, Fundamentals; Chapter: Motion commands

#### Axis mode

The spindle can be switched from spindle mode to axis mode (rotary axis) if the same motor is used for spindle and axis operation.

## 16.2.2 Mode change

Switching between spindle and axis operation can be done as follows:

- Control mode → Oscillation mode

The spindle changes to oscillation mode if a new gear stage has been specified using automatic gear step selection (M40) in conjunction with a new S value or by M41 to M45. The spindle only changes to oscillation mode if the new gear step is not equal to the current actual gear step.

- Oscillation mode → Control mode

When the new gear is engaged, the interface signal: DB31, ... DBX84.6 (Oscillation mode) is reset and the interface signal: DB31, ... DBX16.3 (Gear changed) is used to go to control mode.

The last programmed spindle speed (S value) is reactivated.

- Control mode → Positioning mode

To stop the spindle from rotation (M3 or M4) with orientation or to reorient it from standstill (M5), SPOS, M19 or SPOSA are used to switch to positioning mode.

- Positioning mode → Control mode

M3, M4 or M5 are used to change to control mode if the orientation of the spindle is to be terminated. The last programmed spindle speed (S value) is reactivated.

- Positioning mode → Oscillation mode

If the orientation of the spindle is to be terminated, M41 to M45 can be used to change to oscillation mode. When the gear change is complete, the last programmed spindle speed (S value) and M5 (control mode) are reactivated.

- Positioning mode → Axis mode

If a spindle was stopped with orientation, the assigned axis name is used to program a change to axis mode. The gear step is retained.

- Control mode → Axis mode

Switching from control mode to axis mode can be also achieved by the programming of M70. In this case, a rotating spindle is decelerated in the same way as for M5, position control activated and the zero parameter set selected.

- Axis mode → Control mode

To terminate axis mode, M3, M4 or M5 can be used to change to control mode. The last programmed spindle speed (S value) is reactivated.

- Axis mode → Oscillation mode

To terminate axis mode, M41 to M45 can be used to change to oscillation mode (only if the programmed gear step is not the same as the actual gear step). When the gear change is complete, the last programmed spindle speed (S value) and M5 (control mode) are reactivated.

### 16.2.3 Control mode

#### When open-loop control mode?

The spindle is in control mode with the following functions:

- Constant spindle speed:
  - S... M3/M4/M5 and G93, G94, G95, G97, G971
  - S... M3/M4/M5 and G33, G34, G35
  - S... M3/M4/M5 and G63
- Constant cutting rate:
  - G96/G961 S... M3/M4/M5

The spindle need not be synchronized.

#### Preconditions

A spindle position actual-value sensor is absolutely essential for M3/M4/M5 in connection with:

- Revolutional feedrate (G95)
- Constant cutting rate (G96, G961, G97, G971)
- Thread cutting (G33, G34, G35)

- Tapping without compensating chuck (G331, G332)
- Activate position control (SPCON, M70)

A spindle position actual-value encoder is **not** required for M3/M4/M5 in connection with:

- Inverse-time feedrate coding (G93)
- Feedrate in mm/min or inch/min (G94)
- Tapping with compensating chuck (G63)

### Speed control mode

Speed control mode is particularly suitable if a constant spindle speed is required, but the position of the spindle is not important (e.g. constant milling speed for even appearance of the workpiece surface).

- Speed control mode is activated in the part program with `M3, M4, M5` or with `SPCOF`.
- The following NC/PLC interface signal is set:  
DB31, ... DBX84.7 (control mode)
- NC/PLC IS:  
DB31, ... DBX61.5 (Position controller active)  
is reset if position control is not used.
- Acceleration in speed control mode is defined independently of the gear stage in the machine data:

MD35200 \$MA\_GEAR\_STEP\_SPEEDCTRL\_ACCEL

The value should reflect the physical circumstances, if possible.

### Position control mode

Position control is particularly suitable if the position of the spindle needs to be tracked over a longer period or if synchronous spindle setpoint value linkage is to be activated.

- Position control mode is switched on in the part program with: `SPCON(<spindle number>)`
- The following NC/PLC interface signal is set:  
DB31, ... DBX61.5 (position controller active)
- Acceleration in position control mode is defined independent of the gear stage in the machine data:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

### Independent spindle reset

The spindle response after a reset or the end of the program (M2, M30) is set with the machine data:

MD35040 \$MA\_SPIND\_ACTIVE\_AFTER\_RESET (individual spindle reset)

| Value | Meaning                                                                                                                                                                                                         |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | When the spindle is reset or at the end of the program, the spindle immediately decelerates to a stop at the active acceleration rate. The last programmed spindle speed and direction of rotation are deleted. |
| 1     | Upon reset or at the end of the program, the last programmed spindle speed (S-value) and the last programmed direction of spindle rotation (M3, M4, M5) are retained. The spindle is not braked.                |

If prior to reset or end of program the constant cutting rate (G96, G961) is active, the current spindle speed (in relation to 100% spindle override) is internally accepted as the spindle speed last programmed.

The spindle can only be stopped with the NC/PLC interface signal:

DB31, ... DBX2.2 (delete distance to go / spindle reset)

The direction of rotation is deleted in the event of all alarms generating a spindle quick stop. The last programmed spindle speed (S value) is retained. Once the source of the alarm has been eliminated, the spindle must be restarted.

### Spindle actual speed display and spindle behavior with G96, G961

#### DB31, ... DBX61.4 (axis/spindle stationary)

The speed at which the spindle is deemed to be "stationary" is set with the machine data:

MD36060 \$MA\_STANDSTILL\_VELO\_TOL

The value should be measured in such a way that the following NC/PLC interface signal is reliably present at a standstill:

DB31,... DBX61.4 (axis/spindle stationary)

If DB31,... DBX61.4 (axis/spindle stationary) is signaled and there is no closed-loop position control active for the spindle, an actual speed of zero is displayed at the operator interface, and zero is read with the system variable \$AA\_S[<n>].

#### References:

Function Manual, Basic Functions; Various Interface Signals and Functions (A2)

#### Spindle response at constant cutting rate G96, G961

- At the start of machining (transition from G0 to Gx) and after NC stop, G60 (exact stop, modal) and G9 (exact stop, non-modal) the system waits until the actual speed has reached the speed setpoint tolerance range before starting the path.  
DB31, ... DBX83.5 (nact = nset)
- The NC/PLC IS:  
DB31, ... DBX83.5 (nact = nset)  
and  
DB31, ... DBX83.1 (setpoint speed limited) are also set to defined values even if significant speed changes are specified (transverse axis travels towards position 0).

- If the speed drops below the minimum speed or when NC/PLC IS: DB31, ... DBX61.4 (axis/spindle stationary) is detected, NC/PLC IS: DB31, ... DBX83.5 (nact = nset) is reset (e.g. for an emergency machine strategy).
- A path operation which has started (G64, rounding), is not interrupted.

In addition, the spindle response is influenced by the following machine data:

MD35500 \$MA\_SPIND\_ON\_SPEED\_AT\_IPO\_START (feed enable with spindle in setpoint range).

#### **Spindle behavior at the end of gear stage change**

- NC/PLC IS: DB31, ... DBX16.3 (Gear changed) tells the NC that the new gear stage (NC/PLC IS DB31, ... DBX16.0-16.2 (Actual gear stage A to C)) applies and oscillation mode is terminated.

In this case, it does not matter whether NC/PLC IS: DB31, ... DBX18.5 (oscillation mode) is still set.

The actual gear stage should correspond to the set gear stage.

The actual gear stage signaled is relevant for selection of the parameter set.

- Once the gear stage change (GSW) has been acknowledged via the PLC (DB31, ... DBX16.3), the spindle is in speed control mode (DB31, ... DBX84.7 = 1).

If a direction of rotation (M3, M4, M5 or FC18: "Start spindle rotation") or a spindle speed (S value) was programmed before the gear stage change, then the last speed and direction of rotation will be reactivated after the gear stage change.

## **16.2.4 Oscillation mode**

Oscillation mode is activated for the spindle during the gear step change.

The mode of operation is described in detail in the topic "Gear step change with oscillation mode (Page 1334)".

## **16.2.5 Positioning mode**

### **16.2.5.1 General functionality**

#### **When is positioning mode used?**

The spindle positioning mode stops the spindle at the defined position and activates the position control, which remains active until it is de-activated.

For the following functions the spindle is in positioning mode:

- SPOS[<n>]=...
- SPOS[<n>]=ACP(...)
- SPOS[<n>]=ACN(...)
- SPOS[<n>]=AC(...)
- SPOS[<n>]=IC(...)
- SPOS[<n>]=DC(...)
- SPOSA[<n>]=ACP(...)
- SPOSA[<n>]=ACN(...)
- SPOSA[<n>]=AC(...)
- SPOSA[<n>]=IC(...)
- SPOSA[<n>]=DC(...) equal to SPOSA[<n>]=...
- M19 or M[<n>]=19

The address extension [<n>] with <n> = spindle number may not apply for the main spindle.

#### **SPOS[<n>]=AC(...)**

Spindle positioning to an absolute position (0 to 359.999 degrees). The positioning direction is determined either by the current direction of spindle rotation (spindle rotating) or the distance-to-go.

#### **SPOS[<n>]=IC(...)**

Spindle positioning to an incremental position (+/- 999999.99 degrees) in relation to the last programmed position. The positioning direction is defined by the sign of the path to be traversed.

#### **SPOS[<n>]=DC(...)**

Spindle positioning across the shortest path to an absolute position (0 to 359.999 degrees). The positioning direction is determined either by the current direction of spindle rotation (spindle rotating) or automatically by the control (spindle stationary).

#### **SPOS[<n>]=...**

Same functional sequence as SPOS [<n>]=DC(...).

#### **SPOS[<n>]=ACP(...)**

Approaches the position from the positive direction.

When positioning from a negative direction of rotation, the speed is decelerated to zero and accelerated in the opposite direction to execute the positive approach.

## SPOS[<n>]=ACN(...)

Approaches the position from the negative direction.

When positioning from a positive direction of rotation, the speed is decelerated to zero and accelerated in the opposite direction to execute the negative approach.

## M19 (DIN 66025)

M19 can be used to position the spindle. The position and the position approach mode are read here from the following setting data:

SD43240 \$SA\_M19\_SPOS[<n>] (spindle position for spindle positioning with M19)

SD43250 \$SA\_M19\_SPOSMODE[<n>] (spindle position for spindle positioning with M19)

The positioning options of M19 are identical to those of:

SPOS = <approach mode> <position/path>

M19 is output as an auxiliary function to the NC/PLC interface as an alternative to M3, M4, M5, and M70. The M19 block remains active in the interpolator for the duration of positioning (like SPOS).

Part programs using M19 as a macro (e.g. `DEFINE M19 AS SPOS = 0`) or as a subroutine, continue to remain executable. For the sake of compatibility with previous controls, the internal processing of M19 (NCK positions the spindle) can be disabled as shown in the following example:

```
MD22000 $MC_AUXFU_ASSIGN_GROUP[0] = 4 ; Auxiliary function group: 4
MD22010 $MC_AUXFU_ASSIGN_TYPE[0] = "M" ; Auxiliary function type: "M"
MD22020 $MC_AUXFU_ASSIGN_EXTENSION[0] = 0 ; Auxiliary functions expansion: 0
MD22030 $MC_AUXFU_ASSIGN_VALUE[0] = 19 ; Auxiliary function value: 19
```

## Implicitly generated auxiliary function M19

To achieve uniformity in terms of how M19 and SPOS or SPOSA behave at the NC/PLC interface, auxiliary function M19 can be output to the NC/PLC interface in the event of SPOS and SPOSA.

The two following options are available for activating this function:

- Channel-specific activation for all the spindles in the channel via the machine data:  
MD20850 \$MC\_SPOS\_TO\_VDI (Output of M19 to the PLC with SPOS/SPOSA)

| Bit | Value | Meaning                                                                                                                                                                                                        |
|-----|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 0     | If bit 19 is also set to "0" in the MD35035 \$MA_SPIND_FUNCTION_MASK, no auxiliary function M19 is generated in SPOS and SPOSA. This therefore eliminates the acknowledgement time for the auxiliary function. |
|     | 1     | The auxiliary function M19 is generated and output to the PLC during the programming of SPOS and SPOSA in the part program. The address extension corresponds to the spindle number.                           |

- Spindle-specific and cross-channel activation via the machine data:

MD35035 \$MA\_SPIND\_FUNCTION\_MASK (spindle functions)

| Bit | Value | Meaning                                                                                                                                                                                               |
|-----|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19  | 0     | If bit 0 is also set to "0" in the MD20850 \$MC_SPOS_TO_VDI, no auxiliary function M19 is generated in SPOS and SPOSA. This therefore eliminates the acknowledgement time for the auxiliary function. |
|     | 1     | The implicit auxiliary function M19 is generated and output to the PLC during the programming of SPOS and SPOSA. The address extension corresponds to the spindle number.                             |

---

#### Note

Activation via MD35035 should be preferred when using a spindle in multiple channels (axis/spindle exchange).

---

The auxiliary function M19 is implicitly generated if either of the MD configurations = 1.

After activation, the minimum duration of an SPOS/SPOSA block is increased to the time for output and acknowledgment of the auxiliary functions by the PLC.

The properties of the implicitly generated auxiliary function output M19 are "Quick" and "Output during motion". These properties are fixed settings and are independent of the M19 configuration in the auxiliary function-specific machine data (MD...\_\$M...\_AUXFU...).

There is **no** auxiliary function M19 implicitly generated in the case of spindle positioning instructions via FC 18.

## End of positioning

The positioning can be programmed with:

FINEA[S<n>]: End of motion on reaching "Exact stop fine" (DB31, ... DBX60.7)  
 COARSEA[S<n>]: End of motion on reaching "Exact stop coarse" (DB31, ... DBX60.6)  
 IPOENDA[S<n>]: End of motion on reaching "IPO stop"

In addition, an end-of-motion criterion for block changes can be set in the braking ramp (100-0%) with IPOBRKA for single-axis interpolation.

#### References:

Function Manual, Extended Functions; Positioning Axes (P2)

## Block change

The program advances to the next block if the end-of-motion criteria for all spindles or axes programmed in the current block, plus the block change criterion for path interpolation, are fulfilled. This applies to both part-program and technology-cycle blocks.

SPOS, M19 and SPOSA have the same functionality but differ in their block change behavior:

- SPOS and M19

The block change is carried out if all functions programmed in the block have reached their end-of-block criterion (e.g. all auxiliary functions acknowledged by the PLC, all axes have reached their end points) and the spindle has completed its positioning motion.

- SPOSA

The program moves to the next block if all the functions (except for spindle) programmed in the current block have reached their end-of-block criterion. If `SPOSA` is the only entry in the block, block change is performed immediately. The spindle positioning operation may be programmed over several blocks (see `WAITS`).

## Coordination

A coordination of the sequence of motions can be achieved with:

- PLC
- MD configuration
- Programming in the part program

### PLC

If the NC/PLC interface signal:

DB31, ... DBX83.5 (spindle in the setpoint range)

is not available, then the channel-specific NC/PLC interface signal:

DB21, ... DBX 6.1 (read-in inhibit)

can be set in order to wait for a spindle to reach a certain position.

### MD configuration

Setting:

MD35500 \$MA\_SPIND\_ON\_SPEED\_AT\_IPO\_START = 1

is used to perform path interpolation taking the tolerance:

MD35150 \$MA\_SPIND\_DES\_VELO\_TOL

into account only if the spindle has rotated up to the preselected speed.

The setting

MD35500 \$MA\_SPIND\_ON\_SPEED\_AT\_IPO\_START = 2

is used to stop traveling path axes before the start of machining at the last G0.

Machining continues:

- On the next traversing command
- If the spindle speed is reached
- When MD35510 \$MA\_SPIND\_STOPPED\_AT\_IPO\_START = 1 (path feed enable, if spindle stationary)

### Programming in the part program

Coordination actions in the part program have the following advantages:

- The part program author can decide at what point in the program the spindle needs to be up to speed, e.g. in order to start machining a workpiece.
- This avoids unnecessary delays.

Coordination in the part program involves programming the `WAITS` instruction:

|                                                 |                                                           |
|-------------------------------------------------|-----------------------------------------------------------|
| <code>WAITS:</code>                             | for main spindle (master spindle)                         |
| <code>WAITS [&lt;n&gt;]:</code>                 | for spindles with number <n>                              |
| <code>WAITS [&lt;n&gt;, &lt;m&gt;, ...]:</code> | for several spindles up to the maximum number of spindles |

### CAUTION

The part program author must ensure that one of the following maintenance conditions occurs for `WAITS`.

- Position reached
- Spindle stationary
- Spindle up to programmed speed

In cases where one spindle is used in several channels, the part program author must ensure that `WAITS` starts at the earliest in the phase in which the spindle from another channel has already started to accelerate or decelerate towards the required new speed or direction of rotation.

The control waits before executing subsequent blocks until:

- position(s) programmed with `SPOSA` are reached.
- spindle standstill is reached with M5:  
DB31, ..., DBX 61.4 (spindle stationary)  
taking into account the tolerance:  
MD36060 `$MA_STANDSTILL_VELO_TOL`  
WAITS is terminated and the next block loaded when the first occurrence of the signal is detected.
- In M3/M4 (speed control mode), the speed in the setpoint range is:  
DB31, ..., DBX83.5 (spindle in setpoint range)  
taking into account the tolerance:  
MD35150 `$MA_SPIND_DES_VELO_TOL`  
WAITS is terminated and the next block loaded when the first occurrence of the signal is detected.  
  
This WAITS function applies in the programmed channel.  
  
WAITS can be used to wait for all spindles known to this channel, although spindles may also have been started in other channels.

### Special cases

- **Tolerance for spindle speed:**  
If the machine data setting is:  
MD35150 `$MA_SPIND_DES_VELO_TOL` = 0  
the NC/PLC interface signal:  
DB31, ... DBX83.5 (spindle in setpoint range)  
is always set to 1.  
  
WAITS is terminated as soon as the spindle has reached the setpoint-side target after a change in speed or direction (M3/M4).
- **Missing enable signals:**  
If the WAITS function waits for the "Spindle in setpoint range" signal in speed control mode and the spindle stops or fails to rotate because an enable signal (axial feed enable, controller, pulse enable, etc.) is missing, the block is not terminated until the "Spindle in setpoint range" signal is active, once enable signals are being received again.
- **Response to NC and mode-group stop:**  
If an NC or mode-group stop is triggered during WAITS, the wait operation is resumed after the NC start with all the above conditions.

---

#### Note

In particular when using spindles across different channels, care should be taken when programming not to start WAITS too early in one channel, i.e. at a time when the spindle in the other channel is still rotating at its "old" speed.  
In such cases, the "Spindle in setpoint range" signal is activated and WAITS is stopped too soon.  
To prevent this happening, it is strongly recommended to set a WAITM before WAITS.

---

## Feed

The positioning speed is configured in the machine data:

MD35300 \$MA\_SPIND\_POSCTRL\_VELO (position control switching speed)

The configured positioning speed can be modified by programming or by synchronized actions:

FA[S<n>]=<value>

where: <n>: Spindle number  
<value>: Positioning speed in degrees/min

With FA[S<n>]=0, the configured speed takes effect.

## Acceleration

The accelerations are configured in the machine data:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL (acceleration in position control mode)

MD35200 \$MA\_GEAR\_STEP\_SPEEDCTRL\_ACCEL (acceleration in the speed control mode)

The configured dynamic response during positioning can be modified by programming or by synchronized actions:

ACC[S<n>]=<value>

where: <n>: Spindle number  
<value>: Acceleration as a percentage of the configured acceleration

With ACC[S<n>]=0, the configured acceleration takes effect.

## Aborting the positioning process

The positioning action is aborted:

- By the NC/PLC interface signal:  
DB31, ... DBX2.2 (delete distance to go / spindle reset)
- With every reset (e.g. operator panel front reset)
- by NC-STOP.

The abort response is independent of the machine data:

MD35040 \$MA\_SPIND\_ACTIVE\_AFTER\_RESET (individual spindle reset)

## Special features

The spindle override switch is active.

## 16.2.5.2 Positioning from rotation

### Initial situation

The spindle can be in speed control mode or in position control mode when positioning starts (SPOS, M19 or SPOSA command in the program).

One must distinguish between the following cases:

|         |                                                                     |
|---------|---------------------------------------------------------------------|
| Case 1: | Spindle in speed control mode, encoder limit frequency exceeded     |
| Case 2: | Spindle in speed control mode, encoder limit frequency not exceeded |
| Case 3: | Spindle in position control mode                                    |
| Case 4: | Spindle speed < Position-control activation speed                   |

### Procedure

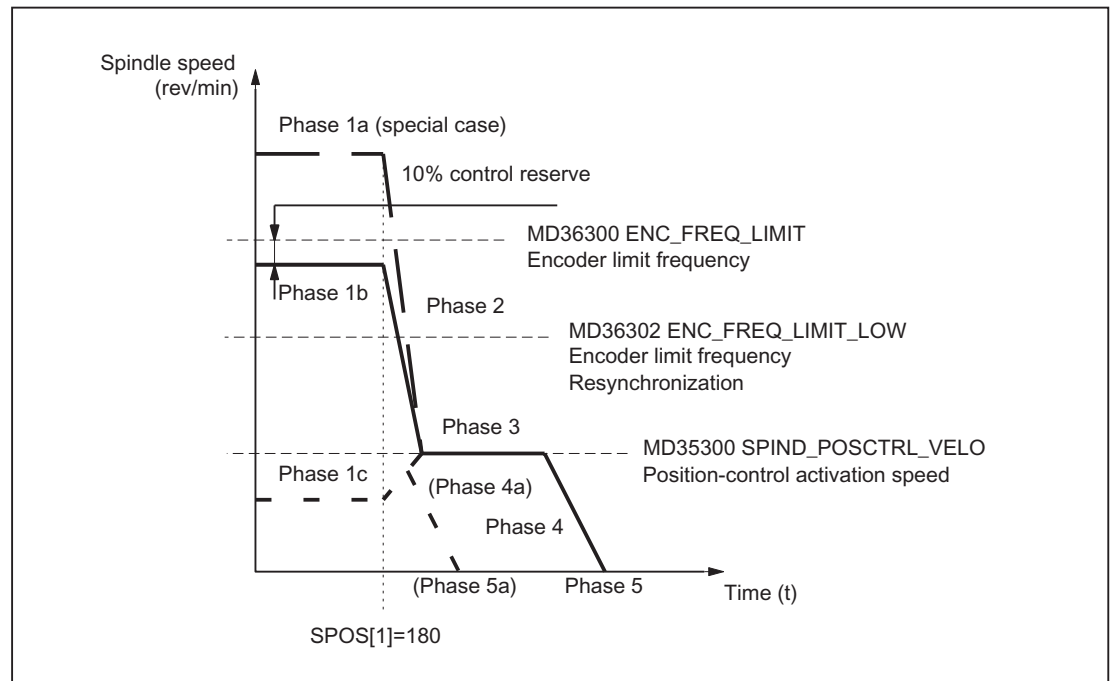

Figure 16-1 Positioning from rotation

### Note

The speed arising from the configuration of the encoder limit frequency for the resynchronization of the encoder (MD36302 \$MA\_ENC\_FREQ\_LOW) must be greater than the position-control activation speed (MD35300 \$MA\_SPIND\_POSCTRL\_VELO).

## Phase 1

### Positioning from phase 1a:

The spindle is rotating at a higher speed than the encoder limit frequency. The spindle is not synchronized.

### Positioning from phase 1b:

The spindle is rotating at a lower speed than the encoder limit frequency. The spindle is synchronized.

---

### Note

If the position control is active, the speed can only amount to 90% of the maximum speed of the spindle or the encoder limit frequency (10% control reserve required).

---

### Positioning from phase 1c:

The spindle rotates at the programmed spindle speed whereby the speed is lower than the configured position-control activation speed:

MD35300 \$MA\_SPIND\_POSCTRL\_VELO

The spindle is synchronized.

## Phase 2

### Spindle speed > Position-control activation speed

When the `SPOS`, `M19` or `SPOSA` command is activated, the spindle begins to slow down to the position-control activation speed with the configured acceleration:

MD35200 \$MA\_GEAR\_STEP\_SPEEDCTL\_ACCEL

The spindle is synchronized once the encoder limit frequency threshold is crossed.

### Spindle speed < Position-control activation speed

`SPOS`, `M19` or `SPOSA` are programmed to switch the spindle to position control mode (if it is not already in that mode).

The configured acceleration in position control mode is activated:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

The travel path to the target point is calculated.

The spindle travels to the programmed end point optimally in terms of time. This means that the end point is approached at the highest possible speed (maximum MD35300 \$MA\_SPIND\_POSCTRL\_VELO). Depending on the appropriate secondary conditions, phases 2 - 3 - 4 - 5 or 4a - 5a are executed.

### Phase 3

#### Spindle speed > Position-control activation speed

When the configured position-control activation speed (MD35300 \$MA\_SPIND\_POSCTRL\_VELO) is reached:

- Position control is activated (if not already active).
- The distance-to-go (to the target point) is calculated.
- There is a switch to the configured configured acceleration in position control mode (or this acceleration is retained):

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

#### Spindle speed < Position-control activation speed

The spindle was accelerated up to the configured position-control activation speed (MD35300 \$MA\_SPIND\_POSCTRL\_VELO) to reach the end point. This is not exceeded.

The braking start point calculation detects when the programmed spindle position can be approached accurately at the acceleration configured in position control mode (MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL).

### Phase 4

#### Spindle speed > Position-control activation speed

The spindle brakes from the calculated "braking point" with machine data: MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL to the target position.

#### Spindle speed < Position-control activation speed

At the time identified by the braking start point calculation in phase 3, the spindle brakes to a standstill with the acceleration configured in position control mode (MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL).

#### Phase 4a:

When the `SPPOS` command is activated the proximity of the end point is such that the spindle can no longer be accelerated to the configured position-control activation speed (MD35300 \$MA\_SPIND\_POSCTRL\_VELO).

The spindle brakes to a standstill with the acceleration configured in position control mode (MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL).

### Phase 5

#### Spindle speed > Position-control activation speed

Position control remains active and holds the spindle in the programmed position.

---

#### Note

The maximum encoder limit frequency of the spindle position actual-value encoder is monitored by the control (it may be exceeded); in position control mode, the setpoint speed is reduced to 90% of the measuring system limit speed.

The following NC/PLC interface signal is set:

DB31, ... DBX83.1 (programmed speed too high)

If "MS limit frequency exceeded" is still pending following a reduction in the setpoint speed, an alarm is output.

---

**Spindle speed < Position-control activation speed (Phase 5, 5a)**

The spindle is stationary and it has reached the position. The position control is active and stops the spindle in the programmed position.

If the distance between the spindle actual position and the programmed position (spindle setpoint position) is less than the configured exact stop fine and coarse limits, the following NC/PLC interface signals are set:

DB31, ... DBX60.7 (Position reached with coarse exact stop)

DB31, ... DBX60.7 (Position reached with fine exact stop)

The exact stop limits are defined with the machine data:

MD36010 \$MA\_STOP\_LIMIT\_FINE (exact stop fine)

MD36000 \$MA\_STOP\_LIMIT\_COARSE (exact stop coarse)

---

**Note**

The positioning procedure is considered complete when the end-of-positioning criterion is reached and signaled.

The condition is "Exact stop fine". This applies to *SPOS*, *M19* or *SPOSA* from the part program, synchronized actions and spindle positioning by the PLC using FC 18.

---

### 16.2.5.3 Positioning from standstill

#### Procedure

A distinction is made between two cases with regard to positioning from standstill:

- Case 1: The spindle is not synchronized.

This is the case if the spindle is to be positioned after switching on the control and drive or after a gear step change (e.g. for a tool change).

MD31040 \$MA\_ENC\_IS\_DIRECT = 0

- Case 2: The spindle is synchronized.

This is the case if, after switching on the control and drive, the spindle is to be rotated through a minimum of one revolution with M3 or M4 and then stopped with M5 (synchronization with the zero mark) before the first positioning action.

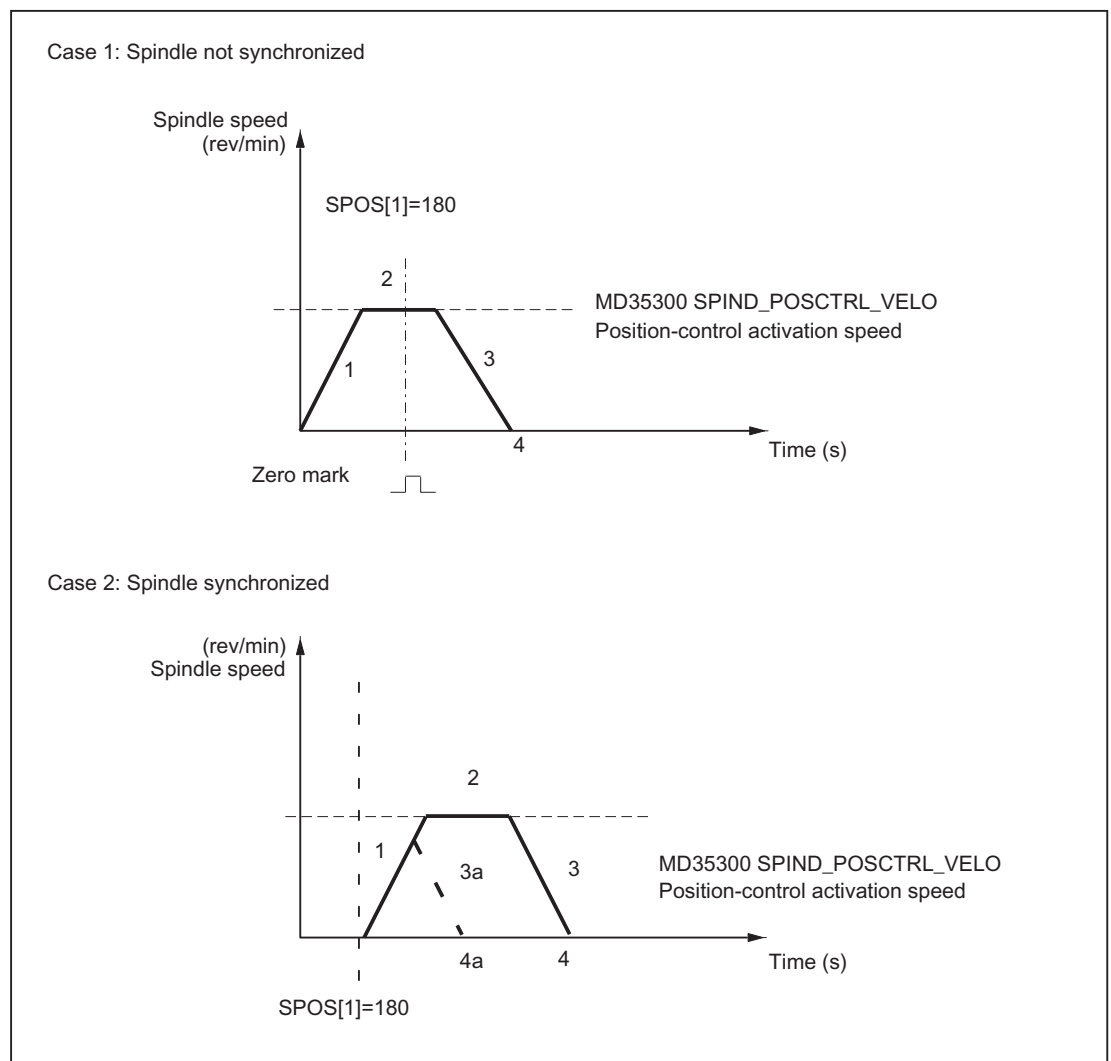

Figure 16-2 Positioning with stationary spindle

## Phase 1

### Case 1: Spindle not synchronized

With the programming of `SPOS`, `M19` or `SPOSA` the spindle accelerates with the acceleration from the machine data:

MD35200 `$MA_GEAR_STEP_SPEEDCTRL_ACCEL` (Acceleration in the speed control mode)

This direction of rotation is defined by the machine data:

MD35350 `$MA_SPIND_POSITIONING_DIR` (Direction of rotation while positioning to standstill)

Exception:

If `ACN`, `ACP`, `IC` is used for positioning, the programmed direction of travel is activated.

The spindle is synchronized at the next zero mark of the spindle position actual-value encoder and switches to the position control mode.

Whether the zero mark is found in the traversed path (except for `IC`), is monitored:

MD34060 `$MA_REFP_MAX_MARKER_DIST` (maximum distance to the reference mark)

If the speed defined in machine data:

MD35300 `$MA_SPIND_POSCTRL_VELO` (Positioning speed)

is reached before the spindle is synchronized, the spindle will continue to rotate at the positioning activation speed (it is not accelerated further).

### Case 2: Spindle synchronized

`SPOS`, `M19` or `SPOSA` will switch the spindle to position control mode.

The acceleration from the following machine data is active:

MD35210 `$MA_GEAR_STEP_POSCTRL_ACCEL` (acceleration in position control mode)

The direction of rotation is defined by the programmed motion (`ACP`, `ACN`, `IC`, `DC`) or via the pending distance-to-go.

The speed entered in

MD35300 `$MA_SPIND_POSCTRL_VELO` (position control activation speed)

is not exceeded in the machine data.

The travel path to the end position is calculated.

The spindle travels to the programmed end point optimally in terms of time. This means that the end point is approached at the highest possible speed (maximum MD35300 `$MA_SPIND_POSCTRL_VELO`). Depending on the appropriate secondary conditions, the phases 1 - 2 - 3 - 4 or 1- 3a - 4a are executed.

## Phase 2

### Case 1: Spindle not synchronized

When the spindle is synchronized, position control is activated.

The spindle rotates at the maximum speed stored in machine data:

MD35300 `$MA_SPIND_POSCTRL_VELO`

until the braking start point calculation identifies the point at which the programmed spindle position can be approached accurately with the defined acceleration.

### Case 2: Spindle synchronized

To reach the end point, the spindle is accelerated up to the speed defined in machine data:  
MD35300 \$MA\_SPIND\_POSCTRL\_VELO.  
This is not exceeded.

The braking start point calculation identifies when the programmed spindle position can be approached accurately at the acceleration defined in machine data:  
MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL.

At the point, which is determined by the braking start point calculation in Phase 1, the spindle decelerates to a standstill with the acceleration given in the following machine data:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

### Phase 3

At the point, which is determined by the braking start point calculation in Phase 2, the spindle decelerates to a standstill with the acceleration given in the following machine data:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

#### Phase 3a:

When the `SPPOS` command is activated the proximity of the end point is such that the spindle can no longer be accelerated up to machine data:  
MD35300 \$MA\_SPIND\_POSCTRL\_VELO.

The spindle is braked to a standstill with the acceleration given in the following machine data:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

### Phase 4, 4a

The spindle is stationary and it has reached the position. The position control is active and stops the spindle in the programmed position.

NC/PLC IS:

DB31, ... DBX60.6 (Position reached with exact stop coarse)

and

DB31, ... DBX60.7 (Position reached with exact stop fine)

are set if the distance between the spindle actual position and the programmed position (spindle setpoint position) is less than the settings for the exact stop fine and coarse limits.

This is defined in the machine data:

MD36010 \$MA\_STOP\_LIMIT\_FINE

MD36000 \$MA\_STOP\_LIMIT\_COARSE

**Phase 3:**

At the point, which is determined by the braking start point calculation in Phase 2, the spindle decelerates to a standstill with the acceleration given in the following machine data:

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

**Phase 4:**

The spindle is stationary and it has reached the position. The position control is active and stops the spindle in the programmed position.

NC/PLC IS:

DB31, ... DBX60.6 (Position reached with exact stop coarse)

and

DB31, ... DBX60.7 (Position reached with exact stop fine)

are set if the distance between the spindle actual position and the programmed position (spindle setpoint position) is less than the settings for the exact stop fine and coarse limits.

This is defined in the machine data:

MD36010 \$MA\_STOP\_LIMIT\_FINE

MD36000 \$MA\_STOP\_LIMIT\_COARSE

#### 16.2.5.4 "Spindle in position" signal for tool change

##### Function

The motion sequence for a tool change, especially for milling machines, mainly comprises positioning the spindle and then the subsequent (for optimization runs, also at the same time) approach to the tool change position with the path axes. In this case, the mandatory precondition is that the spindle is reached before approaching the tool change position.

If the tool change cycle is interrupted by the machine operator (e.g. with an NC stop, NC stop axes plus spindles, mode group stop etc.), then it must be completely ruled out that the spindle moves into the tool changer at an incorrect position.

This is the reason that for spindle positioning, when the last programmed spindle position is reached with "Exact stop fine" the following NC/PLC interface signal is output to check the position:

DB31, ... DBX85.5 (spindle in position)

---

**Note**

The signal is only output for the "Spindle positioning" function.

This includes:

- SPOS, SPOSA and M19 in the part program
  - SPOS and M19 in synchronized actions
  - Spindle positioning, using FC18
  - Spindle positioning via PLC interface (DB31, ... DBX30.4)
-

## Setting the signal

Preconditions for output of signal DB31, ... DBX85.5 (spindle in position) are as follows:

- The reference state of the spindle:  
DB31, ... DBX60.4/5 (referenced/synchronized 1/2) = 1

---

### Note

When positioning the spindle, the zero mark is automatically searched for. This is the reason that for an error-free sequence, the referenced signal is always available at the end of positioning movement.

---

- "Exact stop fine" must have been reached:  
DB31, ... DBX60.7 (exact stop fine) = 1  
Additionally, the last programmed spindle position must have been reached on the setpoint side.

## Deleting the signal

When signal DB31, ... DBX60.7 is withdrawn (exact stop fine), then signal DB31, ... DBX85.5 (spindle in position) is also always reset.

## Additional properties

- If the spindle is already at the programmed position after a positioning, then the NC/PLC interface signal DB31, ... DBX85.5 (spindle in position) remains set.
- If, after a positioning ("Spindle in position" signal was output) the spindle is traversed, e.g. in the JOG mode, then the NC/PLC interface signal DB31, ... DBX85.5 (spindle in position) is deleted.

If the spindle is returned to its original position in this mode, then the NC/PLC interface signal DB31, ... DBX85.5 (spindle in position) is set again. The last position selection is kept.

## 16.2.6 Axis mode

### 16.2.6.1 General functionality

#### Why axis mode?

For certain machining tasks (e.g. on lathes with end-face machining), the spindle not only has to be rotated with M3, M4 and M5 and positioned with SPOS, M19 and SPOSA, but also addressed as an axis with its axis identifier (e.g. "C").

### Prerequisites

- The same spindle motor is used for spindle mode and axis mode.
- The same position measurement system or separate position measurement systems can be used for spindle mode and axis mode.
- A position actual-value encoder is a mandatory requirement for axis mode.
- If the axis is not synchronized, e.g. M70 is programmed after POWER ON, the axis must first be referenced with G74. Only then does the mechanical position match the programmed one.

Example:

```
M70
G74 C1=0 Z100
G0 C180 X50
```

### Configurable M function

The M function used to switch the spindle to axis mode can be configured in the machine data:

MD20094 \$MC\_SPIND\_RIGID\_TAPPING\_M\_NR

The value on delivery is 70.

---

#### Note

From software version 2.6, the control system detects the transition to axis mode automatically from the program sequence (see "Implicit transition to axis mode (Page 1305)"). Therefore, there is no need at all for the explicit programming in the part program of the configured M function for switching the spindle to axis mode (default: M70). However, the M function can continue to be programmed, e.g. to increase the readability of the part program.

---

### Functionality

If the axis mode is active and the rotary axis homed, all axis functions can be used.

The most important functions are:

- Programming with axis name
- Use of zero offsets (G54, G55, TRANS, etc.)
- G90, G91, IC, AC, DC, ACP, ACN
- Use of kinematic transformations (e.g. TRANSMIT)
- Interpolation with other axes (path interpolation)
- Programming as a positioning axis

#### References:

Function Manual, Extended Functions; Rotary Axes (R2)

### Special points to be noted

- The feed override switch is active.
- NC/PLC IS:  
DB21, ... DBX7.7 (Reset)  
does not terminate axis mode as standard.
- The NC/PLC interface signals:  
DB31, ... DBB16 to DBB19 and DBB82 to DBB91  
are not important if:  
DB31, ... DBX60.0 (axis / no spindle) = 0
- Axis mode can be activated in all gear steps.  
  
If the position actual value encoder is installed on the motor (indirect measuring system), the positioning and contouring accuracy can vary for the different gear steps.
- The gear step cannot be changed when the axis mode is active.  
The spindle must be switched to control mode.  
This is done with M41 ... M45 or M5, SPCOF.
- In axis mode, the machine data from the servo parameter set with index zero are effective in order to carry out adaptations in this mode.

### Servo parameter set

The relevant machine data from the servo parameter set are:

| Machine data                       | Meaning                                                               |
|------------------------------------|-----------------------------------------------------------------------|
| MD31050 \$MA_DRIVE_AX_RATIO_DENOM  | Measuring gear denominator                                            |
| MD31060 \$MA_DRIVE_AX_RATIO_NUMERA | Numerator load gearbox                                                |
| MD32200 \$MA_POSCTRL_GAIN          | Kv factor                                                             |
| MD32452 \$MA_BACKLASH_FACTOR       | Weighting factor for backlash                                         |

## Dynamic response

The dynamic limits of the axis stored in the machine data are applicable in axis operation.

The axis switches to the current feedforward control mode as designated by the MD and the commands `FFWON` and `FFWOF`.

## Use of resolution changes

When using resolution changes in (analog) drive actuators, the following NC program steps are required:

### 1. Changeover to axis mode

| Programming | Comment                                                                       |
|-------------|-------------------------------------------------------------------------------|
| SPOS=...    |                                                                               |
| M5          | ; Controller enable off (by PLC)<br>→ is output on PLC                        |
| M70         | ; Switch actuator (by PLC on account of M70)<br>Controller enable on (by PLC) |
| C=...       | ; NC traverses with axis parameter set                                        |

### 2. Switch back to spindle mode

| Programming        | Comment                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C=...              |                                                                                                                                                                                               |
| M71                | ; → Output to PLC<br>Closed-loop controller enable off (by PLC)<br>Switch actuator (by PLC)<br>Switched to spindle parameter set (1-5) internally in<br>the NC, controller enable on (by PLC) |
| M3/4/5 or SPOS=... | ; NC traverses with spindle parameter set                                                                                                                                                     |

## Change to spindle mode

The interpolation parameter (set 1 ... 5) is selected according to the currently valid gear step.

The feedforward control function is always activated, except for tapping with compensating chuck.

Machine data:

MD32620 \$MA\_FFW\_MODE (feedforward control type)  
must always be not equal to 0.

Feedforward control should always be operated with the value 100% to avoid alarms being output during positioning.

| Parameter set | Axis mode | Spindle mode |
|---------------|-----------|--------------|
| 0             | Valid     |              |
| 1             |           | Valid        |
| 2             |           | Valid        |
| 3             |           | Valid        |
| 4             |           | Valid        |
| 5             |           | Valid        |

Depending on gear step

Figure 16-3 Validity of parameter sets for axis and spindle modes

### 16.2.6.2 Implicit transition to axis mode

#### Function

The control system detects the transition to axis mode automatically from the program sequence and generates the requisite M70 sequence within the control system. The situation will dictate which steps are performed. At most, these will include:

1. Stopping the spindle
2. Switching on of the position control, treatment of feedforward control, and parameter block changeover
3. Position synchronization of the block preparation (internal preprocessing stop, if necessary)

This function is always active. Explicit programming of M70 in the part program is, therefore, essentially not necessary.

#### Procedure

Sequence of the implicit transition to axis mode (M70 is not programmed in the part program):

- Transition from speed control mode (M3, M4, M5, SPCOF, ...) to axis mode:  
The transition is detected internally by the control, and an intermediate block is inserted in front of the block which requests the axis mode. The block created contains the M70 functionality. The execution duration for this block is more or less the same as the time required to execute a programmed M70 block. Differences may arise in the event of short switchovers when the spindle is stationary (no braking time) if the implicit generation and output of the auxiliary function M70 to the PLC is dispensed with (see MD35035).
- Transition from positioning mode (M19, SPOS, SPOSA) to axis mode:  
The transition is executed immediately and without the generation of an intermediate block. Configured accordingly (see MD35035), the auxiliary function M70, which is generated implicitly, is output to the PLC when the block in which the spindle has its axis mode is loaded.

## Output of auxiliary functions to PLC

The implicit transition to axis mode can be notified to the PLC in the form of an auxiliary function output.

### Activation/deactivation

The activation/deactivation of this functionality is done using machine data:

MD35035 \$MA\_SPIND\_FUNCTION\_MASK (spindle functions)

| Bit | Value | Meaning                                                                                                                                                                                         |
|-----|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20  | 0     | No auxiliary function output to the PLC in the case of M70 functionality which is generated inside the control.                                                                                 |
|     | 1     | In the case of M70 functionality which is generated inside the control, the auxiliary function M70 is generated and output to the PLC. The address extension corresponds to the spindle number. |

### Note

An auxiliary function M70 which is programmed in the part program is always output to the PLC.

### Properties

The properties of the implicitly generated auxiliary function output M70 are "Quick" and "Output during motion". These properties are fixed settings and are independent of the M70 configuration in the auxiliary-function-specific machine data (MD...\_\$M...\_AUXFU...).

M70 is only generated once during transition to axis mode. No further M70 auxiliary functions are generated and output in adjacent blocks in which the spindle is operated as an axis. M70 is not implicitly generated and output again until axis mode is exited via, for example, SPOS, M3, M4, M5, SPCOF, etc. and following a renewed transition to axis mode.

## Constraints

### Synchronized actions

When the spindle is programmed as an axis in synchronized actions, it is essential to continue making provisions in the application to ensure there are criteria for the transition to axis mode.

If the spindle is in speed control mode, the instruction `M70` or `SPOS` must be programmed prior to programming as an axis. Otherwise alarm signals occur during axis programming.

### FC 18

As with synchronized actions, transition to axis mode must also be undertaken on the application side in FC 18, e.g. through preparatory positioning instructions. Otherwise, the FC 18 call is acknowledged with an error bit in the FC 18 status word.

**No** auxiliary function M70 is implicitly generated in the event of transition to axis mode through programming via FC 18.

## Examples

### Example 1:

#### Part program: Transition from rotating spindle to axis mode

Configuration: MD35035 \$MA\_SPIND\_FUNCTION\_MASK, bit 20 = 1

| Program code  | Comment                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------|
| N05 M3 S1000  |                                                                                                                             |
| N10 ...       |                                                                                                                             |
| N15 POS[C]=77 | ; Before loading N15, an M70 intermediate block is generated in which the spindle is stopped, and M70 is output to the PLC. |
| ...           |                                                                                                                             |

### Example 2:

#### Part program: Transition from positioning mode to axis mode

Configuration: MD35035 \$MA\_SPIND\_FUNCTION\_MASK, bit 20 = 1

| Program code | Comment                                                         |
|--------------|-----------------------------------------------------------------|
| N05 SPOS=0   |                                                                 |
| N10 ...      |                                                                 |
| N15 C77      | ; Output of the implicit M70 to the PLC, no intermediate block. |
| ...          |                                                                 |

### Example 3:

#### Synchronized actions: Transition from spindle positioning mode to axis mode

Configuration: MD35035 \$MA\_SPIND\_FUNCTION\_MASK, bit 20 = 1

| Program code                   | Comment                                  |
|--------------------------------|------------------------------------------|
| WHEN COND1==TRUE DO SPOS=180   |                                          |
| WHEN COND2==TRUE DO POS[C]=270 | ; Output of the implicit M70 to the PLC. |

### Example 4:

#### Synchronized actions: Transition from speed control mode to axis mode with M70

Configuration: MD35035 \$MA\_SPIND\_FUNCTION\_MASK, bit 20 = 1

| Program code                    | Comment                                                              |
|---------------------------------|----------------------------------------------------------------------|
| WHEN COND11==TRUE DO M3 S1000   |                                                                      |
| WHEN COND12==TRUE DO M70        | ; Output of M70 to the PLC.                                          |
| WHEN COND13==TRUE DO POS[C]=270 | ; No generation of an implicit M70 because axis mode already exists. |

**Example 5:**

**Synchronized actions: Invalid transition from speed control mode to axis mode**

Configuration: MD35035 \$MA\_SPIND\_FUNCTION\_MASK, bit 20 = 1

| Program code                    | Comment        |
|---------------------------------|----------------|
| WHEN COND21==TRUE DO M3 S1000   |                |
| WHEN COND22==TRUE DO POS[C]=270 | ; Alarm 20141! |

**16.2.7 Initial spindle state**

**Spindle basic setting**

The following machine data is used to specify a spindle mode as basic setting:

MD35020 \$MA\_SPIND\_DEFAULT\_MODE

| Value | Spindle basic setting                           |
|-------|-------------------------------------------------|
| 0     | Speed control mode, position control deselected |
| 1     | Speed control mode, position control activated  |
| 2     | Positioning mode                                |
| 3     | Axis mode                                       |

**Time when the spindle basic setting takes effect**

The time when the spindle basic setting takes effect is set in the machine data:

MD35030 \$MA\_SPIND\_DEFAULT\_ACT\_MASK

| Value | Effective time                |
|-------|-------------------------------|
| 0     | POWER ON                      |
| 1     | POWER ON and program start    |
| 2     | POWER ON and RESET (M2 / M30) |

## 16.3 Reference / synchronize

### Why synchronize?

In order to ensure that the control detects the exact position of the spindle when it is switched on, the control must be synchronized with the position measuring system of the spindle.

The following functions are possible only with a synchronized spindle:

- Thread cutting
- Rigid tapping
- Axis programming

#### References:

For further explanations about synchronization of the spindle, see Function Description "R1: Reference point approach (Page 1223)".

### Why reference?

In order to ensure that the control detects the exact machine zero when it is switched on, the control must be synchronized with the position measurement system of the rotary axis. This process is known as referencing. The sequence of operations required to home an axis is known as homing.

Only a homed axis can approach a programmed position accurately on the machine.

#### References:

For further explanations about referencing the rotary axis, see Function Description "R1: Reference point approach (Page 1223)".

### Installation position of the position measurement system

The position measurement systems can be installed as follows:

- Direct on the motor in combination with a Bero proximity switch on the spindle as a zero-mark encoder
- On the motor via a measuring gearbox in combination with a Bero proximity switch on the spindle as a zero-mark encoder
- Directly on the spindle
- On the spindle via a measuring gearbox in combination with a Bero proximity switch on the spindle as a zero-mark encoder (only with ratios not equal to 1:1)

Where two position measuring systems are provided, they can be installed either in the same location or separately.

**Synchronization procedure**

When the spindle is switched on, the spindle can be synchronized as follows:

- The spindle is started with a spindle speed (*S* value) and a spindle rotation (*M3* or *M4*) and synchronized with the next zero mark of the position measurement system or with the next Bero signal.
- The spindle is to be positioned from standstill using *SPOS*, *M19* or *SPOSA*. The spindle synchronizes with the next zero mark of the position measurement system or with the next Bero signal. It is then positioned to the programmed position.
- The spindle can be synchronized from the movement (after *M3* or *M4*) using *SPOS*, *M19* or *SPOSA*.

The responses are as follows:

- With *SPOS*=<Pos>, *SPOS*=DC (<Pos>) and *SPOS*=AC (<Pos>), the direction of motion is retained and the position is approached.
- With *SPOS* = ACN (<Pos>) or *SPOS* = ACP (<Pos>), the position is always approached with a negative or positive direction of motion. If necessary, the direction of motion is inverted prior to positioning.
- Crossing the zero mark in JOG mode by means of direction keys in speed control mode.

---

**Note**

If does not make any difference whether the synchronization procedure is initiated from the part program, FC 18 or synchronized actions.

---

---

**Note**

During synchronization of the spindle, all four possible home position values are effective depending on the measuring system selected. The measurement system offset has the same effect.

The following machine data must be observed:

- MD34080 \$MA\_REFP\_MOVE\_DIST  
(Reference point distance/destination point for a distance-coded system)
- MD34090 \$MA\_REFP\_MOVE\_DIST\_CORR  
(Reference point offset/absolute offset, distance-coded)
- MD34100 \$MA\_REFP\_SET\_POS  
(Reference point value, with distance-coded system without any significance)

If a non-homed spindle with *SPOS*=IC (...) and a path < 360 degrees is positioned, it may be the case that the zero mark is not crossed and the spindle position is still not synchronized with the zero mark. This can happen:

- after POWER ON
  - by setting the axial NC/PLC interface signals:  
DB31, ... DBX17.5 (resynchronize spindle when positioning 2)  
DB31, ... DBX17.4 (resynchronize spindle when positioning 1)
-

## Special features for synchronization with BERO

The position falsification caused by the signal delay with BERO can be corrected internally in the NC by entering a signal runtime compensation.

The signal runtime compensation is set by means of the machine data:

- MD31122 \$MA\_BERO\_DELAY\_TIME\_PLUS  
(BERO delay time for a positive direction of motion)
- MD31123 \$MA\_BERO\_DELAY\_TIME\_MINUS  
(BERO delay time for a negative direction of motion)

The effect depends on the setting in machine data:

MD34200 \$MA\_ENC\_REFP\_MODE (referencing mode)

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MD34200 = 7 | <p>The setting MD34200 \$MA_ENC_REFP_MODE = 7 only executes position synchronization at a velocity/speed which is fixed in machine data:</p> <p>MD34040 \$MA_REFP_VELO_SEARCH_MARKER (reduced velocity)</p> <p>The zero mark is not automatically sought, it has to be requested explicitly with the 0-1 edge of the NC/PLC interface signal:<br/>DB31, ... DBX16.4/5 (resynchronize spindle 1/2*)</p> <p>*) 1/2 stands for the selected measuring system.</p> <p>The velocity defined in MD34040 is also effective when referencing in JOG-REF mode and through the part program with G74.</p> |
| MD34200 = 2 | <p>Setting MD34200 \$MA_ENC_REFP_MODE = 2 executes position synchronization without specifying a specific velocity/speed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

---

### Note

Compensating the signal runtime via the NC requires the use of SIMODRIVE 611D drives. Signal propagation delays are preset on delivery so that the content generally does not have to be changed.

---

## Homing sequence

If the spindle is to be programmed in axis mode directly after control power up, it must be ensured that the axis is homed.

When the control is switched on, the spindle can be homed (condition is one zero mark per revolution).

### References:

For information about the referencing procedure, see Function Description "R1: Reference point approach (Page 1223)".

The rotary axis is referenced at the same time as the spindle is synchronized (see section "Synchronization procedure") if the position measuring system used for the spindle is also used for the rotary axis.

### Position measurement systems, spindle

The spindle can be switched from spindle mode to axis mode (rotary axis) if a single motor is used for spindle mode and axis mode.

The spindle (spindle mode and axis mode) can be equipped with one or two position measurement systems. With two position measurement systems, it is possible to assign one position measurement system to the spindle and the other to the rotary axis, or to assign two position measurement systems to the spindle. Where two position measurement systems are provided, both are updated by the control, but only one can be active.

The active position measuring system is selected using the NC/PLC interface signal:

DB31, ... DBX1.5 (position measuring system 1)

or

DB31, ... DBX1.6 (position measuring system 2)

The active position measurement system is required for the following functions:

- Position control of the spindle (*SPCON*)
- Spindle positioning (*SPOS*, *M19* and *SPOSA*)
- Thread cutting (*G33*, *G34*, *G35*)
- Tapping without compensating chuck (*G331*, *G332*)
- Revolutional feedrate (*G95*)
- Constant cutting rate (*G96*, *G961*, *G97*, *G971*)
- Spindle actual speed display
- Axis mode
- Synchronous spindle setpoint value linkage.

### Resynchronizing the position measuring system for the spindle

In the following cases, the spindle position measurement system must be resynchronized:

- The position encoder is on the motor, a Bero proximity switch is mounted on the spindle and a gear stage change is performed. Synchronization is triggered internally once the spindle is rotating in the new gear stage (see Synchronization procedure).
- The machine has a selector switch for a vertical and horizontal spindle. Two different position encoders are used (one for the vertical spindle and one for the horizontal spindle), but only one actual value input is used on the control. When the system switches from the vertical to the horizontal spindle, the spindle must be resynchronized.

This synchronization is initiated with the NC/PLC interface signal:

DB31, ... DBX16.4 (resynchronize spindle 1)

or

DB31, ... DBX16.5 (resynchronize spindle 2)

The spindle must be in open-loop control mode.

## Position restoration with POWER ON

For spindles with incremental position measuring systems, it is possible to buffer the actual values after a POWER OFF and after POWER ON, to restore the position last buffered before switching-off, in order that position-dependent functions such as e.g. transformation can be restored (see "Position restoration with POWER ON (Page 1245)"). One application is e.g. tool retraction after POWER OFF when machining with tool orientation (see "Tool withdrawal after POWER OFF with orientation transformation (Page 643)").

The following NC/PLC interface signals display the state of the position measuring system after position restoration:

DB31, ... DBX71.4 ("Restored 1") for position measuring system 1

DB31, ... DBX71.5 ("Restored 2") for position measuring system 2

Once the tool has been retracted in the JOG mode, axes whose positions have been restored are referenced. As a consequence, signals DB31, ... DBX71.4/5 ("Restored 1/2") are deleted and signals DB31, ... DBX60.4/5 ("Referenced/synchronized 1/2") are set.

---

### Note

If machine data MD20700 \$MC\_REFP\_NC\_START\_LOCK is set to a value of "2", then an NC start is also possible with "restored" axis positions (in the MDA mode or when overstoring).

---

## 16.4 Configurable gear adaptation

### 16.4.1 Gear steps for spindles and gear step change

#### Why do we need gear stages?

gear stages are used on spindles to step down the speed of revolution of the motor in order to generate a high torque at low spindle speeds or to step up in order to maintain a high speed.

#### No. of gear stages

5 gear stages can be configured for each spindle.

The number of used gear stages is defined in machine data:

MD35090 \$MA\_NUM\_GEAR\_STEPS

#### Parameterization of the gear stages

The gear stages 1 to 5 can be parameterized via the following machine data:

| Machine data                                  | Meaning                                              |
|-----------------------------------------------|------------------------------------------------------|
| MD35012 \$MA_GEAR_STEP_CHANGE_POSITION[<n>]   | Gear stage change position                           |
| MD35110 \$MA_GEAR_STEP_MAX_VELO[<n>]          | Maximum speed for automatic gear stage change        |
| MD35120 \$MA_GEAR_STEP_MIN_VELO[<n>]          | Minimum speed for automatic gear stage change        |
| MD35130 \$MA_GEAR_STEP_MAX_VELO_LIMIT[<n>]    | Maximum speed of gear stage                          |
| MD35135 \$MA_GEAR_STEP_PC_MAX_VELO_LIMIT[<n>] | Maximum speed of gear stage in position control      |
| MD35140 \$MA_GEAR_STEP_MIN_VELO_LIMIT[<n>]    | Minimum speed of gear stage                          |
| MD35200 \$MA_GEAR_STEP_SPEEDCTRL_ACCEL[<n>]   | Acceleration in speed control mode                   |
| MD35210 \$MA_GEAR_STEP_POSCTRL_ACCEL[<n>]     | Acceleration in position control mode                |
| MD35300 \$MA_SPIND_POSCTRL_VELO[<n>]          | position control activation speed                    |
| MD35310 \$MA_SPIND_POSIT_DELAY_TIME[<n>]      | Positioning delay time                               |
| MD35550 \$MA_DRILL_VELO_LIMIT[<n>]            | Maximum speed for tapping without compensating chuck |

### Type of gear stage change

The type of gear stage change is set in machine data:

MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE

| Bit | Value | Meaning                                                                                                                                                                                                                                                                                                                          |
|-----|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 0     | The spindle motor is attached to the spindle directly (1:1) or with a non-variable transmission ratio (basic setting).<br>The machine data of the first gear stage are effective.                                                                                                                                                |
|     | 1     | Spindle motor with up to 5 gear stages.<br>The gear stage change takes place: <ul style="list-style-type: none"> <li>• in oscillation mode</li> <li>• at indefinite change position</li> </ul>                                                                                                                                   |
| 1   | 0     | Meaning as in Bit 0 = 0.                                                                                                                                                                                                                                                                                                         |
|     | 1     | Meaning as in Bit 0 = 1, however, the gear stage change takes place at the configured spindle position.<br>The change position is set in machine data:<br>MD35012 \$MA_GEAR_STEP_CHANGE_POSITION<br>The position is approached in the current gear stage before the gear stage change.<br>If Bit 1 is set, the Bit 0 is ignored! |
| 3   | 1     | The gear stage change dialog between NCK and PLC is simulated.                                                                                                                                                                                                                                                                   |
| 5   | 1     | The second gear stage data set is used while tapping with G331/G332 (see the following paragraph "Second gear stage data set"). The bit must be set for the master spindle used during the tapping.                                                                                                                              |

### Requirement for a gear stage change

In principle, the gear stage change is only performed if the requested gear stage is not the same as the active gear stage.

### Parameter set selection during gear stage change

The servo parameter set is also changed over with the gear stage if:

MD35590 \$MA\_PARAMSET\_CHANGE\_ENABLE = 0 or 1

For further information, please refer to Chapter "Parameter set selection during gear step change (Page 1329)".

### Request gear stage change

A gear stage change can be requested:

- in the part program using:
  - M40 S...  
Automatic gear stage selection to the programmed speed s...
  - M41 ... M45  
Direct selection of gear stages 1 ... 5
  - M70  
For MD35014 \$MA\_GEAR\_STEP\_USED\_IN\_AXISMODE = 1 ... 5  
(see "Configurable gear step in M70 (Page 1347)")
  - G331 S...  
For MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE, Bit 5 = 1
- in synchronized actions using:
  - DO M40 S...  
Automatic gear stage selection to the programmed speed s...
  - DO M41... M45  
Direct selection of gear stages 1 ... 5
  - DO M70  
For MD35014 \$MA\_GEAR\_STEP\_USED\_IN\_AXISMODE = 1 ... 5
- through the PLC using the FC18 function block
- in the reset state through description of NC/PLC interface:  
DB31, ... DBX16.0-16.2 (actual gear stage A to C)  
The mechanically active gear stage can be communicated to the NC especially after a POWER ON.

---

#### Note

If the spindle motor is attached to the spindle directly (1:1) or with a non-variable transmission ratio (MD35010 = 0), then the M40 and M41 ... M45 auxiliary functions are not relevant to this spindle.

---

## Gear stage change

gear stage selection between two gear stages with specification of a maximum spindle speed is shown in the example below:

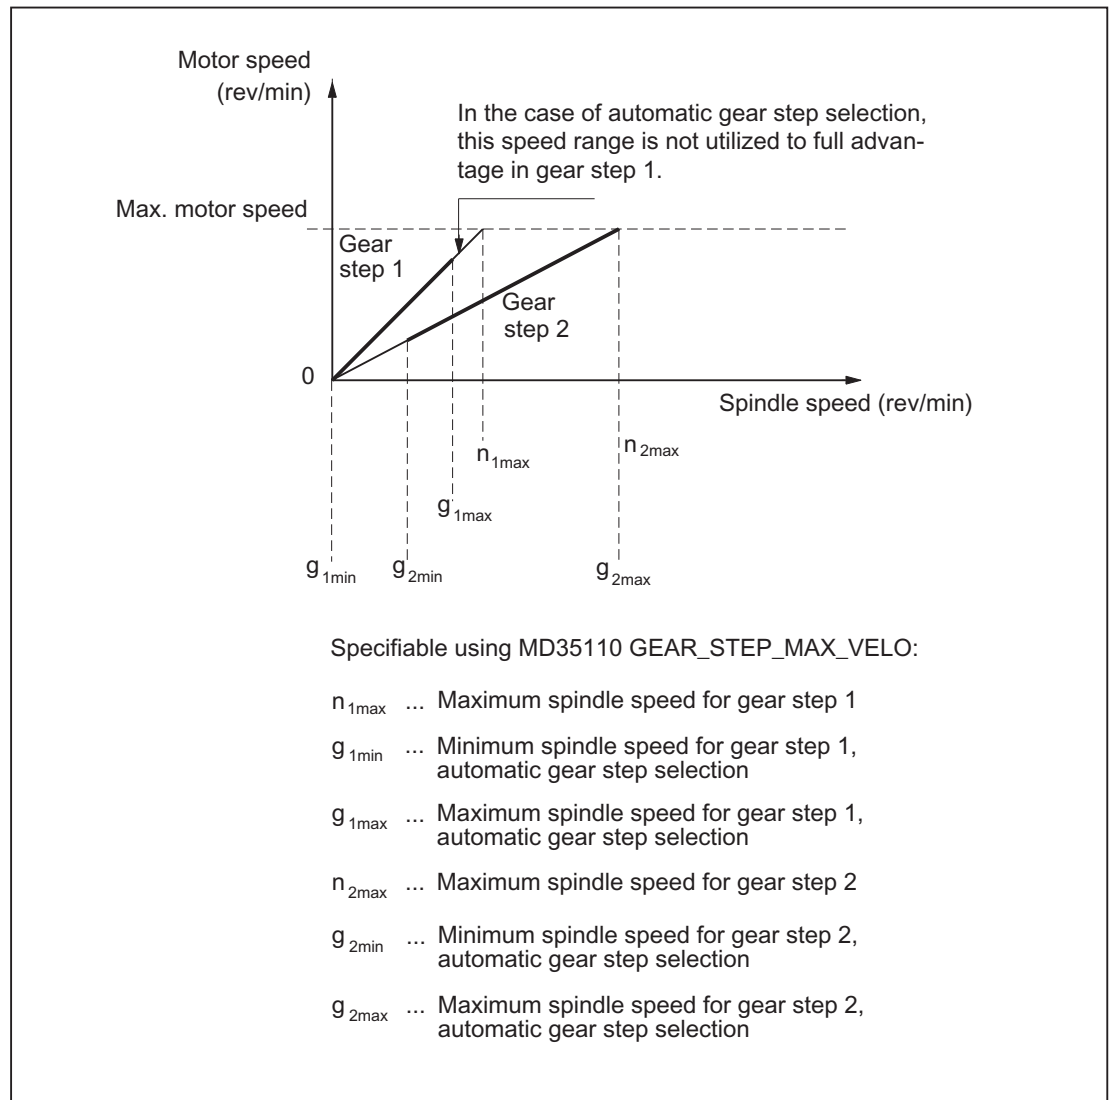

Figure 16-4 gear stage change with selection between two gear stages

## Process sequence of the gear stage change

If the new gear stage is preselected, the following sequence is implemented:

### 1. Changeover sequence

The two following NC/PLC interface signals are set:

DB31, ... DBX82.0-82.2 (setpoint gear stage A to C)

DB31, ... DBX82.3 (change over gear stage)

In accordance with the point at which NC/PLC IS:

DB31, ... DBX18.5 (Oscillation speed)

is set, the spindle decelerates to a standstill at the acceleration for oscillation or at the acceleration for speed control/position control.

Oscillation can be activated at the latest when the spindle reaches a standstill:

DB31, ... DBX61.4 (Axis/Spindle stationary)

with NC/PLC IS:

DB31, ... DBX18.5 (Oscillation speed).

In principle, the new gear stage can also be engaged without oscillation

When the new gear stage is engaged, the following NC/PLC interface signals are set by the PLC program:

DB31, ... DBX16.0-16.2 (actual gear stage A to C)

DB31, ... DBX16.3 (gear is changed)

### 2. End of gear stage change

The gear stage change is treated as completed (spindle operation type "oscillation mode" is deselected), if the following NC/PLC interface signal is set:

DB31, ... DBX16.3 (gear is changed)

The new actual gear stage is changed to the servo and interpolation parameter set when the motor is stationary.

With NC/PLC interface signal:

DB31, ... DBX16.3 (gear is changed)

is used to communicate to the NC that the new gear stage is valid and the oscillation mode can be completed.

NC/PLC IS:

DB31, ... DBX82.3 (Change gear)

is reset by the NCK,

which causes the PLC program to reset NC/PLC IS:

DB31, ... DBX16.3 (Gear changed).

In this case, it does not matter whether NC/PLC IS:

DB31, ... DBX18.5 (oscillation mode)

is still set.

The actual gear stage, which should correspond to the set gear stage, is relevant for selecting the parameter set.

If this is not the case, then Alarm 22010:

MD11410 \$MN\_SUPPRESS\_ALARM\_MASK, Bit 3 = 0

is output.

Following acknowledgment of gear stage change via the PLC with NC/PLC IS:  
 DB31, ... DBX16.3 (Gear changed)  
 the spindle is in speed control mode (DB31, ... DBX84.7).

For further instructions on signal exchange between PLC and NC, see:

**References:**

Function Manual - Basic Functions; Various NC/PLC Interface Signals and Functions (A2)

## Second gear stage data set

The automatic gear stage change M40 can be extended by a second configurable gear stage data set.

The second gear stage data set is used **exclusively** in connection with tapping without compensation chuck (G331, G332) so that an effective adjustment of spindle speed and motor torque can be achieved.

The activation is undertaken by setting the following bit for the master spindle:

MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE, Bit 5 = 1

The number of used gear stages of the two gear stage datasets is defined with the machine data:

MD35092 \$MA\_NUM\_GEAR\_STEPS2

The second gear stage block dataset is deactivated if:

MD35092 \$MA\_NUM\_GEAR\_STEPS2 = 0 (basic setting)

The first gear stage data set then selects the gear stage when M40 is active.

---

### Note

The number of gear stages in the second data set can vary from the first. If no appropriate gear stage is found for a programmed speed for M40, then no gear stage change is carried out (exceptions, see "M40: Automatic gear stage selection for speeds outside the configured switching thresholds (Page 1379)").

For more information about a typical program sequence in thread cutting without compensating chuck G331/G332 see:

**References:**

Programming Manual - Fundamentals; Chapter: Motion commands

---

The gear stages 1 to 5 of the second gear stage dataset can be parameterized via the following machine data:

| Machine data                             | Meaning                                       |
|------------------------------------------|-----------------------------------------------|
| MD35112 \$MA_GEAR_STEP_MAX_VELO2[n]      | Maximum speed for automatic gear stage change |
| MD35122 \$MA_GEAR_STEP_MIN_VELO2[n]      | Minimum speed for automatic gear stage change |
| MD35212 \$MA_GEAR_STEP_POSCTRL_ACCEL2[n] | Acceleration in position control mode         |

**Note**

The number of servo parameter sets concerning the mechanical factors remain unchanged. Furthermore, five mechanical gear stages for the spindle and one for the axis operation can be configured.

The speed limitations are configured only once for each gear stage with the following machine data, independently of the different switching thresholds:

| Machine data                             | Meaning                     |
|------------------------------------------|-----------------------------|
| MD35130 \$MA_GEAR_STEP_MAX_VELO_LIMIT[n] | Maximum speed of gear stage |
| MD35140 \$MA_GEAR_STEP_MIN_VELO_LIMIT[n] | Minimum speed of gear stage |

For tapping without compensating chuck (G331, G332) the speed can be limited to the linear acceleration range of the motor additionally. For this, the maximum speed of the linear motor characteristics range is specified in the following machine data as a function of the gear stage:

MD35550 \$MA\_DRILL\_VELO\_LIMIT[n]

**Specify gear stage in the part program****Automatic selection with active M40**

The gear stage is automatically selected by the control. The gear stage in which the programmed spindle speed (*s . . .*) is possible is checked in this context. If a gear stage results from this that is not equal to the current (actual) gear stage, then the following NC/PLC interface signals are set:

DB31, ... DBX82.3 (change over gear stage)

DB31, ... DBX82.0-82.2 (setpoint gear stage A to C)

While the appropriate gear stage is being determined, a gear stage change is only requested if the new speed is not within the permissible speed range of the active gear stage.

The speed is limited to the maximum speed of the current gear stage or raised to the minimum speed of the current gear stage and the appropriate NC/PLC interface signal is set:

DB31, ... DBX83.1 (Setpoint speed restricted)

DB31, ... DBX83.2 (Setpoint speed restricted)

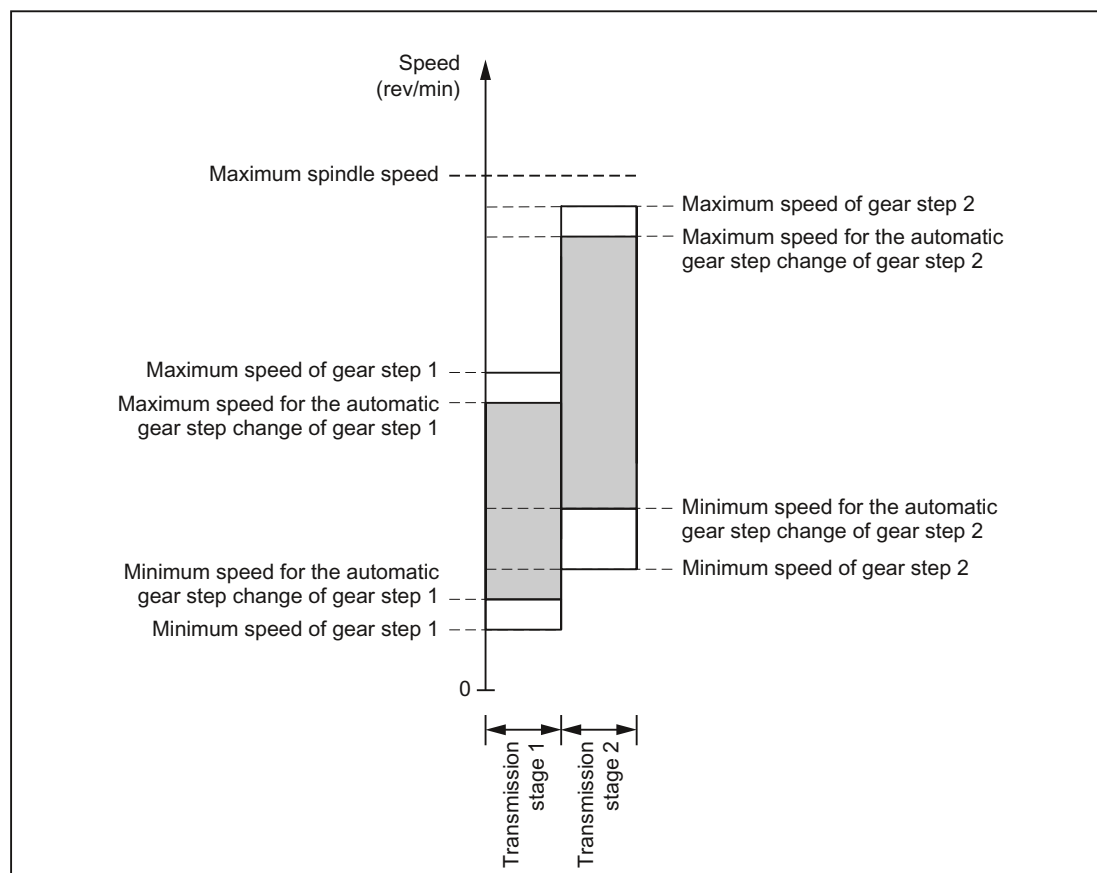

Figure 16-5 Example for two gear stages with overlapping speed ranges for automatic gear stage change (M40)

#### Note

In the case of M40, the spindle must be in open-loop control mode for automatic gear stage selection with an *s* word. Otherwise the gear stage change is rejected and the following alarm is set:

Alarm 22000 "gear stage change is not possible"

#### Note

An active reduction gear is not considered in the selection for the automatic gear stage change.

#### Permanently defining the gear stage with M41 to M45

The gear stage can be permanently defined in the part program with *M41* to *M45*.

If a gear stage is specified via *M41* to *M45* that is not equal to the current (actual) gear stage, then the following NC/PLC interface signals are set:

DB31, ... DBX82.3 (change over gear stage)

DB31, ... DBX82.0-82.2 (setpoint gear stage A to C)

The programmed spindle speed ( $s...$ ) then refers to this permanently defined gear stage:

- If a spindle speed is programmed and it is more than the maximum speed of the permanently defined gear stage (MD35130 \$MA\_GEAR\_STEP\_MAX\_VELO\_LIMIT), then the speed is decreased to this limit and the following NC/PLC interface signal is set:  
DB31, ... DBX83.1 (Setpoint speed restricted)
- If a spindle speed is programmed and it is less than the minimum speed of the permanently defined gear stage (MD35140 \$MA\_GEAR\_STEP\_MIN\_VELO\_LIMIT), then the speed is increased to this minimum and the following NC/PLC interface signal is set:  
DB31, ... DBX83.2 (Setpoint speed restricted)

#### Block change

When programming the gear stage change in the part program, the gear stage change set remains active until the gear stage change is aborted by PLC.

This corresponds to the effect as if the following NC/PLC interface signal were set:

DB21, ... DBX6.1 (read-in disable)

### Specification of gear stage via PLC with FC18

The gear stage change can also be performed by function block FC18 during a part program, in the reset state or in all operating modes.

If the speed and direction of rotation is specified with FC18, the NC can be requested to select the gear stage as appropriate for the speed. This corresponds to an automatic gear stage change with M40.

