| Signal state 1 or edge change<br>0 → 1 | <p>The signal is active in one channel in all operating modes.</p> <p>The signal disables the feed for all of the axes (geometry and synchronized) that interpolate relative to one another as long as G33 (thread) is not active.</p> <p>All axes are brought to a standstill but still maintaining the path contour. When the feed disable is canceled (0 signal), the interrupted part program is continued.</p> <p>The signal triggers a feed disable for all positioning axes. This signal brings all traversing axes to a standstill with controlled braking (ramp stop). No alarm is output.</p> <p>The position control is retained, i.e. the following error is eliminated.</p> <p>If a travel request is issued for an axis with an active "Feed disable", then this is kept. The queued travel request is executed immediately when the "Feed disable" is canceled.</p> <p>If the axis is interpolating in relation to others, this also applies to these axes.</p> |  |
| Signal state 0 or edge change<br>1 → 0 | <p>The feed rate is enabled for all axes of the channel.</p> <p>If a travel request ("travel command") exists for an axis or group of axes when the "feed disable" is canceled, then this is executed immediately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |
| Application example(s)                 | Stopping machining by selecting FEED OFF on the machine control panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |  |

| Signal state 1 or edge change<br>0 → 1 | <p>The signal is active in all modes.</p> <p><b>Feed stop:</b></p> <p>The signal triggers a "feed stop" for the axis. This signal brings all traversing axes to a standstill with controlled braking (ramp stop). No alarm is output.</p> <p>The signal triggers a "feed stop" for all path axes interpolating relative to each other when the "feed stop" is activated for any one of these path axes. In this case, all the axes are brought to a stop with adherence to the path contour. When the "feed stop" signal is canceled, execution of the interrupted parts program is resumed.</p> <p>The position control is retained, i.e. the following error is eliminated.</p> <p>If a travel request is issued for an axis with an active "feed stop", this is kept. This queued travel request is executed immediately after the "feed stop" is canceled.</p> <p>If the axis is interpolating in relation to others, this also applies to these axes.</p> <p><b>Spindle stop:</b></p> <p>The spindle is brought to a standstill along the acceleration characteristic.</p> <p>In the positioning mode, when the "Spindle stop" signal is set positioning is interrupted. The above response applies with respect to individual axes.</p> |  |
| Signal state 0 or edge change<br>1 → 0 | <p><b>Feed stop:</b></p> <p>The feed rate is enabled for the axis.</p> <p>If a travel request ("travel command") is active when the "feed stop" is canceled, this is executed immediately.</p> <p><b>Spindle stop:</b></p> <p>The speed is enabled for the spindle.</p> <p>The spindle is accelerated to the previous speed setpoint with the acceleration characteristic or, in positioning mode, positioning is resumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |

| FEPROM   | Flash EPROM: Read and write memory                                                                                                       |
| FIFO     | First In First Out: Memory that works without address specification and whose data are read in the same order in which they were stored. |
| FIPO     | Fine interpolator                                                                                                                        |
| FRAME    | Coordinate transformation                                                                                                                |
| FST      | Feed Stop                                                                                                                                |
| FW       | Firmware                                                                                                                                 |

|          |                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------|
| <b>G</b> |                                                                                                     |
| GC       | Global Control (PROFIBUS: Broadcast telegram)                                                       |
| GEO      | Geometry, e.g. geometry axis                                                                        |
| GIA      | Gear Interpolation dAta                                                                             |
| GND      | Signal Ground                                                                                       |
| GP       | Basic Program (PLC)                                                                                 |
| GS       | Gear stage                                                                                          |
| GSD      | Device master file for describing a PROFIBUS slave                                                  |
| GSDML    | Generic Station Description Markup Language: XML-based description language for creating a GSD file |
| GUD      | Global User Data                                                                                    |
| GWPS     | Grinding Wheel Peripheral Speed                                                                     |

|                 |                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------|
| <b>H</b>        |                                                                                                    |
| HEX             | Abbreviation for hexadecimal number                                                                |
| HHU             | HandHeld Unit                                                                                      |
| HMI             | Human Machine Interface, SINUMERIK user interface                                                  |
| HW              | Hardware                                                                                           |
| HW Config       | SIMATIC S7 tool for configuration and parameterization of hardware components within an S7 project |
| HW limit switch | Hardware limit switch                                                                              |

|          |                                                       |
|----------|-------------------------------------------------------|
| <b>I</b> |                                                       |
| I        | Input                                                 |
| I/RF     | Infeed/regenerative feedback unit of SIMODRIVE 611(D) |

