## Legal information

### Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

**⚠ DANGER**

indicates that death or severe personal injury **will** result if proper precautions are not taken.

**⚠ WARNING**

indicates that death or severe personal injury **may** result if proper precautions are not taken.

**⚠ CAUTION**

indicates that minor personal injury can result if proper precautions are not taken.

**NOTICE**

indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

### Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

### Proper use of Siemens products

Note the following:

**⚠ WARNING**

Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

### Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

### Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

# Table of contents

**1 Security information ..... 43**

**2 Basics of APL ..... 45**

2.1 Functions of the blocks ..... 45
2.1.1 General information ..... 45
2.1.1.1 User-configured message classes ..... 45
2.1.1.2 Forcing operating modes ..... 45
2.1.1.3 Resetting the block in case of interlocks or errors ..... 47
2.1.1.4 Neutral position for motors, valves and controllers ..... 54
2.1.1.5 Specifying warning times for control functions at motors and valves ..... 56
2.1.1.6 Output signal as a static signal or pulse signal ..... 57
2.1.1.7 Recording the first signal for interlock blocks ..... 58
2.1.1.8 Outputting a signal for start readiness ..... 59
2.1.1.9 Simulating signals ..... 64
2.1.1.10 Dead band ..... 67
2.1.1.11 Request for maintenance release ..... 68
2.1.1.12 Release for maintenance ..... 70
2.1.1.13 SIMATIC BATCH functionality ..... 73
2.1.1.14 Flutter suppression for channel blocks ..... 73
2.1.1.15 Startup characteristics over Trigger block ..... 75
2.1.1.16 Parameters that cannot be connected ..... 75
2.1.2 Operating modes of the blocks ..... 76
2.1.2.1 Overview of the modes ..... 76
2.1.2.2 On ..... 77
2.1.2.3 Out of service ..... 77
2.1.2.4 Manual and automatic mode for control blocks ..... 79
2.1.2.5 Manual and automatic mode for motors, valves and dosers ..... 82
2.1.2.6 Program mode for controllers ..... 85
2.1.2.7 Local mode ..... 86
2.1.2.8 State graph of the operating modes ..... 90
2.1.3 Monitoring functions ..... 92
2.1.3.1 Monitoring functions in the Advanced Process Library ..... 92
2.1.3.2 Group display for limit monitoring, CSF and ExtMsgx ..... 92
2.1.3.3 Limit monitoring ..... 93
2.1.3.4 Feedbacks ..... 104
2.1.3.5 Motor protection function ..... 106
2.1.4 Interlocking functions ..... 107
2.1.4.1 Interlocks ..... 107
2.1.4.2 Disabling interlocks ..... 111
2.1.4.3 Influence of the signal status on the interlock ..... 112
2.1.4.4 Forming the group status for interlock information ..... 113
2.1.4.5 Rapid stop for motors ..... 115
2.1.4.6 Bypassing signals ..... 115
2.1.5 Form signal status ..... 116
2.1.5.1 Forming and outputting signal status for blocks ..... 116
2.1.5.2 Forming and outputting the signal status for technologic blocks ..... 117

2.1.5.3 Forming and outputting the signal status of digital logic blocks ..... 119
2.1.5.4 Forming and outputting the signal status of analog logic blocks ..... 120
2.1.5.5 Forming and outputting the signal status of redundancy blocks ..... 121
2.1.5.6 Forming and outputting the signal status for blocks with configurable status prioritization ..... 122
2.1.5.7 Forming and outputting the signal status for interlock blocks ..... 124
2.1.5.8 Forming and outputting the signal status for mathematical blocks ..... 126
2.1.5.9 Forming and outputting the signal status for PCS 7 channel blocks ..... 127
2.1.5.10 Forming and outputting the signal status for channel blocks for field devices ..... 127
2.1.6 Error handling ..... 128
2.1.6.1 Error handling ..... 128
2.1.6.2 Outputting group errors ..... 130
2.1.7 Ramp function ..... 131
2.1.7.1 Using setpoint ramp ..... 131
2.1.7.2 Gradient limit of the setpoint ..... 132
2.1.7.3 Using a manipulated variable ramp ..... 133
2.1.7.4 Gradient limiting of the manipulated variable ..... 134
2.1.8 Internal/external setting ..... 135
2.1.8.1 Applying the dynamically activated dead band during the PV settling time ..... 135
2.1.8.2 Setpoint specification - internal/external ..... 136
2.1.8.3 Manipulated variable specification - internal/external ..... 137
2.1.9 Configurable response using the Feature I/O ..... 139
2.1.9.1 Configurable functions using the Feature I/O ..... 139
2.1.9.2 Stopping dosing at a flow alarm ..... 147
2.1.9.3 Failure handling ..... 148
2.1.9.4 Set startup characteristics ..... 148
2.1.9.5 Applying the dynamically activated dead band during the PV settling time ..... 152
2.1.9.6 Evaluation of signal status ..... 152
2.1.9.7 Evaluation of the signal status of the interlock signals ..... 153
2.1.9.8 Automatic post dosing for underdosing in automatic mode ..... 153
2.1.9.9 Block as summing unit or integrator ..... 154
2.1.9.10 Switching operator controls for external setpoint to visible ..... 154
2.1.9.11 Limit output Out ..... 154
2.1.9.12 Activating calculation of the flow rate for dosing by scale ..... 155
2.1.9.13 Condition monitoring information at MOD_Blocks ..... 155
2.1.9.14 Condition monitoring information at the channel blocks ..... 155
2.1.9.15 Disabling operating points ..... 156
2.1.9.16 Enabling direct changeover between forward and reverse ..... 156
2.1.9.17 Specifying the dosing type ..... 157
2.1.9.18 Flow setpoints in percent ..... 157
2.1.9.19 Specifying the influence of the signal status on the dosing process ..... 158
2.1.9.20 Unit for the rate of change ..... 158
2.1.9.21 Reading messages ..... 158
2.1.9.22 Setting the scaling for the process values ..... 159
2.1.9.23 Outputting a de-energized value for block-external simulation ..... 159
2.1.9.24 Switch to substitute value ..... 159
2.1.9.25 Substitute value switch in the event of an error ..... 160
2.1.9.26 Output substitute value if raw value is invalid ..... 160
2.1.9.27 Activating recording of the first signal ..... 161
2.1.9.28 External control deviation ..... 161
2.1.9.29 Activating error state for external process control error CSF ..... 162
2.1.9.30 Frequency converter with separate device feed ..... 162
2.1.9.31 Separate evaluation for excluded and simulated interlock signals ..... 162

2.1.9.32 Use an internal or external setpoint for the absolute fine dosing quantity ..... 164
2.1.9.33 Activating the run time of feedback signals ..... 164
2.1.9.34 Outputting last valid value if raw value is invalid ..... 165
2.1.9.35 Use the last value following a complete download as the current value during startup of the block ..... 165
2.1.9.36 Activate LowCutOff ..... 166
2.1.9.37 Selecting values associated with messages ..... 167
2.1.9.38 Reporting with BATCH parameters ..... 167
2.1.9.39 Motor feedback is not available ..... 168
2.1.9.40 Display only input values that are interconnected in the faceplate ..... 168
2.1.9.41 Activate OS_Perm bits ..... 168
2.1.9.42 Disabling opening and closing ..... 169
2.1.9.43 Enabling local operator authorization ..... 169
2.1.9.44 Enable configuration of the dribbling quantity ..... 170
2.1.9.45 Enabling program mode ..... 170
2.1.9.46 Update acknowledgment and error status of the message call ..... 171
2.1.9.47 Control zone with frozen I component ..... 171
2.1.9.48 Control zone with specified I component ..... 171
2.1.9.49 Resetting the commands for changing the mode ..... 172
2.1.9.50 Enabling resetting of commands for the control settings ..... 172
2.1.9.51 Resetting the dosing quantity when dosing starts ..... 173
2.1.9.52 Process value with separate scale range ..... 173
2.1.9.53 Resetting via input signals in the event of interlocking (Protection) or errors ..... 174
2.1.9.54 Set reset depending on the operating mode or the LiOp parameter ..... 174
2.1.9.55 Activating reset of protection / error in manual mode ..... 175
2.1.9.56 Reset even with locked state ..... 176
2.1.9.57 Neutral position manipulated variable takes effect at startup ..... 176
2.1.9.58 Neutral position manipulated variable takes effect with "out of service" operating mode ..... 177
2.1.9.59 Setting switch or button mode ..... 177
2.1.9.60 Specifying switching mode ..... 178
2.1.9.61 Creep rate is always detected in the dosing quantity ..... 179
2.1.9.62 Enabling rapid stop via faceplate ..... 179
2.1.9.63 Position feedback signals are active ..... 179
2.1.9.64 Separate monitoring time for stopping the motor ..... 180
2.1.9.65 Separate interlock for each direction, position, or speed ..... 180
2.1.9.66 Separate delay times for each alarm ..... 181
2.1.9.67 Signaling limit violation ..... 181
2.1.9.68 Alarm setpoint difference ..... 182
2.1.9.69 Setpoint specification with separate display area and custom unit ..... 182
2.1.9.70 Control via auxiliary valve ..... 182
2.1.9.71 Enabling bumpless change to the proportional gain, derivative time and amplification of the differentiator ..... 183
2.1.9.72 Enable bumpless switchover to "Automatic" mode for operator only ..... 183
2.1.9.73 Disabling bumpless switchover to automatic mode for controllers ..... 183
2.1.9.74 Enabling bumpless switchover to automatic mode for valves, motors, and dosers ..... 184
2.1.9.75 Summing characteristics continuous or triggered ..... 184
2.1.9.76 Suppression of all messages ..... 185
2.1.9.77 Output invalid raw value ..... 185
2.1.9.78 Transmission of status information of devices ..... 186
2.1.9.79 Control priority in the event of invalid or not plausible input commands ..... 186
2.1.9.80 Sealing the valve ..... 187
2.1.9.81 First-in detection response to deactivation ..... 187

2.1.9.82 Reaction of the switching points in the "Out of service" operating mode ..... 188
2.1.9.83 Reaction to the out of service mode ..... 188
2.1.9.84 Exiting local mode ..... 189
2.1.9.85 Interlock display with LocalSetting 2 or 4 ..... 189
2.1.9.86 Vibrate after torque monitoring ..... 190
2.1.9.87 With acknowledge overdosage ..... 190
2.1.9.88 Ramp rate calculation ..... 191
2.1.9.89 SP following PV in open loop has no priority over SP_Ext and SP limits ..... 193
2.1.9.90 With accelerated return of the integral action from the manipulated variable limit ..... 193
2.1.9.91 External/internal selection specification ..... 194
2.1.9.92 Setting switch or button mode for local commands ..... 195
2.1.9.93 Gradient limitation with time duration ..... 197
2.1.9.94 Analog input 1 is reserved for the operator ..... 197
2.1.9.95 Operator can change the setpoint via faceplate also in the "Local" mode ..... 197
2.1.9.96 Define the setpoint after stop and start of the motor ..... 198
2.1.9.97 Retain last output value in case of bad input signal status ..... 198
2.1.9.98 Forcing commands in the Local mode ..... 198
2.1.9.99 Motor stop in end position depends only on the corresponding feedback signal ..... 199
2.1.9.100 Substitution value is active if the block is in bypass ..... 199
2.1.9.101 Enable external message ..... 200
2.1.9.102 Considering bad quality of automatic commands or external values ..... 200
2.1.9.103 Disable calculation of impulse control in LocalSetting 2 and 4 ..... 200
2.1.9.104 Inverter enable ..... 201
2.1.9.105 Scale dosing can be started only if StandStill = 1 ..... 201
2.1.9.106 Delete history of MV and DV moves during restart ..... 201
2.1.9.107 Status output calculation ..... 202
2.1.9.108 Suppress MsgLock and “Out of service” mode for a connected message block ..... 202
2.1.9.109 Variants of CPI calculation ..... 202
2.1.9.110 Scalable measuring range ..... 203
2.1.9.111 2 decimal points (scalable measuring range) ..... 203
2.1.9.112 3 decimal points (scalable measuring range) ..... 204
2.1.9.113 Output substitute values in case of communications error ..... 204
2.1.9.114 Output last values in case of communications error ..... 204
2.1.9.115 Dosing controls are deactivated during scale is in taring mode ..... 205
2.1.9.116 Do not evaluate the first run of the diagnostic blocks ..... 205
2.1.9.117 Selection of metadata and diagnostic blocks ..... 205
2.1.9.118 Limits disabled in faceplate ..... 206
2.1.9.119 Keep last valid raw value if input value is bad ..... 207
2.1.9.120 With PID initialization if mode SP intern extern changes ..... 207
2.1.9.121 Changes signal status of outputs in OOS ..... 208
2.1.9.122 Behavior in the case of Bus failure ..... 208
2.1.9.123 Button mode with triggered local control commands ..... 209
2.1.9.124 Understeering / underflow for measuring range 0...10V ..... 209
2.1.9.125 Disable limit act output when limit value message is disabled ..... 209
2.1.9.126 Resetting the Pending Error in Local Mode 1 and 3 ..... 210
2.1.9.127 Timestamp calculation ..... 210
2.1.9.128 Reversal of control direction for fail-open valves ..... 211
2.1.9.129 External Input to enable or Disable ..... 211
2.1.9.130 Switch over to internal time enable or Disable ..... 211
2.1.9.131 AS time enable or Disable ..... 212
2.1.9.132 Use connectable inputs OpenLi, StopLi, CloseLi with CtrlLiOp ..... 212
2.1.9.133 Selecting the Feature Bit when Namur Off = 1 ..... 212

2.1.9.134 Bypass over both connection BypLix OR Inx ... 212
2.1.9.135 Resynchronization after startup ... 213
2.1.9.136 Resynchronization after out of service or after simulation ... 213
2.1.9.137 Resynchronization after CSF ... 214
2.1.9.138 Resynchronization with StateTrkOn input ... 214
2.1.9.139 Control with output StopCtrl and state "No Cmd" ... 214
2.1.10 Functions for controllers ... 216
2.1.10.1 Delay alarm for control deviation at setpoint step changes ... 216
2.1.10.2 Inverting control direction ... 217
2.1.10.3 Error signal generation and dead band ... 217
2.1.10.4 Using control zones ... 220
2.1.10.5 Setpoint limiting for external setpoints ... 222
2.1.10.6 Tracking setpoint in manual mode ... 222
2.1.10.7 Tracking and limiting a manipulated variable ... 222
2.1.10.8 Feedforwarding and limiting disturbance variables ... 223
2.1.10.9 Structure segmentation at controllers ... 224
2.1.11 Messaging ... 225
2.1.11.1 Area of application of the alarm delays ... 225
2.1.11.2 One time value for all limits ... 226
2.1.11.3 One time value per limit pair ... 226
2.1.11.4 Two time values per limit pair ... 227
2.1.11.5 Two time values for each individual limit ... 228
2.1.11.6 Generating instance-specific messages ... 230
2.1.11.7 Suppressing messages using the MsgLock parameter ... 231
2.1.11.8 Time stamp ... 231
2.1.11.9 Connection of the time-stamped messages from EventTs or Event16Ts ... 233
2.1.12 Settings for operator control and monitoring ... 233
2.1.12.1 Display and operator input area for process values and setpoints ... 233
2.1.12.2 Opening additional faceplates ... 234
2.1.12.3 Labeling of buttons and text ... 235
2.1.12.4 Displaying auxiliary values ... 239
2.1.12.5 Selecting a unit of measure ... 240
2.1.13 Consumption of Process Objects ... 258
2.1.14 Resynchronization ... 258

2.2 Functions of the block icons ... 260
2.2.1 Block icon structure ... 260
2.2.2 Configuring the block icons ... 267
2.2.3 Operation via the block icon ... 269
2.2.4 Block icons for PID and FM controller ... 269
2.2.5 Block icon for interlock blocks ... 272
2.2.6 Block icons for SFC ... 274
2.2.7 Adding block icons to static picture components ... 276
2.2.8 Decimal points for the analog value display ... 277

2.3 Functions of the faceplates ... 279
2.3.1 Fast Operation for PID Controllers ... 279
2.3.2 Structure of the faceplate ... 279
2.3.3 Operator control permissions ... 285
2.3.4 Display of delay times ... 288
2.3.5 Switching operating states and operating modes ... 289
2.3.6 Changing values ... 291
2.3.7 FM controllers standard view (analog) ... 294

2.3.8 FM controllers standard view (pulse controller) ... 298
2.3.9 FM controllers standard view (step controller with position feedback) ... 302
2.3.10 FM controllers standard view (step controller without position feedback) ... 306
2.3.11 Interlock blocks standard view ... 310
2.3.12 Parameter view of PID controllers ... 315
2.3.13 Parameter view of FM controllers ... 318
2.3.14 Parameter view for motors and valves ... 320
2.3.15 Limit view of FM controllers ... 322
2.3.16 Limit view of PID controllers ... 325
2.3.17 Limit view of motors ... 328
2.3.18 Preview of FM controllers ... 331
2.3.19 Preview of interlock blocks ... 333
2.3.20 Ramp view ... 334
2.3.21 Alarm view ... 336
2.3.22 Batch view ... 336
2.3.23 Memo view ... 338
2.3.24 Trend view ... 341
2.3.25 AddOn View for function blocks ... 343
2.3.26 APL Operator Trend Control (AOTC) ... 343
2.3.27 Limit operation and display in the faceplate ... 355
2.3.28 Central color management ... 356
2.3.29 Bar graph ... 376
2.3.30 Reset of errors during Request 0/1 ... 382

2.4 PCS 7 measuring point browser ... 383
2.4.1 Overview of the "PCS 7 measuring point browser" window ... 383

**3 Operator control blocks ... 387**

3.1 Comparison of large & small blocks ... 387
3.1.1 OpAnL compared to OpAnS ... 387

3.2 OpAnL - Check and output analog signals (large) ... 389
3.2.1 Description of OpAnL ... 389
3.2.2 OpAnL modes ... 390
3.2.3 OpAnL functions ... 391
3.2.4 OpAnL error handling ... 394
3.2.5 OpAnL messaging ... 395
3.2.6 OpAnL I/Os ... 397
3.2.7 OpAnL block diagram ... 403
3.2.8 Operator control and monitoring ... 403
3.2.8.1 OpAnL views ... 403
3.2.8.2 OpAnL standard view ... 404
3.2.8.3 OpAnL parameter view ... 407
3.2.8.4 OpAnL trend view ... 407
3.2.8.5 OpAnL preview ... 409
3.2.8.6 Block icon for OpAnL ... 410

3.3 OpAnS - Check and output analog signals (small) ... 412
3.3.1 Description of OpAnS ... 412
3.3.2 OpAnS modes ... 413
3.3.3 OpAnS functions ... 414
3.3.4 OpAnS error handling ... 416
3.3.5 OpAnS messaging ... 417
3.3.6 OpAnS I/Os ... 417

3.3.7 OpAnS block diagram ... 420
3.3.8 Operator control and monitoring ... 421
3.3.8.1 OpAnS views ... 421
3.3.8.2 OpAnS standard view ... 421
3.3.8.3 OpAnS parameter view ... 423
3.3.8.4 OpAnS preview ... 424
3.3.8.5 OpAnS block icon ... 425

3.4 OpDi01 - Manipulating a digital value (2 pushbuttons) ... 426
3.4.1 Description of OpDi01 ... 426
3.4.2 OpDi01 modes ... 427
3.4.3 OpDi01 functions ... 428
3.4.4 OpDi01 error handling ... 431
3.4.5 OpDi01 messaging ... 431
3.4.6 OpDi01 I/Os ... 432
3.4.7 OpDi01 block diagram ... 435
3.4.8 Operator control and monitoring ... 435
3.4.8.1 OpDi01 views ... 435
3.4.8.2 OpDi01 standard view ... 436
3.4.8.3 OpDi01 preview ... 437
3.4.8.4 Block icon for OpDi01 ... 439

3.5 OpDi03 - Manipulating a digital value (3 pushbuttons) ... 441
3.5.1 Description of OpDi03 ... 441
3.5.2 OpDi03 modes ... 442
3.5.3 OpDi03 functions ... 443
3.5.4 OpDi03 error handling ... 446
3.5.5 OpDi03 messaging ... 447
3.5.6 OpDi03 I/Os ... 448
3.5.7 OpDi03 block diagram ... 451
3.5.8 Operator control and monitoring ... 451
3.5.8.1 OpDi03 view ... 451
3.5.8.2 OpDi03 standard view ... 452
3.5.8.3 OpDi03 preview ... 454
3.5.8.4 Block icon for OpDi03 ... 455

3.6 OpStations - Configuration of the local operator authorization ... 457
3.6.1 Description of OpStations ... 457
3.6.2 OpStations operating modes ... 459
3.6.3 OpStations functions ... 460
3.6.4 OpStations error handling ... 461
3.6.5 OpStations messaging ... 461
3.6.6 OpStations I/Os ... 462
3.6.7 OpStations block diagram ... 464
3.6.8 Operator control and monitoring ... 466
3.6.8.1 OpStations views ... 466
3.6.8.2 OpStations standard view ... 467
3.6.8.3 Block icon of OpStations ... 469

3.7 OpTrig - Manipulating a digital value (1 pushbutton) ... 470
3.7.1 Description of OpTrig ... 470
3.7.2 OpTrig modes ... 471
3.7.3 OpTrig functions ... 471
3.7.4 OpTrig error handling ... 473

3.7.5 OpTrig messaging ..... 474
3.7.6 OpTrig I/Os ..... 474
3.7.7 OpTrig block diagram ..... 477
3.7.8 Operator control and monitoring ..... 477
3.7.8.1 OpTrig views ..... 477
3.7.8.2 OpTrig standard view ..... 478
3.7.8.3 OpTrig preview ..... 479
3.7.8.4 Block icon for OpTrig ..... 480

**4 Condition Monitoring ..... 483**

4.1 PumpMon - Pump monitoring ..... 483
4.1.1 Description of PumpMon ..... 483
4.1.2 PumpMon modes ..... 488
4.1.3 PumpMon functional description ..... 488
4.1.4 PumpMon Functions ..... 495
4.1.5 PumpMon error handling ..... 502
4.1.6 PumpMon messaging ..... 503
4.1.7 PumpMon I/Os ..... 505
4.1.8 PumpMon block diagram ..... 518
4.1.9 PumpMon additional information ..... 519
4.1.10 Operator control and monitoring ..... 521
4.1.10.1 Views of PumpMon ..... 521
4.1.10.2 PumpMon standard view (delivery height characteristic) ..... 522
4.1.10.3 PumpMon efficiency and power characteristic view ..... 524
4.1.10.4 PumpMon NPSH characteristic view ..... 525
4.1.10.5 PumpMon histogram view ..... 526
4.1.10.6 PumpMon parameter view ..... 529
4.1.10.7 PumpMon characteristic parameter view 1 ..... 531
4.1.10.8 PumpMon characteristic parameter view 2 ..... 534
4.1.10.9 Preview of PumpMon ..... 535
4.1.10.10 PumpMon limit value view ..... 537
4.1.10.11 PumpMon tolerances view ..... 538
4.1.10.12 Block icon for PumpMon ..... 539

4.2 PrDrpMon - Pressure drop monitoring ..... 540
4.2.1 Description of PrDrpMon ..... 540
4.2.2 PrDrpMon modes ..... 543
4.2.3 PrDrpMon mode of operation ..... 543
4.2.4 PrDrpMon functions ..... 546
4.2.5 PrDrpMon messaging ..... 550
4.2.6 PrDrpMon I/Os ..... 550
4.2.7 PrDrpMon block diagram ..... 555
4.2.8 Operator control and monitoring ..... 555
4.2.8.1 Views of PrDrpMon ..... 555
4.2.8.2 PrDrpMon standard view ..... 556
4.2.8.3 PrDrpMon limit view ..... 558
4.2.8.4 PrDrpMon parameter view ..... 559
4.2.8.5 Block icon for PrDrpMon ..... 560

4.3 Valve monitoring - VlvMon ..... 561
4.3.1 Description of VlvMon ..... 561
4.3.2 VlvMon modes ..... 565
4.3.3 VlvMon operating principle ..... 566

4.3.4 VlvMon functions ... 574
4.3.5 VlvMon error handling ... 581
4.3.6 VlvMon messaging ... 582
4.3.7 I/Os of VlvMon ... 582
4.3.8 VlvMon block diagram ... 596
4.3.9 VlvMon additional information ... 596
4.3.10 Operator control and monitoring ... 597
4.3.10.1 VlvMon views ... 597
4.3.10.2 VlvMon standard view ... 598
4.3.10.3 VlvMon flow characteristic curve view ... 599
4.3.10.4 VlvMon reaction time characteristic curve view ... 601
4.3.10.5 VlvMon histogram view ... 604
4.3.10.6 VlvMon limit view ... 606
4.3.10.7 VlvMon parameter 1 view ... 608
4.3.10.8 VlvMon parameter 2 view ... 610
4.3.10.9 Block icon for VlvMon ... 612

4.4 Stationary processes - SteadyState ... 614
4.4.1 Description of SteadyState ... 614
4.4.2 SteadyState modes ... 615
4.4.3 SteadyState operating principle ... 615
4.4.4 SteadyState functions ... 617
4.4.5 SteadyState error handling ... 620
4.4.6 SteadyState I/Os ... 620
4.4.7 SteadyState block diagram ... 622
4.4.8 Operator control and monitoring ... 623
4.4.8.1 Views of SteadyState ... 623
4.4.8.2 SteadyState standard view ... 623
4.4.8.3 SteadyState parameter view ... 624
4.4.8.4 SteadyState trend view ... 625
4.4.8.5 Block icon for SteadyState ... 625

4.5 Partial Stroke Test (PST) ... 627
4.5.1 Introduction ... 627
4.5.1.1 What is the Partial Stroke Test? ... 627
4.5.1.2 The Partial Stroke Test application ... 630
4.5.1.3 Hardware overview ... 632
4.5.1.4 Overview of engineering template for Partial Stroke Test ... 638
4.5.1.5 Overview of Partial Stroke Test user interface ... 640
4.5.2 Usage guidelines ... 641
4.5.2.1 Basic rules ... 641
4.5.2.2 Safety instructions ... 641
4.5.3 Getting Started ... 642
4.5.3.1 Hardware requirements ... 642
4.5.3.2 Software prerequisites ... 643
4.5.4 Configuration of the engineering template ... 643
4.5.4.1 Overview of Partial Stroke Test logic ... 643
4.5.4.2 Logic for the solenoid valve test (optional) ... 646
4.5.4.3 Adding the Partial Stroke Test engineering template to a STEP 7 project ... 648
4.5.4.4 Configure blocks ... 651
4.5.4.5 Compile and load logic of the Partial Stroke Test ... 652
4.5.5 Working with the engineering template ... 654
4.5.5.1 Working with the engineering template ... 654

4.5.5.2 Display Partial Stroke Test data ... 654
4.5.5.3 Changing the values of Partial Stroke Test parameters ... 655
4.5.5.4 Changing the values of solenoid valve test parameters ... 656
4.5.5.5 Starting or aborting the Partial Stroke Test manually ... 656
4.5.6 F_PST ... 656
4.5.7 F_PST_S ... 657
4.5.8 PST_Calc block ... 657
4.5.8.1 Description of PST_Calc ... 657
4.5.8.2 I/Os of PST_Calc ... 661
4.5.9 PST_OrQC block ... 662
4.5.9.1 Description of PST_OrQC ... 662
4.5.9.2 I/Os of PST_OrQC ... 663
4.5.10 PST_Time block ... 664
4.5.10.1 Description of PST_Time ... 664
4.5.10.2 I/Os of PST_Time ... 664
4.5.11 PST Block ... 665
4.5.11.1 Description of PST ... 665
4.5.11.2 PST operating modes ... 669
4.5.11.3 PST functions ... 669
4.5.11.4 PST error handling ... 671
4.5.11.5 PST reporting ... 672
4.5.11.6 PST I/Os ... 674
4.5.11.7 Operator control and monitoring ... 686
4.5.12 Create reports ... 692

**5 Monitoring blocks ... 701**

5.1 Comparison of large & small blocks ... 701
5.1.1 MonAnL compared to MonAnS ... 701
5.1.2 MonDiL compared to MonDiS ... 703

5.2 AV - Displaying and monitoring additional value ... 705
5.2.1 Description of AV ... 705
5.2.2 AV modes ... 707
5.2.3 AV functions ... 707
5.2.4 AV error handling ... 709
5.2.5 AV messaging ... 710
5.2.6 AV I/Os ... 711
5.2.7 AV block diagram ... 714

5.3 MonAnL - Monitoring of an analog process tag (Large) ... 715
5.3.1 Description of MonAnL ... 715
5.3.2 MonAnL modes ... 718
5.3.3 MonAnL functions ... 719
5.3.4 MonAnL error handling ... 726
5.3.5 MonAnL messaging ... 727
5.3.6 MonAnL I/Os ... 729
5.3.7 MonAnL block diagram ... 738
5.3.8 Operator control and monitoring ... 739
5.3.8.1 MonAnL views ... 739
5.3.8.2 MonAnL standard view ... 740
5.3.8.3 MonAnL limit view ... 743
5.3.8.4 MonAnL parameter view ... 745
5.3.8.5 MonAnL preview ... 746

5.3.8.6 MonAnL AddOn view ... 747
5.3.8.7 Block icon for MonAnL ... 748

5.4 MonAnS - Monitoring of an analog process tag (Small) ... 750
5.4.1 Description of MonAnS ... 750
5.4.2 MonAnS operating modes ... 752
5.4.3 MonAnS functions ... 753
5.4.4 MonAnS error handling ... 755
5.4.5 MonAnS messaging ... 756
5.4.6 MonAnS I/Os ... 758
5.4.7 MonAnS block diagram ... 762
5.4.8 Operator control and monitoring ... 762
5.4.8.1 MonAnS views ... 762
5.4.8.2 MonAnS standard view ... 763
5.4.8.3 MonAnS limit view ... 765
5.4.8.4 MonAnS parameter view ... 766
5.4.8.5 MonAnS preview ... 767
5.4.8.6 Block icon for MonAnS ... 768

5.5 MonDiL - Monitoring of a digital process tag (Large) ... 770
5.5.1 Description of MonDiL ... 770
5.5.2 MonDiL modes ... 773
5.5.3 MonDiL functions ... 774
5.5.4 MonDiL error handling ... 779
5.5.5 MonDiL messaging ... 780
5.5.6 MonDiL I/Os ... 781
5.5.7 MonDiL block diagram ... 786
5.5.8 Operator control and monitoring ... 787
5.5.8.1 MonDiL views ... 787
5.5.8.2 MonDiL standard view ... 788
5.5.8.3 MonDiL parameter view ... 790
5.5.8.4 MonDiL preview ... 792
5.5.8.5 Block icon for MonDiL ... 793

5.6 MonDiS - Monitoring of a digital process tag (Small) ... 796
5.6.1 Description of MonDiS ... 796
5.6.2 MonDiS operating modes ... 799
5.6.3 MonDiS functions ... 800
5.6.4 MonDiS error handling ... 803
5.6.5 MonDiS messaging ... 804
5.6.6 MonDiS I/Os ... 805
5.6.7 MonDiS block diagram ... 808
5.6.8 Operator control and monitoring ... 809
5.6.8.1 MonDiS views ... 809
5.6.8.2 MonDiS standard view ... 809
5.6.8.3 MonDiS parameter view ... 811
5.6.8.4 MonDiS preview ... 812
5.6.8.5 Block icon for MonDiS ... 813

5.7 MonDi08 - Monitoring 8 digital process tags ... 816
5.7.1 Description of MonDi08 ... 816
5.7.2 MonDi08 modes ... 818
5.7.3 MonDi08 functions ... 819
5.7.4 MonDi08 error handling ... 822

5.7.5 MonDi08 messaging ... 823
5.7.6 MonDi08 I/Os ... 824
5.7.7 MonDi08 block diagram ... 829
5.7.8 Operator control and monitoring ... 829
5.7.8.1 MonDi08 views ... 829
5.7.8.2 MonDi08 standard view ... 830
5.7.8.3 MonDi08 parameter view ... 832
5.7.8.4 MonDi08 preview ... 833
5.7.8.5 Block icon for MonDi08 ... 834

**6 Controller blocks ... 837**

6.1 Comparison of large & small blocks ... 837
6.1.1 PIDConL compared to PIDConS ... 837

6.2 ConPerMon - Monitoring of the control performance of control loops ... 841
6.2.1 Description of ConPerMon ... 841
6.2.2 ConPerMon modes ... 845
6.2.3 ConPerMon functions ... 845
6.2.4 ConPerMon error handling ... 857
6.2.5 ConPerMon messaging ... 857
6.2.6 ConPerMon I/Os ... 860
6.2.7 ConPerMon block diagram ... 866
6.2.8 Operator control and monitoring ... 866
6.2.8.1 ConPerMon views ... 866
6.2.8.2 ConPerMon standard view ... 867
6.2.8.3 ConPerMon limit view ... 869
6.2.8.4 ConPerMon parameter view ... 870
6.2.8.5 ConPerMon preview ... 871
6.2.8.6 ConPerMon setpoint view ... 872
6.2.8.7 Block icon for ConPerMon ... 874

6.3 FmCont - Interface to module FM 355 ... 876
6.3.1 Description of FmCont ... 876
6.3.2 FmCont modes ... 880
6.3.3 FmCont functions ... 882
6.3.4 FmCont error handling ... 892
6.3.5 FmCont messaging ... 894
6.3.6 FmCont I/Os ... 897
6.3.7 FmCont block diagram ... 913
6.3.8 Operator control and monitoring ... 915
6.3.8.1 FmCont views ... 915

6.4 FmTemp - Interface to temperature controller modules FM 355-2 ... 916
6.4.1 Description of FmTemp ... 916
6.4.2 FmTemp modes ... 920
6.4.3 FmTemp functions ... 922
6.4.4 FmTemp error handling ... 934
6.4.5 FmTemp messaging ... 935
6.4.6 FmTemp I/Os ... 938
6.4.7 FmTemp block diagram ... 956
6.4.8 Operator control and monitoring ... 958
6.4.8.1 FmTemp views ... 958

6.5 GainSched - Adapting parameter values for a PID controller ... 959

6.5.1 Description of GainSched ... 959
6.5.2 GainSched modes ... 961
6.5.3 GainSched functions ... 962
6.5.4 GainSched error handling ... 963
6.5.5 GainSched messaging ... 963
6.5.6 GainSched I/Os ... 964
6.5.7 GainSched block diagram ... 966
6.5.8 Operator control and monitoring ... 967
6.5.8.1 GainSched views ... 967
6.5.8.2 GainSched standard view ... 967
6.5.8.3 GainSched parameter view ... 968
6.5.8.4 GainSched preview ... 969

6.6 ModPreCon - Model predictive controller ... 970
6.6.1 Description of ModPreCon ... 970
6.6.2 ModPreCon modes ... 975
6.6.3 ModPreCon functions ... 976
6.6.4 ModPreCon error handling ... 989
6.6.5 ModPreCon messaging ... 990
6.6.6 ModPreCon I/Os ... 990
6.6.7 ModPreCon block diagram ... 1001
6.6.8 Operator control and monitoring ... 1002
6.6.8.1 ModPreCon views ... 1002
6.6.8.2 ModPreCon standard view ... 1003
6.6.8.3 ModPreCon parameter view ... 1008
6.6.8.4 ModPreCon parameter view channel 1 to 4 ... 1010
6.6.8.5 ModPreCon preview ... 1011
6.6.8.6 ModPreCon trend view ... 1013
6.6.8.7 Block icon for ModPreCon ... 1014

6.7 PIDConL - Continuous PID controller (Large) ... 1017
6.7.1 Description of PIDConL ... 1017
6.7.2 PIDConL modes ... 1022
6.7.3 PIDConL functions ... 1024
6.7.4 PIDConL error handling ... 1034
6.7.5 PIDConL messaging ... 1036
6.7.6 PIDConL I/Os ... 1039
6.7.7 PIDConL block diagram ... 1058
6.7.8 Operator control and monitoring ... 1060
6.7.8.1 PIDConL views ... 1060
6.7.8.2 PIDConL, PIDConS and PIDConR standard views ... 1061
6.7.8.3 PIDConL, PIDConS and PIDConR previews ... 1066

6.8 PIDConS - Continuous PID controller (Small) ... 1069
6.8.1 Description of PIDConS ... 1069
6.8.2 PIDConS modes ... 1072
6.8.3 PIDConS functions ... 1073
6.8.4 PIDConS error handling ... 1079
6.8.5 PIDConS messaging ... 1080
6.8.6 PIDConS I/Os ... 1082
6.8.7 PIDConS block diagram ... 1091
6.8.8 Operator control and monitoring ... 1093
6.8.8.1 PIDConS views ... 1093

6.9 PIDConR - Continuous PID controller with external reset ... 1094
6.9.1 Description of PIDConR ... 1094
6.9.2 PIDConR modes ... 1100
6.9.3 PIDConR functions ... 1103
6.9.4 PIDConR error handling ... 1117
6.9.5 PIDConR messaging ... 1118
6.9.6 PIDConR I/Os ... 1121
6.9.7 PIDConR block diagram ... 1140
6.9.8 Operator control and monitoring ... 1140
6.9.8.1 PIDConR views ... 1140

6.10 PIDStepL - Step controller ... 1141
6.10.1 Description of PIDStepL ... 1141
6.10.2 PIDStepL modes ... 1146
6.10.3 PIDStepL functions ... 1147
6.10.4 PIDStepL error handling ... 1159
6.10.5 PIDStepL messaging ... 1160
6.10.6 PIDStepL I/Os ... 1163
6.10.7 PIDStepL block diagram ... 1179
6.10.8 Operator control and monitoring ... 1184
6.10.8.1 PIDStepL views ... 1184
6.10.8.2 PIDStepL standard view without position feedback ... 1185
6.10.8.3 PIDStepL standard view with position feedback ... 1189
6.10.8.4 PIDStepL preview ... 1193

6.11 Ratio - Ratio controlling ... 1196
6.11.1 Description of Ratio ... 1196
6.11.2 Ratio modes ... 1198
6.11.3 Ratio functions ... 1198
6.11.4 Ratio error handling ... 1201
6.11.5 Ratio messaging ... 1202
6.11.6 Ratio I/Os ... 1202
6.11.7 Ratio block diagram ... 1207
6.11.8 Operator control and monitoring ... 1207
6.11.8.1 Ratio views ... 1207
6.11.8.2 Ratio standard view ... 1208
6.11.8.3 Ratio parameter view ... 1211
6.11.8.4 Ratio preview ... 1212
6.11.8.5 Block icon for Ratio ... 1213

6.12 SplRange - Signal splitter ... 1216
6.12.1 Description of SplRange ... 1216
6.12.2 SplRange modes ... 1217
6.12.3 SplRange functions ... 1218
6.12.4 SplRange error handling ... 1221
6.12.5 SplRange messaging ... 1221
6.12.6 SplRange I/Os ... 1222
6.12.7 SplRange block diagram ... 1223

6.13 AutoExcitation - Process trigger for predictive controller ... 1224
6.13.1 Description of AutoExcitation ... 1224
6.13.2 AutoExcitation modes ... 1226
6.13.3 AutoExcitation functions ... 1226
6.13.4 AutoExcitation error handling ... 1227

6.13.5 AutoExcitation messaging ... 1227
6.13.6 AutoExcitation I/Os ... 1227
6.13.7 AutoExcitation block diagram ... 1228

6.14 LPOptim - Optimization after traversing the linear programming ... 1229
6.14.1 Description of LPOptim ... 1229
6.14.2 LPOptim modes ... 1230
6.14.3 LPOptim functions ... 1230
6.14.4 LPOptim error handling ... 1230
6.14.5 LPOptim messaging ... 1230
6.14.6 LPOptim I/Os ... 1230
6.14.7 LPOptim block diagram ... 1233

6.15 MPC10x10 - Large predictive controller ... 1234
6.15.1 Description of MPC10x10 ... 1234
6.15.2 MPC10x10 modes ... 1241
6.15.3 MPC10x10 functions ... 1243
6.15.4 MPC10x10 error handling ... 1253
6.15.5 MPC10x10 messaging ... 1254
6.15.6 MPC10x10 I/Os ... 1254
6.15.7 MPC10x10 block diagram ... 1260
6.15.8 Operator control and monitoring ... 1261
6.15.8.1 MPC10x10 views ... 1261
6.15.8.2 MPC10x10 standard view ... 1261
6.15.8.3 MPC10x10 parameter view ... 1267
6.15.8.4 MPC10x10 CV parameter view ... 1269
6.15.8.5 MPC10x10 MV parameter view ... 1270
6.15.8.6 MPC10x10 preview ... 1271
6.15.8.7 MPC10x10 trend view ... 1273
6.15.8.8 Block icon for MPC10x10 ... 1274

6.16 KalFilt - State observer ... 1276
6.16.1 Description of KalFilt ... 1276
6.16.2 KalFilt modes ... 1282
6.16.3 KalFilt functions ... 1284
6.16.4 KalFilt error handling ... 1286
6.16.5 KalFilt I/Os ... 1287
6.16.6 KalFilt messaging ... 1292
6.16.7 KalFilt block diagram ... 1292
6.16.8 Operator control and monitoring ... 1293
6.16.8.1 KalFilt views ... 1293
6.16.8.2 KalFilt standard view ... 1293
6.16.8.3 KalFilt parameter view ... 1297
6.16.8.4 KalFilt parameter view 2 ... 1298
6.16.8.5 KalFilt preview ... 1299
6.16.8.6 KalFilt measurements view ... 1301
6.16.8.7 KalFilt trend view ... 1302
6.16.8.8 Block icon for KalFilt ... 1302

**7 Dosing blocks ... 1305**

7.1 DoseL - Dosing device ... 1305
7.1.1 Description of DoseL ... 1305
7.1.2 DoseL modes ... 1310
7.1.3 DoseL functions ... 1312

7.1.4 DoseL error handling ... 1327
7.1.5 DoseL messaging ... 1329
7.1.6 DoseL I/Os ... 1332
7.1.7 DoseL block diagram ... 1348
7.1.8 Operator control and monitoring ... 1349
7.1.8.1 DoseL views ... 1349
7.1.8.2 DoseL standard view ... 1350
7.1.8.3 DoseL limit view ... 1354
7.1.8.4 DoseL parameter view ... 1356
7.1.8.5 DoseL flow setpoint view ... 1358
7.1.8.6 DoseL quantity setpoint view ... 1361
7.1.8.7 DoseL preview ... 1363
7.1.8.8 Block icon for DoseL ... 1366

**8 Motor and valve blocks ... 1369**

8.1 Comparison of large & small blocks ... 1369
8.1.1 MotL compared to MotS ... 1369
8.1.2 VlvL compared to VlvS ... 1372
8.1.3 ShrdResL compared to ShrdResS ... 1375

8.2 MotL - Motor (Large) ... 1376
8.2.1 Description of MotL ... 1376
8.2.2 MotL modes ... 1380
8.2.3 MotL functions ... 1382
8.2.4 MotL error handling ... 1390
8.2.5 MotL messaging ... 1392
8.2.6 MotL I/Os ... 1394
8.2.7 MotL block diagram ... 1404
8.2.8 Operator control and monitoring ... 1404
8.2.8.1 MotL views ... 1404
8.2.8.2 MotL standard view ... 1405
8.2.8.3 MotL preview ... 1408
8.2.8.4 Block icon for MotL ... 1412

8.3 MotS - Motor (Small) ... 1415
8.3.1 Description of MotS ... 1415
8.3.2 MotS modes ... 1418
8.3.3 MotS functions ... 1419
8.3.4 MotS error handling ... 1424
8.3.5 MotS messaging ... 1425
8.3.6 MotS I/Os ... 1426
8.3.7 MotS block diagram ... 1432
8.3.8 Operator control and monitoring ... 1432
8.3.8.1 MotS views ... 1432
8.3.8.2 MotS standard view ... 1433
8.3.8.3 MotS preview ... 1436
8.3.8.4 Block icon for MotS ... 1438

8.4 MotRevL - Reversible motor ... 1440
8.4.1 Description of MotRevL ... 1440
8.4.2 MotRevL modes ... 1445
8.4.3 MotRevL functions ... 1447
8.4.4 MotRevL error handling ... 1457
8.4.5 MotRevL messaging ... 1461

8.4.6 MotRevL I/Os ... 1463
8.4.7 MotRevL block diagram ... 1474
8.4.8 Operator control and monitoring ... 1475
8.4.8.1 MotRevL views ... 1475
8.4.8.2 MotRevL standard view ... 1475
8.4.8.3 MotRevL preview ... 1479
8.4.8.4 Block icon for MotRevL ... 1485

8.5 MotSpdCL - Controllable reversible motor ... 1488
8.5.1 Description of MotSpdCL ... 1488
8.5.2 MotSpdCL modes ... 1494
8.5.3 MotSpdCL functions ... 1496
8.5.4 MotSpdCL error handling ... 1512
8.5.5 MotSpdCL messaging ... 1516
8.5.6 MotSpdCL I/Os ... 1518
8.5.7 MotSpdCL block diagram ... 1535
8.5.8 Operator control and monitoring ... 1535
8.5.8.1 MotSpdCL views ... 1535
8.5.8.2 MotSpdCL standard view ... 1536
8.5.8.3 MotSpdCL preview ... 1542
8.5.8.4 MotSpdCL limit view for readback values ... 1546
8.5.8.5 MotSpdCL parameter view ... 1548
8.5.8.6 MotSpdCL trend view ... 1550
8.5.8.7 MotSpdCL AddOn view ... 1552
8.5.8.8 Block icon for MotSpdCL ... 1552

8.6 MotSpdL - Two-speed motor ... 1556
8.6.1 Description of MotSpdL ... 1556
8.6.2 MotSpdL modes ... 1561
8.6.3 MotSpdL functions ... 1563
8.6.4 MotSpdL error handling ... 1574
8.6.5 MotSpdL messaging ... 1577
8.6.6 MotSpdL I/Os ... 1578
8.6.7 MotSpdL block diagram ... 1590
8.6.8 Operator control and monitoring ... 1590
8.6.8.1 MotSpdL views ... 1590
8.6.8.2 MotSpdL standard view ... 1591
8.6.8.3 MotSpdL preview ... 1595
8.6.8.4 Block icon for MotSpdL ... 1600

8.7 ShrdResL - Multiplexer for shared resources (Large) ... 1603
8.7.1 Description of ShrdResL ... 1603
8.7.2 ShrdResL modes ... 1606
8.7.3 ShrdResL functions ... 1607
8.7.4 ShrdResL error handling ... 1613
8.7.5 ShrdResL messaging ... 1613
8.7.6 ShrdResL I/Os ... 1614
8.7.7 ShrdResL block diagram ... 1619
8.7.8 Operator control and monitoring ... 1619
8.7.8.1 ShrdResL views ... 1619
8.7.8.2 ShrdResL standard view ... 1620
8.7.8.3 ShrdResL general preview ... 1622
8.7.8.4 ShrdResL preview ... 1622
8.7.8.5 ShrdResL parameter view ... 1624

8.7.8.6 Block icon for ShrdResL ... 1625

8.8 ShrdResS - Multiplexer for shared resources (Small) ... 1626
8.8.1 Description for ShrdResS ... 1626
8.8.2 ShrdResS modes ... 1629
8.8.3 ShrdResS functions ... 1629
8.8.4 ShrdResS error handling ... 1632
8.8.5 ShrdResS messaging ... 1632
8.8.6 ShrdResS I/Os ... 1633
8.8.7 ShrdResS block diagram ... 1641
8.8.8 Operator control and monitoring ... 1642
8.8.8.1 ShrdResS views ... 1642
8.8.8.2 ShrdResS standard view ... 1642
8.8.8.3 ShrdResS preview ... 1644
8.8.8.4 Block icon for ShrdResS ... 1645

8.9 Vlv2WayL - Two-way valve ... 1647
8.9.1 Description of Vlv2WayL ... 1647
8.9.2 Vlv2WayL modes ... 1651
8.9.3 Vlv2WayL functions ... 1653
8.9.4 Vlv2WayL error handling ... 1660
8.9.5 Vlv2WayL messaging ... 1663
8.9.6 Vlv2WayL I/Os ... 1664
8.9.7 Vlv2WayL block diagram ... 1676
8.9.8 Operator control and monitoring ... 1677
8.9.8.1 Vlv2WayL views ... 1677
8.9.8.2 Vlv2WayL standard view ... 1677
8.9.8.3 Vlv2WayL parameter view ... 1681
8.9.8.4 Vlv2WayL preview ... 1683
8.9.8.5 Block icon for Vlv2WayL ... 1688

8.10 VlvL - Valve (Large) ... 1691
8.10.1 Description of VlvL ... 1691
8.10.2 VlvL modes ... 1694
8.10.3 VlvL functions ... 1696
8.10.4 VlvL error handling ... 1703
8.10.5 VlvL messaging ... 1705
8.10.6 VlvL I/Os ... 1707
8.10.7 VlvL block diagram ... 1715
8.10.8 Operator control and monitoring ... 1716
8.10.8.1 VlvL views ... 1716
8.10.8.2 VlvL standard view ... 1717
8.10.8.3 VlvL preview ... 1721
8.10.8.4 VlvL block icon ... 1725

8.11 VlvS - Valve (small) ... 1728
8.11.1 Description of VlvS ... 1728
8.11.2 VlvS modes ... 1731
8.11.3 VlvS functions ... 1732
8.11.4 VlvS error handling ... 1736
8.11.5 VlvS reporting ... 1738
8.11.6 VlvS I/Os ... 1739
8.11.7 VlvS block diagram ... 1745
8.11.8 Operator control and monitoring ... 1746

8.11.8.1 VlvS views ... 1746
8.11.8.2 VlvS standard view ... 1746
8.11.8.3 VlvS preview ... 1749
8.11.8.4 VlvS block icon ... 1751

8.12 VlvMotL - Motor valve ... 1754
8.12.1 Description of VlvMotL ... 1754
8.12.2 VlvMotL modes ... 1759
8.12.3 VlvMotL functions ... 1762
8.12.4 VlvMotL error handling ... 1774
8.12.5 VlvMotL messaging ... 1777
8.12.6 VlvMotL I/Os ... 1778
8.12.7 VlvMotL block diagram ... 1791
8.12.8 Operator control and monitoring ... 1791
8.12.8.1 VlvMotL views ... 1791
8.12.8.2 VlvMotL standard view ... 1792
8.12.8.3 VlvMotL parameter view ... 1797
8.12.8.4 VlvMotL preview ... 1799
8.12.8.5 Block icon for VlvMotL ... 1805

8.13 VlvAnL - Control valve ... 1808
8.13.1 Description of VlvAnL ... 1808
8.13.2 VlvAnL modes ... 1813
8.13.3 VlvAnL functions ... 1816
8.13.4 VlvAnL error handling ... 1832
8.13.5 VlvAnL messaging ... 1833
8.13.6 VlvAnL I/Os ... 1835
8.13.7 VlvAnL block diagram ... 1850
8.13.8 Operator control and monitoring ... 1851
8.13.8.1 VlvAnL views ... 1851
8.13.8.2 VlvAnL standard view with auxiliary valve ... 1852
8.13.8.3 VlvAnL standard view without auxiliary valve ... 1857
8.13.8.4 VlvAnL limit view ... 1863
8.13.8.5 VlvAnL preview ... 1865
8.13.8.6 VlvAnL parameter view ... 1871
8.13.8.7 Block icon for VlvAnL ... 1872

8.14 VlvPosL - Valve positioner ... 1876
8.14.1 Description of VlvPosL ... 1876
8.14.2 VlvPosL modes ... 1882
8.14.3 VlvPosL functions ... 1884
8.14.4 VlvPosL error handling ... 1908
8.14.5 VlvPosL messaging ... 1910
8.14.6 VlvPosL I/Os ... 1912
8.14.7 VlvPosL block diagram ... 1928
8.14.8 Operator control and monitoring ... 1929
8.14.8.1 VlvPosL views ... 1929
8.14.8.2 VlvPosL standard view ... 1930
8.14.8.3 VlvPosL limit value view ... 1935
8.14.8.4 VlvPosL parameter view ... 1937
8.14.8.5 VlvPosL preview ... 1941
8.14.8.6 Block icon for VlvPosL ... 1947

**9 Interlock blocks ..... 1949**

9.1 Intlk02 - Interlock display with 2 input signals ..... 1949
9.1.1 Description of Intlk02 ..... 1949
9.1.2 Intlk02 modes ..... 1952
9.1.3 Intlk02 functions ..... 1952
9.1.4 Intlk02 error handling ..... 1956
9.1.5 Intlk02 messaging ..... 1957
9.1.6 Intlk02 I/Os ..... 1957
9.1.7 Intlk02 block diagram ..... 1961
9.1.8 Operator control and monitoring ..... 1961
9.1.8.1 Interlock block views ..... 1961

9.2 Intlk04 - Interlock display with 4 input signals ..... 1962
9.2.1 Description of Intlk04 ..... 1962
9.2.2 Intlk04 modes ..... 1965
9.2.3 Intlk04 functions ..... 1965
9.2.4 Intlk04 error handling ..... 1969
9.2.5 Intlk04 messaging ..... 1970
9.2.6 Intlk04 I/Os ..... 1970
9.2.7 Intlk04 block diagram ..... 1974
9.2.8 Operator control and monitoring ..... 1975
9.2.8.1 Interlock block views ..... 1975

9.3 Intlk08 - Interlock display with 8 input signals ..... 1976
9.3.1 Description of Intlk08 ..... 1976
9.3.2 Intlk08 modes ..... 1979
9.3.3 Intlk08 functions ..... 1980
9.3.4 Intlk08 error handling ..... 1984
9.3.5 Intlk08 messaging ..... 1985
9.3.6 Intlk08 I/Os ..... 1985
9.3.7 Intlk08 block diagram ..... 1991
9.3.8 Operator control and monitoring ..... 1991
9.3.8.1 Interlock block views ..... 1991

9.4 Intlk16 - Interlock display with 16 input signals ..... 1992
9.4.1 Description of Intlk16 ..... 1992
9.4.2 Intlk16 modes ..... 1997
9.4.3 Intlk16 functions ..... 1997
9.4.4 Intlk16 error handling ..... 2002
9.4.5 Intlk16 messaging ..... 2002
9.4.6 Intlk16 I/Os ..... 2003
9.4.7 Intlk16 block diagram ..... 2010
9.4.8 Operator control and monitoring ..... 2011
9.4.8.1 Interlock block views ..... 2011

9.5 FirstIn - Transform output Intlck FirstIn for message associated value ..... 2012
9.5.1 Description of FirstIn ..... 2012
9.5.2 FirstIn modes ..... 2013
9.5.3 FirstIn functions ..... 2014
9.5.4 FirstIn error handling ..... 2014
9.5.5 FirstIn messaging ..... 2015
9.5.6 FirstIn I/Os ..... 2015
9.5.7 FirstIn block diagram ..... 2016

**10 Message blocks ... 2017**

10.1 Event - Creating messages ... 2017
10.1.1 Description of Event ... 2017
10.1.2 Event modes ... 2020
10.1.3 Event functions ... 2020
10.1.4 Event error handling ... 2022
10.1.5 Event messaging ... 2023
10.1.6 Event I/Os ... 2025
10.1.7 Event block diagram ... 2029

10.2 EventNck - Generating messages without acknowledgment ... 2030
10.2.1 Description of EventNck ... 2030
10.2.2 EventNck modes ... 2032
10.2.3 EventNck functions ... 2033
10.2.4 EventNck error handling ... 2035
10.2.5 EventNck messaging ... 2036
10.2.6 EventNck I/Os ... 2037
10.2.7 EventNck block diagram ... 2041

10.3 EventTs - Creating messages with time stamp ... 2042
10.3.1 Description of EventTs ... 2042
10.3.2 EventTs modes ... 2045
10.3.3 EventTs functions ... 2046
10.3.4 EventTs error handling ... 2048
10.3.5 EventTs messaging ... 2049
10.3.6 EventTs I/Os ... 2052
10.3.7 EventTs block diagram ... 2056

10.4 Event16Ts - Creating 16 messages with time stamp ... 2057
10.4.1 Description of Event16Ts ... 2057
10.4.2 Event16Ts operating modes ... 2062
10.4.3 Event16Ts functions ... 2062
10.4.4 Event16Ts error handling ... 2065
10.4.5 Event16Ts messages ... 2065
10.4.6 Event16Ts I/Os ... 2071
10.4.7 Event16Ts block diagram ... 2073

**11 Counter blocks ... 2075**

11.1 CountScL - Counter with up and down counting direction ... 2075
11.1.1 Description of CountScL ... 2075
11.1.2 CountScL modes ... 2079
11.1.3 CountScL functions ... 2080
11.1.4 CountScL error handling ... 2084
11.1.5 CountScL messaging ... 2084
11.1.6 CountScL I/Os ... 2085
11.1.7 CountScL block diagram ... 2090
11.1.8 Operator control and monitoring ... 2090
11.1.8.1 CountScL views ... 2090
11.1.8.2 CountScL standard view ... 2091
11.1.8.3 CountScL limit view ... 2093
11.1.8.4 CountScL parameter view ... 2094
11.1.8.5 CountScL preview ... 2095
11.1.8.6 Block icon for CountScL ... 2096

11.2 CountOh - Determining runtime ... 2098
11.2.1 Description of CountOh ... 2098
11.2.2 CountOh modes ... 2102
11.2.3 CountOh functions ... 2103
11.2.4 CountOh error handling ... 2107
11.2.5 CountOh messaging ... 2108
11.2.6 CountOh I/Os ... 2109
11.2.7 CountOh block diagram ... 2114
11.2.8 Operator control and monitoring ... 2115
11.2.8.1 CountOh views ... 2115
11.2.8.2 CountOh standard view ... 2116
11.2.8.3 CountOh limit view ... 2118
11.2.8.4 CountOh parameter view ... 2119
11.2.8.5 CountOh preview ... 2120
11.2.8.6 Block icon for CountOh ... 2121

11.3 TotalL - Additive counter with upward or downward counting direction (totalizer) ... 2123
11.3.1 Description of TotalL ... 2123
11.3.2 TotalL operating modes ... 2132
11.3.3 TotalL functions ... 2133
11.3.4 TotalL error handling ... 2138
11.3.5 TotalL messaging ... 2139
11.3.6 TotalL I/Os ... 2140
11.3.7 TotalL block diagram ... 2146
11.3.8 Operator control and monitoring ... 2146
11.3.8.1 TotalL views ... 2146
11.3.8.2 TotalL standard view ... 2147
11.3.8.3 TotalL limit view ... 2150
11.3.8.4 TotalL parameter view ... 2151
11.3.8.5 TotalL preview ... 2153
11.3.8.6 TotalL block icon ... 2154

11.4 CntOhSc - Runtime determination and counters with counting direction "up" ... 2156
11.4.1 Description of CntOhSc ... 2156
11.4.2 CntOhSc operating modes ... 2158
11.4.3 CntOhSc functions ... 2158
11.4.4 CntOhSc error handling ... 2161
11.4.5 CntOhSc messaging ... 2161
11.4.6 CntOhSc I/Os ... 2161
11.4.7 CntOhSc block diagram ... 2165
11.4.8 Operator control and monitoring ... 2165
11.4.8.1 CntOhSc views ... 2165
11.4.8.2 CntOhSc standard view ... 2166
11.4.8.3 CntOhSc limit view ... 2168
11.4.8.4 CntOhSc preview ... 2169
11.4.8.5 Block icon for CntOhSc ... 2170

**12 Timers ... 2173**

12.1 TimerP - Time delays signal forwarding / pulse generator ... 2173
12.1.1 Description of TimerP ... 2173
12.1.2 TimerP modes ... 2174
12.1.3 TimerP functions ... 2174
12.1.4 TimerP error handling ... 2177

12.1.5 TimerP messaging ... 2178
12.1.6 TimerP I/Os ... 2178
12.1.7 TimerP block diagram ... 2180

12.2 TimeTrig - Calculations with the date formats DT and TIME ... 2181
12.2.1 Description of TimeTrig ... 2181
12.2.2 TimeTrig modes ... 2183
12.2.3 TimeTrig functions ... 2184
12.2.4 TimeTrig error handling ... 2191
12.2.5 TimeTrig messaging ... 2192
12.2.6 TimeTrig I/Os ... 2192
12.2.7 TimeTrig block diagram ... 2197
12.2.8 Operator control and monitoring ... 2197
12.2.8.1 TimeTrig views ... 2197
12.2.8.2 TimeTrig standard view ... 2198
12.2.8.3 TimeTrig parameter view ... 2201
12.2.8.4 TimeTrig preview ... 2203
12.2.8.5 Block icon for TimeTrig ... 2205

**13 Mathematical blocks ... 2207**

13.1 AbsR - Absolute value of a real value ... 2207
13.1.1 Description of AbsR ... 2207
13.1.2 AbsR modes ... 2208
13.1.3 AbsR functions ... 2208
13.1.4 AbsR error handling ... 2208
13.1.5 AbsR messaging ... 2208
13.1.6 AbsR I/Os ... 2208
13.1.7 AbsR block diagram ... 2209

13.2 Add04 - Adder with 4 values ... 2210
13.2.1 Description of Add04 ... 2210
13.2.2 Add04 modes ... 2211
13.2.3 Add04 functions ... 2211
13.2.4 Add04 error handling ... 2212
13.2.5 Add04 messaging ... 2212
13.2.6 Add04 I/Os ... 2213
13.2.7 Add04 block diagram ... 2214

13.3 Add08 - Adder with 8 values ... 2215
13.3.1 Description of Add08 ... 2215
13.3.2 Add08 modes ... 2216
13.3.3 Add08 functions ... 2216
13.3.4 Add08 error handling ... 2217
13.3.5 Add08 messaging ... 2217
13.3.6 Add08 I/Os ... 2218
13.3.7 Add08 block diagram ... 2219

13.4 Average - Mean value calculation ... 2220
13.4.1 Description of Average ... 2220
13.4.2 Average modes ... 2221
13.4.3 Average functions ... 2222
13.4.4 Average error handling ... 2222
13.4.5 Average messaging ... 2223
13.4.6 Average I/Os ... 2224

13.4.7 Average block diagram ... 2225

13.5 DeadTime - Delayed signal output ... 2226
13.5.1 Description of DeadTime ... 2226
13.5.2 DeadTime modes ... 2228
13.5.3 DeadTime functions ... 2228
13.5.4 DeadTime error handling ... 2229
13.5.5 DeadTime messaging ... 2230
13.5.6 DeadTime I/Os ... 2230
13.5.7 DeadTime block diagram ... 2231

13.6 Derivative - Obtaining a derivative ... 2233
13.6.1 Description of Derivative ... 2233
13.6.2 Derivative modes ... 2235
13.6.3 Derivative functions ... 2236
13.6.4 Derivative error handling ... 2237
13.6.5 Derivative messaging ... 2237
13.6.6 Derivative I/Os ... 2238
13.6.7 Derivative block diagram ... 2239

13.7 Div02 - Division of two values ... 2240
13.7.1 Description of Div02 ... 2240
13.7.2 Div02 modes ... 2241
13.7.3 Div02 functions ... 2241
13.7.4 Div02 error handling ... 2242
13.7.5 Div02 messaging ... 2243
13.7.6 Div02 I/Os ... 2243
13.7.7 Div02 block diagram ... 2244

13.8 FlowCorr - Flow correction ... 2245
13.8.1 Description of FlowCorr ... 2245
13.8.2 FlowCorr modes ... 2247
13.8.3 FlowCorr functions ... 2247
13.8.4 FlowCorr error handling ... 2249
13.8.5 FlowCorr messaging ... 2250
13.8.6 FlowCorr I/Os ... 2250
13.8.7 FlowCorr block diagram ... 2252

13.9 Integral - Generating a time integral ... 2253
13.9.1 Description of Integral ... 2253
13.9.2 Integral modes ... 2254
13.9.3 Integral functions ... 2255
13.9.4 Integral error handling ... 2257
13.9.5 Integral messaging ... 2258
13.9.6 Integral I/Os ... 2258
13.9.7 Integral block diagram ... 2259

13.10 Lag - Low-pass filter ... 2261
13.10.1 Description of Lag ... 2261
13.10.2 Lag modes ... 2263
13.10.3 Lag functions ... 2263
13.10.4 Lag error handling ... 2264
13.10.5 Lag messaging ... 2265
13.10.6 Lag I/Os ... 2266
13.10.7 Lag block diagram ... 2267

13.11 MeanTime - Averaging ... 2268
13.11.1 Description of MeanTime ... 2268
13.11.2 MeanTime modes ... 2269
13.11.3 MeanTime functions ... 2270
13.11.4 MeanTime error handling ... 2272
13.11.5 MeanTime messaging ... 2272
13.11.6 MeanTime I/Os ... 2273
13.11.7 MeanTime block diagram ... 2274

13.12 Mul04 - Multiplier with 4 values ... 2275
13.12.1 Description of Mul04 ... 2275
13.12.2 Mul04 modes ... 2276
13.12.3 Mul04 functions ... 2277
13.12.4 Mul04 error handling ... 2278
13.12.5 Mul04 messaging ... 2278
13.12.6 Mul04 I/Os ... 2278
13.12.7 Mul04 block diagram ... 2279

13.13 Mul08 - Multiplier with 8 values ... 2281
13.13.1 Description of Mul08 ... 2281
13.13.2 Mul08 modes ... 2282
13.13.3 Mul08 functions ... 2282
13.13.4 Mul08 error handling ... 2283
13.13.5 Mul08 messaging ... 2284
13.13.6 Mul08 I/Os ... 2284
13.13.7 Mul08 block diagram ... 2285

13.14 Polygon - Converting the first signal (non-linear) ... 2287
13.14.1 Description of Polygon ... 2287
13.14.2 Polygon modes ... 2290
13.14.3 Polygon functions ... 2290
13.14.4 Polygon error handling ... 2291
13.14.5 Polygon messaging ... 2292
13.14.6 Polygon I/Os ... 2293
13.14.7 Polygon block diagram ... 2296

13.15 Smooth - Low pass filter ... 2297
13.15.1 Description of Smooth ... 2297
13.15.2 Smooth modes ... 2298
13.15.3 Smooth functions ... 2298
13.15.4 Smooth error handling ... 2299
13.15.5 Smooth messaging ... 2300
13.15.6 Smooth I/Os ... 2301
13.15.7 Smooth block diagram ... 2302

13.16 SqrRoot - Derive the root of a value ... 2303
13.16.1 Description of SqrRoot ... 2303
13.16.2 SqrRoot modes ... 2304
13.16.3 SqrRoot functions ... 2304
13.16.4 SqrRoot error handling ... 2305
13.16.5 SqrRoot messaging ... 2305
13.16.6 SqrRoot I/Os ... 2306
13.16.7 SqrRoot block diagram ... 2307

13.17 Sub02 - Subtracting two values ... 2308

13.17.1 Description of Sub02 ... 2308
13.17.2 Sub02 modes ... 2309
13.17.3 Sub02 functions ... 2309
13.17.4 Sub02 error handling ... 2310
13.17.5 Sub02 messaging ... 2310
13.17.6 Sub02 I/Os ... 2311
13.17.7 Sub02 block diagram ... 2312

13.18 PowerXY - General power function ... 2313
13.18.1 Description of PowerXY ... 2313
13.18.2 PowerXY modes ... 2314
13.18.3 PowerXY functions ... 2315
13.18.4 PowerXY error handling ... 2315
13.18.5 PowerXY messaging ... 2316
13.18.6 PowerXY I/Os ... 2316
13.18.7 PowerXY block diagrams ... 2317

**14 Analog logic blocks ... 2319**

14.1 CompAn02 - Comparison of two analog values ... 2319
14.1.1 Description of CompAn02 ... 2319
14.1.2 CompAn02 modes ... 2320
14.1.3 CompAn02 functions ... 2320
14.1.4 CompAn02 error handling ... 2321
14.1.5 CompAn02 messaging ... 2322
14.1.6 CompAn02 I/Os ... 2322
14.1.7 CompAn02 block diagram ... 2323

14.2 Limit - Limiting an analog value ... 2324
14.2.1 Description of Limit ... 2324
14.2.2 Limit modes ... 2326
14.2.3 Limit functions ... 2326
14.2.4 Limit error handling ... 2327
14.2.5 Limit messaging ... 2328
14.2.6 Limit I/Os ... 2328
14.2.7 Limit block diagram ... 2329

14.3 MuxAn03 - Selection of an analog value to increase availability / safety ... 2330
14.3.1 Description of MuxAn03 ... 2330
14.3.2 MuxAn03 modes ... 2331
14.3.3 MuxAn03 functions ... 2331
14.3.4 MuxAn03 error handling ... 2334
14.3.5 MuxAn03 messaging ... 2335
14.3.6 MuxAn03 I/Os ... 2335
14.3.7 MuxAn03 block diagram ... 2337

14.4 MuxAn08 - Selection of an analog value to increase availability / safety ... 2338
14.4.1 Description of MuxAn08 ... 2338
14.4.2 MuxAn08 modes ... 2338
14.4.3 MuxAn08 functions ... 2339
14.4.4 MuxAn08 error handling ... 2341
14.4.5 MuxAn08 messaging ... 2341
14.4.6 MuxAn08 I/Os ... 2341
14.4.7 MuxAn08 block diagram ... 2343

14.5 RateLim - Signal ramp ... 2344

14.5.1 Description of RateLim ... 2344
14.5.2 RateLim modes ... 2345
14.5.3 RateLim functions ... 2345
14.5.4 RateLim error handling ... 2348
14.5.5 RateLim messaging ... 2348
14.5.6 RateLim I/Os ... 2349
14.5.7 RateLim block diagram ... 2351

14.6 RedAn02 - 1 out of 2 selection for redundant analog values ... 2352
14.6.1 Description of RedAn02 ... 2352
14.6.2 RedAn02 modes ... 2353
14.6.3 RedAn02 functions ... 2353
14.6.4 RedAn02 error handling ... 2354
14.6.5 RedAn02 messaging ... 2354
14.6.6 RedAn02 I/Os ... 2354
14.6.7 RedAn02 block diagram ... 2356

14.7 SelA02In - Output of two analog values ... 2357
14.7.1 Description of SelA02In ... 2357
14.7.2 SelA02In modes ... 2358
14.7.3 SelA02In functions ... 2358
14.7.4 SelA02In error handling ... 2359
14.7.5 SelA02In messaging ... 2360
14.7.6 SelA02In I/Os ... 2360
14.7.7 SelA02In block diagram ... 2361

14.8 SelA16In - Output of 16 analog values ... 2362
14.8.1 Description of SelA16In ... 2362
14.8.2 SelA16In modes ... 2363
14.8.3 SelA16In functions ... 2364
14.8.4 SelA16In error handling ... 2367
14.8.5 SelA16In messaging ... 2368
14.8.6 SelA16In I/Os ... 2368
14.8.7 SelA16In block diagram ... 2372
14.8.8 Operator control and monitoring ... 2373
14.8.8.1 SelA16In views ... 2373
14.8.8.2 SelA16In standard view ... 2374
14.8.8.3 SelA16In preview ... 2376
14.8.8.4 Block icon for SelA16In ... 2377

14.9 SelAn16L - Large version of SelAn16In ... 2380
14.9.1 Description of SelAn16L ... 2380
14.9.2 SelAn16L modes ... 2382
14.9.3 SelAn16L functions ... 2382
14.9.4 SelAn16L error handling ... 2385
14.9.5 SelAn16L messaging ... 2386
14.9.6 SelAn16L I/Os ... 2386
14.9.7 SelAn16L block diagram ... 2392
14.9.8 Operaror control and monitoring ... 2393
14.9.8.1 SenAn16L views ... 2393
14.9.8.2 SelAn16L standard view ... 2394
14.9.8.3 SelAn16L preview ... 2395
14.9.8.4 Block icon for SelAn16L ... 2397

**15 Digital logic blocks ..... 2399**

15.1 And04 - Forming an AND signal from 4 binary input signals ..... 2399
15.1.1 Description of And04 ..... 2399
15.1.2 And04 modes ..... 2400
15.1.3 And04 functions ..... 2400
15.1.4 And04 error handling ..... 2401
15.1.5 And04 messaging ..... 2401
15.1.6 And04 I/Os ..... 2401
15.1.7 And04 block diagram ..... 2402

15.2 And08 - Forming an AND signal from 8 binary input signals ..... 2404
15.2.1 Description of And08 ..... 2404
15.2.2 And08 modes ..... 2405
15.2.3 And08 functions ..... 2405
15.2.4 And08 error handling ..... 2405
15.2.5 And08 messaging ..... 2406
15.2.6 And08 I/Os ..... 2406
15.2.7 And08 block diagram ..... 2408

15.3 FlipFlop - Flip Flop with Clock Input ..... 2409
15.3.1 Description of FlipFlop ..... 2409
15.3.2 FlipFlop modes ..... 2412
15.3.3 FlipFlop functions ..... 2412
15.3.4 FlipFlop error handling ..... 2413
15.3.5 FlipFlop messaging ..... 2414
15.3.6 FlipFlop I/Os ..... 2414
15.3.7 FlipFlop block diagram ..... 2416

15.4 Or04 - Forming an OR signal from 4 binary input signals ..... 2417
15.4.1 Description of Or04 ..... 2417
15.4.2 Or04 modes ..... 2418
15.4.3 Or04 functions ..... 2419
15.4.4 Or04 error handling ..... 2419
15.4.5 Or04 messaging ..... 2420
15.4.6 Or04 I/Os ..... 2420
15.4.7 Or04 block diagram ..... 2421

15.5 Or08 - Forming an OR signal from 8 binary input signals ..... 2422
15.5.1 Description of Or08 ..... 2422
15.5.2 Or08 modes ..... 2423
15.5.3 Or08 functions ..... 2423
15.5.4 Or08 error handling ..... 2424
15.5.5 Or08 messaging ..... 2424
15.5.6 Or08 I/Os ..... 2425
15.5.7 Or08 block diagram ..... 2426

15.6 Not01 - Inversion of an input signal ..... 2427
15.6.1 Description of Not01 ..... 2427
15.6.2 Not01 modes ..... 2428
15.6.3 Not01 functions ..... 2428
15.6.4 Not01 error handling ..... 2428
15.6.5 Not01 messaging ..... 2429
15.6.6 Not01 I/Os ..... 2429
15.6.7 Not01 block diagram ..... 2430

15.7 RedDi02 - 1 out of 2 selection for redundant digital values ... 2431
15.7.1 Description of RedDi02 ... 2431
15.7.2 RedDi02 modes ... 2432
15.7.3 RedDi02 functions ... 2432
15.7.4 RedDi02 error handling ... 2433
15.7.5 RedDi02 messaging ... 2433
15.7.6 RedDi02 I/Os ... 2433
15.7.7 RedDi02 block diagram ... 2435

15.8 SelD02In - Output of one of two digital signals ... 2436
15.8.1 Description of SelD02In ... 2436
15.8.2 SelD02In modes ... 2437
15.8.3 SelD02In functions ... 2437
15.8.4 SelD02In error handling ... 2438
15.8.5 SelD02In messaging ... 2438
15.8.6 SelD02In I/Os ... 2439
15.8.7 SelD02In block diagram ... 2440

15.9 StrctCom - Structure composer for 32-bit structures ... 2441
15.9.1 Description of StrctCom ... 2441
15.9.2 StrctCom modes ... 2442
15.9.3 StrctCom functions ... 2442
15.9.4 StrctCom error handling ... 2443
15.9.5 StrctCom messaging ... 2443
15.9.6 StrctCom I/Os ... 2443
15.9.7 StrctCom block diagram ... 2444

15.10 StrctDeC - Structure decomposer for 32-bit structures ... 2446
15.10.1 Description of StrctDeC ... 2446
15.10.2 StrctDeC modes ... 2447
15.10.3 StrctDeC functions ... 2447
15.10.4 StrctDeC error handling ... 2448
15.10.5 StrctDeC messaging ... 2448
15.10.6 StrctDeC I/Os ... 2448
15.10.7 StrctDeC block diagram ... 2449

15.11 Trigger - Detection of rising and falling edges ... 2451
15.11.1 Description of Trigger ... 2451
15.11.2 Trigger modes ... 2452
15.11.3 Trigger functions ... 2453
15.11.4 Trigger error handling ... 2453
15.11.5 Trigger messaging ... 2454
15.11.6 Trigger I/Os ... 2454
15.11.7 Trigger block diagram ... 2455

15.12 XOr04 - EXCLUSIVE OR logic operation ... 2456
15.12.1 Description of XOr04 ... 2456
15.12.2 XOr04 modes ... 2457
15.12.3 XOr04 functions ... 2457
15.12.4 XOr04 error handling ... 2458
15.12.5 XOr04 messaging ... 2458
15.12.6 XOr04 I/Os ... 2459
15.12.7 XOr04 block diagram ... 2460

**16 Generator blocks ..... 2461**

16.1 NoiseGen - Generating signal noise ..... 2461
16.1.1 Description of NoiseGen ..... 2461
16.1.2 NoiseGen I/Os ..... 2461

**17 Channel blocks ..... 2463**

17.1 Information on using channel blocks ..... 2463

17.2 FbAnIn - Analog input channel block for field devices ..... 2466
17.2.1 Description of FbAnIn ..... 2466
17.2.2 FbAnIn modes ..... 2468
17.2.3 FbAnIn functions ..... 2468
17.2.4 FbAnIn error handling ..... 2471
17.2.5 FbAnIn messaging ..... 2472
17.2.6 FbAnIn I/Os ..... 2472
17.2.7 FbAnIn block diagram ..... 2475

17.3 FbAnOu - Analog output channel block for field devices ..... 2476
17.3.1 Description of FbAnOu ..... 2476
17.3.2 FbAnOu modes ..... 2478
17.3.3 FbAnOu functions ..... 2478
17.3.4 FbAnOu error handling ..... 2480
17.3.5 FbAnOu messaging ..... 2480
17.3.6 FbAnOu I/Os ..... 2481
17.3.7 FbAnOu block diagram ..... 2486

17.4 FbAnTot - Analog totalizer channel block for field devices ..... 2487
17.4.1 Description of FbAnTot ..... 2487
17.4.2 FbAnTot modes ..... 2488
17.4.3 FbAnTot functions ..... 2488
17.4.4 FbAnTot error handling ..... 2490
17.4.5 FbAnTot messaging ..... 2491
17.4.6 FbAnTot I/Os ..... 2491
17.4.7 FbAnTot block diagram ..... 2494

17.5 FbDiIn - Digital input channel block for field devices ..... 2495
17.5.1 Description of FbDiIn ..... 2495
17.5.2 FbDiIn modes ..... 2496
17.5.3 FbDiIn functions ..... 2497
17.5.4 FbDiIn error handling ..... 2499
17.5.5 FbDiIn messaging ..... 2500
17.5.6 FbDiIn I/Os ..... 2500
17.5.7 FbDiIn block diagram ..... 2503

17.6 FbDiOu - Digital output channel block for field devices ..... 2505
17.6.1 Description of FbDiOu ..... 2505
17.6.2 FbDiOu modes ..... 2506
17.6.3 FbDiOu functions ..... 2507
17.6.4 FbDiOu error handling ..... 2509
17.6.5 FbDiOu messaging ..... 2510
17.6.6 FbDiOu I/Os ..... 2510
17.6.7 FbDiOu block diagram ..... 2515

17.7 FbDrive - Channel block for compact drives ..... 2516

17.7.1 Description of FbDrive ... 2516
17.7.2 FbDrive modes ... 2517
17.7.3 FbDrive functions ... 2517
17.7.4 FbDrive error handling ... 2519
17.7.5 FbDrive messaging ... 2519
17.7.6 FbDrive status word ... 2520
17.7.7 FbDrive I/Os ... 2520
17.7.8 FbDrive block diagram ... 2527

17.8 FbEnMe - Channel block for ET 200SP Energy Meter ... 2528
17.8.1 Description of FbEnMe ... 2528
17.8.2 FbEnMe modes ... 2529
17.8.3 FbEnMe functions ... 2530
17.8.4 FbEnMe error handling ... 2531
17.8.5 FbEnMe messaging ... 2532
17.8.6 FbEnMe I/Os ... 2532
17.8.7 FbEnMe block diagram ... 2539

17.9 FbSwtMMS - Channel block for MM starter ... 2541
17.9.1 Description of FbSwtMMS ... 2541
17.9.2 FbSwtMMS modes ... 2542
17.9.3 FbSwtMMS functions ... 2542
17.9.4 FbSwtMMS error handling ... 2543
17.9.5 FbSwtMMS messaging ... 2544
17.9.6 FbSwtMMS status word ... 2544
17.9.7 FbSwtMMS I/Os ... 2545
17.9.8 FbSwtMMS block diagram ... 2550

17.10 Pcs7AITC - Analog input driver, dynamic measuring range center ... 2551
17.10.1 Pcs7AITC description ... 2551
17.10.2 Pcs7AITC functions ... 2554
17.10.3 Pcs7AITC error handling ... 2558
17.10.4 Pcs7AITC messaging ... 2559
17.10.5 Pcs7AITC I/Os ... 2559

17.11 Pcs7AnIn - Analog input channel block ... 2564
17.11.1 Description of Pcs7AnIn ... 2564
17.11.2 Pcs7AnIn modes ... 2566
17.11.3 Pcs7AnIn functions ... 2567
17.11.4 Pcs7AnIn error handling ... 2571
17.11.5 Pcs7AnIn messaging ... 2572
17.11.6 Pcs7AnIn I/Os ... 2572
17.11.7 Pcs7AnIn block diagram ... 2576

17.12 Pcs7AnOu - Analog output channel block ... 2577
17.12.1 Description of Pcs7AnOu ... 2577
17.12.2 Pcs7AnOu modes ... 2580
17.12.3 Pcs7AnOu functions ... 2580
17.12.4 Pcs7AnOu error handling ... 2582
17.12.5 Pcs7AnOu messaging ... 2583
17.12.6 Pcs7AnOu I/Os ... 2584
17.12.7 Pcs7AnOu block diagram ... 2587

17.13 Pcs7DiCnt - Digital input driver with count functionality ... 2588
17.13.1 Pcs7DiCnt description ... 2588

17.13.2 Pcs7DiCnt functions ... 2589
17.13.3 Pcs7DiCnt error handling ... 2591
17.13.4 Pcs7DiCnt messaging ... 2591
17.13.5 Pcs7DiCnt I/Os ... 2592

17.14 Pcs7DiIn - Digital input channel block ... 2596
17.14.1 Description of Pcs7DiIn ... 2596
17.14.2 Pcs7DiIn modes ... 2598
17.14.3 Pcs7DiIn functions ... 2598
17.14.4 Pcs7DiIn error handling ... 2600
17.14.5 Pcs7DiIn messaging ... 2601
17.14.6 Pcs7DiIn I/Os ... 2601
17.14.7 Pcs7DiIn block diagram ... 2604

17.15 Pcs7DiIT - Digital input channel block with time stamp ... 2605
17.15.1 Description of Pcs7DiIT ... 2605
17.15.2 Pcs7DiIT modes ... 2607
17.15.3 Pcs7DiIT functions ... 2607
17.15.4 Pcs7DiIT error handling ... 2610
17.15.5 Pcs7DiIT messaging ... 2610
17.15.6 Pcs7DiIT I/Os ... 2611
17.15.7 Pcs7DiIT block diagram ... 2614

17.16 Pcs7DiOu - Digital output channel block ... 2616
17.16.1 Description of Pcs7DiOu ... 2616
17.16.2 Pcs7DiOu modes ... 2618
17.16.3 Pcs7DiOu functions ... 2619
17.16.4 Pcs7DiOu error handling ... 2620
17.16.5 Pcs7DiOu messaging ... 2621
17.16.6 Pcs7DiOu I/Os ... 2621
17.16.7 Pcs7DiOu block diagram ... 2624

17.17 Pcs7Cnt1 - Controlling and reading FM 350 modules ... 2625
17.17.1 Description of Pcs7Cnt1 ... 2625
17.17.2 Pcs7Cnt1 modes ... 2627
17.17.3 Pcs7Cnt1 functions ... 2627
17.17.4 Pcs7Cnt1 error handling ... 2629
17.17.5 Pcs7Cnt1 messaging ... 2630
17.17.6 Pcs7Cnt1 I/Os ... 2630
17.17.7 Pcs7Cnt1 block diagram ... 2635

17.18 Pcs7Cnt2 - Control and read an 8-DI_NAMUR module of the ET 200iSP ... 2636
17.18.1 Description of Pcs7Cnt2 ... 2636
17.18.2 Pcs7Cnt2 modes ... 2639
17.18.3 Pcs7Cnt2 functions ... 2639
17.18.4 Pcs7Cnt2 error handling ... 2641
17.18.5 Pcs7Cnt2 messaging ... 2642
17.18.6 Pcs7Cnt2 I/Os ... 2642
17.18.7 Pcs7Cnt2 block diagram ... 2645

17.19 Pcs7Cnt3 - Control and read the 1 COUNT 24V/100kHz module for count mode ... 2646
17.19.1 Description of Pcs7Cnt3 ... 2646
17.19.2 Pcs7Cnt3 modes ... 2648
17.19.3 Pcs7Cnt3 functions ... 2648
17.19.4 Pcs7Cnt3 error handling ... 2649

17.19.5 Pcs7Cnt3 messaging ... 2650
17.19.6 Pcs7Cnt3 I/Os ... 2650
17.19.7 Pcs7Cnt3 block diagram ... 2654

17.20 Pcs7Cnt4 - Handling counting functionality of TM modules ... 2655
17.20.1 Description of Pcs7Cnt4 ... 2655
17.20.2 Pcs7Cnt4 modes ... 2658
17.20.3 Pcs7Cnt4 functions ... 2658
17.20.4 Pcs7Cnt4 error handling ... 2659
17.20.5 Pcs7Cnt4 messaging ... 2660
17.20.6 Pcs7Cnt4 I/Os ... 2660
17.20.7 Pcs7Cnt4 block diagram ... 2664

17.21 Pcs7HaAI - HART variable channel block for AI-HART modules ... 2665
17.21.1 Description of Pcs7HaAI ... 2665
17.21.2 Pcs7HaAI modes ... 2666
17.21.3 Pcs7HaAI functions ... 2666
17.21.4 Pcs7HaAI error handling ... 2667
17.21.5 Pcs7HaAI messaging ... 2668
17.21.6 Pcs7HaAI I/Os ... 2668
17.21.7 Pcs7HaAI block diagram ... 2671

17.22 Pcs7HaAO - HART variable channel block for AO-HART modules ... 2672
17.22.1 Description of Pcs7HaAO ... 2672
17.22.2 Pcs7HaAO modes ... 2673
17.22.3 Pcs7HaAO functions ... 2673
17.22.4 Pcs7HaAO error handling ... 2674
17.22.5 Pcs7HaAO messaging ... 2675
17.22.6 Pcs7HaAO I/Os ... 2675
17.22.7 Pcs7HaAO block diagram ... 2678

17.23 Pcs7ReIn - REAL input channel block ... 2679
17.23.1 Description of PCS7ReIn ... 2679
17.23.2 PCS7ReIn modes ... 2680
17.23.3 PCS7ReIn functions ... 2680
17.23.4 PCS7ReIn error handling ... 2682
17.23.5 PCS7ReIn messaging ... 2683
17.23.6 PCS7ReIn I/Os ... 2683
17.23.7 PCS7ReIn block diagram ... 2686

17.24 Annex for channel blocks ... 2687
17.24.1 Mode Settings for SM Modules ... 2687
17.24.2 Mode settings for field devices ... 2698
17.24.3 Mode settings for Channel blocks ... 2700

**18 Conversion blocks ... 2701**

18.1 StrgToBy - String in byte structure (Struct of Byte) ... 2701
18.1.1 Description of StrgToBy ... 2701
18.1.2 StrgToBy modes ... 2702
18.1.3 StrgToBy functions ... 2702
18.1.4 StrgToBy error handling ... 2703
18.1.5 StrgToBy messaging ... 2703
18.1.6 StrgToBy I/Os ... 2703
18.1.7 StrgToBy block diagram ... 2704

18.2 StruAnIn - Separating an analog structured variable ... 2706
18.2.1 Description of StruAnIn ... 2706
18.2.2 StruAnIn modes ... 2707
18.2.3 StruAnIn functions ... 2707
18.2.4 StruAnIn error handling ... 2707
18.2.5 StruAnIn messaging ... 2708
18.2.6 StruAnIn I/Os ... 2708
18.2.7 StruAnIn block diagram ... 2709

18.3 StruAnOu - Creating an analog structured variable ... 2710
18.3.1 Description of StruAnOu ... 2710
18.3.2 StruAnOu modes ... 2711
18.3.3 StruAnOu functions ... 2711
18.3.4 StruAnOu error handling ... 2711
18.3.5 StruAnOu messaging ... 2712
18.3.6 StruAnOu I/Os ... 2712
18.3.7 StruAnOu block diagram ... 2713

18.4 StruDiIn - Separating a digital structured variable ... 2714
18.4.1 Description of StruDiIn ... 2714
18.4.2 StruDiIn modes ... 2715
18.4.3 StruDiIn functions ... 2715
18.4.4 StruDiIn error handling ... 2715
18.4.5 StruDiIn messaging ... 2716
18.4.6 StruDiIn I/Os ... 2716
18.4.7 StruDiIn block diagram ... 2717

18.5 StruDiOu - Creating a digital structured variable ... 2718
18.5.1 Description of StruDiOu ... 2718
18.5.2 StruDiOu modes ... 2719
18.5.3 StruDiOu functions ... 2719
18.5.4 StruDiOu error handling ... 2719
18.5.5 StruDiOu messaging ... 2720
18.5.6 StruDiOu I/Os ... 2720
18.5.7 StruDiOu block diagram ... 2721

18.6 StruScIn - Separating a display area into two variables ... 2722
18.6.1 Description of StruScIn ... 2722
18.6.2 StruScIn modes ... 2723
18.6.3 StruScIn functions ... 2723
18.6.4 StruScIn error handling ... 2723
18.6.5 StruScIn messaging ... 2724
18.6.6 StruScIn I/Os ... 2724
18.6.7 StruScIn block diagram ... 2725

18.7 StruScOu - Merging two variables into a display area ... 2726
18.7.1 Description of StruScOu ... 2726
18.7.2 StruScOu modes ... 2727
18.7.3 StruScOu functions ... 2727
18.7.4 StruScOu error handling ... 2727
18.7.5 StruScOu messaging ... 2728
18.7.6 StruScOu I/Os ... 2728
18.7.7 StruScOu block diagram ... 2729

18.8 STIn - Separating the signal status into individual binary displays ... 2730

18.8.1 Description of STIn ... 2730
18.8.2 STIn modes ... 2731
18.8.3 STIn functions ... 2731
18.8.4 STIn error handling ... 2731
18.8.5 STIn messaging ... 2732
18.8.6 STIn I/Os ... 2732
18.8.7 STIn block diagram ... 2733

18.9 STOu - Merging individual binary signals into a signal status ... 2734
18.9.1 Description of STOu ... 2734
18.9.2 STOu modes ... 2735
18.9.3 STOu functions ... 2735
18.9.4 STOu error handling ... 2735
18.9.5 STOu messaging ... 2736
18.9.6 STOu I/Os ... 2736
18.9.7 STOu block diagram ... 2737

18.10 MSTIn - Separating the maintenance status into individual status displays ... 2738
18.10.1 Description of MSTIn ... 2738
18.10.2 MSTIn modes ... 2739
18.10.3 MSTIn functions ... 2739
18.10.4 MSTIn error handling ... 2739
18.10.5 MSTIn messaging ... 2740
18.10.6 MSTIn I/Os ... 2740
18.10.7 MSTIn block diagram ... 2741

18.11 MSTOu - Merging individual status displays into a maintenance status ... 2742
18.11.1 Description of MSTOu ... 2742
18.11.2 MSTOu modes ... 2743
18.11.3 MSTOu functions ... 2743
18.11.4 MSTOu error handling ... 2744
18.11.5 MSTOu messaging ... 2744
18.11.6 MSTOu I/Os ... 2744
18.11.7 MSTOu block diagram ... 2745

18.12 RealToDw - Converting REAL to DWORD ... 2747
18.12.1 Description of RealToDw ... 2747
18.12.2 RealToDw modes ... 2748
18.12.3 ReaLToDw functions ... 2748
18.12.4 RealToDw error handling ... 2748
18.12.5 RealToDw messaging ... 2748
18.12.6 RealToDw I/Os ... 2749
18.12.7 RealToDw block diagram ... 2749

18.13 StateMap - Conversion of other signal states into APL signal states ... 2750
18.13.1 Description of StateMap ... 2750
18.13.2 StateMap modes ... 2751
18.13.3 StateMap functions ... 2751
18.13.4 StateMap error handling ... 2751
18.13.5 StateMap messaging ... 2751
18.13.6 StateMap I/Os ... 2751
18.13.7 StateMap block diagram ... 2752

18.14 StruCmIn - Splitting a structure to outputs ... 2753
18.14.1 Description of StruCmIn ... 2753

18.14.2 StruCmIn modes ... 2753
18.14.3 StruCmIn functions ... 2754
18.14.4 StruCmIn error handling ... 2754
18.14.5 StruCmIn messaging ... 2754
18.14.6 StruCmIn I/Os ... 2754
18.14.7 StruCmIn block diagram ... 2755

18.15 StruCmOu - Merging inputs to a structure ... 2756
18.15.1 Description of StruCmOu ... 2756
18.15.2 StruCmOu modes ... 2756
18.15.3 StruCmOu functions ... 2757
18.15.4 StruCmOu error handling ... 2757
18.15.5 StruCmOu messaging ... 2757
18.15.6 StruCmOu I/Os ... 2757
18.15.7 StruCmOu block diagram ... 2758

18.16 StruCnIn - Separating a counter structured variable ... 2759
18.16.1 Description of StruCnIn ... 2759
18.16.2 StruCnIn modes ... 2759
18.16.3 StruCnIn functions ... 2760
18.16.4 StruCnIn error handling ... 2760
18.16.5 StruCnIn messaging ... 2760
18.16.6 StruCnIn I/Os ... 2760
18.16.7 StruCnIn block diagram ... 2761

18.17 StruCnOu - Creating a structured counter variable ... 2762
18.17.1 Description of StruCnOu ... 2762
18.17.2 StruCnOu modes ... 2762
18.17.3 StruCnOu functions ... 2763
18.17.4 StruCnOu error handling ... 2763
18.17.5 StruCnOu messaging ... 2763
18.17.6 StruCnOu I/Os ... 2763
18.17.7 StruCnOu block diagram ... 2764

**19 Maintenance blocks ... 2765**

19.1 MuxMST - Determination of the worst maintenance status ... 2765
19.1.1 Description of MuxMST ... 2765
19.1.2 MuxMST modes ... 2766
19.1.3 MuxMST functions ... 2766
19.1.4 MuxMST error handling ... 2767
19.1.5 MuxMST messaging ... 2767
19.1.6 MuxMST I/Os ... 2767
19.1.7 MuxMST block diagram ... 2768

19.2 MuxST- Determination of the worst signal status ... 2770
19.2.1 Description of MuxST ... 2770
19.2.2 MuxST modes ... 2771
19.2.3 MuxST functions ... 2771
19.2.4 MuxST error handling ... 2772
19.2.5 MuxST messaging ... 2772
19.2.6 MuxST I/Os ... 2773
19.2.7 MuxST block diagram ... 2774

19.3 STRep - Status display of block groups ... 2775
19.3.1 Description of STRep ... 2775

19.3.2 STRep modes ... 2776
19.3.3 STRep functions ... 2776
19.3.4 STRep error handling ... 2776
19.3.5 STRep messaging ... 2776
19.3.6 STRep I/Os ... 2776
19.3.7 STRep block diagram ... 2777

19.4 AssetM - Process variable monitoring for violation of limits ... 2778
19.4.1 Description of AssetM ... 2778
19.4.2 AssetM modes ... 2781
19.4.3 AssetM functions ... 2781
19.4.4 AssetM error handling ... 2782
19.4.5 AssetM messages ... 2782
19.4.6 AssetM I/Os ... 2783
19.4.7 AssetM block diagram ... 2785

**20 System blocks ... 2787**

20.1 AddInt64 - Addition of two 64-bit integer variables ... 2787
20.1.1 Description of AddInt64 ... 2787

20.2 AddR64 - Addition of two 64-bit REAL variables ... 2788
20.2.1 Description of AddR64 ... 2788

20.3 DiToInt64 - Converting from DINT to Int64 ... 2789
20.3.1 Description of DiToInt64 ... 2789

20.4 Int64ToDi - Converting from Int64 to DINT ... 2790
20.4.1 Description of Int64ToDi ... 2790

20.5 MemR256 - Increasing the number of internal previous values ... 2791
20.5.1 Description of MemR256 ... 2791

20.6 NegInt64 - Negation of an Int64 variable ... 2792
20.6.1 Description of NegInt64 ... 2792

20.7 NegR64 - Negation of a Real64 variable ... 2793
20.7.1 Description of NegR64 ... 2793

20.8 PIDCoefR - Calculation of coefficients ... 2794
20.8.1 Description of PIDCoefR ... 2794

20.9 R64ToReal - Converting Real64 to REAL ... 2795
20.9.1 Description of R64ToReal ... 2795

20.10 RealToR64 - Converting REAL to Real64 ... 2796
20.10.1 Description of RealToR64 ... 2796

20.11 SelST16 - Output of the best or worst signal status ... 2797
20.11.1 Description of SelST16 ... 2797

20.12 ShLeInt64 - Left shift of an Int64 variable ... 2798
20.12.1 Description of ShLeInt64 ... 2798

20.13 ShRiInt64 - Right shift of an Int64 variable ... 2799
20.13.1 Description of ShRiInt64 ... 2799

20.14 PIDKernR - Calculation of the manipulated variable ... 2800
20.14.1 Description of PIDKernR ... 2800

**21 Communication blocks ..... 2801**

21.1 Snd_DigVal - Send Boolean values including quality code (Snd_DigVal) ..... 2801
21.1.1 Description of Snd_DigVal ..... 2801
21.1.2 Snd_DigVal modes ..... 2802
21.1.3 Snd_DigVal functions ..... 2802
21.1.4 Snd_DigVal error handling ..... 2803
21.1.5 Snd_DigVal messages ..... 2803
21.1.6 Snd_DigVal I/Os ..... 2803
21.1.7 Snd_DigVal block diagram ..... 2804

21.2 Rcv_DigVal - Receive Boolean values including quality code (Rcv_DigVal) ..... 2805
21.2.1 Description of Rcv_DigVal ..... 2805
21.2.2 Rcv_DigVal modes ..... 2806
21.2.3 Rcv_DigVal functions ..... 2807
21.2.4 Rcv_DigVal error handling ..... 2807
21.2.5 Rcv_DigVal messages ..... 2807
21.2.6 Rcv_DigVal I/Os ..... 2807
21.2.7 Rcv_DigVal block diagram ..... 2808

21.3 Snd_AnaVal - Send analog values including quality code (SND_AnaVal) ..... 2809
21.3.1 Description of Snd_AnaVal ..... 2809
21.3.2 Snd_AnaVal modes ..... 2810
21.3.3 Snd_AnaVal functions ..... 2810
21.3.4 Snd_AnaVal error handling ..... 2810
21.3.5 Snd_AnaVal messages ..... 2811
21.3.6 Snd_AnaVal I/Os ..... 2811
21.3.7 Snd_AnaVal block diagram ..... 2811

21.4 Rcv_AnaVal - Receive analog values including quality code (Rcv_AnaVal) ..... 2812
21.4.1 Description of Rcv_AnaVal ..... 2812
21.4.2 Rcv_AnaVal modes ..... 2813
21.4.3 Rcv_AnaVal functions ..... 2813
21.4.4 Rcv_AnaVal error handling ..... 2814
21.4.5 Rcv_AnaVal messages ..... 2814
21.4.6 Rcv_AnaVal I/Os ..... 2814
21.4.7 Rcv_AnaVal block diagram ..... 2815

**22 Process tag types (insertible templates) ..... 2817**

22.1 Introduction to process tag types ..... 2817

22.2 PID controller (PIDControl_Lean) ..... 2820

22.3 PID controller for PA/FF devices (PIDControl_Lean_Fb) ..... 2821

22.4 PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) ..... 2822

22.5 PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) ..... 2823

22.6 PID controller with safety logic and manipulated variable ramp (PIDConR_MV_Ramp) ..... 2824

22.7 PID - control with operating-point-oriented parameter control (GainScheduling) ..... 2825

22.8 PID controller with dynamic feedforward control (FfwdDisturbCompensat) ..... 2827

22.9 PID controller with Smith predictor (SmithPredictorControl) ..... 2830

22.10 Step controller with direct access to the actuator and without position feedback (StepControlDirect) ... 2831
22.11 Step controller with assigned actuator block and position feedback (StepControlActor) ... 2832
22.12 Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) ... 2833
22.13 Split-Range control (SplitRangeControl_Lean) ... 2835
22.14 Ratio control with control loop monitoring through ConPerMon (RatioControl) ... 2836
22.15 Ratio control (RatioControl_Lean) ... 2838
22.16 Ratio control with PIDConR (RatioR) ... 2839
22.17 Cascade control with control loop monitoring through ConPerMon (CascadeControl) ... 2840
22.18 Cascade control (CascadeControl_Lean) ... 2842
22.19 Cascade control with PIDConR (CascadeR) ... 2843
22.20 Cascade control with PIDStepL (CascadeStepControl) ... 2844
22.21 Source chart for GainSched function block (gain scheduling) ... 2845
22.22 Override control ... 2846
22.23 Override control with PIDConR (OverrideR) ... 2848
22.24 Model-based predictive control (ModPreCon) ... 2849
22.25 Monitoring of a digital process tag (DigitalMonitoring) ... 2851
22.26 Monitoring a digital process tag for PA/FF devices (DigitalMonitoring_Fb) ... 2852
22.27 Monitoring eight digital process tags (Digital8Monitoring) ... 2853
22.28 Monitoring an analog process tag (AnalogMonitoring) ... 2854
22.29 Monitoring of an analog process tag for PA/FF devices (AnalogMonitoring_Fb) ... 2855
22.30 Dosing (Dose_Lean) ... 2856
22.31 Dosing with PA/FF devices (Dose_Lean_Fb) ... 2857
22.32 Motor (Motor_Lean) ... 2858
22.33 Motor with PROFIdrive Drive Profile telegram 1 and 20 (Namur) ... 2859
22.34 Two-speed motor (Motor2Speed) ... 2860
22.35 Reversing motor (MotorReversible) ... 2861
22.36 Reversible motor with controllable speed (MotorSpeedControlled) ... 2862
22.37 Motor with an additional analog value and time-stamped signals (Motor_AV_EventTs) ... 2863
22.38 Motor according to the profile for low voltage switchgear devices with profile 1 of the MM_Starter ... 2864
22.39 Valve (Valve_Lean) ... 2865
22.40 Two-way valve (Valve2Way) ... 2866
22.41 Motor valve (ValveMotor) ... 2867
22.42 Control valve (VlvAnL) ... 2868

22.43 Control valve for PA/FF devices (ValveAnalog_Fb) ..... 2869
22.44 Example project APL_Example_xx ..... 2870
22.44.1 Introduction to the PCS 7 example project for Advanced Process Control ..... 2870
22.44.2 Process simulation including noise generator (ProcSimC; ProcSimS) ..... 2871
22.44.3 Cascade control of temperature by using the heat flow (CascadeSim) ..... 2873
22.44.4 Control loop monitoring for simulation with colored noise (ConPerMonSim) ..... 2875
22.44.5 Feedforward control to compensate a measurable disturbance variable (DisturbCompSim) ..... 2875
22.44.6 Operating point-oriented adaptation of parameters (gain scheduling) for non-linear processes (GainSchedSim) ..... 2876
22.44.7 Override control on a pipeline (OverrideSim) ..... 2877
22.44.8 Smith predictor for a dead time system (SmithPredictorSim) ..... 2877
22.44.9 Filtering of noisy measured values in a control loop (SigSmoothSim) ..... 2877
22.44.10 Predictive control of a 2x2 multi-variable controlled system (ModPreConSim) ..... 2879
22.44.11 Predictive control of a non-linear process (ModPreConNonLinSim) ..... 2879

**23 Definitions ..... 2881**

23.1 Batch process ..... 2881
23.2 Approximation ..... 2882
23.3 Prediction horizon ..... 2883
23.4 Trajectory ..... 2884
23.5 Maverick ..... 2885
23.6 Ergodic process ..... 2886
23.7 Conti process ..... 2887
23.8 Multivariable controller ..... 2888
23.9 non-phase minimum ..... 2889

**Index ..... 2891**

# Security information

# 1

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit
https://www.siemens.com/industrialsecurity.