The gear stage is not changed if:

- the spindle is positioned via FC18.
- the spindle is traversed in the axis mode.

Further instructions on function block FC18 can be found under:

#### References:

Function Manual Basic Functions; PLC Basic Program (P3)

### Specification of a gear stage in synchronized actions

The gear stage change can be requested by synchronized actions using:

- DO M40  $s...$   
Automatic gear stage selection to the programmed speed  $s...$
- DO M41... M45  
Direct selection of gear stages 1 ... 5
- DO M70  
For MD35014 \$MA\_GEAR\_STEP\_USED\_IN\_AXISMODE = 1 ... 5  
(see "Configurable gear step in M70 (Page 1347)")

The gear stage is **not** changed if:

- the spindle is positioned via synchronized actions.
- the spindle is traversed in the axis mode.

---

**Note**

For further details, please refer to the section "Specification of a gear stage in part program".

Exception:

The block change is not affected by the specification of a gear stage in synchronized actions.

---

### Manual specification of a gear stage

Outside a part program that is running, the gear stage can also be changed without a request from the NC or the machine. This is the case, for example, when a gear stage is changed directly by hand.

To select the appropriate parameter set, the NC must be informed of the current gear stage. For this to work, the control or the part program must be in the reset state.

#### Boundary conditions

Transfer of the gear stage to the NC is initiated when

NC/PLC IS:

DB31, ... DBX16.0-16.2 (Actual gear stage A to C) changes.

These three bits must be set continuously during operation.

Successful transfer is acknowledged with NC/PLC IS:

DB31, ... DBX82.0-82.2 (Set gear stage A to C)

to the PLC.

NC/PLC IS:

DB31, ... DBX16.3 (Gear changed)

must not be set.

If position control is active when a new gear stage is specified by PLC with DB31, ... DBX16.0-16.2, then it is switched off for the duration of this changeover sequence.

### NC stop during gear stage change

The spindle cannot be stopped with NC/PLC IS:

DB21, ... DBX7.4 (NC stop)

if:

- the spindle is not yet in oscillation mode for the gear stage change.
- NC/PLC IS:  
DB31, ... DBX16.3 (Gear changed)  
is not set.

---

#### Note

Options for aborting:

DB31, ... DBX2.2 (Delete distance-to-go/Spindle reset)

or

DB31, ... DBX16.3 (Gear changed)

with corresponding acknowledgment from actual gear stage:

DB31, ... DBX16.0-16.2 (Actual gear stage).

---

### Spindle response after a gear stage change

How the spindle behaves once the gear stage has been changed depends on the following initial conditions:

- If the spindle was in the stop state before the gear stage change (M5, FC18: "Stop rotate spindle"), in positioning or axis mode, M5 (spindle stop) is active after completion of the gear stage change.
- If a direction of rotation (M3, M4, FC18: "Start spindle rotation"), then the last speed and direction of rotation will become active again after the gear stage change. In the new gear stage, the spindle accelerates to the last spindle speed programmed (s . . .).
- If position control was active before the gear stage change ( $s_{PCON}$ ), then it is reactivated after the gear stage change.

The next block in the part program can be executed.

## Special features

The following points must be observed on gear stage change:

- The gear stage change is not terminated by selecting NC/PLC IS: DB31, ... DBX20.1 (Ramp-up switchover to V/f mode). Setpoint 0 is output.

The gear stage change is acknowledged as usual via the NC/PLC interface signal:

DB31, ... DBX16.3 (gear is changed)

- The "Ramp-function generator rapid stop" signal must be reset by the PLC before the gear stage change is completed by the PLC.
- The process sequence of the gear stage change is ended during NC reset without any alarm output.

The gear stage output with NC/PLC IS: DB31, ... DBX16.0-16.2 (Actual gear stage A to C) is applied by the NC.

## Star/Delta switchover with FC17

Digital main spindle drives can be switched in both directions between star and delta using FC17, even when the spindle is running. This automatic switchover is controlled by a defined logic circuit in FC17, which provides the user with a configurable switchover time for the relevant spindle.

Further instructions on function block FC17 can be found under:

Function Manual Basic Function; PLC Basic Program (P3)

## 16.4.2 Spindle gear stage 0

### Technical background

For machine's where the spindle load gear can be changed over, situations can occur where the gear train between the motor and load (workpiece/tool) is interrupted. This state can occur, e.g. when pressing Reset or Emergency Stop while performing a gear stage change or when the machine is commissioned for the first time while it is being installed. The control must identify this state where the gear train is open and the next gear stage change request must be unconditionally executed.

## Function

When the gear is disengaged, the binary-coded value "0" ( $\Delta$  gear stage 0) is transferred to the NC from the PLC using the interface signal bits DB31, ... DBX16.0-2 (actual gear stage A to C):

DB31, ... DBX16.0-2 = 0

The value is used by the control to identify the state where the gear train is open.

## Effects on the gear stage change

### Gear stage change in the part program

The actual gear stage signaled from the PLC is read by the NC when starting a part program. If, at this instant in time, a value of "0" is read for the actual gear stage, then the next gear stage change is executed and the gear stage change dialog is performed by the PLC. If a value greater than "0" is read, then already in the program a comparison is made between the requested and active gear stage. If both gear stages are the same, the gear stage is not changed and a possibly programmed path motion is not interrupted.

### Gear stage change in synchronized actions, FC18 and DBB30

The actual gear stage signaled from the PLC is always evaluated by the NC when the gear stage is changed. The gear stage is always changed if a value of "0" is read from the NC. When reading a value greater than "0", a comparison is made between the requested and active gear stage. The gear stage is only changed with the PLC if the two values are not equal and the NC/PLC interface signal DB31, ... DBX82.3 (change over gear) is then output.

## Boundary conditions

- **Output of DB31, ... DBX16.0-2 = 0**

When the gear is disengaged, the PLC must enter gear stage 0 in the NC/PLC interface DB31, ... DBX16.0-2 (actual gear stage A to C).
- **Enabling the gear stage change**

The precondition for a gear stage change after reaching gear stage 0 is the general enable of the gear stage change via machine data:

MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE (assign parameters to the gear stage change)

MD35090 \$MA\_NUM\_GEAR\_STEPS (number of gear stages set up)

MD35092 \$MA\_NUM\_GEAR\_STEPS2 (2nd gear stage data set: Number of gear stages that have been created) if MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE, bit 5 = 1 (tapping without compensating chuck)
- **PLC user program/ POWER ON ASUB**

The PLC user program or POWER ON ASUB should ensure that when the gear is disengaged (gear stage 0) before spindle motion, a gear stage change request is programmed. For instance, this can be realized with M41 in the ASUB. Spindle motion such as e.g. in JOG or in axis operation does not generate any gear stage change itself.

## Example

Example for the sequence to select the first gear stage after POWER ON

1. POWER ON.
2. The PLC user program determines, in the mechanical environment, the "Gear is disengaged" state.
3. The PLC transfers the "Gear is disengaged" state to the NC by setting:  
DB31, ... DBX16.0-2 = 0
4. Part program start or POWER ON ASUB.
5. N05 (part program, refer below) is executed:  
The gear stage is changed to gear stage 1.  
From the NC:
  - the following NC/PLC-interface signal is set:  
DB31, ... DBX82.3 (change over gear stage)
  - the setpoint gear stage 1 is signaled to the PLC:  
DB31, ... DBX82.0 = 1  
DB31, ... DBX82.1 = 0  
DB31, ... DBX82.2 = 0

6. Mechanical gear stage change, acknowledgement

If the gear stage is selected, then from the PLC:

- the following NC/PLC-interface signal is set:

DB31, ... DBX16.3 (gear is changed)

- Actual gear stage 1 signaled to the NC:

DB31, ... DBX16.0 = 1

DB31, ... DBX16.1 = 0

DB31, ... DBX16.2 = 0

7. N80 is executed:

Due to the optimization of the gear stage change frequency in the part program, the gear stage is not changed.

Part program:

| Program code | Comment                                                    |
|--------------|------------------------------------------------------------|
| N05 M41      | ; Select 1st gear stage                                    |
| ...          |                                                            |
| N80 M41      | ; No gear stage change, if the 1st gear stage is selected. |

Configuring data for spindle 1 (AX5):

MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE[AX5] = 1 (enable gear stage change)

### 16.4.3 Determining the spindle gear stage

The actual stage of a spindle can be read using system variables:

- For the display in the user interface, in synchronized actions or with a preprocessing stop in the part program via the system variables:

**\$VC\_SGEAR[<n>]**                      Currently selected spindle gear stage  
 \$VC\_SGEAR reads the actual gear stage signaled from the PLC.  
 Value range:            0 ... 5

**\$AC\_SGEAR[<n>]**                      Active spindle gear stage  
 \$AC\_SGEAR reads the setpoint gear stage in the main run.  
 Value range:            1 ... 5  
 The data set for the spindle is activated corresponding to this gear stage.

**Note**

For a search, the actual gear stage (\$VC\_SGEAR[<n>]) can differ from the setpoint gear stage (\$AC\_SGEAR[<n>]) as, during the search, no gear stage change takes place. Therefore, using \$VC\_SGEAR[<n>] and \$AC\_SGEAR[<n>], it can be interrogated whether a gear stage change should be made after a search.

- Without preprocessing stop in the part program via system variables:

|                       |                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$P_SGEAR[<n>]        | Setpoint gear stage<br>\$P_SGEAR reads the gear stage programmed in the part program (M41 ... M45), for M40 selected, or for M70, the configured gear stage. |
| \$P_SEARCH_SGEAR[<n>] | Search: Gear-specific M function<br>\$P_SEARCH_SGEAR contains the last programmed gear stage M function collected with the block search.                     |

#### 16.4.4 Parameter set selection during gear step change

##### Servo parameter sets

The servo parameter sets 1 to 6 adapt the position controller to the changed properties of the machine during a gear change of the spindle.

##### Parameter set selection during gear stage change

The gear stage parameter set (interpolation parameters) and, depending on the setting in the following machine data, the servo parameter set are also modified during gear stage change.

MD35590 \$MA\_PARAMSET\_CHANGE\_ENABLE (parameter set change possible)

| Value | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | <p>In-system parameter set selection</p> <p>The parameter sets of the servo are assigned permanently.</p> <p>The following applies:</p> <ul style="list-style-type: none"> <li>For axes and spindles in the axis mode, the first parameter set is active in principle.</li> </ul> <p>Exception:</p> <p>For G33, G34, G35, G331 and G332, for the axes involved, the parameter set with the following number is activated:</p> <p>Master spindle gear stage + 1 (corresponds to parameter set No. 2 ... 6)</p> <ul style="list-style-type: none"> <li>For spindles in the spindle mode, the parameter set is set matching the gear stage.</li> </ul> |
| 1     | <p>Besides the in-system parameter set selection, there is also the option of an "external" parameter set selection.</p> <ul style="list-style-type: none"> <li>by the PLC (DB31, ... | 2     | <p>The servo parameter set is specified <b>exclusively</b> by the PLC (DB31, ... DBX 9.0 - 9.2) or through the programming of <i>SCPARA</i> in the part program or in synchronized actions (for axes and spindles).</p> <p>The 1st parameter set is selected after POWER ON.</p>                                                                                                                                                                                                                                                                                                                                                                    |

### Spindle mode

MD35590 \$MA\_PARAMSET\_CHANGE\_ENABLE = 0 or 1

The parameter set is selected according to the gear stage + 1.

The active gear stage is located in:

DB31, ... DBX16.0-16.2 (actual gear stage A to C)

The active parameter set is output in:

DB31, ... DBX69.0-69.2 (controller parameter set A to C)

One set of parameters, with the following assignment, is provided by the NC for each of the 5 gear stages:

| Dataset for ... | NC/PLC interface<br>DBX 69.2 / 69.1 / 69.0 | Parameter set<br>Number | Parameter set<br>Index [n] |
|-----------------|--------------------------------------------|-------------------------|----------------------------|
| Axis mode       | last active gear stage                     | 1                       | 0                          |
| Gear stage 1    | 001                                        | 2                       | 1                          |
| Gear stage 2    | 010                                        | 3                       | 2                          |
| Gear stage 3    | 011                                        | 4                       | 3                          |
| Gear stage 4    | 100                                        | 5                       | 4                          |
| Gear stage 5    | 101<br>110<br>111                          | 6                       | 5                          |

## Spindle in axis mode

If the spindle is in axis mode, the parameter set index "0" is selected in the servo (note MD35590 \$MA\_PARAMSET\_CHANGE\_ENABLE!).

The gear stage change behavior depends on the setting in the machine data:

MD35014 \$MA\_GEAR\_STEP\_USED\_IN\_AXISMODE (gear stage for axis mode in M70)

If there is no gear stage configured for axis mode (MD35014 = 0), no implicit gear stage change takes place in M70 (default setting!). The last gear stage is saved internally and is reactivated with the associated parameter set during the next spindle programming.

If, however, a gear stage is configured for axis mode (MD35014 = 1 ... 5), a gear stage change to gears 1 ... 5 takes place during the execution of M70. When changing from axis mode to spindle mode, the gear stage loaded with M70 remains activated. The gear stage which is activated in spindle mode prior to M70 is not automatically loaded again.

See also "Configurable gear step in M70 (Page 1347)".

## Load gearbox transmission ratio

It is possible to configure positive or negative **load gearbox factors** for each gear stage and in axis mode.

The setting is undertaken separately for numerator and denominator via the machine data:

MD31050 \$MA\_DRIVE\_AX\_RATIO\_DENOM[n] (load gearbox denominator)

MD31060 \$MA\_DRIVE\_AX\_RATIO\_DENOM[n] (load gearbox numerator)

The setting range is the same size for positive and negative load gearbox factors.

It is not possible to enter the value "0".

---

### Note

If an indirect encoder is configured, and the load gearbox transmission ratio changes, then the reference is lost and the NC/PLC interface signal: DB31, ... DBX60.4/60.5 (referenced / synchronized 1 or 2) is reset for the relevant measuring system.

---

### 16.4.5 Intermediate gear

#### Application and functions

A configured intermediate gear can be used to adapt a variety of rotating tools. The intermediate gear on the tool side has a multiplicative effect on the motor/load gearbox.

It is set via machine data:

MD31066 \$MA\_DRIVE\_AX\_RATIO2\_NUMERA (Intermediate gear numerator)

MD31064 \$MA\_DRIVE\_AX\_RATIO2\_DENOM (Intermediate gear denominator)

An encoder on the tool for the intermediate gear

is configured with machine data:

MD31044 \$MA\_ENC\_IS\_DIRECT2 (Encoder on intermediate gear).

Change parameters for these machine data can be activated with "NewConfig" either using the SinuCOM-NC commissioning software or via a softkey on the operator panel (HMI). The existing motor/load gearboxes, on the other hand, are active after POWER ON.

#### Tool change

If the intermediate gear is changed at the same time as the tool, the user must also reconfigure the transmission ratio of the numerator and denominator via the machine data of the intermediate gear.

#### Example:

In the case of an installed tool with a transmission ratio of 2:1, a suitable intermediate gear is configured and is activated immediately in the part program with the command `NEWCONF`.

```
N05 $MA_DRIVE_AX_RATIO2-NUMERA[AX5] = 2
M10 $MA_DRIVE_AX_RATIO2-DENOM[AX5] = 1
N15 NEWCONF
```

|                                                                                                    |
|----------------------------------------------------------------------------------------------------|
|  <b>CAUTION</b> |
|----------------------------------------------------------------------------------------------------|

|                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| It remains the task of the user to stop within the appropriate period in order to make changes to the machine data when required and then activate a "NewConfig". |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Switchover

Switchover to a new transmission ratio is performed immediately by means of NewConfig. From a technological viewpoint, the associated mechanical switchover process takes some time, since, in mechanical terms, a different intermediate gear with rotating tool is being installed.

---

### Note

At zero speed, switchover is jerk-free. The user is therefore responsible for taking appropriate precautions.

Applications in which switchover takes place during motion and which require smoothed or soft speed transition can be handled using existing setpoint speed filters.

---

For further instructions for control technical dependencies see:

**Reference:**

/FB1/ Function Manual, Basic Functions; Speeds, Setpoint/Actual Value System, Control (G2)

## 16.4.6 Non-acknowledged gear step change

### Mode change

A gear step change that has not been acknowledged cannot be interrupted by a change in operating mode (e.g., switchover to JOG).

The switchover is delayed by the maximum period entered in machine data:  
MD10192 \$MN\_GEAR\_CHANGE\_WAIT\_TIME.

If the gear step change is not acknowledged within this time, the NC will output an alarm:

### Further events

Events that initiate reorganization will also wait until a gear step change is completed.

The time entered in machine data:

MD10192 \$MN\_GEAR\_CHANGE\_WAIT\_TIME

determines how long the control waits before executing the gear step change.

If this time elapses without the gear step change being completed, the NC responds with an alarm.

The following events have an analog response:

- User ASUB
- Mode change
- Delete distance-to-go
- Axis replacement

- Activate PI user data
- Enable PI service machine data
- Switch over skip block, switch over Dry Run
- Editing in the modes
- Compensation block alarms
- Overstore
- Rapid retraction with G33, G34, G35
- Subroutine level abort, subroutine abort

### Response after POWER ON

The active gear step on the machine can be specified by the PLC control after POWER ON and in the RESET state.

The NCK will then select the appropriate parameter set and check back the NC/PLC interface signals: DB31, ... DBX82.0-82.2 (Set gear step A to C) to the PLC.

## 16.4.7 Gear step change with oscillation mode

### What is oscillation?

Oscillation in this context means that the spindle motor rotates alternately in the clockwise and counterclockwise directions. This oscillation movement makes it easy to engage a new gear step.

### Oscillation mode

NC/PLC IS:  
DB31, ... DBX82.3 (Change gear)  
displays that a gear step change is required.

In principle, the new gear step can also be engaged without oscillation

1. MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE must be set to 1.
2. NC/PLC interface signals DB31, ... DBX84.6 (oscillation mode) is set.
3. The acceleration is set in the machine data:  
MD35410 \$MA\_SPIND\_OSCILL\_ACCEL

### DB31, ... DBX18.5 (oscillation speed)

The spindle is in oscillation mode if a new gear step was defined using automatic gear step selection (M40) or M41 to M45 (DB31, ... DBX82.3 (Change gear) is set).

NC/PLC IS:

DB31, ... DBX82.3 (Change gear)

is only enabled when a new gear step is defined that is not the same as the current actual gear step.

If NC/PLC IS:

DB31, ... DBX18.5 (Oscillation speed)

is simply set by the PLC without a new gear step being defined by the NC, the spindle does not change to oscillation mode.

Oscillation mode is activated with NC/PLC IS:

DB31, ... DBX18.5 (Oscillation speed).

Depending on NC/PLC IS:

DB31, ... DBX18.4 (Oscillation via PLC)

while the function is in operation, a distinction is made between:

- Oscillation via NCK
- Oscillation via PLC
- Oscillation with FC 18

**References:**

Function Manual, Basic Functions; PLC Basic Program (P3)

## Oscillation time

The oscillation time for oscillation mode can be defined in a machine date for each direction of rotation:

|                                                                           |                                    |
|---------------------------------------------------------------------------|------------------------------------|
| Oscillation time in M3 direction<br>(referred to as t1 in the following): | MD35440 \$MA_SPIND_OSCILL_TIME_CW  |
| Oscillation time in M4 direction<br>(referred to as t2 in the following): | MD35450 \$MA_SPIND_OSCILL_TIME_CCW |

## Oscillation via NCK

### Phase 1:

NC/PLC IS:

DB31, ... DBX18.5 (Oscillation speed)

accelerates the spindle motor to the speed (with oscillation acceleration) defined in machine data:

MD35400 \$MA\_SPIND\_OSCILL\_DES\_VELO (oscillation speed).

Start direction is defined through the following machine data:

MD35430 \$MA\_SPIND\_OSCILL\_START\_DIR (Start direction with oscillation)

The time t1 (or t2) is started,

according to which start direction is given in the machine data:

MD35430 \$MA\_SPIND\_OSCILL\_START\_DIR

The time - and not the fact that the oscillation speed is reached - is always decisive.

**Phase 2:**

If time t1 (t2) has passed, the spindle motor accelerates in the opposite direction to the speed defined in machine data: MD35400 \$MA\_SPIND\_OSCILL\_DES\_VELO.

Time t2 (t1) starts.

**Phase 3:**

If time t2 (t1) has passed, the spindle motor accelerates in the opposite direction (same direction as in Phase 1) to the speed defined in machine data: MD35400 \$MA\_SPIND\_OSCILL\_DES\_VELO.

Time t1 (t2) starts. The process continues with Phase 2.

**Oscillation via PLC**

NC/PLC IS:

DB31, ... DBX18.4 (Oscillation via PLC)

and

DB31, ... DBX18.5 (oscillation speed)

accelerates the spindle motor to the speed (with oscillation acceleration) defined in machine data:

MD35400 \$MA\_SPIND\_OSCILL\_DES\_VELO (oscillation speed).

The direction of rotation is defined by NC/PLC IS:

DB31, ... DBX18.7 (Set direction of rotation CCW)

and

DB31, ... DBX18.6 (Set direction of rotation CW).

The oscillation movement and the two times t1 and t2 (for clockwise and counterclockwise rotation) must be simulated on the PLC.

**Special points to be noted**

Setting/Resetting the NC/PLC IS and machine data in oscillation mode:

- To decelerate the spindle, the PLC user need not set NC/PLC IS: DB31, ... DBX4.3 (Spindle stop).

The spindle is brought to a standstill internally by the control when a gear step change is requested.

- The gear step change should always be terminated with NC/PLC IS: DB31, ... DBX16.3 (Gear changed).

- NC/PLC IS:  
DB31, ... DBX18.5 (Oscillation speed)  
should be used to support mechanical engagement of the gear.  
  
It has no effect on the internal control mechanism for the gear step change procedure and should therefore only be set as necessary.
- If NC/PLC IS:  
DB31, ... DBX18.5 (Oscillation speed)  
is reset, oscillation mode stops.  
  
However, the spindle remains in "oscillation mode".
- The acceleration is defined in the following machine data:  
MD35410 \$MA\_SPIND\_OSCILL\_ACCEL
- The spindle will cease to be synchronized if an indirect measuring system (motor encoder) is used.  
  
If the machine data is set to:  
MD31050 \$MA\_ENC\_IS\_DIRECT = 0,  
NC/PLC IS:  
DB31, ... DBX60.4/5 = 0 (Homed/Synchronized)  
is automatically deleted.  
  
The zero mark is synchronized the next time it is crossed.

### End of oscillation mode

On termination of oscillation mode, the spindle returns to open-loop control mode and automatically changes to the mode defined by `SPCON` or `SPCOF`.

All gear-specific limit values (min./max. speed, etc.) correspond to the set values of the actual gear step.

### Functionality

Machine tools of conventional design require a gear step change of the spindle in oscillation mode.

If the machine data configuration is:  
**MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE = 1**  
the following sequence is implemented:

- Deceleration of the spindle.  
  
The braking action corresponds to an M5 movement.
- Output of VDI interface signals:  
DB31, ... DBX84.6 (Oscillation mode)  
DB31, ... DBX82.3 (Change gear)  
DB31, ... DBX82.0-82.2 (Set gear step A to C).  
  
If position control has been enabled, it is disabled:  
DB31, ... DBX61.5 = 0.
- The load gearbox can now "disengage".

- NC/PLC IS:  
DB31, ... DBX18.5 (Oscillation enable)  
can be set by the PLC.  
  
The spindle motor then performs an oscillation motion with preset values.  
The oscillation motion is designed to facilitate and accelerate the re-engaging of the gear wheels.
- Writing of NC/PLC IS:  
DB31, ... DBX16.0-16.2 (Actual gear step A to C)  
by the PLC.
- Once the PLC has sent:  
DB31, ... DBX16.3 (Gear changed)  
to the NCK, the last movement to be active is continued, if available.  
  
For indirect encoders (motor encoders), the homing status is cleared:  
DB31, ... DBX60.4/5 = 0.

**Block change**

If the spindle is switched to oscillation mode with NC/PLC IS:  
DB31, ... DBX82.3 (Change gear),  
the processing of the part program remains suspended.  
A new block is not executed.

If oscillation mode is terminated with NC/PLC IS:  
DB31, ... DBX16.3 (Gear changed),  
the processing of the part program is resumed.  
A new block is executed.

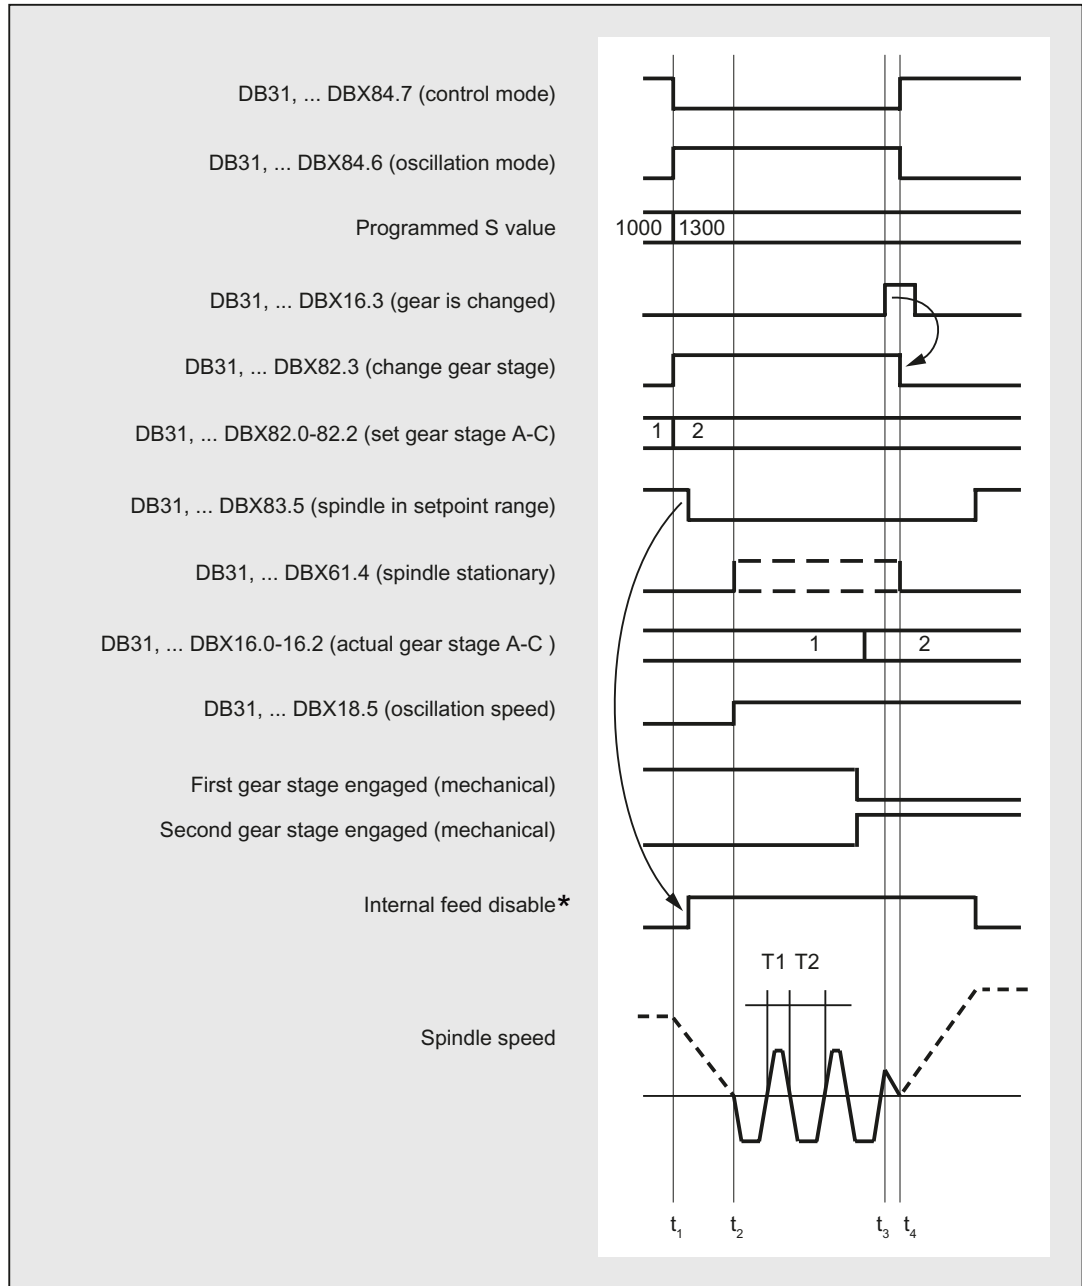

Figure 16-6 Block change following oscillation mode

## Oscillation mode

Typical time sequence for the gear step change with a spindle:

- $t_1$ : With the programming of S1300, NCK detects a new gear step (second gear step), sets NST DB31, ... DBX82.3 (change gear) and blocks processing for the next part program block (= internal feed disable\*).
- $t_2$ : The spindle is stationary, and oscillation starts (oscillation via the NCK). NST DB31, ... DBX18.5 (oscillation speed) must be set at the latest by  $t_2$ .
- $t_3$ : The new gear step is engaged. The PLC user transmits the new (actual) gear step to the NCK and sets NST DB31, ... DBX16.3 (gear is changed).

- t<sub>4</sub>: NCK then retracts NST DB31, ... DBX82.3 (change gear), ends the oscillation, releases the next part program block for processing, and accelerates the spindle to the new S value (S1300).
- \*: The internal feed disable is set if:
- The spindle gear step change has been programmed via the part program **and**
  - A processing block is activated (i.e. G0 is not active)
- The internal feed disable is **not** set during a gear step change from synchronized actions or in the case of specifications via the PLC with FC 18.

Figure 16-7 gear step change with stationary spindle

## 16.4.8 Gear step change at fixed position

### Application and advantages

Machine tools increasingly use standardized spindle drives, firstly to save technological dead time on a gear stage change and secondly to gain the cost benefits of using standardized components.

The gear stage change at fixed position function supports the "directed gear stage change" of load gearboxes that need to be activated in a different way than the NC. The gear stage change can in this case only be performed at a defined spindle position. An oscillation motion as required by conventional load gearboxes is thus no longer necessary.

## Sequence for gear stage change at fixed position

Gear stage change at fixed position

Machine data configuration:

**MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE = 2**

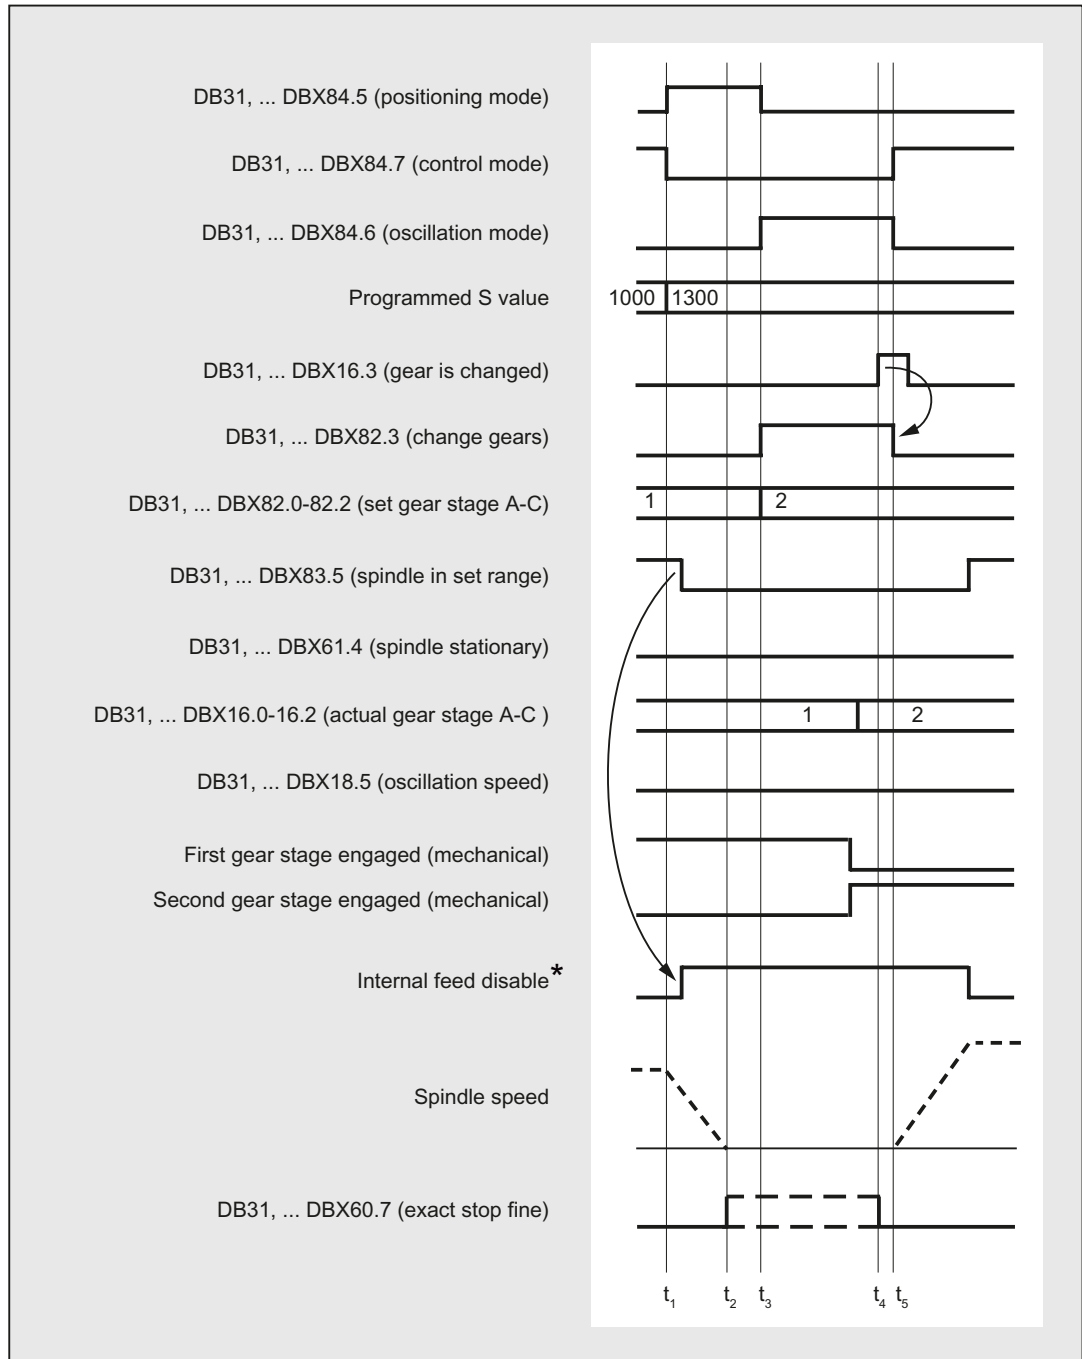

runs the following sequence:

- Positioning of the spindle from standstill or movement to the position configured in machine data:  
MD35012 \$MA\_GEAR\_STEP\_CHANGE\_POSITION.  
  
If the gear stage change is performed out of a movement, then the current direction of rotation is maintained. The spindle is in positioning mode during the positioning action.  
  
NC/PLC IS:  
DB31, ... DBX84.5 (positioning mode)  
is output.  
  
If no reference is available:  
DB31, ... DBX60.4/5 = 0  
or NC/PLC IS:  
DB31, ... DBX17.4/5 (Resynchronize on positioning MS 1/2)  
is set, the positioning action is extended by the time it takes to find the zero mark.
- After reaching the gear stage change position configured in machine data:  
MD35012\$MA\_GEAR\_STEP\_CHANGE\_POSITION  
the machine waits for the time in machine data:  
MD35310 \$MA\_SPIND\_POSIT\_DELAY\_TIME  
before switching to oscillation mode,  
and the known gear stage change dialog starts.
- Output of VDI interface signals:  
DB31, ... DBX84.6 (Oscillation mode)  
DB31, ... DBX82.3 (Change gear)  
DB31, ... DBX82.0-82.2 (Set gear stage A to C).
- Position control is not disabled when an active measuring system with indirect encoder (motor encoder) is used:  
MD31040 \$MA\_ENC\_IS\_DIRECT = 0  
  
If a measuring system with a direct encoder (load encoder) is active, position control is deactivated:  
DB31, ... DBX61.5 = 0,  
because the induction flux to the load is interrupted and closed-loop position control is no longer possible.
- If position-controlled operation is not possible, it can be disabled by resetting "Controller enable":  
DB31, ... DBX2.1 = 0.
- Mechanical switchover of the gear stage on the machine.  
  
No oscillation motion is required from the drive.  
  
NC/PLC IS:  
DB31, ... DBX18.5 (Oscillation enable)  
and  
DB31, ... DBX18.4 (Oscillation via PLC)  
should **not** be set.  
  
In principle, oscillation movement is still possible at this point.

- Writing of NC/PLC IS:  
DB31, ... DBX16.0-16.2 (Actual gear stage A to C)  
by the PLC.
- After signal:  
DB31, ... DBX16.3 (gear stage changed),  
the last movement to be active is continued, if available.  
  
For indirect encoders (motor encoders), the homing status is cleared:  
DB31, ... DBX60.4/5 = 0.  
  
The spindle is in speed control mode and NC/PLC IS:  
DB31, ... DBX84.7 (Open-loop control mode)  
is output.

## Gear stage change at fixed position

Typical time sequence for the gear stage change at fixed position:

- $t_1$ : With the programming of S1300, NCK detects a new gear stage (second gear stage), NCK sets NST DB31, ... DBX84.5 (positioning mode) and blocks processing for the next part program block (= internal feed disable\*).
- $t_2$ : The spindle is stationary, and exact stop is signaled.
- $t_3$ : Gear stage change - wait time

- t<sub>4</sub>: The new gear stage is engaged. The PLC user transmits the new (actual) gear stage to the NCK and sets NST DB31, ... DBX16.3 (gear is changed).
- t<sub>5</sub>: NCK then retracts NST DB31, ... DBX82.3 (change gear), releases the next part program block for processing, and accelerates the spindle to the new S value (S1300).
- \*: The internal feed disable is set if:
- The spindle gear stage change has been programmed via the part program **and**
  - A processing block is activated (i.e. G0 is not active)
- The internal feed disable is **not** set during a gear stage change from synchronized actions or in the case of specifications via the PLC with FC 18.

Figure 16-8 Gear stage change with stationary spindle

### Gear stage change position MD35012

The gear stage change position is defined in machine data:  
MD35012 \$MA\_GEAR\_STEP\_CHANGE\_POSITION  
for each gear stage.

### Gear stage change wait time MD35310

After the positioning action the machine waits for the time configured in machine data:  
MD35310 \$MA\_SPIND\_POSIT\_DELAY\_TIME  
until gear change request:  
DB31, ... DBX84.6 (Oscillation mode)  
DB31, ... DBX82.3 (Change gear)  
and  
DB31, ... DBX82.0-82.2 (Set gear stage A to C)  
are output.

### Position identifiers/position

The position is always approached via the shortest path (corresponds to DC).

If no reference is available and the spindle is in stillstand (e.g. after Power On), then the direction of travel is determined by the following machine data:

MD35350 \$MA\_SPIND\_POSITIONING\_DIR

If an adjustable gear stage change position is required, then this can be achieved by writing the machine data and by a subsequent NewConfig.

The change of the MD value can be achieved by the part program or HMI.

If the system is unable to reach the preset position, then alarm 22020 is signaled and the gear stage change dialog between NCK and PLC does not take place in order not to destroy the gears. As this alarm is serious, the part program cannot continue and the cause must be eliminated under all circumstances. Experience has shown that the abortion of positioning is usually due to incorrect MD settings or incompatible PLC signals.

## Velocity

The positioning speed is taken from the machine data which is configured depending on the gear stage:

MD35300 \$MA\_SPIND\_POSCTRL\_VELO

NC/PLC IS "Spindle speed override"/"Feedrate override" at  
DB31, ... DBX17.0=0: DB31, ... DBB19)

as well as:

DB31, ... DBX17.0=1: DB31, ... DBB0

are effective as normal for positioning.

The positioning speed can be changed proportionally through the program instruction

OVRA[S<sub>n</sub>].

---

### Note

OVRA[S<sub>n</sub>] is valid modally. After the gear stage change, a value appropriate for the machining should be reset.

---

The part-program instruction FA[S<sub>n</sub>] does not change the positioning speed during gear stage change.

## Acceleration

The acceleration values are determined by the machine data which is configured depending on the gear stage:

MD35200 \$MA\_GEAR\_STEP\_SPEEDCTRL\_ACCEL

and

MD35210 \$MA\_GEAR\_STEP\_POSCTRL\_ACCEL

The acceleration can be changed proportionally by programming ACC[S<sub>n</sub>].

---

### Note

ACC[S<sub>n</sub>] is valid modally. After the gear stage change, a value appropriate for the machining should be reset.

---

## Speed-dependent acceleration

The "knee-shaped acceleration characteristic" is effective as in positioning with SPOS or FC18.

## Jerk

It is currently not possible to limit the change in acceleration.

### End of positioning

The transition between the end of the positioning action (DB31, ... DBX84.5) and the start of oscillation mode (DB31, ... DBX84.6) is defined on reaching "Exact stop fine" (DB31, ... DB60.7) and the time value entered in machine data: MD3510 \$MA\_SPIND\_POSIT\_DELAY\_TIME.

The determination of the transition condition has an effect firstly on the gear stage change time and secondly on the accuracy of the approach to the preset gear stage change position.

### Block change

The block change is stopped and the machining blocks are not started until the gear stage has been changed by the PLC (DB31, ... DBX16.3).

### End of gear stage change

Once the gear stage change has been completed, the spindle returns to open-loop control mode and will automatically change to the controller mode defined by `SPCON` or `SPCOF`.

All gear-specific limit values (min./max. speed of gear stage, etc.) correspond to the check-back values of the actual gear stage.

### Boundary conditions

- The spindle must have at least one measuring system.
- Position-controlled operation must be possible and must have been activated.
- Generally, it must be possible to execute `SPOS` from the part program, from a synchronized action or via FC18: "Start spindle positioning" without errors.

Unless all requirements can be met, the function described cannot be used successfully.

### Activation

The function of gear stage change at fixed position is activated by the configuration:  
MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE = 2

## 16.4.9 Configurable gear step in M70

### Technical background

In some machines the spindle needs to be in a particular gear step during axis mode.

Possible reasons:

- Only one optimization ( $K_v$ , feedforward control, filter) to suit a gear step can be found in the servo parameter set for axis mode (index 0). The machine data for this parameter set should not be rewritten.
- There is only one mechanical transmission ratio which, unlike the others, possesses little or no backlash compensation. The spindle can only follow a path motion or transformations (e.g. TRANSMIT) together with other axes in this gear step.

### Function

If the function is activated, a predefined gear step is loaded automatically during transition to axis mode.

The gear step change is integrated into the M70 process and occurs after spindle deceleration and before the loading of the servo parameter set with index 0 (note MD35590 \$MA\_PARAMSET\_CHANGE\_ENABLE!).

The typical dialog between NC and PLC which occurs during gear step changes is executed in a similar way to programmed gear step changes (M41 ... M45).

### Requirements

Gear step changes during transition to axis mode require general enabling of the gear step change via the machine data:

MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE (assign parameters to the gear step change).

MD35090 \$MA\_NUM\_GEAR\_STEPS (number of gear steps set up)

### Activation/deactivation

The function is activated / deactivated via the machine data:

MD35014 \$MA\_GEAR\_STEP\_USED\_IN\_AXISMODE (gear step for axis mode in M70)

| Value   | Meaning                                                                                           |
|---------|---------------------------------------------------------------------------------------------------|
| 0       | No implicit gear step change occurs in M70. The current gear step is retained (default setting!). |
| 1 ... 5 | A gear step change to gears 1 ... 5 occurs during the processing of M70.                          |

## Boundary conditions

### Gear step change at fixed position (MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE = 2)

The "gear step change at fixed position" function is supported. The sequence in M70 is then extended by the time it takes to position the spindle. The position is approached at the current gear step.

### Transition to axis mode without programming M70

The control system detects the transition to axis mode automatically from the program sequence (see "Implicit transition to axis mode (Page 1305)") and generates the requisite M70 sequence, including the gear step change, within the control system.

### Transition to axis mode with FC 18

Implicit gear step change is not supported in transition to axis mode with the FC 18 ("Start axis"). This requires the right gear step to be engaged by the PLC application before switching to axis mode. The gear step change is also possible with the FC 18 ("Start gear step change").

### Change from axis mode to spindle mode

When changing from axis mode to spindle mode, the gear step loaded with M70 remains activated. The gear stage which is activated in spindle mode prior to M70 is not automatically loaded again. The servo parameter set is changed from parameter set 1 (index 0) to parameter sets 2 ... 6 (index 1 ... 5) to suit the gear step (with MD35590 \$MA\_PARAMSET\_CHANGE\_ENABLE < 2).

## Example

Gear step 4 should be loaded in the case of spindle transition to axis mode.

Configuration: MD35014 \$MA\_GEAR\_STEP\_USED\_IN\_AXISMODE[<spindle identifier>] = 4

| Program code      | Comment                  |
|-------------------|--------------------------|
| N05 M3 S1000      |                          |
| N10 G1 X100 F1000 |                          |
| N15 M70           | ; Gear step 4 is loaded. |
| N20 POS[C]=77     |                          |
| N25 ...           |                          |

### Note

MD35014 can be changed in the NewConfig. Thus, the gear step being loaded can still be changed in the part program before transition to axis mode, if necessary.

## 16.4.10 Suppression of the gear stage change for DryRun, program test and SERUPRO

### Function

For test feed rate (DryRun), program test and SERUPRO, normally, a gear stage change is not required. This is the reason that it can be suppressed for these functions. The corresponding configuration is realized with bits 0 ... 2 in machine data:

MD35035 \$MA\_SPIND\_FUNCTION\_MASK

| <b>Dry run feedrate (DryRun)</b>           |                                                                                                                                                                               |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit 0 = 0                                  | When the DryRun function is active - for part program blocks - gear stages are changed with M40, M41 to M45, or programming via FC18 and synchronized actions.                |
| Bit 0 = 1                                  | When the DryRun function is active - for part program blocks - a gear stage change is suppressed with M40, M41 to M45, programming via FC18 and synchronized actions.         |
| <b>Program test and SERUPRO</b>            |                                                                                                                                                                               |
| Bit 1 = 0                                  | For active program test / SERUPRO function - for part program blocks - gear stages are selected with M40, M41 to M45, programming via FC18 and synchronized actions.          |
| Bit 1 = 1                                  | For active program test / SERUPRO function - for part program blocks - a gear stage change is suppressed with M40, M41 to M45, programming via FC18 and synchronized actions. |
| <b>DryRun, program testing and SERUPRO</b> |                                                                                                                                                                               |
| Bit 2 = 0                                  | Gear stage change for programmed gear stage is <b>not</b> performed subsequently on REPOS after deselection of functions DryRun, Program Test and SERUPRO.                    |
| Bit 2 = 1                                  | Gear stage change for programmed gear stage is performed after deselection of functions DryRun and SERUPRO if possible.                                                       |

### Sequence

If a gear stage change is suppressed, if necessary, the interpolator will limit the programmed spindle speed to the permissible speed range of the active gear stage.

NC/PLC interface signals DB31, ... DBX83.2 (setpoint speed increased) and DB31, ... DBX83.1 (setpoint speed limited) generated as a result of this limit are suppressed.

Monitoring by the PLC program is not necessary during DryRun and in dry run feedrate.

When the gear stage change is suppressed, no new gear stage setpoint (DB31,... DBX82.0-82.2) is output to the PLC.

The gear stage change request DB31, ... DBX82.3 (change gear) is also suppressed.

This ensures that no gear stage change information has to be processed by the PLC program.

### Determining the last active gear stage

System variable \$P\_GEAR returns the gear stage programmed in the part program (which may not have been output to the PLC).

System variable \$AC\_SGEAR can be used to read the last active gear stage from the part program, synchronized actions and at the user interface.

### Behavior after deselection

The DryRun function can be deselected within a running part program. Once it has been deselected, the correct gear stage requested by the part program must be identified and selected.

It cannot be assured that the remainder of the part program will run without errors until the correct gear stage has been activated. Any necessary gear stage change is performed in the system REPOS started on deselection if the spindle is in speed control mode. A complete gear stage change dialog takes place with the PLC and the last programmed gear stage is activated.

If, for REPOS, there is a mismatch between the gear stage programmed in the part program and the actual gear stage supplied via the NC/PLC interface, then no gear stage change takes place.

The same applies to the SERUPRO function.

Further explanations regarding the block search function SERUPRO, see:

**References:**

Function Manual, Basic Functions; Mode Group, Channel, Program Mode, Reset Response (K1)

### Boundary conditions

If the gear stage change is suppressed, the output spindle speed moves within the speed range specified by the current gear stage.

The following restrictions apply to the subsequent activation of a gear stage change with REPOS:

- The gear stage change is not activated subsequently if the spindle in the deselection or target block is a command spindle (synchronized action) or PLC spindle (FC18).
- If the gear stage cannot be activated because the spindle is in position or axis mode or a link is active, alarm 22011"Channel%1 block%3 spindle2% Change to programmed gear stage not possible" is signaled.

### Example

Gear stage change in DryRun

```

; Activate 1st gear stage for output state
N00 M3 S1000 M41 ; 1st gear stage is selected
M0 ; Part program stops

; PI service: Activate dry run feedrate (DryRun)
 ; (Configuring)

```

```
N10 M42 ; 2nd gear stage requested, no gear stage change
 takes place
N11 G0 X0 Y0 Z0 ; Positioning axes
N12 M0 ; Part program stops

; PI service: Deactivate dry run feedrate (DryRun)
 ; REORG and REPOS are performed
 ; now the gear stage change to the 2nd gear
 stage takes place

N20 G1 Z100 F1000
...
N99 M30 ; Part program end
```

## 16.5 Additional adaptations to the spindle functionality that can be configured

Spindle-specific functions are set using machine data:

MD35035 \$MA\_SPIND\_FUNCTION\_MASK (spindle functions)

MD35035 is bit coded:

| Bit     | Meaning                                                                                                                                                                                                                                                                                 |                                                                                                |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|

DBX17.6 (invert M3/M4) <b>before part program start</b> to a stable value.</li> <li>• Existing application-based solutions, e.g. as are used in tapping cycles, must, if required, be adapted. It is known, for example, in tapping cycles, that the spindle direction of rotation can be inverted using MIRROR depending on a cyclic-specific setting data.</li> </ul> |
|     | Bit 22 = 1                                                                                                                                                                                           | The NC/PLC interface signal DB31, ... DBX17.6 (invert M3/M4) does <b>not</b> affect the function "interpolatory tapping (G331/G332)".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Changes to MD35035 become effective after an NC reset.

## 16.6 Selectable spindles

### Function

The "selectable spindles" function allows you to write part programs with reference to the spindles used ("channel spindle, logical spindle") regardless of the actual assignment of configured spindles ("physical spindles") to a channel.

The physical spindles loaded or unloaded by "axis replacement" no longer have to be specified explicitly in the part program.

### Spindle number converter (SD42800)

Each spindle is uniquely mapped to a machine axis using a configurable number:

```
MD35000 $MA_SPIND_ASSIGN_TO_MACHAX[AX...] = <spindle number>
```

This number always applies to one spindle, whereby it is of no importance in which channel the spindle is actively handled.

The channel spindles can be switched over because an intermediate level is introduced between the logical spindle numbers used in the part program and the physical spindles existing in the channel.

Every logical spindle used in the part program is assigned a physical spindle in a table comprising setting data:

```
SD42800 $SC_SPIND_ASSIGN_TAB[<n>] (spindle number converter) = ...
```

Index <n> corresponds to the programmed spindle number or the programmed address extension. The contents of the particular SD is the physical spindle that is actually available.

The spindle number converter is effective in spindle programming by means of:

- The part program
- Synchronized actions

The spindle number converter has no effect with PLC commands, which use function block FC18. The physical spindle must always be addressed there within the context of the axis.

Logical spindles can be changed over by changing SD42800. The changeover can be made from the part program, from the PLC and/or HMI.

---

### Note

The logical master spindle is contained in setting data SD42800 \$SC\_SPIND\_ASSIGN\_TAB[0]. It is only used for display purposes.

This setting data is defined in the part program by `SETMS` (logical spindle).

Unused spindles are assigned the value 0 in SD42800.

System variables, which are involved in the spindle changeover:

```
$P_S, $P_SDIR, $P_SMODE, $P_GWPS, $AC_SDIR, $AC_SMODE, $AC_MSNUM, $AA_S
```

---

**References:**

Programming Manual, Job Planning

The converted, physical spindle number is always output as the address extension in the auxiliary function output.

**Boundary conditions**

- Switchable channel spindles are **not** a substitute for the Axis replacement function.
- You can only switch spindles, which have been assigned to the channel by means of configuration.
- If spindles, which are presently active in another channel, are designated for switchover, either the "Auto-Get" function is triggered for the physical spindle or alarm 16105 "Assigned spindles do not exist" is output, depending on the configuration variant.
- If SD42800 \$SC\_SPIND\_ASSIGN\_TAB[<n>] is specified by the PLC or from HMI, then the channel whose table is changed should be in Reset status or the spindle to be changed should not be used in the running part program.

A synchronized response can be achieved by means of a `STOPRE` preprocessor stop.

- The multiple mapping of logical to physical spindles is not prevented in the NC. However, with the display of logical spindle in the operator interface, there are ambiguities corresponding to the change table.
- Spindle conversion operates on spindles via FC 18.

**Activation**

SD42800 \$SC\_SPIND\_ASSIGN\_TAB[<n>] is enabled by setting the following machine data setting:

MD20092 \$MC\_SPIND\_ASSIGN\_TAB\_ENABLE=1

**Basic setting SD42800**

After switching on the NC with the commissioning switch in setting 1 (delete SRAM) SD42800 \$SC\_SPIND\_ASSIGN\_TAB[<n>] is in the basic setting.

The numbers of the logical and physical spindles are identical.

SD42800 \$SC\_SPIND\_ASSIGN\_TAB[1] = 1

SD42800 \$SC\_SPIND\_ASSIGN\_TAB[2] = 2

SD42800 \$SC\_SPIND\_ASSIGN\_TAB[3] = 3

SD42800 \$SC\_SPIND\_ASSIGN\_TAB[4] = 4

SD42800 \$SC\_SPIND\_ASSIGN\_TAB[5] = 5

...

## Example

Spindle configurations:

- Assignment, spindle number and machine axis:

```
MD35000 $MA_SPIND_ASSIGN_TO_MACHAX [AX4] = 1
MD35000 $MA_SPIND_ASSIGN_TO_MACHAX [AX5] = 2
MD35000 $MA_SPIND_ASSIGN_TO_MACHAX [AX6] = 3
MD35000 $MA_SPIND_ASSIGN_TO_MACHAX [AX7] = 5
```

- Accepting a machine axis in a channel:

```
MD20070 $MC_AXCONF_MACHAX_USED[0] = 4
MD20070 $MC_AXCONF_MACHAX_USED[1] = 5
MD20070 $MC_AXCONF_MACHAX_USED[2] = 6
MD20070 $MC_AXCONF_MACHAX_USED[3] = 7
```

- Specifying the master spindle:

```
MD20090 $MC_SPIND_DEF_MASTER_SPIND = 1
```

Spindle number converter:

```
MD20092 $MC_SPIND_ASSIGN_TAB_ENABLE=1 ; Activate spindle number converter

SD42800 $SC_SPIND_ASSIGN_TAB[0]=1 ; Master spindle as configured

SD42800 $SC_SPIND_ASSIGN_TAB[1]=1 ; Basic setting of the table

SD42800 $SC_SPIND_ASSIGN_TAB[2]=2
SD42800 $SC_SPIND_ASSIGN_TAB[3]=3
SD42800 $SC_SPIND_ASSIGN_TAB[4]=0 ; Logical spindle not assigned

M3 S1000 ; Address extension=1, M1=3 S1=1000 is output
; The spindle with configured No. "1" (No. of the physical master
; spindle) rotates.

...
...
SD42800 $SC_SPIND_ASSIGN_TAB[1]=5 ; Assignment of logical spindle 1 to
; physical spindle 5
SD42800 $SC_SPIND_ASSIGN_TAB[2]=3 ; Assignment of logical spindle 2 to
; physical spindle 3.

Notice: physical spindle 3 has now been
assigned twice.
```

When programming logical spindles 2 and 3, physical spindle 3 is always addressed. In the basic machine displays, both spindles rotate.

```
SETMS(2) ; SD42800 $SC_SPIND_ASSIGN_TAB[0] = 2 defined internally by NCK.
...
M5 ; Master spindle = address extension=2, the unset spindle number
 ; is output. M3=5
 ; The physical spindle configured with number "3" stops.
...
GET(S4) ; Alarm 16105, as logical spindle "4" cannot be switched.
...
RELEASE(S1) ; Channel spindle "1" = physical. Spindle "5" is enabled.
...
M30
```

## 16.7 Programming

### 16.7.1 Programming from the part program

#### Programming statements

| Statement                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |        |               |                       |                                            |             |                                               |        |                                 |                |                |              |               |            |                                   |

**Note**

M functions M3, M4, M5, and M70 are not output in DB21, ... DBB194 and DBB202 if a spindle is configured in a channel. These M functions are offered as extended M functions in DB21, ... DBB68 ff. and in the relevant axis DBs, DB31, ... DBB86 ff.

More detailed explanations for programming the spindle can be found in:

- Programming Manual, Fundamentals

### 16.7.2 Programming via synchronized actions

M functions M40 to M45 can also be programmed in synchronized actions.

Please note:

- The programming of M40 ... M45 in the part program has no effect on the current status of the automatic gear step change of synchronized actions, and vice versa.
- When programming S values with M40, automatic gear step change is effective separately for synchronized actions and the part program.
- M40 is deactivated after POWER ON.

The gear step is not adjusted if an S value is specified from a synchronized action.

- An M40 command programmed using synchronized actions always remains active for synchronized actions (modal) and is not reset on reset.
- M41 ... M45 selects first to fifth gear steps in accordance with the programming in the part program.

An axis replacement is necessary in order to run the function.

Once the gear step change has been performed, the spindle status is neutral (same response to M3, M4, M5 programming).

### 16.7.3 Programming spindle controls via PLC with FC18 - only 840D sl

When the PLC specifies the direction of rotation and speed using FC18, the NCK can determine and select a gear step to match the speed. This is equivalent to the M40 functionality when programming via the part program.

The correct start code must be set when FC18 is called in a PLC user program, in order to activate gear step selection.

#### References

More detailed explanations regarding the programming of spindle controls by PLC with FC18 can be found in:

- Function Manual, Basic Functions, Basic PLC Program (P3)

## 16.7.4 Special spindle movements via PLC interface

---

### Note

The function is only available when using SINUMERIK Operate!

---

### Why use a special spindle interface?

This function can be used to program the spindle via an axial PLC interface as an alternative to the FC18. The simplicity of the settings results in slightly restricted functionality. This functionality can be used preferably for simple control applications.

### Functionality

Spindles can be started and stopped outside a part program that is being executed via the internal DBB30 spindle interface:

- DB31, ... DBX30.0 (spindle stop)
- DB31, ... DBX30.1 (spindle start, clockwise)
- DB31, ... DBX30.2 (spindle start, counter-clockwise)
- DB31, ... DBX30.3 (select gear stage)

Supplementary signal to the signal "spindle start, clockwise/counter-clockwise"; determines the gear stage that matches the speed analog to M40 in the part program.

- DB31, ... DBX30.4 (spindle positioning start)

In order to start a spindle job, the channel handling the spindle must be in the acceptance status. A spindle job is always started on the Low-High edge of an internal DBB30 signal.

Generally, the internal DBB30 start signals do not have any meaning in the static status and do not prevent the spindle being programmed by FC18, synchronized actions, the part program or JOG traversing movements (e.g. when the STOP signal is statically at "1").

### Preconditions

In order that spindle jobs are accepted via the DBB30 spindle interface, the following conditions must be fulfilled (**acceptance state**):

- The channel status must be in the "interrupted" or "reset" mode:
  - DB21, ... DBX35.6 = 1 (channel status "interrupted")
  - DB21, ... DBX35.7 = 1 (channel status "reset")
- The program status must be in the "interrupted" or "cancelled" mode:
  - DB21, ... DBX35.3 = 1 (program status "interrupted")
  - DB21, ... DBX35.4 = 1 (program status "interrupted")

These states will occur on RESET and in JOG mode.

At the start time, the spindle concerned must meet the following requirements:

- It must be in the status "Channel axis" or "Neutral axis" and must not be moved by means of the JOG keys.
- When the spindle is specified, no positioning movement may be carried out by FC18 or synchronized actions.

---

**Note**

**Spindle job outside the acceptance range**

Low-high edges outside the acceptance range will be ignored. No alarm message is output by the NCK. It can be conceivable that the acceptance range will be indicated to the operator by a user-side PLC application.

Spindle jobs outside the acceptance range can also be carried out using FC18 or ASUB.

---

**Multi-channel operation**

In the case of multi-channel operation, the spindle started by the PLC becomes active in the channel that handles the spindle at the appropriate moment.

The channel can be determined on the PLC side by reading the NC/PLC interface signals:

DB31, ... DBX68.0-68.3 (NC axis/spindle in channel A to D)

**Spindle definitions**

The spindle settings are retained after a change in mode (e.g. from JOG mode to AUTOMATIC). The spindle definitions are applied to the part program at the start of the program and can be modified again using part program operations.

Using the following settings in the machine data:

MD35035 \$MA\_SPIND\_FUNCTION\_MASK (spindle functions),

certain spindle definitions (speed or cutting rate, feedrate type) can be taken from the part program, synchronized action and FC18 and entered in the corresponding setting data:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit 4 = 1  | <p>The programmed <b>speeds</b> . . . including speed setpoints via FC18 and synchronized actions are accepted in the following setting data:<br/>SD43200 \$SA_SPIND_S (speed for spindle start via PLC interface)</p> <p>Programmed S values that are not programmed speed values are not accepted in the SD. These include, for example:</p> <ul style="list-style-type: none"> <li>• S value at constant cutting rate (G96, G961)</li> <li>• S value for rotation-related dwell time (G4)</li> </ul>                                        |

## Speed default

Speed defaults from part program, FC18 or synchronized actions are written to the following setting data from all the usual sources:

SD43200 \$SA\_SPIND\_S (speed for spindle start via PLC interface)

The setting data can be written to as follows:

- Through speed programming
- Through direct programming in the part program
- Through HMI software

---

### Note

The setting data is written immediately and asynchronously to part-program execution.

---

The following conditions apply when writing:

| Programming through:                   | Conditions:                                                                                                                                                                                                                                                                                     |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Speed programming                      | <ul style="list-style-type: none"> <li>MD35035 \$MA_SPIND_FUNCTION_MASK Bit 4 = 1 must be set.</li> <li>Constant cutting rate G96, G961 must not be active.</li> <li>The following NC/PLC interface signal must be set:<br/>DB31, ... DBX 84.0 = 0 (constant cutting rate is active)</li> </ul> |
| Direct programming in the part program | A programmed S-value and the value of the directly written SD can be outdated with respect to time. If this is the case, after programming the SD, the statement <code>STOPRE</code> should be executed.                                                                                        |
| HMI                                    | Only positive values including zero can be accepted. Otherwise, a corresponding message is generated.                                                                                                                                                                                           |

### Gear stage change and effect on speed

In the current version, no gear stage change is triggered if the setpoint speed is out of the speed range of the gear stage (exceptions, see "M40: Automatic gear stage selection for speeds outside the configured switching thresholds (Page 1379)"). The usual speed limitations and the speed increase to the setpoint speed are active.

### Setpoint speed for JOG

For the following MD configuration:

MD35035 \$MA\_SPIND\_FUNCTION\_MASK bit 5 = 1

the content from SD43200 \$SA\_SPIND\_S is active as setpoint speed for JOG.

You can use the JOG keys to operate the spindle at the speed defined in SD43200.

If the content is zero, other JOG speed definitions are active (see SD41200 \$SN\_JOGSPIND\_SET\_VELO).

### Constant cutting rate setting

Defaults for constant cutting rate from part program, FC18 or synchronized actions are written to the following setting data from all the usual sources:

SD43202 \$SA\_SPIND\_CONSTCUT\_S (cutting rate for spindle start via PLC interface)

#### Preconditions

The precondition for the definition of a constant cutting rate to be active is:

- The spindle involved must be the master spindle in the channel that handles the spindle.

This condition is fulfilled if the following NC/PLC interface signal is set:

DB31, ... DBX84.0 = 1 (constant cutting rate is active)

#### Writing from the part program

When writing from the part program, the value for the constant cutting rate is interpreted as follows:

- if G710 is active in the 12th G Group: Metric
- if G700 is set in the 12th G Group: inch as [feet/min]

For G70, G71 and when writing from an external (HMI), the setting in the machine data: MD10240 \$MN\_SCALING\_SYSTEM\_IS\_METRIC determines the interpretation of the written values.

Further explanations regarding the system of units (metric/inch) can be found in:

**References:**

Function Manual, Basic Functions; Velocities, Setpoint/Actual Value Systems, Closed-Loop Control (G2)

**Definition via FC18**

If the constant cutting rate is defined using FC18, the setting of bit 6 in byte 2 in the "Signals to concurring positioning axes" area determines how the speed value (bytes 8 ... 11) is interpreted.

**Setting via synchronized actions**

For definition via synchronized actions, analog to the part program, the feedrate type defines how the S value is interpreted.

**Reading from part program and synchronized actions**

The programmed cutting rate actual value can be determined in the part program and in the synchronized actions by reading the following system variables:

- \$P\_CONSTCUT\_S[<n>] (last programmed constant cutting rate)
- \$AC\_CONSTCUT\_S[<n>] (actual constant cutting rate)

Defined range of values of the two new system variables: RV = {0, DBL\_Max}

The programmed cutting rate value can also be read via the OPI interface.

**Definition of the spindle speed type for the master spindle**

Definition of the spindle speed type **for the master spindle** from part program, FC18 or synchronized actions are written to the following setting data from all the usual sources:

SD43206 \$SA\_SPIND\_SPEED\_TYPE (spindle speed type for spindle start via PLC interface)

The value range and the functionality correspond to the 15th G group (feedrate type).

Permissible values are G values: 93, 94, 95, 96, 961, 97, and 971.

Depending on the setting, for DB31, ... DBX30.1/2 (spindle start, clockwise/counter-clockwise) either the speed from SD43200 \$SA\_SPIND\_S or the cutting rate from SD43202 \$SA\_SPIND\_CONSTCUT\_S is active:

- |                         |                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| 93, 94, 95, 97 and 971: | The master spindle is started with the speed from SD43200.                                                                       |
| 96 and 961:             | The speed of the master spindle is obtained from the specified cutting velocity (SD43202) and the radius of the transverse axis. |

### Definitions for spindle positioning

The definitions for spindle positioning using DB31, ... DBX30.4 (spindle positioning start) are read from the following setting data:

SD43240 \$SA\_M19\_SPOS (spindle position for spindle positioning with M19)

SD43250 \$SA\_M19\_SPOSMODE (spindle position approach mode for spindle positioning with M19)

## 16.7.5 External programming (PLC, HMI)

### SD43300 and SD42600

The revolutional feedrate behaviour can be selected externally via the axial setting data:  
SD43300 \$SA\_ASSIGN\_FEED\_PER\_REV\_SOURCE (Rotational feedrate for spindles) in JOG operating mode using the channel-specific setting data  
SD42600 \$SC\_JOG\_FEED\_PER\_REV\_SOURCE (Revolutional feedrate control in JOG mode).

The following settings can be made via the setting data:

|     |                                                                                                                               |
|-----|-------------------------------------------------------------------------------------------------------------------------------|
| >0: | The machine axis number of the rotary axis/spindle from which the revolutional feedrate shall be derived.                     |
| -1: | The revolutional feedrate is derived from the master spindle of the channel in which the axis/spindle is active in each case. |
| 0:  | Function is deselected.                                                                                                       |

### FPRAON (S2)

Revolutional feedrate for spindle S2 ON, derived from the master spindle

### FPRAON (S2, A)

Revolutional feedrate for spindle S2 ON, derived from axis A.  
The revolutional feedrate value must be specified with  $FA[S_n]$ .

### FPRAOF (S2)

Revolutional feedrate for spindle S2 OFF.

### SPI(n)

It is also possible to program  $SPI_{(n)}$  instead of  $SPI_{(S_n)}$ .

## 16.8 Spindle monitoring

### 16.8.1 Permissible speed ranges

The spindle monitoring functions and the currently active functions (G94, G95, G96, G961, G97, G971, G33, G34, G35, G331, G332, etc.) define the permissible speed ranges of the spindle.

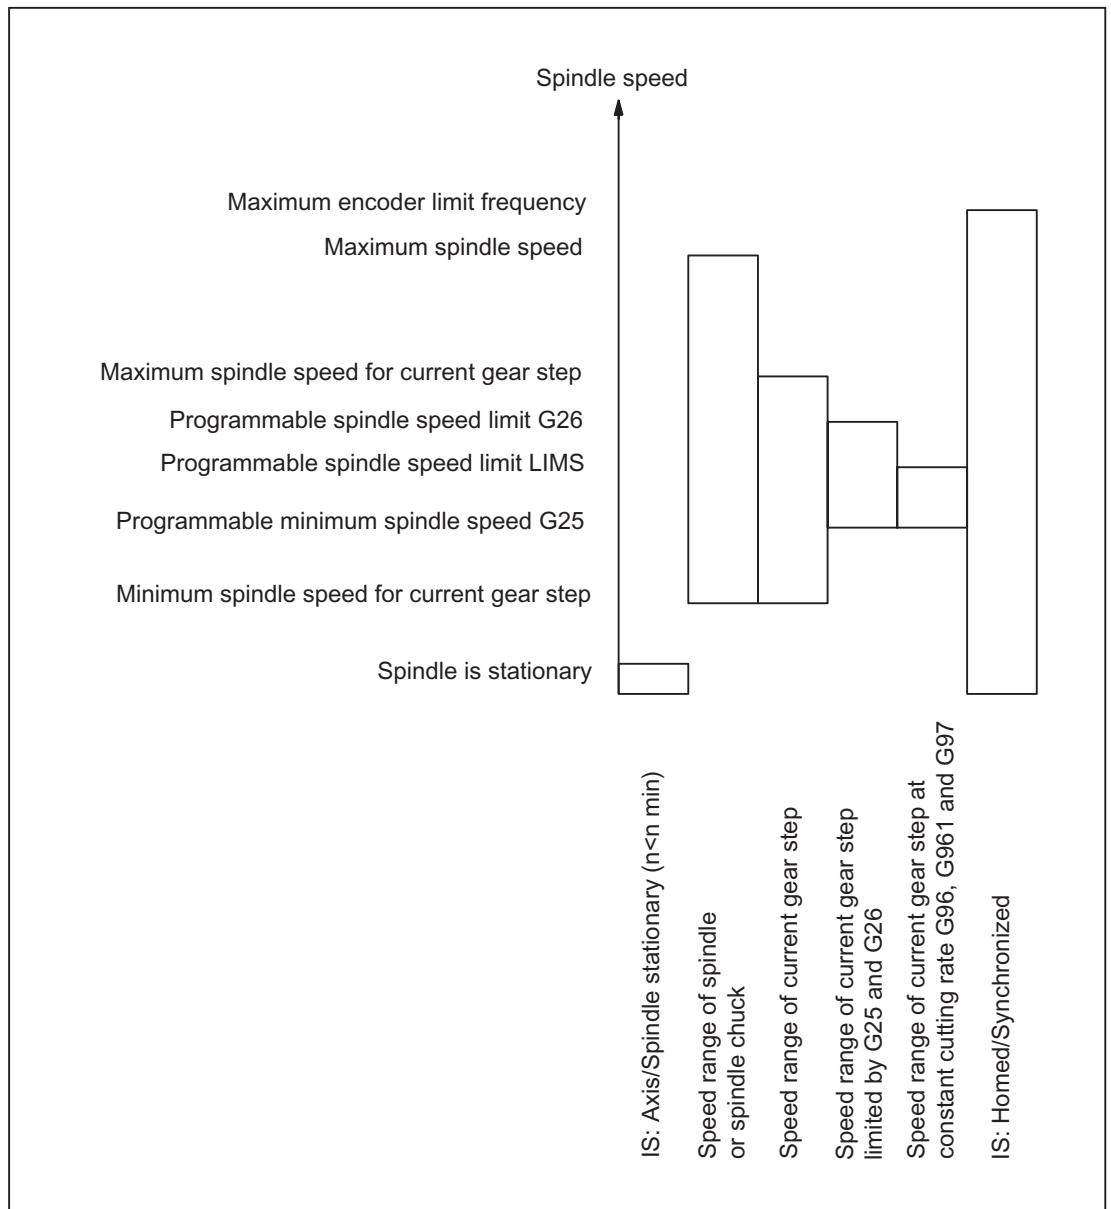

Figure 16-9 Ranges of spindle monitoring functions/speeds

## 16.8.2 Axis/spindle stationary

Functions such as tool change, open machine doors, path feedrate enable, etc. are only possible at the machine when the spindle is stationary.

### Function

The "axis/spindle stationary" state is reached if a setpoint is no longer generated and the spindle actual speed falls below the configured threshold value for "axis/spindle stationary":

MD36060 \$MA\_STANDSTILL\_VELO\_TOL (max. velocity/speed for "axis/spindle stationary")

If the spindle has come to a standstill, the following NC/PLC interface signal is set:

DB31, ... DBX61.4 (axis/spindle stationary)

### Effectiveness

Monitoring for spindle stop is effective in all spindle modes and in axis mode.

### Deactivate path feed

If a spindle is stopped in the open-loop control mode (M5), then path feed is deactivated if the following machine data is set:

MD35510 \$MA\_SPIND\_STOPPED\_AT\_IPO\_START (feedrate enable for spindle stopped)

The path feed is re-enabled if the spindle comes to a standstill.

## 16.8.3 Spindle in setpoint range

### Function

"Spindle in setpoint range" spindle monitoring checks whether:

- The programmed spindle speed is reached.
- the spindle is at a standstill:  
DB31, ... DBX61.4 (axis/spindle stationary) = 1
- The spindle is still in the acceleration or deceleration phase.

In the spindle mode, open-loop control mode, the setpoint speed is compared with the actual speed. If the actual speed deviates by more than the spindle tolerance that can be entered via MD (refer below) then:

- the following axial NC/PLC interface signal is set to "0":  
DB31, ... DBX83.5 (spindle in setpoint range) = 0
- The next machining block is not enabled (depending on the setting in MD35500 \$MA\_SPIND\_ON\_SPEED\_AT\_IPO\_START, see "Axis/spindle stationary (Page 1370)").

### Spindle setpoint speed

The spindle setpoint speed is derived from the programmed speed taking into account the spindle correction and the active limits.

If the programmed speed is limited or increased, this is displayed using DB31, ... DBX83.1 (setpoint speed limited) or DB31, ... DBX83.2 (setpoint speed increased) (see also "Minimum/maximum speed of the gear stage (Page 1372)"). The means that reaching the tolerance range of the setpoint speed is **not** prevented.

### Tolerance range for setpoint speed

The tolerance range of the setpoint speed is defined by the spindle speed tolerance factor:

MD35150 \$MA\_SPIND\_DES\_VELO\_TOL

Example:

MD35150 \$MA\_SPIND\_DES\_VELO\_TOL = 0.1

⇒ The spindle actual speed may deviate  $\pm 10\%$  from the setpoint speed.

The following NC/PLC interface signal is set to "1" if the spindle actual speed lies within the tolerance range:

DB31, ... DBX83.5 (spindle in setpoint range) = 1

#### Special case:

If the spindle speed tolerance is set to "0", then DB31, ... DBX83.5 (spindle in the setpoint range) is permanently set to "1" and no path control is performed.

### Speed change

Path control only takes place at the start of the traverse block and only if a speed change has been programmed. If the speed tolerance range is exited, e.g. due to an overload, the path movement is not automatically brought to a standstill.

## 16.8.4 Minimum/maximum speed of the gear stage

### Minimum speed

The minimum speed of the gear stage of a spindle is configured in the machine data:

MD35140 \$MA\_GEAR\_STEP\_MIN\_VELO\_LIMIT[<n>]

The speed setpoints, generated taking into account the override, do not fall below the minimum speed.