Appendix

A.1 List of abbreviations

|     |                            |
|-----|----------------------------|
| IBN | Commissioning              |
| ICA | Interpolatory compensation |
| INC | Increment                  |
| IPO | Interpolator               |
| IS  | Interface signal           |

|          |                     |
|----------|---------------------|
| <b>J</b> |                     |
| JOG      | Jogging: Setup mode |

|               |                             |
|---------------|-----------------------------|
| <b>K</b>      |                             |
| $K_p$         | Proportional gain           |
| $K_{\bar{u}}$ | Transformation ratio        |
| $K_v$         | Gain factor of control loop |

|          |                              |
|----------|------------------------------|
| <b>L</b> |                              |
| LAD      | LADder diagram               |
| LAI      | Logical Machine Axis Image   |
| LAN      | Local Area Network           |
| LEC      | Leadscrew Error Compensation |
| LEDs     | Light Emitting Diode         |
| LF       | Line Feed                    |
| LSB      | Least Significant Bit        |
| LUD      | Local User Data              |

|          |                                                   |
|----------|---------------------------------------------------|
| <b>M</b> |                                                   |
| MAC      | Media Access Control                              |
| MB       | Megabyte                                          |
| MCI      | Motion Control Interface                          |
| MCIS     | Motion Control Information System                 |
| MCP      | Machine Control Panel                             |
| MCS      | Machine Coordinate System                         |
| MD       | Machine Data                                      |
| MDA      | Manual Data Automatic: Manual input               |
| MLFB     | Machine-Readable Product Code                     |
| MM       | Motor Module                                      |
| MMC      | Man Machine Communication                         |
| MPF      | Main Program File: NC part program (main program) |
| MPI      | Multi Port Interface                              |
| MSD      | Main Spindle Drive                                |
| MSGW     | Message word                                      |

| <b>N</b> |                                             |
|----------|---------------------------------------------|
| NC       | Numerical Control                           |
| NCK      | Numerical Control Kernel                    |
| NCU      | Numerical Control Unit                      |
| NRK      | Name for the operating system of the NCK    |
| NX       | Numerical eXtension (axis extension module) |
| O        | Output                                      |

| <b>O</b> |                                                                          |
|----------|--------------------------------------------------------------------------|
| OB       | Organization block in the PLC                                            |
| OEM      | Original Equipment Manufacturer                                          |
| OLP      | Optical Link Plug: Fiber optic bus connector                             |
| OP       | Operator Panel: Operating equipment                                      |
| OPI      | Operator Panel Interface: Interface for connection to the operator panel |
| OPT      | Options                                                                  |

| <b>P</b> |                                                                                                                                                                                                                          |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PC       | Position Controller                                                                                                                                                                                                      |
| PC       | Personal Computer                                                                                                                                                                                                        |
| PCMCIA   | Personal Computer Memory Card International Association                                                                                                                                                                  |
| PCU      | PC Unit                                                                                                                                                                                                                  |
| PG       | Programming device                                                                                                                                                                                                       |
| PII      | Process Image Input                                                                                                                                                                                                      |
| PIQ      | Process Image Output                                                                                                                                                                                                     |
| PKE      | Parameter identification: Part of a PIV                                                                                                                                                                                  |
| PKW      | Parameter identification: Value: Parameterizing part of a PPO                                                                                                                                                            |
| PLC      | Programmable Logic Control: Adaptation control                                                                                                                                                                           |
| PMS      | Position Measuring System                                                                                                                                                                                                |
| PN       | PROFINET                                                                                                                                                                                                                 |
| PNO      | PROFIBUS user organization                                                                                                                                                                                               |
| PO       | POWER ON                                                                                                                                                                                                                 |
| POS      | Positioning: e.g. POS axis = positioning axis = channel axis which is not traversed to its programmed position in an interpolatory relationship to other axes, i.e. it is traversed independently of other channel axes. |
| POSMO A  | Positioning Motor Actuator: Positioning motor                                                                                                                                                                            |
| POSMO CA | Positioning Motor Compact AC: Complete drive unit with integrated power and control module as well as positioning unit and program memory; AC infeed                                                                     |
| POSMO CD | Positioning Motor Compact DC: Like CA but with DC infeed                                                                                                                                                                 |
| POSMO SI | Positioning Motor Servo Integrated: Positioning motor, DC infeed                                                                                                                                                         |
| POU      | Program Organization Unit                                                                                                                                                                                                |

Appendix

A.1 List of abbreviations

|          |                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------|
| PPO      | Parameter Process data Object; Cyclic data telegram for PROFIBUS DP transmission and "Variable speed drives" profile |
| PROFIBUS | Process Field Bus: Serial data bus                                                                                   |
| PRT      | Program test                                                                                                         |
| PSW      | Program control word                                                                                                 |
| PTP      | Point-To-Point                                                                                                       |
| PUD      | Program global User Data: Global program variable                                                                    |
| PZD      | Process Data: Process data part of a PPO                                                                             |

|          |                             |
|----------|-----------------------------|
| <b>Q</b> |                             |
| QEC      | Quadrant error compensation |

|          |                                                                                                                                  |
|----------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>R</b> |                                                                                                                                  |
| RAM      | Random Access Memory: Read/write memory                                                                                          |
| REF      | REFErence point approach function                                                                                                |
| REPOS    | REPOSition function                                                                                                              |
| RISC     | Reduced Instruction Set Computer: Type of processor with small instruction set and ability to process instructions at high speed |
| ROV      | Rapid Override: Input correction                                                                                                 |
| RP       | R variable, arithmetic parameter, predefined user variable                                                                       |
| RPY      | Roll Pitch Yaw: Rotation type of a coordinate system                                                                             |
| RTCP     | Real Time Control Protocol                                                                                                       |
| RTL      | Rapid Traverse Linear Interpolation: Linear interpolation during rapid traverse motion                                           |