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under
https://www.siemens.com/industrialsecurity.

# 2

## 2.1 Functions of the blocks

### 2.1.1 General information

#### 2.1.1.1 User-configured message classes

**User-configured message classes**

The message classes Alarm, Warning and Tolerance, the corresponding abbreviations in symbols and colors, and the terms used in this documentation are not valid for user-configured message classes.

These terms and colors depend on the project-specific setting. The user-configured messages classes are only supported for block symbols as of V9.

#### 2.1.1.2 Forcing operating modes

**Forcing operating modes**

The "forcing of operating modes" function lets you set the function block into a different operating mode using interconnectable input parameters, regardless of the currently active control. This can, for example, be:

- Forces tracking for closed-loop controllers and control valves
- Enabling and disabling at motors
- Opening and closing of valves

It is only possible to force operating modes with "Large" blocks in the following operating modes:

- Manual mode
- Automatic mode
- Local mode "1" and "3" (only if `Feature2.Bit8` = 1)

Forcing operating modes has the highest priority over all three operating modes.

**Forcing operating modes at closed-loop controllers**

In control engineering, this procedure is also known as forced tracking of values. Refer to the Tracking and limiting a manipulated variable (Page 222) section for more on this.

### Forcing operating modes at motors and valves

The input parameter `xxxxForce = 1` (for example `OpenForce` and `CloseForce` at a valve) is used for forced controlling of the function block and thus an intervention in the function of the block, irrespective of currently active controls, interlock conditions and monitoring errors. If the input parameters are inconsistent (for example `OpenForce = 1` and `CloseForce = 1` at valves), an error number (Page 128) is output at the parameter `ErrorNum` and the control remains unchanged.

**Note**

If you have set the parameters for the advance warning time `WarnTiMan` and the idle time `IdleTime` to values higher than 0, the control will only take effect once the set times have elapsed.

**Note**

With block VlvAnl, the warning time is ignored in tracking `MV_TrkOn` = 1 and in forced tracking `MV_ForOn`.

The Enabling direct changeover between forward and reverse (Page 156) `Feature` bit has no effect when forcing the operating modes of the MotRevL and MotSpdCL blocks. Direct switchover between forward and reverse is always possible.

### Display in the faceplate and in the block icon

If an operating mode is forced, this is displayed in the block icon and in the standard view of the faceplate:

**Block icon**: In the block icon, the display for motors, valves and dosers involves the use of a red F and a crossed-out padlock.

There is no display for closed-loop controllers.

**Faceplate:** An information text on the forced operating mode is displayed in the standard view of the faceplate, for example, "Forced stop" for motors. This is also indicated by a crossed-out padlock:

### Messaging

No messages are assigned to the forcing of operating modes. However, if you want to have corresponding messages, you can use the freely interconnectable input parameters to generate the messages. Refer also to the Generating instance-specific messages (Page 230) section for more on this.

### 2.1.1.3 Resetting the block in case of interlocks or errors

#### Resetting the block

The block must be reset when an interlock has been set via the `Protect` input ("Protection"), Trip ("Protection") or an error has occurred ("Runtime" or "Control", external error `FaultExt` or `CSF` with `Feature.Bit18`).

**Note**

"Small" blocks do not feature protection (`Protect`).

The `RdyToReset` output signals when a reset can be carried out via the `RstLi` input parameter or the automatic commands.

There are different ways to reset the block:

- Reset by interconnection (input `RstLi`).
- Reset by the operator using a button in the faceplate (input `RstOp`).
- Reset with a 0-1 edge transition in the corresponding automatic or local signal (except with motor protection). Refer to the following sections for more information.

**Note**

The reset via input RstLi or RstOp does not depend on the selected operating mode.

The operator must have the appropriate authorization to use the reset function in the faceplate (`OS_Perm`). After a reset, the output parameter `P_Rst` is set for a cycle.

**Note**

**Note for VlvMotL and VlvPosL**

After resetting the block, in the case of interlocks or errors, the valve position will always be tracked, depending on `FbkOpen` and `FbkClose`.

### Resetting monitoring errors and interlocks in manual and automatic mode

You can influence the reaction using the following `Feature` Bits:

- `Feature.Bit9`: Resetting via input signals in the event of interlocking (Protection) or errors (Page 174)
- `Feature.Bit30`: Set reset depending on the operating mode or the LiOp parameter (Page 174)
- `Feature.Bit31`: Activating reset of protection / error in manual mode (Page 175)

**Note**

With `MonSafePos = 0`, a reset is not required, the valve and motor can be driven despite feedback failure.

### Resetting monitoring errors, external errors and interlocks in local mode

The monitoring error can occur in local mode if you have set 1, 3 or 5 for the input parameter `LocalSetting` (see Local mode (Page 86)). When `LocalSetting` is set to 2 or 4, a monitoring error can only occur when a rapid stop is triggered.

The following applies with `LocalSetting` 1 or 3:

The monitoring error, the external error and the interlocks cannot be reset when the control and feedback signals do not match.

With `Feature2.Bit13 = 0`: the following applies:

- When the control and feedback signals match, the monitoring error, external error and the interlocks are reset by stopping (`StopLocal = 1`) the drive.
- With `Vlv2WayL` in the `MonSafePos = 1` setting, a monitoring error is reset by `Pos0Local = 1`.
- With `VlvL`, `VlvMotL` in the `MonSafePos = 1` setting, a monitoring error is reset with the local command, which moves the valve to the neutral position.
- With `Vlv2WayL`, `VlvMotL` and `VlvL` in the `MonSafePos = 0` setting, no reset of the monitoring error is required. The currently pending control is in effect.
- With `Vlv2WayL`, `VlvL` and `VlvMotL`, an external error is reset with the local command, which moves the valve to the neutral position
- With `DoseL`, you must acknowledge the protection (`Protect`) and flow alarms with a positive edge at the "`CancelLocal`" or "`PauseLocal`" output parameter.
- With MotL, MotRevL, MotSpdCL or MotSpdL in the MonSafePos =1 setting, an external or monitoring error or an interlock protection is reset with the local stop command.

With `Feature2.Bit13 = 1`: The reset can be done from the reset button in the standard view of the faceplate.

The following applies with `LocalSetting` 2, 4 or 5:

No reset required.

### Resetting motor protection (Trip) in local mode

There are two ways for resetting the Motor protection In Local mode 1 & 3. Once the trip is healthy and feedback is withdrawn then:

- If `Feature2.Bit13 = 0` the reset of pending errors will not be possible via faceplate.
- If `Feature2.Bit13 = 1` then reset button will be enabled in the standard view of the faceplate and operator can reset using this button.

### Resetting monitoring errors, external errors and interlocks using the "Forcing operating states" function

With "Forcing operating states", monitoring errors, external errors, interlocks or the motor protection function are reset under the following conditions and a reset pulse is output at the `P_Rst` output:

- The block is in an operating mode in which a reset is necessary and
- a monitoring error, an external error, a "Protection" interlock or the motor protection function is ready to be reset. This can be seen in the faceplate with the reset button or with the Request 0/1 indicator in the faceplate. When `Feature.Bit19` = 1, the block is ready to reset as soon as the protection `(Protect = 0)` or motor protection `(Trip = 0)` interlock is set, whereby enabled motor protection prevents the motor from starting.

See also the following chapter: Forcing operating modes (Page 45).

### Tabular overview for resetting for interlocks and errors

| | **Permit** | **Interlock** | **Protect** | **PermitSafePos** |
|---|---|---|---|---|
| **Meaning** | Activation enable ("Permission") | Interlock without reset ("Interlock") | Interlock with reset ("Protection") | Activation enable ("PermitSafePos") |
| **Description** | The activation enable (input `Permit` = 1) makes it possible to leave the neutral position of the block in response to operator input or a command from the program (CFC/SFC). The activation enable has no effect if the block is not in the neutral position. | A pending interlock condition brings the block to the neutral position (input `Intlock` = 0). | A pending interlock condition brings the block to the neutral position (input `Protect` = 0). | The activation enable (input PermitSafePos = 0) prevents the control in neutral position or the stop command of the block in response to operator input or a command from the program (CFC/SFC). |

| **Mode:**<br>**Manual** | Feature.Bit30 **and** Feature.Bit31 **= 0:** Resetting not necessary<br>Feature.Bit30 **= 1 and** Feature.Bit31 **= 0:** Resetting not necessary<br>Feature.Bit30 **= 0 and** Feature.Bit31 **= 1** Reset via faceplate or RstLi = 1<br>Feature.Bit30 **and** Feature.Bit31 **= 1:** Reset via faceplate | | The rapid stop function is unlocked in the faceplate via the "Reset" button (RstOp = 1). In CFC, unlocking is carried out using the input parameter RstLi = 1 |

### 2.1.1.4 Neutral position for motors, valves and controllers

#### Neutral position for motors, valves and controllers

The neutral position always represents the deenergized state.

#### Neutral position for motors

The neutral position for motors is always the stopped motor.

The neutral position is adopted when:

- The function Monitoring the feedbacks (Page 104) was triggered.
- One of the interlock conditions is active (see Interlocks (Page 107)).
- An external error via `FaultExt` or `CSF` was triggered (see Error handling (Page 128)).
- The Motor protection function (Page 106) was triggered.
- The function Rapid stop for motors (Page 115) was triggered.
- During start-up (see Set startup characteristics (Page 148)).
- The "Out of service" mode is active.
- One of the automatic commands has bad signal status (16#00 or 16#28) and the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1.

#### Neutral position for valves

There are different forms of the deenergized state for valves:

- Valve is closed in a de-energized state
- Valve is open in a de-energized state
- Valve is stopped in a de-energized state (e.g. motor valve)

The input parameter `SafePos` is used to set these properties of the valve:

- `SafePos = 0`: Valve is closed in a de-energized state
- `SafePos = 1`: Valve is open in a de-energized state
- `SafePos = 2`: Valve is stopped in a de-energized state (e.g. motor valve)

The neutral position is adopted when:

- The function Monitoring the feedbacks (Page 104) was triggered.
- One of the interlock conditions is active (see Interlocks (Page 107)).
- An external error via `FaultExt` or `CSF` was triggered (see Error handling (Page 128)).
- During start-up (see Set startup characteristics (Page 148)).
- The "Out of service" mode is active.
- One of the automatic commands has bad signal status (16#00 or 16#28) and the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1.

### Neutral position for the VlvAnL and VlvPosL blocks (actuator)

The possible neutral positions are set by the SafePos parameter:

- SafePos = 0: Neutral position of the control valve is "Closed" (MV.Value = MV_LoLim)
- SafePos = 1: Neutral position of the control valve is "Open" (MV.Value = MV_HiLim)
- SafePos = 2: Neutral position of the control valve is "Stop" (MV.Value = RbkOut, if Rbk.ST <> 16#FF, else MV.Value remains unchanged)

The control valve VlvAnL is brought to the neutral position when the FbkAuxVCloseOut = 1 auxiliary valve is closed.

The neutral position of the control valve VlvAnL and VlvPosL is adopted when:

- The function Monitoring the feedbacks (Page 104) was triggered.
- One of the interlock conditions is active (see Interlocks (Page 107)).
- An external error via FaultExt or CSF was triggered (see Error handling (Page 128)).
- During start-up (see Set startup characteristics (Page 148)).
- The "Out of service" mode is active.
- One of the automatic commands has bad signal status (16#00 or 16#28) and the Feature2 bit Considering bad quality of automatic commands or external values (Page 200) is set to 1.

In case of startup or “Out of service” mode, the valve VlvAnL has additional Feature bits for adopting the neutral position:

- During start-up, if the Feature bit Set startup characteristics (Page 148) and the Feature bit Neutral position manipulated variable takes effect at startup (Page 176) are set.
- In the "Out of service" mode, if the Feature bit Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) is set.

### Neutral position for continuous controllers (does not apply to controller modules)

- Only the limits or a special analog value for the manual value are taken into consideration for the neutral position with continuous controllers.
  The input parameter SafePos is used to specify the neutral position:
  - SafePos = 0 corresponds to the low limit (ManLoLim or MV_LoLim for PIDConS)
  - SafePos = 1 corresponds to the high limit (ManHiLim or MV_HiLim for PIDConS)
- The input parameters SafePos and SafePos2 are used to determine the neutral position:

| SafePos | SafePos2 | Neutral position | Remarks |
|---|---|---|---|
| =0 | =0 | ManLoLim for PIDConL, PIDConR or MV_LoLim for PIDConS | Low limit for manipulated variable in manual mode |
| =1 | =0 | ManHiLim for PIDConL, PIDConR or MV_HiLim for PIDConS | High limit for manipulated variable in manual mode |
| x | =1 | MV_SafePos | Manipulated variable neutral position |
| x | =2 | Last manipulated variable (stop) | Last manipulated variable (stop) |

x: Not relevant

The neutral position is adopted:

- The interlock conditions is active (see Interlocks (Page 107) only at PIDConL and PIDConR).

In case of startup or "Out of service" mode, the controller has additional `Feature` bits for adopting the neutral position:

- During start-up, if the `Feature` bit Set startup characteristics (Page 148) and the `Feature` bit Neutral position manipulated variable takes effect at startup (Page 176) are set.
- In the "Out of service" mode, if the `Feature` bit Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) is set.

#### Neutral position for step controllers (does not apply to controller modules)

You can use the input parameter `SafePos` to determine if the step controller should close, open or stop the valve when it enters the neutral position:

`SafePos = 0`: close valve

`SafePos = 1`: open valve

`SafePos = 2`: stop valve

When the neutral position (fully opened or fully closed) is reached and a limit stop signal (`FbkOpened` or `FbkClosed`) is set, the valve is stopped (Stop = 1).

The neutral position is adopted:

- during start-up if the `Feature` bit Set startup characteristics (Page 148) and the `Feature` bit Neutral position manipulated variable takes effect at startup (Page 176) are set.
- in the "Out of service" mode if the `Feature` bit Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) is set.

#### Safety control for controllers of the FM 355 or FM 355-2 modules

The controller modules have their own mechanism for feedforwarding a safety value (see Temperature Controller FM 355-2 manual or Controller Module FM 355 manual)

### 2.1.1.5 Specifying warning times for control functions at motors and valves

#### Specifying warning times for control functions at motors and valves

This function is only supported by "Large" blocks.

You can generate warning signals when, for example, motors are started or valves are opened. Warning signals can be generated in the following modes:

- Manual mode (input parameter `WarnTiMan`)
- Automatic mode (input parameter `WarnTiAut`)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a motor is started then, this is displayed at the output parameter with `WarnAct = 1`. The motor then starts after the configured warning time has expired and `WarnAct` is reset (`WarnAct = 0`).

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

**Note**

In this case, the warning time is only active if the block is controlled from the de-energized state.

### Disabling warnings

Configure each parameter with 0 seconds to generate no warnings.

## 2.1.1.6 Output signal as a static signal or pulse signal

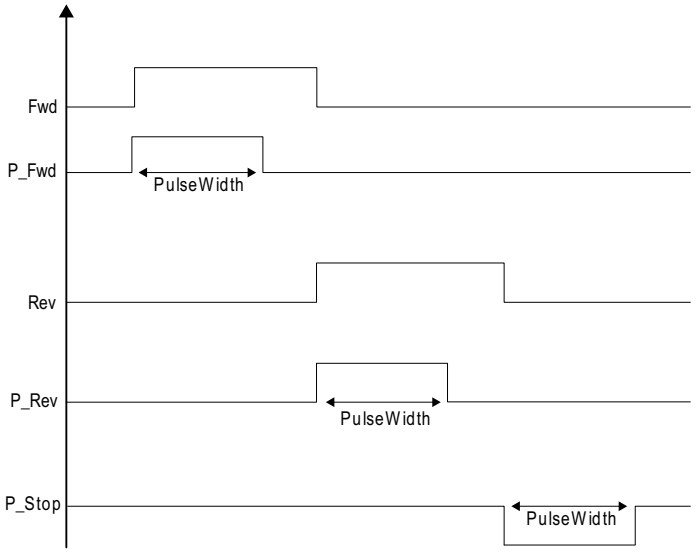
### Output signal as a static signal or pulse signal

You can output the control signals for motors, valves and dosers as:

- Static signal or as a
- Pulse signal with configurable pulse length.

You can find the signals in the I/O table of the individual blocks.

**Note**



The pulse signal is available only for the "large" blocks.

### Output signal as a static signal

The control settings are made available as a static signal in the blocks in the form of interconnectable output parameters. The MotRevL block, for example, provides these as static signals via the alternative output parameters `Fwd`, `Rev` and `Run`.

### Output signal as a pulse signal

The control is made available as pulse signals at the blocks using interconnectable output parameters. You specify the pulse length of the output signals in seconds using the input parameter `PulseWidth`. The MotRevL block, for example, provides these as pulse signals via the output parameters `P_Fwd`, `P_Rev` and `P_Stop`.

**Note**

Almost all output parameters for pulse control, for example `P_Fwd`, `P_Rev`, `P_Ctrl`, have a positive effective direction, i.e. a 0→1→0 pulse triggers activation.

The only exception is the `P_Stop` output parameter with a negative effective direction, i.e. a 1→0→1 pulse triggers activation.

## 2.1.1.7 Recording the first signal for interlock blocks

### Recording the first signal

You activate the function described below using the `Feature` bit " Activating recording of the first signal (Page 161)".

The number of the input that caused the last output signal change from 1 to 0 (good state to locked) is displayed for you in bit coding at the `FirstIn` output. The cause may be:

- A signal change at the input or a change in inversion
  Example: With an OR logic operation, the single 1 changes to 0. The output then changes from 1 to 0.
- A change to the I/O
  Example: Excluding the single 1 then results in an output of 0 with an OR logic operation.

- A change to the signal status
  If the signal status of the input, which forms the output value alone and has the value 1, changes from 16#80 to 16#00, the output value changes from 1 to 0.
- `FirstIn` is not changed if the following events occur, despite a change to the output:
  - Change in output value from or to `DefaultOut`

If several signals are at the same time responsible for the change, all responsible inputs are indicated in the faceplate and output in bit coding in the `FirstIn` output. If the input signals change without this causing the signal at the output to change, `FirstIn` does not change.

Inputs which are not interconnected or which are excluded are not taken into account.

You can reset `FirstIn` to 0 if you set the `RstLi` input from 0 to 1 (positive edge) or you can operate the `RstOp` input using the faceplate ("Reset" button).

If at least one bit in `FirstIn` is set, other signal changes are not taken into account.

### 2.1.1.8 Outputting a signal for start readiness

#### Outputting a signal for start readiness

The `RdyToStart = 1` output parameter is used to indicate start readiness in automatic mode.

Start readiness is output when the following conditions are met:

- No group error pending (group fault with consideration of `Feature.Bit18` for `CSF` and `MonSafePos` for feedback errors)
- No interlock is active
- No forced operating mode or manipulated variable is active
- No rapid stop is active (only applies to motors or `VlvMotL`)
- The block is in automatic mode (not with controller blocks)
- The waiting time for the restart must have expired (only applies to motors or `VlvMotL`)

The start readiness is shown at the following block groups via the `RdyToStart` output parameter:

- Motors
- Valves
- Dosers
- Software controller
- Hardware controller

### Start readiness for motors

The start readiness for motor blocks is formed as follows:

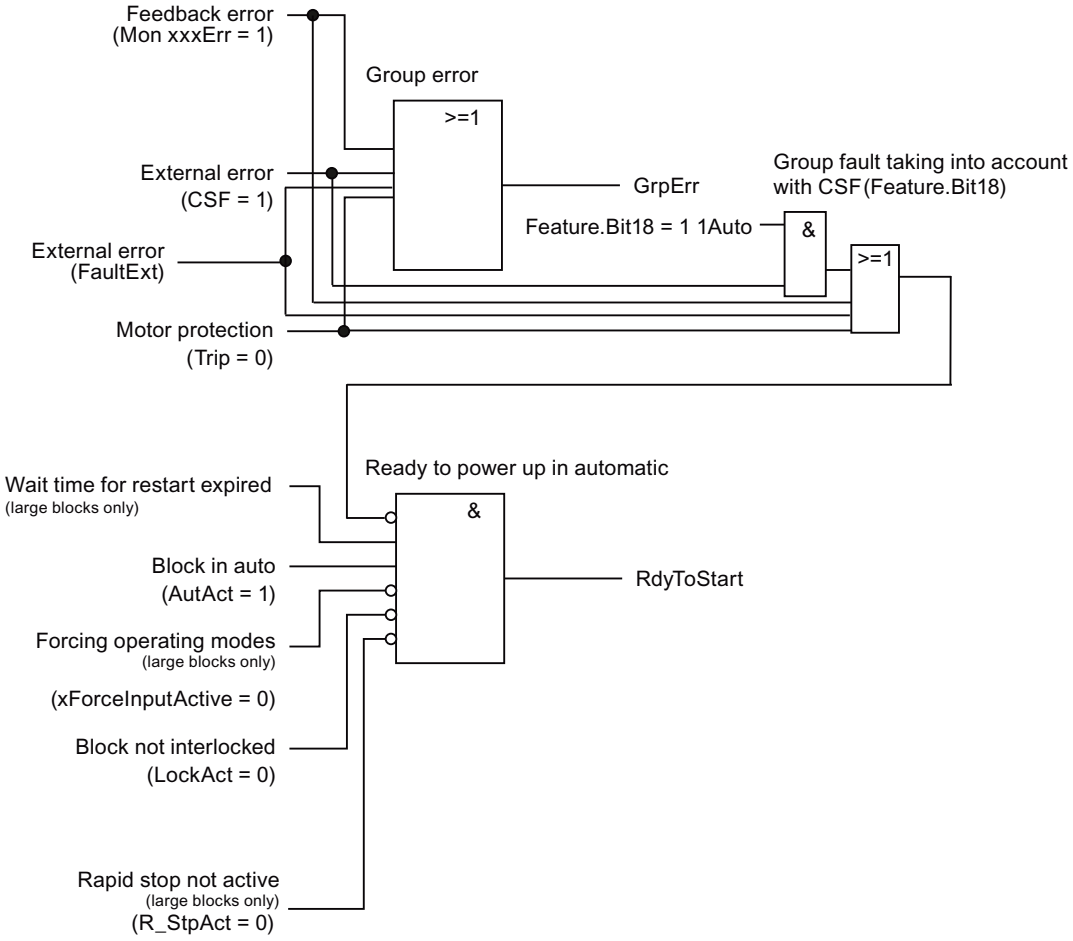


Figure 2-1 Output signal for start readiness for motors

## Start readiness for valves

The start readiness for valve blocks is formed as follows:

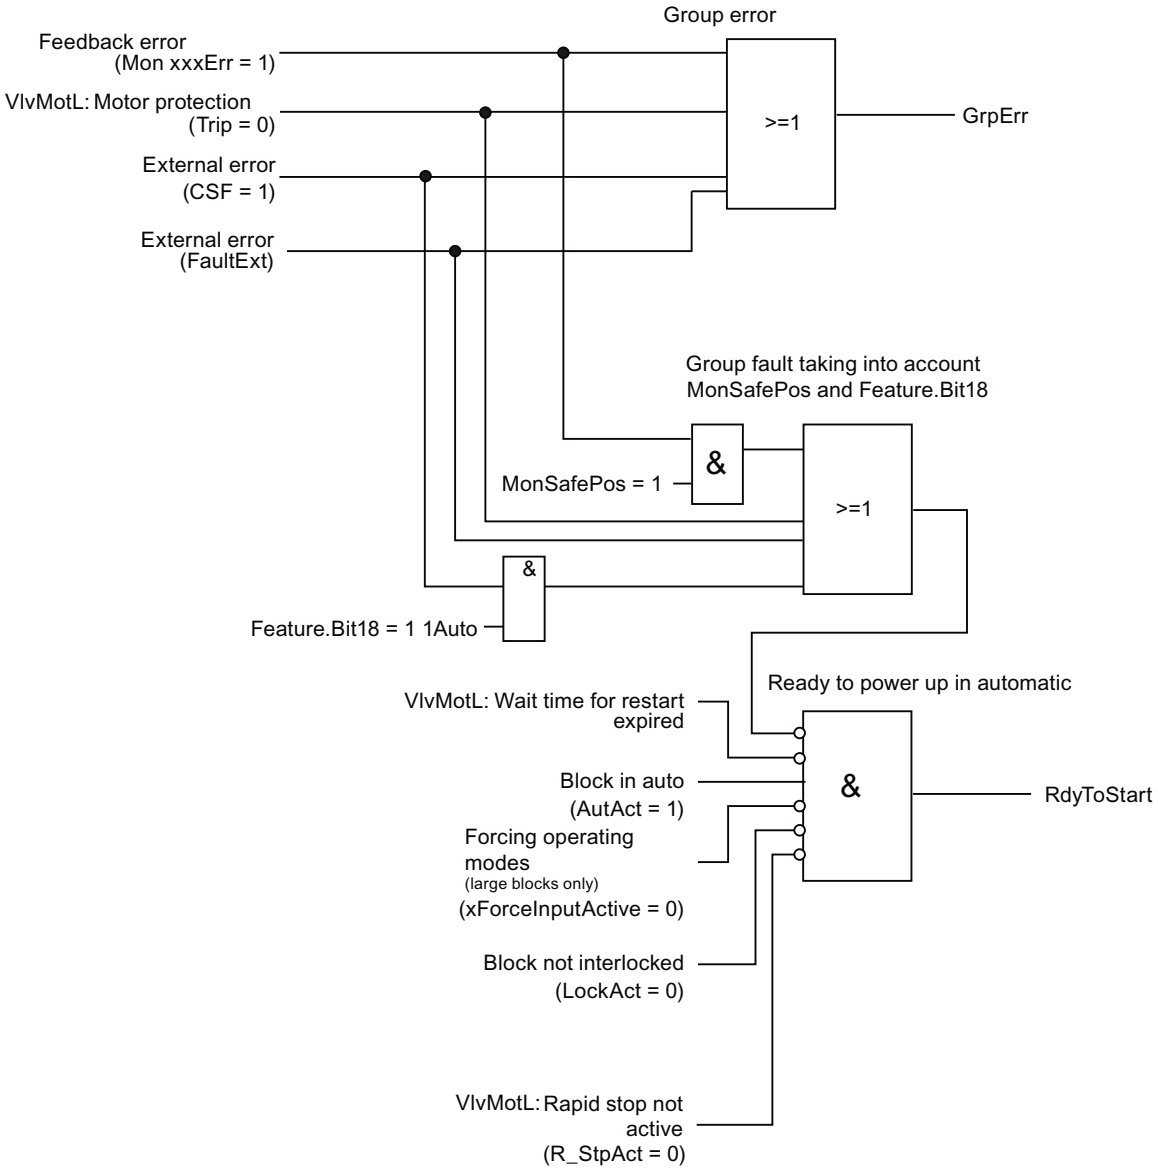

Figure 2-2 Output signal for start readiness for valves

### Start readiness for dosers

The start readiness for dosers is formed as follows:

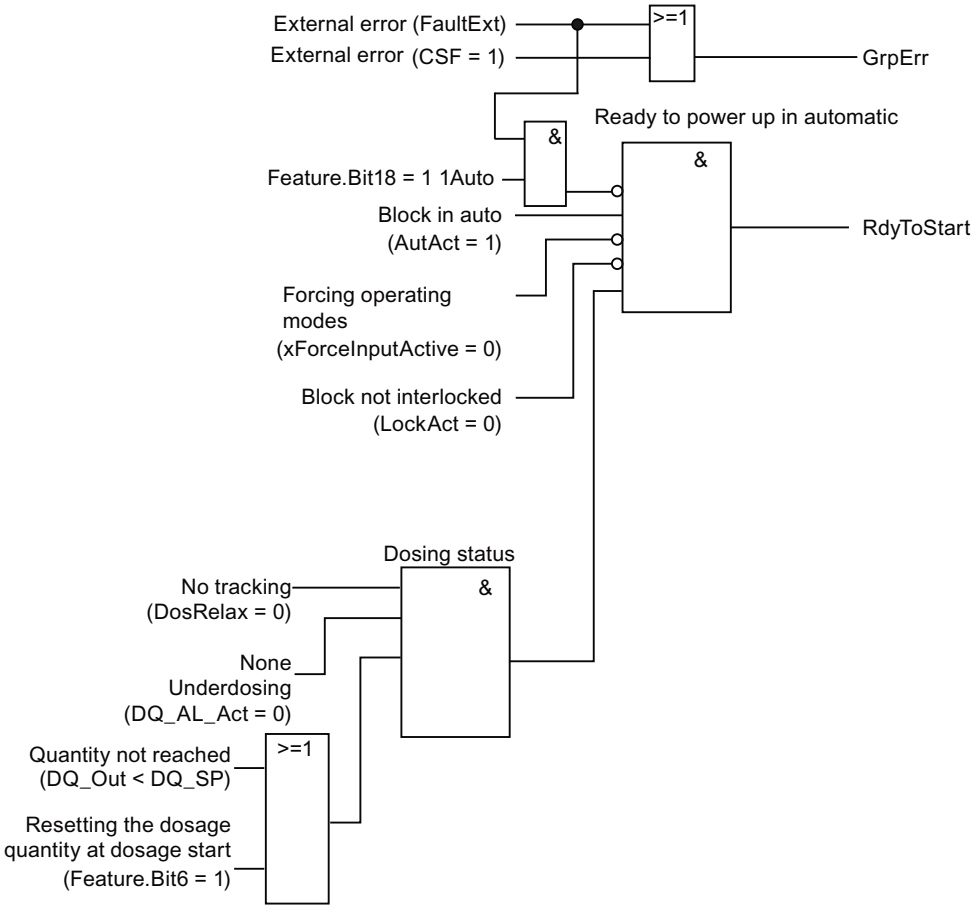

Figure 2-3 Output signal for start readiness for dosers

### Start readiness for software controllers

The start readiness for software controllers is formed as follows:

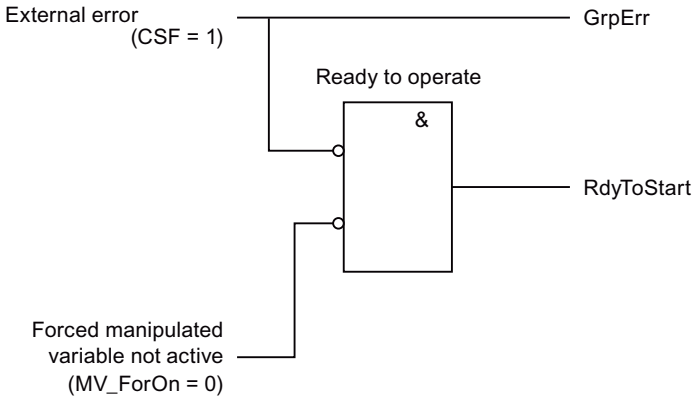

Figure 2-4 Output signal for start readiness for software controllers

### Start readiness for hardware controllers

The start readiness for hardware controllers is formed as follows:

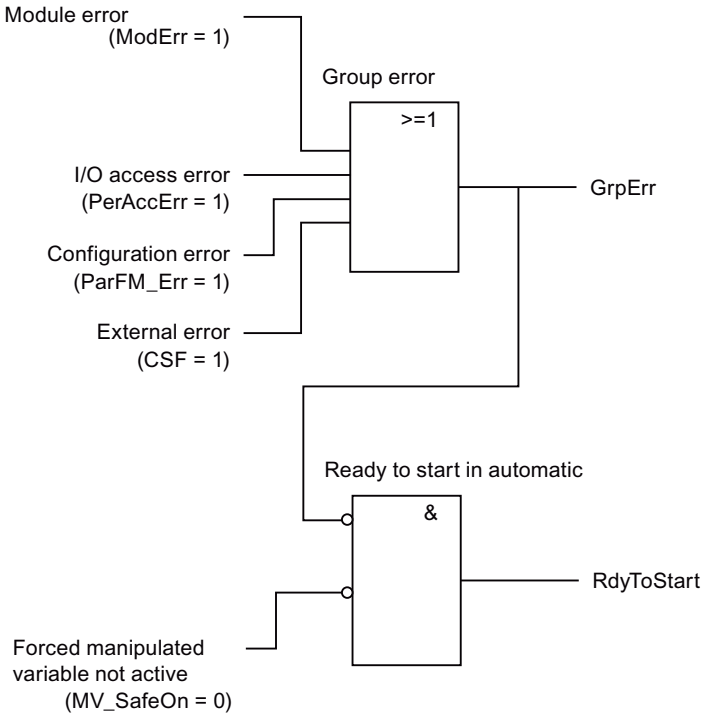

Figure 2-5 Output signal for start readiness for hardware controllers

## 2.1.1.9 Simulating signals

### Simulating signals

Simulation means the manipulation of a signal regardless of the actual source of the signal or logic that generates this signal.

Simulation is carried out either at the field device (externally from the control system) itself or at a block (internally in the control system).

In either case, the associated status in the signal is set to the simulation value (see also Forming and outputting signal status for blocks (Page 116)).

During the simulation, every block is considered in isolation. There are two different forms of simulation here, namely:

- Block-external simulation and
- Block-internal simulation.

### Block-external simulation

Block-external simulation is characterized by the fact that:

- The simulation function is not executed in the block itself and
- A signal whose status has the simulation state, for example, a simulation of the signal at another block or directly in the I/O device, is applied at an input parameter.

The block-external simulation has the following effects on the functionality of the block:

- The technological functions are not influenced
- All the process-relevant output signals do not receive the simulation status. In the case of technologic blocks, process-related output signals are parameters that actively affect the process, e.g. "`Start`" for block MotL.
- In the case of blocks with operator control or monitoring functions (for example faceplates), these signals are identified in the faceplate with the status for the simulation as follows:

- Blocks with one or more input parameters for signals with "Generate status from individual status" receive a group status in accordance with the priority table. This group status is displayed in the status bar of the block icon and of the faceplate with the simulation status as follows:

- The interlocking functions of the block are not influenced.

**Note**

For the output channel blocks, you need to specify the exact block response with external simulation using the `Feature` bit Outputting a de-energized value for block-external simulation (Page 159).

### Block-internal simulation

Block-internal simulation is characterized by the "simulation" function being run in the block itself.

With operator control and monitoring blocks, all process values that cannot be controlled (e.g. `PV`, `AV`, `In`) can be simulated. This is used primarily as an aid for commissioning and servicing of the system. For example, the control settings of a motor can be simulated and the feedback values corrected without the monitoring functions being active.

For specific technological blocks (e.g. large blocks) that can be operated and monitored, simulation can take place via the faceplate as well as interconnectable inputs:

- `SimLiOp` = 0: The simulation is activated/deactivated via faceplate (parameter view) at the input `SimOn`.

- `SimLiOp` = 1: The simulation is activated/deactivated via the input `SimOnLi`. The interconnectable simulation values (e.g. `SimPV_Li`, `SimAV_Li`, `SimInLi`) will become effective in the process. In this case, the inputs `SimOn`, `SimPV`, `SimAV`, `SimIn`, `SimRbk` are written back with `SimOnLi`, `SimPV_Li`, `SimAV_Li`, `SimInLi`, `SimRbkLi`.

The `Feature` bit Activating the run time of feedback signals (Page 164) can be used to delay tracking of the feedback signals for motors and valves (for example, `Fbkxxx`).

Simulation can also be carried out for blocks (such as channel blocks) that cannot be controlled and monitored by the operator.

The control is simulated in the CFC by setting parameters directly in the block with the input parameters `SimOn = 1` and `Simxxxx =` for the desired simulation value (e.g. `SimPV` , `SimAV` or `SimIn`).

**Note**

With channel blocks, ensure that the `Mode` parameter is set correctly during simulation.

**Note**

If the block is not in simulation, the simulation values (`SimPV`, `SimAV`, `SimIn`, `SimRbk`) are updated to the process values (`PV`, `AV`, `In`, `Rbk`).

Simulation is triggered during runtime in the faceplate's parameter view by clicking on the "Simulation" button.

This simulation is characterized by the fact that:

- The simulation can only be enabled / disabled with the operator authorization level for system authorization.
- The technological functions are not influenced.
- All the process-related output signals receive the "simulation" status. In the case of technologic blocks, process-related output signals are parameters that actively affect the process, e.g. "`Start`" for block MotL.
- In the case of blocks with operator control or monitoring functions (for example faceplates), these signals are identified in the faceplate with the status for the simulation as follows:

- The group status of the block is displayed in the status bar of the block icon and of the faceplate with the simulation status as follows:

- All the process values displayed in the faceplate that cannot be operated-controlled in normal operation (e.g. `PV`).
- When the block control can be manipulated, the readback and feedback values (for example `Rbk`, `FbkSpd1`) are adjusted according to the manipulation of the control.
- Associated values (for example `UserAna1`) cannot be simulated.
- The interlocking functions of the block are activated in accordance with input parameter `BypProt = 0` or deactivated (`BypProt = 1`). This is shown as follows in the faceplate and block icon:

| | |
|---|---|
| Enabled |  |
| Disabled |  |

### Block-internal simulation for controllers

How block-internal simulation for controllers works (`SimOn = 1`):

- In manual mode, both the simulated process value `SimPV` and the simulated repeated manipulated variable `SimRbk` can be entered in the faceplate as a simulated value.
- When a switchover to automatic mode is performed, the simulated process value `SimPV` is set so that it is equal to the setpoint `SP` (= tracking). This means the control deviation is no longer present and the pending manipulated variable (from the bumpless manual-automatic switchover, for example) remains constant. `SimRbk` can still be controlled.

**Note**

If you switch a controller block to block-internal simulation during automatic mode and the controller is connected to the actual process on the actuator side, you will open the control loop as a result.

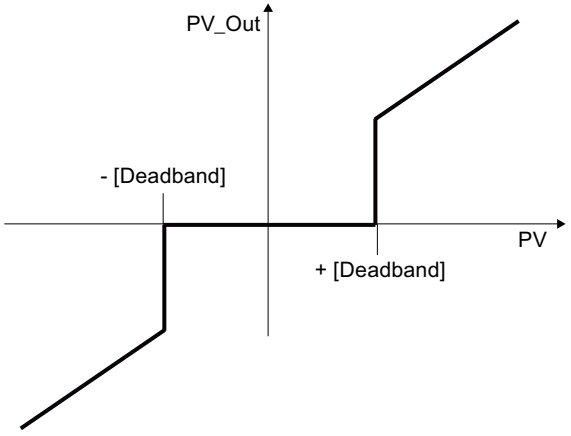
The actuating signals calculated on the basis of the simulated actual value are switched to the process, but the resulting motion in the process is no longer visible in terms of the controller actual value, as a copy of the setpoint is present at this point instead, where it takes the form of a simulated actual value. The process could move away from the setpoint without the controller doing anything to counteract this and without you seeing this happen in the controller faceplate.

Manipulated variable step changes occur during switchover to automatic mode if an error signal was already present before the switchover.

The following applies to program mode:

- Program mode with setpoint specification should be considered the same as automatic mode from a control engineering point of view. Block-internal simulation reacts in the same way as it does in automatic mode: The process value `PV` is set so that it is equal to the setpoint `SP`, which in this case is derived from the input parameter `AdvCoMV`.
- Program mode with manipulated variable specification should be considered the same as manual mode from a control engineering point of view. Block-internal simulation reacts in the same way as it does in manual mode: The simulated process value `SimPV` can be entered as a simulated value. In this case the manipulated variable `MV` is derived from the input parameter `AdvCoMV`.

## 2.1.1.10 Dead band



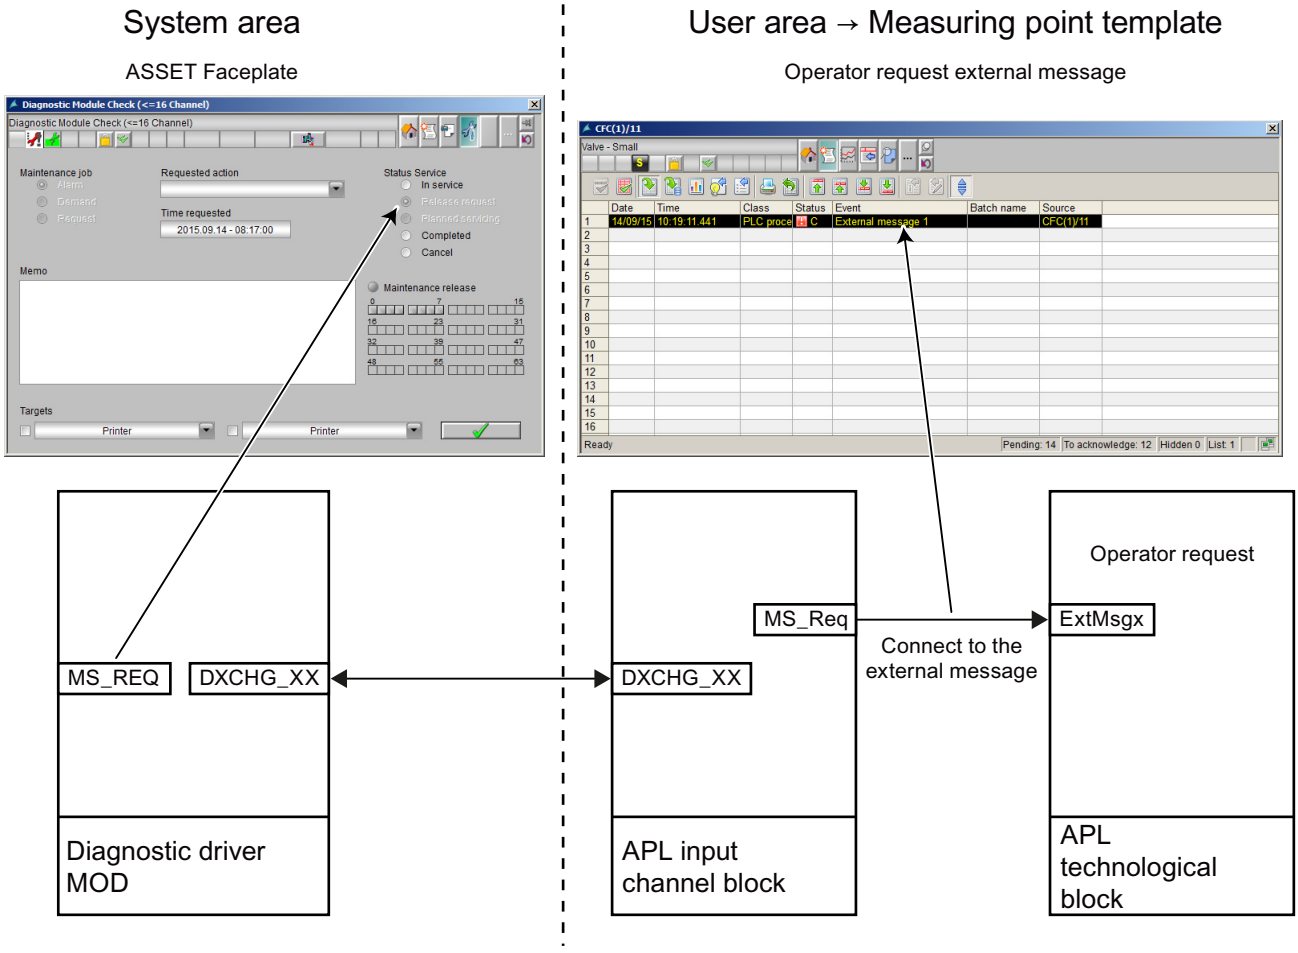
### Dead band

To suppress values fluctuating around zero, you can set a dead band (`Deadband`):

`Deadband = 0`: Dead band is disabled

`Deadband ≠ 0`: Dead band is enabled

With a negative dead band (`Deadband < 0.0`), calculation is continued internally with this value



### 2.1.1.11 Request for maintenance release

#### Issuing a request for maintenance (MS → APL)

An operator can issue a request for maintenance release from the Maintenance view of the ASSET faceplate ("Status service" → "Release request"). After issuing a maintenance request, the operator can set the maintenance release. This will display the message which the operator has configured. Later, operator can set the Maintenance Release in the technological Block (Page 70). It indicates that the maintenance operator can start the maintenance.

## Functional sequence in APL

- The output parameter `MS_Req` of the channel block will be set to 1 when an operator issues a maintenance request in Maintenance view of the ASSET faceplate.
- The output parameter `MS_Req` has to be connected to the input parameter `ExtMsgx` of the desired technological block for which the user wants to issue an operator request message.
- The operator has to configure the "Message class" and enter a suitable text in the "Event" field for the operator request message in the "PCS 7 Message Configuration" window of the technological block.
- With the configured message and issued maintenance release, the maintenance operator can start the maintenance.
- The operator request message stays active until the user changes to "In service" or "Cancel" mode in the Maintenance view of ASSET faceplate.
- Once the maintenance is done, the operator can change the mode to "Completed". This will deactivate the "In service" mode (`OosAct` = 0).

### 2.1.1.12 Release for maintenance

#### Issuing a release for maintenance

The release for maintenance serves as information about a process tag at which maintenance, service or calibration should be carried out. You can use the signal for release for maintenance to transfer the information about the enabling of a process tag from the OS to a Maintenance Station.

**Note**

The block must be in either "Manual," "On" or "Out of service" mode to set the release for maintenance.

You set the release for maintenance (operator control permission "System control" required) in the parameter view using the input parameter `MS_RelOp = 1`. A release for maintenance is then made available via the interconnectable output parameter `MS_Release = 1` for further processing. In order to make this information of the Maintenance Station available, you have to interconnect the output parameter `MS_Release` of the technologic block with the input parameter `MS_Release`of the corresponding channel block.

The issuing of a release for maintenance does not have any influence on the function of the block. An operation message is generated.

#### Use of the state "In progress" on the Maintenance Station

The status "In progress" is implemented on the Maintenance Station for a process tag or a field device using the channel blocks and the interconnectable output parameter `OosAct = 1`. You can interconnect the output parameter `OosAct` of the channel block with the input parameter `OosLi` of a technologic block.

Use the `Feature` bit Reaction to the out of service mode (Page 188) to specify, in case the input parameter is `OosLi = 1`, if:

- there is a switchover to the "out of service" mode and the symbol for the "In progress" (see table) status is displayed. You can change to manual mode at any time.
- Only the "In progress" display (see table) in the block icon and in the faceplate of the assigned technologic block is made.

| Display | Meaning |
|---|---|
|  | In progress |

#### Function sequence in the APL

- The OS operator issues the release for maintenance (`MS_RelOp = 1`) in the technologic block's parameter view.
- The technologic block then sets the `MS_Release = 1` output parameter.
- The channel block's `MS_Rel` input is now also 1.

- The channel block signals the release for maintenance to the diagnostics block via the `DXCHG` parameter.
- The release for maintenance is only signaled to the Maintenance Station once all 0 bits of the parameter `DXCHG_XX` are set on the diagnostics block.

- The channel block determines the "in progress" state of the Maintenance Station using the `MS` input parameter and makes this information available at the `OosAct` output parameter.
- On the technologic block, the "working" state is displayed at input parameter `OosLi` and forwarded for display to the faceplate.

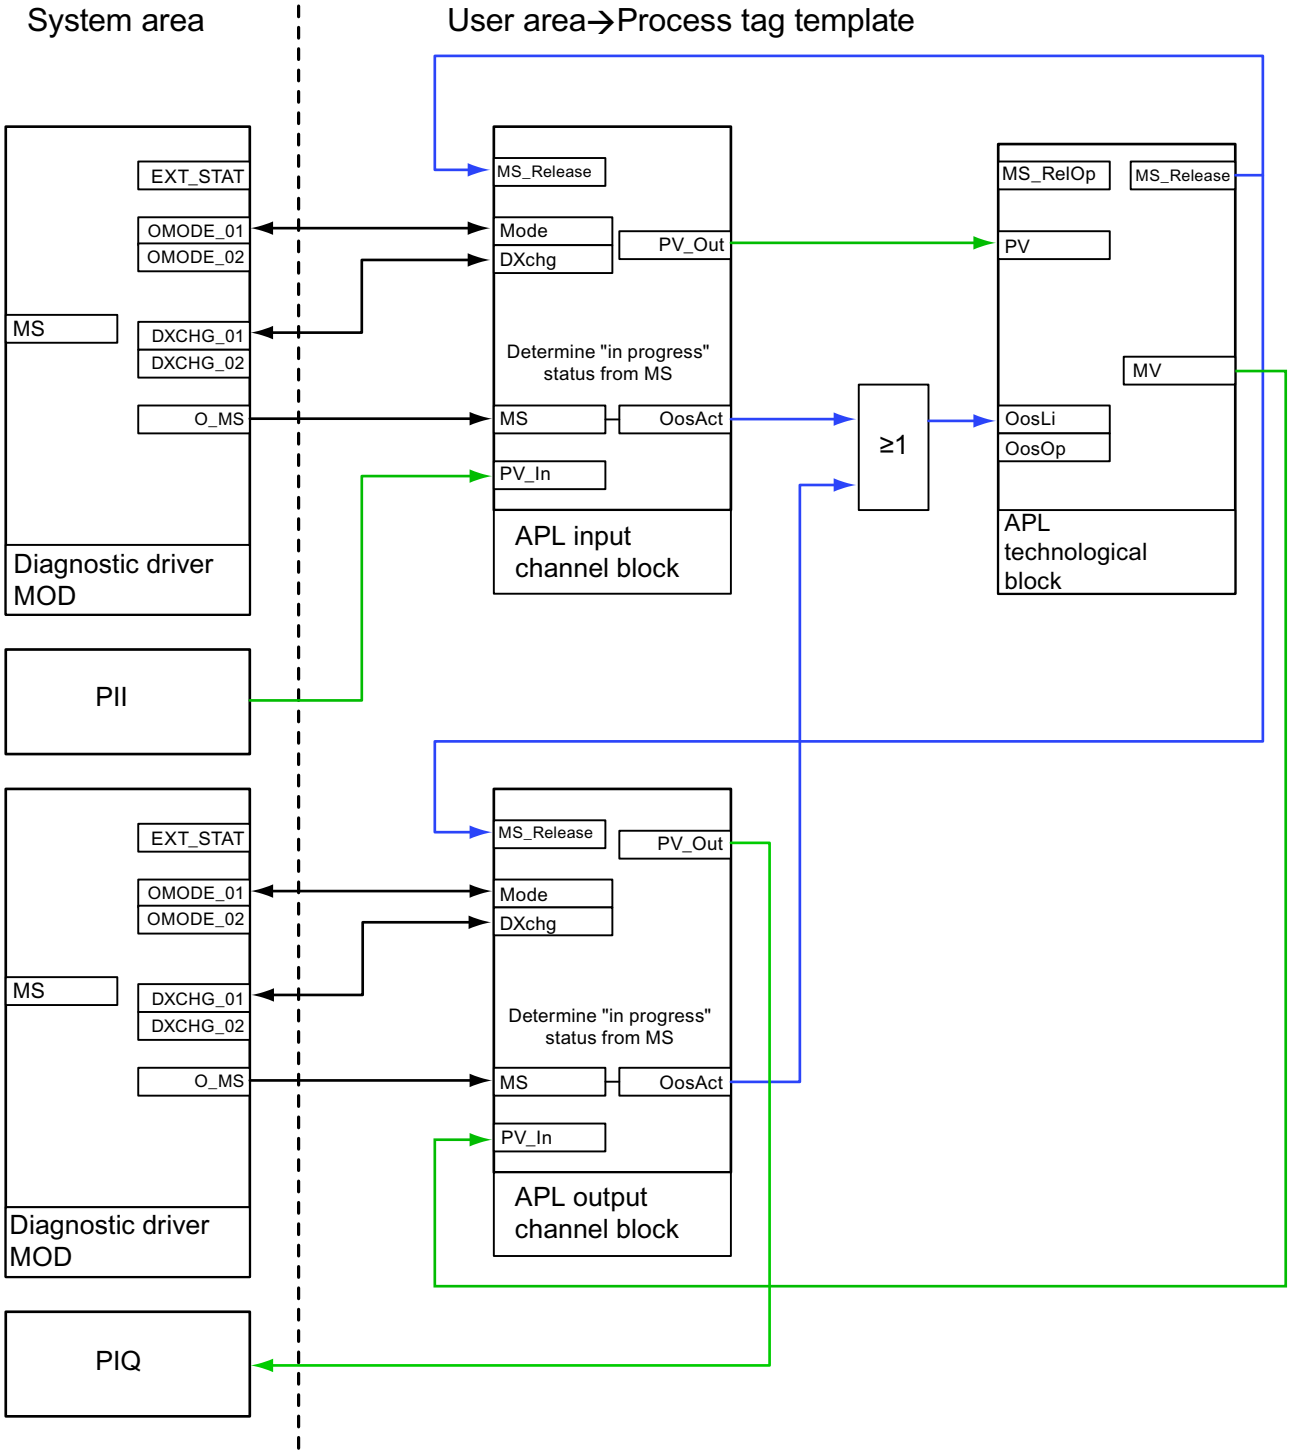


Figure 2-6 Release for maintenance

**Key to diagram:**

| | |

| PII | Process image of inputs |
| PIQ | Process image of outputs |
| Black lines | Automatic system connections |
| Green lines | Process value connections made by the planner |
| Blue lines | Connections for release for maintenance made by the planner |

**Note**

For additional information on the topic of maintenance please refer to PCS 7 OS process management.

### 2.1.1.13 SIMATIC BATCH functionality

#### SIMATIC BATCH functionality

Some blocks have an interface to SIMATIC BATCH. You use them when you connect `BatchEn`, `BatchID`, `BatchName`, `StepNo` and `Occupied` I/Os to the corresponding SIMATIC BATCH blocks. A new `BatchName` becomes effective if the `BatchID` is changed. Refer to the SIMATIC BATCH documentation.

Please refer to the descriptions of the individual blocks for information about whether a block supports the SIMATIC BATCH functionality.

### 2.1.1.14 Flutter suppression for channel blocks

#### Flutter suppression

The time-controlled "Flutter suppression" function is used to delay the outgoing of a message by a configurable period.

Flutter suppression is used for

- OB82 events - diagnostic messages
- OB83 events - fault

used.

The flutter time is entered at the channel block at the `FlutTmIn` parameter. The high byte of the `DataXchg` parameter of the channel blocks contains the flutter time.

Flutter suppression comes into effect when `FlutEN` = 1 and `FlutTmIn` > 0 is set at the channel block.

There is only one flutter message per module. The delay times and fault messages are channel-specific. The fault messages are extended by at least the delay time. Flutter occurs when the status of fault messages changes from "Outgoing" back to "Incoming" within the delay time.

The last fluttering channel and its set delay time deactivates the flutter message.

The following channel blocks have this function:

FbAnIn - Analog input channel block for field devices (Page 2466)

FbAnTot - Analog totalizer channel block for field devices (Page 2487)

FbAnOu - Analog output channel block for field devices (Page 2476)

FbDiIn - Digital input channel block for field devices (Page 2495)

FbDiOu - Digital output channel block for field devices (Page 2505)

Pcs7AnIn - Analog input channel block (Page 2564)

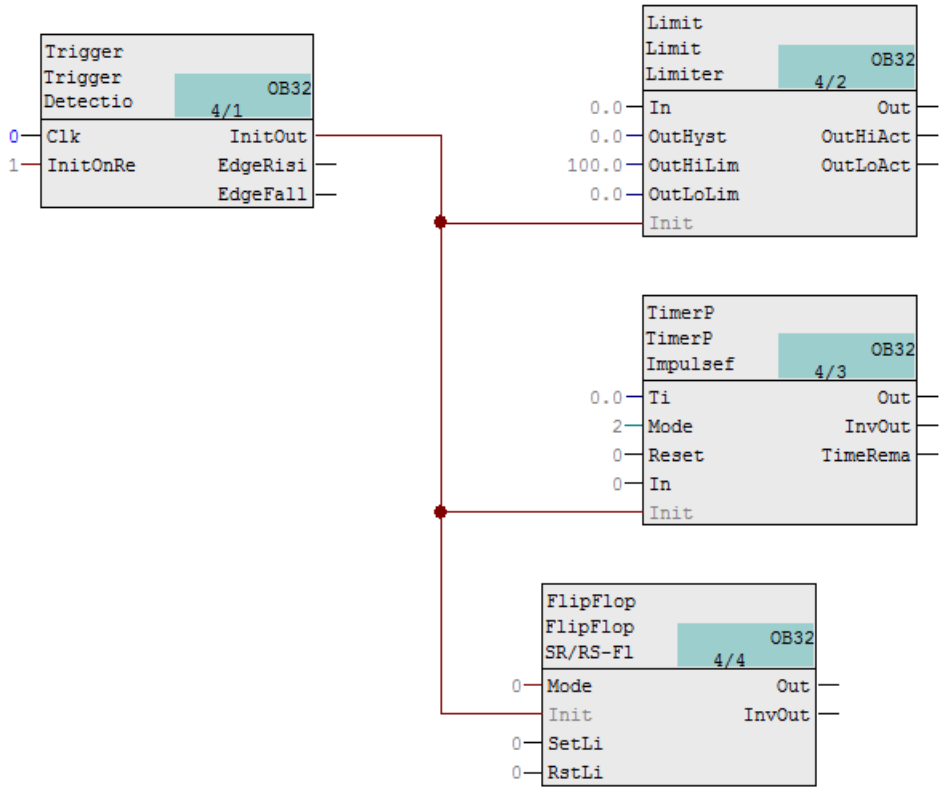
Pcs7AnOu - Analog output channel block (Page 2577)

Pcs7DiIn - Digital input channel block (Page 2596)

Pcs7DiIT - Digital input channel block with time stamp (Page 2605)

Pcs7DiOu - Digital output channel block (Page 2616)

Pcs7Cnt1 - Controlling and reading FM 350 modules (Page 2625)



Pcs7Cnt2 - Control and read an 8-DI_NAMUR module of the ET 200iSP (Page 2636)

Pcs7Cnt3 - Control and read the 1 COUNT 24V/100kHz module for count mode (Page 2646)

### 2.1.1.15 Startup characteristics over Trigger block

#### Startup characteristics over Trigger block

With the function block Trigger, you can influence the startup characteristics of the blocks Limit, TimerP, FlipFlop, and Trigger. Connect the output parameter `InitOut` of the Trigger block with the input parameter `Init` of the block Limit, TimerP, or FlipFlop to initialize these blocks. In the second cycle of OB30 to OB38, the output parameter `InitOut` of the Trigger block will be reset after a startup.

### 2.1.1.16 Parameters that cannot be connected

This section provides information on parameters that cannot be connected by user via CFC connection. (for example: `StartValue` at the Pcs7DiOu).

the following parameters that are not linkable:

| Parameters | Applicable for all the blocks | TimeTrig |
|---|---|---|
| `SampleTime` | x | x |
| `MsgEvId(x)` | x | x |
| All inputs beginning with Old.<br>For example: In CntOhSc: `OldMinutes`, `OldDays`, and so on. | x | x |

| Parameters | Applicable for all the blocks | TimeTrig |
|---|---|---|
| J_Mini | x | x |
| OptimOcc | x | x |
| InPerTrigOn | - | x |
| InSglTrigOn | - | x |
| InSglTrigDT | - | x |

## 2.1.2 Operating modes of the blocks

### 2.1.2.1 Overview of the modes

#### Overview of the individual modes

The available operating modes are assigned to the block families:

- Motors, valves and dosers
- Controllers
- Blocks without "Manual" and "Automatic" modes

You can find an overview below. Click on one of the operating modes to go directly to the relevant detailed description.

You can find a state graph for the operating modes (Page 90) at the end of this section.

#### Operating modes for motors, valves and dosers

The following operating modes are available:

1. Local mode (Page 86)
2. Automatic mode (Page 82)
3. Manual mode (Page 82)
4. Out of service (Page 77)

The mode with the lowest number in the list above has the highest priority. "Manual" and "Automatic" modes have the same priority. General information on the individual modes is available in the following sections. The sections also include block-specific information, for example, non-standard parameter assignment. Refer to the description and function of the relevant blocks.

#### Operating modes for controllers

The following operating modes are available:

1. Automatic mode (Page 79)
2. Manual mode (Page 79)

3. Program mode for controllers (Page 85)
4. Out of service (Page 77)

The mode with the lowest number has highest priority. "Manual" and "Automatic" modes have the same priority. General information on the individual modes is available in the following sections. The sections also include block-specific information, for example, non-standard parameter assignment. Refer to the description and function of the relevant blocks.

### Operating modes for blocks without "Manual" and "Automatic" operation

The following operating modes are available:

1. On (Page 77)
2. Out of service (Page 77)

The mode with the lowest number has highest priority. General information on the individual modes is available in the following sections. The sections also include block-specific information, for example, non-standard parameter assignment. Refer to the description and function of the relevant blocks.

**Note**

Note that the operating modes are realized differently in the individual block families.

## 2.1.2.2 On

### "On" operating mode

The "On" operating mode tells you that the block algorithm is being processed (output parameter `OnAct = 1`). This operating mode is only available for blocks that have faceplates but not the following operating modes:

- Manual mode or
- Automatic mode or
- Local mode

The "On" mode can only be activated via a control on the faceplate (input parameter `OnOp = 1`). The block must be in the "Out of service" operating mode for this to be possible.

## 2.1.2.3 Out of service

### Using the "Out of service" operating mode

The "Out of service" operating mode is available to all blocks that have an operating mode switchover and a direct connection to the process (with a connection to a process tag, for example).

The "Out of service" operating mode is intended for purposes of maintenance and servicing (replacing the device, for example). All of the block's functions are disabled. No incoming or

outgoing messages are generated. The only function still possible is an operating mode switchover.

All outputs for motors and valves are set to the neutral position in this operating mode.

The timer for the function "Restart disable after the shutoff of motor (Page 1762)" is reset in this mode.

**Note**

**Notes on VlvMotL and VlvPosL**

If the neutral position of is "Closed" or "Open", the corresponding control outputs "Closed" or "Open" are set. The control outputs are reset after reaching the neutral position or with an active torque signal. The "Seal valve" function (`Feature.Bit8`) is a component.

**Note**

**Note on VlvMotL**

If the timer of the "Restart disable after the shutoff of motor (Page 1762)" function is running and the block is not in the neutral position, it is not possible to switch to "Out of service" mode.

**Note**

For the `RbkOut.ST` parameter, the status is set to "Out of service (OOS)" in the moment of change and not in every cycle of OOS.

For controllers, the neutral position manipulated variable (high or low manual limit of the manipulated variable) is only used if the `Feature` bit Neutral position manipulated variable takes effect at startup (Page 176) is active. Otherwise the manipulated variable remains at the latest value like all the other output parameters.

See also the section Neutral position for motors, valves and controllers (Page 54) for more on this.

The last value available is output permanently for all other blocks.

### Requirement for the "Out of service" mode

Prerequisite for switching to this operating mode is that the block is in "Manual mode" or "On" mode.

### Activating the "Out of service" operating mode using the faceplate

The "Out of service" operating mode can only be switched on by using the faceplate when it is in the default block view (`OosOp = 1` parameter) and even then, only if `ModLiOp = 0`.

To switch the operating mode using the faceplate, refer to the descriptions relating to the standard view of the individual blocks.

### Switching on the "Out of service" operating mode by using the interconnection

The "Out of service" operating mode is switched on by using the configurable parameter `OosLi = 1`. This is only possible if the block is in manual mode or "On" mode and the `Feature` bit Reaction to the out of service mode (Page 188) was set to 1.

Regardless of operating mode, the parameter view of the faceplate will always display the status of the parameter `OosLi =1` with the symbol for the status "In progress" (see table) next to the Maintenance enable button.

| Display | Meaning |
|---|---|
|  | In progress |

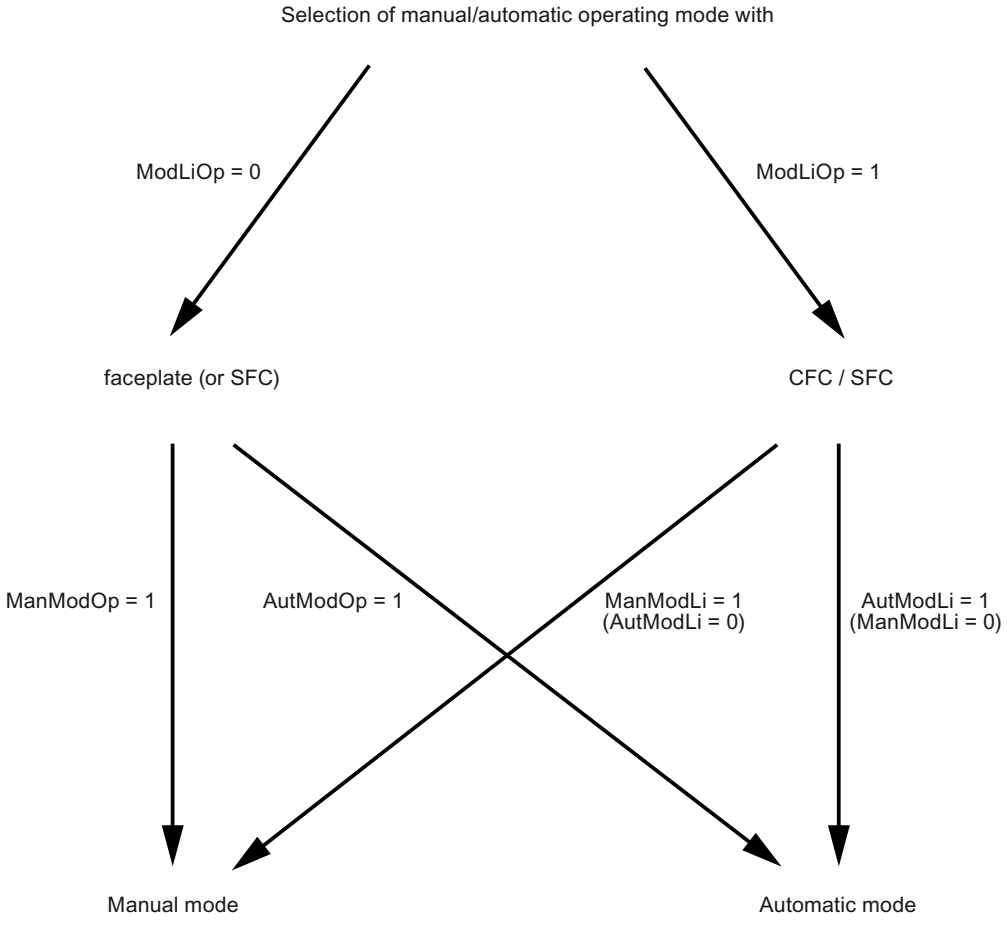
See also the section Release for maintenance (Page 70) for more on this.

### Exiting the "Out of service" operating mode

From this operating mode, a block can only be switched by an operator action at the faceplate into the following operating modes:

- "On"
- "Manual mode"

## 2.1.2.4 Manual and automatic mode for control blocks



### "Manual" and "Automatic" modes for controller blocks

In "manual mode", the control settings for the device are made manually by the operator. The operator decides how to change the block's manipulated variable (output signal). The manipulated variable can be analog or binary.

In "automatic mode", the control settings for the controller are made automatically as calculated by the block algorithm.

### Changing between operating modes

The switchover between manual and automatic modes takes place as shown in the following schematic:

**Switchover initiated in the faceplate** (`ModLiOp` = 0)**:** The switchover between operating modes is carried out in the standard view of the faceplate. In the function block, the parameters `ManModOp` for "manual mode" and `AutModOp` for "automatic mode" are used.

If both signals (`ManModOp =1`, `AutModOp = 1` ) are set, `ManModOp = 1` has priority.

**Switchover per interconnection (CFC or SFC instance)** (`ModLiOp = 1`)**:** The switchover between the operating modes is carried out with an interconnection on the function block. The parameters `ManModLi` for "manual mode" and `AutModLi` for "automatic mode" are used in pushbutton operation. In switching mode (requirement: `Feature.Bit4` = 1, see Setting switch or button mode (Page 177)) connection `AutModLi` is used exclusively.

If both signals (ManModLi =1, AutModLi = 1), the previous operating mode is retained and the ErrorNum output is assigned with the error number 51.

**Note**

You can access the variable parameters AutModOp and ManModOp from a normal SFC (in contrast to the instance of an SFC type). The SFC can thus change the operating mode without revoking the access rights of the operator (i.e. without setting ModLiOp = 1).

### Switchover from automatic mode to manual mode

When changing over from "automatic mode" to "manual mode", the last valid control settings (**M**anipiulated **V**alue MV)for the controller set in "automatic mode" remain valid until you change the control settings manually.

### Switchover from automatic mode to manual mode

The switchover from manual to automatic mode can take place with or without the internal setpoint tracking the process value. You specify this behavior on the SP_TrkPV I/O, which can also be operated from the faceplate in the parameter view (Option "SP = PV"). For the blocks PIDConL and PIDStepL you can also change the behavior for the switchover via the parameter Feature bit Disabling bumpless switchover to automatic mode for controllers (Page 183):

- **Switchover with internal setpoint tracking process variable**(SP_TrkPV = 1) means that in "Manual" mode the setpoint (SP) tracks the process value (PV) (bumpless switchover). After switching back to "Automatic" mode, the manipulated variable remains constant until the setpoint value (SP) is changed or the process value (PV) changes.
- **Switchover without internal setpoint tracking process variable** (SP_TrkPV = 0) means that the block immediately recalculates the value of the manipulated variable based on the setpoint and process value (PV) when the mode is changed. The Feature parameter is used to choose between the two variants:
  - **Switchover without P step** (standard setting, Feature bit = 0):
    During switchover, the I action of the controller is set in such a way that the switchover is carried out without a P step (virtually bumpless referring to the manipulated variable). A control deviation is only regulated via the I action.
  - **Switchover with P step** (Feature bit = 1):
    During switchover, the I action of the controller is set in such a way that the switchover is carried out with a P step (not bumpless referring to the manipulated variable). A control deviation is regulated via the P and the I action.

    **Note**

    **Points to note about switchovers with a P step change:**

    - The P action must be active for the setting "Switchover with P step" (PropSel = 1)
    - If the P action is in the feedback (PropFacSP = 0), the "Switchover with P step" setting has no effect.
    - If the switchover function with the internal setpoint tracking the process variable is active (SP_TrkPV = 1), the "Switchover with P step" setting has no effect.

### Reaction of signals when operating mode is changed

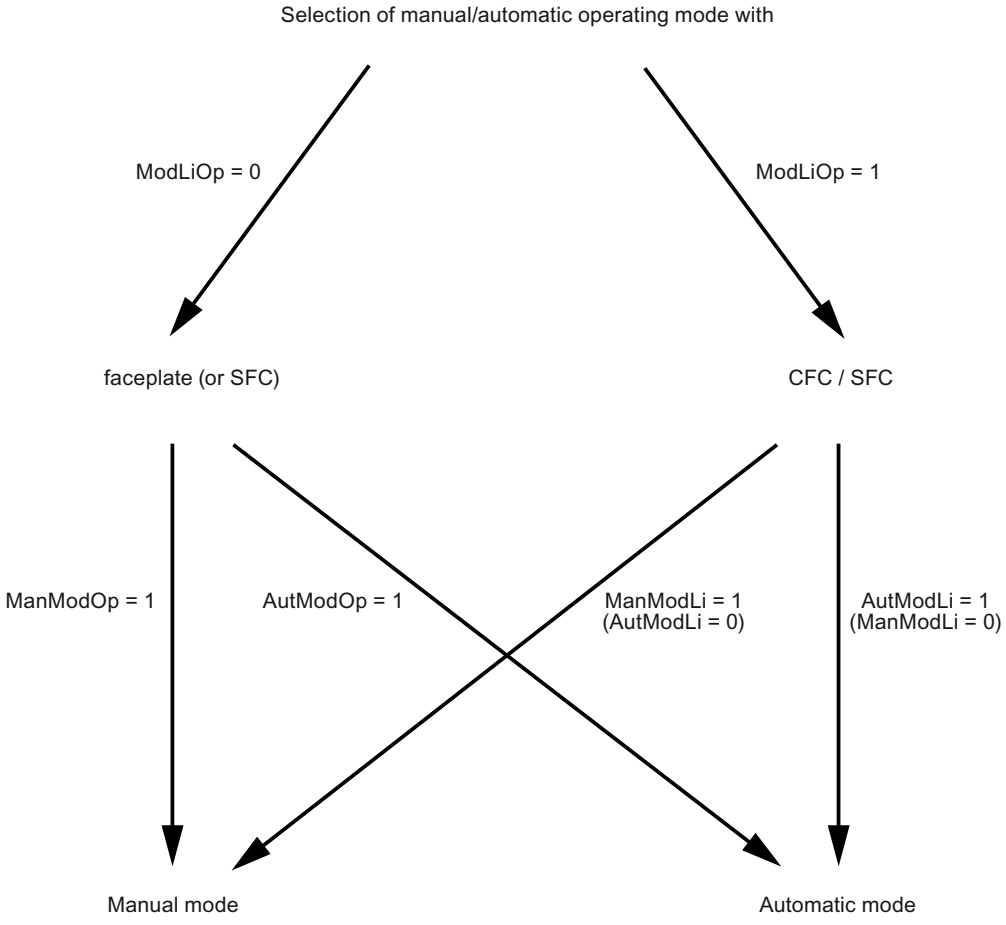
Using the `Feature` bit Resetting the commands for changing the mode (Page 172), you can choose whether the block automatically resets the signal for changing the operating mode.

### Switch on program mode

A few controller blocks allow you to operate in program mode. Refer to the relevant sections for the controller blocks to learn whether a control block allows program mode.

Also refer to the section Program mode for controllers (Page 85) for information on program mode.

## 2.1.2.5 Manual and automatic mode for motors, valves and dosers



### Manual and automatic mode for motors, valves and dosers

In "manual mode", the control settings for the device are made manually by the operator. The operator decides how to change the block's manipulated variable (output signal). The manipulated variable can be analog or binary in accordance with the function block.

In "automatic mode", the control settings for the device are made by the block algorithm via interconnected inputs or inputs controlled by SFC.

## Changing between operating modes

The switchover between "manual and automatic mode" takes place as shown in the following schematic:

**Note**

The two selections (manual and automatic) cannot both be set to "1" in switching mode.

**Switchover using faceplates** (`ModLiOp = 0`)**:** The switchover between operating modes is carried out in the standard view of the faceplate. In the function block, the parameters `ManModOp` for "manual mode" and `AutModOp` for "automatic mode" are used.

**Switchover per interconnection (CFC or SFC instance)** (`ModLiOp = 1`)**:** The switchover between the operating modes is carried out with an interconnection on the function block. The parameters `ManModLi` for "manual mode" and `AutModLi` for "automatic mode" are used in

pushbutton operation. In switching mode (requirement: `Feature.Bit4` = 1, see Setting switch or button mode (Page 177)) connection `AutModLi` is used exclusively.

**Note**

The `Feature.Bit4` is available only for the "large" blocks.

**Note**

You can access the variable parameters `AutModOp` and `ManModOp` from a normal SFC (in contrast to the instance of an SFC type). The SFC can thus change the operating mode without revoking the access rights of the operator (i.e. without setting `ModLiOp = 1`).

### Switchover from automatic mode to manual mode

When changing over from "automatic mode" to "manual mode", the last valid control settings for the block set in "automatic mode" remain valid until you change the control settings manually.

**Note**

For VlvAnL, the bumplessness of the switchover depends on the parameter `MV_TrkExt`.

### Switchover from manual to automatic mode

You can set the following options for changing over from "manual mode" to "automatic mode" using the `Feature` bit Bumpless switchover to automatic mode (Page 184). Refer to the I/O descriptions for the relevant block.

- A switchover from manual to automatic mode is possible at any time (standard setting, `Feature` bit = 0). The control settings for the automatic mode become effective immediately.
- Switchover from manual to automatic mode is only possible if the control settings for the manual and automatic modes match (Bumpless switchover), (`Feature` bit = 1). An error message is output if they do not match. In this case, you will need to adapt the control settings in "manual mode" to the control settings in "automatic mode".

  **Note**

  The "Bumpless switchover to automatic mode" function is supported only by "large" blocks.

### Reaction of signals when operating mode is changed

Using the `Feature` bit Resetting the commands for changing the mode (Page 172), you can choose whether the block automatically resets the signal for changing the operating mode.

### Resetting the commands for the control settings

With the `Feature` bit Enabling resetting of commands for the control settings (Page 172), you select how the block handles commands for the control settings (for example motor on) via the interconnected input parameters.

## 2.1.2.6 Program mode for controllers

### Program mode for controllers - interface for higher-level control functions

The interface for primary controller functions (external Advanced Control software package) provides primary controller functions, which run on an external PC as an OPC client, the option of using the control from the controller function block and specifying the setpoint or manipulated variable from a remote location. This procedure is called program mode.

You can use the `Feature` bit Enabling program mode (Page 170) to specify whether or not the controller block is intended for program mode.

Program mode requires an enable signal (input parameter `AdvCoEn = 1`) from a central control block. If this enable signal goes from 1 to 0, for example, due to errors in the OPC communication, the controller block switches to manual mode if it is in program mode with manipulated variable specification or to automatic mode if it is in program mode with setpoint specification.

You activate program mode in the standard view of the controller faceplate. In addition to switching from manual to automatic mode, you are also given the option of using program mode as the operating mode. You exit program mode by operator input or by switching back into manual or automatic mode.

A 0-1 edge transition of the interconnectable input parameter `AdvCoMstrOn` activates program mode depending on the conditions described below. You can use this to put an entire group of downstream controller blocks into program mode at the same time from a central control block. Both the input parameter `AdvCoOn` and the interconnectable input parameter `AdvCoMstrOn` can be used at the same time, since the parameter `AdvCoMstrOn` only reacts to edges of the binary signal.

Program mode is deactivated with a 1 - 0 edge transition.

**Note**

The output parameters `ManAct` or `AutAct` display the mode to which the controller changes with a 1 - 0 edge transition.

The output parameter `AdvCoRdy = 1` indicates if the PID controller is ready to switch to program mode. At a central control block, you can use an AND operation for all `AdvCoRdy` signals of the downstream controllers to enable central switchover.

The output parameter `AdvCoAct = 1` indicates of the block is in program mode.

**Selecting the type of program mode**

There are two types of program mode:

- Program mode driven by setpoint (in automatic mode only)
- Program mode driven by manipulated variable (in manual mode only, not for step controllers without position feedback)

**Program mode with setpoint**: If you set the input parameter `AdvCoModSP = 1`, the analog value provided by the OPC client (`AdvCoMV`) is used as an external setpoint for the controller. The controller and faceplate otherwise react as they do with automatic mode and an external setpoint. Refer to section Setpoint specification - internal/external (Page 136) for more about this.

Requirements for program mode with setpoint:

- `AdvCoModSP = 1`,
- `AdvCoEn = 1`,
- Controller has to be in automatic mode
- The setpoint can be set to internal as well as external.

**Program mode with manipulated variable**: If you set the input parameter `AdvCoModSP = 0`, the analog value provided by the OPC client (`AdvCoMV`) is used as an external manipulated variable for the controller. The algorithm of the PID controller is bypassed. The controller and faceplate otherwise react as they do with tracking (`MV_TrkOn = 1`). Refer to section Tracking and limiting a manipulated variable (Page 222) for more about this.

Requirements for program mode with manipulated variable:

- `AdvCoModSP = 0`,
- `AdvCoEn = 1`,
- Controller is preferably in manual mode, but it can also be in automatic mode.
- The setpoint can be set to internal as well as external.

**Note**

Program mode with manipulated variable is not available for step controllers without position feedback (available in PIDStepL, FmCont and FmTemp). `ErrorNum = 50` is output on the controller block and the controller cannot switch into program mode `(AdvCoAct=0)`.

### 2.1.2.7 Local mode

#### Areas of application for local mode

This operating mode is used for motors, valves and dosing units. The control settings are made directly or via a control station that is located "locally". In addition, you can set different control strategies with the parameter `LocalSetting`.

With `LocalSetting = 0`, you prevent a change to "local mode".

**Note**

**Differences between "Large" and "Small" blocks**

The operating mode described here is valid for "Large" blocks. For "Small" blocks, `LocalSetting` can be configured only on a limited basis. For more information, refer to the respective description for the operating modes of the blocks.

### Changing to local mode

Changing to local mode is only possible from the manual and automatic operating modes. The change to this mode is initiated by:

- An operation on the faceplate (input parameter `LocalOp = 1`, valid if `LocalSetting = 3` or `LocalSetting = 4` and `ModLiOp = 0`) or
- The interconnected input parameter (`LocalLi = 1`, valid if `LocalSetting = 1` or `LocalSetting = 2`).

### Exiting local mode

You leave local mode using:

- An operation on the faceplate (`LocalSetting = 3` or `LocalSetting = 4` and `ModLiOp = 0`) or
- the interconnected input parameter (`LocalSetting = 1` or `LocalSetting = 2`). In order to exit local mode via the interconnected input parameter, you can configure various reactions using a `Feature` bit Exiting local mode (Page 189).

### Operator input in "local mode" using a faceplate

You are not permitted to functionally operate the block in local mode. You can only use the faceplate to exit local mode if you have also activated "local mode" using the faceplate. The rules you specified for exiting "local mode" apply here.

### Input in "local mode" via interconnected inputs

In "local mode", the way the block functions is influenced via interconnected input parameters according to the settings of the `LocalSetting` parameter. You have the following options:

- `LocalSetting = 1` and `LocalSetting = 3`
  - The control settings for the block are adjusted (tracking) via an interconnected input parameter. The interconnected input parameter includes the control signal for the local operator station on the system.
  - The runtime monitoring of the block is effective in accordance with your configuration.
  - The interlocking functions of the block are activated in accordance with input parameter `BypProt = 0` or deactivated (`BypProt = 1`).

    **Note**

    The block VlvAnL does not support `LocalSetting` = 1/3.

- `LocalSetting = 2` and `LocalSetting = 4`
  - The control settings for the block are made based on internal adjustment of the feedback value.
  - Runtime monitoring of the block is active if more than one available feedback signals are set (discrepancy).
    An exception is VlvMotL:

    **Note**

    **VlvMotL**

    The motor and valve feedback signals are monitored if the motor feedback signlas exist and are connected with `FbkOpening` and `FbkClosing` (`Feature.Bit2` = 0). The motor feedback signals are only monitored in the end positions of the valve and in discrepancy. For example, if the valve is in end position `FbkOpen` =1 and the motor feedback `FbkOpening` =1 is pending, an error message is generated upon expiration of the monitoring time.

    **VlvAnL:** The auxiliary valve is controlled via internal tracking of the feedback signals `FbkAuxVCloseOut` and `FbkAuxVOpenOut`. The control of the main valve via the feedback value `Rbk` is not affected by this.

The texts for labeling the command buttons in the faceplates of the motor and valve blocks can now be assigned for each specific instance.
The configuration of the texts is performed with the "Text 1" property of the respective control inputs of the motor and valve blocks in the CFC.

If no instance-specific text is configured, the previous default texts are used and displayed in the faceplate.

The following table shows the assignment of the command buttons to the corresponding block input:

The interlock functions of the block are deactivated.

## Overview of behavior in local mode

| **LocalSetting=** | **0** | **1** | **2** | **3** | **4** | **5 (VlvS only)** |
|---|---|---|---|---|---|---|
| Switch on operating mode | Cannot be set | CFC/SFC | CFC/SFC | Faceplate | Faceplate | CFC |

## 2.1.3 Monitoring functions

### 2.1.3.1 Monitoring functions in the Advanced Process Library

#### Monitoring functions in the Advanced Process Library

This and the following chapters encompass the standard monitoring functions in the Advanced Process Library. The monitoring functions include:

- Limit value monitoring
- Feedback monitoring
- Motor protection

Some of the configured time values (e.g. `MonTiStatic`, `MonTiDynamic`) are limited at the low end to the sampling time by the block algorithm and written back to the block input. "Reset Program" (after a "Download Entire Program" for example) writes the parameter values changed in this way to the offline data storage system.

For further and detailed information, refer to the following chapters. For the block-specific monitoring functions, also refer to the description of the particular block.

### 2.1.3.2 Group display for limit monitoring, CSF and ExtMsgx

#### Group display for limit monitoring, CSF and ExtMsgx

The SumMsgAct output parameter assembles the following signals of a block and makes them available to you:

- Limit monitoring of the process value
- Limit monitoring of the count value
- Limit monitoring of the feedback
- Limit monitoring of setpoint difference, manipulated variable difference and error signal
- External control system fault (CSF)
- Freely selectable messages ExtMsg1..4

**Note**

The signal status of the individual signals is not taken into consideration for forming the group error.

### 2.1.3.3 Limit monitoring

#### Limit monitoring of the process value

You can monitor the process value to the following high and low alarm, warning and tolerance limits:

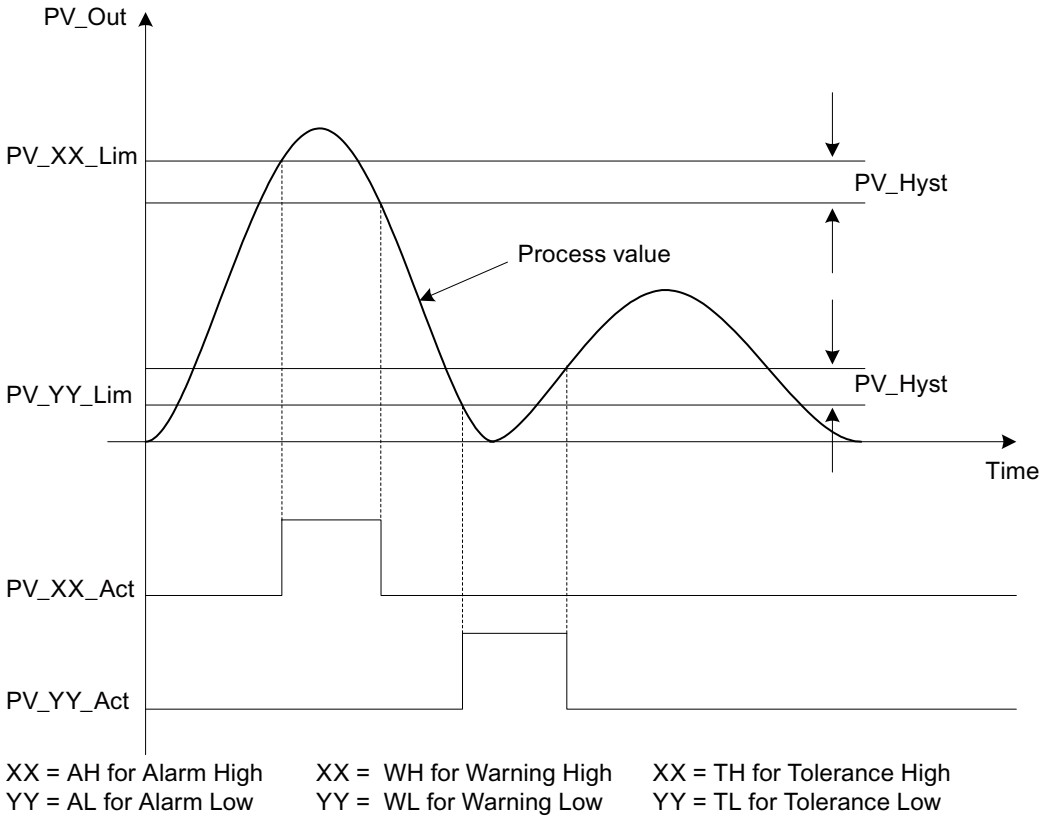
- `PV_AH_Lim`: Limit for high alarm
- `PV_AL_Lim`: Limit for low alarm
- `PV_WH_Lim`: Limit for high warning
- `PV_WL_Lim`: Limit for low warning
- `PV_TH_Lim`: Limit for the high tolerance
- `PV_TL_Lim`: Limit for the low tolerance

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

**Note**

**Special note for "Small" blocks**



"Small" blocks provide only the monitoring for alarms and warnings.

#### Result of the limit monitoring

The result of limit monitoring is made available at the interconnectable output parameters:

- `PV_AH_Act = 1`: Limit for high alarm reached or exceeded
- `PV_AL_Act = 1`: Limit for low alarm reached or undershot
- `PV_WH_Act = 1`: Limit for high warning reached or exceeded
- `PV_WL_Act = 1`: Limit for low warning reached or undershot
- `PV_TH_Act = 1`: Limit for high tolerance reached or exceeded
- `PV_TL_Act = 1`: Limit for low tolerance reached or undershot

made available (see figure). The `SumMsgAct = 1` output parameter is also set when at least one limit value is reached or violated.

You can use `Feature.Bit29` Signaling limit violation (Page 181) to determine whether the output parameter triggers limit monitoring with the value "0" or "1".

You can use `Feature.Bit28` Disabling operating points (Page 156) to disable limit monitoring when message suppression is enabled (`MsgLock = 1`).

### Activating limit monitoring

Monitoring is always enabled using the input parameters:

- `PV_AH_En = 1`: Monitoring of the high alarm limits
- `PV_AL_En = 1`: Monitoring of the low alarm limits
- `PV_WH_En = 1`: Monitoring of the high warning limits
- `PV_WL_En = 1`: Monitoring of the low warning limits
- `PV_TH_En = 1`: Monitoring of the high tolerance limits
- `PV_TL_En = 1`: Monitoring of the low tolerance limits

**Predefinition:** When the block is installed, monitoring of the tolerance limits is disabled, meaning that the parameters are configured with 0. To activate monitoring, assign 1 to these parameters.

All other monitoring functions are enabled.

### Message suppression

| | |
|---|---|
|  | Symbol for message suppression |

The corresponding message is suppressed using the parameters:

- `PV_AH_MsgEn = 0`: Alarm (high) messages are suppressed
- `PV_AL_MsgEn = 0`: Alarm (low) messages are suppressed
- `PV_WH_MsgEn = 0`: Warning (high) messages are suppressed
- `PV_WL_MsgEn = 0`: Warning (low) messages are suppressed
- `PV_TH_MsgEn = 0`: Tolerance (high) messages are suppressed
- `PV_TL_MsgEn = 0`: Tolerance (low) messages are suppressed

The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

### Hysteresis

You can specify a hysteresis (`PV_Hyst`) for the limits, for example, to suppress signal flutter. Refer to the Limit monitoring with hysteresis (Page 104) chapter for more on this.

### Alarm delays

You can set alarm delays for incoming and outgoing alarms, warnings and tolerances. Refer to the Area of application of the alarm delays (Page 225) chapter for more on this.

### Operating in the faceplate

You can also change the limits and the hysteresis using the faceplate. Refer to the Limit operation and display in the faceplate (Page 355) chapter for more on this.

### See also

Two time values per limit pair (Page 227)

Two time values for each individual limit (Page 228)

User-configured message classes (Page 45)

### Limit monitoring of the count value

You can monitor the count value to the following high and low alarm, warning and tolerance limits:

- `OutAH_Lim`: Limit for high alarm
- `OutAL_Lim`: Limit for low alarm
- `OutWH_Lim`: Limit for high warning
- `OutWL_Lim`: Limit for low warning
- `OutTH_Lim`: Limit for the high tolerance
- `OutTL_Lim`: Limit for the low tolerance

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

**Note**

**Monitoring the limits**

The limits monitored depend on the direction of counting:

- In Mode 1 (summing up or integrating), the high limits are monitored:
  - OutAH_Lim
  - OutWH_Lim
  - OutTH_Lim
- In Mode 2 (summing down or integrating), the low limits are monitored:
  - OutAL_Lim
  - OutWL_Lim
  - OutTL_Lim

### Example for limit monitoring with a counter

Monitoring of the high limit is performed only if the counter is running in "up" direction.

If you count "up" but with negative values, for example, from 100 down, you need to adjust the high limit accordingly (for example, the high limit could be -15).

This behavior applies to the blocks CountScL, CountOh and TotalL.

### Result of the limit monitoring

The result of limit monitoring is made available at the interconnectable output parameters:

- `OutAH_Act = 1`: Limit for high alarm reached or exceeded
- `OutAL_Act = 1`: Limit for low alarm reached or undershot
- `OutWH_Act = 1`: Limit for high warning reached or exceeded
- `OutWL_Act = 1`: Limit for low warning reached or undershot

- `OutTH_Act = 1`: Limit for high tolerance reached or exceeded
- `OutTL_Act = 1`: Limit for low tolerance reached or undershot

made available (see figure). The `SumMsgAct = 1` output parameter is also set when at least one limit value is reached or violated.

You can use `Feature.Bit29` Signaling limit violation (Page 181) to determine whether the output parameter triggers limit monitoring with the value "0" or "1".

You can use `Feature.Bit28` Disabling operating points (Page 156) to disable limit monitoring when message suppression is enabled (`MsgLock = 1`).

### Activating limit monitoring

Monitoring is always enabled using the input parameters:

- `OutAH_En = 1`: Monitoring of the high alarm limits
- `OutAL_En = 1`: Monitoring of the low alarm limits
- `OutWH_En = 1`: Monitoring of the high warning limits
- `OutWL_En = 1`: Monitoring of the low warning limits
- `OutTH_En = 1`: Monitoring of the high tolerance limits
- `OutTL_En = 1`: Monitoring of the low tolerance limits

**Predefinition:** When the block is installed, monitoring of the tolerance limits is disabled, meaning that the parameters are configured with 0. To activate monitoring, assign 1 to these parameters.

All other monitoring functions are enabled.

### Message suppression

The corresponding message is suppressed using the parameters:

- `OutAH_MsgEn = 0`: Alarm (high) messages are suppressed
- `OutAL_MsgEn = 0`: Alarm (low) messages are suppressed
- `OutWH_MsgEn = 0`: Warning (high) messages are suppressed
- `OutWL_MsgEn = 0`: Warning (low) messages are suppressed
- `OutTH_MsgEn = 0`: Tolerance (high) messages are suppressed
- `OutTL_MsgEn = 0`: Tolerance (low) messages are suppressed

The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

### Operating in the faceplate

You can also change the limits using the faceplate. Refer to the Limit operation and display in the faceplate (Page 355) chapter for more on this.