If an S value is programmed, which is less than the minimum speed, the setpoint speed is increased to the minimum speed and the following NC/PLC interface signal is set:

DB31, ... DBX83.2 (Setpoint speed restricted)

The minimum gear stage speed is effective only in speed mode and can only be undershot by:

- Spindle override 0%
- M5
- S0
- DB31, ... DBX4.3 (spindle stop)
- DB31, ... DBX2.1 (withdraw controller enable)
- DB21, ... DBX7.7 (reset)
- DB31, ... DBX2.2 (delete distance to go/spindle reset)
- DB31, ... DBX18.5 (oscillation speed)
- DB21, ... DBX7.4 (NC-STOP axes plus spindles)
- DB31, ... DBX1.3 (axis/spindle disable)
- DB31, ... DBX16.7 (delete S value)

### Maximum speed

The maximum speed of the gear stage of a spindle is configured in machine data:

MD35130 \$MA\_GEAR\_STEP\_MAX\_VELO\_LIMIT[<n>]

The speed setpoints, generated taking into account the override, are limited to this speed.

The following NC/PLC interface signal is set in the case that the speed is limited:

DB31, ... DBX83.1 (Setpoint speed restricted)

## 16.8.5 Diagnosis of spindle speed limitation

### Function

The limit or increase of the spindle speed is signaled by the output of the following NC/PLC interface signals:

- DB31, ... DBX83.1 (setpoint speed limited)
- DB31, ... DBX83.2 (setpoint speed increased)

To diagnose the effective/limiting spindle parameters, one can have read access to the most important parameters of spindle motion via system variables. The system variables are indexed with the spindle number and they return only values that are relevant to the speed control and spindle position modes.

The following system variables are available in the spindle mode:

| System variable                                                                  | Meaning                                                                                           |
|----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| \$AC_SMAXVELO[<n>]                                                               | Maximum possible spindle speed [rpm] resulting from the active limiting data.                     |
| \$AC_SMAXVELO_INFO[<n>]                                                          | Specification of the speed limiting data as numerical value. *)                                   |
| \$AC_SMINVELO[<n>]                                                               | Minimum possible spindle speed [rpm], corresponds to the minimum speed in the speed control mode. |
| \$AC_SMINVELO_INFO[<n>]                                                          | Specification of the speed increasing data as numerical value. *)                                 |
| \$AC_SMAXACC[<n>]                                                                | Acceleration value of spindle [ $r/s^2$ ].                                                        |
| \$AC_SMAXACC_INFO[<n>]                                                           | Acceleration limiting cause in the form of a numerical value. *)                                  |
| \$AC_SPIND_STATE[<n>]                                                            | Status bits of the spindle.                                                                       |
| <n>: Spindle no. (n= 0: the variables are related to the current master spindle) |                                                                                                   |

\*) The text of the numerical value should be taken from from the description of the system variables.

Evaluation of diagnosis data:

The system variables for each spindle can be read via synchronized actions and in the part program, giving due consideration to the preprocessing stop in the **NCK**.

## Boundary conditions

The values delivered by the system variables depend on the spindle mode:

- Speed control mode:  
All system variables deliver current values.
- Positioning mode:  
The system variables \$AC\_SMAXVELO, \$AC\_SMAXACC and \$AC\_SPIND\_STATE deliver valid values. The system variables \$AC\_SMINVELO and \$AC\_SMINVELO\_INFO deliver the data that becomes effective on changing to the speed control mode.
- Axis mode (e.g. if the spindle is used by a transformation TRANSMIT, TRACYL,... or follows a path motion as a special axis):  
The system variable \$AC\_SPIND\_STATE can also be used in the axis mode. Separate system variables are available in the axis mode for dynamic data:  
\$AA\_VMAXM, \$AA\_VMAXB and \$AA\_VLFCT.

The following control response is obtained for a type SERUPRO block search:

- The system variable \$AC\_SMAXVELO / \$AC\_SMAXACC delivers the maximum representable speed / acceleration.
- \$AC\_SMAXVELO\_INFO and \$AC\_SMAXACC\_INFO deliver the VALUE "0" (no limitation is active).
- \$AC\_SMINVELO and \$AC\_SMINVELO\_INFO deliver data as in case of normal part program processing.
- \$AC\_SPIND\_STATE returns the states as they are set for SERUPRO.

## Example

Example of the visualization of the content of the system variables for Spindle 1. The variables are written to the R parameters cyclically. These can be displayed on HMI in the R Parameters area.

### Program code

```
N05 IDS=1 WHENEVER TRUE DO $R10=$AC_SMAXVELO[1]
N10 IDS=2 WHENEVER TRUE DO $R11=$AC_SMAXVELO_INFO[1]
N15 IDS=3 WHENEVER TRUE DO $R12=$AC_SMINVELO[1]
N20 IDS=4 WHENEVER TRUE DO $R13=$AC_SMINVELO_INFO[1]
N25 IDS=5 WHENEVER TRUE DO $R14=$AC_SPIND_STATE[1]
```

## 16.8.6 Maximum spindle speed

### Maximum permissible spindle speed

The absolute speed upper limit, which the spindle must not exceed (the spindle chuck with the workpiece or the tool), is configured in machine data:

MD35100 \$MA\_SPIND\_VELO\_LIMIT (maximum spindle speed)

A change to the set value becomes effective after an NC reset.

---

#### Note

##### Machine manufacturer

Before reducing the value set in MD35100, the spindle involved should be stopped. Otherwise, Alarm 22100 (refer below) can occur, as the monitoring value is correspondingly reduced. Stopping especially applies to spindles that as a result of the setting in MD35040 SPIND\_ACTIVE\_AFTER\_RESET, are active beyond an NC reset.

---

### Monitoring

The maximum permissible spindle speed is monitored on the actual value side.

### Error case

If the actual speed exceeds the maximum permissible spindle speed by more than the configured spindle speed tolerance (MD35150 \$MA\_SPIND\_DES\_VELO\_TOL), then the following NC/PLC interface signal is set:

DB31, ... DBX83.0 (speed limit exceeded)

Further, the following alarm is output:

Alarm 22100 "Chuck speed exceeded"

All axes and spindles of the channel are braked (precondition: encoder is still functioning).

### Additional speed limiting by the user

Using the following setting data, the machine operator also has the option of setting a maximum permissible spindle speed, e.g. to adapt the upper speed limit to the maximum speed of the currently mounted chuck after a chuck change:

SD43235 \$SA\_SPIND\_USER\_VELO\_LIMIT (maximum spindle speed)

A change to the set value becomes effective immediately. The control limits an excessive spindle speed setpoint to this value.

---

**Note**

As standard setting, SD43235 has a speed limit of 10,000 rpm. For a software upgrade and spindle speeds above 10,000 rpm, if required, SD43235 must be increased.

---

**Note**

The machine operator preferably changes the setting data via the user interface. However, taking into account the fact that it becomes immediately effective in the part program, it can be read and/or written.

---

**Diagnostics**

Speed limiting using SD43235 is active, if the system variable \$AC\_SMAXVELO\_INFO[<n>] has the value "21".

## 16.8.7 Maximum encoder limit frequency

 **CAUTION**

The maximum encoder frequency limit of the actual spindle position encoder is monitored by the control (the limit can be exceeded). It is the responsibility of the machine tool manufacturer to ensure that the configuration of the spindle motor, gearbox, measuring gearbox, encoder and machine data prevents the maximum speed of the actual spindle position encoder being exceeded.

### Maximum encoder frequency exceeded

If the spindle speed reaches a speed (large S value programmed), which exceeds the maximum encoder limit frequency (the maximum mechanical speed limit of the encoder must not be exceeded), the synchronization is lost. The spindle continues to rotate, but with reduced functionality.

With the following functions, the spindle speed is reduced until the active measurement system is operating below the encoder limit frequency again:

- Thread cutting (G33, G34, G35)
- Tapping without compensating chuck (G331, G332)
- Revolutional feedrate (G95)
- Constant cutting rate (G96, G961, G97, G971)
- SPCON (position-controlled spindle operation)

When the encoder limit frequency is exceeded  
NC/PLC IS:  
DB31, ... DBX60.4 (Homed/Synchronized 1)  
or  
DB31, ... DBX60.5 (Homed/Synchronized 2)  
are reset for the measurement system in question and NC/PLC IS:  
DB31, ... DBX60.2 (encoder limit frequency 1 exceeded)  
or  
DB31, ... DBX60.3 (encoder limit frequency 2 exceeded)  
are set.

If the spindle is in axis mode, the maximum encoder limit frequency must not be exceeded. The maximum velocity (MD32000 \$MA\_MAX\_AX\_VELO) must lie below the maximum encoder limit frequency; otherwise, alarm 21610 is output and the axis is brought to a standstill.

### **Maximum encoder limit frequency undershot**

If the maximum encoder frequency limit has been exceeded and the speed subsequently falls below the maximum encoder limit frequency (smaller S value programmed, spindle offset switch changed, etc.), the spindle is automatically synchronized with the next zero mark or the next Bero signal. The new synchronization will always be carried out for the active position measuring system that has lost its synchronization and whose max. encoder limit frequency is currently undershot.

### **Special points to be noted**

If the following functions are active, the maximum encoder frequency cannot be exceeded:

- Spindle positioning mode, axis mode
- Thread cutting (G33, G34, G35)
- Tapping without compensating chuck G331, G332 (does not apply to G63)
- Revolutional feedrate (G95)
- Constant cutting rate (G96, G961, G97, G971)
- SPCON

### 16.8.8 End point monitoring

#### End point monitoring

During positioning (the spindle is in positioning mode), the system monitors the distance from the spindle (with reference to the actual position) to the programmed spindle position setpoint (end point).

For this to work, in machine data:

MD36000 \$MA\_STOP\_LIMIT\_COARSE (Exact stop limit coarse)

and

MD36010 \$MA\_STOP\_LIMIT\_FINE (Exact stop limit fine)

two limit values can be defined as an incremental path starting from the spindle position setpoint.

Regardless of the two limit values, the positioning of the spindle is always as accurate as defined by the connected spindle measurement encoder, the backlash, the transmission ratio, etc.

#### Exact stop window dependent on parameter set

Various parameter-set-dependent exact stop windows can be configured.

This makes it possible to work to different levels of accuracy in axis mode and spindle positioning. The exact stop window can be configured separately for each gear step for spindle positioning.

Figure 16-10 Exact stop zones of a spindle

**DB31, ... DBX60.7 and DB31, ... DBX60.6 (position reached with exact stop coarse / fine)**

The two limit values defined by machine data:  
MD36000 \$MA\_STOP\_LIMIT\_COARSE (Exact stop limit coarse)  
and  
MD36010 \$MA\_STOP\_LIMIT\_FINE (Exact stop limit fine)  
are output to the PLC using NC/PLC IS:  
DB31, ... DBX60.7 (Position reached with exact stop coarse)  
and  
DB31, ... DBX60.6 (Position reached with exact stop fine).

**Block change for SPOS and M19**

When positioning the spindle with `SPOS` or `M19` the block is changed dependent on end point monitoring with NC/PLC IS:  
DB31, ... DBX60.6 (Position reached with exact stop fine).

All other functions programmed in the block must have achieved their end criterion (e.g., all auxiliary functions acknowledged by the PLC).

With `SPOSA`, the block change does not depend on the monitoring of the end point.

**16.8.9 M40: Automatic gear stage selection for speeds outside the configured switching thresholds****Function**

When M40 is active, an automatic gear stage selection is also made if the programmed spindle speed `s...` lies outside the configured switching thresholds.

In this case, a distinction is made between the following cases:

- **Programmed speed too high**

The programmed speed is higher than the configured maximum speed of the numerically largest gear stage:

S... > MD35110 \$MA\_GEAR\_STEP\_MAX\_VELO[<n>]

In this case, the **highest gear stage** is selected (according to MD35090 \$MA\_NUM\_GEAR\_STEPS).

- **Programmed speed too low**

The programmed spindle speed is less than the configured minimum speed of the first gear stage:

S... < MD35120 \$MA\_GEAR\_STEP\_MIN\_VELO[1]

In this case, the **first gear stage** is selected.

- **Programmed speed = 0**

When programming speed 0 ( $s_0$ ) the behavior depends on the configuration of the minimum speed of the first gear stage MD35120 \$MA\_GEAR\_STEP\_MIN\_VELO[1]:

- If MD35120 \$MA\_GEAR\_STEP\_MIN\_VELO[1] = 0 is configured, then when programming  $s_0$ , the **first gear stage** is selected.
- If MD35120 \$MA\_GEAR\_STEP\_MIN\_VELO[1] > 0 is configured, when programming  $s_0$  **no gear stage change** is performed and the last gear stage remains active. This means that it remains possible to stop the spindle with  $s_0$  (instead of  $m_5$ ) without initiating a gear stage change.

## Effectiveness

Selecting the highest gear stage or the first gear stage for automatic gear stage selection (M40) is active when programming spindle speeds  $s_{...}$  using the part program, in synchronized actions or when entering via PLC FC18.

For speed programming from the part program for tapping with G331, the behavior is also supported for the second data set to select the gear stage (precondition: MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE, bit 5 = 1).

## Boundary conditions

### Enabling the gear stage change

The precondition for the function is that the gear stage change is generally enabled via machine data:

MD35010 \$MA\_GEAR\_STEP\_CHANGE\_ENABLE (assign parameters to the gear stage change)

MD35090 \$MA\_NUM\_GEAR\_STEPS (number of gear stages set up)

## Example

Automatic gear stage selection M40 is the initial setting after NC reset.

Part program:

| Program code | Comment                                                                                |
|--------------|----------------------------------------------------------------------------------------|
| ...          |                                                                                        |
| N15 S3500 M3 | ; S3500 is greater than MD35110 of the 2nd gear stage. The 2nd gear stage is selected. |
| ...          |                                                                                        |
| N50 S0 M3    | ; Spindle is stopped, S0 does not request a gear stage change (special handling, S0).  |
| ...          |                                                                                        |
| N95 S5 M3    | ; S5 is less than MD35120 of the 1st gear stage. The 1st gear stage is selected.       |
| ...          |                                                                                        |

Configuring data for spindle 1 (AX5):

|                                               |                                              |
|-----------------------------------------------|----------------------------------------------|
| MD35010 \$MA_GEAR_STEP_CHANGE_ENABLE[AX5] = 1 | ; Enable gear stage change                   |
| MD35090 \$MA_NUM_GEAR_STEPS[AX5] = 2          | ; Number of existing gear stages             |
| MD35110 \$MA_GEAR_STEP_MAX_VELO[1,AX5] = 500  | ; Upper switching threshold for gear stage 1 |
| MD35120 \$MA_GEAR_STEP_MIN_VELO[1,AX5] = 10   | ; Lower switching threshold for gear stage 1 |
| MD35110 \$MA_GEAR_STEP_MAX_VELO[2,AX5] = 2000 | ; Upper switching threshold for gear stage 2 |
| MD35120 \$MA_GEAR_STEP_MIN_VELO[2,AX5] = 500  | ; Lower switching threshold for gear stage 2 |

## 16.9 Examples

### 16.9.1 Automatic gear step selection (M40)

#### Example

To illustrate the contents of the new block search variables:  
 Assumptions about automatic gear step selection (M40):

|             |               |
|-------------|---------------|
| S0...500    | 1st gear step |
| S501..1000  | 2nd gear step |
| S1001..2000 | 3rd gear step |

Content of system variables:

|                 |                                   |
|-----------------|-----------------------------------|
| \$P_SEARCH_S    | ; Collected S value               |
| \$P_SEARCH_DIR  | ; Collected direction of rotation |
| \$P_SEARCH_GEAR | ; Collected gear step             |

| Collected             | S value:            | Direction of rotation: | Gear step: |
|-----------------------|---------------------|------------------------|------------|
|                       | ; 0/last speed      | -5                     | 40/last GS |
| N05 G94 M40 M3 S1000  | ; 1000              | 3                      | 40         |

| 31066  | DRIVE_AX_RATIO2_NUMERA | Intermediate gear numerator        |
| 31070  | DRIVE_ENC_RATIO_DENOM  | Measuring gear denominator         |
| 31080  | DRIVE_ENC_RATIO_NUMERA | Measuring gear numerator           |
| 31122  | BERO_DELAY_TIME_PLUS   | BERO delay time in plus direction  |
| 31123  | BERO_DELAY_TIME_MINUS  | BERO delay time in minus direction |

| Number | Identifier: \$MA_              | Description                                                              |
|--------|--------------------------------|--------------------------------------------------------------------------|
| 32200  | POSCTRL_GAIN                   | Kv factor                                                                |
| 32800  | EQUIV_CURRCTRL_TIME            | Equivalent time constant current control circuit for feedforward control |
| 32810  | EQUIV_SPEEDCTRL_TIME           | Equivalent time constant speed control circuit for feedforward control   |
| 32910  | DYN_MATCH_TIME                 | Time constant for dynamic matching                                       |
| 34040  | REFP_VELO_SEARCH_MARKER        | Reference point creep speed                                              |
| 34060  | REFP_MAX_MARKER_DIST           | Monitoring of zero mark distance                                         |
| 34080  | REFP_MOVE_DIST                 | Reference point distance/destination point for distance-coded system     |
| 34090  | REFP_MOVE_DIST_CORR            | Reference point offset/absolute offset, distance-coded                   |
| 34100  | REFP_SET_POS                   | Reference point value                                                    |
| 34200  | ENC_REFP_MODE                  | Homing mode                                                              |
| 35000  | SPIND_ASSIGN_TO_MACHAX         | Assignment of spindle to machine axis                                    |
| 35010  | GEAR_STEP_CHANGE_ENABLE        | Type of gear step change                                                 |
| 35012  | GEAR_STEP_CHANGE_POSITION      | Gear step change position                                                |
| 35014  | GEAR_STEP_USED_IN_AXISMODE     | Gear step for axis mode with M70                                         |
| 35020  | SPIND_DEFAULT_MODE             | Basic spindle setting                                                    |
| 35030  | SPIND_DEFAULT_ACT_MASK         | Activate initial spindle setting                                         |
| 35035  | SPIND_FUNCTION_MASK            | Setting of spindle-specific functions                                    |
| 35040  | SPIND_ACTIVE_AFTER_RESET       | Spindle active after reset                                               |
| 35090  | NUM_GEAR_STEPS                 | Number of installed gear steps                                           |
| 35092  | NUM_GEAR_STEPS2                | 2nd gear step data set: Number of installed gear steps                   |
| 35100  | SPIND_VELO_LIMIT               | Maximum spindle speed                                                    |
| 35110  | GEAR_STEP_MAX_VELO[n]          | Maximum speed for automatic gear stage change                            |
| 35112  | GEAR_STEP_MAX_VELO2[n]         | 2nd gear step data set: Maximum speed for automatic gear stage change    |
| 35120  | GEAR_STEP_MIN_VELO[n]          | Minimum speed for automatic gear stage change                            |
| 35122  | GEAR_STEP_MIN_VELO2[n]         | 2nd gear step data set: Minimum speed for automatic gear stage change    |
| 35130  | GEAR_STEP_MAX_VELO_LIMIT[n]    | Maximum speed of gear step                                               |
| 35135  | GEAR_STEP_PC_MAX_VELO_LIMIT[n] | Maximum speed of gear step in position control                           |
| 35140  | GEAR_STEP_MIN_VELO_LIMIT[n]    | Minimum speed of gear step                                               |
| 35150  | SPIND_DES_VELO_TOL             | Spindle speed tolerance                                                  |
| 35160  | SPIND_EXTERN_VELO_LIMIT        | Spindle speed limitation via PLC                                         |
| 35200  | GEAR_STEP_SPEEDCTRL_ACCEL[n]   | Acceleration in speed control mode                                       |
| 35210  | GEAR_STEP_POSCTRL_ACCEL[n]     | Acceleration in position control mode                                    |
| 35212  | GEAR_STEP_POSCTRL_ACCEL2[n]    | 2nd gear step data set: Acceleration in position control mode            |

| Number | Identifier: \$MA_           | Description                                                      |
|--------|-----------------------------|------------------------------------------------------------------|
| 35220  | ACCEL_REDUCTION_SPEED_POINT | Speed limit for reduced acceleration                             |
| 35230  | ACCEL_REDUCTION_FACTOR      | Reduced acceleration                                             |
| 35300  | SPIND_POSCTRL_VELO          | position control activation speed                                |
| 35350  | SPIND_POSITIONING_DIR       | Positioning direction of rotation for a non-synchronized spindle |
| 35400  | SPIND_OSCILL_DES_VELO       | Oscillation speed                                                |
| 35410  | SPIND_OSCILL_ACCEL          | Oscillation acceleration                                         |
| 35430  | SPIND_OSCILL_START_DIR      | Oscillation start direction                                      |
| 35440  | SPIND_OSCILL_TIME_CW        | Oscillation time for M3 direction                                |
| 35450  | SPIND_OSCILL_TIME_CCW       | Oscillation time for M4 direction                                |
| 35500  | SPIND_ON_SPEED_AT_IPO_START | Feed enable with spindle in setpoint range                       |
| 35510  | SPIND_STOPPED_AT_IPO_START  | Feed enable with stationary spindle                              |
| 35550  | DRILL_VELO_LIMIT[n]         | Maximum speeds for tapping                                       |
| 35590  | PARAMSET_CHANGE_ENABLE      | Parameter set definition possible from PLC                       |
| 36060  | STANDSTILL_VELO_TOL         | Threshold velocity "Axis/spindle stationary"                     |
| 36200  | AX_VELO_LIMIT               | Threshold value for velocity monitoring.                         |

## 16.10.2 Setting data

### 16.10.2.1 Channel-specific setting data

| Number | Identifier: \$SC_       | Description                                                                                    |
|--------|-------------------------|------------------------------------------------------------------------------------------------|
| 42600  | JOG_FEED_PER_REF_SOURCE | Revolutional feedrate control in JOG mode                                                      |
| 42800  | SPIND_ASSIGN_TAB        | Spindle number converter                                                                       |
| 42900  | MIRROR_TOOL_LENGTH      | Mirror tool length offset                                                                      |
| 42910  | MIRROR_TOOL_WEAR        | Mirror wear values of tool length compensation                                                 |
| 42920  | WEAR_SIGN_CUTPOS        | Mirror wear values of machining plane                                                          |
| 42930  | WEAR_SIGN               | Invert sign of all wear values                                                                 |
| 42940  | TOOL_LENGTH_CONST       | Retain the assignment of tool length components when changing the machining plane (G17 to G19) |

### 16.10.2.2 Axis/spindle-specific setting data

| Number | Identifier: \$SA_ | Description                                      |
|--------|-------------------|--------------------------------------------------|
| 43200  | SPIND_S           | Speed for spindle start via PLC interface        |
| 43202  | SPIND_CONSTCUT_S  | Cutting rate for spindle start via PLC interface |

## S1: Spindles

### 16.10 Data lists

| Number | Identifier: \$SA_          | Description                                                        |
|--------|----------------------------|--------------------------------------------------------------------|
| 43206  | SPIND_SPEED_TYPE           | For spindle start via PLC interface                                |
| 43210  | SPIND_MIN_VELO_G25         | Progr. spindle speed limiting G25                                  |
| 43220  | SPIND_MAX_VELO_G26         | Progr. spindle speed limiting G26                                  |
| 43230  | SPIND_MAX_VELO_LIMS        | Progr. spindle speed limiting G96/G96.1                            |
| 43235  | SPIND_USER_VELO_LIMIT      | Maximum spindle speed                                              |
| 43240  | M19_SPOS                   | Spindle position for spindle positioning with M19                  |
| 43250  | M19_SPOSMODE               | Spindle positioning approach mode for spindle positioning with M19 |
| 43300  | ASSIGN_FEED_PER_REF_SOURCE | Rotational feedrate for positioning axes/spindles                  |

### 16.10.3 Signals

#### 16.10.3.1 Signals to axis/spindle

| Signal name                                                                 | SINUMERIK 840D sl    | SINUMERIK 828D     |
|-----------------------------------------------------------------------------|----------------------|--------------------|
| Feedrate override A to H                                                    | DB31, ... .DBX0.0-7  | DB380x.DBX0.0-7    |
| Axis/spindle disable                                                        | DB31, ... .DBX1.3    | DB380x.DBX1.3      |
| Follow-up mode                                                              | DB31, ... .DBX1.4    | DB380x.DBX1.4      |
| Position measuring system 1                                                 | DB31, ... .DBX1.5    | DB380x.DBX1.5      |
| Position measuring system 2                                                 | DB31, ... .DBX1.6    | DB380x.DBX1.6      |
| Override active                                                             | DB31, ... .DBX1.7    | DB380x.DBX1.7      |
| Controller enable                                                           | DB31, ... .DBX2.1    | DB380x.DBX2.1      |
| Spindle reset/delete distance-to-go                                         | DB31, ... .DBX2.2    | DB380x.DBX2.2      |
| Velocity/spindle speed limitation                                           | DB31, ... .DBX3.6    | DB380x.DBX3.6      |
| Program test Axis/Spindle Enable                                            | DB31, ... .DBX3.7    | DB380x.DBX3.7      |
| Actual gear step A to C                                                     | DB31, ... .DBX16.0-2 | DB380x.DBX2000.0-2 |
| Gear changed                                                                | DB31, ... .DBX16.3   | DB380x.DBX2000.3   |
| Resynchronize spindle 1                                                     | DB31, ... .DBX16.4   | DB380x.DBX2000.4   |
| Resynchronize spindle 2                                                     | DB31, ... .DBX16.5   | DB380x.DBX2000.5   |
| no n-monitoring with gear change                                            | DB31, ... .DBX16.6   | DB380x.DBX2000.6   |
| Delete S value                                                              | DB31, ... .DBX16.7   | DB380x.DBX2000.7   |

## V1: Feedrates

### 17.1 Brief description

#### Types of feedrate

The feedrate determines the machining speed (axis or path velocity) and is observed in every type of interpolation, even where allowance is made for tool offsets on the contour or on the tool center point path (depending on G commands).

The following types of feedrate allow optimum adaptation to the various technological applications (turning, milling, drilling, etc.):

- Rapid traverse feedrate (G0)
- Inverse-time feedrate (G93)
- Linear feedrate (G94)
- Revolutional feedrate (G95)
- Constant cutting rate (G96, G961)
- Constant speed (G97, G971)
- Feed rate for thread cutting (G33, G34, G35)
- Feedrate for tapping with compensating chuck (G63)
- Feedrate for tapping without compensating chuck (G331, G332)
- Feedrate for chamfer/rounding FRC, FRCM
- Non-modal feedrate FB

#### Programmable run-in, run-out path for G33

The thread run-in and run-out path can be programmed. The thread axis is accelerated or braked inside the specified path.

---

#### Note

The axis can be overloaded if the specified path is too short.

---

#### Axis assignment of the feedrates

Feedrates can be assigned to the axes variably to adjust to the different technological requirements.

The following versions are possible:

- Separate feedrates for the working plane and the infeed axis
- Variable axis assignment for path feedrate
- Feedrate for positioning axes

## Feedrate control

The programmed feedrate can be changed during the machining or for test purposes to enable adjustment to the changed technological conditions.

- via the machine control panel
- via the operator panel front
- via the PLC
- per program command

## Feedrate interpolation

To permit flexible definition of the feed characteristic, the feed programming according to DIN 66205 has been extended by linear and cubic characteristics.

The cubic profiles can be programmed directly or as an interpolating spline.

You can program the following feedrate profiles:

- **FNORM**

Response as per DIN 66025 (default setting).

An **F**-value programmed in the block is applied over the entire path of the block, and is subsequently regarded as a fixed modal value.

- **FLIN**

An **F**value programmed in the block is traversed linearly over the path from the current value at the beginning of the block to the end of the block, and is subsequently regarded as modal value.

- **FCUB**

The blockwise programmed **F**values are - relative to the end of the block - connected by a spline. The spline starts and ends tangentially to the previous or following feedrate setting. If the **F** address is missing in one block, then the last programmed **F** value is used for it.

- **FPO**

The **F** address [Syntax: **F**=**FPO** (...,...)] designates the course of the feedrate via a polynomial from the current value to the end of the block in which it was programmed. The end value is treated as modal from there onwards.

The machine data:

MD20172 \$MC\_COMPRESS\_VELO\_TOL

allows a tolerance to be defined for the path feedrate if **FLIN** and **FCUB** are used in connection with compression **COMPON**.

Explanations on programmable course of the feedrate are available in:

### References:

/PGA/ Programming Manual - Job Planning

### Feedrate for chamfer/rounding FRC, FRCM

The machining conditions can change significantly during surface transitions to chamfer/rounding. The chamfer/rounding contour elements therefore need their own optimized feedrate values in order to achieve the required surface finish.

You can program the feedrate for the chamfer/rounding with `FRC` (non-modal) or `FRCM` (modal).

### Non-modal feedrate FB

A separate feedrate can be specified for an individual block with the `FB` command. The earlier active path feedrate is overwritten for this block; the earlier effective modal path feedrate is active again after this block.

### Programmable single-axis dynamic response

The dynamic response of individual axes can be changed in a targeted manner via programming.

- Percentage acceleration override (`ACC`) in part program and synchronized actions
- Programmable end of motion criterion: `FINEA` (exact stop fine), `COARSEA` (exact stop coarse), `IPOENDA` (Interpolator stop) in the part program and in synchronized actions
- Programmable servo parameter set (`SCPARA`) in the part program and in synchronized actions

## 17.2 Path feedrate F

### 17.2.1 General

#### Path feedrate F

The path feedrate represents the geometrical total of the velocity components in the participating axes. It is therefore generated from the individual motions of the interpolating axes.

The default uses the axial velocities of the geometry axes which have been programmed. The `FGROUP` command can be used to include other geometry and/or synchronized axes in the calculation of the path feedrate.

The path feedrate F determines the machining speed and is observed in every type of interpolation even where allowance is made for tool offsets. The value programmed under the address F remains in a program until a new F value or a new type of feedrate is programmed.

#### Value range for path feedrate F

**References:**

Programming Manual, Fundamentals

Function Manual, Basic Functions; Velocities, Setpoint/Actual Value Systems, Closed-Loop Control (G2)

#### F value at PLC interface

The F value of the current path feedrate is always entered in the channel-specific PLC interface for auxiliary functions (DB21, ... DBB158 to 193).

You can find explanations about the corresponding interface signals (change signal, F value) in:

**References:**

Function Manual, Basic Functions; Auxiliary Function Output to PLC (H2)

#### Feedrate with transition circle

**References:**

Programming Manual, Fundamentals

## Feedrate for internal radius and external radius path sections

For circular blocks or spline blocks with curvature in the same direction and tool radius offset activated (G41/G42), the programmed feedrate can act on the center point path or on the contour (depending on the internal radius or external radius path sections).

A group of G commands is provided for this purpose:

- CFTCP  
Programmed feedrate acting on the center point path.
- CFC  
Programmed feedrate acting on the contour.
- CFCIN  
Programmed feedrate acting only on the contour with a concave spline.

### References:

Programming Manual, Fundamentals

## Maximum tool path velocity

The maximum path velocity results from the maximum velocities of the linear or rotary axes involved (MD32000 \$MA\_MAX\_AX\_VELO), i.e. the axis with the lowest maximum velocity determines the maximum path velocity. This cannot be exceeded.

If G0 is programmed, traversing is at the path velocity resulting from the MD32000 \$MA\_MAX\_AX\_VELO limitation.

## Limit velocity for path axes

In addition, the FL[<axis>] command can be used to program a limit velocity for path axes (geometry and synchronized axes).

This enables separate feedrates to be programmed for the working plane and infeed axis. This means that a feedrate is specified for both path-related interpolation and for the infeed axis. The axis perpendicular to the selected machining plane is designated as the infeed axis. The infeed axis-specific feedrate can be programmed to limit the axis velocity and therefore the path velocity. No coordinate rotations through frames should be included, i.e., the infeed axis must be an axis of the standard coordinate system. This function can be used to compensate for the fact that a cutter has a lower cutting performance on the face side than across the cutter circumference.

Programming example:

| Program code  | Comment                               |
|---------------|---------------------------------------|
| ... G94...    | ; Selection of feedrate type (mm/min) |
| X30 Y20 F200  | ; Path feedrate = 200 mm/s            |
| FL[Z]=50 Z-30 | ; Max. feedrate for Z axis: 50 mm/s   |

## 17.2.2 Type of feedrate G93, G94, G95

### Effectivity

The feedrate types G93, G94, G95 are active for the G functions of group 1 (except G0) in the automatic modes.

G94 or G95 can be used for traversing in JOG mode.

#### References:

Function Manual, Extended Functions; Jog With/Without Handwheel (H1)

### Inverse-time feedrate (G93)

The inverse-time feedrate is used when it is easier to program the duration, rather than the feedrate, for retraction of a block.

The inverse-time feedrate is calculated from the following formula:

$$F = \frac{v}{s}$$

Where

- F: Inverse-time feedrate in rpm
- v: Required path velocity in mm/min or inch/min
- s: Path length in mm/inch

Programming example:

| Program code            | Comment                                        |
|-------------------------|------------------------------------------------|
| N10 G1 G93 X100 Y200 F2 | ; The programmed path is traversed in 0.5 min. |
| ...                     |                                                |

#### Note

G93 may not be used when G41/G42 is active. If the block length varies greatly from block to block, a new F value should be programmed in each block for G93.

### Linear feedrate (G94)

The linear feedrate is programmed in the following units relative to a linear or rotary axis:

- [mm/min, degrees/min] on standard metric systems
- [inch/min, degrees/min] on standard imperial systems

## Revolutional feedrate (G95)

The revolutional feedrate is programmed in the following units relative to a master spindle:

- [mm/rev] on standard metric systems
- [inch/rev] on standard imperial systems
- [degrees/rev] on a rotary axis

The path velocity is calculated from the actual speed of the spindle according to the following formula:

$$V = n * F$$

and

V: Path velocity in mm/min or inch/min  
n: Speed of the master spindle in rpm  
F: Programmed revolutional feedrate in mm/rev or inch/rev

### Note

The programmed F value is deleted when the system switches between the feedrate types G93, G94 and G95.

### Tooth feedrate

Primarily for milling operations, the tooth feedrate  $F_Z$  . . . , which is more commonly used in practice, can be programmed instead of the revolutional feedrate  $F$  . . . : (feed distance per tooth).

The control uses the \$TC\_DPNT (number of teeth per revolution) tool parameter associated with the active tool offset data record to calculate the effective revolutional feedrate for each traversing block from the programmed tooth feedrate.

$$F = F_Z * \$TC\_DPNT$$

with

F: Revolutional feedrate in mm/rev or inch/rev  
 $F_Z$ : Tooth feedrate in mm/tooth or inch/tooth  
\$TC\_DPNT: Tool parameter: Number of teeth/rev

Example: Milling cutter with 5 teeth (\$TC\_DPNE = 5)

| Program code       | Comment                                           |
|--------------------|---------------------------------------------------|
| N10 G0 X100 Y50    |                                                   |
| N20 G1 G95 FZ=0.02 | ; Tooth feedrate 0.02 mm/tooth                    |
| N30 T3 D1          | ; Load tool and activate tool offset data record. |
| M40 M3 S200        | ; Spindle speed 200 rpm                           |

| Program code | Comment                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| N50 X20      | ; Milling with:<br>FZ = 0.02 mm/tooth<br><input type="checkbox"/> effective revolutional feedrate:<br>F = 0.02 mm/tooth * 5 teeth/rev = 0.1 mm/rev<br>or:<br>F = 0.1 mm/rev * 200 rpm = 20 mm/min |
| ...          |                                                                                                                                                                                                   |

### Revolutional feedrate in JOG mode

In JOG mode, the response of the axis/spindle also depends on the following setting data:

SD41100 \$SN\_JOG\_REV\_IS\_ACTIVE (revolutional feed rate for JOG active)

If this setting data is active, an axis/spindle is always moved with revolutional feedrate:

MD32050 \$MA\_JOG\_REV\_VELO (revolutional feedrate with JOG)

or

MD32040 \$MA\_JOG\_REV\_VELO\_RAPID (revolutional feedrate with JOG with rapid traverse overlay)

depending on the master spindle.

If the setting data is inactive:

- the response of the axis / spindle depends on the setting data:

SD43300 \$SA\_ASSIGN\_FEED\_PER\_REV\_SOURCE (revolutional feedrate for position axes/spindles)

- the response of a geometry axis on which a frame acts is to rotate, depending on the channel-specific setting data:

SD42600 \$SC\_JOG\_FEED\_PER\_REV\_SOURCE

### DB31, ... DBX62.2 (revolutional feedrate active)

A programmed, active revolutional feedrate (G95) is displayed using the following NC/PLC interface signal.

DB31, ... DBX62.2 (revolutional feedrate active)

### 17.2.3 Type of feedrate G96, G961, G962, G97, G971

#### Constant cutting rate (G96, G961)

The constant cutting rate is used on turning machines to keep the cutting conditions constant, independently of the work diameter of the workpiece. This allows the tool to be operated in the optimum cutting performance range and therefore increases its service life.

##### Selection of G96, G961:

When programming G96, G961, the corresponding S value is interpreted as the cutting rate in m/min or ft/min along the transverse axis. If the workpiece diameter decreases during machining, the speed is increased until the constant cutting speed is reached.

When G96, G961 is first selected in the part program, a constant cutting rate must be entered in mm/min or ft/min.

With G96, the control system will automatically switch to revolutionary feedrate (as with G95), i.e. the programmed feedrate F is interpreted in mm/rev or inch/rev.

When programming G961, linear feedrate is selected automatically (as with G94). A programmed feedrate F is interpreted in mm/min or inch/min.

##### Determining the spindle speed

Based on the programmed cutting rate (either  $S_{G96}$  or  $S_{G961}$ ) and the actual cartesian position of the transverse axis (radius), the control system calculates the spindle speed at the TCP using the following formula:

$$n = \frac{S_{Speed}}{2 * \pi * r}$$

- n: Spindle speed  
 $S_{Speed}$ : Programmed cutting rate  
 $\pi$ : Circle constant  
r: Radius (distance, center of rotation to TCP)

The following is assumed when determining the radius:

- The transverse axis position 0 in the Work represents the center of rotation.
- Position offsets (such as online tool offset, external work offset, \$AA\_OFF, DRF offset and compile cycles) and position components through couplings (e.g. following axis for TRAIL) are not taken into account when determining the radius.

Frames (e.g. programmable frames such as SCALE, TRANS or ROT) are taken into account in the calculation of the spindle speed and can bring about a change in speed, if the effective diameter at the TCP changes.

**Diameter programming and reference axis for several transverse axes in one channel:**

One or more transverse axes are permitted and can be activated simultaneously or separately:

- Programming and displaying in the HMI operator interface in the diameter
- Assignment of the specified reference axis with `SCC[AX]` for a constant cutting rate `G96`, `G961`, `G962`

**References:**

Function Manual Basic Functions; Transverse Axes (P1), example

**Example**

$S_{G96} = 230 \text{ m/min}$

- where  $r = 0.2 \text{ m} \rightarrow n = 183.12 \text{ rpm}$
- where  $r = 0.1 \text{ m} \rightarrow n = 366.24 \text{ rpm}$

⇒ The smaller the workpiece diameter, the higher the speed.

For `G96`, `G961` or `G962` a geometry axis must be defined as the transverse axis.

The transverse axis, whose position affects the speed of the mater spindle, is defined using channel-specific machine data:

MD20100 \$MC\_DIAMETER\_AX\_DEF (geometry axis with transverse axis function)

The function `G96`, `G961` or `G962` requires the machine zero and the workpiece zero of the transverse axis to be in the turning center of the spindle.

**Constant speed (G97, G971)**

`G97`, `G971` deactivates the "Constant cutting rate function" (`G96`, `G961`) and saves the last calculated spindle speed. With `G97`, the feedrate is interpreted as a revolutional feedrate (as with `G95`).

When programming `G971`, linear feedrate is selected (as with `G94`). The feedrate `F` is interpreted in mm/min or inch/min.

When `G97`, `G971` is active, an S value can be reprogrammed to define a new spindle speed. This will not modify the cutting rate programmed in `G96`, `G961`.

G97, G971 can be used to avoid speed variations in movements along the transverse axis without machining (e.g. cutting tool).

---

#### Note

G96, G961 is only active during workpiece machining (G1, G2, G3, spline interpolation, etc., where feedrate F is active).

The response of the spindle speed for active G96, G961 and G0 blocks can be defined in the channel-specific machine data:

MD20750 ALLOW\_G0\_IN\_G96 (G0 logic for G96, G961)

When constant cutting rate G96, G961 is selected, no gear stage change can take place.

The spindle speed override switch acts on the spindle speed calculated.

A DRF offset in the transverse axis does not affect the spindle speed setpoint calculation.

At the start of machining (after G0) and after NC Stop, G60, G09, ... the path start waits for "nAct= nSet".

The interface signals "nAct = nSet" and "Set speed limited" are not modified by internal speed settings.

When the speed falls below the minimum speed or if the signal "Axis/spindle stationary" is recognized, "nAct =nSet" is reset.

A path operation, which has started (G64, rounding), is not interrupted.

---

### Spindle speed limitation with G96, G961

For the function "Constant cutting rate", in setting data:

SD43230 \$SA\_SPIND\_MAX\_VELO\_LIMS

(spindle speed limitation with G96/G961)

and in the part program (for the master spindle) with the programming command LIMS, a maximum spindle speed can be set.

The most recently changed value (LIMS or SD) is active.

LIMS is effective with G96, G961, G97 and can be specified on up to four speed limitations in the part program in one block. Spindle number Sn=1, 2, 3, or 4 of the master spindle that is possible in the particular instance can be programmed in part program instruction LM[Sn].

---

#### Note

When the block is loaded in the main run, all programmed values are transferred to setting data SD43230 \$SA\_SPIND\_MAX\_VELO\_LIMS.

---

The speed limit set with LIMS remains stored after the control is switched off, depending on the machine data:

MD10710 PROG\_SD\_RESET\_SAVE\_TAB[n] (setting data to be updated).

When G96, G961, G97 are reactivated, this spindle speed limitation is also activated.

The maximum permissible spindle speed defined by means of G26 or setting data: SD43220 \$SA\_SPIND\_MAX\_VELO\_G26 (maximum spindle speed), cannot be exceeded.

In the event of incorrect programming that would cause one of the speed limits (G26 or SD43220 \$SA\_SPIND\_MAX\_VELO\_G26) to be exceeded, the "Programmed speed too high" interface signal (DB31, ... DBX83.1) is set.

In order to ensure smooth rotation with large part diameters, the spindle speed is not permitted to fall below a minimum level.

This speed can be set via the setting data:

SD43210 \$SA\_SPIND\_MIN\_VELO\_G25 (minimum spindle speed)

and, depending on the gear step, with the machine data:

MD35140 \$MA\_GEAR\_STEP\_MIN\_VELO\_LIMIT (minimum speed of the gear step).

The minimum spindle speed can be changed in the part program with G25. In the event of programming that would mean one of the spindle limits (G25 or SD43220 \$SA\_SPIND\_MAX\_VELO\_G26) is not reached, the "Set speed too low" interface signal (DB31, ... DBX83.2) is set.

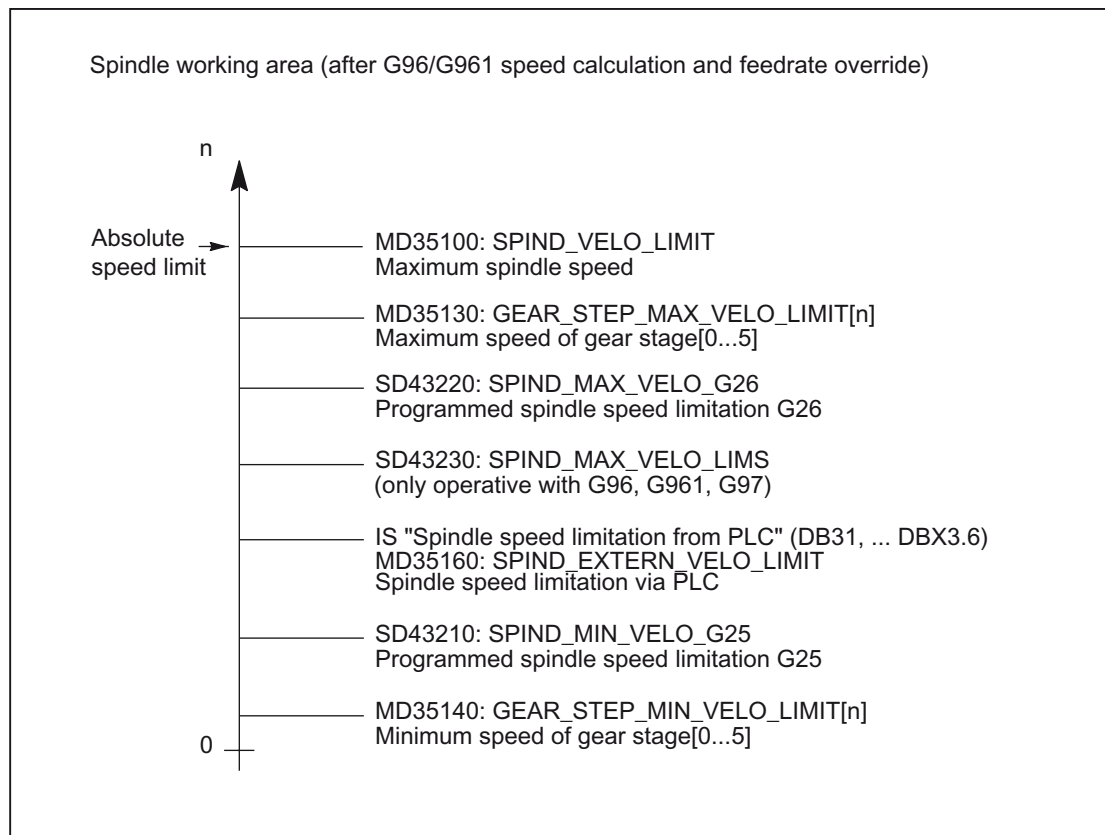

Figure 17-1 Spindle speed limitations

The various spindle speed limits are illustrated in the figure above. For more information and for information on the effect of the setting data see:

**References:**

/FB1/ Function Manual Basic Functions; Spindles (S1);  
Section: Spindle Monitoring Functions, Setting Data

## Master spindle switchover with G96, G961

If the master spindle is switched over when G96, G961 are active, the speed of the former master spindle is retained. This corresponds to a transition from G96 to G97. The master spindle newly defined with SETMS executes the "Constant cutting rate" function generated in this way.

## Interrupts

### Constant cutting rate G96, G961, G962

- If no F value is programmed, alarm 10860 "No feedrate programmed" is output. The alarm is not generated with G0 blocks.
- Alarm 14800 "Programmed path velocity smaller than or equal to zero" is output while programming a negative path velocity.
- If, with an active G96, G961 or G962, no transverse axis is defined in the machine data: MD20100 \$MC\_DIAMETER\_AX\_DEF (geometry axis with transverse axis function), alarm 10870 "No transverse axis defined" is issued.
- If a negative maximum spindle speed is programmed with the LIMS program command when G96, G961 are active, alarm 14820 "Negative maximum spindle speed programmed for G96, G961" is output.
- If no constant cutting rate is programmed when G96, G961 is selected for the first time, alarm 10900 "No S value programmed for constant cutting rate" is output.

## 17.2.4 Feedrate with G33, G34, G35 (thread cutting)

### 17.2.4.1 General

#### Application of G33

The function G33 can be used to machine threads with constant lead of the following type:

**References:**

/PA/ Programming Manual, Fundamentals

/PAZ/ Programming Manual, Cycles

#### Speed S, feedrate F, thread lead

A revolutional feedrate [mm/revolution] is used for G33 threads. The revolutional feedrate is defined by programming the thread lead increase [mm/revolution].

The speed of the axes for the thread length is calculated from the programmed spindle speed  $s$  and the thread lead.

Feedrate  $F$  [mm/min] = speed  $s$  [rev/min] \* thread lead [mm/rev]

At the end of the acceleration ramp, the position coupling between the spindle actual value (spindle setpoint with  $S_{PCON}$  on master spindle) and the axis setpoint is established. At this moment, the position of the axis in relation to the zero mark of the spindle (including zero mark offsets) is as if the axis had accelerated abruptly at the start of the block when the thread start position (zero mark plus  $S_F$ ) was crossed. Compensation is made for the following error of the axis.

#### Minimum spindle speed

In order to ensure smooth rotation at low speeds, the spindle speed is not permitted to fall below a minimum level.

This speed is defined using setting data:

SD43210 \$SA\_SPIND\_MIN\_VELO\_G25 (minimum spindle speed)

and can be set for each gear step with the machine data:

MD35140 \$MA\_GEAR\_STEP\_MIN\_VELO\_LIMIT (minimum velocity for gear step change) .

The minimum spindle speed can be changed in the part program with G25.

#### NC STOP, single block

NC STOP and single block (even at the block boundary) are only active after completion of thread chaining. All subsequent G33 blocks and the first subsequent non-G33 block are traversed like a single block.

#### Premature abortion without destruction

Thread cutting can be aborted without destruction before the end point is reached. This can be done by activating a retraction motion.

## Thread cutting with ROT frame

With `ROT` frame and `G33`, `G34`, `G35`, alarm 10607 "Thread with frame not executable" is activated if the rotation causes a change in the thread length and thus the lead. Rotation around the thread axis is permissible.

Alarm 10607 "Thread with frame not executable" can be suppressed by setting bit 12 in machine data:

MD11410 \$MN\_SUPPRESS\_ALARM\_MASK,  
if the `ROT` statement is used intentionally in the application.

All other frames are accepted by the NC without alarm. Attention is drawn to the lead-changing effect of `SCALE`.

### 17.2.4.2 Programmable run-in and run-out path for G33, G34 and G35

#### Application

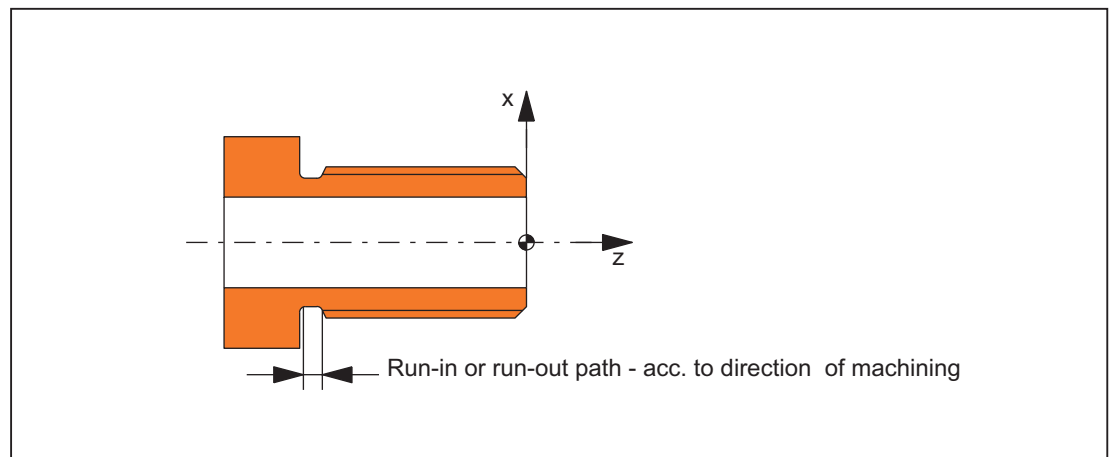

Figure 17-2 Run-in or run-out path too short

- **Short run-in path**

Due to the collar on the thread run-in, little room is left for the tool (T) start ramp. This must therefore be set shorter via `DITS`.

- **Short run-out path**

Due to the collar on the thread run-out, little room is left for the tool deceleration ramp, leading to the risk of collision between the workpiece and the tool edge. The tool braking ramp can be set shorter via `DITE`. Due to the inertia of the mechanical system, however, a collision can nevertheless occur.

Remedy: Program a shorter thread, reduce the spindle speed.

The programmed run-in and run-out path only increases the rate of acceleration on the path. If one of the two paths is set larger than the thread axis needs with active acceleration, the thread axis is accelerated or decelerated with maximum acceleration.

## Activation

The `DITS` and `DITE` functions are always active during thread cutting.

### Example:

```

N...
N59 G90 G0 Z100 X10 SOFT M3 S500
N60 G33 Z50 K5 SF=180 DITS=1 DITE=3 ; Start of corner rounding with Z=53
N61 G0 X20

```

## SD42010

Only paths, and not positions, are programmed with `DITS` and `DITE`.

The part program instructions are related to the setting data:

SD42010 `$SC_THREAD_RAMP_DISP[0,1]`,

which defines the following acceleration response of the axis on thread cutting:

- **SD42010 ≤ 0 to -1**

Identical with previous response.

Starting/braking of the feedrate axis at configured acceleration rate.

Jerk according to current `BRISK/SOFT` programming.

- **SD42010 = 0**

Abrupt starting/braking of the feedrate axis on thread cutting.

- **SD42010 ≥ 0**

The thread run-up/deceleration distance is specified.

To avoid technology alarm 22280, the acceleration limits of the axis must be observed in case of very small run-in and run-out paths.

---

### Note

`DITE` acts at the end of the thread as a rounding clearance. This achieves a smooth change in the axis movement.

---

## Compatibility

Machine data:

MD20650 `$MC_THREAD_START_IS_HARD`

is dispensed with and is replaced by:

SD42010 `$SC_THREAD_RAMP_DISP[0]`

or

SD42010 `$SC_THREAD_RAMP_DISP[1]` .

The response of the new setting data with:

SD42010 `$SC_THREAD_RAMP_DISP[0] = 0`

or

SD42010 `$SC_THREAD_RAMP_DISP[1] = 0`

is identical to the previous machine data setting:

MD20650 `$MC_THREAD_START_IS_HARD = 1` .

The response with:  
SD42010 \$SC\_THREAD\_RAMP\_DISP[0] = -1  
or  
SD42010 \$SC\_THREAD\_RAMP\_DISP[1] = -1  
is identical to the previous machine data setting:  
MD20650 \$MC\_THREAD\_START\_IS\_HARD = 0 (default).

## Constraints

When a block containing command `DITS` and/ or `DITE` is loaded in the interpolator, the path programmed in `DITS` is transferred to setting data:  
SD42010 \$SC\_THREAD\_RAMP\_DISP[0]  
and the path programmed in `DITE` is transferred to setting data:  
SD42010 \$SC\_THREAD\_RAMP\_DISP[1].

The programmed run-in path is handled according to the current setting (inches, metric).

If no run-in/deceleration path is programmed before or in the first thread block, the value is determined by the current value in setting data:  
SD42010 \$SC\_THREAD\_RAMP\_DISP[0,1].

In the event of `RESET`, the setting data:  
SD42010 \$SC\_THREAD\_RAMP\_DISP[0,1]  
is set to "-1".

### 17.2.4.3 Linear progressive/degressive thread-lead change with G34 and G35

#### Application G34, G35

The functions can be used to produce self-shearing threads.

#### Functionality

The thread lead increase (`G34`) defines the numerical increase in the lead value. A larger pitch results in a larger distance between the threads on the workpieces. The velocity of the thread axis thus increases assuming that the spindle speed is constant. The opposite naturally applies to decreasing thread lead (`G35`).

The following definitions have been made for the thread-lead changes with respect to the new G codes:

- `G34`: Increase in thread lead corresponds to progressive change.
- `G35`: Decrease in thread lead corresponds to degressive change.

Both functions `G34` and `G35` imply the functionality of `G33` and additionally provide the option of programming an absolute lead change value for the thread under `F`. If the start and end lead of a thread is known, the thread-lead change can be determined using the following equation:

$$F = \frac{|k_e^2 - k_a^2|}{2 * l_G}$$

The identifiers have the following meanings:

- F: The thread-lead change to be programmed [mm/rev<sup>2</sup>]  
 k<sub>e</sub>: Thread lead of axis target point coordinate, thread axis [mm/rev]  
 k<sub>a</sub>: Initial thread lead (programmed under I, J or K) [mm/rev]  
 l<sub>G</sub>: Thread length [mm]

The absolute value of F must be applied to G34 or G35 according to the desired lead increase or lead decrease.

When the thread length l<sub>G</sub>, lead change F and initial lead k<sub>a</sub> are known, the lead increase at the end of block k<sub>e</sub> can be determined as follows by modifying the formula:

- G34 (progressive lead):

$$k_e = \sqrt{k_a^2 + F * 2 * l_G}$$

- G35 (degressive lead):

$$k_e = \sqrt{k_a^2 - F * 2 * l_G}$$

### Note

If the formula results in a negative root expression, the thread cannot be machined!

In this case, the NC signals alarm 10605 or alarm 22275.

### Sample program

Thread cutting G33 with degressive thread lead G35

```

N1608 M3 S10 ; Spindle speed
N1609 G0 G64 Z40 X216 ; Approach starting point
N1610 G33 Z0 K100 SF=R14 ; Thread with constant pitch 100 mm/rev
N1611 G35 Z-220 K100 F17.045455 ; Thread lead decrease 17.045455 mm/rev2
; Thread lead at end of block 50 mm/rev
N1612 G33 Z-240 K50 ; Traverse thread block without jerk
N1613 G0 X218 ;
N1614 G0 Z40 ;
N1616 M17 ;

```

## Suppress special alarms

Any lead changes that would overload the thread axis when G34 is active or would result in an axis standstill when G35 is active are detected in advance during block preparation.

Alarm 10604 "Thread lead increase too high" or alarm 10605 "Thread lead decrease too high" are output if bit 10 in machine data:

MD11410 SUPPRESS\_ALARM\_MASK  
is not set.

During thread cutting, certain practical applications require a correction of the spindle speed. In this case, the operator will base his correction on the permissible velocity of the thread axis.

The output of the alarm generated during monitoring (10604 or 10605) can be suppressed by setting bit 10 in machine data:

MD11410 SUPPRESS\_ALARM\_MASK.

Block preparation continues as normal when alarms are suppressed.

The following situations are monitored cyclically when the thread is machined (interpolation):

- Exceeding of maximum velocity of thread axis
- Reaching of axis standstill with G35.

In these cases,

alarm 22270 "Maximum velocity of thread axis reached"

or

alarm 22275 "Zero velocity of thread axis reached"

is output.

## Alarms

Thread cutting G33, G34, G35

- The following alarms are output when programming is incorrect:

|       |       |                                              |
|-------|-------|----------------------------------------------|
| Alarm | 10604 | "Thread lead increase too high"              |
| Alarm | 10605 | "Thread lead decrease too high"              |
| Alarm | 10607 | "Thread with frame (ROT) cannot be executed" |
| Alarm | 16005 | "Illegal lift-off path"                      |
| Alarm | 16710 | "Master spindle not programmed"              |
| Alarm | 16720 | "Thread lead is zero"                        |
| Alarm | 16730 | "Incorrect parameters"                       |
| Alarm | 16740 | "No geometry axis programmed"                |

- If the spindle speed is too high when G33, G34, G35 are active, e.g., spindle override set to 200%, alarm 22270 "Spindle speed for thread cutting too high" is output.

Alarm 22270 is output when the rapid traverse speed of the thread axis is exceeded. It is possible to reduce the spindle speed using the spindle override switch to prevent serious alarms.

Chapter: General Machine Data

/DA/ Diagnostics Manual

#### 17.2.4.4 Stop for thread cutting

##### Stop for thread cutting

---

**Note**

The non-destructive interrupt function should only be used for thread cutting, not for tapping with G33.

---

##### Retraction movement

The retraction motion (`liftfast`) for thread cutting is controlled by the following keywords:

- LFOF  
⇒ Enable `liftfast` for thread cutting.
- LFOF  
⇒ Disable `liftfast` for thread cutting.

These G functions can always be programmed.

The default setting for NC Reset and/or NC Start is specified in machine data: MD20150 GCODE\_RESET\_VALUES.

The following sources can initiate a retraction motion during thread cutting:

- Fast inputs (programming with `SETINTLIFTFAST` for "LIFTFAST" option)
- NC Stop
- Alarms that implicitly initiate the NC stop.

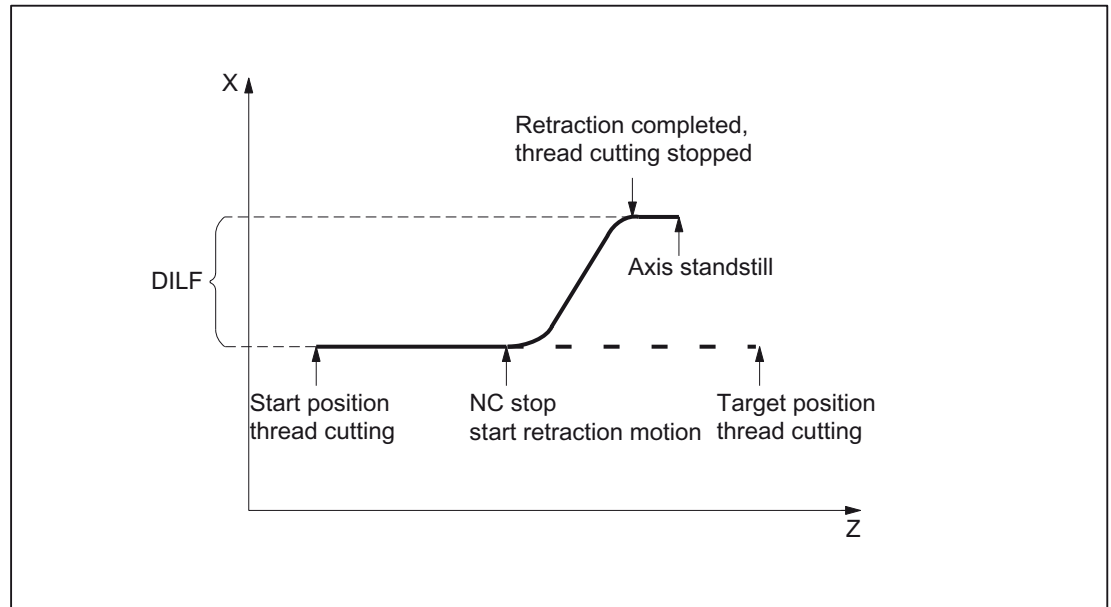

Figure 17-3 Interruption of G33 through retraction motion

## Retraction path

The retraction path can be configured in machine data:  
MD21200 LIFTFAST\_DIST.

If required, this path in the part program can be changed by writing `DILF` at any point.

Following an NC reset, the value entered in machine data:  
MD21200 LIFTFAST\_DIST  
(default value) is always active.

### Retraction direction

The method for defining the retraction direction is controlled in conjunction with the variable `ALF` using the following keywords:

- `LFTXT`

The plane of the retraction movement is determined by the path tangent and the tool direction. This G code (default setting) is used to program the response on a fast lift.

For information about `ALF` programming, refer to:

**References:**

/PGA/ Programming Manual, Operations Planning

/FB1/ Function Manual, Basic Functions; Mode Group, Channel, Program Operation (K1); Chapter: Asynchronous Subroutines (ASUBs), Interrupt Routines

- `LFWP`

The plane of the retraction movement is the active working plane selected with G codes `G17`, `G18` or `G19`. The direction of the retraction plane is independent of the path tangent. This allows a fast lift to be programmed parallel to the axis.

These G functions can always be programmed.

The default setting for NC Reset and/or NC Start is specified in machine data: `MD20150 GCODE_RESET_VALUES`.

In the plane of the retraction movement, `ALF` is used, as before, to program the direction in discrete steps of 45 degrees. With `LFTXT`, retraction in the tool direction was defined for `ALF=1`.

With `LFWP` the direction in the working plane is derived from the following assignment:

|      |           |       |                           |
|------|-----------|-------|---------------------------|
| G17: | X/Y plane | ALF=1 | Retraction in X direction |
|      |           | ALF=3 | Retraction in Y direction |
| G18: | Z/X plane | ALF=1 | Retraction in Z direction |
|      |           | ALF=3 | Retraction in X direction |
| G19: | Y/Z plane | ALF=1 | Retraction in Y direction |
|      |           | ALF=3 | Retraction in Z direction |

**Note**

The extension for programming the plane of the retraction movement can be used independently of thread cutting.

### Retraction speed

Retraction is performed at maximum axis velocity.

This can be configured in machine data:

`MD32000 MAX_AX_VELO`.

## Retraction acceleration, jerk

Acceleration is performed at maximum possible values.  
This can be configured in machine data:  
MD32300 MAX\_AX\_ACCEL.

## Example

```

N55 M3 S500 G90 G18 ; Set active machining plane
...
N65 MSG ("thread cutting")
MM_THREAD:
N67 $AC_LIFTFAST=0 ; Reset before beginning of
thread
N68 G0 Z5
N69 X10
N70 G33 Z30 K5 LFON DILF=10 LFWP ALF=7 ; Enable fast retraction for
thread cutting
; Retraction path = 10 mm
; Retraction plane Z/X
(due to G18)
; Retraction direction -X
(with ALF=3; retraction
direction +X)

N71 G33 Z55 X15
N72 G1 ; Deactivate thread cutting
N69 IF $AC_LIFTFAST GOTOB MM_THREAD ; If thread cutting
; was aborted

N90 MSG ("")
...
N70 M30
N55 M3 S500 G90 G0 X0 Z0
...
N87 MSG ("tapping")
N88 LFOF ; Deactivate fast retraction
before tapping
N89 CYCLE... ; Thread drilling cycle with G33
N90 MSG ("")
...
N99 M3012.97

```

## Control system response

At POWER ON and RESET, the retraction path is set as configured (MD), as is the state of LFON or LFOF and LFTXT or LFWP using machine data: MD20150 GCODE\_RESET\_VALUES from the corresponding G group.

### Smoothed actual values

If low-resolution encoders are being used, smoothed actual values can be applied for constant coupled path and axis motions.

Machine data:

MD34990 ENC\_ACTVAL\_SMOOTH\_TIME

can be used to change the time constant for more effectively smoothed actual values for:

- Thread cutting with feedrate for G33, G34, G35
- Revolutional feedrate for G95, G96, G97, FRAPON
- Display of actual positions and actual speed/velocity

The larger the time constant, the better the smoothing of the actual values and the longer the overtravel.

### 17.2.5 Feedrate for G331/G332, rigid tapping

G331 (tapping) and G332 (tapping retraction) can be used to tap a thread without a compensating chuck (rigid tapping) if the spindle is technically capable of operating in position control mode.

#### Speed S, feedrate F, thread lead

A revolutional feedrate [mm/rev.] is used for G331 and G332. The revolutional feedrate is defined by programming the thread lead increase [mm/rev.].

The speed of the axes for the thread length is calculated from the programmed spindle speed  $s$  and the thread lead.

Feedrate  $F$  [mm/min] = speed  $s$  [rev/min] \* thread lead [mm/rev]

---

**Note**

For further information about programming G63/G331/G332, please see:

**References:**

Programming Manual, Fundamentals

Programming Manual, Cycles

---

#### Override

The revolutional feedrate in G331 and G332 can be influenced by an override.

Depending on the configuration, the override affects either the spindle speed or the path feedrate:

MD12090 \$MN\_OVR\_FUNCTION\_MASK

| Bit | Value | Significance                                                                                                                                                                                                                                                              |
|-----|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 0     | The override influences the spindle speed (initial setting).<br>Depending on the setting in the machine data:<br>MD12080 \$MN_OVR_REFERENCE_IS_PROG_FEED<br>the override is related either to the programmed spindle speed or to the configured spindle speed limitation. |
|     | 1     | The override influences the path feedrate<br>Depending on the setting in machine data:<br>MD12082 \$MN_OVR_REFERENCE_IS_MIN_FEED<br>the override is related either to the programmed path feedrate or to the configured path feedrate limitation.                         |

#### Note

The following overrides are not effective in G331 and G332:

- Programmable path feedrate override  $OVR$
- Rapid traverse override

### Inhibiting stop events for G331/G332

During tapping, a stop can be prevented if the block contains a path movement or a G4.

For this purpose, bit 0 must be set to 0 in machine data:  
MD11550 \$MN\_STOP\_MODE\_MASK.

The stop, which was activated previously, is possible again after G331/G332 has been executed.

## 17.2.6 Feedrate for G63, tapping with compensation chuck

### Application

G63 is a subfunction for tapping threads using a tap with compensating chuck. An encoder (position encoder) is not required.

#### Speed S, feedrate F, thread lead

With G63, a speed  $S$  must be programmed for the spindle and a feedrate  $F$  for the infeed axis (axis for thread length).

The feedrate  $F$  must be calculated by the programmer on the basis of the speed  $S$  and the thread lead.

$$\text{Feedrate } F \text{ [mm/min]} = \text{speed } S \text{ [rev/min]} * \text{thread lead [mm/rev]}$$

## 17.3 Feedrate FA for positioning axes

### Syntax

FA[<positioning axis>] = <feedrate value>

### Functionality

The velocity of a positioning axis is programmed with axis-specific feedrate `FA`.

- Effectiveness: Modal
- Special points to be noted
  - No more than 5 axis-specific feedrates can be programmed in each part program block.
  - The feedrate is always `G94`.
  - If no axial feedrate `FA` is programmed, the axial default: MD32060 \$MA\_POS\_AX\_VELO (initial setting for positioning axis velocity) takes effect.

#### Parameter: Positioning axis

- Value range: Identifier of channel axes  
MD20080 \$MC\_AXCONF\_CHANAX\_NAME\_TAB

**Parameter: Feed value**

- Value range  
0.001...999,999.999 mm/min, degrees/min or 0.001, ...39 999.9999 inch/min

For more information about the value range of the axial feedrate see:

**References:**

/PG/ Programming Manual Fundamentals

/FB1/ Function Manual Basic Functions; Velocities, Setpoint/ Actual Value Systems, Closed-Loop Control (G2)

- NC/PLC interface (channel-specific)  
The feedrate is output at the channel-specific NC/PLC interface:  
DB21, ... DBB158 - DBB193  
For a description of the channel-specific NC/PLC interface signals (modification signal, machine axis number of positioning axis, etc.) see:

**References:**

/FB1/ Function Manual, Basic Functions; Various Interface Signals and Functions (A2)

- NC/PLC interface (axis-specific)  
The feed value is output at the axis-specific NC/PLC interface:  
DB31, ... DBB78 - DBB81

**Note****Maximum axis velocity**

The maximum axis velocity is not exceeded:

MD32000 \$MA\_MAX\_AX\_VELO (maximum axis velocity)

**F function output to the NC/PLC interface**

Output of the F functions to the NC/PLC interface is not recommended. Activating the output of F functions to the NC/PLC interface can cause a drop in velocity in continuous-path mode. The output of F functions to the NC/PLC interface can be suppressed:

MD22240 \$MC\_AUXFU\_F\_SYNC\_TYPE (output time of the F functions)

For a detailed description please refer to:

**References:**

/FB1/ Function Manual, Basic Functions; Auxiliary Functions (H2)

**RESET response**

After end of program or NC-RESET, the feedrate value takes effect depending on machine data:

MD22410 \$MC\_F\_VALUES\_ACTIVE\_AFTER\_RESET = <value>

| Value | Meaning                                                           |
|-------|-------------------------------------------------------------------|
| 0     | After NC RESET the default values are effective.                  |
| 1     | After NC RESET the last FA values to be programmed are effective. |

## 17.4 Feedrate control

### 17.4.1 General

#### Programming and controlling the feedrate

The figure below shows the options for feedrate programming and control.

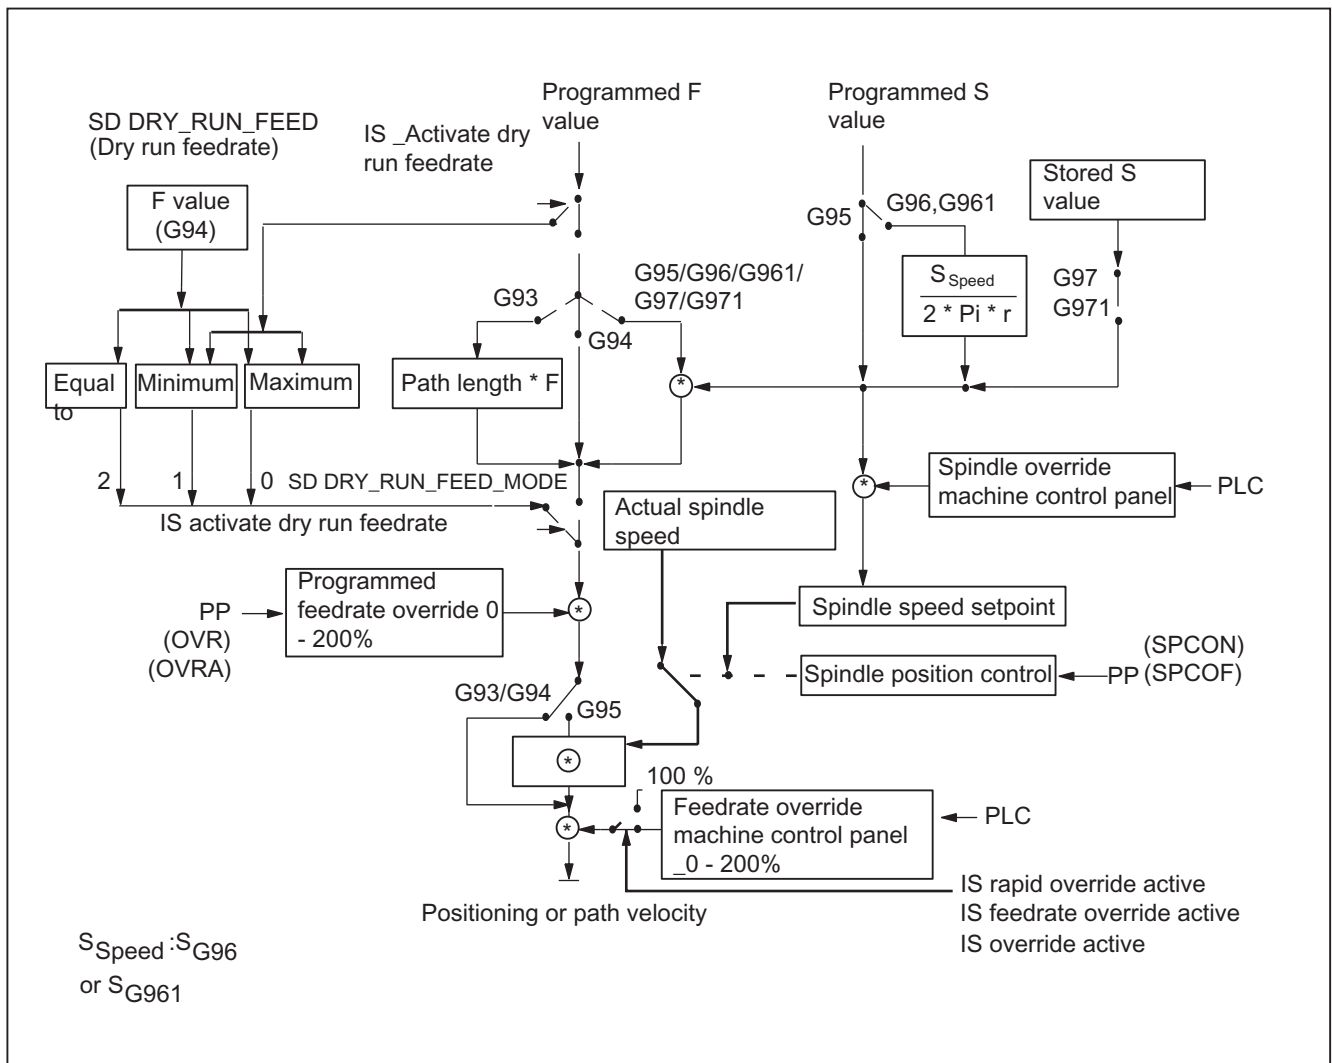

Figure 17-4 Programming and controlling the feedrate

## 17.4.2 Feedrate disable and feedrate/spindle stop

### General

The feedrate disable or feedrate/spindle stop brings the axes to a standstill with adherence to the braking characteristics and the path contour (exception: G33 block).

#### References:

/FB1/ Function Manual, Basic Functions; Continuous-Path Mode, Exact Stop and Look Ahead (B1)

### "Feedrate disable" DB21, ... DBX6.0

Interface signal "Feedrate disable" (DB21, ... DBX6.0) shuts down all axes (geometry and auxiliary axes) of a channel in all modes.

| Activation of channel-specific feedrate disable |               |
|-------------------------------------------------|---------------|
| If G33, G34, G35 active:                        | Not effective |
| If G63 active:                                  | Effective     |
| If G331, G332 active:                           | Effective     |

### "Feed stop" DB21, ...DBX12.3 geometry axes

Interface signals "Feed stop" (DB21, ... DBX12..3 and the following signals) for geometry axes 1, 2, and 3 stop the geometry axes of a channel in JOG mode.

### "Feed stop" DB31, ...DBX4.3 axis-specific

The axis-specific "Feed stop" interface signal (DB31, ... DBX4.3) is used to stop the relevant machine axis.

In automatic mode:

- If the "Feed stop" is performed for a path axis, all the axes traversed in the current block and all axes participating in the axis group are stopped.
- If the "Feed stop" is performed for a positioning axis, only this axis is stopped.

Only the current axis is stopped in JOG mode.

| Activation of axis-specific function "Feed stop" |                                          |
|--------------------------------------------------|------------------------------------------|
| Active in G33, G34, G35                          | Effective<br>(causes contour deviations) |
| For active G63                                   | Effective                                |
| In active G331, G332                             | Effective                                |

**Axis/spindle disable" DB31, ... DBX1.3**

Activating "Axis/spindle disable" (DB31, ...DBX1.3) disables the axial PLC interlocks "No controller enable" and "Feed stop".