|          |                                                              |
|----------|--------------------------------------------------------------|
| <b>S</b> |                                                              |
| SBC      | Safe Brake Control                                           |
| SBL      | Single Block                                                 |
| SD       | Setting Data                                                 |
| SEA      | Setting Data Active: Identifier (file type) for setting data |
| SERUPRO  | SEArch RUn by PROgram test                                   |
| SGA      | Safety-related output                                        |
| SGE      | Safety-related input                                         |
| SH       | Safe standstill                                              |
| SIM      | Single Inline Module                                         |
| SK       | Softkey                                                      |
| SKP      | SKIP: Function for skipping a part program block             |
| SLM      | Synchronous Linear Motor                                     |
| SM       | Stepper motor                                                |
| SMC      | Sensor Module Cabinet Mounted                                |
| SME      | Sensor Module Externally Mounted                             |
| SPF      | Sub Program File: Subprogram                                 |

|                 |                                               |
|-----------------|-----------------------------------------------|
| SRAM            | Static RAM (non-volatile)                     |
| SRM             | Synchronous Rotary Motor                      |
| SSI             | Synchronous Serial Interface (interface type) |
| SSL             | Block search                                  |
| STW             | Control word                                  |
| SW              | Software                                      |
| SW limit switch | Software limit switch                         |
| SYF             | System Files                                  |
| SYNACT          | SYNchronized ACTION                           |

|          |                                                                                               |
|----------|-----------------------------------------------------------------------------------------------|
| <b>T</b> |                                                                                               |
| T        | Tool                                                                                          |
| TB       | Terminal Board (SINAMICS)                                                                     |
| TC       | Tool Change                                                                                   |
| TCP      | Tool Center Point: Tool tip                                                                   |
| TCP/IP   | Transport Control Protocol / Internet Protocol                                                |
| TCU      | Thin Client Unit                                                                              |
| TEA      | Testing Data Active: Identifier for machine data                                              |
| TIA      | Totally Integrated Automation                                                                 |
| TLC      | Tool Length Compensation                                                                      |
| TM       | Terminal Module (SINAMICS)                                                                    |
| TM       | Tool Management                                                                               |
| TNRC     | Tool Nose Radius Compensation                                                                 |
| TO       | Tool Offset                                                                                   |
| TOA      | Tool Offset Active: Identifier (file type) for tool offsets                                   |
| TRANSMIT | Transform Milling Into Turning: Coordination transformation for milling operations on a lathe |
| TRC      | Tool Radius Compensation                                                                      |
| TTL      | Transistor-Transistor Logic (interface type)                                                  |

|          |                              |
|----------|------------------------------|
| <b>U</b> |                              |
| UP       | User program                 |
| UPS      | Uninterruptible Power Supply |
| USB      | Universal Serial Bus         |

|          |                                                                                 |
|----------|---------------------------------------------------------------------------------|
| <b>V</b> |                                                                                 |
| VDE      | Verband Deutscher Elektrotechniker [Association of German Electrical Engineers] |
| VDI      | Internal communication interface between NCK and PLC                            |
| VDI      | Verein Deutscher Ingenieure [Association of German Engineers]                   |
| VI       | Voltage Input                                                                   |
| VO       | Voltage Output                                                                  |

| <b>W</b> |                                                 |
|----------|-------------------------------------------------|
| WCS      | Workpiece coordinate system                     |
| WO       | Work Offset                                     |
| WOA      | Work Offset Active: Identifier for work offsets |
| WOP      | Workshop-Oriented Programming                   |
| WPD      | WorkPiece Directory                             |

| <b>X</b> |                            |
|----------|----------------------------|
| XML      | Extensible Markup Language |

| <b>Z</b> |                        |
|----------|------------------------|
| ZSW      | Status word (of drive) |

## A.2 Feedback on the documentation

This document will be continuously improved with regard to its quality and ease of use. Please help us with this task by sending your comments and suggestions for improvement via e-mail or fax to:

|                                                                                                                                          | Zip code:            City:         |
|                                                                                                                                          | Phone:                /            |
| Fax:                    /                                                                                                                |                                    |

Suggestions and/or corrections

## A.3 Overview

# Glossary

## Absolute dimensions

A destination for an axis movement is defined by a dimension that refers to the origin of the currently active coordinate system. See → Incremental dimension

## Acceleration with jerk limitation

In order to optimize the acceleration response of the machine whilst simultaneously protecting the mechanical components, it is possible to switch over in the machining program between abrupt acceleration and continuous (jerk-free) acceleration.

## Address

An address is the identifier for a certain operand or operand range, e.g. input, output etc.

## Alarms

All → messages and alarms are displayed on the operator panel in plain text with date and time and the corresponding symbol for the cancel criterion. Alarms and messages are displayed separately.

### 1. Alarms and messages in the part program:

Alarms and messages can be displayed in plain text directly from the part program.

### 2. Alarms and messages from PLC

Alarms and messages for the machine can be displayed in plain text from the PLC program. No additional function block packages are required for this purpose.

## Archive

Reading out of files and/or directories on an **external** memory device.

## Asynchronous subroutine

Part program that can be started asynchronously to (independently of) the current program status using an interrupt signal (e.g. "Rapid NC input" signal).