### See also

User-configured message classes (Page 45)

### Limit monitoring of an additional analog value

### Limit monitoring of an additional analog value

Limit monitoring is performed for an additional analog value on the basis of the AV block, see Description of AV (Page 705) chapter.

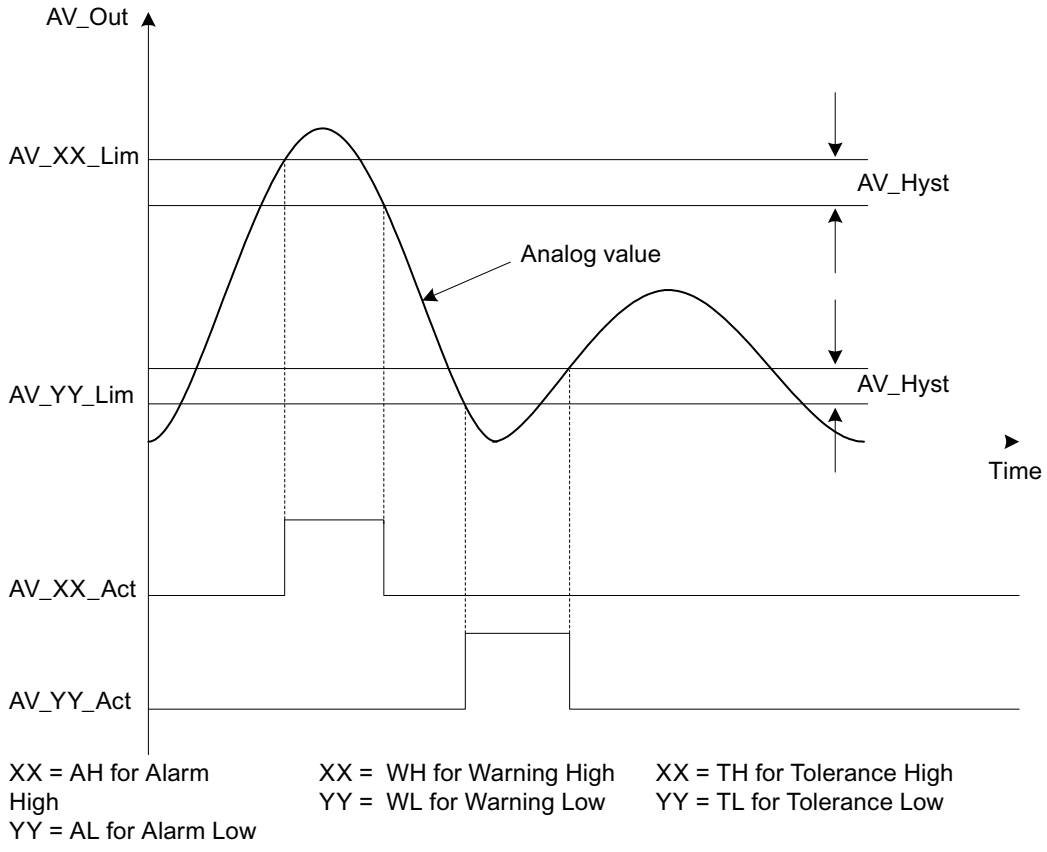
You can monitor an additional analog value to the following high and low limits for alarms warnings and tolerances at the technologic block:

- `AV_AH_Lim`: Limit for high alarm
- `AV_AL_Lim`: Limit for low alarm
- `AV_WH_Lim`: Limit for high warning
- `AV_WL_Lim`: Limit for low warning
- `AV_TH_Lim`: Limit for the high tolerance
- `AV_TL_Lim`: Limit for the low tolerance

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

**Note**



The AV block and the technologic block must be built into the same cyclic interrupt OB.

### Result of the limit monitoring

The result of limit monitoring is made available at the interconnectable output parameters of the AV block:

- `AV_AH_Act = 1:` Limit for high alarm reached or exceeded
- `AV_AL_Act = 1:` Limit for low alarm reached or undershot
- `AV_WH_Act = 1:` Limit for high warning reached or exceeded
- `AV_WL_Act = 1:` Limit for low warning reached or undershot
- `AV_TH_Act = 1:` Limit for high tolerance reached or exceeded
- `AV_TL_Act = 1:` Limit for low tolerance reached or undershot

made available (see figure).

You can use `Feature.Bit29` Signaling limit violation (Page 181) to determine whether the output parameter triggers limit monitoring with the value "0" or "1".

You can use `Feature.Bit28` Disabling operating points (Page 156) to disable limit monitoring when message suppression is enabled (`MsgLock = 1`).

### Activating limit monitoring

Monitoring is always enabled using the input parameters of the AV block:

- `AV_AH_En = 1`: Monitoring of the high alarm limits
- `AV_AL_En = 1`: Monitoring of the low alarm limits
- `AV_WH_En = 1`: Monitoring of the high warning limits
- `AV_WL_En = 1`: Monitoring of the low warning limits
- `AV_TH_En = 1`: Monitoring of the high tolerance limits
- `AV_TL_En = 1`: Monitoring of the low tolerance limits

**Predefinition:** When the block is installed, monitoring of the tolerance limits is disabled, meaning that the parameters are configured with 0. To activate monitoring, assign 1 to these parameters.

All other monitoring functions are enabled.

### Message suppression

The corresponding message is suppressed at the block AV using the parameters:

- `AV_AH_MsgEn = 0`: Alarm (high) messages are suppressed
- `AV_AL_MsgEn = 0`: Alarm (low) messages are suppressed
- `AV_WH_MsgEn = 0`: Warning (high) messages are suppressed
- `AV_WL_MsgEn = 0`: Warning (low) messages are suppressed
- `AV_TH_MsgEn = 0`: Tolerance (high) messages are suppressed
- `AV_TL_MsgEn = 0`: Tolerance (low) messages are suppressed

The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

### Hysteresis

You can specify a hysteresis (`AV_Hyst`) at the technologic block for the limits, for example, to suppress signal flutter. Refer to the Limit monitoring with hysteresis (Page 104) chapter for more on this.

### Alarm delays

You can set alarm delays for incoming and outgoing alarms, warnings and tolerances. Refer to the Area of application of the alarm delays (Page 225) chapter for more on this.

### Operating in the faceplate

You can also change the limits and the hysteresis using the faceplate. Refer to the Limit operation and display in the faceplate (Page 355) chapter for more on this.

### See also

User-configured message classes (Page 45)

## Limit monitoring of the feedback

### Limit monitoring of position feedback

The position feedback of the manipulated variable can be monitored for the following high and low warning limits:

- `RbkWH_Lim`: Limit for high warning
- `RbkWL_Lim`: Limit for low warning

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

### Result of limit monitoring of the position feedback

The result of limit monitoring of the position feedback is made available at the interconnectable output parameters:

- `RbkWH_Act = 1`: High limit reached or exceeded
- `RbkWL_Act = 1`: Low limit reached or undershot

made available. The `SumMsgAct = 1` output parameter is also set when at least one limit value is reached or violated.

When the limits are reached or exceeded, messages that can be suppressed are output.

You can use `Feature.Bit29` Signaling limit violation (Page 181) to determine whether the output parameter triggers limit monitoring with the value "0" or "1".

You can use `Feature.Bit28` Disabling operating points (Page 156) to disable limit monitoring when message suppression is enabled (`MsgLock = 1`).

### Activating limit monitoring

Monitoring is always enabled using the input parameters:

- `RbkWH_En = 0`: Monitoring of the high warning limit is disabled
- `RbkWL_En = 0`: Monitoring of the low warning limit is disabled

**Predefinition:** When the block is installed, monitoring is enabled (default is 1).

### Message suppression

The corresponding message is suppressed using the parameters:

- `RbkWH_MsgEn = 0`: Messages from the high limit monitoring are suppressed
- `RbkWL_MsgEn = 0`: Messages from the low limit monitoring are suppressed

The output of messages is not suppressed when the block is installed (for example, `RbkWH_MsgEn = 1`). Messages can only be output if limit monitoring of the position feedback has been enabled.

### Hysteresis

You can specify a hysteresis (`RbkHyst`) for the limits, for example, to suppress signal flutter. Refer also to chapter Limit monitoring with hysteresis (Page 104) for more on this.

### Alarm delays (only for the PIDConR and MotSpdCL blocks)

You can set alarm delays for incoming and outgoing warnings. Refer to the Area of application of the alarm delays (Page 225) chapter for more on this.

### Operating in the faceplate

You can also change the limits and the hysteresis using the faceplate. Refer to the Limit operation and display in the faceplate (Page 355) chapter for more on this.

### See also

User-configured message classes (Page 45)

### Limit monitoring of setpoint, manipulated variable and control deviation

### Limit monitoring of setpoint, manipulated variable and error signal

The setpoint, manipulated variable and error signal can be monitored for the following high and low alarm limits:

- `ER_AH_Lim`: Limit for high alarm
- `ER_AL_Lim`: Limit for low alarm

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

### Result of the limit monitoring

The result of limit monitoring is made available at the interconnectable output parameters:

- `ER_AH_Act =1`: High limit violated (reached or exceeded)
- `ER_AL_Act =1`: Low limit (reached or undershot)

made available. The `SumMsgAct = 1` output parameter is also set when at least one limit value is reached or violated.

When the limits are reached or exceeded, messages that can be suppressed are output.

You can use `Feature.Bit29` Signaling limit violation (Page 181) to determine whether the output parameter triggers limit monitoring with the value "0" or "1".

You can use `Feature.Bit28` Disabling operating points (Page 156) to disable limit monitoring when message suppression is enabled (`MsgLock = 1`).

### Activating limit monitoring

Alarm monitoring is enabled using the input parameters:

- `ER_AH_En = 1`: Monitoring of the high alarm limit
- `ER_AL_En = 1`: Monitoring of the low alarm limit

**Predefinition:** When the block is installed, monitoring is disabled.

### Message suppression

The corresponding message is suppressed using the parameters:

- `ER_AH_MsgEn = 0`: Messages from the high limit monitoring are suppressed
- `ER_AL_MsgEn = 0`: Messages from the low limit monitoring are suppressed

The output of messages is not suppressed when the block is installed (for example, `ER_AH_MsgEn = 1`). Messages can only be output if limit monitoring has been enabled.

**Note**

With the MotSpdCL block, messages are only output if you have enabled `Feature.Bit5` (Alarm setpoint difference (Page 182)).

### Hysteresis

You can specify a hysteresis (`ER_Hyst`) for these limits, for example, in order to suppress signal flutter . Refer also to chapter Limit monitoring with hysteresis (Page 104) for more on this.

### Alarm delays

You can set alarm delays for incoming and outgoing alarms. Refer to the Area of application of the alarm delays (Page 225) chapter for more on this.

### Operating in the faceplate

You can also influence the limits and the hysteresis by means of the faceplate. Refer to the Limit operation and display in the faceplate (Page 355) chapter for more on this.

### See also

User-configured message classes (Page 45)

### Limit monitoring with hysteresis

### Limit monitoring with hysteresis

You can additionally define a hysteresis for all limit monitoring functions (parameter `xxx_Hyst`, xxx can, for example, be `PV` for the process value). You use the hysteresis, for example, to suppress signal flutter.

Enter the hysteresis as a physical variable at the block and faceplate (if you have the appropriate operator control permissions (WinCC)).

For the WinCC operator control permissions, refer to the help on WinCC.

## 2.1.3.4 Feedbacks

### Monitoring the feedbacks

### Feedback monitoring

You can use the following monitoring functions:

- Monitoring the start-up and stop characteristics for motors or the runtime of valves
- Monitoring the operation of motors or the maintenance of the position of valves
- Disabling feedback

This monitoring function is enabled via the `Monitor = 1` input.

Static and dynamic errors are reset by disabling the monitoring (`Monitor = 0`). If you reactivate monitoring during the plant runtime, only dynamic monitoring (`MonTiDynamic`) will be performed.

**Note**

In Manual mode with Reset functionality deactivated (`Feature.Bit31` = 0), you can control all the valves (including the motor valve but not the motors) despite the setting `MonSafePos` = 1 and with "Monitoring error" without reaching the neutral position.

### Monitoring the start-up and stop characteristics for motors or the runtime of valves

Monitoring of the startup characteristics is implemented using the parameter `MonTiDynamic`. The monitoring time specifies the period within which the feedback value, for example, `FbkStart` with motors, must be available in response to a control signal. If this is not the case, the text "Control error" is displayed in the standard view of the faceplate. An error message is generated at the same time. The block then goes to its neutral position. In the case of motors, this is always the stop state. With other blocks, this is an neutral position you have specified (`SafePos` parameter). The block signals this at the corresponding output parameter of the error message with 1, for example, with `MonDynErr = 1` for motors.

With the motors MotL, MotRevL, MotSpdL, MotSpdCL and the motor valve VlvMotL, the `Feature.Bit13` can be set to use a separate monitoring time `MonTiDyStop` for the stop behavior. The monitoring time for the stop behavior is displayed at the `MonDynStopErr` output.

Parameters are set in seconds.

### Monitoring the operation of motors or the maintenance of the position of valves

**The following applies for "Large" blocks:** Monitoring of the operation or the maintenance of the position of valves is implemented using the parameter `MonTiStatic`. The monitoring time specifies the period in which the feedback value can change its value briefly without an error message being output. An example would be a running motor with the feedback via the input parameter `FbkStart`. This parameter should be static in accordance with the control function. However, its value can change within the monitoring time. If the change in the `FbkStart` parameter takes longer than the monitoring time, the text "End position error" is displayed in the standard view of the faceplate. An error message is generated at the same time. The block then goes to its neutral position. In the case of motors, this is always the stop state. With other blocks, this is an neutral position you have specified (`SafePos` parameter). The block signals this at the corresponding output parameter of the error message with 1, for example, with `MonStaErr = 1` for motors.

Parameters are set in seconds.

**Note**

Please note that `MonTiDynamic ≥ MonTiStatic` and `MonTiDynamic ≥ SampleTime` have to be configured. If something is set outside these limits, the block always returns the respective limit at the input.

If `SampleTime` changes, `MonTiDynamic` may be tracked to the new value for `SampleTime`. `MonTiStatic` is tracked if `MonTiDynamic < MonTiStatic` changes. With `MonTiStatic = 0`, each feedback change without change of the control immediately results in a runtime error.

After a static monitoring error (e.g.: `MonStaErr` =1), an impulse output control is set to drive the motor or the valve in rest position even if the block is already in rest position.

When Monitoring Error occurs, `STOP` output pin value remains 0 until the error state got rectified and reset.

When `Trip`, `FaultExt`, `CSF`(with `Feature.Bit18` = 1) becomes active and error occurs, `STOP` outpin pin is set to 1, even at the error state and before reset.

**The following applies for "Small" blocks:** These blocks operate like "Large" blocks; however, the monitoring time is set to 0 within the block and cannot be changed. Any change is displayed immediately at the output parameter `MonStaErr` with 1.

### Disabling feedback for valves

You can also disable feedback completely. Please refer to section Disabling feedback for valves (Page 106) for further information.

**Note**

This function is only supported by "Large" blocks.

### Resetting the block in case of interlocks or errors

In the event of an interlock or error, the block has to be reset. Refer to the Resetting the block in case of interlocks or errors (Page 47) section for more on this.

### Disabling feedback for valves

### Disabling monitoring of feedback for valves

This function is only supported by "Large" blocks.

If you operate a block without feedback, use the parameter `NoFbkOpen = 1` bzw. `NoFbkClose = 1`. This means, for example, that you do not have any feedbacks for the opened state of the valve. Monitoring is thus disabled for this feedback. The feedback at the block is adjusted according to the control signal.

### Disabling monitoring of feedback for valves and motors

This function is only supported by "Large" blocks.

If you operate a block without feedback, use the parameter `NoFbkXxx` = 1. This means, for example, that you do not have any feedbacks for the opened state of the valve or running/ stopped state of the motor.

Monitoring is thus disabled for this feedback. The feedback at the block is adjusted according to the control signal and the other available feedbacks.

## 2.1.3.5 Motor protection function

### Motor protection function

The motor protection function is used to turn off the motor if there is thermal overload (`Trip = 0`, interconnectable input parameter).

If the motor is turned off by the motor protection function, a message (process control message) is generated. This is indicated in the faceplate by the "Motor protection" text. You can influence the reset using a various `Feature` bits. Refer to the Resetting the block in case of interlocks or errors (Page 47) section for more on this.

You can find more information in Section Influence of the signal status on the interlock (Page 112).

## 2.1.4 Interlocking functions

### 2.1.4.1 Interlocks

#### Interlocks at blocks

A maximum of three types of interlock can be used depending on the block. Three separate inputs named `Permit`, `Intlock` and `Protect` are available for these functions.

- **Activation enable ("Permission"):** The activation enable makes it possible to switch the motor in the direction which is enabled. The activation disable is displayed with a padlock in the standard view. The motor cannot switch in the direction which is disabled.
- **Interlock without reset ("Interlock"):** An active interlock condition puts the block to the neutral position (`Intlock` = 0). After the interlock condition has gone, the currently active control function becomes active again in automatic or local mode. In manual mode, the faceplate can be operated again after the interlock condition has gone.
- **Interlock with reset ("Protection"):** An active interlock condition puts the block to the neutral position (input `Protect` = 0). Once the interlock condition is cleared, a reset is necessary. Refer to the Resetting the block in case of interlocks or errors (Page 47)section for more information.
- **Permission for safe position ("Permit neutral pos." or "Permission stop"):**
  - The activation enable ("PermitSafePos = 0") prevents stop command to the motor.
  - The activation enable ("PermitSafePos = 0") prevents the control in safe position direction for VlvL & VlvAnL.
  - The activation enable ("PermitSafePos = 0") & Feature2.Bit16 = 0 prevents the control in safe position direction for VlvMotL & VlvPosL.
  - The activation enable ("PermitSafePos = 0") & Feature2.Bit16 = 1 prevents the stop command for VlvMotL & VlvPosL.

**Note**

**Interlocks for "small" blocks and controller blocks**

Ensure that "small" blocks and controller blocks PIDConL and PIDConR have only the `Intlock` parameter. The other two interlocks are not included in these block variants.

**Permission stop for VlvPosL**

Permission stop does not restrict manipulated variable when position control is active.

**Permission stop for MotRevL & MotSpdCL**

Permission stop does not restrict the direct changeover between forward and revrese direction (`Feature.Bit7` = 1)

**Interlock dependent on direction, position or speed**

The blocks MotRevL, MotSpdL, VlvMotL, VlvPosL, VlvAnL and MotSpdCL with `Feature2.Bit16` = 1 (see section Separate interlock for each direction, position, or speed (Page 180)) have inputs for interlock functionality with direction:

| **MotRevL, MotSpdCL (`Feature2.Bit16` = 1)** | **MotSpdL (`Feature2.Bit16` = 1)** | **VlvMotL, VlvPosL, VlvAnL (`Feature2.Bit16` = 1)** |
|---|---|---|
| `Permit`: Enable forward | `Permit`: Enable speed1 | `Permit`: Enable open |
| `PermRev`: Enable reverse | `PermSp2`: Enable speed2 | `PermCls`: Enable close |
| `Intlock`: Interlock forward | `Intlock`: Interlock speed1 | `Intlock`: Interlock open |
| `IntlRev`: Interlock reverse | `IntlSp2`: Interlock speed2 | `IntlCls`: Interlock close |
| `Protect`: Protection forward | `Protect`: Protection speed1 | `Protect`: Protection open |
| `ProtRev`: Protection reverse | `ProtSp2`: Protection speed2 | `ProtCls`: Protection close |

**Interlock function dependent on direction (`Feature2.Bit16` = 1) for MotRevL:**

- **Activation enable forward/reverse:** The activation enable makes it possible to switch the motor in the direction which is enabled. The activation disable is displayed with a padlock in standard view. The motor cannot switch in the direction which is disabled.
- **Interlock forward/reverse without reset:** An active interlock condition only puts the block in the stop position, when the motor is running in direction which is interlocked. Once interlock condition is cleared, the currently active control function becomes active again in automatic or local mode. In manual mode, the faceplate can be operated again in this direction.
- **Interlock forward/reverse with reset:** An active interlock condition only puts the block in the stop position, when the motor is running in the direction which is interlocked. Once the interlock condition is cleared, a reset is necessary. Interlock forward and reverse can be reset separately. Refer to the Resetting the block in case of interlocks or errors (Page 47) section for more information.

**Interlock function dependent on speed (`Feature2.Bit16` = 1) for MotSpdL:**

- **Activation enable speed1/speed2:** The activation enable makes it possible to switch the motor in the speed which is enabled. The activation disable is displayed with a padlock in standard view. The motor cannot switch in the speed which is disabled.
- **Interlock speed1/speed2 without reset**: An active interlock condition only puts the block in the stop position, when the motor is running with the peed which is interlocked. Once interlock condition is cleared, the currently active control function becomes active again in automatic or local mode. In manual mode, the faceplate can be operated again in this speed.
- **Interlock speed1/speed2 with reset:** An active interlock condition only puts the block in the stop position, when the motor is running with the speed which is interlocked. Once the interlock condition is cleared, a reset is necessary. Interlock speed1 and speed2 can be reset separately. Refer to the Resetting the block in case of interlocks or errors (Page 47) section for more information.

**Interlock function dependent on position (`Feature2.Bit16` = 1) for VlvMotL, VlvPosL, VlvAnL:**

- **Activation enable open/close:** The activation enable makes it possible to move the valve in the direction of the position which is enabled. The activation disable is displayed with a padlock in standard view. The valve cannot move in the direction of the position which is disabled.
- **Interlock open/close without reset:** An active interlock condition only puts the block in the neutral position, when the valve is moving to a position which is interlocked. If the interlocked position is the neutral position open or close, valve goes only to stop position. Once interlock condition is cleared, the currently active control function becomes active again in automatic or local mode. In manual mode, the faceplate can be operated again from this position.
- **Interlock open/close with reset:** An active interlock condition only puts the block in the neutral position, when the valve is moving to a position which is interlocked. If the interlocked position is the neutral position open or close, valve goes only to stop position. Once the interlock condition is cleared, a reset is necessary. Interlock open and close can be reset separately. Refer to the Resetting the block in case of interlocks or errors (Page 47) section for more information.

## Display of the interlock in the faceplate and in the block icon

The interlock state is visualized in the faceplate and in the block icon by a status display (padlock) as follows:

- Open padlock: No interlock pending
- Closed padlock: One or more interlocks are pending
- No padlock: Individual interlocks are not active
  - `Perm_En` = 0 or `Permit.ST` = 16#FF:
    The input parameter `Permit` has no effect, the button in the faceplate is invisible.
  - `PermRevEn`/`PermClsEn`/`PermSp2En` = 0 or `PermRev.ST`/`PermCls.ST`/`PermSp2.ST` = 16#FF or `Feature2.Bit16` = 0:
    The input parameter `PermRev`/`PermCls`/`PermSp2` has no effect, the button in the faceplate is invisible.
  - `Prot_En` = 0 or `Protect.ST` = 16#FF:
    The input parameter `Protect` has no effect, the button in the faceplate is invisible.
  - `ProtRevEn`/`ProtClsEn`/`ProtSp2En` = 0 or `ProtRev.ST`/`ProtCls.ST`/`ProtSp2.ST` = 16#FF or `Feature2.Bit16` = 0:
    The input parameter `ProtRev`/`ProtCls` has no effect, the button in the faceplate is invisible.
  - `Intl_En` = 0 or `Intlock.ST` = 16#FF:
    The input parameter `Intlock` has no effect, the button in the faceplate is invisible
  - `IntlRevEn`/`IntlClsEn`/`IntlSp2En` = 0 or `IntlRev.ST`/`IntlCls.ST`/`IntlSp2.ST` = 16#FF or `Feature2.Bit16` = 0:
    The input parameter has no effect, the button in the faceplate is invisible.
  - PermSf_En = 0 or PermitSafePos.ST = 16#FF or for VlvAnL when SafePos = 2 :
    The input parameter PermitSafePos has no effect, the button in the faceplate is invisible.

The block icon indicates the prioritized group status according to the active operating state. See also the section Forming the group status for interlock information (Page 113) for more on this.

The faceplate visualizes the state of each interlock type separately.

The padlock is not shown in the block icon if all parameters for enabling the button are set to 0 or all parameters have the signal status `16#FF`.

**Note**

Motors and values are not put into the neutral position if one of the interlock inputs is active (for example `Intlock = 0`) and the corresponding signal status is `16#FF` (`Intlock.ST = 16#FF`).

### Influence of the signal status on the interlock

See also the section Influence of the signal status on the interlock (Page 112) for more on this.

### Outputting "Interlock active" using the `LockAct` parameter

If an interlock is set at the parameter:

- `Intlock`
- `Permit`
- `Protect`
- `IntlRev`/`IntlCls`/`IntlSp2` (only for blocks with directional interlock and `Feature2.Bit16` = 1)
- `PermRev`/`PermCls`/`PermSp2` (only for blocks with directional interlock and `Feature2.Bit16` = 1)
- `ProtRev`/`ProtCls`/`ProtSp2` (only for blocks with directional interlock and `Feature2.Bit16` = 1)
- `Trip` (only for motors and motor valves),
- PermitSafePos

the `LockAct` parameter is set automatically to active (=1). The parameter `LockAct` is set to 0 if the interlock is no longer present and those interlocks which require acknowledgement have been acknowledged.

You can bypass the interlock using `BypProt = 1` in local mode and during simulation. This also makes `LockAct = 0`.

**Note**

The `LockAct` parameter is not set despite a pending interlock, if a value in the block is forced. See also the section Forcing operating modes (Page 45) for more on this.

### Messaging

No messages are assigned to the interlock types. However, if you want to have a message when an interlock condition is violated, you can use the freely interconnectable input parameters to generate the messages. See also the section Generating instance-specific messages (Page 230) for more on this.

### See also

Neutral position for motors, valves and controllers (Page 54)

## 2.1.4.2 Disabling interlocks

### Disabling individual interlocks

You can disable the block interlocks that are implemented using the input parameters `Intlock`, `Protect`, `Permit`, `IntlRev/Cls/Sp2`, `ProtRev/Cls/Sp2`,and `PermRev/Cls/Sp2`.

If you want to disable the block interlock, you have to set the following parameters:

- `Perm_En = 0` or `Permit.ST = 16#FF`:
  The input parameter `Permit` has no effect.
- `PermRevEn/PermClsEn/PermSp2En = 0` or `PermRev.ST/PermCls.ST/PermSp2.ST = 16#FF` or `Feature2.Bit16` = 0:
  The input parameter `PermRev/PermCls/PermSp2` has no effect.
- `Prot_En = 0` or `Protect.ST = 16#FF`:
  The input parameter `Protect` has no effect.
- `ProtRevEn/ProtClsEn/ProtSp2En = 0` or `ProtRev.ST/ProtCls.ST/ProtSp2.ST = 16#FF` or `Feature2.Bit16` = 0:
  The input parameter `ProtRev/ProtCls/ProtSp2` has no effect.
- `Intl_En = 0` or `Intlock.ST = 16#FF`:
  The input parameter `Intlock` has no effect.
- `IntlRevEn/IntlClsEn/IntlSp2En = 0` or `IntlRev.ST/IntlCls.ST/IntlSp2.ST = 16#FF` or `Feature2.Bit16` = 0:
  The input parameter `IntlRev/IntlCls/IntlSp2` has no effect.
- PermSf_En = 0 or PermitSafePos.ST = 16#FF or for VlvAnL when SafePos = 2 :
  The input parameter PermitSafePos has no effect.

**Note**

**"Small" blocks have only the `Intlock` parameter**

With "Small" blocks, you can only assign parameters to "Interlock without reset" (input parameter `Intlock` or for the deactivation of the interlock for the input parameter `Intl_En`).

### Disabling of all the interlocks (only for local operation and for simulation)

You can use the input parameter `BypProt = 1` to disable all the interlocks, irrespective of the parameter assignment of the individual interlock, in local mode as well as for the "simulation" function.

## 2.1.4.3 Influence of the signal status on the interlock

### Influence of the signal status on the interlock

There are three ways in which the signal status affects the interlocks:

- Simulation signal status
- Signal status "Bad, device related" (value 16#00) or "Bad, process related" (value 16#28)
- Signal status ≠ "Simulation" and "Bad, device related"

### "Simulation" signal status

An interlock signal is displayed differently depending on the "Separate evaluation for excluded and simulated interlock signals (Page 162)" function and the status of the interlock (see "Forming the group status for interlock information (Page 113)").

### Signal status "Bad, device related" (value 16#00) or "Bad, process related" (value 16#28)

An interlock signal with this status is always processed as an active interlock signal in the block and displayed with the following icons in the faceplate:

for 16#00 or

for 16#28 and

A motor protection signal (`Trip` parameter) with signal status 16#00 or 16#28 is used to activate motor protection. This is indicated by "Motor protection" in the standard view of the faceplates.

A torque-monitoring signal (`TorqOpen`, `TorqClose` parameters) with signal status 16#00 or 16#28 is used to activate torque monitoring for motor valve VlvMotL.

### Signal status ≠ "Simulation" as well as "Bad, device related" and "Bad, process related"

Only signal states "Simulation", "Bad, device related" and "Bad, process related" have an effect on the processing in the block; all others are only displayed with their relevant icon in the faceplate.

### 2.1.4.4 Forming the group status for interlock information

#### Forming the group status for interlock information

A group status for interlock information is required for:

- Interlock state for:
  - Interlocked
  - Not interlocked
  - Disabled

#### Group status for the interlock state

All the effective interlock states are combined and displayed in the block icon. The interlock states are displayed with the following prioritization:

1. Function interlocked, shown in the block icon with a closed padlock

2. Function not interlocked, shown in the block icon as an open padlock

3. Function disabled, shown in the block icon as a crossed-out, closed padlock

#### Overview: Display for the interlock status in faceplate

If the Separate evaluation for excluded and simulated interlock signals (Page 162) function is not enabled (`Feature` bit =0), the bypass signals in the structures Permission, Protection, and Interlock are not evaluated.

Interlocks are shown in the faceplate as follows:

| **Parameter: BypProt** | **Parameter: Perm_En[2] or Prot_En[2] or Intl_En [2] or PermSf_En** | **Value: Permission[2] or Protection[2] or Intlock [2] PermitSafe-Pos** | **Status: Permission[2] or Protection[2] or Intlock[2] PermitSafePos** | **Button** | **Icon** | **Icon** |
|---|---|---|---|---|---|---|
| x | x | X | 16#FF | - | - | - |
| x | 0 | x | x | - | - | - |
| 0 | 1 | 1 | 16#00 | Visible |  |  |
| 0 | 1 | 1 | 16#28 | Visible |  |  |

| **Parameter: BypProt** | **Parameter: Perm_En[2] or Prot_En[2] or Intl_En [2] or PermSf_En** | **Value: Permission[2] or Protection[2] or Intlock [2] PermitSafe-Pos** | **Status: Permission[2] or Protection[2] or Intlock[2] PermitSafePos** | **Button** | **Icon** | **Icon** |
|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 16#60 | Visible |  |  |
| 0 | 1 | 1 | 16#60 | Visible |  |  |
| 0 | 1 | 0 | ≠ 16#FF | Visible |  | Status based on priority |
| 0 | 1 | 1 | ≠ (16#FF, 16#60, 16#00, 16#28) | Visible |  | Status based on priority |
| 1 (for local mode and simulation only) | 1 | x | ≠ 16#FF | Visible |  | Status based on priority |

Comments on table:

- X: The value is irrelevant for the display of the icon.
- [2]: Blocks with directional interlock and `Feature2.Bit16` = 1: "`Perm_En`", "`Intl_En`", "`Prot_En`", "Enable", "Interlock" and "Protection" also include the direction

**Note**

If values are forced in the block, this is indicated in the block icon by a crossed-out, closed padlock.

If the Separate evaluation for excluded and simulated interlock signals (Page 162) function is enabled (`Feature` bit =1), the bypass signals in the structures Permission, Protection, and Interlock are evaluated. The bypass signals can be read from the upstream interlock block at the output Bypass.

Excluded interlock signals are shown in the faceplate as follows:

| **Parameter: Perm_En[2] or Prot_En[2] or Intl_En[2]** | **Status: Permission[2] or Protection[2] or Intlock[2]** | **Bypass: Permission[2] or Protection[2] or Intlock[2]** | **Button** | **Icon** | |
|---|---|---|---|---|---|
| x | 16#FF | x | - | - | |
| 0 | x | x | - | - | |
| 1 | ≠ 16#FF | 0 | Visible | | 1) |
| 1 | ≠ 16#FF | 1 | Visible |  | 1) |

Comments on table:

- X: The value is irrelevant for the display of the icon.
- 1): Icon corresponding to the status of the interlock signal (for 16#80 no icon)
- 2): Blocks with directional interlock and `Feature2.Bit16` = 1: "`Perm_En`", "`Intl_En`", "`Prot_En`", "Enable", "Interlock" and "Protection" also include the direction

### 2.1.4.5 Rapid stop for motors

#### Rapid stop for motors

Rapid stop has the highest priority in all operating modes (manual and automatic mode as well as local mode) and operating states (such as the forcing of states). It is activated via the faceplate. This depends on the setting at the `Feature` bit Enabling rapid stop via faceplate (Page 179).

**Note**

**"Small" blocks do not feature rapid stop.**

The "rapid stop" function is supported only by "Large" blocks.

You issue the command for rapid stop state using the `RapidStp = 1` input parameter.

When you click on the "Rapid Stop" button in the faceplate, the drive stops immediately, shown as follows in the faceplate:

The `R_StpAct = 1` output parameter is set to implement the rapid stop function for local mode. You need to interconnect this parameter with the corresponding channel block and in the I/O to realize the rapid stop function in the hardware.

Rapid stop is unlocked for all operating modes using the "Reset" button in the faceplate (`RstOp = 1`); in CFC it is unlocked using the `RstLi = 1` input parameter. In automatic mode, the unlocking can also be performed via a 0-1 edge transition in the control if `Feature.Bit9` = 1.

Rapid stop can be selected even with the motor in stop state. In this case, the motor start is prevented.

### 2.1.4.6 Bypassing signals

#### Bypassing signals

With this function, you can flag a block as bypassed. If the bypass function is active, the output parameter `BypassAct` will be set from the block. With a connection from `BypassAct` to an input parameter `BypLixx` of an interlock block, you can bypass the corresponding input of the interlock block.

If the block is set to bypass, the bypass information bit of the process output and the limit switch points listed in the following table are set. If you connect one of this listed parameter with bypass information bit to an interlock input `Inx`, you can use the bypass information bit to switch the interlock signal in bypass. For this in the interlock block the corresponding bypass enable bit `BypEn.Inx` and the `Feature.Bit2` Separate evaluation for excluded and simulated interlock signals (Page 162) have to set.

Additionally, you can define over the `Feature` bit Substitution value is active if the block is in bypass (Page 199) if the block shall use the process value or a substitution value in case of an active bypass.

| Block | Process value/ signal | Process value/ signal | Parameter with bypass information bits |
|---|---|---|---|
| MonAnL | `PV_Out` | `BypPV` | `PV_Out`, `PV_AH_Act`, `PV_WH_Act`, `PV_TH_Act`, `PV_AL_Act`, `PV_WL_Act`, `PV_TL_Act`, `GradHUpAct`, `GradHDnAct`, `GradLAct` |
| PIDConL, PID-ConR, and PID-StepL | `PV_Out` | `BypPV` | `PV_Out`, `PV_AH_Act`, `PV_WH_Act`, `PV_TH_Act`, `PV_AL_Act`, `PV_WL_Act`, `PV_TL_Act`, `ER_AH_Act`, `ER_AL_Act` |
| MonDiL | `Out` | `BypIn` | `Out` |
| TotalL | `Out` | `BypOut` | `Out`, `OutAH_Act`, `OutWH_Act`, `OutTH_Act`, `OutAL_Act`, `OutWL_Act`, `OutTL_Act` |

With the parameter `BypLiOp`, you can decide whether the switching on/off will be done by the input parameters which are connected in CFC or by the faceplate from an operator.

- `BypLiOp` = 0: In the "Parameter view", the operator can switch on/off the bypass function over the parameter `BypPVOp` or `RstBypOp`. If `BypLock` = 1, you cannot make any change to the parameters `BypPVOp` or `ResBypOp`. The button for switching the bypass functionality on/off in the "Parameter view" is deactivated.
- `BypLiOp` = 1: With a connection of the parameter `BypPVLi` or `RstBypLi`, the bypass function will be switched on/off.

## 2.1.5 Form signal status

### 2.1.5.1 Forming and outputting signal status for blocks

#### General information on forming and outputting the signal status

The process values of the function blocks are generated and transferred along with a signal status as a structured variable. This contains a statement about the signal quality. The function blocks determine the appropriate signal status for their process outputs depending on the signal status of the process inputs, which are involved in calculating the process outputs. If multiple process inputs are involved in calculating a process output, the signal status is formed according to prioritization defined by function block groups. The highest priority is the signal status with the value 0.

The blocks are grouped into the following function block groups:

- Technologic blocks (Page 117)
- Digital logic blocks (Page 119)
- Analog logic blocks (Page 120)
- Redundancy blocks (Page 121)
- Blocks with configurable status prioritization (Page 122)
- Interlock blocks (Page 124)
- Mathematical blocks (Page 126)
- PCS 7 channel blocks (Page 127)
- Channel blocks for field devices (Page 127)

All blocks of a group use the same priority specifications and form the signal status of the process outputs based on them.

**Note**

The status / quality of control inputs for logic functions and parameters have no influence on the status / quality of process values and logic functions of the blocks.

The status / quality of process values inherit the results of mathematic and logic functions, which are directly related to the process value.

The status/quality of process values immediately inherit the results of monitoring and limiting functions directly related to the process value.

### 2.1.5.2 Forming and outputting the signal status for technologic blocks

#### Forming the signal status for technology blocks

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

In technology blocks, a group status is formed from the input parameters (see description of the relevant blocks) according to the priority table below (highest priority is 0). This group status is displayed in the status bar of the faceplate and of the block icon.

The group status is set to 16#68 (Uncertain, device related) with an undefined signal status at a control input, which is involved in the formation of the group status.

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 0 | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 1 | 16#00 | Bad, device related |
|  | 2 | 16#28 | Bad, process related |

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 3 | 16#68 | Uncertain, device related |
|  | 4 | 16#78 | Uncertain, process related |
|  | 5 | 16#A4 | Maintenance request |
|  | 6 | 16#80 | Good |

Interconnectable output parameters for limits (for example, `PV_AH_Act`) that can be influenced directly by an interconnectable input parameter (for example, `PV`) inherit the status from the associated output parameter (for example, `PV_Out`).

If an output parameter for limits is influenced directly by several interconnectable input parameters (limit monitoring), it receives the status of the input parameter with the highest priority (see overview above). Thus, for example, the control deviation is formed from the setpoint (`SP`) and the process value (`PV`). The output parameter for limits `ER_AH_Act`, for example, which signals an active violation of the high limit for the error signal, has a signal status based on the group status formed from the process value and setpoint (`ER`).

### Evaluation of the signal status in case of interlocks in technology blocks

The signal states of the interconnectable input parameters of the interlocking and protective signals are treated exactly like process values with the following exceptions:

- The signal status is displayed in the faceplate at the buttons for calling the series-connected interlocking blocks.
- If the input signal has "Simulation" status and the input signal is therefore inactive (for example, `Protect` = 1), the input signal in this case is interpreted as a bypassed signal and is displayed by the icon for bypassing:

- If the input signal has "Simulation" status and the input signal is therefore inactive (for example, `Protect` = 0), the input signal in this case is interpreted as a simulated signal and is displayed by the icon for simulation:

- If the input signal has the "Bad, device related" or "Bad, process related" signal status, this is evaluated as an active input signal, regardless of its value, i.e. safety interlock signal (`Protect` = 1) that is inactive due to its value, triggers a safety interlock when its status is "Bad, device related" or "Bad, process related".

### Display of the signal status in the faceplate and block icon for technology blocks

The signal status is displayed for each individual input parameter in the faceplate next to the process values or the interlock buttons. The group status is displayed in the block icon and in the group display of the faceplate.

**Note**

The interlocks and additional values are not included in the formation of the group status.

## 2.1.5.3 Forming and outputting the signal status of digital logic blocks

### Forming the signal status of digital logic blocks

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The status for the result of the output is formed within digital logic blocks from all input parameters, according to the following priority table (highest priority is 0)

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 0 | 16#00 | Bad, device related |
|  | 1 | 16#28 | Bad, process related |
|  | 2 | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 3 | 16#68 | Uncertain, device related |
|  | 4 | 16#78 | Uncertain, process related |
|  | 5 | 16#A4 | Maintenance request |
|  | 6 | 16#80 | Good |

The group status is set to 16#68 (uncertain, device-related), with an undefined signal status at a control input that is involved in forming the group status.

A signal status 16#FF at a control input is not used for the calculation of the group status. If all relevant control inputs are 16#FF, the group status is 16#80.

If only one process input is decisive for calculating the output value, the status of the process input is transferred to the status of the output.

**Special notes for the Andxx blocks**

- If the output value is 1, it has the signal status with the highest priority of all input signals.
- If the output value is 0, it has the signal status with the lowest priority of all input signals, which have a value of 0.

**Special notes for the Orxx blocks**

- If the output value is 1, it has the signal status with the lowest priority of all input signals, which have a value of 1.
- If the output value is 0, it has the signal status with the highest priority of all input signals.

**Special notes for the Xor04 block**

The worst signal status of all input parameters is always selected and output with the `Out` output parameter.

### 2.1.5.4 Forming and outputting the signal status of analog logic blocks

#### Forming the signal status of analog logic blocks

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The signal status of the Out output value within the block is taken directly from the `Inx` input value.

#### Special notes for the CompAn02 block

This block evaluates the signal status of the two input parameters `In1` and `In2` as shown in the following table.

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 0 | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 1 | 16#00 | Bad, device related |
|  | 2 | 16#28 | Bad, process related |
|  | 3 | 16#68 | Uncertain, device related |
|  | 4 | 16#78 | Uncertain, process related |
|  | 5 | 16#A4 | Maintenance request |
|  | 6 | 16#80 | Good |

### 2.1.5.5 Forming and outputting the signal status of redundancy blocks

#### Forming the signal status of redundancy blocks RedAn02 and RedDi02

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The signal status is evaluated according to the following priority:

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 0 | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 1 | 16#80 | Good |
|  | 2 | 16#A4 | Maintenance request |
|  | 3 | 16#78 | Uncertain, process related |
|  | 4 | 16#68 | Uncertain, device related |
|  | 5 | 16#28 | Bad, process related |
|  | 6 | 16#00 | Bad, device related |

The output value is generated based on the signal status of the process value with the above table of priorities. In addition, the output parameters `SimAct`, `Uncertain`, and `LossRed` are still set according to the signal status.

| In1.ST | In2.ST | Out.ST | Out.Value | SimAct.Value | Uncertain.Value | LossRed.Value |
|---|---|---|---|---|---|---|
| 16#80 | 16#80 | 16#80 | In1 | 0 | 0 | 0 |
| 16#80 | 16#60 | 16#60 | In2 | 1 | 1 | 0 |
| 16#80 | 16#A4 | 16#80 | In1 | 0 | 1 | 0 |
| 16#80 | 16#78 | 16#80 | In1 | 0 | 1 | 0 |
| 16#80 | 16#68 | 16#80 | In1 | 0 | 1 | 0 |
| 16#80 | 16#28 | 16#68 | In1 | 0 | 1 | 1 |
| 16#80 | 16#00 | 16#68 | In1 | 0 | 1 | 1 |
| 16#60 | 16#80 | 16#60 | In1 | 1 | 1 | 0 |
| 16#60 | 16#60 | 16#60 | In1 | 1 | 1 | 0 |
| 16#60 | 16#A4 | 16#60 | In1 | 1 | 1 | 0 |
| 16#60 | 16#78 | 16#60 | In1 | 1 | 1 | 0 |
| 16#60 | 16#68 | 16#60 | In1 | 1 | 1 | 0 |
| 16#60 | 16#28 | 16#60 | In1 | 1 | 1 | 1 |
| 16#60 | 16#00 | 16#60 | In1 | 1 | 1 | 1 |
| 16#A4 | 16#80 | 16#80 | In2 | 0 | 1 | 0 |

| In1.ST | In2.ST | Out.ST | Out.Value | SimAct.Value | Uncertain.Value | LossRed.Value |
|---|---|---|---|---|---|---|
| 16#A4 | 16#60 | 16#60 | In2 | 1 | 1 | 0 |
| 16#A4 | 16#A4 | 16#A4 | In1 | 0 | 1 | 0 |
| 16#A4 | 16#78 | 16#A4 | In1 | 0 | 1 | 0 |
| 16#A4 | 16#68 | 16#A4 | In1 | 0 | 1 | 0 |
| 16#A4 | 16#28 | 16#68 | In1 | 0 | 1 | 1 |
| 16#A4 | 16#00 | 16#68 | In1 | 0 | 1 | 1 |
| 16#78 | 16#80 | 16#80 | In2 | 0 | 1 | 0 |
| 16#78 | 16#60 | 16#60 | In2 | 1 | 1 | 0 |
| 16#78 | 16#A4 | 16#A4 | In2 | 0 | 1 | 0 |
| 16#78 | 16#78 | 16#78 | In1 | 0 | 1 | 0 |
| 16#78 | 16#68 | 16#78 | In1 | 0 | 1 | 0 |
| 16#78 | 16#28 | 16#68 | In1 | 0 | 1 | 1 |
| 16#78 | 16#00 | 16#68 | In1 | 0 | 1 | 1 |
| 16#68 | 16#80 | 16#80 | In2 | 0 | 1 | 0 |
| 16#68 | 16#60 | 16#60 | In2 | 1 | 1 | 0 |
| 16#68 | 16#A4 | 16#A4 | In2 | 0 | 1 | 0 |
| 16#68 | 16#78 | 16#78 | In2 | 0 | 1 | 0 |
| 16#68 | 16#68 | 16#68 | In1 | 0 | 1 | 0 |
| 16#68 | 16#28 | 16#68 | In1 | 0 | 1 | 1 |
| 16#68 | 16#00 | 16#68 | In1 | 0 | 1 | 1 |
| 16#28 | 16#80 | 16#68 | In2 | 0 | 1 | 1 |
| 16#28 | 16#60 | 16#60 | In2 | 1 | 1 | 1 |
| 16#28 | 16#A4 | 16#68 | In2 | 0 | 1 | 1 |
| 16#28 | 16#78 | 16#68 | In2 | 0 | 1 | 1 |
| 16#28 | 16#68 | 16#68 | In2 | 0 | 1 | 1 |
| 16#28 | 16#28 | 16#28 | In1 | 0 | 1 | 1 |
| 16#28 | 16#00 | 16#28 | In1 | 0 | 1 | 1 |
| 16#00 | 16#80 | 16#68 | In2 | 0 | 1 | 1 |
| 16#00 | 16#60 | 16#60 | In2 | 1 | 1 | 1 |
| 16#00 | 16#A4 | 16#68 | In2 | 0 | 1 | 1 |
| 16#00 | 16#78 | 16#68 | In2 | 0 | 1 | 1 |
| 16#00 | 16#68 | 16#68 | In2 | 0 | 1 | 1 |
| 16#00 | 16#28 | 16#28 | In2 | 0 | 1 | 1 |
| 16#00 | 16#00 | 16#00 | In1 | 0 | 1 | 1 |

### 2.1.5.6 Forming and outputting the signal status for blocks with configurable status prioritization

#### Forming the signal status for blocks with configurable status priority

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The SelPrio parameter is used for this block to define the priority setting for linking the individual states. You have the option between the following specifications:

| Priority | SelPrio = 0 | SelPrio = 1 | SelPrio = 2 | SelPrio = 3 | SelPrio = 4 | SelPrio = 5 | SelPrio = 6 | SelPrio = 7 |
|---|---|---|---|---|---|---|---|---|
| 0 |  16#60 |  16#80 |  16#A4 |  16#80 |  16#A4 |  16#60 |  16#80 |  16#60 |
| 1 |  16#00 |  16#00 |  16#00 |  16#A4 |  16#80 |  16#80 |  16#A4 |  16#80 |
| 2 |  16#28 |  16#28 |  16#28 |  16#60 |  16#60 |  16#A4 |  16#78 |  16#A4 |
| 3 |  16#68 |  16#68 |  16#68 |  16#00 |  16#00 |  16#00 |  16#68 |  16#78 |
| 4 |  16#78 |  16#78 |  16#78 |  16#28 |  16#28 |  16#28 |  16#28 |  16#68 |
| 5 |  16#A4 |  16#60 |  16#60 |  16#68 |  16#68 |  16#68 |  16#00 |  16#28 |
| 6 |  16#80 |  16#A4 |  16#80 |  16#78 |  16#78 |  16#78 |  16#60 |  16#00 |

## Special notes for the MuxAn03 block

The status priority for this block, which is used by the block to process the status of the PV1 ... PV3 process value inputs, can be set with the SelPrio parameter.

**Note**

The parameter SelPrio can take a value from 0 to 7 . SelPrio = 6 is set by default.

If you enter a value greater than 7, the setting for 7 is used. If you enter a value lower than 0, the setting for 0 is used.

For information on evaluating the status of the process value inputs, refer to the section MuxAn03 functions (Page 2331).

### 2.1.5.7 Forming and outputting the signal status for interlock blocks

## Forming the signal status for interlock blocks

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The block determines the signal status of the output signal, based on the signal status of the input values from the configured logical operation according to the following table (highest priority is 0):

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 0 | 16#00 | Bad, device related |
|  | 1 | 16#28 | Bad, process related |
|  | 2 | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 3 | 16#68 | Uncertain, device related |
|  | 4 | 16#78 | Uncertain, process related |
|  | 5 | 16#A4 | Maintenance request |
| No icon | 6 | 16#80 | Good |
| No icon | - | 16#FF | Input is not connected |

### General rules

- If a given input causes a signal change at the output, the signal status of the input with the highest priority (worst signal status) is set at the output, since each input can influence the output:
  - Logical AND operation (logic = 1):
    If the output value is 1, it has the signal status with the highest priority of all interconnected input signals.
  - Logical OR operation (logic = 0):
    If the output value is 0, it has the signal status with the highest priority of all interconnected input signals.
- If several inputs have the same priority and the output therefore cannot be changed, the signal status of the input with the lowest priority (highest signal status) is set at the output, since the output is uniquely determined by the signal with the best signal status:
  - Logical AND operation (logic = 1):
    If the output value is 0, it has the signal status with the lowest priority of all interconnected input signals, which have a value of 0.

    **Note**

    With `Feature.Bit23` = 1 (evaluation signal status), input signals with a bad signal status (`16#28` or `16#00`) are processed with the value 0, regardless of their actual value

  - Logical OR operation (logic = 0):
    If the output value is 1, it has the signal status with the lowest priority of all interconnected input signals, which have a value of 1.
- If no inputs are interconnected, the signal status of the output is set to simulation (`16#60`).

### Display of the signal status in the faceplate and block icon for interlocking blocks

The signal status is displayed for each individual parameter (except for the analog values) in the faceplate next to the process values.

If you bypass a signal, it is displayed in the faceplate of the interlocking block next to the button for excluding, as well as in the block icon as follows.

**Note**

If an excluded interlock signal can become switchover-relevant, the status of the output Out.ST is set to simulation 16#60, as long as it is not forced by other interlock inputs to Bad, device-related 16#00 or Bad, process-related 16#28.

An excluded interlock input has no influence on the status when the Separate evaluation for excluded and simulated interlock signals (Page 162) function is enabled.

The currently valid status for the output signal is also displayed in the faceplate.

### 2.1.5.8 Forming and outputting the signal status for mathematical blocks

#### Forming the signal status for mathematical blocks

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The status for the result of the output is formed within mathematical blocks from all process inputs involved in the calculation, according to the following table (highest priority is 0)

| Signal status icon | Priority | Value | Meaning |
|---|---|---|---|
|  | 0 | 16#00 | Bad, device related |
|  | 1 | 16#28 | Bad, process related |
|  | 2 | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 3 | 16#68 | Uncertain, device related |
|  | 4 | 16#78 | Uncertain, process related |
|  | 5 | 16#A4 | Maintenance request |
|  | 6 | 16#80 | Good |

The group status is set to 16#68 (uncertain, device-related), with an undefined signal status at a control input that is involved in forming the group status.

A 16#FF signal status at a control input is not used for the calculation of the group status. If all relevant control inputs are 16#FF, the group status in the search for the worst group status is 16#80 and 16#00 in the search for the best group status.

If only one process input is decisive for calculating the output value, the status of the process input is transferred to the status of the output.

**Note**

**Special notes for the Integral mathematical block**

Due to its application area (time integral, I-component for the configuration of a controller), the Integral block generates the signal status like the technological blocks.

#### Special notes for the mathematical blocks Addxx, Mulxx, Div02 and Sub02

If the result of the mathematic operation is a floating-point number that cannot be displayed, the result of the status is set to 16#28. Floating-point numbers that cannot be displayed are labeled in the CFC with #+Inf (+ infinite), #-Inf (- infinite) or with #NaN (not a number).

### 2.1.5.9 Forming and outputting the signal status for PCS 7 channel blocks

#### Forming the signal status for PCS 7 channel blocks

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The signal status for PCS 7 channel blocks can assume the following values:

| Signal status icon | Value | Meaning |
|---|---|---|
|  | 16#80 | Good |
|  | 16#78 | Uncertain, process related:<br>Limitation of input parameter `PV_In` is active (analog output channel blocks only) |
|  | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 16#00 | Bad, device related (value not valid) |
|  | 16#A4 | Maintenance required, maintenance demanded |
|  | 16#68 | Uncertain, device related |

### 2.1.5.10 Forming and outputting the signal status for channel blocks for field devices

#### Forming the signal status for channel blocks (field devices)

For more general information on forming the status signal, refer to the section: Forming and outputting signal status for blocks (Page 116).

The signal status of channel blocks for field devices can assume the following values:

| Signal status icon | Value | Meaning |
|---|---|---|
|  | 16#80 | Good |
|  | 16#78 | Uncertain, process related |
|  | 16#68 | Uncertain, device related |
|  | 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
|  | 16#28 | Bad, process related |

| Signal status icon | Value | Meaning |
|---|---|---|
|  | 16#00 | Bad, device related (value not valid) |
|  | 16#A4 | Maintenance required, maintenance demanded |

## 2.1.6 Error handling

### 2.1.6.1 Error handling

#### Error handling

The channel and technologic blocks feature error handling routines. A distinction must be made between the following areas:

- Error numbers
- External process control error (CSF)
- Process-specific errors
- Invalid signal states
- Mode switchover error
- Errors in channel blocks

#### Error numbers

Most blocks have an output parameter `ErrorNum` that can be used to output internal error states of the block as error numbers.

With some blocks, input parameters are checked for permissible values. They are therefore only used to prevent the output value from remaining invalid when the input value is once again in the valid range. If an invalid value is detected, and the corresponding output value is held at the last displayed value instead of an invalid value being displayed. If blocks do not have this check, an invalid value can appear at the output. However, a valid value is displayed again at the output as soon as the input values of the block have changed correspondingly.

Any value set over an interconnection or as a result of a parameter assignment that is outside the range of values (e.g. "Not a Number") is not processed by the block algorithm. The last valid value is processed instead.

In addition to the errors stated above, a limit violation is also signaled for example. Each error number is assigned to a specific error.

If there is more than one error, all error numbers have the same priority. The routine always displays the error number of the error most recently detected in a block cycle.

### External process control error (CSF)

An external process control error always lies outside the process - it exists in the form of device or other hardware faults. If, for example, a run-time error occurs at a valve, there is an error or fault in the pneumatic system.

A process control error is output if an external error is set at the input `CSF`. You can enable this output function, for example, by interconnecting output `Bad` of the channel block with input `CSF` of the technologic block.

The error message "$$BlockComment$$ External error occurred" is output at `CSF = 1`.

This state is visualized in the group display by an "S" character in the faceplate overview and in the block icon.

With motor, valve and dosing blocks, there is also the possibility that the block switches to error processing. `Feature.Bit18` Activating error state for external process control error CSF (Page 162) must be set for this. The device goes into error processing and moves the drive to the neutral position or switches the dosing operation to off for a doser. If the dosing operation is already finished, it remains in the completed state. Resetting the error is described in Resetting the block in case of interlocks or errors (Page 47).

### External error (FaultExt)

The `FaultExt` input can be used to pass an external error without the generation of a message. The device goes into error processing and moves the drive to the neutral position or switches the dosing operation to off for a doser. If the dosing operation is already finished, it remains in the completed state. Separate messages can be generated by interconnecting the external error to `ExtMsgx` messages that can be freely selected. Resetting the error is described in Resetting the block in case of interlocks or errors (Page 47).

### Process-specific errors

Process-specific errors can have the following causes:

- Runtime monitoring: If the feedback signals do not match the control settings after a selected time has expired, a process-related error is output.
- Feedback monitoring: Refer to the Monitoring the feedbacks (Page 104) section for more on this.

If the block algorithm detects a monitoring error while monitoring is enabled, the corresponding output parameter is set to 1 in the block. The "$$BlockComment$$ Feedback error xxx" error message is also output, where xxx, for example, stands for the valve.

This state is visualized in the group display by an "S" character in the faceplate overview and in the block icon.

The block must be reset after the monitoring error was cleared and if automatic mode is set.

### Invalid input signals

This error is output if inconsistencies are detected between associated I/Os. The close and open commands cannot be output simultaneously to the valve, for example.

If the block algorithm detects an invalid combination of input signals, an error number (`ErrorNum`) is output that depends on the block type.

In the case of motors, valves and batches, the faceplates' standard view will additionally output the text "invalid signal".

### Mode switchover error

This error is reported if you change the mode of the block from:

- Manual to automatic mode or
- Local mode to automatic mode

and the previous and target state are **inconsistent** (bumpless switchover). You can only change the block mode if the subsequent state corresponds with the previous state.

Bumpless switchover can be activated / deactivated using the `Feature` connection on the Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) or Disabling bumpless switchover to automatic mode for controllers (Page 183) bit.

Bumpless switchover from local to automatic mode is undertaken using the `LocalSetting` parameter, as described in section Local mode (Page 86).

In the standard view of the faceplate, the text "Changeover error" is displayed in the event of an unwanted switchover with bumps.

The block retains local mode if the operator changes the mode from local to automatic and the error mentioned above occurs. The block changes to manual mode if the mode is changed from local to automatic over interconnected inputs and the error mentioned above occurs.

### Errors in channel blocks

The following errors may be displayed by the channel blocks:

- Channel error
- Device or module fault
- Higher-level error
- Invalid measuring range

## 2.1.6.2 Outputting group errors

### Outputting group errors

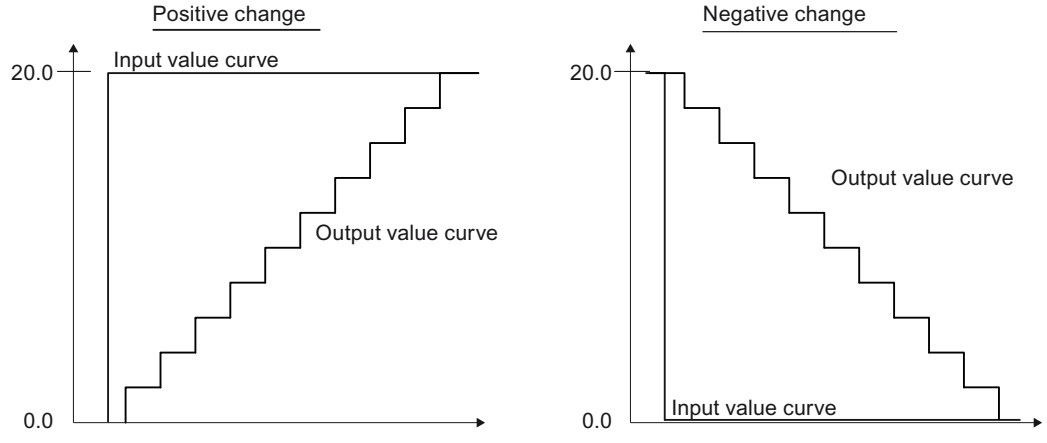
The `GrpErr` output parameter assembles the faults of a block and makes them available to you. A group error is compiled from the following error information:

- Feedback errors (static or dynamic feedback monitoring)
- External error (CSF and `FaultExt`)
- Motor protection (only for motors)
- Module errors (only for hardware controllers)

- I/O access errors (only for hardware controllers)
- Parameter assignment errors (only for hardware controllers)

For information on how the signal is formed for the group error at the `GrpErr` output parameter, refer to the corresponding block descriptions in the "Functions" chapter.

**Note**



The signal status of the individual signals is not taken into consideration for forming the group error. The outputs therefore always have the status, `16#80`.

## 2.1.7 Ramp function

### 2.1.7.1 Using setpoint ramp

#### Using setpoint ramp

Starting at the current internal setpoint, the setpoint can be set to a target setpoint value over a ramp-shaped function. In the faceplate, you can start the function in ramp view (`SP_RmpOn = 1`).

Use the `SP_RmpModTime` input parameter or the ramp view of the faceplate to specify whether the setpoint ramp is defined by time or by gradients:

- If you select time `(SP_RmpModTime = 1)`: The ramp of the setpoint is calculated automatically by the block so that after the ramp has started `(SP_RmpOn = 1)`, the setpoint will reach the target setpoint (`SP_RmpTarget`) after the selected time `(SP_RmpTime)`.
- If you select gradients `(SP_RmpModTime = 0)`: The inclination of the ramp matches the selected rates of change `SP_UpRaLim` (positive) or `SP_DnRaLim` (negative).

Once the setpoint has reached the target setpoint, the function is terminated automatically (SP_RmpOn = 0). The ramp trip can be prematurely aborted in the faceplate by setting SP_RmpOn = 0.

**Requirements for using a setpoint ramp**

| Block | Setpoint | Gradient limit | Operating mode |
|---|---|---|---|
| Controller | Internal | Off | Automatic |
| OpAnL | Internal | Off | |
| MotSpdCL | Internal | Off | |

If the requirements are not fulfilled during the ramp trip, the ramp trip is automatically canceled.

**Note**

**Special note for the MotSpdCL block**

In the case of an interlock, a monitoring error, motor protection or rapid stop, the motor is switched off and the internal ramp setpoint is reset to the starting setpoint of the ramp trip.

### 2.1.7.2 Gradient limit of the setpoint

**Gradient limit of the setpoint**

The gradient limit is activated via the SP_RateOn = 1 input parameter.

The values are set at the SP_UpRaLim and SP_DnRaLim parameters depending on the TimeFactor.

- TimeFactor = 0: Unit of the gradient limiting is Unit/Second, Unit of ramp time is Second
- TimeFactor = 1: Unit of the gradient limiting is Unit/Minute, Unit of ramp time is Minute
- TimeFactor = 2: Unit of the gradient limiting is Unit/Hour, Unit of ramp time is Hour
- SP_UpRaLim sets the gradient high limit
- SP_DnRaLim sets the gradient low limit

**Note**

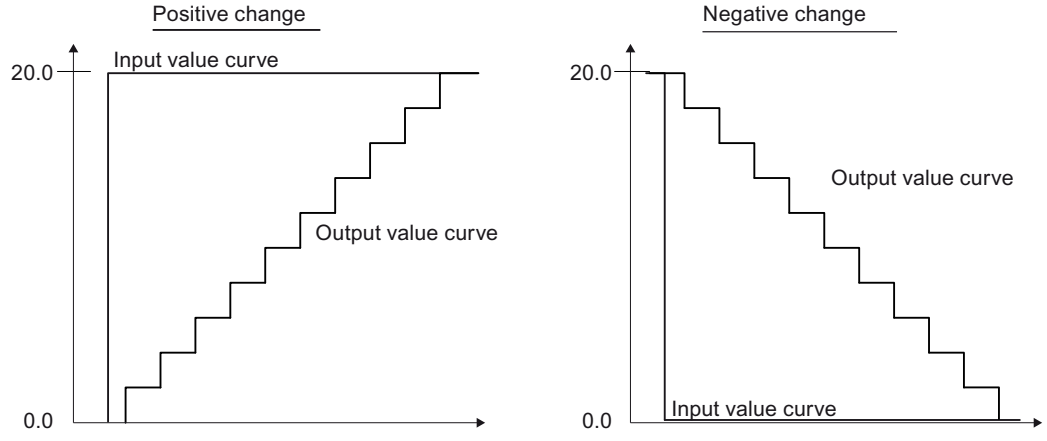
ParametersSP_UpRaLim and SP_DnRaLim are always evaluated according to their magnitude.

With the Feature Bit Gradient limitation with time duration (Page 197), you can also use the parameters SP_RmpModTime and SP_RmpTime in the gradient limit function. If this Feature Bit = 1 and SP_RmpModTime = 1 is parameterized, the ramp rate is calculated with a change of setpoint such that the new value of the setpoint will reach after the time of SP_RmpTime.

### External setpoint

If the external setpoint (SP_ExtAct.Value = 1) is switched on, the linkable values SP_LiUpRaLim, SP_LiDnRaLim, SP_LiRmpTime, of SP_UpRaLim, SP_DnRaLim, SP_RmpTime respectively will be used. The values will be active only if they are connected (SP_LiX.ST <> 16#FF).

### Displaying active limitation



A gradient limit is indicated at the following output parameters:

- SP_UpRaAct = 1: Gradient has a high limit
- SP_DnRaAct = 1: Gradient has a low limit

## 2.1.7.3 Using a manipulated variable ramp

### Using a manipulated variable ramp

Starting at the current internal manipulated variable, the manipulated variable can be brought to a target value in the form of a ramp. In the faceplate, you can start the function in ramp view (MV_RmpOn = 1)).

Use the MV_RmpModTime input parameter or the ramp view of the faceplate to specify whether the manipulated variable ramp is defined by time or by gradients:

- If you select time (MV_RmpModTime = 1): The gradients of the manipulated variable are calculated automatically by the block so that after the ramp has started (MV_RmpOn = 1), the manipulated variable will reach the target value (MV_RmpTarget) after the configured time (MV_RmpTime).
- Specification with gradients (MV_RmpModTime = 0): The ramp slope matches the configured rates of change MV_UpRaLim (positive) or MV_DnRaLim (negative).

Once the manipulated variable has reached the target value, the function is terminated automatically (MV_RmpOn = 0). The ramp trend can be prematurely aborted in the faceplate by setting MV_RmpOn = 0.

**Requirements for using a manipulated value ramp:**

| Block | Manipulated variable | Gradient limit | Operating mode |
|---|---|---|---|
| VlvAnL without auxiliary valve | Internal | Off | Manual |
| VlvAnL with auxiliary valve | Internal | Off | |

If the requirements are not fulfilled during the ramp trip, the ramp trip is automatically canceled.

### 2.1.7.4 Gradient limiting of the manipulated variable

#### Gradient limiting of the manipulated variable

The gradient limit is activated via the `MV_RateOn = 1` input parameter.

The values are set at the `MV_UpRaLim` and `MV_DnRaLim` parameters depending on the `TimeFactor`.

- `TimeFactor = 0`: Unit of the gradient limiting is Unit/Second, Unit of ramp time is Second
- `TimeFactor = 1`: Unit of the gradient limiting is Unit/Minute, Unit of ramp time is Minute
- `TimeFactor = 2`: Unit of the gradient limiting is Unit/Hour, Unit of ramp time is Hour
- `MV_UpRaLim` sets the gradient high limit
- `MV_DnRaLim` sets the gradient low limit

**Note**

Parameters `MV_UpRaLim` and `MV_DnRaLim` are always evaluated according to their magnitude.

With the `Feature` Bit Gradient limitation with time duration (Page 197), you can also use the parameters `MV_RmpModTime` and `MV_RmpTime` in the gradient limit function. If this `Feature` Bit = 1 and `MV_RmpModTime` = 1 is parameterized, the ramp rate is calculated with a change of manipulated variable such that the new value of the manipulated variable will reach after the time of `MV_RmpTime`.

#### External maniputaed variable

If the external maniputaed variable (`MV_ExtAct.Value` = 1) is switched on, the linkable values `MV_LiUpRaLim`, `MV_LiDnRaLim`, `MV_LiRmpTime`, of `MV_UpRaLim`, `MV_DnRaLim`, `MV_RmpTime` respectively will be used. The values will be active only if they are connected (`MV_LiX.ST` <> `16#FF`).

#### Displaying active limitation

A gradient limit is indicated at the following output parameters:

- `MV_UpRaAct = 1`: Gradient has an high limit
- `MV_DnRaAct = 1`: Gradient has a low limit

## 2.1.8 Internal/external setting

### 2.1.8.1 Applying the dynamically activated dead band during the PV settling time

#### `Feature` bit

Number of the `Feature` bit: 30.

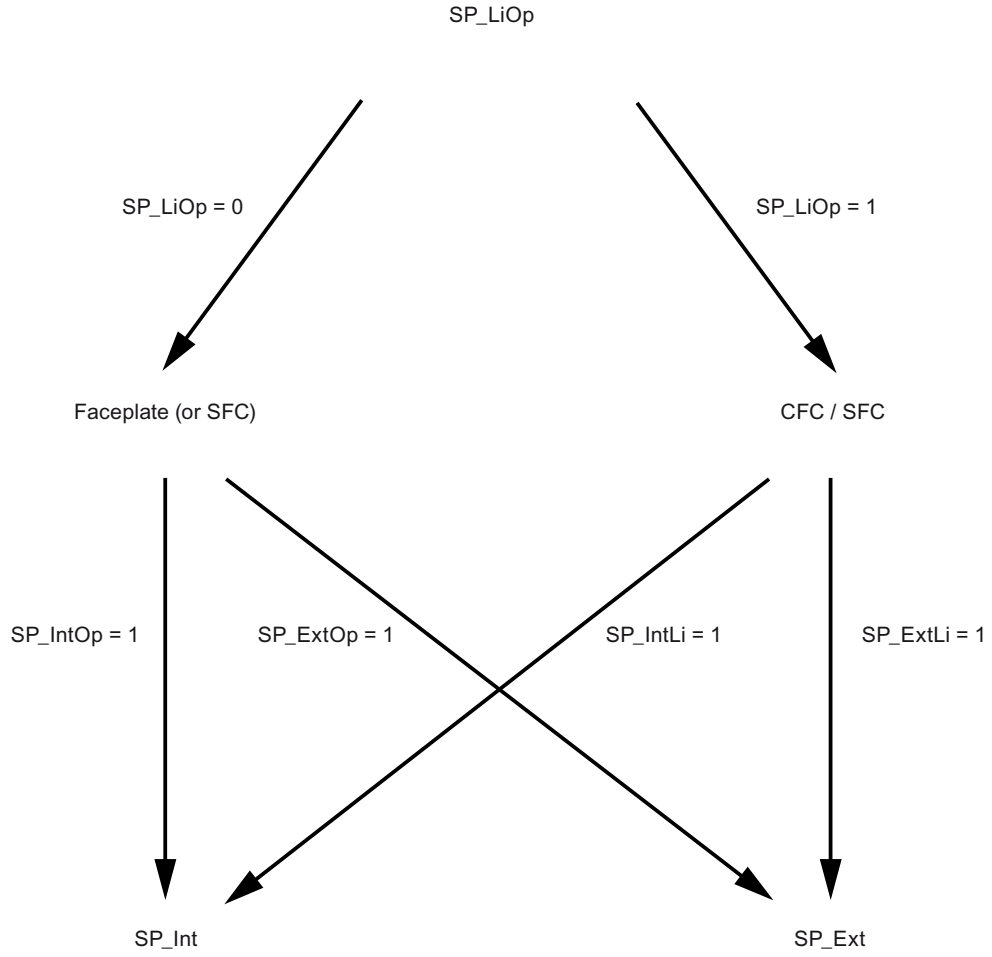
#### Dynamic deactivation of the dead band by the `PV` settling time

You can use this `Feature` bit to improve the `PV` settling time in the range of the dead band.

The deadband is deactivated until the `PV` settles more in the center than at the edges of the dead band. The probability that the controlled variable is within the dead zone time is increased, and further control actions are no longer necessary. This leads to reduced wear and less energy consumption.

**Bit = 0**: Dead band width is constant

**Bit = 1:** The dead band is deactivated for the `PV` settling time. When the `PV` settling time is over, the dead zone gets the value of the `DeadBand` parameter.



**Note**

If `Feature.Bit30` = 1 is set, the ConPerMon block has to be connected with the controller. The blocks PIDConL or PIDConR monitor this by checking the status signal of `MeanMV.ST`. In case of `Feature.Bit30` = 1 and `MeanMV.ST` = 16#78 the dynamic deactivation of deadband is not possible and the output `ErrorNum` will be set to 52.

### 2.1.8.2 Setpoint specification - internal/external

#### Setpoint specification internal & external

Some blocks have a function that allows setpoints to be specified. This specification is carried out either by means of a CFC/SFC program or by means of the faceplate (operator). With doser blocks and frequency converters, the operator can specify the internal setpoint value (`SP_Int`) or a higher-level open-loop control will specify an external setpoint value (`SP_Ext`). In principle, the blocks operate according to the same scheme:

First you define whether the setpoint specification is to be carried out by means of a CFC/SFC program or by means of the faceplate. In the next step you specify whether the internal or the external setpoint is to be used.

**Setpoint specification by means of faceplate or interconnection**

With the SP_LiOp parameter, you define whether the setpoint will be set by a CFC/SFC program or using the faceplate.

- Parameterize Sp_LiOp with 0 so that the setpoint specification is carried out by means of the faceplate.
- Parameterize SP_LiOp with 1 so that the setpoint specification is carried out by means of a CFC / SFC program.

**Setpoint specification internal & external**

You have to set the corresponding parameters depending on how the setpoint specification is to be carried out.

If the setpoint is set in the faceplate (SP_LiOp = 0), you have to set the parameter:

- SP_IntOp = 1 in order to achieve an internal setpoint specification by means of the faceplate.
- SP_ExtOp = 1 to have an external setpoint set in the faceplate.

If both signals are set, SP_IntOp = 1 has priority.

If the setpoint is set by a CFC / SFC program (SP_LiOp =1), you have to set the parameter:

1. SP_IntLi = 1 to have an internal setpoint set by a CFC / SFC program.
2. SP_ExtLi = 1 in order to achieve an external setpoint specification by means of a CFC / SFC program.

**Note**

For PIDConL, PIDStepL, FmCont, FmTemp: If both signals are set, SP_IntLi = 1 has priority.

### Bumpless switchover from external to internal setpoint

The parameter SP_TrkExt = 1 is used so that the internal setpoint tracks the external setpoint to achieve a Bumpless switchover from the external to the internal setpoint. This allows unwanted jumps at the output parameter to be avoided.

## 2.1.8.3 Manipulated variable specification - internal/external

### Manipulated variable specification internal and external

The VlvAnl block provides a function for specifying manipulated variables. This specification is carried out either using a CFC/SFC program or using a faceplate (operator).

If a auxiliary valve is used for operation, it is possible to switch between internal and external in the both manual and automatic mode.

If no auxiliary valve is used for operation, the external manipulated variable is used for automatic mode and the internal manipulated variable is used for manual mode. It is not possible to switch between internal and external.

**Note**

If no auxiliary valve is used and either the "Open" or "Close" command is active, a new manipulated variable (internal or external) only takes effect after the change. In automatic mode, the manipulated variable is ignored as long as the "Open" or "Close" command is pending.

### Manipulated variable specification using a faceplate or interconnection

You can use the `MV_LiOp` parameter to determine if the manipulated variable should be set by a CFC/SFC program or via the faceplate.

- Set `MV_LiOp` to 0 for manipulated variable specification to be performed with the faceplate.
- Set `MV_LiOp` to 1 for manipulated variable specification to be performed by a CFC/SFC program.

### Manipulated variable specification internal and external

You need to set the corresponding parameters depending on the selected method for manipulated variable specification.

If the manipulated variable is to specified via the faceplate `MV_LiOp = 0`, you have to set the parameter:

- `MV_IntOp = 1` in order to achieve internal manipulated variable specification via the faceplate.
- `MV_ExtOp = 1` in order to achieve external manipulated variable specification via the faceplate.

If both signals are set, the most recently active state is retained.

If the manipulated variable is set by a CFC/SFC program (`MV_LiOp = 1`), you have to set the parameter:

- `MV_IntLi = 1` to have an internal manipulated variable set by a CFC/SFC program.
- `MV_ExtLi = 1` in order to achieve an external manipulated variable specification by a CFC/SFC program.

If both signals are set, `MV_IntLi = 1` has priority.

**Note**

It is only possible to switch between internal and external when operating with a auxiliary valve.

#### Bumpless switchover of the manipulated variable from external to internal

The parameter `SP_TrkExt = 1` is used so that the internal setpoint tracks the external setpoint to achieve a Bumpless switchover from the external to the internal setpoint. This allows unwanted jumps at the output parameter to be avoided.

#### Forming the manipulated variable externally

With external manipulated variable specification, the manipulated variable is restricted to the `MV_HiLim` and `MV_LoLim` limits and sent to the `MV_ExtOut` output.

## 2.1.9 Configurable response using the Feature I/O

### 2.1.9.1 Configurable functions using the Feature I/O

#### Configurable functions using the `Feature` I/O

Some blocks have an input called `Feature`. This input can be used to influence the way in which the block works.

The `Feature` bits are assigned in the following order:

| Bit number | Meaning | Block |
|---|---|---|
| 0 | Set startup characteristics (Page 148) | AV, Average, CountOh, CountScL, DeadTime, Derivative, DoseL, FmCont, FmTemp, Integral, Lag, MeanTime, ModPreCon, MonAnL, MonAnS, MonDi08, MonDiL, MonDiS, MotL, MotS, MotRevL, MotSpdCL, MotSpdL, OpAnL, Pcs7AnOu, Pcs7DiOu, PIDConL, PIDConR, PIDStepL, RateLim, Ratio, ShrdResS, TotalL, Vlv2WayL, VlvAnL, VlvMotL, VlvL, VlvS |
| 1 | Reaction to the out of service mode (Page 188) | ConPerMon, CountOh, CountScL, DoseL, Event, EventNck, EventTs, FmCont, ModPreCont, MonAnL, MonAnS, MonDi08, MonDiL, MonDiS, MotL, MotS, MotRevL, MotRevSpdL, OpAnL, OpDi01, OpDi03, OpTrig, PIDConL, PIDConR, PIDStepL, Ratio, SelA16In, TotalL, Vlv2Way, VlvAnL, VlvL, VlvS, VlvMotL |
| | Changes signal status of outputs in OOS (Page 208) | MotL, MotS, MotRevL, MotSpdL, MotSpdCL, VlvS, VlvL, Vlv2WayL, VlvMotL, VlvAnL, VlvPosL |

| Bit number | Meaning | Block |
|---|---|---|
| 2 | Resetting the commands for changing the mode (Page 172) | DoseL, FmCont, FmTemp, ModPreCon, MotL, MotS, MotRevL, MotSpdCL, MotSpdL, PIDConL, PIDConR, PIDStepL, Vlv2WayL, VlvAnL, VlvL, VlvS, VlvMotL, SelA16In |
| | Separate evaluation for excluded and simulated interlock signals (Page 162) | Intlk02, Intlk04, Intlk08, Intlk16, OpDi01, OpDi03 |
| 3 | Enabling resetting of commands for the control settings (Page 172) | DoseL, MotL, MotS, MotRevl, MptSpdCL, MotSpdL, Vlv2WayL, VlvAnL, VlvL, VlvMotL |
| | Control priority in the event of invalid or not plausible input commands (Page 186) | DoseL, MotL, MotS, MotRevL, MotSpdCL, MotSpdL, Vlv2WayL, VlvL, VlvS, VlvMotL, VlvAnL, VlvPosL, |
| | Changes signal status of outputs in OOS (Page 208) | SelA16In, SelAn16L |
| | Disable limit act output when limit value message is disabled (Page 209) | MonAnL, MonAnS, PIDConS, AV, CountOh, CountScL, TotalL, PumpMon |
| | Bypass over both connection BypLix OR Inx (Page 212) | Intlk02, Intlk04, Intlk08, Intlk16 |
| 4 | Setting switch or button mode (Page 177) | DoseL, FMCont, FMTemp, ModPreCon, MotL, MotRevL, MotSpdCL, MotSpdL, PIDConL, PIDStepL, Vlv2WayL, VlvAnL, VlvL, VlvMotL, SelA16In |
| | Setting switch or button mode for local commands (Page 195) | MotL, MotRevL, MotSpdCL, MotSpdL, VlvL, Vlv2WayL, VlvMotL, VlvPosL |
| | Changes signal status of outputs in OOS (Page 208) | CntOhSc, CountScL, CountOh, TotalL |

| Bit number | Meaning | Block |
|---|---|---|
| 5 | Specifying the dosing type (Page 157) | DoseL |
| | Control via auxiliary valve (Page 182) | VlvAnL |
| | Alarm setpoint difference (Page 182) | MotSpdCL |
| | Specifying switching mode (Page 178) | MotSpdL |
| | Use the last value following a complete download as the current value during startup of the block (Page 165) | TotalL |
| | Display only input values that are interconnected in the faceplate (Page 168) | SelA16In |
| | Activate OS_Perm bits (Page 168) | Intlk02, Intlk04, Intlk08, Intlk16 |
| | Limit output Out (Page 154) | Polygon |
| | Setting the scaling for the process values (Page 159) | FbDrive |
| | Activate LowCutOff (Page 166) | Pcs7AnIn |
| | Evaluation of the signal status of the interlock signals (Page 153) | OpDi01, OpDi03 |
| | | DoseL, MotL,MotRevL,MotS, MotSpdCL,MotSpdL,Vlv2WayL,VlvAnL,VlvL,VlvS, VlvMotL |
| | Retain last output value in case of bad input signal status (Page 198) | MeanTime |
| | Changes signal status of outputs in OOS (Page 208) | PIDConS, PIDConR, PIDConL, PIDStepL, FmTemp, FmCont, MPC 10x10, KalFit, ModPreCon, TimeTrig, AV, MonAnL, MonAnS, MonDiL, MonDi08, MonDiS |
| | Timestamp calculation (Page 210) | Pcs7DiIT |

## 2.1.9.2 Stopping dosing at a flow alarm

### Feature bit

Number of the `Feature` bit: 11

### Stopping dosing at a flow alarm

You can use this `Feature` bit to enable stopping dosing at a flow alarm.

The default setting is 0.

**Bit = 0**: Disabled, dosing is not stopped when a flow alarm occurs

**Bit = 1**: Enabled, dosing is stopped when a flow alarm occurs

### 2.1.9.3 Failure handling

#### Feature bit

Number of the `Feature` Bit: 6

#### Failure handling

Use this `Feature` bit to configure "Failure handling" in the case of device failure.

The default setting is 0.

**Bit = 0**: Commands `Local` and `Ackn` only active

**Bit = 1:** All commands active

#### See also

Configurable functions using the Feature I/O (Page 139)

### 2.1.9.4 Set startup characteristics

#### Feature bit

Number of the `Feature` bit: 0

#### Set startup characteristics

With this `Feature` bit, you set the startup characteristics of the function blocks, for example, for:

- Motors, valves and controllers
- Channel blocks
- Monitoring blocks, e.g. `MonAnL` and `MonDiL`.
- Mathematical and analog logic blocks
- The OpAnL, OpAnS, OpDi01, and OpDi03 block
- The TimeTrg block
- Dosing block DoseL
- Counter blocks
- The Average block
- The TimeTrig block
- The Trigger block

The default setting is 0.

**Note**

This `Feature` bit has no function in the "Out of service" operating mode. The process tag remains in the "Out of service" operating mode after a warm restart of the CPU.

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

**Note**

With a Run-Stop-Run transition of the CPU and internally pending messages, non-stuck-through messages with time stamps and auxiliary values beginning with `RunUpCycle` occur for blocks with the startup characteristic `Feature` bit = 0 after expiration of the `RunUpCycle` counter in the following cases:

- Alarm, warning or tolerance messages from the operating points (motor, valve, dosing, controller and analog monitoring blocks)
- Feedback errors (motor and valve blocks)
- Output signals of digital process tags (MonDiL, MonDi08)
- Flutter limits violated (MonDiL)

The restart routines of the blocks reset the following outputs in OB100:

- Operating point outputs `xx_AH_Act`, `xx_AL_Act`, `xx_WH_Act`, `xx_WL_Act`, `xx_TH_Act`, `xx_TL_Act` or `GradHUpAct`, `GradHDnAct`, `GradLAct`
- Feedback error outputs `MonDynErr` and `MonStaErr`
- Output binary signals `Out`, `Out1..8` for MonDiL or MonDi08
- Flutter suppression `FlutAct` for MonDiL

This causes an outgoing message when initializing Alarm8_P in OB100 and an incoming message after expiration of the `RunUpCycle` counter on the cyclic interrupt level.

**Note**

During a complete download with AS stop, the blocks (with `Feature.Bit0` = 1) cannot resume operation in their previous mode and control when restarted.

### Set startup characteristics for motors, valves and controllers

**Bit = 0**: Starting the block in manual mode and in neutral position. With controllers, the setpoint is set to (`SP_Int`) internally. See also the section Neutral position for motors, valves and controllers (Page 54) for more on this.

The controller blocks PIDConL, PIDConS, PIDConR, PIDStepL, ModPreCon, MPC10x10, and the valve block VlvAnL have the additional `Feature.Bit16`, Neutral position manipulated variable takes effect at startup (Page 176), which specifies whether the neutral position is approached

**Bit = 1**: Starting the block with the last stored values, in other words in the last operating mode set (manual, automatic or local mode) and at the last valid position.

**Note**

**Special note following complete download to the CPU**

Following a complete download to the CPU, the motor protection signal `Trip` is evaluated during the initial run as good (=1).

When a motor protection signal is pending, this causes a non-struck-through message with time stamp and auxiliary values beginning with `RunUpCycle` after the complete download and after expiration of the `RunUpCycle` counter.

### Startup characteristics for the ShrdResS block

**Bit = 0**: The output command interface is reset to 0.

**Bit = 1**: The block leaves the output command interface unchanged.

### Defining the startup characteristics for channel blocks

**Bit = 0**: The channel block uses either the process value `PV_In` or the value of `SimPV_In` as the startup value, depending on the setting of the input parameter `SimOn` (`PV_In = PV_Out` or `SimPV_In = PV_Out`).

**Bit = 1**: The channel block uses the value `StartVal` as the startup value (`StartVal = PV_Out`).

### Defining the startup characteristics for monitoring blocks

**Bit = 0**: The most recently stored values are reset on startup.

**Bit = 1**: The most recently used value at the output parameter `Out` is output on startup.

### Defining the startup characteristics for mathematical, analog logic blocks

**Bit = 0**: The `Out` output parameter is reset to 0 on startup.

**Bit = 1**: The most recently saved value is output at the `Out` output parameter on startup.

### Defining startup characteristics for the OpAnL/OpAnS blocks

**Bit = 0**: The internal setpoint is used for startup.

**Bit = 1**: The most recently saved value is output at the `Out` output parameter on startup.

### Defining startup characteristics for the OpDi01/OpDi03 blocks

**Bit = 0**: The output parameters `Out` or `Out1`...`Out3` will be reset on startup.

**Bit = 1**: The most recently used value at the output parameter `Out` or `Out1`...`Out3` is outputted on startup.

### Defining the startup characteristics for dosing block DoseL

Bit = 0: On startup, the dosing is ended and reset to the value specified in the input parameter. For example, the dribbling quantity is reset to input `DribbIn`.

Bit = 1: On startup (no complete download), dosing continues with the most recently stored value.
For example, the learned dribbling quantity in output `DribbOut` can further used.

Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter `RunUpCyc`.

**Note**

**Advanced configuration of the startup characteristics for the dosing block**

Note that you can further affect the startup characteristics of the dribbling quantity via the `Feature2.Bit7` as a function of this `Feature.Bit0`. Refer to the sectionUse the last value following a complete download as the current value during startup of the block (Page 165)

### Defining the startup characteristics for counter blocks

**Bit = 0**: On startup, the counter is stopped and reset to the value specified in the input parameter.

**Bit = 1**: On startup, counting continues with the most recently stored value.

Input parameters for the startup characteristics of the counter blocks:

- Block CountOh: Input parameter `PresetTime`
- Block CountScL: Input parameter `PresetVal`
- Block TotalL: Input parameter `PresetVal`

Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter `RunUpCyc`.

**Note**

**Advanced configuration of the startup characteristics for the counter blocks**

Note that you can further affect the startup characteristics via the `Feature.Bit5` as a function of this `Feature.Bit0`. Refer to the section Use the last value following a complete download as the current value during startup of the block (Page 165).

### Defining startup characteristics for the Average block

**Bit = 0**: At startup, averaging begins with the value that is currently at the input parameter `(Out = In, NumCycles = 1)`.

**Bit = 1**: When starting-up, the last `Out` and `NumCycles` values saved are used as the last value for averaging `(Out ≠ In)`.

### Defining startup characteristics for the TimeTrig block

**Bit 0 =0**: Periodic trigger and single trigger can be shut off. The trigger pulse `Trigger` is reset.

**Bit 0 =1**: The activation of the periodic trigger and single trigger as well as the single trigger point are retained.

The InPerTrigOn, InSglTrigOn and InSglTrigDT inputs are applied for this. If you want to use the reset for a complete download, you must read back the marked parameters in addition to the operated and monitored parameters before a complete download.

### See also

User-configured message classes (Page 45)

## 2.1.9.5 Applying the dynamically activated dead band during the PV settling time

### `Feature` bit

Number of the `Feature` bit: 30.

### Dynamic deactivation of the dead band by the `PV` settling time

You can use this `Feature` bit to improve the `PV` settling time in the range of the dead band.

The deadband is deactivated until the `PV` settles more in the center than at the edges of the dead band. The probability that the controlled variable is within the dead zone time is increased, and further control actions are no longer necessary. This leads to reduced wear and less energy consumption.

**Bit = 0**: Dead band width is constant

**Bit = 1:** The dead band is deactivated for the `PV` settling time. When the `PV` settling time is over, the dead zone gets the value of the `DeadBand` parameter.

**Note**

If `Feature.Bit30` = 1 is set, the ConPerMon block has to be connected with the controller. The blocks PIDConL or PIDConR monitor this by checking the status signal of `MeanMV.ST`. In case of `Feature.Bit30` = 1 and `MeanMV.ST` = 16#78 the dynamic deactivation of deadband is not possible and the output `ErrorNum` will be set to 52.

## 2.1.9.6 Evaluation of signal status

### Feature bit

Number of the `Feature` bit: 23

### Evaluation of signal status

You can use the Feature bit to specify if the signal status of the inputs is to be checked for the values 16#00 or 16#28. The signal status of the inputs itself remains unchanged here.

The default setting is 0.

**Bit = 0**: No evaluation of the signal status for 16#00 or 16#28.

**Bit = 1**: the signal status is determined, an input with ST = 16#00 or 16#28 is forwarded with value = 0. The "Negate signal" function at the input of the block has no influence on the reaction in this case.

## 2.1.9.7 Evaluation of the signal status of the interlock signals

Feature / Feature2 bit

Number of the Feature / Feature2 bit: 5

### Family

Family: Operate number of the Feature bit: 5

Family: Control, drives, dosage number of the Feature2 bit: 5

### Evaluation of the signal status of the interlock signals

You can use the Feature / Feature2 bit to specify if the signal status of the interlock inputs is to be checked for the values 16#00 or 16#28. The signal status of the inputs itself remains unchanged here.

The default setting is 0.

**Bit = 0**: the signal status is determined, an input with ST = 16#00 or 16#28 is forwarded with value = 0.

**Bit = 1**: No evaluation of the signal status for 16#00 or 16#28.

## 2.1.9.8 Automatic post dosing for underdosing in automatic mode

### Feature bit

Number of the Feature bit: 12

### Automatic post dosing for underdosing in automatic mode

Use this Feature bit to enable automatic post dosing for underdosing in automatic mode.

The default setting is 0.

**Bit = 0**: Disabled, no automatic post dosing is started for underdosing in automatic mode.

**Bit = 1**: Enabled, automatic post dosing is started for underdosing in automatic mode.

### 2.1.9.9 Block as summing unit or integrator

#### Feature bit

Number of the `Feature` bit: 6

#### Specifying the summing unit or integrator function mode

You can define the summing response of the block via this `Feature` bit.

The default setting is 0.

**Bit = 0**: The block operates as a summing unit.

**Bit = 1**: The block operates as an integrator.

---

**Note**

**Special note for the summing unit**

Note that the characteristics of the block as a summing unit (`Feature.Bit6` = 0) can be further affected via the `Feature.Bit7`.

Refer to the section: Summing characteristics continuous or triggered (Page 184).

---

### 2.1.9.10 Switching operator controls for external setpoint to visible

#### Feature bit

Number of the `Feature` bit: 21

#### Switching operator controls for external setpoint to visible

Use this `Feature` bit to switch all operator controls for the external setpoint to visible in the faceplates for the OS operator. This is always required when the external setpoint should actually be used, for example, for slave controllers in cascade and ration controlling.

The default setting is 0, which keeps the faceplate as clear as possible for simple applications.

**Bit = 0**: The operator controls for the external setpoint are **not visible** in the faceplate.

**Bit = 1**: The operator controls for the external setpoint are **visible** in the faceplate.

### 2.1.9.11 Limit output Out

#### Feature bit

Number of the `Feature` Bit: 5

#### Limit output `Out`

Use this `Feature` bit to define the limit for the output `Out`.

The default setting is 0.

**Bit = 0**: Beyond the end interpolation points, the `Out` output is extrapolated based on the first two or last two interpolation points.

**Bit = 1**: The `Out` output is limited to the first and last interpolation point.

#### See also

Configurable functions using the Feature I/O (Page 139)

### 2.1.9.12 Activating calculation of the flow rate for dosing by scale

#### Feature bit

Number of the `Feature` bit: 7

#### Calculation of the flow rate for dosing by scale

Use this `Feature` bit to activate calculation of the flow rate for dosing by scale.

The default setting is 0.

**Bit = 0**: Deactivated

**Bit = 1**: Calculation activated.

The flow is determined by the change to the dosing quantity per second.

### 2.1.9.13 Condition monitoring information at MOD_Blocks

#### Feature bit

Number of the `Feature` bit: 10

**Bit = 0**: Not forwarded

**Bit = 1**: forwarded

### 2.1.9.14 Condition monitoring information at the channel blocks

#### Feature bit

Number of the `Feature` bit: 10

#### Transferring condition monitoring information to the Maintenance Station

With this `Feature` bit, the data which is entered at the parameters `MS_Ext` and `TextRef` will be transferred to the corresponding driver block and the same data will be displayed on the asset faceplate of the Maintenance Station. For more information, refer to the *Maintenance Handbook*.

The default setting is 0.

**Bit = 0**: Data will not be transferred.

**Bit = 1**: Data will be transferred.

### 2.1.9.15 Disabling operating points

#### Feature bit

Number of the `Feature` bit: 28

#### Disabling operating points

You can use this `Feature` bit to determine if the operating point function of a limit for disabling the message (`MsgLock = 1`) should also be disabled.

The default setting is 0.

**Bit = 0**: Operating point is not suppressed

**Bit = 1**: Operating point is suppressed

### 2.1.9.16 Enabling direct changeover between forward and reverse

#### Feature bit

Number of the `Feature` bit: 7

#### Direct changeover between forward and reverse

With this `Feature` bit, you can enable direct reversal of the direction of motors.

The default setting is 0.

**Bit = 0**: Direct reversal of the direction is disabled.

You can only change the direction of the motor by first stopping and starting the motor again in the required direction. The motor can only be started again after the time set in the `IdleTime` parameter has elapsed.

**Bit = 1**: Direct changeover is enabled.

You can reverse the motor direction directly. The motor block reverses the direction automatically. The motor is stopped and is started in the other direction when the time set in the `IdleTime` parameter has elapsed.

**Note**

In case of automatic / local mode and Bit = 0:

If additional `Feature2.Bit3` =1 Control priority in the event of invalid or not plausible input commands is active, an automatic / local command for reverse direction is still possible. The motor stops for the time of IdleTime (minimum one cycle) then the reverse automatic / local command is plausible and a change of direction take place automatically.

### 2.1.9.17 Specifying the dosing type

#### Feature bit

Number of the `Feature` bit: 5

#### Specifying the dosing type

You can specify the dosing type to be used for the block using this `Feature` bit.

The default setting is 0.

**Bit = 0**: Flow

**Bit = 1**: Scales

### 2.1.9.18 Flow setpoints in percent

#### `Feature` bit

Number of the `Feature` bit: 15

#### Flow setpoints in percent

You can use this `Feature` bit to specify if the doser block should display the flow setpoints in the faceplate as percentages.

The default setting is 0.

**Bit = 0:** Deactivated. The display of the flow setpoints is made in the unit specified with the `PV_Unit` parameter.

**Bit = 1:** Activated: The display of the flow setpoints is made in the unit %.

### 2.1.9.19 Specifying the influence of the signal status on the dosing process

#### Feature bit

Number of the `Feature` bit: 23

#### Specifying the influence of the signal status on the dosing process

You can use this `Feature` bit to specify how the doser should react dependent on the signal status.

The default setting is 0.

**Bit = 0:** Dosing process does not stop with bad signal status of the process value `PV`.

**Bit = 1:** Dosing process stops with bad signal status of the process values `PV`. The doser is also set to the "Off" state (see state diagram: DoseL functions (Page 1312)).

See also the following section:

- Forming and outputting signal status for blocks (Page 116)

### 2.1.9.20 Unit for the rate of change

#### Feature bit

Number of the `Feature` bit: 8

#### Specifying the unit for the rate of change

You can use this `Feature` bit to specify the unit for the rate of change:

The default setting is 0.

**Bit = 0:** unit for the rate of change in the unit of measurement to or from the field device

**Bit = 1:** unit for the rate of change as a percentage to or from the field device

### 2.1.9.21 Reading messages

#### Feature bit

Number of the `Feature` bit: 28

#### Use of the input data

You can use this `Feature` bit to specify the format for reading messages.

Default setting is 0

Bit = 0: Messages are read as PV freely configurable

Bit = 1: Messages are read as MsgNamur

**Note**

This `Feature` bit is only used when "Telegram type 20" and the "PZD 6" parameter are active.

### 2.1.9.22 Setting the scaling for the process values

#### Feature Bit

Number of the Feature Bit: 5

#### Calculation for the outputs CurrentLi, Power1Li, Power2Li, FreeLi

`Feature.Bit5` defines whether the PZDIN**X**Scale is used for the calculation for the other process values.

Bit = 0: **xxxx**.Value := (PZD**X**In*(100/16384.0));

Bit = 1: **xxxx.**Value := (PZD**X**In*(( PZDIn**X**Scale.HIGH- PZDIn**X**Scale.LOW)/16384.0))+ PZDInXScale.LOW;

### 2.1.9.23 Outputting a de-energized value for block-external simulation

#### Feature bit

Number of the `Feature` bit: 30

#### Outputting a de-energized value for block-external simulation

Use this `Feature` bit for channel blocks to specify which value is to be output during the block-external simulation (Simulating signals (Page 64)).