The axial and channel-specific override, however, is active.

**"Spindle stop" DB31, ... DBX4.3**

IS "Spindle stop" (DB31, ... DBX4.3) is used to stop the relevant spindle.

| Activation of the "Spindle stop" function |                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------|
| Active in G33, G34, G35                   | Effective<br>(may cause contour deviations depending on dynamic characteristics) |
| For active G63                            | Effective                                                                        |
| In active G331, G332                      | <b>not functional</b>                                                            |

**17.4.3 Feedrate override on machine control panel****General**

The operator can use the feedrate override switch to increase or decrease the path feedrate relative to the programmed percentage with immediate effect. The feedrates are multiplied by the override values.

An override between 0 and 200% can be programmed for the path feedrate.

The rapid traverse override switch is used to reduce the traversing velocity when testing a part program.

An override between 0 and 100% can be programmed for the rapid traverse.

The feedrate can be changed axis-specifically for positioning axes. The override can be between 0 and 200%.

The spindle override can be used to modify the spindle speed and the cutting rate (with G96, G961). The override can be between 0 and 200%.

The override is not permitted to exceed the machine-specific acceleration and speed limits or generate a contour error.

The feedrate override can be changed separately for path and position axes.

The overrides influence the programmed values or the limiting (e.g. G26, LIMS in spindle speed).

A sequence of G63 blocks is traversed regardless of the feedrate override. A sequence of G63 blocks consists of directly following blocks having the G code G63. It starts with the first G63 block and ends with the first path motion block that does not have G63.

### Channel-specific "Feedrate override" DB21, ...DBB4 / "rapid traverse override" DB21, ...DBB5

One enable signal and one byte are provided on the PLC interface for the override factor, for the two feedrate types.

IS "Feed override" (DB21, ... DBB4)

IS "Feed override active" (DB21, ... .. DBB4)

IS "Rapid traverse override" (DB21, ... DBB5)

IS "Rapid traverse override active" (DB21, ... DBB6.6)

The interface for the override can be provided by the PLC in binary-coded or gray-coded form.

Whether binary or gray-coded is valid is defined via machine data:

MD12020 OVR\_FEED\_IS\_GRAY\_CODE (path feedrate override switch, gray-coded)

and

MD12040 OVR\_RAPID\_IS\_GRAY\_CODE (rapid traverse override switch, gray coded).

The following permanent assignment applies to binary code:

| Code     | Override factor |
|----------|-----------------|
| 00000000 | 0.00 ± 0%       |
| 00000001 | 0.01 ± 1%       |
| 00000010 | 0.02 ± 2%       |
| 00000011 | 0.03 ± 3%       |
| 00000100 | 0.04 ± 4%       |
| .        | .               |
| .        | .               |
| .        | .               |
| 01100100 | 1.00 ± 100%     |
| .        | .               |
| .        | .               |
| .        | .               |
| 11001000 | 2.00 ± 200%     |

In gray coding, the override factors corresponding to the switch position is entered in machine data:

MD12030 OVR\_FACTOR\_FEEDRATE [n]  
(evaluation of path feedrate override switch)

or

MD12050 OVR\_FACTOR\_RAPID\_TRA [n] (evaluation of rapid traverse override switch).

An active feedrate override has an effect on all path axes that are assigned to the current channel.

An active rapid traverse override has an effect on all the axes that are traversed with rapid traverse and that are assigned to the current channel.

If there is no dedicated rapid traverse override switch, you can switch between effective rapid traverse override and feedrate override. In this case, feedrate overrides above 100% are limited to 100% for rapid traverse override.

The override to be active can be selected via the PLC or operator panel front. On activating the rapid traverse override via the operator panel front, the "feedrate override for rapid traverse" is selected (DB21, ... DBX25.3) is transferred via the PLC basic program to the "rapid traverse override effective" interface signal (DB21, ... DBX6.6) and the IS "feedrate override" (DB21, ... DBB4) is copied to the IS "Rapid traverse override" (DB21, ... DBB5).

On selecting via PLC, the "rapid traverse override active" interface signal (DB21, ... DBX6.6) is to be set by the PLC user program and the interface signal of the feedrate override (DB21, ... DBB4) is to be copied to the Rapid traverse override (DB21, ... DBB5).

| Effectiveness of the channel-specific feedrate and rapid traverse override |                |
|----------------------------------------------------------------------------|----------------|
| Active in G33, G34, G35                                                    | not functional |
| For active G63                                                             | not functional |
| In active G331, G332                                                       | not functional |

### Reference speed for path feedrate override

The reference speed for the path feedrate override specified via machine control panel can be set as different from the standard or default.

The machine data:  
MD12082 OVR\_REFERENCE\_IS\_MIN\_FEED  
enables the corresponding selection.

### Axis-specific "Feedrate override" DB31, ...DBB0

One enable signal and one byte for the feedrate override are available on the PLC interface for each positioning axis:

IS "Feed override" (DB21, ... DBB0)

IS "Override active" (DB31, ... DBX1.7)

The interface for the feedrate override can be provided by the PLC in binary-coded or gray-coded form.

Machine data:  
MD12000 OVR\_AX\_IS\_GRAY\_CODE (gray-coded axis feedrate override switch)  
is used to define whether binary or gray code is valid.

The following permanent assignment applies to binary code:

| Code     | Override factor      |
|----------|----------------------|
| 00000000 | 0.00 $\triangleq$ 0% |
| 00000001 | 0.01 $\triangleq$ 1% |
| 00000010 | 0.02 $\triangleq$ 2% |
| 00000011 | 0.03 $\triangleq$ 3% |
| 00000100 | 0.04 $\triangleq$ 4% |
| .        | .                    |
| .        | .                    |
| .        | .                    |

| Code     | Override factor |
|----------|-----------------|
| 01100100 | 1.00 ± 100%     |
| .        | .               |
| .        | .               |
| .        | .               |
| 11001000 | 2.00 ± 200%     |

In gray coding, the override factors corresponding to the switch position are entered in machine data:  
MD12010 OVR\_FACTOR\_AX\_SPEED [n] (evaluation of axis feedrate override switch).

| Effectiveness of the axis-specific feedrate override |                                                                   |
|------------------------------------------------------|-------------------------------------------------------------------|
| Active in G33, G34, G35                              | not functional                                                    |
| For active G63                                       | not active<br>(the override is set in the NC permanently to 100%) |
| In active G331, G332                                 | not active<br>(the override is set in the NC permanently to 100%) |

### Spindle override" DB31, ... DBB0"

One enable signal and one byte for the spindle override factor are available on the PLC interface for each spindle.

IS "Spindle override" (DB31, ... DBB19)

IS "Override active" (DB31, ... DBX1.7)

The interface for the spindle override can be provided from the PLC in binary-coded or gray-coded form.

Machine data:

MD12060 OVR\_SPIND\_IS\_GRAY\_CODE (spindle override switch is gray-coded)  
is used to define whether binary or gray code is valid.

The following permanent assignment applies to binary code:

| Code     | Override factor |
|----------|-----------------|
| 00000000 | 0.00 ± 0%       |
| 00000001 | 0.01 ± 1%       |
| 00000010 | 0.02 ± 2%       |
| 00000011 | 0.03 ± 3%       |
| 00000100 | 0.04 ± 4%       |
| .        | .               |
| .        | .               |
| .        | .               |
| 01100100 | 1.00 ± 100%     |
| .        | .               |

| Code     | Override factor |
|----------|-----------------|
| .        | .               |
| .        | .               |
| 11001000 | 2.00 $\pm$ 200% |

In gray coding, the override factors corresponding to the switch position are entered in machine data:

MD12070 OVR\_FACTOR\_SPIND\_SPEED [n] (evaluation of spindle override switch).

| Effectiveness of the spindle override |                                                                                             |
|---------------------------------------|---------------------------------------------------------------------------------------------|
| Active in G33, G34, G35               | active<br>(if the spindle is in position control, then the override switch can be actuated) |
| For active G63                        | <b>not</b> active<br>(the override is set in the NC permanently to 100%)                    |
| In active G331, G332                  | Effective                                                                                   |

### Limiting the override factor

In a binary-coded interface, the maximum possible override factors for path, axis feedrate and spindle speed can be limited further with machine data:

MD12100 OVR\_FACTOR\_LIMIT\_BIN (limiting in binary-coded override switch).

### Override active DB21, ...DBX6.6 / DB21, ... DBX6.7 / DB31, ... DBX1.7

The override values set with the selector switch on the machine control panel are immediately active for all modes and machine functions, provided that IS "Rapid traverse override active", (DB21, ... DBX6.6) "Feedrate override active" (DB21, ... DBX6.7) or "Override active" (DB31, ... DBX1.7) are set.

An override factor of 0% acts as a feedrate disable.

### Override inactive

If override is inactive (above IS signals are set to 0), the override factor 1 is used internally in the NC, i.e. the override is 100%. The value that is entered in the PLC interface is not relevant.

An exception is the zero setting for a binary interface and the 1st switch setting for a gray-coded interface. In these cases, the override factors entered at the PLC interface are used. With a binary interface, the override factor = 0. With a Gray-coded interface, the value entered in the machine data for the 1st switch setting is output as the override value. It should be populated with 0.

An override factor of 0% acts as a feedrate disable.

### Reference to spindle override

Whether the spindle override is related to the speed limited by MD or SD, or to the programmed speed is specified in machine data:

MD12080 OVR\_REFERENCE\_IS\_PROG\_FEED (override reference speed).

## 17.4.4 Programmable feedrate override

### Function

The programmable feedrate override can be used to change the velocity level of path and positioning axes by means of a command in the part program.

A separate feedrate override can be programmed for positioning axes.

### Programming

The feedrate override can be changed with the following commands:

|                 |                                                |
|-----------------|------------------------------------------------|
| OVR= . . . .    | Feedrate change for path feedrate $F$          |
| OVRA[X1]= . . . | Feedrate change for positioning feedrate $F_A$ |

The programmable range is between 0 and 200%.

The default setting is 100%.

### Effectivity

Interface signals "Rapid traverse and feedrate override" (DB21, ... DBB6) and "Axis-specific override active" (DB31, ... DBX1.7) do not apply to the programmable feedrate override. The programmable feedrate override remains active when these signals are deactivated.

The active override is calculated from the product of the programmable feedrate override and the feedrate override from the machine control panel.

The default setting is 100%. It is active if no feedrate override has been programmed or following a `RESET`, if machine data:

MD22410 `F_VALUES_ACTIVE_AFTER_RESET` (F function active via `RESET`) is not set.

`OVR` is not active with `G33`, `G34`, `G35`.

## 17.4.5 Dry run feedrate

### Application

The dry run feedrate is used when testing part programs without machining the workpiece in order to allow the program or program sections to execute with an increased path feedrate, for example.

### "Dry run feedrate selected" DB21, .... DBX24.6

The dry run feedrate can be activated from the PLC or the operator panel.

When activated from the operator panel, interface signal "Dry run feedrate selected" (DB21, ... DBX24.6) is set and transferred by the PLC basic program to interface signal "Activate dry run feedrate" (DB21, ... DBX0.6).

When selected on the PLC, the "Activate dry run feedrate" interface signal is required to be set by the PLC user program.

The execution of the program is triggered with G94.

The dry run feedrate also takes precedence over the feedrates for G93, G95 and G33, G34, G35.

In this case, the programmed feedrate is compared to the dry run feedrate in:

SD42100 DRY\_RUN\_FEED

and the axis is then traversed at the higher of the two feedrates.

### Dry run feedrate change "Dry run feedrate active" DB21, .... DBX318.6.

The dry run feedrate (SD42100 DRY\_RUN\_FEED = 1) can be changed via the operator panel in the operating area "Parameters".

The interface signal "Dry run feedrate active" (DB21, ... DBX318.6) is set if the selection has been accepted by the NCK. DRY is displayed in the operator panel status bar to indicate an active dry run feedrate if

- selection takes place when the program stops at the end of a block or if the machine data
- MD10704 DRY\_RUN\_MASK = 1 has been set during execution of the program.

If MD10704 DRYRUN\_MASK = 0 has been set a dry run feedrate may only be activated/deactivated at the end of a block.

If the dry run feedrate is no longer selected, the interface signal "Dry run feedrate active" (DB21, ... DBX318.6) is reset.

## Evaluation

The effect of:  
SD42100 DRY\_RUN\_FEED  
can be controlled via another setting data:  
SD42101 DRY\_RUN\_FEED\_MODE .

| SD42101<br>DRY_RUN_FEED_MODE | Effectivity                                                                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | As long as the "Activate dry run feedrate" interface signal is set, instead of the programmed feedrates, the feedrate value set in SD42100 DRY_RUN_FEED is effective as follows: |
| 0                            | The maximum value from SD42100 DRY_RUN_FEED and the programmed velocity is effective. This is the same as the default setting.                                                   |
| 1                            | The minimum value from SD42100 DRY_RUN_FEED and the programmed velocity is effective.                                                                                            |
| 2                            | Setting data SD42100 DRY_RUN_FEED is effective directly, regardless of the programmed velocity.                                                                                  |
| 3 -9                         | reserved                                                                                                                                                                         |
| 10                           | As for configured value 0 except for thread cutting (G33, G34, G35) and tapping (G33, G34, G35). These functions are executed as programmed.                                     |
| 11                           | As for configured value 1 except for thread cutting (G33, G34, G35) and tapping (G33, G34, G35). These functions are executed as programmed.                                     |
| 12                           | As for configured value 2 except for thread cutting (G33, G34, G35) and tapping (G33, G34, G35). These functions are executed as programmed.                                     |

A dry run feedrate can be selected in the automatic modes and activated on interruption of an automatic mode or end of a block. Using machine data:  
MD10704 DRYRUN\_MASK = 1,  
the dry run feedrate can also be activated during execution of the program (in the part program block).

### Note

Activation during machining triggers an internal reorganization task on the control which causes the axes to be stopped for a short time. This can affect the surface finish of the workpiece being machined.

With MD10704 DRYRUN\_MASK = 2,  
the dry run feedrate can be activated/ deactivated at any time without the axes stopping. The function only becomes effective with a block which comes later in the program run.

## 17.4.6 Multiple feedrate values in one block

### Application

The functionality described in the following is used primarily for grinding, but is not restricted to it.

#### References:

- Function Manual, Extended Functions; Grinding (W4)
- Function Manual, Extended Functions; Oscillation (P5)

### Functionality

The function "Multiple feedrates in one block" can be used to activate 6 different feedrate values of an NC block, a dwell time or a retraction motion synchronously, depending on the external digital and/or analog inputs.

### Retraction

Retraction by the programmed amount is initiated in the IPO cycle.

### Signals

The HW input signals are combined in one input byte for the function "Multiple feedrate in one block". A permanent functional assignment applies within the byte:

Table 17- 1 Input byte for "Multiple feedrates in one block"

|                  | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
|------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| Input no.        | I7    | I6    | I5    | I4    | I3    | I2    | I1    | I0    |
| Feedrate address | F7    | F6    | F5    | F4    | F3    | F2    | ST    | SR    |

I7 to I2                    Activation of feedrates F7 to F2  
 I1                            Activation of dwell time ST (in seconds)  
 I0                            Activation of retraction motion SR

### Priorities

The signals are scanned in ascending order starting at I0.

Therefore, the retraction motion (SR) has the highest priority and the feedrate F7 the lowest priority.

SR and ST end the feedrate motions that were activated with F2 - F7.  
 SR also ends ST, i.e. the complete function.

The highest-priority signal determines the current feedrate.

Machine data:

MD21230 MULTFEED\_STORE\_MASK

(store input signals for the "Multiple feedrates in one block" function)

can be used to define the response on loss of the highest-priority input in each case (F2 - F7).

The end-of-block criterion is satisfied when:

- The programmed end position is reached
- The retraction motion ends (SR)
- The dwell time elapses (ST)

### Delete distance-to-go

A retraction motion or dwell time causes the distance-to-go to be deleted.

### Hardware assignment

The channel-specific machine data:

MD21220 MULTFEED\_ASSIGN\_FASTIN

(assignment of the input byte of the NCK I/Os for "Multiple feedrates in one block")

can be used to assign up to two digital input bytes or comparator input bytes to the NCK I/O.

Machine data:

MD21220 MULTFEED\_ASSIGN\_FASTIN

can also be used to invert the input bits.

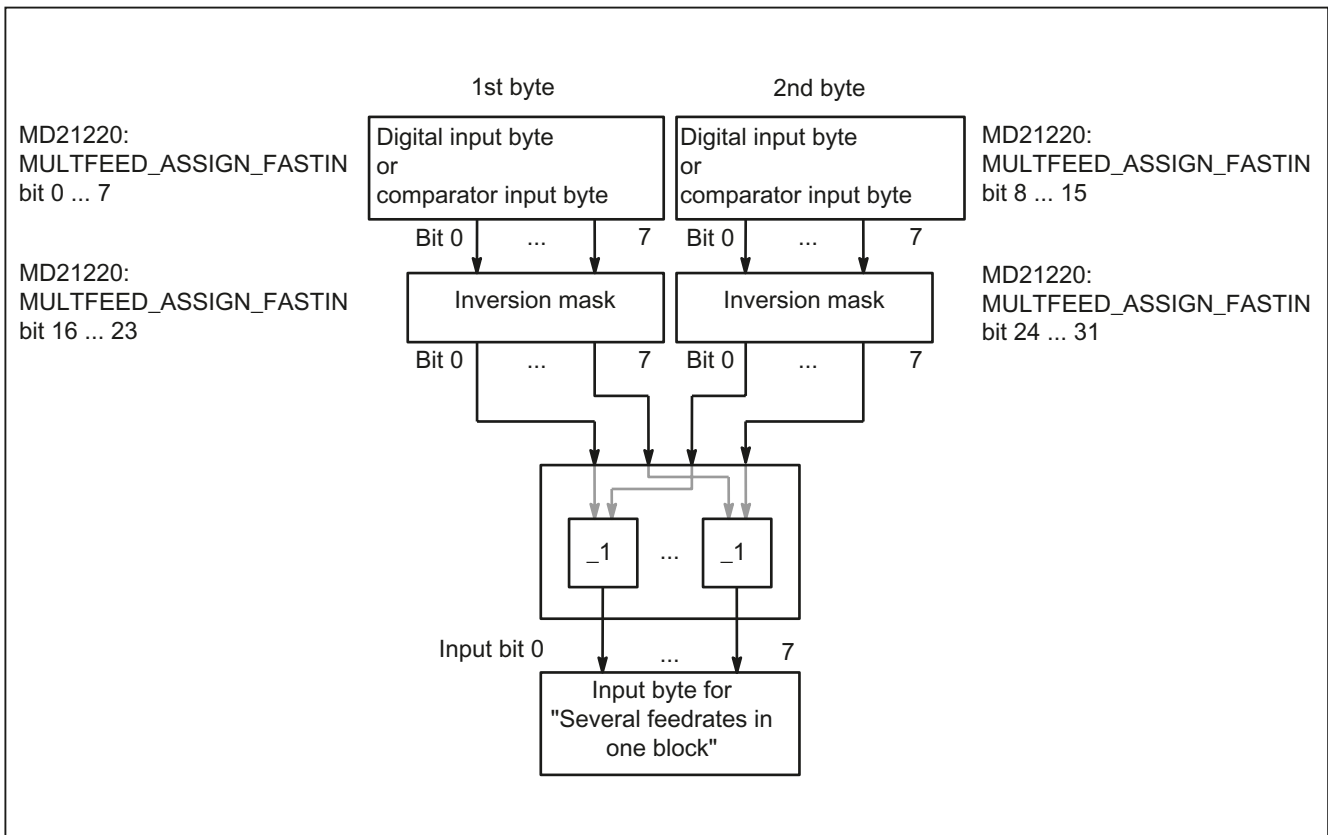

Figure 17-5 Signal routing for "Multiple feeds in one block"

Marshaling of the digital input bytes and parameterization of the comparators are described in:

**Reference:**

Function Manual, Basic Functions; Various Interface Signals (A2)

**Programming path motion**

The path feedrate is programmed under the address  $F$  and remains valid until an input signal is present. This value acts modally.

$F2=...$  to  $F7=...$  can be used in addition to the path feedrate to program up to 6 further feedrates in the block.

The numerical expansion indicates the bit number of the input that activates the feedrate when changed:

e.g.  $F7=1000$  ; 7 corresponds to input bit 7.

Bits 2 to 7 are permissible for numerical expansion of the feedrate. The programmed values act non-modally. The path feedrate programmed under  $F$  applies in the next block.

Dwell (sparking out time) and retraction path are programmed under separate addresses in the block:

|        |                                        |
|--------|----------------------------------------|
| ST=... | Dwell (for grinding sparking out time) |
| SR=... | Retraction path                        |

These addresses apply non-modally.

## Programming axial motion

The axial feedrates are programmed under address `FA` and remain valid until an input signal is present. They act modally.

`FMA[2, x]=...` to `FMA[7, x]=...` can be used to program up to 6 further feedrates per axis in the block.

The first expression in square brackets indicates the bit number of the input that activates the feedrate when changed. The second expression indicates the axis to which the feedrate applies.

Example:

```
FMA[3, Y]=1000 ;axial feedrate for Y axis,
 ;corresponds to input bit 3
```

Bits 2 to 7 are permissible for the numerical expansion of the axial feedrate. The values programmed under `FMA` are active non-modally. The feedrate programmed under `FA` applies to the next block.

Dwell (sparking out time) and retraction path can also be defined for a single axis:

|                         |                                           |
|-------------------------|-------------------------------------------|
| <code>STA[x]=...</code> | ;dwell (sparking out time), axis-specific |
| <code>SRA[x]=...</code> | ;retraction path, axis-specific           |

The expression in square brackets indicates the axis for which the sparking out time and retraction path apply.

```
STA[X]=2.5 ;sparking out time 2.5 seconds
SRA[X]=3.5 ;retraction path 3.5 (unit e.g.: mm)
```

These addresses apply non-modally.

If feedrates, a sparking out time (dwell) or retraction path are programmed for an axis on account of an external input, this axis must not be programmed as a `POSA` axis in this block (positioning axis beyond end of block).

When the input for the sparking out time or retraction path is activated, the distance-to-go for the path axes or the particular single axis is deleted and the dwell or retraction is started.

---

**Note**

The unit for the retraction path refers to the current valid unit of measurement (mm or inch).

The reverse stroke is always made in the opposite direction to the current motion.  $SR/SRA$  always programs the value for the reverse stroke. No sign is programmed.

It is also possible to poll the status of an input for synchronous commands of various axes.

Look Ahead is also active for multiple feedrates in one block. In this way, the current feedrate is restricted by the Look Ahead value.

---

**Application**

Typical applications include:

- Analog or digital calipers

Depending on whether the external inputs are analog or digital, various feedrate values, a dwell and a retraction path can be activated. The limit values are defined via the setting data.

- Switching from infeed to working feedrate via proximity switch

**Example**

Internal grinding of a conical ring, where the actual diameter is determined using calipers and, depending on the limits, the feedrate value required for roughing, finishing or fine finishing is activated. The position of the calipers also provides the end position. Thus, the block end criterion is determined not only by the programmed axis position of the infeed axis but also by the calipers.

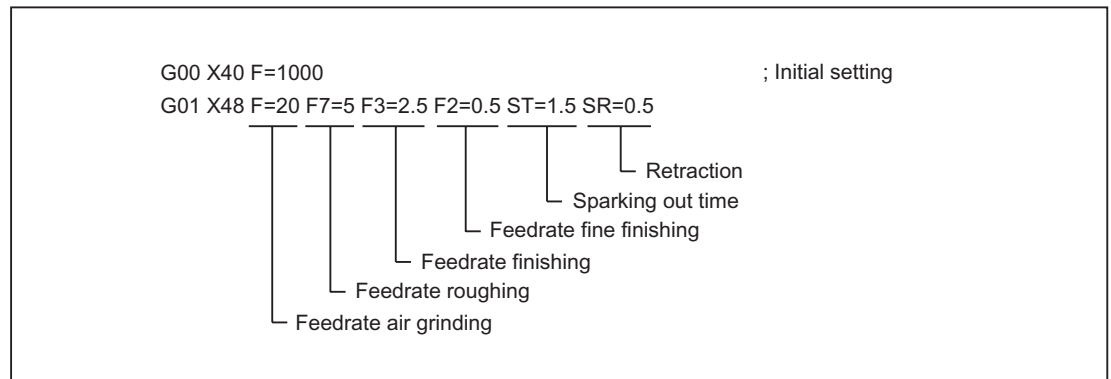

Figure 17-6 Calipers

### Part program

### Note

The axial feedrate/path feedrate ( $F$  value) is the 100% feedrate.

Feedrates smaller than or equal to the axial feedrate/path feedrate can be implemented with "Multiple feedrate values in one block" ( $F2$  to  $F7$  values).

The "Multiple feedrate values in one block" functionality is only available in conjunction with the "Synchronized actions" function.

### Reference:

Function Manual, Basic Functions; Various Interface Signals and Functions (A2)

## 17.4.7 Fixed feedrate values

### Function

The machine data can be used to define 4 fixed feedrate values, which can be activated via the interface signal. The function is possible in AUTOMATIC and JOG modes.

### Behavior in AUTOMATIC mode

The fixed feedrate, which has been selected, is used instead of the programmed feedrate. The following MDs and interface signals can be used to select fixed feedrates for path/geometry axes:

- MD12202 \$MN\_PERMANENT\_FEED[n] (fixed feedrates for linear axes)
- MD12204 \$MN\_PERMANENT\_ROT\_AX\_FEED[n] (fixed feedrates for rotary axes)
- IS "Activate fixed feedrate x for path/geometry axes" (DB21, ... DBX29.0- 29.3)

The contour travels at the activated fixed feedrate, instead of using the programmed feedrate.

### Behavior in JOG mode

The fixed feedrate selected via the interface signal is applied during travel instead of the JOG velocities set.

The travel direction is specified via the interface signal.

The following MDs and interface signals can be used to select fixed feedrates for path/geometry axes and for machine data:

- MD12202 \$MN\_PERMANENT\_FEED[n] (fixed feedrates for linear axes)
- MD12202 \$MN\_PERMANENT\_ROT\_AX\_FEED[n] (fixed feedrates for rotary axes)
- IS "Activate fixed feedrate x for machine axes" (DB31, ... DBX3.2-3.5)

The axis travels at the activated fixed feedrate, instead of at the JOG velocity/JOG-rapid traverse velocity set in MD.

### Constraints

- Fixed feedrate does not influence spindles, positioning axes and tapping.
- While traversing with fixed feedrate, the override depends on machine data:  
MD12200 \$MN\_RUN\_OVERRIDE\_0 (traveling with override 0)
- The DRF offset cannot be activated for a selected fixed feedrate.
- The fixed feedrates are always linear feedrate values. Switchover to linear feedrate is conducted internally even in case of revolutionary feedrate.

### Interface signals

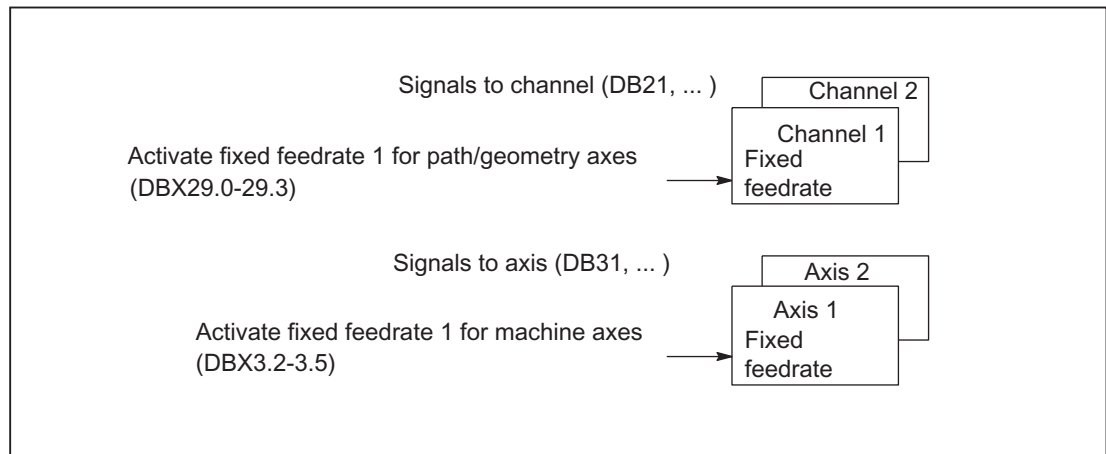

Figure 17-7 Overview of interface signals for fixed feedrate

## 17.4.8 Feedrate for chamfer/rounding FRC, FRCM

### General

The machining conditions can change significantly during surface transitions to chamfer/rounding. Hence, the chamfer/rounding contour elements require dedicated, optimized feedrate values to achieve the desired surface quality.

### Function

You can program the feedrate for the chamfer/rounding with `FRC` (non-modal) or `FRCM` (modal).

The feedrate value is interpreted according to the type of feedrate active:

|                  |                                             |
|------------------|---------------------------------------------|
| G94, G961, G971: | Feedrate in mm/min, inch/min or %/min       |
| G95, G96, G97:   | Revolutional feedrate in mm/rev or inch/rev |

The `FRC/FRCM` value is applied depending upon the machine data:  
MD20201 CHFRND\_MODE\_MASK

|            |                                                                  |
|------------|------------------------------------------------------------------|
| Bit 0 = 0: | <code>FRC/FRCM</code> from following block (default setting)     |
| Bit 1 = 0: | <code>FRC/FRCM</code> from preceding block (recommended setting) |

Reason: The feedrate type (`G94, G95, G96, G961` etc.) and thus the conversion to the internal format must be consistent within the block for `F` and `FRC/FRCM`.

### Empty blocks

When chamfer or rounding is active, the possible number of blocks containing no traversing information is limited.

The maximum number is defined in machine data:  
MD20200 CHFRND\_MAXNUM\_DUMMY\_BLOCKS.

The possible blocks without traversing information in the compensation plane are pure dummy commands and are called empty blocks. For this reason, they may only be written between two blocks with traversing information.

### Boundary conditions

- Feedrate interpolation `FLIN` and `FCUB` is not possible for chamfer/rounding.
- `FRC/FRCM` has no effect if a chamfer is being machined with `G0`; the command can be programmed according to the `F` value without error message.
- `FRC` is only effective if a chamfer/rounding is programmed in the same block or if `RNDM` has been activated.
- `FRC` overwrites the `F` or `FRCM` value for chamfer/rounding in the current block.
- `FRC/FRCM` must be set to a value greater than zero.

- $FRCM=0$  activates the feedrate programmed in  $F$  for the chamfer/rounding.
- If  $FRCM$  is programmed, the  $FRCM$  value must be reprogrammed, equivalent to  $F$ , on a  $G94 \leftrightarrow G95$  change, etc. If only  $F$  is reprogrammed and  $FRCM > 0$  before the feedrate type is changed, error message 10860 (no feedrate programmed) appears.

## 17.4.9 Non-modal feedrate FB

### General

A separate feedrate can be specified for a single block with the command  $FB$  (Feed Block). The previously active path feedrate is overwritten for this block. After this block, the previous modal path feedrate is active again.

### Function

The non-modal feedrate is programmed with  $FB=<value>$ .

The feedrate is interpreted according to the active feedrate type:

|                    |                                             |
|--------------------|---------------------------------------------|
| $G94, G961, G971:$ | Feedrate in mm/min or inches/min or %/min   |
| $G95, G96, G97:$   | Revolutional feedrate in mm/rev or inch/rev |

### Boundary conditions

- The programmed value of  $FB=<value>$  must be greater than zero.
- If no traversing motion is programmed in the block (e.g.: Computational block), the  $FB$  has no effect.
- If no explicit feed for chamfering/rounding is programmed, then the value of  $FB$  also applies for any contour element chamfering/rounding in this block.
- The path speed profile programmed with  $FLIN$  or  $FCUB$  is not active together with revolutional feedrate for  $G95$  as well as with constant cutting speed for  $G96/G961$  and  $G97/G971$ .
- Feedrate interpolations  $FLIN, FCUB, ..$  are also possible without restriction.
- Simultaneous programming of  $FB$  and  $FD$  (handwheel travel with feed overlay) or  $F$  (modal path feedrate) is not possible.

## 17.4.10 Programmable single-axis dynamic response

### Single axes

Single axes can be programmed:

|                                        |                   |
|----------------------------------------|-------------------|
| In the part program                    | POS[Axis]=...     |
|                                        | POSA[Axis]=...    |
|                                        | SPOS[Axis]=...    |
|                                        | SPOSA[Axis]=...   |
|                                        | OS[Axis]=...      |
|                                        | OSCILL[Axis]=...  |
| In synchronized actions (command axes) | EVERY ... DO      |
|                                        | POS[Axis]=...     |
|                                        | SPOS[Spindle]=... |
|                                        | MOV[Axis]=...     |
| In the PLC                             | FC18              |

### Dynamic response of an axis/spindle

The dynamic response of an axis is dependent on:

- the preset feed value (MD32060 POS\_AX\_VELO)
  - Can be programmed in the part program with `FA[axis]= ...`, or a feedrate override `OVRA[axis]= ...` in percent.
  - Programmable in synchronized actions using `FA[Axis]= ....`
  - Modifiable from the PLC by entering `FRate`, or overwriting the axial override.
- The acceleration value (MD32300 MAX\_AX\_ACCEL)
  - Programmable indirectly in the part program by overwriting the machine data with subsequent `NewConfig`, or directly using a percentage acceleration override `ACC[Axis]= ....`
  - Modifiable indirectly in synchronized actions by overwriting the MD (no `NewConfig` possible) or by executing an `ASUB`, or programmable directly using a percentage acceleration override `ACC[Axis]= ...` (cannot be preset by the PLC).
  - The PLC has the same options as synchronized actions.

- The acceleration characteristics

Programmable in the part program using `BRISKA(axis)`, `SOFTA(axis)`, `DRIVEA(axis)` and `JERKA(axis)`.

Not programmable in synchronized actions (only directly using an `ASUB`).

Cannot be preset by the PLC (only indirectly using an `ASUB`).

- The selected servo parameter set

A parameter set describes the most important setting options for control purpose in the servo.

It comprises, e.g., the following axis-specific/spindle-specific machine data:

|                                |                            |
|--------------------------------|----------------------------|
| 31050 DRIVE_AX_RATIO_DENOM[n]  | Parameter set n for 0 to 5 |
| 31060 DRIVE_AX_RATIO_NUMERA[n] | Parameter set n for 0 to 5 |
| 32200 POSCTRL_GAIN[n]          | Parameter set n for 0 to 5 |
| 32452 BACKLASH_FACTOR[n]       | Parameter set n for 0 to 5 |
| 32610 VELO_FFW_WEIGHT[n]       | Parameter set n for 0 to 5 |
| 32800 EQUIV_CURRCTRL_TIME[n]   | Parameter set n for 0 to 5 |
| 32810 EQUIV_SPEEDCTRL_TIME[n]  | Parameter set n for 0 to 5 |
| 32910 DYN_MATCH_TIME[n]        | Parameter set n for 0 to 5 |
| 36012 STOP_LIMIT_FACTOR[n]     | Parameter set n for 0 to 5 |
| 36200 AX_VELO_LIMIT[n]         | Parameter set n for 0 to 5 |

For additional information on the parameter sets and programming, see:

**Reference:**

- Function Manual, Basic Functions; Velocities, Setpoint-Actual Value Systems, Closed-Loop Control (G2)
- Programming Manual Fundamentals, Path Response and Feedrate Control

### Dynamic criteria and feedforward control

With dynamic response criteria, it must be distinguished from where they were set:

- In the part program
- or
- From a main-run interpolation (synchronized action or PLC default)

---

**Note**

Changes in the dynamic response made in a part program do not affect command axis or PLC axis movements.

Changes from synchronized actions do not affect the movements from a part program.

---

### Travel with feedforward control ON/OFF

The type of feedforward control and the path axes to which feedforward is to be applied are determined:

- Programmable in the part program with `FFWON/ FFWOF` for axes selected using machine data.
- Only indirectly programmable in synchronized actions (ASUB).
- Only indirectly programmable from the PLC (ASUB).

### Percentage acceleration override

#### ACC[Axis]

`ACC[Axis]=0...200` can be used to modify the acceleration set in machine data: `MD32300 MAX_AX_ACCEL` in a range between 0% and 200% in part programs and synchronized actions.

|                                       |       |         |                                                        |
|---------------------------------------|-------|---------|--------------------------------------------------------|
| <code>ACC[Axis]= &lt;value&gt;</code> | where | Axis =  | Channel axis name (X, Y ....), spindle (S1, ...)       |
|                                       |       | Value = | Percent of MD32300 MAX_AX_ACCEL<br>(0 <= value <= 200) |

The current acceleration value can be called with the system variables `$AA_ACC[Axis]`. It is determined by:

$$\$AA\_ACC[Axis] = \text{Content}(\text{MD32300 MAX\_AX\_ACCEL}[Axis]) * \text{ACC}[Axis] / 100$$

`MD 32320 DYN_LIMIT_RESET_MASK` can be used to control maintaining the ACC value in the event of channel RESET/M30.

#### Note

The acceleration offset programmed with `ACC[...]` is always considered as specified above for the output in `$AA_ACC`. However, `$AA_ACC` is not output in the part program at the same time as in a synchronized action.

The value described in the part program is only considered in the system variable `$AA_ACC` as described in the part program, if `ACC` has not been changed in the meantime by a synchronized action.

The value described in the synchronized action is only considered in the system variable `$AA_ACC` as described in the synchronized action, if `ACC` has not been changed in the meantime by a part program.

### Main run axes

Main run axes (MR axes) are axes that are interpolated by the main run and can be:

- Command axes (activated by synchronized actions)
- PLC axes (started by PLC via function block)
- Asynchronous oscillating axes (setting data or from part program)
- Neutral axes

**Note**

Depending on whether \$AA\_ACC is programmed in a part program or in a synchronized action, the ACC value is output for the NC axes or the main run axes.

Variable \$AA\_ACC must always be queried in the mode in which the acceleration was written (either part program or synchronized action).

**Examples****In the part program:**

```
...
N80 G01 POS[X]=100 FA[X]=1000 ACC[X]=90 IPOENDA[X]
...
```

**or via a synchronized action:**

```
...
N100 EVERY $A_IN[1] DO POS[X]=50 FA[X]=2000 ACC[X]=140 IPOENDA[X]
...
```

**Acceleration factor written in part program:**

```
...
ACC[X]=50
RO $AA_ACC[X]

IF (RO <> $MA_MAX_AX_ACCEL[X] * 0.5
SETAL(61000)
ENDIF
```

**Acceleration factor is set by the synchronized action:**

```
WHEN TRUE DO ACC[X]=25 $R1 = $AA_ACC[X]
G4 F1

IF (RO <> $MA_MAX_AX_ACCEL[X] * 0.25
SETAL(61001)
ENDIF

M30
```

## End-of-motion criterion for single axes

Similar to the block change criterion for path interpolation (G601, G602 and G603) it is also possible to program the movement end criterion for single-axis interpolation in a part program or in synchronized actions for main run axes: command/PLC axes.

| Programmable criterion | end-of-motion on reaching      |
|------------------------|--------------------------------|
| FINEA[Axis]            | "Exact stop fine"              |
| COARSEA[Axis]          | "Exact stop coarse"            |
| IPOENDA[Axis]          | "Interpolator stop" (IPO stop) |

Axis: Channel axis name (X, Y ....), spindle (S1, ...)

The end-of-motion criterion set will affect how quickly or slowly part program blocks and technology cycle blocks with single-axis movements are completed.  
The same applies for PLC positioning operations via FC18.

The set end-of-motion criterion can be scanned with system variable \$AA\_MOTEND[Axis].

|                       |                                        |
|-----------------------|----------------------------------------|
| \$AA_MOTEND[Axis] = 1 | end-of-motion with "Exact stop fine"   |
| \$AA_MOTEND[Axis] = 2 | end-of-motion with "Exact stop coarse" |
| \$AA_MOTEND[Axis] = 3 | end-of-motion with "IPO stop"          |

### Note

Depending on whether \$AA\_MOTEND is programmed in a part program or a synchronized action, the MOTEND value is output for the NC axes or the main-run axes.

The last programmed value is retained following a RESET.

### Example:

```

...
N80 G01 POS[X]=100 FA[X]=1000 ACC[X]=90 IPOENDA[X]
...

```

or via a synchronized action:

```

...
N100 EVERY $A_IN[1] DO POS[X]=50 FA[X]=2000 ACC[X]=140 IPOENDA[X]

```

For more information about block changes and end-of-motion criteria for FINEA, COARSEA and IPOENDA, please refer to:

### Reference:

Function Manual, Extended Functions; Positioning Axes (P2);  
Chapter: Block change

**Programmable servo parameter set**

**SCPARA[Axis] = ...**

SCPARA[axis]= ... can be used to program the parameter set (consisting of MDs) in the part program and in synchronized actions (previously, this could only be done via the PLC).

|                       |       |         |                                                 |
|-----------------------|-------|---------|-------------------------------------------------|
| SCPARA[Axis]= <value> | where | Axis =  | Channel axis name (X, Y ...), spindle (S1, ...) |
|                       |       | Value = | Desired parameter set (1 ≤ value ≤ 6)           |

**DB3n DBB9 bit3**

To prevent conflicts between the PLC user request and NC user request, a further bit is defined on the PLC→NCK interface:

DB3n DBB9 bit3 "Parameter set selection by SCPARA disabled".

The PLC user is thereby able to set up a structured sequence when using PLC parameter switchover and entries from synchronized actions or part programs simultaneously.

On a change of bit 3 (0 ⇒ 1 or 1 ⇒ 0), the entry is written to bits 0 - 2.

**Note**

If parameter set selection via SCPARA is disabled, there is no error message if the latter is programmed nevertheless.

The current parameter set can be scanned by system variable \$AA\_SCPAR[Axis].

**Example:**

```

...
N100 SCPARA[X]=3 ; The 3rd parameter set is selected for axis X.
...

```

**Boundary conditions**

- Different end-of-motion criteria will affect how quickly or slowly part program blocks are completed. This can have side effects for technology cycles and PLC user parts.
- The PLC user program must be expanded if the servo parameter set is to be changed both inside a part program or synchronous action and the PLC.
- After POWER ON, the following initial settings are made:

|                                                                     |       |
|---------------------------------------------------------------------|-------|
| Percentage acceleration override for all single-axis interpolations | 100%  |
| end-of-motion criterion for all single-axis interpolations          | FINEA |
| Servo parameter set defined by the NC                               | 1     |

- When the operating mode is changed from AUTO ⇒ JOG, the programmed dynamic response changes remain valid.
- In the event of a `RESET`, the last programmed value remains for the part program specifications. The settings for main-run interpolations do not change.
- Block search:

The last end-of-motion criterion programmed for an axis is collected and output in an action block. The last block with a programmed end-of-motion criterion that was processed in the search run serves as a container for all programmed end-of-motion criteria for all axes.

**Example:**

```
N01 G01 POS[X]=20 POS[Y]=30 IPOENDA[X] IPOENDA[Y]
N02 POS[Z]=55 FINEA[Z]
N03 $A_OUT[1]=1
N04 POS[X]=100 COARSEA[X]
N05
TARGET: ; Block search target
```

- In this example, `N04` serves as a container for all programmed end-of-motion criteria. Two action blocks are saved. The digital output (`N03`) is issued in the first action block and in the second, `COARSEA` is set for the X axis, `IPOENDA` for the Y axis and `FINEA` for the Z axis.

The same applies to the programmed servo parameter set. The last programmed acceleration override is effective from the first approach block.

## 17.5 Supplementary conditions

### 17.5.1 General boundary conditions

#### Several feeds in one block

The "Several feeds in one block" function is only available in conjunction with the: "Synchronized Actions" function.

**References:**

/FBSY/ Function Manual Synchronized Actions

### 17.5.2 Supplementary conditions for feedrate programming

#### Unit of measurement

The applicable unit of measurement for feedrates is based on the value entered in machine data:

MD12240 SCALING\_SYSTEM\_IS\_METRIC

(standard control system metric/imperial)

and the type of axis entered in machine data:

MD30300 IS\_ROT\_AX

(rotary or linear axis).

#### Standard setting for feedrate type

G94 is displayed on the screen as the standard setting.

The initial setting (standard programming setting) for the feedrate type is only displayed when the part program starts up.

The initial setting is set in machine data:

MD20150 GCODE\_RESET\_VALUES (initial setting for G groups).

## Activation of the F values

Machine data:

MD22140 F\_VALUES\_ACTIVE\_AFTER\_RESET (F function active via `RESET`) can be used to define whether the following most recently programmed `F` values are to remain active following a `RESET`.

- Programmed path feedrate: `F=...`
- Programmed feedrate change for path feedrate: `OVR=...`
- Programmed positioning feedrate: `FA=...`
- Programmed feedrate change for positioning feedrate: `OVRA[U]=...`

For more detailed information about syntax, please see:

**References:**

/PG/ Programming Manual, Fundamentals

## Position spindle

If `G95, G96, G961, G97, G971, G33, G34, G35` is active, spindle positioning should not be performed, because the derived path feedrate following spindle positioning = 0.

⇒ If the programmed axis position has not yet been reached, the block cannot be completed.

## 17.6 Examples

### 17.6.1 Feedrate programming for chamfer/rounding FRC, FRCM

#### Example 1: Following block feedrate

MD20201 CHFRND\_MODE\_MASK Bit0 = 0  
(apply feedrate from following block; default setting)

```
N10 G0 X0 Y0 G17 F100 G94
N20 G1 X10 CHF=2 ; Chamfer N20-N30 with F=100 mm/min
N30 Y10 CHF=4 ; Chamfer N30-N40 with FRC=200 mm/min
N40 X20 CHF=3 FRC=200 ; Chamfer N40-N60 with FRCM=50 mm/min
N50 RNDM=2 FRCM=50
N60 Y20 ; Modal rounding N60-N70 with
; FRCM=50 mm/min
N70 X30 ; Modal rounding N70-N80 with
; FRC=100 mm/min
N80 Y30 CHF=3 FRC=100 ; Chamfer N80-N90 with
; FRCM=50 mm/min (modal)
N90 X40 ; Modal rounding N90-N100 with
; F=100 mm/min (deselection of FRCM)
N100 Y40 FRCM=0 ; Modal rounding N100-N120 with G95
; FRC=1 mm/rev
N110 S1000 M3
N120 X50 G95 F3 FRC=1
...
M02
```

## Example 2: Feedrate of previous block

MD20201 CHFRND\_MODE\_MASK Bit0 = 1  
(accept feedrate of previous block; recommended setting)

```
N10 G0 X0 Y0 G17 F100 G94
N20 G1 X10 CHF=2 ; Chamfer N20-N30 with F=100 mm/min
N30 Y10 CHF=4 FRC=120 ; Chamfer N30-N40 with FRC=120 mm/min
N40 X20 CHF=3 FRC=200 ; Chamfer N40-N60 with FRC=200 mm/min
N50 RNDM=2 FRCM=50
N60 Y20 ; Modal rounding N60-N70 with
 FRCM=50 mm/min
N70 X30 ; Modal rounding N70-N80 with
 FRCM=50 mm/min
N80 Y30 CHF=3 FRC=100 ; Chamfer N80-N90 with
 FRC=100 mm/min (modal)
N90 X40 ; Modal rounding N90-N100 with
 FRCM=50 mm/min
N100 Y40 FRCM=0 ; Modal rounding N100-N120 with
 F=100 mm/min
N110 S1000 M3
N120 X50 CHF=4 G95 F3 FRC=1 Chamfer N120-N130 with G95
 FRC=1 mm/rev
N130 Y50 Modal rounding N130-N140
 with F=3 mm/rev
N140 X60
...
M02
```

## 17.7 Data lists

### 17.7.1 Machine data

#### 17.7.1.1 NC-specific machine data

| Number | Identifier: \$MN_          | Description                                      |
|--------|----------------------------|--------------------------------------------------|
| 10704  | DRYRUN_MASK                | Activation of dry run feedrate                   |
| 10710  | PROG_SD_RESET_SAVE_TAB     | Setting data to be updated                       |
| 11410  | SUPPRESS_ALARM_MASK        | Mask for suppressing special alarms              |
| 11550  | STOP_MODE_MASK             | Defines the stop behavior                        |
| 12000  | OVR_AX_IS_GRAY_CODE        | Axis feedrate override switch, gray-coded        |
| 12010  | OVR_FACTOR_AX_SPEED        | Evaluation of the axis feed override switch      |
| 12020  | OVR_FEED_IS_GRAY_CODE      | Path feed override switch, gray-coded            |
| 12030  | OVR_FACTOR_FEEDRATE        | Evaluation of the path feed override switch      |
| 12040  | OVR_RAPID_IS_GRAY_CODE     | Rapid traverse override switch, gray-coded       |
| 12050  | OVR_FACTOR_RAPID_TRA       | Evaluation of the rapid traverse override switch |
| 12060  | OVR_SPIND_IS_GRAY_CODE     | Spindle override switch, gray-coded              |
| 12070  | OVR_FACTOR_SPIND_SPEED     | Evaluation of the spindle override switch        |
| 12080  | OVR_REFERENCE_IS_PROG_FEED | Override reference velocity                      |
| 12082  | OVR_REFERENCE_IS_MIN_FEED  | Defining the reference of the path override      |
| 12090  | OVR_FUNCTION_MASK          | Selection of override specifications             |
| 12100  | OVR_FACTOR_LIMIT_BIN       | Limit for binary-coded override switch           |
| 12200  | RUN_OVERRIDE_0             | Traversing with override 0                       |
| 12202  | PERMANENT_FEED             | Fixed feedrates for linear axes                  |
| 12204  | PERMANENT_ROT_AX_FEED      | Fixed feedrates for rotary axes                  |

#### 17.7.1.2 Channel-specific machine data

| Number | Identifier: \$MC_          | Description                                                  |
|--------|----------------------------|--------------------------------------------------------------|
| 20100  | DIAMETER_AX_DEF            | Geometry axes with transverse axis functions                 |
| 20150  | GCODE_RESET_VALUES         | Initial setting of the G groups                              |
| 20172  | COMPRESS_VELO_TOL          | Maximum permissible deviation from path feed for compression |
| 20200  | CHFRND_MAXNUM_DUMMY_BLOCKS | Empty blocks with phase/radii                                |
| 20201  | CHFRND_MODE_MASK           | Behavior for chamfer/rounding                                |
| 20750  | ALLOW_GO_IN_G96            | G0 logic for G96, G961                                       |
| 21200  | LIFTFAST_DIST              | Traversing path for fast retraction from the contour         |

| Number | Identifier: \$MC_           | Description                                                  |

## W1: Tool offset

### 18.1 Short description

#### Calculating tool compensation data

The SINUMERIK 840D control can be used to calculate the following tool compensation data:

- Length compensation
- Radius compensation
- Storage of tool data in a flexible tool offset memory:
  - Tool identification with T numbers from 0 to 32000
  - Definition of a tool with a maximum of 9 cutting edges
  - Cutting edge described by up to 25 tool parameters
- Tool selection selectable: Immediate or via selectable M function
- Tool radius compensation:
  - Selection and deselection strategy configurable: Normal or contour-related
  - Compensation active for all interpolation types:
    - Linear
    - Circle
    - Helical
    - Spline
    - Polynomial
    - Involute
  - Compensation at outer corners selectable:
    - Transition circle/ellipse (G450) or equidistant intersection (G451)
  - Parameter-driven adaptation of G450/G451 functions to the contour
  - Free traversing on outer corners with G450 and DISC parameter
  - Number of dummy blocks without axis motion selectable in the compensation plane
  - Collision detection selectable:
    - Possible contour violations are detected predictively, if:
      - Path is shorter than tool radius
      - Width of an inside corner is shorter than the tool diameter
  - Keep tool radius compensation constant
  - Intersection procedure for polynomials

### Toolholder with orientation capability

This function permits the machining of inclined surfaces with allowance for tool length compensation, provided that the kinematics of the toolholder (without NC axes) permits a static orientation of the tool. The more complex 5-Axis transformation is not required for this case.

**References:**

/FB3/ Function Manual, Special Functions; 3- to 5-Axis Transformation (F2)

Appropriate selection of the tool data and toolholder data describes the kinematics for the control such that it can make allowance for the tool length compensation. The control can take some of the description data direct from the current frame.

---

**Note**

Please refer to the following documentation for further information on tools and tool compensations and a full technical description of the general and specific programming features for tool compensation (TLC and TRC):

**References:**

/PG/ Programming Manual Fundamentals

---

### Flat/Unique D number structure

Compensations can be selected via unique D numbers with management function.

### Special handling of tool compensations

The evaluation of signs can be controlled for tool length and wear by the setting data:

SD42900 \$SC\_MIRROR\_TOOL\_LENGTH (Sign change tool length when mirroring)

SD42960 \$SC\_TOOL\_TEMP\_COMP (Temperature compens. regarding tool).

The same applies to the response of the wear components when mirroring geometry axes or changing the machining plane via setting data.

**References:**

/PG/ Programming Manual Fundamentals; Tool compensations

## **G461/G462**

In order to enable the solid machining of inside corners in certain situations with the activation and deactivation of tool radius compensation, commands G461 and G462 have been introduced and the approach/retraction strategy has thus been extended for tool radius compensation.

- G461

If no intersection is possible between the last TRC block and a previous block, the control calculates an intersection by extending the offset curve of this block with a circle whose center point coincides with the end point of the non-corrected block, and whose radius is equal to the tool radius.

- G462

If no intersection is possible between the last TRC block and a previous block, the control calculates an intersection by inserting a straight line at the end point of the last block with tool radius compensation (the block is extended by its end tangent).

## **Changing from G40 to G41/G42**

The change from G40 to G41/G42 and vice versa is no longer treated as a tool change for tools with relevant tool point direction (turning and grinding tools).

## **Tool compensation environments**

Functions, which enable the following actions in relation to the current states of tool data, are available in SW 7.1:

- Save
- Deletion
- Read
- Modify

Some of the functions were previously implemented in measuring cycles. They are now universally available.

A further function can be used to determine information about the assignment of the tool lengths of the active tool to the abscissa, ordinate and applicate.

## 18.2 Tool

### 18.2.1 General

#### Select tool

A tool is selected in the program with the T function.

Whether the new tool will be loaded immediately by means of the T function depends on the setting in the machine data:

\$MC\_TOOL\_CHANGE\_MODE (new tool compensation with M function) determines whether the new tool is loaded immediately on execution of the T function.

#### Change tool immediately

MD22550 \$MC\_TOOL\_CHANGE\_MODE = 0 (new tool compensation with M function).

The new tool is changed immediately with the T function.

This setting is used mainly for turning machines with tool revolver.

#### Change tool with M06

MD22550 \$MC\_TOOL\_CHANGE\_MODE = 1 (new tool compensation with M function).

The new tool is prepared for changing with the T function.

This setting is used mainly on milling machines with a tool magazine, in order to bring the new tool into the tool change position without interrupting the machining process.

The old tool is removed from the spindle and the new tool is loaded into the spindle with the entered M function in the machine data:

MD22560 \$MC\_TOOL\_CHANGE\_M\_CODE (M function for tool change)

This tool change must be programmed with the M function M06, in accordance with DIN 66025.

The next tool is preselected with the machine data:

MD20121 \$MC\_TOOL\_PRESEL\_RESET\_VALUE (Preselected tool at RESET)

Its tool length compensation values must be considered at RESET and powerup according to machine data:

MD20110 \$MC\_RESET\_MODE\_MASK (Determination of control default settings after RESET/TP end).

#### Value range of T

The T function accepts the following whole numbers:

- From T0 (no tool)
- To T32000 (tool number 32000).

## Tool cutting edge

Each tool can have up to 9 cutting edges. The 9 tool cutting edges are assigned to the D functions D1 to D9.

Figure 18-1 Example of a tool T... with 9 cutting edges (D1 to D9)

## D function

The tool cutting edge is programmed with D1 (edge 1) to D9 (edge 9). The tool cutting edge always refers to the currently active tool. An active tool cutting edge (D1 to D9) without an active tool (T0) is inactive. Tool cutting edge D0 deselects all tool compensations of the active tool.

## Selection of the cutting edge when changing tool

When a new tool (new T number) has been programmed and the old one replaced, the following options are available for selecting the cutting edge:

- The cutting edge number is programmed.
- The cutting edge number is defined by the machine data:  
MD20270 \$MC\_CUTTING\_EDGE\_DEFAULT (Basic setting of tool cutting edge without programming)

| Value | Significance                                                                                                       |
|-------|--------------------------------------------------------------------------------------------------------------------|
| = 0   | No automatic cutting edge selection in accordance with M06                                                         |
| < > 0 | Number of the cutting edge, which is selected in accordance with M06                                               |
| = -1  | The cutting edge number of the old tool is retained and is also selected for the new tool, in accordance with M06. |

## Activating the tool compensations

D1 to D9 activate the tool compensation for a cutting edge on the active tool. Tool length compensation and tool radius compensation can be activated at different times:

- **Tool length compensation (TLC)** is performed on the first traversing motion of the axis, on which the TLC is to act.

This traversing motion must be a linear interpolation (G0, G1, POS, POSA) or polynomial interpolation (POLY). If the POS/POSA axis is one of the active geometry axes, the tool length compensation is applied with the first axis motion in which the WLK is supposed to act.

- **Tool radius compensation (TRC)** becomes active when G41/G42 is programmed in the active plane (G17, G18 or G19).

The selection of tool radius compensation with G41/G42 is only permitted in a program block with G0 (rapid traverse) or G1 (linear interpolation).

## 18.2.2 Compensation memory structure

### Tool compensation memory size

Each channel can have a dedicated tool compensation memory (TO unit).

Which tool compensation memory exists for the relevant channel is set with the machine data:

MD28085 \$MC\_MM\_LINK\_TOA\_UNIT (Assignment of TO unit to a channel).

The maximum number of tool cutting edges for all tools managed by the NCK is set with the machine data:

MD18100 \$MN\_MM\_NUM\_CUTTING\_EDGES\_IN\_TOA (number of tool cutting edges in NCK).

### Tools

The TO memory consists of tools numbered T1 to T32000.

Each tool can be set up via TOA files or individually, using the "New tool" soft key. Compensation values not required must be assigned the value zero. (this is the default setting when the offset memory is created): The individual values in the offset memory (tool parameters) can be read and written from the program using system variables.

---

#### Note

The tools (T1 to T32000) do not have to be stored in ascending order or contiguously in the tool compensation memory, and the first tool does not have to be assigned number T1.

---

### Tool cutting edges

Each tool can have up to 9 cutting edges ( $D_1$  to  $D_9$ ). The first cutting edge ( $D_1$ ) is set up automatically when a new tool is loaded in the tool compensation memory. Other cutting edges (up to 8) are set up consecutively and contiguously using the "New cutting edge" soft key. A different number of tool cutting edges can be assigned to each tool in this way.

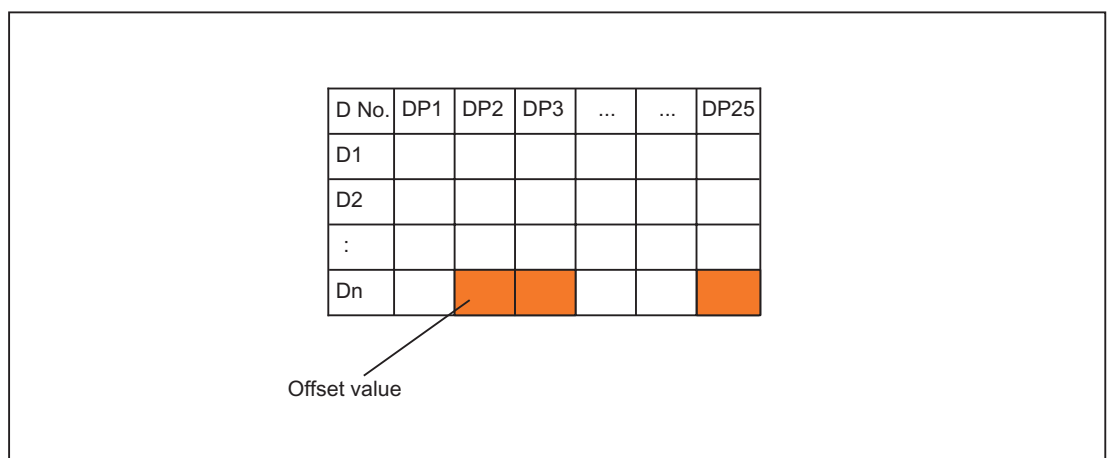

Figure 18-2 Example of a tool compensation memory structure for 2 channels

### 18.2.3 Calculating the tool compensation

#### D No.

The **D no.** is sufficient for calculating the tool compensations (can be set via MD).

## Programming

The above compensation block is to be calculated in the NC.

Part program call:

```
| ...
| Dn
```

### 18.2.4 Address extension for NC addresses T and M

#### MD20096

Whether also with tool management **not** activated, the address extension of T and M is to be interpreted as spindle number, can be set through the machine data:

MD20096 \$MC\_T\_M\_ADDRESS\_EXT\_IS\_SPINO (spindle number as address extension).

The same rules then apply to the reference between the D number and T number as when the "Tool management" function is active.

#### Effect on the D number

A compensation data set is determined by the D number.

The D address cannot be programmed with an address extension.

The evaluation of the D address always refers to the currently active tool.

The programmed D address refers to the active tool in relation to the master spindle (same as for tool management function), when machine data is set:

MD20096 \$MC\_T\_M\_ADDRESS\_EXT\_IS\_SPINO = TRUE (spindle number as address extension).

#### Effect on the T number

If the "Tool management" function is active, the values programmed with reference to the master spindle (or master toolholder) are displayed as programmed/active T numbers.

If tool management is not active, **all** programmed T values are displayed as programmed/active, regardless of the programmed address extension.

Only the T value programmed in relation to the master spindle is shown as programmed/active, when:

MD20096 \$MC\_T\_M\_ADDRESS\_EXT\_IS\_SPINO = TRUE (spindle number as address extension).

## Example

The example below shows the effect of MD20096.

Two spindles are considered. Spindle 1 is the master spindle. M6 was defined as the tool change signal.

```
T1 = 5
M1 = 6
T2 = 50
M2 = 6
D4
```

- If tool management is active, D4 refers to tool "5".  
T2=50 defines the tool for the secondary spindle, whose tool does not influence the path compensation. The path is determined exclusively by the tool programmed for the master spindle.
- D4 relates to tool "50" without active tool management and with the machine data:  
MD20096 \$MC\_T\_M\_ADDRESS\_EXT\_IS\_SPINO = **FALSE** (significance of address extension on T, M tool change).  
The address extensions of neither T nor M are evaluated in the NCK.  
Each tool change command defines a new path compensation.
- D4 relates to tool "5" (as when tool management is active) without active tool management and with the machine data:  
MD20096 \$MC\_T\_M\_ADDRESS\_EXT\_IS\_SPINO = **TRUE**.  
Address extension 1 (T1= ..., M1= ...) addresses the master spindle.

---

### Note

Previously, when tool management was not activated, each tool change command (programmed with T or M) caused the tool compensation to be recalculated in the path. The address extension is not defined further by this operation. The significance of the extension is defined by the user (in the PLC user program).

---

## 18.2.5 Free assignment of D numbers

### "Relative" D numbers

In the NCK, it is possible to manage the D numbers as "relative" D numbers for the tool compensation data sets. The corresponding D numbers are assigned to each T number. The maximum number of D numbers was previously limited to 9.

## Functions

Expansions to functions when assigning D numbers:

- The maximum permitted D numbers are defined via the machine data:  
MD18105 \$MN\_MM\_MAX\_CUTTING\_EDGE\_NO (Max. value of the D numbers (DRAM))  
The default value is 9, in order to maintain compatibility with existing applications.
- The number of cuts (or the offset data sets) **for each tool** can be defined via the machine data:  
MD18106 \$MN\_MM\_MAX\_CUTTING\_EDGE\_PERTOOL (Max. number of the D numbers per tool (DRAM))  
This allows you to customize the number of cutting edges to be configured for each tool to the actual number of real cutting edges for monitoring purposes.
- It is also possible to rename D numbers in the NCK and thus to allocate any D numbers to the cutting edges.

---

### Note

In addition to relative D number allocation, the D numbers can also be assigned as "flat" or "absolute" D numbers (1-32000) without a reference to a T number (within the "Flat D number structure" function).

---

## Cutting edge number CE

When you rename D numbers, the information in the tool Catalog detailing the numbers defined for these cutting edges is lost. It is, therefore, impossible to determine, following renaming, which cutting edge of the Catalog is being referenced.

Since this information is required for retooling procedures, a **cutting edge number CE** has been introduced for each cutting edge. This number remains stored when the D number is renamed.

The D number identifies the cutting edge compensation in the part program. This **compensation number D** is administered separately from the **cutting edge number CE** (the number in the tool Catalog). Any number can be used. The number is used to identify a compensation in the part program and on the display.

The CE number identifies the actual physical cutting edge during retooling. The cutting edge number CE is not evaluated by the NCK on compensation selection during a tool change (only available via the OPI).

The cutting edge number CE is defined with system variable **\$TC\_DPCE[t,d]**:

- **t** stands for the internal T number.
- **d** stands for the D number.

Write accesses are monitored for collisions, i.e., all cutting edge numbers of a tool must be different. The variable \$TC\_DPCE is a component of the cutting edge parameter data set \$TC\_DP1 to \$TC\_DP25.

It is only practical to parameterize \$TC\_DPCE if the maximum cutting edge number (MD18105) is greater than the maximum number of cutting edges per tool (MD18106).

In this case, the default cutting edge number is the same as the classification number of the cutting edge. Compensations of a tool are created starting at number 1 and are incremented up to the maximum number of cutting edges per tool (MD18106).

The cutting edge number CE is the same as the D number (in compatibility with the behavior till now) if:

$MD18105 \leq MD18106$ .

A read operation returns  $CE=D$ . A write operation is ignored without an alarm message.

### Note

The compensation values \$TC\_DP1 to \$TC\_DP25 of the active tool compensation can be read with system variable \$P\_AD[n], where n=1 to 25. The CE cutting edge number of the active compensation is returned with n=26.

## Commands

When the maximum cutting edge number:

MD18105 \$MN\_MM\_MAX\_CUTTING\_EDGE\_NO (Max. value of the D numbers (DRAM))  
is greater than the maximum number of cutting edges per tool:

MD18106 \$MN\_MM\_MAX\_CUTTING\_EDGE\_PERTOOL (Max. number of D numbers per  
tool (DRAM))

the following commands are available:

| Command  | Significance                                                                                                                                                                                                                                                                                                                                                          |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHKDNO   | Checks the uniqueness of the available D numbers.<br>The D numbers of all tools defined within a TO unit may not occur more than once.<br>No allowance is made for replacement tools.                                                                                                                                                                                 |
| GETDNO   | Determines the D number for the cutting edge of a tool.<br>If no D number matching the input parameters exists, d=0.<br>If the D number is invalid, a value greater than 32000 is returned.                                                                                                                                                                           |
| SETDNO   | Sets or changes the D number of the CE cutting edge of tool T.<br>If there is no data block for the specified parameter, the value FALSE is returned.<br>Syntax errors generate an alarm. The D number cannot be set explicitly to 0.                                                                                                                                 |
| GETACTTD | Determines the associated T number for an absolute D number.<br>There is not check for uniqueness. If several D numbers within a TO unit are the same, the T number of the first tool found in the search is returned.<br>This command is not suitable for use with "flat" D numbers, because the value 1 is always returned in this case (no T numbers in database). |
| DZERO    | Marks all D numbers of the TO unit as invalid.<br>This command is used for support during retooling.<br>Compensation data sets tagged with this command are no longer verified by the<br>CHKDNO language command. These data sets can be accessed again by setting the<br>D number once more with SETDNO.                                                             |

---

**Note**

If the maximum cutting edge number is smaller than the maximum number of cutting edges per tool (**MD18105 < MD18106**), the language commands described do not affect the system.

This relation is preset in the NCK as standard, in order to maintain compatibility with existing applications.

The individual commands are described in detail in:

**References:**

/PG/ Programming Manual Fundamentals

---

**Activation**

In order to work with unique D numbers and, therefore, with the defined language commands, it must be possible to name D numbers freely for the tools.

The following conditions must be fulfilled for this purpose:

- MD18105 > MD18106
- The 'flat D number' function is not activated.

MD18102 \$MN\_MM\_TYPE\_OF\_CUTTING\_EDGE (type of D number programming (SRAM)).

**Examples**

**MD18105 \$MN\_MM\_MAX\_CUTTING\_EDGE\_NO** (Max. value of the D numbers (DRAM))

A maximum of one compensation can be defined per tool (with D number = 1).

---

**Note**

When the "Flat D numbers" function is active, only one D compensation can be defined in the TO unit.

---

**MD18105 \$MN\_MM\_MAX\_CUTTING\_EDGE\_NO = 9999**

Tools can be assigned unique D numbers.

For example:

- D numbers 1, 2, 3 are assigned to T number 1
- D numbers 10, 20, 30, 40, 50 are assigned to T number 2
- D numbers 100, 200 are assigned to T number 3
- etc.

CHKDNO; **MD18105 \$MN\_MM\_MAX\_CUTTING\_EDGE\_NO = 9999**

The following data are to be checked for unique D numbers:

- T number 1 with D numbers 1, 2, 3
- T number 2 with D numbers 10, 20, 30, 40, 50
- T number 3 with D numbers 100, 200, 30  
(typing error during definition: 30 was entered instead of 300)

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| CHKDNO             | The FALSE state is returned when the above constellation is checked because D=30 has been entered twice.                |
| CHKDNO (2, 3, 30)  | The FALSE state is returned when the specified D number 30 is checked because D=30 has been entered twice.              |
| CHKDNO (2, 3, 100) | The TRUE state indicates that D=100 has been entered just once.                                                         |
| CHKDNO (1, 3)      | The TRUE state is returned although there is a conflict between the D=30 of the third tool and D=30 of the second tool. |

MD18106 \$MN\_MM\_MAX\_CUTTING\_EDGE\_PERTOOL = 1 (Max. number of the D numbers per tool (DRAM))

Only tools with just one cutting edge are used. The value 1 of the machine data inhibits the definition of a second cutting edge for a tool.

MD18106 \$MN\_MM\_MAX\_CUTTING\_EDGE\_PERTOOL = 12

A maximum of 12 cutting edges can be defined per tool.

## Programming examples

### Renaming a D number

The D number of cutting edge CE = 3 is to be renamed from 2 to 17. The following specifications apply:

- Internal T number T = 1
- D number = 2
- Tool with one cutting edge with:

```
$TC_DP2[1, 2] = 120
$TC_DP3[1, 2] = 5.5
$TC_DPCE[1, 2] = 3 ;Cutting edge number CE
```

- MD18105 \$MN\_MM\_MAX\_CUTTING\_EDGE\_NO = 20 (Max. value of the D numbers (DRAM))

Within the part program, this compensation is programmed as standard with T1, ...D2.

You assign the current D number of cutting edge 3 to a variable (DNoOld) and define the variable DNoNew for the new D number:

```
def int DNoOld, DNoNew = 17
DNoOld = GETDNO(1, 3)
SETDNO(1, 3, DNoNew)
```

The new D value 17 is then assigned to cutting edge CE=3.

Now the data for the cutting edge are addressed via D number 17, both via the system variable and in programming with the NC address D.

This compensation is now programmed in the part program with T1, ...D17 and the data are addressed as follows:

```
$TC_DP2[1, 17] = 120
$TC_DP3[1, 17] = 5.5
$TC_DPCE[1, 17] = 3 ;Cutting edge number CE
```

### Note

If a further cutting edge has been defined for the tool, e.g., \$TC\_DPCE[ 1, 2 ] = 1 ; = CE, the D number 2 of the cutting edge 1 cannot have the same name as the D number of the cutting edge 3 i.e.: SETDNO( 1, 1, 17 ) returns the status = FALSE as return value.

### DZERO - Invalidate D numbers

The activation of this command invalidates all D numbers of the tools in the TO unit. It is no longer possible to activate a compensation until valid D numbers are again available in the NCK. The D numbers must be reassigned using the SETDNO command.

The following tools must be defined (all with cutting edge number 1):

|          |                            |
|----------|----------------------------|
| T1, D1   | D no. of cutting edge CE=1 |
| T2, D10  | D no. of cutting edge CE=1 |
| T3, D100 | D no. of cutting edge CE=1 |

The following command is then programmed:

```
DZERO
```

If one of the compensations is now activated (e.g., with T3 D100), an alarm is generated, because D100 is not currently defined.

The D numbers are redefined with:

```
SETDNO(1, 1, 100) ;T=1, cutting edge 1 receives the (new) D number 100
SETDNO(2, 1, 10) ;T=2, cutting edge 1 receives the (old) D number 10
SETDNO(3, 1, 1) ;T=3, cutting edge 1 receives the (new) D number 1
```

**Note**

In the event of a power failure, the `DZERO` command can leave the NCK in an undefined state with reference to the D numbers. If this happens, repeat the `DZERO` command when the power is restored.

**Operating principle of a retooling program**

Let us assume you want to ensure that the required tools and cutting edges are available. The status of the tool-holding magazine of the NCK is arbitrary. The D numbers in the part programs for the new machining operation generally do not match the D numbers of the actual cutting edges. The retooling program can have the following appearance:

```

DZERO ; All D numbers of the TO unit are tagged as invalid.
.... ; One or more loops over the locations of the magazine(s)
 ; to check the tools and their cutting edge numbers.
 ; If a tool is found, which is still enabled ($TC_TP8) and
 ; has the required cutting edge number CE (GETDNO), the new
 ; D number is allocated to the cutting edge (SETDNO).
.... ; Loading and unloading operations are performed.
 ; It is possible to work with the tool status "to be
 ; unloaded" and "to be loaded".
CHKDNO ; Loading/unloading and the operation for renaming D
 ; numbers are complete.
 ; Individual tools and/or D numbers can be checked, and
 ; collisions can be handled automatically according to the
 ; return value.

```

**18.2.6 Compensation block in case of error during tool change****MD22550**

If a tool preparation has been programmed in the part program and the NCK detects an error (e.g., the data set for the programmed T number does not exist in the NCK), the user can assess the error situation and perform appropriate tasks, in order to subsequently resume machining.

The tool change may be programmed independently, depending on the machine data:

**MD22550 \$MC\_TOOL\_CHANGE\_MODE** (new tool compensation with M function).

**MD22550 \$MC\_TOOL\_CHANGE\_MODE = 0**

```

T= "T no." ; Tool preparation + tool change in one NC block,
 ; i.e., when T is programmed a new D compensation becomes
 ; active in the NCK (see
 ; machine data MD20270 $MC_CUTTING_EDGE_DEFAULT)

```

**MD22550 \$MC\_TOOL\_CHANGE\_MODE = 1**

```

T= "T no." ; Tool preparation
M06 ;Change tool
 ; (the number of the tool-change M code can be changed),
 ; i.e., when M06 is programmed a new D compensation becomes
 ; active in the NCK (see
 ; machine data MD20270 $MC_CUTTING_EDGE_DEFAULT)

```

The following problems can occur if tool management is not active:

- D compensation data set missing
- Error in part program

**Note**

The "tool not in magazine" problem cannot be detected since the NCK did not have access to any magazine information during tool compensation.

**D compensation data set missing**

Program execution is interrupted at the block containing the invalid D value (regardless of the value of machine data MD22550). The operator must either correct the program or reload the missing data set.

To do this, he needs the D number for the flat D number function, or otherwise the T number as well. These parameters are transferred when the alarm is triggered.

**Error in part program**

The options for intervention in the event of an error depend on how the tool change was programmed, defined via the machine data:

MD22550 \$MC\_TOOL\_CHANGE\_MODE (new tool compensation with M function).

**Tool change with T programming (MD22550 = 0)**

In this case, the "Compensation block" function available in the NCK is used. The NC program stops at the NC block in which a programmed T value error was detected. The "Compensation block" is executed again when the program is resumed.

The operator can intervene as follows:

- Correct the part program.
- Reload the missing cutting edge compensation data from the HMI.
- Include the missing cutting edge compensation data in the NCK using "Overstore".

Following operator intervention, the START key is pressed and the block, which caused the error, is executed again. If the error was corrected, the program is continued. Otherwise, an alarm is output again.

#### Tool change with T and M06 programming (MD22550 = 1)

In this case, an error is detected in the NC block containing the tool preparation (T programming), however this error is to be ignored initially. Processing continues until the tool change request (usually M06) is executed. The program is to stop at this point.

The programmed T address can contain any number of program lines ahead of the M06 command, or the two instructions can appear in different (sub)programs. For this reason, it is not usually possible to modify a block or a compensation block, which has already been executed.

The operator has the same options for intervention as with = 0.

Reloading of missing data is possible. In this case, however, T must be programmed with "Overstore".