## Automatic

Operating mode of the control (block sequence operation according to DIN): Operating mode for NC systems in which a → subprogram is selected and executed continuously.

### Auxiliary functions

Auxiliary functions enable → part programs to transfer → parameters to the → PLC, which then trigger reactions defined by the machine manufacturer.

### Axes

In accordance with their functional scope, the CNC axes are subdivided into:

- Axes: interpolating path axes
- Auxiliary axes: non-interpolating feed and positioning axes with an axis-specific feed rate. Auxiliary axes are not involved in actual machining, e.g. tool feeder, tool magazine.

### Axis address

See → Axis identifier

### Axis identifier

Axes are identified using X, Y, and Z as defined in DIN 66217 for a dextrorotatory, right-angled → coordinate system.

Rotary axes rotating around X, Y, and Z are identified using A, B, and C. Additional axes situated parallel to the specified axes can be designated using other letters.

### Axis name

See → Axis identifier

### Backlash compensation

Compensation for a mechanical machine backlash, e.g. backlash on reversal for ball screws. Backlash compensation can be entered separately for each axis.

### Backup battery

The backup battery ensures that the → user program in the → CPU is stored so that it is safe from power failure and so that specified data areas and bit memory, timers and counters are stored retentively.

### Base axis

Axis whose setpoint or actual value position forms the basis of the calculation of a compensation value.

**Basic coordinate system**

Cartesian coordinate system which is mapped by transformation onto the machine coordinate system.

The programmer uses axis names of the basic coordinate system in the → part program. The basic coordinate system exists parallel to the → machine coordinate system if no → transformation is active. The difference between the two coordinate systems lies in the → axis identifiers.

**Baud rate**

Rate of data transfer (Bit/s).

**Blank**

Workpiece as it is before it is machined.

**Block**

"Block" is the term given to any files required for creating and processing programs.

**Block search**

For debugging purposes or following a program abort, the "Block search" function can be used to select any location in the part program at which the program is to be started or resumed.

**Booting**

Loading the system program after power ON.

**C axis**

Axis around which the tool spindle describes a controlled rotational and positioning movement.

**Channel**

A channel is characterized by the fact that it can process a → part program independently of other channels. A channel exclusively controls the axes and spindles assigned to it. Part program runs of different channels can be coordinated through → synchronization.

**Circular interpolation**

The → tool moves on a circle between specified points on the contour at a given feed rate, and the workpiece is thereby machined.

## CNC

See → NC

## COM

Component of the NC for the implementation and coordination of communication.

## Compensation axis

Axis with a setpoint or actual value modified by the compensation value

## Compensation memory

Data range in the control, in which the tool offset data are stored.

## Compensation table

Table containing interpolation points. It provides the compensation values of the compensation axis for selected positions on the basic axis.

## Compensation value

Difference between the axis position measured by the encoder and the desired, programmed axis position.

## Connecting cables

Connecting cables are pre-assembled or user-assembled 2-wire cables with a connector at each end. This connecting cable connects the → CPU to a → programming device or to other CPUs by means of a → multi-point interface (MPI).

## Continuous-path mode

The objective of continuous-path mode is to avoid substantial deceleration of the → path axes at the part program block boundaries and to change to the next block at as close to the same path velocity as possible.

## Contour

Contour of the → workpiece

## Contour monitoring

The following error is monitored within a definable tolerance band as a measure of contour accuracy. An unacceptably high following error can cause the drive to become overloaded, for example. In such cases, an alarm is output and the axes are stopped.

**Coordinate system**

See → Machine coordinate system, → Workpiece coordinate system

**CPU**

Central processing unit, see → PLC

**C-Spline**

The C-Spline is the most well-known and widely used spline. The transitions at the interpolation points are continuous, both tangentially and in terms of curvature. 3rd order polynomials are used.

**Curvature**

The curvature  $k$  of a contour is the inverse of radius  $r$  of the nestling circle in a contour point ( $k = 1/r$ ).

**Cycles**

Protected subroutines for execution of repetitive machining operations on the → workpiece.

**Data block**

1. Data unit of the → PLC that → HIGHSTEP programs can access.
2. Data unit of the → NC: Data modules contain data definitions for global user data. These data can be initialized directly when they are defined.

**Data word**

Two-byte data unit within a → data block.

**Diagnosis**

1. Operating area of the control.
2. The control has both a self-diagnostics program as well as test functions for servicing purposes: status, alarm, and service displays

**Dimensions specification, metric and inches**

Position and lead values can be programmed in inches in the machining program. Irrespective of the programmable dimensions ( $G70/G71$ ), the controller is set to a basic system.

## **DRF**

Differential Resolver Function: NC function which generates an incremental zero offset in Automatic mode in conjunction with an electronic handwheel.

## **Drive**

The drive is the unit of the CNC that performs the speed and torque control based on the settings of the NC.

## **Dynamic feedforward control**

Inaccuracies in the → contour due to following errors can be practically eliminated using dynamic, acceleration-dependent feedforward control. This results in excellent machining accuracy even at high → path velocities. Feedforward control can be selected and deselected on an axis-specific basis via the → part program.

## **Editor**

The editor makes it possible to create, edit, extend, join, and import programs/texts/program blocks.