The default setting is 1.

**Bit = 0:** If process value input has the status `16#60`, the output value will be set to the input value.

**Bit = 1:** If process value input has the status `16#60`, the output value will be set to “0”.

### 2.1.9.24 Switch to substitute value

#### Feature bit

Number of the `Feature` bit: 8

### Switch to substitute value

You can use this `Feature` bit to specify whether a substitute value should be applied or the last valid value should be retained when certain conditions occur.

The default setting is 0.

**Bit = 0**: Retain last valid value

**Bit = 1**: Apply the substitute value

### See also

Output invalid raw value (Page 185)

Outputting last valid value if raw value is invalid (Page 165)

## 2.1.9.25 Substitute value switch in the event of an error

### Feature bit

Number of the `Feature` bit: 6

### Substitute value switch in the event of an error

You can specify the substitute value activation at errors using this `Feature` bit.

The default setting is 0.

**Bit = 0**: No substitute value switch

**Bit = 1**: The substitute value `SubV_In` is output at `Out` for `ErrorNum` ≠

### See also

Configurable functions using the Feature I/O (Page 139)

## 2.1.9.26 Output substitute value if raw value is invalid

### Feature bit

Number of the `Feature` bit: 29

### Output substitute value if raw value is invalid

Use this `Feature` bit to activate output of the substitute value (input parameter `SubsPV_In`) for channel blocks if there is an invalid raw value or the device is in the initialization phase (input parameter `PV_ST` 16#4C..4F).

The default setting is 0.

**Bit = 0**: If there is an invalid raw value or the device is in the initialization phase, the substitute value is not output.

**Bit = 1**: If there is an invalid raw value or the device is in the initialization phase, the substitute value is output. The signal status of the output value is set to "Manipulated value (for example, substitute value, simulation, last valid value).

If there is an invalid raw value or the device is in the initialization phase, the output parameter `Bad = 1` is set automatically.

#### Prioritizing the `Feature` bits for channel blocks:

You need to assign parameters for three `Feature` bits for the response to an invalid raw value for the channel blocks.

If more than one of these `Feature` bits are set (=1), the following priority applies:

- Output invalid raw value (Page 185) (`Feature.Bit28` = highest priority)
- Output substitute value if raw value is invalid (`Feature.Bit29`)
- Outputting last valid value if raw value is invalid (Page 165) (`Feature.Bit30` = lowest priority)

The raw value is output of none of the `Feature.Bit28`, `Feature.Bit29` or `Feature.Bit30` is set.

### 2.1.9.27 Activating recording of the first signal

#### Feature Bit

Number of the `Feature` bit: 31

#### Activating recording of the first signal

Use this `Feature` bit to activate recording of the first signal with interlock blocks. Please also refer to the section Recording the first signal for interlock blocks (Page 58).

Default setting is 0

**Bit = 0**: Recording of the first signal is deactivated.

**Bit = 1**: Recording of the first signal is activated.

### 2.1.9.28 External control deviation

#### Feature bit

Number of the `Feature` bit: 14

#### External control deviation

You can use this `Feature` bit to specify whether the external control deviation is to be activated.

The default setting is 0.

**Bit = 0**: The external control deviation is deactivated, the internal control deviation is active.

**Bit = 1**: The external control deviation is activated.

### 2.1.9.29 Activating error state for external process control error CSF

#### Feature bit

Number of the `Feature` bit: 18

#### Activating error state for external process control error CSF

You can use this `Feature` bit to specify whether the block should switch to the error state at an external process control error CSF =1.

The default setting is 0.

**Bit = 0**: : Block does not go to error state with process control error CSF = 1.

**Bit = 1**: Activated: Block goes to error state with process control error CSF = 1.

### 2.1.9.30 Frequency converter with separate device feed

#### Feature bit

Number of the `Feature` bit: 15

#### Frequency converter with separate device feed

You can use this `Feature` bit to specify if a frequency converter with a separate device feed or the inverter enable should be used.

The default setting is 0.

**Bit = 0**: Motor without device feed or without inverter enable

**Bit = 1**: Frequency converter with separate device feed or with inverter enable

### 2.1.9.31 Separate evaluation for excluded and simulated interlock signals

#### Feature bit

Number of the `Feature2` bit: 2

### Separate evaluation for excluded and simulated interlock signals

You can use this `Feature` bit to set the reaction of the block to an interlock signal of an interlock block that is excluded or simulated.

The default setting is 0

**Bit = 0**: Switch-relevant excluded and simulated interlock signals are processed with the status 16#60 and are displayed as simulated or excluded, depending on the interlock status.

**Bit = 1**: Excluded and simulated interlock signals are evaluated separately. All excluded interlock signals in a sequence of interlock blocks are displayed as excluded. Switch-relevant simulated interlock signals are processed with the status 16#60 and displayed as simulated.

**Note**

If the `Feature` Bit is enabled, the signal cannot be inverted via CFC during interconnections at the inputs, as, otherwise, the bypass display would not update.

The interlocking inputs of the following blocks are affected:

- **Intlk02**, **Intlk04**, **Intlk08**, **Intlk16**: `In01, In02, …`
- **DoseL**, **Vlv2WayL**: `Permit, Interlock, Protect`
- **MotL**, **VlvL:** Permit, `Interlock, Protect,PermitSafePos`
- **MotRevL, MotSpdCL**: `Permit, Interlock, Protect , PermRev, IntlRev, ProtRev, PermitSafePos`
- **MotSpdL**: `Permit, Interlock, Protect , PermSp2, IntlSp2, ProtSp2, PermitSafePos`
- **VlvAnL,VlvMotL**, **VlvPosL**: `Permit, Interlock, Protect , PermCls, IntlCls, ProtCls, PermitSafePos`
- **MotS**, **VlvS**, **OpDi01**, **OpDi03**, **PIDConL**, **PIDConR**: `Interlock`

The inversion of the interlocking signals occurs via the `InvIn01`, `InvIn02`, ... inputs on the interlocking blocks.

### 2.1.9.32 Use an internal or external setpoint for the absolute fine dosing quantity

#### Feature Bit

Number of the `Feature` bit: 8

#### Use an internal and external setpoint for the absolute fine dosing quantity

Use this `Feature` bit to determine whether the doser processes the internal and external setpoint for the fine dosing quantity in an absolute manner and is displayed or operated in an absolute manner in the faceplate.

The default setting is 0.

**Bit = 0**: Deactivated. The internal and external I/Os as well as the display and operation of the fine dosing quantity setpoint are processed in the % unit.

**Bit = 1**: Activated: The internal and external I/Os as well as the display and operation of the fine dosing quantity setpoint are processed in the unit that was set using the parameter `DQ_Unit`.

### 2.1.9.33 Activating the run time of feedback signals

#### Feature Bit

Number of the `Feature` bit: 11

#### Activating the run time of feedback signals

Use this `Feature` bit to activate the run time of feedback signals.

The default setting is 0.

**Bit = 0**: Deactivated: Tracking of feedback for simulation immediately after the trigger signal.

**Bit = 1**: Activated: Tracking of feedback for simulation after the trigger signal and expiration of the monitoring time (`MonTiDynamic`). The feedback signals are generated after expiration of the monitoring time.

### 2.1.9.34 Outputting last valid value if raw value is invalid

#### Feature bit

Number of the `Feature` bit: 30

#### Outputting last valid value if raw value is invalid

Use this `Feature` bit to activate output of the last valid value for channel blocks if there is an invalid raw value or the device is in the initialization phase (input parameter PV_ST = 16#4C..4F).

The default setting is 0.

**Bit = 0**: If there is an invalid raw value or the device is in the initialization phase, the last valid value is not output.

**Bit = 1**: If there is an invalid raw value or the device is in the initialization phase, the last valid value is output. The signal status of the output value is set to local "Manipulated value (for example, substitute value, simulation, last valid value).

If there is an invalid raw value or the device is in the initialization phase, the output parameter `Bad = 1` is set.

#### Prioritizing the `Feature` bits for channel blocks:

You need to assign parameters for three `Feature` bits for the response to an invalid raw value for the channel blocks.

If more than one of these `Feature` bits are set (=1), the following priority applies:

- Output invalid raw value (Page 185) (`Feature.Bit28` = highest priority)
- Output substitute value if raw value is invalid (Page 160) (`Feature.Bit29`)
- Output the last valid value if raw value is invalid (`Feature.Bit30`, lowest priority)

The raw value is output of none of the `Feature.Bit28`, `Feature.Bit29` or `Feature.Bit30` is set.

### 2.1.9.35 Use the last value following a complete download as the current value during startup of the block

#### Feature bit

Number of the `Feature` bit: 5

Number of the `Feature2` bit: 7

#### Use the last value during startup of the block after a complete download of the CPU

You can use this `Feature` bit to define the startup characteristics of the block as a function of the `Feature` bit `0`.

This `Feature` bit is used on the following parameters:

- Block TotalL: `OldOut`, `OldCntOut`
- Block CountScL: `OldOut`
- Block CountOh: `OldDays`, `OldHours`, `OldMinutes`, `OldSeconds`
- Block DoseL: `OldDribbOut`

For the settings on `Feature.Bit0`, refer to the section: Set startup characteristics (Page 148).

**Note**

If you want to use this function, you must read back the marked parameters in addition to the operated and monitored parameters before a complete download.

The default setting is 0.

**Bit = 0**: Define the startup characteristics as a function of `Feature.Bit0`:

- Counter blocks:
  - `Feature.Bit0` = 0: The block is set to the default value (input parameter Preset) during startup.
  - `Feature.Bit0` = 1: On startup, counting continues with the most recently stored value.
- Block DoseL:
  - `Feature.Bit0` = 0: The dosing is ended, and the dribbling quantity is set to input `DribbIn`.
  - `Feature.Bit0` = 1: On startup, dosing works with the most recently stored value of `DribbOut`.

**Bit = 1**: During startup of the block after a complete download, the last value `(Oldxxx)` is used as the current value regardless of `Feature.Bit0` ( Set startup characteristics (Page 148)).

### 2.1.9.36 Activate LowCutOff

#### Feature bit

Number of the `Feature` bit: 5

#### Activate LowCutOff

You use this `Feature` bit to activate the use of LowCutOff bits.

The default setting is 0.

**Bit = 0**: Low signal cut-off - OFF (default)

**Bit = 1**: Low signal cut-off - ON

### 2.1.9.37 Selecting values associated with messages

#### Feature Bit

Number of the `Feature` bit: 27

#### Selecting values associated with messages

Use this `Feature` bit to select which values associated with messages are to be output.

The default setting is 0.

**Bit = 0**: The signal status of the binary input is output as the value associated with messages.

**Bit = 1**: The associated analog value is output as the value associated with messages.

### 2.1.9.38 Reporting with BATCH parameters

#### Feature bit

Number of the `Feature` bit: 8

**Reporting with BATCH parameters**

You can use this `Feature` bit to specify whether the block transfers the BATCH parameters

- `BatchID`: Batch ID
- `BatchName`: Batch name
- `StepNo`: Batch step number

Are transferred as associated values to the OS during messaging.

The default setting is 0.

**Bit = 0**: The block does not transfer any BATCH parameters to the OS.

**Bit = 1**: The block transfers BATCH parameters to the OS.

---

**Note**

**Information about the setting "Bit = 1:**

The Event block can no longer transfer the `In8.ST` or `AV8.Value` as an associated value.

The EventTS block can no longer transfer the signal status of the signal `In7` and `In8` or `InTS7` and `InTS8` as an associated value.

---

You will find more information in the following chapters:

- Event messaging (Page 2023)
- EventTs messaging (Page 2049)

### 2.1.9.39 Motor feedback is not available

#### Feature bit

Number of the `Feature` bit: 12

#### Motor feedback is not available

You can use this `Feature` bit to specify whether or not motor feedback should be available.

The default setting is 0.

**Bit = 0**: Motor feedback is available.

**Bit = 1:** Motor feedback is not available. The motor feedback is derived from the control signals internally in the block; this disables the monitoring of the motor feedback.

### 2.1.9.40 Display only input values that are interconnected in the faceplate

#### Feature bit

Number of the `Feature` bit: 5

#### Display only input values that are interconnected in the faceplate

You can use this `Feature` bit to specify whether only interconnected input values `In01` to `In16` (status not equal to 16#FF) should be displayed in the faceplate.

The default setting is 0.

**Bit = 0**: Display all input values.

**Bit = 1**: Display only interconnected input values (status not equal to 16#FF) and in case inputs are not connected, the faceplate size should shrink to the last connected input.

### 2.1.9.41 Activate OS_Perm bits

#### Feature bit

Number of the `Feature` bit: 5

#### Display only input values that are interconnected in the faceplate

You use this `Feature` bit to activate the use of additional `OS_Perm` bits in the faceplate.

The default setting is 0.

**Bit = 0**: `OS_Perm` bits XXX inactive

**Bit = 1**: `OS_Perm` bits XXX active

**With XXX**:

| Block | OS_Perm.BitX |
|---|---|
| Intlk02 | 16-17 |
| Intlk04 | 16-19 |
| Intlk08 | 16-23 |
| Intlk16 | 16-31 |

| OS_Perm.Bit16 | OS_Perm.Bit0 | OS_Perm.Bit1 | Operation exclusion "Set" In01 | Operation exclusion "Reset" In01 |
|---|---|---|---|---|
| 0 | 0 | 0 | No | No |
| 0 | 0 | 1 | No | Yes |
| 0 | 1 | 0 | Yes | No |
| 0 | 1 | 1 | Yes | Yes |
| 1 | X | X | Yes | Yes |

### 2.1.9.42 Disabling opening and closing

#### Feature bit

Number of the `Feature` bit: 6

#### Disabling the Open and Close commands

Only applicable when no auxiliary valve is used (bit 5 = 0)

**Bit = 0:** Open and Close commands affect control valve

**Bit = 1:** Disable the Open and Close commands

### 2.1.9.43 Enabling local operator authorization

#### Feature bit

Number of the `Feature` bit: 24

#### Enabling local operator authorization

You can use this `Feature` bit to enable local permission for a technologic block.

The default setting is 0.

**Bit = 0**: Disabled

**Bit = 1**: Enabled

For information on this operator permission, refer to the section Operator control permissions (Page 285).

### 2.1.9.44 Enable configuration of the dribbling quantity

**Feature bit**

Number of the `Feature` bit: 27

#### Enable configuration of the dribbling quantity

With this `Feature` bit, you can enable configuration of the dribbling quantity during dosing.

The default setting is 0.

**Bit = 0**: Disabled, the dribbling quantity can only be configured in the "End" state or with the automatic determination of the dribbling quantity (`DribbCor` = 1).

**Bit = 1**: Enabled, the dribbling quantity can always be configured, but not in the "Dribbling" state. The automatic determination of the dribbling quantity must be switched off (`DribbCor` = 0).

### 2.1.9.45 Enabling program mode

#### Feature bit

Number of the `Feature` bit: 19

#### Enabling program mode

You can use this `Feature` bit to specify whether or not the controller block should be used for program mode.

Default setting is 0.

**Bit = 0**: The block is not intended for program mode.

**Bit = 1**: The block can be used for program mode. The operator control elements required for this are then visible in the faceplate.

**Note**

This `Feature` bit only applies to the PIDConR block.

#### What is the program mode?

Program mode provides primary controller functions (external Advanced Control software package), which run on an external PC as an OPC client, the option of using the control from the controller function block and specifying the setpoint or manipulated variable from a remote location.

### 2.1.9.46 Update acknowledgment and error status of the message call

#### Feature bit

Number of the `Feature` bit: 22

#### Update acknowledgment and error status of the message call

You can use the `Feature` bit to determine if the acknowledgment and error status of the message call at the block output should be updated.

The default setting is 0.

- **Bit = 0**: The `MsgErr`, `MsgStat` and `MsgAckn` block outputs are set to the default settings and not updated. The block will run faster with this setting.
- **Bit = 1**: The `MsgErr`, `MsgStat`and `MsgAckn` block outputs re updated based on the feedback of the lower level message blocks. The lower level message blocks are called every other cycle as long as an acknowledgment is expected or error information is pending.

### 2.1.9.47 Control zone with frozen I component

#### Feature bit

Number of the `Feature` bit: 13

#### Freezing the I component for control with control zone

You can use this `Feature` bit to specify how the controller should react to control zone operation. The I component must be enabled for this TI <> 0.

The default setting is 0.

**Bit = 0**: The I component is set in such a way that the manipulated variable reacts bumplessly when the error signal reoccurs in the control zone.

**Bit = 1**: If the error signal is outside the control zone, the I component is frozen internally. When it enters the control zone, the controller starts with the value of the I component that was in effect when it left the control zone.

The reaction depends on additional `Feature` bits and controller settings. See also the following section:

- Using control zones (Page 220)

### 2.1.9.48 Control zone with specified I component

#### Feature bit

Number of the `Feature` bit: 12

### Specifying I component for control with control zone

You can use this `Feature` bit to specify how the controller should react to control zone operation. The I component must be enabled for this TI <> 0.

The default setting is 0.

**Bit = 0**: The I component is set in such a way that the manipulated variable reacts bumplessly when the error signal reoccurs in the control zone.

**Bit = 1**: If the error signal is outside the control zone, the I component is set internally as follows:

- `I_Part := MV_Offset`.

The reaction depends on additional `Feature` bits and controller settings. See also the following section:

Using control zones (Page 220)

## 2.1.9.49 Resetting the commands for changing the mode

### Feature Bit

Number of the `Feature` bit: 2

### Resetting the commands for changing the mode

Using this `Feature` bit, you define how the block handles the incoming control commands:

- `SP_IntLi` and `SP_ExtLi` for controllers
- `AutModLi` and `ManModLi` for controllers, drives, and dosage block
- `SaPo_Ext` for KalFilt block
- `OffLi`, `UpLi`, and `DnLi` for TotalL block

The default setting is 0.

**Bit = 0**: The control commands are not reset by the block. If there are two pending control commands for changing mode, the mode is not changed. In this case, the note text "Invalid command" is displayed in the faceplate.

**Bit = 1**: The control commands are reset by the block. This, for example, ensures that if a control command is sent from the SFC, the command is reset automatically after a step is exited.

## 2.1.9.50 Enabling resetting of commands for the control settings

### Feature bit

Number of the `Feature` bit: 3

### Enabling resetting of commands for the control settings

With this `Feature` bit, you select how the block handles commands for the control settings (for example motor on) via the interconnected input parameters.

The default setting is 0.

**Bit = 0**: The control commands are not reset by the block. If there are two commands relating to the control settings at the same time, the status of the control settings is retained. In this case, the "Invalid signal" message is displayed in the standard view of the faceplate.

**Bit = 1**: The control commands are reset by the block. This, for example, ensures that if a control command is sent from the SFC, the command is reset automatically after the step is exited.

## 2.1.9.51 Resetting the dosing quantity when dosing starts

### Feature bit

Number of the `Feature` bit: 6

### Resetting the dosing quantity when dosing starts

Use this `Feature` bit to enable resetting the dosing quantity when dosing starts.

The default setting is 0.

**Bit = 0**: Disabled, the dosing quantity is not reset when dosing starts

**Bit = 1**: Enabled, the dosing quantity is reset when dosing starts.

## 2.1.9.52 Process value with separate scale range

### Feature bit

Number of the `Feature` bit: 16

### Process value with separate scale range

You can use this `Feature` bit to assign a separate scale range to the process value. The default setting is 0.

**Bit = 0**: Apply scale range from `SP`.

**Bit = 1**: `PV` has a separate scale range.

### See also

Neutral position for motors, valves and controllers (Page 54)

Neutral position manipulated variable takes effect at startup (Page 176)

Use the last value following a complete download as the current value during startup of the block (Page 165)

### 2.1.9.53 Resetting via input signals in the event of interlocking (Protection) or errors

#### Feature Bit

Number of the `Feature` bit: 9

#### Resetting with automatic commands (e.g. `OpenAut`, `CloseAut`)

With this `Feature` bit, you define that an automatic control with its input commands (e.g. `OpenAut`, `CloseAut`) also resets an interlock protection or an error.

The default setting is 0.

**Bit = 0**: No resetting.

**Bit = 1**: Reset an interlock protection or an error with a 0-1 edge change in the inputs for automatic commands (e.g. `OpenAut`, `CloseAut`).

### 2.1.9.54 Set reset depending on the operating mode or the LiOp parameter

#### `Feature` Bit

Number of the `Feature` Bit: 30

#### Set reset depending on the operating mode (motor, valve and dosing blocks)

When the "Protection" interlock, feedback error ("Status error", "Control error") or "Motor protection" signal is present again, use this `Feature` bit to specify if a reset can be made depending on the mode only by the operator in manual mode or only by the automatic I/Os in automatic mode.

Resetting to manual mode is enabled with `Feature.Bit31` (Activating reset of protection / error in manual mode (Page 175)). Also refer to the Resetting the block in case of interlocks or errors (Page 47) chapter.

The default setting is 0.

**Bit = 0:** Reset does not depend on the operating mode

**Bit = 1:** In manual mode, manual reset by the operator is only possible if `Feature.Bit31` is set, otherwise no reset is required in manual mode.

In automatic mode, reset can only be made with automatic I/Os, regardless of `Feature.Bit31`. This is performed either with a 0-1 edge transition at the `RstLi` input or, when `Feature.Bit9` is set, with a 0-1 edge transition at the automatic inputs, for example `OpenAut`, `CloseAut`.

**Note**

Rapid stop is unlocked for all operating modes using the "Reset" button in the faceplate (`RstOp = 1`); in CFC it is unlocked using the `RstLi = 1` input parameter.

**Note**

The local operating mode does not depend on this Feature Bit and has a separate reset mechanism.

### Resetting the dosing mode depending on the operating mode (dosing blocks)

You can also use this Feature bit to set whether or not the reset of the dosing quantity is dependent on the operating mode.

The default setting is 0.

**Bit = 0:** Reset does not depend on the operating mode

**Bit = 1:**In manual mode, only a manual reset by the operator is possible at the input RstDQ_Op. In automatic mode, a reset is only possible by a 0-1 edge transition at the input RstDQ_Li.

**Note**

The operating mode Local is independent of this Feature bit. The dosing quantity can be reset by the operator at the input RstDQ_Op or via a 0-1 edge transition at the input RstDQ_Li.

### Set reset depending on the LiOp parameter (counter blocks)

You can use this Feature Bit to determine whether the setting or resetting to a default value should be made dependent on the LiOp parameter.

The default setting is 0.

**Bit = 0:** Setting or resetting to a default value does not depend on the LiOp parameter.

**Bit = 1:** Setting or resetting to a default value depends on the LiOp parameter.

LiOp **=0:** Setting or resetting to a default value can only be made via the faceplate or at the parameter for the faceplate.

LiOp **=1**: Setting or resetting to a default value can only be made at the parameter for interconnections.

## 2.1.9.55 Activating reset of protection / error in manual mode

### Feature bit

Number of the Feature bit: 31

### Activating reset of protection / error in manual mode

Use this Feature bit to specify whether a reset is necessary once the "Protection" interlock signal, feedback errors ("Runtime error", "Control deviation"), or "Motor protection" are present again. See also the following section: Resetting the block in case of interlocks or errors (Page 47).

The default setting is 0.

**Bit = 0:** No reset required in manual mode.

**Bit = 1:** Reset required in manual mode. The reset is performed using the "Reset" button (`RstOp = 1`) or, in CFC, using the input parameter `RstLi`.

**Note**

Rapid stop is unlocked for all operating modes using the "Reset" button in the faceplate (`RstOp = 1`); in CFC it is unlocked using the `RstLi = 1` input parameter.

**Note**

The local operating mode has a separate reset mechanism.

### 2.1.9.56 Reset even with locked state

#### Feature Bit

Number of the `Feature` bit: 19

#### Reset even with locked state

With this `Feature` bit, you specify if it is possible to perform a reset with an active "Protection" or "Motor protection" type interlock. This can be used, for example, to reset hardware interlocks.

The default setting is 0.

**Bit = 0**: No reset is possible with a "Protection" type interlock or with active motor protection.

**Bit = 1**: Reset is possible with a "Protection" type interlock or with active motor protection.

### 2.1.9.57 Neutral position manipulated variable takes effect at startup

#### Feature Bit

Number of the `Feature` bit: 16

#### Neutral position manipulated variable takes effect at startup

You can use this `Feature` bit to specify if the block should go to the neutral position at startup.

Default setting is 0

**Bit = 0**: The block does not go to the neutral position at startup

With control valve VlvAnL, the main valve is closed and the auxiliary valve (if configured) opened.

**Bit = 1**: The block goes to the neutral position at startup

With control valve VlvAnL, the main valve and auxiliary valve (if configured) go to the neutral position.

You can find more information in Section Neutral position for motors, valves and controllers (Page 54).

**Note:**

`Feature.Bit16` is only effective when `Feature.Bit0` = 0.

### 2.1.9.58 Neutral position manipulated variable takes effect with "out of service" operating mode

#### Feature Bit

Number of the `Feature` bit: 15

#### Neutral position manipulated variable takes effect with "out of service" operating mode

You can use this `Feature` bit to specify if the block should go to the neutral position when it transitions to the "Out of service" operating mode.

Default position is "0".

**Bit = 0**: The block does not go to the neutral position at the transition to the "out of service" operating mode.

**Bit = 1**: The block goes to the neutral position at the transition to the "out of service" operating mode.

Refer to the Neutral position for motors, valves and controllers (Page 54) section for more information.

### 2.1.9.59 Setting switch or button mode

#### Feature bit

Number of the `Feature` bit: 4

#### Setting switch or button mode (input signal as pulse signal or as static signal)

You can use this `Feature` bit to determine whether a separate interconnectable 1-active control input has to be used for every automatic command of the block or two automatic commands are assigned to a control input.

The `Feature` bit impacts the following control inputs for automatic mode in the form of a pulse (push-button operation) or a static signal (switch operation):

- Starting and stopping a motor
- Opening and closing a valve

- Switching modes: Automatic and Manual (parameters `AutModLi` and `ManModLi`)
- Setpoint specification: Internal and External (parameters `SP_ExtLi` and `SP_IntLi`)

is given in the form of a pulse (pushbutton operation) or a static signal (switching mode).

**Note**

The input commands are checked for plausibility. For more information, see Error handling (Page 128), e.g. MotL error handling (Page 1390) and `Feature2.Bit3` (Control priority in the event of invalid or not plausible input commands (Page 186)).

You can find the commands for controlling the block in the relevant section on block operating modes. They are always the parameters that are used for the automatic operation of a block.

**Bit = 0**: Button mode: Each automatic command is assigned to a control input. This has a latching reaction and is 1-active.

**Example with a motorMotRevL**: In this case, use the interconnectable input parameters.

- `FwdAut` = `1` for the command "Start forward"
- `RevAut` = `1` for the command "Start backwards"
- `StopAut` = `1` for the stop command and
- `AutModLi` = `1` for setting "Automatic" operating mode
- `ManModLi` = `1` for setting "Manual" operating mode

**Bit = 1**: Switching mode: two static automatic commands are assigned to a control input.

**Example with a motorMotRevL**: In this case, use the interconnectable input parameters.

- `FwdAut` = `1` for the command "Start forward"
- `RevAut` = `1` for the command "Start backwards" and
- `FwdAut` = `0` and `RevAut` = `0` for the stop command
- `AutModLi` = `1` for setting "Automatic" operating mode
- `AutModLi` = `0` for setting "Manual" operating mode

The `StopAut` and `ManModLi` control inputs are irrelevant in this case.

### 2.1.9.60 Specifying switching mode

#### Feature Bit

Number of the `Feature` bit: 5

#### Specifying switching mode

Use this `Feature` bit to specify switching mode for the motor block.

The default setting is 0.

**Bit = 0**: Switching mode "On over speed 1" with the `SwOverTi > 0` parameter

**Bit = 1**: Switching mode "Off over speed 1" with the `SwOverTi > 0` parameter

**Note**

This `Feature` bit is only used with the `SwOverTi > 0` parameter. Refer also to the MotSpdL functions (Page 1563) section for more on this.

### 2.1.9.61 Creep rate is always detected in the dosing quantity

#### Feature Bit

Number of the `Feature` bit: 13

#### Enable: Creep rate is always detected in the dosing quantity

Use the `Feature` bit to specify the response for detecting the creep rate in the dosing quantity.

The default setting is 0.

**Bit = 0**: Disabled, the creep rate is only detected in the dosing quantity over the limit `CR_AH_Lim` (high alarm for creep rate). With `CR_AH_En = 0`, the creep rate has no effect on the dosing quantity calculation.

**Bit = 1**: Enabled, the creep rate is always detected in the dosing quantity.

**Note**

Creep rate is the flow in the states "End", "Off", and "Pause".

### 2.1.9.62 Enabling rapid stop via faceplate

#### Feature bit

Number of the `Feature` bit: 14

#### Enabling rapid stop via faceplate

You can use the `Feature` bit "Enable rapid stop via faceplate" to specify if the OS operator can use rapid stop for the block via the standard view of the faceplate.

The default setting is 0.

**Bit = 0**: The "Rapid stop" button is not visible in the faceplate.

**Bit = 1**: The OS operator can use the button for rapid stop.

### 2.1.9.63 Position feedback signals are active

**Feature bit**

Number of the `Feature` bit: 12

### Position feedback signals are active

You can use this `Feature` bit to activate the position feedback signals (`FbkP1` and `FbkP2`) and deactivate the separate valve feedback signals (`FbkV0`, `FbkV1` and `FbkV2`). In the trend view and preview, the position feedback signals and control signals `Pos0Out, Pos1Out, Pos2Out` are used for display.

Default: 0

**Bit = 0**: The valve feedback signals `FbkV0`, `FbkV1`, `FbkV2` are active. The position feedback signals `FbkP1`, `FbkP2` are deactivated.

**Bit = 1**: The position feedback signals `FbkP1`, `FbkP2` are activate. The valve feedback signals `FbkV0`, `FbkV1`, `FbkV2` are deactivated.

**Note**

`SafeV0`, `SafeV1, SafeV2` and `DefPos1`, `DefPos2` are only used for configuring the icon displays in the OS.

## 2.1.9.64 Separate monitoring time for stopping the motor

### Feature bit

Number of the `Feature` bit: 13

### Separate monitoring time for stopping the motor

You can use this `Feature` bit to activate a separate monitoring time for stopping the motor.

The default setting is 0.

**bit = 0:** A monitoring time for starting and stopping the motor

**Bit = 1**: Separate monitoring time for stopping the motor

## 2.1.9.65 Separate interlock for each direction, position, or speed

### Feature bit

Number of the `Feature`2 bit: 16

### Separate interlock for each direction or position

You can use this `Feature` bit to enable the use of the "Separate interlock for each direction, position, or speed" function.

Default setting is 0

**Bit = 0**: One interlock for each direction, position, or speed.

**Bit = 1**: Separate interlock for each direction, position, or speed.

### 2.1.9.66 Separate delay times for each alarm

#### Feature bit

Number of the `Feature` bit: 8

#### Separate delay times for each alarm

You can use this `Feature` bit to activate the alarm delay type Two time values for each individual limit (Page 228).

The default setting is 0.

**Bit = 0**: The alarm delay type Two time values for each individual limit (Page 228) is deactivated.

**Bit = 1**: The alarm delay type Two time values for each individual limit (Page 228) is activated.

#### See also

User-configured message classes (Page 45)

Two time values per limit pair (Page 227)

### 2.1.9.67 Signaling limit violation

#### Feature bit

Number of the `Feature` bit: 29

#### Signaling limit violation

With this `Feature` bit, you specify how limit violation should be sent to the respective limit outputs.

The default setting is 0.

**Bit = 0**: Output value of the limit output = 1 (1 active)

**Bit = 1**: Output value of the limit output = 0 (0 active)

**Note**

To learn about the parameters with which you can influence this behavior, refer to the description of the connections for the respective blocks.

### 2.1.9.68 Alarm setpoint difference

#### Feature bit

Number of the `Feature` bit: 5

#### Setpoint difference should be alarmed

Use this `Feature` bit to activate alarming when a setpoint difference occurs.

The default setting is 0.

**Bit = 0:** Disabled: The message for the `ExtMsg2` and `ExtMsg3` parameters are output.

**Bit = 1:** Enabled: The messages for the `ER_H_Lim` or `ER_L_Lim` parameter are output instead of the message parameters `ExtMsg2` and `ExtMsg3`.

### 2.1.9.69 Setpoint specification with separate display area and custom unit

#### Feature bit

Number of the `Feature` bit: 16

#### Setpoint specification with separate display area and custom unit

You can use this `Feature` bit to specify the display area and the unit of the setpoint specification.

The default setting is 0.

**Bit = 0**: Setpoint specification and readback value have the same display area (`RbkOpScale`, `RbkUnit`)

**Bit = 1**: The setpoint specification has a separate display area and a custom unit (`SP_OpScale`, `SP_Unit`)

### 2.1.9.70 Control via auxiliary valve

#### Feature Bit

Number of the `Feature` bit: 5

#### Control via a auxiliary valve

You can use this `Feature` bit to specify if control should be performed by a auxiliary valve.

The default setting is 0.

**Bit = 0**: Control without auxiliary valve / no auxiliary valve present

**Bit = 1**: Control via auxiliary valve

### 2.1.9.71 Enabling bumpless change to the proportional gain, derivative time and amplification of the differentiator

#### Feature Bit

Number of the `Feature` bit: 20

#### Enabling bumpless change to the proportional gain, derivative time and amplification of the differentiator

Use this `Feature` bit to enable bumpless change to proportional gain `Gain`, derivative action time `TD` and gain of the differentiator in automatic mode.

The default setting is 0.

**Bit = 0**: The bumpless switchover is deactivated.

**Bit = 1**: The bumpless switchover is activated.

### 2.1.9.72 Enable bumpless switchover to "Automatic" mode for operator only

#### Feature bit

Number of the `Feature` bit: 21

#### Enable bumpless switchover to automatic mode for operator only

You can use this `Feature` bit to specify whether bumpless switchover to automatic mode for valves, motors and dosing unit should be enabled only if switching via the faceplate is in effect, or whether switching using interconnectable inputs `AutModLi` and `ManModLi` (`ModLiOp = 1`) is also possible.

The default setting is 0

**Bit = 0**: The function "Bumpless switchover to automatic mode for valves, motors and dosers" works when switching via the faceplate and switching using interconnectable inputs `AutModLi` and `ManModLi` (`ModLiOp = 1`).

**Bit = 1**: Bumping switchover can be activated via the inputs `AutModLi` and `ManModLi` (`ModLiOp = 1`)

### 2.1.9.73 Disabling bumpless switchover to automatic mode for controllers

#### Feature Bit

Number of the `Feature` bit: 18

### Changeover with or without P step change when the internal setpoint is not in tracking mode

Use this `Feature` bit to specify if a changeover should occur with or without a P step change when the internal setpoint (`SP_TrkPv = 0`) does not track the process value.

The default setting is 0.

**Bit = 0**: Changeover without P step change (bumpless)

**Bit = 1**: Changeover with P step change (not bumpless)

For more detailed information, refer to the description of Manual and automatic mode for control blocks (Page 79).

## 2.1.9.74 Enabling bumpless switchover to automatic mode for valves, motors, and dosers

### Feature bit

Number of the `Feature` bit: 17

### Bumpless switchover

You can use this `Feature` bit to enable the bumpless switchover from local/manual mode to automatic mode.

Default setting is 0

**Bit = 0**: Bumpless switchover is disabled. You can switch from local/manual mode to automatic mode at any time.

**Bit = 1**: Bumpless switchover from local/manual mode to automatic mode is enabled. A switchover from local/manual mode to automatic mode is only possible if the control settings of the local/manual mode and automatic modes match. If switchover occurs at a different point in time, this is indicated in the faceplate with the text "Switchover error".

Refer to the Manual and automatic mode for motors, valves and dosers (Page 82) section for more on this.

A second `Feature` bit is used to specify if pure bumpless switchover to automatic mode is only possible via the faceplate or if switching is also possible via the interconnectable parameters `AutModLi` and `ManModLi` (`ModLiOp = 1`).

Refer to the section Enable bumpless switchover to "Automatic" mode for operator only (Page 183).

## 2.1.9.75 Summing characteristics continuous or triggered

### Feature bit

Number of the `Feature` bit: 7

### Define summing characteristics

You can use this `Feature` bit to define the summing characteristics of the block as a function of the `Feature.Bit6` = 0. If you have set the `Feature.Bit6` = 1, this `Feature` bit has no function.

The default setting is 0.

**Bit = 0**: Triggered summing characteristics.

**Bit = 1**: Continuous summing characteristics.

## 2.1.9.76 Suppression of all messages

### Feature Bit

Number of the `Feature` bit: 25

### Suppression of all messages

You can use this `Feature` bit to determine whether all messages of the block are to be suppressed.

**Bit = 0:** Process messages are suppressed.

**Bit = 1:** All messages are suppressed.

## 2.1.9.77 Output invalid raw value

### Feature bit

Number of the `Feature` bit: 28

### Output invalid raw value

Use this `Feature` bit to activate output of the invalid raw value for channel blocks.

Default setting is 1

**Bit = 0**: The invalid raw value is not output. Either the substitute value (`Feature` bit Output substitute value if raw value is invalid (Page 160)) or the last valid value (`Feature` bit Outputting last valid value if raw value is invalid (Page 165)) is output.

**Bit = 1**: The invalid raw value is output. The signal status of the output value is set to "Bad, device related" or "Bad, process related".

If there is no valid raw value the output parameter `Bad` = `1` is set automatically.

### Prioritizing the `Feature` bits for channel blocks:

You need to assign parameters for three `Feature` bits for the response to an invalid raw value for the channel blocks.

If more than one of these `Feature` bits are set (=1), the following priority applies:

- Output invalid raw value (`Feature.Bit28` = highest priority)
- Output substitute value if raw value is invalid (Page 160) (`Feature.Bit29`)
- Outputting last valid value if raw value is invalid (Page 165) (`Feature.Bit30` = lowest priority)

The raw value is output of none of the `Feature.Bit28, Feature.Bit29 or Feature.Bit30` is set.

### 2.1.9.78 Transmission of status information of devices

#### Feature bit

Number of the `Feature` bit: 29

#### Transmission of status information of devices

You can use this `Feature` bit to specify if status information of the device should be transferred to the upstream diagnostics block.

The default setting is 1.

Bit = 0: No transfer of status information.

Bit = 1: Transfer status information of the device to the upstream diagnostics block.

### 2.1.9.79 Control priority in the event of invalid or not plausible input commands

`Feature2` **Bit**

Number of the `Feature`2 bit: 3

#### Control priority in the event of invalid or not plausible input commands

You can use this function to define the control priority in the event of invalid or not plausible input commands.

Default setting: 0

**Bit = 0**: In the event of invalid or not plausible input commands, the control output is retained.

**Bit = 1**: In the event of invalid or not plausible input commands, the control output switches to the "neutral position".

**Note**

To Bit = 1:

A change of direction in automatic / local mode with block `MotRevL`, `MotSpdCL` is possible although the `Feature.Bit7` =0 Enabling direct changeover between forward and reverse is not parameterized. The motor stops for the time of IdleTime (minimum one cycle) then the reverse automatic / local command is plausible and a change of direction take place automatically.

### 2.1.9.80 Sealing the valve

**Feature Bit**

Number of the `Feature` bit: 8

#### Sealing the valve

You can use this `Feature` to enable the valve sealing function. The torque shutoff is then also evaluated when the valve is closed.

The default setting is 0.

**Bit = 0**: "Seal valve" function is disabled.

**Bit = 1**: "Seal valve" function is enabled.

### 2.1.9.81 First-in detection response to deactivation

#### Feature Bit

Number of the `Feature` Bit: 21

#### First-in detection response to deactivation

You can use this `Feature` Bit to define the first-in detection response of the interlock blocks depending on the `FirstInEn = 0` input parameter.

The default setting is 0.

- **Bit = 0**: When first-in detection is deactivated via `FirstInEn = 0`, the output parameter `FirstIn` is reset.
- **Bit = 1**: When first-in detection is deactivated via `FirstInEn =0`, the output parameter `FirstIn` is maintained. When first-in detection is activated for the first time by an edge change of `FirstInEn 0->1`, the output parameter `FirstIn` is reset.

### 2.1.9.82 Reaction of the switching points in the "Out of service" operating mode

**Feature Bit**

Number of the `Feature` bit: 26

#### Reaction of the switching points in the "Out of service" operating mode

You can use this `Feature` bit to specify the reaction of the switching points to the "Out of service" operating mode.

The default setting is 0.

**Bit = 0**: Last state of the switching points before switching to the "Out of service" operating mode is retained.

**Bit = 1**: The state of the switching points is reset to "Good".

**Note**

The `Feature` "Changes signal status of outputs in OOS" has higher priority over the `Feature` "Reaction of the switching points in the "Out of service" operating mode".

### 2.1.9.83 Reaction to the out of service mode

#### Feature bit

Number of the `Feature` bit: 1

#### Reaction to the out of service mode

You can use this `Feature` bit to define the reaction of the technologic block based on the interconnectable input parameter `OosLi = 1`.

The default setting is 0.

- **Bit = 0**: The symbol for the "In progress" status (see below) appears in the block icon and in the faceplate of the assigned technologic block. A 0-1 edge transition at the input parameter `OosLi` has no further influence on the reaction of the technological block; the previous status is retained. No switch to the "Out of service" mode is performed.
- **Bit = 1**: The mode switches to "Out of service" assuming that the block is "On" or "Manual" mode. If this is not the case, the mode does not change. The symbol for the "In progress" (see below) status also appears in the block icon and in the faceplate of the assigned technologic block regardless of the mode change. No message is output to indicate whether or not the mode change took place.

The status display for "In progress" appears as follows:

A 1-0 edge transition at the input parameter `OosLi` has no influence on the reaction of the technologic block, the previous status is retained.

See also the section Release for maintenance (Page 70) for more on this.

### 2.1.9.84 Exiting local mode

#### Feature bit

Number of the `Feature` bit: 10

#### Reaction to exiting local mode

Use this `Feature` bit to define how "Local mode" is be exited with `LocalSetting` = `1` or `LocalSetting` = `2` and if the mode is not specified by `AutModLi` or `ManModLi`.

Default setting is 0

**Bit = 0**: Exiting local mode in manual mode (bumpless because the control signals are continuously adjusted).

**Bit = 1**: When local mode is exited, the mode changes back to the last mode that was active prior to local mode (not bumpless).

For more detailed information, refer to the description of Local mode (Page 86).

**Note**

**Functionality of "`Feature.Bit10`" is supressed over "`Feature.Bit17`"**

When `Feature.Bit17`=1 and `Feature.Bit10`=1 , after a change from "Automatic Mode" to "Local Mode" the block leaves the "Local Mode" in case of not matching commands to "Manual Mode" and not to "Automatic mode".

### 2.1.9.85 Interlock display with LocalSetting 2 or 4

#### Feature bit

Number of the `Feature` bit: 27

#### Interlock display with LocalSetting 2 or 4

Use this `Feature` bit to specify the display of interlocks with `LocalSetting` `2` or `4` at the faceplate and at the block output `LockAct` .

The default setting is 0

**Bit = 0**: `LocalSetting` `2` and `4` crossed out locks are displayed in the standard view. `LockAct` is not set with interlock.

**Bit = 1**: `LocalSetting 2` and `4` locks are displayed in the standard view according to the interlock. `LockAct` is set according to interlock. This setting is used for hardware interlock.

**Note**

A decreasing motor protection (`Trip.Value`=0) is displayed at the output parameter `LockAct`, regardless of the `Feature` bit setting.

This `Feature` bit is also applicable for the `LocalSetting 5` in VlvS.

### 2.1.9.86 Vibrate after torque monitoring

#### Feature2 bit

Number of the `Feature2` bit: 6

#### Vibrate after torque monitoring

You can use this `Feature2` bit to determine whether vibration should be started after a torque monitoring error `TorqOpen` or `TorqClose`.

The default setting is 0.

**Bit** = **0**: No vibration.

**Bit** = **1**: Vibration is started after a torque monitoring error.

### 2.1.9.87 With acknowledge overdosage

#### Feature2 bit

Number of the `Feature2` bit: 24

#### With acknowledge overdosage

You can use this `Feature2` bit to change the acknowledgment behavior of overdosage and underdosage.

The default setting is 0.

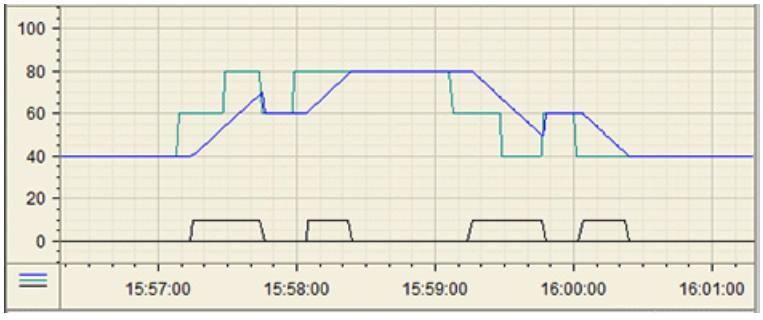
**Bit = 0**: After an overdosage is identified, the block changes directly to the "End" state.

**Bit = 1**: After an overdosage is identified, the block changes and continues to be in the "Off" state. An acknowledgment is necessary to change the dosing state to "End". In the standard view, status display shows the state "Ack Dos End".

## 2.1.9.88 Ramp rate calculation

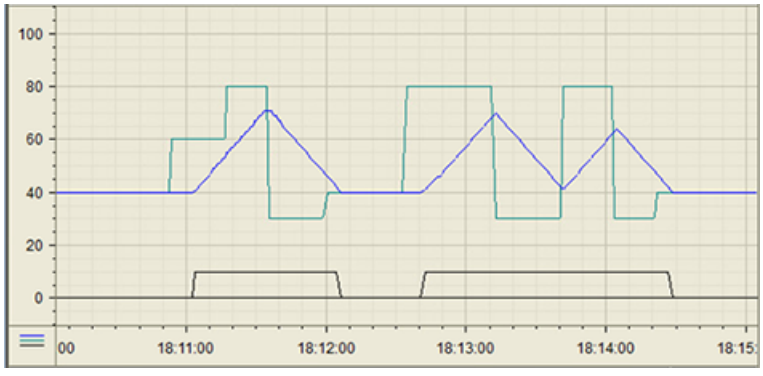
### Feature bit

Number of the `Feature` bit: 6 (7 for VlvAnL)



### Define ramp gradient after a change of ramp target value

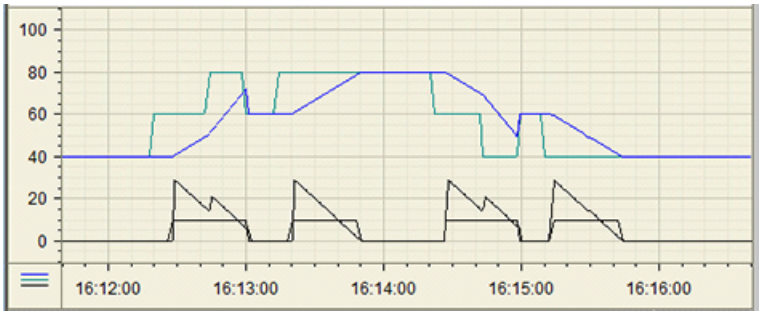
You can use this `Feature` bit in the standard functions "Using setpoint ramp" or "Using a manipulated variable ramp" to define the new ramp gradient after a change of ramp target value during a ramp trip.



The default setting is 0.

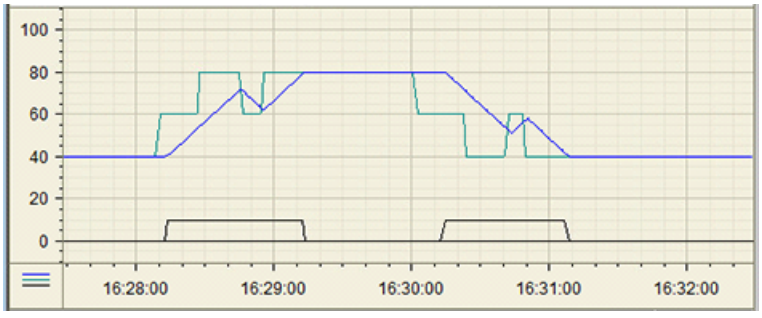
Bit = 0:
New ramp gradient is calculated with the start point of ramp trip and the new ramp target value.

Ramp mode =Gradient:
Ramp gradient stays Constant. Ramp Trip is aborted, if new ramp target value crosses the instantaneous ramp trip value. After an abort the setpoint is tracked to the ramp target value.



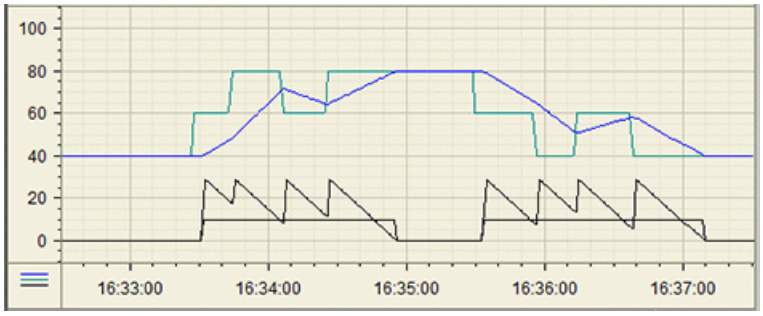
Ramp gradient changes if new ramp target value is at the other side of the start point. Ramp Trip is not aborted.

- `SP_RmpTarget`: Ramp target value
- `SP`: Setpoiont
- `SP_RmpOn`: Ramp On/Off



Ramp mode =Duration:
Ramp gradient will be adapted. Ramp Trip is aborted,if new ramp target value crosses the instantaneous ramp trip value. After an abort the setpoint is tracked to the ramp target value. The remaining ramp time is adapted (not reset), because the calculation of ramp gradient depends on start point and causes the increase of remaining ramp time.

- `SP_RmpTarget`: Ramp target value
- `SP`: Setpoiont
- `SP_RmpOn`: ramp On/Off
- `SP_RemRT`: Remaining ramp time



Bit = 1:
Ramp rate is calculated with the actual SP or MV and the new ramp target value.

Ramp mode =Gradient:
Ramp gradient stays Constant . Ramp Trip is not aborted,if new ramp target value crosses the instantaneous ramp trip value.

- `SP_RmpTarget`: Ramp target value
- `SP`: Setpoiont
- `SP_RmpOn`: ramp On/Off

Ramp mode =Duration:
Ramp gradient will be adapted. Ramp Trip is not aborted,if new ramp target value crosses the instantaneous ramp trip value. The ramp remaining time is completely reset with every change of ramp target value.

- SP_RmpTarget: Ramp target value
- SP: Setpoiont
- SP_RmpOn: ramp On/Off
- SP_RemRT: Remaining ramp time

### 2.1.9.89 SP following PV in open loop has no priority over SP_Ext and SP limits

#### Feature bit

Number of the Feature bit: 23

#### SP following PV in open loop has no priority over SP_Ext and SP limits

You can use this Feature bit to specify whether the setpoint follows the process value in "manual mode" with tracking (SP_TrkPV = 1). You can specify this function in case of setpoint is external or limited.

The default setting is 0.

**Bit = 0**: Setpoint follows process value (SP = PV) irrespective of whether setpoint is external or limited.

**Bit = 1**: If the setpoint is external, setpoint follows the external setpoint (SP = SP_Ext) and will be limited to the external limits (SP_ExHiLim and SP_ExLoLim). If the setpoint is internal, setpoint follows the process value (SP = PV) and will be limited to the internal limits (SP_InHiLim and SP_InLoLim).

### 2.1.9.90 With accelerated return of the integral action from the manipulated variable limit

#### Feature bit

Number of the Feature bit: 17

### With accelerated return of the integral action from the manipulated variable limit

When switching to the automatic mode (manually, by tracking, forced tracking, or program mode with manipulated variable specification) or when the controller is initialized by the `InitPid` input, the integral action (reset) is moved to preserve bumpless operation in case of an impending control deviation. The greater the control deviation and the controller gain, the greater is this shift. The result may be that the integral action is set far outside the manipulated variable limits. If the control deviation decreases after switching to the automatic mode, it may happen that in controllers with large `TI` values, the manipulated variable stays within the limit for a longer duration.

You can use this `Feature` bit to accelerate the return of the integral action from the limit. In case of a pending control deviation, the integral action is moved only in the direction of the control range to the extent that the manipulated variable can remove itself quickly and bumplessly from the manipulated variable limits (`MV_HiLim`/`MV_LoLim`).

The default setting is 0.

**Bit = 0**: Without accelerated return of the integral action.

**Bit = 1**: With accelerated return of the integral action when the integral action and the manipulated variable are outside or at the manipulated variable limits.

**Note**

In regular control mode, the integral action cannot move outside the manipulated variable limits because the manipulated variable is limited first and then fed back to the reset memory (see also anti-windup in PIDConR functions (Page 1103)).

## 2.1.9.91 External/internal selection specification

### Feature bit

Number of the `Feature` bit: 6

### External/internal selection specification

You can use this `Feature` bit to switch from the faceplate between internal and external selection of the inputs `In01` to `In10` (`SelInt` or `SelExt`).

The default setting is 0.

- **Bit = 0**:

| | |
|---|---|
| LiOp = 0 | Selection of In01 to In16 is internal; SelInt is active and can be used via faceplate. |
| LiOp = 1 | Selection of In01 to In16 is external; SelExt is active and can be used via interconnection. |

- **Bit = 1**:

| | |
|---|---|
| LiOp = 0 | With the input parameter SelIntOp or SelExtOp, you can change the selection between internal (SelInt) and external (SelExt) via faceplate. |
| LiOp = 1 | With the input parameter SelIntLi or SelExtLi, you can change the selection between internal (SelInt) and external (SelExt) via interconnection. |

### 2.1.9.92 Setting switch or button mode for local commands

#### Feature2 bit

Number of the Feature2 bit: 4

#### Setting switch or button mode for local commands (input signal as pulse signal or as static signal)

You can use this Feature2 bit to determine whether a separate interconnectable 1-active control input has to be used for every local command of the block or two local commands are assigned to a control input.

The Feature2 bit affects the following control inputs for local mode in the form of a pulse (pushbutton operation) or a static signal (switching mode):

- Starting and stopping a motor
- Opening and closing a valve

**Note**

- The input commands are checked for plausibility. For more information, see Error handling (Page 128), e.g. MotL error handling (Page 1390) and Feature2.Bit3 (Control priority in the event of invalid or not plausible input commands (Page 186)).
- With Feature2.Bit9 =1 (Button mode with triggered local control commands (Page 209)), the local input commands for button mode always need a 0->1 trigger to activate the control output signal.

You can find the commands for controlling the block in the relevant section on block operating modes. They are always the parameters that are used for the local operation of a block.

**Bit = 0**: Button mode: Each local command is assigned to a control input. This has a latching reaction and is 1-active.

**1. Example with a motor MotRevL**: In this case, use the interconnectable input parameters.

- `FwdLocal` = 1 for the command "Start forward"
- `RevLocal` = 1 for the command "Start backwards"
- `StopLocal` = 1 for the stop command

**Bit = 1**: Switching mode: two static local commands are assigned to a control input.

**2. Example with a motor MotRevL**: In this case, use the interconnectable input parameters.

- `FwdLocal` = 1 for the command "Start forward"
- `RevLocal` = 1 for the command "Start backwards"
- `FwdLocal` = 0 and `RevLocal` = 0 for the stop command

The `StopLocal` control input is irrelevant in this case.

**3. Example with motor MotSpdL**: In this case, use the interconnectable input parameters.

- `Spd1Local` = 1 for the command Motor to run with Speed1
- `Spd2Local` = 1 for the command Motor to run with Speed2
- `Spd1Local` = 0 and `Spd2Local` = 0 for the stop Command

**4. Example with motor MotSpdCL**: In this case, use the interconnectable input parameters.

- `FwdLocal` = 1 for the command "Start forward"
- `RevLocal` = 1 for the command "Start backwards"
- `FwdLocal` = 0 and `RevLocal` = 0 for the stop command

**5. Example with VlvPosL**: In this case, use the interconnectable input parameters.

- `OpenLocal` = 1, Command for Valve to "Open”
- `CloseLocal` = 1, Command for Valve to "Close”
- `OpenLocal` = 0 and `CloseLocal` = 0 for the stop command

**6. Example with Vlv2WayL**: In this case, use the interconnectable input parameters.

- `Pos1Local` = 1, Command for Valve1 to "Open"
- `Pos2Local` = 1, Command for Valve2 to "Open"
- `Pos1Local` = 0 and `Pos2Local` = 0, Command for "Position 0" (neutral position),

**7. Example with VlvL**

- `OpenLocal` = 1, Command for Valve to "Open"
- `OpenLocal` = 0, Command for Valve to "Close"

With `Feature2.Bit4` = 1, two static local commands are assigned to a control input.

### 2.1.9.93 Gradient limitation with time duration

#### Feature bit

Number of the `Feature` bit:

- 11 for PIDConL, PIDConR, and PIDStepL
- 12 for MotSpdCL, VlvAnL, and OpAnL

#### Gradient limitation with time duration

You can use this `Feature` bit to ramp up or ramp down the setpoint `SP` respectively `MV` as a function of time duration. With this `Feature` bit, the gradient limitation function can also work with the time duration.

The default setting is 0.

**Bit = 0**: Gradient limitation works only with the gradient values: `SP`/`MV_UpRaLim`, `SP`/`MV_DnRaLim`

**Bit = 1**: Gradient limitation also works with the time duration with the following parameters: `SP`/`MV_RmpModTime`, `SP`/`MV_RmpTime`.

### 2.1.9.94 Analog input 1 is reserved for the operator

#### Feature bit

Number of the `Feature` bit: 7

#### Analog input 1 is reserved for the operator

You can use this `Feature` bit to reserve the analog input 1 (`In01`) for the operator.

The default setting is 0.

**Bit = 0**: Operator cannot use the analog input 1 (`In01`).

**Bit = 1**: Operator can change the value of analog input 1 (`In01`) if the input is not connected and `OS_Perm.Bit22` is set to 1.

### 2.1.9.95 Operator can change the setpoint via faceplate also in the "Local" mode

#### Feature2 bit

Number of the `Feature2` bit: 6

#### Operator can change the setpoint via faceplate also in the "Local" mode

You can use this `Feature2` bit to enable the input of a setpoint for the operator in the "Local" mode.

The default setting is 0.

**Bit = 0**: Operator cannot change the setpoint in the "Local" mode.

**Bit = 1**: Operator can change the setpoint via faceplate in the "Local" mode.

### 2.1.9.96 Define the setpoint after stop and start of the motor

#### Feature2 bit

Number of the `Feature2` bit: 7

#### Define the setpoint after stop and start of the motor

You can use this `Feature2` bit to define the setpoint after stop and start of the motor.

The default setting is 0.

**Bit = 0**: The setpoint is retained after the motor is stopped.

**Bit = 1**: After the motor is stopped, the setpoint will be set to `SP_Off`. If the motor is started and the setpoint is in internal mode, the setpoint will be set to the low limitation `SP_LoLim`. Up to this value, the internal setpoint can be changed. In case the setpoint is external after the start of the motor, the setpoint will be changed directly to the external setpoint. The low limitation will be limited downwards to `SP_Off` and will be written back if the limitation is reached.

### 2.1.9.97 Retain last output value in case of bad input signal status

#### Feature bit

Number of the `Feature` bit: 5

#### Retain last output value in case of bad input signal status

You can use this `Feature` bit to specify that the block holds its output value if the input signal status is bad (16#00 or 16#28).

The default setting is 0.

**Bit = 0**: Default state of the block.

**Bit = 1**: Retain last output value in case of bad input signal status.

### 2.1.9.98 Forcing commands in the Local mode

#### Feature2 bit

Number of the `Feature2` bit: 8

### Forcing commands in the Local mode

You can use this `Feature2` bit to specify whether forcing commands is possible in the "Local" modes "1" and "3".

The default setting is 0.

**Bit = 0**: In the "Local" mode, forcing commands is not possible.

**Bit = 1**: In the "Local" mode, forcing commands is possible.

## 2.1.9.99 Motor stop in end position depends only on the corresponding feedback signal

### Feature bit

Number of the `Feature` bit: 15

### Motor stop in end position depends only on the corresponding feedback signal

With this `Feature` bit, you can specify whether the motor stop in end position depends only on the corresponding feedback signal or on both feedback signals.

The default setting is 0.

**Bit = 0**: Motor stop in end position depends on two feedback signals (`FbkOpen` and `FbkClose`). For example, motor stop in the end position "Open" depends on both feedback signals "Opened" and "Closed". In this case, `FbkOpen` = 1 and `FbkClose` = 0 are parameterized such that the drive output control of the motor "Open" is reset.

**Bit = 1**: Motor stop in end position depends only on the corresponding feedback signal. For example, motor stop in the end position "Open" depends only on the feedback signal "Opened". In this case, only `FbkOpen` = 1 is parameterized such that the drive output control of the motor "Open" is reset.

## 2.1.9.100 Substitution value is active if the block is in bypass

### Feature bit

Number of the `Feature` bit: 9

### Substitution value is active if the block is in bypass

You can use this `Feature` bit to specify whether the block uses the process value or a substitution value in case of an active bypass.

The default setting is 0.

**Bit = 0**: Block will use the process value (`PV`/`In`/`Out`).

**Bit = 1**: Block will use the substitution value (`BypPV`/`BypIn`/`BypOut`).

### 2.1.9.101 Enable external message

#### Feature bit

Number of the `Feature` bit: 9

#### Enable external message

You can use this `Feature` bit to specify if you want to use the quality code of `Inx`/`InTSx` or the external values `ExtValxx` as the associated value.

The default setting is 0.

**Bit = 0**: Use quality code of Inx or InTSx as the associated value.

**Bit = 1**: Use external values `ExtValxx` as the associated value.

### 2.1.9.102 Considering bad quality of automatic commands or external values

#### Feature/Feature2 bit

Number of the `Feature`/`Feature2` bit: 10

#### Considering bad quality of automatic commands or external values

You can use this `Feature/Feature2` bit to consider the bad signal status (16#00 or 16#28) in the parameter for the automatic commands or external values to move the block into the neutral position.

The default setting is 0.

**Bit = 0**: A bad signal status will not be considered.

**Bit = 1**: A bad signal status (16#00 or 16#28) in the automatic commands or external values will be considered from the block. The block goes to a defined neutral position.

### 2.1.9.103 Disable calculation of impulse control in LocalSetting 2 and 4

#### Feature bit

Number of the `Feature` bit: 20

#### Disable calculation of impulse control in `LocalSetting` 2 and 4

You can use this `Feature` bit to disable the tracking of feedback signals in the "Local" mode setting 2 and 4.

The default setting is 0.

**Bit = 0**: Calculation of impulse controls in `LocalSetting` 2 and 4.

**Bit = 1**: Disable calculation of Impulse controls in `LocalSetting` 2 and 4.

### 2.1.9.104 Inverter enable

#### Feature bit

Number of the `Feature` bit: 8

#### Inverter enable

You can use this `Feature` bit to specify whether, after the activation of `Feature.Bit15` (`Feature.Bit15` = 1), a frequency converter with a separate device infeed is to be used or the inverter enable.

The default setting is 0.

**Bit = 0**: Frequency converter with separate device infeed

**Bit = 1**: Inverter enable

### 2.1.9.105 Scale dosing can be started only if StandStill = 1

#### Feature bit

Number of the `Feature` bit: 14

#### Scale dosing can be started only if `StandStill` = 1

You can use this `Feature` bit to specify the start of scale dosing.

The default setting is 0.

**Bit = 0**: Start scale dosing independent of standstill.

**Bit = 1**: Start scale dosing only with `StandStill` = 1

### 2.1.9.106 Delete history of MV and DV moves during restart

#### Feature bit

Number of the `Feature` bit: 8

#### Delete history of MV and DV moves during restart

You can use this `Feature` bit to determine whether the history of MV and DV moves will be deleted after CPU restart or block restart.

The default setting is 0.

**Bit = 0**: The history of MV and DV will be deleted only after CPU restart if OB100 is running.

**Bit = 1**: The history of MV and DV will be deleted after CPU restart and also after a block restart (`Restart` = 1), if user DBs/FCs will be loaded in controller.

### 2.1.9.107 Status output calculation

#### Feature bit

Number of the `Feature` bit: 8

#### Status output calculation

You can use this `Feature` bit to define how the block calculates the status of output `Out`.

**Bit = 0**: The Status output is calculated with actual status input `In.ST` and the last status output `Out.ST`. The block makes a worst status calculation like technological blocks over the whole integration. With function "Tracking values" (`OutTrkOn` = 1) the status is reset to `OutTrk.ST`.

**Bit = 1**: The Status output is equal to status input (`Out.ST` = `In.ST`).

### 2.1.9.108 Suppress MsgLock and “Out of service” mode for a connected message block

#### Feature/Feature2 bit

Number of the `Feature2` bit: 11

#### Suppress `MsgLock` and “Out of service” mode for a connected message block

With this `Feature/Feature2` bit, you can suppress the message lock with the parameter `MsgLock` and the switchover to the “Out of service” mode for a connected message block (EventTs, Event16Ts). Only the connected block over the parameter `EventTsIn` is concerned. This allows generating messages also in the case of `MsgLock` = 1 or during a switchover to the "Out of Service" mode in the main block. For example, if the main block goes to the “Out of service” mode, the switchover can be messaged over a connection from the main block output `OosAct` to an input `Inx` of EventTs/Event16Ts.

The default setting is 0.

**Bit = 0**: No suppression.

**Bit = 1**: A message lock with the parameter `MsgLock` and a switchover to the “Out of service” mode are supressed for connected message block over `EventTsIn`.

### 2.1.9.109 Variants of CPI calculation

#### Feature bit

Number of the `Feature` bit: 8

### Variants of CPI calculation

With this `Feature` bit, you can choose between the two variants of CPI calculation.

The default setting is 0.

**Bit = 0**: Approximate calculation with reduced computing power consumption.

**Bit = 1**: More precise calculation corresponding to mathematical definition of variance.

**Note**

If you change the variant of calculation, the limits `CPI_AL_Lim` and `CPI_WL_Lim` may have to be adapted.

## 2.1.9.110 Scalable measuring range

### Feature bit

Number of the `Feature` bit: 6

### Scalable measuring range

With this `Feature` bit, the scalable measuring range is activated. This `Feature` bit is used by the driver generator according to the information from the HW Config / STEP 7 attribute and therefore this `Feature` bit is set by the driver wizard.

The default setting is 0.

**Bit = 0**: Scalable measuring range is not active.

**Bit = 1**: Scalable measuring range is active.

## 2.1.9.111 2 decimal points (scalable measuring range)

### Feature bit

Number of the `Feature` bit: 7

### 2 decimal points (scalable measuring range)

With this `Feature` bit, the measuring range resolution is set to 2 decimal points. This `Feature` bit is used by the driver generator according to the information from the HW Config / STEP 7 attribute and therefore this `Feature` bit is set by the driver wizard.

The default setting is 0.

**Bit = 0**: Measuring range resolution is not set to 2 decimal points.

**Bit = 1**: Measuring range resolution is set to 2 decimal points.

### 2.1.9.112 3 decimal points (scalable measuring range)

#### Feature bit

Number of the `Feature` bit: 8

#### 3 decimal points (scalable measuring range)

With this `Feature` bit, the measuring range resolution is set to 3 decimal points. This `Feature` bit is used by the driver generator according to the information from the HW Config / STEP 7 attribute and therefore this `Feature` bit is set by the driver wizard.

The default setting is 0.

**Bit = 0**: Measuring range resolution is not set to 3 decimal points.

**Bit = 1**: Measuring range resolution is set to 3 decimal points.

### 2.1.9.113 Output substitute values in case of communications error

#### Feature bit

Number of the `Feature` bit: 29

#### Output substitute values in case of communications error

Use this `Feature` bit to specify if substitute values are to be outputted in case of communication error.

The default setting is 0.

**Bit = 0**: Substitute values are not outputted in case of communication error.

**Bit = 1**: Substitute values are outputted in case of communications error

### 2.1.9.114 Output last values in case of communications error

#### Feature bit

Number of the `Feature` bit: 29

#### Output last values in case of communications error

Use this `Feature` bit to specify if last values are to be outputted in case of communication error.

The default setting is 0.

**Bit = 0**: Last values are not outputted in case of communication error.

**Bit = 1**: Last values are outputted in case of communications error.

### 2.1.9.115 Dosing controls are deactivated during scale is in taring mode

#### Feature bit

Number of the `Feature` bit: 14

#### The dosing controls are deactivated during scale is in taring mode

You can specify the dosing controls `Ctrl`, `P_Ctrl`, `Ctrl2`, `P_Ctrl2` after the start of scale dosing using this `Feature` bit.

The default setting is 0.

**Bit = 0**: After start of scale dosing the controls are active and independent of `StandStill`.

**Bit = 1**: After start of scale dosing the controls are deactivated during scale is in taring mode (`StandStill` = 0).

**Note**

After start of scale dosing during taring mode (`StandStill` = 0) the display area in the standard view shows "Taring".

### 2.1.9.116 Do not evaluate the first run of the diagnostic blocks

#### Feature bit

Number of the `Feature` bit: 27

#### Do not evaluate the first run of the diagnostic blocks

Use this `Feature` bit to deactivate the evaluation of the first run detection in parameter `DXCHG1` for channel blocks in case of manually configuration of the parameter `Mode`.

The default setting is 0.

**Bit = 0:** Activates the evaluation of the first run detection in parameter `DXCHG1`.

**Bit = 1:** Deactivates the evaluation of the first run detection in parameter `DXCHG1`.

### 2.1.9.117 Selection of metadata and diagnostic blocks

#### Feature bit

Number of the `Feature` bit: 9

### Selection of metadata and diagnostic blocks

Use this `Feature` bit to specify how PCS 7 driver generator proceeds with the connected hardware.

The default setting is 0.

**Bit = 0:** PCS 7 driver generator uses PCS 7 Basis Library metadata and function blocks.

**Bit = 1:** PCS 7 driver generator uses metadata and function blocks from an additionally installed AddOn Library.

## 2.1.9.118 Limits disabled in faceplate

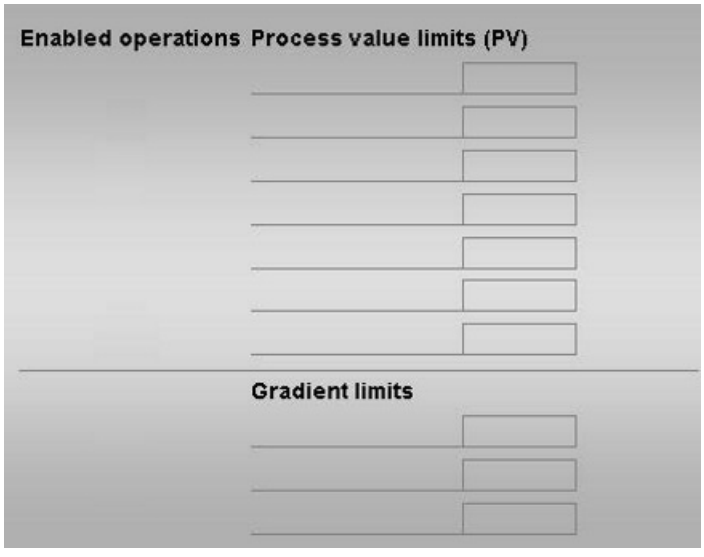
### Feature bit

Number of the `Feature` bit: 23

Blocks: CntOhSc, CountOh, CountScL, TotalL, MonAnL, MonAnS, MotL, MotRevL, MotSpdCL, MotSpdL, VlvAnL, VlvMotL, and VlvPosL

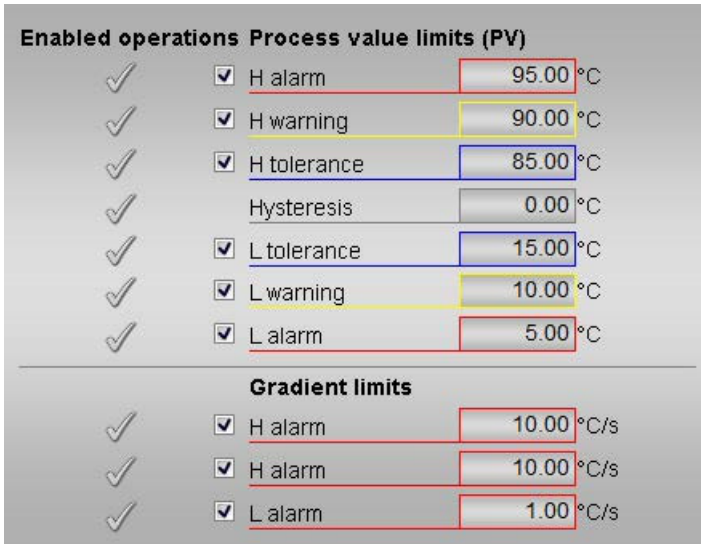
Number of the `Feature` bit: 16

Blocks: DoseL



Number of the `Feature` bit: 31

Blocks: FmCont, FmTemp, PIDConL, PIDConR, PIDConS, PIDStepL, and ConPerMon



### Limits disabled in faceplate

You can use this `Feature` bit to make the limits visible but disabled in faceplate when limits are disabled.

The default setting is 0.

**Bit** = **0**: Limits are invisible in faceplate when disabled from block.

**Bit** = **1**: Limits are visible but disabled in faceplate when disabled from block.

### 2.1.9.119 Keep last valid raw value if input value is bad

#### Feature bit

Number of the `Feature` bit: 31

#### Keep last valid raw value if input value is bad

Use this `Feature` bit to hold the raw output value if the input value is bad (16#00 or 16#28).

The default setting is 0.

**Bit = 0:** Transfers the data. Status of input value is not bad.

**Bit = 1:** Does not transfer the data. Status of input value is bad.

### 2.1.9.120 With PID initialization if mode SP intern extern changes

#### Feature bit

Number of the `Feature` bit: 14

#### With PID initialization if mode SP intern extern change

You can use this `Feature` bit to define the PID behavior after a change of mode SP intern/extern (`SP_ExtAct`). This means MV makes a jump or not.

The default setting is 0.

**Bit = 0:** No PID initialization after a change of mode SP intern/extern (`SP_ExtAct`). If the setpoint intern is different to SP extern, MV makes a jump to reach the new setpoint faster.

**Bit = 1**: With PID initialization after a change of mode SP intern/extern (`SP_ExtAct`). MV makes no jump, but the process needs more time to reach the new setpoint.

### 2.1.9.121 Changes signal status of outputs in OOS

#### Feature/Feature2 bit

Number of the `Feature` bit:

- 3 for SelA16In, SelAn16L
- 4 for CntOhSc, CountScL, CountOh, TotalL
- 5 for PIDConS, PIDConR, PIDConL, PIDStepL, FmTemp, FmCont, MPC 10x10, KalFit, ModPreCon, TimeTrig, AV, MonAnL, MonAnS, MonDiL, MonDi08, MonDiS

Number of the `Feature2` bit:

- 1 for MotL, MotS, MotRevL, MotSpdL, MotSpdCL, VlvS, VlvL, Vlv2WayL, VlvMotL, VlvAnL, VlvPosL
- 6 for DoseL

Refer the section "Out of service mode" of the respective blocks to know about the applicable outputs.

#### Changes signal status of outputs in OOS

This `Feature` bit changes the signal status of outputs in Out of service mode.

The default setting is 0.

Bit = 0: Default state of the block.

Bit = 1: Signal status of the respective output parameters changes to 16#60.

**Note**

Number of the `Feature` bit is different for various families of the blocks. The `Feature` "Changes signal status of outputs in OOS" has higher priority over the `Feature` "Reaction of the switching points in the "Out of service" operating mode".

### 2.1.9.122 Behavior in the case of Bus failure

#### Feature bit

Number of the `Feature` bit: 7

#### Behavior in the case of Bus failure

With this `Feature` bit, you can set the signal status of all output signals to 16#68 in the case of Bus failure (`ModErr` = 1).

The default setting is 0.

**Bit = 0**: The signal status of all output signals is set to 16#00 ("Bad, device related").

**Bit = 1**: The signal status of all output signals is set to 16#68 ("Uncertain, device related").

### 2.1.9.123 Button mode with triggered local control commands

#### `Feature2` bit

Number of the `Feature2` bit: 9

#### Button mode with triggered local control commands

You can use this to change the behavior of local mode with local commands (LocalSetting =1 or 3). The precondition is - Button mode: `Feature2.Bit4` = 0.

**Bit = 0**: Button mode with static input commands - After a plausibility control, the local input commands are active.

**Bit = 1**: Button mode with triggered input commands - The local input commands always trigger a 0->1 switching before the control output signal is active. If a block changes into local mode from another mode or to an error state, then a trigger is necessary.

### 2.1.9.124 Understeering / underflow for measuring range 0...10V

#### `Feature` bit

Number of the `Feature` bit: 11

#### Activate understeering / underflow for measuring range 0...10V

You can use this `Feature` bit to activate understeering / underflow handling for measuring range 0...10V.

The default setting is 0.

Bit = 0: understeering / underflow handling for measuring range 0...10V - OFF (default).

Bit = 1: understeering / underflow handling for measuring range 0...10V - ON.

### 2.1.9.125 Disable limit act output when limit value message is disabled

#### Feature/Feature2 bit

Number of the `Feature2` bit: 12

Number of the `Feature` bit: 3

### Disable limit act output when limit value message is disabled

You can use the `Feature/Feature2` bit to disable the limit value act output (`xx_xx_Act`) when the limit value message (`xx_xx_MsgEn`) is disabled.

The default setting is 0.

**Bit = 0**: Limit active output is not disabled when limit value message is disabled

**Bit = 1**: Limit active output is disabled when limit value message is disabled

## 2.1.9.126 Resetting the Pending Error in Local Mode 1 and 3

### Feature bit

Number of the `Feature2` Bit: 13

Resetting Pending Error in Local Mode 1 & 3.

With this `Feature` bit, you define you can define whether the Pending Errors can be resetted by using the faceplate/RstLi or not.

The default setting is 0.

**Bit = 0**: Resetting of pending errors cannot be possible via faceplate/RstLi.

**Bit = 1**: Resetting of pending errors can be possible via faceplate/RstLi.

## 2.1.9.127 Timestamp calculation

### Feature bit

Number of the Feature bit: 5

### Timestamp calculation

The calculation of the time stamp `TS_Out` has been improved. You can select via `Feature.Bit5` whether the CPU time or the IO time is used.

- Bit5=0: IO time stamp (default setting)
- Bit5=1: CPU time stamp

**Note**

Modifications are done in the Pcs7DiIT block prevent invalid time stamping error messages.

### 2.1.9.128 Reversal of control direction for fail-open valves

#### Feature bit

Number of the Feature bit: 5

#### Reversal of control direction for fail-open valves

`Feature.Bit5` = 1 turns around the control direction of scaled input `PV_In.Value` or `SimPV_In.Value`.

Example, with `Scale.Low` = 0 and `Scale.High` = 100 :

- With `Feature.Bit5` = 1, `PV_In.Value` = 0 leads to `PV_Out.Value` = 16#6C00.
- With `Feature.Bit5` = 1, `PV_In.Value` = 100 leads to `PV_Out.Value` = 0.
- With `Feature.Bit5` = 0, `PV_In.Value` = 0 leads to `PV_Out.Value` = 0.
- With `Feature.Bit5` = 0, `PV_In.Value` = 100 leads to `PV_Out.Value` = 16#6C00.

### 2.1.9.129 External Input to enable or Disable

#### Feature bit

Number of `Feature` Bit: 6

External Input to enable or Disable.

With this function you can activate External input.

Default = 0.

Bit = 0: External input disabled.

Bit = 1: External input enabled.

### 2.1.9.130 Switch over to internal time enable or Disable

#### Feature bit

Number of `Feature` Bit: 7

Switch over to internal time enable or Disable.

With this function you can switch to Internal time if the signal status of the external signal is bad.

Default = 0.

Bit = 0: internal switch over disabled.

Bit = 1: internal switch over enabled.

### 2.1.9.131 AS time enable or Disable

**Feature bit**

Number of `Feature` Bit: 8

AS time enable or Disable.

With this function you can activate AS Time or the CPU time.

Default = 0.

Bit = 0: AS time disabled.

Bit = 1: AS time enabled.

### 2.1.9.132 Use connectable inputs OpenLi, StopLi, CloseLi with CtrlLiOp

**Feature bit**

Number of the `Feature` bit: 7

Use connectable inputs `OpenLi`, `StopLi`, `CloseLi` with `CtrlLiOp`

You can use this `Feature` bit to specify whether the block uses the inputs `OpenLi`, `StopLi`, `CloseLi` as a function of `CtrlLiOp` or `ModLiOp`.

The default setting is 0.

Bit = 0: `OpenLi`, `StopLi`, `CloseLi` are used as a function of `ModLiOp`.

Bit = 1: `OpenLi`, `StopLi`, `CloseLi` are used as a function of `CtrlLiOp`.

### 2.1.9.133 Selecting the Feature Bit when Namur Off = 1

**Feature bit**

Number of the `Feature` bit: 12

With `Feature.Bit12` = 1 and `NamurOff` = 1

- Exceeding of the limit defined at input parameter HighLimit, leads to `PV_HiAct`.Value=1.
- Undershooting of the limit defined at input parameter LowLimit, leads to `PV_LoAct`.Value=1.

Regardless `Feature.Bit`12, `PV_HiAct`.Value and `PV_LoAct`.Value will be set in case of nominal range is left.

### 2.1.9.134 Bypass over both connection BypLix OR Inx

**Feature bit**

Number of the `Feature` bit: 3

With this Feature bit you can use both connected bypass information BypLix, Inx to bypass an interlock input.

The default setting is 0

**Bit3 = 0:** BypLix.Value is used to bypass an interlock input.

**Prerequisite:** BypLix <> 16#FF

With a change of BypLix.Value the bypass of an interlock input BypInx is set to BypLix.Value.

**Bit3 = 1:** BypLix.Value, Inx.Bit1 are used to bypass interlock inputs.

**Prerequisite:** BypLix <> 16#FF, Feature Bit2 =1, BypEn.Inx = 1

With a change of BypLix.Value, Inx.Bit1 the bypass of an interlock input BypInx is set to "BypLix.Value OR Inx.Bit1". Both inputs are false to reset the bypass. After that operator can change bypass over faceplate.

With changes of BypLix.Value or Inx.Bit1 the input BypInx is tracked. After that operator can change again bypass over faceplate.

### 2.1.9.135 Resynchronization after startup

#### Feature/Feature2 Bit

Number of the Feature bit: 17

**Drives (**Feature2bit17) **:** MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL

**Operate blocks (**Featurebit17)**:** OpDi01, OpDi03, OpAnL

You can use the Feature bit "**Resynchronization after startup**" to track controls and block state after CPU startup through feedback signals and readback value.

The default setting is 0.

**Bit = 0:** Startup without Resynchronization

**Bit = 1:** Startup with Resynchronization: The control outputs and block state are tracked through the feedback signals and readback value.

### 2.1.9.136 Resynchronization after out of service or after simulation

#### Feature/Feature2 Bit

Number of the Feature bit: 18

**Drives:** MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL
After leaving "Out of service" mode or after leaving simulation function you can use the Feature2 bit to track controls and block state through feedback signals and readback value.

**Operate blocks:** OpDi01, OpDi03, OpAnL
After leaving "Out of service" mode you can use the Feature bit to track controls and block state through feedback signals and readback value.

The default setting is 0.

**Bit = 0:** Without Resynchronization

**Bit = 1:** Resynchronization after leaving "Out of service" mode or after leaving simulation function.

### 2.1.9.137 Resynchronization after CSF

#### Feature2 Bit

Number of the `Feature` bit: 19

**Drives:** MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL

After a control system fault (input CSF 1->0) you can use the `Feature2` bit to track controls and the block state through feedback signals and readback value.

The default setting is 0.

**Bit = 0:** Without Resynchronization

**Bit = 1:** Resynchronization after a control system fault

### 2.1.9.138 Resynchronization with StateTrkOn input

#### Feature/Feature2 Bit

Number of the `Feature` bit: 20

**Drives (**`Feature2`bit20) **:** MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL

**Operate blocks (**`Feature`bit20)**:** OpDi01, OpDi03, OpAnL

After a trigger (0->1) at StateTrkOn input, you can use the feature bit to track controls and the block state through feedback signals and readback value.

The default setting is 0.

**Bit = 0:** Without Resynchronization

**Bit = 1:** Resynchronization after a trigger with StateTrkOn input

### 2.1.9.139 Control with output StopCtrl and state “No Cmd”

#### Feature2 Bit 21

Feature2 bit: MotL, MotRevL, MotSpdL, MotSpdCL, VlvL

Number of the feature bit: 21

**Control with output StopCtrl and state "No Cmd"**

You can use this feature bit if the control outputs together with StopCtrl should be able to realize the "No Cmd" mode. In this case all control outputs are reset.

The default setting is 0.

Bit = 0: Control position "No Cmd" is not used.

Bit = 1: The control outputs with StopCtrl are able to use the control position "No Cmd".

## Using StopCtrl with control position "No Cmd"

Some actors or sometimes a subordinate building block structure need for every position a separate static control output. The following motors and valves have the control output StopCtrl to realize the stop control separately: MotL, MotRevL, MotSpCL, MotSpdL, VlvL

Normally the value of the output StopCtrl is the opposite of the control outputs which activate the drive.

| | |
|---|---|
| MotL | StopCtrl = NOT Start |
| MotRevL | StopCtrl = NOT Fwd AND NOT Rev |
| MotSpdCL | StopCtrl = NOT Fwd AND NOT Rev |
| MotSpdL | StopCtrl = NOT Spd1 AND NOT Spd2 |
| VlvL | StopCtrl = NOT Ctrl |

Sometimes after a resynchronization it is not possible to see in which position and condition the valve or the motor is, because the feedback signals are not plausible. In this case you have the opportunity with Feature2 Bit21 Control with output StopCtrl and state “No Cmd” to parameterize that the drive can control the position/state “No Cmd”.

| | Controls “No Cmd” | Not plausible combinations |
|---|---|---|
| MotL | StopCtrl =0, Start =0 | FbkStart =0, FbkStop =0,<br>FbkStart =1, FbkStop =1 |
| MotRevL | StopCtrl = 0, Fwd =0, Rev =0 | FbkFwd =0, FbkRev =0, FbkStop =0<br>FbkFwd =1, FbkRev =1, FbkStop =1<br><br>FbkFwd =1, FbkRev =1, FbkStop =0<br>FbkFwd =0, FbkRev =1, FbkStop =1<br>FbkFwd =1, FbkRev =0, FbkStop =1 |
| MotSpdCL | StopCtrl = 0, Fwd =0, Rev =0 | See MotRevL |
| MotSpdL | StopCtrl = 0, Spd1 =0, Spd2 =0 | FbkSpd1 =0, FbkSpd2 =0, FbkStop =0<br>FbkSpd1 =1, FbkSpd2 =1, FbkStop =1<br><br>FbkSpd1 =1, FbkSpd2 =1, FbkStop =0<br>FbkSpd1 =0, FbkSpd2 =1, FbkStop =1<br>FbkSpd1 =1, FbkSpd2 =0, FbkStop =1 |
| VlvL | StopCtrl =0, Ctrl =0 | FbkOpen =0, FbkClose =0,<br>FbkOpen =1, FbkClose =1 |

## 2.1.10 Functions for controllers

### 2.1.10.1 Delay alarm for control deviation at setpoint step changes

#### Alarm delay for blocks with the function "Delay alarm for control deviation at setpoint step changes"

This type of alarm delay is used when temporary violations of set alarm thresholds of the control deviation are to be suppressed at setpoint step changes. The alarm delay is parameterized at the following inputs:

| Parameter for the delay time | Explanation |
|---|---|
| ER_AH_DFac | Delay factor at positive setpoint step changes for incoming alarms at the control deviation monitoring ER_AH_Lim |
| ER_AL_DFac | Delay factor at negative setpoint step changes for incoming alarms at the control deviation monitoring ER_AL_Lim |

The effective delay time is calculated from the delay factor and the setpoint difference and is specified at the output parameter:

| Parameter | Explanation |
|---|---|
| ER_A_DCOut | Effective delay time at setpoint step changes for incoming alarms during control deviation monitoring |

#### Calculation of the output parameter ER_A_DCOut

ER_A_DC is assigned by default to the output before a setpoint change.

ER_A_DCOut = ER_A_DC
In the case of a setpoint change in the positive direction during automatic mode, the output is calculated as follows:

ER_A_DCOut = Maximum (ER_A_DC, ER_AH_DFac * Setpoint difference)

In the case of a setpoint change in the negative direction during automatic mode, the output is calculated as follows:

ER_A_DCOut = Maximum (ER_A_DC, -1*ER_AL_DFac * Setpoint difference)

When the loop control has stabilized again, meaning (ER_AL_Lim + ER_Hyst) <= ER <= (ER_AH_Lim – ER_Hyst), and the delay time for outgoing alarms ER_A_DG has expired, the output is reset again to ER_A_DC: ER_A_DCOut = ER_A_DC.

**Note**

After a setpoint jump the function "**Delay alarm for control deviation at setpoint step changes**" always only affects the limit to the direction of the setpoint jump and not to the opposite limit. If the deviation value ER reaches the opposite limit (loop is overshooting), the switch-on delay of the opposite side acts ER_A_DCOut =ER_A_DC, ER_AH_DC.

### Activating the alarm delay

The alarm delay factors have a default value of 0, meaning that the function is deactivated. Specify a delay factor > 0 in order to use the function.

### Pending alarms

Pending alarms are output at the output parameters `ER_AL_Act` and `ER_AH_Act`.

### Activating and deactivating the function

The function is deactivated (default) when `ER_AH_DFac` = 0.0 and `ER_AL_DFac` = 0.0.

## 2.1.10.2 Inverting control direction

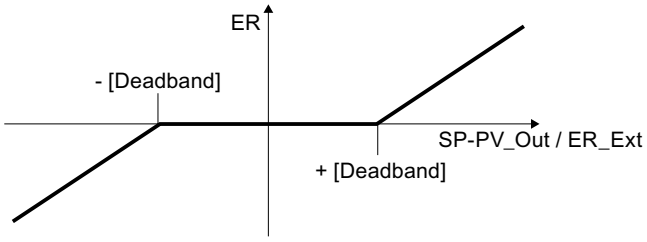
### Inverting control direction

For some processes (for example cooling processes), negative control gain is necessary. This is achieved by the inverting the control direction by means of the input parameter `NegGain = 1`. The gain is always entered positively at the input parameter `Gain` . If there is an inversion, this is indicated at the output parameter `GainEff` by a negative number.

## 2.1.10.3 Error signal generation and dead band

### Error signal generation and dead band

The signal error is formed from the effective setpoint `SP` and the process value `PV` and is available at the `ER` output.The `ER` Output will be calculated as follows:



1. Without `Deadband`
   `ER = SP - PV_Out`
   PIDConR (`ER =PV_Out - SP`)
2. With `Deadband`
   `ER = SP - (PV - Deadband)`

In the case of activated error signal generation (only at block PIDConL, `Feature.Bit14`), `ER` is formed by `ER_Ext`.

To suppress disturbances in the steady state, you can assign a dead band `(Deadband)`:

- `Deadband = 0`: Dead band is disabled
- `Deadband ≠ 0`: Dead band is enabled

With a negative dead band (`Deadband < 0.0`), calculation is continued internally with this value

A dead zone in the controller can help reduce the movements of the actuator and thus reduce the energy consumption and wear of the actuator. This applies especially to mechanical actuators, such as valves and pumps. The dead zone may also required in order to avoid small, stable, continuous oscillations (working movement), which are caused by the quantization of the control actions in the control loop.

**Note**

Calming the control signals via dead band is only possible when no structure splitting is active, i.e. when `PropFacSP` = 1 and `DiffToFbk` = 0. Controller actions in the feedback branch directly process the measured actual value instead of the control deviation and are therefore not affected by the dead band.

- Remaining control deviations smaller than the dead band are ignored by the controller, i.e. it does nothing even it can. Therefore, steady states of the actual value can occur, the average time of which significantly differs from the setpoint.
- When such steady states occur at the edges of the dead zone, it must be expected that even the smallest problems will cause control intervention (i.e. actuator energy consumption).
- Large dead zones have a negative effect on the control response of the control loop for setpoint changes. This is because the controller "stops work", for example, in the rising phase of a positive step response when entering the dead band. This can lead to creeping settling time, or cause the controller to be activated again when the actual value exceeds the high limit of the dead band in the form of an overshoot.
- After a fault event that leads to exiting the dead band, the controller brings the actual value back only to the edge of the dead band, which has the above-mentioned disadvantages.

By setting `Feature.Bit30`, you can activate dynamic adjustment of the dead band. This allows you to benefit from the advantages of a dead band without having to tolerate the above-mentioned disadvantages.

When large control deviations occur (i.e. the dead band is exited), it is temporarily deactivate until the controller returns the actual value to the proximity of the setpoint. The controller also demonstrates control response for setpoint changes without a dead band in this way.

There is then a wait until it can be assumed that the process has settled on operating point. Only then is the dead band activated again. When it is reactivated, the manipulated variable is set to the mean of a sliding time window. This ensures that the actual value to be controlled settles more in the middle of the dead band than at the edges. This avoids unnecessary shifting of the mean value of the controlled variable from the setpoint, and thus poor stationary control performance. The probability that the controlled variable is within the dead zone time is

increased, and further control actions are no longer necessary. This leads to reduced wear and less energy consumption.

**Note**

If `Feature.Bit30` = 1 is set, the ConPerMon block has to be connected with the controller. The blocks PIDConL or PIDConR monitor this by checking the status signal of `MeanMV.ST`. In case of `Feature.Bit30` = 1 and `MeanMV.ST` = 16#78 the dynamic deactivation of deadband is not possible and the output `ErrorNum` will be set to 52.

## Configuration and commissioning

- Use a process tag type that contains the ConPerMon function block for monitoring the control performance in addition to the controller.
- Check whether the additional interconnections between the monitoring block and controller are available:
  - `PIDConL.MV_Mean:= ConPerMon.MV_Mean`
  - `PIDConL.SettliTime:= ConPerMon.SettliDeadBand`
- Put the controller into operation as usual with the PID Tuner, and then initialize the ConPerMon block.
- Perform a setpoint step with activated control performance monitoring and without dead band (`PIDConL.DeadBand:=0`). Various characteristics of the step response can be determined by the ConPerMon block in this way. Check if the determined settling time at the `ConPerMon.SettliTime` output parameter appears plausible.
- Specify the width of the dead band at the `PIDConL.DeadBand` input parameter.
- Check the actuating signal signal in the steady state of the control loop. Has the desired calming of the signal form been achieved?
- Activate `Feature.Bit30`.
- Check the control response of the control loop. If the control loop has not sufficiently settled as expected near the center of the dead band after a setpoint change, it may help to increase the value of the `PIDConL.SettliTime` input parameter.

### Notes on selecting the width of the dead band

The width of the dead band primarily depends on the desired precision of the control, in other words, after the maximum, permanent, control deviations permissible by process engineering and after the change of the manipulated variable based on a minimum possible change of the manipulated variable (caused, for example, by a switching actuator). With regard to the minimization of control interventions, the following adjustment rules help to select the dead band wide enough that unavoidable variances of the control variables due to measurement noise or quantization noise do not lead to permanent control movements:

- Assuming a normal distribution of the statistical control variables around the setpoint, two to three times the standard deviation of the actual value in the steady state is used as the width of the dead band. This information can be obtained from the control loop monitoring block: `PIDConL.DeadBand:= (2...3)*ConPerMon.RefStdDev`.
- If working movements in the control loop are systematically caused by the manipulated variable quantization, for example, due to a pulse width modulation with a defined minimum pulse duration and pulse period, a step controller with defined minimum step size or an electro-pneumatic positioner, the width of the dead band depends on the manipulated variable quantization multiplied by the process gain.
  **Example**: A control signal resolution of 5% for temperature regulation with the process gain 1.5°C/% means that only temperatures in a grid of 5%, 1.5°C/% = 7.5°C can be reached exactly. The dead band must then be selected wide enough sp that at least one grid point falls within the dead band in which the process can remain in a steady-state, i.e. DeadBand > 3.8°C in this case.

## 2.1.10.4 Using control zones

### Using control zones

The control zone function is mainly used for temperature processes in which the time lag is small compared to the recovery time (no more than a tenth of the recovery time). This is typically the case when the temperature controller accesses the actuator directly (e.g. heating, steam valve), and typically not the case with master controllers of cascade interconnections (e.g. control of the internal temperature of a reactor via the shell temperature).

The control zone can result in large overshoots in processes with an excessively large time lag.

During commissioning with the PCS 7 PID-Tuner, you can check whether the process order is smaller than 2 and the process type "VZ2 model" is displayed. An initial approach for dimensioning the control zone: `ConZone= MV_HiLim/Gain`.

If `ConZone > 0`, the controller works with a control zone; if `ConZone <= 0`, the "control zone" function is deactivated. With a negative control zone, an error ID is output at the

ErrorNum parameter. When the control zone is enabled, the controller operates according to the following algorithm:

- If the process value PV exceeds the setpoint SP by more than ConZone, the value MV_LoLim is output as the manipulated variable (controlled mode, in order to return to the control zone as fast as possible).
- If the process value PV falls below the setpoint SP by more than ConZone, MV_HiLim is output (controlled mode).
- (Only possible with PIDConL, not with FmTemp) In controlled mode of the control zone and when the I component is enabled (TI<>0), the I component can be set in a variety of ways when the control zone is entered, depending on three Feature bits:

| Feature.Bit12 | Feature.Bit13 | Feature.Bit18 | Response |
|---|---|---|---|
| 0 | 0 | 0 | I_Part := MV.Value -P_Part -FFwd ; The controller operates bumplessly when entering automatic control mode. (This corresponds to the reaction up to V9.0) |
| 0 | 0 | 1 | I_Part := MV.Value -FFwd ; A P jump of the manipulated variable occurs when entering automatic control mode (use only in exceptional cases) |
| 1 | x | x | I_Part := MV_Offset.Value; The controller starts with the default value MV_Offset as I component when entering automatic control mode |
| 0 | 1 | x | I component is frozen. When it enters the control zone, the controller starts with the value of the I component that was in effect when it left the control zone. This can be useful for continuous processes, where it can be assumed that the controller is at the same operating point as it was when it left the control zone, nearly in a steady state. |

x = any

The I component is always set to MV_Offset when the I component is disabled (TI=0). I.e.: The control zone operates with the specified I_Part := MV_Offset with P or PD controlling.

Freezing of the I component with IntHoldPos or IntHoldNeg has no effect during controlled mode due to the control zone.

- If the process value PV stays within the control zone (ConZone), the manipulated variable assumes the value of the PID algorithm (automatic closed-loop mode).