If a program error has occurred, the line with the error cannot be corrected (Txx); only the line at which the program stopped and which generated the alarm can be edited. Only when machine data:

MD22562 \$MC\_TOOL\_CHANGE\_ERROR\_MODE Bit0 = 1 (response on errors in tool change).

The sequence is as follows:

```
Txx ; Error! Data set with xx does not exist.
 ; Detect state; detect xx;
 ; continue in program
....
M06 ; Detect bit memory "xx missing" → output alarm,
 ; stop program
 ; Correct block with, e.g., Tyy M06, start,
 ; block Tyy M06 interpreted and OK.
 ; Machining continues.
```

The following occurs when this part of the program is executed again:

```
Txx ; Error! Data set with xx does not exist,
 ; Detect state; detect xx;
 ; continue in program
....
Tyy M06 ; Detect bit memory "xx missing" → cancel without further response,
 ; as Tyy M06 is correct → program does not stop (correct).
```

If necessary, the original point of the T call can be corrected after the end of the program. If the tool change logic on the machine cannot process this, the program must be aborted and the point of the error corrected.

If only one data set is missing, it is transferred to the NCK, Txx is programmed in "Overstore" and the program is subsequently resumed.

As in the case of "missing D number", the required parameter (T number) can be accessed by the user for "missing T number" via the appropriate alarm (17191).

---

**Note**

In order to enable program correction, it stops immediately at the faulty Txx block.

The program text operation is also stopped when machine data:

MD22562 \$MC\_TOOL\_CHANGE\_ERROR\_MODE Bit0=1 (response on errors in tool change).

---

## 18.2.7 Definition of the effect of the tool parameters

### MD20360

The effect of the tool parameters on the transverse axis in connection with diameter programming can be controlled selectively with the machine data:

MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK (definition of tool parameters).

Details are described with the mentioned MD

### DRF handwheel traversal with half distance

During DRF handwheel traversal, it is possible to move a transverse axis through only half the distance of the specified increment as follows:

Specify the distance with handwheel via the machine data:

MD11346 \$MN\_HANDWHEEL\_TRUE\_DISTANCE = 1 (handwheel path or speed specification).

Define the DRF offset in the transverse axis as a diameter offset with the machine data:

MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK Bit 9 = 1 (definition of tool parameters).

Deselecting an axial DRF compensation ( $DRFOF$ ) also deletes an existing tool compensation (handwheel override in tool direction).

---

#### Note

For further information about superimposed movements with the handwheel, please refer to:

#### References:

/FB2/ Function Manual, Extended Functions; Jog With/Without Handwheel (H1)

/PG/ Programming Manual Fundamentals (the Programming Manual describes the complete technical descriptions in order to deselect the DRF offset by axis.)

---

## 18.3 Flat D number structure

### 18.3.1 General

#### Simple tool management

Simple tool management (no replacement tools, no magazines) using D numbers is possible for turning machines.

The function is available in the basic level of tool management (without tool management function activated). Grinding tools cannot be defined using this function.

#### Activation

Which type of D number management is valid may be set via the machine data:

MD18102 \$MN\_MM\_TYPE\_OF\_CUTTING\_EDGE (type of D number programming).

| Value | Significance                                                      |
|-------|-------------------------------------------------------------------|
| 0     | As previously = default setting                                   |
| 1     | Flat D number structure with absolute <b>direct D programming</b> |

Cutting edges can be deleted individually via PI command or NC programming command. Cutting edges with a specific number can also be created selectively using HMI.

### 18.3.2 Creating a new D number (compensation block)

#### Programming

Tool compensations can be programmed with system variables \$TC\_DP1 to \$TC\_DP25. The contents have the same meaning as before.

The syntax changes: no T number is specified.

- "Flat D number" function **active**:

**\$TC\_DPx[d]** = value ;where x=parameter no., d=D number

i.e., data with this syntax can only be loaded to the NCK if the "Flat D number" function is activated.

- "Flat D number" function **inactive**:

**\$TC\_DPx[t][d]** = value ;where t=T number, d=D number

A D number can only be assigned once for each tool, i.e., each D number stands for exactly one compensation data block.

A new data block is stored in the NCK memory when a D number that does not exist is created for the first time.

The maximum number of D or offset data blocks (max. 600) is set via the machine data:

MD18100 \$MN\_MM\_NUM\_CUTTING\_EDGES\_IN\_TOA (tool compensations in TO area).

## Data backup

Data backup is carried out in the same format, i.e., a backup file created with the "Flat D number" function cannot be loaded on the NCK of a control that has not activated the function.

This also applies in reverse for transfer.

## D range

1 - 99 999 999

### 18.3.3 D number programming

#### MD18102 = 1

If MD18102 \$MN\_MM\_TYPE\_OF\_CUTTING\_EDGE = 1, then D compensation is activated without reference to a certain tool.

D0 still contains the previous significance, "Deselection of active compensation in NCK".

#### Address extension of D

It is not possible to extend the address of D. Only one active compensation data block is possible for the tool path at a given time.

#### Programming

Programming in the part program is carried out as before. Only the value range of the programmed D number is increased.

##### Example 1:

| MD parameterization                  |      | Meaning                                                   |
|--------------------------------------|------|-----------------------------------------------------------|
| MD22550 \$MC_TOOL_CHANGE_MODE        | = 0  | Tool change with programming of T.                        |
| MD18102 \$MN_MM_TYPE_OF_CUTTING_EDGE | = 1  | D number programming without reference to a certain tool. |
| MD20270 \$MC_CUTTING_EDGE_DEFAULT    | = -1 | D compensation remains unchanged if tool is changed.      |

| Program code | Comment                                    |
|--------------|--------------------------------------------|
| ...          |                                            |
| D92          |                                            |
| X0           | ; Traverse with compensations from D92.    |
| T17          | ; Outputs T=17 to the PLC                  |
| X1           | ; Traverse with compensations from D92.    |
| D16          |                                            |
| X2           | ; Traverse with compensations from D16.    |
| D32000       |                                            |
| X3           | ; Traverse with compensations from D32000. |
| T29000       | ; Outputs T=29000 to the PLC.              |
| X4           | ; Traverse with compensations from D32000. |
| D1           |                                            |
| X5           | ; Traverse with compensations from D1.     |
| ...          |                                            |

**Example 2:**

MD22550 = 0

| Program code | Comment                                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------------------|
| T1           |                                                                                                                           |
| T2           |                                                                                                                           |
| T3           |                                                                                                                           |
| D777         | ; No waiting, D777 is activated, T3= programmed and active tool in the display, D777= programmed and active compensation. |

**Note**

The tool change and the assignment of a D compensation to an actual tool are the responsibility of the NC program and of the PLC program, if applicable.

### Delete D no. via part program

- **With** flat D number:  
 $\$TC\_DP1[d] = 0$   
 Compensation data block with the number D in the TO unit is deleted.  
 The memory is then free for the definition of another D number.
- **Without** flat D number:  
 $\$TC\_DP1[t][d] = 0$   
 Cutting edge d of tool t is deleted.
- $\$TC\_DP1[0] = 0$   
 All D compensations of the TO unit are deleted.

Active compensation data blocks (D numbers) cannot be deleted. This means, that it may be necessary to program `D0` before deleting.

### Tool MDs

The following machine data affect the way tools and cutting edges (D numbers) work in the NCK:

| Machine data                          | Meaning                                                              |
|---------------------------------------|----------------------------------------------------------------------|
| MD20270 \$MC_CUTTING_EDGE_DEFAULT     | Standard tool cutting edge after tool change                         |
| MD20130 \$MC_CUTTING_EDGE_RESET_VALUE | Tool cutting edge - Length compensation on power-up (RESET / TP end) |
| MD20120 \$MC_TOOL_RESET_VALUE         | Tool - Length compensation on power-up (RESET / TP end)              |
| MD20121 \$MC_TOOL_PRESEL_RESET_VALUE  | Preselect tool on RESET                                              |
| MD22550 \$MC_TOOL_CHANGE_MODE         | Tool change with M function instead of T function                    |
| MD22560 \$MC_TOOL_CHANGE_M_CODE       | M function for tool change                                           |
| MD20110 \$MC_RESET_MODE_MASK          | Definition of basic control settings after RESET/TP end)             |
| MD20112 \$MC_START_MODE_MASK          | Determination of basic control settings after NC start               |

### 18.3.4 Programming the T number

When the "Flat D number structure" function is active, NC address T continues to be evaluated, i.e., the programmed T number and the active T number are displayed. However, the NC determines the D number without reference to the programmed T value.

The NC detects 1 master spindle per channel (via the spindle number, which can be set using MD). Compensations and the `M6` command (tool change) are only calculated in reference to the master spindle.

An address extension T is interpreted as a spindle number (e.g., T2 = 1; tool 1 to be selected on spindle 2); a tool change is only detected if spindle 2 is the master spindle.

### 18.3.5 Programming M6

#### MD22550 and MD22560

The NC detects 1 master spindle per channel (via the spindle number, which can be set using MD). Compensations and the `M6` command (tool change) are only calculated in reference to the master spindle.

Whether the tool change command is performed with an M function is defined via the machine data:

MD22550 `$MC_TOOL_CHANGE_MODE` (new tool compensation with M function).

T is used as the tool preparation command.

The name of the M function for the tool change is defined via the machine data:

MD22560 `$MC_TOOL_CHANGE_M_CODE` (M function for tool change).

The default is M6. An address extension of M6 is interpreted as a spindle number.

#### Example

Two spindles are defined, spindle 1 and spindle 2, and the following applies:

```
MD20090 = 2 ; Spindle no. 2 is the master spindle.
M6 ; Tool change desired, command refers implicitly to the master
 ; spindle
M1 = 6 ; No tool change, since spindle no. 2 is the master spindle
M2 = 6 ; Tool is changed, since spindle no. 2 is the master spindle
```

## 18.3.6 Program test

### MD20110

To have the active tool and the tool compensation included as follows, can be defined via the machine data:

MD20110 \$MC\_RESET\_MODE\_MASK, Bit 3 (Definition of control default settings after RESET/TP end).

| Value |     | Significance                                                          |
|-------|-----|-----------------------------------------------------------------------|
| Bit 3 | = 1 | From the last test program to finish in test mode                     |
|       | = 0 | From the last program to finish before activation of the program test |

### Prerequisite

The bits 0 and 6 must be set by the machine data:

MD20110 \$MC\_RESET\_MODE\_MASK, Bit 3 (Definition of control default settings after RESET/TP end).

## 18.3.7 Tool management or "Flat D numbers"

### Tool management

NCK active tool management works on the basis of the following assumptions:

1. Tools are managed in magazines.
2. Cutting edges are monitored; limits reached cause the tool to be disabled.
3. Idea behind replacement tools: Tools are programmed for selection only the on the basis of their identifier. NCK then selects the concrete tool according to the strategy.

---

#### Note

For SINUMERIK 828D, this function is only available as option!

---

This means that it only makes sense to employ tool management when specific tools have been defined and these are to be utilized by the NCK.

### Flat D number

Flat D number means that tool management is carried out outside the NCK and there is no reference made to T numbers.

### No mixture of tool management and flat D no.

It does not make sense to mix or distribute the tool management functions over the NCK and PLC, since the main reason for tool management on the NCK is **to save time**.

This only works if the tasks that are time-critical are carried out on the NCK. This is not the case for "Flat D number", however.

---

#### Note

Activation of both of the functions "Flat D number structure" and "Tool management" is monitored. If both are activated at the same time, "Tool management" takes priority.

---

## 18.4 Tool cutting edge

### 18.4.1 General

#### Tool cutting edge

The following data are used to describe a tool cutting edge uniquely:

- Tool type (end mill, drill, etc.)
- Geometrical description
- Technological description

#### Tool parameter

The geometrical description, the technological description and the tool type are mapped to tool parameters for each tool cutting edge.

The following tool parameters are available for the relevant tool types:

| Tool parameter          | Significance                      | Note                                                                     |
|-------------------------|-----------------------------------|--------------------------------------------------------------------------|
| 1                       | Tool type                         |                                                                          |
| 2                       | Cutting edge position             | for turning tools or for milling/grinding tools with 2D TRC contour tool |
| Geometry - tool lengths |                                   |                                                                          |
| 3                       | Length 1                          |                                                                          |
| 4                       | Length 2                          |                                                                          |
| 5                       | Length 3                          |                                                                          |
| Geometry - tool shape   |                                   |                                                                          |
| 6                       | Radius 1/Length 1                 | for 3D face milling                                                      |
| 7                       | Length 2                          | for 3D face milling                                                      |
| 8                       | Radius 1                          | for 3D face milling                                                      |
| 9                       | Radius 2                          | for 3D face milling                                                      |
| 10                      | Angle 1 / minimum threshold angle | for 3D face milling with 2D TRC contour tool                             |
| 11                      | Angle 2 / minimum threshold angle | for 3D face milling with 2D TRC contour tool                             |
| Wear - tool length      |                                   |                                                                          |
| 12                      | Length 1                          |                                                                          |
| 13                      | Length 2                          |                                                                          |
| 14                      | Length 3                          |                                                                          |
| Wear - tool shape       |                                   |                                                                          |

| Tool parameter                          | Significance                     | Note                                             |
|-----------------------------------------|----------------------------------|--------------------------------------------------|
| 15                                      | Radius 1/Length 1                | for 3D face milling                              |
| 16                                      | Length 2                         | for 3D face milling                              |
| 17                                      | Radius 1                         | for 3D face milling                              |
| 18                                      | Radius 2                         | for 3D face milling                              |
| 19                                      | Angle 1 /<br>minimum limit angle | for 3D face milling<br>with 2D TRC contour tool. |
| 20                                      | Angle 2 /<br>maximum limit angle | for 3D face milling<br>with 2D TRC contour tool. |
| Tool base dimension / adapter dimension |                                  |                                                  |
| 21                                      | Basic length 1                   |                                                  |
| 22                                      | Basic length 2                   |                                                  |
| 23                                      | Basic length 3                   |                                                  |
| Technology                              |                                  |                                                  |
| 24                                      | Undercut angle                   | only for turning tools                           |
| 25                                      | Reserved*                        |                                                  |

\* "Reserved" means that this tool parameter is not used and is reserved for expansions.

### 3D-face milling

Milling cutter types 111, 120, 121, 130, 155, 156 and 157 are given special treatment for 3D-face milling by evaluating tool parameters (1 -23).

### References

For more information about various tool types, see:

## 18.4.2 Tool parameter 1: Tool type

### Description

The tool type (3-digit number) defines the tool in question. The selection of this tool type determines further components such as geometry, wear and tool base dimensions in advance.

### Conditions

The following is applicable to the "Tool type" parameter:

- The tool type must be specified for each tool cutting edge.
- Only the values specified can be used for the tool type.
- Tool type "0" (zero) means that no valid tool has been defined.

### Tool types and tool parameters

Different tool types and the most important tool parameters are listed in the following table. The tool parameters available for a certain tool type are designated with "x".

| Table of the most important available tool parameters (only tool type necessary)                                                                    |                                                           |                       |                     |            |            |                     |                         |                           |                     |                   |                                   |                      |                   |                       |             |                        |                       |   |

| 700                                                                                                                                                 | slotting saw                                              |                       | x                   | x          | x          | x                   | x                       | x                         | x                   | x                 | x                                 |                      |                   |                       |             |                        |                       |   |
| CLDATA* <sup>1</sup> "cutter Location Data" — tool position data according to DIN 66215,<br>BI 1SUG* <sup>2</sup> — grinding wheel peripheral speed |                                                           |                       |                     |            |            |                     |                         |                           |                     |                   |                                   |                      |                   |                       |             |                        |                       |   |

**Note**

The tool type has no significance in the turning tool groups.

Non-listed numbers are also permitted, in particular with grinding tools (400-499).

**Tool offset data**

Tool offset data (TOA data) is stored in the system variables.

Example: Slotting saw tool type (Type 700)

|                               | Geometry | Wear      | Base      | Unit |
|-------------------------------|----------|-----------|-----------|------|
| <b>Length compensation</b>    |          |           |           |      |
| Length 1                      | \$TC_DP3 | \$TC_DP12 | \$TC_DP21 | mm   |
| Length 2                      | \$TC_DP4 | \$TC_DP13 | \$TC_DP22 | mm   |
| Length 3                      | \$TC_DP5 | \$TC_DP14 | \$TC_DP23 | mm   |
| <b>Saw blade compensation</b> |          |           |           |      |
| Diameter d                    | \$TC_DP6 | \$TC_DP15 |           | mm   |
| Slot width b                  | \$TC_DP7 | \$TC_DP16 |           | mm   |
| Projection k                  | \$TC_DP8 | \$TC_DP17 |           | mm   |

Figure 18-3 Geometry of slotting saw (analogous to angle head cutter)

The width of the saw blade is accounted for with tool radius compensation (G40 to G42 as follows:

| Command | Significance                 |
|---------|------------------------------|
| G40     | No saw blade compensation    |
| G41     | Saw blade compensation left  |
| G42     | Saw blade compensation right |

### 18.4.3 Tool parameter 2: Cutting edge position

#### Description

The cutting edge position describes the position of the tool tip P in relation to the cutting edge center point S. It is entered in tool parameter 2.

The cutting edge position is required together with the cutting edge radius (tool parameter 8) for the calculation of the tool radius compensation for turning tools (tool type 5xx).

Figure 18-4 Dimensions for turning tools: Turning tool

#### Cutting edge position parameter values

Figure 18-5 Tool parameter 2 (P2): Machining behind the turning center

Figure 18-6 Tool parameter 2 (P2): Machining in front of the turning center

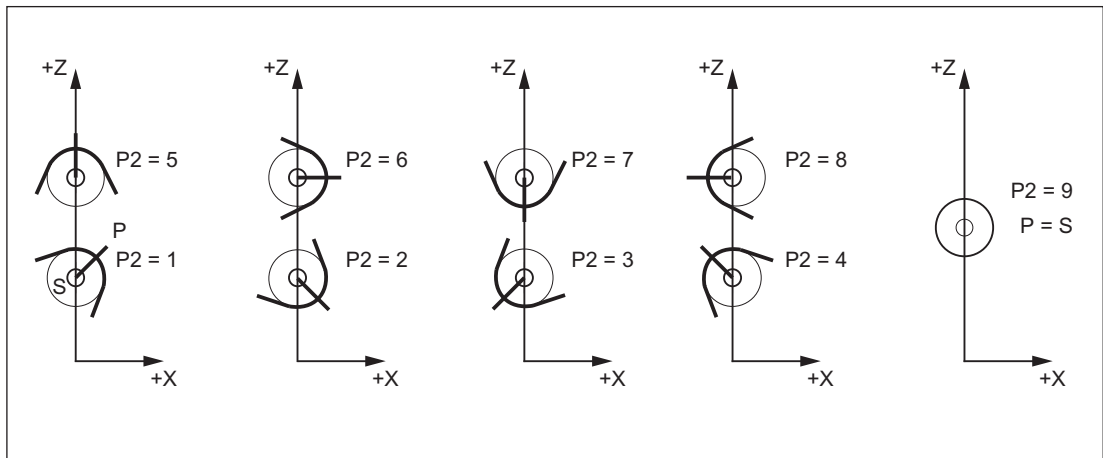

Figure 18-7 Tool parameter 2 (P2): Cutting edge position for vertical boring and turning mills

**Special points to be noted**

- If the cutting edge center point S is used instead of point P as a reference point to calculate the tool length compensation, the identifier 9 must be entered for the cutting edge position.
- The identifier 0 (zero) is not permitted as a cutting edge position.

**18.4.4 Tool parameters 3 - 5: Geometry - tool lengths**

**Description**

The lengths of the tools are required for the geometry tool length compensation. They are input as tool lengths 1 to 3 in the tool parameters 3 to 5. The following length specifications must be entered as a minimum for each tool type:

| Tool type                     | Required tool lengths                           |
|-------------------------------|-------------------------------------------------|
| Tool type 12x, 140, 145, 150: | Tool length 1                                   |
| Tool type 13x:                | Tool length 1 to 3 (depending on plane G17-G19) |

| Tool type      | Required tool lengths |
|----------------|-----------------------|
| Tool type 2xx: | Tool length 1         |
| Tool type 5xx: | Tool length 1 to 3    |

Example: Twist drill (tool type 200) with tool length (tool parameter 3)

#### Note

All three tool parameters 3 to 5 (tool length 1 to 3) are always calculated in the three geometry axes, irrespective of the tool type.

If more tool lengths are input in the tool parameters 3 to 5 for a tool type than is required as the minimum, then these extra tool lengths are settled in the geometry axes without any alarm.

#### Special points to be noted

The active size of the tool is only defined when the geometry tool length compensation (tool parameters 3 to 5) and the wear tool length compensation (tool parameters 12 to 14) are added together. The base-dimension/adaptor-dimension tool length compensation is also added in order to calculate the total tool length compensation in the geometry axes.

#### References

For information about entering tool dimensions (lengths) in tool parameters 3 to 5 (tool lengths 1 to 3) and how these are calculated in the three geometry axes, please refer to → Operating Manual.

### 18.4.5 Tool parameters 6 - 11: Geometry - tool shape

#### Description

The shape of the tool is defined with the help of tool parameters 6 to 11. The data is required for the geometry tool radius compensation.

In most cases, only tool parameter 6 (tool radius 1) is used.

| Tool parameter | Description   | Application                                                                                                                                                                             |               |
|----------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| 6              | Tool length 1 | Not used                                                                                                                                                                                |               |
| 7              | Tool length 2 | Not used                                                                                                                                                                                |               |
| 8              | Tool radius 1 | The tool radius must be entered for the following tool types in tool parameter 6 (tool radius 1):                                                                                       |               |
|                |               | Tool type 1xx                                                                                                                                                                           | Milling tools |
|                |               | Tool type 5xx                                                                                                                                                                           | Turning tools |
|                |               | A tool radius does not have to be entered for drilling tools (tool type 2xx).<br>The cutting edge position (tool parameter 2) also has to be entered for turning tools (tool type 5xx). |               |
| 9              | Tool radius 2 | Not used                                                                                                                                                                                |               |
| 10             | Tool angle 1  | Not used                                                                                                                                                                                |               |
| 11             | Tool angle 2  | Not used                                                                                                                                                                                |               |

#### 2D TRC with contour tools

For the definition of contour tools with multiple tool cutting edges, the minimum and maximum limit angle can be entered. Both limit angles each relate to the vector of the cutting edge center point to the cutting edge reference point and are counted clockwise.

|              |                                           |
|--------------|-------------------------------------------|
| Tool angle 1 | Minimum limit angle per tool cutting edge |
| Tool angle 2 | Maximum limit angle per tool cutting edge |

### 3D-face milling

All the tool parameters 6 to 11 are required for tool description of 3D-face milling.

### References

Please refer to the following documentation for information about entering tool shapes (radius for tool radius compensation) in tool parameters 6 to 11 and how these are calculated by geometry tool radius compensation in the three geometry axes:

- Programming Manual Fundamentals; Chapter: "Tool compensations" > "2½ D-tool compensation"
- Function Manual - Special Functions; 3D-tool radius compensation (W5)

For 3D-face milling, please refer to:

- Programming Manual, Job Planning; Chapter: "Transformations" > "Three, Four and Five axis Transformation (TRAORI)"

### 18.4.6 Tool parameters 12 - 14: Wear - tool lengths

#### Description

While geometry tool length compensation (tool parameters 3 to 5) is used to define the size of the tool, wear tool length compensation can be used to correct the change in the active tool size.

The active tool dimensions can change due to:

- Differences between the tool fixture on the tool measurement machine and the tool fixture on the machine tool
- Tool wear caused during service life by machining
- Definition of the finishing allowances

### Active tool size

The geometry tool compensation (tool parameters 3 to 5) and the wear tool length compensation (tool parameters 12 to 14) are added together (geometry tool length 1 is added to wear tool length 1, etc.) to arrive at the size of the active tool.

## 18.4.7 Tool parameters 15 - 20: Wear - tool shape

### Description

While geometry tool radius compensation (tool parameters 6 to 11) is used to define the shape of the tool, wear tool radius compensation can be used to correct the change in the active tool shape.

The active tool dimensions can change due to:

- Tool wear caused during service life by machining
- Definition of the finishing allowances

### Active tool shape

The geometry tool radius compensation (tool parameters 6 to 11) and the wear tool radius compensation (tool parameters 15 to 20) are added together (geometry tool radius 1 is added to wear tool radius 1, etc.) to arrive at the shape of the active tool.

## 18.4.8 Tool parameters 21 - 23: Tool base dimension/adapter dimension

### Description

Tool base dimension/adapter dimension can be used when the reference point of the toolholder (tool size) differs from the reference point of the toolholder.

This is the case when:

- The tool and the tool adapter are measured separately but are installed on the machine in one unit (the tool size and adapter size are entered separately in a cutting edge).
- The tool is used in a second tool fixture located in another position (e.g. vertical and horizontal spindle).
- The tool fixtures of a tool turret are located at different positions.

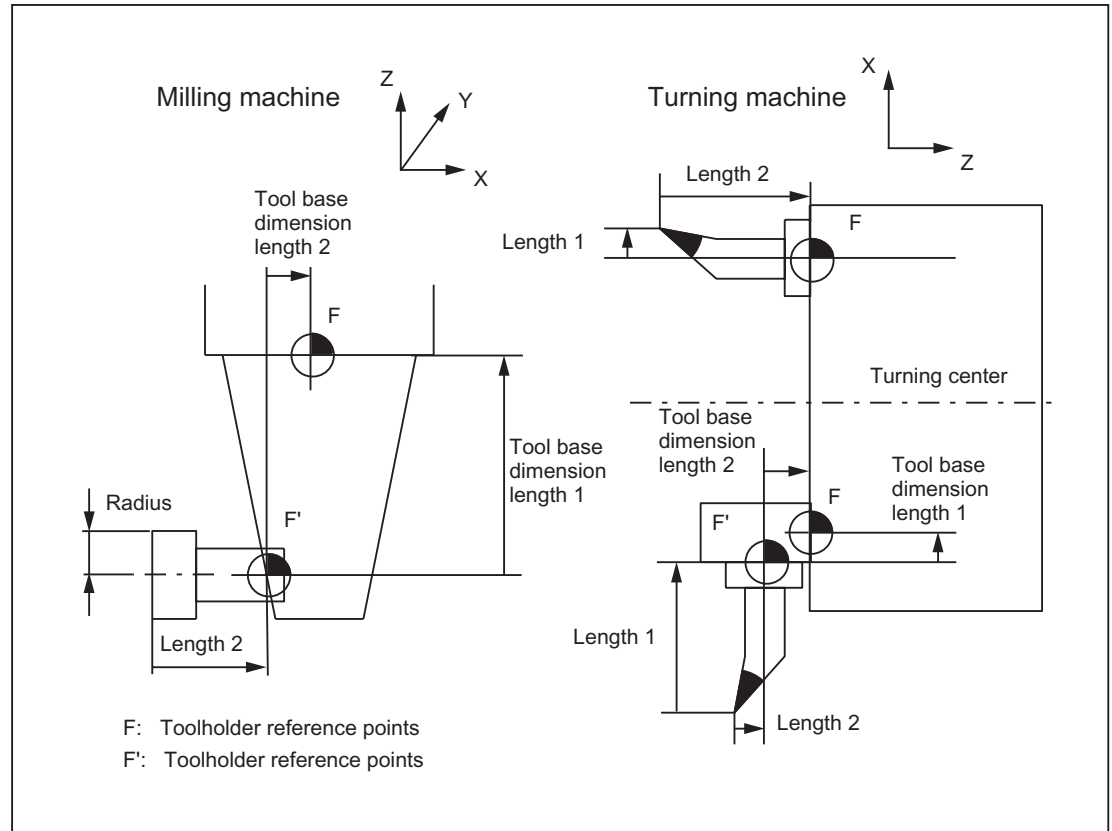

Figure 18-8 Application examples for base-dimension/adapter-dimension TLC

### Tool basic length 1 to 3 (tool parameters 21 to 23)

In order that the discrepancy between the toolholder reference point F and the toolholder reference point F' can be corrected on the three geometry axes (three dimensional), all 3 basic lengths are active irrespective of the tool type. In other words, a twist drill (tool type 200) with a tool length compensation (length 1) can also have a tool base dimension/adapter dimension in 3 axes.

### References

Please refer to the following documentation for more information about base-dimension/adapter-dimension tool length compensation:

- Programming Manual, Fundamentals

### 18.4.9 Tool parameter 24: Undercut angle

#### Meaning

Certain turning cycles, in which traversing motions with tool clearance are generated, monitor the tool clearance angle of the active tool for possible contour violations.

#### Value range

The angle (0 to 90° with no leading sign) is entered in tool parameter 24 as the tool clearance angle.

Figure 18-9 Tool clearance angle of the turning tool during relief cutting

#### Machining type, longitudinal or transverse

The tool clearance angle is entered in different ways according to the type of machining (longitudinal or face). If a tool is to be used for both longitudinal and face machining, two cutting edges must be entered for different tool clearance angles.

Figure 18-10 Tool clearance angle for longitudinal and face machining

---

**Note**

If a tool clearance angle (tool parameter 24) of zero is entered, relief cutting is not monitored in the turning cycles.

---

**References**

Please refer to the following documentation for a detailed description of the tool clearance angle:

- Programming Manual Cycles

**18.4.10 Tools with a relevant tool point direction**

The following must be observed for tools with relevant cutting edge position:

- The straight line between the tool edge center points at the block start and block end is used to calculate intersection points with the approach and retraction block. The difference between the tool edge reference point and the tool edge center point is superimposed on this movement.

For approach and/or retraction with `KONT`, the movement is superimposed in the linear subblock of the approach or retraction movement. Therefore, the geometric conditions for tools with or without relevant cutting edge position are identical.

- In circle blocks and in motion blocks containing rational polynomials with a denominator degree  $> 4$ , it is not permitted to change a tool with active tool radius compensation in cases where the distance between the tool edge center point and the tool edge reference point changes. With other types of interpolation, it is now possible to change when a transformation is active (e.g. `TRANSMIT`).
- For tool radius compensation with variable tool orientation, the transformation from the tool edge reference point to the tool edge center point can no longer be performed by means of a simple zero offset. Tools with a relevant cutting edge position are therefore not permitted for 3D peripheral milling (an alarm is output).

---

**Note**

The subject is irrelevant with respect to face milling as only defined tool types without relevant cutting edge position are permitted for this operation anyway. (A tool with a type, which has not been explicitly approved, is treated as a ball end mill with the specified radius. A cutting edge position parameter is ignored).

---

## 18.5 Tool radius compensation 2D (TRC)

### 18.5.1 General

---

**Note**

For tool radius compensation (WRK) see:

**References:**

/PG/ Programming Manual Fundamentals

Only the Programming Manual contains a complete technical description of the tool radius compensation (TRC) and its special aspects.

---

#### Why TRC?

The contour (geometry) of the workpiece programmed in the part program should be independent of the tools used in production. This makes it necessary to draw the values for the tool length and tool radius from a current offset memory. Tool radius compensation can be used to calculate the equidistant path to the programmed contour from the current tool radius.

Figure 18-11 Workpiece contour (geometry) with equidistant path

#### TRC on the plane

TRC is active on the current plane (G17 to G19) for the following types of interpolation:

|                            |     |                           |
|----------------------------|-----|---------------------------|
| • Linear interpolation     | ... | G0, G1                    |
| • Circular interpolation   | ... | G2, G3, CIP               |
| • Helical interpolation    | ... | G2, G3                    |
| • Spline interpolation     | ... | ASPLINE, BSPLINE, CSPLINE |
| • Polynomial interpolation | ... | POLY                      |

## 18.5.2 Selecting the TRC (G41/G42)

### Direction of compensation

TRC calculates a path, which is equidistant to the programmed contour. Compensation can be performed on the left- or right-hand side of the programmed contour in the direction of motion.

| Command | Significance                                                         |
|---------|----------------------------------------------------------------------|
| G41     | TRC on the left-hand side of the contour in the direction of motion  |
| G42     | TRC on the right-hand side of the contour in the direction of motion |
| G40     | Deselection of TRC                                                   |

### Intermediate blocks

In general, only program blocks with positions on geometry axes in the current plane are programmed when TRC is active. However, dummy blocks can still also be programmed with active TRC. Dummy blocks are program blocks, which do not contain any positions on a geometry axis in the current plane:

- Positions on the infeed axis
- Auxiliary functions,
- etc.

The maximum number of dummy blocks can be defined in the machine data:

MD20250 \$MC\_CUTCOM\_MAXNUM\_DUMMY\_BLOCKS (Max no. of dummy blocks with no traversing movements for TRC).

### Special points to be noted

- TRC can only be selected in a program block with G0 (rapid traverse) or G1 (linear interpolation).
- A tool must be loaded (T function) and the tool cutting edge (tool compensation) (D1 to D9) activated no later than in the program block with the tool radius compensation selection.
- Tool radius compensation is not selected with a tool cutting edge/tool compensation of D0.
- If only one geometry axis is programmed on the plane when tool radius compensation is selected, the second axis is automatically added on the plane (last programmed position).
- If no geometry axis is programmed for the current plane in the block with the tool radius compensation selection, no selection takes place.
- If tool radius compensation is deselected (G40) in the block following tool radius compensation selection, no selection takes place.
- If tool radius compensation is selected, the approach behavior is determined by the NORM/KONT instructions.

### 18.5.3 Approach and retraction behavior (NORM/KONT/KONTC/KONTT)

#### NORM and KONT

The `NORM` and `KONT` instructions can be used to control approach behavior (selection of tool radius compensation with `G41/42`) and retraction behavior (deselection of tool radius compensation with `G40`):

| Command            | Significance                                              |
|--------------------|-----------------------------------------------------------|
| <code>NORM</code>  | Normal setting at start point/end point (initial setting) |
| <code>KONT</code>  | Follow contour at start point/end point                   |
| <code>KONTC</code> | Approach/retraction with constant curvature               |
| <code>KONTT</code> | Approach/retraction with constant tangent                 |

### Special points to be noted

- `KONT` only differs from `NORM` when the tool start position is behind the contour.

Figure 18-12 Example for selecting TRC with `KONT` or `NORM` in front of and behind the contour

- `KONT` and `G450/G451` (corner behavior at outer corners) has a general effect and determines the approach and retraction behavior with TRC.
- When tool radius compensation is deselected, the retraction behavior is determined by the `NORM/KONT` instructions.

### Supplementary conditions

The approach and retraction blocks are polynomials in the following two variants. Therefore, they are only available for control variants, which support polynomial interpolation.

- `KONTT`  
With `KONTT`, approach and retraction to/from the contour is with a constant tangent. The curvature at the block transition is not usually constant.
- `KONTC`  
With `KONTC`, not only the tangent but also the curvature is constant at the transition, with the result that a **jump in acceleration** can no longer occur on activation/deactivation.

Although `KONTC` includes the `KONTT` property, the constant tangent version `KONTT` is available on its own, because the constant curvature required by `KONTC` can produce undesired contours.

## Axes

The continuity condition is observed in all **three** axes. It is thus possible to program a simultaneous path component perpendicular to the compensation plane for approach/retraction.

Only **linear blocks** are permitted for the original approach and retraction blocks with `KONTT/KONTC`. These programmed linear blocks are replaced in the control by the corresponding polynomial curves.

## Exception

`KONTT` and `KONTC` are not available in 3D variants of tool radius compensation (`CUT3DC`, `CUT3DCC`, `CUT3DF`).

If they are programmed, the control switches internally to `NORM` without an error message.

## Example for KONTC

The two figures below show a typical application for approach and retraction with constant curvature:

The full circle is approached beginning at the circle center point. The direction and curvature radius of the approach circle at the block end point are identical to the values of the next circle. Infeed takes place in the Z direction in both approach/retraction blocks simultaneously.

The associated NC program segment is as follows:

```

$TC_DP1[1,1]=121 ; Milling tool
$TC_DP6 [1,1]=10 ; Radius 10 mm
N10 G1 X0 Y0 Z60 G64 T1 D1 F10000
N20 G41 KONTC X70 Y0 Z0
N30 G2 I-70 ; Full circle
N40 G40 G1 X0 Y0 Z60
N50 M30

```

### Explanation:

In this example, a full circle with a radius of 70 mm is machined in the X/Y plane. Since the tool has a radius of 10 mm, the resulting tool center point path describes a circle with a radius of 60 mm. The start/end points are at X0 Y0 Z60, with the result that a movement takes place in the Z direction at the same time as the approach/retraction movement in the compensation plane.

Figure 18-13 Approach and retraction with constant curvature during inside machining of a full circle: Projection in the X-Y plane.

Figure 18-14 Approach and retraction with constant curvature during inside machining of a full circle: 3D representation.

### KONTT and KONTC compared

The figure below shows the differences in approach/retraction behavior between `KONTT` and `KONTC`. A circle with a radius of 20 mm about the center point at X0 Y-40 is compensated with a tool with an external radius of 20 mm. The tool center point therefore moves along a circular path with radius 40 mm. The end point of the approach blocks is at X40 Y30. The transition between the circular block and the retraction block is at the zero point. Due to the extended continuity of curvature associated with `KONTC`, the retraction block first executes a movement with a negative Y component. This will often be undesired. This response does not occur with the `KONTT` retraction block. However, with this block, an acceleration step change occurs at the block transition.

If the `KONTT` or `KONTC` block is the approach block rather than the retraction block, the contour is exactly the same, but is simply machined in the opposite direction, i.e. the **approach and retraction behavior are symmetrical**.

Figure 18-15 Differences between `KONTT` and `KONTC`

#### Note

The figure shows that a straight line bordering on the contour quadrant, e.g. to X20 Y-20, would be violated with `KONTC` on retraction/approach to X0, Y0.

## 18.5.4 Smooth approach and retraction

### 18.5.4.1 Function

#### Description

The SAR (Smooth Approach and Retraction) function is used to achieve a tangential approach to the start point of a contour, regardless of the position of the start point.

The approach behavior can be varied and adapted to special needs using a range of additional parameters.

The two functions, smooth approach and smooth retraction, are largely symmetrical. The following section is, therefore, restricted to a detailed description of approach; special reference is made to differences affecting retraction.

### Sub-movements

There are maximum 4 sub-movements in case of soft retraction and approach with the following positions:

- Start point of the movement  $P_0$
- Intermediate points  $P_1$ ,  $P_2$  and  $P_3$
- End point  $P_4$

Points  $P_0$ ,  $P_3$  and  $P_4$  are always defined. Intermediate points  $P_1$  and  $P_2$  can be omitted, according to the parameters defined and the geometrical conditions.

On retraction, the points are traversed in the reverse direction, i.e. starting at  $P_4$  and ending at  $P_0$ .

### 18.5.4.2 Parameters

The response of the smooth approach and retraction function is determined by up to 9 parameters:

### Non-modal G code for defining the approach and retraction contour

This G code cannot be omitted.

- G147: Approach with a straight line
- G148: Retraction with a straight line
- G247: Approach with a quadrant
- G248: Retraction with a quadrant
- G347: Approach with a semicircle
- G348: Retraction with a semicircle

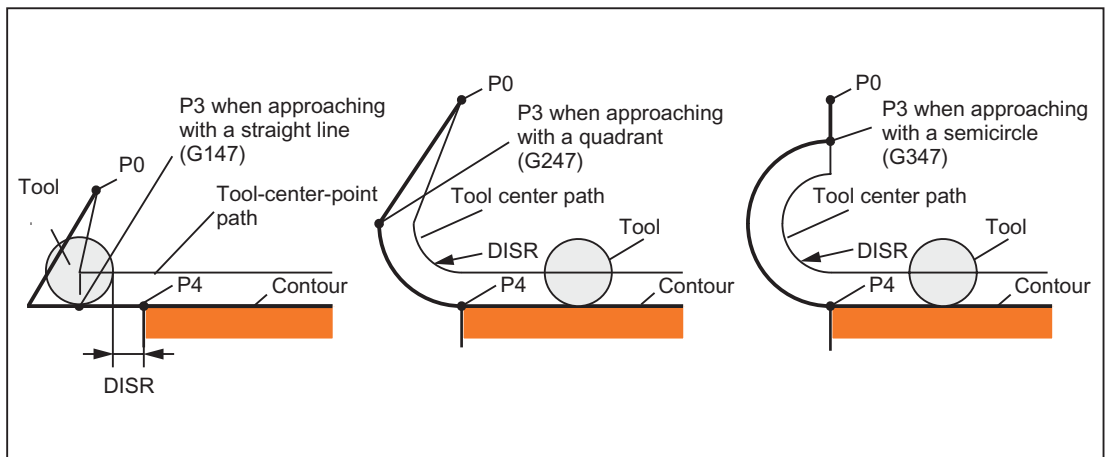

Figure 18-16 Approach behavior depending on G147 to G347 and DISR (with simultaneous activation of tool radius compensation)

### Modal G code for defining the approach and retraction contour

This G code is only relevant if the approach contour is a quadrant or semicircle. The approach and retraction direction can be determined as follows:

- G140:

Defining the approach and retraction direction using active tool radius compensation. ((G140 is the initial setting.)

With positive tool radius:

- G41 active → approach from left
- G42 active → approach from right

If no tool radius compensation is active (G40), the response is identical to G143. In this case, an alarm is not output. If the radius of the active tool is 0, the approach and retraction side is determined as if the tool radius were positive.

- G141:

Approach contour from left, or retract to the left.

- G142:

Approach contour from right, or retract to the right.

- G143:

Automatic determination of the approach direction, i.e., the contour is approached from the side where the start point is located, relative to the tangent at the start point of the following block (P<sub>4</sub>).

---

#### Note

The tangent at the end point of the preceding block is used accordingly on **retraction**. If the end point is not programmed explicitly on retraction, i.e., if it is to be determined implicitly, G143 is not permitted on retraction, since there is a mutual dependency between the approach side and the position of the end point. If G143 is programmed in this case, an alarm is output. The same applies if, when G140 is active, an automatic switchover to G143 takes place as a result of an inactive tool radius compensation.

---

Modal G code (G340, G341), which defines the subdivision of the movement into individual blocks from the start point to the end point

Figure 18-17 Sequence of the approach movement depending on G340/G341

- G340: The approach characteristic from P<sub>0</sub> to P<sub>4</sub> is shown in the figure.  
 If G<sub>247</sub> or G<sub>347</sub> is active (quadrant or semicircle) and start point P<sub>3</sub> is outside the machining plane defined by the end point P<sub>4</sub>, a helix is inserted instead of a circle. Point P<sub>2</sub> is not defined or coincides with P<sub>3</sub>.  
 The circle plane or the helix axis is determined by the plane, which is active in the SAR block (G<sub>17</sub> - G<sub>19</sub>), i.e., the projection of the start tangent is used by the following block, instead of the tangent itself, to define the circle.  
 The movement from point P<sub>0</sub> to point P<sub>3</sub> takes place along two straight lines at the velocity valid before the SAR block.
- G341: The approach characteristic from P<sub>0</sub> to P<sub>4</sub> is shown in the figure.  
 P<sub>3</sub> and P<sub>4</sub> are located within the machining plane, with the result that a circle is always inserted instead of a helix with G<sub>247</sub> or G<sub>347</sub>.

**Note**

Active, rotating frames are included in all cases where the position of the active plane G<sub>17</sub> - G<sub>19</sub> (circle plane, helix axis, infeed movements perpendicular to the active plane) is relevant.

**DISR**

DISR Specifies the length of a straight approach line or the radius of an approach arc.

**Retraction/approach with straight lines**

On approach/retraction along a straight line, DISR specifies the distance from the cutter edge to the start point of the contour, i.e., the length of the straight line with active TRC is calculated as the total of the tool radius and the programmed value of DISR.

An alarm is displayed:

- If  $DISR$  is negative and the amount is greater than the tool radius (the length of the resulting approach line is less than or equal to zero).

#### Retraction/approach with circles

Approach/retraction with circles  $DISR$  indicates always the radius of the tool center point path. If tool radius compensation is activated, a circle is generated internally, the radius of which is dimensioned such that the tool center path is derived, in this case also, from the programmed radius.

An alarm is output on approach and retraction with circles:

- If the radius of the circle generated internally is zero or negative
- If  $DISR$  is not programmed
- If the radius value  $\leq 0$ .

## DISCL

$DISCL$  specifies the distance from point  $P_2$  from the machining plane.

If the position of point  $P_2$  is to be specified by an absolute reference on the axis perpendicular to the circle plane, the value must be programmed in the form  $DISCL = AC$  (....).

If  $DISCL$  is not programmed, points  $P_1$ ,  $P_2$  and  $P_3$  are identical with  $G340$  and the approach contour is mapped from  $P_1$  to  $P_4$ .

The system checks that the point defined by  $DISCL$  lies between  $P_1$  and  $P_3$ , i.e., in all movements, which have a component perpendicular to the machining plane (e.g., infeed movements, approach movements from  $P_3$  to  $P_4$ ), this component must have the same leading sign. It is not permitted to change direction. An alarm is output if this condition is violated.

On detection of a direction reversal, a tolerance is permitted that is defined by the machine data:

MD20204 \$MC\_WAB\_CLEARANCE\_TOLERANCE (direction reversal on SAR).

However, if  $P_2$  is outside the range defined by  $P_1$  and  $P_3$  and the deviation is less than or equal to this tolerance, it is assumed that  $P_2$  is in the plane defined by  $P_1$  and/or  $P_3$ .

#### Example:

An approach is made with  $G17$  starting at position  $Z=20$  of point  $P_1$ . The SAR plane defined by  $P_3$  is at  $Z=0$ . The point defined by  $DISCL$  must, therefore, lie between these two points.  $MD20204=0.010$ . If  $P_2$  is between 20.000 and 20.010 or between 0 and -0.010, it is assumed that the value 20.0 or 0.0 is programmed. The alarm is output if the  $Z$  position of  $P_2$  is greater than 20.010 or less than -0.010.

Depending on the relative position of start point  $P_0$  and end point  $P_4$  with reference to the machining plane, the infeed movements are performed in the negative (normal for approach) or positive (normal for retraction) direction, i.e., with  $G17$  it is possible for the  $Z$  component of end point  $P_4$  to be greater than that of start point  $P_0$ .

**Programming the end point P<sub>4</sub> (or P<sub>0</sub> for retraction) generally with X... Y... Z...**

**Possible ways of programming the end point P<sub>4</sub> for approach**

End point P<sub>4</sub> can be programmed in the actual SAR block.

P<sub>4</sub> can be determined by the end point of the next traversing block.

Further blocks (dummy blocks) can be inserted between the SAR block and the next traversing block without moving the geometry axes.

The end point is deemed to have been programmed in the actual SAR block for approach if at least one geometry axis is programmed on the machining plane (X or Y with G<sub>17</sub>). If only the position of the axis perpendicular to the machining plane (Z with G<sub>17</sub>) is programmed in the SAR block, this component is taken from the SAR block, but the position in the plane is taken from the following block. In this case, an alarm is output if the axis perpendicular to the machining plane is also programmed in the following block.

**Example:**

```

$TC_DP1[1,1]=120 ; Milling tool T1/D1
$TC_DP6[1,1]=7 ; Tool with 7 mm radius

N10 G90 G0 X0 Y0 Z30 D1 T1
N20 X10

### Possible ways of programming the end point P<sub>0</sub> for retraction

The end position is always taken from the SAR block, no matter how many axes have been programmed. We distinguish between the following situations:

1. No geometry axis is programmed in the SAR block.

In this case, the contour ends at point P<sub>2</sub> (or at point P<sub>1</sub>, if P<sub>1</sub> and P<sub>2</sub> coincide). The position in the axes, which describe the machining plane, is determined by the retraction contour (end point of the straight line or arc). The axis component perpendicular to this is defined by DISCL. If, in this case, DISCL = 0, the movement takes place completely within the plane.

2. Only the axis perpendicular to the machining plane is programmed in the SAR block.

In this case, the contour ends at point P<sub>1</sub>. The position of the two other axes is determined in the same way as in 1.

### Retraction with SAR with simultaneous deactivation of TRC

If the SAR retraction block is also used to deactivate tool radius compensation, in the case of 1. and 2., an additional path from P<sub>1</sub> to P<sub>0</sub> is inserted such that no movement is produced when tool radius compensation is deactivated at the end of the retraction contour, i.e., this point defines the tool center point and not a position on a contour to be corrected.

3. At least one axis of the machining plane is programmed.

The second axis of the machining plane can be determined modally from its last position in the preceding block. The position of the axis perpendicular to the machining plane is generated as described in 1. or 2., depending on whether this axis is programmed or not. The position generated in this way defines the end point P<sub>0</sub>.

No special measures are required for deselection of tool radius compensation, because the programmed point P<sub>0</sub> already directly defines the position of the tool center point at the end of the complete contour.

The start and end points of the SAR contour (P<sub>0</sub> and P<sub>4</sub>) can coincide on approach and retraction.

**Velocity of the preceding block (typically G0)**

All movements from point P<sub>0</sub> to point P<sub>2</sub> are performed at this velocity, i.e., the movement parallel to the machining plane and the part of the infeed movement up to the safety clearance.

**Programming the feedrate with FAD**

| FAD programmed with ... |                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------|
| G340                    | Feedrate from P <sub>2</sub> or P <sub>3</sub> to P <sub>4</sub> .                                           |
| G341                    | Feedrate of the infeed movement perpendicular to the machining plane from P <sub>2</sub> to P <sub>3</sub> . |

If *FAD* is not programmed, this part of the contour is traversed at the velocity, which is active modally from the preceding block, in the event that no F command defining the velocity is programmed in the SAR block.

**Programmed response:**

- FAD*=0 or negative → Alarm output
- FAD*=... → Programmed value acts in accordance with the active G code of group 15 (feed type; G<sub>93</sub>, G<sub>94</sub>, etc.)
- FAD*=PM(...) → Programmed value is interpreted as linear feed (like G<sub>94</sub>), irrespective of the active G code of group 15
- FAD*=PR(...) → Programmed value is interpreted as revolutionary feed (like G<sub>95</sub>), irrespective of the active G code of group 15

**Example:**

```

$TC_DP1[1,1]=120 ;Milling tool T1/D1
$TC_DP6[1,1]=7 ;Tool with 7mm radius

N10 G90 G0 X0 Y0 Z20 D1 T1
N20 G41 G341 G247 DISCL=AC(5) DISR=13FAD 500 X40 Y-10 Z=0 F2000
N30 X50
N40 X60
...

```

### Programming feed F

This feed value is effective from point P<sub>3</sub> (or from point P<sub>2</sub>, if FAD is not programmed). If no F command is programmed in the SAR block, the speed of the preceding block is valid. The velocity defined by FAD is not used for following blocks.

### 18.5.4.3 Velocities

#### Velocities at approach

In both approach diagrams below, it is assumed that no new velocity is programmed in the block following the SAR block. If this is not the case, the new velocity comes into effect after point P<sub>4</sub>.

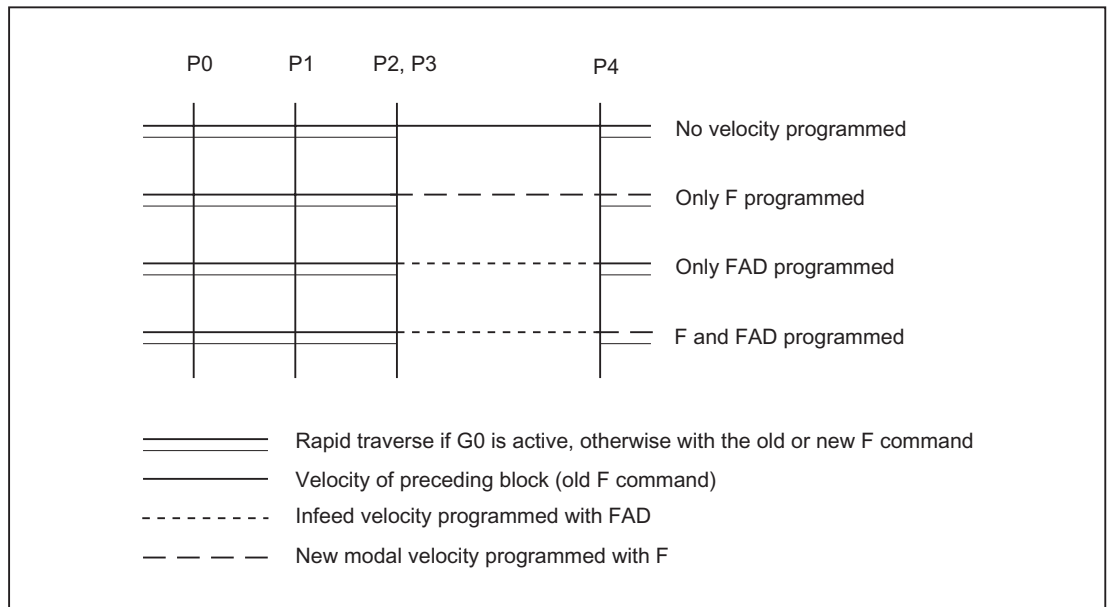

Figure 18-18 Velocities in the SAR subblocks on approach with G340

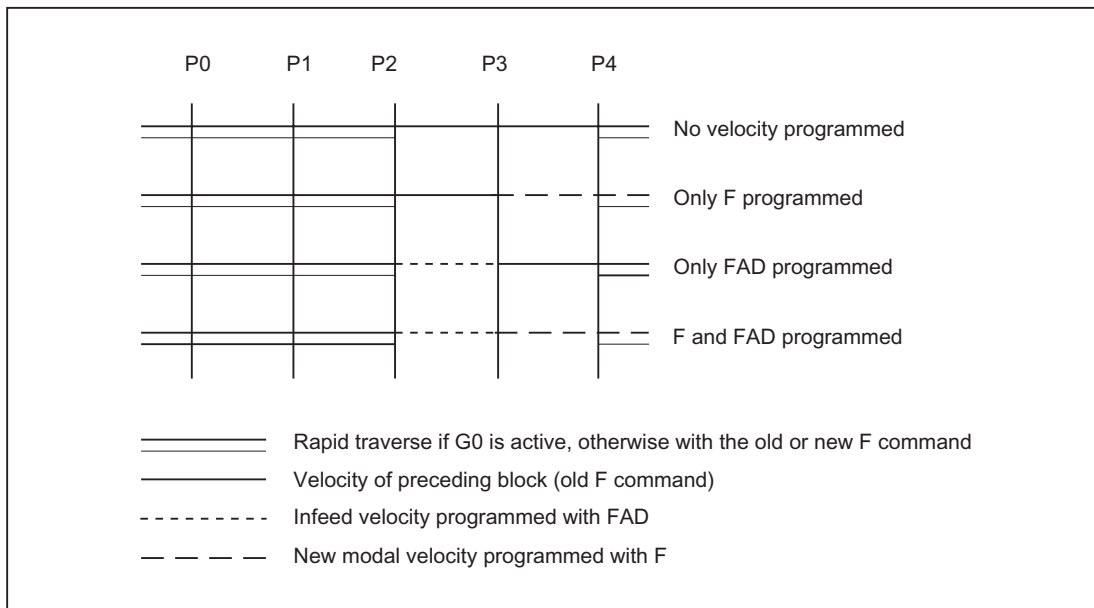

Figure 18-19 Velocities in the SAR subblocks on approach with G341

### Velocities at retraction

During retraction, the rolls of the modally active feedrate from the previous block and the programmed feedrate value in the SAR block are interchanged, i.e., the actual retraction contour (straight line, circle, helix) is traversed with the old feedrate value and a new velocity programmed with the F word applies from point P<sub>2</sub> up to P<sub>0</sub>.

If even retraction is active and F<sub>AD</sub> is programmed, the path from P<sub>3</sub> to P<sub>2</sub> is traversed with F<sub>AD</sub>, otherwise it is traversed with the old velocity. The last F command programmed in a preceding block always applies for the path from P<sub>4</sub> to P<sub>2</sub>. G<sub>0</sub> has no effect in these blocks.

Traversing from P<sub>2</sub> to P<sub>0</sub> takes place with the F command programmed in the SAR block or, if no F command is programmed, with the modal F command from a preceding block. This applies on the condition that G<sub>0</sub> is not active.

If rapid traverse is to be used on retraction in the blocks from P<sub>2</sub> to P<sub>0</sub>, G<sub>0</sub> must be activated before the SAR block or in the SAR block itself. If an additional F command is programmed in the actual SAR blocks, it is then ineffective. However, it remains modally active for following blocks.

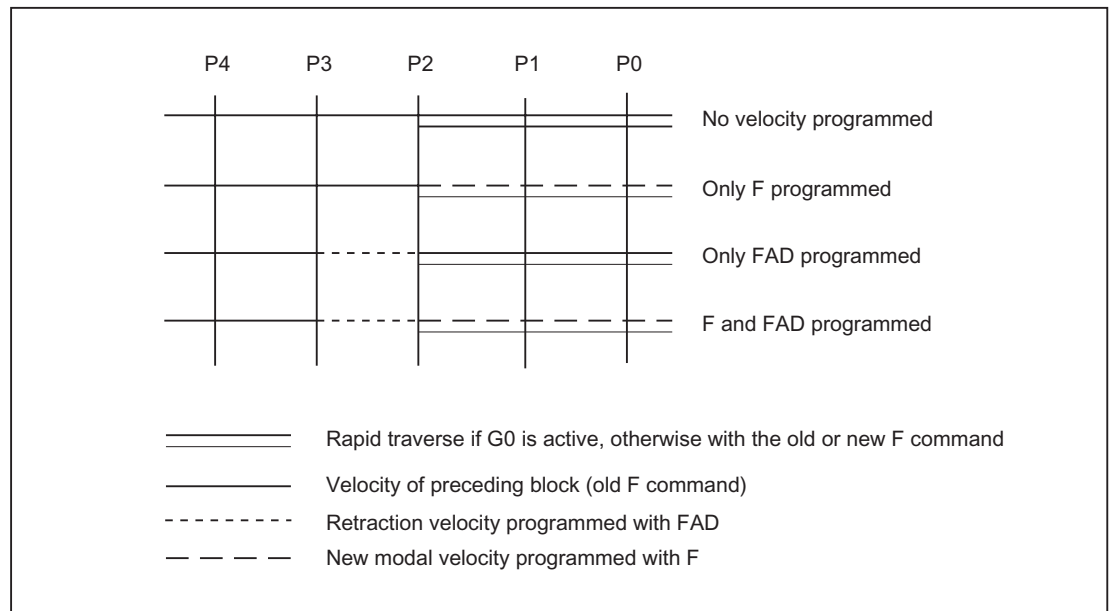

Figure 18-20 Velocities in the SAR subblocks on retraction

#### 18.5.4.4 System variables

Points P<sub>3</sub> and P<sub>4</sub> can be read in the WCS as system variables during approach.

|          |                                                  |                                                                                                                                                 |
|----------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| \$P_APR: | Read P <sub>3</sub> (start point) in WCS         |                                                                                                                                                 |
| \$P_AEP: | Read P <sub>4</sub> (contour start point) in WCS |                                                                                                                                                 |
| \$P_APDV | =1                                               | If the content of \$P_APR and \$P_AEP is valid, i.e., if these contain the position values belonging to the last SAR approach block programmed. |
|          | =0                                               | The positions of an older SAR approach block are read.                                                                                          |

Changing the WCS between the SAR block and the read operation has no effect on the position values.

#### 18.5.4.5 Supplementary conditions

##### Supplementary conditions

- Any further NC commands (e.g., auxiliary function outputs, synchronous axis movements, positioning axis movements, etc.) can be programmed in a SAR block.

These are executed in the first subblock on approach and in the last subblock on retraction.

- If the end point P<sub>4</sub> is taken not from the SAR block but from a subsequent traversing block, the actual SAR contour (straight line, quadrant or semicircle) is traversed in this block.

The last subblock of the original SAR block does not then contain traversing information for geometry axes. It is always output, however, because further actions (e.g., single axes) may have to be executed in this block.

- At least two blocks must always be taken into consideration:
  - The SAR block itself
  - The block, which defines the approach or retraction direction

Further blocks can be programmed between these two blocks.

The number of possible dummy blocks is limited with the machine data:

MD20202 \$MC\_WAB\_MAXNUM\_DUMMY\_BLOCKS (Maximum number of blocks with no traversing motions with SAR).

- If tool radius compensation is activated simultaneously in an approach block, the first linear block of the SAR contour is the block, in which activation takes place.

The complete contour generated by the SAR function is treated by tool radius compensation as if it has been programmed explicitly (collision detection, calculation of intersection, approach behavior  $NORM/KONT$ ).
- The direction of the infeed movement and the position of the circle plane or the helix axis are defined exclusively by the active plane ( $G17 - G19$ ) - rotated with an active frame where appropriate.
- On approach, a preprocessor stop must not be inserted between the SAR block and the following block, which defines the direction of the tangent.

Whether programmed explicitly or inserted automatically by the controller, a preprocessor stop results, in this case, in an alarm.

## Response with REPOS

If an SAR cycle is interrupted and repositioned, it resumes at the point of interruption on  $RMI$ . With  $RME$ , the contact point is the end point of the last SAR block; with  $RMB$ , it is the start point of the first SAR block.

If  $RMI$  is programmed together with  $DISPR$  (reapproach at distance  $DISPR$  in front of interruption point), the reapproach point can appear in a subblock of the SAR cycle before the interruption subblock.

### 18.5.4.6 Examples

#### Example 1

The following conditions must be true:

- Smooth approach is activated in block  $N20$
- $X=40$  (end point);  $Y=0$ ;  $Z=0$
- Approach movement performed with quadrant ( $G247$ )
- Approach direction not programmed,  $G140$  is valid, i.e., because TRC is active ( $G42$ ) and compensation value is positive (10), the contour is approached from the right
- Approach circle generated internally (SAR contour) has radius 20, so that the radius of the tool center path is equal to the programmed value  $DISR=10$

- Because of  $G341$ , the approach movement takes place with a circle in the plane, resulting in a start point at (20, -20, 0)
- Because  $DISCL=5$ , point P2 is at position (20, -20, 5) and, because of  $Z30$ , point P1 is in  $N10$  at (20, -20, 30)

Figure 18-21 Contour example 1

**Part program:**

```

$TC_DP1[1,1]=120 ; Tool definition T1/D1
$TC_DP6[1,1]=10 ; Radius
N10 G0 X0 Y0 Z30
N20 G247 G341 G42 NORM D1 T1 Z0 FAD=1000 F=2000 DISCL=5 DISR=10
N30 X40
N40 X100
N50 Y-30
...

```

**Example 2**

The following conditions must be true for approach:

- Smooth approach is activated in block  $N20$
- Approach movement performed with quadrant ( $G247$ )
- Approach direction not programmed,  $G140$  is valid, i.e., because TRC is active ( $G41$ ), the contour is approached from the left
- Contour offset  $OFFN=5$  ( $N10$ )
- Current tool radius=10, and so the effective compensation radius for TRC=15; the radius of the SAR contour is thus equal to 25, with the result that the radius of the tool center path is equal to  $DISR=10$

18.5 Tool radius compensation 2D (TRC)

- The end point of the circle is obtained from N30, since only the Z position is programmed in N20
- Infeed movement
  - From Z20 to Z7 (DISCL=AC(7)) with rapid traverse
  - Then on to Z0 with FAD=200
  - Approach circle in X-Y-plane and following blocks with F1500  
(In order that this velocity becomes effective in the following blocks, the active G-code G0 in N30 must be overwritten with G1. Otherwise, the contour would continue to be machined with G0.)

The following conditions must be true for retraction:

- Smooth retraction is activated in block N60
- Retraction movement performed with quadrant (G248) and helix (G340)
- FAD not programmed, since irrelevant for G340
- Z=2 in the start point; Z=8 in the end point, since DISCL=6
- When DISR=5, the radius of SAR contour=20; that of the tool center path=5
- After the circle block, the retraction movement leads from Z8 to Z20 and the movement is parallel to the X-Y plane up to the end point at X70 Y0.

Figure 18-22 Contour example 2

Part program:

```

$TC_DP1[1,1]=120 ; Tool definition T1/D1
$TC_DP6[1,1]=10 ; Radius
N10 G0 X0 Y0 Z20 G64 D1 T1 OFFN = 5 (P0app)
N20 G41 G247 G341 Z0 DISCL = AC(7) DISR = 10 F1500 FAD=200 (P3app)
N30 G1 X30 Y-10 (P4app)

```

---

```

N40 X40 Z2
N50 X50 (P4ret)
N60 G248 G340 X70 Y0 Z20 DISCL = 6 DISR = 5 G40 F10000 (P3ret)
N70 X80 Y0 (P0ret)
N80 M 30

```

---

**Note**

The contour generated in this way is modified by tool radius compensation, which is activated in the SAR approach block and deactivated in the SAR retraction block.

The tool radius compensation allows for an effective radius of 15, which is the sum of the tool radius (10) and the contour offset (5). The resulting radius of the tool center path in the approach block is therefore 10, and 5 in the retraction block.

---

## 18.5.5 Deselecting the TRC (G40)

### G40 instruction

TRC is deselected with the G40 instruction.

### Special points to be noted

- TRC can only be deselected in a program block with G0 (rapid traverse) or G1 (linear interpolation).
- If D0 is programmed when tool radius compensation is active, compensation is not deselected and error message 10750 is output.
- If a geometry axis is programmed in the block with the tool radius compensation deselection, then the compensation is deselected even if it is not on the current plane.

## 18.5.6 Compensation at outside corners

### G450/G451

The G functions G450/G451 can be used to control the response with discontinuous block transitions at outside corners:

| Command | Significance                                                           |
|---------|------------------------------------------------------------------------|
| G450    | Discontinuous block transitions with transition circle                 |
| G451    | Discontinuous block transitions with intersection of equidistant paths |

Figure 18-23 Example of a 90 degree outside corner with G450 and G451

### G450 (transition circle)

With the G function G450 active, on outside corners, the center point of the tool travels a circular path along the tool radius. The circular path starts with the normal position (perpendicular to the path tangent) at the end point of the previous path section (program block) and ends in normal position at the start point of the new path section (program block).

Where outside corners are very flat, the response with G450 (transition circle) and G451 (intersection) becomes increasingly similar → refer to very flat outside corners.

If pointed outside corners are desired, the tool must be retracted from the contour (→ see "DISC").

### DISC

The G450 transition circle does not produce sharp outside contour corners because the path of the tool center point through the transition circle is controlled so that the cutting edge stops at the outside corner (programmed position). When sharp outside corners are to be machined with G450, the DISC instruction can be used to program an overshoot. Thus, the transition circle becomes a conic and the tool cutting edge retracts from the outside corner.

The range of values of the DISC instruction is 0 to 100, in increments of 1.

| Value      | Significance                                                                               |
|------------|--------------------------------------------------------------------------------------------|
| DISC = 0   | Overshoot disabled, transition circle active                                               |
| DISC = 100 | Overshoot large enough to theoretically produce a response similar to intersection (G451). |

The programmable maximum value for DISC can be set via the machine data:  
 MD20220 \$MC\_CUTCOM\_MAX\_DISC (max. value for DISC).  
 Values greater than 50 are generally not advisable with DISC.

Figure 18-24 Example: Overshoot with DISC= 25

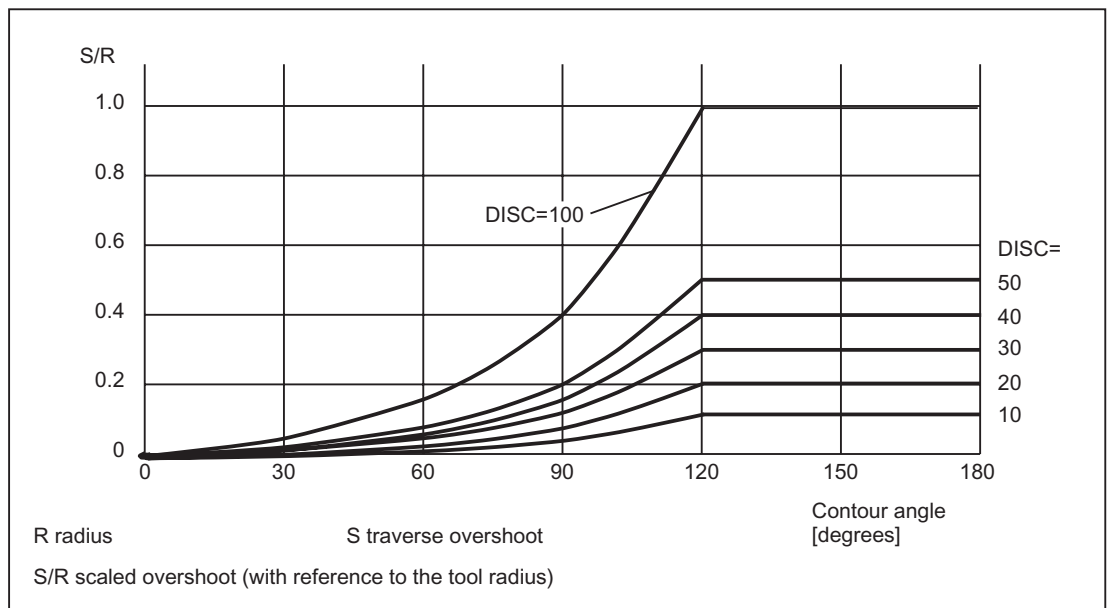

Figure 18-25 Overshoot with DISC depending on contour angle

### G451 (intersection)

If G function G451 is active, the position (intersection) resulting from the path lines (straight line, circle or helix only) located at a distance of the tool radius to the programmed contour (center-point path of the tool), is approached. Spines and polynomials are never extended.

### Very pointed outside corners

Where outside corners are very pointed, G451 can result in excessive idle paths. Therefore, the system switches automatically from G451 (intersection) to G450 (transition circle, with DISC where appropriate) when outside corners are very pointed.

The threshold angle (contour angle) for this automatic switchover (intersection point → transition circle) can be specified in the machine data:

MD20210 \$MC\_CUTCOM\_CORNER\_LIMIT (Max. angle for compensation blocks with tool radius compensation).

Figure 18-26 Example of automatic switchover to transition circle

### Very flat outside corners

Where outside corners are very flat, the response with G450 (transition circle) and G451 (intersection) becomes increasingly similar. In this case, it is no longer advisable to insert a transition circle. One reason why it is not permitted to insert a transition circle at these outside corners with 5-axis machining is that this would impose restrictions on speed in contouring mode (G64). Therefore, the system switches automatically from G450 (transition circle, with DISC where appropriate) to G451 (intersection) when outside corners are very flat.

The threshold angle (contour angle) for this automatic switchover (transition circle → intersection point) can be specified in the machine data:

MD20230 \$MC\_CUTCOM\_CURVE\_INSERT\_LIMIT (Max. angle for intersection calculation with tool radius compensation).

Figure 18-27 Example of automatic switchover to intersection

## 18.5.7 Compensation at inside corners

### Intersection

If two consecutive blocks form an inside corner, an attempt is made to find a point at which the two equidistant paths intersect. If an intersection is found, the programmed contour is shortened to the intersection (first block shortened at end, second block shortened at beginning).

Figure 18-28 Example of a shortened contour

### No intersection

In certain cases, no intersection is found between two consecutive blocks for inside corners (see figure below).

### Predictive contour calculation

If no intersection is found between two consecutive blocks, the control automatically checks the next block and attempts to find an intersection with the equidistant paths of this block (see figure below: intersection S). This automatic check of the next block (predictive contour calculation) is always performed until a number of blocks defined via machine data has been reached.

MD20240 \$MC\_CUTCOM\_MAXNUM\_CHECK\_BLOCKS (blocks for predictive contour calculation for TRC).

If no intersection is found within the number of blocks defined for the check, program execution is interrupted and an alarm is output.

Figure 18-29 If there is no intersection between N30 and block N40, the intersection between block N30 and block N50 is calculated.

## Multiple intersections

→ see also "Collision detection"

It can be the case with inside corners that predictive contour calculation finds multiple intersections of the equidistant paths in several consecutive blocks. In these cases, the last intersection is always used as the valid intersection:

Figure 18-30 Example: Inside corner with TRC without contour violation (predicting 3 blocks)

## Special points to be noted

Where multiple intersections with the next block are found, the intersection nearest the start of the next block applies.

## 18.5.8 Collision detection and bottleneck detection

### Collision detection

Collision detection (bottleneck detection) examines whether the equidistant paths of non-consecutive blocks intersect. If an intersection is found, the response is the same as for inside corners with multiple intersections: The last intersection to be found is valid:

The maximum number of blocks used for the predictive check can be entered in the machine data:

MD20240 \$MC\_CUTCOM\_MAXNUM\_CHECK\_BLOCKS (blocks for predictive contour calculation for TRC).

## Programming

Collision detection can be activated or deactivated in the program:

| Command | Significance            |
|---------|-------------------------|
| CDON    | Collision detection ON  |
| CDOF    | Collision detection OFF |
| CDOF2   | Collision detection OFF |

With CDOF, the search for an intersection initially examines two consecutive blocks. Other blocks are not included in the search. If an intersection is found between adjacent blocks, no further blocks are examined. With outside corners, an intersection can always be found between two consecutive blocks.

Predictive examination of more than two adjacent blocks is thus possible with CDON and CDOF.

---

### Note

CDOF2 is only effective for 3D peripheral milling and has the same significance as CDOF for all other types of machining (e.g. 3D face milling).

---

## Omission of block

If an intersection is detected between two blocks, which are not consecutive, none of the motions programmed between these blocks on the compensation plane are executed. All other motions and executable instructions (M commands, traversal of positioning axes, etc.) contained in the omitted blocks are executed at the intersection position in the sequence, in which they are programmed in the NC program.

## Warning 10763

If a block has been omitted as a result of the collision or bottleneck detection functions, warning 10763 is output. The program is not interrupted.

This warning is suppressed if bit 1 is enabled in machine data:

MD11410 \$MN\_SUPPRES\_ALARM\_MASK (Mask for suppressing special alarm outputs).

### Special points to be noted

When the intersections of non-consecutive blocks are checked, it is not the programmed original contours that are examined, but the associated calculated equidistant paths. This can result in a "bottleneck" being falsely detected at outside corners. The reason for this is that the calculated tool path does not run equidistant to the programmed original contour when  $DISC > 0$ .

Figure 18-31 Bottleneck detection and outside corners

## 18.5.9 Blocks with variable compensation value

### Supplementary conditions

A variable compensation value is permissible for all types of interpolation (including circular and spine interpolation).

It is also permitted to change the sign (and, therefore, the compensation side).

Figure 18-32 Tool radius compensation with variable compensation value

### Calculation of intersection

When the intersections in blocks with variable compensation value are calculated, the intersection of the offset curves (tool paths) is always calculated based on the assumption that the compensation value is constant.

If the block with the variable compensation value is the first of the two blocks to be examined in the direction of travel, then the compensation value at the block end is used for the calculation; the compensation value at the block start is used otherwise.

Figure 18-33 Intersection calculation with variable compensation value

### Restrictions

If during machining on the inside of the circle the compensation radius becomes greater than the programmed circle radius, then the machining is rejected with the following alarm:

Alarm 10758 "Curvature radius with variable compensation value too small"

**Maintain stability of closed contour**

If a radius of two circles is increased slightly, a third block may be necessary in order to maintain the stability of the closed contour. This is the case if two adjacent blocks, which represent two possible intersection points for a closed contour, are skipped due to the compensation.

A stable closed contour can be achieved by choosing the first intersection point instead of the second.

SD42496 \$SC\_CUTCOM\_CLSD\_CONT  $\neq$  0 (response of TRC for closed contour).

In that case, the second intersection point is always reached, even if the block is skipped. A third block is then not required.

**18.5.10 Keep tool radius compensation constant****Description**

The "Keep tool radius compensation constant" function is used to suppress tool radius compensation for a number of blocks, whereby a difference between the programmed and the actual tool center path traveled set up by tool radius compensation in the previous blocks is retained as the compensation.

It can be an advantage to use this method when several traversing blocks are required during line milling in the reversal points, but the contours produced by the tool radius compensation (follow strategies) are not wanted.

**Activation**

The "Keep tool radius compensation constant" function is activated with the G code `CUTCONON` (CUTter compensation CONstant ON) and deactivated with the G code `CUTCONOF` (CUTter compensation CONstant OFF).

`CUTCONON` and `CUTCONOF` form a modal G-code group.

The initial setting is `CUTCONOF`.

The function can be used independently of the type of tool radius compensation (2<sup>1</sup>/<sub>2</sub>D, 3D face milling, 3D circumferential milling).

**Normal case**

Tool radius compensation is normally active before the compensation suppression and is still active when the compensation suppression is deactivated again.

In the last traversing block before `CUTCONON`, the offset point in the block end point is approached. All following blocks, in which compensation suppression is active, are traversed without compensation. However, they are offset by the vector from the end point of the last offset block to its offset point. These blocks can have any type of interpolation (linear, circular, polynomial).

The deactivation block of the compensation suppression, i.e. the block that contains `CUTCONOF`, is compensated normally. It starts in the offset point of the start point. One linear block is inserted between the end point of the previous block, i.e. the last programmed traversing block with active `CUTCONON`, and this point.

Circular blocks, for which the circle plane is perpendicular to the compensation plane (vertical circles), are treated as though they had `CUTCONON` programmed. This implicit activation of compensation suppression is automatically canceled in the first traversing block that contains a traversing motion in the compensation plane and is not such a circle. Vertical circle in this sense can only occur during circumferential milling.

**Example:**