## **Exact stop**

When an exact stop statement is programmed, the position specified in a block is approached exactly and, if necessary, very slowly. To reduce the approach time, → exact stop limits are defined for rapid traverse and feed.

## **Exact stop limit**

When all path axes reach their exact stop limits, the control responds as if it had reached its precise destination point. A block advance of the → part program occurs.

## **External zero offset**

Zero offset specified by the → PLC.

## **Fast retraction from contour**

When an interrupt occurs, a motion can be initiated via the CNC machining program, enabling the tool to be quickly retracted from the workpiece contour that is currently being machined. The retraction angle and the distance retracted can also be parameterized. After fast retraction, an interrupt routine can also be executed (SINUMERIK 840D).

## **Feed override**

The programmed velocity is overridden by the current velocity setting made via the → machine control panel or from the → PLC (0 to 200%). The feedrate can also be corrected by a programmable percentage factor (1-200%) in the machining program.

**Finished-part contour**

Contour of the finished workpiece. See → Raw part.

**Fixed machine point**

Point that is uniquely defined by the machine tool, e.g. machine reference point.

**Fixed-point approach**

Machine tools can approach fixed points such as a tool change point, loading point, pallet change point, etc. in a defined way. The coordinates of these points are stored in the control. The control moves the relevant axes in → rapid traverse, whenever possible.

**Frame**

A frame is an arithmetic rule that transforms one Cartesian coordinate system into another Cartesian coordinate system. A frame contains the following components: → zero offset, → rotation, → scaling, → mirroring.

**Functionality**

The path-jerk limitation can be activated/deactivated by programming the setting data.

Parameter: *Value*

- Value range: TRUE, FALSE

Application:

- Part program
- Static synchronized action

**Geometry**

Description of a → workpiece in the → workpiece coordinate system.

**Geometry axis**

Geometry axes are used to describe a 2- or 3-dimensional area in the workpiece coordinate system.

**Ground**

Ground is taken as the total of all linked inactive parts of a device which will not become live with a dangerous contact voltage even in the event of a malfunction.

### Helical interpolation

The helical interpolation function is ideal for machining internal and external threads using form milling cutters and for milling lubrication grooves.

The helix comprises two movements:

- Circular movement in one plane
- A linear movement perpendicular to this plane

### High-level CNC language

The high-level language offers: → user-defined variables, → system variables, → macro techniques.

### High-speed digital inputs/outputs

The digital inputs can be used for example to start fast CNC program routines (interrupt routines). The digital CNC outputs can be used to trigger fast, program-controlled switching functions (SINUMERIK 840D).

### HIGHSTEP

Summary of programming options for → PLCs of the AS300/AS400 system.

### Identifier

In accordance with DIN 66025, words are supplemented using identifiers (names) for variables (arithmetic variables, system variables, user variables), subroutines, key words, and words with multiple address letters. These supplements have the same meaning as the words with respect to block format. Identifiers must be unique. It is not permissible to use the same identifier for different objects.

### Inch measuring system

Measuring system, which defines distances in inches and fractions of inches.

### Inclined surface machining

Drilling and milling operations on workpiece surfaces that do not lie in the coordinate planes of the machine can be performed easily using the function "inclined-surface machining".

### Increment

Travel path length specification based on number of increments. The number of increments can be stored as → setting data or be selected by means of a suitably labeled key (i.e. 10, 100, 1000, 10000).

**Incremental dimension**

Also incremental dimension: A destination for axis traversal is defined by a distance to be covered and a direction referenced to a point already reached. See → Absolute dimension.

**Intermediate blocks**

Motions with selected → tool offset ( $G_{41}/G_{42}$ ) may be interrupted by a limited number of intermediate blocks (blocks without axis motions in the offset plane), whereby the tool offset can still be correctly compensated for. The permissible number of intermediate blocks which the control reads ahead can be set in system parameters.

**Interpolator**

Logic unit of the → NCK that defines intermediate values for the motions to be carried out in individual axes based on information on the end positions specified in the part program.

**Interpolatory compensation**

Interpolatory compensation is a tool that enables manufacturing-related leadscrew error and measuring system error compensations (SSFK, MSFK).

**Interrupt routine**

Interrupt routines are special → subroutines that can be started by events (external signals) in the machining process. A part program block which is currently being worked through is interrupted and the position of the axes at the point of interruption is automatically saved.

**Inverse-time feedrate**

With SINUMERIK 840D, the time required for the path of a block to be traversed can be programmed for the axis motion instead of the feed velocity ( $G_{93}$ ).

**JOG**

Control operating mode (setup mode): In JOG mode, the machine can be set up. Individual axes and spindles can be traversed in JOG mode by means of the direction keys. Additional functions in JOG mode include: → Reference point approach, → Repos, and → Preset (set actual value).

**Key switch**

The key switch on the → machine control panel has four positions that are assigned functions by the operating system of the control. The key switch has three different colored keys that can be removed in the specified positions.

## Keywords

Words with specified notation that have a defined meaning in the programming language for → part programs.

## KV

Servo gain factor, a control variable in a control loop.

## Leading axis

The leading axis is the → gantry axis that exists from the point of view of the operator and programmer and, thus, can be influenced like a standard NC axis.

## Leadscrew error compensation

Compensation for the mechanical inaccuracies of a leadscrew participating in the feed. The control uses stored deviation values for the compensation.