**Note**

The change from controlled closed-loop mode to automatic closed-loop mode is based on a hysteresis of 20% of the control zone. Make sure that the control zone has an adequate width before you manually activate the control zone. An insufficient width of the control zone leads to oscillation of the manipulated variable and of the process value.

Advantages of the control zone:

Once the control zone is entered, the manipulated variable is quickly reduced by the applied D component. The control zone is therefore only useful if the derivative component is activated. Without the derivative component, only the reducing proportional component would reduce the manipulated variable to any significant degree. The control zone speeds up settling without

overshoot or undershoot if the value of the output minimum or maximum manipulated variable is a long way from the stationary manipulated variable required for the new operating point.

### 2.1.10.5 Setpoint limiting for external setpoints

#### Setpoint limiting for external setpoints

With this function you can limit the external setpoint to a range by means of the parameters `SP_ExHiLim` (high limit) and `SP_ExLoLim` (low limit). If the setpoint lies outside the range defined by you, it is limited to the valid range.

If the external setpoint lies on or above the limit `SP_ExHiLim`, this is displayed at the output `SP_ExHiAct = 1`.

If the external setpoint lies on or below the limit of `SP_ExLoLim`, this is displayed at the output `SP_ExLoAct = 1`.

The external setpoint limits can be tracked internally via the interconnection of the output parameters `SP_InHiOut` or `SP_InLoOut` following `SP_ExHiLim` or `SP_ExLoLim`. You can control the two limit pairs from the faceplate.

### 2.1.10.6 Tracking setpoint in manual mode

#### Tracking setpoint in manual mode

To allow a bumpless transfer to automatic mode, the setpoint tracks the process value. When tracking,(`SP_TrkPV = 1`) the internal setpoint `SP_Int` is tracked to the process value `PV`.

Additional information on setpoint tracking is available in Manual and automatic mode for control blocks (Page 79).

### 2.1.10.7 Tracking and limiting a manipulated variable

#### Manipulated variable tracking

You adjust the manipulated value (tracking) in order to implement a Bumpless switchover of controllers. A typical use case is cascade control: If the assigned secondary controller is no longer in automatic mode with external setpoint, the primary controller must track it.

To adjust the manipulated variable (tracking), you have to set the parameter `MV_TrkOn = 1`. Now the manipulated variable is taken from the interconnected tracking value `MV_Trk` and passed to the output `MV`. The MV output is limited to the `MV_HiLim` and `MV_LoLim` parameters.

Manual mode takes priority over tracking to allow a plant operator to set the controller to manual mode using the faceplate even when tracking the manipulated variable and therefore continue to normal operation.

The text "Tracking" is also displayed in the standard view of the faceplate.

### Activating forced tracking mode for the manipulated variable

Forced tracking is used to set the controller output of a higher-level controller to a value that can be specified.

You can use forced tracking, for example, to implement a centralized emergency stop in the plant. This can be put into effect regardless of the operating mode the controller is currently in.

To force adjustment of the manipulated variable (tracking), you have to set the parameter `MV_ForOn = 1`. Now the manipulated variable is taken from the interconnected tracking value `MV_Forced` and passed to the output `MV`.

With forced tracking, it is not possible to limit the manipulated variable, nor can the plant operator change to manual mode in the faceplate. The text "Forced tracking" is also displayed in the standard view of the faceplate.

**Note**

This function is not available for the FmCont, FmTemp, and ModPreCon blocks.

### Limiting the value of a manipulated variable in automatic mode

In automatic mode, the manipulated variable is set to its automatic manipulated variable limits as specified by the input parameters `MV_HiLim` and `MV_LoLim` and output at the output parameter `MV`. Reaching the limit is then displayed at the output parameter `MV_HiAct = 1` for the high limit and `MV_LoAct = 1` for the low limit.

Interconnecting the output parameter `ManHiOut` or `ManLoOut` to `MV_HiLim` or `MV_LoLim` allows the automatic manipulated variable limits to tracked to manual manipulated variable limits. You can keep both limit pairs in synch and control the manual manipulated variable limits in the faceplate.

### Limiting the value of a manipulated variable in manual mode

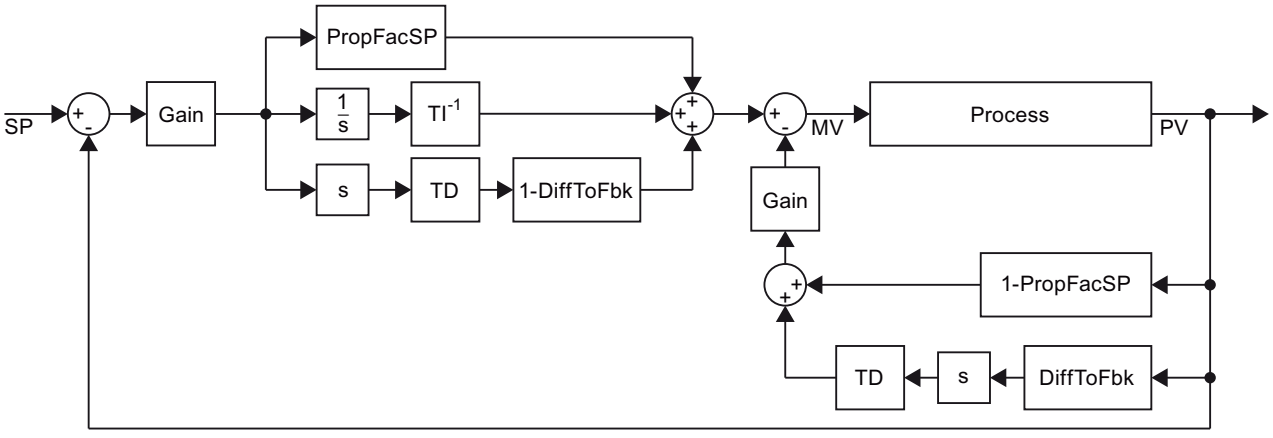
In manual mode, the manipulated variable is set to its manual manipulated variable limits as specified by the input parameters `ManHiLim` and `ManLoLim` and output at the output parameter `MV`.

### See also

Forcing operating modes (Page 45)

## 2.1.10.8 Feedforwarding and limiting disturbance variables

### Feedforward control and limitation



The feedforward control is used in order to compensate measurable disturbance variables, such as temperature or pressure, that can have an effect on the process. In automatic mode, the disturbance variable is added to the result of the PID algorithm.

The disturbance variable is connected to the `FFwd` Parameter. It is limited to the `FFwdHiLim` and `FFwdLoLim` limits. If the disturbance variable is outside or at the limits, this is indicated by the `FFwdHiAct = 1` or `FFwdLoAct = 1` output parameters.

### 2.1.10.9 Structure segmentation at controllers

#### Structure segmentation at controllers

In order to avoid jumps at the manipulated value (controller output) during setpoint changes, proportional and derivative actions can be switched into the feedback path. I.e.: The proportional action (proportionally) and the derivative action are then only influenced by the process value.

#### Switching proportional action into the feedback path

A proportion of the P action can be placed in the feedback using the `PropFacSP` parameter. Setpoint jumps then only affect the proportional action proportionally.

`PropFacSP = 0`: Proportional action is completely in the feedback path. Setpoint jumps do not affect the proportional action.

`PropFacSP = 1`: Proportional action is not in the feedback path. Proportional action is affected by setpoint and process variable (default setting).

#### Switching derivative action into the feedback path

The parameter `DiffToFbk` can be used to switch the D action into the feedback path. Setpoint jumps then no longer affect the derivative action directly.

`DiffToFbk = 0`: Derivative action is not in the feedback path. Derivative action is affected by setpoint and process variable (default setting).

`DiffToFbk = 1`: Derivative action is in the feedback path. Setpoint jumps do not affect the derivative action.

### Implementation of the structure segmentation

The implementation of the structure segmentation differs from the figure shown above such that changing `PropFacSP` does not change `MV`. Control behavior corresponds to the figure.

## 2.1.11 Messaging

### 2.1.11.1 Area of application of the alarm delays

### Area of application

A sensible area of application for setting alarm delays can, for example, be a motor. When it is started, an elevated starting current can occur and this could be reported depending on the configured limit. Since this usually settles down to a value below the set limit, the alarm would not make sense. In this case, the alarm delay that is intended to bridge the duration of the active alarm is used.

**Note**

Alarms that are really wanted are, naturally, also delayed when an alarm delay is used. Therefore select the delay period prudently!

### Alarm delays in the Advanced Process Library

There are three block types with a different application of the alarm delay for:

- One time value for all limits (Page 226)
- One time value per limit pair (Page 226)
- Two time values per limit pair (Page 227)
- Two time values for each individual limit (Page 228)

**Note**

An alarm delay is displayed with the following symbol in the limit view and in the faceplate overview:

### 2.1.11.2 One time value for all limits

#### Blocks with one time value for the alarm delay

This form of alarm delay is used for blocks without a unit designation in the name, for example, ConPerMon.

The alarm delay is used when brief violations of the set alarm thresholds are to be suppressed. The duration of the time delay is parameterized at the input `AlmDelay`. Parameter assignment is always carried out in seconds.

#### Activating the alarm delay

The alarm delay is disabled by default (`AlmDelay = 0`). To use the function, set a delay time [s] with the `AlmDelay` parameter.

### 2.1.11.3 One time value per limit pair

#### Blocks with one time value for the alarm delay per limit pair

The alarm delay is used when brief violations of the set alarm thresholds are to be suppressed.

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

The alarm delay is configured at the following inputs:

| Parameter for the delay time | Explanation |
|---|---|
| `XXX_A_DC` | Delay time for incoming events of the class<br>• Alarm<br>**XXX_A**larm_**D**elay**C**oming<br>XXX: Value to be monitored |
| `XXX_W_DC` | Delay time for incoming events of the class<br>• Warning<br>**XXX_W**arning_**D**elay**C**oming<br>XXX: Value to be monitored |

#### Activating the alarm delay

By default, the alarm delay is disabled for each limit, meaning that each individual parameter has 0 [s] pre-assigned.

To use the function, set a delay time [s] for each parameter.

### Pending alarms

Pending alarms, warnings, or tolerances are output at the corresponding output parameters:

- `XXX_AH_Act = 1`: Alarm limit (high) reached or violated
- `XXX_AL_Act = 1`: Alarm limit (low) reached or violated
- `XXX_WH_Act = 1`: Warning limit (high) reached or violated
- `XXX_WL_Act = 1`: Warning limit (low) reached or violated

If a message is active at one of these outputs, this is indicated by a 1.

### See also

User-configured message classes (Page 45)

## 2.1.11.4 Two time values per limit pair

### Blocks with two time values for the alarm delay per limit pair

The alarm delay is used when brief violations of the set alarm thresholds are to be suppressed.

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

The alarm delay is configured at the following inputs:

| Parameter for the delay time | Explanation |
|---|---|
| `XXX_A_DC` | Delay time for incoming events of the class<br>• Alarm<br>**XXX_A**larm_**D**elay**C**oming<br>XXX: Value to be monitored |
| `XXX_A_DG` | Delay time for outgoing events of the class<br>• Alarm<br>**XXX_A**larm_**D**elay**G**oing<br>XXX: Value to be monitored |
| `XXX_W_DC` | Delay time for incoming events of the class<br>• Warning<br>**XXX_W**arning_**D**elay**C**oming<br>XXX: Value to be monitored |
| `XXX_W_DG` | Delay time for outgoing events of the class<br>• Warning<br>**XXX_W**arning_**D**elay**G**oing<br>XXX: Value to be monitored |

| Parameter for the delay time | Explanation |
|---|---|
| XXX_T_DC | Delay time for incoming events of the class<br>• Tolerance<br>**XXX_T**olerance_**D**elay**C**oming<br>XXX: Value to be monitored |
| XXX_T_DG | Delay time for outgoing events of the class<br>• Tolerance<br>**XXX_T**olerance_**D**elay**G**oing<br>XXX: Value to be monitored |

### Activating the alarm delay

By default, the alarm delay is disabled for each individual pair, meaning that each individual parameter has 0 [s] pre-assigned.

To use the function, set a delay time [s] for each parameter.

### Pending alarms

Pending alarms, warnings, or tolerances are output at the corresponding output parameters:

- `XXX_AH_Act = 1`: Alarm limit (high) reached or violated
- `XXX_AL_Act = 1`: Alarm limit (low) reached or violated
- `XXX_WH_Act = 1`: Warning limit (high) reached or violated
- `XXX_WL_Act = 1`: Warning limit (low) reached or violated
- `XXX_TH_Act = 1`: Tolerance limit (high) reached or violated
- `XXX_TL_Act = 1`: Tolerance limit (low) reached or violated

If a message is active at one of these outputs, this is indicated by a 1.

### See also

User-configured message classes (Page 45)

## 2.1.11.5 Two time values for each individual limit

### Alarm delay for blocks with two time values for each individual limit

This form of alarm delay is used for the blocks PIDConL, PIDConR, and MonAnL.

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

The alarm delay is used when brief violations of the set alarm thresholds are to be suppressed. The alarm delay is configured at the following inputs:

| Parameter for the delay time | Explanation |
|---|---|
| XX_AH_DC | Delay time for incoming events of the class<br>• Alarm (for high limit)<br>**XX_A**larm**H**igh_**D**elay**C**oming<br>XX: Value to be monitored |
| XX_AH_DG | Delay time for outgoing events of the class<br>• Alarm (for high limit)<br>**XX_A**larm**H**igh_**D**elay**G**oing<br>XX: Value to be monitored |
| XX_AL_DC[1)] | Delay time for incoming events of the class<br>• Alarm (for low limit)<br>**XX_A**larm**L**ow_**D**elay**C**oming<br>XX: Value to be monitored |
| XX_AL_DG[1)] | Delay time for outgoing events of the class<br>• Alarm (for low limit)<br>**XX_A**larm**L**ow_**D**elay**G**oing<br>XX: Value to be monitored |
| XX_WH_DC | Delay time for incoming events of the class<br>• Warning (for high limit)<br>**XX_W**arning**H**igh_**D**elay**C**oming<br>XX: Value to be monitored |
| XX_WH_DG | Delay time for outgoing events of the class<br>• Warning (for high limit)<br>**XX_W**arning**H**igh_**D**elay**G**oing<br>XX: Value to be monitored |
| XX_WL_DC[1)] | Delay time for incoming events of the class<br>• Warning (for low limit)<br>**XX_W**arning**L**ow_**D**elay**C**oming<br>XX: Value to be monitored |
| XX_WL_DG[1)] | Delay time for outgoing events of the class<br>• Warning (for low limit)<br>**XX_W**arning**L**ow_**D**elay**G**oing<br>XX: Value to be monitored |
| XX_TH_DC | Delay time for incoming events of the class<br>• Tolerance (for high limit)<br>**XX_T**olerance**H**igh_**D**elay**C**oming<br>XX: Value to be monitored |
| XX_TH_DG | Delay time for outgoing events of the class<br>• Tolerance (for high limit)<br>**XX_T**olerance**H**igh_**D**elay**G**oing<br>XX: Value to be monitored |

| Parameter for the delay time | Explanation |
|---|---|
| XX_TL_DC[1)] | Delay time for incoming events of the class<br>• Tolerance (for low limit)<br>**XX_T**olerance**L**ow_**D**elay**C**oming<br>XX: Value to be monitored |
| XX_TL_DG[1)] | Delay time for outgoing events of the class<br>• Tolerance (for low limit)<br>**XX_T**olerance**L**ow_**D**elay**G**oing<br>XX: Value to be monitored |

[1)] In the "MonAnL" block, the inputs for a low delay time do not have the separate "L" letters (e.g. XX_AL_DC: the input name is XX_A_DC).

### Activating the alarm delay

By default, the alarm delay is disabled for each individual limit, meaning that each individual parameter has 0 [s] pre-assigned.

To use the function, set a delay time [s] for each parameter.

### Pending alarms

Pending alarms, warnings, or tolerances are output at the corresponding output parameters:

- `XX_AL_Act = 1`: Alarm limit (low) reached or violated
- `XX_AH_Act = 1`: Alarm limit (high) reached or violated
- `XX_WL_Act = 1`: Warning limit (low) reached or violated
- `XX_WH_Act = 1`: Warning limit (high) reached or violated
- `XX_TL_Act = 1`: Tolerance limit (low) reached or violated
- `XX_TH_Act = 1`: Tolerance limit (high) reached or violated

If a message is active at one of these outputs, this is indicated by a 1.

### See also

User-configured message classes (Page 45)

Separate delay times for each alarm (Page 181)

## 2.1.11.6 Generating instance-specific messages

### Generating instance-specific messages

You can generate instance-specific messages for a binary signal of every block.

The number of interconnectable input parameters that can be used freely varies with relation to the blocks. The X in the parameter name designates the position.

You can specify the following messages for these instance-specific messages:

- Message class
- Priority of the message
- Message text
- Message auxiliary value
- Acknowledge behavior

Additional information is available in the descriptions of the message functionality of the individual blocks and in the PCS 7 Configuration Manual Operator Station under "How to configure the user-specific messages".

**See also**

Time stamp (Page 231)

### 2.1.11.7 Suppressing messages using the MsgLock parameter

The `MsgLock = 1` parameter is used to selectively suppress the following messages depending on `Feature.Bit25`:

- All messages at the block

or

- All messages at the block, except for process control messages (for example, `CSF`, motor protection, feedback error) and external messages.

Messages already queued received the "outgoing" status with `MsgLock = 1` .

You can find additional information on `Feature.Bit25` in the section Suppression of all messages (Page 185)

**Note**

With the block OpAnL, this function is independent of `Feature.Bit25`.

### 2.1.11.8 Time stamp

**Time stamp**

The time stamp is the assignment of time information to the status change of a binary process signal. The status change of the signal is signaled together with the time information.

Use the EventTS block to report time stamped signals.

For more information on time stamping and how to configure it, please refer to the "PCS 7 - High-Precision Time Stamping Function Manual".

### Areas of application

Areas of application of the time stamp are for example:

- Accurately-timed detection of problems in process-related equipment. The time stamp enables you to explicitly identify signals that indicate the cause of the failure of a process unit.
- Analysis of system-wide interrelationships
- Detection and reporting of the sequence of time-critical signal changes

### Forming the time information

The time information is generated by one of the following methods and is specified at the block by means of the input parameter `TimeStampOn`:

- `TimeStampOn = 0`: Use time stamp of the CPU (default)
- `TimeStampOn = 1`: Use time stamp of the I/O

### Time stamping in the EventTS block

Connect the binary output parameter of another block (e.g. Pcs7DiIn) with a message input Inx (x = 1 ... 8) of the EventTS block.

When the EventTS block recognizes a change in the signal state at this message input, it uses the current time of the CPU as the time stamp. Only the signal changes that are slower than the cycle time of the block can be detected.

### High-precision time stamp in the process I/O

You have configured the hardware of your system for high-precision time stamping as explained in the "PCS 7 - High-Precision Time Stamping Function Manual". The signal changes are recognized in the I/O devices and the time stamp assigned to them. This data is available at the output parameter `TS_Out` of the Pcs7DiIT block.

The high-precision time stamp is independent of the cycle time of the blocks. The actual time resolution for two different status changes depends on your plant configuration and the hardware you are using.

Interconnect the output parameter `TS_Out` of Pcs7DiIT with a message input `InTSx(x = 1 ... 8)` of the EventTS block.

### Error handling

The system block ImDrvTs recognizes when the time stamp function in the I/O devices is defective and forwards this information to the Pcs7DiIT block. This then forms the time stamp using the current CPU time and sets the signal status of `TS_Out` output parameter to "Bad, due to device". The EventTS block then uses the current time of the CPU as the time stamp. You can find additional information in the "PCS 7 - High-Precision Time Stamping Function Manual".

#### 2.1.11.9 Connection of the time-stamped messages from EventTs or Event16Ts

If the output parameter `EventTsOut` of the block EventTs or Event16Ts is connected to the input parameter `EventTsIn` or `EventTs2In` of another block, the time-stamped messages of the block EventTs or Event16Ts will be displayed at the connected block. The following functionalities or parameters of the block are transferred to the connected message blocks:

- Maintenance release status (`MS_Release`)
- Operating mode "Out of service" (depends on `Feature2.Bit11`)
- Message lock with the parameter `MsgLock` (depends on `Feature2.Bit11`)
- Batch parameters (`BatchEn`, `Occupied`, `BatchID`, `BatchName`, and `StepNo`)

With `Feature2.Bit11` Suppress MsgLock and "Out of service" mode for a connected message block (Page 202), you can suppress the change to the "Out of service" mode and the message lock over `MsgLock`.

### 2.1.12 Settings for operator control and monitoring

#### 2.1.12.1 Display and operator input area for process values and setpoints

**Display and operator input area for process values and setpoints**

You specify the upper and lower area limits in the faceplate using interconnectable input parameters for the following:

- Display areas (bar display)
- Operator input area (for example setpoint and manipulated value)
- Input area for the limit values
  - Up to 7 numbers (including a decimal separator and a minus sign) are possible in the faceplates

The interconnectable input parameter is a structured variable that contains two analog values. Refer to the descriptions of the individual blocks for the relevant input parameters.

**Using a structured variable for scaling**

There are three possibilities with which you can influence the contents of the structured variables, namely with:

- The corresponding channel function block, for example, the FbAnIn block
- A conversion block, for example, the StruScIn block
- Direct parameter assignment at the block input

Additional information on data types is available in the documentation of CFC and STEP 7.

### 2.1.12.2 Opening additional faceplates

#### Opening additional faceplates

You can open standard views of other faceplates from various faceplate views. Here, you have the following options:

- Two buttons that you can assign freely and that are used to call faceplates of other blocks.
- Two predefined buttons for calling faceplates with a fixed assignment to the controller blocks.
- Buttons predefined for interlock functions

**Note**

**"Small" blocks**

With "Small" blocks, you can call up only one faceplate from the standard view.

#### Freely assignable buttons

From the standard view and from the preview, you can use a button to open the standard view of a block that can be selected freely. In order to use this function, in the CFC you need to interconnect the `SelFp1` input parameter for the button in the standard view or `SelFp2` for the button in the preview to any given output parameter of the block whose faceplate is to be opened. This makes the buttons in the faceplates visible.

**Note**

You can only configure the button in the standard view (`SelFp1`) with interlock blocks. There are no buttons with the GainSched block.

#### Button label

You can change the button labels in the "OS additional text" attribute to "SelFp1"/"SelFp2".

**Note**

There is also an alternative solution for labeling the buttons:

- Open the process picture in WinCC GraphicsDesigner.
- Open the object properties of the block icon.
- Under Configurations, assign the desired text to the attribute UserButtonText1 or UserButtonText2.

The main difference between this solution and the first solution is that the labels are only specified when the faceplate above the block icon is opened. This solution is therefore outdated.

### Predefined buttons for controller blocks

You can open the standard view for the following blocks from a controller standard view or parameter view (for example PIDConL):

- ConPerMon (can be called from the standard view)
  - To do this, you need to interconnect the output parameter `CPI` of the ConPerMon block to the input parameter `CPI_In` of the controller block.
- GainSched (can be called from the parameter view)
  - To do this, you need to interconnect the output parameter `Link2Gain` of the GainSched block to the input parameter `Gain` of the controller block.

The labels of the buttons cannot be changed here.

### Predefined buttons for interlocks

You can open the following interlock blocks from the standard view of the technology blocks:

- Activation enable
- Interlock without reset (interlock)
- Interlock with reset (protection)

The buttons intended for this are visible when the relevant input parameter (`Permit`, `Intlock` or `Protect`) is interconnected to an interlock block.

You can open the standard view for the following faceplates from the standard view of the interlock blocks:

- The blocks interconnected to the input values.
- The block interconnected to the output value.

The buttons intended for this are visible when the input parameters (for example `In01`) or the `Out` output parameter of the interlock block is interconnected to a block that has a faceplate.

**Note**

Interconnection of the `Out` output parameter to multiple blocks is not permitted. The reason for this is that a direct relationship must be established between the button in the faceplate and the faceplate to be opened by it.

## 2.1.12.3 Labeling of buttons and text

### Labeling of buttons and text

You can change the text of buttons (such as start/stop) for each specific instance. For binary OpDiXX faceplates, you can also change the static text for the "x command" for each specific instance.

To do this, you need to specify how the buttons are labeled yourself using the attributes "Text0" and "Text1" in the object properties of the block. These texts are displayed in the standard view and preview of the faceplate.

| Block type | Command button | Block I/O for parameter assignment "Text 1" |
|---|---|---|
| **DoseL** | Permission | `Permit.Value` |
| | Protection | `Protect.Value` |
| | Interlock | `Intlock.Value` |

| **VlvS** | Open | OpenMan |
| | Close | CloseMan |
| | Interlock | Intlock.Value |

The default text is shown if no text is configured.

If the text is longer than can be displayed with the default font size, the font size is automatically reduced until the text is fully shown. The smallest font size is 7 point.

Refer to the function description of the faceplate to learn which parameters are affected by this function.

### 2.1.12.4 Displaying auxiliary values

## Displaying auxiliary values

Up to two auxiliary values can be displayed in the standard view of some faceplates. This feature can be used, for example, with motors to indicate the motor current and winding temperature.

To do so interconnect the value that you want to have displayed with the input parameters UserAna1 or UserAna2.

In the object properties (I/Os > Identifier) of the block in CFC, you can specify the text to be displayed for these parameters in the standard view of the faceplate.

### 2.1.12.5 Selecting a unit of measure

#### Coded unit of measure

The parameter `XXX_Unit` is used to specify the unit of measure for the corresponding input parameter (XXX stands for a specific parameter, for example, `PV_Unit`). Entry is carried out in the form of a code. Exactly one unit of measure is assigned to each code and is displayed on the faceplate.

You can interconnect the `XXX_Unit` input parameter of a technologic block with the `XXXUnit` output parameter of an analog input channel block. At the analog input channel block, enter the unit of measure at the `XXXUnit` input parameter (`XXX` stands for a specific parameter, for example `PV_InUnit, PVOutUnit`).

If the parameter value of `XXX_Unit` is out of range (that is, the value is not defined), the faceplate displays "!undef.!" in the place of unit.

**Note**

**Special notes for channel blocks PCS7AnIn, PCS7AnOu, FbAnIn and FbAnOu**

You can use the S7_enum attribute to display the unit in plain text in the CFC editor for these blocks.

**Note**

In block icons, the update/refresh time of the units is 1 h. If the unit is changed from CFC, the new unit will be visible in the block icon after 1 hour or if the process picture is reloaded. In faceplates, the update/refresh time of the units is 5 seconds, so the new unit will be visible after 5 s.

#### Customer-specific units

It is possible to use units which differ from the IEC 61158-2 standard. You can define your own units in the range 1 to 199 in an XML file.

The name of the XML should be APLCustomerUnits.xml and should be placed in the project path in the folder "GraCS" on both server and client.

Below is an example to describe the content of the XML file APLCustomerUnits.xml:

```
<?xml version="1.0" encoding="utf-8"?>
<UserDefinedUnits>                          <!-- Root node start -->
    <!-- Define the first unit for different languages -->
    <Unit id="1">                           <!-- first node with unit ID 1 start -->
      <Name lcid="1031">German1</Name>      <!-- unit value (e.g. German1) in German -->
      <Name lcid="1033">English1</Name>     <!-- unit value (e.g. English1) in English -->
      <Name lcid="1034">Spanish1</Name>     <!-- unit value (e.g. Spanish1) in Spanish -->
      <Name lcid="1036">French1</Name>      <!-- unit value (e.g. French1) in French -->
      <Name lcid="1040">Italian1</Name>     <!-- unit value (e.g. Italian1) in Italian -->
      <Name lcid="1041">Japanese1</Name>    <!-- unit value (e.g. Japanese1) in Japanese -->
      <Name lcid="2052">Chinese1</Name>     <!-- unit value (e.g. Chinese1) in Chinese -->
```

```
    </Unit>                              <!-- first node with unit ID 1 end -->
    <!-- Define the second unit for different languages -->
    <Unit id="2">
      <Name lcid="1031">German2</Name>     <!-- lcid="1031" is for German -->
      <Name lcid="1033">English2</Name>    <!-- lcid="1033" is for English -->
      <Name lcid="1034">Spanish2</Name>    <!-- lcid="1034" is for Spanish -->
      <Name lcid="1036">French2</Name>     <!-- lcid="1036" is for French -->
      <Name lcid="1040">Italian2</Name>    <!-- lcid="1040" is for Italian -->
      <Name lcid="1041">Japanese2</Name>   <!-- lcid="1041" is for Japanese -->
      <Name lcid="2052">Chinese2</Name>    <!-- lcid="2052" is for Chinese -->
    </Unit>
<!-- similarly define other units up to unit id = 199-->
</UserDefinedUnits>                      <!-- Root node end -->
```

The "Unit id" value should be given to `XXX_Unit` parameter in the function blocks.

**Note**

The XML is read in only once when WinCC runtime is activated. If any changes are done in the XML later, you must deactivate, close, and activate the WinCC runtime again to reflect the changes.

### Using the unit of measure with controllers for the ConPerMon block

For controller blocks, the current unit of measure is output via output parameter `XX_UnitOut` . If you use the ConPerMon block, you must switch this output parameter with the corresponding input parameter `XXX_Unit` on the ConPerMon block.

### Using the S7_unit attribute

If you set the `xxx_Unit` parameter to 0, the entry is displayed by the `S7_Unit` attribute in the faceplate and in the block symbol.

### Overview of the units of measure

The units of measure are listed in the following tables:

List of the most commonly used units of measure in accordance with specification PROFIBUS PA Profile for Process Control Devices up to version PNO V3.02.

**Note**

Due to space constraints on the system, not all units referred to can be displayed in totality. The display of the measurement units is left-aligned. If you want to abbreviate the unit of measurement, use the function **Customer-specific units**.

| 1633 | hl/s | Hectoliters per second |
| 1634 | hl/min | Hectoliters per minute |
| 1635 | hl/h | Hectoliters per hour |
| 1636 | hl/d | Hectoliters per day |
| 1637 | bbl (liq)/s | Barrels (US liquid) per second |
| 1638 | bbl (liq)/min | Barrels (US liquid) per minute |
| 1639 | bbl (liq)/h | Barrels (US liquid) per hour |
| 1640 | bbl (liq)/d | Barrels (US liquid) per day |
| 1641 | bbl (fed) | Barrel (U.S. federal) = 31 gallons |
| 1642 | bbl (fed)/s | Barrels (US federal) per second |
| 1643 | bbl (fed)/min | Barrels (US federal) per minute |
| 1644 | bbl (fed)/h | Barrels (US federal) per hour |
| 1645 | bbl (fed)/d | Barrels (US federal) per day |
| 1998 | Unknown unit | To be used when the unit of measure is not known during configuration |
| 1999 | Special | Special units |
| | | |

[1] A notation different to the PA profile must be used in order to represent this unit in conformity with the system.

[2] "m2" is used instead of "m3" in the Chinese and Japanese documentation.

## 2.1.13 Consumption of Process Objects

### Process Objects (PO) Count

All function blocks of the APL uses in general one PO. Exceptions are listed in the table:

| Block type | PO count |
|---|---|
| AV | 0 |
| Evt16Ts | 0 |
| EventTs | 0 |
| KalFilt | 50 |
| ModPrCon | 50 |
| MPC10x10 | 100 |
| PrDrpMon | 5 |
| PST | 15 |
| PumpMon | 10 |
| SteadySt | 1 |
| VlvMon | 5 |
| VlvPosL | 2 |

## 2.1.14 Resynchronization

With a resynchronization the control outputs and the state of a block are adapted to a running process. This is acheived by tracking the control outputs for one cycle through the actual feedback signals (FbkXxx) or readback values (Rbk, PV_In).

The resynchronization is enabled over feature bits.

**Resynchronization after CPU Startup:**

| | |
|---|---|
| Feature Bit17 =1 | OpDi01, OpDi03, OpAnL |
| Feature2 Bit17 =1 | MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL |

In the first cycle after OB100 commands, block state and control outputs are tracked through the feedback signals and readback values from the process. If they are not available or plausible, the controls are put on hold.

**Resynchronization after Out of service:**

| | |
|---|---|
| Feature Bit18 =1 | OpDi01, OpDi03, OpAnL |
| Feature2 Bit18 =1 | MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL |

In the first cycle after leaving "Out of service" commands, block state and control outputs are tracked through the feedback signals and readback values from the process. If they are not available or plausible, the actual position is not changed. In the standard view and preview the operator can see which state the block would assume after leaving "Out of service" mode.

**Resynchronization after Simulation:**

| | |
|---|---|
| Feature2 Bit18 =1 | MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL |

In the first cycle after leaving simulation function commands, block state and control outputs are tracked through the feedback signals and readback values from the process. If they are not available or plausible, the actual position is not changed. In the standard view and preview the operator can see which state the block would assume after leaving simulation function.

**Resynchronization after CSF:**

| | |
|---|---|
| Feature2 Bit19 =1 | MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL |

In the first cycle after leaving control system fault (CSF 1->0) commands, block state and control outputs are tracked through the feedback signals and readback values from the process. If they are not available or plausible, the actual position is not changed. In the standard view and preview the operator can see which state the block would assume after leaving control system fault.

**Resynchronization with input StateTrkOn:**

| | |
|---|---|
| Feature Bit20 | OpDi01, OpDi03, OpAnL |
| Feature2 Bit20 =1 | MotL, MotRevL, MotSpdL, MotSpdCL, VlvL, VlvMotL, VlvAnL, VlvPosL |

After a trigger (0->1) at StateTrkOn input commands, block state and control outputs are tracked through feedback signals and readback value. If they are not available or plausible, the actual position is not changed. In the standard view and preview the operator can see which state the block would assume after a trigger of StateTrkOn input.

**General restrictions of resynchronization:**

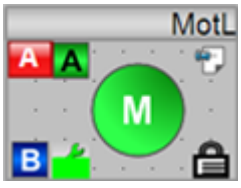
In many cases the control outputs are not tracked from the feedback signals or readback values:

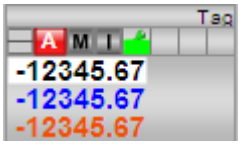
- **Active commands** in automatic, local mode or forcing:
  - XxxAut =1 in button mode (Feature Bit4 =0)
  - XxxLocal =1 in local button mode (Feature2 Bit4 =1)
  - In Switch mode (Feature Bit4 =1, Feature2 Bit4 =1) the commands are always active and cannot be tracked.
- **Interlocks:** Tracking of an interlocked control is not possible. On the other hand the resynchronization can set the block to a position where an interlock permission is active. Or in case of an interlock (not protected), regarding the direction of the resynchronization can be set to a none interlocked position.
- **Active errors** like monitoring errors with MonSafePos =1, FaultExt =1, CSF =1 with error behavior Feature Bit18 =1, Trip =1: Tracking of a control is not possible. But the state/position can be adapted by resynchronization.
- **Rapid Stop**: Tracking of a control is not possible. But the state/position can be adapted by resynchronization.

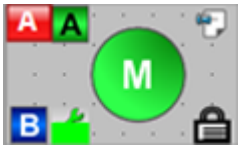
Tracking of state is independent from the interlock permission

# 2.2 Functions of the block icons

## 2.2.1 Block icon structure



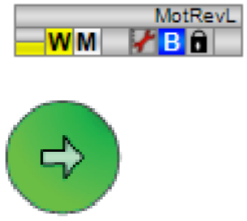


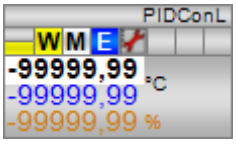


### Block icon structure

The new block icons are located in the template "@PCS7TypicalsAPLV9.PDL" and "@TemplateAPLV9.PDL".

**Note**





@PCS7TypicalsAPLV7.PDL and @TemplateAPLV7.PDL is no longer supplied with the Setup

There are two types of block icons (V9.0), those with a display of the instance-specific name and those without:

| | |
|---|---|
|  | Block icon of MotL with instance-specific name |
|  | Block icon of PIDConL with instance-specific name |
|  | Block icon of MotL without instance-specific name The toolbar only shows the information that is actually available. |
|  | Block icon of PIDConL without instance-specific name The toolbar only shows the information that is actually available. |

The old block icons are located in the template "@PCS7TypicalsAPLV7.pdl" and "@TemplateAPLV7.PDL".

There are two types of block icons (V7.1), those with a display of the instance-specific name and those without:

| | |
|---|---|
|  | Block icon of MotRevL with instance-specific name |
|  | Block icon of PIDConL with instance-specific name |
|  | Block icon of MotRevL without instance-specific name The toolbar only shows the information that is actually available. |
|  | Block icon of PIDConL without instance-specific name The toolbar only shows the information that is actually available. |

You can select one of these block icons. See section Configuring the block icons (Page 267) for more information.

A block icon has several display areas:

- CPU stop
- Instance-specific name
- Icon for the block
- Analog value display
- Status bar for the block status

**NoteView documents**

You can configure a maximum of three files per block symbol instance, which can be selected in the memo view during the process control and are displayed in a separate window.

These files must be located in the GraCS folder in the NoteView subdirectory.

The file names are configured at the block icon at the attributes NoteView1, NoteView2 and NoteView3. Only .mht file formats are supported and the file extension ".mht" must be given (for exmaple, " File1.mht") at the configuration.

**Note**

1. A maximum of three files are configured per block instance.
2. Only .mht file formats are permitted.
3. The file extension *.mht must be given at the configuration.
4. In multi-projects, all relevant files are stored in the path of the server project (OS project path >> GraCS >> NoteView >> (files in MHT format)).
5. If the files are not configured at the block icon, the file selection and the "Open" button are deactivated in the memo view (that is, grayed out).
6. If the file formats other than .mht files are configured, the error message "Invalid file format" is displayed when the file is opened.
7. The maximum allowed file size is 25 MB. If a file exceeds this size, the error message "File size exceeded" is displayed when the file is opened.

## Displaying CPU stop

With a CPU stop, boxes are unavailable and a yellow warning triangle is displayed in the group display for blocks with messaging.

## Instance-specific name

The name of the associated block is shown in the instance-specific name, for example for the PIDConL block:

You can change this name in the object properties of the instance block.

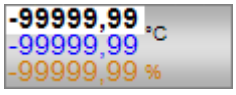
There are block icons with or without display of the instance-specific name. Refer to the individual block descriptions to learn about them.

You can reach the visible display for blocks without display of the instance-specific name in two different ways:

- **Displaying individual instance-specific names**: Click on the block icon while holding down the Shift key: The name remains visible as long as the process picture is displayed.
- **Displaying all instance-specific names at once**: All instance-specific names can be made visible in a process picture at once by clicking a button. To do this, copy this button into the process picture of the chart from the @TemplateAPLV9.PDL or insert this button in the "button area" of WinCC. If you insert it into the button area, read the manual section "PCS 7 OS Process Control " > "Layout of the User Interface".
  The instance-specific names are hidden once more by clicking the button again.

## Icon for the block

Block icons for technologic blocks have their own operable symbols (for example, for the MotRevL block) and represent a status display of the block.



This symbol can be positioned at various locations, 0°, 90°, 180° and 270°. Refer to the Configuring the block icons (Page 267) section for more on this. You can change the operating mode of the block by right-clicking on the status display. Refer to the Operation via the block icon (Page 269) section for more on this.

**Note**

Block icons for motors and valves are available in various mounting positions and forms of representation. However, a general state icon is always displayed in the faceplates that does not consider the mounting position and form of representation in the block icons.

## Analog value display

For block icons with analog value displays (for example, for the PIDConL block), there are basic settings that differ depending of the associated unit of measure:

Refer to the Configuring the block icons (Page 267) section for more on this.

These analog values can be controlled according to the Operator control permissions (Page 285). See also the section Operation via the block icon (Page 269) for more on this.

As of V9.0 block icons, when the actual values are displayed with limit monitoring in the analog value displays, the background and font colors for an alarm, warning or tolerance correspond to the message colors.

**Note**

As of V9.0 block icons, when the actual values are displayed with limit monitoring in the analog value displays, the background and font colors for an alarm, warning or tolerance, control system fault or control system fault correspond to the message colors.

If the analoge value display shows *****, the display field is too small for the parameterized format specification. In this case, adapt the format specification AnalogValueFormatx in the block icon APL_BLOCK_ICON.

For specification of the format, refer to Decimal points for the analog value display (Page 277).

### Status bar for the block status

The status bar of the block icon provides an overview of the overall status of the block (see figure below).

The arrangement of icons in the following tables is prioritized from high to low.

The following elements can be displayed:

### Alarms, warnings, tolerances, and messages

Refer to the Monitoring functions in the Advanced Process Library (Page 92) section for more on this.

| Icon | Meaning |
|---|---|
|  | No messages are output. |
|  | A fault has occurred. |
|  | An alarm is triggered. |
|  | An alarm for the high alarm limit is triggered. |
|  | An alarm for the low alarm limit is triggered. |
|  | An warning is triggered. |
|  | A warning for the high warning limit is triggered. |
|  | A warning for the low warning limit is triggered. |
|  | A tolerance violation has occurred. |
|  | A tolerance violation for the high tolerance limit has been triggered. |
|  | A tolerance violation for the low tolerance limit has been triggered. |
|  | The block has an operator prompt. |
|  | There is a process status determination. |

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. Please take into consideration the validity of terms for user-configured message classes (Page 45).

**Note**

For user-configured message classes, the symbols for high/low alarm, warning and tolerance limits are displayed only for limit violations which are triggered within the APL blocks with the colors of the user-configured message classes.

## Operating modes

Refer to the Overview of the modes (Page 76) section for more on this.

| Icon | Meaning |
|---|---|
|  | The block is in automatic mode. |
|  | The block is in the "On" operating mode. |
|  | The block is in manual mode. |
|  | The block is in program mode (only for controllers). |
|  | The block is in local mode. |
|  | The block is in the "Out of service" operating mode.<br>In this operating mode, no other symbols are displayed and no values are shown in the analog value display except for:<br>- Display for an active message in the memo view<br>- Display for the maintenance enable |

**Note**

No symbol is displayed for the "On" operating mode (no green "O" displayed) if the block only has the operating modes "On" and "Out of service".

## Internal or external setpoint

Refer to the section Setpoint specification - internal/external (Page 136).

| Icon | Meaning |
|---|---|
|  | Setting the setpoint internally |
|  | External setpoint specification |
|  | SP/MV ramp active |

## Signal status

Refer to the Forming and outputting signal status for blocks (Page 116) section for more on this.

| Icon | Meaning |
|---|---|
|  | The block is in simulation. |
|  | Signal status is "Bad, device related". |
|  | Signal status is "Bad, process related". |
|  | Signal status is "Uncertain, device related". |
|  | Signal status is "Uncertain, process related". |
|  | A maintenance request is pending. |
|  | Block is released for maintenance |

## Tracking and forcing of values and bypasses

See sections Forcing operating modes (Page 45), Interlocks (Page 107) and Manual and automatic mode for control blocks (Page 79).

| Icon | Meaning |
|---|---|
|  | At least one value has been forced |
|  | Value is tracked |
|  | There is a bypass of an interlock or a bypass condition of an upstream Intlock FB or tag bypass is active. |

## Interlocks

Refer to the Interlocks (Page 107) section for more on this.

| Icon | Meaning |
|---|---|
|  | Block is not interlocked. |
|  | Block is interlocked. |
|  | Bypass protection. |
|  | Rapid stop is commanded. |

### Memo display

| Icon | Meaning |
|---|---|
|  | A message is available in the memo view. |

### Customer-specific icons

In the block icons, the icons can be replaced with customer-specific icons. A subdirectory must therefore be created in the OS project directory "GraCS" and the customer-specific icons must be inserted there with the same name as before. The name of the subdirectory must be adapted in the block icon in the "**PictureDirectory**" property ("Configurations" group). The icons in the subdirectory are not changed by the OS project editor or a new version of APL faceplates.

**Note**

- The "PictureDirectory" property is an instance-specific property. This means that the adaptations of block icons already configured in the process pictures are not changed by an update of the block icons in the process picture.
- We recommend that you adapt this property in the process picture and not in the "@PCS7TypicalsAPLVx.pdl" or "@TemplateAPLVx.PDL" pictures. The "@" pictures are system pictures and are replaced by the new version of APL faceplates. Customer changes will be lost.
- In the WinCC Graphics Designer, the PCS 7 "Export Objects" wizard can be used to generate a list of adaptations of instance-specific properties in the block icons. The "PictureDirectory" property can be changed in the exported list and collectively transferred back into the block icons with the PCS 7 "Import Objects" wizard.
- It is possible to use several subdirectories. This can be useful to create different variants of block icons in the process pictures.

User-configured message classes (Page 45)

## 2.2.2 Configuring the block icons

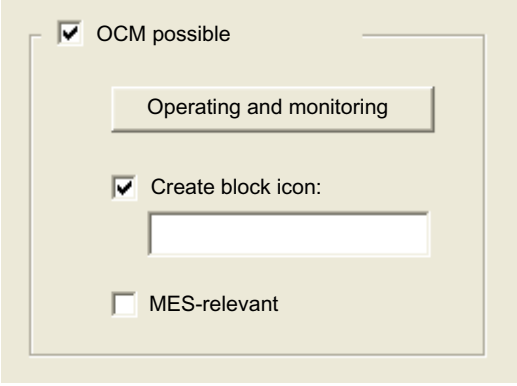
### Configuring the block icons

There are two ways to configure your block icons:

- Automatically
- Manually

The new block icons are in the template picture "@PCS7TypicalsAPLV9.PDL" and "@TemplateAPLV9.PDL".

**Note**



@PCS7TypicalsAPLV7.PDL and @TemplateAPLV7.PDL is no longer supplied with the Setup.

If you still use the V7 block icons in your project and they should continue to be used, the V7 template "@PCS7TypicalsAPLV7.PDL" must be present in the OS project directory (GraCS). In addition, you must delete the newer template images "@PCS7TypicalsAPLV9.PDL" or "@PCS7TypicalsAPLV8.PDL" from the OS project directory.

Deselect also the update for the V9 template in the OS project editor on the basic data tab.

### Automatic configuration of block icons

There is a variety of block icons, which you can select for a block. You select a block icon by entering the number of the block icon in the field "OCM possible" > "Create block icon" in the object properties of the block instance:

You can find the names (numerical entry) of the respective block icons in the description for the blocks (Operator Control and Monitoring section).

If you do not enter a number for a block icon, the number 1 is always used for the block icon. The template for automatically generated block icons is @PCS7TypicalsAPLV9.PDL.

### Additional information

- Manual *Process Control System PCS 7; Engineering System*

### Manual configuration of block icons

You can configure block icons manually by copying them from the @TemplateAPLV7.PDL/ @TemplateAPLV9.PDL template and inserting them into plant pictures.

The connection to the process tag is established with the "Connect faceplate with process tag" Wizard, see WinCC Information System, section "Making Process Pictures Dynamic" and "Standard Dynamics".

You can find information on exporting/importing and updating these objects in the WinCC Information System, section "Graphic Object Update Wizard". Use the "TemplateControlAPL.cfg" configuration file for these wizards.

**Note**

- The procedure for changing the tooltip text of the block icons is described in the *APL Style Guide*. Otherwise, this property may not be changed.

## 2.2.3 Operation via the block icon

### Operation via the block icon

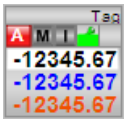
The block icon can be used to operate elements directly if a relevant operator control permission (`OS_Perm`) is available. This operator control permission can be configured in the engineering system (ES).

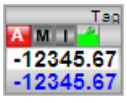
The operation is performed by right-clicking on the element involved. The operable elements in the block icon include:

- Switching the operating mode
- Internal and external setpoint specification
- Changing the process value, setpoint and manipulated variable
- Changing the operating state

The operation is then performed in the same way as in the faceplate. Refer to the section Switching operating states and operating modes (Page 289) as well as Changing values (Page 291).

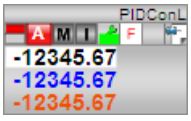
## 2.2.4 Block icons for PID and FM controller

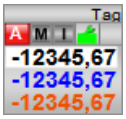


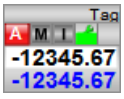


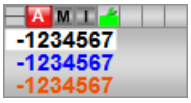
### Block icons for PID and FM controller

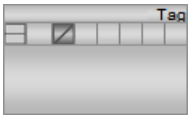
A variety of block icons are available with the following functions:











- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits (tolerance limits not with PIDConS) as well as control system faults
- Operating modes
- Internal and external setpoint specification
- Signal status, release for maintenance
- Memo display

- Process value (black, with and without decimal places, with and without color change at limit violations)
- Setpoint (blue, with decimal places)
- Feedback value (red, with decimal points), not available for types 3 and 4
  With FmCont and FmTemp as a step controller without feedback, there is no feedback value
- "Ramp active" indication is not available in FMCont and FMTemp blocks.
- only `PIDStepL`: Position feedback value (green, with decimal points), not available for types 3 and 4
- Interlock without reset (only for PIDConR and PIDConL)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in the CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | Block icon in the full display |
|  | 6 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |
| Special case for `PIDStepL`: | | |
|  | - | In the case of the `PIDStepL` block only, the green value shows the position feedback (only visible if `WithRbk = 1` has been assigned parameters). With operation by means of the block icon, however, the manipulated variable is operated. |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## 2.2.5 Block icon for interlock blocks

### Properties of the block icon for interlock blocks Intlk02, Intlk04, Intlk08, Intlk16

A variety of block icons are available with the following functions:

- Signal status
- Memo display
- Output signal

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Block icon for |
|---|---|---|
|  | 1 | Intlk02 |
|  | 1 | Intlk04 |
|  | 1 | Intlk08 |
|  | 1 | Intlk16 |
|  | 2 | Intlk02 |
|  | 2 | Intlk04 |
|  | 2 | Intlk08 |
|  | 2 | Intlk16 |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Block icon for |
|---|---|---|
|  | 1 | Intlk02 |
|  | 1 | Intlk04 |
|  | 1 | Intlk08 |

| Icons | Selection of the block icon in CFC | Block icon for |
|---|---|---|
|  | 1 | Intlk16 |
|  | 2 | Intlk02 |
|  | 2 | Intlk04 |
|  | 2 | Intlk08 |
|  | 2 | Intlk16 |
|  | 3 | Intlk02 |
|  | 3 | Intlk04 |
|  | 3 | Intlk08 |
|  | 3 | Intlk16 |

## Block icons (mini) without display of instance-specific names

These icons only show the output signal. They take the form of a small rectangle.

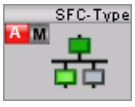
## Display of the output signal

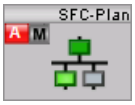
The display can show the following states for the output signal (priority from high to low):

- Gray: No inputs interconnected at the interlock block, the block is not used
- Blue: The output signal is 1, at least one input signal is bypassed. There is no gray state.
- Yellow: The signal status is 16#60; the output signal is simulated. There are no gray and blue states.
- Red: The output signal is 0; there is an interlock. There are no gray, blue, and yellow states.
- Green: The output signal is 1; the block is in the good state. There are no gray, blue, yellow, and red states.

Additional information on the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)





## 2.2.6 Block icons for SFC

### Block icons for SFC

A variety of SFC block icons are available with the following functions:

- Alarm indicator
- Current active mode indicator ("Manual" or "Automatic" mode)
- Operator request icon
- Indicator for SFC operating status

The block icons from template @PCS7TypicalsAPLV9.PDL:

| Block icons | Type 2 | Type 3 |
|---|---|---|
| SFC-Type |  |  |
| SFC-Plan |  |  |

The following icons are dispayed in the SFC block icon:

1. Mode indicators:

| Icon | Bit number | Tag name | Description |
|---|---|---|---|
|  | 7 | .SFC_STATE | The block is in "Automatic" mode. |
|  | 7 | .SFC_STATE | The block is in "Manual" mode. |

2. Status indicators:

| Icon | Bit number | | | | Tag name | Description |
|---|---|---|---|---|---|---|
| | 0 | 1 | 2 | 3 | | |
|  | 0 | 0 | 0 | 0 | .SFC_STATE | IDLE |
|  | 0 | 0 | 0 | 1 | .SFC_STATE | RUN |
|  | 0 | 0 | 1 | 0 | .SFC_STATE | COMPLETED |
|  | 0 | 0 | 1 | 1 | .SFC_STATE | HELD |
|  | 0 | 1 | 0 | 0 | .SFC_STATE | ABORTED |
|  | 0 | 1 | 0 | 1 | .SFC_STATE | STARTING |
|  | 0 | 1 | 1 | 0 | .SFC_STATE | COMPLETING |
|  | 0 | 1 | 1 | 1 | .SFC_STATE | ERROR_COMPLETING |
|  | 1 | 0 | 0 | 0 | .SFC_STATE | HOLDING |
|  | 1 | 0 | 0 | 1 | .SFC_STATE | RESUMING |
|  | 1 | 0 | 1 | 0 | .SFC_STATE | ERROR |
|  | 1 | 0 | 1 | 1 | .SFC_STATE | HELD_ERROR |
|  | 1 | 1 | 0 | 0 | .SFC_STATE | RESU_ERROR |
|  | 1 | 1 | 0 | 1 | .SFC_STATE | ABORTING |
|  | 1 | 1 | 1 | 0 | .SFC_STATE | STOPPING |
|  | 1 | 1 | 1 | 1 | .SFC_STATE | STOPPED |

3. Acquired status indicators (for SFC type only):

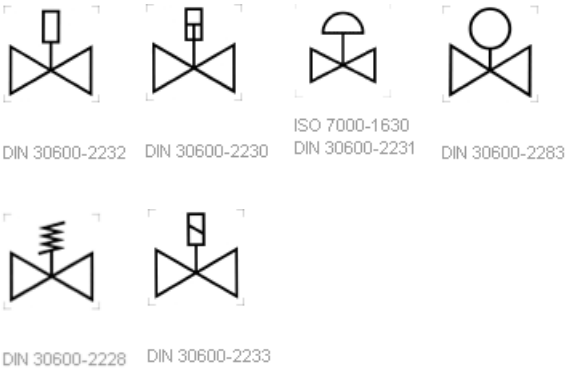
| Icon | Bit number | Tag name | Description |
|---|---|---|---|
|  | 14 | .VSTATUS | EM-SFC is acquired by a superordinated equipment phase (EPH) |
|  | 15 | .VSTATUS | Acquiring of at least one subordinated equipment module (EM) failed |

**See also**

Block icon structure (Page 260)
Configuring the block icons (Page 267)
Operation via the block icon (Page 269)

## 2.2.7 Adding block icons to static picture components

### Static picture component for the block icons



The block icons for drives and valves contain no static picture components. However, you can add static picture components to the block icons by copying them from the @TemplateAPLV9.PDL/@TemplateAPLV7.PDL template and placing them over the block icons.

The following static picture components are available:

- Static picture components for motor blocks:

- Static picture components for valve blocks:

**Note**

The static picture components for the valves are visible here above the valve icon.

Note that all the block icons of the APL are located on layer 0 of the process picture. Layer 1 is intended for the static picture component. This ensures that the static picture component is always over the block icon. If you have changed this layer of the block icon, the static picture component should always be placed in a higher layer.

## 2.2.8 Decimal points for the analog value display

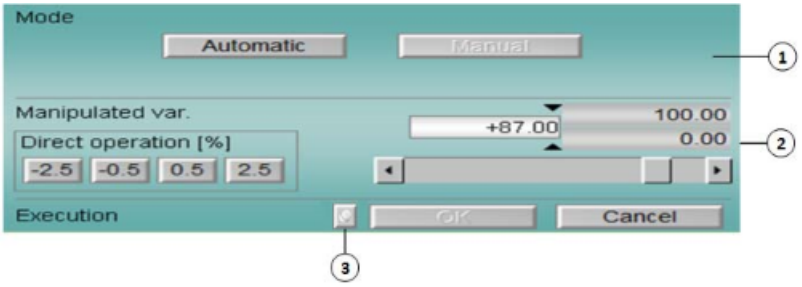
The decimal points for the analog value display can parameterize centrally in the block icon at the attribute Configurations > AnalogValueFormat1...AnalogValueFormat5. If the attribute is empty, the format specification will be taken directly from the faceplate PDL file.

The parameterization in the block icon takes effect in the standard view, limit view, and the block icon. The following table shows the analog values for which format specification can be parametrized in the block icon:

| Blocks | AnalogValue-Format1<br><br>Standard view, Limit view | AnalogValue-Format2<br><br>Standard view, Limit view | AnalogValue-Format3<br><br>Standard view, Limit view | AnalogValue-Format4<br><br>Standard view | AnalogValue-Format5<br><br>Limit view for motors |
|---|---|---|---|---|---|
| **MotL** | | | UserAna1 | UserAna2 | AV values |
| **MotRevL** | | | UserAna1 | UserAna2 | AV values |
| **MotSpdL** | | | UserAna1 | UserAna2 | AV values |
| **MotSpdCL** | Rbk values<br>ER values | SP values | UserAna1 | UserAna2 | AV values |
| **VlvL** | | | UserAna1 | UserAna2 | - |
| **VlvMotL** | | | UserAna1 | UserAna2 | AV values |
| **VlvPosL** | Rbk values<br>MV value | | UserAna1 | UserAna2 | AV values |
| **VlvAnL** | Rbk values<br>MV value | | UserAna1 | UserAna2 | - |
| **Vlv2WayL** | | | UserAna1 | UserAna2 | - |
| **DoseL** | PV values | SP values | UserAna1 | UserAna2 | - |
| **MonAnL** | PV values | | UserAna1 | UserAna2 | - |
| **MonAnS** | PV values | | | | - |
| **OpAnL** | PV values | SP values | | | - |
| **OpAnS** | PV values | SP values | | | - |
| **PIDConL** | PV values | SP values | UserAna1<br>MV values<br>Rbk values | UserAna2 | - |
| **PIDConS** | PV values | SP values | MV values<br>Rbk values | | - |
| **PIDConR** | PV values | SP values | UserAna1<br>MV values<br>Rbk values | UserAna2 | - |
| **PIDStepL** | PV values | SP values | UserAna1<br>MV values<br>Rbk values | UserAna2 | - |

| Blocks | AnalogValueFormat1...AnalogValueFormat4 | AnalogValueFormat5...AnalogValueFormat8 | AnalogValueFormat9 |
|---|---|---|---|
| **ModPreCon** | CV1...CV4, SP1...SP4 values | MV5...MV8 values | DV values |

| Blocks | AnalogValueFormat1...AnalogValueFormat10 | AnalogValueFormat11...AnalogValueFormat20 | AnalogValueFormat21...AnalogValueFormat24 |
|---|---|---|---|
| **MPC10x10** | CV1...CV10, SP1...SP10 values | MV1...MV10 values | DV1...DV5 values |



**Note**

If the analoge value display shows *****, the display field is too small for the parameterized format specification. In this case, adapt the format specification AnalogValueFormatx in the block icon APL_BLOCK_ICON.

# 2.3 Functions of the faceplates

## 2.3.1 Fast Operation for PID Controllers

### Fast Operation for PID Controllers

The concerned blocks are:

- PIDConL
- PIDStepL
- PIDConR

### Enabling Fast Operation

When internal tag "@APLFastOperationEnable" is set to 1, the above mini faceplate can be opened from the block icon. You can right-click on the mode and the manipulated variable fields on block icon will open this faceplate.

1. **Changing modes**
   Only two modes - automatic and manual are available.You can click on the respective buttons to change the mode.
2. **Changing manipulated variable**
   Manipulated variable can be changed by either entering the value directly through slider or by direct operation buttons. Both 2 and 3 step operation are available when changing manipulated variable.
3. **Pin**
   Faceplate is always pinned by default. Pin button is not operable and therefore faceplate can not be unpinned.

## 2.3.2 Structure of the faceplate

### General functions of the faceplates

This section provides general information that applies to all faceplates.

### Recommended screen resolution

The faceplates are shown in full on the screen with a resolution of 1280 x 1024. The full-screen mode (press the F11 key) must also be activated on the Web client.

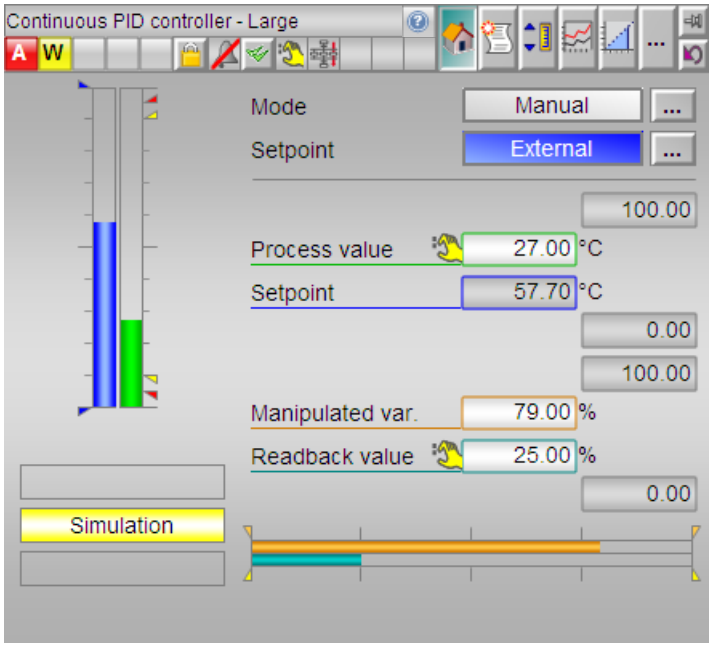
### Scaling the faceplates

You can scale the faceplates from 50% to 200%. The value to scale is given in the internal variable "@APLFaceplateScaleFactor" which is of type unsigned 32-bit value. The default value of the scale is 100. You can scale the faceplates from 101% to 200% by providing a value in the range of 101 to 200 in the internal variable. Similarly, you can scale down the faceplates from 50% to 99% by providing a value in the range of 50 to 99. The reference for calculation is default size of the faceplates which is 100%. This means if the value given is 150, the faceplates will be scaled to 150% of the default size. Similarly, if the value given is 90, the faceplate will be scaled down to 90% of the default size.

The faceplates can also be scaled up or down using the following buttons in a process picture. These buttons are contained in @TemplateAPLV9.PDL and should be configured for both OS-server and OS-client.

| Button | Name | Description |
|---|---|---|
|  | BtnIncreaseZoom | Increase the zoom factor by 5% |
|  | BtnDecreaseZoom | Decrease the zoom factor by 5% |
|  | BtnResetZoom | Reset the zoom factor to 100% |
|   | ZoomValue | Displays the current Zoom value |

**Note**



You must reopen the faceplate after changing the scale value. Already opened faceplate will not be scaled if the scale value is changed.

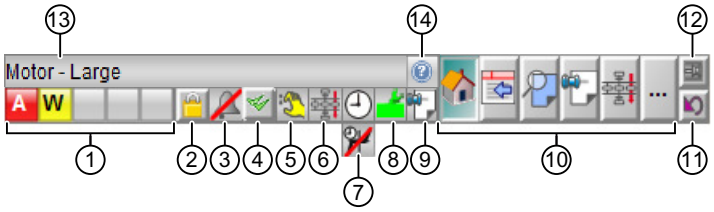
### Displaying CPU stop

With a CPU stop, boxes are unavailable or hidden and a yellow warning triangle is displayed in the group display for blocks with messaging. No operations are possible.

## Opening the faceplate

Click on the block icon in WinCC to open the faceplate with the standard view; in this example this is the standard view of PIDConL:

**Note**



Some of the illustrations of the faceplate views and block icons in the help for the PCS 7 Advanced Process Library are examples or offline representations. The representations on runtime may vary.

The views differ depending on the block functions. All blocks that have faceplates provide a status bar where you can see the most important information relating to the block status. There are additional functions available that are described in the next sections.

**Note**

Display elements of block inputs with `16#FF` as their status default, are only shown when their block inputs are interconnected (status ≠ FF). Exception: The values for `Gain`, `TI` and `TD` are always displayed for controller blocks.

## Displays and operator controls

The faceplate provides the following display and operator controls:

(1) Group display

(2) Lock/unlock messages

(3) Suppress messages / alarm delays with the icon 

(4) Acknowledge alarms

(5) Worst signal status

(6) Batch display

(7) At least one delay time effective at the block

(8) Maintenance request and release

(9) Memo display

(10) Open views of the block

(11) Back to block icon

(12) Pin faceplate

(13) Instance name of the block

(14) Help button

## (1) Group display

The group display shows the information that is transferred from ALARM_8P of the block instance to WinCC.

- Alarms
- Warnings
- Tolerances
- Faults
- Operator prompts
- Process messages

**Note**

The message classes Alarm, Warning and Tolerance are not valid for user-configured message classes. For user-configured message classes, message types depend on the project-specific setting. Please take into consideration the validity of terms for user-configured message classes (Page 45).

### (2) Lock/unlock messages

The Lock/unlock messages button is used to lock/unlock the triggering of messages for all single control units in the process picture affected by group displays directly in the automation system.

### (3) Suppress messages

Message suppression indicates whether or not the "Suppress process messages" function in the AS block is activated with the `MsgLock` parameter. If message suppression is activated, all messages in this block instance – except for process control messages – are suppressed.

### (4) Acknowledge alarms

You can acknowledge all alarms from the block instance using this button.

You can hide this button from specific users / user groups using the permissions in PCS 7-OS. Refer to the *Process Control System PCS 7; OS Process Control* documentation for more on this.

### (5) Display for worst signal status

This display shows the worst signal status currently present. You will find more detailed information in section Forming and outputting signal status for blocks (Page 116).

### (6) Batch display

The batch display shows whether or not the block instance is in use by SIMATIC BATCH.

You will find more detailed information in section SIMATIC BATCH functionality (Page 73).

### (7) At least one delay time effective at the block

| | |
|---|---|
|  | This display shows you the active delay time. You will find more detailed information in section Display of delay times (Page 288). |
|  | The "dead band" function is temporarily deactivated. |

### (8) Maintenance request and release

This display shows you if a maintenance request or release has been made for this block.

You will find more detailed information in section Release for maintenance (Page 70).

### (9) Memo display

This display shows you if a message has been left in the memo view for you. You will find more detailed information in section Memo view (Page 338).

### (10) Open views of a block

You can use this field to open the various views of a block. Refer to the block description to learn of the available views. Left clicking shows the view in the same window. Right clicking opens a new window.

You can select from the following typical views here:

| Icon | Identifier |
|---|---|
|  | Standard view |
|  | Message view |
|  | Limit view (several limit views within a block are possible) |
|  | Trend view |
|  | Ramp view |
|  | Parameter view (several parameter views within a block are possible) |
|  | Preview |
|  | Memo view |
|  | Batch view |
|  | Setpoint view |
|  | Parameter view 1 (continues to parameter view 4, see line below) |
|  | Parameter view 4 |
|  | Quantity view |
|  | Flow view |
|  | Views (additional views within a block are possible) |

**Note**

The buttons are unavailable when views cannot be selected.

### (11) Back to block icon

Use this button to return to the block icon in the process image of the corresponding faceplate. You can use this function, for example, when you have pinned a block **(12)** and the process picture has changed in the meantime.

### (12) Pin faceplate

You can pin the faceplate on top of the user interface using this button. This allows you to change to another picture or area without closing the faceplate.

**Note**

You can learn about additional operator controls in the descriptions of the individual blocks.

### (13) Instance name of the block

This area displays the instance specific name of the block.

### (14) Help button

Click this button to open the *APL Operator Guide* online help of the corresponding view of the faceplate.

## 2.3.3 Operator control permissions

### Operator control permissions for blocks

The following conditions have an effect on operator control permissions:

- User management in the PCS 7 OS
- Local operating permission using the OpStations block
- Dependencies on operating modes in blocks
- Permissions via parameter assignment / interconnection of blocks
- Permissions via the `OS_Perm` input parameter at the block itself

### User management in the PCS 7 OS

The following operator authorization levels from user management are used in the APL:

- Process control (for example, manual/automatic mode switchover, changing setpoints and manipulated variables).
  With this operator control permission, operations can be performed in the standard view of all blocks and input can be made in the ramp and memo views. The "Out of service" operating mode cannot be used with process controlling.
- Higher process controls (for example, changing limits, controller parameters and monitoring times).
  With this operator control permission, all operations in all views of all blocks are possible, including the operations for "Out of service" operating mode. Exception: The operations listed under "Highest process controlling".
- Highest process controls (simulate process values and release process tag for maintenance).
  With this operator control permission, simulation can be switched on and off in the parameter view and the process tag for maintenance work can be released.
- Extended operation 1
  Free project-specific operator authorization
- Extended operation 2
  Free project-specific operator authorization

**Note**

Exceptions to the uses described above are listed in the descriptions of the individual views.

Each operation is assigned with an operator authorization level in the faceplates. This fixed assignment can be changed for each instance at the "operator authorization level" property of an I/O in the AS block (for example, SP_Int with PIDConL). The following assignment applies:

| Operator authorization level in the user management | Value "Operator authorization level" property |
|---|---|
| Process controls | 1 |
| Higher process controls | 2 |
| Highest process controls | 3 |
| Extended operation 1 | 4 |
| Extended operation 2 | 5 |

**Note**

- The free three assignments in the upper table can be changed in the block icon at the properties "OperationLevel1_backup", "OperationLevel2_backup" and "OperationLevel3_backup". Any operator authorization level from the user management can be assigned the values 1 to 3. This type of instance-specific configuration is still available only for reasons of downward compatibility and should no longer be used in new projects.
- The controls for the message system (e.g. acknowledge messages) and trend display (e.g. export) are fixed across the system and cannot be changed via the AS block.
  The "Lock messages" control can be changed per OS Server/ Station via the internal variable "`@LockMessageAuthLevel`" with the value of the operator authorization level from the user management (for example, value "6" for "Higher process controls").

### Local operating permission using the OpStations block

Local operating permission is an upstream operator control permission which is determined before the operator control permissions for user management and the release of the block, and is realized via the OpStations (Page 457) block.

If local operating permission is missing, operation of a block instance on an OS is usually blocked. Otherwise, when local operating permission is allowed, the operator control permission is normally determined through user management and the block.

Local operating permission can be set for each specific instance; in other words, block instances can be enabled or disabled for use on an operator station independently of one another.

You can find additional information for the use of local operating permission in the section Description of OpStations (Page 457).

### Dependencies on operating modes in blocks

You can execute various functions depending on the block mode. These permissions are stored in the block algorithm and are determined dynamically in online mode.

### Permissions via parameter assignment / interconnection of blocks

The block is either controlled by the operator or by the controller, depending on parameter settings or on the interconnection. An example for this is the switchover from manual to automatic mode by a higher-level controller or by the operator. These permissions are stored in the block algorithm and are determined dynamically in online mode.

### Permissions via the OS_Perm input parameter at the block itself

Controllable blocks have the OS_Perm input parameter which allows you to implement individual operator control strategies by setting the operator control permissions. A pressure relief valve, for example, can only be opened by the master control system. The operator may only close the valve. These authorizations are defined during configuration. These operator control permissions are displayed in the preview view of the faceplate. For information about setting the individual operator control permissions (OS_Perm) refer to the description of the functions of the individual blocks.

The relevant operator controls are enabled if the operator has suitable permissions. The block algorithm processes the input data.

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

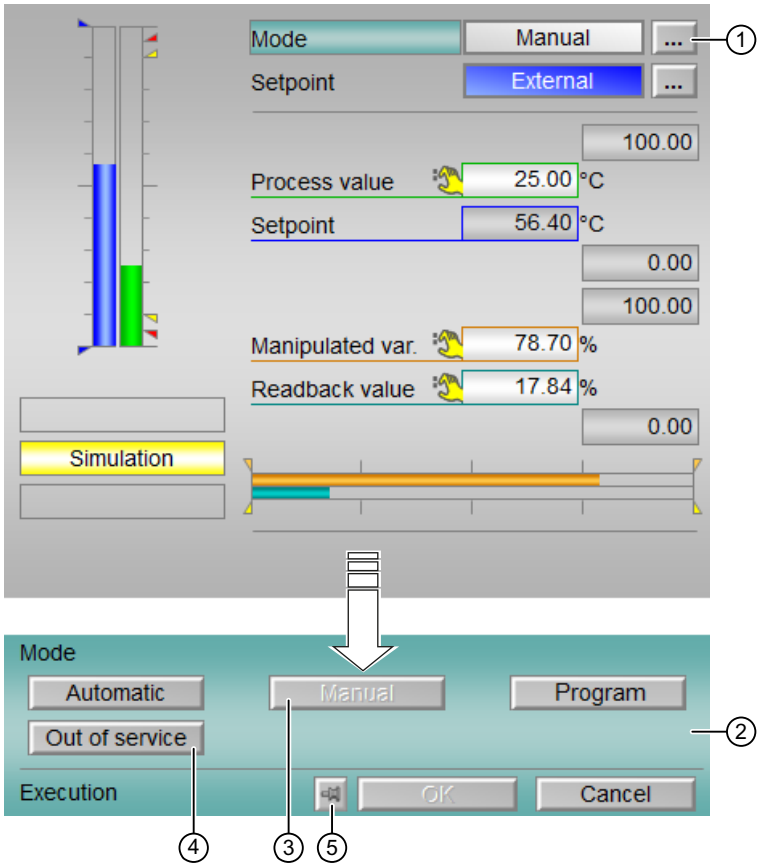
### See also

Enabling local operator authorization (Page 169)

## 2.3.4 Display of delay times

### Display of delay times

As soon as the immediate command output is delayed due to an active delay time at the "Large" blocks of the "Drives" family, this fact is signaled by a bit in the status word and a display in the faceplate.



These times include:

- Pre-warning time
- On/Off delays
- Restart inhibit

## 2.3.5 Switching operating states and operating modes

### Requirements

You can change the operating state, operating mode and other parameters if needed in faceplates if you have the corresponding operator control permission (`OS_Perm`). This operator control permission can be configured in the engineering system (ES).

**(1)** The mouse cursor changes when you place it over the following button:

The mouse pointer now looks as follows:

When you click on the button with the mouse pointer, the bottom of the faceplate expands. You now see the field for changing the operating mode, for example.

**(2)** Field for changing the operating mode, operating state etc. This example describes changing the operating mode.

If the indicators for the operating state is currently located in this field and you have configured text for specific instances, this text is also shown. You can find more information about this in the section Labeling of buttons and text (Page 235).

**(3)** The text on this button is gray. You cannot select this operating mode due to the following reasons:

- This operator control permission for this operating mode cannot be configured in the engineering system (ES).

or

- The operating mode is already selected at this time.

or

- Due to the technology, you cannot switch from the operating mode currently set and the desired operating mode.

**(4)** The text on this button is black. You can switch to this operating mode.

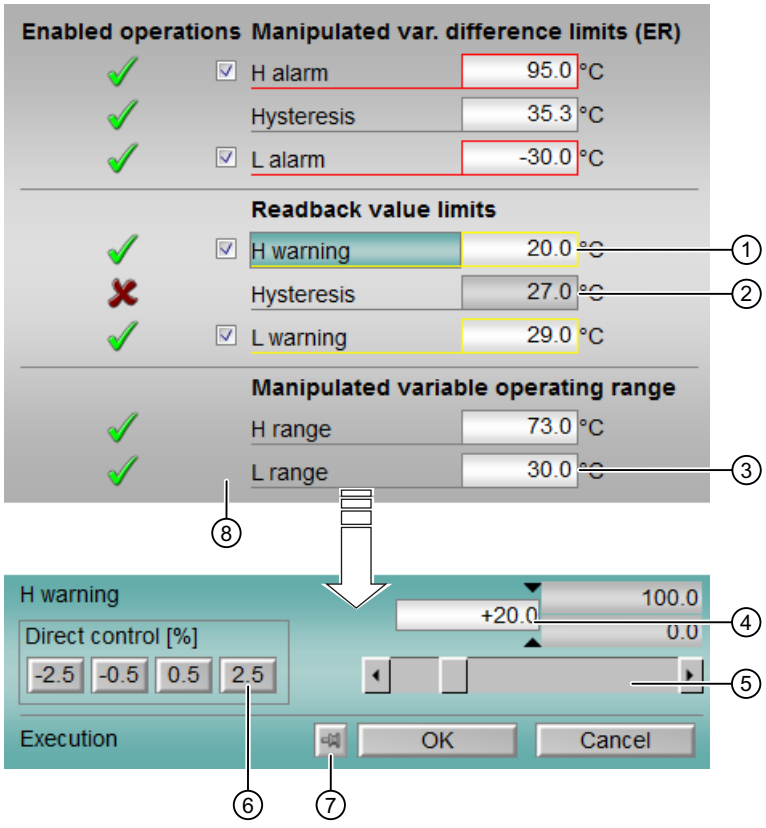
### How to change the operating mode (using the PIDConL block in standard view as an example)

1. Click one of the selectable buttons in the operating mode field.
2. Confirm your selection by clicking "OK".
3. If you do not want to apply your selection, click "Cancel".

After clicking the "OK" or "Cancel" button, the faceplate is reduced again to its original form.

### (5) Multiple operation

If the operating window is not to close after the confirmation of a command, it can be "attached". The following button is located below the operating window for this purpose:



Operating window is closed after the value is applied

Operating window remains open after the value is applied

## 2.3.6 Changing values

### Requirements

You can change the values in faceplates and in the block icons if you have the corresponding operator authorization (`OS_Perm`). This operator permission can be configured in the engineering system (ES). The following example shows how values are changed via the faceplate.

**(1)** The background color of the input box is white. You can change the value. The mouse pointer changes when you place it over the input box:

**(2)** The background color of the input box is gray. You cannot change the value.

**(3)** If you click on the input box, the bottom of the faceplate expands. You now see the field for changing values.

### How to change values in faceplates

You have three options for changing values:

- "Direct control": Click on a button such as "2.5" in the box **(6)**. The value is immediately changed and applied. It is no longer necessary to confirm this value.
- Changing values using the slide control **(5)**: move the slide control until the desired value is shown in the box. Then confirm the value using the Enter key or by clicking "OK". Read the section "Setting the multiple step operation".
- Change the values in the input box **(4)**: Click the input box and enter the new value. If the new values are outside the limits, they are rejected and the old values are retained. Then confirm the value using the Enter key and clicking "OK". Read the section "Setting the multiple step operation".

### Setting the multiple step operation

You can use the internal @APLCommandExecutionSteps tag in the Tag Management of the WinCC Explorer to specify if values are to be changed in two or three steps.

Follow the steps outlined below:

1. Double-click on the internal @APLCommandExecutionSteps tag
2. Change the start value to 2 or 3 in the Limits/Reporting tab.
   **Start value = 2**: It is no longer necessary to confirm the value in the faceplate by clicking "OK"; values are applied immediately.
   **Start value = 3**: Each value change in the faceplate (with the exception of those for direct control) needs to be confirmed with "OK".

### Changing the values for "Direct control"

Specify the percentage values for the two inner keys for direct control with the `DirectOperationValue` property at the block icon. The outer two keys are automatically determined with `DirectOperationValue` times the factor 5.

If `DirectOperationValue` is not an integer but the values in the faceplate are integers, then `DirectOperationValue` is rounded up to the next integer.

If the rounded value is 0, 1 is used for `DirectOperationValue`.

The default value for `DirectOperationValue` is 0.5. With integer format, the "+/-1%" results for the inner keys and "+/-5%" for the outer keys.

The value change also depends on the change in the range of value, which is given by a high limit and a low limit:

| Blocks | Kind of value | High limit | Low limit |
|---|---|---|---|
| MotSpdCL | Setpoint | SP_HiLim | SP_LoLim |
| VlvAnL, VlvPosL | Manipulated variable MV | MV_HiLim | MV_LoLim |
| PIDConL, PIDConS, PIDConR, PIDStepL, FmCont, FmTemp | Setpoint,<br>Manual value Man | SP_HiLim,<br>ManHiLim | SP_LoLim,<br>ManLoLim |
| OpAnL | Setpoint | SP_HiLim | SP_LoLim |

**Note**

When the interlock is active, the High and Low limits of the operation area are considered for VlvPosL and VlvAnL blocks.

The value change is calculated as follow:

value change = button value * (high limit - low limit) / 100.0

**Note**

Analog value format should be configured to accommodate the smallest change triggered by operating range and `DirectOperationValue`. This ensures proper operation and no disabling of direct operation in operation area.

- Example 1:
  Operating range: 0 ~ 1
  Direct Operation Value: 0.5%
  Smallest possible change is 0.005.
  Hence AnalogValueFormat should have atleast 3 decimal places - ##0.000.
- Example 2:
  Operating range: 0 ~ 100
  Direct Operation Value: 0.5%
  Smallest possible change is 0.5.
  Hence AnalogValueFormat should have atleast 1 decimal place - ##0.0Properties

`DirectOperationValue`: Block Icon>Object Properties>Configurations>`DirectOperationValue`

`AnalogValueFormat`: Block Icon>Object Properties>Configurations>`AnalogValueFormat`

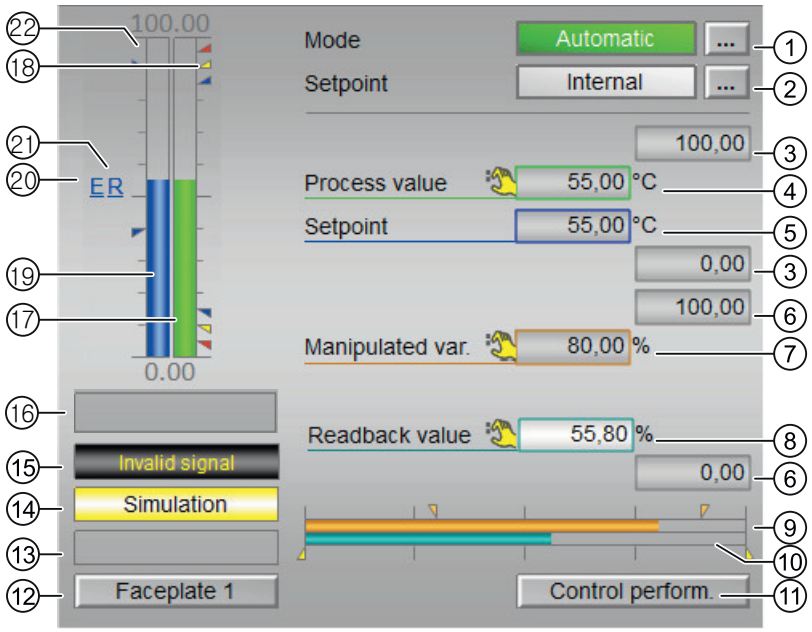
### (7) Multiple operation

If the operating window is not to close after the confirmation of a command, it can be "pinned". The following button is located below the operating window for this purpose:

Operating window unpinned.

When the value of a parameter is set using the "Direct control" button, the value is applied to the parameter and the "Cancel" button is disabled. Click "OK" to close the operating window.

Operating window pinned.



When the value of a parameter is applied using the "Direct control" button, the value is applied to the parameter and the "OK" button is disabled. Click "Cancel" to close the operating window.

### (8) Suppress messages

You can enable / disable messages by setting the check mark.

## 2.3.7 FM controllers standard view (analog)

### Standard view (analog) of FM controllers

### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

For more information on the setpoint specification, refer to the Setpoint specification - internal/ external (Page 136) chapter.

If text is configure for these commands, it is displayed as additional text and as button labels for command selection. You can find more information about this in chapter Labeling of buttons and text (Page 235)

### (3) High and low scale range for the process value

These values provide information on the display range (PV_OpScale) for the bar graph of the process value. The scale range is defined in the Engineering System.

### (4) Display of the process value including signal status

This area provides information on the current process value (PV) with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area provides information on the current setpoint (SP) with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification **(2)** also needs to be set to "Internal" for this block.

### (6) High and low scale range for the setpoint

This area is already set and cannot be changed.

### (7) Display and change the manipulated variable including signal status

This area shows the current "Manipulated variable" (MV) with the corresponding signal status.

Refer to chapter Changing values (Page 291) for information on changing the manipulated variable. You can only make a change in manual mode.

### (8) Display of the position feedback including signal status

This display is only visible when the corresponding block input is connected.

This area provides information on the current readback value of the manipulated variable with the corresponding signal status. This display is only available when the readback value in the box is interconnected to the Rbk input parameter.

### (9) Bar graph for the "Manipulated variable"

This area shows the current "Manipulated variable" in the form of a bar graph (MV_OpScale). The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (10) Bar graph for position feedback

This display is only visible when the corresponding block input is connected.

This area shows the current position feedback in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (11) Navigation button for switching to the standard view of the ConPerMon block

Use this navigation button to reach the standard view of the ConPerMon block. The visibility of this navigation button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (12) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System. The visibility of this navigation button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (13) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in chapter Release for maintenance (Page 70) Display area for block states.

### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in chapter Simulating signals (Page 64).

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (16) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Fuzzy Optim." (FmCont only)
- "Tracking FB"
- "Tracking FM"

- "Safety mode FM"
- "Fuzzy control" (FmCont only)

**Note**

"Ramp active" indication is not available for FMCont and FMTemp blocks in the Standard view.

### (17) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

**Note**

The symbols displayed are not valid for user-configured message classes. Please take into consideration the validity of terms for User-configured message classes (Page 45).

### (18) Bar graph for the "Process value"

This area shows the current "Process value" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (19) Bar graph for the "Setpoint"

This area shows the current "Setpoint" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

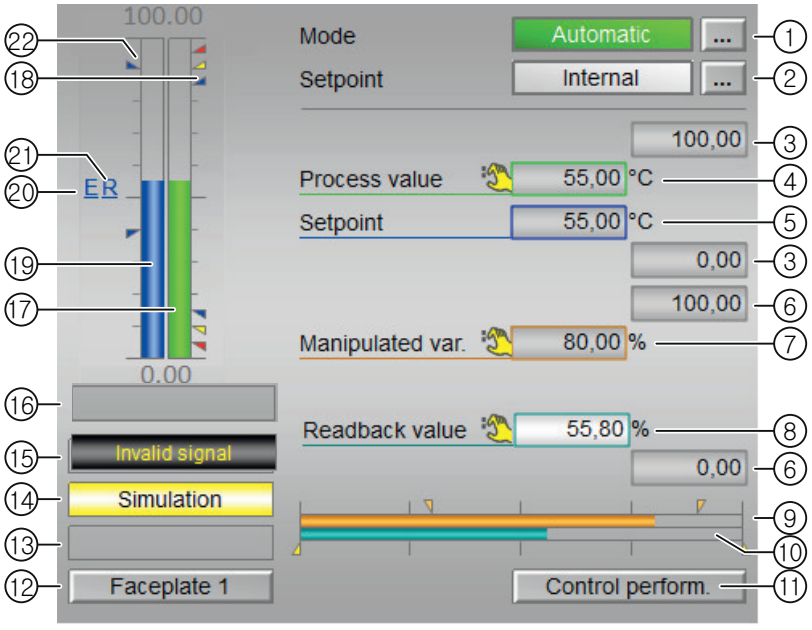
### (20) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (21) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (22) Limit display for the setpoint



These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the ES.

### (23) High and low scale range of bar graph

These values provide the high and low limit values of the bargraph.

## 2.3.8 FM controllers standard view (pulse controller)

### Standard view (pulse) of FM controllers

### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

For more information on the setpoint specification, refer to the Setpoint specification - internal/ external (Page 136) chapter.

### (3) High and low scale range for the process value

These values provide information on the display range (`PV_OpScale`) for the bar graph of the process value. The scale range is defined in the Engineering System.

### (4) Display of the process value including signal status

This area provides information on the current process value (`PV`) with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area provides information on the current setpoint (`SP`) with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification **(2)** also needs to be set to "Internal" for this block.

### (6) High and low scale range for the setpoint

This area is already set and cannot be changed.

### (7) Display and change the manipulated variable including signal status

This area shows the current "Manipulated variable" (`MV`) with the corresponding signal status.

Refer to chapter Changing values (Page 291) for information on changing the manipulated variable. You can only make a change in manual mode.

### (8) Display of the position feedback including signal status

This display is only visible when the corresponding block input is interconnected.

This area shows the current feedback of the manipulated variable with the corresponding signal status. This display is only available when the readback value in the box is interconnected to the `Rbk` input parameter.

### (9) Bar graph for the "Manipulated variable"

This area shows the current "Manipulated variable" in the form of a bar graph (`MV_OpScale`). The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (10) Bar graph for position feedback

This display is only visible when the corresponding block input is interconnected.

This area shows the current position feedback in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (11) Button for switching to the standard view of the ConPerMon block

Use this button for the standard view of the ConPerMon block. The visibility of this button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (12) Button for switching to the standard view of any faceplate

Use this button for the standard view of a block configured in the engineering system. The visibility of this button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (13) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in chapter Release for maintenance (Page 70) Display area for block states.

### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in section Simulating signals (Page 64).

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (16) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Fuzzy Optim." (FmCont only)
- "Tracking FB"
- "Tracking FM"
- "Safety mode FM"
- "Fuzzy control" (FmCont only)

**Note**

"Ramp active" indication is not available for FMCont and FMTemp blocks in the Standard view.

### (17) Bar graph for the "Process value"

This area shows the current "Process value" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (18) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

**Note**

The symbols displayed are not valid for user-configured message classes. Please take into consideration the validity of terms for User-configured message classes (Page 45).

### (19) Bar graph for the "Setpoint"

This area shows the current "Setpoint" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (20) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

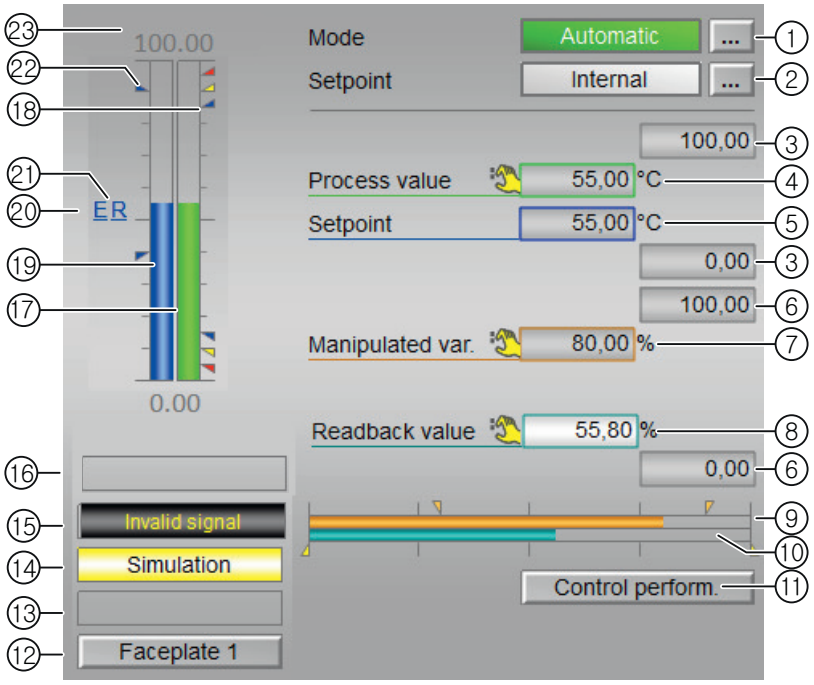
### (21) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (22) Limit display for the setpoint

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the ES.

### (23) High and low scale range of bar graph



These values provide the high and low limit values of the bargraph.

### See also

Labeling of buttons and text (Page 235)

## 2.3.9 FM controllers standard view (step controller with position feedback)

### Standard view with position feedback of FM controllers

### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

For more information on the setpoint specification, refer to the Setpoint specification - internal/ external (Page 136) chapter.

### (3) High and low scale range for the process value

These values provide information on the display range (`PV_OpScale`) for the bar graph of the process value. The scale range is defined in the Engineering System.

### (4) Display of the process value including signal status

This area provides information on the current process value (`PV`) with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area provides information on the current setpoint (`SP`) with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification **(2)** also needs to be set to "Internal" for this block.

### (6) High and low scale range for the setpoint

This area is already set and cannot be changed.

### (7) Display and change the manipulated variable including signal status

This area shows the current "Manipulated variable" (`MV`) with the corresponding signal status.

Refer to chapter Changing values (Page 291) for information on changing the manipulated variable. You can only make a change in manual mode.

### (8) Display of the position feedback including signal status

This display is only visible when the corresponding block input is interconnected.

This area shows the current feedback of the manipulated variable with the corresponding signal status. This display is only available when the readback value in the box is interconnected to the `Rbk` input parameter.

### (9) Bar graph for the "Manipulated variable"

This area shows the current "Manipulated variable" in the form of a bar graph (`MV_OpScale`). The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (10) Bar graph for position feedback

This display is only visible when the corresponding block input is interconnected.

This area shows the current position feedback in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (11) Button for switching to the standard view of the ConPerMon block

Use this button for the standard view of the ConPerMon block. The visibility of this button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (12) Button for switching to the standard view of any faceplate

Use this button for the standard view of a block configured in the Engineering System. The visibility of this button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (13) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in chapter Release for maintenance (Page 70) Display area for block states.

### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in section Simulating signals (Page 64).

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (16) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Fuzzy Optim." (FmCont only)
- "Tracking FB"
- "Tracking FM"
- "Safety mode FM"
- "Fuzzy control" (FmCont only)

**Note**

"Ramp active" indication is not available for FMCont and FMTemp blocks in the Standard view.

### (17) Bar graph for the "Process value"

This area shows the current "Process value" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (18) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

**Note**

The symbols displayed are not valid for user-configured message classes. Please take into consideration the validity of terms for User-configured message classes (Page 45).

### (19) Bar graph for the "Setpoint"

This area shows the current "Setpoint" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (20) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

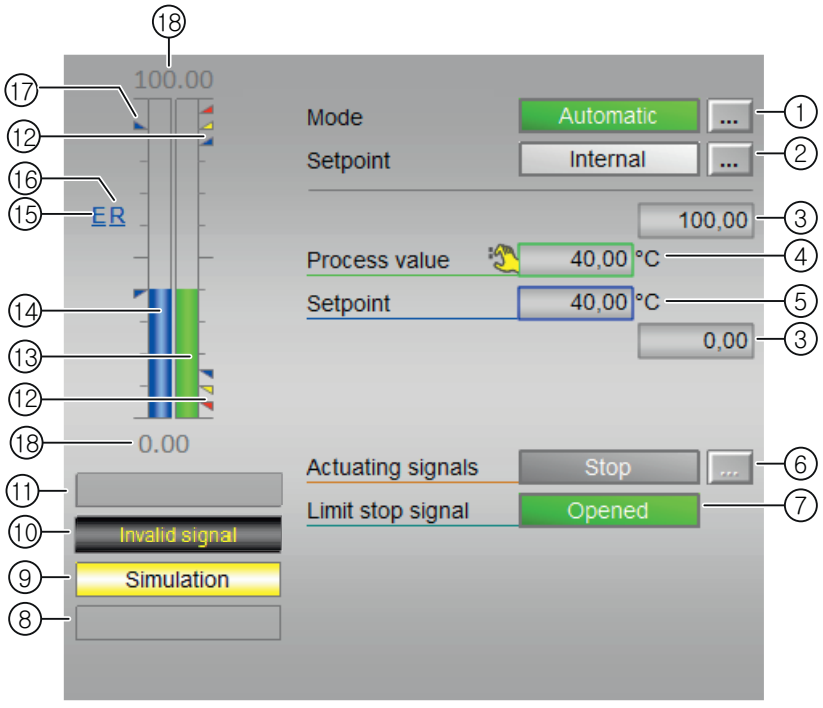
### (21) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (22) Limit display for the setpoint

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the ES.

### (23) High and low scale range of bar graph



These values provide the high and low limit values of the bargraph.

### See also

Labeling of buttons and text (Page 235)

## 2.3.10 FM controllers standard view (step controller without position feedback)

### Standard view without position feedback of FM controllers

### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

For more information on the setpoint specification, refer to the Setpoint specification - internal/ external (Page 136) chapter.

### (3) High and low scale range for the process value

These values provide information on the display range (`PV_OpScale`) for the bar graph of the process value. The scale range is defined in the Engineering System.

### (4) Display of the process value including signal status

This area provides information on the current process value (`PV`) with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area provides information on the current setpoint (`SP`) with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification **(2)** also needs to be set to "Internal" for this block.

### (6) Operating and displaying the actuating signal

This area shows the current feedback of the actuating signal.

- "Open"
- "Stop"
- "Close"

The button is shown next to the display in manual mode. You can influence the actuating signal here. Refer to the Switching operating states and operating modes (Page 289) chapter for more on this.

If text is configured for these commands, it is displayed as status text and as button labels for command selection. You can find more information about this in section Labeling of buttons and text (Page 235)

### (7) Display of the limit stop value including signal status

This area shows the limit stop signal with the corresponding signal status.

- "Open"
- "Closed"

If text is configured for these commands, it is displayed as status text and as button labels for command selection. You can find more information about this in section Labeling of buttons and text (Page 235)

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in chapter Release for maintenance (Page 70) Display area for block states.

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in section Simulating signals (Page 64).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (11) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Fuzzy Optim." (FmCont only)
- "Tracking FB"
- "Tracking FM"

- "Safety mode FM"
- "Fuzzy control" (FmCont only)

**Note**

"Ramp active" indication is not available for FMCont and FMTemp blocks in the Standard view.

### (12) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

**Note**

The symbols displayed are not valid for user-configured message classes. Please take into consideration the validity of terms for User-configured message classes (Page 45).

### (13) Bar graph for the "Process value"

This area shows the current "Process value" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (14) Bar graph for the "Setpoint"

This area shows the current "Setpoint" in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (15) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (16) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (17) Limit display for the setpoint

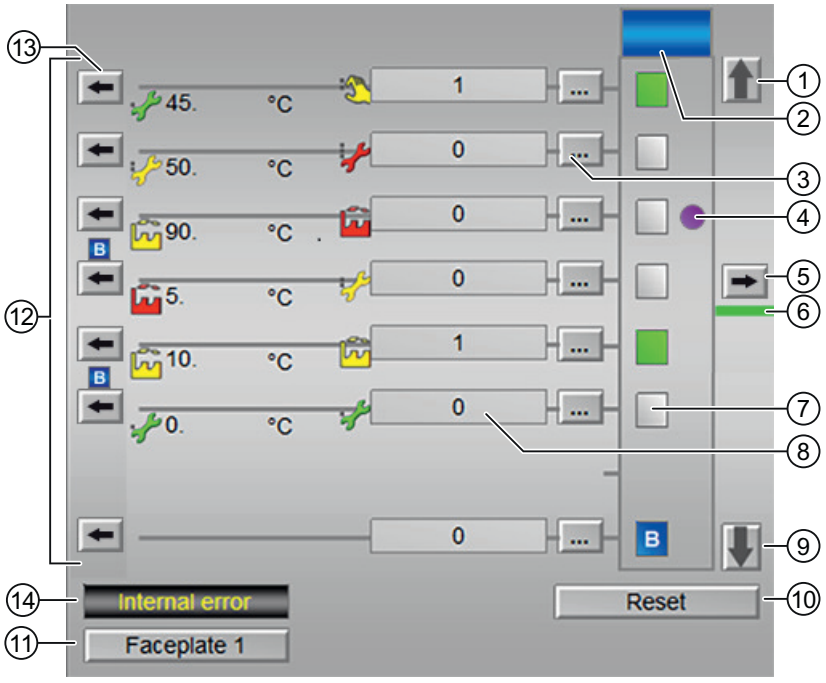
These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the ES.