```

N10 ; Definition of tool d1
N20 $TC_DP1[1,1] = 110 ; Type
N30 $TC_DP6[1,1]= ; Radius
N40

N70 X20 G42 NORM
N80 X30
N90 Y20
N100 X10 CUTCONON ; Activate compensation suppression
N110 Y30 KONT ; On deactivation of contour suppression,
 insert bypass circle, if necessary
N120 X-10 CUTCONOF
N130 Y20 NORM ; No bypass circle on deactivation of TRC
N140 X0 Y0 G40
N150 M30

```

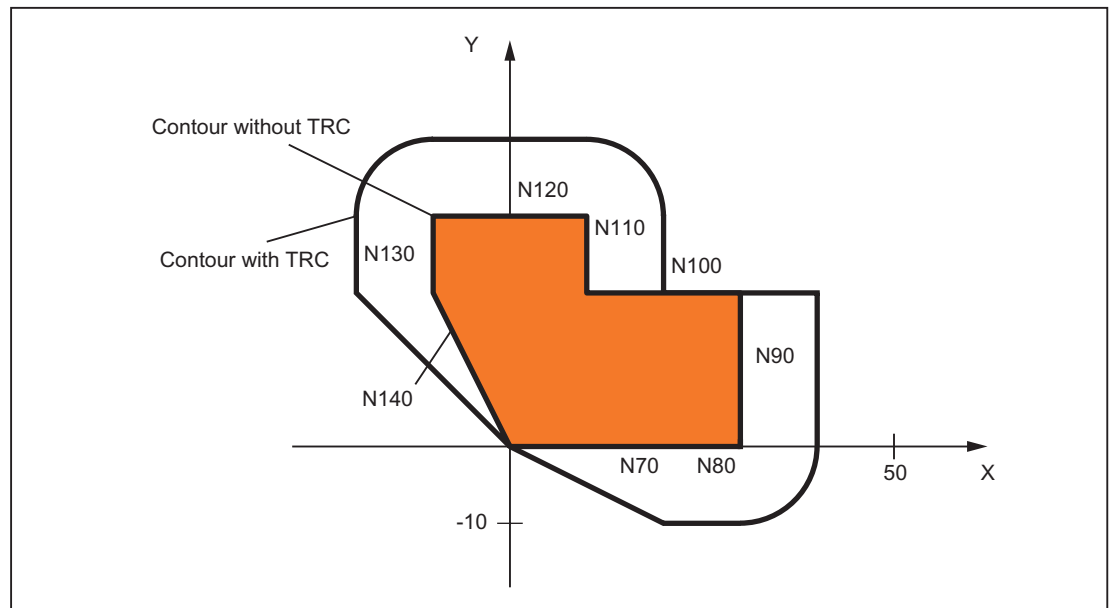

Figure 18-34 Sample program for contour suppression

### Special cases

- If tool radius compensation is not active ( $G40$ ),  $CUTCONON$  has no effect. No alarm is produced. The G code remains active, however.  
This is significant if tool radius compensation is to be activated in a later block with  $G41$  or  $G42$ .
- It is permissible to change the G code in the 7th G-code group (tool radius compensation;  $G40 / G41 / G42$ ) with  $CUTCONON$  active. A change to  $G40$  is active immediately.  
The offset used for traversing the previous blocks is traveled.
- If  $CUTCONON$  or  $CUTCONOF$  is programmed in a block without traversing in the active compensation plane, activation is delayed until the next block that has such a traversing motion.
- If  $CUTCONON$  is programmed with active tool radius compensation and not canceled before the end of the program, the traversing blocks are traversed with the last valid compensation.  
The same applies for reprogramming of  $G41$  or  $G42$  in the last traversing block of a program.
- If tool radius compensation is activated with  $G41$  or  $G42$  and  $CUTCONON$  is also already active, activation of compensation is delayed until the next traversing block with  $CUTCONOF$ .
- When reapproaching the contour with  $CUTCONOF$ , the 17th G-code group (approach and retraction behavior with tool compensation;  $NORM / KONT$ ) is evaluated, i.e. a bypass circle is inserted if necessary for  $KONT$ . A bypass circle is inserted under the same conditions as for activation of tool radius compensation with  $G41$  or  $G42$ .

- The number of blocks with suppressed tool radius compensation is restricted:  
MD20252 \$MC\_CUTCOM\_MAXNUM\_SUPPR\_BLOCKS (Maximum number of blocks with compensation suppression).  
If it is exceeded, machining is aborted and an error message issued.  
The restriction is necessary because the internal block processing in the last block before `CUTCONON` must be resumed when repositioning.
- The response after reprogramming `G41` or `G42` when tool radius compensation is already active is similar to compensation suppression.  
The following deviations apply:
  - Only linear blocks are permissible
  - A single traversing block that contains `G41` or `G42` is modified so that it ends at the offset point of the start point in the following block. Thus it is not necessary to insert a dummy block. The same applies to the last block in a sequence of traversing blocks where each contains `G41` or `G42`.
  - The contour is always reapproached with `NORM`, independent of the G code of the 17th group (approach and retraction behavior with tool compensation; `NORM / KONT`).
- If `G41 / G42` is programmed several times in consecutive traversing blocks, all blocks are machined as for `CUTCONON`, except for the last one.
- The type of contour suppression is evaluated only in the first traversing block of a sequence of consecutive traversing blocks.  
If both `CUTCONON` and `G41` or `G42` are programmed in the first block, the response to deactivating contour suppression is determined by `CUTCONON`.  
Changing from `G41` to `G42` or vice versa makes sense in this case as a means of changing the compensation side (left or right of the contour) when restarting.  
A change of compensation side (`G41/G42`) can also be programmed in a later block, even if contour suppression is active.
- Collision detection and bottleneck detection is deactivated for all blocks with active contour suppression.

## 18.5.11 Alarm behavior

### Alarm during preprocessing

If a tool radius compensation alarm is output during preprocessing, main-run machining stops at the next block end reached, i.e. usually at the end of the block currently being interpolated (if Look Ahead is active, once the axes have come to a stop).

## Alarms for preprocessing stop and active tool radius compensation

Tool radius compensation generally requires at least one of the following traversing blocks (even more for bottlenecks) to determine the end point of a block. Since the preprocessing stop of such a block is not available, traversing continues to the offset point in the last block. Correspondingly, the offset point in the start point is approached in the first block after a preprocessing stop.

The contour obtained may deviate considerably from the one that would result without preprocessing stop. Contour violations in particular are possible. Therefore the following setting data was introduced:

SD42480 \$MC\_STOP\_CUTCOM\_STOPRE (alarm response for TRC and preprocessing stop).

The response of the tool radius compensation remains unchanged compared to the previous status, and/or an alarm is output for preprocessing stop during active tool radius compensation and the program is halted, depending on the value.

The user can acknowledge this alarm and continue the NC program with NC start or abort it with `RESET`.

## 18.5.12 Intersection procedure for polynomials

### Function

If two curves with active tool radius compensation form an outside corner, depending on the G code of the 18th group (corner behavior with tool compensation; `G450 / G451`) and regardless of the type of curves involved (straight lines, circles, polynomials):

- Either a conic is inserted to bypass the corner
- Or
- The curves involved are extrapolated to form an intersection.

If no intersection is found with `G451` activated, or if the angle formed by the two curves is too steep, switchover to insert mode is automatic.

The intersection procedure for polynomials is released with the machine data:

MD20256 \$MC\_CUTCOM\_INTERS\_POLY\_ENABLE (Intersection process possible for polynomials)

---

### Note

If this machine data is set to inactive, a block (can be very short) is always inserted (even if transitions are almost tangential). These short blocks always produce unwanted drops in speed during `G64` operation.

---

### 18.5.13 G461/G462 Approach/retract strategy expansion

#### Function

In certain special geometrical situations, extended approach and retraction strategies, compared with the previous implementation, are required in order to activate or deactivate tool radius compensation (see figure below).

#### Note

The following example describes only the situation for deactivation of tool radius compensation. The response for approach is virtually identical.

#### Example

```
G42 D1 T1 ; Tool radius 20 mm
...
G1 X110 Y0
N10 X0
N20 Y10
N30 G40 X50 Y50
```

Figure 18-35 Retraction behavior with G460

The last block with active tool radius compensation (N20) is so short that an intersection no longer exists between the offset curve and the preceding block (or a previous block) for the current tool radius. An intersection between the offset curves of the following and preceding blocks is therefore sought, i.e., between N10 and N30 in this example. The curve used for the retraction block is not a real offset curve, but a straight line from the offset point at the end of block N20 to the programmed end point of N30. The intersection is approached if one is found. The colored area in the figure is not machined, although the tool used would be capable of this.

**G460**

With G460, the approach/retraction strategy is the same as before.

**G461**

If no intersection is possible between the last TRC block and a preceding block, the offset curve of this block is extended with a circle whose center point lies at the end point of the uncorrected block and whose radius is equal to the tool radius.

Figure 18-36 Retraction behavior with G461

The control attempts to cut this circle with one of the preceding blocks. If `CDOF` is active, the search is terminated when an intersection is found, i.e., the system does not check for more intersections with even earlier blocks.

If `CDON` is active, the search for more intersections continues after the first intersection is found.

An intersection point, which is found in this way, is the new end point of a preceding block and the start point of the deactivation block. The inserted circle is used exclusively to calculate the intersection and does not produce a traversing movement.

**Note**

If no intersection is found, the following alarm is output:

Alarm "10751 Collision danger"

### G462

If no intersection is possible between the last TRC block and a preceding block, a straight line is inserted, on retraction with G462 (initial setting), at the end point of the last block with tool radius compensation (the block is extended by its end tangent).

Figure 18-37 Retraction behavior with G462

The search for the intersection is then identical to the procedure for G461.

With G462, the corner generated by N10 and N20 in the sample program is not machined to the full extent actually possible with the tool used. However, this behavior may be necessary if the part contour (as distinct from the programmed contour), to the left of N20 in the example, is not permitted to be violated even with y values greater than 10 mm.

If KONT is active (travel round contour at start or end point), behavior will differ according to whether the end point is in front of or behind the contour.

#### End point in front of contour

If the end point is located in front of the contour, the retraction behavior is the same as for NORM. This feature does not change, even if the last contour block with G451 is extended with a straight line or a circle. Additional circumnavigation strategies to avoid a contour violation in the vicinity of the contour end point are therefore not required.

## End point behind contour

If the end point is behind the contour, a circle or straight line is always inserted depending on G450/G451. In this case, G460-G462 has no effect.

If, in this situation, the last traversing block has no intersection with a preceding block, an intersection with the inserted contour element or with the linear section from the end point of the circumnavigation circle to the programmed end point can result.

If the inserted contour element is a circle (G450), and it intersects with the preceding block, this is the same as the intersection, which would be produced with NORM and G461. In general, however, a remaining section of the circle still has to be traversed. An intersection calculation is no longer required for the linear section of the retraction block.

In the second case (if no intersection is found between the inserted contour element and the preceding blocks), the intersection between the retraction straight line and a preceding block is approached.

Therefore, when G461 or G462 is active, behavior deviating from G460 can only arise if NORM is active or if behavior with KONT is identical to NORM due to the geometrical conditions.

---

### Note

The approach behavior is symmetrical to the retraction behavior.

The approach/retraction behavior is determined by the state of the G command in the approach/retraction block. The approach behavior can therefore be set independently of the retraction behavior.

---

### Example:

Program for using G461 during approach:

```

N10 $TC_DP1[1,1]=120 ; Tool type mill
N20 $TC_DP6[1,1]=10 ; Radius
N30 X0 Y0 F10000 T1 D1
N40 Y20
N50 G42 X50 Y5 G461
N60 Y0 F600
N70 X30
N80 X20 Y-5
N90 X0 Y0 G40
N100 M30

```

## 18.6 Toolholder with orientation capability

### 18.6.1 General

#### Introduction

The orientation of the tool can vary (e.g. **due to retooling**) for one single class of machine tools. When the machine is operating, the orientation that has been set is **permanent**, however, and cannot be changed during traversing. For this reason, kinematic orientation transformation (3-, 4- or 5-axis transformations, `TRAORI`) is neither necessary nor does it make sense for such machines. However, it is necessary to take account of the changes in the tool length components caused by changing the orientation, without having to trouble the user with mathematics involved. The control performs these calculations.

#### Availability

For SINUMERIK 828D, the "toolholder with orientation capability" function is only available for the milling versions.

#### Required data

The following requirements must be met if the control is to take tool compensations into account for toolholders with orientation capability:

- Tool data (geometry, wear, etc.)
- Toolholder data (data for the geometry of the toolholder with orientation capability)

#### Toolholder selection

A toolholder defined in the control must be specified for the "Toolholder with orientation capability" function. The NC program command below is used for this purpose:

```
TCARR = m
```

m: Number of the toolholder

The toolholder has an associated toolholder data block, which describes its geometry.

Activating the toolholder and its block has an immediate effect, i.e. from the next traversing block onwards.

#### Assignment tool/toolholder

The tool that was active previously is assigned to the new toolholder.

From the point of view of the control, toolholder number m and tool numbers T can be combined freely. In the real application, however, certain combinations can be ruled out for machining or mechanical reasons. The control does not check whether the combinations make sense.

### Description of the kinematics of the toolholder

The kinematics of the toolholder with orientation capability is described with a total of 33 parameter sets.

The data of the data block can be edited by the user.

### Toolholder with orientation capability

Example: Cardan toolholder with two axes for the tool orientation

Figure 18-38 Cardan toolholder with two axes

### Processing toolholder data blocks

Two options are available:

- Explicit entry in the toolholder data block from the part program
- Automatic acceptance of certain values (angles) from a frame

A requirement for this is that  $T_{COFR}$  (Tool Carrier Orientation FRame) is also specified when the toolholder is selected.

The tool orientation used to calculate the tool length is determined again from the frame active at this time when a toolholder is changed.

### Orientation in Z direction

The G function `TOFRAME` defines a frame such that the Z direction in this frame is the same as the current tool orientation.

If no tool carrier or a tool carrier without change in orientation is active, then the Z direction is in the new frame:

- The same as the old Z direction with `G17`
- The same as the old Y direction with `G18`
- The same as the old X direction with `G19`.

### TCOABS for active frame

The absolute toolholder orientation is set using:

`TCOABS` (Tool Carrier Orientation ABSolute)

The orientation taken into account for the tool length compensation is **independent** of the orientation of the active frame.

Only one of the instructions `TCOABS` or `TCOFR` can be valid.

### Frame change

The user can change the frame following selection of the tool. This does not have any effect on the tool length compensation components.

#### Angles in the toolholder data:

The programmed angles of rotation stored in the toolholder data are not affected by the angle of rotation defined by the frames. When changing from `TCOFR` to `TCOABS`, the original (programmed) angles of rotation in the toolholder data are reactivated.

### Tool compensation types

TRC takes account of the current tool orientation when `CUT2D` or `CUT3DFS` is active.

#### All other tool compensation types

These are all the compensation types of G-code group 22, with the exception of `CUT3DC` and `CUT3DF`. The response remains the same with respect to the plane used for compensation. This is determined independent of the tool orientation from the active frame.

For `CUT2DF` and `CUT3DF`, the compensation plane used for TRC is determined from the frame **independently** of the current tool orientation. The active plane (`G17/G18/G19`) is considered.

#### CUT3DC and CUT3DF

3D tool compensation for circumferential milling

3D tool compensations for face milling with active 5-axis transformation are not affected by the "Toolholder with orientation capability" function.

The orientation information is determined by the active kinematic 5-axis transformation.

### Limited toolholder orientation

An alarm is output if an orientation that cannot be reached with the defined toolholder kinematic is specified by the frame.

The following kinematics cannot achieve any orientation:

- If the two rotary axes, which are necessary to define the kinematic, are not perpendicular to each other and if the tool axis, which defines the tool direction, does not stand perpendicular to the second rotary axis  
or
- Fewer than two axes have been defined.

### Non-rotary toolholders

The tool orientation used internally is dependent only on the basic orientation of the tool and the active plane (G17 - G19).

### Ambiguities

With two axes, a particular tool orientation defined by the frame can generally be set with **two** different rotary angle pairs. Of these two, the control selects the setting with which the rotary angle is as close as possible to the programmed rotary angle.

### Storing angles in the toolholder data

In virtually any case where ambiguities may arise, it is necessary to store the approximate angle expected from the frame in the toolholder data.

### Parameter sets

A complete set of parameters for a toolholder with orientation capability consists of 33 values.

The following system variables are available:

- \$TC\_CARR1 to \$TC\_CARR33
- In addition, \$TC\_CARR34 to \$TC\_CARR65 are freely available for the user and for fine offsets.

The significance of the individual parameters is distinguished as follows:

#### Machine kinematics:

\$TC\_CARR1 to \$TC\_CARR20 and \$TC\_CARR23

\$TC\_CARR18 to \$TC\_CARR20 define a further vector  $l_4$ , which is needed to describe the machine with extended kinematics (both tool and workpiece can be rotated).

\$TC\_CARR21 and \$TC\_CARR22 contain the channel-axis identifiers of the rotary axes, the positions of which can be used to determine the orientation of the toolholder with orientation capability, if necessary.

#### Kinematic type:

\$TC\_CARR23 using letter T, P or M

The following three options are available for the kinematic type, for which both upper and lower case text are permissible:

|    |                                                      |
|----|------------------------------------------------------|
| T: | Only the (Tool) can be rotated (basic value).        |
| P: | Only the workpiece (Part) can be rotated.            |
| M: | Both tool and workpiece can be rotated (Mixed mode). |

Any character other than the three mentioned here will result in the alarm if it is tried to activate the toolholder with orientation capability:

Alarm "14153 Channel %1 block %2 unknown tool carrier type: %3"

**Rotary axis parameters:**

\$TC\_CARR24 to \$TC\_CARR33

The system variables in \$TC\_CARR24 to \$TC\_CARR33 can be used to define offsets, angle compensations, Hirth tooth system, and axis limits.

---

**Note**

The system variables are available with and without active tool management.

---

**Components and presetting of the chain/data block**

The values \$TC\_CARR1 to \$TC\_CARR20 and \$TC\_CARR24 to \$TC\_CARR33 in the toolholder data block are of NC language format type REAL.

The values \$TC\_CARR21 and \$TC\_CARR22 for the axis identifier of the first rotary axis (v1) and the second rotary axis (v2) are of NC language format type AXIS. They are all preset to zero.

The value \$TC\_CARR23 is initialized with the uppercase letter "T" (only tool can be rotated).

\$TC\_CARRn[m]

\$TC\_CARR[0]= 0 has a special significance

**System variables for toolholders with orientation capability**

\$TC\_CARRn[m]

n: Parameters 1...33

m: Number of the tool carrier 1 that can be oriented...Value of the machine data:

MD18088 \$MN\_MM\_NUM\_TOOL\_CARRIER (Maximum number of definable tool carriers)

| Description                                        | NCK variables | Language format | Preassignment |

## 18.6.2 Kinematic interaction and machine design

### Representation of the kinematic chain

The concept of the kinematic chain is used to describe the kinematic interaction between a reference point and the tool tip.

The chain specifies all the data required for the toolholder data block in a schematic. To describe the concrete case with a particular kinematic, the relevant components of the chain must be assigned real vectors, lengths and angles. The chain represents the maximum constellation. In simpler applications, individual components can be zero (e.g. kinematics with one or no rotary axis).

The machine does not have to have axes that rotate the tool and/or workpiece table. The function can be used even if the orientations are set manually by handwheels or reconfiguration.

The machine design is described by the following parameters:

- Two rotary axes ( $v_1$  and  $v_2$ ), each with one angle of rotation ( $\alpha_1$  or  $\alpha_2$ ), which counts positively for clockwise rotation facing the direction of the rotation vector.
- Up to four offset vectors ( $l_1$  to  $l_4$ ) for relevant machine dimensions (axis distances, distances to machine or tool reference points).

### Zero vectors

Vectors  $v_1$  and  $v_2$  can be zero. The associated angle of rotation (explicitly programmed or calculated from the active frame) must then also be zero, since the direction of the rotating axis is not defined. If this condition is not satisfied, an alarm is produced when the toolholder is activated.

### Less than two rotating axes

The option not to define a rotating axis makes sense when the toolholder to be described can only rotate the tool in one plane. A sensible minimum data block may, therefore, contain only one single entry not equal to 0 in the toolholder data; namely, a value in one of the components of  $v_1$  or  $v_2$  for describing a rotating axis parallel to the axis where the angle of rotation  $\alpha_1$  or  $\alpha_2$  is determined from one frame.

### Further special cases

Vectors  $v_1$  and  $v_2$  can be colinear. However, the degree of freedom for orientation is lost, i.e. this type of kinematic is the same as one where only one rotary axis is defined. All possible orientations lie on one cone sheath. The conical sheath deforms to a straight line if tool orientation  $t$  and  $v_1$  or  $v_2$  become colinear. Change of orientation is, therefore, not possible in this special case. The cone sheath deforms to a circular surface (i.e. all orientations are possible in one plane), if tool orientation  $t$  and  $v_1$  or  $v_2$  are perpendicular to each other.

It is permissible for the two vectors  $v_1$  and  $v_2$  to be zero. A change in orientation is then no longer possible. In this special case, any lengths  $l_1$  and  $l_2$ , which are not equal to zero, act as additional tool length compensations, in which the components in the individual axes are not affected by changing the plane ( $G17 - G19$ ).

### Kinematics data expansions

- Possibility of direct access to existing machine axes in order to define the toolholder setting via the rotary axis positions.
- Extension of the kinematics with rotary workpiece and on kinematics with rotary tool and rotary workpiece.
- Possibility to permit only discrete values in a grid for the rotary axis positions (Hirth tooth system).

The extensions are compatible with earlier software versions and encompass the kinematic data blocks from \$TC\_CARR18 to \$TC\_CARR23.

### Machine with rotary tool

On machines with rotary tool there is no change in the definition of the kinematics compared to older software versions. The newly introduced vector  $l_4$ , in particular, has no significance. Should the contents of  $l_4$  not be zero, this is ignored.

The term "Toolholder with orientation capability" is actually no longer really appropriate for the new kinematic types, with which the table can also be rotated, either alone or additionally to the tool. However, it has been kept for reasons of compatibility.

The kinematic chains used to describe the machine with rotary tool (general case) are shown in the figure below:

Figure 18-39 Kinematic chain to describe a tool with orientation

Vectors, which describe offsets in the rotary head, are positive in the direction from the tool tip to the reference point of the toolholder.

The following kinematic type is defined for machines with a rotary tool:

\$TC\_CARR23 using letter T

### Machine with rotary workpiece

On machines with rotary workpiece, the vector  $l_1$  has no significance. If it contains a value other than zero, this is ignored.

The kinematic chain for machines with rotary workpiece is shown in the figure below.

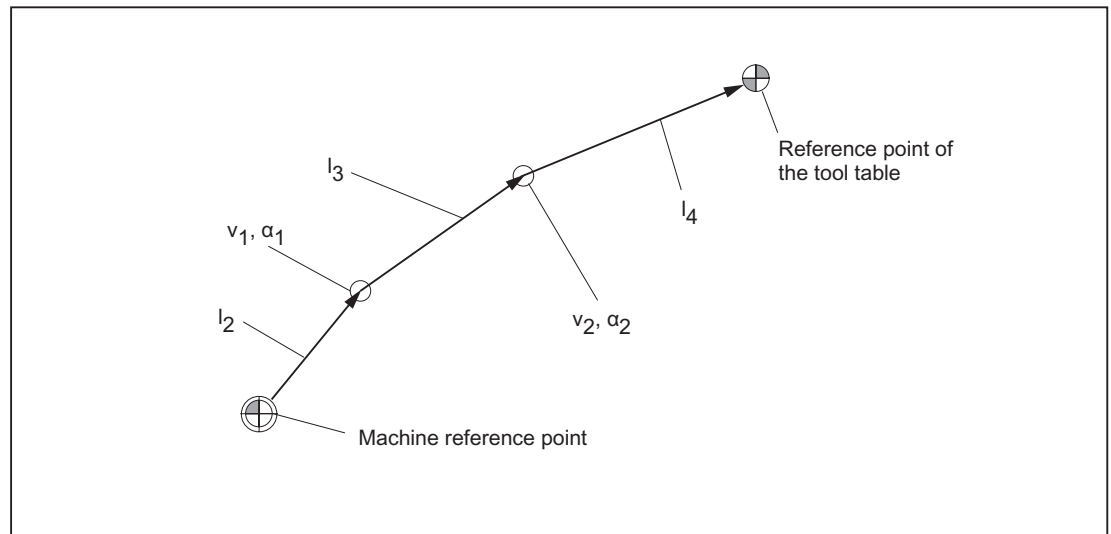

Figure 18-40 Kinematic chain to describe a rotary table

Vectors, which describe offsets in the rotary table, are positive in the direction from the machine reference point to the table.

The following kinematic type is defined for machines with a rotary workpiece:

\$TC\_CARR23 using letter P

#### Note

On machines with rotary workpiece it is generally useful if the selected machine reference point and the reference point of the table are identical. Selecting the reference points in this way has the advantage that the position of the workpiece zero in the initial state (i.e. with rotary axes not turned) does not change when the rotary table is activated. The (open) kinematic chain (see figure) is then closed.

In this special case, therefore, the following formula applies:  $l_2 = -(l_3 + l_4)$

### Machines with extended kinematics

On machines with extended kinematics (both tool and workpiece are rotary), it is only possible to turn each of the components with one axis.

The kinematic of the rotary tool is described with the first rotary axis ( $v_1$ ) and the two vectors  $l_1$  and  $l_2$ , that of the rotary table with the second rotary axis ( $v_2$ ) and the two vectors  $l_3$  and  $l_4$ . The two kinematic chain components for machines with rotary tool and rotary workpiece are shown in the figure below.

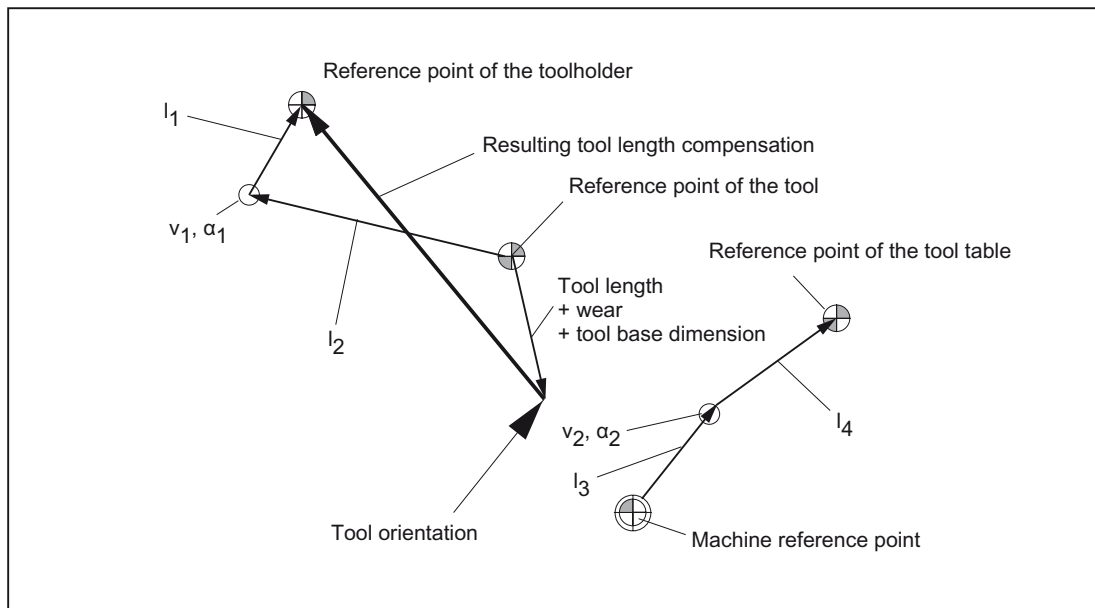

Figure 18-41 Kinematic sequence with extended kinematics

The following kinematic type is defined for machines with a rotary tool and rotary workpiece: \$TC\_CARR23 using letter M (extended kinematics)

#### Note

On machines with extended kinematics it is generally useful, as with machines where only the table can be rotated, for the machine reference point and the reference point of the table to be identical. The (open) chain component to describe the table (see figure) is then closed.

In this special case, the following formula applies:  $l_3 = -l_4$

### Rotary tool types T and M

For machine kinematics with a rotary tool (types T and M), the toolholder component with orientation capability, which describes the tool or head component (as opposed to the table component), acts, in conjunction with the active tool, as a new overall tool.

## Fine offset

The offset vectors  $l_1$  to  $l_4$  and the offsets of the rotary axes  $v_1$  and  $v_2$  can be represented as the sum of a basic value and a fine offset. The fine offset parameters assigned to the basic values are achieved by **adding a value of 40 to the index of the basic value**.

### Example:

The parameter \$TC\_CARR5 is assigned to the fine offset \$TC\_CARR45.

### Note

For the significance of the system variables \$TC\_CARR41 to \$TC\_CARR65 available for the fine offset see:

### References:

/PGA/ Programming Manual Job Planning; Tool Compensations

### Activation

The following setting adds the fine offset values to the basic values:

SD42974 \$SC\_TOCARR\_FINE\_CORRECTION = 1 (fine offset TCARR on/off)

### Supplementary conditions

The amount is limited to the permissible fine offset.

The maximum permissible value is defined:

| For:                                                                                                                        | With machine data:               |
|-----------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| <ul style="list-style-type: none"> <li>The components of vectors <math>l_1</math> to <math>l_4</math>:</li> </ul>           | MD20188 \$MC_TOCARR_FINE_LIM_LIN |
| <ul style="list-style-type: none"> <li>The offsets of the two rotary axes <math>v_1</math> and <math>v_2</math>:</li> </ul> | MD20190 \$MC_TOCARR_FINE_LIM_ROT |

An illegal fine offset value is only detected when:

- A toolholder with orientation capability, which contains such a value, is activated and
- at the same time the following setting data is set:  
SD42974 \$SC\_TOCARR\_FINE\_CORRECTION

## Description of a rotation

A data block for describing a rotation comprises one vector  $v_1/v_2$  to describe the direction of rotation of the rotary axis in its initial state and an angle  $\alpha_1/\alpha_2$ . The angle of rotation is counted positively for clockwise rotation facing the direction of the rotation vector.

The two toolholder angles  $\alpha_1$  and  $\alpha_2$  are determined using a frame, independent of the active plane currently selected (G17 - G19).

The tool orientation in the initial state (both angles  $\alpha_1$  and  $\alpha_2$  are zero) is (as in the default case):

- G17: Parallel to Z
- G18: Parallel to Y
- for G19: Parallel to X

**Assigning data to the toolholder**

**Example of a machine with rotary toolholder**

The following settings are obtained at the mill head shown for a machine with toolholder with orientation capability of kinematic type T:

|                                             |              |
|---------------------------------------------|--------------|
| Component of the offset vector $l_1 =$      | (-200, 0, 0) |
| Component of the offset vector $l_2 =$      | (0, 0, 0)    |
| Component of offset vector $l_3 =$          | (-100, 0, 0) |
| Component of rotary axis $v_1 =$            | (1, 0, 0)    |
| Component of rotary axis $v_2 =$            | (-1, 0, 1)   |
| Tool base dimension of tool reference point | (0, 0, 250)  |

**Note**

The tool reference point for the tool base dimension is defined by the reference point at the machine.

For more information about the reference points in the working area, please refer to:

**References:**

/FB1/ Function Manual Basic Functions; Axes, Coordinate Systems, Frames (K2).

Figure 18-42 Assignment of the toolholder data

Suitable assumptions were made for the following values in the data block:

- The two rotary axes intersect at one point.  
All components of  $l_2$  are therefore zero.
- The first rotary axis lies in the x/z plane, the second rotary axis is parallel to the x axis.  
These conditions define the directions of  $v_1$  and  $v_2$  (the lengths are irrelevant, provided that they are not equal to zero).
- The reference point of the toolholder lies 200 mm in the negative x direction viewed from the intersection of the two rotary axes.  
This condition defines  $l_1$ .

### Specify associated data block values

The following associated data block values are specified for the toolholder shown on a machine with rotary toolholder:

| Description                               | NCK variables | Value |
|-------------------------------------------|---------------|-------|
| x component of offset vector $l_1$        | \$TC_CARR1    | - 200 |
| y component of offset vector $l_1$        | \$TC_CARR2    | 0     |
| z component of offset vector $l_1$        | \$TC_CARR3    | 0     |
| x component of offset vector $l_2$        | \$TC_CARR4    | 0     |
| y component of offset vector $l_2$        | \$TC_CARR5    | 0     |
| z component of offset vector $l_2$        | \$TC_CARR6    | 0     |
| x component of rotary axis $v_1$          | \$TC_CARR7    | 1     |
| y component of rotary axis $v_1$          | \$TC_CARR8    | 0     |
| z component of rotary axis $v_1$          | \$TC_CARR9    | 0     |
| x component of rotary axis $v_2$          | \$TC_CARR10   | -1    |
| y component of rotary axis $v_2$          | \$TC_CARR11   | 0     |
| z component of rotary axis $v_2$          | \$TC_CARR12   | 1     |
| Angle of rotation $\alpha_1$ (in degrees) | \$TC_CARR13   | 0     |
| Angle of rotation $\alpha_2$ (in degrees) | \$TC_CARR14   | 0     |
| x component of offset vector $l_3$        | \$TC_CARR15   | -100  |
| y component of offset vector $l_3$        | \$TC_CARR16   | 0     |
| z component of offset vector $l_3$        | \$TC_CARR17   | 0     |

### Explanation

The toolholder kinematic chosen in the example is such that the two rotary axes form an angle of 45 degrees, which means that the orientation cannot take just any value. In concrete terms, this example does not permit the display of orientations with negative X components.

x component of the tool base dimension: 0  
y component of the tool base dimension: 0  
z component of the tool base dimension: 250

---

#### Note

The required data cannot be determined unequivocally from the geometry of the toolholder, i.e. the user is free to a certain extent to decide the data to be stored. Thus, for the example, it is possible to specify only one z component for the tool base dimension up to the second axis. In this case,  $l_2$  would no longer be zero, but would contain the components of the distance between this point on the second axis and a further point on the first axis. The point on the first axis can also be selected freely. Depending on the point selected,  $l_1$  must be selected such that the reference point (which can also be selected freely) is reached.

**In general:** vector components that are not changed by rotation of an axis can be distributed over any vectors "before" and "after" rotation.

---

### 18.6.3 Oblique machining with 3 + 2 axes

#### Description of function

Inclined machining with 3 + 2 axes describes an extension of the concept of toolholders with orientation capability and applies this concept to machines with a rotary table, on which the orientation of tool and table can be changed simultaneously.

The "Inclined machining with 3 + 2 axes" function is used to machine surfaces with any rotation with reference to the main planes X/Y (G17), Z/X (G18) and Y/Z (G19).

It is possible to produce any orientation of the tool relative to the workpiece by rotating either the tool, the workpiece or both the tool and the workpiece.

The software automatically calculates the necessary compensating movements resulting from the tool lengths, lever arms and the angle of the rotary axis. It is always assumed that the required orientation is set first and not modified during a machining process such as pocket milling on an inclined plane.

Furthermore, the following 3 functions are described, which are required for oblique machining:

- **Position programming** in the direction of the tool orientation independent of an active frame
- Definition of a **frame rotation** by specifying the solid angle
- Definition of the **component of rotation in tool direction** in the programmed frame while maintaining the remaining frame components

### Demarcation to 5-axis transformation

If the required functionality specifies that the TCP (Tool Center Point) does not vary in the event of reorientation with reference to the workpiece, even during interpolation, the 5-axis software is required.

For more explanations on 5-axis transformations, see:

**References:**

/FB3/ Function Manual, Special Functions; 3- to 5-Axis Transformation (F2)

### Specification of the toolholder with orientation capability

The toolholder with orientation capability is represented by a general 5-axis kinematic sequence described by a data block in the tool compensation memory with a total of 33 REAL values. For toolholders that have two rotary axes for setting the orientation (e.g. a millhead), 31 of these values are constant.

In the current SW version, a data block in the tool compensation memory is described with a total of 47 REAL values. For toolholders that have two rotary axes for setting the orientation, 45 of these values are constant.

The remaining two values are variable and are used to specify the orientation. The constant values describe offsets and directions and setting options for the rotary axes; the variable values describe the angles of the rotary axes.

## 18.6.4 Machine with rotary work table

### System variables

To date, the angles stored in \$TC\_CARR13 and \$TC\_CARR14 were used for the calculation of the active tool length with `TCOABS`. This still applies if \$TC\_CARR21 and \$TC\_CARR22 do not refer to rotary axes. If \$TC\_CARR21 or \$TC\_CARR22 contains a reference to a rotary axis in the channel, the axis position of the relevant axis at the start of the current block is used as the angle, rather than the entry in \$TC\_CARR13 or \$TC\_CARR14.

A mixed operating mode is permissible, i.e. the angles can be determined from the entry in the system variables \$TC\_CARR13 or \$TC\_CARR14 for one axis, and from the position of a channel axis for the other.

This makes it possible for machines, on which the axes used to set the toolholder with orientation capability are known within the NC, to access their position directly, whereas it was previously necessary, for example, to read system variable \$AA\_IM[axis] and write the result of the read operation to \$TC\_CARR13/14. In particular, this removes the implicit preprocessing stop when reading the axis positions.

**MD20180**

The rotary axis position is used with its programmed or calculated value, when the machine data:

MD20180 \$MC\_TOCARR\_ROT\_ANGLE\_INCR[i] = 0 (Rotary axis increment of the tool carrier that can be oriented)

If the machine data is not zero however, the position used is the nearest grid point obtained for a suitable integer value n from the equation:

$$\varphi = \$MC\_TOCARR\_ROT\_ANGLE\_OFFSET[i] + n * \$MC\_TOCARR\_ROT\_ANGLE\_INCR[i]$$

This functionality is required if the rotary axes need to be indexed and cannot, therefore, assume freely-defined positions (e.g. with Hirth tooth systems). System variable \$P\_TCANG[i] delivers the approximated value and system variable \$P\_TCDIFF[i] the difference between the exact and the approximated value.

**Frame orientation TCOFR**

With TCOFR (determination of the angle from the orientation defined by an active frame), the increments are scaled after determination of the angle from the active frame rotation. If the requested orientation is not possible due to the machine kinematic, the machining is aborted with an alarm. This also applies if the target orientation is very close to an achievable orientation. In particular the alarm in such situations cannot be prevented through the angle approximation.

**TCARR frame offset**

A frame offset as a result of a toolholder change becomes effective immediately on selection of TCARR=... A change in the tool length, on the other hand, only becomes effective immediately if a tool is active.

**TCOFR/TCOABS frame rotation**

A frame rotation does not take place on activation and a rotation, which is already active, is not changed. As in case T (only the tool can be rotated), the position of the rotary axes used for the calculation is dependent on the G code TCOFR / TCOABS and determined from the rotation component of an active frame or from the entries \$TC\_CARRn.

Activation of a frame changes the position in the workpiece coordinate system accordingly, without compensating movement by the machine itself. The ratios are shown in the figure below:

Figure 18-43 Zero offset on activation of a rotary table with `TCARR`

### Example

On the machine in the figure, the rotary axis of the table is pointing in the positive Y direction. The table is rotated by +45 degrees. `PAROT` defines a frame, which similarly describes a rotation of 45 degrees about the Y axis. The coordinate system is not rotated relative to the actual environment (marked in the figure with "Position of the coordinate system after `TCARR`"), but is rotated by -45 degrees relative to the defined coordinate system (position after `PAROT`). If this coordinate system is defined with `ROT Y-45`, for example, and if the toolholder is then selected with active `TCOFR`, an angle of +45 degrees will be determined for the rotary axis of the toolholder.

### Rotary table

With rotary tables (kinematic types P and M), activation with `TCARR` similarly does not lead to an immediate rotation of the coordinate system (see figure), i.e. even though the zero point of the coordinate system is offset relative to the machine, while remaining fixed relative to the zero point of the workpiece, the orientation remains unchanged in space.

### Activation of kinematic types P and M

With kinematics of type P and M the selection of a toolholder activates an additive frame (table offset of the toolholder with orientation capability), which takes into account the zero point offset as a result of the rotation of the table.

The zero offset can be written to a dedicated system frame `$P_PARTFR`. For this, the bit 2 must be set in the machine data:

```
MD28082 $MC_MM_SYSTEM_FRAME_MASK (System frames (SRAM))
```

The basic frame identified by following machine data is then no longer required for the zero offset:

MD20184 \$MC\_TOCARR\_BASE\_FRAME\_NUMBER (Number of the basic frames for taking the table offset)

### Activation of kinematic type M

With kinematics of type M (tool and table are each rotary around one axis), the activation of a toolholder with `TCARR` simultaneously produces a corresponding change in the effective tool length (if a tool is active) and the zero offset.

### Rotations

Depending on the machining task, it is necessary to take into account not only a zero offset (whether as frame or as tool length) when using a rotary toolholder or table, but also a rotation. However, the activation of a toolholder with orientation capability never leads directly to a rotation of the coordinate system.

### TOROT

If only the tool can be rotated, a frame whose Z axis points in the direction of the tool can be defined with `TOFRAME` or `TOROT`.

### PAROT

If the coordinate system needs to be fixed relative to the workpiece, i.e. not only offset relative to the original position but also rotated according to the rotation of the table, then `PAROT` can be used to activate such a rotation in a similar manner to the situation with a rotary tool.

With `PAROT`, the translations, scalings and mirrorings in the active frame are retained, but the rotation component is rotated by the rotation component of a toolholder with orientation capability corresponding to the table.

`PAROT` and `TOROT` take into account the overall change in orientation in cases where the table or the tool are oriented with two rotary axes. With mixed kinematics only the corresponding component caused by a rotary axis is considered. It is thus possible, for example, when using `TOROT`, to rotate a workpiece such that an oblique plane lies parallel to the X-Y plane fixed in space, whereby rotation of the tool must be taken into account in machining where any holes to be drilled, for example, are not perpendicular to this plane.

Language command `PAROT` is not rejected if no toolholder with orientation capability is active. This causes no changes in the programmed frame.

---

#### Note

For more information about the `TCARR` and `TOROT` functions, as well as `PAROT` in relation to channel-specific system frames, please refer to:

## 18.6.5 Procedure when using toolholders with orientation capability

### Creating a toolholder

The number of available toolholder data sets in the NCK is defined with machine data:

MD18088 `$MN_MM_NUM_TOOL_CARRIER` (Maximum number of definable tool carriers)

1. The value is calculated as follows:

**MD18088 = "Number of TO units" \* "Number of tool holder data sets of a TO unit"**

**MD18088/"number of TO units"** is permanently allocated to each TO unit.

---

#### Note

For further explanations on the definition and assignment of a TO unit by machine data:

MD28085 `$MC_MM_LINK_TOA_UNIT` (Assignment of a TO unit to a channel (SRAM))

#### References:

/FB/ Function Manual for Extended Functions; Memory Configurations (S7)

---

2. Zero setting of toolholder data:

You can use the command `$TC_CARR1[0] = 0` to zero all values of all data sets.

Individual toolholder data sets can be deleted selectively with the NC command `DELTC` or the PI service `_N_DELTCAR`.

3. Accessing the data of a toolholder:

- Part program

→  $\$TC\_CARRn[m] = \text{value}$

This describes the previous value of the system variables n for toolholder m with the new value "value".

→  $\text{value} = \$TC\_CARRn[m]$

With "def real value" - the parameters of a toolholder m can be read if they have already been defined (e.g. set MD18088). Otherwise, an alarm is signaled.

- OPI interface

The parameters of a toolholder with orientation capability can be read and written with the NCK-HMI (OPI) variable services using system variable  $\$P\_TCANG[<n>]$ .

4. Data backup:

The system variables specified above are saved as part of the general NCK data backup.

### Selecting the toolholder

A tool holder with number m is selected with the  $TCARR = m$  NC program command ( $TCARR$  Tool Carrier).

$TCARR = 0$  deselects an active toolholder.

#### New tool or new toolholder

When a new tool is activated, it is always treated as if it was mounted on the active toolholder.

A new toolholder is activated immediately when it is programmed. It is not necessary to change tools or reprogram the active tool. The toolholder (number) and tool (number) are independent and can be used in any combination.

### Toolholder from G code of group 42

Absolute tool orientation  $TCOABS$  (Tool Carrier Orientation **ABS**olute):

Tool orientation is determined explicitly if the corresponding values are entered in system variable  $\$TC\_CARR13$  or  $\$TC\_CARR14$  and G code  $TCOABS$  is activated in G-code group 42.

Frame tool orientation  $TCOFR$  (Tool Carrier Orientation **FR**ame):

Tool orientation can also be determined automatically from the current orientation of an active frame when selecting a tool, if one of the following G codes is active in G-code group 42 when the toolholder is selected:

- `TCOFR` or `TCOFRZ`

The toolholder with orientation capability is set so that the tool points in the Z direction.

- `TCOFRX`

The toolholder with orientation capability is set so that the tool points in the X direction.

- `TCOFRY`

The toolholder with orientation capability is set so that the tool points in the Y direction.

The effect of `TCOFR` is such that, when machining on an inclined surface, tool compensations are considered implicitly as if the tool were standing vertically on the surface.

---

### Note

The tool orientation is not bound strictly to the frame orientation. When a frame is active and G code `TCOABS` is active, you can select a tool, whereby the orientation of the tool is independent of the orientation of the active frame.

Following tool selection, you can change the frame, which does not affect the components of tool length compensation. It is then no longer certain that the tool is positioned perpendicular to the machining plane. You should therefore first check that the intended tool orientation is maintained on an inclined surface.

When `TCOFR`, etc., is active, the tool orientation used in the tool length calculation is always determined from the active frame each time the toolholder is changed.

---

## Toolholder from G code of group 53

The G codes of group 53 (`TOFRAME`, `TOROT`, etc.) can be used to define a frame such that an axis direction (Z, Y or X) in this frame is equal to the current tool orientation.

The G code of group 6 (`G17` - `G19`), which is active at the time `TOFRAME` is called, determines the tool orientation.

If no toolholder is active, or if a toolholder is active but does not cause the tool orientation to change, the Z direction in the new frame is:

- The same as the old Z direction with `G17`
- The same as the old Y direction with `G18`
- The same as the old X direction with `G19`.

These directions are modified accordingly for rotating toolholders. The same applies to the new X and Y directions.

Instead of `TOFRAME` or `TOROT`, one of the G codes `TOFRAMEX`, `TOFRAMEY`, `TOROTX`, or `TOROTY` can be used. The meanings of the axes are interchanged accordingly.

## Group change

Changing the G code from group 42 (`TCOABS`, `TCOFR`, etc.) causes recalculation of the tool length components.

The (programmed) angles of rotation stored in the toolholder data are not affected, with the result that the angles originally stored in the toolholder data are reactivated on a change from `TCOFR` to `TCOABS`.

### Read rotary angle ( $\alpha_1$ or $\alpha_2$ ):

The angles currently used to calculate the orientation can be read via system variable `$P_TCANG[n]` where  $n = 1$  or  $n = 2$ .

If two permissible solutions (i.e. a second valid pair of angles) are available for a particular orientation, the values can be accessed with `$P_TCANG[3]` or `$P_TCANG[4]`. The number of valid solutions 0 to 2 can be read with `$P_TCSOL`.

### Tool radius compensation with `CUT2D` or `CUT3DFS`:

The current tool orientation is included in the tool radius compensation if either `CUT2D` or `CUT3DFS` is active in G-code group 22 (tool compensation type).

For non-rotating toolholders, the behavior depends solely on the active plane of G code group 6 (`G17` - `G19`) and is, therefore, identical to the previous behavior.

### All other tool compensation types:

The behavior for all other tool compensation types is unchanged.

For `CUT2DF` and `CUT3DF` in particular, the compensation plane used for TRC is determined from the active frame, independent of the current tool orientation. Allowance is made for the active plane (`G17` - `G19`) and the behavior is, therefore, the same as before.

The two remaining G codes of group 22, `CUT3DC` and `CUT3DF`, are not affected by the toolholder functionality because the tool orientation information in these cases is made available by the active kinematic transformation.

## Two rotary axes

Two general solutions exist for two rotary axes. The control itself chooses these two solution pairs such that the orientation angles resulting from the frame are as close as possible to the specified angles.

The two following options are available for specifying the angles:

1. If `$TC_CARR21` or `$TC_CARR22` contains a reference to a rotary axis, the position of this axis at the start of the block in which the toolholder is activated is used to specify the angle.
2. If `$TC_CARR21` or `$TC_CARR22` does not contain a reference to a rotary axis, the values contained in `$TC_CARR13` or `$TC_CARR14` are used.

## Example

The control first calculates an angle of 10 degrees for one axis. The specified angle is 750 degrees. 720 degrees (= 2 \* 360 degrees) are then added to the initial angle, yielding a final angle of 730 degrees.

## Rotary axis offset

Rotary axis offsets can be specified with system variables \$TC\_CARR24 and \$TC\_CARR25. A value not equal to zero in one of these parameters means that the initial state of the associated rotary axis is the position specified by the parameter (and not position zero). All angle specifications then refer to the coordinate system displaced by this value.

When the machining plane is changed (G17 - G19), only the tool length components of the active tool are interchanged. The components of the toolholder are not interchanged. The resulting tool length vector is then rotated in accordance with the current toolholder and, if necessary, modified by the offsets belonging to the toolholder.

The two toolholder angles  $\alpha_1$  and  $\alpha_2$  are determined using a frame, independent of the active plane currently selected (G17 - G19).

## Limit values

Limit angles (software limits) can be specified for each rotary axis in the system variable set (\$TC\_CARR30 to \$TC\_CARR33) used to describe the toolholder with orientation capability. These limits are not evaluated if both the minimum and maximum value is zero.

If at least one of the two limits is not equal to zero, the system checks whether the previously calculated solution is within the permissible limits. If this is not the case, an initial attempt is made to reach a valid setting by adding or subtracting multiples of 360 degrees to or from the invalid axis position. If this is impossible and two different solutions exist, the first solution is discarded and the second solution is used. The second solution is treated the same as the first with reference to the axis limits.

If the first solution is discarded and the second used instead, the contents of \$P\_TCANG[1/2] and \$P\_TCANG[3/4] are swapped, hence the solution actually used is also stored in \$P\_TCANG[1/2] in this case.

The axis limits are monitored even if the axis angle is specified instead of being calculated. This is the case if TCOABS is active when a toolholder with orientation capability is activated.

## 18.6.6 Programming

### Selecting the toolholder

A toolholder is selected with the number **m** of the toolholder with:

```
TCARR = m
```

### Access to toolholder data blocks

The following access is possible from the part program:

The current value of the parameter **n** for the tool holder **m** is **written** with the new "value" with:

```
$TC_CARRn[m] = value
```

The parameters of a tool holder **m** can, as far as the toolholder data set is already defined, **read** with:

```
value = $TC_CARRn[m] (Value must be a REAL variable)
```

The toolholder data set number must lie in the range, which is defined by the machine data:

MD18088 \$MN\_MM\_NUM\_TOOL\_CARRIER (Total number of toolholder data sets that can be defined)

This number of toolholder data sets, divided by the number of active channels, can be defined for a channel.

#### Exception:

If settings, which deviate from the standard, are selected via the machine data:

MD28085 \$MC\_MM\_LINK\_TOA\_UNIT (Assignment of TO unit to a channel).

### Canceling all toolholder data blocks

All values of all toolholder data sets can be deleted from within the part program using one command.

```
$TC_CARR1[0] = 0
```

Values not set by the user are preset to 0.

### Activation

A toolholder becomes active when both a **toolholder** and a **tool** have been activated. The selection of the toolholder alone has no effect. The effect of selecting a toolholder depends on the G code `TCOABS` / `TCOFR` (modal G-code group for toolholders).

Changing the G code in the `TCOABS` / `TCOFR` group causes recalculation of the tool length components when the toolholder is active. With `TCOABS`, the values stored in the toolholder data for both angles of rotation  $\alpha_1$  and  $\alpha_2$  are used to determine the tool orientation.

With  $TCOFR$ , the two angles are determined from the current frame. The values stored in the toolholder data are not changed, however. These are also used to resolve the ambiguity that can result when the angle of rotation is calculated from one frame. Here, the angle that deviates least from the programmed angle is selected from the various possible angles.

---

## 18.6.7 Supplementary conditions and control system response for orientation

### Full orientation

For a given data set that describes a certain kinematic, all the conceivable special orientations can only be displayed when the following conditions are satisfied:

- The two vectors  $v_1$  and  $v_2$ , that describe the rotary axes, must be defined (i.e., must not be equal to zero).
- The two vectors  $v_1$  and  $v_2$  must be perpendicular to each other.
- The tool orientation must be perpendicular to the second rotary axis.

### Non-defined orientation

If these conditions are not satisfied and an orientation that cannot be achieved by an active frame is requested with  $TCOFR$ , an alarm is output.

#### Vector/angle of rotation dependencies

If vector  $v_1$  or  $v_2$ , which describes the direction of a rotary axis, is set to zero, the associated angle of rotation  $\alpha_1$  or  $\alpha_2$  must also be set to zero. Otherwise, an alarm is produced. The alarm is not output until the toolholder is activated, i.e., when the toolholder is changed.

#### Tool fine compensation combined with orientation

Tool fine compensations and toolholders **cannot** be combined. The activation of tool fine compensation when a toolholder is active, and vice versa the activation of the toolholder when tool fine compensation is active, produces an alarm.

### Automatic toolholder selection, RESET

For  $RESET$  or at program start, a toolholder can be selected automatically via the machine data:

MD20126 \$MC\_TOOL\_CARRIER\_RESET\_VALUE (Active toolholder at RESET)

It is handled similar to the controlled selection of a tool via the machine data:

MD20120 \$MC\_TOOL\_RESET\_VALUE (Tool length compensation Power up (RESET/TP-End))

The behavior at `RESET` or at program start is controlled as in the case of tool selection via the same bit 6 in the machine data:

MD20110 \$MC\_RESET\_MODE\_MASK (definition of initial control settings after RESET/TP-End)

Or:

MD20112 \$MC\_START\_MODE\_MASK (definition of initial control system settings at NC-START)

**References:**

/FB1/ Function Manual Basic Functions; Mode Group, Channel, Program Operation, Reset Response (K1)

**SW 6.3 and higher**

If `TCOABS` was active for the last selection before reset, the behavior is unchanged compared to previous versions. A different active G code causes the toolholder with orientation capability to be activated with the frame that was active before the last reset. Modified toolholder data (`$TC_CARR...`) are also considered. If these data are unchanged, the toolholder is activated in exactly the same state as before reset. If the toolholder data were changed after the toolholder selection before reset, selection corresponding to the last frame is not always possible. In this case, the toolholder with orientation capability is selected according to the G-Code (group 42) values valid at this time and the active frame.

**MD22530 output of auxiliary functions to PLC**

That, optionally, a constant or an M code is output when the toolholder is selected, whose number of the code is derived from the toolholder number. Can be set with the machine data:

MD22530 \$MC\_TOCARR\_CHANGE\_M\_CODE (M-Code at toolholder change)

**References:**

/FB1/ Function Manual Basic Functions; Output of Auxiliary Functions to PLC (H2)

## Toolholder kinematics

The following supplementary conditions must be met for toolholder kinematics:

- Tool orientation in initial state, both angles  $\alpha_1$  and  $\alpha_2$  zero, as per default setting, even if:
  - G17 parallel to Z
  - G18 Parallel to Y
  - G19 parallel to Z
- A permissible position in terms of the axis limits must be achievable.
- For any possible orientation to be set, the two rotary axes must be perpendicular to each other.

For machines, on which the table is rotated by both axes, the tool orientation must also be perpendicular to the first rotary axis.

For machines with mixed kinematics, the tool orientation must be perpendicular to the axis, which rotates the tool, i.e., also the first rotary axis.

The following applies to orientations specified **in a frame**:

- The orientation specified in a frame must be achievable with the defined toolholder kinematics, otherwise an alarm is output.
 

This situation can occur if the two rotary axes required to define the kinematics are not perpendicular to each other.

This applies if fewer than two rotary axes are defined and is the case:

  - With **kinematic type T with rotary tool**, if the tool axis, which defines the tool direction, is not perpendicular to the **second** axis.
  - With **kinematic types M and P with rotary workpiece**, if the tool axis, which defines the tool direction, is not perpendicular to the **first** axis.
- Rotary axes, which require a frame with a defined tool orientation in order to reach a specific position, are only determined unambiguously in the case of one rotary axis. Two general solutions exist for two rotary axes.
- In all cases where ambiguities may arise, it is particularly important that the approximate angles expected from the frame are stored in the tool data, and that the rotary axes are in the vicinity of the expected positions.

## Response with ASUP, REPOS

The toolholder can be changed in an asynchronous subprogram (ASUB). When the interrupted program is resumed with `REPOS`, the approach motion of the new toolholder is taken into account and the program continues with this motion. The treatment here is analogous to tool change in an ASUB.

## 18.7 Cutting data modification for tools that can be rotated

### 18.7.1 Function

Using the function "cutting data modification for rotatable tools", the changed geometrical relationships, that are obtained relative to the workpiece being machined when rotating tools (predominantly turning tools, but also drilling and milling tools) can be taken into account.

### 18.7.2 Determination of angle of rotation

The actual rotation of the tool is always determined from a currently active, orientable toolholder (refer to Chapter "Tool Holder with Orientation Capacity").

The angle of rotation of the tool holder with orientation capacity is normally (but not necessarily) defined with the `TCOFR` command from an active frame. This method can be used to define the tool orientation independently of the actual kinematics with which the tool is rotated, identically in each case with the help of two angles.

The two machine-independent orientation angles  $\beta$  (Beta) and  $\gamma$  (Gamma) are used to define the tool rotation.  $\beta$  is the angle of rotation and the applicator (typically a B axis in `G18`) and  $\gamma$  a rotation around the ordinate (Typically a C axis in `G18`). The rotation is first executed around Y, finally around  $\beta$ , i.e. the y axis is rotated by the  $\beta$  axis:

### 18.7.3 Cutting edge position, cut direction and angle for rotary tools

#### Turning tools

Turning tools means the following tools whose tool type (\$TC\_DP1) has values in the range of 500 to 599. Grinding tools (tool types 400 to 499) are equivalent to turning tools.

Tools are treated independently of tool type such as turning tools if:

SD42950 \$SC\_TOOL\_LENGTH\_TYPE = 2

#### Cutting edge position and cut direction

Turning tools are limited by their main and secondary cutting edges. The tool parameter "Cutting edge position" is defined via the position of these two cutting edges relative to the coordinate axes. The ratios are displayed with diagram in the following figure:

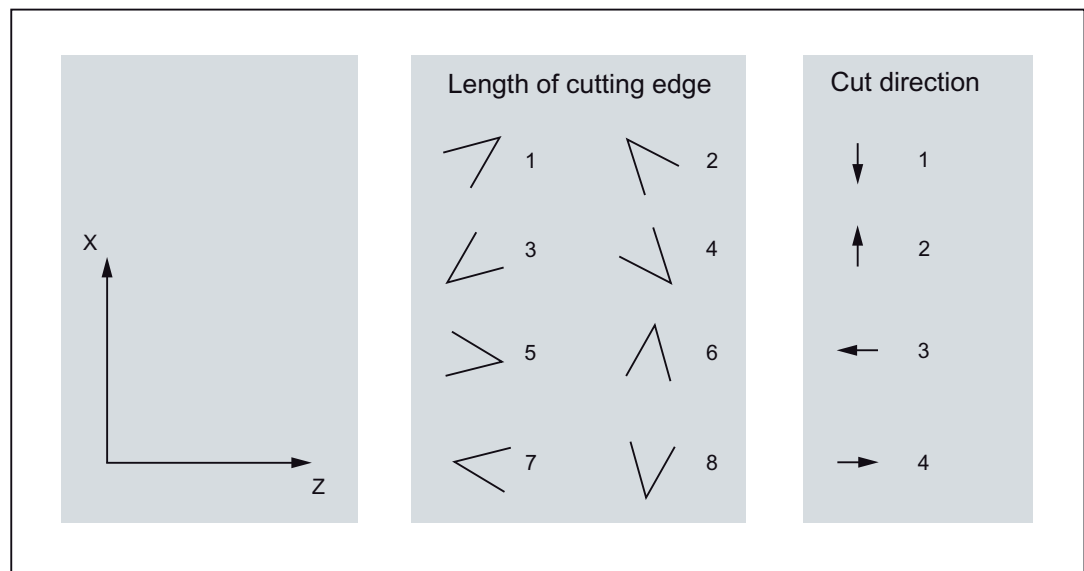

Figure 18-44 Cutting edge position and cut direction for turning tools

The values 1 to 4 characterize the cases in which both cutting edges lie in the same quadrant; the values 5 to 8 characterize the cases in which both cutting edges lie in neighboring quadrants or there is a coordinate axis between the two cutting edges. The cutting edge position is stored in the tool parameter \$TC\_DP2.

A cut direction can be defined for each turning tool. It is stored in the tool parameter \$TC\_DP11. It has values between 1 and 4, and it characterizes a positive or negative direction of the coordinate axes:

| Value: | Meaning:   |
|--------|------------|
| 1      | Ordinate - |
| 2      | Ordinate + |
| 3      | Abscissa - |
| 4      | Abscissa + |

Two different cut directions can be assigned to each cutting edge position:

|                        |      |      |      |      |      |      |      |      |
|------------------------|------|------|------|------|------|------|------|------|
| Cutting edge position: | 1    | 2    | 3    | 4    | 5    | 6    | 7    | 8    |
| Cut direction:         | 2, 4 | 2, 3 | 1, 3 | 1, 4 | 1, 2 | 3, 4 | 1, 2 | 3, 4 |

### Holder angle and clearance angle

The following figure depicts the two angles (holder angle and clearance angle) of a turning tool with cutting edge position 3, that are necessary for describing the geometry of the tool cutting edge. The cut direction in this example is 3, i.e. it denotes the negative Z direction (abscissa direction for G18).

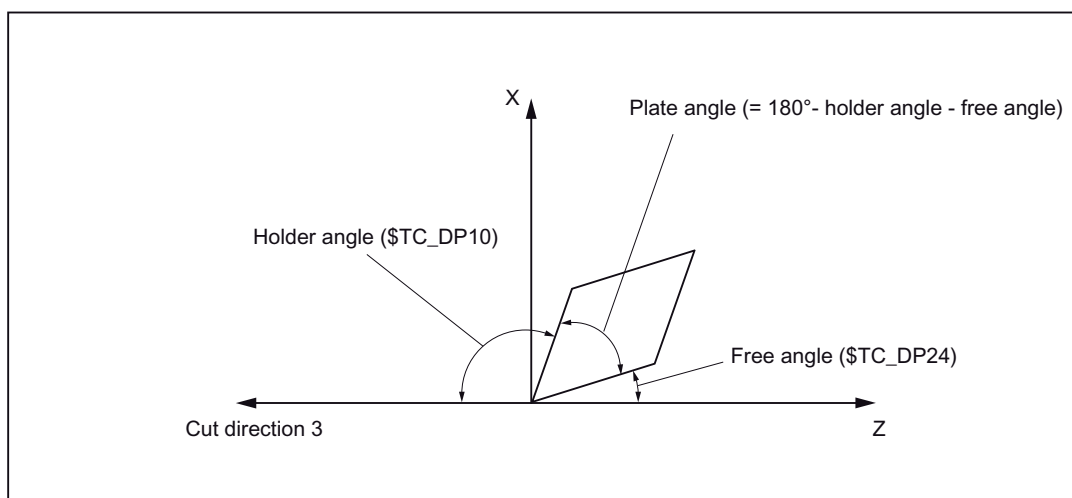

Figure 18-45 Angle and cut direction for a turning tool with cutting edge position 3

The cut direction specifies the reference direction of the holder angle. The clearance angle is the angle measured between the inverse cut direction and the adjacent cutting edge (positive). Holder angle and clearance angle are stored in the tool parameters \$TC\_DP10 or \$TC\_DP24.

**Note**

Cut direction and tool angle are relevant only in the cutting edge positions 1 to 8.

## 18.7.4 Modifications during the rotation of turning tools

### Tool orientation

Unlike milling tools, turning tools are not rotation-symmetric. This means that normally 3 degrees of freedom or three rotary axes are required to describe the tool orientation. The concrete kinematics therefore, is independent of the machine only to the extent the desired orientation can be set. If necessary, the third degree of freedom can be substituted by a rotation of the tool coordinate system.

---

#### Note

The division of the orientation into one portion created by the tool holder with orientation capacity, and a second portion achieved via a rotation of the coordinate system is the responsibility of the application. The control does not provide any further functionality in this regard.

---

### Shape of cutting edge

If a turning tool turns by an angle against the machining plane (i.e. around an axis in the machining plane, typically a C axis) that is not a multiple of  $180^\circ$ , then the configuration of the (circular) tool cutting edge in the machining plane becomes an ellipse. It is assumed that the deviations from the circular form arising on account of such rotations is so insignificant that they can be ignored (tilt angle  $< 5^\circ$ ), i.e. the control always ignores the tool orientation and assumes a circular cutting edge.

This also means that with reference to the active plane, the control accepts only a rotation by  $180^\circ$  as a setting deviating from the initial position. This limitation is valid for the shape of cutting edge only. The tool lengths are always considered correctly in random spatial rotations.

### Cutting edge position, cut direction and angle

A rotation by  $180^\circ$  around an axis in the machining plane means that while using the tool at the same position, the spindle rotation direction with reference to the use of the unturned tool must be inverted.

Cut direction and cutting edge position are also not modified like the cutting edge reference point (see below) if the tool is rotated from the plane by  $\pm 90^\circ$  (with a tolerance of app.  $1^\circ$ ) because then the configuration of the cutting edge is not defined in the current plane.

If the tool rotates in the plane (rotation around an axis vertical to the machining plane or around the Y axis for G18), the cutting edge position is determined from the resulting angle for the clearance and holder angles. If these two angles are not specified for the tool (i.e. \$TC\_DP10 and \$TC\_DP24 are both zero), then the new cutting edge position is determined from the turning angle alone. The cutting edge position changes only in 90° steps, i.e. the cutting edge position remains independent of the initial state either in the value range 1 to 4 or 5 to 8. The new cutting edge position is then determined exclusively from the angle of rotation if the specified values for holder angle and clearance angle are not allowed (negative values, resulting plate angle negative or more than 90°). Clearance angle and holder angle are not modified in all these cases.

Depending on the rotation, the cut direction is modified in such a way that the resulting clearance angle remains less than 90°. If the original cut direction and the original cutting edge position do not fit together (refer to "Cutting edge position, cut direction and angle for turning tools"), then the cut direction is not modified during rotation of the tool.

The angle of rotation in the plane, as it was determined from the tool holder with orientation capacity, is available in the system variable \$P\_CUTMOD\_ANG or \$AC\_CUTMOD\_ANG. This angle is the original angle without any final rounding to multiples of 45° or 90°.

#### Limit cases

If, for a turning tool, the cutting edge position, cut direction, clearance and holder angles have valid values so that all cutting edge positions (1 to 8) are possible through suitable rotations in the plane, then the cutting edge positions 1 to 4 are preferred to cutting edge positions 5 to 8 in the cases in which one of the cutting edges (main or secondary cutting edge) is away from the coordinate axis by less than half the input increment ((0.0005° for an input specification of 3 decimal digits).

The following is applicable in all other cases (milling tools or turning tools without valid cutting edge parameters) in which rotation is possible only in 90° steps: If the amount of the rotation angle is smaller than 45° + 0.5 input increments (corresponds to 45.0005° for an input specification of 3 decimal points), the cutting edge position and cut direction are not changed, i.e. these cases are treated as rotations that are smaller than 45°. Rotations, the amount of which deviates from 180° by less than 45° + 0.5 input increments are treated identically as rotations in the range of 135° to 225°.

### Cutting edge reference point

The cutting edge center point and the cutting edge reference point are defined for turning tools. The position of these two points relative to each other is defined by the cutting edge position.

The distance of the two points for cutting edge positions 1 to 4 is equal to  $\sqrt{2}$  times the cutting edge radius; for cutting edge positions 5 to 8 it is equal to 1 times the cutting edge radius. In the first case, the cutting edge reference point relative to the cutting edge center point lies in the machining plane on a bisecting line, while in the second case it lies on a coordinate axis.

If you rotate the tool by a random angle around an axis vertical to the machining plane, the cutting edge reference point would also rotate if it had a fixed position relative to the tool. The above-mentioned condition (position on an axis or a bisecting axis) is not fulfilled in most cases. This is not desirable. Instead, the cutting edge reference point should always be modified in such a way that the distance vector between cutting edge reference point and cutting edge center point has one of the mentioned 8 directions. The cutting edge position must be modified for this if necessary.

The ratios are shown with examples in the figure below:

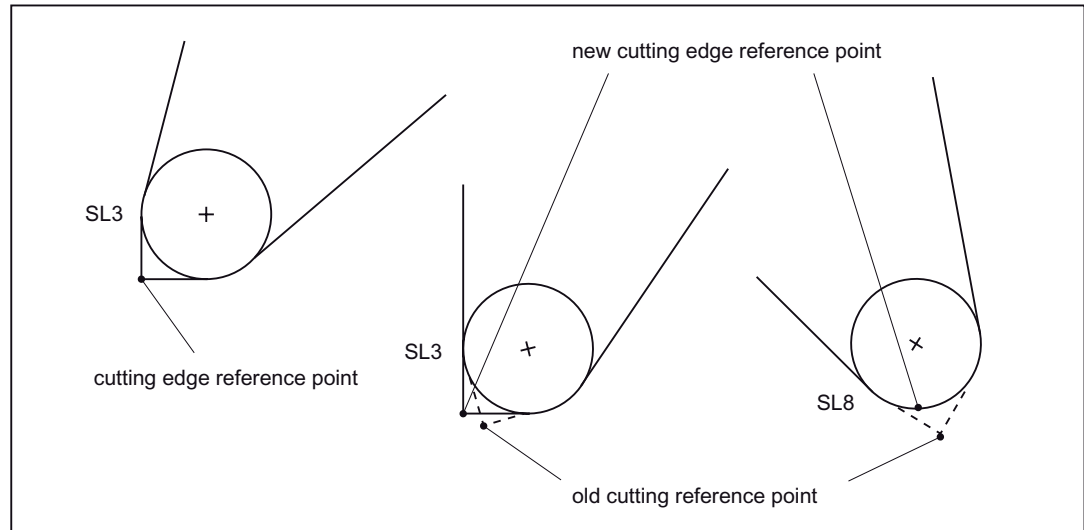

Figure 18-46 Cutting edge reference point and cutting edge position (SL) for tool rotation

A tool with the cutting edge position 3, the clearance angle  $22.5^\circ$  and holder angle  $112.5^\circ$  is rotated. For rotations up to  $22.5^\circ$ , the cutting edge position is maintained, the position of the cutting edge reference point relative to the tool however, is compensated in such a way that the relative position of both points are maintained in the machining plane. For bigger rotations (up to  $67.5^\circ$ ), the cutting edge position changes to value 8.

#### Note

As the cutting edge reference point is defined by the tool length vector, modifying the cutting edge reference point changes the effective tool length.

### 18.7.5 Cutting edge position for milling and tapping tools

#### Milling and tapping tools

Milling and tapping tools means the following tools whose tool type (\$TC\_DP1) has values in the range of 100 to 299.

Tools are treated independently of tool type such as milling and tapping tools if:

SD42950 \$SC\_TOOL\_LENGTH\_TYPE = 1

#### Length of cutting edge

A cutting edge position is also introduced for the so defined milling and tapping tools which is modified according to the following description, in case of rotations.

Any specified cutting edge position for tools that are not milling and tapping tools or turning tools according to the mentioned definitions, is not evaluated.

The cutting edge position of the tapping and milling tools is stored in tool parameter \$TC\_DP2 as in the case of turning tools. Based on the definition of the cutting edge position for turning tools, this parameter can assume the values 5 to 8. Here, the cutting edge position specifies the orientation (the direction of the rotation axis) of the tool:

| Length of cutting edge | Direction of rotation axis of tool |
|------------------------|------------------------------------|
| 5                      | Abscissa +                         |
| 6                      | Ordinate +                         |
| 7                      | Abscissa -                         |
| 8                      | Ordinate -                         |

Example:

Figure 18-47 Milling tool with cutting edge position 7

## 18.7.6 Modifications during rotation of milling and tapping tools

The cutting edge position is recalculated appropriately during a rotation of a milling or tapping tool. Cut direction and tool angle (clearance angle or holder angle) are not defined for milling and tapping tools so that the change in cutting edge position is derived exclusively from the rotation. Thus, for milling and tapping tools, the cutting edge position always changes when the amount of rotation with reference to the zero setting is more than  $45^\circ$ .

## 18.7.7 Parameter assignment

### Reaction to errors

Different fault conditions can occur during the activation of the "Cutting edge data modification for rotary tools" function (via explicit call with `CUTMOD` or through a tool selection).

For each of these possible fault conditions, one can define whether the error is to trigger an alarm output, whether such an alarm is only to be displayed (warning), or whether additionally the interpretation of the part program must be cancelled. The setting is done via the following machine data:

MD20125 \$MC\_CUTMOD\_ERR

Two bits of the machine data are assigned to each fault condition:

| Fault condition                                                                                                                                                                                                      | Bit | Description                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-----------------------------------------------------------------------------------|
| No valid cut direction is defined for the active tool.                                                                                                                                                               | 0   | Alarm output for error "Invalid cut direction"                                    |
|                                                                                                                                                                                                                      | 1   | Program stop for error "Invalid cut direction"                                    |
| The cutting edge angle (clearance angle and holder angle) of the active tool are both zero.                                                                                                                          | 2   | Alarm output for error "Not defined cutting edge angle"                           |
|                                                                                                                                                                                                                      | 3   | Program stop for error "Not defined cutting edge angle"                           |
| The clearance angle of the active tool has an impermissible value (< 0° or > 180°).                                                                                                                                  | 4   | Alarm output for error "Invalid clearance angle"                                  |
|                                                                                                                                                                                                                      | 5   | Program stop for error "Invalid clearance angle"                                  |
| The holder angle of the active tool has an impermissible value (< 0° or > 90°).                                                                                                                                      | 6   | Alarm output for error "Invalid holder angle"                                     |
|                                                                                                                                                                                                                      | 7   | Program stop for error "Invalid holder angle"                                     |
| The plate angle of the active tool has an impermissible value (< 0° or > 90°).                                                                                                                                       | 8   | Alarm output for error "Invalid plate angle"                                      |
|                                                                                                                                                                                                                      | 9   | Program stop for error "Invalid plate angle"                                      |
| The cutting edge position - holder angle combination of the active tool is not permitted (the holder angle must be ≤ 90° for cutting edge position 1 to 4; for cutting edge positions 5 to 8 it must be ≥ 90°).      | 10  | Alarm output for error "Invalid cutting edge position - holder angle combination" |
|                                                                                                                                                                                                                      | 11  | Program stop for error "Invalid cutting edge position - holder angle combination" |
| Inadmissible rotation of the active tool (the tool was rotated from the active machining plane by ± 90° (with a tolerance of about 1°). Hence the cutting edge position is no longer defined in the machining plane. | 12  | Alarm output for error "Invalid rotation"                                         |
|                                                                                                                                                                                                                      | 13  | Program stop for error "Invalid rotation"                                         |

### Response to POWER ON

The "cutting edge data modification for rotary tools" function (CUTMOD) is initialized automatically during POWER ON with the value stored in machine data:

MD20127 \$MC\_CUTMOD\_INIT

If the value of this machine data is "-2", CUTMOD is set to the value that is set in machine data:

MD20126 \$MC\_TOOL\_CARRIER\_RESET\_VALUE (Active toolholder at RESET)

## 18.7.8 Programming

The "Cutting edge data modification for rotary tools" function is activated with the `CUTMOD` command.

### Syntax

`CUTMOD=<value>`

### Description

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <code>CUTMOD</code>        | Command to switch-in the function "cutting data modification for tools that can be rotated"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>&lt;value&gt;</code> | The following values can be assigned to the <code>CUTMOD</code> command:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0                          | <p>The function is deactivated.</p> <p>The values supplied from system variables <code>\$P_AD...</code> are the same as the corresponding tool parameters.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| > 0                        | <p>The function is activated if a toolholder that can be orientated with the specified number is active, i.e. the activation is linked to a specific toolholder that can be orientated.</p> <p>The values supplied from system variables <code>\$P_AD...</code> may be modified with respect to the corresponding tool parameters depending on the active rotation.</p> <p>The deactivation of the designated toolholder that can be orientated temporarily deactivates the function; the activation of another toolholder that can be orientated permanently deactivates it. This is the reason that in the first case, the function is re-activated when again selecting the same toolholder that can be orientated; in the second case, a new selection is required - even if at a subsequent time, the toolholder that can be orientated is re-activated with the specified number.</p> <p>The function is not influenced by a reset.</p> |
| -1                         | <p>The function is always activated if a toolholder that can be orientated is active.</p> <p>When changing the toolholder or when de-selecting it and a subsequent new selection, <code>CUTMOD</code> does not have to be set again.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -2                         | <p>The function is always activated if a toolholder that can be orientated is active whose number is the same as the currently active toolholder that can be orientated.</p> <p>If a toolholder that can be orientated is not active, then this has the same significance as <code>CUTMOD=0</code>.</p> <p>If a toolholder that can be orientated is active, then this has the same significance as when directly specifying the actual toolholder number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

< -2 Values less than 2 are ignored, i.e. this case is treated as if `CUTMOD` was not programmed.

**Note:**

This value range should not be used as it is reserved for possible subsequent expansions.

---

**Note**

**SD42984 \$SC\_CUTDIRMOD**

The function can be activated using the `CUTMOD` command replaces the function that can be activated using the setting data SD42984 \$SC\_CUTDIRMOD. However, this function remains available unchanged. However, as it doesn't make sense to use both functions in parallel, it can only be activated if `CUTMOD` is equal to zero.

---

### Effectiveness of the modified cutting data

The modified tool nose position and the modified tool nose reference point are immediately effective when programming, even for a tool that is already active. A tool does not have to be re-selected for this purpose.

### Influence of the active machining plane

To determine modified tool nose position, cutting direction and holder or clearance angle, the evaluation of the cutting edge in the active plane (`G17 - G19`) is decisive.

However, if setting data SD42940 \$SC\_TOOL\_LENGTH\_CONST (change of the tool length component when selecting the plane), a valid value not equal to zero (plus or minus 17, 18 or 19), then its contents define the plane in which the relevant quantities are evaluated.

## System variables

The following system variables are available:

| System variables                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| \$P_CUTMOD_ANG /<br>\$AC_CUTMOD_ANG | Supplies the (non-rounded) angle in the active machining plane, that was used as basis for the modification of the cutting data (tool nose position, cut direction, clearance angle and holder angle) for the functions activated using <code>CUTMOD</code> and/or <code>\$SC_CUTDIRMOD</code> .<br><br>\$P_CUTMOD_ANG refers to the actual state in the preprocessing, \$AC_CUTMOD_ANG to the actual main run block.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| \$P_CUTMOD /<br>\$AC_CUTMOD         | Reads the currently valid value that was last programmed using the command <code>CUTMOD</code> (number of the toolholder that should be activated for the cutting data modification).<br><br>If the last programmed <code>CUTMOD</code> value = -2 (activation with the currently active toolholder that can be orientated), then the value -2 is not returned in <code>\$P_CUTMOD</code> , but the number of the active toolholder that can be orientated at the time of programming.<br><br>\$P_CUTMOD refers to the actual state in the preprocessing, \$AC_CUTMOD to the actual main run block.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| \$P_CUT_INV /<br>\$AC_CUT_INV       | Supplies the value TRUE if the tool is rotated so that the spindle direction of rotation must be inverted. To do this, the following four conditions must be fulfilled in the block to which the read operations refer: <ol style="list-style-type: none"> <li>1. If a turning or grinding tool is active (tool types 400 to 599 and / or SD42950 <code>\$SC_TOOL_LENGTH_TYPE = 2</code>).</li> <li>2. The cutting influence was activated using the language command <code>CUTMOD</code>.</li> <li>3. A toolholder that can be orientated is active, which was designated using the numerical value of <code>CUTMOD</code>. Check - I reformulated.</li> <li>4. The toolholder that can be orientated rotates the tool around an axis in the machining plane (this is typically the C axis) so that the resulting perpendicular of the tool cutting edge is rotated with respect to the initial position by more than 90° (typically 180°).</li> </ol> <p>The contents of the variable is FALSE if at least one of the specified four conditions is not fulfilled. For tools whose tool nose position is not defined, the value of the variable is always FALSE.</p> <p>\$P_CUT_INV refers to the actual state in the preprocessing and \$AC_CUT_INV to the actual main run block.</p> |

All main run variables (`$AC_CUTMOD_ANG`, `$AC_CUTMOD` and `$AC_CUT_INV`) can be read in synchronized actions. A read access operation from the preprocessing generates a preprocessing stop.

### Modified cutting data

If a tool rotation is active, the modified data are made available in the following system variables:

| System variable | Description            |
|-----------------|------------------------|
| \$P_AD[2]       | Length of cutting edge |
| \$P_AD[10]      | Holder angle           |

18.7 Cutting data modification for tools that can be rotated

| System variable | Description     |
|-----------------|-----------------|
| \$P_AD[11]      | Cut direction   |
| \$P_AD[24]      | Clearance angle |

**Note**

The data are always modified with respect to the corresponding tool parameters (\$TC\_DP2[... , ...] etc.) if the function "cutting data modification for rotatable tools" was activated using the command CUTMOD and a toolholder that can be orientated, which causes a rotation, is activated.

**18.7.9 Example**

The following example refers to a tool with tool nose position 3 and a toolholder that can be orientated, which can rotate the tool around the B axis.

The numerical values in the comments specify the end of block positions in the machine coordinates (MCS) in the sequence X, Y, Z.

| N280 Z-20              | ; 8.696 0.000 -21.330  |
| N290 X10               | ; 12.696 0.000 -21.330 |
| N300 G40 X20 Z0        | ; 28.696 0.000 -7.330  |
| N310 M30               |                        |

## Explanations:

In block N180, initially the tool is selected for `CUTMOD=0` and non-rotated toolholders that can be orientated. As all offset vectors of the toolholder that can be orientated are 0, the position that corresponds to the tool lengths specified in `$TC_DP3[1,1]` and `$TC_DP4[1,1]` is approached.

The toolholder that can be orientated with a rotation of 30° around the B axis is activated in block N200. As the tool nose position is not modified due to `CUTMOD=0`, the old tool nose reference point is decisive just as before. This is the reason that in block N210 the position is approached, which keeps the old tool nose reference point at the zero (i.e. the vector (1, 12) is rotated through 30° in the Z/X plane).

In block N260, contrary to block N200 `CUTMOD=2` is effective. As a result of the rotation of the toolholder that can be orientated, the modified tool nose position becomes 8. The consequence of this is also the different axis positions.

The tool radius compensation (TRC) is activated in blocks N220 and/or N270. The different tool nose positions in both program sections has no effect on the end positions of the blocks in which the TRC is active; the corresponding positions are therefore identical. The different tool nose positions only become effective again in the deselect blocks N260 and/or N300.

## 18.8 Incrementally programmed compensation values

### 18.8.1 G91 extension

#### Prerequisites

Incremental programming with G91 is defined such that the compensation value is traversed additively to the incrementally programmed value when a tool compensation is selected.

#### Applications

For applications such as scratching, it is necessary only to traverse the path programmed in the incremental coordinates. The activated tool compensation is not traversed.

#### Sequence

Selection of a tool compensation with incremental programming

- Scratch workpiece with tool tip.
- Save the actual position in the basic frame (set actual value) after reducing it by the tool compensation.
- Traverse incrementally from the zero position.

#### Activation

With setting data:

SD42442 \$SC\_TOOL\_OFFSET\_INCR\_PROG,

it is possible to define whether a changed tool length is traversed with FRAME and incremental programming of an axis, or whether only the programmed path is traversed.

#### Zero offset/frames G91

With setting data:

SD42440 \$SC\_FRAME\_OFFSET\_INCR\_PROG,

it is possible to define whether a zero offset is traversed as standard with value = 1 with FRAME and incremental programming of an axis, or whether only the programmed path is traversed with value = 0.

#### References:

/FB1/ Function Manual, Basic Functions; Axes, Coordinate Systems, Frames (K2), Chapter: "Frames"

### Supplementary condition

If the behavior is set such that the offset remains active even after the end of the program and RESET (MD20110 \$MC\_RESET\_MODE\_MASK, bit6=1), and if an incremental path is programmed in the first part program block, the compensation is always traversed additively to the programmed path.

---

#### Note

With this configuration, part programs must always begin with absolute programming.

---

## 18.8.2 Machining in direction of tool orientation

### Typical application

On machines with toolholders with orientation capability, traversing should take place in the tool direction (typically, when drilling) without activating a frame (e.g., using `TOFRAME` or `TOROT`), on which one of the axes points in the direction of the tool.

This is also true of machines on which a frame defining the oblique plane is active during oblique machining operations, but the tool cannot be set exactly perpendicular because an indexed toolholder (Hirth tooth system) is restricting the setting of the tool orientation.

In these cases it is then necessary - contrary to the motion actually requested perpendicular to the plane - to drill in the tool direction, as the drill would otherwise not be guided in the direction of its longitudinal axis, which, among other things, would lead to breaking of the drill.

### MOV<sub>T</sub>

The end point of such a motion is programmed with `MOVT= . . .`. The programmed value is effective incrementally in the tool direction as standard. The positive direction is defined from the tool tip to the toolholder. The content of `MOVT` is thus generally negative for the infeed motion (when drilling), and positive for the retraction motion. This corresponds to the situation with normal paraxial machining, e.g., with `G91Z . . .`.

If the motion is programmed in the form `MOVT=AC( . . . )`, `MOVT` functions absolutely. In this case a plane is defined, which runs through the current zero point, and whose surface normal vector is parallel to the tool orientation. `MOVT` then gives the position relative to this plane:

Figure 18-48 Definition of the position for absolute programming of a motion in tool direction

The reference to this auxiliary plane serves only to calculate the end position. Active frames are not affected by this internal calculation.

Instead of `MOVT=...` it is also possible to write `MOVT=IC(...)` if it is to be plainly visible that `MOVT` is to function incrementally. There is no functional difference between the two forms.

### Supplementary conditions

The following supplementary conditions apply to programming with `MOVT`:

- It is independent of the existence of a toolholder with orientation capability. The direction of the motion is dependent on the active plane. It runs in the direction of the vertical axes, i.e., with `G17` in Z direction, with `G18` in Y direction and with `G19` in X direction. This applies both where no toolholder with orientation capability is active and for the case of a toolholder with orientation capability without rotary tool or with a rotary tool in its basic setting.
- `MOVT` acts similarly for active orientation transformation (3-4-5-axis transformation).
- If in a block with `MOVT` the tool orientation is changed simultaneously (e.g., active 5-axis transformation by means of simultaneous interpolation of the rotary axes), the orientation at the start of the block is decisive for the direction of movement of `MOVT`. The path of the tool tip (TCP - Tool Center Point) is not affected by the change in orientation.
- Linear or spline interpolation (`G0`, `G1`, `ASPLINE`, `BSPLINE`, `CSPLINE`) must be active. Otherwise, an alarm is produced. If a spline interpolation is active, the resultant path is generally not a straight line, since the end point determined by `MOVT` is treated as if it had been programmed explicitly with X, Y, Z.
- A block with `MOVT` must not contain any programming of geometry axes (alarm 14157).

## 18.9 Basic tool orientation

### Application

Normally, the orientation assigned to the tool itself depends exclusively on the active machining plane. For example, the tool orientation is parallel to Z with G17, parallel to Y with G18 and parallel to X with G19.

Different tool orientations can only be programmed by activating a 5-axis transformation. The following system variables have been introduced in order to assign a separate orientation to each tool cutting edge:

| System variable | Description of tool orientation  | Format | Preassignment |
|-----------------|----------------------------------|--------|---------------|
| \$TC_DPV[t, d]  | Tool cutting edge orientation    | INT    | 0             |
| \$TC_DPV3[t, d] | L1 component of tool orientation | REAL   | 0             |
| \$TC_DPV4[t, d] | L2 component of tool orientation | REAL   | 0             |
| \$TC_DPV5[t, d] | L3 component of tool orientation | REAL   | 0             |

Indexing: Same as tool system variable \$TC\_DPx[t, d]

t: T number of cutting edge

d: D number of cutting edge

Identifiers \$TC\_DPV3 to \$TC\_DPV5 are analogous to identifiers \$TC\_DP3 to \$TC\_DP5 of the tool length components.

### MD18114

The system variables for describing the tool orientation are only available if machine data is not equal to zero:

MD18114 \$MN\_MM\_ENABLE\_TOOL\_ORIENT (assign orientation to tool cutting)

| MD18114 \$MN_MM_ENABLE_TOOL_ORIENT |                                                   |
|------------------------------------|---------------------------------------------------|
| Value = 1                          | Only system variable \$TC_DPV[t, d] is available. |
| Value = 2                          | All four system variables are available.          |

### Define direction vector

If all four system variables contain 0, the orientation is defined only by the active plane (as before).

If system variable \$TC\_DPV[t, d] is equal to zero, the other three parameters - if available - define a direction vector. The amount of the vector is insignificant.

**Example:**