## Limit speed

Maximum/minimum (spindle) speed: The maximum speed of a spindle can be limited by specifying machine data, the → PLC or → setting data.

## Linear axis

In contrast to a rotary axis, a linear axis describes a straight line.

## Linear interpolation

The tool travels along a straight line to the destination point while machining the workpiece.

## Load memory

The load memory is the same as → RAM for the CPU 314 of the → PLC.

## Look Ahead

The **Look Ahead** function is used to achieve an optimal machining speed by looking ahead over an assignable number of traversing blocks.

**Machine axes**

Physically existent axes on the machine tool.

**Machine control panel**

An operator panel on a machine tool with operating elements such as keys, rotary switches, etc., and simple indicators such as LEDs. It is used to directly influence the machine tool via the PLC.

**Machine coordinate system**

A coordinate system, which is related to the axes of the machine tool.

**Machine zero**

Fixed point of the machine tool to which all (derived) measuring systems can be traced back.

**Machining channel**

A channel structure can be used to shorten idle times by means of parallel motion sequences, e.g. moving a loading gantry simultaneously with machining. Here, a CNC channel must be regarded as a separate CNC control system with decoding, block preparation and interpolation.

**Macro techniques**

Grouping of a set of statements under a single identifier. The identifier represents the set of consolidated statements in the program.

**Main block**

A block prefixed by ":" introductory block, containing all the parameters required to start execution of a → part program.

**Main program**

The → part program designated by a number or an identifier in which additional main programs, subroutines, or → cycles can be called.

**MDA**

Control operating mode: Manual Data Automatic. In the MDA mode, individual program blocks or block sequences with no reference to a main program or subroutine can be input and executed immediately afterwards through actuation of the NC start key.

## Messages

All messages programmed in the part program and → alarms detected by the system are displayed on the operator panel in plain text with date and time and the corresponding symbol for the cancel criterion. Alarms and messages are displayed separately.

## Metric measuring system

Standardized system of units: For length, e.g. mm (millimeters), m (meters).

## Mirroring

Mirroring reverses the signs of the coordinate values of a contour, with respect to an axis. It is possible to mirror with respect to more than one axis at a time.

## Mode group

Axes and spindles that are technologically related can be combined into one mode group. Axes/spindles of a BAG can be controlled by one or more → channels. The same → mode type is always assigned to the channels of the mode group.

## Mode of operation

An operating concept on a SINUMERIK control. The following modes are defined: → Jog, → MDA, → Automatic.

## NC

Numerical Control: Numerical control (NC) includes all components of machine tool control: → NCK, → PLC, HMI, → COM.

---

### Note

A more correct term for SINUMERIK 840D controls would be: Computerized Numerical Control

---

## NCK

Numerical Control Kernel: Component of NC that executes the → part programs and basically coordinates the motion operations for the machine tool.

## Network

A network is the connection of multiple S7-300 and other end devices, e.g. a programming device via a → connecting cable. A data exchange takes place over the network between the connected devices.

**NRK**

Numeric robotic kernel (operating system of → NCK)

**NURBS**

The motion control and path interpolation that occurs within the control is performed based on NURBS (**N**on **U**niform **R**ational **B**-**S**plines). As a result, a uniform process is available within the control for all interpolations for SINUMERIK 840D.

**OEM**

The scope for implementing individual solutions (OEM applications) for the SINUMERIK 840D has been provided for machine manufacturers, who wish to create their own operator interface or integrate process-oriented functions in the control.

**Operator interface**

The user interface (UI) is the display medium for a CNC in the form of a screen. It features horizontal and vertical softkeys.

**Oriented spindle stop**

Stops the workpiece spindle in a specified angular position, e.g. in order to perform additional machining at a particular location.

**Oriented tool retraction**

**RETT** RETT **TOOL**: If machining is interrupted (e.g. when a tool breaks), a program command can be used to retract the tool in a user-specified orientation by a defined distance.

**Overall reset**

In the event of an overall reset, the following memories of the → CPU are deleted:

- → Work memory
- Read/write area of → load memory
- → System memory
- → Backup memory

**Override**

Manual or programmable control feature, which enables the user to override programmed feedrates or speeds in order to adapt them to a specific workpiece or material.

### Part program block

Part of a → part program that is demarcated by a line feed. There are two types: → main blocks and → subblocks.

### Part program management

Part program management can be organized by → workpieces. The size of the user memory determines the number of programs and the amount of data that can be managed. Each file (programs and data) can be given a name consisting of a maximum of 24 alphanumeric characters.

### Path axis

Path axes include all machining axes of the → channel that are controlled by the → interpolator in such a way that they start, accelerate, stop, and reach their end point simultaneously.

### Path feedrate

Path feed affects → path axes. It represents the geometric sum of the feed rates of the → geometry axes involved.

### Path velocity

The maximum programmable path velocity depends on the input resolution. For example, with a resolution of 0.1 mm the maximum programmable path velocity is 1000 m/min.

### PCIN data transfer program

PCIN is an auxiliary program for sending and receiving CNC user data (e.g. part programs, tool offsets, etc.) via a serial interface. The PCIN program can run in MS-DOS on standard industrial PCs.