### (18) High and low scale range of bar graph

These values provide the high and low limit values of the bargraph.

### See also

Opening additional faceplates (Page 234)



## 2.3.11 Interlock blocks standard view

### Interlock blocks standard view Intlk02, Intlk04, Intlk08, Intlk16

The number of the displayed input values depends on the interlock block you have selected.

The operation and functions are identical for all interlock blocks and do not depend on the number of input values.

The **Intlk16** interlock block has two additional buttons for switching between the input values 1 to 8 and 9 to 16.

### (1), (9) Switching between the input values 1 to 8 and 9 to 16 (for Intlk16 only)

The buttons (1) or (9) are displayed depending on the view you are in. These buttons are only available for the **Intlk16** block.

The **Intlk16** block provides two views:

- When you are in the first view, the input values 1 to 8 are available in the area (12). The button (9) is displayed. You switch to the second view by clicking on the button (9).
- When you are in the second view, the input values 9 to 16 are available in the area (12). The button (1) is displayed. You switch back to the first view by clicking on the button (1).

### (2) Status of the output signal of the interlock block

This area (2) shows the status of the output signal of the interlock block (priority from high to low). You can configure the logic in the engineering system (ES).

| | Logic | |
|---|---|---|
| **Color of the field** | **AND** | **OR** |
| Gray | Block is not used (only for display in the faceplate, interlock logic still enabled), set using the `NotUsed` = 1 parameter | |
| Blue | Excluded (bypass) | |
| Yellow | Simulated | |
| Red | Interlocked | |
| Green | Not interlocked | |

### (3) Exclude input values

You can use the button (3) to exclude input values from processing. Depending on the previous settings, you can "Set" or "Reset" this property.

If the input value has been excluded, the following symbol appears in the field (8):

For more information on the operation, refer to the section Switching operating states and operating modes (Page 289).

**Note**

This function can only be executed in the faceplate with "high-level operating permission".

**Note**

Operator permissions via `OS_Perm` do not depend on the `Feature.Bit5` setting. You can find additional information in section Activate OS_Perm bits (Page 168).

### (4) "First in" status display

The following symbol is displayed next to an input value, if this input value has caused the last output signal change from 1 to 0 (good state to locked):

You can reset the first-in (initial) signal with the button (10).

**Note**

This function can only be executed in the faceplate with "process control" operating permission.

You can find additional information on this in the section Recording the first signal for interlock blocks (Page 58).

For more information on the operation, refer to the section Switching operating states and operating modes (Page 289).

### (5) Open faceplate of the output value

When you press the button (5), you can open the faceplate associated with the output value. The function of this button depends on the configuration in the engineering system (ES). See also the section Opening additional faceplates (Page 234) for more on this.

### (6) Status of the block output

The line color indicates the status of the block output:

| Color of the line | Output status |
|---|---|
| Green | Output is enabled |
| White | Output is disabled |

### (7) Display the status for further processing

The symbol shows the status for further processing of the input values:

| Icon | Further processing |
|---|---|
|  | The input value is processed further with value 1. |
|  | The input value is processed further with value 0. |
|  | The input value is excluded from further processing. |

### (8) Display of input values (BOOL) with signal status (in front of the field)

These fields show the interlock information associated with the analog value (13) with a signal status:

- 1 = "Good" state
- 0 = "Locked"

**Changing the display**

You can change the displays for 0 and 1 in the CFC in the object properties of the Interlock block:

- Navigate to the I/Os (object properties).
- Change the default for the input parameters (`Inxx`) in the Text 0 and Text 1 columns to what you later want to see in runtime.

### (9) Switching input values

Read point (1) for this.

### (10) "Reset" the settings for further processing

When you press the button (10), you can "Reset" all input values:

- "Reset exclusions": the exclusions of the input values are reset.
- "Reset first-in": First-in detection / status display (4) is reset.

You can find additional information on this in the section Recording the first signal for interlock blocks (Page 58).

### (11) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (12) Displaying analog input values

The interconnected analog input values (`AVxx`) are displayed in this area. Set a unit of measure (`AVxx_Unit` as shown in the picture with [Unit]) for each input in the engineering system (ES).

**Changing the display**

You can change the displays in the CFC in the object properties of the Interlock block:

- Navigate to the I/Os (object properties).
- In the “OS additional text” column, change the default setting for the input parameter (`INxx`) to what you want to see during runtime later.
- In the "Identifier" column, change the default setting for the input parameter (`AVxx`) to what you want to see during runtime later.

- The text is used as a label and is therefore always displayed, in other words, it is independent of the signal status of the corresponding AVxxx input.
- The font size is reduced during the runtime if the input text length is greater than the label width.

**Note**

If a text is added to the "OS additional text" field of the input parameter (INxx), this text will be displayed even if the "Identifier" text field of the input parameter (AVxx) is not empty. If the "OS additional text" field of the input parameter (INxx) is empty, the "Identifier" text of the input parameter (AVxx) is displayed.

The number of input values may vary depending on the selected interlock block:

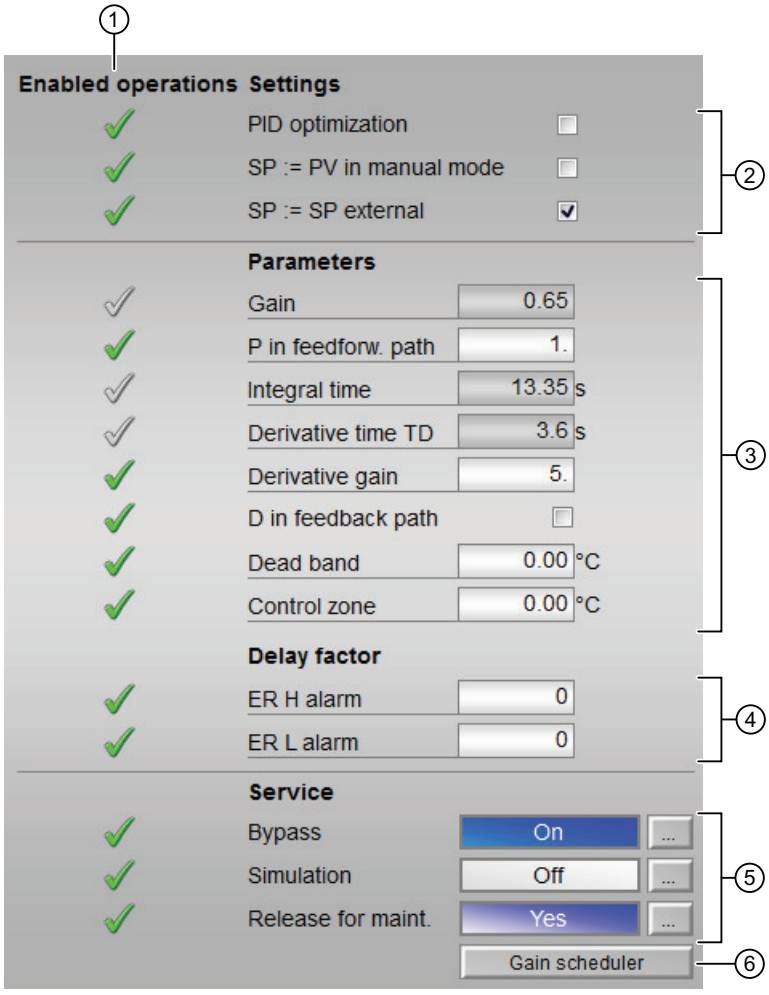
- **Intlk02:** the input values 1 and 2 are available.
- **Intlk04:** the input values 1 to 4 are available.
- **Intlk08:** the input values 1 to 8 are available.
- **Intlk16:** the input values 1 to 8 are available. The input values 9 to 16 become available by pressing the button (9). You can find additional information on this topic in the description for (1) and (9).

### (13) Open faceplate of the input value

When you press the button (13), you can open the faceplate associated with each input value. The function of this button depends on the configuration in the engineering system (ES). See also the section Opening additional faceplates (Page 234) for more on this.

The connected block is in bypass if the following small bypass symbol is displayed over the arrow symbol:

This display can be used only if Feature2.Bit2 Separate evaluation for excluded and simulated interlock signals (Page 162) is active. If additionally the input BypEn.Inx = 1, this interlock input will be set in bypass.



### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"

## 2.3.12 Parameter view of PID controllers

### Parameter view of PID controllers

### (1) "Enabled operation"

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### (2) "Settings"

You can activate the following functions for the controller in this area:

- "PID optimization": ☑ (OptimEn) With pushing the button “Start Controller Optimization” in the tool “PCS7 PID-Tuner” a controller optimization will be activated.
- "SP := PV in manual mode": ☑ Bumpless switchover from manual mode to automatic mode
- "SP := SP external": ☑ Bumpless switchover of the setpoint for setpoint switchover from "external" to "internal". The internal setpoint is tracked to the external one.
  - With the PIDConR block, this area is only visible if you have set the `Feature` bit Switching operator controls for external setpoint to visible (Page 154) to 1.

### (3) "Parameters"

In this area, you change parameters and therefore influence the controller. Refer to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- "Gain": Proportional gain
- "P in feedforw path" : Proportional action to the feedback path (0 to 1),
  - 0 = Proportional action is completely in the feedback path
  - 1 = Proportional action is completely in the feedforward path

  (only with PIDConL, PIDConR, and PIDStepL)
- "Integral time": Integral action time in [s]
- "Derivative time TD": Derivative action time in [s]
- "Derivative gain": Gain of the derivative action
- "D in feedback path": Derivative action is moved to the feedback path (only with PIDConL, PIDConR, and PIDStepL)
- "Dead band": Width of dead band
   Dead band is temporarily disabled
- "Control zone": Width of the control zone (only with PIDConL block)
- "Motor actuating time": Motor actuating time [s] (for PIDStepL block only)
- "Minimum pulse duration": Minimum pulse duration [s] (for PIDStepL block only)
- "Minimum break duration": Minimum break duration [s] (for PIDStepL block only)

### (4) “Delay factor” (only for PIDConL and PIDConR)

In this area, you can change the following parameters:

- "ER H alarm": Delay factor at the positive setpoint step changes for incoming alarms at the control deviation monitoring `ER_AH_Lim`.
- "ER L alarm": Delay factor at the negative setpoint step changes for incoming alarms at the control deviation monitoring `ER_AL_Lim`.

### (5) "Service"

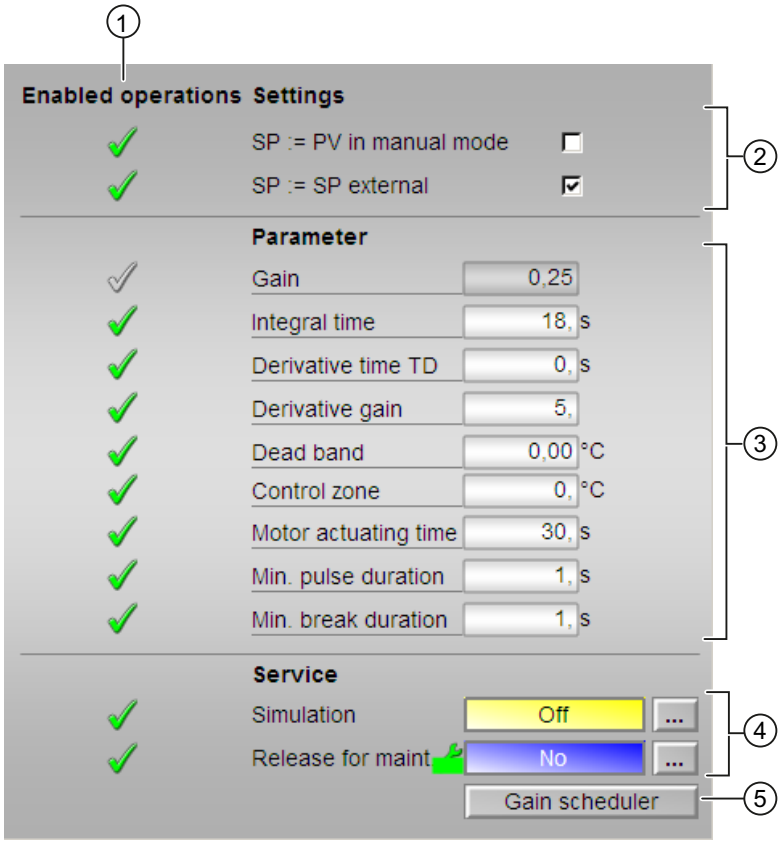
You can select the following functions in this area:

- "Bypass" (only with PIDConL, PIDConR, and PIDStepL)
- "Simulation"
- "Release for maintenance" (with display for a maintenance request)

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Bypassing signals (Page 115) (for PIDConL, PIDConR, and PIDStepL)
- Simulating signals (Page 64)
- Release for maintenance (Page 70)



### (6) Navigation button for the GainSched block

You can use this navigation button to reach the GainSched block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

## 2.3.13 Parameter view of FM controllers

### Parameter view of FM controllers

### (1) "Enabled operations"

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### (2) "Settings"

You can activate the following functions for the controller in this area:

- "SP := PV in manual mode": ☑ Bumpless switchover from manual mode to automatic mode
- "SP := SP external": ☑ Bumpless switchover of the setpoint for setpoint switchover from "external" to "internal" The internal setpoint is tracked to the external one.

### (3) "Parameters"

In this area, you change parameters and therefore influence the controller. Refer to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- "Gain": Proportional gain
- "Integral time" Integral action time in [s]
- "Derivative time TD": Derivative action time in [s]
- "Derivative gain": Gain of the derivative action
- "Dead band": Width of dead band
- "Control zone": Width of the control zone (for block FmTemp only)
- "Motor actuating time": Motor actuating time [s]
- "Minimum pulse duration": Minimum pulse duration [s]
- "Minimum break duration": Minimum break duration [s]

### (4) "Service"

You can activate the following functions in this area:

- "Simulation"
- "Release for maintenance" (with display for a maintenance request)

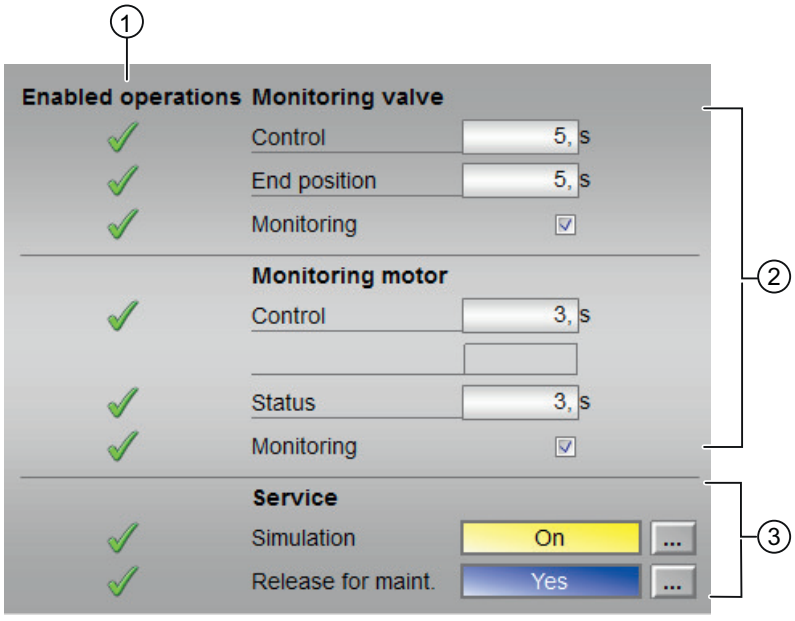
Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

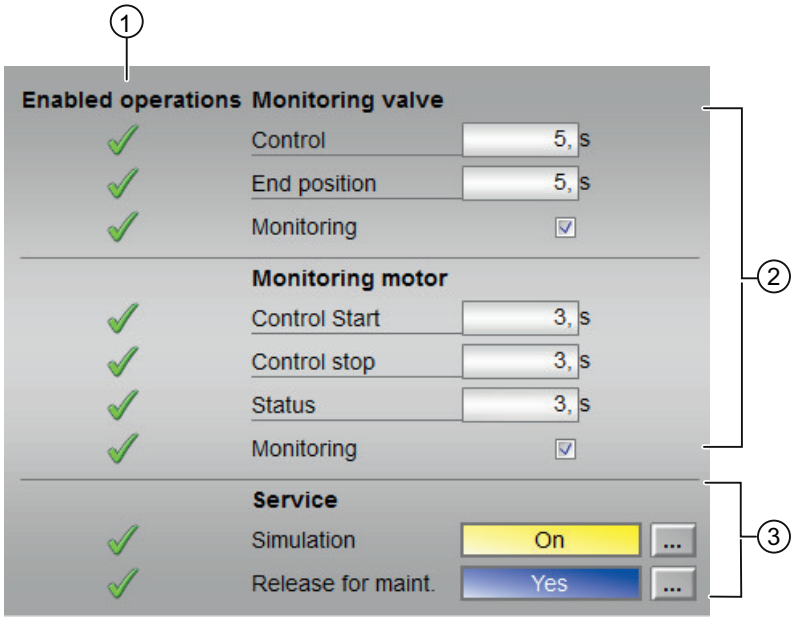
### (5) Navigation button for the GainSched block

You can use this navigation button to reach the GainSched block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).



You can find additional information on this in the Opening additional faceplates (Page 234) section.

## 2.3.14 Parameter view for motors and valves



### Parameter view for motors and valves

The following parameter view applies to the following bocks:

- MotL - Motor (Large) (Page 1376)
- MotRevL - Reversible motor (Page 1440)
- MotS - Motor (Small) (Page 1415)
- MotSpdL - Two-speed motor (Page 1556)
- VlvL - Valve (Large) (Page 1691)
- VlvS - Valve (small) (Page 1728)

Parameter view for MotL, MotRevL, MotS, MotSpdL, VlvL and VlvS with `Feature.Bit13` = 0.

Parameter view for MotL, MotRevL, MotS, MotSpdL, VlvL and VlvS with `Feature.Bit13` = 1.

## (1) "Enabled operation"

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

## (2) "Monitoring"

In this area, you change parameters and therefore influence the motor. Refer to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- "Control": Monitoring time during startup and shutdown of the motor (dynamic)
- "Control stop": Monitoring time during shutdown of the motor (dynamic)
  only for MotL, MotRevL, MotSpdL and MotS with `Feature.Bit13` = 1
- "Control start": Monitoring time during startup of the motor (dynamic)
  only for MotL, MotRevL, MotSpdL and MotS with `Feature.Bit13` = 1
  "End position": Monitoring time during permanent operation of the motor (static)
- "Status": Monitoring time during permanent operation of the motor (static)
  The state is not displayed for small blocks.

**Enabling "Monitoring"**

You can enable monitoring by selecting the check box (☑)

You can find additional information on this in the section Monitoring the feedbacks (Page 104).

### (3) "Service"

You can select the following functions in this area:

- "Simulation"
- "Release for maintenance" (with display for a maintenance request)

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

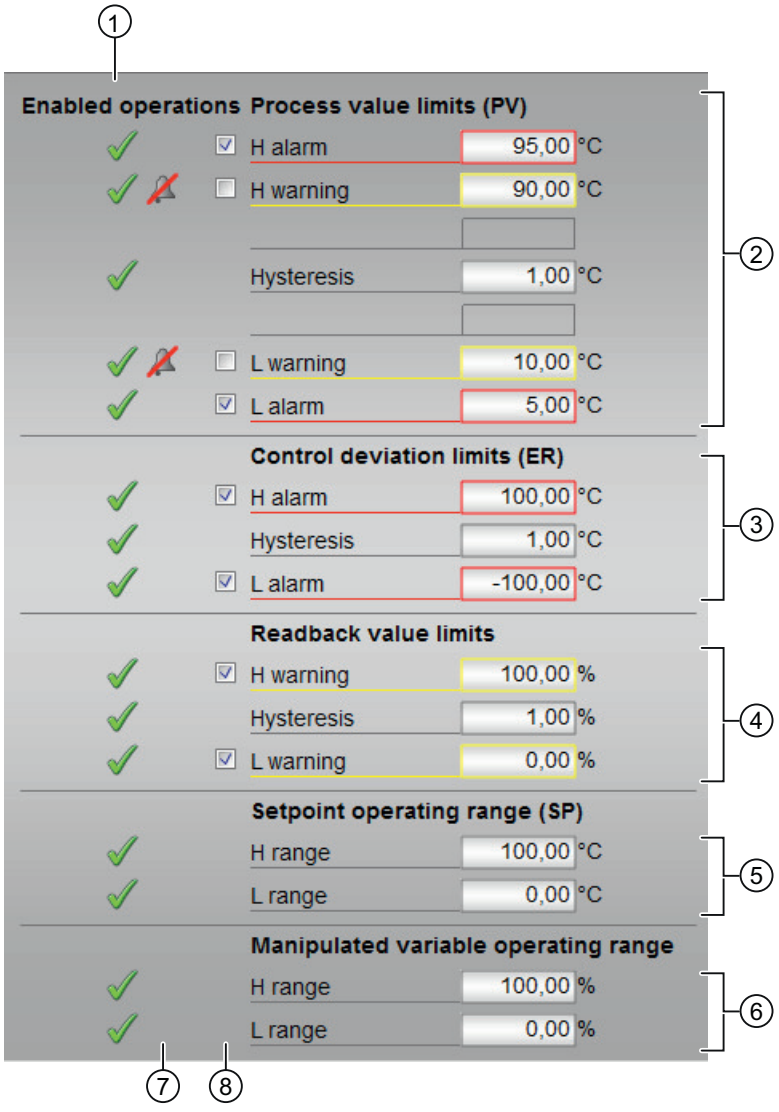
- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### See also

Description of VlvS (Page 1728)

## 2.3.15 Limit view of FM controllers

### Limit view of FM controllers



Several values are set in this view by default:

- Process value limits
- Error signal limits
- Readback value limits
- Setpoint operation range

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

**Note**

The symbols displayed are not valid for user-configured message classes. Take into consideration the validity of terms for User-configured message classes (Page 45)

## (1) "Enabled operation"

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (2) "Process value limits (PV)"

In this area, you can enter the limits for the process value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "H tolerance": Tolerance high
- "Hysteresis"
- "L tolerance": Tolerance low
- "L warning": Warning low
- "L alarm": Alarm low

### (3) "Error signal limits (ER)"

In this area, you can enter the limits for the control deviation. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "Hysteresis"
- "L alarm": Alarm low

### (4) "Readback value limits (RBK)"

In this area, you can enter the limits for the readback value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H warning": Warning high
- "Hysteresis"
- "L warning": Warning low

### (5) "Setpoint operation range (SP)"

In this area, you can enter the limits for the setpoint operation range. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H range": Range limit high
- "L range": Range limit low

### (6) "Manipulated variable operating range"

In this area, you can enter the limits for the manipulated variable operation range. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H range": Range limit high
- "L range": Range limit low

### (7) "Message suppression/delay"

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

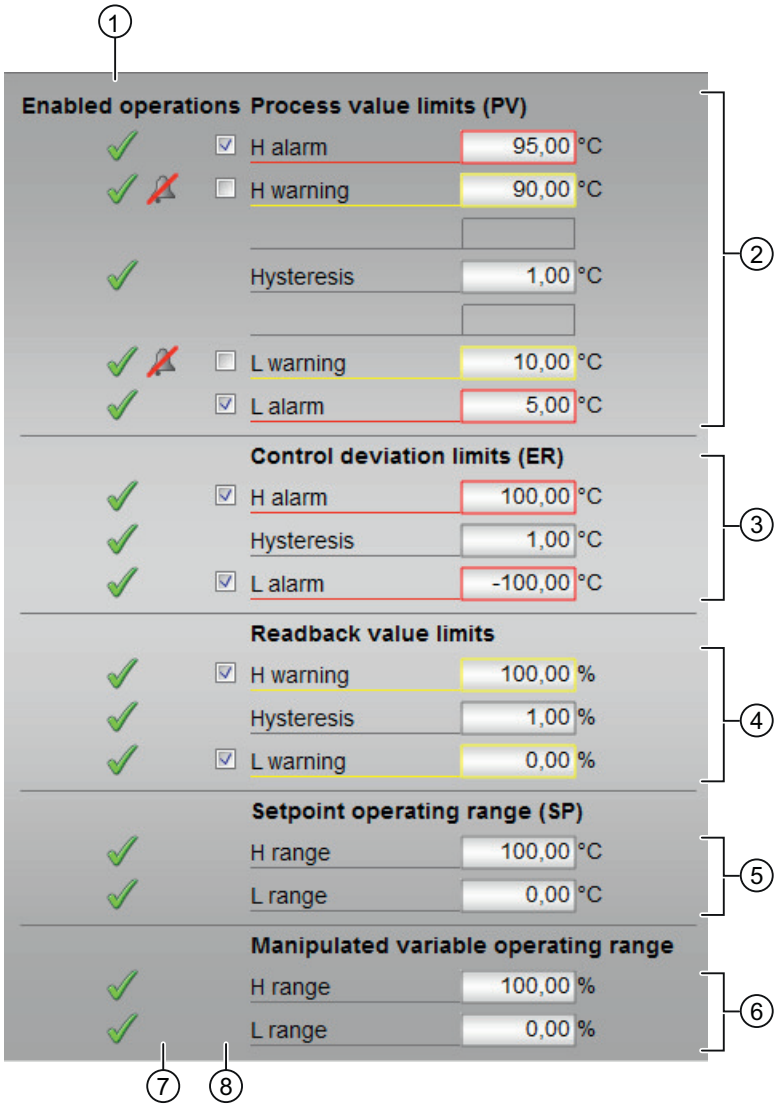
Alarm delays are also displayed in this position; for more on this see section Area of application of the alarm delays (Page 225).

### (8) Suppressing messages

You can enable / disable messages by setting the check mark.

## 2.3.16 Limit view of PID controllers

### Limit view of PID controllers



Several values are set in this view by default:

- Process value limits
- Error signal limits
- Readback value limits
- Setpoint operation range

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

**Note**

The symbols displayed are not valid for user-configured message classes. Take into consideration the validity of terms for User-configured message classes (Page 45).

## (1) "Enabled operation"

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (2) "Process value limits (PV)"

In this area, you can enter the limits for the process value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "H tolerance": Tolerance high (not with PIDConS)
- "Hysteresis"
- "L tolerance": Tolerance low (not with PIDConS)
- "L warning": Warning low
- "L alarm": Alarm low

### (3) "Error signal limits (ER)" (not with PIDConS)

In this area, you can enter the limits for the control deviation. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "Hysteresis"
- "L alarm": Alarm low

### (4) "Readback value limits (RBK)" (not with PIDConS)

In this area, you can enter the limits for the readback value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H warning": Warning high
- "Hysteresis"
- "L warning": Warning low

### (5) Setpoint operation range (SP)

In this area, you can enter the limits for the setpoint operation range. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H range": Range limit high
- "L range": Range limit low

### (6) Manipulated variable operating range

In this area, you can enter the limits for the manipulated variable operation range. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H range": Range limit high
- "L range": Range limit low

### (7) "Message suppression / delay"

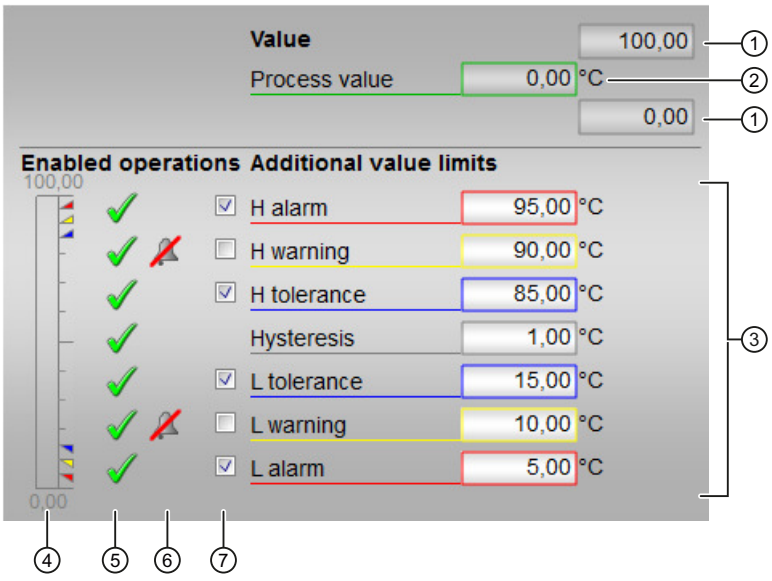
Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

Alarm delays are also displayed in this position; for more on this see section Area of application of the alarm delays (Page 225).

### (8) Suppress messages

You can enable / disable messages by setting the check mark.

## 2.3.17 Limit view of motors



### Limit view of motors

The limit view of motors is only available when an AV block has been interconnected to the motor.

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

**Note**

The symbols displayed are not valid for user-configured message classes. Take into consideration the validity of terms for User-configured message classes (Page 45).

### (1) High and low scale range for the additional value

These values provide information on the display range for the bar graph of the additional value. The scale range is defined in the engineering system.

### (2) Display of the additional value including signal status

This area shows the current additional value with the corresponding signal status.

### (3) "Limits for the additional value"

In this area, you can enter the limits for the additional value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "H tolerance": Tolerance high
- Hysteresis
- "L tolerance": Tolerance low
- "L warning": Warning low
- "L alarm": Alarm low

### (4) Bar graph for the additional value

This area shows you the current additional value in the form of a bar graph. You can also see the high low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

You can find additional information about this in the Bar graph (Page 376) section.

### (5) "Enabled operation"

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

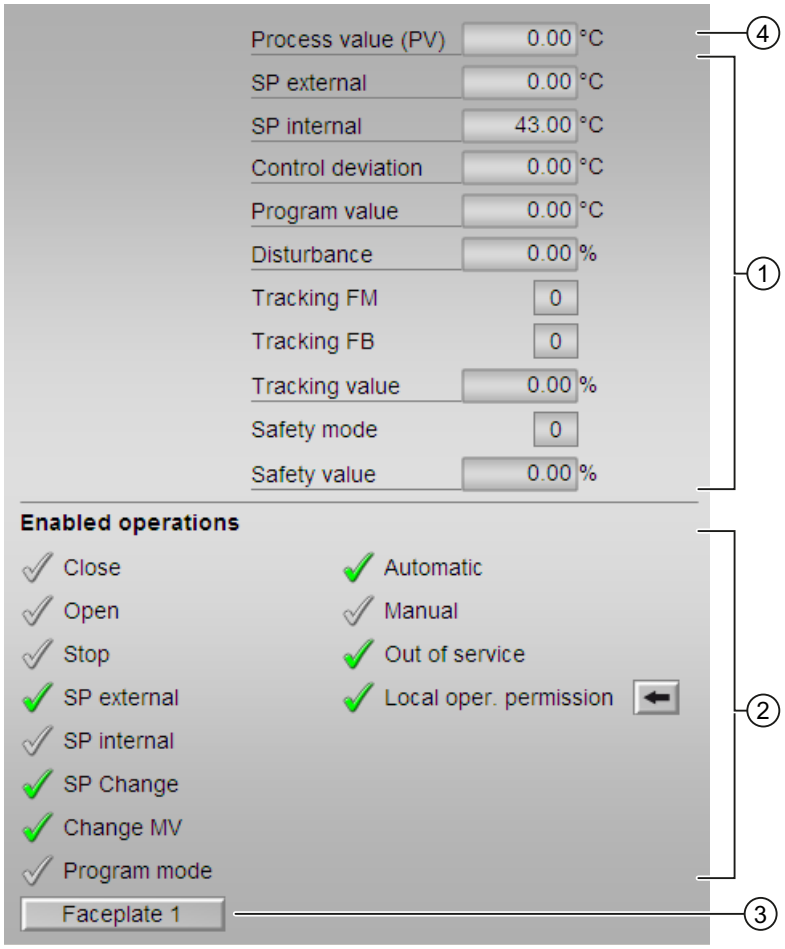
- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The colored triangles indicate the specified limits **(3)** for the additional value.

### (6) Message suppression / delay

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

Alarm delays are also displayed in this position; for more on this see section Area of application of the alarm delays (Page 225).



### (7) Suppress messages

You can enable / disable messages by setting the check mark.

## 2.3.18 Preview of FM controllers

### Preview of FM controllers

The preview shows you the parameters that you, as an OS operator, can control in the entire block. You cannot control anything in this view, however.

### (1) Preview area

This area shows you a preview for the following values:

- "SP external": currently applicable external setpoint
- "SP internal": currently applicable internal setpoint
- "Control deviation": Current Control deviation
- "Program mode": Specified value for program mode
- "Disturbance variable": additive value for feedforward control
- "Tracking FM": track a manipulated variable in the FM module (value is 1)
- "Tracking FB": Track manipulated variable at the block (value is 1)

- "Tracking value": Effective manipulated variable for "Track manipulated variable at block"
- "Safety mode": safety mode in the FM module (value is 1)
- "Safety value": effective manipulated variable for "Safety mode"

### (2) "Enabled operations"

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

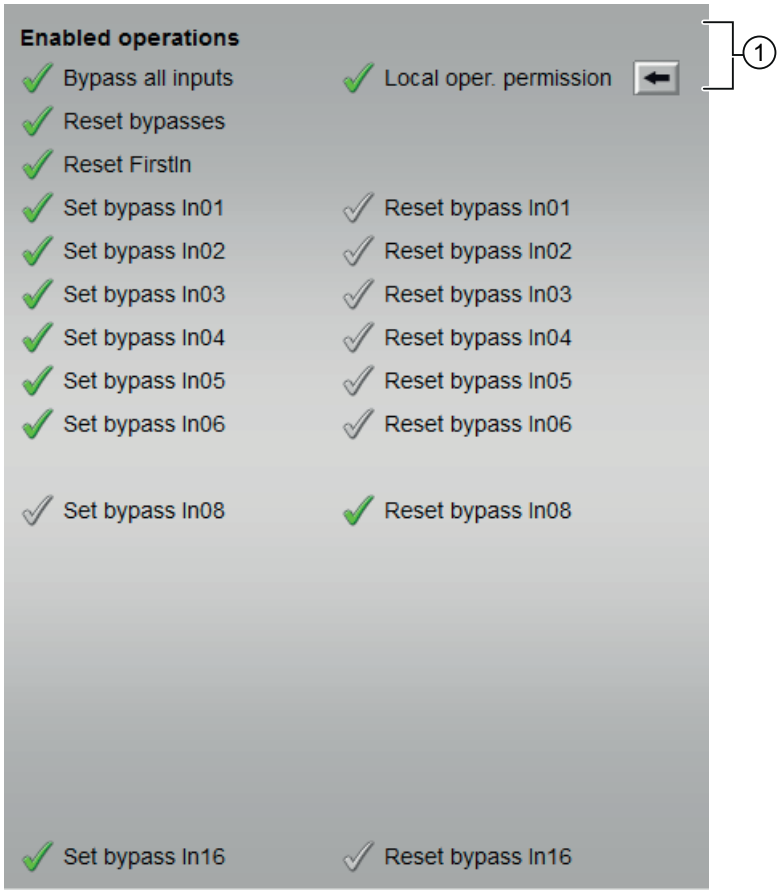
- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Close": You can select the manipulated variable "Close". If text is configured for this command, it is also displayed in brackets. You can find more information about this in the Section Labeling of buttons and text (Page 235).
- "Open": You can select the manipulated variable "Open". If text is configured for this command, it is also displayed in brackets. You can find more information about this in the Section Labeling of buttons and text (Page 235).
- "Stop": You can select the manipulated variable "Stop". If text is configured for this command, it is also displayed in brackets. You can find more information about this in the Section Labeling of buttons and text (Page 235).
- "SP external": You can feedforward the external setpoint.
- "SP internal": You can feedforward the internal setpoint.
- "Change SP": You can change the setpoint.
- "Change MV": You can change the manipulated variable.
- "Program mode": You can switch to program mode.
- "Automatic": You can switch to automatic mode.
- "Manual": You can switch to manual mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the "OpStations"" block. Additional information is available in the section Operator control permissions (Page 285).

### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).



See also the Opening additional faceplates (Page 234) section for more on this.

### (4) Process value

This area displays the real process value (PV).

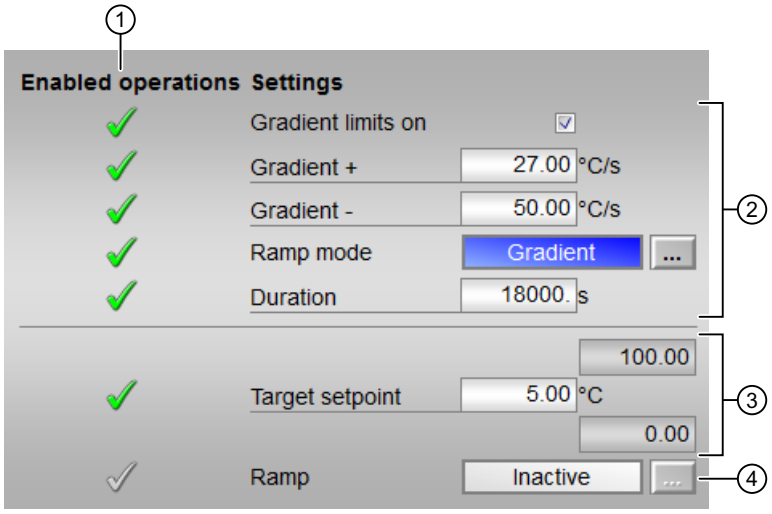
## 2.3.19 Preview of interlock blocks

### Preview of interlock blocks

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:



- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations are shown here:

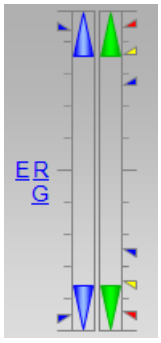
- "Local operating permission": Use the <-- button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

## 2.3.20 Ramp view

### Ramp view

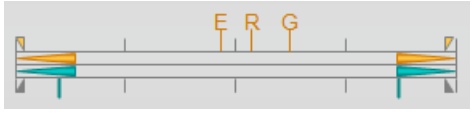
### (1) "Enabled operations"

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.



Symbols for enabled operations:

- Green check mark: the OS operator can control this parameter
- Gray check mark: the OS operator cannot control this parameter at this time due to the process
- Red cross: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)



### (2) Enable "gradient limit"

Use this check box to enable "gradient limit" for the setpoint. "Gradient limit" can be set separately for positive or negative setpoint changes ("Gradient +" or "Gradient -"). Refer to the Changing values (Page 291) section for more on this.

If there is a difference between target setpoint and currently effective setpoint, a blue "G" may be displayed at the bar in standard view of FmCont, FmTemp, PIDConL, PIDConR, PIDStepL, OpAnL and MotSpdCL with parameter assignment of `SP_RateTarget` (target setpoint for gradient limit).

If there is a difference between the target manipulated variable and the currently effective manipulated variable, an orange "G" may be displayed at the bar in the standard view of VlvAnl with parameter assignment of `MV_RateTarget` (target manipulated variable for gradient limit).

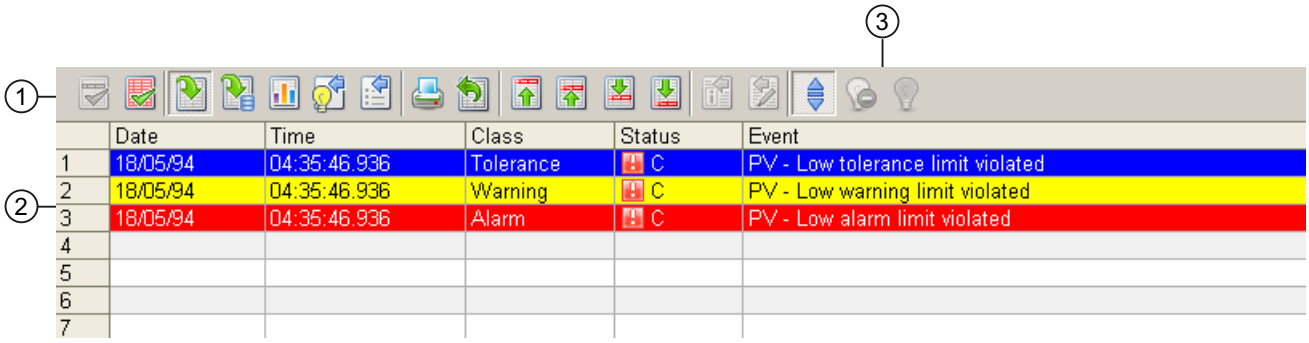
The gradient limitation includes the Ramp function (Page 131). You can set the ramp mode in the following two ways:

- Gradient
- Duration [s]

### (3) "Target setpoint"

In this area, you can set the type of ramp function for the setpoint.

You can set the time duration and the target setpoint. Refer to the Changing values (Page 291) section for more on this.



### (4) Enable "Ramp"

You can use this control to enable or disable the configured function in the ramp function for the setpoint change.

You can only enable this when the setpoint specification is set to "Internal" in the standard view of the block. The enable is only valid for one setpoint change and is subsequently disabled again.

## 2.3.21 Alarm view

### Message view

**(1) Toolbar**

If the short-term archive list is selected, a new button appears in the toolbar:

You can use this button to toggle between the "History" and "Operator messages" views.

You must be registered with the "Higher process control" operating permission in order to export and hide messages.

**(2) Display area for alarms**

For additional information about the alarm view, refer to the *WinCC Information System* Online Help.

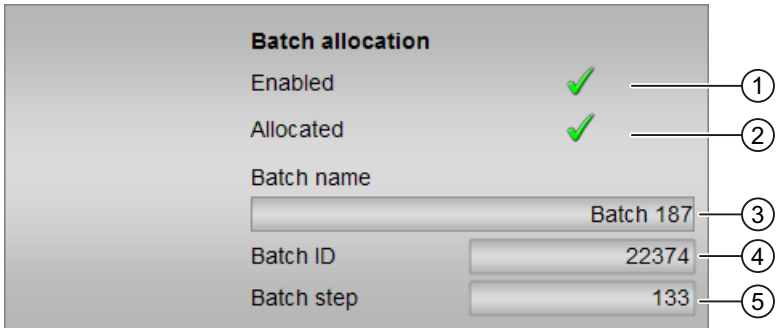
**(3) "Hide messages" button**

Messages can be displayed and/or hidden with this button. The view of this button changes accordingly:

 Show messages

 Hide messages

"Higher process controlling" operating permission is required and manual hiding must be active. You can find additional information in the manual "Process Control System PCS 7 Operator Station".



## 2.3.22 Batch view

### Batch view

This area shows a display of the batch that is currently running (`Batchview`).

You can use the internal tag "@APLBatchEnable" to enable/disable the "Batch" button in the toolbar.

| Value of @APLBatchEnable | Operating the "Batch" button in the toolbar | Icon of the "Batch" button in the toolbar |
|---|---|---|
| 0 | Disabled |  |
| 1 | Enabled |  |

### (1) "Enabled"

This area shows you if the block is enabled for operation via SIMATIC BATCH `(BatchEn = 1)`.

### (2) "Allocated"

This area shows if the block is currently in use by SIMATIC BATCH (Occupied = 1).

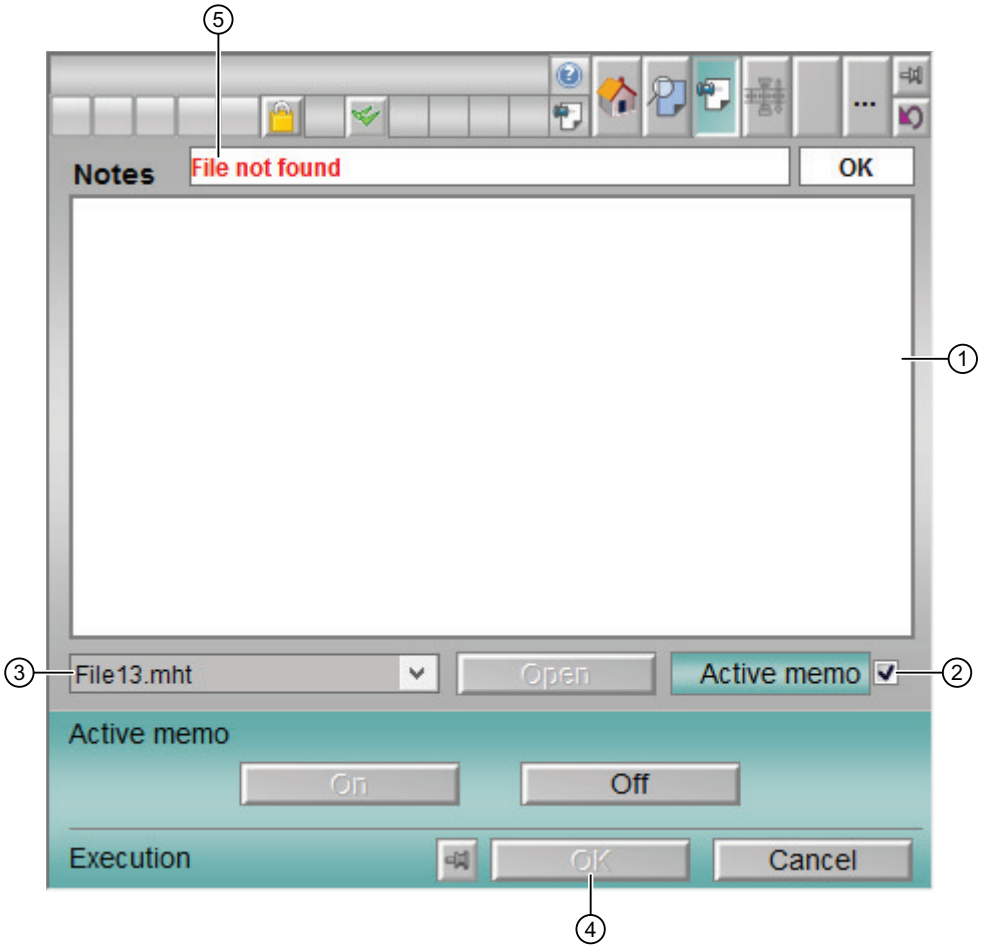
### (3) "Batch name"

This area shows the name of the batch that is currently running `(Batchname)`.

### (4) "Batch ID"

This area shows the identification number of the batch that is currently running `(BatchID)`.

The batch view is disabled if `BatchID` = 16#00000000.



### (5) "Batch step"

This area shows the step number of the batch that is currently running `(StepNo)`.

## 2.3.23 Memo view

### Memo view

You can leave temporary messages for other OS operators in this view. Messages are entered in the text box, and saved and activated by selecting the check box in the lower right corner of the faceplate.

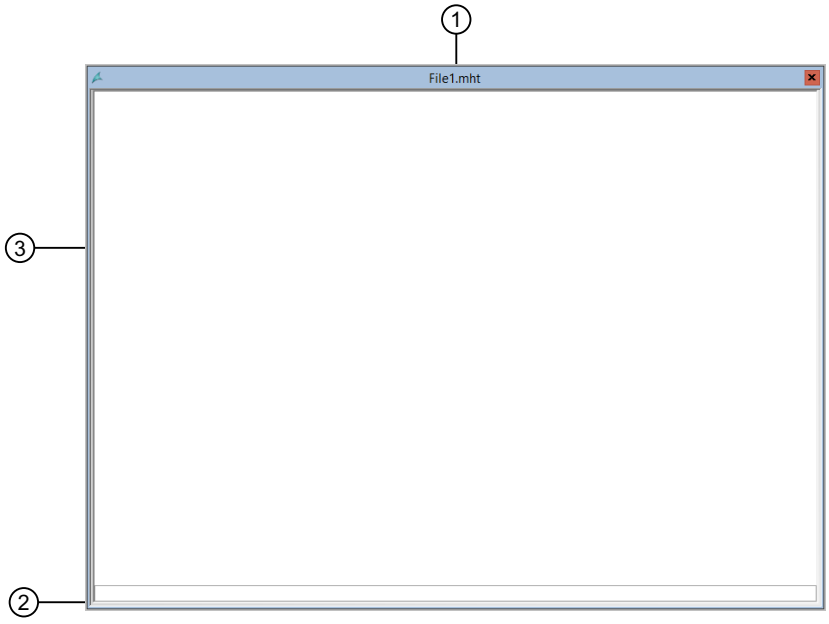
**(1)** Entry field for "Notes"

**(2)** Activating the note

**(3)** Selection of NoteView documents (maximum of three .mht files)

**(4)** Open the selected file and click "OK" to open a new window displaying the selected file

**(5)** Diplays error message



Possible error messages:

- File not found: If the selected file is not avaialbe in the NoteView folder.
- File size exceeded: If the selected file is larger than the allowable limit (> 25 MB).

- Invalid file format: If the file format is not .mht extension.
- File name length exceeded: If the file name exceeds more than 32 characters excluding file extension .mht.

**Note**

- Files that are configured for NoteVew should be saved with UTF-8 encoding. This is applicable to all the intermediate files also, before they are converted to .mht files.
- Jump instruction within the file in NoteView window will not work in the OS Client, Web Server and Web Client.
- No permission levels are required for combo box and open button in the APL_Memo.PDL.
- Document - internal skip marks are not supported.

**(1)** Window Title: indicates the title of Window and name of the file opened as well.

**(2)** Indicates the loading status of the selected MHT document

**(3)** NoteView display area: displays content of the selected file.

Advised maximum size of the file is <= 25 MB for a smooth operation.

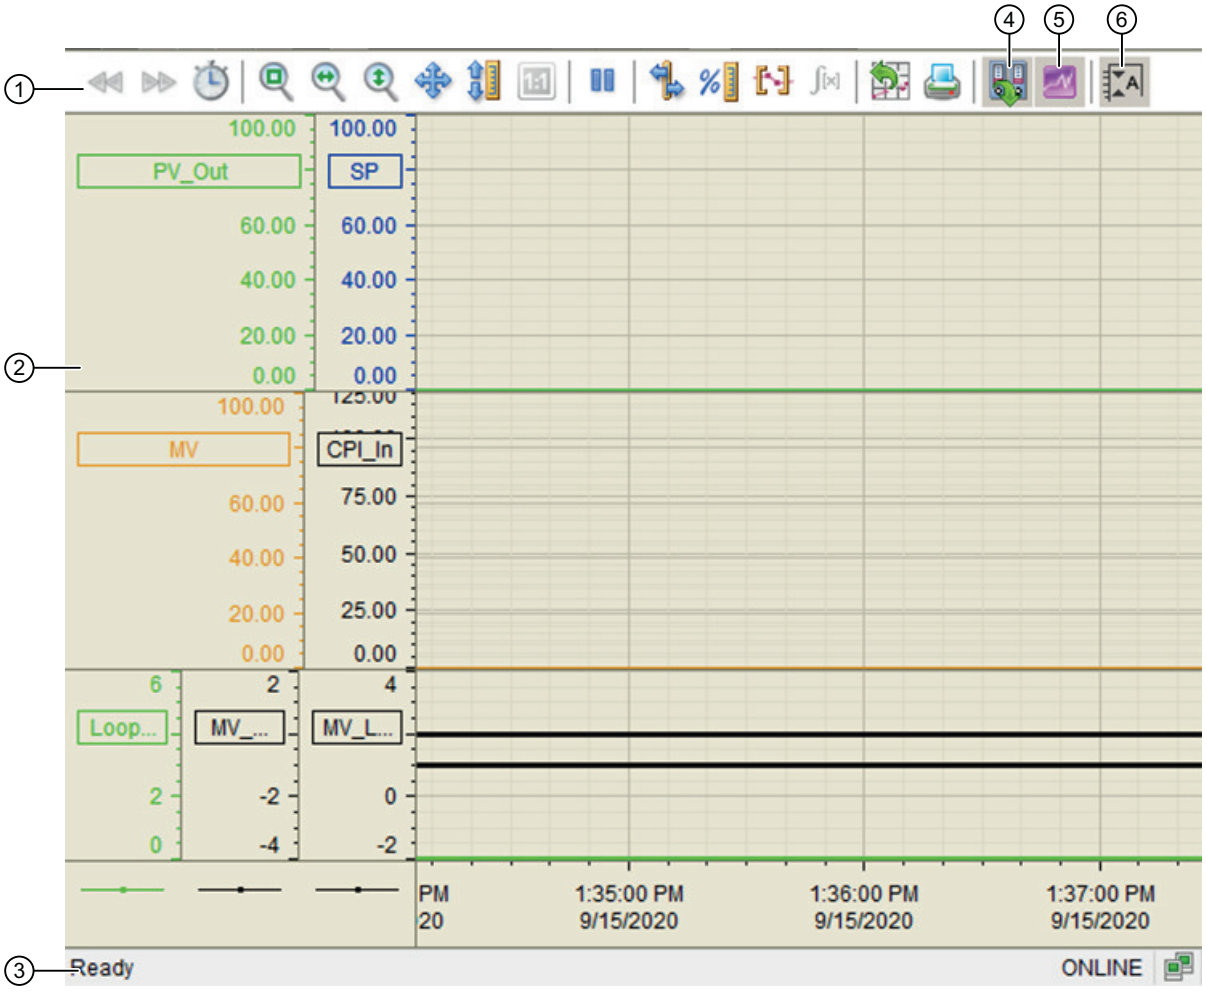
**Note**

- This window cannot be resized but it is movable.
- This window is not supported by the "screen composition" functionality.

All the .mht files (NoteView documents) should be placed in the "OS project path\Gracs \NoteView". In case of a Multiproject, standard server(SSM) holds all .mht files and these files are not available in the client. If SSM is not configured then files should be placed in local project folder of client

**Error Handling**

- If selected file is not found in the folder path, an error message is shown as “File not found”.
- If configured file format is other than .mht, an error message is shown as "Invalid file format".
- If selected file is more than 25 MB and if tried to open same, an error is shown as “File size exceeds 25 MB”.
- If file name length exceeds 32 characters, an error is shown as "File name length exceeded 32 characters".



The next time the faceplate is opened or there is a process picture change, you can see in the status bar of the block icon and the faceplate that there is a new message for you.

Clearing the check box deletes the indicators in the status bars.

The message is not deleted automatically.

## 2.3.24 Trend view

### Trend view

**(1)** Toolbar

**(2)** Display area for trends

**(3)** Status bar

**(4)** Button for switching between archive tags and online tags. The status bar shows if the trend view is working with online data or archive data.

**(5)** Button for opening the "Scatter plot" window

(6) Button for "Automatic scaling": This button enables automatic calculation of the range of values. This change is temporary and will revert to original setting when the view is changed, or the faceplate is reopened.

The Export button is only visible and operable with the "Higher-level process control" operating permission.

For additional information about the trend view, refer to the *WinCC Information System* Online Help.

### Configuration of the trend view

The trend view can be configured so that archive values are displayed immediately after opening. A prerequisite for this is that archive variables exist. Proceed as follows:

- A "1" is attached at the block icon in the "TrendPictureName" property. A semicolon is used as the separator to the name of the trend view.
  Example: @pg_apl_trendPID_Statistic.pdl;1

### Special considerations for controllers

You can select two different representations for the display area:

**1. Detailed display (default setting):**

Display area consisting of three coordinate systems:

- Setpoint trend, actual value trend;
- Manipulated variable, control performance index trend;
- Binary trend via automatic/manual, manipulated variable at high or low limit

Open the scatterplot diagram with the user button (number 2) in the toolbar. It shows a coordinate system with the process value on the value axis and the manipulated variable or position feedback on the X axis. A new value pair is entered into the coordinate system with each cycle.

If you want to use the detail display, you need to enter the following in the block icon under Trends in the WinCC Graphics Designer:

TrendPictureName = @pg_apl_trendPID_Statistic.pdl

**2. Simple display:**

Display area consisting of two coordinate systems:

- Setpoint trend, actual value trend;
- Manipulated variable;

If you want to use the simple display, you need to enter the following in the block icon under Trends in the WinCC Graphics Designer:

TrendPictureName =@pg_apl_trendPID.pdl

**Notes on step controllers with position feedback:**

If you use a step controller with position feedback as the controller type, you need to enter the following in the block icon under Trends in the WinCC Graphics Designer:

TrendConfiguration5 = *.MV#Value;...

TrendConfiguration6 = .RbkOut#Value;...

**The following applies to all other controller types (default setting):**

TrendConfiguration5 = .MV#Value;...

TrendConfiguration6 = *.RbkOut#Value;...

## 2.3.25 AddOn View for function blocks

The AddOn view allows you to display an additional view from a connected block in an APL faceplate. This view can either created by yourself or provided by a third-party vendor.

For example, additional values from a field device block connected with the MonAnL block can be displayed in the faceplate.

Messages of the interconnected blocks are also displayed in the "Message" view of the APL faceplate.

**Note**

Alarms for the device specific view can be displayed in message view of the block but there will not be any indication in the overview or block icon.

Configuration:

- To create an additional view, a new picture must be created in the GraCS project directory with the file name @PG_xxx_AddOn.pdl. Where xxx denotes "Blocktype" of the AddOn view. For example, @PG_MyType_AddOn.pdl can be used for displaying an additional view of the "Mytype" block.
- In the CFC, connect the input AddOn of the APL block with any output of the block whose additional view is to be displayed.

After compiling and loading the OS and AS, the additional view in the APL faceplate is available.

Following are the blocks that support additional view:

| AddOn view supported block family | Function blocks |
|---|---|
| Monitoring block for analog values | MonAnL |
| Motor and valve blocks | MotSpdCL |

## 2.3.26 APL Operator Trend Control (AOTC)

### Opening the AOTC window

Press and hold the Ctrl key and left-click the value on the block icon to open the AOTC window. The first value is added to the Trend Control and the detailed information is displayed in the first row of the overview area.

### Adding values to the AOTC window

To add values to the AOTC window, press and hold the Ctrl key and left-click the value on the block icon. The value is added to the Trend Control. You can add up to 8 values in the AOTC window. The following colors are assigned to the trends in the sequence they are added:

1. Black (HTML code 000000)
2. Red (HTML code FF0000)
3. Green (HTML code 00FF00)
4. Blue (HTML code 0000FF)
5. Yellow (HTML code FFFF00)
6. Turkish (HTML code 00FFFF)
7. Pink (HTML code FF00FF)
8. Orange (HTML code FFA100)

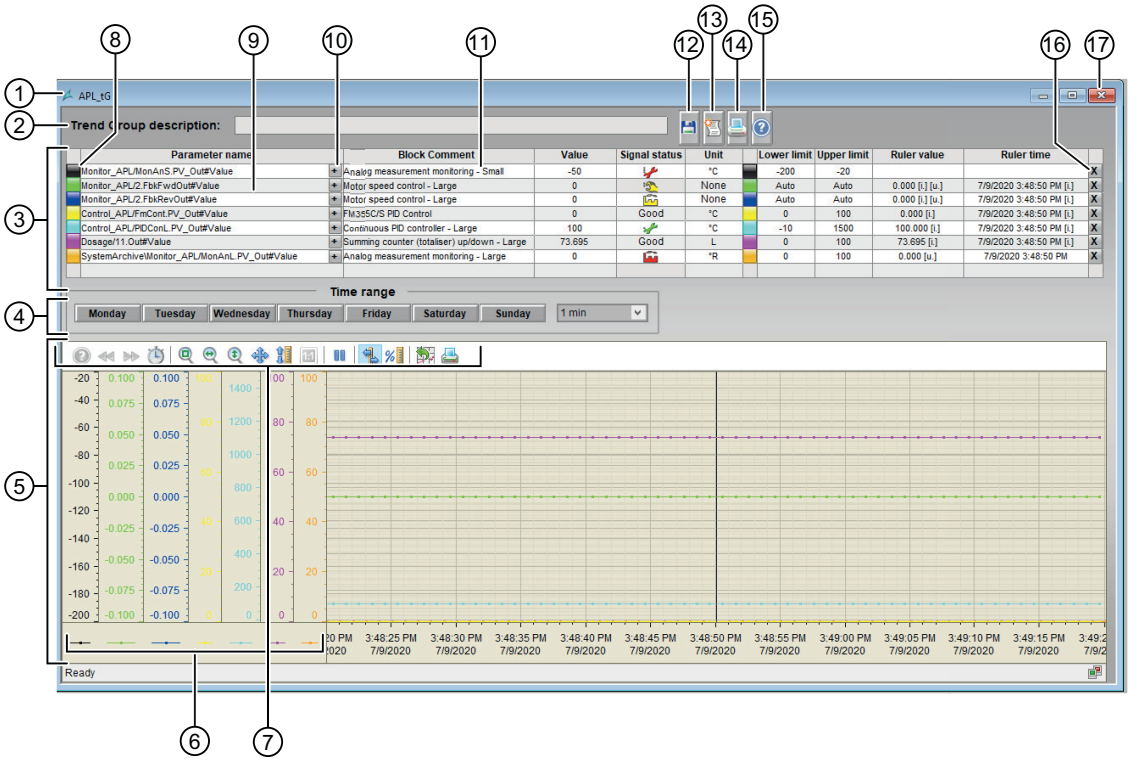
If the value is an archived value, the value is displayed from the archive. If the value is not archived, it is displayed as an online value. The default time range for the time axis is 1 minute.

**Note**

For the Web Navigator, when a new value is added, the Trend Control always displays only the online value. You can switch to display the archived values through the buttons "Monday", "Tuesday", and so on.

For information on adding additional values to the AOTC window, refer to **(10) Adding additional values**.

### Adding digital values to the AOTC window



To add digital values to the AOTC window, press and hold the Ctrl key and left-click the value on the block icon. You can add digital values from the following blocks:

| Family | Blocks |
|---|---|
| Drives | MotL, MotRevL, MotSpdCL, MotSpdL, MotS, VlvL, VlvS, Vlv2WayL, VlvAnL, VlvMotL, VlvPosL |
| Operate | OpDi01, OpTrig, OpDi03 |
| Monitor | MonDiL, MonDiS, MonDi08 |

**Example**: If you perform Ctrl key + left-click operation on the MotL block icon, the AOTC window opens showing its current status taken from the parameter `FbkRunOut.Value`. After opening the AOTC window, if you perform Ctrl key + left-click operation on any other block then the parameter corresponding to that block is added to the AOTC window.

For information on adding additional values to the AOTC window, refer to **(10) Adding additional values**.

## The AOTC window

1. Title
2. Trend group description
3. Tag row
4. Time range selection
5. WinCC online trend control
6. Value axis
7. Toolbar of the trend window
8. Enabling/disabling a trend
9. Opening a faceplate
10. Adding additional values
11. Block comment
12. Enabling/disabling a value axis
13. Saving a trend group
14. Opening a separate message window
15. Printing screenshot of the AOTC window
16. Help button

17. Deleting a trend
18. Closing the AOTC window

### (1) Title

The title displays the name of the AOTC. If the trend group is not saved, the default title "APL Operator Trend Control" is displayed. If a saved trend group is opened, title displays the group name.

### (2) Trend group description

This field displays the description of the trend group if it is saved with a description otherwise it is empty.

### (3) Tag row

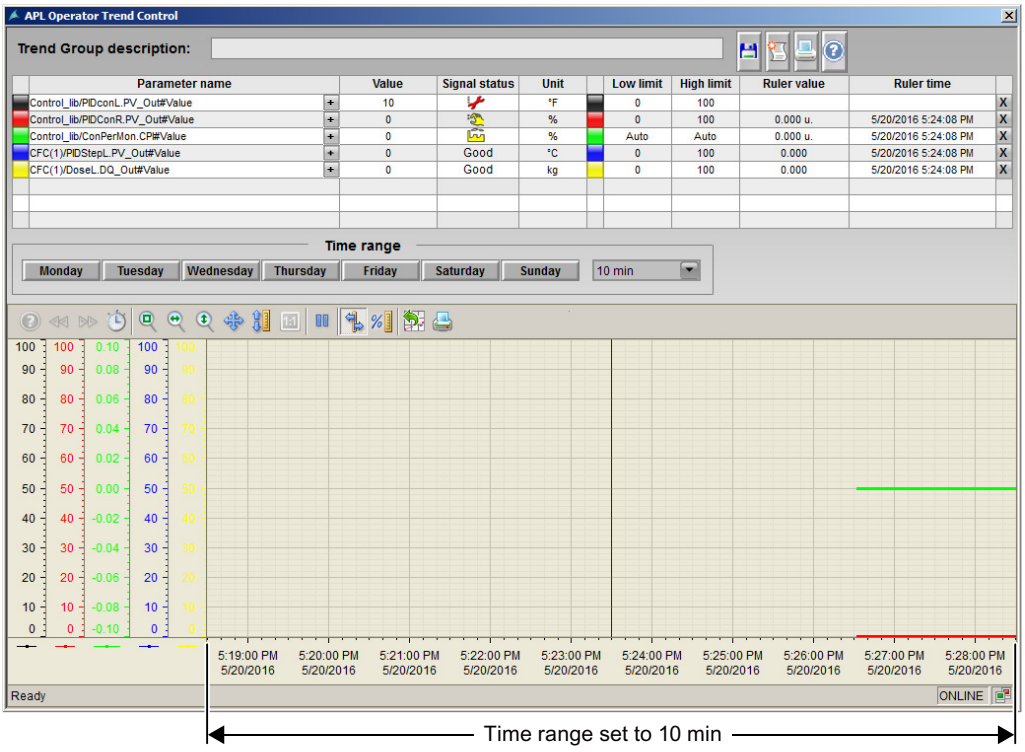
The tag row displays the following information about the trend added.

- Button to enable/disable the trend:
  Click this button to enable or disable the trend. For more information, refer to the description of **(8) Enabling/disabling a trend**.
- "Parameter name":
  This field displays the name of the trend.
- Button to add additional values:
  Click this button to add additional values to the corresponding parameter. For more information, refer to the description of **(10) Adding additional values**.
- "Value":
  This field displays the current value of the trend.
- "Signal status":
  This field displays the signal status of the trend. The corresponding icon is displayed in case the quality is not good that is the quality code is not 0x80. In case of good quality (quality code 0x80), the text "Good" is displayed.
- "Unit":
  This field displays the unit of the trend. Units are calculated only while adding a trend to the AOTC window. If the unit of a trend changes after it has been added to the AOTC window, the new unit will not be updated in the AOTC window. For example, if `PV_Unit` changes, the trend must be removed and added again.
- Button to enable/disable the value axis:
  Click this button to enable or disable the value axis. For more information, refer to the description of **(11) Enabling/disabling a value axis**.
- "Low limit":
  This field displays the low limit of the trend. The low limit is taken from the tag "XX_OpScale#Low". If the tag is not present, the value is taken automatically by the Trend control and low limit field displays "Auto".

- "High limit":
  This field displays the high limit of the trend. The high limit is taken from the tag "XX_OpScale#High". If the tag is not present, the value is taken automatically by the Trend Control and the high limit field displays "Auto".
- "Ruler value":
  This field displays the ruler value of the trend where the ruler intersects with the trend in the Trend Control.
- "Ruler time":
  This field displays the ruler time of the trend where the ruler intersects with the trend in the Trend Control.
- Button to delete the trend:
  Click this button to delete the trend. For more information, refer to the description of **(15) Deleting a trend**.

### (4) Time range selection

This area provides the option to select the time range based on the weekdays for the archived view and fixed time frame for the online view.



Press the buttons named "Monday" to "Sunday" to switch to the archive view for that day. For example, if today is Tuesday and the "Tuesday" button is pressed, the archived values from today will be displayed. If the "Sunday" button is pressed, the archived values from last Sunday will be displayed. The time range is 24 hours. If the trend is not archived, no value will be displayed.

Press the "Start/stop" button from the trend toolbar to switch back to the online view.

Use the drop-down list in the time range selection area to change the time range of the time axis. The following preconfigured time ranges are available:

- Hour/minute based
  - 1 min
  - 2 min
  - 5 min
  - 10 min
  - 15 min
  - 30 min
  - 1 h
  - 2 h
  - 3 h
  - 5 h
  - 12 h
  - 24 h

The following figure shows the AOTC window when the time range is selected to "10 min" from the drop-down list in "Time range" section:

### (5) WinCC online trend control

The Trend Control displays the trends added to the AOTC window. Each trend added to the AOTC window will appear in different color.

The following colors have been defined default for the 8 trends:

1. Black
2. Red
3. Green
4. Blue
5. Yellow
6. Turkish
7. Pink
8. Orange

### (6) Value axis

Each trend is shown in a separate value axis, therefore there can be maximum of 8 value axis. The value axis appears in the same color as the corresponding trend.

### (7) Toolbar of the trend window

Use these button to operate the trend window.

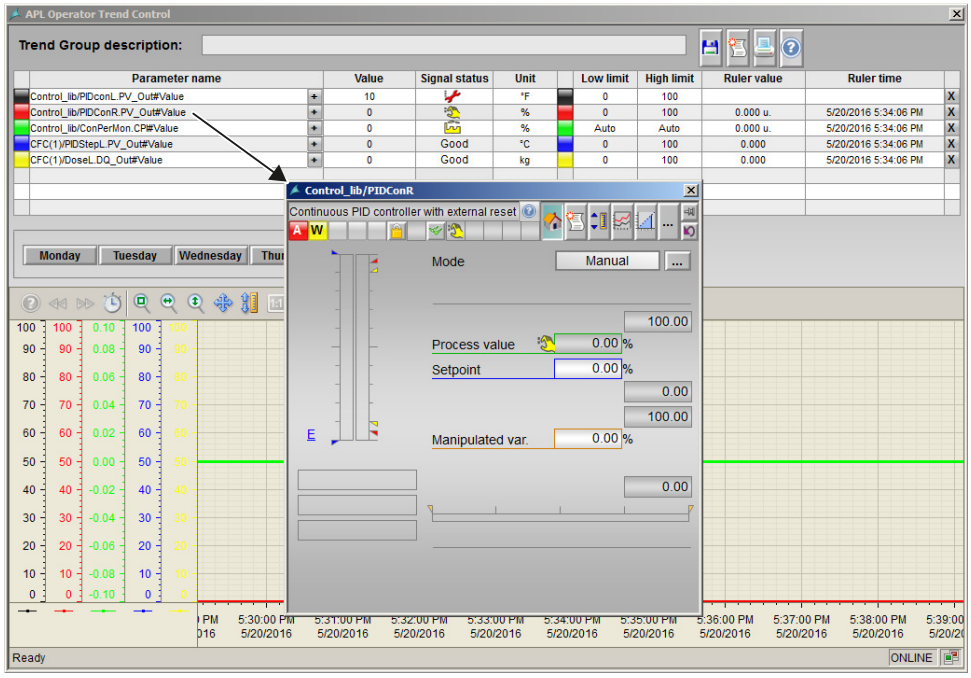
For more information, refer to *WinCC Information System* Online Help.

## (8) Enabling/disabling a trend

Press these buttons to disabled or enabled trends.

If a trend is enabled, the corresponding button will be displayed in the same color as the value trend.

If a trend is disabled, the corresponding button will be displayed in Grey color.



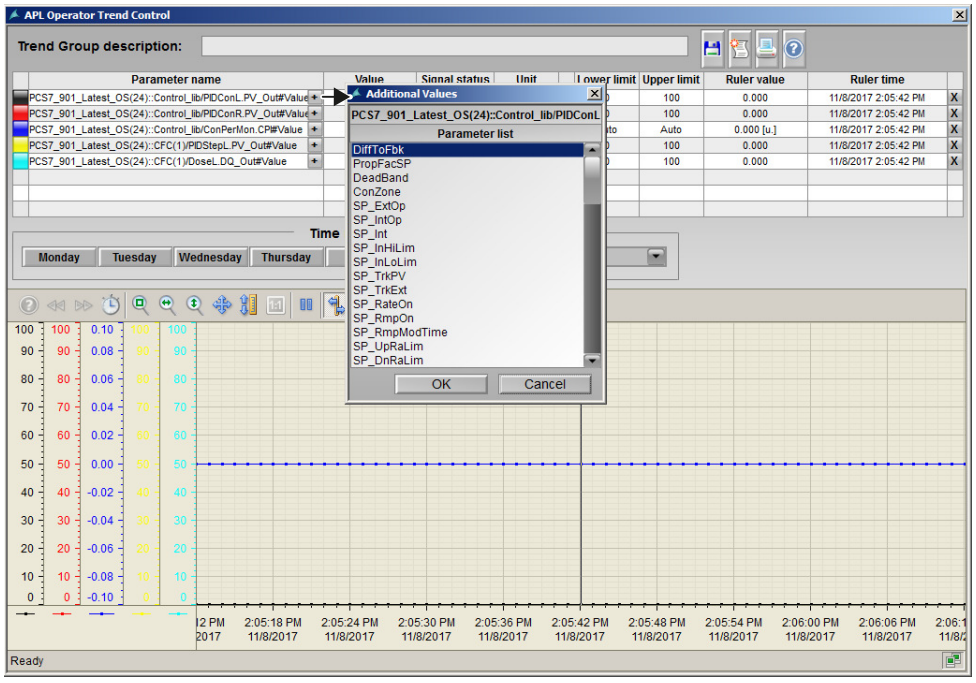
By default the trend added to the AOTC is enabled, therefore the corresponding button is visible and appears in the the same color as the value trend.

When the button is pressed the first time, the corresponding trend is hidden from the Trend Control. The color of the button changes to Grey. The corresponding tag row in the overview area is hidden except the "Parameter name".

On pressing the button again, the corresponding trend is visible again in the Trend Control. The color of the button changes to the same color as the value trend. The corresponding row of values is visible again.

## (9) Opening a related faceplate

Click the parameter name in the tag row to open the corresponding faceplate.



## (10) Adding additional values

This button is used to configure values of a particular function block which is already configured in the parameter list of the AOTC window. This button is visible only for the parameters which are configured in the AOTC window.

Perform the following steps to configure additional values to the AOTC window:

1. Click the [+] button which is available in the right corner of a configured parameter. The "Additional Values" window opens which displays a list of parameters of the corresponding function block.

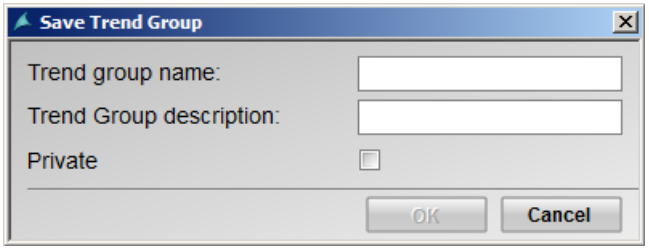
2. Select a value from the list and click OK to configure the selected value in the AOTC window.

**Note**

- You can select only one value at a time. Multiple selections are disabled.
- Additional value buttons are visible only if the number of trends configured is less than the maximum number of trends allowed (8 values).
- Additional value buttons will be disabled if the configured values in the AOTC reaches its maximum allowed limit.
- Unit of the parameter added from the "Additional Values" window will not be displayed.

## (11) Block Comment

This section provides the name of the block selected corresponding to the selected parameter.



## (12) Enabling/disabling a value axis

Click the button next to the I/O field of the unit to enable or disable the value axis. The value itself will stay in the Trend Control, only the value axis will be hidden from the Trend Control.

## (13) Saving and reopening a trend group

**Saving a trend group:**

1. Click the "Save" button to save the trend group. The "Save Trend Group" window appears to save the trend group:

2. Enter the following details in the "Save Trend Group" window:
   - Trend group name (maximum of 32 characters)
   - Trend group description (maximum of 64 characters)
   - Select the checkbox if you want to save the trend group as private. If the checkbox is not selected (default), the trend group will be saved as public.
     **Saving trend group as private:**
     Saving trend group as private allows only the originator to open the trend again. Private trends cannot be opened by other users. Public trends can be opened and modified by every operator.
3. Press the "OK" button to save the trend group.
   You can abort the operation by pressing the "Cancel" button. The dialog will close without saving the name or description.
   The "OK" button is enabled only if the trend group name is entered and the Enter key is pressed. The trend group descitption is optional.

Once the trend group is saved, further changes made in that trend group from the AOTC window will be saved automatically.

The trend group name should be different from the previously saved trend groups. You cannot save the trend group again with the same name.

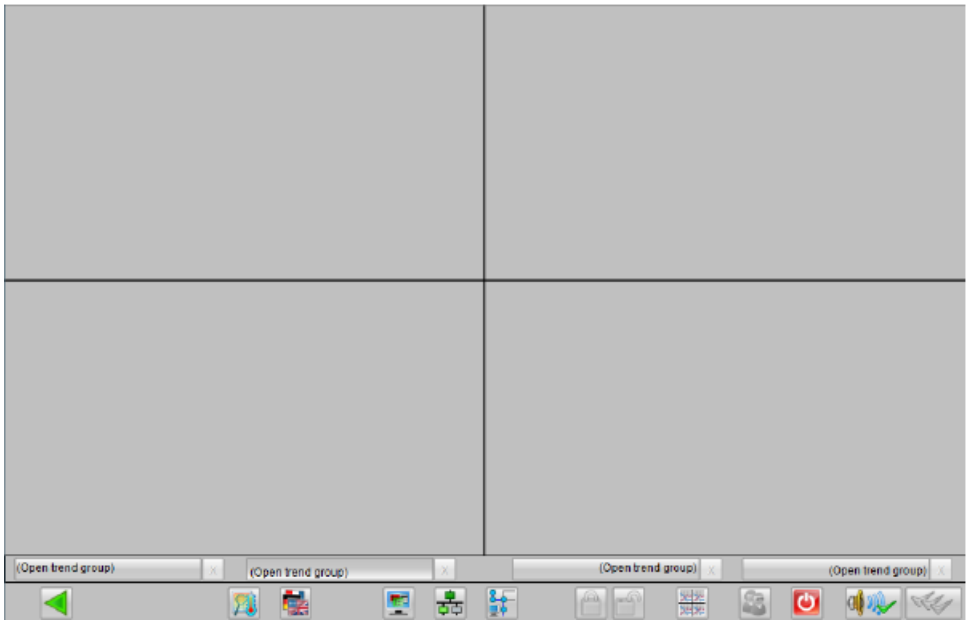
The following special characters are not allowed in the trend group name:

' ' (space character), '.', ',', ';', ':', '/', '=', '\t', '\\', '"', '<', '>', '{', '}', '[', ']', '|', '?', '*'

**Opening a trend group:**

Click the "Trend system" standard button at the bottom of the WinCC runtime window to open a saved trend.

**Opening trend groups in "Full screen display":**

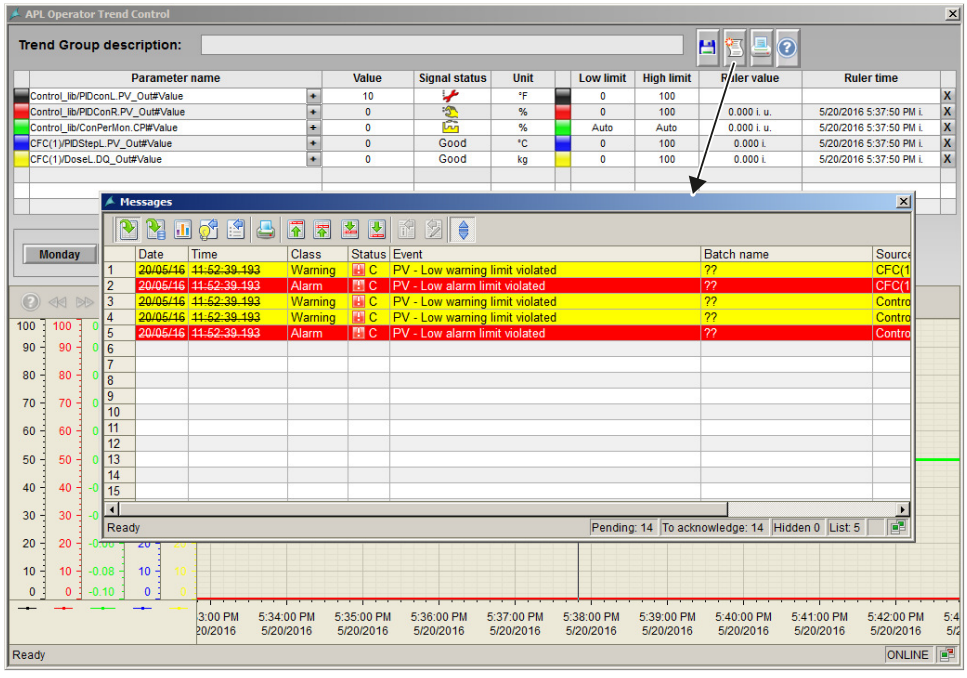


The AOTC full screen display is used to display configured trend groups on a dedicated screen. The AOTC full screen window has four quadrants which means you can display four different trend groups at a time. This window is termed as “Quad trend window” or “Full screen display”.

Perform the following steps to display the trend groups in "Full screen display":

1. Click the AOTC full screen display button at the bottom of the WinCC runtime window.

The AOTC full screen display opens with four empty quadrants and with four buttons at the bottom to select a saved trend group for each quadrant.



2. Click the "(open trend group)" button at the bottom of the AOTC full screen display for the quadrant in which you want to display a particular trend group. A window opens with a list of saved trend groups.

3. Select a trend group from the list and click "Display" to load the trend group into the corresponding quadrant.
4. Use all four buttons to load four different trend groups into the different quadrants of the full screen display.

## (14) Opening a separate message window

Press the "Messages" button to open a new message window which displays the messages for the selected block types corresponding to the trends added in the AOTC window.

In the online mode, only the actual messages (all active messages, acknowledged and unacknowledged) will be displayed.

If you select a time range displaying values from the archive, the message window will display all the messages within this time range.

Messages only from the enabled trend will be displayed. If a trend is enabled or disabled and the message window is open, the corresponding messages will be displayed or not displayed accordingly. Similarly if a trend is deleted, the corresponding messages will disappear from the messages window.

If two or more trends of the same block type are added to the AOTC window, and one of them is disabled, the corresponding messages will not be removed from message window. All the trends should be disabled or deleted to remove the corresponding messages from the message window.

Only one message window can be opened at a time. If one more AOTC window is opened and you want to display the messages for the values in that window, the already opened message view should be closed and opened again from the specific AOTC window.

### (15) Printing screenshot of the AOTC window

Press the "Print" button to print the screenshot of the complete AOTC window. WinCC runtime (also the Web Navigator) should be in full screen mode without scroll bar. As screenshot is taken from the process picture visible in runtime, the AOTC window should be visible completely in the runtime, otherwise the screenshot will show only the visible section of the AOTC faceplate.

### (16) Help button

Click this button to open the AOTC chapter in the *APL Operator Guide* online help. You will find detailed information about the AOTC window and its functionalities in this online help.

### (17) Deleting a trend

Click the "X" button at the end of the row in the overview area to delete existing values.

The corresponding trend is removed from the Trend Control. In the overview area, the rows below the deleted row are moved up and an empty row is added at the end.

New values are added to the first empty row.

### (18) Closing the AOTC window

Click the "Close" button in the title bar to close the AOTC window.

### Operator permissions

The operator permissions are similar to the existing online trend function.

The following fields are enabled only if the area authorization is available:

1. Delete buttons to delete trends.
2. Save button to open the pop-up window to save the trend group.

3. Field to enter the trend group name in the pop-up window.
4. Field to enter the trend group description in the pop-up window.
5. Checkbox to select private trend group.
6. The "OK" button to save the trend in the pop-up window.

**Note**

The functions for example, disable/enable trend, disable/enable value axis, delete trend, open message window, print AOTC screenshot, select private trend group, need no operation area or quitting function. The feature "Save Trend Group" needs an operation area where only 3 step operation is possible. It does not support 2 step operation.

## 2.3.27 Limit operation and display in the faceplate

### Limit operation and display in the faceplate

The limit value view of the faceplate can be used to modify limits and the hysteresis if the corresponding operating permission (higher process controlling) is available. The limits are displayed graphically in the standard view of the faceplate.

If the limits are reached or exceeded, an alarm, warning or tolerance class message is triggered. This is indicated graphically as follows:

| Symbol | Meaning |
|---|---|
|  | Alarm |
|  | Warning |
|  | Tolerance |

**Note**

The text displayed at the labels for the limit fields in limit view depends on the setting of the PCS 7 message system.

If the “User-configured message classes (Page 45)” is activated then the displayed text is taken from the “TextOp” property of the limit object else it is taken from property “AnaText”

## 2.3.28 Central color management

### Central color management

As of version 8.1, the colors in the faceplates and block icons can be changed centrally via the central color palette in WinCC. The central color palette is located in the "User interface and design" tab of the project properties.

The following colors cannot be changed via the central color palette:

- The colors (except trend colors) of WinCC Alarm Control, WinCC Online Trend Control, WinCC Ruler Control and WinCC Function Control.
- The window titles can only be changed by editing the Windows designs.
- The colors of check boxes cannot be changed.
- Alarm colors are changed via the PCS 7 message system.
- Trend colors are not automatically changed in the block icons in existing projects, because these properties are changeable instance-specific and not in the update mechanisms for the block icons.

The user can use the color range of 0-199; the APL color range begins with the color index 200.

Description of the APL color index:

### Color index for block icons

The following color indexes can be created for block icons.

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Type block icons |
|---|---|---|---|---|---|---|---|
| 200 | 1 | 0 | B6B6B6 | Gray | Background: Background color | BackgroundColor | Block icons with analog values |
| 201 | 1 | 0 | DADADA | Very light gray | Background: Fill pattern color | BackgroundFillPatternColor | Block icons with analog values |
| 202 | 1 | 0 | B6B6B6 | Gray | Tag display: Background color | TagBackColor | All block icons with tag display |
| 203 | 1 | 0 | DADADA | Very light gray | Tag display: Fill pattern color | TagFillColor | All block icons with tag display |
| 204 | 1 | 0 | 919191 | Dark gray | Tag display: Border color | TagBorderColor | All block icons with tag display |
| 205 | 1 | 0 | 000000 | Black | Tag display: Font color | TagFontColor | All block icons with tag display |
| 206 | 1 | 0 | 00FFFA | Pure cyan | Tag highlight: Background color | BlockIconHighlightBackColor | All block icons |
| 207 | 1 | 0 | 5CC2BC | Medium cyan | Tag highlight: Fill pattern color | BlockIconHighlightFillColor | All block icons |
| 208 | 1 | 0 | FFFFFF | White | Tag highlight: Font color | BlockIconHighlightFontColor | All block icons |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Type block icons |
|---|---|---|---|---|---|---|---|
| 209 | 1 | 0 | B6B6B6 | Gray | Display of high limit: Background color | LimitObjectHighBackColor | Block icons with display of the high limit |
| 210 | 1 | 0 | DADADA | Very light gray | Display of high limit: Fill pattern color | LimitObjectHighFillColor | Block icons with display of the high limit |
| 211 | 1 | 0 | B6B6B6 | Gray | Display of the low limit: Background color | LimitObjectLowBackColor | Block icons with display of the low limit |
| 212 | 1 | 0 | DADADA | Very light gray | Display of the low limit: Fill pattern color | LimitObjectLowFillColor | Block icons with display of the low limit |
| 213 | 1 | 0 | B6B6B6 | Gray | Empty rectangle: Background color | EmptyRectBackColor"[1] | Block icons with status bar |
| 214 | 1 | 0 | DADADA | Very light gray | Empty rectangle: Fill pattern color | EmptyRectFillColor[1] | Block icons with status bar |
| 215 | 1 | 0 | 808080 | Dark gray | Empty rectangle: Border color | EmptyRectBorderColor[1] | Block icons with status bar |
| 216 | 1 | 0 | FFFFFF | White | Process value: Background color | Value1BackColorValue10BackColor | Block icons with analog value |
| 217 | 1 | 0 | 000000 | Black | Process value: Font color | Value1FontColorValue10FontColor | Block icons with analog value |
| 218 | 1 | 100 | C0C0C0 | None (transparent) | Setpoint: Background color | Value2BackColor | Block icons with analog value |
| 219 | 1 | 0 | 0000FF | Pure blue | Setpoint: Font color | Value2FontColor | Block icons with analog value |
| 220 | 2 | 100 | C0C0C0 | None (transparent) | Changed variable: Background color | Value3BackColor | Block icons with analog value |
| 221 | 2 | 0 | F24F00 | Pure orange | Changed variable: Font color | Value3FontColor | Block icons with analog value |
| 222 | 2 | 100 | C0C0C0 | None (transparent) | Read-back value: Background color | Value3BackColor Value4BackColor | Block icons with analog value |
| 223 | 2 | 0 | 008080 | Dark cyan | Read-back value: Font color | Value3FontColor Value4FontColor | Block icons with analog value |
| 224 | 2 | 100 | B6B6B6 | None (transparent) | Unit[2], process value/ setpoint: Background color | UnitBackColor, Unit1BackColor-Unit4BackColor | Block icons with analog value |
| 225 | 2 | 0 | 494949 | Very dark gray | Unit, process value/ setpoint: Font color | UnitFontColor, Unit1FontColor-Unit4FontColor | Block icons with analog value |
| 226 | 2 | 100 | B6B6B6 | None (transparent) | Unit[2], changed variable: Background color | Unit2BackColor | Block icons with analog value |
| 227 | 2 | 0 | 494949 | Very dark gray | Unit, changed variable: Font color | Unit2FontColor | Block icons with analog value |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Type block icons |
|---|---|---|---|---|---|---|---|
| 228 | 2 | 100 | B6B6B6 | None (transparent) | Unit[2], read-back value: Background color | Unit1BackColor, Unit2BackColor | Block icons with analog value |
| 229 | 2 | 0 | 494949 | Very dark gray | Unit, read-back value: Font color | Unit1FontColor, Unit2FontColor | Block icons with analog value |
| 230 | 2 | 0 | 6D6D6D | Very dark gray | "Not used" state: background color | BackColorOn1 | Interlock |
| 231 | 2 | 0 | 919191 | Dark gray | "Not used" state: fill pattern color | FillColorOn1 | Interlock |
| 232 | 2 | 0 | 0000FF | Pure blue | "Bypassed" state: background color | BackColorOn2 | Interlock |
| 233 | 2 | 0 | 00A2E8 | Pure blue | "Bypassed" state: fill pattern color | FillColorOn2 | Interlock |
| 234 | 2 | 0 | E4D400 | Pure yellow | "Simulation" state: background color | BackColorOn3 | Interlock |
| 235 | 2 | 0 | FFFF00 | Pure yellow | "Simulation" state: fill pattern color | FillColorOn3 | Interlock |
| 236 | 2 | 0 | 00B500 | Bright lime green | "Unlocked" state: background color | BackColorOn4 | Interlock |
| 237 | 2 | 0 | 00FF00 | Pure lime green | "Unlocked" state: fill pattern color | FillColorOn4 | Interlock |
| 238 | 2 | 0 | E60000 | Pure red | "Locked" state: background color | BackColorOn5 | Interlock |
| 239 | 2 | 0 | FF0000 | Pure red | "Locked" state: fill pattern color | FillColorOn5 | Interlock |
| 240 | 3 | 0 | 00B500 | Bright lime green | "On" state: Background color | BackColorOn, OnBackColor | Family counter / MonDi08/ MonDiL-MonDiS (type 1 and 4) / OpDi03 / ShrdResS/ TimeTrig/ TotalL |
| 241 | 3 | 0 | 00FF00 | Pure lime green | "On" state: Fill pattern color | FillColorOn, OnFillColor | |
| 242 | 3 | 0 | 00FF00 | Pure lime green | "On" state: Background color | Value2BackColor | OpDi01, OpTrig |
| 243 | 3 | 0 | 000000 | Black | "On" state: Font color | Value2FontColor | OpDi01, OpTrig |
| 244 | 3 | 0 | FFFFFF | White | "On" state: Background color | Value2BackColor | MonDiL-MonDiS (types 2, 3 and 5) |
| 245 | 3 | 0 | 000000 | Black | "On" state: Font color | Value2FontColor | MonDiL-MonDiS (types 2, 3 and 5) |
| 246 | 3 | 0 | FFFFFF | White | "On" state: Font color | FontColorOn | MonDiL-MonDiS (type 4) |
| 247 | 3 | 0 | B6B6B6 | Gray | "Off" state: Background color | BackColorOff, BackColorOn | |
| 248 | 3 | 0 | DADADA | Very light gray | "Off" state: Fill pattern color | FillColorOff, FillColorOn | |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Type block icons |
|---|---|---|---|---|---|---|---|
| 249 | 3 | 0 | DADADA | Very light gray | "Off" state: Background color | BackColorOff | Family counter, MonDi08, TimeTrig |
| 250 | 3 | 0 | FFFFFF | White | "Off" state: Fill pattern color | FillColorOff | Family counter, MonDi08, TimeTrig |
| 251 | 3 | 0 | FFFFFF | White | "Off" state: Background color | Value1BackColor | MonDiLMonDiS (types 2, 3 and 5) |
| 252 | 3 | 0 | 000000 | Black | "Off" state: Font color | Value1FontColor | MonDiLMonDiS (types 2, 3 and 5) |
| 253 | 3 | 0 | 000000 | Black | "Off" state: Font color | FontColorOff | MonDiLMonDiS (type 4) |
| 254 | 3 | 0 | B6B6B6 | Gray | "Not used" state: Background color | BackColorNA | MonDi08 |
| 255 | 3 | 0 | 000000 | Black | "No operation" state: Font color | ForeColorValue | OpStations |
| 256 | 3 | 0 | C0C0C0 | Light gray | Display of the selected analog value: Background color | Value2BackColor | SelA16In |
| 257 | 3 | 0 | 6D6D6D | Very dark gray | Display of the selected analog value: Font color | Value2FontColor | SelA16In |
| 258 | 3 | 0 | 494949 | Very dark gray | ISO/DIN symbols: Line color | BorderColor | |

[1] New property

[2] Note: The pattern in the block icon must be changed to "single color" for the color to take effect.

## Color indexes for faceplates

The following color indexes can be created for faceplates.