```
$TC_DPV[1, 1] = 0
$TC_DPV3[1, 1] = 1.0
$TC_DPV4[1, 1] = 0.0
$TC_DPV5[1, 1] = 1.0
```

In this example, the basic orientation points in the direction of the bisector in the L1-L3 plane, i.e., the basic orientation in the bisector for a milling tool and active plane G17 lies in the Z/X plane.

### Basic orientation of tools

| Basic orientation of:      | With : |
|----------------------------|--------|
| Turning and grinding tools | G18    |
| Milling tools              | G17    |

The active tool orientation is unchanged in these cases and is equivalent to the original settings in \$TC\_DPVx[t, d].

The basic orientation is always the direction perpendicular to the plane in which tool radius compensation is performed. With turning tools, in particular, the tool orientation generally coincides with the longitudinal tool axis.

The setting data specified below are effective only if the basic orientation of the tool is defined by an entry in at least one of the system variables \$TC\_DPVx[t, d].

They have no effect if the tool orientation is only determined by the plane selection G17 - G19 and is compatible with previous behavior.

The plane of the basic orientation for a cutting edge is treated either like a milling tool or like a turning tool, irrespective of the entry in \$TC\_DP1, if the following setting data is not equal to zero:

SD42950 \$SC\_TOOL\_LENGTH\_TYPE (allocation of the tool length components independent of tool type)

### Plane change

A change of plane causes a change in orientation.

The following rotations are initiated:

| When changing from:                    | Rotations                                                                                               |
|----------------------------------------|---------------------------------------------------------------------------------------------------------|
| G17 ⇒ G18:<br>G18 ⇒ G19:<br>G19 ⇒ G17: | Rotation through -90 degrees about the Z axis followed by rotation through -90 degrees about the X axis |
| G17 ⇒ G19:<br>G18 ⇒ G17:<br>G19 ⇒ G18: | Rotation through 90 degrees about the X axis followed by rotation through 90 degrees about the Z axis   |

These rotations are the same as those that have to be performed in order to interchange the components of the tool length vector on a change of plane.

The basic orientation is also rotated when an adapter transformation is active.

If the following setting data is not equal to zero, the tool orientation is not rotated on a change of plane:

SD42940 \$SC\_TOOL\_LENGTH\_CONST (change of tool length components on change of planes).

### Tool length components

The components of the tool orientation are treated the same as the components of the tool length, with respect to setting data:

SD42910 \$SC\_MIRROR\_TOOL\_LENGTH (Sign change tool wear when mirroring).

SD42950 \$SC\_TOOL\_LENGTH\_TYPE (allocation of the tool length components independent of tool type)

Therefore the components are changed respectively and assigned to the geometry axis.

### System variable \$TC\_DPV[t, d]

The purpose of system variable \$TC\_DPV[t, d] is to allow the simple specification of certain basic orientations (parallel to coordinate axes) that are required frequently. The permissible values are shown in the table below. The values in the first and second/third columns are equivalent.

| \$TC_DPV[t, d] | Basic orientation                                             |                                                               |
|----------------|---------------------------------------------------------------|---------------------------------------------------------------|
|                | Milling tools *                                               | Turning tools *                                               |
| ≤ 0 or > 6     | (\$TC_DPV5[t, d],<br>\$TC_DPV4[t, d],<br>\$TC_DPV3[t, d],) ** | (\$TC_DPV3[t, d],<br>\$TC_DPV5[t, d],<br>\$TC_DPV4[t, d],) ** |
| 1              | (0, 0, V)                                                     | (0, V, 0)                                                     |
| 2              | (0, V, 0)                                                     | (0, 0, V)                                                     |
| 3              | (V, 0, 0)                                                     | (V, 0, 0)                                                     |
| 4              | (0, 0, -V)                                                    | (0, -V, 0)                                                    |

| \$TC_DP1[t, d] | Basic orientation |                 |
|----------------|-------------------|-----------------|
|                | Milling tools *   | Turning tools * |
| 5              | (0, -V, 0)        | (0, 0, -V)      |
| 6              | (-V, 0, 0)        | (-V, 0, 0)      |

\* Turning tools in this context are any tools whose tool type (\$TC\_DP1[t, d]) is between 400 and 599. All other tool types refer to milling tools.

\*\* If all three values \$TC\_DP3[t, d], \$TC\_DP4[t, d], \$TC\_DP5[t, d] are equal to zero in this case, the tool orientation is determined by the active machining plane (default).

V Stands for a positive value in the corresponding system variables.

**Example:**

For milling tools:

\$TC\_DP1[t, d] = 2 is equal to:

\$TC\_DP3[t, d] = 0, \$TC\_DP4[t, d] = 0, \$TC\_DP5[t, d] = V.

**Supplementary conditions**

If the "Scratch" function is used in the RESET state, the following must be noted with respect to the initial setting:

- The wear components are evaluated depending on the initial settings of the G-code groups TOWSTD, TOWMCS and TOWWCS.
- If a value other than the initial setting is needed to ensure correct calculation, scratching may be performed only in the STOP state.

---

**Note**

"Special handling of tool compensations" pays particular attention to tool compensations with evaluation of sign for tool length with wear and temperature fluctuations.

The following are taken into account:

- Tool type
  - Transformations for tool components
  - Assignment of tool length components to geometry axes independently of tool type
-

## 18.10 Special handling of tool compensations

### 18.10.1 Relevant setting data

#### SD42900- 42960

Setting data SD42900 - SD42940 can be used to make the following settings with reference to tool compensation:

- Sign of the tool length
- Sign of the wear
- Behavior of the wear components when mirroring geometry axes
- Behavior of the wear components when changing the machining plane via setting data
- Allocation of the tool length components independent of actual tool type
- Transformation of wear components into a suitable coordinate system for controlling the effective tool length

---

#### Note

In the following description, the wear includes the total values of the following components:

- Wear values: \$TC\_DP12 to \$TC\_DP20
  - Sum offset, consisting of:
    - Wear values: \$SCPX3 to \$SCPX11
    - Setup values: \$ECPX3 to \$ECPX11
- 

You will find detailed information about sum and tool offsets in:

#### References:

/FBW/ Function Manual Tool Management

/PG/ Programming Manual Fundamentals; Tool Compensations

#### Required setting data

- SD42900 \$SC\_MIRROR\_TOOL\_LENGTH (mirroring of tool length components and components of the tool base dimension)
- SD42910 \$SC\_MIRROR\_TOOL\_WEAR (mirroring of wear values of tool length components)
- SD42920 \$SC\_WEAR\_SIGN\_CUTPOS (sign evaluation of the wear components)
- SD42930 \$SC\_WEAR\_SIGN (inverts the sign of the wear dimensions)
- SD42940 \$SC\_TOOL\_LENGTH\_CONST (allocation of the tool length components to the geometry axes)

- SD42950 \$SC\_TOOL\_LENGTH\_TYPE (allocation of the tool length components independent of tool type)
- SD42935 \$SC\_WEAR\_TRANSFORM (transformation of wear values)
- SD42960 \$SC\_TOOL\_TEMP\_COMP (tool length offsets)

## 18.10.2 Mirror tool lengths (SD42900 \$SC\_MIRROR\_TOOL\_LENGTH)

### Activation

Tool length mirroring is activated via the setting data:

SD42900 \$SC\_MIRROR\_TOOL\_LENGTH <> 0 (TRUE) (Sign change tool length when mirroring)

### Function

The following components are mirrored by inverting the sign:

- Tool lengths: \$TC\_DP3, \$TC\_DP4, \$TC\_DP5
- Tool base dimensions: \$TC\_DP21, \$TC\_DP22, \$TC\_DP23

Mirroring is performed for all tool base dimensions whose associated axes are mirrored. Wear values are **not** mirrored.

### Mirror wear values

The following setting data should be set in order to mirror the wear values:

SD42910 \$SC\_MIRROR\_TOOL\_WEAR <> 0 (Sign change tool wear when mirroring)

Inverting the sign mirrors the wear values of the tool length components whose associated axes are mirrored.

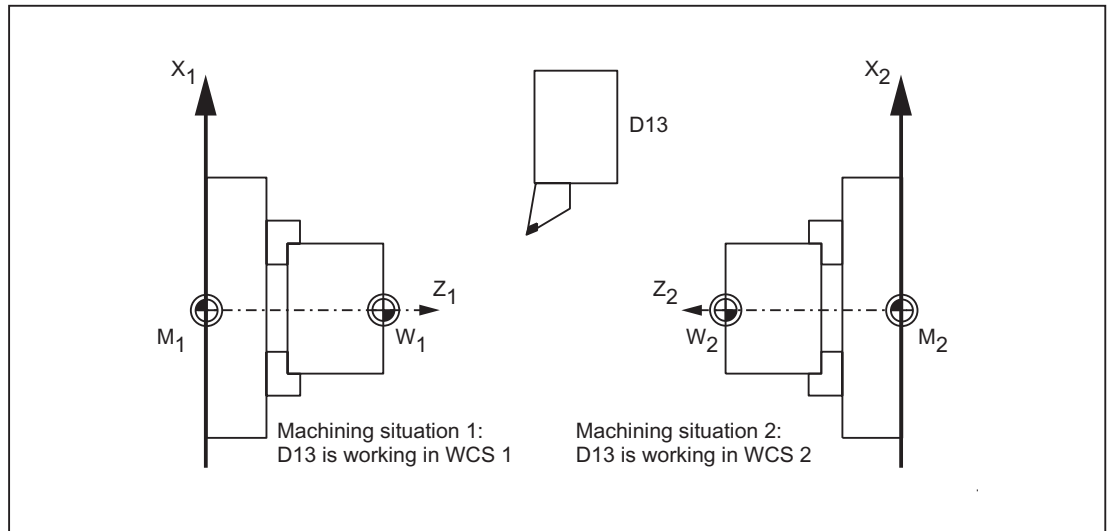

Figure 18-49 Application example: Double-spindle turning machine

### 18.10.3 Mirror wear lengths (SD42920 \$SC\_WEAR\_SIGN\_CUTPOS)

#### Activation

Wear length mirroring is activated by:

SD42920 \$SC\_WEAR\_SIGN\_CUTPOS <> 0 (TRUE) (Sign of wear for tools with cutting edge systems)

#### Function

| Length of cutting edge | Length 1 | Length 2 |
|------------------------|----------|----------|
| 1                      | ---      | ---      |
| 2                      | ---      | Inverted |
| 3                      | Inverted | Inverted |
| 4                      | Inverted | ---      |
| 5                      | ---      | ---      |
| 6                      | ---      | ---      |
| 7                      | ---      | Inverted |
| 8                      | Inverted | ---      |
| 9                      | ---      | ---      |

In the case of tool types without a relevant cutting edge position, the wear length is not mirrored.

---

#### Note

The mirroring (sign inversion) in one or more components can cancel itself through a simultaneous activation of the functions:

Tool length-mirroring (SD42900 <> 0)

And:

Tool length-mirroring (SD42920 <> 0)

---

### SD42930 \$SC\_WEAR\_SIGN

Setting data not equal to zero:

Inverts the sign of all wear dimensions. This affects both the tool length and other variables such as tool radius, rounding radius, etc.

Entering a positive wear dimension makes the tool "shorter" and "thinner".

### Activation of modified setting data

When the setting data described above are modified, the tool components are not reevaluated until the next time a tool edge is selected. If a tool is already active and the data of this tool are to be reevaluated, the tool must be selected again.

#### Example:

```

N10 $SC_WEAR_SIGN = 0 ; No sign inversion of the wear values
N20 $TC_DP1[1,1] = 120 ; End mill
N30 $TC_DP6[1,1] = 100 ; Tool radius 100 mm
N40 $TC_DP15[1,1] = 1 ; Wear dimension of tool radius 1 mm, resulting
 tool radius 101 mm

N100 T1 D1 G41 X150 Y20
....
N150 G40 X300N10
....
N200 $SC_WEAR_SIGN = 1 ; Sign inversion for all wear values; the new
 radius of 99 mm is activated on a new
 selection (D1). Without D1, the radius would
 continue to be 101 mm.

N300 D1 G41 X350 Y-20
N310

```

The same applies in the event that the resulting tool length is modified due to a change in the mirroring status of an axis. The tool must be selected again after the mirror command, in order to activate the modified tool-length components.

## 18.10.4 Tool length and plane change (SD42940 \$SC\_TOOL\_LENGTH\_CONST)

### Plane change

The assignment of tool length components (length, wear and tool base dimension) to geometry axes does not change when the machining plane is changed (G17-G19).

### Assignment of tools

The assignment of tool length components to geometry axes for turning and grinding tools (tool types 400 to 599) is generated from the value of the following setting data in accordance with the following table:

SD42940 \$SC\_TOOL\_LENGTH\_CONST (change of tool length components on change of planes).

| Layer                                                                                                       | Length 1 | Length 2 | Length 3 |
|-------------------------------------------------------------------------------------------------------------|----------|----------|----------|
| 17                                                                                                          | Y        | X        | Z        |
| *)                                                                                                          | X        | Z        | Y        |
| 19                                                                                                          | Z        | Y        | X        |
| -17                                                                                                         | X        | Y        | Z        |
| -18                                                                                                         | Z        | X        | Y        |
| -19                                                                                                         | Y        | Z        | X        |
| *) Each value not equal to 0, which is not equal to one of the six listed values, is evaluated as value 18. |          |          |          |

The following table shows the assignment of tool length components to geometry axes for **all other tools** (tool types < 400 or > 599):

| Layer                                                                                                       | Length 1 | Length 2 | Length 3 |
|-------------------------------------------------------------------------------------------------------------|----------|----------|----------|
| *)                                                                                                          | Z        | Y        | X        |
| 18                                                                                                          | Y        | X        | Z        |
| 19                                                                                                          | X        | Z        | Y        |
| -17                                                                                                         | Z        | X        | Y        |
| -18                                                                                                         | Y        | Z        | X        |
| -19                                                                                                         | X        | Y        | Z        |
| *) Each value not equal to 0, which is not equal to one of the six listed values, is evaluated as value 17. |          |          |          |

---

**Note**

For representation in tables, it is assumed that geometry axes 1 to 3 are named X, Y, Z. The axis order and not the axis identifier determines the assignment between a compensation and an axis.

Three tool length components can be arranged on the 6 different types above.

---

### 18.10.5 Tool type (SD42950 \$SC\_TOOL\_LENGTH\_TYPE)

Definition of the assignment between tool length components (length, wear and tool base dimension) and geometry axes independent of tool type.

Setting data **not equal to zero**: (the default definition is applied)

A distinction is made between turning and grinding tools (tool types 400 to 599) and other tools (milling tools).

The value range is from 0 to 2. Any other value is interpreted as 0.

The assignment of tool length components is always independent of the actual tool type.

- Value = 1: Always as for milling tools
- Value = 2: Always as for turning tools

### Toolholder with orientation capability

#### Setting data SD42900 - SD42950

Setting data SD42900 - SD42950 have no effect on the components of an active toolholder with orientation capability. The calculation with a toolholder with orientation capability always allows for a tool with its total resulting length (tool length + wear + tool base dimension). The calculation of the resulting total length allows for all modifications caused by the setting data.

---

**Note**

When toolholders with orientation capability are used, it is common to define all tools for a non-mirrored basic system, even those, which are only used for mirrored machining. When machining with mirrored axes, the toolholder is then rotated such that the actual position of the tool is described correctly. All tool-length components then automatically act in the correct direction, dispensing with the need for control of individual component evaluation via setting data, depending on the mirroring status of individual axes.

The use of toolholders with orientation capability is also practical if the physical characteristics of the machine type prevents tools, which are permanently installed with different orientations, from being rotated. Tool dimensioning can then be performed uniformly in a basic orientation, where the dimensions relevant for machining are calculated according to the rotations of a virtual toolholder.

---

## 18.10.6 Temperature offsets in tool direction (SD42960 \$SC\_TOOL\_TEMP\_COMP)

---

### Note

Temperature offset in the tool direction is operative only as an option with generic 5-axis transformation, types 24 and 56.

---

## 18.10.7 Tool lengths in the WCS, allowing for the orientation

### Change tool or working plane

The values displayed for the tool correspond to the expansion in the WCS. If a toolholder with an inclined clamping position is to be used, you should make sure that the transformation used supports the toolholder. If this is not the case, incorrect tool dimensions will be displayed. When changing the working plane from G17 to G18 or G19, you should ensure that the transformation can also be used for these working planes. If the transformation is only available for G17 machining, the dimensions continue to be displayed for a tool in the Z direction after the plane change.

When transformation is deactivated, the basic tool is displayed in the x, y or z direction, according to the working plane. Allowance is made for a programmed toolholder. These tool dimensions are not altered when traversing without a transformation.

## 18.10.8 Tool length offsets in tool direction

### Temperature compensation in real time

On 5-axis machines with a moving tool, temperature fluctuations can occur in the machining heads. These can result directly in expansion fluctuations, which are transmitted to the tool spindle in the form of linear expansion. A typical case on 5-axis heads, for example, is thermal expansion in the direction of the longitudinal spindle axis.

It is possible to compensate this thermal expansion even when the tool is orientated by assigning the temperature compensation values to the tool rather than to the machine axes. In this way, linear expansion fluctuations can be compensated even when the tool orientation changes.

Using the orientation transformation whose direction is determined by the current tool orientation, it is possible to overlay motions in real time and rotate them simultaneously. At the same time, the compensation values are adjusted continuously in the tool coordinate system.

Compensation applies to the "Temperature compensation" option and is active only when the axis to be compensated is really referenced.

### Activation

Temperature compensation in the tool direction is an option, which must be enabled beforehand.

It is activated by setting the following machine data to a value **other than zero**.

MD20390 \$MC\_TOOL\_TEMP\_COMP\_ON (Activation of temperature compensation for tool length)

In addition, the bit 2 must be set for each affected channel axis in the machine data:

MD32750 \$MA\_TEMP\_COMP\_TYPE [<axis index>] (temperature compensation type)

This can be more than three axes in cases where more than three channel axes in succession can be temporarily assigned to geometry axes as a result of geometry axis replacement of transformation switchover. If this bit is not set for a particular channel axis, the compensation value cannot be applied in the axis. This does not have any effect on other axes. In this case, an alarm is not output.

### Applicability

Temperature compensation in the tool direction is operative only with generic 5-axis transformations with:

- Transformation type 24

Two axes rotate the tool

- Transformation type 56

One axis rotates the tool, the other axis rotates the workpiece without temperature compensation

In generic 5-axis transformation with:

- Transformation type 40

The tool orientation is constant with a rotary workpiece, which means that the movement of the rotary axes on the machine does not affect the temperature compensation direction.

Temperature compensation in the tool direction also works in conjunction with orientation transformations (not generic 5-axis transformations) with:

- Transformation type 64 to 69

Rotating linear axis

---

#### Note

Temperature compensation can be activated with all other types of transformation. It is not affected by a change in tool orientation. The axis move as if no orientation transformation with temperature compensation were active.

---

### Supplementary conditions

Temperature compensation in the tool direction is an option, which must be enabled in advance and is available:

- For generic 5-axis transformation
- For transformation with rotated linear axis for transformation types 64 to 69

### Limit values

The compensation values are restricted to the maximum values by the machine data:

MD20392 \$MC\_TOOL\_TEMP\_COMP\_LIMIT[0] (Maximum temperature compensation for tool length)

To:

MD20392 \$MC\_TOOL\_TEMP\_COMP\_LIMIT[2]

The limit value default setting is 1 mm. If a temperature compensation value higher than this limit is specified, it will be limited without an alarm.

### SD42960

The three temperature compensation values together form a compensation vector and are contained in setting data:

SD42960 \$SC\_TOOL\_TEMP\_COMP[0] (Temperature compensation with reference to tools)

To:

SD42960 \$SC\_TOOL\_TEMP\_COMP[2]

The setting data are user-defined, e.g., using synchronized actions or from the PLC. The compensation values can, therefore, also be used for other compensation purposes.

In the initial state or when orientation transformation is deactivated, all three compensation values apply in the direction of the three geometry axes (in the typical order X, Y, Z). The assignment of components to geometry axes is independent of the tool type (turning, milling or grinding tools) and the selected machining plane G17 to G19. Changes to the setting data values take effect immediately.

### Toolholder with orientation capability

If a toolholder with orientation capability is active, the temperature compensation vector is rotated simultaneously to any change in orientation. This applies independently of any active orientation transformation.

If a toolholder with orientation capability is active in conjunction with a generic 5-axis transformation or a transformation with rotating linear axis, the temperature compensation vector is subjected to both rotations.

---

#### Note

While transformations with rotating linear axes take changes in the tool vector (length) into account, they **ignore** its change in orientation, which can be effected by a toolholder with orientation capability.

---

Temperature compensation values immediately follow any applied change in orientation. This applies in particular when an orientation transformation is activated or deactivated.

The same is true when the assignment between geometry axes and channel axes is changed. The temperature compensation value for an axis is reduced to zero (interpolatively), for example, when it ceases to be a geometry axis after a transformation change. Conversely, any temperature compensation value for an axis, which changes over to geometry axis status, is applied immediately.

### Examples

#### Temperature compensation in tool direction

Example of a 5-axis machine with rotating tool, on which the tool can be rotated about the C and B axes.

In its initial state, the tool is parallel to the Z axis. If the B axis is rotated through 90 degrees, the tool points in the X direction.

Therefore, a temperature compensation value in the following setting data is also effective in the direction of the machine X axis if transformation is active:

SD42960 \$SC\_TOOL\_TEMP\_COMP[2] (Temperature compensation with reference to tools)

If the transformation is deactivated with the tool in this direction, the tool orientation is, by definition, parallel again to the Z axis and thus different to its actual orientation. The temperature offset in the X axis direction is therefore reduced to zero and reapplied simultaneously in the Z direction.

Example of a 5-axis machine with rotating tool (transformation type 24). The relevant machine data are listed below:

- The first rotary axis rotates about Z C-axis
- The second rotary axis rotates about Y B-axis

The essential machine data are shown in the table below:

|                                         |                                         |
|-----------------------------------------|-----------------------------------------|
| MD20390 TOOL_TEMP_COMP_ON = TRUE        | ; Temperature compensation active       |
| Option                                  | ; Activate option                       |
| MD32750 TEMP_COMP_TYPE[ AX1 ] = 4       | ; Compensation in tool direction        |
| MD32750 TEMP_COMP_TYPE[ AX2 ] = 4       | ; Compensation in tool direction        |
| MD32750 TEMP_COMP_TYPE[ AX3 ] = 4       | ; Compensation in tool direction        |
|                                         |                                         |

## NC program

### Temperature compensation values in the NC program

The compensation values assigned to axes X and Z are not zero and are applied for temperature compensation with respect to tool length. The machine axis positions reached in each case are specified as comments in the program lines.

18.10 Special handling of tool compensations

```

SD42960 TOOL_TEMP_COMP[0] = -0.3 ; First compensation value
SD42960 TOOL_TEMP_COMP[1] = 0.0 ;
SD42960 TOOL_TEMP_COMP[2] = -1.0 ; Second compensation value

 ; Position setpoints of the
 machine axes

N10 g74 x0 y0 z0 a0 b0 ; X Y Z
N20 x20 y20 z20 f10000 ; 20.30 20.00 21.00
N30 traori() ; 20.30 20.00 21.00
N40 x10 y10 z10 b90 ; 11.00 10.00 9.70
N50 trafoof ; 10.30 10.00 11.00
N60 x0 y0 z0 b0 c0 ; 0.30 0.00 1.00
N70 m30

```

With the exception of block N40, temperature compensation always acts in the original directions, as the tool is pointing in the basic orientation direction. This applies particularly in block N50. The tool is actually still pointing in the direction of the X axis because the B axis is still at 90 degrees. However, because the transformation is already deactivated, the applied orientation is parallel to the Z axis again.

## 18.11 Sum offsets and setup offsets

### 18.11.1 General

#### Sum offsets

Sum offsets can be treated as **programmable process compensations** during machining and are composed of all the error sizes (including the wear), which cause the workpiece to deviate from the specified dimensions.

Sum offsets are a generalized type of wear. They are part of the cutting edge data. The parameters of the sum offset refer to the geometrical data of a cutting edge.

The compensation data of a sum offset are addressed by a **DL number** (DL: location-dependent; compensations with reference to the location of use).

In contrast, the wear values of a D number describe the physical wear of the cutting edge, i.e., in special situations, the sum offset can match the wear of the cutting edge.

Sum offsets are intended for general use, i.e., with active or inactive tool management or with the flat D number function.

Machine data are used to classify the sum offsets into:

- Sum offset fine
- Sum offset coarse (setup offset)

#### Setup offset

The setup offset is the compensation to be entered by the setup engineer before machining. These values are stored separately in the NCK. The operator subsequently only has access to the "sum offset fine" via HMI.

The "sum offset fine" and "sum offset coarse" are added internally in the NCK. This value is referred to below as the sum offset.

---

#### Note

The function is enabled via the machine data setting:

MD18080 \$MN\_MM\_TOOL\_MANAGEMENT\_MASK, Bit 8=1 (Gradual memory reservation for tool management).

---

If kinematic transformations (e.g., 5-axis transformations) are active, the tool length is calculated first after allowing for the various wear components. The total tool length is then used in the transformation. Unlike the case of a toolholder with orientation capability, the wear values are thus always included in the transformation irrespective of the G code of group 56.

## 18.11.2 Description of function

### Sum offsets

Several sum offsets (DL numbers) can be defined per D number. This allows you to determine, for example, **workpiece-location-dependent** compensation values and assign them to a cutting edge. Sum offsets have the same effect as wear, i.e., they are added to the compensation values of the D number. The data are permanently assigned to a D number.

### Attitudes

You can define the following settings in machine data:

- Activate sum offset
- Define maximum quantity of DL data sets to be created in NCK memory
- Define maximum quantity of DL numbers to be assigned to a D number
- Define whether the sum offsets (fine/coarse) are to be saved during data backup
- Define the sum offset to be activated, if:
  - A new cutting edge compensation is activated
  - An operator panel front `RESET` is performed
  - An operator panel front `START` is performed
  - The end of the program has been reached

The name is oriented to the logic of the corresponding machine data for tools and cutting edges.

The "setup offset" and "sum offset fine" can be read and written via system variables and corresponding OPI services.

---

#### Note

When tool management is active, a machine data can be used to define whether the sum offset of a tool activated during a programmed tool change remains unchanged or is set to zero.

---

#### Summary of compensation parameters \$TC\_DPx

The following general system variables were previously defined for describing a cutting edge:

|          |                        |
|----------|------------------------|
| \$TC_DP1 | Tool type              |
| \$TC_DP2 | Length of cutting edge |

## Parameters for geometry and wear

Tool geometry compensations are assigned to system variables \$TC\_DP3 to \$TC\_DP11. System variables \$TC\_DP12 to \$TC\_DP20 allow you to name a wear for each of these parameters.

| Geometry  | Wear      | Length compensations                                                          |
|-----------|-----------|-------------------------------------------------------------------------------|
| \$TC_DP3  | \$TC_DP12 | Length 1                                                                      |
| \$TC_DP4  | \$TC_DP13 | Length 2                                                                      |
| \$TC_DP5  | \$TC_DP14 | Length 3                                                                      |
| Geometry  | Wear      | Radius compensation                                                           |
| \$TC_DP6  | \$TC_DP15 | Radius                                                                        |
| \$TC_DP7  | \$TC_DP16 | Corner radius (tool type 700; slotting saw)                                   |
| Geometry  | Wear      | Further compensations                                                         |
| \$TC_DP8  | \$TC_DP17 | Length 4 (tool type 700; slotting saw)                                        |
| \$TC_DP9  | \$TC_DP18 | Length 5                                                                      |
| \$TC_DP10 | \$TC_DP19 | Angle 1 (angle between face of tool and torus surface)                        |
| \$TC_DP11 | \$TC_DP20 | Angle 2 (angle between tool longitudinal axis and upper end of torus surface) |

## Tool base dimension/adaptor dimension

|           |                  |
|-----------|------------------|
| \$TC_DP21 | Adapter length 1 |
| \$TC_DP22 | Adapter length 2 |
| \$TC_DP23 | Adapter length 3 |

## Technology

| System variable | Clearance angle                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$TC_DP24       | <ul style="list-style-type: none"> <li>The clearance angle is stored here for ManualTurn; tool type 5xx. Same significance as in standard cycles for turning tools.</li> <li>The tip angle of the drill is stored here for ShopMill; tool type 2xx.</li> <li>Used in standard cycles for turning tools; tool type 5xx. This is the angle at the secondary cutting edge for these tools.</li> </ul> |
| \$TC_DP25       | <ul style="list-style-type: none"> <li>The value for the cutting rate is stored here for ManualTurn.</li> <li>A bit-coded value for various states of tool types 1xx and 2xx is stored here for ShopMill.</li> </ul>                                                                                                                                                                               |

**Parameters of the sum and setup offsets (\$TC\_SCPxy-, \$TC\_ECPxy)**

The numbering of the parameters is oriented to the numbering of system variables \$TC\_DP3 to \$TC\_DP11.

The effect of the parameters is similar to the wear (additive to the tool geometry). Up to six sum/setup parameters can be defined per cutting edge parameter.

| Tool geometry parameter, to which the compensation is added. | Sum/setup parameters, length compensations                                                                                                                                                                                                                                                                                                                                           | Tool wear parameters |

### Supplementary conditions

The maximum number of DL data sets of a cutting edge and the total number of sum offsets in the NCK are defined by machine data. The default value is zero, i.e., no sum offsets can be programmed.

Activate the "monitoring function" to monitor a tool for wear or for "sum offset".

The additional sum/setup data sets use additional buffered memory. 8 bytes are required per parameter.

A sum-offset data set requires: 8 bytes \* 9 parameters = 72 bytes

A setup data set requires an equal amount of memory. A certain number of bytes is also required for internal administration data.

### 18.11.3 Activation

#### Function

The function must be activated via the machine data:

MD18108 \$MN\_MM\_NUM\_SUMCORR (sum offsets in TO area).

System variables \$TC\_ECPx and \$TC\_SCPx and setup and sum offsets ("fine") defined via the OPI interface can be activated in the part program.

This is done by programming the language command `DL="number"`.

When a new D number is activated, either a new DL number is programmed, or the DL number defined via the following machine data becomes active:

MD20272 \$MC\_SUMCORR\_DEFAULT (basic setting of the additive offset without a program)

#### DL programming

The sum offset is always programmed relative to the active D number with the command:

`DL = "n"`

The sum offset "n" is added to the wear of the active D number.

---

#### Note

If you use "setup offset" **and** "sum offset fine", both compensations are combined and added to the tool wear.

---

The sum offset is deselected with the command:

DL = 0

**Note**

DL0 is not allowed. If compensation is deselected (D0 and T0), the sum offset also becomes ineffective.

Programming a sum offset that does not exist triggers an alarm, similar to programming a D compensation that does not exist.

Thus, only the defined wear remains part of the compensation (defined in system variables \$TC\_DP12 to \$TC\_DP20).

Programming a sum offset when a D compensation is active (also applies to deselection) has the same effect on the path as programming a D command. An active radius compensation will, therefore, lose its reference to adjacent blocks.

**Configuration**

MD18112 \$MN\_MM\_KIND\_OF\_SUMCORR, bit 4=0: (Properties of sum offset in the TO area) default setting:

Only one set of sum offsets exists per DL number.

We refer in general to the sum offset.

This describes the data represented by \$TC\_SCPx.

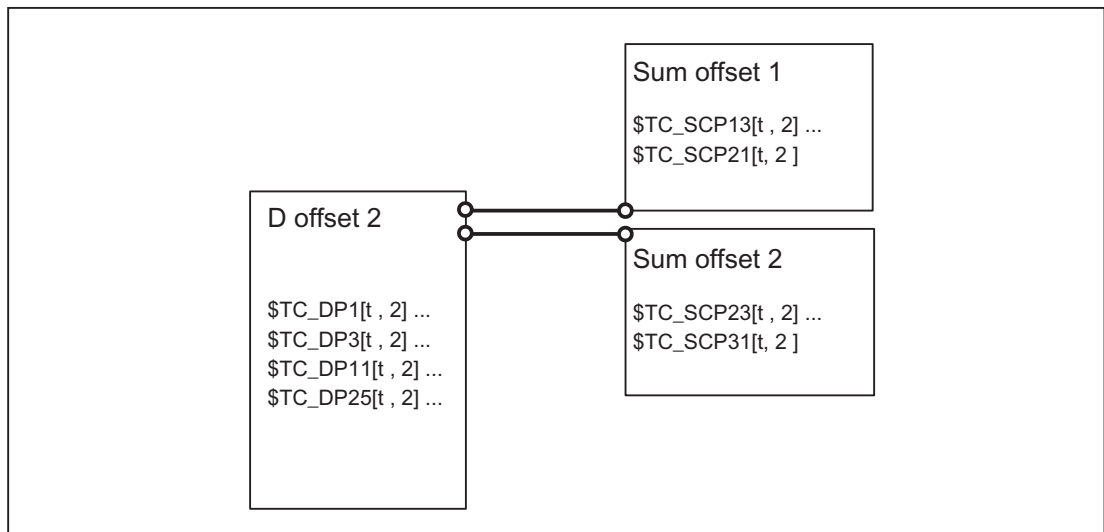

Figure 18-50 MD18112 \$MN\_MM\_KIND\_OF\_SUMCORR, bit 4 = 0

Tool T = t is active. With the data in the figure, the following is programmed:

```

D2 ; Cutting edge offsets, i.e., $TC_DP3 to $TC_DP11 + wear
 ($TC_DP12 to $TC_DP20) + adapter dimension
...
DL=1 ; Sum offset 1 is added to the previous D2 compensations, i.e.,
 $TC_SCP13 to $TC_SCP21.

```

```

...
DL=2 ; Sum offset 2 is added to the D2 compensation instead of sum
 offset 1, i.e., $TC_SCP23 to $TC_SCP31.
...
DL=0 ; Deselection of sum offset;
 only the data of D2 remain active.

```

**MD18112 \$MN\_MM\_KIND\_OF\_SUMCORR, bit 4=1: Setup offsets are available**

The sum offset is now composed of the "sum offset fine" (represented by \$TC\_SCPx) and the setup offset (represented by \$TC\_ECPx). Two data sets therefore exist for one DL number. The sum offset is calculated by adding the corresponding components (\$TC\_ECPx + \$TC\_SCPx).

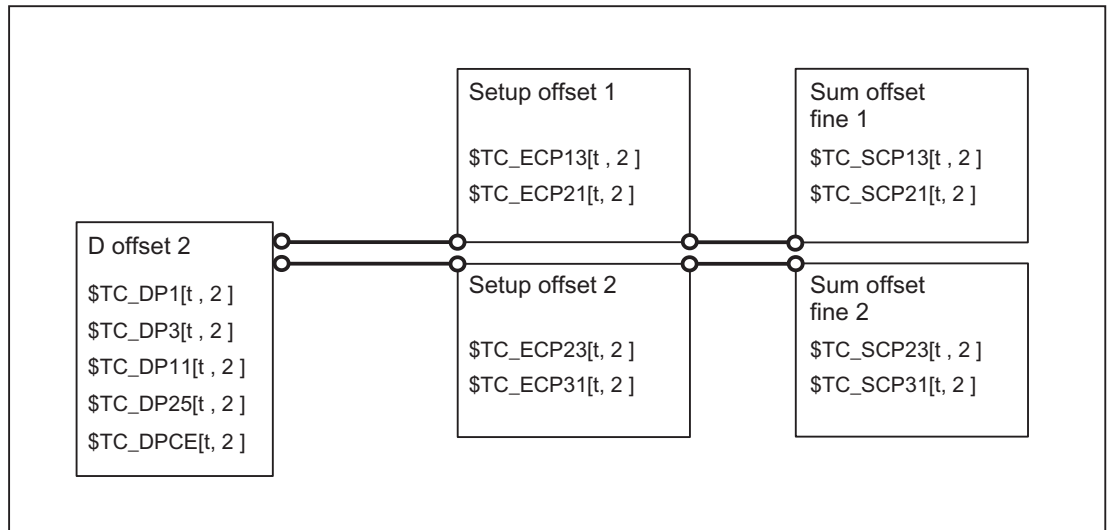

Figure 18-51 MD18112 \$MN\_MM\_KIND\_OF\_SUMCORR, bit 4 = 1 "setup offsets" + "sum offsets fine"

Tool T = t is active. With the data in the figure, the following is programmed:

```

D2 ; Cutting edge compensations, i.e., $TC_DP3 to $TC_DP11 + wear
 ($TC_DP12 to $TC_DP20) + adapter dimension
...
DL=1 ; Sum offset 1 is added to the previous D2 compensations, i.e.,
 $TC_ECP13 + $TC_SCP13 to $TC_ECP21 + $TC_SCP21.
...
DL=2 ; Sum offset 2 is added to the D2 compensation instead of sum
 offset 1; i.e., $TC_ECP23 + $TC_SCP23,...$TC_ECP31 + $TC_SCP31
...
DL=0 ; Deselection of sum offset. Only the data of D2 remain active.

```

### Reading/writing in the part program

The individual sets of sum offset parameters are differentiated according to the number ranges of system variable \$TC\_SCP.

The significance of the individual variables is similar to geometry variables \$TC\_DP3 to \$TC\_DP11. Only length 1, length 2 and length 3 are enabled for the basic functionality (variables \$TC\_SCP13 to \$TC\_SCP15 for the first sum offset of the cutting edge).

```
R5 = $TC_SCP13[t, d] ; Sets the value of the R parameter to the value
 ; of the first component of sum offset 1 for
 ; cutting edge (d) on tool (t).

R6 = $TC_SCP21[t, d] ; Sets the value of the R parameter to the value
 ; of the last component of sum offset 1 for
 ; cutting edge (d) on tool (t).

R50 = $TC_SCP23[t, d] ; Sets the value of the R parameter to the value
 ; of the first component of sum offset 2 for
 ; cutting edge (d) on tool (t).

$TC_SCP43[t, d] = 1.234 ; Sets the value of the first component of sum
 ; offset 4 for cutting edge (d) on tool (t) to the
 ; value 1.234.
```

The above statements also apply to the setup offsets (if the NCK is configured with this option), i.e.,

```
R5 = $TC_ECP13[t, d] ; Sets the value of the R parameter to the value
 ; of the first component of setup offset 1 for
 ; cutting edge (d) on tool (t).

R6 = $TC_ECP21[t, d] ; Sets the value of the R parameter to the value
 ; of the last component of setup offset 1 for
 ; cutting edge (d) on tool (t).

etc.
```

When working with setup offsets, "sum offsets fine" are written with the \$TC\_SCPx system variables.

### Creating a new sum offset

If the compensation data set (x) does not yet exist, it is created on the first write operation to one of its parameters (y).

```
$TC_SCPxy[t, d] = r.r ; Parameter y of sum offset x is assigned the
 ; value "r.r.". The other parameters of x have a
 ; value of zero.
```

When working with setup offsets, "sum offsets fine" are written with the \$TC\_SCPx system variables.

---

#### Note

When working with setup offsets, the data set for the setup offset is created when a data set is created for "sum offset fine", if a data set did not already exist for [t, d].

---

### Creating a new setup offset

If the compensation data set (x) does not yet exist, it is created on the first write operation to one of its parameters (y).

```
$TC_ECPxy[t, d] = r.r ; The value "r.r" is assigned to the parameter y
 of setup offset x. The other parameters of x
 have the value zero.
```

---

#### Note

When working with setup offsets, the data set for the "sum offset fine" is created when a data set is created for setup offsets, if a data set did not already exist for [t, d].

---

### DELDL - Delete sum offset

Sum offsets are generally only relevant when machining with a cutting edge at a certain time at a certain location of the workpiece. You can use the NC language command `DELDL` to delete sum offsets from cutting edges (in order to release memory).

```
status = DELDL(t, d) ; Deletes all sum offsets for cutting edge d on tool t.
 ; t, d are optional parameters.
```

If d is not specified, all sum offsets of all cutting edges of tool t are deleted.

If d and t are not specified, all sum offsets for the cutting edges on all tools of the TO unit are deleted (for the channel, in which the command is programmed).

When working with setup offsets, the `DELDL` command deletes both the setup offset and the "sum offsets fine" of the specified cutting edge(s).

---

**Note**

The memory used for the data sets is released after deletion.

The deleted sum offsets can subsequently no longer be activated or programmed.

---

Sum offsets and setup offsets on active tools cannot be deleted (similar to the deletion of D compensations or tool data).

The "status" return value indicates the result of the deletion command:

|     |                                                                                          |
|-----|------------------------------------------------------------------------------------------|
| 0:  | Deletion was successful                                                                  |
| -1: | Deletion was not (one cutting edge) or not completely (several cutting edges) successful |

## Data backup

The data are saved during a general tool-data backup (as a component of the D number data sets).

It is advisable to save the sum offsets, in order to allow the current status to be restored in the event of an acute problem. Machine data settings can be made to exclude sum offsets from a data backup (settings can be made separately for "setup offsets" and "sum offsets fine").

---

**Note**

Sum offsets behave in the same way as D compensations with reference to block search and REPOS. The behavior on Reset and PowerOn can be defined by machine data.

If the setting of the following machine data indicates that the last active tool compensation number (D) is to be activated after PowerOn, the last active DL number is then no longer active:

MD20110 \$MC\_RESET\_MODE\_MASK (definition of initial control system settings after RESET/TP end)

---

## 18.11.4 Examples

### Example 1

That no compensation and no sum offset will come into effect must be defined during tool change via the machine data:

- MD20270 \$MC\_CUTTING\_EDGE\_DEFAULT=0 (Basic setting of tool cutting edge without programming)
- MD20272 \$MC\_SUMCORR\_DEFAULT=0 (default setting sum offset without program).

```
T5 M06 ; Tool number 5 is loaded - no compensation active.
D1 DL=3 ; Compensation D1 + sum offset 3 of D1 are activated.
X10
DL=2 ; Compensation D1 + sum offset 2 are activated.
X20
DL=0 ; Sum offset deselection, only compensation D1 is now active.
D2 ; Compensation D2 is activated - the sum offset is not included
 ; in the compensation.
X1
DL=1 ; Compensation D2 + sum offset 1 are activated.
X2
D0 ; Compensation deselection
X3
DL=2 ; No effect - DL2 of D0 is zero (same as programming T0 D2).
```

### Example 2

During tool change it has to be defined that offset `D2` and sum offset `DL=1` are activated via the machine data:

MD20270 \$MC\_CUTTING\_EDGE\_DEFAULT=2 (Basic setting of tool cutting edge without programming)

MD20272 \$MC\_SUMCORR\_DEFAULT=1 (default setting sum offset without program)

```
T5 M06 ; Tool number 5 is loaded - D2 + DL=1 are active (= values of
 ; machine data)
D1 DL=3 ; Compensation D1 + sum offset 3 of D1 are activated.
X10
DL=2 ; Compensation D1 + sum offset 2 are activated.
X20
DL=0 ; Sum offset deselection, only compensation D1 is now active.
D2 ; Compensation D2 is activated - sum offset DL=1 is activated.
X1
DL=2 ; Compensation D2 + sum offset 2 are activated.
D1 ; Compensation D1 + sum offset 1 are activated.
```

### 18.11.5 Upgrades for tool length determination

#### 18.11.5.1 Taking the compensation values into account location-specifically and workpiece-specifically

#### Composition of the effective tool length

For a tool compensation without active kinematic transformation, the effective tool length consists of up to 8 vectors:

- Tool length (geometry) (\$TC\_DP3 - \$TC\_DP5)
- Wear (\$TC\_DP12 - \$TC\_DP14)
- Tool base dimension (see note) (\$TC\_DP21 - \$TC\_DP23)
- Adapter dimension (see note) (\$TC\_ADPT1 - \$TC\_ADPT3)
- Total offsets fine (\$TC\_SCPx3 - \$TC\_SCPx5)
- Sum offsets coarse or setup offsets (\$TC\_ECPx3 - \$TC\_ECPx5)
- Offset vector I<sub>1</sub> of toolholder with orientation capability (\$TC\_CARR1 - \$TC\_CARR3)
- Offset vector I<sub>2</sub> of toolholder with orientation capability (\$TC\_CARR4 - \$TC\_CARR6)
- Offset vector I<sub>3</sub> of toolholder with orientation capability (\$TC\_CARR15 - \$TC\_CARR17)

---

#### Note

The tool base dimension and adapter dimension can only be applied as alternatives.

---

#### Type of action of the individual vectors

The type of action of the individual vectors or groups of vectors depends on the following further quantities:

| Influencing quantity                   | Operating principle                                                                               |
|----------------------------------------|---------------------------------------------------------------------------------------------------|
| G codes                                | Active processing level                                                                           |
| Tool type                              | Milling tool or turning/grinding tools                                                            |
| Machine data                           | Tool management active/not active, toolholder with orientation capability available/not available |
| Setting data                           | Behavior of tool length components when mirroring or when changing the plane                      |
| Toolholder with orientation capability | Set values of toolholder with orientation capability                                              |
| Adapter transformations                | Transformed tool compensation values                                                              |

## Distribution over the geometry-axis components

How the three vector components of partial totals of the vectors involved are distributed over the three geometry-axis components is determined by the following quantities:

| Influencing quantity                                                                                                                                                                           | dependencies                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Active processing level:<br>G17 X/Y direction<br>G18 Z/X direction<br>G19 Y/Z direction                                                                                                        | Infeed plane:<br>Z<br>Y<br>X                                                    |
| Tool type:<br>Milling tools, drilling tools, grinding tools, turning tools                                                                                                                     | See:<br>Section "Tool type", Table "Minimum number of required tool parameters" |
| SD42900 \$SC_MIRROR_TOOL_LENGTH<br>SD42910 \$SC_MIRROR_TOOL_WEAR<br>SD42920 \$SC_WEAR_SIGN_CUTPOS<br>SD42930 \$SC_WEAR_SIGN<br>SD42940 \$SC_TOOL_LENGTH_CONST<br>SD42950 \$SC_TOOL_LENGTH_TYPE | See:<br>Sections "Special handling of tool compensations" and "Setting data".   |
| Adapter transformations                                                                                                                                                                        | See: "FB Tool management"                                                       |

The resulting tool orientation always remains parallel to one of the three axis directions X, Y or Z and exclusively depends on the active machining plane G17-G19, since it has not yet been possible to assign the tool an orientation.

## Stepless variation of the tool orientation

The toolholder with orientation capability also enables the tool orientation to be varied steplessly, in addition to providing further offsets or linear expansion fluctuations with the aid of offset vectors  $l_1 - l_3$ .

For more information, see:

### References:

/FB1/ Function Manual Basic Functions; Tool Offset (W1),  
Section: Toolholder with orientation capability

## Minor operator compensations

Minor compensations, however, must also be modified during the normal production mode.

The reasons for this are e.g.:

- Tool wear
- Clamping errors
- Temperature sensitivity of the machine:

These compensations are defined as follows:

| Definition                          | Wear components          |
|-------------------------------------|--------------------------|
| Wear                                | \$TC_DP12 - \$TC_DP14,   |
| Total offsets fine                  | \$TC_SCPx3 - \$TC_SCPx5, |
| Sum offsets coarse or setup offsets | \$TC_ECPx3 - \$TC_ECPx5  |

In particular, compensations, which affect the tool length calculation, should be entered in the coordinates used for measurement.

These workpiece-specific compensations can be achieved more simply using the G-code group 56 with the three values `TOWSTD`, `TOWMCS` and `TOWWCS` and the setting data:

SD42935 \$SC\_WEAR\_TRANSFORM (transformation of tool components)

### SD42935

Which of the wear components:

- Wear (\$TC\_DP12 - \$TC\_DP14)
- Setup offsets or sum offsets coarse (\$TC\_ECPx3 - \$TC\_ECPx5)
- Sum offsets fine (\$TC\_SCPx3 - \$TC\_SCPx5)

are to be transformed in the transformations:

- Adapter transformation
- Toolholder with orientation capability

or not to be transformed, can be defined via the setting data:

SD42935 \$SC\_WEAR\_TRANSFORM (transformation of wear values)

With the setting data in its initial state, all wear values are transformed.

The setting data is considered in the following functions:

- Wear values in the machine coordinate system

Part program instruction: TOWMCS

- Wear values in the workpiece coordinate system

Part program instruction: TOWWCS

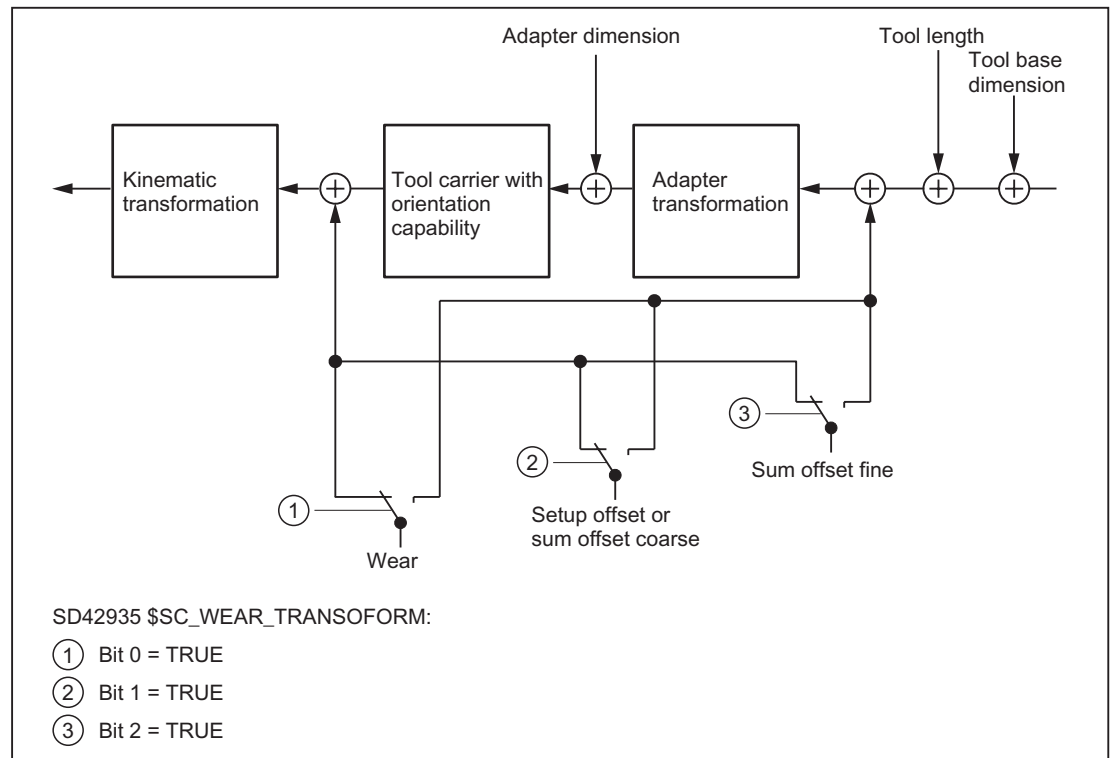

Figure 18-52 Transformation of wear data dependent on SD42935

## Programming

G-code group 56 can be used to define the following values:

| Syntax | Corrections                                                                                        |
|--------|----------------------------------------------------------------------------------------------------|
| TOWSTD | Initial setting value for offsets in tool length                                                   |
| TOWMCS | Wear data in the machine coordinate system (MCS)                                                   |
| TOWWCS | Wear values in workpiece coordinate system (WCS)                                                   |
| TOWBCS | Wear values in basic coordinate system (BCS)                                                       |
| TOWTCS | Wear values in the TCS (Tool Coordinate System) at the toolholder (tool carrier reference point T) |
| TOWKCS | Wear values in tool coordinate system for kinematic transformation (KCS) of tool head              |

### Coordinate systems for offsets in tool length

G codes `TOWMCS`, `TOWWCS`, `TOWBCS`, `TOWTCS` and `TOWKCS` can be used, e.g. to measure the wear tool length component in five different coordinate systems.

- |                                                       |     |
|-------------------------------------------------------|-----|
| 1. Machine coordinate system                          | MCS |
| 2. Basic coordinate system                            | BCS |
| 3. Workpiece coordinate system                        | WCS |
| 4. Tool coordinate system of kinematic transformation | KCS |
| 5. Tool coordinate system                             | TCS |

The calculated tool length or a tool length component can be represented and read out in one of these coordinate systems using the `GETTCOR` function (predefined subprogram).

Section: Read tool lengths, tool length components

Figure 18-53 Coordinate system for the evaluation of tool lengths

### 18.11.5.2 Functionality of the individual wear values

#### TOWSTD

Initial setting (default behavior):

- The wear values are added to the other tool length components.  
The resulting total tool length is then used in further calculations.

In the case of an active toolholder with orientation capability:

- The wear values are subjected to the appropriate rotation.

#### TOWMCS

Wear data in the MCS (machine coordinate system):

In the case of an active rotation by means of a toolholder with orientation capability:

- The toolholder only rotates the vector of the resultant tool length. Wear is ignored.

Then the tool length vector rotated in this way and the wear are added. The wear is not subjected to the rotation.

If **no** toolholder with orientation capability is active or this does not result in a rotation, `TOWMCS` and `TOWSTD` are identical.

#### Linear transformation

The tool length can be uniquely defined in the MCS only if the MCS is generated by linear transformation from the BCS.

This would be the case when:

- no kinematic transformation is active
- or orientation transformations (3-axis, 4-axis and 5-axis transformations) are active.

#### TOWWCS

Wear values in WCS (workpiece coordinate system):

- If a toolholder with orientation capability is active, the tool vector is calculated as for `TOWMCS`, without taking the wear into account.
- The wear data are interpreted in the workpiece coordinate system.

The wear vector in the workpiece coordinate system is converted to the machine coordinate system and added to the tool vector.

## TOWBCS

Wear values in BCS (basic coordinate system):

- If a toolholder with orientation capability is active, the tool vector is calculated as for  $TOWMCS$ , without taking the wear into account.
- The wear data are interpreted in the workpiece coordinate system.

The wear vector in the basic coordinate system is converted to the workpiece coordinate system and added to the tool vector.

### Nonlinear transformation

If a nonlinear transformation is active, e.g., with  $TRANSMIT$ , and the MCS is specified as the desired coordinate system, the BCS is automatically used instead of the MCS.

### Toolholder with orientation capability

A table component of the toolholder with orientation capability, if available, is not applied directly to the coordinate systems, unlike a table (or part) component of the kinematic transformation. A rotation described by such a component is represented in a basic frame or system frame and is thus included in the transition from WCS to BCS.

### Kinematic transformation

The table (or part) component of the kinematic transformation is described by the transition from BCS to MCS.

## TOWTCS

Wear values in TCS (tool coordinate system):

- If a toolholder with orientation capability is active, the tool vector is calculated as for  $TOWMCS$ , without taking the wear into account.
- The wear data are interpreted in the tool coordinate system.

The wear vector in the TCS (Tool Coordinate System) is converted to the machine coordinate system by way of the tool coordinate system of the kinematic transformation (KCS) and added to the tool vector.

## TOWKCS

The wear value specifications for the kinematic transformation are interpreted in the associated TCS (Tool Coordinate System).

The wear vector is converted to the machine coordinate system by way of the tool coordinate system of the kinematic transformation and added to the tool vector.

## G code change when a tool is active

Changing the G code in the group TOWSTD, TOWMCS, TOWWCS, TOWBCS, TOWTCS, and TOWKCS does not affect an already active tool, and does not become effective until the next tool is selected.

A new G code of this group will also come into effect if it is programmed in the same block, in which a tool is selected.

## Evaluation of individual wear components

Evaluation of individual wear components (assignment to geometry axes, sign evaluation) is influenced by:

- The active plane
- The adapter transformation
- The five setting data shown in the table below:

| Setting Data                   | Wear components |        |        |
|--------------------------------|-----------------|--------|--------|
|                                | TOWSTD          | TOWMCS | TOWWCS |
| SD42910 \$SC_MIRROR_TOOL_WEAR  |                 |        |        |
| SD42920 \$SC_WEAR_SIGN_CUTPOS  | X               | X      | —      |
| SD42930 \$SC_WEAR_SIGN         | X               | —      | —      |
| SD42940 \$SC_TOOL_LENGTH_CONST | X               | X      | X      |
| SD42950 \$SC_TOOL_LENGTH_TYPE  | X               | X      | X      |

### Note

Wear components, which are subjected to an active rotation by an adapter transformation or a toolholder with orientation capability, are referred to as non-transformed wear components.

### Special points to be noted

If `TOWMCS` or `TOWWCS` is active, the following setting data does not affect the non-transformed wear components:

SD42920 `$SC_WEAR_SIGN_CUTPOS` (Sign of wear for tools with cutting edge systems)

The following setting data also does not affect the non-transformed wear components in case of `TOWWCS`:

SD42910 `$SC_MIRROR_TOOL_WEAR` (Sign change tool wear when mirroring)

In this case, a possibly active mirroring is already contained in the frame, which is referred to for evaluating the wear components.

On a plane change, the assignment between the non-transformed wear components and the geometry axes is retained, i.e., these are not interchanged as with other length components. The assignment of components depends on the active plane for tool selection.

### Example

Let's assume a milling tool is used where only the wear value `$TC_DP12` assigned to length L1 is not equal to zero.

If `G17` is active, this length is effective in the direction of the Z axis.

This measure always acts in the Z-direction also upon a plane change after the tool selection, when `TOWMCS` or `TOWWCS` are active and the bit 1 is set in the setting data:

SD42935 `$SC_WEAR_TRANSFORM` (transformations for tool components)

If, for example, `G18` is active on tool selection, the component is always effective in the Y direction instead.

## 18.12 Working with tool environments

### 18.12.1 General

#### Functions

The current states of tool data can be processed using the functions below, which are generally available:

- Save
- Deletion
- Read
- Modify

A further function can be used to determine information about the assignment of the tool lengths of the active tool to the abscissa, ordinate and applicate.

### 18.12.2 Saving with TOOLENV

#### Scope of a tool environment

The `TOOLENV` memory function is used to save any current states needed for the evaluation of tool data stored in the memory.

The individual data are as follows:

- The active G code of group 6 (`G17, G18, G19`)
- The active G code of group 56 (`TOWSTD, TOWMCS, TOWWCS, TOWBCS, TOWTCS, TOWKCS`)
- The active transverse axis
- Machine data:
  - MD18112 `$MN_MM_KIND_OF_SUMCORR` (Properties of sum offsets in the TO area)
- Machine data:
  - MD20360 `$MC_TOOL_PARAMETER_DEF_MASK` (definition of tool parameters).
- Setting data:
  - SD42900 `$SC_MIRROR_TOOL_LENGTH` (Sign change tool length when mirroring)
- Setting data:
  - SD42910 `$SC_MIRROR_TOOL_WEAR` (Sign change tool wear when mirroring)

- Setting data:  
SD42920 \$SC\_WEAR\_SIGN\_CUTPOS (Sign of wear for tools with cutting edge systems)
- Setting data:  
SD42930 \$SC\_WEAR\_SIGN (sign of wear)
- Setting data:  
SD42935 \$SC\_WEAR\_TRANSFORM (transformations for tool components)
- Setting data:  
SD42940 \$SC\_LENGTH\_CONST (change of tool components on change of planes)
- Setting data:  
SD42950 \$SC\_TOOL\_LENGTH\_TYPE (allocation of the tool length components independent of tool type)
- The orientation component of the current complete frame (rotation and mirroring, no work offsets or scales)
- The orientation component and the resulting length of the active toolholder with orientation capability
- The orientation component and the resulting length of an active transformation
- In addition to the data describing the environment of the tool, the T number, D number and DL number of the active tool are also stored, so that the tool can be accessed later in the same environment as the `TOOLENV` call, without having to name the tool again.

### Not in the tool environment

The value of the machine data determines whether the adapter length or the tool base dimension is included in the tool length calculation:

MD18104 \$MN\_MM\_NUM\_TOOL\_ADAPTER (tool adapter in TO area).

Since a change to this machine data only takes effect after Power On, it is not saved in the tool environment.

---

#### Note

Resulting length of **toolholders with orientation capability** and **transformations**:

Both toolholders with orientation capability and transformations can use system variables or machine data, which act as additional tool length components, and which can be subjected partially or completely to the rotations performed. The resulting additional tool length components must also be stored when `TOOLENV` is called, because they represent part of the environment, in which the tool is used.

---

#### Adapter transformation:

The adapter transformation is a property of the tool adapter and thus of the complete tool. It is, therefore, not part of a tool environment, which can be applied to another tool.

By saving the complete data necessary to determine the overall tool length, it is possible to calculate the effective length of the tool at a later point in time, even if the tool is no longer active or if the conditions of the environment (e.g., G codes or setting data) have changed. Similarly, the effective length of different tool can be calculated assuming that it would be used under the same conditions as the tool, for which the status was saved.

## TOOLENV function

Saving a tool environment

The `TOOLENV` function is a predefined subprogram. It must, therefore, be programmed in a separate block.

*Syntax:*

**Status = TOOLENV(\_NAME)**

*Value/parameter:*

**Status**                   INT

0:    Function OK

-1:    No memory reserved for tool environments:

MD18116 \$MN\_MM\_NUM\_TOOL\_ENV = 0 (number of tool environments in TO area).

i.e. the "tool environments" functionality is not available.

-2:    No more free memory locations for tool environments available.

-3:    Null string illegal as name of a tool environment.

-4:    No parameter (name) specified.

**\_NAME**                    STRING

Name, under which the current data set is stored.

If a data set of the same name already exists, it is overwritten. In this case, the status is 0.

### 18.12.3 Delete tool environment

#### DELTOOLENV function

This function can be used to delete sets of data used to describe tool environments. Deletion means that the set of data stored under a particular name can no longer be accessed (an access attempt triggers an alarm).

The `DELTOOLENV` function is a predefined subprogram.

It must, therefore, be programmed in a separate block.

*Syntax:*

There are two call formats:

**Status = DELTOOLENV()**

**Status = DELTOOLENV(\_NAME)**

*Value/parameter:*

**Status**                    INT

0:    Function OK

-1:   No memory reserved for tool environments:

MD18116 \$MN\_MM\_NUM\_TOOL\_ENV = 0 (number of tool environments in TO area).

i.e. the "tool environments" functionality is not available.

-2:   A tool environment with the specified name does not exist.

**\_NAME**                    STRING

Name of data set to be deleted.

The first call format deletes all data sets.

The second call format deletes the data set with the specified name.

Data sets can only be deleted using the `DELTOOLENV` command, by an INITIAL.INI download or by a cold start (NCK powerup with default machine data). There are no further automatic deletion operations (e.g., on `RESET`).

## 18.12.4      How many environments and which ones are saved?

### **\$P\_TOOLENVN**

This system variable returns the number of available data sets for describing tool environments. (Data sets defined by `TOOLENV` and not yet deleted.)

The value range is from 0 to machine data:

MD18116 \$MN\_MM\_NUM\_TOOL\_ENV (number of tool environments in TO area).

This system variable can be accessed even if no tool environments are possible (MD18116 = 0). In this case, the return value is 0.

*Syntax:*

**\_N = \$P\_TOOLENVN**

*Data type:*

**\_N**                        INT

Number of defined `TOOLENV`.

## \$P\_TOOLENV

This system variable returns the number of the nth data set for describing a tool environment.

The assignment of numbers to data sets is not fixed, but can be changed as a result of deleting or creating data sets. The data sets are numbered internally. The range is from 1 to \$P\_TOOLENVN.

*Syntax:*

```
_NAME = $P_TOOLENV[i]
```

*Data type:*

**\_NAME**                    STRING

Name of the data set with number i

**i**                            INT

Number of the data set.

If an index is specified, which does not point to a defined data set, the following alarm is output:

Alarm "17020 (inadmissible array-index1)"

## 18.12.5 Read T, D, DL from a tool environment

### GETTENV function

The `GETTENV` function is used to read the T, D and DL numbers stored in a tool environment.

The `GETTENV` function is a predefined subprogram. It must, therefore, be programmed in a separate block.

*Syntax:*

```
Status = GETTENV(_NAME, _TDDL)
```

*Value/parameter:*

**Status**                    INT

**0:**    Function OK

**-1:**    No memory reserved for tool environments:

MD18116 \$MN\_MM\_NUM\_TOOL\_ENV = 0 (number of tool environments in TO area).

i.e. the "tool environments" functionality is not available.

**-2:**    A tool environment with the name specified in **\_NAME** does not exist.

**\_NAME**                    STRING

Name of the tool environment, from which the T, D and DL numbers can be read.

**\_TDDL[3]**            INT

This integer array contains:

- in "\_TDDL[0]" the T number of the tool,
- in "\_TDDL[1]" the D number of the tool,
- in "\_TDDL[2]" the DL number of the tool,

whose tool environment in the data set is stored with the name "\_NAME".

It is possible to omit the first parameter in the `GETTENV` function call (e.g., `GETTENV(, _TDDL)`) or to pass a null string as the first parameter (e.g., `GETTENV("", _TDDL)`). In both of these two special cases, the T, D and DL numbers of the **active** tool are returned in `_TDDL`.

## 18.12.6 Read tool lengths, tool length components

### GETTCOR function

The `GETTCOR` function is used to read out tool lengths or tool length components.

The parameters can be used to specify, which components are considered, and the conditions, under which the tool is used.

The `GETTCOR` function is a predefined subprogram. It must, therefore, be programmed in a separate block.

#### *Syntax:*

**Status = GETTCOR(\_LEN, \_COMP, \_STAT, \_T, \_D, \_DL)**

All parameters can be omitted with the exception of the first parameter (`_LEN`).

#### *Value/parameter:*

**Status**            INT

- 0:** Function OK
- 1:** No memory reserved for tool environments:  
MD18116 \$MN\_MM\_NUM\_TOOL\_ENV = 0 (number of tool environments in TO area).  
i.e. the "tool environments" functionality is not available.
- 2:** A tool environment with the name specified in `_STAT` does not exist.
- 3:** Invalid string in parameter `_COMP`.  
Causes of this error can be invalid characters or characters programmed twice.
- 4:** Invalid T number

- 5: Invalid D number
- 6: Invalid DL number
- 7: Attempt to access non-existent memory module
- 8: Attempt to access a non-existent option (programmable tool orientation, tool management).
- 9: The **\_COMP** string contains a colon (identifier for the specification of a coordinate system), but it is not followed by a valid character denoting the coordinate system.

### **\_LEN[11]** REAL

Result vector

The vector components are arranged in the following order:

|                        |          |
|------------------------|----------|
| Tool type              | (LEN[0]) |
| Length of cutting edge | (LEN[1]) |
| Abscissa               | (LEN[2]) |
| Ordinate               | (LEN[3]) |
| Applicate              | (LEN[4]) |
| Tool radius            | (LEN[5]) |

The coordinate system defined in **\_COMP** and **\_STAT** is used as the reference coordinate system for the length components. If no coordinate system is defined in **\_COMP**, the tool lengths are represented in the machine coordinate system.

The assignment of the abscissa, ordinate and applicate to the geometry axes depends on the active plane in the tool environment, i.e. with **G17**, the abscissa is parallel to X, with **G18** it is parallel to Z, etc.

Components **LEN[6]** to **LEN[10]** contain the additional parameters, which can be used to specify the geometry description of a tool (e.g. **\$TC\_DP7** to **\$TC\_DP11** for the geometry and the corresponding components for wear or sum and setup offsets).

These 5 additional elements and the tool radius are only defined for components E, G, S, and W. Their evaluation does not depend on **\_STAT**. The corresponding values in **LEN[5]** to **LEN[10]** can thus only be not equal to zero if at least one of the four specified components is involved in the tool length calculation. The remaining components do not influence the result. The dimensions refer to the control's basic system (inch or metric).

**\_COMP**

STRING

This string consists of two substrings, which are separated from one another by a **colon**.

The individual characters (letters) of the **first substring** identify the tool length components to be taken into account when calculating the tool length.

The **second substring** identifies the coordinate system, in which the tool length is to be output. It consists of only one single relevant character.

The order of the characters in the strings, and their notation (upper or lower case), is arbitrary. Any number of blanks or white spaces can be inserted between the characters.

The letters in the substrings **cannot** be programmed twice. The meanings in the **first substring** are as follows:

- : (Minus symbol, only allowed as first character): The complete tool length is calculated, minus the components specified in the next string.
- C: Adapter or tool base dimension (whichever of the two alternative components is active for the tool in use)
- E: Setup offsets
- G: Geometry
- K: Kinematic transformation (is only evaluated for generic 3, 4 and 5-axis transformation)
- S: Sum offsets
- T: Toolholder with orientation capability
- W: Wear

If the first substring is empty (except for white spaces), the complete tool length is calculated allowing for all components. This applies even if the **\_COMP** parameter is not specified.

An optional programmable colon must be followed by a single character specifying the coordinate system, in which the tool length components are to be evaluated. If no coordinate system is specified, the evaluation is performed in the MCS (machine coordinate system). If any rotations are to be taken into account, they are specified in the tool environment defined in **\_STAT**.

The characters have the following significance:

- B: Basic coordinate system (BCS)
- K: Tool coordinate system of kinematic transformation (KCS)
- M: Machine coordinate system (MCS)
- T: Tool coordinate system (TCS)
- W: Workpiece coordinate system (WCS)

**\_STAT**                      STRING

Name of the data set for describing a tool environment.

If the value of this parameter is the null string ("") or is not specified, the current status is used.

**\_T**                              INT

Internal T number of tool

If this parameter is not specified, or if its value is 0, the tool stored in **\_STAT** is used.

If the value of this parameter is -1, the T number of the active tool is used. It is also possible to specify the number of the active tool explicitly.

---

### Note

If **\_STAT** is not specified, the current status is used as the tool environment. Since **\_T = 0** refers to the T number saved in the tool environment, the active tool is used in that environment, i.e. parameters **\_T = 0** and **\_T = -1** have the same meaning in this special case.

---

**\_D**                              INT

Cutting edge of the tool. If this parameter is not specified, or if its value is 0, the D number used is based on the source of the T number. If the T number from the tool environment is used, the D number of the tool environment is also read, otherwise the D number of the currently active tool is read.

**\_DL**                             INT

Number of the local compensation. If this parameter is not specified, the DL number used is based on the source of the T number. If the T number from the tool environment is used, the D number of the tool environment is also read, otherwise the D number of the currently active tool is read.

Any rotations and component exchanges initiated by the adapter transformation, toolholder with orientation capability and kinematic transformation, are part of the tool environment. They are thus always performed, even if the corresponding length component is not supposed to be included. If this is undesirable, tool environments must be defined, in which the corresponding transformations are not active. In many cases (i.e. any time a transformation or toolholder with orientation capability is not used on a machine), the data sets stored for the tool environments automatically fulfill these conditions, with the result that the user does not need to make special provision.

### MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK

The two least significant bits of this machine data specify how the wear (bit 0) and tool length (bit 1) are to be evaluated if a diameter axis is used for turning and grinding tools.

If the bits are set, the associated entry is weighted with the factor 0.5. This weighting is reflected in the tool length returned by `GETTCOR`.

**Example:**

MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK = 3 (definition of tool parameters).

MD20100 \$MC\_DIAMETER\_AX\_DEF="X" (Geometry axis with face axis function)

X is diameter axis (standard turning machine configuration):

```

N30 $TC_DP1[1.1] = 500
N40 $TC_DP2[1.1] = 2
N50 $TC_DP3[1.1] = 3.0 ; Geometry L1

### Kinematic transformation, toolholder with orientation capability

If a toolholder with orientation capability is taken account of during the tool length calculation, the following vectors are included in that calculation:

| Type | Vectors                                                                      |
|------|------------------------------------------------------------------------------|
| M    | $l_1$ and $l_2$                                                              |
| T    | $l_1$ , $l_2$ and $l_3$                                                      |
| P    | Tool length is not influenced by the toolholder with orientation capability. |

In generic **5-axis transformation**, the following machine data are included in the tool length calculation for transformer types 24 and 56:

| Transformer type | Machine data                                                                                                                       |
|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 24               | MD24550/24650 \$MC_TRAFO5_BASE_TOOL_1/2<br>MD24560/24660 \$MC_TRAFO5_JOINT_OFFSET_1/2<br>MD24558/24658 \$MC_TRAFO5_PART_OFFSET_1/2 |
| 56               | MD24550/24650 \$MC_TRAFO5_BASE_TOOL_1/2<br>MD24560/24660 \$MC_TRAFO5_JOINT_OFFSET_1/2                                              |

Transformation type 56 corresponds to type M for a toolholder with orientation capability.