### Peripheral module

I/O modules represent the link between the CPU and the process.

I/O modules are:

- → Digital input/output modules
- → Analog input/output modules
- → Simulator modules

## PLC

**Programmable Logic Control:** → Programmable logic controller. Component of → NC: Programmable controller for processing the control logic of the machine tool.

## PLC program memory

SINUMERIK 840D: The PLC user program, the user data and the basic PLC program are stored together in the PLC user memory.

## PLC programming

The PLC is programmed using the **STEP 7** software. The STEP 7 programming software is based on the **WINDOWS** standard operating system and contains the STEP 5 programming functions with innovative enhancements.

## Polar coordinates

A coordinate system, which defines the position of a point on a plane in terms of its distance from the origin and the angle formed by the radius vector with a defined axis.

## Polynomial interpolation

Polynomial interpolation enables a wide variety of curve characteristics to be generated, such as **straight line, parabolic, exponential functions** (SINUMERIK 840D).

## Positioning axis

Axis that performs an auxiliary movement on a machine tool (e.g. tool magazine, pallet transport). Positioning axes are axes that do not interpolate with → path axes.

## Pre-coincidence

Block change occurs already when the path distance approaches an amount equal to a specifiable delta of the end position.

## Program block

Program blocks contain the main program and subroutines of → part programs.

## Programmable frames

Programmable → frames enable dynamic definition of new coordinate system output points while the part program is being executed. A distinction is made between absolute definition using a new frame and additive definition with reference to an existing starting point.

### **Programmable Logic Control**

Programmable logic controllers (PLC) are electronic controls, the function of which is stored as a program in the control unit. This means that the layout and wiring of the device do not depend on the function of the control. The programmable logic controller has the same structure as a computer; it consists of a CPU (central module) with memory, input/output modules and an internal bus system. The peripherals and the programming language are matched to the requirements of the control technology.

### **Programmable working area limitation**

Limitation of the motion space of the tool to a space defined by programmed limitations.

### **Programming key**

Character and character strings that have a defined meaning in the programming language for → part programs.

### **Protection zone**

Three-dimensional zone within the → working area into which the tool tip must not pass.

### **Quadrant error compensation**

Contour errors at quadrant transitions, which arise as a result of changing friction conditions on the guideways, can be virtually entirely eliminated with the quadrant error compensation. Parameterization of the quadrant error compensation is performed by means of a circuit test.

### **R parameters**

Arithmetic parameter that can be set or queried by the programmer of the → part program for any purpose in the program.

### **Rapid traverse**

The highest traverse rate of an axis. For example, rapid traverse is used when the tool approaches the → workpiece contour from a resting position or when the tool is retracted from the workpiece contour. The rapid traverse velocity is set on a machine-specific basis using a machine data element.

### **Reference point**

Machine tool position that the measuring system of the → machine axes references.

**Rotary axis**

Rotary axes apply a workpiece or tool rotation to a defined angular position.

**Rotation**

Component of a → frame that defines a rotation of the coordinate system around a particular angle.

**Rounding axis**

Rounding axes rotate a workpiece or tool to an angular position corresponding to an indexing grid. When a grid index is reached, the rounding axis is "in position".

**Safety Functions**

The control is equipped with permanently active monitoring functions that detect faults in the → CNC, the → PLC, and the machine in a timely manner so that damage to the workpiece, tool, or machine is largely prevented. In the event of a fault, the machining operation is interrupted and the drives stopped. The cause of the malfunction is logged and output as an alarm. At the same time, the PLC is notified that a CNC alarm has been triggered.

**Scaling**

Component of a → frame that implements axis-specific scale modifications.

**Selecting**

Series of statements to the NC that act in concert to produce a particular → workpiece. Likewise, this term applies to execution of a particular machining operation on a given → raw part.

**Serial RS-232-C interface**

For data input/output, the PCU 20 has one serial V.24 interface (RS232) while the PCU 50/70 has two V.24 interfaces. Machining programs and manufacturer and user data can be loaded and saved via these interfaces.

**Setting data**

Data, which communicates the properties of the machine tool to the NC, as defined by the system software.

### Softkey

A key, whose name appears on an area of the screen. The choice of soft keys displayed is dynamically adapted to the operating situation. The freely assignable function keys (soft keys) are assigned defined functions in the software.

### Software limit switch

Software limit switches limit the traversing range of an axis and prevent an abrupt stop of the slide at the hardware limit switch. Two value pairs can be specified for each axis and activated separately by means of the → PLC.

### Spline interpolation

With spline interpolation, the controller can generate a smooth curve characteristic from only a few specified interpolation points of a set contour.

### SRT

Transformation ratio

### Standard cycles

Standard cycles are provided for machining operations, which are frequently repeated:

- Cycles for drilling/milling applications
- for turning technology

The available cycles are listed in the "Cycle support" menu in the "Program" operating area. Once the desired machining cycle has been selected, the parameters required for assigning values are displayed in plain text.

### Subblock

Block preceded by "N" containing information for a sequence, e.g. positional data.

### Subroutine

Sequence of statements of a → part program that can be called repeatedly with different defining parameters. The subroutine is called from a main program. Every subroutine can be protected against unauthorized read-out and display. → Cycles are a form of subroutines.

### Synchronization

Statements in → part programs for coordination of sequences in different → channels at certain machining points.

## Synchronized actions

### 1. Auxiliary function output

During workpiece machining, technological functions (→ auxiliary functions) can be output from the CNC program to the PLC. For example, these auxiliary functions are used to control additional equipment for the machine tool, such as quills, grabbers, clamping chucks, etc.

### 2. Fast auxiliary function output

For time-critical switching functions, the acknowledgement times for the → auxiliary functions can be minimized and unnecessary hold points in the machining process can be avoided.

## Synchronized axes

Synchronized axes take the same time to traverse their path as the geometry axes take for their path.

## Synchronized axis

A synchronized axis is the → gantry axis whose set position is continuously derived from the motion of the → leading axis and is, thus, moved synchronously with the leading axis. From the point of view of the programmer and operator, the synchronized axis "does not exist".

## Syntax

```
$SC_IS_SD_MAX_PATH_JERK = value
```

## System memory

The system memory is a memory in the CPU in which the following data is stored:

- Data required by the operating system
- The operands times, counters, markers

## System variables

A variable that exists without any input from the programmer of a → part program. It is defined by a data type and the variable name preceded by the character \$. See → User-defined variable.

### **Tapping without compensating chuck**

This function allows threads to be tapped without a compensating chuck. By using the interpolating method of the spindle as a rotary axis and the drilling axis, threads can be cut to a precise final drilling depth, e.g. for blind hole threads (requirement: spindles in axis operation).

### **Text editor**

See → Editor

### **TOA area**

The TOA area includes all tool and magazine data. By default, this area coincides with the → channel area with regard to the reach of the data. However, machine data can be used to specify that multiple channels share one → TOA unit so that common tool management data is then available to these channels.

### **TOA unit**

Each → TOA area can have more than one TOA unit. The number of possible TOA units is limited by the maximum number of active → channels. A TOA unit includes exactly one tool data block and one magazine data block. In addition, a TOA unit can also contain a toolholder data block (optional).

### **Tool**

Active part on the machine tool that implements machining (e.g. turning tool, milling tool, drill, LASER beam, etc.).

### **Tool nose radius compensation**

Contour programming assumes that the tool is pointed. Because this is not actually the case in practice, the curvature radius of the tool used must be communicated to the control which then takes it into account. The curvature center is maintained equidistantly around the contour, offset by the curvature radius.

### **Tool offset**

Consideration of the tool dimensions in calculating the path.

### **Tool radius compensation**

To directly program a desired → workpiece contour, the control must traverse an equidistant path to the programmed contour taking into account the radius of the tool that is being used (G41/G42).

**Transformation**

Additive or absolute zero offset of an axis.

**Traversing range**

The maximum permissible travel range for linear axes is  $\pm 9$  decades. The absolute value depends on the selected input and position control resolution and the unit of measurement (inch or metric).

**User memory**

All programs and data, such as part programs, subroutines, comments, tool offsets, and zero offsets/frames, as well as channel and program user data, can be stored in the shared CNC user memory.

**User Program**

User programs for the S7-300 automation systems are created using the programming language STEP 7. The user program has a modular layout and consists of individual blocks.

The basic block types are:

- Code blocks  
These blocks contain the STEP 7 commands.
- Data blocks  
These blocks contain constants and variables for the STEP 7 program.

**User-defined variable**

Users can declare their own variables for any purpose in the → part program or data block (global user data). A definition contains a data type specification and the variable name. See → System variable.

**Variable definition**

A variable definition includes the specification of a data type and a variable name. The variable names can be used to access the value of the variables.

**Velocity control**

In order to achieve an acceptable traverse rate in the case of very slight motions per block, an anticipatory evaluation over several blocks (→ Look Ahead) can be specified.

### **WinSCP**

WinSCP is a freely available open source program for Windows for the transfer of files.

### **Working area**

Three-dimensional zone into which the tool tip can be moved on account of the physical design of the machine tool. See → Protection zone.

### **Working area limitation**

With the aid of the working area limitation, the traversing range of the axes can be further restricted in addition to the limit switches. One value pair per axis may be used to describe the protected working area.

### **Working memory**

RAM is a work memory in the → CPU that the processor accesses when processing the application program.

### **Workpiece**

Part to be made/machined by the machine tool.

### **Workpiece contour**

Set contour of the → workpiece to be created or machined.

### **Workpiece coordinate system**

The workpiece coordinate system has its starting point in the → workpiece zero-point. In machining operations programmed in the workpiece coordinate system, the dimensions and directions refer to this system.

### **Workpiece zero**

The workpiece zero is the starting point for the → workpiece coordinate system. It is defined in terms of distances to the → machine zero.

## Zero offset

Specifies a new reference point for a coordinate system through reference to an existing zero point and a  $\rightarrow$  frame.

### 1. Settable

SINUMERIK 840D: A configurable number of settable zero offsets are available for each CNC axis. The offsets - which are selected by means of G functions - take effect alternately.

### 2. External

In addition to all the offsets which define the position of the workpiece zero, an external zero offset can be overridden by means of the handwheel (DRF offset) or from the PLC.

### 3. Programmable

Zero offsets can be programmed for all path and positioning axes using the `TRANS` statement.