With this 5-axis transformation in the software versions used up to now, the following vector is equivalent to the sum of the two vectors  $l_1$  and  $l_3$  for a toolholder with orientation capability type M.

MD24560/24660 \$MC\_TRAFO5\_JOINT\_OFFSET\_1/2 (vector of kinematic offset of the first/second 5-axis transformation in the channel)

Only the sum is relevant for the transformation in both cases. The way, in which the two individual components are composed, is insignificant. When calculating the tool length, however, it is relevant which component is assigned to the tool and which is assigned to the tool table.

This explains the introduction of new machine data:

MD24558/24658 \$MC\_TRAFO5\_JOINT\_OFFSET\_PART\_1/2 (vector kinematic offset in table).

It is equivalent to the vector  $l_3$ .

The following machine data no longer corresponds to the sum of  $l_1$  and  $l_3$ , but only to vector  $l_1$ .

MD24560/24660 \$MC\_TRAFO5\_JOINT\_OFFSET\_1/2 (vector of kinematic offset of the first 5-axis transf. in the channel).

The new response is identical to the current response, if the following machine data equals zero:

MD24558/24658 \$MC\_TRAFO5\_JOINT\_OFFSET\_PART\_1/2 (vector kinematic offset in table).

### GETTCOR examples

|                                            |                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GETTCOR(_LEN):</b>                      | Calculates the tool length of the currently active tool in the machine coordinate system allowing for all components.                                                                                                                                                                            |
| <b>GETTCOR(_LEN; "CGW : W" ):</b>          | Calculates the tool length for the active tool, consisting of the adapter or tool base dimension, geometry and wear. Further components, such as toolholder with orientation capability or kinematic transformation, are not considered. The workpiece coordinate system is used for the output. |
| <b>GETTCOR(_LEN, "-K :B" ):</b>            | Calculates the complete tool length of the active tool without allowing for the length components of an active kinematic transformation. Output in the basic coordinate system.                                                                                                                  |
| <b>GETTCOR(_LEN, ":M", "Testenv1",,3):</b> | Calculates the complete tool length in the machine coordinate system for the tool stored in the tool environment named "Testenv1". The calculation is performed for cutting edge number D3, regardless of the cutting edge number stored.                                                        |

### Compatibility

The `GETTCOR` function is used in conjunction with the `TOOLENV` and `SETTCOR` functions to replace parts of the functionality, which were previously implemented externally in the measuring cycles.

Only some of the parameters, which actually determine the effective tool length, were implemented in the measuring cycles. The above functions can be configured to reproduce the behavior of the measuring cycles in relation to the tool length calculation.

## 18.13 Tool lengths L1, L2, L3 assignment: LENTOAX

### LENTOAX function

The "LENTOAX" function provides information about the assignment of tool lengths  $L_1$ ,  $L_2$  and  $L_3$  of the **active** tool to the abscissa, ordinate and applicate. The assignment of abscissa, ordinate and applicate to the geometry axes is affected by frames and the active plane (G17 - G19).

Only the geometry component of a tool (\$TC\_DP3[x,y] to \$TC\_DP5[x,y]) is considered, i.e., a different axis assignment for other components (e.g., wear) has no effect on the result.

The "LENTOAX" function is a predefined subprogram. It must, therefore, be programmed in a separate block.

#### Syntax:

**Status = LENTOAX(\_AXIND, \_MATRIX, \_COORD)**

The first two parameters must always be programmed; the last parameter can be omitted.

#### Value/parameter:

**Status** INT

- 0: Function OK, information in **\_AXIND** sufficient for description (all tool length components are parallel to the geometry axes).
- 1: Function is OK, however, the content of **\_MATRIX** must be evaluated for a correct description (the tool length components are not parallel to the geometry axes).
- 1: Invalid string in parameter **\_COORD**.
- 2: No tool active.

**\_AXIND[3]** INT array

Indices 0 to 2 are assigned to the abscissa (0), ordinate (1) and applicate (2) (e.g., **\_AXIND[0]** contains the number of the tool length components, which are effective in the direction of the abscissa).

The content has the following significance:

- 0: Assignment exists (axis does not exist)
- 1 to 3: Number of the length effective in the corresponding coordinate axis. The sign is negative if the tool length component is pointing in the negative coordinate direction.
- 1 to -3: coordinate direction.

**\_MATRIX[3][3]**      REAL      array

Matrix, which represents the vector of the tool lengths ( $L_1=1$ ,  $L_2=1$ ,  $L_3=1$ ) to the vector of the coordinate axes (abscissa, ordinate, applicate), i.e., the tool length components are assigned to the **columns** in the order  $L_1$ ,  $L_2$ ,  $L_3$  and the axes are assigned to the **lines** in the order abscissa, ordinate, applicate.

All elements are always valid in the matrix, even if the geometry axis belonging to the coordinate axis is not available, i.e., if the corresponding entry in **\_AXIND** is 0.

**\_COORD**      STRING

Specifies the coordinate system used for the assignment.

**MCS** or **M**:      The tool length is represented in the machine coordinate system.

**BCS** or **B**:      The tool length is represented in the basic coordinate system.

**WCS** or **W**:      The tool length is represented in the workpiece coordinate system (default).

**KCS** or **K**:      The tool length is represented in the tool coordinate system of the **kinematic transformation**.

**TCS** or **T**:      The tool length is represented in the tool coordinate system.

The notation of the characters in the string (upper or lower case) is arbitrary.

## Further explanations

If the tool length components are parallel to the geometry axes, the axis indices assigned to length components  $L_1$  to  $L_3$  are returned in the **\_AXIND** array.

If a tool length component points in the negative axis direction, the associated axis index contains a minus sign. In this case, the return value (**status**) is 0. If an axis does not exist, the associated return value is 0. The assignment can also be read from the **\_MATRIX** parameter. Six of the nine matrix elements are then zero, and three elements contain the value +1 or -1.

---

### Note

In the TCS, all tool length components are always parallel or antiparallel to the axes.

The components can only be antiparallel when mirroring is active and the following setting data is activated:

SD42900 \$SC\_MIRROR\_TOOL\_LENGTH (Sign change tool length when mirroring)

---

If not all length components are parallel or antiparallel to the geometry axes, the index of the axis, which contains the largest part of a tool length component, is returned in **\_AXIND**. In this case (if the function does not return an error for a different reason), the return value is 1. The mapping of tool length components  $L_1$  to  $L_3$  onto geometry axes 1 to 3 is then described completely by the contents of the 3rd parameter **\_MATRIX**.

The **\_COORD** parameter can be used to specify, which coordinate system is to be used for the geometry axes. If the **\_COORD** parameter is not specified (notation **LENTOAX(\_AXIND, \_MATRIX)**), the **WCS** is used (default).

**Example:**

Standard situation: milling tool with **G17**

**L1** applies in Z (applicate), **L2** applies in Y (ordinate), **L3** applies in X (abscissa).

Function call in the form:

**Status = LENTOAX(\_AXIND, \_MATRIX, "WCS")**

The result parameter **\_AXIND** contains the values:

**\_AXIND[0] = 3**

**\_AXIND[1] = 2**

**\_AXIND[2] = 1**

Or, in short: ( 3, 2, 1)

In this case, the associated matrix **\_MATRIX** is:

$$\text{\_MATRIX} = \begin{matrix} & & 1 \\ & 1 & \\ 1 & & \end{matrix}$$

A change from **G17** to **G18** or **G19** does not alter the result, because the assignment of the length components to the geometry axes changes in the same way as the assignment of the abscissa, ordinate and applicate.

A frame rotation of Z through 60 degrees is now programmed with **G17** active, e.g., **rot Z60**. The direction of the applicate (Z direction) remains unchanged; the main component of **L2** now lies in the direction of the new X axis; the main component of **L1** now lies in the direction of the negative Y axis. The return axis is thus 1, and **\_AXIND** contains the values (2, -3, 1).

In this case, the associated matrix **\_MATRIX** is:

$$\text{\_MATRIX} = \begin{matrix} & \text{sn}(\ ) & \text{s}(\ ) \\ & \text{s}(\ ) & \text{sn}(\ ) \\ 1 & & \end{matrix}$$

**Note**

## 18.14 Supplementary conditions

### 18.14.1 Flat D number structure

#### Grinding tools

Grinding tools (tool types 400-499) cannot be defined using the simple tool management structure (flat D numbers).

#### Block search

T number output to PLC triggers a synchronization process in the NCK: with absolute, indirect D programming, the PLC returns the D values via VDI. The NCK waits until the output of a T number is followed by a response from the PLC: "I have written the D number". With block search without calculation, this process of synchronization must be deactivated until the first valid T number has been output again. That means that the NCK must not wait on D programming.

---

#### Note

At what point the auxiliary functions can be output to PLC after block search is complete, can be controlled with the machine data:

\$MC\_AUXFU\_AT\_BLOCK\_SEARCH\_END (auxiliary function output after block search)

Automatic on end or on NC start.

---

#### REORG

The (only) writable variable \$A\_MONIFACT, which is defined here, is stored by main-run data. Since the write process takes place synchronously to the main run, no special measures are required for Reorg.

### 18.14.2 SD42935 expansions

#### SD42935

Which of the wear components are to be transformed and which are not to be transformed in conjunction with the functions `TOWMCS` and `TOWWCS` can be defined via the setting data:

SD42935 \$SC\_WEAR\_TRANSFORM (transformation of wear values)

## 18.15 Examples

### 18.15.1 Toolholder with orientation capability

#### 18.15.1.1 Example: Toolholder with orientation capability

##### Requirement

The following example uses a toolholder, which is described fully by a rotation about the Y axis. It is therefore sufficient to enter only one value to define the rotary axis (block N20).

Blocks N50 to N70 describe an end mill with radius 5 mm and length 20 mm.

Block N90 defines a rotation of 37 degrees about the Y axis.

Block N120 activates the tool radius compensation and all settings are made to describe the compensation in the following blocks with a rotation of 37 degrees about the Y axis.

```
N10 ; Definition of toolholder 1
N20 $TC_CARR8[1] = 1 ; Component of the first rotary axis in
 ; the Y direction
N30
N40 ; Definition of tool-compensation memory
 ; T1/D1
N50 $TC_DP1[1,1] = 120 ; End mill
N60 $TC_DP3[1,1] = 20 ; Length l
N70 $TC_DP6[1,1] = 5 ; Radius
N80
N90 ROT Y37 ; 37-degree rotation about y axis
N100
N110 X0 Y0 Z0 F10000
N120 G42 CUT2DF TCOFR TCARR = 1 T1 D1 X10
N130 X40
N140 Y40
N150 X0
N160 Y0
N170 M30
```

### 18.15.1.2 Example of toolholder with orientation capability with rotary table

#### Use of the MOV command

For use of the `MOV` command it is assumed that the program is running on a 5-axis machine, on which the tool rotates about the Y axis in case of a rotation of the B axis:

```
N10 TRAORI()
N20 X0 X0 Z0 B45 F2000 ; Setting the tool orientation
N30 MOV=-10 ; Infeed movement 10 mm in tool
 ; direction
 ; (under 45 degrees in the Y-Z plane)
N40 MOV=AC(20) ; Retraction in tool direction at
 ; distance of
 ; 20 mm from the zero point
```

#### Machine with rotary table

Complete definition for the use of a toolholder with orientation capability with rotary table:

```
N10 $TC_DP1[1,1]=120
N20 $TC_DP3[1,1]= 13 ; Tool length 13 mm

 ; Definition of toolholder 1:

N30 $TC_CARR1[1] = 0 ; X component of 1st offset vector
N40 $TC_CARR2[1] = 0 ; Y component of 1st offset vector
N50 $TC_CARR3[1] = 0 ; Z component of 1st offset vector

N60 $TC_CARR4[1] = 0 ; X component of 2nd offset vector
N70 $TC_CARR5[1] = 0 ; Y component of 2nd offset vector
N80 $TC_CARR6[1] = -15 ; Z component of 2nd offset vector

N90 $TC_CARR7[1] = 1 ; X component of 1st axis
N100 $TC_CARR8[1] = 0 ; Y component of 1st axis
N110 $TC_CARR9[1] = 0 ; Z component of 1st axis

N120 $TC_CARR10[1] = 0 ; X component of 2nd axis
N130 $TC_CARR11[1] = 1 ; Y component of 2nd axis
N140 $TC_CARR12[1] = 0 ; Z component of 2nd axis

N150 $TC_CARR13[1] = 30 ; Angle of rotation of 1st axis
N160 $TC_CARR14[1] = -30 ; Angle of rotation of 2nd axis
```

```

N170 $TC_CARR15[1] = 0 ; X components of 3rd offset vector
N180 $TC_CARR16[1] = 0 ; Y component of 3rd offset vector
N190 $TC_CARR17[1] = 0 ; Z component of 3rd offset vector

N200 $TC_CARR18[1] = 0 ; X component of 4th offset vector
N210 $TC_CARR19[1] = 0 ; Y component of 4th offset vector
N220 $TC_CARR20[1] = 15 ; Z component of 4th offset vector

N230 $TC_CARR21[1] = A ; Reference for 1st axis

N370 X20 Y0 Z0 D0
N380 Y20
N390 X0 Y0 Z20
N400 M30

```

The definition of the toolholder with orientation capability is given in full. The components which contain the value 0 need not actually be given, as they are preset to zero in any case.

The toolholder is activated in N270.

As *\$TC\_CARR21* and *\$TC\_CARR22* refer to the machine axes A and B and TCOABS is active, the values in *\$TC\_CARR13* and *\$TC\_CARR14* are ignored, i.e. the axis position A0 B45 is used for the rotation.

The rotation of the 4th offset vector (length 15 mm in Z direction) around the B axis causes an offsetting of the zero point by X10.607 [= 15 \* sin(45)] and Z-4.393 [= -15 \* (1. - cos(45))]. This zero offset is taken into account by an automatically written basic or system frame so that the position X10.607 Y10.000 Z8.607 is approached. In the Z direction the tool selection leads to an additional offset of 13 mm; the Y component is not affected by the table rotation.

N280 defines a rotation in accordance with the rotation of the table of the toolholder with orientation capability. The new X direction thus points in the direction of the bisecting line in the 4th quadrant, the new Z axis in the direction of the bisecting line in the 1st quadrant.

The zero point is approached in N290, i.e. the machine position X10.607 Y0 Z-4.393, since the position of the zero point is not changed by the rotation.

N300 traverses in Y to the position Y33.000, since G18 is active and the Y component is not affected by the active frame. The X and Z positions remain unchanged.

The position X17.678 Y0 Z1.536 is approached in N310.

N320 changes only the Z position to the value -8.464 as a result of the MOVZ command. As only the table can be rotated, the tool orientation remains unchanged parallel to the machine Z direction, even if the Z direction of the active frame is rotated by 45 degrees.

N330 deletes the basic or system frame; thus the frame definition from N280 is undone.

In N340, TCOFR specifies that the toolholder with orientation capability is to be aligned according to the active frame. Since a rotation is no longer active in N330 due to the PAROTOF command, the initial state is applied. The frame offset becomes zero.

N350 thus approaches the position X10 X10 Z0 (= Z-13 + tool length). Note: Through the simultaneous programming of both rotary axes A and B the actual position of the toolholder with orientation capability is made to match that used in N340. The position approached by the three linear axes is dependent on this position, however.

In N360, solid angles are used to define a plane whose intersecting lines in the X-Z and in the Y-Z plane each form an angle of +45 degrees or -45 degrees with the X or Y axis. The plane defined in such a way therefore has the following position: the surface normal points towards the solid diagonals.

N370 traverses to the position X20 Y0 Z0 in the new coordinate system. Since the tool is deselected with D0 at the same time, there is no longer an additional offset in Z. Since the new X axis lies in the old X-Z plane, this block reaches the machine position X14.142 Y0 Z-14.142.

N380 only traverses on the Y axis in the rotated coordinate system. This leads to a motion of all three machine axes. The machine position is X5.977 Y16.330 Z-22.307.

N390 approaches a point on the new Z axis. Relative to the machine axes this is thus on the solid diagonal. All three axes thus reach the position 11.547.

### 18.15.1.3 Basic tool orientation example

#### Basic orientation in the bisector

A milling tool is defined with length L1=10 whose basic orientation is in the bisector of the X-Z plane.

```
N10 $TC_DP1[1,1]=120
N20 $TC_DP3[1,1]=10
N30 $TC_DPV [1,1] = 0
N40 $TC_DPV3[1,1] = 1
N50 $TC_DPV4[1,1] = 0
```

```
N60 $TC_DPV5[1,1] = 1
N70 g17 f1000 x0 y0 z0 t1 d1
N80 movt=10
N80 m30
```

#### Description of example:

In N10 to N60, a milling tool is defined with length  $L_1=10$  (N20). The basic orientation is in the bisector of the X-Z plane N40 to N60.

In N70, the tool is activated and the zero position is approached. As a result of the tool length the machine positions X0 Y0 Z10 are thus obtained in this block.

In N80 an incremental traversing motion is performed from 10 into tool direction. The resulting axis positions are thus X7.071 Y0 Z17.071.

### 18.15.1.4 Calculation of compensation values on a location-specific and workpiece-specific basis

#### Tool with adapter

A tool with adapter and toolholder with orientation capability is defined in the following program example. In order to simplify the overview, only length  $L_1$  is different to zero for the additive and insert offsets and for the adapter in case of the tool itself. The offset vectors of the toolholder with orientation capability are all zero.

```
N10 $TC_TP2[1] = "MillingTool" ; Name of identifier
N20 $TC_TP7[1]=9 ; Location types
N30 $TC_TP8[1]=2 ; Status: enabled and not blocked

; D corr. D=1

N40 $TC_DP1[1,1]=120 ; Tool type - milling
N50 $TC_DP3[1,1]=; tool length compensation
 vector
N60 $TC_DP12[1,1]= ; wear
N70 $TC_SCP13[1,1]=0.1 ; Sum offset DL=1
N80 $TC_ECP13[1,1]=0.01 ; Insert offset DL=1
N90 $TC_ADPTT[1]=5 ; Adapter transformation
N100 $TC_ADPT1[1]=0.001 ; Adapter dimension

; Magazine data
N110 $TC_MAP1[1]=3 ; Magazine type: Revolver
N120 $TC_MAP2[1]="Revolver" ; Magazine identifier
N130 $TC_MAP3[1]=17 ; Status of magazine
N140 $TC_MAP6[1]=1 ; Dimension - line
N150 $TC_MAP7[1]=2 ; Dimension - column -> 2 positions
```

```

N160 $TC_MPP1[1,1]=1 ; Location type
N170 $TC_MPP2[1,1]=9 ; Location types
N180 $TC_MPP4[1,1]=2 ; Location state
N190 $TC_MPP7[1,1]=1 ; Bring adapter into position
N200 $TC_MPP6[1,1]=1 ; T number "MillingTool"
N210 $TC_MAP1[9999]=7 ; Magazine type: buffer
N220 $TC_MAP2[9999]="buffer" ; Magazine identifier
N230 $TC_MAP3[9999]=17 ; Status of magazine
N240 $TC_MAP6[9999]=1 ; Dimension - line
N250 $TC_MAP7[9999]=1 ; Dimension - column -> 1 position
N260 $TC_MPP1[9999.1]=2 ; Location type
N270 $TC_MPP2[9999.1]=9 ; Location types
N280 $TC_MPP4[9999.1]=2 ; Location state
N290 $TC_MPP5[9999,1]=1 ; Spindle no. 1
N300 $TC_MDP2[1,1]=0 ; Distance from spindle to mag. 1

 ; Definition of toolholder 1
N310 $TC_CARR10[1] = 1 ; Component of 2nd rotary axis in
 X direction

### Explanations regarding the example above

Starting at block N390, various methods are used to approach position X0 Y0 Z0. The machine positions reached are specified in the blocks in comments. After the program a description is given of how the positions were reached.

N390: The adapter transformation 5 (block N90) transforms length L1 into length L2. Only the actual adapter dimension is not subject to this transformation. The Y value (L2 with G17) results from the sum of the tool length (10), tool wear (1), sum offset (0.1), and insert offset (0.01). The adapter dimension (0.001) is in Z (L1).

N400: In block N350, bits 0 and 2 are enabled in setting data:

SD42935 \$SC\_WEAR\_TRANSFORM (transformations for tool components)

This means that the tool wear and the insert offset are not subject to the adapter transformation because of `TOWMCS` in block `N400`. The sum of these two compensations is 1.01. The Z position is, therefore, increased by this amount and the Y position is reduced by this amount compared with block `N390`.

`TOWMCS` is active in `N410`. The sum of the tool wear and the insert offset is thus effective in the active workpiece coordinate system. In block `N370`, a rotation through 30 degrees is activated about the X axis. The original compensation value of 1.01 in the Z direction thus yields a new Z component of 0.875 ( $= 1.01 * \cos(30)$ ) and a new Y component of -0.505 ( $= 1.01 * \sin(30)$ ). This yields the dimension specified in the program comment when added to the sum of the tool length, sum offset and adapter dimension produced in block `N390`.

In addition, a toolholder with orientation capability is activated in block `N420`. This executes a rotation through 45 degrees about the X axis (see `N310 - N330`). Since all offset vectors of the toolholder are zero, there is no additional zero offset. The toolholder with orientation capability acts on the sum of the tool length, sum offset and adapter dimension. The resulting vector component is `X0 Y7.141 Z7.142`. To this, as in block `N410`, the sum of tool wear and insert offset evaluated in WCS is added.

`G18` is activated in `N430`. The components of the sum of the tool length, sum offset and adapter dimension are interchanged accordingly. The toolholder with orientation capability continues to act on this new vector (rotation through 45 degrees about X axis). The resulting vector component thereby is `X10.100 Y0.0071 Z0.0071`. The vector formed from tool wear and insert offset (`X0 Y-0.505 Z0.875`) is not affected by the change of plane. The sum of the two vectors yields the dimension specified in the comment in `N430`.

## 18.15.2 Examples 3-6: SETTCOR function for tool environments

### Example 3

```

N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 120 ; Milling tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP12[1,1] = 1.0 ; Wear L1
N50 _CORVAL[0] = 0.333
N60 t1 d1 g17 g0
N70 r1 = settcor(_CORVAL, "GW", 0, 2, 2)
N80 t1 d1 x0 y0 z0 ; ==> MCS position X0.000 Y0.000
 Z0.333
N90 M30

```

`_CORCOMP` is 2, therefore, the compensation effective in the Z direction is entered in the geometry component (the old value is overwritten) and the wear value is deleted. The resulting total tool length is thus:

$$L1 = 0.333 + 0.0 = 0.333.$$

#### Example 4

```
N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 120 ; Milling tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP12[1,1] = 1.0 ; Wear L1
N50 _CORVAL[0] = 0.333
N60 t1 d1 g17 g0
N70 r1 = settcor(_CORVAL, "GW", 0, 3, 2)
N80 t1 d1 x0 y0 z0 ;==> MCS position X0.000 Y0.000
 Z11.333
N90 M30
```

\_CORCOMP is 3, therefore, the wear value and compensation value are added to the geometry component and the wear component is deleted. The resulting total tool length is thus  $L_1 = 11.333 + 0.0 = 11.333$ .

#### Example 5

```
N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 120 ; Milling tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP12[1,1] = 1.0 ; Wear L1
N50 _CORVAL[0] = 0.333
N60 t1 d1 g17 g0
N70 r1 = settcor(_CORVAL, "GW", 0, 3, 0)
N80 t1 d1 x0 y0 z0 ;==> MCS position X0.333 Y0.000
 Z11.000
N90 M30
```

\_CORCOMP is 3, as in the previous example, but the compensation is now effective on the geometry axis with index 0 (X axis). The tool components  $L_3$  are assigned to this geometry axis due to  $G_{17}$  with a milling tool. Calling SETTCOR thus does not affect tool parameters \$TC\_DP3 and \$TC\_DP12. Instead, the compensation value is entered in \$TC\_DP5.

#### Example 6

```
N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 500 ; Turning tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP4[1,1] = 15.0 ; Geometry L2
N50 $TC_DP12[1,1] = 10.0 ; Wear L1
N60 $TC_DP13[1,1] = 0.0 ; Wear L2
N70 _CORVAL[0] = 5.0
```

```

N80 rot y 30
N90 t1 d1 g18 g0
N100 r1 = settcor(_CORVAL, "GW", 0, 3, 1)
N110 t1 d1 x0 y0 z0 ; ==> MCS position X24.330
 Y0.000 Z17.500
N120 M30

```

The tool is a turning tool. A frame rotation is activated in N80, causing the basic coordinate system (BCS) to be rotated in relation to the workpiece coordinate system (WCS). In the WCS, the compensation value (N70) acts on the geometry axis with index 1, i.e., on the X axis because G18 is active. Since "\_CORRMODE = 3", the tool wear in the direction of the X axis of the WCS must become zero once N100 has been executed. The contents of the relevant tool parameters at the end of the program are thus:

```

$TC_DP3[1,1] : 21.830 ; Geometry L1
$TC_DP4[1,1] : 21.830 ; Geometry L2
$TC_DP12[1,1] : 2.500 ; Wear L1
$TC_DP13[1,1] : -4.330 ; Wear L2

```

The total wear including \_CORVAL is mapped onto the X' direction in the WCS. This produces point P2. The coordinates of this point (measured in X/Y coordinates) are entered in the geometry component of the tool. The difference vector P<sub>2</sub> - P<sub>1</sub> remains in the wear. The wear thus no longer has a component in the direction of \_CORVAL.

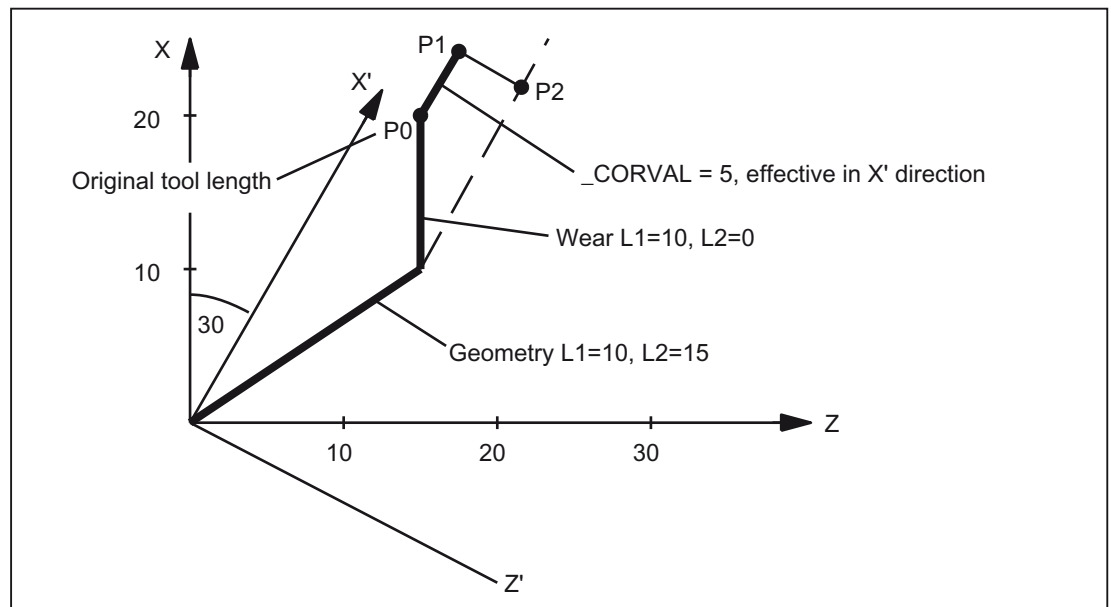

Figure 18-54 Tool length compensation, example 6

If the sample program is continued after N110 with the following instructions:

```
N120 _CORVAL[0] = 0.0
N130 r1 = settcor(_CORVAL, "GW", 0, 3, 0)
N140 t1 d1 x0 y0 z0 ; ==> MCS position X24.330 Y0.000
 Z17.500
```

The remaining wear is included completely in the geometry because the compensation is now effective in the Z' axis (parameter \_GEOAX is 0). Since the new compensation value is 0, the total tool length and thus the position approached in N140 may not change. If \_CORVAL were not equal to 0 in N120, a new total tool length and thus a new position in N140 would result, however, the wear component of the tool length would always be zero, i.e., the total tool length is subsequently always contained in the geometry component of the tool.

The same result as that achieved by calling the SETTCOR function with the \_CORCOMP = 0 parameter twice can also be reached by calling \_CORRCOMP = 1 (vectorial compensation) just once:

```
N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 500 ; Turning tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP4[1,1] = 15.0 ; Geometry L2
N50 $TC_DP12[1,1]= 10.0 ; Wear L1
N60 $TC_DP13[1,1] =0.0 ; Wear L2
N70 _CORVAL[0] = 0.0
N71 _CORVAL[1] = 5.0
N72 _CORVAL[2] = 0.0
N80 rot y 30
N90 t1 d1 g18 g0
N100 r1 = settcor(_CORVAL, "GW", 1, 3, 1)
N110 t1 d1 x0 y0 z0 ; ==> MCS position X24.330 Y0.000
 Z17.500
N120 M30
```

In this case, all wear components of the tool are set to zero immediately after the first call of SETTCOR in N100.

### Example 7

```
N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 500 ; Turning tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP4[1,1] = 15.0 ; Geometry L2
N50 $TC_DP12[1,1]= 10.0 ; Wear L1
N60 $TC_DP13[1,1] =0.0 ; Wear L2
N70 _CORVAL[0] = 5.0
```

```

N80 rot y 30
N90 t1 d1 g18 g0
N100 r1 = settcor(_CORVAL, "GW", 3, 3)
N110 t1 d1 x0 y0 z0 ; ==> MCS position X25.000 Y0.000
 Z15.000

```

As opposed to example 6, parameter `_CORCOMP = 3`, and so the `_GEOAX` parameter can be omitted. The value contained in `_CORVAL[0]` now acts immediately on the tool length component L1, the rotation in `N80` has no effect on the result, the wear components in `$TC_DP12` are included in the geometry component together with `_CORVAL[0]`, with the result that the total tool length is stored in the geometry component of the tool, due to `$TC_DP13`, after the first `SETTCOR` call in `N100`.

### Example 8

```

N10 def real _CORVAL[3]
N20 $TC_DP1[1,1] = 500 ; Turning tool
N30 $TC_DP3[1,1] = 10.0 ; Geometry L1
N40 $TC_DP4[1,1] = 15.0 ; Geometry L2
N50 $TC_DP5[1,1] = 20.0 ; Geometry L3
N60 $TC_DP12[1,1] = 10.0 ; Wear L1
N70 $TC_DP13[1,1] = 0.0 ; Wear L2
N80 $TC_DP14[1,1] = 0.0 ; Wear L3
N90 $SSC_WEAR_SIGN = TRUE
N100 _CORVAL[0] = 10.0
N110 _CORVAL[1] = 15.0
N120 _CORVAL[2] = 5.0
N130 rot y 30
N140 t1 d1 g18 g0
N150 r1 = settcor(_CORVAL, "W", 1, 1)
N160 t1 d1 x0 y0 z0 ; ==> MCS position X7.990 Y25.000
 Z31.160

```

In `N90` the setting data is enabled:

SD42930 `$SSC_WEAR_SIGN` (sign of wear)

i.e. the wear must be valued with a negative sign.

The compensation is vectorial ( $\_CORCOMP = 1$ ), and the compensation vector must be added to the wear ( $\_CORMODE = 1$ ). The geometric conditions in the Z/X plane are shown in the figure below:

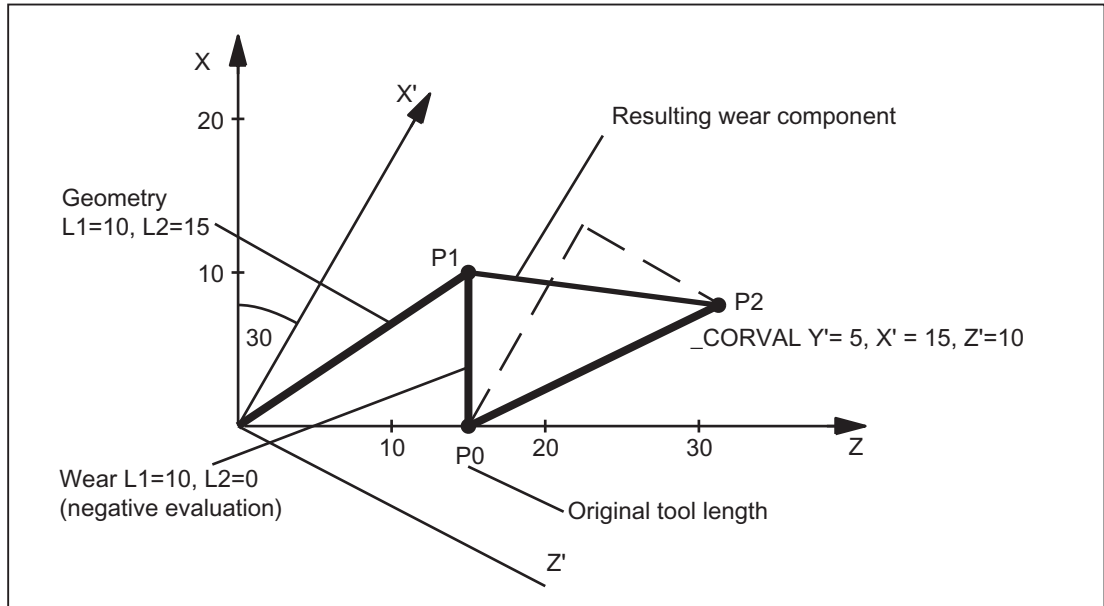

Figure 18-55 Tool length compensation, example 8

The geometry component of the tool remains unchanged due to  $\_CORMODE = 1$ . The compensation vector defined in the WCS (rotation about y axis) must be included in the wear component such that the total tool length in the figure refers to point  $P_2$ . Therefore, the resulting wear component of the tool is given in relation to the distance between points  $P_1$  and  $P_2$ .

However, since the wear is evaluated negatively, due to setting data SD42930, the compensation determined in this way has to be entered in the compensation memory with a negative sign. The contents of the relevant tool parameters at the end of the program are thus:

```

$TC_DP3[1,1] : 10.000 ; Geometry L1 (unchanged)
$TC_DP4[1,1] : 15.000 ; Geometry L2 (unchanged)
$TC_DP5[1,1] : 10.000 ; Geometry L3 (unchanged)

$TC_DP12[1,1] : 2.010 ; Wear L1
 ; (= 10 -15*cos(30) + 10*sin(30))
$TC_DP13[1,1] : -16.160 ; Wear L2
 ; (= -15*sin(30) - 10*cos(30))
$TC_DP14[1,1] : -5.000 ; Wear L3

```

The effect of setting data SD42930 on the  $L_3$  component in the Y direction can be recognized without the additional complication caused by the frame rotation.

## Example 9

2 (tool length must be valued in the diameter axis with the factor 0.5) is the value of machine data:

MD20360 \$MC\_TOOL\_PARAMETER\_DEF\_MASK (definition of tool parameters).

X is diameter axis:

```
N10 def real _LEN[11]
N20 def real _CORVAL[3]
N30 $TC_DP1[1,1]= 500
N40 $TC_DP2[1,1]= 2
N50 $TC_DP3[1,1]= 3.
N60 $TC_DP4[1,1]= 4.
N70 $TC_DP5[1,1]= 5.
N80 _CORVAL[0] = 1.
N90 _CORVAL[1] = 1.
N100 _CORVAL[2] = 1.
N110 t1 d1 g18 g0 x0 y0 z0 ; ==> MCS position X1.5 Y5 Z4
N120 r1 = settcor(_CORVAL, "g", 1, 1)
N130 t1 d1 x0 y0 z0 ; ==> MCS position X2.5 Y6 Z5
N140 r3 = $TC_DP3[1,1] ; = 5. = (3.000 + 2. * 1.000)
N150 r4 = $TC_DP4[1,1] ; = 5. = (4.000 + 1.000)
N160 r5 = $TC_DP5[1,1] ; = 6. = (5.000 + 1.000)
N170 m30
```

The compensation of the tool length is to be 1 mm in each axis (N80 to N100).

1 mm is thus added to the original length in lengths L2 and L3.

Twice the compensation value (2 mm) is added to the original tool length in L1, in order to change the total length by 1 mm as required. If the positions approached in blocks N110 and N130 are compared, it can be seen that each axis position has changed by 1 mm.

| 21080  | CUTCOM_PARALLEL_ORI_LIMIT  | Minimum angle (path tangent and tool orientation) for 3D tool radius compensation |
| 22530  | TOCARR_CHANGE_M_CODE       | M code for change of toolholder                                                   |
| 22550  | TOOL_CHANGE_MODE           | New tool compensations with M function                                            |
| 22560  | TOOL_CHANGE_M_CODE         | M function for tool change                                                        |
| 22562  | TOOL_CHANGE_ERROR_MODE     | Response when errors occur at tool change                                         |
| 24558  | TRAFO5_JOINT_OFFSET_PART_1 | Vector of kinematic offset in table, transformation 1                             |
| 24658  | TRAFO5_JOINT_OFFSET_PART_2 | Vector of kinematic offset in table, transformation 2                             |
| 28085  | MM_LINK_TOA_UNIT           | Assigning 'the TO unit to a channel (SRAM)                                        |

**18.16.1.3 Axis/spindle-specific machine data**

| Number | Identifier: \$MA_ | Description                   |
|--------|-------------------|-------------------------------|
| 32750  | TEMP_COMP_TYPE    | Temperature compensation type |

**18.16.2 Setting data****18.16.2.1 Channel-specific setting data**

| Number | Identifier: \$SC_     | Description                                                        |
|--------|-----------------------|--------------------------------------------------------------------|
| 42442  | TOOL_OFFSET_INCR_PROG | Tool length compensation                                           |
| 42470  | CRIT_SPLINE_ANGLE     | Core limit angle, for compressor                                   |
| 42480  | STOP_CUTCOM_STOPRE    | Alarm response for tool radius compensation and preprocessing stop |
| 42494  | CUTCOM_ACT_DEACT_CTRL | Approach and retraction behavior for tool radius compensation      |
| 42496  | CUTCOM_CLSDT_CONT     | Behavior of the tool radius compensation for closed contour        |
| 42900  | MIRROR_TOOL_LENGTH    | Sign change, tool lengths when mirroring                           |
| 42910  | MIRROR_TOOL_WEAR      | Sign change, tool wear when mirroring                              |
| 42920  | WEAR_SIGN_CUTPOS      | Sign of wear for tools with cutting edge position                  |
| 42930  | WEAR_SIGN             | Sign of the wear                                                   |
| 42935  | WEAR_TRANSFORM        | Transformations for tool components                                |
| 42940  | TOOL_LENGTH_CONST     | Change of tool length components for change of plane               |
| 42950  | TOOL_LENGTH_TYPE      | Assignment of the tool length offset independent of tool type      |
| 42960  | TOOL_TEMP_COMP        | Temperature compensation value in relation to tool                 |
| 42974  | TCARR_FINE_CORRECTION | Fine offset <small>TCARR</small> on/off                            |
| 42984  | CUTDIRMOD             | Modification of \$P_AD[2] or \$P_AD[11]                            |

## 18.16.3 Signals

### 18.16.3.1 Signals from channel

| Active G function of group 18 | DB21, ... .DBB225     | DB3500.DBB17   |
| Active G function of group 23 | DB21, ... .DBB230     | DB3500.DBB22   |

## Z1: NC/PLC interface signals

### 19.1 Brief description

The section entitled "NC/PLC interface signals" includes a detailed description of NC/PLC interface signals relevant to function:

- PLC messages (DB2)
- NC (DB10)
- Mode group (DB11)
- OP (DB19)
- NCK channel (DB21-DB30)
- Axis/spindle (DB31-DB61)
- Loading/unloading a magazine (DB71)
- Spindle as change point (DB72)
- Tool turret (DB73)

## 19.2 Various interface signals and functions (A2)

### 19.2.1 Signals from PLC to NC (DB10)

| <b>DB10</b><br><b>DBX56.4 - DBX56.7</b>  | <b>Key-operated switch positions 0 to 3</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                          |       |       |  |  |                              |             |  |  |  |       |       |       |       |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| Significance of signal                   | <p>Access to certain data types can be disabled depending on the key-operated switch position. Input, changing, deleting data as well as certain operations on the operator panel can be disabled for certain user groups in this way.</p> <p>Key-operated switch position 0 offers the fewest access rights and position 3 the most access rights.</p> <p>The signals "key-operated switch positions 1 to 3" can either be entered directly from the key-operated switch on the machine control panel or from the PLC user program.</p> <p>Only one interface signal may be set in each case. If several positions are set simultaneously (interface signals), then they are no longer valid and key-operated switch position 3 is automatically set by the control.</p> <p>The allocation between the lockable data areas and the key operated switch positions is made by HMI machine data for protection stages.</p> <p>The following signal combinations apply:</p> <table border="1" data-bbox="373 1077 1434 1350"> <thead> <tr> <th colspan="5" style="text-align: center;">The following signal combinations apply:</th> </tr> <tr> <th rowspan="2" style="text-align: center;">Key-operated switch position</th> <th colspan="4" style="text-align: center;">DB10, DBB56</th> </tr> <tr> <th style="text-align: center;">Bit 7</th> <th style="text-align: center;">Bit 6</th> <th style="text-align: center;">Bit 5</th> <th style="text-align: center;">Bit 4</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> </tr> <tr> <td style="text-align: center;">2</td> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> </tr> <tr> <td style="text-align: center;">3</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> </tr> </tbody> </table> | The following signal combinations apply: |       |       |  |  | Key-operated switch position | DB10, DBB56 |  |  |  | Bit 7 | Bit 6 | Bit 5 | Bit 4 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 2 | 0 | 1 | 0 | 0 | 3 | 1 | 0 | 0 | 0 |

| Application example(s)                   | Depending on the rights assigned to the operator, programmer or installation engineer, certain functions will be disabled by the key-operated switch. Unintentional changes to data (e.g. zero offsets) or activation of program conditions (e.g. selecting dry run feed rate) by the operator can therefore be prevented.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                          |       |       |  |  |                              |             |  |  |  |       |       |       |       |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| Signal state 1 or edge change 0 → 1 | The PLC selects the display of actual values in the workpiece coordinate system (WCS). This means that when the machine area is selected, the WCS display is activated; i.e. the machine and the supplementary axes as well as their actual positions and distances to go are displayed in the WCS in the "Position" window.<br><br>The interface signal is only evaluated when it enters the basic machine screen; this means that the operator, within the machine area, can toggle as required between the particular coordinate systems using the softkeys "actual values MCS" and "actual values WCS". |  |
| Signal state 0 or edge change 1 → 0 | This means that when the machine area is selected the coordinate system previously selected (WCS or MCS) is reactivated and displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| Application example(s)              | Using the interface signal: DB19, DBX0.7 (actual value in WCS) = 1 each time that the machine area is re-selected, the workpiece coordinate system display frequently required by the operator (WCS), is selected.                                                                                                                                                                                                                                                                                                                                                                                          |  |
| Corresponding to ....               | DB19 DBX20.7 (changeover MCS/WCS)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |

| Signal state 1 or edge change 0 → 1 | V24 externally active                                                                                                                                                                                                                                                                 |  |
| Signal state 0 or edge change 1 → 0 | V24 externally inactive                                                                                                                                                                                                                                                               |  |
| Application example(s)              | The actual status of the RS 232C is sent to the PLC in acknowledgment byte DB19.DBB24. The bit "RS-232-C external" is delayed until the transfer of the part program to be externally executed has been started and the selection has been made. Only then is an "NC Start" possible. |  |

| Edge evaluation: no                 | Signal(s) updated: cyclic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| Signal state 1 or edge change 0 → 1 | Delete distance-to-go (channel-specific):<br>IS "Delete distance-to-go (channel-specific)" for path axes is only active in AUTOMATIC mode. The rising edge of the interface signal is only effective for the axes involved in the geometry grouping. These are also stopped with a ramp stop and their distance-to-go deleted (setpoint - actual value difference). Any remaining following error is not removed. The next program block is then started.<br>IS "Delete distance-to-go (channel-specific)" is therefore ignored by positioning axes.<br>Note:<br>IS "Delete distance-to-go" does not influence the running dwell time in a program block with dwell time. |  |
| Signal state 0 or edge change 1 → 0 | No effect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |

| Signal state 1 or edge change 0 → 1<br>- Axis disable<br>- Spindle disable | <p>(Test status)</p> <p>If the interface signal "Axis disable" is output - for this axis - no more position partial setpoints are output to the position controller; the axis travel is therefore disabled. The position control loop remains closed and the remaining following error is reduced to zero.</p> <p>If an axis is moved with axis disable the actual value position display shows the setpoint position and the actual velocity value display shows the setpoint velocity even though the machine axis is not actually moving.</p> <p>With a RESET the position actual value display is set to the real actual value of the machine.</p> <p>Travel commands continue to be output to the PLC for this axis.</p> <p>If the interface signal is canceled again the associated axis can again traverse normally.</p> <p>If the interface signal "Axis disable" is set for a traversing axis, the axis is stopped with a ramp stop.</p> <p>If the interface signal "Spindle disable" is set, as for axis disable, for this spindle no more speed setpoints are output to the speed controller in the open-loop control mode and no more position partial setpoints are output to the position controller in positioning mode. The movement of the spindle is thus disabled. The speed actual value display displays the speed setpoint value.</p> <p>Spindle disable can only be canceled per "Reset" or with M2 followed by a program restart.</p> <p>If interface signal "Spindle disable" is set while a spindle is turning, the spindle is stopped according to its acceleration characteristic.</p> |
| Signal state 0 or edge change 1 → 0                                        | <p>(Normal conditions).</p> <p>The position setpoint values are transferred to the position controller cyclically.</p> <p>The speed setpoint values are transferred to the speed controller cyclically.</p> <p>Cancellation of the "Axis/spindle disable" (edge change 1 → 0) does not take effect until the axis/spindle is stationary (i.e. an interpolation setpoint is no longer present).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                                                            | <p>The diagram illustrates the control loop for an axis. It starts with a 'Position setpoint from the interpolator' entering a summing junction. An 'Axis inhibit active' signal also enters this junction with a negative sign. The output of this junction goes to the 'Position controller'. The output of the 'Position controller' enters another summing junction. The 'Actual position value' from the 'Encoder 1' is fed back into this junction with a negative sign. The output of this second junction goes to the 'Speed controller'. The output of the 'Speed controller' is labeled 'i<sub>set</sub>' and enters a third summing junction. The 'Actual speed (n<sub>act</sub>)' from the 'Motor' is fed back into this junction with a negative sign. The output of this third junction goes to the 'Current controller'. The output of the 'Current controller' drives the 'Motor'. The 'Motor' outputs to 'Encoder 1', which provides the 'Actual position value' and 'Actual speed (n<sub>act</sub>)' feedback signals.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Application example(s)                                                     | <p>The interface signal "Axis disable" and "Spindle disable" is used when running-in and testing a new NC part program. In so doing, the machine axes and spindles should not execute any traversing or rotational movement.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Signal state 1              | <p>Follow-up mode is selected for the axis/spindle by the PLC.</p> <p>The means that the position setpoint continually tracks the actual value if the controller enable for the drive is withdrawn.</p> <p>As soon as the follow-up mode is effective, the interface signal: DB31, ... DBX61.3 (follow-up mode active) is set to a 1 signal.</p> <p>The actual value continues to be acquired and updated. If the axis/spindle is moved from its current position by an external effect the zero speed and clamping monitoring do not issue an alarm.</p> <p>When the closed-loop control system is reactivated, a control-internal repositioning operation is performed (REPOSA: linear approach with all axes) to the last programmed position if a part program is active.</p>                                                                                                                                                                                                                                               |
| Signal state 0              | <p>Follow-up mode is not selected (hold).</p> <p>When "controller enable" is removed the previous position setpoint is kept in the control. If the axis/spindle is moved out of position during this time a following error occurs between the position setpoint and the position actual value. This position difference is reduced to zero immediately by issuing "controller enable" so that the previous setpoint position is restored. Then, all the other axis movements start from the setpoint position valid before "controller enable" was removed.</p> <p>When the position control is switched in again the axis may make a speed setpoint jump. Zero speed monitoring or clamping monitoring is still active.</p> <p>In order to disable (switch-out) the zero speed monitoring, when clamping an axis, the interface signal: DB31, ... DBX2.3 (clamping operation running) should be set.</p> <p>In the "holding state", the interface signal: DB31, ... DBX61.3 (follow-up mode active) is set to a 0 signal.</p> |
| Special cases, errors, .... | <p>If the drive controller enable is withdrawn inside the control due to faults, then the following should be carefully observed:</p> <p>Before an NC start, after the queued alarms have been successfully deleted (i.e. inside the control, the controller enable is re-issued), then "holding" should be activated: DB31, ... DBX1.4 (follow-up mode) = 0</p> <p>Otherwise, for an NC start and selected follow-up mode, the traversing distance of the previous NC block would not be executed due to the internal delete distance to go.</p> <p>Notice:</p> <p>When changing over from the "follow-up" state to the "hold" state and in the control mode (a controller enable is issued), a delete distance-to-go command is activated in the control. As a consequence, for example, an NC block - in which only this axis is traversed - is ended directly.</p>                                                                                                                                                          |

DBX60.4/5 (referenced/synchronized) has the signal condition 0<br/><br/>                             As soon as an axis is parked, the interface signals:<br/>                             DB31, ... DBX61.5 (position controller active),<br/><br/>                             DB31, ... DBX61.6 (speed controller active)<br/>                             and<br/>                             DB31, ... DBX61.7 (current controller active)<br/>                             are set to a 0.<br/><br/>                             After parking has been completed the axis must be re-referenced (reference point approach).<br/><br/>                             If interface signals PMS1 and PMS2 are set to 0 while the axis is moving, the axis is stopped with a ramp stop without the controller enable being internally withdrawn.<br/><br/>                             This is appropriate for the following situations:                             <ul style="list-style-type: none"> <li>– Spindle encoder no longer outputs a signal above a certain speed (no longer supplies any pulses).</li> <li>– Spindle encoder is decoupled mechanically because it would not be able to cope with the speed.</li> <li>– The spindle can then continue to run in speed-controlled mode. In order to really bring the axis/spindle to a stop, the controller enable must always be removed additionally by the PLC.</li> </ul> </li> <li>2. The spindle does not have a position measuring system and is only speed controlled.<br/>                             In this case, the interface signal:<br/>                             DB31, ... DBX2.1 (controller enable)<br/>                             should be set to a 1 signal.                         </li> </ol> |

| DB31, ...<br>DBX1.5 - DBX1.6 | Position measuring system 1 (PMS1) / Position measuring system 2 (PMS2)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application example(s)       | <p>1. Changing over from position measuring system 1 to positioning measuring system 2 (and vice versa).</p> <p>If the axis in both position measuring systems was referenced and the limit frequency of the measured value encoder has not been exceeded in the meantime (i.e. DB31, ... DBX60.4 and 60.5 (referenced/synchronized 1 and 2) has signal state 1, then after the changeover, a reference point approach does not have to be repeated.</p> <p>On switchover, the current difference between position measuring system 1 and 2 is traversed immediately.</p> <p>With the machine data:<br/>MD36500 \$MA_ENC_CHANGE_TOL (maximum tolerance on position actual value changeover)<br/>a tolerance bandwidth can be entered - the deviation between the two actual values may lie within this bandwidth when changing over.</p> <p>If the actual value difference is greater than the tolerance, a switchover between the two systems does not take place and alarm 25100 "Measuring system switchover" not possible is triggered.</p> <p>2. Parking axis (i.e. no PMS is active):</p> <p>If the encoder has to be removed - e.g. if a rotary table has to be removed from the machine - the position measuring system monitoring is switched off in the parking position.</p> <p>The mounted axis/spindle encoder turns so quickly in certain applications that it can no longer maintain its electrical characteristics (edge rate-of-rise, etc.).</p> <p>3. Switch-off measuring system:</p> <p>When measuring system 1 or 2 is switched off the associated interface signal:<br/>DB31, ... DBX60.4/60.5 (referenced/synchronized 1/2)<br/>is reset.</p> <p>4. Reference point approach:</p> <p>Reference point approach of the axis is executed with the selected position measuring system. Every PMS must be separately referenced.</p> |
| Special cases, errors, ....  | <p>If the state "parking axis" is active, the interface signal:<br/>DB31, ... DBX60.4/60.5 (referenced/synchronized 1/2)<br/>is ignored at NC start for this axis.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>DB31, ...<br/>DBX2.1</b> | <b>Controller enable</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Application example(s)      | Using controller enable when clamping the axis:<br>The axis is positioned to the clamping position. As soon as it has stopped it is clamped and then controller enable is removed. Controller enable is removed because the axis could be mechanically pressed out of position slightly by clamping and the position controller would continuously have to work against the clamping.<br>When clamping is to be stopped, a controller enable signal is first set again and then the axis is freed from clamping.                                       |
| Special cases, errors, .... | If an attempt is made to traverse the axis/spindle without controller enable, the axis/spindle remains stationary but sends a traversing/move command to the PLC (axis only). The traversing/move command is kept and is executed when the controller enable is re-activated.<br>If the controller enable of a traversing geometry axis is removed the programmed contour cannot be maintained.<br>Controller enable is automatically cancelled by the control when certain faults occur at the machine, the position measuring system or the control. |

| Special cases, errors, .... | "Delete distance-to-go (axial)"<br>After the axes have been stopped with "Delete distance-to-go" the next program block is prepared with the new positions. The axes thus follow a different contour to the one originally defined in the part program after a "Delete distance-to-go".<br>If G90 is programmed in the block after "Delete distance-to-go" it is at least possible to approach the programmed absolute position. On the other hand, with G91, the position originally defined in the part program is not reached in the following block. |

| Signal state 1 or edge change<br>0 → 1 | <p>The PLC requests a filter to smooth the speed setpoint value.</p> <p>In the drive module the interface signal is only effective under the following conditions:</p> <ul style="list-style-type: none"> <li>• Speed setpoint filter 1 is active in the drive</li> <li>• speed setpoint filter 1 has been configured as a low-pass filter (i.e. not as a band-stop filter)</li> </ul> <p>As soon as these conditions exist whereby the smoothing of the speed setpoint is active, the 611D or 611U signals this to the PLC using the interface signal: DB31, ... DBX92.3 (speed setpoint smoothing active).</p> |
| Signal state 0 or edge change<br>1 → 0 | No smoothing of the speed setpoint value is requested by the PLC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Application example(s)                 | With this interface signal, speed setpoint smoothing can - for example - be activated from the PLC user program for a spindle during speed control to achieve smooth torque output. Speed setpoint smoothing can therefore be deactivated when the spindle is in positioning mode.                                                                                                                                                                                                                                                                                                                               |

| Application example(s)                 | <p>Drive parameter switchover can be used for the following:</p> <ul style="list-style-type: none"> <li>• Changing the gear stage</li> <li>• Changing over the measuring circuit</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                     |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Special cases, errors, ....            | In principle it is possible to switch over drive parameter sets at any time. However, as torque jumps can occur when switching over speed controller parameters and motor speed normalization, parameters should only be switched over when in the zero speed state (especially when the axis is stationary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                     |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| Signal state 1 or edge change<br>0 → 1 | The PLC outputs the interface signal: DB31, ... DBX21.5 (motor being selected) to the 611D to confirm that the external contactor has been switched over to the new motor (e.g. that motor contactor 2 has been energized as part of the star/delta switchover process). The pulses are then enabled by the drive. |
| Signal state 0 or edge change<br>1 → 0 | The interface signal: DB31, ... DBX21.5 (motor being selected) must be reset to 0 by the PLC user program before a new motor is selected! Otherwise the pulses from the drive might be enabled too early.                                                                                                          |

|                              | <p>The diagram illustrates the timing of speed control signals during a ramp-up phase. It consists of four vertically aligned time axes:</p> <ul style="list-style-type: none"> <li><b>Top axis:</b> 'Ramp-function generator active (control word servo)'. The signal transitions from 'inactive' to 'active' at the start of the ramp.</li> <li><b>Second axis:</b> 'Speed n'. It shows the 'Speed setpoint' (n<sub>set</sub>) as a step function and the 'Speed actual value n<sub>act</sub>' as a curve that ramps up and then settles around the setpoint. A 'Speed tolerance bandwidth' is indicated by a vertical double-headed arrow around the setpoint level. A parameter 'MD2426 \$MD_SPEED_DES_EQ_ACT_TOL' is associated with this bandwidth.</li> <li><b>Third axis:</b> 'IS "Ramp-up completed"'. This signal is active (1) during the ramp-up phase and becomes inactive (0) once the speed has settled.</li> <li><b>Bottom axis:</b> 'IS "n<sub>act</sub> = n<sub>set</sub>"'. This signal is active (1) when the actual speed is within the tolerance bandwidth. It is inactive (0) when the speed is outside this range. Two conditions are shown: 'T &lt; TD ! therefore no signal' (where T is the time to reach the tolerance band) and 'T &gt; TD ! signal that is interlocked' (where T is the time to reach the tolerance band and TD is a delay time).</li> </ul> <p>At the bottom of the diagram, the delay time is defined as: TD = MD1427 \$MD_SPEED_DES_EQ_ACT_DELAY.</p> |

| Signal state 1       | <p>The SIMODRIVE 611D/611U signals the PLC that the threshold value has exceeded the value being monitored.</p> <p>With the variable signaling function it is possible to monitor for each axis whether a defined threshold - that can be entered - is exceeded for any programmable value of SIMODRIVE 611D/611U. A corresponding interface signal is then sent to the PLC.</p> <p>The parameters for the variables being monitored are set in the following 611D machine data:</p> <ul style="list-style-type: none"> <li>• MD1620 \$MD_PROG_SIGNAL_FLAGS (bits variable signal function)</li> <li>• MD1621 \$MD_PROG_SIGNAL_NR (signal number variable signal function)</li> <li>• MD1622 \$MD_PROG_SIGNAL_ADDRESS (address variable signal function)</li> <li>• MD1623 \$MD_PROG_SIGNAL_THRESHOLD (threshold variable signal function)</li> <li>• MD1624 \$MD_PROG_SIGNAL_HYSTERESIS (hysteresis variable signal function)</li> <li>• MD1625 \$MD_PROG_SIGNAL_ON_DELAY (on delay variable signal function)</li> <li>• MD1626 \$MD_PROG_SIGNAL_OFF_DELAY (off delay variable signal function)</li> </ul> <p><b>Monitoring:</b></p> <p>The parameterized variable is monitored to check whether it exceeds a defined threshold. In addition, a tolerance band (hysteresis) can be defined which is considered when scanning for violation of the threshold value. Further, the "threshold exceeded" signal can be also be logically combined with an on delay and off delay time (refer to the diagram).</p> <p><b>Selection:</b></p> <p>The variable to be monitored can be selected by entering a signal number or by entering a symbolic address.</p> <p>The machine data:<br/>MD1620 \$MD_PROG_SIGNAL_FLAGS (bits, variable signaling function)<br/>can be used to enable and disable the variable signaling function on an axis-for-axis basis. This machine data can also be used to determined whether the threshold value comparison is to be signed or unsigned.</p> <p>For further information see References.</p> |
| Signal state 0       | <p>SIMODRIVE 611D signals the PLC that the threshold value of the variable being monitored has not been exceeded or that the conditions defined in the above 611D-MD are not fulfilled.</p> <p>If the variable signaling function is disabled (MD1620), signal state "0" is output to the PLC.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Edge evaluation: yes                   | Signal(s) updated: Cyclically                                                                                                                                                                                                                                                                                                                                                                                                                   |  |
| Signal state 1 or edge change<br>0 → 1 | When a positive edge of this signal appears, a protection zone is enabled and the active alarm cleared. Then, motion can start in the same protection zone. As a result of the start of motion, the protection zone is enabled, the IS "machine or channel-specific protection zone violated" is set, and the axis starts to move.<br>The enabling signal is canceled if motion is started that does not lead into the enabled protection zone. |  |
| Signal state 0 or edge change<br>1 → 0 | No effect                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
| Application example(s)                 | This allows protection zones to be released: <ul style="list-style-type: none"> <li>• if the current position is within a protection zone (alarm 2 present)</li> <li>• if motion is to be started towards the protection zone limit (alarm 1 or 2 present)</li> </ul>                                                                                                                                                                           |  |

| Edge evaluation: No                    | Signal(s) updated: Cyclically                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Signal state 1 or edge change<br>0 → 1 | The currently active mode (JOG, MDA or AUTOMATIC) of the mode group cannot be changed. The machine functions that can be selected within a mode group can be changed.                                                                                                                                                                                                                                                                                                                                                                                    |
| Signal state 0 or edge change<br>1 → 0 | The mode of the mode group can be changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                        | <p>The diagram illustrates the logic for mode changeover inhibition. On the left, under the heading 'Mode selection', there are three rectangular boxes: 'AUTOMATIC mode', 'MDA operating mode', and 'JOG mode'. Lines from these three boxes converge into a single vertical line. This line then connects to a horizontal line that leads to a switch symbol labeled 'Mode switchover disable'. Below this switch is the text 'DBX0.4 = 0'. The switch is shown in a closed position, allowing current to flow to a box on the right labeled 'NC'.</p> |

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Signal state 1 or edge change<br>0 → 1 | An NC stop is activated for all the channels of the mode group. The channel status of all the active channels changes to the channel status "interrupted". All of the channels in channel status "reset" remain in the channel status "reset". Programs that are running at this point are immediately interrupted (at the earliest possible point, even within a block) and the program status changes to "stopped". All the moving axes of the mode group are decelerated according to their acceleration characteristics without contour violation. The program can be restarted with NC start. None of the spindles of that mode group are affected. |
| Signal state 0 or edge change<br>1 → 0 | Channel status and program execution are not influenced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Special cases, errors, ... ..          | All the axes of a mode group that are not triggered by a program or a program block (e.g. axes traverse because traverse keys are being pressed on the machine control panel) decelerate to rest with mode group stop.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 19.7 Mode group, channel, program operation, reset response (K1)

DBX7.7 (channel reset)<br>DB11 DBX6.7 (all channels in the reset state)                                                                                                                                                                                                                                                                                                                                                                         |  |
| Special cases, errors, .....           | An alarm that withdraws the interface signal DB11 DBX6.3 (mode group ready) ensures that all channels of the mode group are no longer in the reset state. In order to switch to another operating mode, a mode group reset (DB11 DBX0.7) must then be initiated.                                                                                                                                                                                          |  |

| Application example(s)                 | When a fault occurs when executing a part program (e.g. tool breakage), the axis is manually moved away from the fault location in the JOG mode in order to be able to replace the tool. The axis can then be manually returned to the exact previous position using the REPOS machine function so that the program can be continued in the automatic mode. |

| Edge evaluation: No                    | Signal(s) updated: Cyclically                                                                                                                                                                                                                                                                                                                               |  |
| Signal state 1 or edge change<br>0 → 1 | The machine function REPOS is selected by HMI within BAG.                                                                                                                                                                                                                                                                                                   |  |
| Signal state 0 or edge change<br>1 → 0 | The machine function REPOS is not selected by HMI.                                                                                                                                                                                                                                                                                                          |  |
| Application example(s)                 | When a fault occurs when executing a part program (e.g. tool breakage), the axis is manually moved away from the fault location in the JOG mode in order to be able to replace the tool. The axis can then be manually returned to the exact previous position using the REPOS machine function so that the program can be continued in the automatic mode. |  |

| Signal state 1 or edge change<br>0 → 1 | Machine function REPOS is active in the mode group.                                                                                                                                                                                                                                                                                                         |
| Signal state 0 or edge change<br>1 → 0 | Machine function REPOS is not active.                                                                                                                                                                                                                                                                                                                       |
| Application example(s)                 | When a fault occurs when executing a part program (e.g. tool breakage), the axis is manually moved away from the fault location in the JOG mode in order to be able to replace the tool. The axis can then be manually returned to the exact previous position using the REPOS machine function so that the program can be continued in the automatic mode. |

## 19.7.6 Signals from axis/spindle (DB31, ...)

| DB31, ...<br>DBX70.0                   | REPOS offset                                              |
|----------------------------------------|-----------------------------------------------------------|
| Edge evaluation: no                    | Signal(s) updated: cyclic                                 |
| Signal state 1 or edge change<br>0 → 1 | A REPOS offset must be applied for the appropriate axis.  |
| Signal state 0 or edge change<br>1 → 0 | No REPOS offset need be applied for the appropriate axis. |
| Corresponds to ....                    | DB31, ... DBX70.1 (REPOS offset valid)                    |

| DB31, ...<br>DBX70.1                   | REPOS offset valid                                                                                                                                                                             |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Edge evaluation: no                    | Signal(s) updated: cyclic                                                                                                                                                                      |
| Signal state 1 or edge change<br>0 → 1 | The range of validity of the REPOS offset is indicated with the value 1.<br>The REPOS offset was calculated to be valid.                                                                       |
| Signal state 0 or edge change<br>1 → 0 | A value of zero indicates that the REPOS offset was calculated to be invalid.                                                                                                                  |
| Application example(s)                 | Updating the REPOS offset in the range of validity:<br>Between SERUPRO end and start, the axis can be moved in JOG mode with a mode change. The user moves the REPOS offset to the zero value. |
| Corresponds to ....                    | DB31, ... DBX70.0 (REPOS offset)                                                                                                                                                               |

| DB31, ...<br>DBX70.2                   | REPOS Delay Ackn                                                                                                                                                                                                                                                                                         |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Edge evaluation: no                    | Signal(s) updated: cyclic                                                                                                                                                                                                                                                                                |
| Signal state 1 or edge change<br>0 → 1 | The axis was programmed within a traversing block, and the REPOS offset was applied.<br>Note<br>A REPOS offset was available for the axis, and REPOSDELAY was active:<br>DB31, ... DBX10.0 (REPOSDELAY) == 1<br>This signal behaves the same as:<br>DB21, ... DBX319.1 - DBX319.3 (Repos Path Mode Ackn) |
| Signal state 0 or edge change<br>1 → 0 | The value zero is used to acknowledge that the REPOS offset is not active for this axis. This signal is cancelled on activation of the remaining block.                                                                                                                                                  |
| Corresponds to ....                    | DB31, ... DBX10.0 (REPOSDELAY)<br>DB31, ... DBX72.0 (REPOSDELAY)                                                                                                                                                                                                                                         |

| Signal irrelevant for<br>...           | ... spindle modes other than the control mode.                                                                                                                                                                                                                                                                                                                                                                                                                     |  |
| Application example(s)                 | <p>The machine has a selector switch to changeover between a vertical and a horizontal spindle. Two different position encoders are used (one for the vertical spindle and one for the horizontal spindle), but only one actual value input is used on the control. When the system switches from the vertical to the horizontal spindle, the spindle must be resynchronized.<br/>This synchronization is triggered by the IS "re-synchronize spindle 1 or 2".</p> |  |

| Signal state 1 or edge change<br>0 → 1 | The direction of rotation of the spindle motor changes for the following functions: <ul style="list-style-type: none"> <li>• M3</li> <li>• M4</li> <li>• M5</li> <li>• SPOS/M19/SPOSA from the motion; not effective for SPOS/M19/SPOSA from zero speed (stationary).</li> </ul>                                                                                      |  |
| Application example(s)                 | The machine has a selector switch to changeover between a vertical and a horizontal spindle. The mechanical design is implemented so that for the horizontal spindle, one more gearwheel is engaged than for the vertical spindle. The direction of rotation must therefore be changed for the vertical spindle if the spindle is always to rotate clockwise with M3. |  |

| Edge evaluation: yes                   | Signal(s) updated: Cyclically                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| Signal state 1 or edge change<br>0 → 1 | <p>If the interface signal: DB31, ... DBX18.4 (oscillation controlled by the PLC) is not set, then automatic oscillation in the NCK is carried-out using the interface signal: DB31, ... DBX18.5 (oscillation speed).<br/>The two times for the directions of rotation are entered in the machine data: MD35440 \$MA_SPIND_OSCILL_TIME_CW (oscillation time for the M3 direction) and MD35450 \$MA_SPIND_OSCILL_TIME_CCW (oscillation time for the M4 direction).<br/>If the IS "oscillation via PLC" is set, then with the IS "oscillation speed" a speed is only output in conjunction with the interface signals: DB31, ... DBX18.6 - DBX18.7 (setpoint direction of rotation, counter-clockwise and clockwise).<br/>The oscillation, i.e. the continuous change of the direction of rotation, is performed by the PLC user program using the interface signal "setpoint direction of rotation, counter-clockwise and clockwise" (oscillation via the PLC).</p> |  |
| Application example(s)                 | <p>If the new gear stage cannot be engaged in spite of several attempts by the NCK, the system can be switched to oscillation via PLC. Both of the times for the directions of rotation can then be altered by the PLC user program as required. This ensures that the gear satge is reliably changed - even with unfavorable gear wheel positions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |