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Types views/ objects |
|---|---|---|---|---|---|---|---|
| 259 | 3 | 0 | AFAFAF | Gray | View: Background color | BackColor | Views in all faceplates |
| 260 | 4 | 0 | DEDEDE | Very light gray | View: Fill pattern color | FillColor | Views in all faceplates |
| 261 | 4 | 0 | 62ACAA | Dark cyan | Operating area: Background color | BackColor | Total operating area |
| 262 | 4 | 0 | AACFCD | Gray cyan | Operating area: Fill pattern color | FillColor | Total operating area |
| 263 | 4 | 0 | 000000 | Black | Title or label of operating area: Font color | ForeColor | All static texts in the operating area |
| 264 | 4 | 0 | C0C0C0 | Light gray | Slider operating area: Background color | BackColor, BackColorTop, BackColorBottom, ButtonColor, HighLimitColor, LowLimitColor | Operating area "@PG_APL_OA_Analogwithlimits100.PDL" |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Types views/ objects |
|---|---|---|---|---|---|---|---|
| 265 | 4 | 0 | FFFFFF | White | Slider operating area: Border background color | BorderBackColor | Operating area "@PG_APL_OA_Analogwithlimits100.PDL" |
| 266 | 4 | 0 | 000000 | Black | Slider operating area: Border color | BorderColor | Operating area "@PG_APL_OA_Analogwithlimits100.PDL" |
| 267 | 4 | 0 | DADADA | Very light gray | Block comment: Fill pattern color | FillColor | Header in all faceplates |
| 268 | 4 | 0 | 808080 | Dark gray | Block comment: Border color | BorderColor | Header in all faceplates |
| 269 | 4 | 0 | 000000 | Black | Block comment: Font color | FontColor | Header in all faceplates |
| 270 | 4 | 0 | B6B6B6 | Gray | Empty rectangle overview: Background color | BackColor | Header in all faceplates |
| 271 | 4 | 0 | DADADA | Very light gray | Empty rectangle overview: Fill pattern color | FillColor | Header in all faceplates |
| 272 | 4 | 0 | 808080 | Dark gray | Empty rectangle overview: Border color | BorderColor | Header in all faceplates |
| 273 | 4 | 0 | C0C0C0 | Light gray | Group display overview: Background color | BackColor | Header in all faceplates [1] |
| 274 | 4 | 0 | C0C0C0 | Light gray | Toolbar button: Background color | BackColor | Header in all faceplates |
| 275 | 4 | 0 | BABABA | Gray | Toolbar button: Fill pattern color | FillColor | Header in all faceplates |
| 276 | 4 | 0 | 808080 | Dark gray | Toolbar button: Border color | BorderColor | Header in all faceplates |
| 277 | 4 | 0 | 000000 | Black | Toolbar button: Font color | FontColor | Header in all faceplates [2] |
| 278 | 4 | 0 | C0C0C0 | Light gray | Header button[3]: Background color | BackColor | Header in all faceplates |
| 279 | 4 | 0 | 808080 | Dark gray | Toolbar button: Border color | BorderColor 8 | Header in all faceplates |
| 280 | 5 | 0 | 000000 | Black | Title or label in views: Font color | TextFontColor, FontColor, ForeColor, LeftHandTextFontColor[4] | Views with static text and APL objects with type ID=17-20, 22-24, 27, 29, 64, 120, 130 |
| 281 | 5 | 0 | AFAFAF | Gray | Button in views/operating areas: Background color | BackColor | Views with APL objects with type ID=30-34, 50-52 |
| 282 | 5 | 0 | CECECE | Light gray | Button in views/operating areas: Fill pattern color | FillColor | Views with APL objects with type ID=30-34, 50-52 |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Types views/ objects |
|---|---|---|---|---|---|---|---|
| 283 | 5 | 0 | 808080 | Dark gray | Button in views/operating areas: Border color | BorderColor | Views with APL objects with type ID=30-34, 50-52 |
| 284 | 5 | 0 | FFFFFF | White | Button in views/operating areas: 3D border color | BorderColorTop | Views with APL objects with type ID=30-34, 50-52 |
| 285 | 5 | 0 | 808080 | Dark gray | Button in views/operating areas: 3D shadow color | BorderColorBottom | Views with APL objects with type ID=30-34, 50-52 |
| 286 | 5 | 0 | 000000 | Black | Button in views/operating areas: Font color | ForeColor | Views with APL objects with type ID=30-34, 50-52 |
| 287 | 5 | 0 | DADADA | Very light gray | Analog value enabled in views/operating areas: Background color | EnabledBackColor, BackColor, BackColor_OK | Views with I/O fields (also extended) and APL objects with type ID=20, 22-24, 27, 28-29, 130 |
| 288 | 5 | 0 | FFFFFF | White | Analog value enabled in views/operating areas: Fill pattern color | EnabledFillColor, FillColor, FillColor_OK | Views with I/O fields (also extended) and APL objects with type ID=20, 22-24, 27, 28-29, 130 |
| 289 | 5 | 0 | B6B6B6 | Gray | Analog value disabled in views/operating areas: Background color | DisabledBackColor, BackColor, BackColor_OK | Views with I/O fields (also extended) and APL objects with type ID=20, 22-24, 27, 28-29, 91[13],92,130 |
| 290 | 5 | 0 | DADADA | Very light gray | Analog value disabled in views/operating areas: Fill pattern color | DisabledFillColor, FillColor, FillColor_OK | Views with I/O fields (also extended) and APL objects with type ID=20, 22-24, 27, 28-29, 91[13],92,130 |
| 291 | 5 | 0 | 000000 | Black | Analog value or unit in views/operating areas: Font color | ValueFontColor, ForeColor, ForeColor_OK | Views with I/O fields (also extended) and APL objects with type ID=16, 20, 22-24, 27, 28-29, 91, 130 |
| 292 | 5 | 0 | 00B500 | Bright lime green | Analog process value: Border color | LineColor, BorderColor | Views with I/O fields (also extended) and APL objects with type ID=20, 24 |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Types views/ objects |
|---|---|---|---|---|---|---|---|
| 293 | 5 | 0 | 0000FF | Pure blue | Analog setpoint: Border color | LineColor, BorderColor | Views with I/O fields (also extended) and APL objects with type ID=20, 28 |
| 294 | 5 | 0 | D27A00 | Bright orange | Changed analog variable: Border color | LineColor, BorderColor | Views with I/O fields (also extended) and APL objects with type ID=20, 24, 28 |
| 295 | 5 | 0 | 008582 | Dark cyan | Analog read-back value: Border color | LineColor, BorderColor | Views with I/O fields (also extended) and APL objects with type ID=20 |
| 296 | 5 | 0 | 808080 | Dark gray | Analog parameter/ range value: border color | LineColor, BorderColor | Views with I/O fields (also extended) and APL objects with type ID=20, 22-24, 27, 28, 90, 92, 130 |
| 297 | 5 | 0 | 000000 | Black | Analog limit (no alarm), input value, offset, gradient: border color | LineColor, BorderColor | In "@PG_CntOhSc_Limit.PDL", "@PG_MonAnL_Standard.PDL", "@PG_Ratio_Standard.PDL", "@PG_TotalL_Standard.PDL" APL objects with type ID=20, 24, 28, 29 and HMIStaticText |
| 298 | 5 | 0 | 808080 | Dark gray | Empty analog value displays | BorderColor | Views with APL objects with type ID=21, 25, 26 |
| 299 | 5 | 0 | 00B500 | Bright lime green | Binary value on: Background color | OnBackColor, State1BackColor | Views with APL objects with type ID=17,18[13],120 |
| 300 | 6 | 0 | 00FF00 | Pure lime green | Binary value on: Fill pattern color | OnFillColor, State1FillColor | Views with APL objects with type ID=17,18[13],120 |
| 301 | 6 | 0 | FFFFFF | White | Binary value on: Font color | OnFontColor, State1FontColor | Views with APL objects with type ID=17,18[13],120 |
| 302 | 6 | 0 | FFFFFF | White | Binary value off: Background color | OffBackColor, State2BackColor | Views with APL objects with type ID=17,18[13],120 |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Types views/ objects |
|---|---|---|---|---|---|---|---|
| 303 | 6 | 0 | DADADA | Very light gray | Binary value off: Fill pattern color | OffFillColor, State2FillColor | Views with APL objects with type ID=17,18[13],120 |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Types views/ objects |
|---|---|---|---|---|---|---|---|
| 410 | 11 | 0 | 000000 | Black | Bar chart, message gradient value or limit (without alarm): Background color | ValueColor, AlarmColor, WarningColor | Standard view, APL objects with type ID=74 or 71[15] |
| 411 | 11 | 0 | 6D6D6D | Very dark gray | Bar chart, gradient value: Fill pattern color | ValueFillColor | Standard view, APL objects with type ID=74 |
| 412 | 11 | 0 | 808080 | Dark gray | Bar chart: Border color | BorderColor | Standard/setpoint view, APL objects with type ID=7075 |
| 413 | 11 | 0 | 62ACAA | Mostly unsaturated dark cyan | Selection rectangle operation: Background color | BackgroundColor | All views with operation, HMIRectangle object name "rect_selectionBorder" |
| 414 | 11 | 0 | B1CFCD | Gray cyan | Selection rectangle operation: Fill pattern color | FillColor | All views with operation, HMIRectangle object name "rect_selectionBorder" |
| 415 | 11 | 0 | 808080 | Dark gray | Selection rectangle operation: Border color | BorderColor | All views with operation, HMIRectangle object name "rect_selectionBorder" |
| 416 | 11 | 0 | 808080 | Dark gray | Dividing line: Border color | BorderColor | All views with dividing line, HMILine |

[1] Note: Also types without messages have an empty group display

[2] Note: Only important for the "Next" button

[3] "Lock"/"Acknowledgement"/"Attach"/"Back to process picture" buttons; "Attach" button in the operating area

[4] In the standard view Ratio

[5] Used in type ID = 17, 18, 120

[6] In the standard view DoseL

[7] In the standard view Ratio

[8] In the standard view DoseL

[9] In the standard view Ratio

[10] In the standard view DoseL

[11] In the standard view OpDi01, OpDi03, display the confirmation of the command

[12] In the standard view OpDi01, OpDi03, display the confirmation of the command

[13] Not used, only in @PCS7ElementsAPL.pdl

[14] In the standard view OpDi01, OpDi03, display the confirmation of the command

[15] In @PG_CntOhSc_Standard.PDL

## Color indexes for trends

The following color indexes can be created for trends:

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Type block icons |
|---|---|---|---|---|---|---|---|
| 417 | 11 | 0 | 00CE00 | Bright lime green | Actual value | TrendColor1 - TrendColor12 | Trend view |
| 418 | 11 | 0 | 0000FF | Pure blue | Setpoint | TrendColor1 - TrendColor12 | Trend view |
| 419 | 11 | 0 | E69100 | Pure orange | Changed variable | TrendColor1 - TrendColor12 | Trend view |
| 420 | 12 | 0 | 008582 | Dark cyan | Read-back value | TrendColor1 - 1TrendColor12 | Trend view |
| 421 | 12 | 0 | 00CE00 | Bright lime green | Controller, closed loop | TrendColor8 | Trend view controller |
| 422 | 12 | 0 | 000000 | Black | Controller, input for control performance index (CPI) | TrendColor7 | Trend view controller |
| 423 | 12 | 0 | 000000 | Black | Controller, binary message "violated"[1] | TrendColor3, TrendColor4, TrendColor9, TrendColor10 | Trend view controller |
| 424 | 12 | 0 | B100B5 | Bright magenta | Controller, control performance index (CPI) | TrendColor1 | Trend view ConPerMon |
| 425 | 12 | 0 | E69100 | Pure orange | Ratio, analog input "In" | TrendColor1 | Trend view Ratio |
| 426 | 12 | 0 | 00FF00 | Pure lime green | Ratio, input for process variable "InPV" | TrendColor2 | Trend view Ratio |
| 427 | 12 | 0 | 0000FF | Pure blue | Ratio, process value of the secondary component "SecComPV" | TrendColor3 | Trend view Ratio |
| 428 | 12 | 0 | B100B5 | Bright magenta | Ratio, output "Out" | TrendColor4 | Trend view Ratio |
| 429 | 12 | 0 | FF0000 | Pure red | Ratio, current ratio "RatioPV" | TrendColor5 | Trend view Ratio |
| 430 | 12 | 0 | 6D6D6D | Very dark gray | Ratio, applied ratio (RatioInt or RatioExt) "RatioOut" | TrendColor6 | Trend view Ratio |
| 431 | 12 | 0 | 009D00 | Dark lime green | Dosing, dosing amount | TrendColor3 | Trend view Dosing |
| 432 | 12 | 0 | FF0000 | Pure red | Monitoring, gradient value | TrendColor2 | Trend view MonAnL |
| 433 | 12 | 0 | E69100 | Pure orange | Monitoring, output 1 | TrendColor1 | Trend view MonDi08, MonDiL, MonDiS |
| 434 | 12 | 0 | 00CE00 | Bright lime green | Monitoring, output 2 | TrendColor2 | Trend view MonDi08 |

| Color index | Section | Transparency | HTML code (RGB) | Color name | Description | Property(ies) [attribute name] | Type block icons |
|---|---|---|---|---|---|---|---|
| 435 | 12 | 0 | 0000FF | Pure blue | Monitoring, output 3 | TrendColor3 | Trend view MonDi08 |
| 436 | 12 | 0 | B100B5 | Bright magenta | Monitoring, output 4 | TrendColor4 | Trend view MonDi08 |
| 437 | 12 | 0 | FF0000 | Pure red | Monitoring, output 5 | TrendColor5 | Trend view MonDi08 |
| 438 | 12 | 0 | 494949 | Very dark gray | Monitoring, output 6 | TrendColor6 | Trend view MonDi08 |
| 439 | 12 | 0 | 543500 | Very dark orange | Monitoring, output 7 | TrendColor7 | Trend view MonDi08 |
| 440 | 13 | 0 | 005400 | Very dark lime green | Monitoring, output 8 | TrendColor8 | Trend view MonDi08 |
| 441 | 13 | 0 | 00CE00 | Bright lime green | Monitoring, flutter value | TrendColor2 | Trend view MonDiL |
| 442 | 13 | 0 | E69100 | Pure orange | Operation, binary output / binary output 1 | TrendColor1 | Operation, trend view binary |
| 443 | 13 | 0 | 494949 | Very dark gray | Operation, binary output 2 | TrendColor2 | Operation, trend view binary |
| 444 | 13 | 0 | 0000FF | Pure blue | Operation, binary output 3 | TrendColor3 | Operation, trend view binary |
| 445 | 13 | 0 | B100B5 | Bright magenta | Operation, binary feedback 1 | TrendColor4 | Operation, trend view binary |

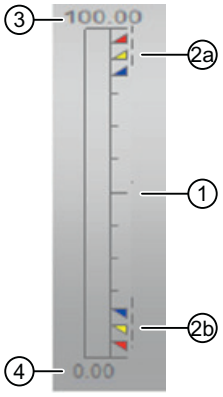
[1] For example, PIDConL "PV_ToleHi#Value", ".MV_HiAct#Value"



[2] ModPreCon=@PG_APL_TrendMPC.PDL; MPC10x10=@PG_APL_TrendMPC_L.PDL

**Note**

If these colors were changed only via the OS project editor, the default values can be assigned again.

## 2.3.29 Bar graph

### Bar graph for the Process Value

(1) Bar graph for the "Process Value"

This area shows the current "Process value" in the form of a bar graph. You can also see the high low limits of the bar graph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

**Note**

The value displayed can be different for different blocks. For example, the Bar graph display other than "Process Value" are as follows

Bar graph display other than "Process Value" are as follows:

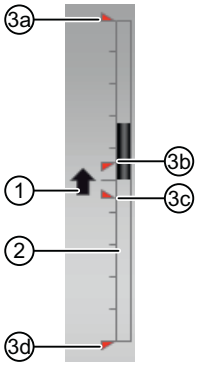
| Block name | Value and Limits displayed | Color |
|---|---|---|
| DoseL | Current quantity | |
| CntOhSc | Current counts (Cnt and Time-Hours(h)). | |
| CountOh | Current count (TimeMin (min)). | |
| CountScL | Current count (Out). | |
| TotalL | Current sum value (Out). | Orange |
| TimeTrig | Amount of time(s) until the next trigger | |
| ConPerMon | Current control performance index (CPI) | |
| MotL, MotRevL, MotSpdCL, MotSpdL, VlvMotL, VlvPosL | Current additional value (AV_Out) in the limit view for additional value. | |
| MotSpdCL | Current readback value in the standard view | Cyan |
| PumpMon | Electrical power<br>Mechanical power<br>Hydraulic power | Green<br>Yellow<br>Cyan |

(2) Limit display

- 2a: High limit display
- 2b: Low limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance



**Note**

- The symbols displayed are not valid for user-configured message classes. Please take into consideration the validity of terms for User-configured message classes.
- The limit triangles visibility depends on the configuration in engineering system (ES).
  - If a limit is not enabled (e.g. `PV_AH_En` = 0 & `Feature.Bit23` =0) then triangle for corresponding limit (high alarm in this example) will not be visible.
  - If a limit is not supported by a block, then the corresponding limit triangle is not displayed. E.g. `DoseL` block only has Alarm high and Alarm low limits. So, limit triangles for Warning and Tolerence will not be visible.
  - For `TotalL`, `CountOh` and `CountScL`, in counting mode "count up", only the colored triangles of the upper limits are visible; and in counting mode "count down", only the colored triangles of the lower limits are visible.
  - For `MotSpdCL`, only the warning high and low limit triangles for readback value are displayed.
  - For `CntOhSc`, only the high limit triangles are available for the following configured limits in the respective bar graph:
    Red: High limit 1
    Yellow: High limit 2
  - For `ConPerMon`, only the low limit triangles are available for the following configured limits in the respective bar graph:
    Red: Low alarm limit
    Yellow: Low warning limit
    For `PumpMon`, only the high and low limit triangles for Alarms and warnings for readback value are displayed.

(3) Bargraph high scale

(4) Bargraph low scale

### Bar graph for the "Gradient value"

(1) Display of the gradient indicator

This display indicates the movement of the gradient up (↑) or down (↓).

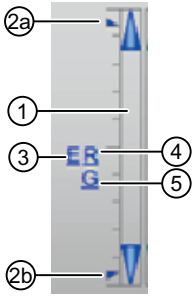
Gradient monitoring is displayed when the gradient value PV_Grad ≠ 0 and one of the following monitoring functions is activated:

- Gradient monitoring for positive changes (`GradHUpEn` = 1)
- Gradient monitoring for negative changes (`GradHDnEn` = 1)
- Gradient monitoring (`GradLEn` = 1)

(2) Bar graph for the gradient

This area shows the current gradient value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

The bar graph is displayed when gradient monitoring is activated for positive (`GradHUpEn` = 1) or negative changes (`GradHDnEn` = 1).



(3) Display of limits in the bar graph

This area shows you the specified limits.

The display only appears when the bar for the gradients is also displayed.

- 3a: Limit (high) for positive gradients (`GradHUpLim`)
- 3b, 3c: Limit (low) for positive and negative gradients (`GradLLim`)
- 3d: Limit (high) for negative gradients (`GradHDnLim`)

### Bar graph for the "Setpoint value"

(1) Bar graph for the setpoint

This area shows the current setpoint in the form of a bar graph. You can also see the high low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

**Note**

For Ratio block, this area shows you the current value for the ratio (`RatioOut`).

(2) Limit display for the setpoint

These triangles show the setpoint limits configured in the ES.

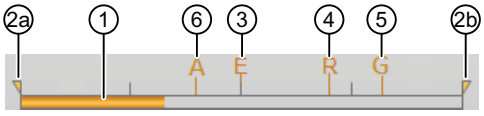
- 2a: High limit for setpoint
- 2b: low limit for setpoint

**Note**

For Ratio block, these blue triangles show the configured High and low range limits for the ratio.

(3) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".



(4) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint of the setpoint ramp and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

(5) Display for the target setpoint of the setpoint gradient ramp

This display [G] shows the target setpoint of the setpoint ramp and is only visible if you have enabled gradient ramp generation in the Ramp view (Page 334).

### Bar graph for the "Manipulated value"

(1) Bar graph for the manipulated variable

This area shows the current manipulated variable in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

**Note**

For Ratio block this display graphically represents the output value, `Out`

(2) Limit display for the manipulated variable

These orange triangles show the limits configured in the ES.

- 2a: low limit for manipulated variable
- 2b: High limit for manipulated variable

**Note**

For Ratio block limits are for output value `Out`.

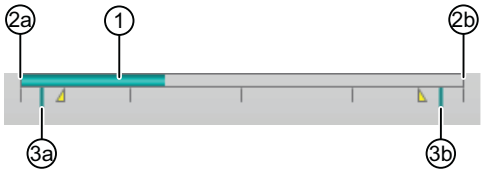
(3) Display of external manipulated variable

This display [E] is only visible when you have selected "Internal" manipulated variable specification. It shows the external manipulated variable that would apply if you were to change the manipulated variable specification to "External".

(4) Display for the target manipulated variable of the manipulated variable ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

(5) Display for the target manipulated variable of the manipulated variable gradient ramp



This display [G] shows the target setpoint and is only visible if you have enabled gradient ramp generation in the Ramp view (Page 334).

(6) Display of the manipulated variable for automatic mode

The display [A] is only visible when the block is not in automatic mode. In Automatic mode, it is displayed when it needs to be reset or when tracking or forced tracking is enabled.

This display shows the manipulated variable that would apply if you were to switch to automatic mode or if you were to reset in automatic mode or disable tracking or forced tracking.

### Bar graph for the "Position Feedback”

(1) Bar graph for position feedback

This display is only visible when the corresponding block input is connected.

This area shows the current position feedback in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

(2) Limit display for the position feedback

These triangles show the limits configured in the ES.

- 2a. low limit for position feedback
- 2b. High limit for position feedback

The limit triangles can have different colors based on the type of limit:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

**Note**

**The limit triangles visibility depends on the configuration in engineering system (ES).**

If a limit is not enabled (e.g. `RbkWH_En`= 0 & `Feature.Bit31` =0 for `PIDConL`) then triangle for corresponding limit (Warning high limit in this example) will not be visible.

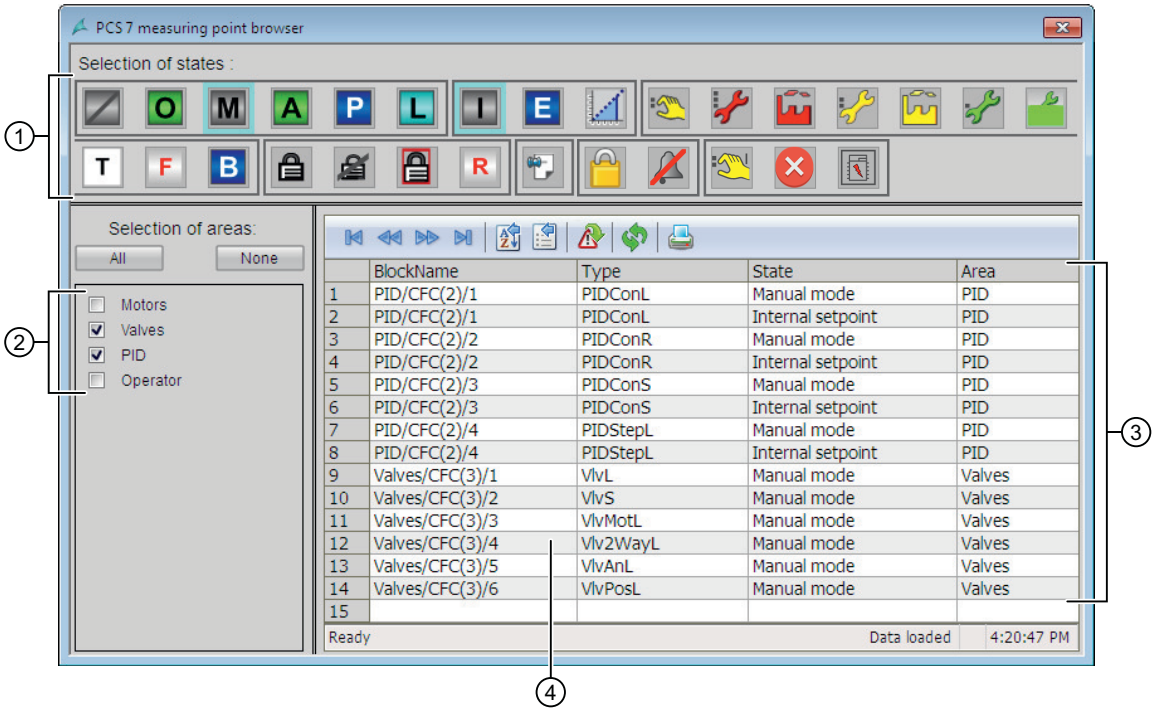
(3) The limits for the "open" and "close" positions (for `VlvAnL`)

- 3a: limits for the "close" position
- 3b: limits for the "open" position

## 2.3.30 Reset of errors during Request 0/1

"Request 0/1" is displayed in faceplate whenever there is a reset pending but reset from faceplate is not possible.

The following table shows the various possibilities to reset the errors.



| Mode | `OS_Perm.Bit7` | `Feature.Bit30` | `Feature.Bit31` | `Feature.Bit9` | `Feature2.Bit13` | Resetting of errors |
|---|---|---|---|---|---|---|
| Auto | 0 | 0 | 0 | 0 | 0 | Possible by `RstLi.Value` |
| | 1 | 1 | 0 | 0 | 0 | |
| | 0 | 0 | 0 | 1 | 0 | Possible by two ways<br><br>1) `RstLi.Value` or<br>2) By Auto Commands |
| | 1 | 1 | 0 | 1 | 0 | |
| Manual | 0 | 1 | 1 | 0 | 0 | Possible by forced commands |
| | 0 | 0 | 1 | 0 | 0 | Possible by `RstLi.Value` |
| Local | 0 | 0 | 0 | 0 | 1 | Reset is possible only via Faceplate hence not recommended to Remove the `OS_Perm.Bit7` |

# 2.4 PCS 7 measuring point browser

## 2.4.1 Overview of the "PCS 7 measuring point browser" window

### Overview

The "PCS 7 measuring point browser" window displays all relevant status information of the APL function blocks.

### (1) "Selection of states"

This area displays all possible states of APL function blocks. All state icons are shown in their respective status group frames. The group name is displayed in the tooltip when the mouse pointer is hovered in the area between the state icon and the group frame. You can select/ deselect one or more states from any status group by clicking the icon. The status information of the selected states is displayed in the status area.

The following states are displayed in this area:

| Icon | State | Status group |
|---|---|---|
|  | Out of service | Operating mode |
|  | On mode | |
|  | Manual mode | |
|  | Automatic mode | |
|  | Program mode | |
|  | Local mode | |
|  | Internal setpoint | Setpoint |
|  | External setpoint | |
|  | Ramp active | |
|  | Manipulated value | Signal status |
|  | Bad, device-related | |
|  | Bad, process-related | |
|  | Uncertain, device-related | |
|  | Uncertain, process-related | |
|  | Maintenance request | |
|  | In progress | |
|  | Tracking | Tracking, Forcing and Bypass |
|  | Forcing | |
|  | Bypass | |

| Icon | State | Status group |
|---|---|---|
|  | Interlock active | Interlock |
|  | Interlock disabled | |
|  | Rapid stop | |
|  | Reset request | |
|  | Active memo | Memo |
|  | Locked messages | Messages |
|  | Suppressed messages | |
|  | Internal simulation | Block status |
|  | Internal error | |
|  | Group error | |

### (2) "Selection of areas"

This area displays the top folders of the plant hierarchy. You can select/deselect one or more areas. The status information from the selected areas is displayed in the status area.

### (3) Status area

This area shows the list of blocks with their corresponding "Type", "State", and "Area" depending on the "Selection of states" and "Selection of areas".

### (4) Opening the faceplate

Double-click a row in the status area to open the corresponding faceplate.

# Operator control blocks

# 3

## 3.1 Comparison of large & small blocks

### 3.1.1 OpAnL compared to OpAnS

#### Comparison of the OpAnL and OpAnS blocks

The following tables are intended to help you decide which block to use.

#### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 60%
- Runtime: ~ 30%

#### Block operating modes

| | OpAnL | OpAnS |
|---|---|---|
| On (Page 77) | X | X |
| Out of service (Page 77) | X | X |

#### Functions of the blocks

| | OpAnL | OpAnS |
|---|---|---|
| Setpoint specification - internal/ external (Page 136) | X | X |
| Setpoint limiting for external set-points (Page 222) | X | |
| Using setpoint ramp (Page 131) | X | |
| Gradient limit of the setpoint (Page 132) | X | |
| Forming and outputting the signal status for technologic blocks (Page 117) | X | X |
| Selecting a unit of measure (Page 240) | X | X |
| Simulating signals (Page 64) | X | X |
| Operator control permissions (Page 285) | X | X |

| | OpAnL | OpAnS |
|---|---|---|
| Display and operator input area for process values and setpoints (Page 233) | X | |
| Opening additional faceplates (Page 234) | X | X |
| SIMATIC BATCH functionality (Page 73) | X | X |
| Generating instance-specific messages (Page 230) | X | |
| Suppressing messages using the MsgLock parameter (Page 231) | X | |
| Process value with separate scale range (Page 173) | X | |

## Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | OpAnL | OpAnS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | X | X |
| 1 | Reaction to the out of service mode (Page 188) | X | X |
| 16 | Process value with separate scale range (Page 173) | X | |
| 22 | Update acknowledgment and error status of the message call (Page 171) | X | |
| 24 | Enabling local operator authorization (Page 169) | X | X |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) | X | X |

## See also

Manual and automatic mode for control blocks (Page 79)

# 3.2 OpAnL - Check and output analog signals (large)

## 3.2.1 Description of OpAnL

### Object name (type + number) and family

Type + number: FB 1865

Family: Operate

### Area of application for OpAnL

The block is used for the following applications:

- Checking and transferring analog input values

### How it works

The block checks incoming, internal (entered in the faceplate) or external (CFC/SFC) analog signals for their limits at the `SP_Int` or `SP_Ext` input and forwards them to the output `SP`, depending on the setting of the `SP_LiOp` input parameter.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

For a description of the individual parameters, see the section OpAnL I/Os (Page 397).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Invalid signal status |
| 6 | `OnAct.Value` |
| 7 | `SP_UpRaAct`, `SP_DnRaAct` limits enabled for gradient mode (`SP_RateOn = 1`) |

| Status bit | Parameter |
|---|---|
| 8 | SP_ExtAct.Value |
| 9 | SP_LoAct.Value |
| 10 | SP_HiAct.Value |
| 11 | Resynchronization: Display preview |
| 12 - 13 | Not used |
| 14 | SP_RmpOn |
| 15 | SP_RmpModTime |
| 16 - 17 | Not used |
| 18 | Feature.Bit16 |
| 19 - 21 | Not used |
| 22 | 1 = SP ramp active |
| 23 - 28 | Not used |
| 29 | 1 = Input parameter SP_LiRmpTime is not interconnected (SP_LiRmpTime.ST = 16#FF) |
| 30 | Internal error |
| 31 | MsgLock |

OpAnL messaging (Page 395)

OpAnL block diagram (Page 403)

OpAnL error handling (Page 394)

OpAnL modes (Page 390)

## 3.2.2 OpAnL modes

### OpAnL modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

**See also**

OpAnL error handling (Page 394)
Description of OpAnL (Page 389)
OpAnL functions (Page 391)
OpAnL block diagram (Page 403)

## 3.2.3 OpAnL functions

### Functions of OpAnL

The functions for this block are listed below.

### Suppressing messages using the MsgLock parameter

This block provides the standard function Resynchronization (Page 258)

### Internal or external setpoint selection

This block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint limitation

Use the `SP_HiLim` and `SP_LoLim` input parameters to limit the setpoint to maximum and minimum limits. If a limit is violated, the setpoint is limited to the limits you have set. If the limits are infringed, the output parameters `SP_HiAct` and `SP_LoAct` display 1.

### Using setpoint ramp

This block provides the standard function Using setpoint ramp (Page 131).

### Gradient limit of the setpoint

This block provides the standard function Gradient limit of the setpoint (Page 132).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `SP_Out.ST`
- `PV_In.ST`
- `SP_Ext.ST` (only if `Feature.Bit10` = 1)

The signal status of the `SP_Out` output parameter is always equivalent to the signal status of input parameter `SP_Ext` or `SP_Int`, depending on how the setpoint is specified. If the internal setpoint `SP_Int` is used, the signal status is always output as 16#80.

In case of `Feature.Bit10` = 1, `SP_Ext.ST` influences `ST_Worst` independent of setpoint specification.

If an external setpoint is used, the signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation.

### Considering bad quality of automatic commands or external values

If the `Feature` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and the parameter `SP_Ext` has bad signal status (16#00 or 16#28), the block works with the last valid value of `SP_Ext` in the "On" mode.

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature Bit17 =1 | Resynchronization after CPU startup |
| Feature Bit18 =1 | Resynchronization after Out of service |
| Feature Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the control outputs are tracked as follow:

SP_Out := PV_In;

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 6 | Ramp rate calculation (Page 191) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 12 | Gradient limitation with time duration (Page 197) |
| 16 | Process value with separate scale range (Page 173) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after Out of service (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 24 | Enabling local operator authorization (Page 169) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 9 | Not used |
| 10 | 1 = Operator can switch to internal |
| 11 | 1 = Operator can switch to external |
| 12 | 1 = Operator can enable bumpless switchover |
| 13 | 1 = Operator can change `SP_Int` |
| 14 | 1 = Operator can enable `SP_RateOn` |
| 15 | 1 = Operator can change `SP_UpRaLim` |
| 16 | 1 = Operator can change `SP_DnRaLim` |
| 17 | 1 = Operator can activate the setpoint ramp (`SP_RmpOn`) |
| 18 | 1 = Operator can switch between specification of the duration (`SP_RmpTime`) and gradient (`SP_DnRaLim`, `SP_UpRaLim`) for calculating the ramp slope |
| 19 | 1 = Operator can change the time for the setpoint ramp (`SP_RmpTime`) |
| 20 | 1 = Operator can change the target setpoint (`SP_RmpTarget`) |
| 21 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Specifying the display area for process and setpoint values as well as operations

The block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

The block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

The block provides the standard function SIMATIC BATCH functionality (Page 73).

## 3.2.4 OpAnL error handling

### Error handling of OpAnL

Refer to the section Error handling (Page 128) in the basic instructions.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 51 | Invalid signal<br>`SP_LiOp` = 1 and `SP_ExtLi` = 1 and `SP_IntLi` = 1 |

Description of OpAnL (Page 389)

## 3.2.5 OpAnL messaging

### Messaging

The following messages can be generated for this block:

- Process messages

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 3 |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 4 |
| | SIG 5 | Reserved | $$BlockComment$$<br>Reserved |
| | SIG 6 | Reserved | $$BlockComment$$<br>Reserved |
| | SIG 7 | Reserved | $$BlockComment$$<br>Reserved |
| | SIG 8 | Reserved | $$BlockComment$$<br>Reserved |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | ExtVa106 |
| 7 | ExtVa107 |

The associated values 4 ... 7 are allocated to the parameters ExtVa104 ... ExtVa107 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 3.2.6 OpAnL I/Os

### OpAnL I/Os

For the parameters that are not linkable refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | Binary input for freely selectable message 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| Feature | I/O for additional functions (Page 391) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| MsgEvId | Message number (assigned automatically) | DWORD | 16#00000000 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operating permission, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operating permissions (Page 391) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| PV_In | Process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_OpScale* | OS display range for process value | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SP_DnRaLim* | Limit (low) for the gradient of the setpoint [Unit/Time unit]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| SP_Ext | external setpoint - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_HiLim | Limit (high) of setpoint | REAL | 100.0 |
| SP_LiDnRaLim | Linkable limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiRmpTime | Linkable time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiUpRaLim | Linkable gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LoLim | Limit (low) of setpoint | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |
| SP_IntLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_LiOp | Select internal/external setpoint source:<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_OpScale | OS display range for setpoint | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>100.0<br>0.0 |
| SP_RateOn | 1 = Activate limitation of setpoint gradients | BOOL | 0 |
| SP_RmpModTime | 1 = Use time values (SP_RmpTime, SP_LiRmpTime)<br>0 = Use gradient limits (SP_DnRaLim, SP_LiDnRaLim, SP_UpRaLim, SP_LiUpRaLim) | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |
| SP_RmpTime* | Time [Time unit] for setpoint ramp from current SP up to SP_RmpTarget or time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 0 |
| SP_Unit | Unit of measure for setpoint | INT | 1001 |
| SP_UpRaLim* | Gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see OpAnL error handling (Page 394) | INT | -1 |
| MsgAckn | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Message error (output ERROR of ALARM_8P) | BOOL | 0 |
| MsgStat | Message status (output STATUS of ALARM_8P) | WORD | 16#0000 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| SP_Out | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_HiAct | High limit for SP_Ext or SP_Int reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_LoAct | Low limit for SP_Ext or SP_Int reached or undershot | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_OpScaleOut | SP_OpScale as output | STRUCT<br>• High REAL<br>• Low: BYTE | <br>• 100.0<br>• 0.0 |
| SP_RateTarget | Target setpoint for the gradient limitation | REAL | 0.0 |
| SP_UpRaAct | 1 = Positive gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_UnitOut | SP_Unit as output | INT | 0 |
| SP_RemRT | Remaining ramp time of the setpoint | REAL | 0.0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word (Page 389) | DWORD | 16#00000000 |

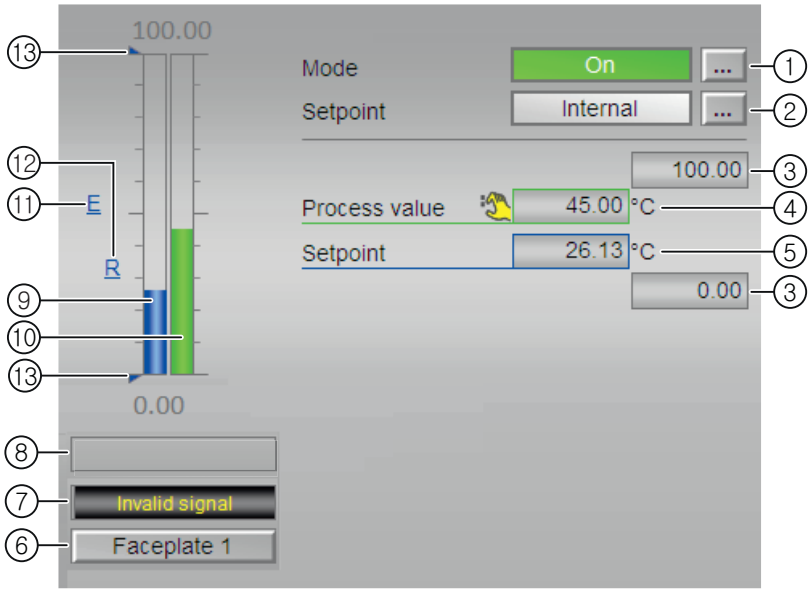
## 3.2.8 Operator control and monitoring

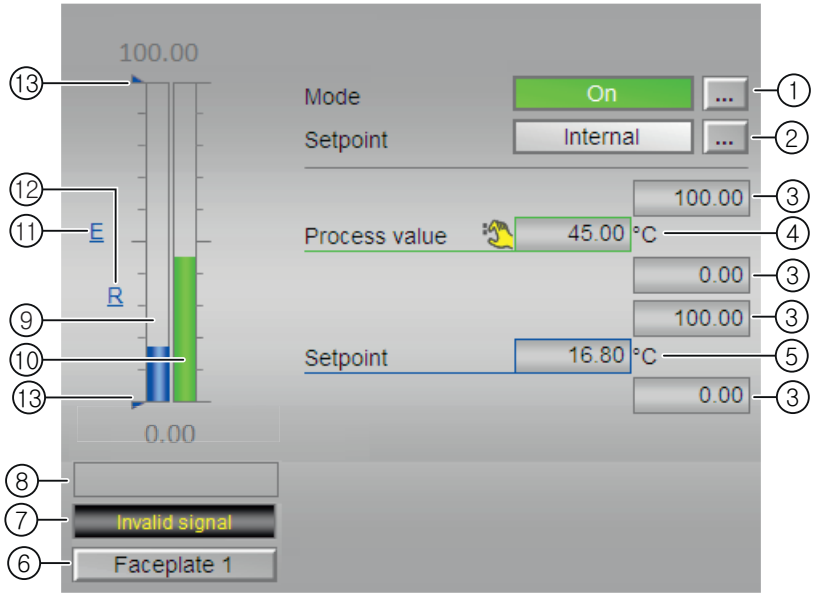
### 3.2.8.1 OpAnL views

### Views of the OpAnL block



The block OpAnL provides the following views:

- OpAnL standard view (Page 404)
- Alarm view (Page 336)
- Trend view (Page 341)
- Ramp view (Page 334)
- OpAnL parameter view (Page 407)
- OpAnL preview (Page 409)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for OpAnL (Page 410)



Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 3.2.8.2 OpAnL standard view

#### OpAnL standard view

The view is switched depending on the `Feature.Bit16` = 1 (process value with separate scale range)

### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Bar graph (Page 376)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

You can find additional information on this in chapter Setpoint specification - internal/external (Page 136).

### (3) High and low scale range for the process value and setpoint

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the Engineering System. For more information refer Bar graph (Page 376) section.

### (4) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area shows the current setpoint with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification also needs to be set to "Internal" for this block.

### (6) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "SP ramp active"

### (9) Bar graph for the process value

This area shows the current process value in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (10) Bar graph for the setpoint

This area shows the current setpoint in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

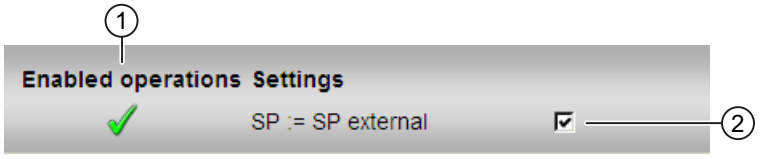
### (11) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (12) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (13) Displaying the limits



These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the Engineering System (ES).

### See also

On (Page 77)

### 3.2.8.3 OpAnL parameter view

#### Parameter view of OpAnL

#### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

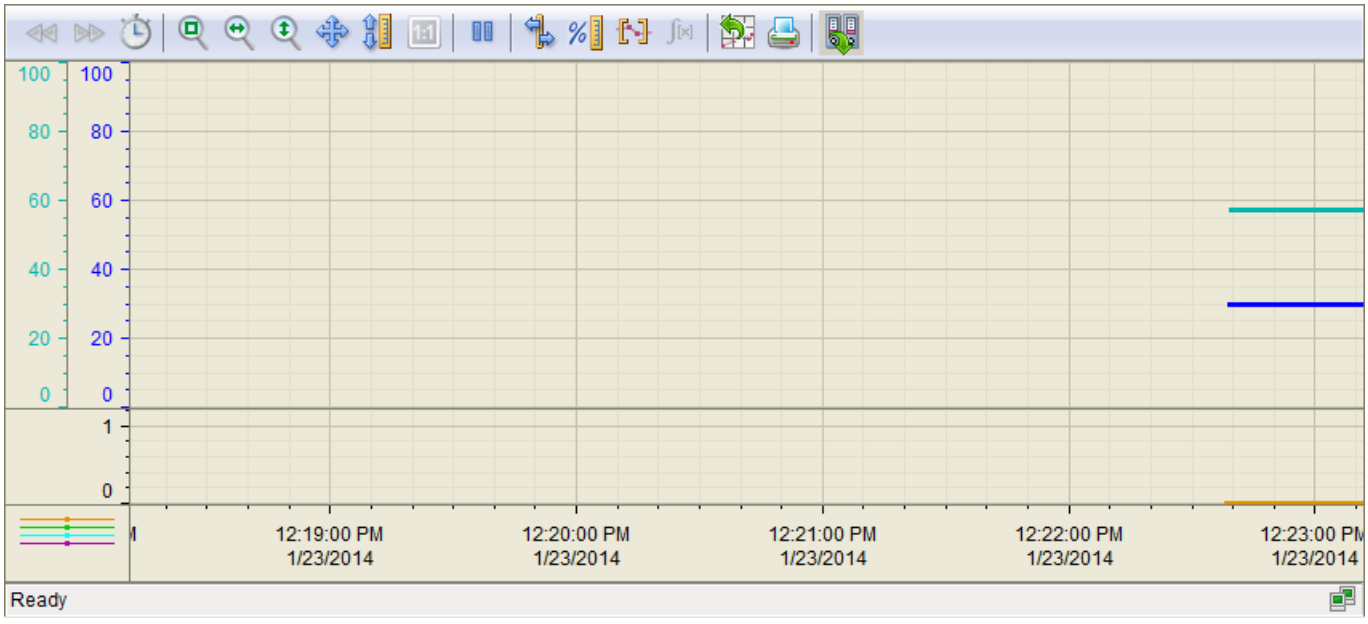
Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

#### (2) Settings

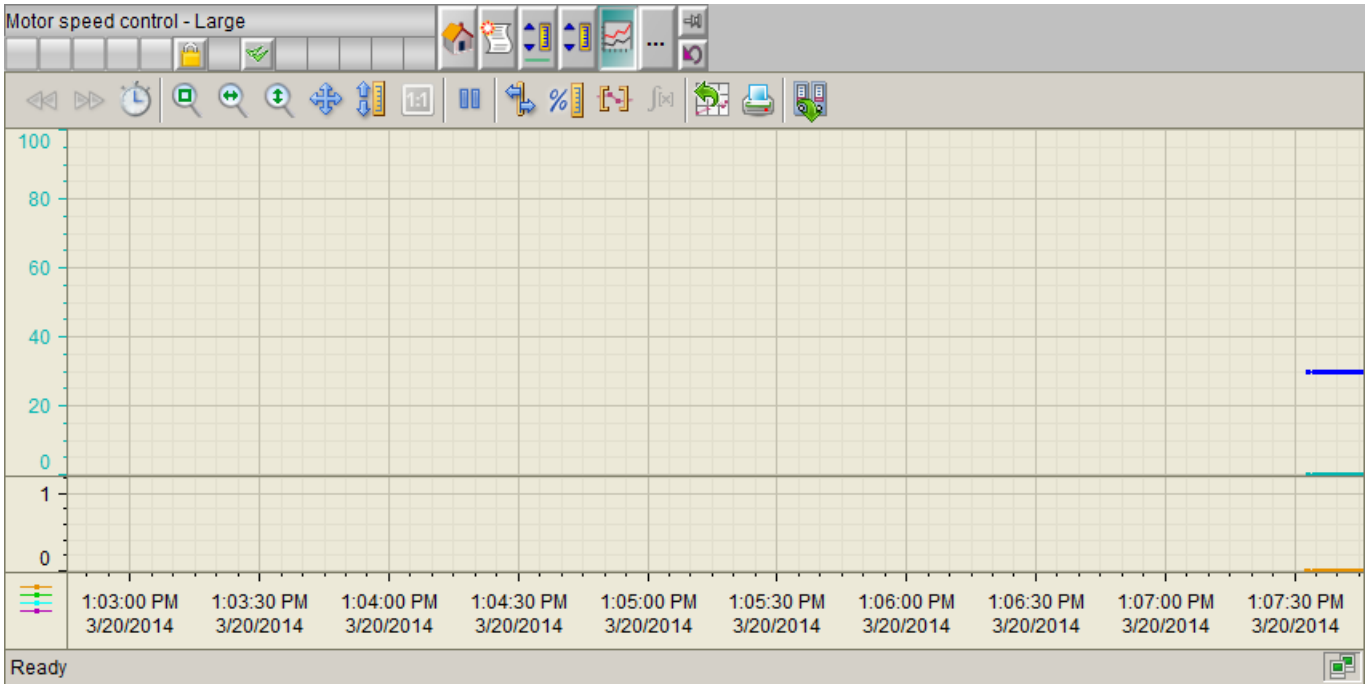
You can select the following functions in this area:

- "SP := SP external": ☑ Bumpless switchover of setpoint from external to internal. The internal setpoint is tracked to the external one.



### 3.2.8.4 OpAnL trend view

#### OpAnL trend view

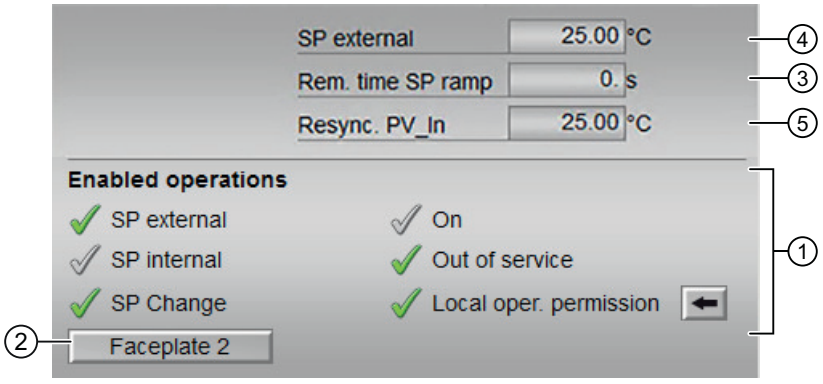


You can find general information in section Trend view (Page 341).

Depending on `Feature.Bit16` (process value with separate scale range) either one or two value axes are shown in the trend view.

- Process value with separate scale range

- Process value without separate scale range



**Note**

This function only has an effect when `SP_Out` is configured in "TrendConfiguration1" and `PV_In` is configured in "TrendConfiguration2" in the block icon (default).

### 3.2.8.5 OpAnL preview

#### Preview of OpAnL

#### (1) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "SP external": You can feedforward the external setpoint.
- "SP internal": You can feedforward the internal setpoint.
- "Change SP": You can change the setpoint.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).

### (2) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the section Opening additional faceplates (Page 234) for more on this.

### (3) Remaining time to reach SP ramp

- "Rem. time SP ramp" : Remaining time to reach the ramp target value.

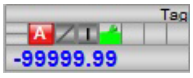
### (4) SP external

Currently applicable external setpoint with the corresponding signal status.

### (5) Resynchronization

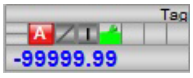
Displays the Resynchronization state based on readback value.

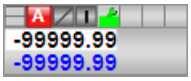
## 3.2.8.6 Block icon for OpAnL

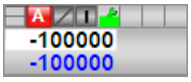


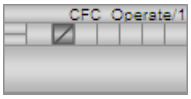
### Block icons for OpAnL

A variety of block icons are available with the following functions:









- Process tag type
- Operating modes
- Internal and external setpoint specification
- Signal status, release for maintenance
- Memo display
- Process value (black, with and without decimal places)
- Setpoint (blue, with and without decimal places)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 3 | |
|  | 4 | |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

# 3.3 OpAnS - Check and output analog signals (small)

## 3.3.1 Description of OpAnS

### Object name (type + number) and family

Type + number: FB 1915

Family: Operate

### Area of application for OpAnS

The block is used for the following applications:

- Checking and transferring analog input values

### How it works

The block forwards incoming, internal (entered in the faceplate) or external (CFC/SFC) analog signals at the `SP_Int` or `SP_Ext` input to the `SP` output, depending on the setting for the `SP_LiOp` input parameter.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status1` parameter

For a description of the individual parameters, see the chapter OpAnS I/Os (Page 417).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Invalid signal status |
| 6 | `OnAct.Value` |
| 7 | Not used |
| 8 | `SP_ExtAct.Value` |

| Status bit | Parameter |
|---|---|
| 9 - 29 | Not used |
| 30 | Internal error |
| 31 | Not used |

### See also

OpAnS messaging (Page 417)

OpAnS block diagram (Page 420)

OpAnS error handling (Page 416)

OpAnS modes (Page 413)

## 3.3.2 OpAnS modes

### OpAnS operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the chapter On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the chapter Out of service (Page 77).

### See also

OpAnS I/Os (Page 417)

OpAnS error handling (Page 416)

Description of OpAnS (Page 412)

OpAnS functions (Page 414)

OpAnS block diagram (Page 420)

## 3.3.3 OpAnS functions

### Functions of OpAnS

The functions for this block are listed below.

### Internal or external setpoint selection

This block provides the standard function Setpoint specification - internal/external (Page 136).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `SP_Out.ST`
- `PV_In.ST`
- `SP_Ext.ST` (only if `Feature.Bit10` = 1)

The signal status of the `SP_Out` output parameter is always equivalent to the signal status of input parameter `SP_Ext` or `SP_Int`, depending on how the setpoint is specified. If the internal setpoint `SP_Int` is used, the signal status is always output as 16#80.

In case of `Feature.Bit10` = 1, `SP_Ext.ST` influences `ST_Worst` independent of setpoint specification.

If an external setpoint is used, the signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation.

### Considering bad quality of automatic commands or external values

If the `Feature` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and the parameter `SP_Ext` has bad signal status (16#00 or 16#28), the block works with the last valid value of `SP_Ext` in the "On" mode.

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 24 | Enabling local operator authorization (Page 169) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 9 | Not used |
| 10 | 1 = Operator can switch to internal |
| 11 | 1 = Operator can switch to external |
| 12 | 1 = Operator can enable bumpless switchover |
| 13 | 1 = Operator can change `SP_Int` |
| 14 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Specifying the display area for process and setpoint values as well as operations

The block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

The block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

The block provides the standard function SIMATIC BATCH functionality (Page 73).

## 3.3.4 OpAnS error handling

### Error handling of OpAnS

Refer to the chapter Error handling (Page 128) in the basic instructions.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 51 | Invalid signal<br>`SP_LiOp` = 1 and `SP_ExtLi` = 1 and `SP_IntLi` = 1 |

## 3.3.6 OpAnS I/Os

### I/Os of OpAnS

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 414) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operating permission, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator control permissions (Page 414) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| PV_In | Process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SP_Ext | external setpoint - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_IntLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 1 |
| SP_LiOp | Select internal/external setpoint source:<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_OpScale | OS display range for setpoint | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>100.0<br>0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 0 |
| SP_Unit | Unit of measure for setpoint | INT | 1001 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see OpAnS error handling (Page 416) | INT | -1 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| SP_Out | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_OpScaleOut | SP_OpScale as output | STRUCT<br>• High REAL<br>• Low: BYTE | <br>• 100.0<br>• 0.0 |
| SP_UnitOut | SP_Unit as output | INT | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word (Page 412) | DWORD | 16#00000000 |

## 3.3.8 Operator control and monitoring

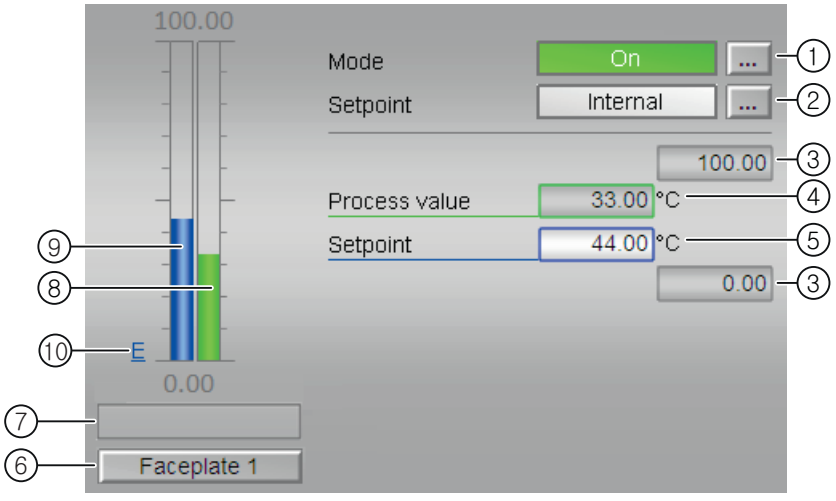
### 3.3.8.1 OpAnS views

#### Views of the OpAnS block

The block OpAnS provides the following views:

- OpAnS standard view (Page 421)
- Trend view (Page 341)
- OpAnS parameter view (Page 423)
- OpAnS preview (Page 424)
- Memo view (Page 338)
- Batch view (Page 336)
- OpAnS block icon (Page 425)

Refer to the chapters Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.



#### See also

Ramp view (Page 334)

Alarm view (Page 336)

### 3.3.8.2 OpAnS standard view

#### OpAnS standard view

### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

You can find additional information on this in chapter Setpoint specification - internal/external (Page 136).

### (3) High and low scale range for the process value

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the Engineering System.

### (4) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area shows the current setpoint with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification also needs to be set to "Internal" for this block.

### (6) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the Engineering System (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (7) Display area for block states

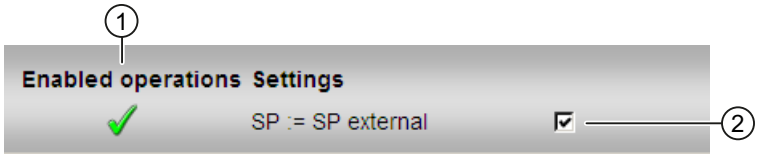
This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (8) Bar graph for the process value

This area shows the current process value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (9) Bar graph for the setpoint



This area shows the current setpoint in the form of a bar graph. The visible area in the bar graph depends on the configuration in the Engineering System (ES).

### (10) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

## 3.3.8.3 OpAnS parameter view

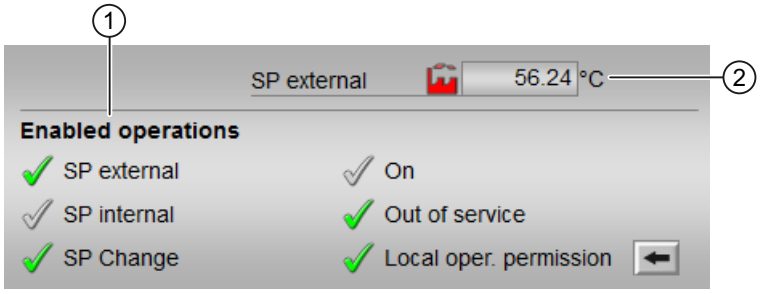
### Parameter view of OpAnS

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).



### (2) Settings

You can select the following functions in this area:

- "SP := SP external": ☑ Bumpless switchover of setpoint from external to internal. The internal setpoint is tracked to the external one.

## 3.3.8.4 OpAnS preview

### Preview of OpAnS

### (1) Enabled operations

This area shows all operations for which special operating permissions are assigned. They depend on the configuration in the Engineering System (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter at all due to the configured AS operating permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

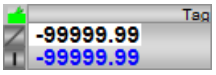
- "SP external": You can feedforward the external setpoint.
- "SP internal": You can feedforward the internal setpoint.
- "Change SP": You can change the setpoint.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in chapter Operator control permissions (Page 285).

### (2) SP external

Currently applicable external setpoint with the corresponding signal status.

### See also

Opening additional faceplates (Page 234)



## 3.3.8.5 OpAnS block icon

### Block icons for OpAnS

A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Internal and external setpoint specification
- Signal status, release for maintenance
- Memo display
- Process value (black, with and without decimal places)
- Setpoint (blue, with and without decimal places)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | Block icon in the full display |
|  | 6 | Block icon in the full display |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

# 3.4 OpDi01 - Manipulating a digital value (2 pushbuttons)

## 3.4.1 Description of OpDi01

### Object name (type + number) and family

Type + number: FB 1866

Family: Operate

### Area of application for OpDi01

The block is used for the following applications:

- Manipulating a digital value

### How it works

A digital value is manipulated by interconnection or via the faceplate.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

If `Feature.Bit0` = 0, the output parameter `Out` will reset to 0.

### Status word allocation for `Status` parameter

You can find a description for each parameter in section OpDi01 I/Os (Page 432).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 | `Out.Value` |
| 8 | `LiOp` |
| 9 | `FbkIn.Value` |
| 10 | Resynchronization preview for Out, Out1 and SP_Out |
| 11 | Resynchronization: Display preview |

| Status bit | Parameter |
|---|---|
| 12 - 13 | Not used |
| 14 | 1 = Invalid signal status |
| 15 | Not used |
| 16 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 17 | Hidden bypass signal in interlock |
| 18 | `Feature2.Bit2`: Separate bypass signal |
| 19 - 22 | Not used |
| 23 | "Interlock" button is enabled |
| 24 - 25 | Not used |
| 26 | Bypass information for display in block icon |
| 27 - 29 | Not used |
| 30 | Internal error |
| 31 | Not used |

OpDi01 error handling (Page 431)

OpDi01 modes (Page 427)

## 3.4.2 OpDi01 modes

### OpDi01 operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

**See also**

OpDi01 functions (Page 428)
Description of OpDi01 (Page 426)

## 3.4.3 OpDi01 functions

### Functions of OpDi01

The functions for this block are listed below.

### Internal or external digital value

Use the `LiOp` input parameter to define whether the digital value is set (0 - 1, parameter `SetOp` or `SetLi`) or is reset (1 - 0, parameter `RstOp` or `RstLi`) via the faceplate or an interconnection.

`LiOp` = 0: Specification of digital value via faceplate (`SetOp` or `RstOp`)

`LiOp` = 1: Specification of digital value via interconnection (`SetLi` or `RstLi`)

### Interlocks

Use the `Intl_En` = 1 and `Intlock.ST` ≠ 16#FF input parameters to activate the interlock function on this block.

An active interlock condition brings the block to the neutral position (`Intlock.Value` = 0 or `Intlock.ST` = 16#00 input). Output parameter `Out` is set to 0. When the interlocking condition no longer applies, the digital value currently valid is output again, depending on the input parameters `LiOp`, `SetOp`, `RstOp`, `SetLi` and `RstLi`.

### Input parameter for feedback value

This block has a `FbkIn` input parameter for displaying a feedback value in the faceplate.

### Opening additional faceplates

This block provides the standard function Resynchronization (Page 258).

### Changing labels on buttons and text

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- Out
- SetOp
- RstOp
- FbkIn

### Forming the signal status for blocks

The worst signal status ST_Worst for the block is formed from the following parameters:

- FbkIn.ST
- SetLi.ST (only if Feature.Bit10 = 1)
- RstLi.ST (only if Feature.Bit10 = 1)

### Considering bad quality of automatic commands or external values

If the Feature bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (Out = 0) in the "On" mode:

- SetLi.ST
- RstLi.ST

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can set the digital value |
| 5 | 1 = Operator can reset the digital value |
| 6 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature Bit17 =1 | Resynchronization after CPU startup |
| Feature Bit18 =1 | Resynchronization after Out of service |
| Feature Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the control outputs are tracked as follow:

Out := FbkIn;

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after Out of service (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 24 | Enabling local operator authorization (Page 169) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 3.4.4 OpDi01 error handling

### Error handling of OpDi01

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |
| 51 | `SetLi` = 1 and `RstLi` = 1 and `LiOp` = 1 |

| RstOp* | Reset by the operator | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SetLi | Connected digital input | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SetOp* | Digital input for operator | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see OpDi01 error handling (Page 431) | INT | -1 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock) is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out | Digital output value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status | Status word (Page 426) | DWORD | 16#00000000 |

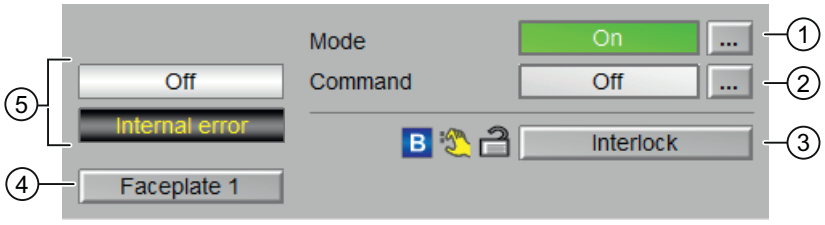
## 3.4.8 Operator control and monitoring

### 3.4.8.1 OpDi01 views

### Views of the OpDi01 block



The block OpDi01 provides the following views:

- OpDi01 standard view (Page 436)
- Trend view (Page 341)
- OpDi01 preview (Page 437)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for OpDi01 (Page 439)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 3.4.8.2 OpDi01 standard view

#### OpDi01 standard view

#### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

You can find additional information on this in section Switching operating states and operating modes (Page 289).

#### (2) Displaying and switching the command

This area shows you the current selection. You can output a continuous signal as follows:

- "On": Continuous signal is output
- "Off"

You can find additional information on this in section Switching operating states and operating modes (Page 289).

You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).

Do this with the following parameters:

- Text for "Command": Parameter `SetOp#string_1`
- Text for "On/Off": Parameter `Out#string_0` / `Out#string_1`

#### (3) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is interconnected.

You can use this button to control the interlock functions of the block. You can find additional information on this in section OpDi01 functions (Page 428).

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (4) Button for switching to the standard view of any faceplate

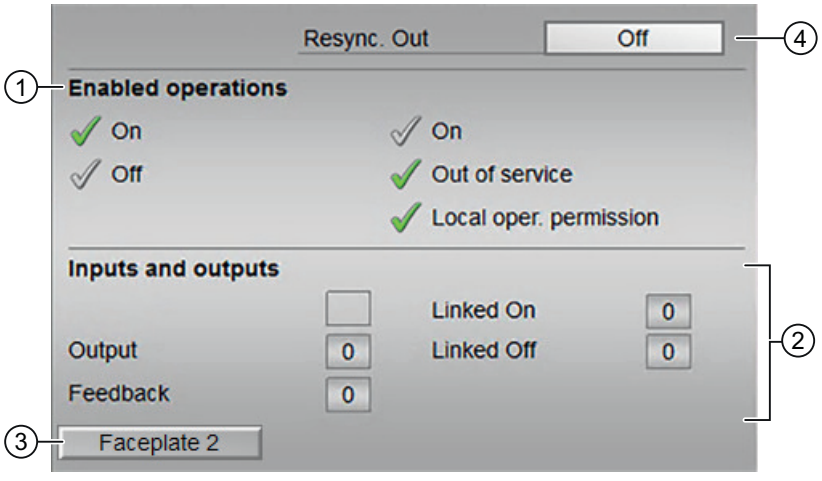
Use this button for the standard view of a block configured in the engineering system. The visibility of this button depends on the configuration in the engineering system (ES).

You can find additional information on this in section Opening additional faceplates (Page 234).

### (5) Displaying the feedback of the command

This area shows you the currently valid command. The following commands can be shown here:

- "On"
- "Off"
- "Internal error"
- "Invalid Signal"



You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).

Do this with the following parameter:

- Text for "On/Off": Parameter `FbkIn#string_0` / `FbkIn#string_1`

## 3.4.8.3 OpDi01 preview

### Preview of OpDi01

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "On": You can set the digital value (0 - 1 edge).
  You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).
  Do this with the following parameters:
  - Text for "On": Parameter `.Out#Value#string_1`
- "Off": You can set the digital value (1 - 0 edge).
  You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).
  Do this with the following parameters:
  - Text for "Off": Parameter `.Out#Value#string_0`
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

### (2) Display of current inputs and outputs

This area shows the most important parameters for this block with the current selection:

- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Output": 1 = Digital output value set
- "Feedback": 1 = Feedback set
- "Linked On": 1 = Linked input on
- "Linked Off": 1 = Linked input off

### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

Refer also to the Opening additional faceplates (Page 234) section for more on this.

### (4) Resynchronization

Displays the Resynchronization state based on feedback value.

## 3.4.8.4 Block icon for OpDi01

### Block icons for OpDi01

A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Bypass
- Interlocks
- Output signal
- Memo display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|   | 1 | |
|   | 2 | |
|   | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|   | 1 | Block icon in the full display |
|   | 2 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 3 | |
|  | 4 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 3.5 OpDi03 - Manipulating a digital value (3 pushbuttons)

## 3.5.1 Description of OpDi03

### Object name (type + number) and family

Type + number: FB 1867

Family: Operate

### Area of application for OpDi03

The block is used for the following applications:

- Manipulating a digital value (3 pushbuttons)

### How it works

A digital value is manipulated at three possible outputs by interconnection or via the faceplate.

If two or three input parameters are set for an interconnection (parameter `SetLix`), the input parameter with the highest index will be set to the corresponding output parameter. For example, if the `SetLi1` and `SetLi2` input parameters are set (= 1), then `Out2` will be set (= 1).

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

If `Feature.Bit0` = 0, the output parameters `Out1` to `Out3` will reset to 0.

### Status word allocation for `Status` parameter

You can find a description for each parameter in section OpDi03 I/Os (Page 448).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 | `Out1.Value` |
| 8 | `Out2.Value` |

| Status bit | Parameter |
|---|---|
| 9 | `Out3.Value` |
| 10 | `LiOp.Value` |
| 11 | `Fbk1In.Value` |
| 12 | `Fbk2In.Value` |
| 13 | `Fbk3In.Value` |
| 14 | 1 = Invalid signal status |
| 15 | Not used |
| 16 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 17 | Hidden bypass signal in interlock |
| 18 | `Feature2.Bit2`: Separate bypass signal |
| 19 | Resynchronization preview for Out1 |
| 20 | Resynchronization preview for Out2 |
| 21 | Resynchronization preview for Out3 |
| 22 | Resynchronization: Display preview |
| 23 | "Interlock" button is enabled |
| 24 - 25 | Not used |
| 26 | Bypass information for display in block icon |
| 27 - 29 | Not used |
| 30 | Internal error |
| 31 | Not used |

OpDi03 messaging (Page 447)
OpDi03 block diagram (Page 451)
OpDi03 error handling (Page 446)
OpDi03 modes (Page 442)

## 3.5.2 OpDi03 modes

### OpDi03 operating modes

The block can be operated using the following modes

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

OpDi03 functions (Page 443)

Description of OpDi03 (Page 441)

## 3.5.3 OpDi03 functions

### Functions of OpDi03

The functions for this block are listed below.

### Internal or external digital value

Use the `LiOp` input parameter to define whether it is through the faceplate or an interconnection using a 1 out of 3 that the selection of the digital value is set (0 - 1) or reset (1 - 0, input parameter `RstOut`).

- `LiOp` = 0: Specification of digital value via faceplate. One of the input parameters `SetOp1`, `SetOp2` or `SetOp3` is now routed to the relevant output `Out1`, `Out2` or `Out3`. For example, if `SetOp2` = 1 , then `Out2` = 1.
- `LiOp` = 1: Specification of digital value via interconnection. One of the input parameters `SetLi1`, `SetLi2` or `SetLi3` is now routed to the relevant output `Out1`, `Out2` or `Out3`. For example, if `SetLi2` = 1 , then `Out2` = 1.

The reset (1 - 0) is always undertaken using the `RstOut` input parameter.

### Interlocks

Use the `Intl_En` = 1 and `Intlock.ST` ≠ 16#FF input parameters to activate the interlock function on this block.

An active interlock condition brings the block to the neutral position (`Intlock.Value` = 0 or `Intlock.ST` = 16#00 input). Output parameter `Out` is set to 0. When the interlocking

condition no longer applies, the digital value currently valid is output again, depending on the input parameters `LiOp`, `SetOp`, `RstOp`, `SetLi` and `RstLi`.

### Input parameter for feedback value

This block has three input parameters `Fbk1In`, `Fbk2In` and `Fbk3In` for displaying three feedback values in the faceplate.

### Resetting all output values

Reset all output parameters (`Out1` ... `Out3`) by setting all interconnected input parameters for setting (`SetLi1` ... `SetLi3`) or enabled input parameters for setting (`SetOp1` ... `SetOp3`) to 0.

A 0 - 1 edge at the `RstOut` parameter then resets the three output parameters `Out1` ... `Out3`.

### Opening additional faceplates

This block provides the standard function Resynchronization (Page 258).

### Changing labels on buttons and text

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- `OutX`
- `SetOpX`
- `FbkXIn`

X = (1 ... 3)

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `Fbk1In.ST`
- `Fbk2In.ST`
- `Fbk3In.ST`
- `SetLi1.ST` (only if `Feature.Bit10` = 1)
- `SetLi2.ST` (only if `Feature.Bit10` = 1)
- `SetLi3.ST` (only if `Feature.Bit10` = 1)
- `RstOut.ST` (only if `Feature.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (`Out1` = 0, `Out2` = 0, and `Out3` = 0) in the "On" mode:

- `SetLi1.ST`
- `SetLi2.ST`
- `SetLi3.ST`
- `RstOut.ST`

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can set the digital value `SetOp1` |
| 5 | 1 = Operator can set the digital value `SetOp2` |
| 6 | 1 = Operator can set the digital value `SetOp3` |
| 7 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Resynchronization

This block provides the standard function Resynchronization.

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature Bit17 =1 | Resynchronization after CPU startup |
| Feature Bit18 =1 | Resynchronization after Out of service |
| Feature Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the control outputs are tracked as follow:

Out1 := Fbk1In;

Out2 := Fbk2In;

Out3 := Fbk3In;

If more than one feedback signals are active: The feedback with the highest index becomes active.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after Out of service (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 24 | Enabling local operator authorization (Page 169) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 3.5.4 OpDi03 error handling

### Error handling of OpDi03

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |
| 51 | The value 1 is set at two or more inputs<br>(`SetLi1` = 1 AND `SetLi2` = 1) or (`SetLi2` = 1 AND `SetLi3` = 1) or (`SetLi1` = 1 AND SetLi3 = 1) and `LiOp` = 1 |

| SetOp1* | Digital input 1 for operator | BOOL | 0 |
| SetOp2* | Digital input 2 for operator | BOOL | 0 |
| SetOp3* | Digital input 3 for operator | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see OpDi03 error handling (Page 446) | INT | -1 |
| LockAct | 1 = Interlock (Intlock) is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out1 | Digital output value 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out2 | Digital output value 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out3 | Digital output value 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status | Status word (Page 441) | DWORD | 16#00000000 |

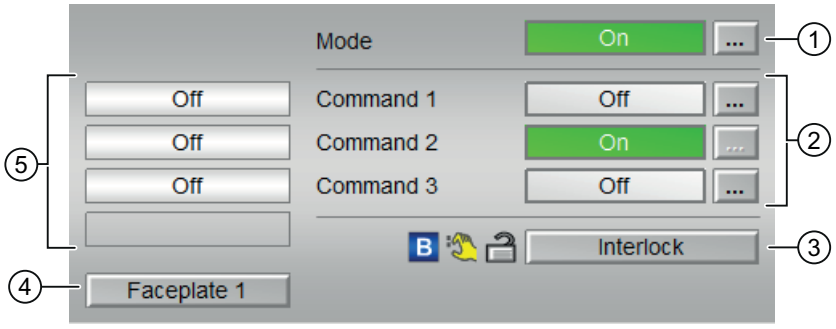
## 3.5.8 Operator control and monitoring

### 3.5.8.1 OpDi03 view

### Views of the OpDi03 block



The block OpDi03 provides the following views:

- OpDi03 standard view (Page 452)
- Trend view (Page 341)
- OpDi03 preview (Page 454)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for OpDi03 (Page 455)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 3.5.8.2 OpDi03 standard view

#### OpDi03 standard view

#### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

You can find additional information on this in section Switching operating states and operating modes (Page 289).

#### (2) Displaying and switching the command 1 to 3

This area shows you the current selection. You can output a continuous signal at the outputs `Out1` to `Out3` as follows:

- "On": Continuous signal is output
- "Off"

You can find additional information on this in section Switching operating states and operating modes (Page 289).

You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).

**Note**

You can configure any of 3 commands available from the operation area of the faceplate.

Do this with the following parameters:

- Text for "Command 1/Command 2/Command 3": Parameter `SetOpX#string_1`, (X = 1 ... 3)
- Text for "On/Off": Parameter `OutX#string_0`, `OutX#string_1`, (X = 1 ... 3)

### (3) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is interconnected.

You can use this button to control the interlock functions of the block. You can find additional information on this in section OpDi03 functions (Page 443).

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (4) Button for switching to the standard view of any faceplate

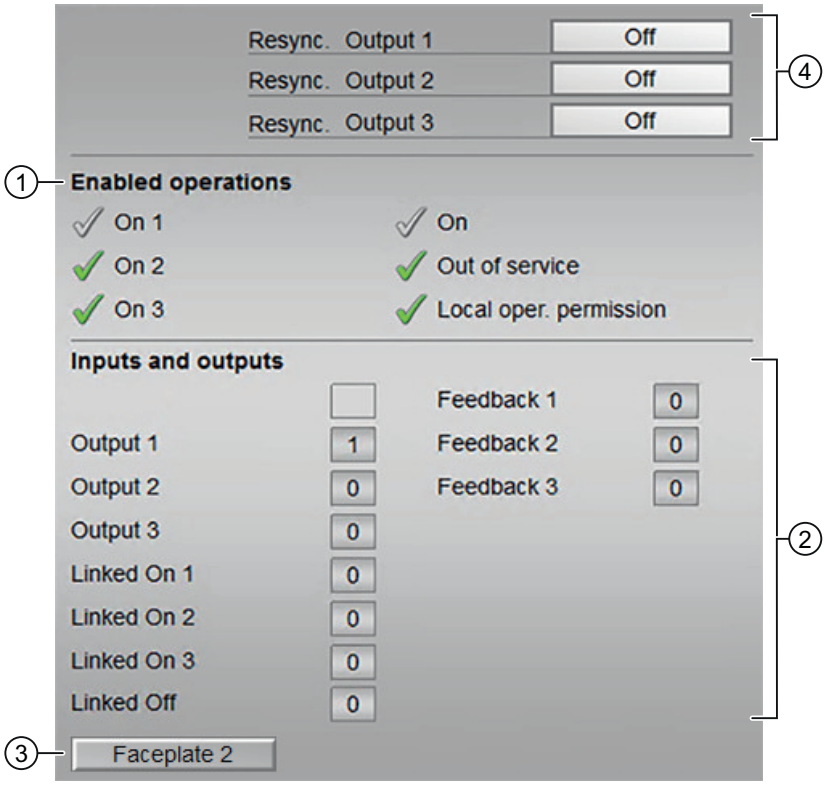
Use this button for the standard view of a block configured in the engineering system. The visibility of this button depends on the configuration in the engineering system (ES).

You can find additional information on this in section Opening additional faceplates (Page 234).

### (5) Displaying the feedback of the command 1 to 3

This area shows you the current valid selection from `Out1` to `Out3`.

- "On"
- "Off"
- "Internal error"
- "Invalid Signal"



You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).

Do this with the following parameters:

- Text for "On/Off": Parameter `FbkInX#string_1`, `FbkInX#string_0`, (X = 1 ... 3)

### 3.5.8.3 OpDi03 preview

**Preview of OpDi03**

**(1) Enabled operations**

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "On 1 to 3": You can now set the digital value (0 - 1 edge).
  You can rename the display text as you please, as described in the section Labeling of buttons and text (Page 235).
  Do this with the following parameters:
  - Text for "Command X": Parameter `OutX#string_1`, (X = 1 ... 3)
- "On": You can switch to "On" operating mode.

- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

### (2) Display of current inputs and outputs

This area shows the most important parameters for this block with the current selection:

- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Output 1 to 3": 1 = Digital output value set
- "Feedback 1 to 3": 1 = Feedback set
- "Linked On 1 to 3": 1 = Linked input on
- "Linked Off": 1 = Linked input off

### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Refer also to the Opening additional faceplates (Page 234) section for more on this.

### (4) Resynchronization

Displays the Resynchronization state based on feedback value.

## 3.5.8.4 Block icon for OpDi03

### Block icons for OpDi03

A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Bypass
- Interlocks

- Output signal
- Memo display

The block icons from template @TemplateAPLV8.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 3.6 OpStations - Configuration of the local operator authorization

## 3.6.1 Description of OpStations

### Object name (type + number) and family

Type + number: FB 1901

Family: Operate

### Area of application for OpStations

The block is used for the following applications:

- Configuration of the local operatorcontrol permission

### How it works

The block converts the enabled operations or locks for up to 16 individual permissions in the bit-coded `Out` output.

Refer also to OpStations block diagram (Page 464).

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The OpStations block and the technologic block must be installed into the same cyclic interrupt OB.

**Note**

Install the blocks in a slower cyclic interrupt OB.

With the default, the local operatorcontrol permission for all block instances on the faceplate is disabled (= 0) and is configured as follows:

1. Assign each operator station a bit-coded ID (1, 2, 4, 8, 16, ...), which you set in the internal APLOpStation variables as a start value. You can set up to 16 different operator stations. The variable is automatically created using the OS project editor and is located in the Split Screen Manager group.

   **Note**

   A redundant server pair can only be represented as an operator station, which also affects referenced client or single stations in the engineering station (ES). If a distinguishable operator station is needed, different groups of referenced clients or single stations must be created

2. Place the OpStations block in the chart.

   **Note**

   If you use the Opening additional faceplates (Page 234) function in multiple technologic blocks, you need to use one OpStations block for every technologic block. Otherwise, the call of the technologic block from the OpStations block is only possible for a technologic block.

3. Enable the function at the technologic block via `Feature.Bit24`(Enabling local operator authorization (Page 169)).
4. Interconnect the `OpSt_In` input parameter of the technologic block to the `Out` output parameter of the OpStations block.
5. Select the operator stations on which the technologic block will usually be used. You can select several at once. The selection is sent bit-coded to the `Out` output of the OpStations block.
6. Specify a list for the texts for the standard view in the OpStations faceplate in the shared declarations under the name APLOpStations in the SIMATIC Manager. Refer also to the section OpStations standard view (Page 467) for more information.

Once these configuration steps are completed, the local operatorcontrol permission is enabled. The enable for a technologic block is made when the bit-by-bit comparison between the `OpSt_Out` parameter and the operator station ID "APLOpStation" does not equal 0.

**Note**

The local operatorcontrol permission is not visualized in the "Enabled operation" icons of the block I/Os.

## Startup characteristics

This block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section OpStations I/Os (Page 462).

| Status bit | Parameter |
|---|---|
| 0 | `In0` |
| 1 | `In1` |
| 2 | `In2` |
| 3 | `In3` |
| 4 | `In4` |
| 5 | `In5` |
| 6 | `In6` |
| 7 | `In7` |
| 8 | `In8` |
| 9 | `In9` |
| 10 | `In10` |
| 11 | `In11` |
| 12 | `In12` |
| 13 | `In13` |
| 14 | `In14` |
| 15 | `In15` |
| 16 - 29 | Not used |
| 30 | `Occupied` |
| 31 | `BatchEn` |

OpStations block diagram (Page 464)

## 3.6.3 OpStations functions

### Functions of OpStations

The functions for this block are listed below.

### Operator control permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can enable `In0` |
| 1 | 1 = Operator can enable `In1` |
| 2 | 1 = Operator can enable `In2` |
| 3 | 1 = Operator can enable `In3` |
| 4 | 1 = Operator can enable `In4` |
| 5 | 1 = Operator can enable `In5` |
| 6 | 1 = Operator can enable `In6` |
| 7 | 1 = Operator can enable `In7` |
| 8 | 1 = Operator can enable `In8` |
| 9 | 1 = Operator can enable `In9` |
| 10 | 1 = Operator can enable `In10` |
| 11 | 1 = Operator can enable `In11` |
| 12 | 1 = Operator can enable `In12` |
| 13 | 1 = Operator can enable `In13` |
| 14 | 1 = Operator can enable `In14` |
| 15 | 1 = Operator can enable `In15` |
| 16 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 3.6.6 OpStations I/Os

### OpStations I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 460) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In0 | 1 = Enable for operator station 1 | BOOL | 0 |
| In1 | 1 = Enable for operator station 2 | BOOL | 0 |
| In2 | 1 = Enable for operator station 3 | BOOL | 0 |
| In3 | 1 = Enable for operator station 4 | BOOL | 0 |
| In4 | 1 = Enable for operator station 5 | BOOL | 0 |
| In5 | 1 = Enable for operator station 6 | BOOL | 0 |
| In6 | 1 = Enable for operator station 7 | BOOL | 0 |
| In7 | 1 = Enable for operator station 8 | BOOL | 0 |
| In8 | 1 = Enable for operator station 9 | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| In9 | 1 = Enable for operator station 10 | BOOL | 0 |
| In10 | 1 = Enable for operator station 11 | BOOL | 0 |
| In11 | 1 = Enable for operator station 12 | BOOL | 0 |
| In12 | 1 = Enable for operator station 13 | BOOL | 0 |
| In13 | 1 = Enable for operator station 14 | BOOL | 0 |
| In14 | 1 = Enable for operator station 15 | BOOL | 0 |
| In15 | 1 = Enable for operator station 16 | BOOL | 0 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OS_Perm | I/O for operator control permissions (Page 460) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out | Output value: for additional interconnections to the OpSt_In input of a technologic block | DWORD | 16#00000000 |
| Status | Status word (Page 457) | DWORD | 16#00000000 |

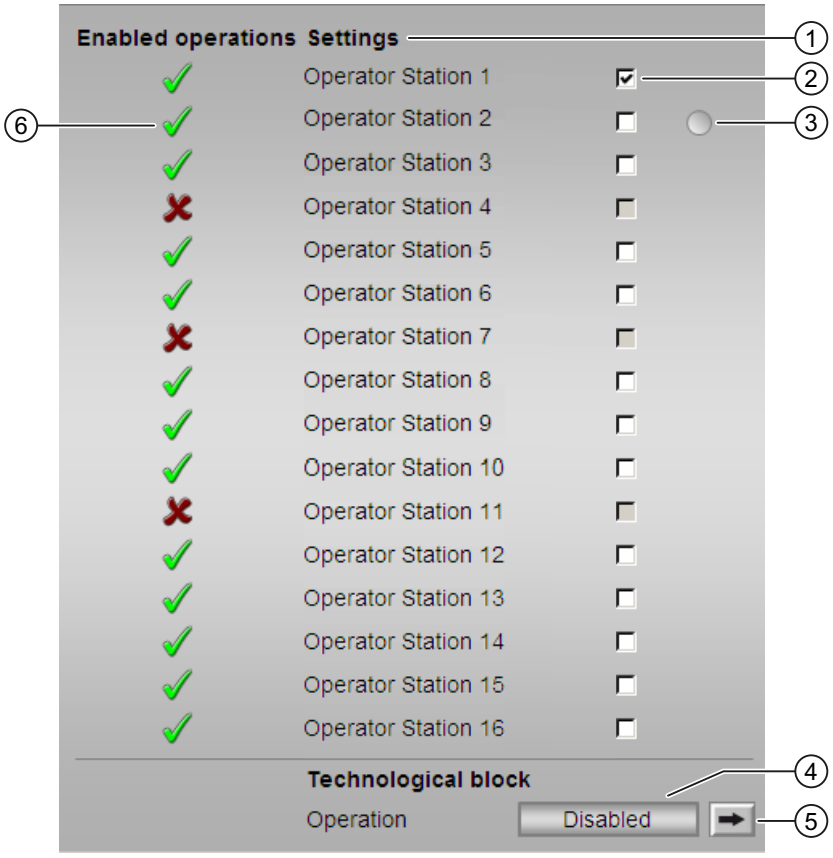
## 3.6.8 Operator control and monitoring

### 3.6.8.1 OpStations views

**Views of the OpStations block**



The `OpStations` block provides the following views:

- OpStations standard view (Page 467)
- Memo view (Page 338)
- Block icon of OpStations (Page 469)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 3.6.8.2 OpStations standard view

## OpStations standard view

## (1) Configurable display text under the settings

You yourself can define the text for operator station 1 to operator station 15 instead of the default text. Follow the steps outlined below:

- Create a list with the name "APLOpStations" in the SIMATIC Manager in the shared declarations. To learn more on this, refer to "How to save shared declarations" in the Process Control System PCS 7 Engineering System Configuration Manual.

Only values from 0 to 15 are permitted, other values will not be saved in the list.

The display names of the values are changed with the names of the operator stations. The display name corresponds to the value 0 of the display for the check box `In0` in the standard view etc.

If the text is not configured, the entire line is not displayed.

### (2) Disabling or enabling operation for operator stations

In this area, you can disable the operation for an operator station or enable the operator station for the connected technologic block. In this case, the upper check box corresponds to the `In0` I/O and the lower check box to the `In15` I/O. Operation is only possible with the highest-level operator control permission (same as simulation) .

### (3) Display for the current operator station

The value of the current operator station is displayed as a gray dot in the corresponding line.

### (4) Display for operability

Display of the operability of the technologic block on the current operator station.

### (5) Navigation button for switching to the standard view of the technologic block

Use this navigation button to reach the standard view of the technologic block. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Additional information is available in the section Opening additional faceplates (Page 234).

### (6) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### 3.6.8.3 Block icon of OpStations

#### Block icons for OpStations

A variety of block icons are available with the following functions:

- Opening the faceplate

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
| Without icon | 1 | Default no block icon |
|  | 2 | The block icon is transparent, if operation on the operator station is possible |

**Note**

The block icon is the size of a field in the status bar of a technologic block icon and can be used as an add-on to the status bar. The layer of the block icon here should always be higher than the layer of the technologic block icon, otherwise the block icon may be hidden after an update.

# 3.7 OpTrig - Manipulating a digital value (1 pushbutton)

## 3.7.1 Description of OpTrig

### Object name (type + number) and family

Type + number: FB 1868

Family: Operate

### Area of application for OpTrig

The block is used for the following applications:

- Generation of a pulse signal (trigger)

### How it works

Operator control block is used to implement single pushbutton control (comparable with RESET pushbutton).

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section OpTrig I/Os (Page 474).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 | `Out.Value` |
| 8 | `LiOpAct.Value` |
| 9 | `FbkIn.Value` |
| 10 - 31 | Not used |

**See also**

OpTrig functions (Page 471)

OpTrig messaging (Page 474)

OpTrig block diagram (Page 477)

OpTrig error handling (Page 473)

OpTrig modes (Page 471)

## 3.7.2 OpTrig modes

### OpTrig operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

**See also**

OpTrig I/Os (Page 474)

OpTrig messaging (Page 474)

OpTrig functions (Page 471)

OpTrig error handling (Page 473)

Description of OpTrig (Page 470)

## 3.7.3 OpTrig functions

### Functions of OpTrig

The functions for this block are listed below.

### Issuing trigger signal internally or externally

Use the parameter `LiOp` to define whether the trigger signal is to be output by interconnection or by the OS operator:

`LiOp` = 0: Trigger signal by OS operator (input parameter `InOp`)

`LiOp` = 1: Trigger signal via interconnection (input parameter `InLi`)

### Input parameter for feedback value

This block has a `FbkIn` input parameter for displaying a feedback value in the faceplate.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameter:

- `FbkIn.ST`
- `InLi.ST` (only if `Feature.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and the parameter `InLi.ST` has bad signal status (16#00 or 16#28), the block goes to the neutral position (`Out` = 0) in the "On" mode.

### Operator control permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can set the input parameter `In` |
| 5 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 24 | Enabling local operator authorization (Page 169) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 3.7.6 OpTrig I/Os

### OpTrig I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| EN | 1 = Called block will be processed | BOOL | 1 |
| FbkIn | Input for feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions (Page 471) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| InLi | Interconnectable binary input | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| InOp* | Binary input for operator | BOOL | 0 |
| LiOp | Switchover of operating mode between:<br>1 = Interconnection<br>0 = Operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operating permission, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator control permissions (Page 471) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelFp1 | Call a block saved in this parameter as additional faceplate (Page 234) in standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as additional faceplate (Page 234) in the preview | ANY | - |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Reserved | INT | -1 |
| LiOpAct | Operator/interconnection is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |

## 3.7.8 Operator control and monitoring

### 3.7.8.1 OpTrig views

### Views of the OpTrig block

The block OpTrig provides the following views:

- OpTrig standard view (Page 478)
- OpTrig preview (Page 479)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for OpTrig (Page 480)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 3.7.8.2 OpTrig standard view

#### OpTrig standard view

#### (1) Displaying and switching the operating mode

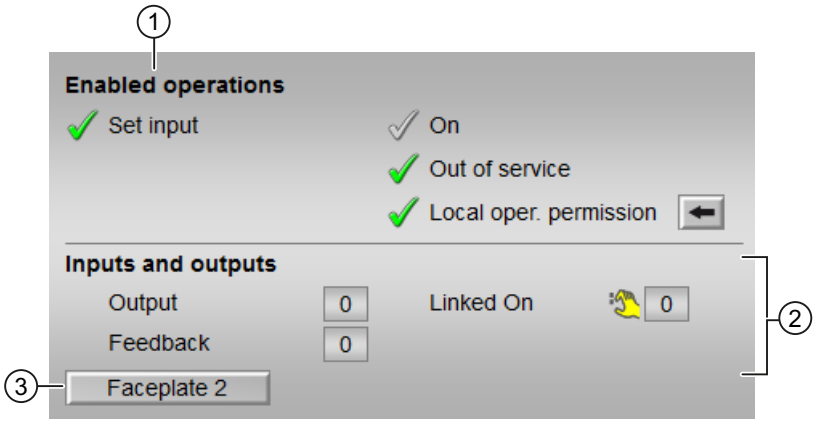
This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

You can find additional information on this in the Switching operating states and operating modes (Page 289) section.

#### (2) Set

Clicking "Set", outputs a pulse signal with the length of the cycle time at the `Out` output.



#### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### 3.7.8.3 OpTrig preview

#### Preview of OpTrig

#### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter.
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process.
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations are shown here:

- "Set input": You can set the input.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

#### (2) Display of current inputs and outputs

This area shows the most important parameters for this block with the current selection:

- "Output": 1 = Digital output value set
- "Feedback": 1 = Feedback set
- "Linked On": 1 = Linked input on

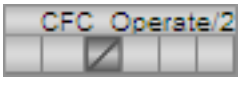
### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Refer also to the Opening additional faceplates (Page 234) section for more on this.

## 3.7.8.4 Block icon for OpTrig

### Block icons for OpTrig



A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Memo display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|   | 1 | |
|   | 2 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|   | 1 | Block icon in the full display |
|  | 2 | |
|   | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

# Condition Monitoring

# 4

## 4.1 PumpMon - Pump monitoring

### 4.1.1 Description of PumpMon

#### Object name (type + number) and family

Type + number: FB 1950

Family: CondMon

Number of process objects: 20 PO

#### Area of application of PumpMon

A lot of the products we use daily are produced in process engineering plants. Pumps are among the most important machines used in these plants. Around 20% of the world's electrical energy is consumed by pumps. If a pump fails, this can cause an entire plant to shut down and the resulting losses can quickly exceed the value of the pump many times over.

This is why the availability of pumps is a very important factor. Redundant systems and special monitoring systems are sometimes implemented to ensure the required availability, although they can be extremely expensive and complex.

The scope for saving energy, however, has yet to be fully leveraged. The PumpMon block for monitoring PCS 7 centrifugal pumps was developed as a cost-efficient monitoring solution and to leverage potential for saving energy.

The block is used to:

- Warn against potential damage to pumps under unfavorable operating conditions
- Provide early detection of imminent damage to pumps
- Optimize the pump design over the long term by means of statistical analyses of the operating data.

The block can be used for electric centrifugal pumps as well as for constant and variable-speed pumps.

#### Mode of operation

Any limit violations of the nominal pump operating range and deviations from the expected characteristic curve are visualized and reported to the operator and made available for further processing via the block outputs. All the values can of course be processed further with the usual PCS 7 tools (calculations, archiving, curve recording, alarm history, etc.).

The block itself is designed purely for diagnostic purposes and, as such, does not intervene directly in the operation of the pump. This means that it can be used (including as a retrofitted

device) without having to worry about affecting the process. If required, active intervention (e.g. to reduce the speed of the pump in response to imminent cavitation) can be undertaken by evaluating the block outputs.

The following views are provided:

- Delivery height characteristic: Displays the delivery height as a function of the flow rate at the current delivery height operating point of the pump
- Power and efficiency characteristic: Displays the pump power and the pump efficiency as a function of the flow rate at the current power and efficiency operating point of the pump
- NPSH characteristic: Displays the cavitation-relevant NPSH (Net Positive Suction Head) of the value as a function of the flow rate at the current NPSHa operating point of the pump
- Compares the recorded electrical performance, the calculated mechanical performance (via a motor model) and the hydraulic performance generated by the pump
- Provides statistical analyses of the operating conditions, taking into account the flow rate and cavitation reserve
- Various views for (one-time) input of pump and medium parameters

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Dynamic input values

As input data, the block requires the electrical power consumption of the motor, the flow rate, the differential pressure across the pump and a binary signal from which the operating state of the motor can be deduced. For cavitation monitoring, the pressure on the input side of the pump and the temperature of the pumped medium are also required. These signals must be provided by upstream blocks.

The following input signals must be interconnected:

- Flow rate of pumped medium (`Flow`)
- Inlet pressure, intake pressure (`P_In`) (if no cavitation monitoring is required, a constant value can be parameterized here)
- Output pressure, flow pressure (`P_Out`)
- Active electrical power (`PoElec`)
- Motor operating state binary signal (`Running`)

In addition for cavitation monitoring:

- Temperature of pumped medium (`Temp`)

The following input must also be interconnected for speed-controlled motors (`ConstSpd = FALSE` input):

- Speed (`Spd`)

If the converter calculates and supplies the mechanical power, the mechanical power must be interconnected at the following input:

- Mechanical power (PoMech) of converter (when ConvAct = TRUE)

### Static input values

The following data must be known and entered as static input data (most parameters can be entered via the faceplate):

- Density of the medium
- For cavitation monitoring, the vapor pressure curve of the medium (in the form of Antoine coefficients or via external calculation)
- Motor characteristic data (rated power, rated speed, for non-standardized motors: polynomial for the relation between mechanical shaft power and recorded electrical power)
- Pump characteristic data (diameter of intake and discharge stubs, characteristics for delivery height, mechanical power, efficiency, and NPSH value as a function of flow rate)

### Startup characteristics

Use Feature.Bit0 (Setting the startup characteristics) to define the startup characteristics of this block.

- **Bit = 0:** The most recently stored values are reset at startup.
- **Bit = 1**: The most recently used values are output to the following output parameters at startup:
  - siPoHydr
  - siPoMech
  - DelHi
  - NPSH
  - EtaOut
  - Devxxx
  - MinTolxxx
  - MaxTolxxx
  - Relxxx

  (xxx = DelHi, Power, Eta or Npsh)

Following startup, the messages are suppressed for the number of cycles assigned in the RunUpCycparameter.

**Note**

Additional information about Feature.Bit0 can be found in Set startup characteristics (Page 148).

### Status word assignment for the `Status1` parameter

For a description of the individual parameters, refer to the section "I/Os of PumpMon (Page 505)".

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `OnAct.Value` |
| 6 – 10 | Not used |
| 11 | `Run.Value` |
| 12 | `Bypass = 0`: No bypass set |
| 13 | `ConstSpd = 0`: Speed-controlled pump |
| 14 | `ConvAct` |
| 15 | `PolyAct` |
| 16 | Display of efficiency (`PolyAct = 0 AND ConvAct = 0`) |
| 17 | `Teach` |
| 18 – 24 | Not used |
| 25 | Idle time is active |
| 26 – 27 | Not used |
| 28 | Internal error |
| 29 – 31 | Not used |

### Status word assignment for `Status2` parameter

For a description of the individual parameters, refer to the section "I/Os of PumpMon (Page 505)".

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `DelHiAct.Value` |
| 2 | `PowerAct.Value` |
| 3 | `EtaAct.Value` |
| 4 | `NpshAct.Value` |
| 5 | `CaviAct.Value` |
| 6 | `DirAct.Value` |
| 7 | `BlkAct.Value` |
| 8 | `DryRunAct.Value` |
| 9 | `PoElecAH_Act.Value` |
| 10 | `PoElecWH_Act.Value` |
| 11 | `PoElecWL_Act.Value` |
| 12 | `PoElecAL_Act.Value` |
| 13 | `PoMechAH_Act.Value` |
| 14 | `PoMechWH_Act.Value` |

| Status bit | Parameter |
|---|---|
| 15 | PoMechWL_Act.Value |
| 16 | PoMechAL_Act.Value |
| 17 | PoHydrAH_Act.Value |
| 18 | PoHydrWH_Act.Value |
| 19 | PoHydrWL_Act.Value |
| 20 | PoHydrAL_Act.Value |
| 21 | DelHiEn |
| 22 | PowerEn |
| 23 | EtaEn |
| 24 | NpshEn |
| 25 | CaviEN |
| 26 | DirEn |
| 27 | BlkEn |
| 28 | DryRunEn |
| 29 | 1= Suppressed messages |
| 30 - 31 | Not used |

### Status word assignment for `Status3` parameter

For a description of the individual parameters, refer to the section "I/Os of PumpMon (Page 505)".

| Status bit | Parameter |
|---|---|
| 0 | PoElecAH_En |
| 1 | PoElecWH_En |
| 2 | PoElecWL_En |
| 3 | PoElecAL_En |
| 4 | PoMechAH_En |
| 5 | PoMechWH_En |
| 6 | PoMechWL_En |
| 7 | PoMechAL_En |
| 8 | PoHydrAH_En |
| 9 | PoHydrWH_En |
| 10 | PoHydrWL_En |
| 11 | PoHydrAL_En |
| 12 | DelHiMsgEn |
| 13 | PowerMsgEn |
| 14 | EtaMsgEn |
| 15 | NpshMsgEn |
| 16 | CaviMsgEn |
| 17 | DirMsgEn |
| 18 | BlkMsgEn |
| 19 | DryRunMsgEn |
| 20 – 31 | Not used |

### Status word assignment for the `Status4` parameter

For a description of the individual parameters, refer to the section "I/Os of PumpMon (Page 505)".

| Status bit | Parameter |
|---|---|
| 0 – 31 | Not used |

## 4.1.2 PumpMon modes

### PumpMon operating modes

The block can be operated using the following modes:

- On
- Out of service

### "On"

General information about the "On" operating mode can be found in the section "On (Page 77)" mode.

### "Out of service"

General information about the "Out of service" operating mode can be found in the section "Out of service (Page 77)" mode.

## 4.1.3 PumpMon functional description

In the CFC, PumpMon is supplied with current process values via the inputs `Flow` (flow rate), `P_In` (inlet pressure, pump intake pressure), `P_Out` (pump outlet pressure), `PoElec` (active electrical power of motor), and `Temp` (temperature of pumped medium). The `Spd` input is also required for speed-controlled drives.

The binary input `Running` signals whether or not the motor is running. A time period can be parameterized via the `IdleTime` input. When the motor is switched on, all messages are blocked until this time has elapsed. The default value is 5 [sec]. This suppression time is not effective when `IdleTime = 0`.

## Preprocessing

The process values are standardized to SI units via the *Offs and *Fact inputs. The normalized values are output again at the output. The status signals of the process values (quality code) are not evaluated but are instead output again at the output.

- siFlow.Value = FlowOffs + Flowfact * Flow.Value
  (normalize to $m^3/s$)
- siP_In.Value = P_Atmos + P_InOffs + P_InFact * P_In.Value
  (normalize to bar)
- siP_Out.Value = P_Atmos + P_OutOffs + P_OutFact * P_Out.Value
  (normalize to bar)
- siPoElec.Value = PoElecOffs + PoElecFact * PoElec.Value
  (normalize to kW)
- siSpd.Value = SpdOffs + SpdFact * Spd.Value
  (normalize to rpm)
- siTemp.Value = TempOffs + TempFact * Temp.Value
  (normalize to °C)

When the temperature value is normalized, note that the generally-applicable factors and offsets for temperature conversion need to be adjusted.

The following rules apply:

- TempFact = 1 / default factor
- TempOffs = - default offset / default factor

| Input variable | Default factor | **TempFact** | Default offset | **TempOffs** |
|---|---|---|---|---|
| °F | 1.8 | 0.555556 | 32.0 | -17.777779 |
| K | 1.0 | 1.0 | 273.15 | -273.15 |

P_Atmos is the air pressure that must be added to the measured pressures P_In and P_Out as an offset if the measured values only determine the overpressure.

## Calculating the mechanical power

The block covers 3 variants:

- Calculation for standard motors (default setting)
  (Parameter assignment: PolyAct = FALSE, ConvAct = FALSE)
  In this case the user only has to specify the efficiency and the rated power of the motor. The mechanical power is then calculated from the electrical power in the block using a generally applicable motor model.
- Calculation for other motors, e.g. canned motor pumps
  (Parameter assignment: PolyAct = TRUE, ConvAct = FALSE)
  In this case a unique motor characteristic is required; it may be requested e.g. from the pump manufacturer. It is used to calculate the mechanical power from the electrical power via a 4th-degree polynomial:

```
siPoMech.Value = CorrMech * (PolyData.K0
                                    + PolyData.K1  * siPoElec.Value
                                    + PolyData.K2  * siPoElec.Value ²
                                    + PolyData.K3  * siPoElec.Value ³
                                    + PolyData.K4  * siPoElec.Value ⁴)
```

In this case, the `Eta` parameter is not taken into account. The coefficients `PolyData.K0` to `PolyData.K4` must be supplied by the manufacturer of the motor/pump.

- The mechanical power is taken from a converter (or other external source)
  (Parameter assignment: `PolyAct = FALSE, ConvAct = TRUE`)
  If a converter outputs the mechanical power, this value is read by PumpMon via the `PoMech` input and, if necessary, normalized with the `PoMechOffs` and `PoMechFact` parameters.

### Slip correction

For electric motors there is slip (speed difference between stator rotary field and rotor) which affects the speed and the mechanical power.

If the value supplied externally (e.g. by the converter) is already slip-corrected for the speed, the block must not perform a second correction. In this case the input must be set to `SlipCorr = FALSE`, otherwise `SlipCorr = TRUE`.

Slip correction can only be carried out for variable-speed motors (`ConstSpd = FALSE`), as no speed is measured. For this reason, the setting for constant-speed motors is reset.

### Calculating the delivery height

The delivery height is calculated from the pressure difference and density of the medium in the pump.

The calculated delivery height (`DelHi.Value)` is limited to values `>= 0`.

### Calculating the hydraulic power

The hydraulic power is calculated from the normalized flow rate, the delivery height, and the density of the medium.

The calculated power (`siPoHydr.Value)` is limited to values `>= 0`.

### Calculating the NPSH value

NPSH stands for **N**et **P**ositive **S**uction **H**ead. The NPSH value, along with the flow rate and delivery height, is one of the key characteristic values of a pump. To ensure that the pump operates smoothly, the following must apply:

*NPSH (plant) > NPSH (pump)*

otherwise cavitation will occur.

The current NPSH value of the plant (NPSHa) is calculated from the vapor pressure, which can be calculated using an Antoine equation (`Antoine = TRUE`).

*Vapor pressure = factor * 10 (A – B/(Temp + C))*

The default values for water in the 1-100°C range are:

- `AntA = 8.07131`
- `AntB = 1730.63`
- `AntC = 233.426`
- `AntFact = 0.0013332` as conversion factor from [mmHg] (Torr) to [bar]

The parameters for other media must be adapted accordingly. The Antoine values for most materials are provided in the technical literature or on the Internet. If the integrated Antoine vapor pressure calculation is not used (`Antoine = FALSE`), the input value `P_Vapor` [bar] is used. In this case the vapor pressure must be calculated externally to the block.

The calculated NPSH value (`Npsh.Value)` is limited to values `>= 0`.

## Calculating the Eta efficiency

The efficiency is calculated from the ratio of the hydraulic power to the mechanical power.

The calculated efficiency (`EtaOut.Value)` is limited to values `>= 0`.

## Characteristics

A total of four characteristics are saved in the block. These are the characteristics for the delivery height, power, efficiency, and NPSH value. The characteristics each have 15 support values, whereby the following applies:

| | | | | |
|---|---|---|---|---|
| • x scale: | 0 <= `Flow1` <= ... | <= | `Flow15` | < = `FlowMax` |
| • y scale (delivery height): | `DelHi1` ... `DelHi15` | <= | `DelHiMax` | |
| • y scale (power): | `Power1` ... `Power15` | <= | `PowerMax` | |
| • y scale (efficiency): | `Eta1` ... `Eta15` | <= | `EtaMax` | |
| • x scale (NPSH): | 0 <= `FlowNp1` <= ... | <= | `FlowNp15` | < = `FlowMax` |
| • y scale (NPSH): | `Npsh1` ... `Npsh15` | <= | `NpshMax` | |

The x scale support values do not have to be equidistant.

The NPSH characteristic has separate support values for the flow rate (`FlowNp1`, ..., `FlowNp15`) because the characteristic cannot be determined by means of the teach function.

The values of the standardized flow rate in $m^3/h$ are used as input values for the x scale of the characteristics. The output values of the characteristics are determined by means of linear interpolation. The characteristic is not extrapolated beyond the operating range. If the flow rate value is less than the first support value, the first y value is output. If the flow rate value is greater than the 15th support value, the 15th y value is output.

The binary signals `DelHiAct.Value`, `PowerAct.Value`, `EtaAct.Value` and `NpshAct.Value` are set if the deviations from the characteristics, a settable time period

(xxx_A_DC and xxx_A_DG), are outside the configurable tolerances (xxxTol). The duration of the limit value violation is determined in separate counters.

### Special feature of variable-speed motors

The input ConstSpd = "variable" (FALSE) must be set for variable-speed motors. In addition, a value must be specified for the rated speed SpdRate and the current speed must be read via the Spd input.

### Blockage and dry running

The electrical power varies (non-linear) with the motor load (i.e. the flow rate).

During dry running, the intake-side valve is closed, the flow rate of the pumped medium is zero, and the electrical power value is reduced to a minimum value (<= PoDryRun).

When a blockage is present, the discharge-side valve is closed, the flow rate of the pumped medium is again zero, and the electrical power value is <= PoBlk.

The value during a blockage is higher than during dry running because the pump still contains pumped media, which is being circulated.

**Note**

The limit values PoBlk and PoDryRun only apply to operation under rated conditions. With variable-speed drives, the effective limits depend on the current speed.

### Reduction in delivery height, gas conveyance, cavitation, and incorrect direction of rotation

- A **reduction in delivery height** can have various causes:
  - Gas conveyance
  - Initial cavitation
  - Draw-in turbulence
  - Damage to the pump (wear)
  - Wrong direction of rotation (roughly half the delivery height with high power consumption)

  The block cannot differentiate this state without further information, so the general "Reduction in delivery height" message is triggered.
- **Gas conveyance** may occur if:
  - the delivery height is reduced, but the NPSH value remains in OK range.

  In this case, however, there may also be a reduction in delivery height as a result of wear, so no specified "Gas conveyance" message is triggered.
  It is possible to differentiate between wear and Gas conveyance by using the time profile of the reduction in delivery height. Wear generally occurs slowly (over weeks or months), whereas gas conveyance typically occurs within a short period (seconds to minutes).

- **Cavitation** is diagnosed when:
  - the NPSH value falls below the NPSH characteristic.
- **Incorrect direction of rotation** is diagnosed when:
  - the delivery height deviates significantly (current value <60% of the characteristic value) and
  - the power deviates slightly (current value > 80% of the characteristic value).

  The motor was connected incorrectly and rotates in the wrong direction.

### Determining the running time of the pump in different loading ranges

The flow rate range `0...FlowMax` is divided into 10 equal sub-ranges. Each of these sub-ranges is assigned a counter for the duration of stay:

- `Load1` = 0-10% of `FlowMax`
- `Load2` = 10-20 % of `FlowMax`
- `Load3` = 20-30% of `FlowMax`
- `Load4` = 30-40% of `FlowMax`
- `Load5` = 40-50% of `FlowMax`
- `Load6` = 50-60% of `FlowMax`
- `Load7` = 60-70 % of `FlowMax`
- `Load8` = 70-80% of `FlowMax`
- `Load9` = 80-90 % of `FlowMax`
- `Load10` = 90-100% of `FlowMax`

An additional counter is used to determine downtime.

- `Load0` is equal to the duration of standstill (`NOT Running.Value` or `PoElec.Value = 0`)

The `LoadRstOp` input is used to reset the counters and the overall counter `LoadTime` to zero and restart them. The counters are also reset when `FlowMax` is changed.

The `LoadTime` counter is incremented with the sampling time and specifies the monitoring duration in [h]. The individual counters are incremented on the basis of the flow rate value. They specify the running time of the pump for the sub-ranges and downtime in %.

### Determining the histogram for deviations of the NPSH value from the characteristic

To clarify the deviation from the NPSH value, 10 sub-ranges are created. A counter for the load period is assigned to each sub-range. The following rules apply:

- `DevNpsh1` = deviation `DevNpsh < -1 m` [%]
- `DevNpsh2` = deviation `DevNpsh` between `-1` and `-0.5 m` [%]
- `DevNpsh3` = deviation `DevNpsh` between `-0.5` and `0 m` [%]
- `DevNpsh4` = deviation `DevNpsh` between `0` and `+0.5 m` [%]

- `DevNpsh5` = deviation `DevNpsh` between `+0.5` and `+1 m` [%]
- `DevNpsh6` = deviation `DevNpsh` between `+1` and `+1.5 m` [%]
- `DevNpsh7` = deviation `DevNpsh` between `+1.5` and `+2 m` [%]
- `DevNpsh8` = deviation `DevNpsh` between `+2` and `+2.5 m` [%]
- `DevNpsh9` = deviation `DevNpsh` between `+2.5` and `+3 m` [%]
- `DevNPSH10` = deviation `DevNpsh > +3 m` [%]

An additional counter is used to determine downtime.

- `DevNpsh0` is equal to the duration of standstill (`NOT Running.Value` or `PoElec.Value = 0`)

The `LoadRstOp` input is used to reset the counters and the overall counter `LoadTime` to zero and restart them. The counters are also reset when `FlowMax` is changed.

The parameter (`LoadTime`) is incremented with the sampling time and specifies the pump monitoring duration in [h]. The individual counters are incremented on the basis of the NPSH value. They specify the running time of the pump for the sub-ranges and the downtime as a % of the monitoring period.

The values are displayed in a histogram on the faceplate and indicate that cavitation has occurred and therefore potential reductions in the life of the pump and a potential need for maintenance.

## Teach function

The characteristics in the pump documentation should normally be used. If the documentation is not available or the current status of the pump is to be used as a reference, the individual pump operating points can also be approached manually and the value determined here for the flow rate, delivery height, power, and efficiency can be used as support values for the characteristic values. The teach function can be used here as a tool for entering the support values for the characteristics. The values calculated for the delivery height, power, and efficiency are used as support values in the characteristics. The values can then be corrected manually if required.

Messages are suppressed while the teach function (`Teach = TRUE`) is active.

**Note**

The above condition of increasing values for the flow rate
(0 <= `Flow1` <= ... <= `Flow15` <= `FlowMax`) must also be met in this case.

**Note**

The teach function should only be used under rated conditions.

**Note**

The NPSH characteristic cannot be determined via the teach function. (This would also not be useful, as the pump would be damaged.) The data on the pump data sheet must be used for this purpose.

### Status signals

Two additional status signals are used to signal the status of the pump:

- **Motor running:** `Run.Value` (`= Running.Value`) and `Status1.Bit11`
- **Motor ramping up:** `Status1.Bit25`
  (Motor is running, but `IdleTime` has not expired)

### Bypass

With a bypass, an additional duct is used to convey pumped media from the discharge side back to the intake side of the pump. This is used to protect the pump and ensure that it is not damaged unintentionally.

A flow rate measurement will be inaccurate because the flow rate through the bypass is not measured. In this case, a substitute value for the flow rate is determined on the basis of the mechanical power.

The flow rate value in the characteristic that equates to the mechanical power is used here.

This calculation is only useful in the case of constant-speed pumps and when the power characteristic climbs continuously (no ambiguity).

**Note**

When the flow rate is determined on the basis of the power characteristic, the power characteristic is no longer monitored.

## 4.1.4 PumpMon Functions

The functions for this block are listed below.

### Alarm delays with two time values per limit pair

This block has the standard function "Alarm delays with two time values per limit pair (Page 227)".

### Limit monitoring of power values

This block uses the standard function "Limit monitoring of the process value (Page 93)" to monitor the following values for limit violations:

- Electrical power
- Mechanical power
- Hydraulic power

You can monitor the process value for the following high and low alarm and warning limits:

- `PoxxxxAH_Lim`: Limit value for high alarm
- `PoxxxxAL_Lim`: Limit value for low alarm

- `PoxxxxWH_Lim`: Limit value for high warning
- `PoxxxxWL_Lim`: Limit value for low warning

**Note**

Overshooting or undershooting of these limit values is not reported by the block.

If these states should nonetheless be reported, you must create these messages yourself with the available alarm outputs (`PoxxxxAH_Act`, `PoxxxxWH_Act`, `PoxxxxWL_Act`, and `PoxxxxAL_Act`) and an additional alarm block.

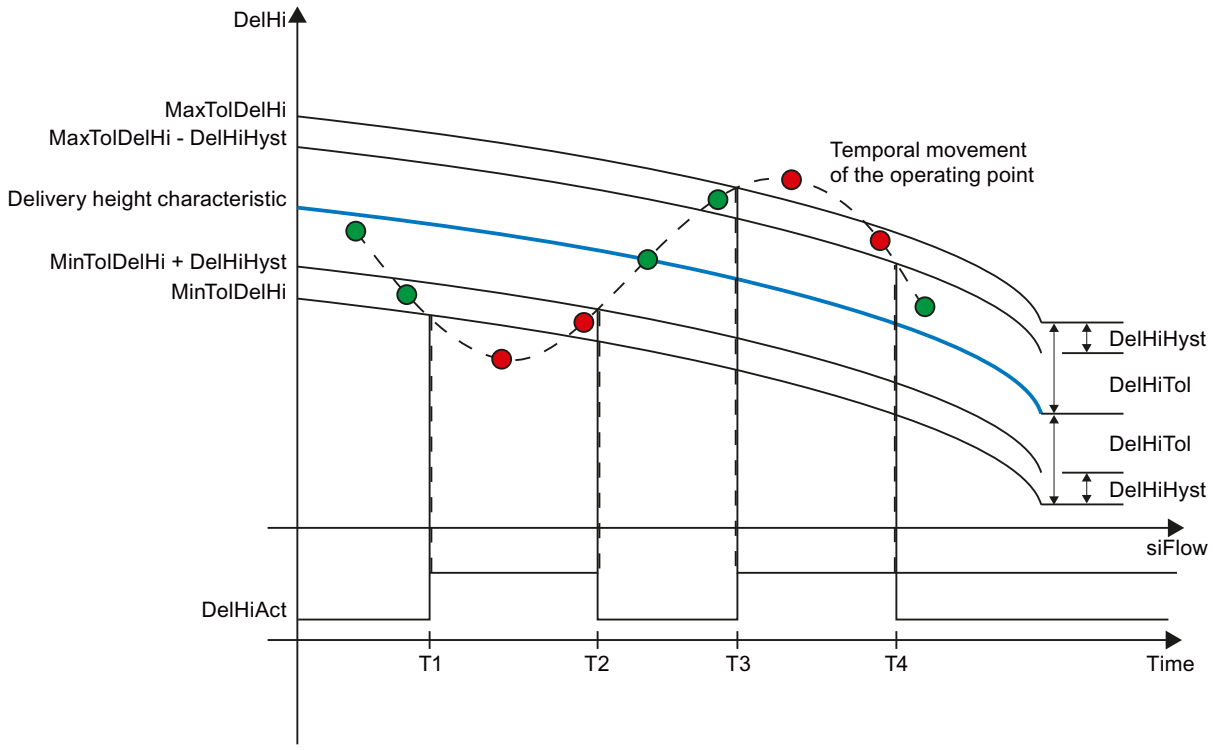
The electrical power is also monitored for the following limit values:

- Blockage
- Dry running

**Note**

Undershooting of these limit values is reported by the block.

### Tolerance monitoring of the characteristic curves



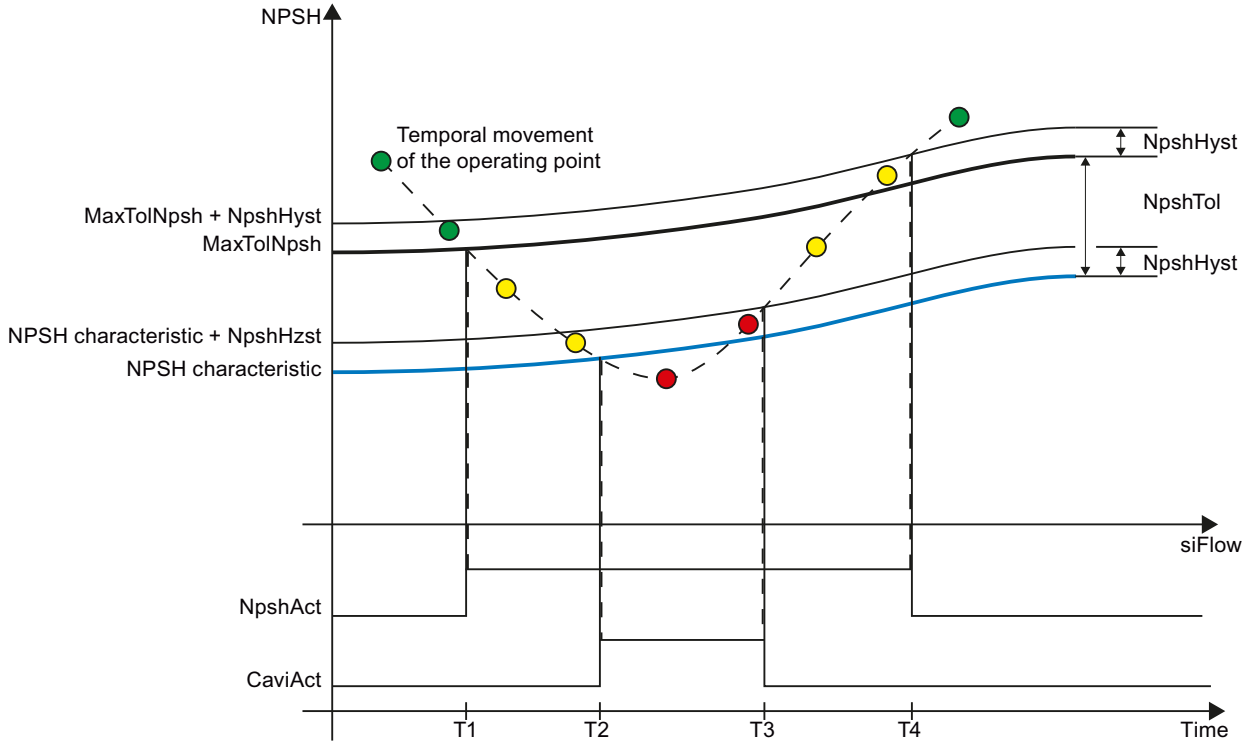
The block monitors the deviation of the applicable pump operating point from the relevant pump characteristic for settable tolerances.

The monitoring functionality is based on the standard "Limit monitoring of the process value (Page 93)" functionality.

The characteristic curve monitoring for

- Delivery height
- Performance
- Efficiency

Checks whether the operating point is within the tolerance range (see figure).



If the operating point leaves the tolerance range, the operating point in the faceplate changes its color from green to red and the corresponding message is triggered (`DelHiAct`, `PowerAct`, `EtaAct`).

Monitoring of the NPSH characteristic monitors the approach to the characteristic from above (see figure).

The following rules apply:

- If the operating point is in the tolerance range above the characteristic, the NPSH warning (`NpshAct`) is triggered and the operating point in the faceplate changes color from green to yellow.
- If the operating point is below the characteristic, the cavitation alarm (`CaviAct`) is triggered and the operating point in the faceplate changes color from yellow to red.

## Suppressing messages using the `MsgLock` parameter

This block has the standard function "Suppressing messages using the MsgLock parameter (Page 231)".

## Message suppression for speed-controlled pumps

In the case of speed-controlled pumps (`ConstSpd = FALSE`), the monitoring function for significant changes in speed for the time `IdleTime` in the block is suppressed. A significant change in speed in this case is a change of more than n% of one block pass to the next. n can be parameterized via the input parameter `DeltaSpd` (default = 5%).

**Note**

If in a specific application false alarms are still generated with this setting when the speed changes, the value can be reduced so that suppression applies even when the changes are smaller. However, it must be noted that the value must not be set too low, as otherwise statistical variations in the measured value or measurement noise would permanently suppress monitoring.

### Forming the signal status for blocks

This block has the standard function "Forming and outputting the signal status for technological blocks (Page 117)".

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `Flow.ST`
- `P_In.ST`
- `P_Out.ST`
- `PoElec.ST`
- `PoMech.ST`
- `Spd.ST`
- `Temp.ST`
- `DelHi.ST`
- `siPoHydr.ST`
- `EtaOut.ST`
- `Npsh.ST`

The following dependencies apply to the formation of the output-side signal status:

| Signal status | Dependencies |
|---|---|
| `siFlow.ST` | `Flow.ST` |
| `siP_In.ST` | `P_In.ST` |
| `siP_Out.ST` | `P_Out.ST` |
| `siSpd.ST` | `Spd.ST` |
| `siTemp.ST` | `Temp.ST` |
| `siPoElec.ST` | `PoElec.ST` |
| `siPoMech.ST` | • `PoElec.ST` (only when `ConvAct = FALSE`)<br>• `PoMech.ST` (only when `ConvAct = TRUE`)<br>• `Spd.ST` |
| `siPoHydr.ST` | • `Flow.ST`<br>• `P_In.ST`<br>• `P_Out.ST` |
| `DelHi.ST` | • `Flow.ST`<br>• `P_In.ST`<br>• `P_Out.ST`<br>• `Spd.ST` |
| `EtaOut.ST` | • `siPoMech.ST`<br>• `siPoHydr.ST` |
| `Npsh.ST` | • `Flow.ST`<br>• `P_In.ST`<br>• `Spd.ST`<br>• `Temp.ST` |

### Selecting a unit of measurement

This block provides the standard function "Selecting a unit of measure (Page 240)".

### Configurable reactions using the `Feature` parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in section "Configurable response using the Feature I/O (Page 139)". The following modes of behavior are available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Setting the startup characteristics |
| 1 | Characteristics for the out of service mode |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 22 | Update acknowledgment and error status of the alarm call |
| 26 | Behavior of the switching points in "Out of service" mode |
| 28 | Disabling of switching points |
| 29 | Signaling limit violation |

### Operator control permissions

This block provides the standard function "Operator control permissions (Page 285)".

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 – 5 | Not used |
| 6 | 1 = Operator can reset the histogram |
| 7 – 9 | Not used |
| 10 | 1 = Operator can change the value for the rated power |
| 11 | 1 = Operator can change the value for the efficiency |
| 12 | 1 = Operator can change the value for the on delay |
| 13 | 1 = Operator can switch between constant and variable speed |
| 14 | 1 = Operator can enable slip correction |
| 15 | 1 = Operator can change the value for the rated speed |
| 16 | 1 = Operator can change the value for the diameter at the intake stub |
| 17 | 1 = Operator can change the value for the diameter at the discharge stub |
| 18 | 1 = Operator can change the value for the minimum flow rate |
| 19 | 1 = Operator can change the value for the optimum flow rate |
| 20 | 1 = Operator can enable the bypass |
| 21 | 1 = Operator can enable the Antoine calculation |
| 22 | 1 = Operator can change the value for the density |

| Bit | Function |
|---|---|
| 23 | 1 = Operator can change the characteristic curve values for the flow |
| 24 | 1 = Operator can change the characteristic curve values for the delivery height |
| 25 | 1 = Operator can change the characteristic curve values for the power |
| 26 | 1 = Operator can change the characteristic curve values for the efficiency |
| 27 | 1 = Operator can change the characteristic curve values for the flow rate (NPSH) |
| 28 | 1 = Operator can change the characteristic curve values for the NPSH value |
| 29 | 1 = Operator can enable the teach function |
| 30 – 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (`siPoElec`) for the high alarm |
| 1 | 1 = Operator can change the limit (`siPoElec`) for the high warning |
| 2 | 1 = Operator can change the limit (`siPoElec`) for the hysteresis |
| 3 | 1 = Operator can change the limit (`siPoElec`) for the low warning |
| 4 | 1 = Operator can change the limit (`siPoElec`) for the low alarm |
| 5 | 1 = Operator can change the limit (`siPoMech`) for the high alarm |
| 6 | 1 = Operator can change the limit (`siPoMech`) for the high warning |
| 7 | 1 = Operator can change the limit (`siPoMech`) for the hysteresis |
| 8 | 1 = Operator can change the limit (`siPoMech`) for the low warning |
| 9 | 1 = Operator can change the limit (`siPoMech`) for the low alarm |
| 10 | 1 = Operator can change the limit (`siPoHydr`) for the high alarm |
| 11 | 1 = Operator can change the limit (`siPoHydr`) for the high warning |
| 12 | 1 = Operator can change the limit (`siPoHydr`) for the hysteresis |
| 13 | 1 = Operator can change the limit (`siPoHydr`) for the low warning |
| 14 | 1 = Operator can change the limit (`siPoHydr`) for the low alarm |
| 15 | 1 = Operator can change the limit for the deviation from the delivery height characteristic curve |
| 16 | 1 = Operator can change the limit for the deviation from the power characteristic curve |
| 17 | 1 = Operator can change the limit for the deviation from the efficiency characteristic curve |
| 18 | 1 = Operator can change the limit for the deviation from the NPSH characteristic curve |
| 19 | 1 = Operator can change the limit for the blockage alarm |
| 20 | 1 = Operator can change the limit for the dry running alarm |
| 21 – 31 | Not used |

## Opening additional faceplates

You can open the standard view of the motor block (e.g. MotL) interconnected to the `Running` input parameter from the standard view via a button. The interconnection makes the button in the standard view visible.

### SIMATIC BATCH functionality

This block has the standard function "SIMATIC BATCH functionality (Page 73)".

## 4.1.5 PumpMon error handling

The block overwrites the following parameters with 0 if they were configured with a negative value:

- `DelHi_A_DC, DelHi_A_DG`
- `Power_A_DC, Power_A_DG`
- `Eta_A_DC, Eta_A_DG`
- `Npsh_W_DC, Npsh_W_DG`
- `Cavi_A_DC, Cavi_A_DG`
- `Blk_A_DC, Blk_A_DG`
- `DryRun_A_DC, DryRun_A_DG`
- `PoElec_A_DC, PoElec_A_DG`
- `PoElec_W_DC, PoElec_W_DG`
- `PoMech_A_DC, PoMech_A_DG`
- `PoMech_W_DC, PoMech_W_DG`
- `PoHydr_A_DC, PoHydr_A_DG`
- `PoHydr_W_DC, PoHydr_W_DG`
- `DelHiHyst`
- `PowerHyst`
- `EtaHyst`
- `NpshHyst`
- `BlkHyst`
- `DryRunHyst`
- `PoElecHyst`
- `PoMechHyst`
- `PoHydrHyst`
- `IdleTime`

### Parameter error

The output parameter `ER_PARA` is set to TRUE for one block cycle if one of the following conditions is met:

- `SampleTime <= 0.001`
- `PolyAct = TRUE` and `ConvAct = TRUE`

### Overview of error numbers

The `ErrorNum` I/O can be used to output various error numbers:

| Error ID | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |

## 4.1.6 PumpMon messaging

### Message behavior

The block uses an Alarm_8P block to generate messages. Messages can be triggered in the following cases:

- Limit violation of the electrical power (`siPoElec.Value`), the mechanical power (`siPoMech.Value`) and the hydraulic power (`siPoHydr.Value`) (e.g. overload state on overshoot of the high limit values for the electrical power). Cause of overload may be, for example: Increase of the viscosity of the pumped medium, valve opening is too large on the discharge side or bearing failure. Consequences of overload may include, for example: Overheating of the motor, more rapid wear.
- Deviation of the operating point from the configured characteristic (delivery height, power, Eta, and NPSH).
- Cavitation, dry running, blockage, and false alarm

### Process messages

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | High alarm | $$BlockComment$$<br>Reduction in delivery height: Delivery height (@8%.3f@m) deviates from characteristic (siFlow.Value =@4%f@m3/s) |
| | SIG 2 | High alarm | $$BlockComment$$<br>Mechan. power (@6%.3f@kW) deviates from characteristic<br>(siFlow.Value =@4%f@m3/s) |
| | SIG 3 | Low warning | $$BlockComment$$<br>Low NPSH value (@9%.2f@m)<br>(siFlow.Value =@4%f@m3/s) |
| | SIG 4 | High alarm | $$BlockComment$$<br>Efficiency (@10%.2f@%) deviates from characteristic<br>(siFlow.Value =@4%f@m3/s) |
| | SIG 5 | Low alarm | $$BlockComment$$<br>Cavitation<br>(DelHi.Value =@8%.2f@m, Npsh.Value =@9%.2f@m, siFlow.Value =@4%f@m3/s) |
| | SIG 6 | High alarm | $$BlockComment$$<br>Incorrect direction of rotation<br>(siFlow.Value =@4%f@m3/s) |
| | SIG 7 | High alarm | $$BlockComment$$<br>Blockage<br>(siPoElec.Value =@5%.3f@kW, siPoMech.Value =@6%.3f@kW, siPoHydr.Value =@7%.3f@kW, siFlow.Value =@4%f@m3/s) |
| | SIG 8 | High alarm | $$BlockComment$$<br>Dry running<br>(siPoElec.Value =@5%.3f@kW, siPoMech.Value =@6%.3f@kW, siPoHydr.Value =@7%.3f@kW, siFlow.Value =@4%f@m3/s) |

Explanation:

$$BlockComment$$: Content of the instance-specific block comment

### Associated values for the message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `siFlow.Value` |
| 5 | `siPoElec.Value` |
| 6 | `siPoMech.Value` |
| 7 | `siPoHydr.Value` |
| 8 | `DelHi.Value` |
| 9 | `Npsh.Value` |
| 10 | `EtaOut.Value` |

## 4.1.7 PumpMon I/Os

### I/Os of PumpMon

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Accept` | 1 = Accept current values for teach function | BOOL | 0 |
| `AntA` | A value of the Antoine equation<br>For water from 1°C to 100°C `AntA = 8.07131` | REAL | 8.07131 |
| `AntB` | B value of the Antoine equation<br>For water from 1°C to 100°C `AntB = 1730.63` | REAL | 1730.63 |
| `AntC` | C value of the Antoine equation<br>For water from 1°C to 100°C `AntC = 233.426` | REAL | 233.426 |
| `AntFact` | Normalization factor of the vapor pressure in bar | REAL | 0.0013332 |
| `Antoine` | 1 = Antoine calculation is active | BOOL | 1 |
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |
| `Blk_A_DC*` | Delay time for incoming blockage warnings [s] | REAL | 5.0 |
| `Blk_A_DG*` | Delay time for outgoing blockage warnings [s] | REAL | 5.0 |
| `BlkEn` | 1 = Enable blockage alarm limit | BOOL | 1 |
| `BlkHyst*` | Hysteresis for blockage alarm limit [kW] | REAL | 10.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkMsgEn | 1 = Enable message for blockage alarm | BOOL | 1 |
| Bypass | 1 = Bypass calculation is active | BOOL | 0 |
| Cavi_A_DC* | Delay time for incoming cavitation warnings [s] | REAL | 5.0 |
| Cavi_A_DG* | Delay time for outgoing cavitation warnings [s] | REAL | 5.0 |
| CaviEn | 1 = Enable cavitation alarm limit | BOOL | 1 |
| CaviMsgEn | 1 = Enable message for cavitation alarm | BOOL | 1 |
| ConstSpd | 1 = Motor is running at constant speed | BOOL | 1 |
| ConvAct | 1= Mechanical power is passed to PoMech<br>Used to calculate the mechanical shaft power (see PumpMon Functions (Page 495)). | BOOL | 0 |
| DelHi_A_DC* | Delay time for incoming alarm in the event of deviation from the delivery height characteristic [s] | REAL | 5.0 |
| DelHi_A_DG* | Delay time for outgoing alarm in the event of deviation from the delivery height characteristic [s] | REAL | 5.0 |
| DelHi1 | y value 1, delivery height [m] | REAL | 0.0 |
| DelHi2 | y value 2, delivery height [m] | REAL | 0.0 |
| DelHi3 | y value 3, delivery height [m] | REAL | 126.0 |
| DelHi4 | y value 4, delivery height [m] | REAL | 126.0 |
| DelHi5 | y value 5, delivery height [m] | REAL | 125.5 |
| DelHi6 | y value 6, delivery height [m] | REAL | 124.5 |
| DelHi7 | y value 7, delivery height [m] | REAL | 123.0 |
| DelHi8 | y value 8, delivery height [m] | REAL | 121.0 |
| DelHi9 | y value 9, delivery height [m] | REAL | 118.0 |
| DelHi10 | y value 10, delivery height [m] | REAL | 114.0 |
| DelHi11 | y value 11, delivery height [m] | REAL | 109.0 |
| DelHi12 | y value 12, delivery height [m] | REAL | 103.0 |
| DelHi13 | y value 13, delivery height [m] | REAL | 96.0 |
| DelHi14 | y value 14, delivery height [m] | REAL | 88.0 |
| DelHi15 | y value 15, delivery height [m] | REAL | 79.0 |
| DelHiCorr | Delivery height correction factor | REAL | 1.0 |
| DelHiEn | 1 = Enable alarm limit for deviation from the delivery height characteristic | BOOL | 1 |
| DelHiHyst* | Hysteresis for alarm limit in the event of deviation from the delivery height characteristic [%] | REAL | 0.1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DelHiMax | Maximum delivery height value [m]<br>Used for the y axis of the delivery height characteristic | REAL | 140.0 |
| DelHiMsgEn | 1 = Enable message for alarm in the event of deviation from the delivery height characteristic | BOOL | 1 |
| DelHiTol | Tolerance for deviation from the delivery height characteristic [%] | REAL | 3.0 |
| DelHiUnit | Unit of measurement for the delivery height<br>(cannot be changed) | INT | 1010 |
| DeltaSpd | Speed change limit for message suppression in speed-controlled pumps [%]<br>In the event of a speed change of more than n% (n = DeltaSpd) from one block pass to the next, the monitoring functions are suppressed for the period IdleTime. | REAL | 5.0 |
| Density | Density of the pumped medium [kg/m³] | REAL | 1000.0 |
| DirEn | 1= Enable alarm limit for incorrect direction of rotation | BOOL | 1 |
| DirMsgEn | 1 = Enable message for alarm in the event of incorrect direction of rotation | BOOL | 1 |
| DryRun_A_DC* | Delay time for incoming dry running alarm [s] | REAL | 5.0 |
| DryRun_A_DG* | Delay time for outgoing dry run alarm [s] | REAL | 5.0 |
| DryRunEn | 1 = Enable dry running alarm limit | BOOL | 1 |
| DryRunHyst* | Hysteresis for dry running alarm limit [kW] | REAL | 10.0 |
| DryRunMsgEn | 1 = Enable message for dry running alarm | BOOL | 1 |
| EN | 1 = Called block is executed | BOOL | 1 |
| Eta | Efficiency of the motor (cos φ) [%] | REAL | 80.0 |
| Eta_A_DC* | Delay time for incoming alarm in the event of deviation from the efficiency characteristic [s] | REAL | 5.0 |
| Eta_A_DG* | Delay time for outgoing alarm in the event of deviation from the efficiency characteristic [s] | REAL | 5.0 |
| Eta1 | y value 1, efficiency [%] | REAL | 0.0 |
| Eta2 | y value 2, efficiency [%] | REAL | 0.0 |
| Eta3 | y value 3, efficiency [%] | REAL | 33.0 |
| Eta4 | y value 4, efficiency [%] | REAL | 41.0 |
| Eta5 | y value 5, efficiency [%] | REAL | 48.5 |
| Eta6 | y value 6, efficiency [%] | REAL | 54.5 |
| Eta7 | y value 7, efficiency [%] | REAL | 60.0 |
| Eta8 | y value 8, efficiency [%] | REAL | 64.5 |
| Eta9 | y value 9, efficiency [%] | REAL | 68.0 |
| Eta10 | y value 10, efficiency [%] | REAL | 70.5 |
| Eta11 | y value 11, efficiency [%] | REAL | 71.5 |
| Eta12 | y value 12, efficiency [%] | REAL | 71.5 |
| Eta13 | y value 13, efficiency [%] | REAL | 70.0 |
| Eta14 | y value 14, efficiency [%] | REAL | 67.0 |
| Eta15 | y value 15, efficiency [%] | REAL | 63.0 |
| EtaCorr | Efficiency correction factor | REAL | 1.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EtaEn | 1 = Enable message for alarm in the event of deviation from the efficiency characteristic | BOOL | 1 |
| EtaHyst* | Hysteresis for alarm limit in the event of deviation from the efficiency characteristic [%] | REAL | 0.1 |
| EtaMax | Maximum value of efficiency [%]<br>Used for the y axis of the efficiency characteristic | REAL | 100.0 |
| EtaMsgEn | 1 = Enable message for alarm in the event of deviation from the efficiency characteristic | BOOL | 1 |
| EtaTol | Tolerance for deviation from the efficiency characteristic [%] | REAL | 3.0 |
| EtaUnit | Unit of measurement for efficiency (cannot be changed) | INT | 1342 |
| Feature | I/O for additional functions (see PumpMon Functions (Page 495)) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |

| Npsh_W_DG* | Delay time for outgoing alarm in the event of deviation from the NPSH characteristic [s] | REAL | 5.0 |
| Npsh1 | y value 1, NPSH [m] | REAL | 0.00 |
| Npsh2 | y value 2, NPSH [m] | REAL | 0.00 |
| Npsh3 | y value 3, NPSH [m] | REAL | 0.95 |
| Npsh4 | y value 4, NPSH [m] | REAL | 1.00 |
| Npsh5 | y value 5, NPSH [m] | REAL | 1.07 |
| Npsh6 | y value 6, NPSH [m] | REAL | 1.17 |
| Npsh7 | y value 7, NPSH [m] | REAL | 1.29 |
| Npsh8 | y value 8, NPSH [m] | REAL | 1.44 |
| Npsh9 | y value 9, NPSH [m] | REAL | 1.62 |
| Npsh10 | y value 10, NPSH [m] | REAL | 1.83 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Npsh11 | y value 11, NPSH [m] | REAL | 2.07 |
| Npsh12 | y value 12, NPSH [m] | REAL | 2.34 |
| Npsh13 | y value 13, NPSH [m] | REAL | 2.64 |
| Npsh14 | y value 14, NPSH [m] | REAL | 2.96 |
| Npsh15 | y value 15, NPSH [m] | REAL | 3.30 |
| NpshCorr | NPSH correction factor | REAL | 1.0 |
| NpshEn | 1 = Enable message for alarm in the event of deviation from the NPSH characteristic | BOOL | 1 |
| NpshHyst* | Hysteresis for alarm limit in the event of deviation from the NPSH characteristic [m] | REAL | 0.1 |
| NpshMax | Maximum value of NPSH [m]<br>Used for the y axis of the NPSH characteristic | REAL | 3.5 |
| NpshMsgEn | 1 = Enable message for alarm in the event of deviation from the NPSH characteristic | BOOL | 1 |
| NpshTol | Tolerance for deviation from the NPSH characteristic [m] | REAL | 0.5 |
| NpshUnit | Unit of measurement for the NPSH value (cannot be changed) | INT | 1010 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator input | BOOL | 0 |
| OS_Perm | I/O for operator control permissions (see PumpMon Functions (Page 495)) | STRUCT<br>• Bit0: BOOL<br>• Bit10: BOOL<br>• Bit31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator control permissions (see PumpMon Functions (Page 495)) | STRUCT<br>• Bit0: BOOL<br>• Bit10: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| P_Atmos | Air pressure [bar] | REAL | 1.0 |
| P_In | Interconnectable process value of the intake pressure | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| P_InFact | Normalization factor of the intake pressure in bar | REAL | 1.0 |
| P_InOffs | Normalization offset of the intake pressure in bar | REAL | 0.0 |
| P_InUnit | Unit of measure for the input pressure | INT | 0 |
| P_Out | Interconnectable process value of the flow pressure | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| P_OutFact | Normalization factor of the flow pressure in bar | REAL | 1.0 |
| P_OutOffs | Normalization offset of the flow pressure in bar | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| P_OutUnit | Unit of measure for the flow pressure | INT | 0 |
| P_Vapor | Vapor pressure of the pumped medium [bar] | REAL | 0.0 |
| PoBlk | Limit alarm for the electrical power in the event of blockage [kW] | REAL | 200.0 |
| PoDryRun | Limit alarm for the electrical power in the event of dry running [kW] | REAL | 150.0 |
| PoElec | Interconnectable process value of the electrical power | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PoElec_A_DC* | Delay time for incoming electrical power alarms [s] | REAL | 5.0 |
| PoElec_A_DG* | Delay time for outgoing electrical power alarms [s] | REAL | 5.0 |
| PoElec_W_DC* | Delay time for incoming electrical power warnings [s] | REAL | 5.0 |
| PoElec_W_DG* | Delay time for outgoing electrical power warnings [s] | REAL | 5.0 |
| PoElecAH_En | 1 = Enable electrical power alarm limit (high) | BOOL | 1 |
| PoElecAH_Lim | Electrical power (high) alarm limit [kW] | REAL | 700.0 |
| PoElecAL_En | 1 = Enable electrical power alarm limit (low) | BOOL | 1 |
| PoElecAL_Lim | Electrical power (low) alarm limit [kW] | REAL | 210.0 |
| PoElecFact | Normalization factor of the electrical power in kW | REAL | 1.0 |
| PoElecHyst* | Hysteresis for the electrical power alarm and warning limits [kW] | REAL | 10.0 |
| PoElecOffs | Normalization offset of the electrical power in kW | REAL | 0.0 |
| PoElecUnit | Unit of measurement for electrical power | INT | 0 |
| PoElecWH_En | 1 = Enable electrical power warning limit (high) | BOOL | 1 |
| PoElecWH_Lim | Electrical power (high) warning limit | REAL | 650.0 |
| PoElecWL_En | 1 = Enable electrical power warning limit (low) | BOOL | 1 |
| PoElecWL_Lim | Electrical power (low) warning limit [kW] | REAL | 250.0 |
| PoHydr_A_DC* | Delay time for incoming hydraulic power alarms [s] | REAL | 5.0 |
| PoHydr_A_DG* | Delay time for outgoing hydraulic power alarms [s] | REAL | 5.0 |
| PoHydr_W_DC* | Delay time for incoming hydraulic power warnings [s] | REAL | 5.0 |
| PoHydr_W_DG* | Delay time for outgoing hydraulic power warnings [s] | REAL | 5.0 |
| PoHydrAH_En | 1 = Enable hydraulic power alarm limit (high) | BOOL | 1 |
| PoHydrAH_Lim | Hydraulic power (high) alarm limit [kW] | REAL | 500.0 |
| PoHydrAL_En | 1 = Enable hydraulic power alarm limit (low) | BOOL | 1 |
| PoHydrAL_Lim | Hydraulic power (low) alarm limit [kW] | REAL | 160.0 |
| PoHydrCorr | Hydraulic power correction factor | REAL | 1.0 |
| PoHydrHyst* | Hysteresis for the hydraulic power alarm and warning limits [kW] | REAL | 10.0 |
| PoHydrWH_En | 1 = Enable hydraulic power warning limit (high) | BOOL | 1 |
| PoHydrWH_Lim | Hydraulic power (high) warning limit [kW] | REAL | 450.0 |
| PoHydrWL_En | 1 = Enable hydraulic power warning limit (low) | BOOL | 1 |
| PoHydrWL_Lim | Hydraulic power (low) warning limit [kW] | REAL | 190.0 |
| PolePairs | Number of motor pole pairs for slip correction | REAL | 1.0 |
| PolyAct | 1 = Polynomial calculation active<br>Used to calculate the mechanical shaft power (see PumpMon Functions (Page 495)). | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PolyData | Polynomial coefficients<br>Used to calculate the mechanical shaft power (see PumpMon Functions (Page 495)). | STRUCT<br>• K0: REAL<br>• K1: REAL<br>• K2: REAL<br>• K3: REAL<br>• K4: REAL | -<br>• 0.0<br>• 0.0<br>• 0.0<br>• 0.0<br>• 0.0 |
| PoMech | Interconnectable process value of the mechanical power (e.g. from converter) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PoMech_A_DC* | Delay time for incoming mechanical power alarms [s] | REAL | 5.0 |
| PoMech_A_DG* | Delay time for outgoing mechanical power alarms [s] | REAL | 5.0 |
| PoMech_W_DC* | Delay time for incoming mechanical power warnings [s] | REAL | 5.0 |
| PoMech_W_DG* | Delay time for outgoing mechanical power warnings [s] | REAL | 5.0 |
| PoMechAH_En | 1 = Enable mechanical power alarm limit (high) | BOOL | 1 |
| PoMechAH_Lim | Mechanical power (high) alarm limit [kW] | REAL | 600.0 |
| PoMechAL_En | 1 = Enable mechanical power alarm limit (low) | BOOL | 1 |
| PoMechAL_Lim | Mechanical power (low) alarm limit [kW] | REAL | 180.0 |
| PoMechCorr | Mechanical power correction factor | REAL | 1.0 |
| PoMechFact | Mechanical power normalization factor in kW | REAL | 1.0 |
| PoMechHyst* | Hysteresis for the mechanical power alarm and warning limits [kW] | REAL | 10.0 |
| PoMechOffs | Normalization offset of mechanical power in kW | REAL | 0.0 |
| PoMechUnit | Unit of measurement for mechanical power | INT | 0 |
| PoMechWH_En | 1 = Enable mechanical power warning limit (high) | BOOL | 1 |
| PoMechWH_Lim | Mechanical power (high) warning limit [kW] | REAL | 550.0 |
| PoMechWL_En | 1 = Enable mechanical power warning limit (low) | BOOL | 1 |
| PoMechWL_Lim | Mechanical power (low) warning limit [kW] | REAL | 220.0 |
| PoRate | Rated power of the motor [kW] | REAL | 600.0 |
| PosTeach | Current position of the teach function | INT | 1 |
| Power_A_DC* | Delay time for incoming alarm in the event of deviation from the power characteristic [s] | REAL | 5.0 |
| Power_A_DG* | Delay time for outgoing alarm in the event of deviation from the power characteristic [s] | REAL | 5.0 |
| Power1 | y value 1, power [kW] | REAL | 0.0 |
| Power2 | y value 2, power [kW] | REAL | 0.0 |
| Power3 | y value 3, power [kW] | REAL | 318.0 |
| Power4 | y value 4, power [kW] | REAL | 339.0 |
| Power5 | y value 5, power [kW] | REAL | 360.0 |
| Power6 | y value 6, power [kW] | REAL | 380.0 |
| Power7 | y value 7, power [kW] | REAL | 399.0 |
| Power8 | y value 8, power [kW] | REAL | 417.0 |
| Power9 | y value 9, power [kW] | REAL | 434.0 |
| Power10 | y value 10, power [kW] | REAL | 450.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Power11 | y value 11, power [kW] | REAL | 465.0 |
| Power12 | y value 12, power [kW] | REAL | 480.0 |
| Power13 | y value 13, power [kW] | REAL | 495.0 |
| Power14 | y value 14, power [kW] | REAL | 509.0 |
| Power15 | y value 15, power [kW] | REAL | 522.0 |
| PowerEn | 1 = Enable message for alarm in the event of deviation from the power characteristic | BOOL | 1 |
| PowerHyst* | Hysteresis for alarm limit in the event of deviation from the power characteristic [%] | REAL | 0.1 |
| PowerMax | Maximum value of power [kW]<br>Used for the y axis of the power characteristic | REAL | 600.0 |
| PowerMsgEn | 1 = Enable message for alarm in the event of deviation from the power characteristic | BOOL | 1 |
| PowerOpScale | Limit for scale on the power bar graphs of the faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 750.0<br>• 0.0 |
| PowerTol | Tolerance for deviation from the power characteristic [%] | REAL | 3.0 |
| PresSocket | Discharge stub diameter [mm] | REAL | 300.0 |
| Running | 1 = Motor is running<br>The faceplate of the block interconnected at this block input can be called from the standard view | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| RunUpCyc | Number of cycles during startup, within these cycles messages are suppressed | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 1.0 |
| siFlowUnit | Unit of measurement for the normalized flow (cannot be changed) | INT | 1347 |
| siP_Unit | Unit of measurement for the normalized pressure (cannot be changed) | INT | 1137 |
| siPoUnit | Unit of measurement for the normalized power rating (cannot be changed) | INT | 1190 |
| siSpdUnit | Unit of measurement for the normalized speed (cannot be changed) | INT | 1083 |
| siTempUnit | Unit of measurement for the normalized temperature (cannot be changed) | INT | 1001 |
| SlipCorr* | 1 = Slip correction active | BOOL | 0 |
| Spd | Interconnectable process value for the speed | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SpdFact | Normalization factor of speed in rpm | REAL | 1.0 |
| SpdOffs | Normalization offset of speed in rpm | REAL | 0.0 |
| SpdRate | Rated speed [rpm] | REAL | 2900.0 |
| SpdUnit | Unit of measurement for the speed | INT | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| Teach | 1 = Teach function is active | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Temp` | Interconnectable process value for the temperature of the pumped medium | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `TempFact` | Normalization factor of the medium temperature in °C | REAL | 1.0 |
| `TempOffs` | Normalization offset of the medium temperature in °C | REAL | 0.0 |
| `TempUnit` | Unit of measurement for the temperature of the medium | INT | 0 |
| `TimeBase` | Time basis for the flow values of the characteristic (3600 = hour) [s]<br>The parameter cannot be changed. In the latest version, the characteristics can only be displayed with `TimeBase` = 3600 (equivalent to $m^3/h$). | REAL | 3600.0 |
| `UserStatus` | First freely assignable bits for use in OS | BYTE | 16#00 |
| `UserStatus2` | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `BlkAct` | 1 = Blockage alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `CaviAct` | 1 = Cavitation alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `DelHi` | Output delivery height [m] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `DelHiAct` | 1 = Deviation from the delivery height characteristic curve is too large<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `DevDelHi` | Deviation from the delivery height characteristic curve [m] | REAL | 0.0 |
| `DevEta` | Deviation from the efficiency characteristic curve [%] | REAL | 0.0 |
| `DevNpsh` | Deviation from the NPSH characteristic curve [m] | REAL | 0.0 |
| `DevNpsh0` | Downtime for NPSH histogram (`Not Running`) [%] | REAL | 0.0 |
| `DevNpsh1` | Running time of the NPSH value in the range < -1 m [%] | REAL | 0.0 |
| `DevNpsh2` | Running time of the NPSH value in the range -1 to -0.5 m [%] | REAL | 0.0 |
| `DevNpsh3` | Running time of the NPSH value in the range -0.5 to 0 m [%] | REAL | 0.0 |
| `DevNpsh4` | Running time of the NPSH value in the range 0 to 0.5 m [%] | REAL | 0.0 |
| `DevNpsh5` | Running time of the NPSH value in the range 0.5 to 1 m [%] | REAL | 0.0 |
| `DevNpsh6` | Running time of the NPSH value in the range 1 to 1.5 m [%] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DevNpsh7 | Running time of the NPSH value in the range 1.5 to 2 m [%] | REAL | 0.0 |
| DevNpsh8 | Running time of the NPSH value in the range 2 to 2.5 m [%] | REAL | 0.0 |
| DevNpsh9 | Running time of the NPSH value in the range 2.5 to 3 m [%] | REAL | 0.0 |
| DevNpsh10 | Running time of the NPSH value in the range > 3 m [%] | REAL | 0.0 |
| DevPower | Deviation from the power characteristic [kW] | REAL | 0.0 |
| DirAct | 1 = Alarm for incorrect direction of rotation active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DryRunAct | 1 = Dry running alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER_Para | 1 = Parameter error | BOOL | FALSE |
| ErrorNum | Output of the existing error number. For the error numbers that can be output by this block, see section PumpMon error handling (Page 502). | INT | -1 |
| EtaAct | 1 = Deviation from the efficiency characteristic is too large<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| EtaOut | Efficiency output [%] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Flow_h | Normalized flow rate for display in the faceplate [m³/h] | REAL | 0.0 |
| Load0 | Downtime for flow rate histogram (Not Running) [%] | REAL | 0.0 |
| Load1 | Running time of the pump in the range 0-10% FlowMax [%] | REAL | 0.0 |
| Load2 | Running time of the pump in the range 10-20% FlowMax [%] | REAL | 0.0 |
| Load3 | Running time of the pump in the range 20-30% FlowMax [%] | REAL | 0.0 |
| Load4 | Running time of the pump in the range 30-40% FlowMax [%] | REAL | 0.0 |
| Load5 | Running time of the pump in the range 40-50% FlowMax [%] | REAL | 0.0 |
| Load6 | Running time of the pump in the range 50-60% FlowMax [%] | REAL | 0.0 |
| Load7 | Running time of the pump in the range 60-70% FlowMax [%] | REAL | 0.0 |
| Load8 | Running time of the pump in the range 70-80% FlowMax [%] | REAL | 0.0 |
| Load9 | Running time of the pump in the range 80-90% FlowMax [%] | REAL | 0.0 |
| Load10 | Running time of the pump in the range 90-100% FlowMax [%] | REAL | 0.0 |
| LoadTime | Recording period of the histogram data [h] | REAL | 0.0 |
| MaxTolDelHi | Upper tolerance limit for deviation from the delivery height characteristic [m] | REAL | 0.0 |
| MaxTolEta | Upper tolerance limit for deviation from the efficiency characteristic [%] | REAL | 0.0 |
| MaxTolNpsh | Upper tolerance limit for approach to the NPSH characteristic [m] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MaxTolPower | Upper tolerance limit for deviation from the power characteristic [kW] | REAL | 0.0 |
| MinTolDelHi | Lower tolerance limit for deviation from the delivery height characteristic [m] | REAL | 0.0 |
| MinTolEta | Lower tolerance limit for deviation from the efficiency characteristic [%] | REAL | 0.0 |
| MinTolPower | Lower tolerance limit for deviation from the power characteristic [kW] | REAL | 0.0 |
| MsgAckn1 | Message acknowledgment status 1 (output STATUS of first ALARM_8P) | WORD | 0 |
| MsgErr1 | 1 = Message error 1 (output ERROR of first ALARM_8P) | BOOL | FALSE |
| MsgStat1 | Message status 1 (output ERROR of first ALARM_8P) | WORD | 16#00 |
| Npsh | NPSH value output [m] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| NpshAct | 1 = NPSH warning active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| PoElecAH_Act | 1 = Electrical power (high) alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoElecAL_Act | 1 = Electrical power (low) alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoElecWH_Act | 1 = Electrical power (high) warning active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoElecWL_Act | 1 = Electrical power (low) warning active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>Value: BOOL<br>ST: BYTE | -<br>0<br>16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PoHydrAH_Act | 1 = Hydraulic power (high) alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoHydrAL_Act | 1 = Hydraulic power (low) alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoHydrWH_Act | 1 = Hydraulic power (high) warning active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoHydrWL_Act | 1 = Hydraulic power (low) warning active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PoMechAH_Act | 1 = Mechanical power (high) alarm active<br>You can change the reaction for this parameter by setting Feature Bit 28 (disabling operating points) and Feature Bit 29 (signaling limit violation) accordingly (see section PumpMon Functions (Page 495)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

### 4.1.8 PumpMon block diagram

A block diagram is not provided for this block.

### 4.1.9 PumpMon additional information

#### Relationship between measuring variables and diagnosable problems

| | Flow | Pressure differential across the pump | Active electrical power | Pressure upstream of the pump | Temperature of pumped medium | Density | Vapor pressure equation |
|---|---|---|---|---|---|---|---|
| Blockage | (X) [1] | | X[4] | | | | |
| Dry running | (X) [1] | | X[4] | | | | |
| Gas conveyance | (X) [2] | X | | | | X[6] | |
| Cavitation | X | | | X | X[5] | | X[7] |
| Wear | X | (X) [3] | X | | | | |
| Overload | | | X | | | | |
| Low pump efficiency | X | X | X | | | | |

Annotations:

- [1] Not strictly necessary, but useful for additional plausibility checks.
- [2] For correction purposes when the diameters of the intake and discharge stubs are different.
- [3] More apparent in the flow characteristic than in the power characteristic.
- [4] Used to calculate the mechanical power (more significant than the electrical power).
- [5] Insofar as this is not constant.
- [6] Insofar as this is not constant; can be used as auxiliary value for flow rate measurement.
- [7] Implemented in the block for water with a temperature of up to 100°C (Antoine equation); to be supplied by adjusted Antoine coefficients or by external calculation for other media.

## Diagnostics logic

The block features the following diagnostic functions:

- **Generating process alarms to warn operating personnel in unfavorable operating conditions**
  The following messages can be generated by the block supplied:
  - Limit violation for the three power values (e.g. electrical overload)

    **Note**

    No messages are generated by the block for this purpose. The three power values are only monitored for the limits and a limit violation is provided for processing to the block as binary output.

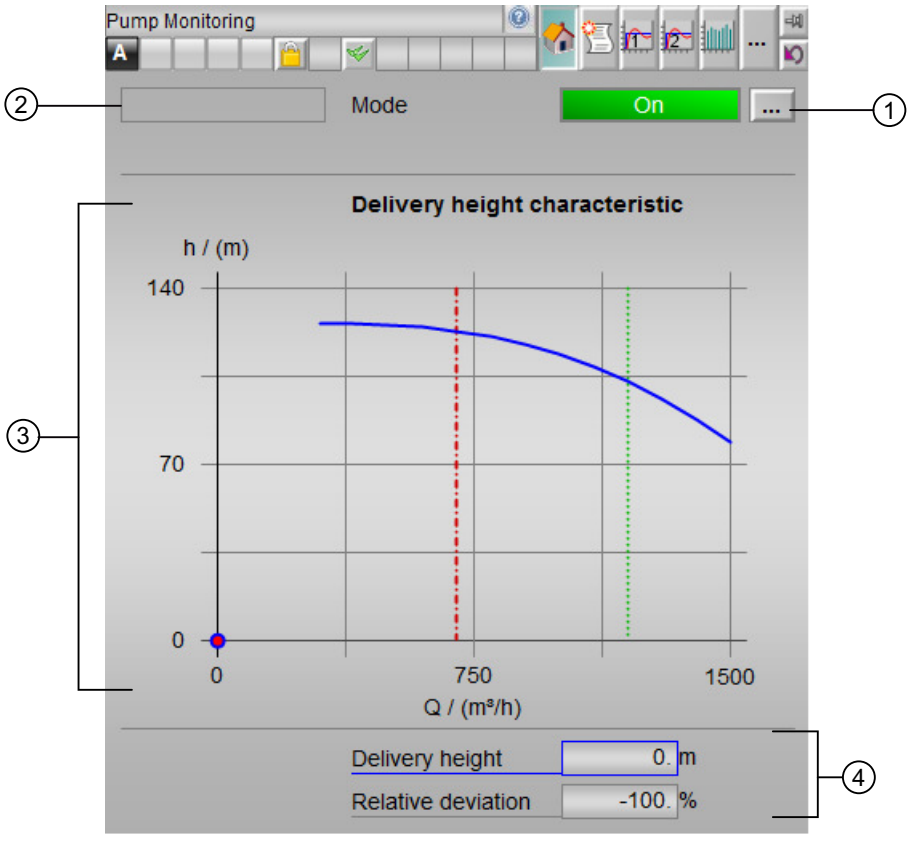
  - Deviation of the operating point from the delivery height characteristic (i.e. reduction in delivery height: indication of gas conveyance, cavitation, blockage, or dry running).
  - Deviation of the operating point from the power characteristic.
  - Low pump efficiency: determined by means of the deviation of the current pump efficiency (ratio of hydraulic power to mechanical power) from the efficiency characteristic.
  - Cavitation: determined by means of the calculated NPSHa value; early warning when an NPSH reserve is undershot vis-à-vis the NPSHr curve by x meters (default: x = 0.5m).
  - Gas conveyance: determined by means of the reduction in delivery height (> x% deviation from the flow characteristic; default: x = 3%) when cavitation is not present.
  - Blockage: determined on the basis of a limit value for the electrical power being undershot. Can also be detected when the flow rate value (if available) is (almost) zero.
  - Dry running: determined on the basis of a (second, lower) limit value for the electrical power being undershot. Can also be detected when the flow rate value (if available) is (almost) zero.
  - Wrong direction: (i.e. motor has been connected incorrectly and is rotating in the wrong direction): determined when the delivery height falls significantly (> 40%) but with only a slight deviation (< 20%) of the power characteristic.

  All limits are settable and all alarms can be suppressed.
- **Generating maintenance alarms to indicate advanced pump wear**
  This is not done directly from the block, but via a downstream AssetMon block (PCS 7 standard libraries). A range of different applications are possible here; a typical scenario would be as follows:
  Pump wear is indicated by a continuous reduction (over hours or days) in the delivery height (gas conveyance and cavitation can also have the same effect, although this should only be temporary). The "Deviation from flow characteristic" alarm could, therefore, be integrated chronologically by means of an operating hours counter (included in the standard scope of delivery of PCS 7) and a maintenance alarm ("Pump worn out?") triggered when a particular limit (e.g. three days) is reached.
  However, there is currently limited operating experience of how large a conformity error must be to indicate a pending pump failure.
  Another useful diagnostic alarm could be generated when a particular number of operating hours for the pump in cavitation is reached. For this purpose, a second operating hours counter would have to be started when NPSHa < NPSH characteristic. In this case, an alarm

("Pump damaged due to cavitation?") should be triggered after just a few hours in cavitation, although no generally-applicable guidelines have yet been defined for this.

- **Creating statistics (display of the pump's load profile) to analyze the suitability of the pump design**
  The distribution of flow values is displayed in the top diagram in the "Histogram view of PumpMon". Ideally, this distribution should reach its maximum close to the optimum operating point of the pump (vertical green line). It is generally presumed, however, that many pumps in the process industry are intentionally overdimensioned, although this means that energy is lost when the flow rate is controlled by means of throttle valves (which is the usual case). This diagram can help to choose a more suitable design when the pump is replaced – or to justify installing a converter (Siemens supplies an extensive range of converters).
  The distribution of the distances of the pump operating point from the NPSH curve (the "cavitation reserve") is displayed in the bottom diagram. Ideally, none of the values should fall below 0. If this continues to occur in the histogram, the data recorded in the control system can be analyzed to determine which (unexpected) boundary conditions have led to this. If needed, the operating time in cavitation can also be used for remaining life time calculations as operating experience increases.

## 4.1.10 Operator control and monitoring



### 4.1.10.1 Views of PumpMon

The PumpMon block provides the following views:

- PumpMon standard view (Page 522) (delivery height characteristic)
- Alarm View (Page 336)
- Efficiency and power characteristic (Page 524)
- NPSH characteristic (Page 525)
- Histogram (Page 526)
- Parameter view 1 (Page 529)
- Parameter view 2 (Page 531)
- Parameter view 3 (Page 534)
- Preview (Page 535)
- View of power limits (Page 537)
- View of characteristic tolerances (Page 538)
- Trend view (Page 341)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for PumpMon (Page 539)

For general information on the faceplate and block icon, refer to the sections "Structure of the faceplate (Page 279)" and "Block icon structure (Page 260)".

### 4.1.10.2 PumpMon standard view (delivery height characteristic)

**(1) Display and switchover of operating mode**
This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On
- Out of service

**(2) Display area for block states**
This area provides additional information on the operating state of the block:

- "Delay"
- "Teach"

**(3) Jump button for switching to the standard view of any faceplate**
This display is only visible when the corresponding `Running` block input is connected. Use this jump button to reach the standard view of the interconnected block.

(4) Displays the delivery height/delivery capacity characteristic (delivery height)
The interpolation points for the characteristic curve are entered in the "Characteristic parameters" view.

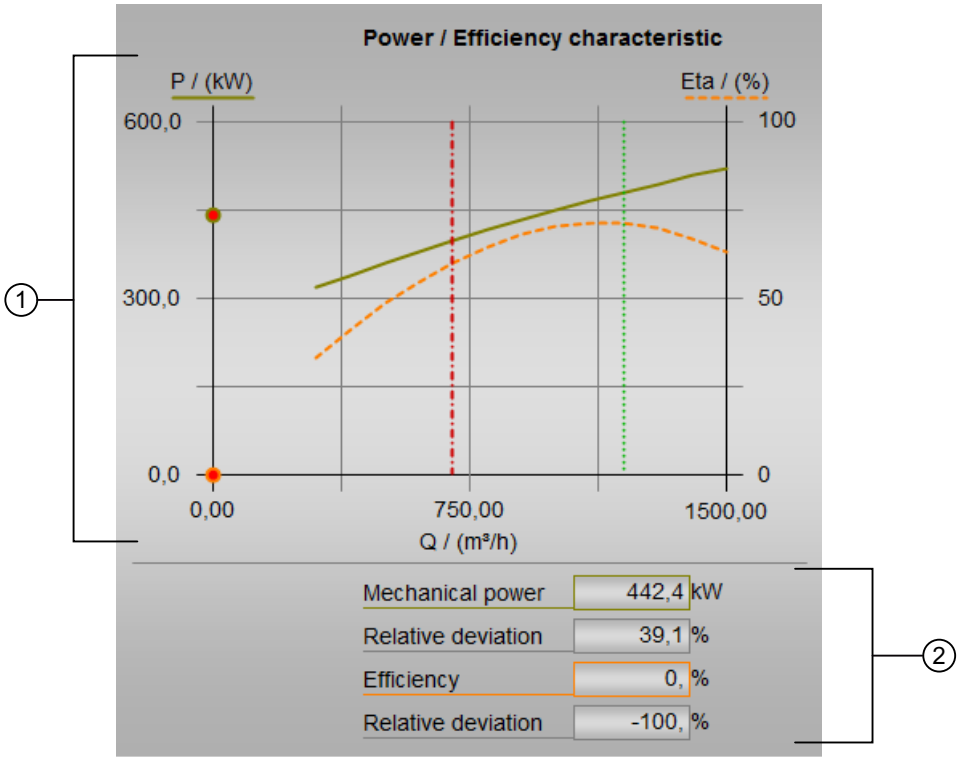
If the distance of the current operating point exceeds a predefined tolerance (`DelHiTol`), the color of the operating point changes from green to red and a corresponding alarm is triggered (`DelHiAct.Value`).

The red line indicates the minimum permissible flow rate (FlowMin), while the green line indicates the optimum flow rate (FlowOpt).

The red line is only shown when FlowMin is > 5% of FlowMax.

The scaling of the X and Y axis is dynamic

- Y: 0 -> DelHiMax / 2 -> DelHiMax
- X: 0-> FlowMax / 2 -> FlowMax



For ergonomic reasons as well as to optimize the computing time and refresh speed when the speed of variable-speed pumps changes (ConstSpd = 0), the characteristic is not re-calculated but, instead, the influence of the speed change is factored into the positions of the operating points. This occurs in accordance with the following dependencies:

```
siFlow_new(i)   = siFlow.Value(i)   * siSpd.Value  /  SpdRate
DelHi_new(i)    = DelHi.Value(i)    * (siSpd.Valu  /  SpdRate)2
                                      e
NPSH_new(i)     = Npsh.Value(i)     * (siSpd.Valu  /  SpdRate)2
                                      e
Power_new(i)    = Power.Value(i)    * (siSpd.Valu  /  SpdRate)3
                                      e
```

This re-scaling does not affect the original characteristic. However, the x and y axis scales would have to be permanently adjusted, which would lead to high load on the system and poor readability. The axis labels are therefore hidden instead. The positions of the lines for minimum ((FlowMin) and optimum (FlowOpt) flow rate are adjusted.

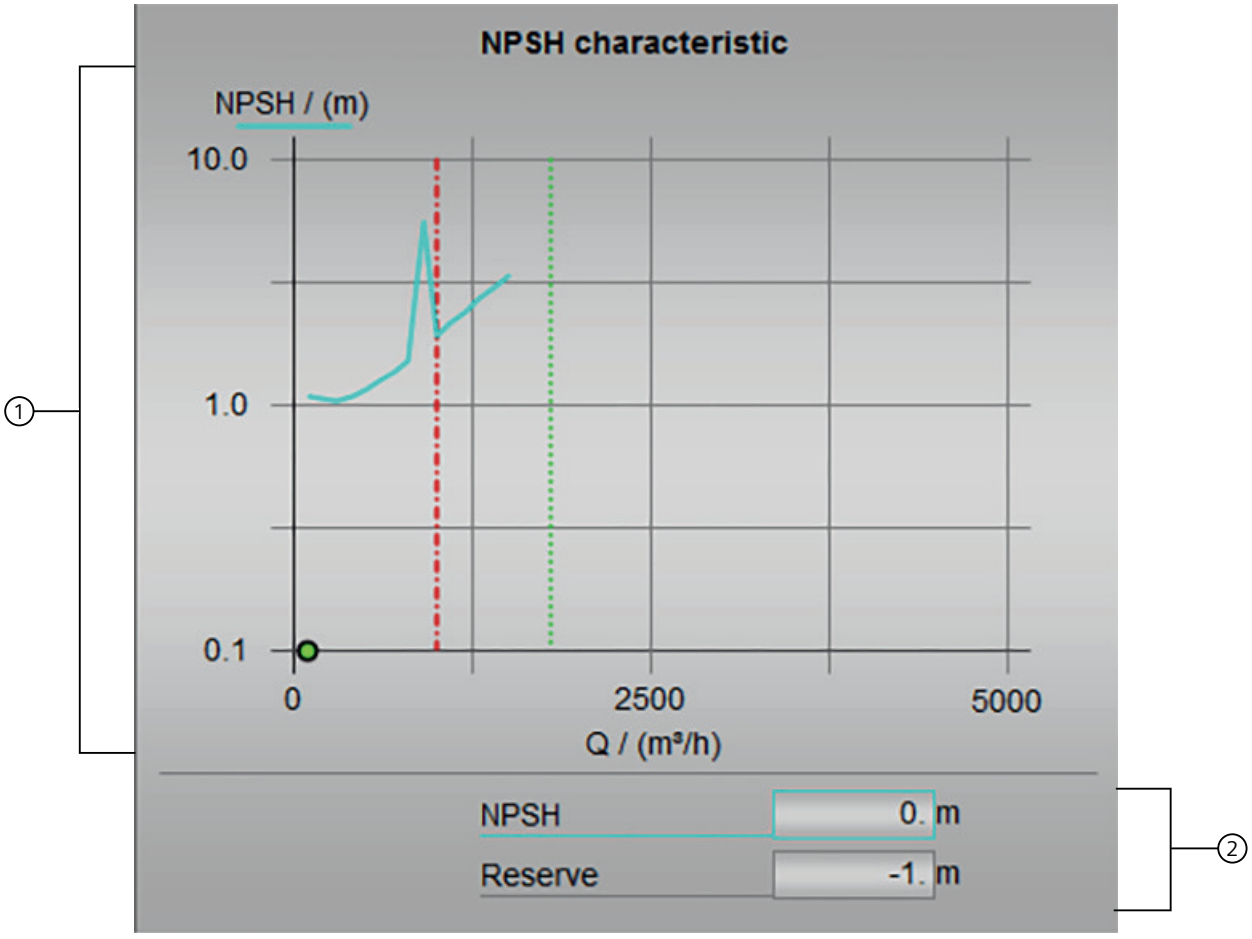
**(5) Display of the characteristic values**
This area shows the currently calculated delivery height (DelHi.Value) and the relative deviation (RelDelHi) from the characteristic. The values cannot be operated.

### 4.1.10.3 PumpMon efficiency and power characteristic view

**(1) Displays the power and efficiency characteristic with operating points**
This view contains the characteristics for power and efficiency.

Again, the color of the operating points changes to red when the distance between the operating point and the characteristic exceeds a predefined tolerance (`PowerTol` and `EtaTol`). An alarm is also triggered (`PowerAct.Value` and `EtaAct.Value`).

The scaling of the X and Y axes is dynamic:



- **Y Power:** `0 -> PowerMax / 2 -> PowerMax`
- **Y Eta:** `0 -> EtaMax / 2 -> EtaMax`
- **X:** `0 -> FlowMax / 2 -> FlowMax`

The axis scale is displayed as per the behavior described above, dependent on the `ConstSpd` input parameter.

For more information. refer:Bar graph (Page 376)

**(2) Display of the characteristic values**
This area shows the currently calculated values for the mechanical power (`siPoMech.Value`), the efficiency (`EtaOut.Value`) and the relative deviations from the characteristics (`RelPower`) and (`RelEta`). The values cannot be operated.

### 4.1.10.4 PumpMon NPSH characteristic view

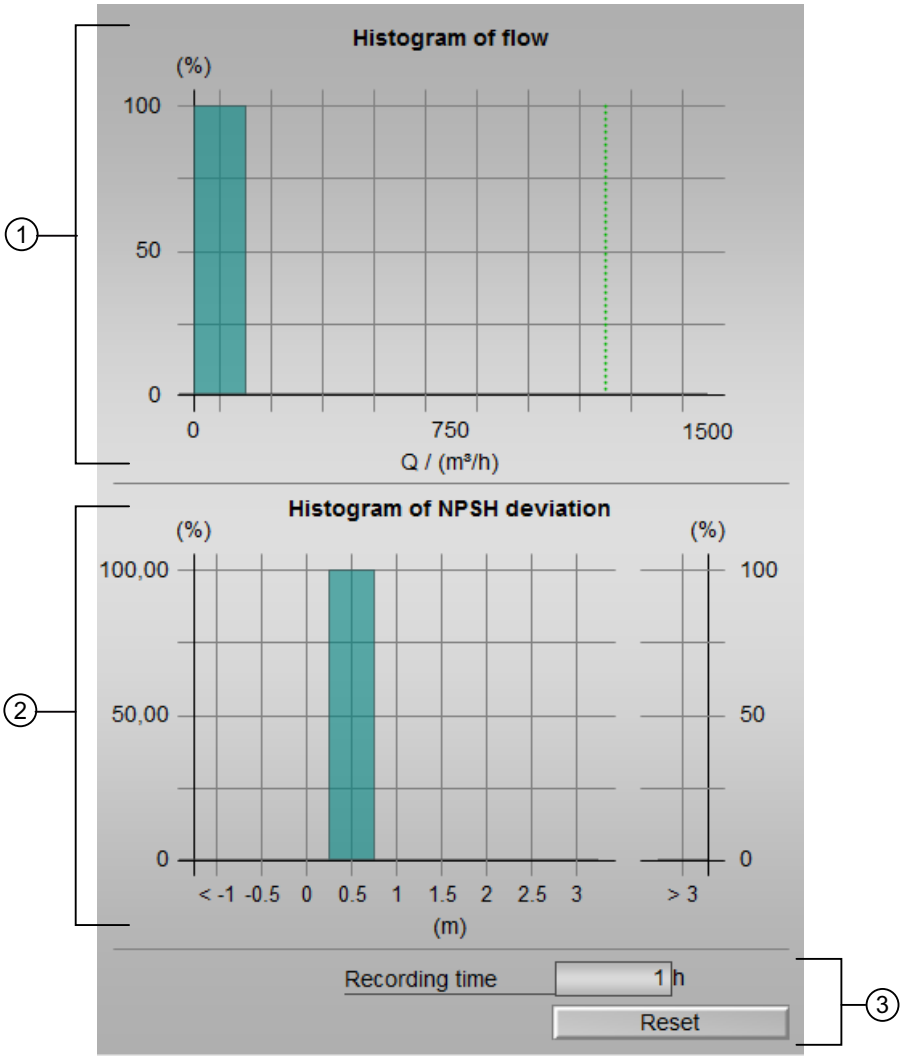
**(1) Display of the NPSH characteristic with operating point**
The NPSH value is displayed semi-logarithmically. The unit of measurement is [m]. A warning (`NpshAct.Value`) is triggered in this case when the operating point of the characteristic approaches a programmable value (`NpshTol` default = `+0.5 m`) from above. The operating point then changes color from green to yellow.

If the operating point falls below the characteristic, an alarm (`CaviAct.Value`) is triggered. The operating point changes color from yellow to red.

The minimum (`FlowMin`) and optimum (`FlowOpt`) flow rate is indicated in the same way as in the other characteristics.

The scaling of the X and Y axes is dynamic:

- **Y:**`0.1 -> Exp((Log(NpshMax)+Log(0.1)) / 2) -> NpshMax`
- **X:** `0 -> FlowMax / 2 -> FlowMax`



The axis scale is displayed as per the behavior described above, dependent on the `ConstSpd` input parameter.

For more information, refer:Bar graph (Page 376)

**(2) Display of the characteristic values**
This area shows the current NPSH value (`Npsh.Value`) and the relative deviation (`RelNpsh`) from the characteristic. The values cannot be operated.

### 4.1.10.5 PumpMon histogram view

These histograms are used to evaluate the "load profile" to which the corresponding pump has been exposed.

**(1) Flow rate histogram**
The histogram consists of a total of 11 bars. The first bar on the left (purple) indicates the idle times (`Load0`). The other 10 bars (cyan) divide the flow rate range from 0 to `FlowMax` into 10 equal sub-ranges. Each of these sub-ranges is assigned a counter for the duration of stay. The following rules apply:

- `Load1` = 0-10% of `FlowMax`
- `Load2` = 10-20% of `FlowMax`

- Load3 = 20-30% of FlowMax
- Load4 = 30-40% of FlowMax
- Load5 = 40-50% of FlowMax
- Load6 = 50-60% of FlowMax
- Load7 = 60-70% of FlowMax
- Load8 = 70-80% of FlowMax
- Load9 = 80-90% of FlowMax
- Load10 = 90-100% of FlowMax

The green line indicates the optimum flow rate (FlowOpt).

The scaling of the X and Y axes is dynamic:

- **Y:** 0 -> 50 -> 100%
- **X:** 0 -> FlowMax / 2 -> FlowMax

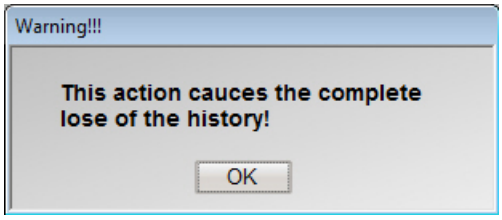
**(2) Histogram for deviation from the NPSH value**

To clarify the deviation from the NPSH value, 10 sub-ranges are created. A counter for the load period is assigned to each sub-range. The following rules apply:

- DevNpsh1 = deviation DevNpsh < -1 [m]
- DevNpsh2 = deviation DevNpsh between -1 and -0.5 [m]
- DevNpsh3 = deviation DevNpsh between -0.5 and 0 [m]
- DevNpsh4 = deviation DevNpsh between 0 and +0.5 [m]
- DevNpsh5 = deviation DevNpsh between +0.5 and +1 [m]
- DevNpsh6 = deviation DevNpsh between +1 and +1.5 [m]
- DevNpsh7 = deviation DevNpsh between +1.5 and +2 [m]
- DevNpsh8 = deviation DevNpsh between +2 and +2.5 [m]
- DevNpsh9 = deviation DevNpsh between +2.5 and +3 [m]
- DevNpsh10 = deviation DevNpsh > + 3 [m]

An additional counter is used to determine downtime (DevNpsh0).

In contrast to the flow rate histogram, this histogram is divided into two bar charts. The counters 0 to 9 (DevNpsh0...DevNpsh9) are shown in the chart on the left, while the tenth counter (DevNpsh10) is shown in the chart on the right. The chart is divided into two because, under normal circumstances, the deviation from the NPSH characteristic at 99% is in the range "> 3m". The other counters would then be too small to appear on the chart. For this reason, the maximum value of the Y axis on the chart on the left is derived from the difference of the tenth counter (DevNpsh10) at 100%.



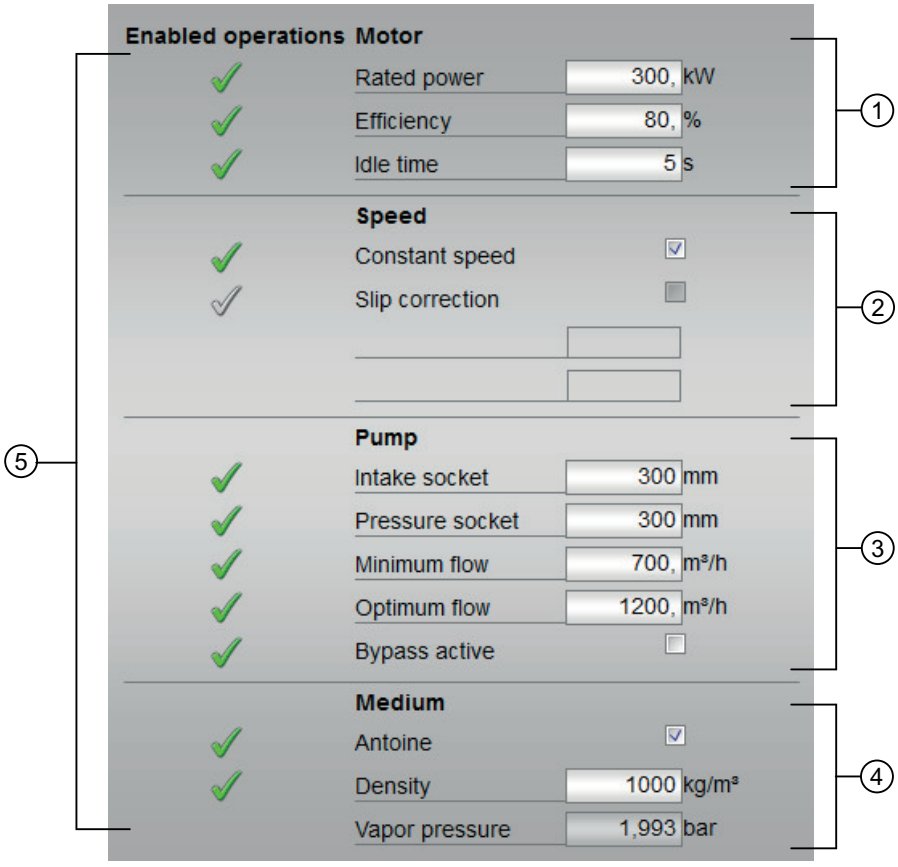
When DevNpsh10 = 99%, therefore, the Y axis on the left is shown with a maximum value of 1% and the values of the other counters, which together comprise 1% of the total recording time, can be displayed and analyzed.

The Y axis scaling is dynamic:

- **Y0-9:** `0 -> (100% - DevNpsh10) / 2 -> 100% - DevNpsh10`
- **Y10:** `0 -> 50 -> 100%`

For more information, refer:Bar graph (Page 376)

**(3) Display of the characteristic values**
The "Recording duration" field displays the time period in (`LoadTime`) over which these statistics were collected. The reset button can be used to reset all the stored values to zero and restart. The following message is displayed prior to this:



All collected statistics will be lost with this action!

**Note**

When the upper limit of the flow rate range (FlowMax) is changed, the counters are also reset.

### 4.1.10.6 PumpMon parameter view

**(1) Motor parameters**

You can change the following parameters here:

- "Rated power": Rated power (`PoRate`)
- "Efficiency": Efficiency (`Eta`)
- "Idle time": Message suppression running period (`IdleTime`)

**Note**

If one of the parameters for "Converter active" (`ConvAct`) or "Characteristic active" (`PolyAct`) has been set on the block (ES), the field to enter the efficiency is not visible.

**(2) Speed parameters**

The following functions may be enabled here:

- "Constant speed": Motor with variable or constant speed (`ConstSpd`)
- "Slip correction": Slip correction (`SlipCorr`)

You can also change the following parameter:

- "Rated speed": Rated speed (`SpdRate`)

The following parameter is only displayed and cannot be changed:

- "Speed": Actual speed (`siSpd.Value`)

**Note**

If the pump is a constant speed pump, the rated speed, the actual speed, and slip correction are not needed. In this case, the control permission for the slip correction checkbox is revoked and the rated and actual speeds are hidden.

**(3) Pump parameters**
You can change the following parameters here:

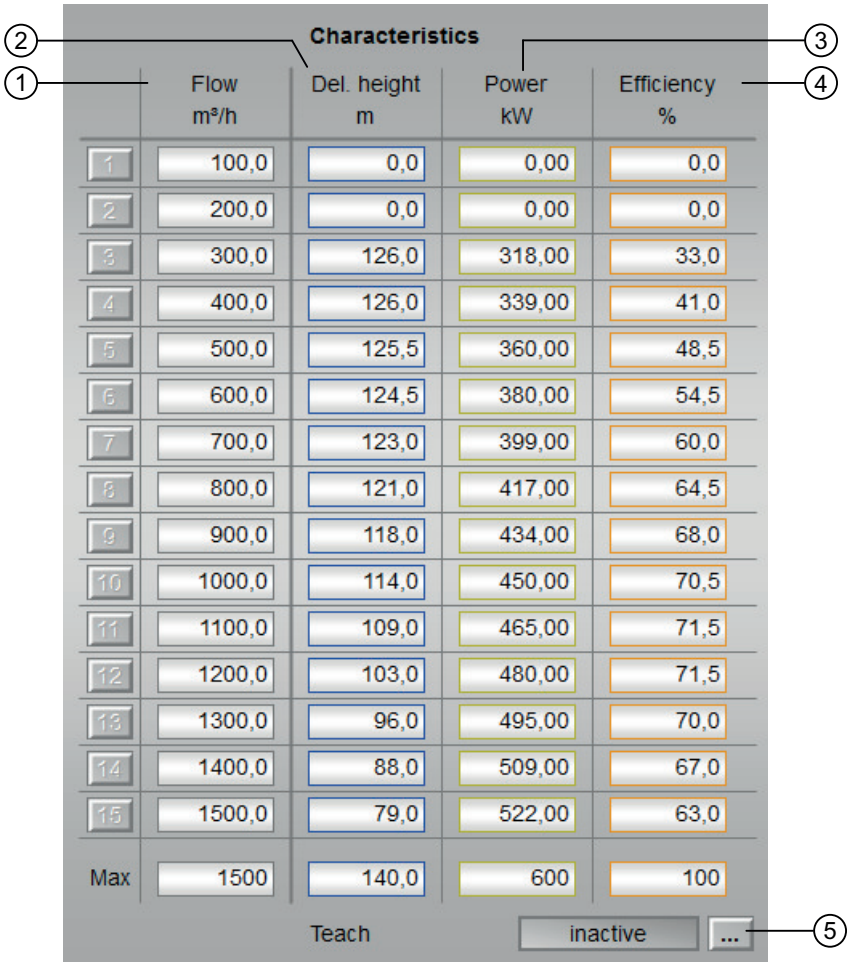
- "Intake socket": Diameter of the intake stub (`InSocket`)
- "Pressure socket": Diameter of the discharge stub (`PresSocket`)
- "Minimum flow": Minimum flow rate (`FlowMin`)
- "Optimum flow": Optimum flow rate (`FlowOpt`)

The following functions can also be enabled:

- "Bypass active": Enable bypass calculation (`Bypass`)

**(4) Medium parameters**
For a wide range of different media, the vapor pressure (`siP_Vapor`) can be calculated as a function of the temperature in accordance with the Antoine equations. The parameters for water at 1-100°C are set as default.

The delivery height (`Density`) of the medium is also required to calculate the delivery height from the measured pressure values.



If this equation is not to be used, it can be disabled by unchecking the checkbox (`Antoine`). The vapor pressure is then supplied via the block input `P_Vapor`. The input can be interconnected and so cannot be used via the faceplate.

**(5) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### 4.1.10.7 PumpMon characteristic parameter view 1

The support values for the characteristic must either be taken from the data sheet for the pump and entered here, or taught by means of the teach function (see below). The former scenario provides a direct comparison with the theoretical optimum pump behavior. The latter scenario, however, can also be used to record the "ideal status" under non-ideal circumstances (e.g. pressure measurement not taken directly at the pump outlet, etc.) to obtain a reference for subsequent deviations.

**(1) Flow rate parameters**
The 15 flow rate support values each specify the x axis for the delivery height, power, and efficiency characteristics.

The display is within the range:

```
0 <= Flow1 <= ... <= Flow15 <= FlowMax
```

Support values at the beginning or end of the characteristic with the value "zero" are not shown.

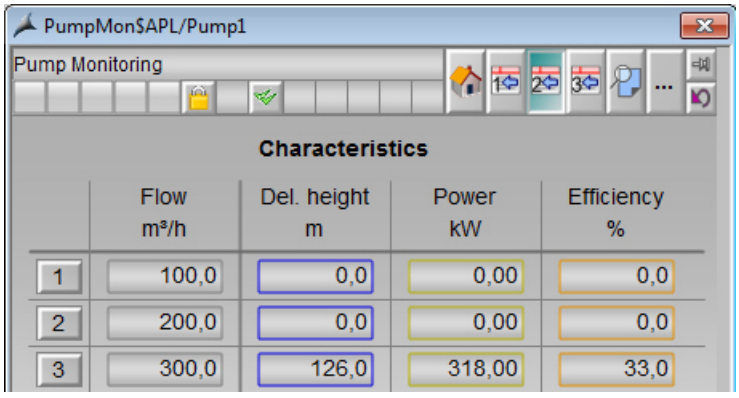
The values for the flow rate always have the unit [m³/h].

**Note**

When `FlowMax` is changed, the values saved in the histograms are lost. The same warning message is shown as when resetting the histograms.

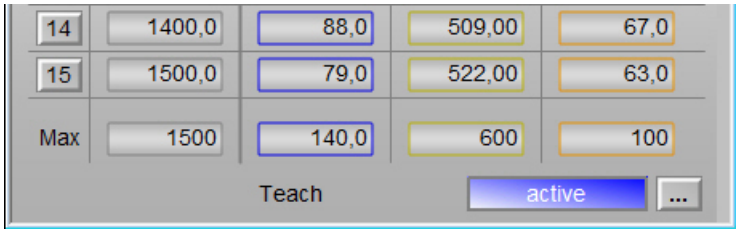
**(2) Delivery height parameters**
The parameters `DelHi1` to `Delhi15` for the delivery height characteristic can be entered in this area. Parameters that have the value 0 (see parameter 1) are ignored in the characteristic curve.

The values for the delivery height always have the unit [m].



**(3) Power parameters**
The parameters `Power1` to `Power15` for the power characteristic are entered in this area. Parameters that have the value 0 are ignored on the characteristic curve.

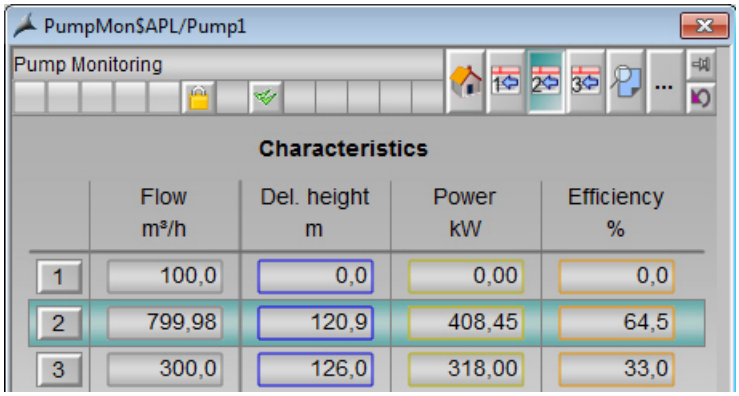
The values for the power always have the unit [kW].



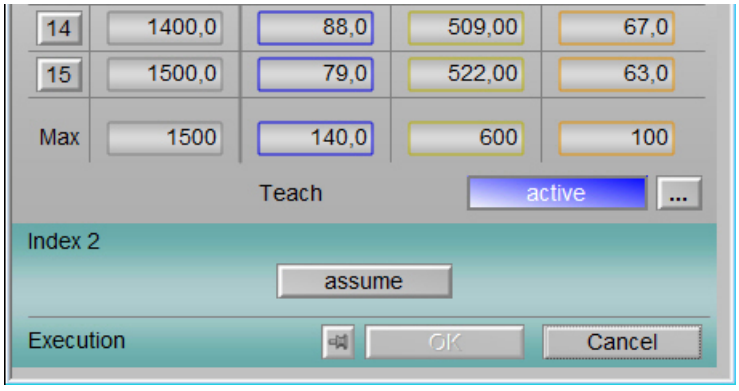
**(4) Efficiency parameters**
The parameters `Eta1` to `Eta15` for the efficiency characteristic are entered in this area. Parameters that have the value 0 are ignored on the characteristic curve.

The values for the efficiency always have the unit [%].

**(5) Teach function**
The teach function is used to apply the characteristic values calculated from the current process values for an operating point as support values. The operating point must be approached for this purpose and it is necessary to wait until the values are steady.

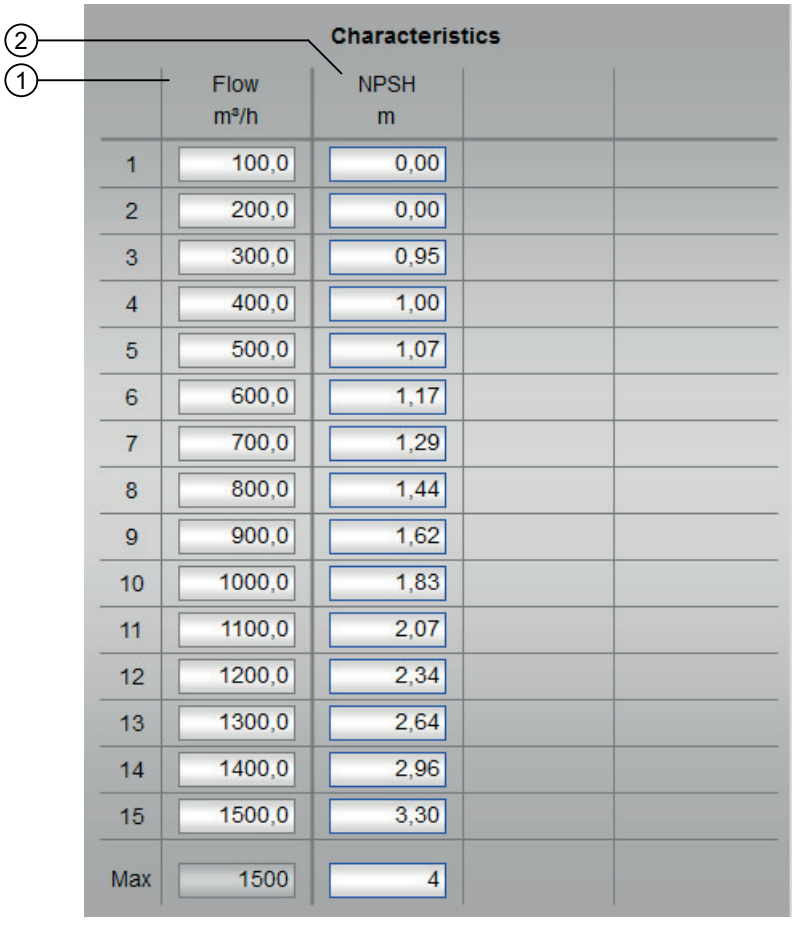


...



After enabling the "Teach" button, the operator control permissions for all characteristic parameters are revoked and the numbered buttons at the start of the parameter line are enabled.

Clicking on one of these buttons extends the "SelectionBorder" used to display the currently operated element to the entire line. Otherwise, the save parameters are no longer shown – only the parameters currently calculated by the block. The visible values are applied via binary acknowledgment.



...

**Note**

There is no undo function. Incorrect entires must be corrected individually and "by hand".

### 4.1.10.8 PumpMon characteristic parameter view 2

The NPSH characteristic cannot be configured by means of the teach function, which is why it is assigned separate support values for the flow rate.

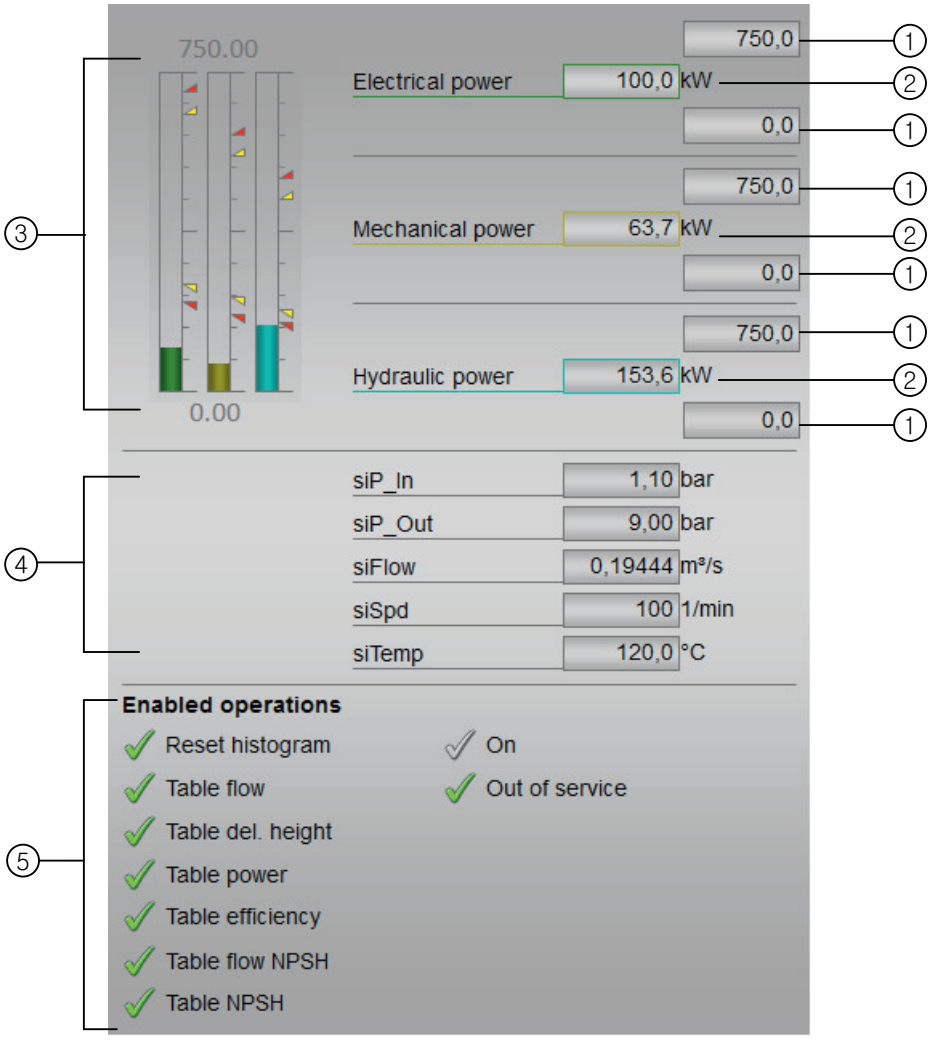
**(1) Flow rate parameters**
The 15 support values for the flow rate define the x axis for the NPSH characteristic.

The display is within the range:

```
0 <= FlowNp1 <= ... <= FlowNp15 <= FlowMax
```

Support values at the beginning or end of the characteristic with the value "zero" are not shown. The values for the flow rate always have the unit [m³/h].

**Note**



The value for the maximum flow rate (`FlowMax`) is only displayed in this view. This is the same value as the value for the other three characteristics from the "Characteristic parameter view 1 of PumpMon" view. Any change to the value must be made in that view.

**(2) NPSH parameters**

The parameters `Npsh1` to `Npsh15` for the NPSH characteristic and the maximum value `NpshMax` are entered in this area. Parameters that have the value 0 are ignored in the characteristic curve.

The NPSH values always have the unit [m].

### 4.1.10.9 Preview of PumpMon

**Note**

The "Preview" label has been chosen for reasons of compatibility with other blocks of the Advanced Process Library. The displayed process values are the **current** process values. The "Preview" refers to the enabled operations.

**(1) Upper and lower scale range of the power values**
These values provide information about the display range for the bar graph of the power values. The scale range is specified in the engineering system (`PowerOpScale`).

**(2) Display of the power values including signal status**
This area shows you the current power values with the associated signal status:

- Electrical power (`siPoElec.Value`)
- Mechanical power (`siPoMech.Value`)
- Hydraulic power (`siPoHydr.Value`)

**(3) Bar graph for the power values**
This area shows you the current power values in form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

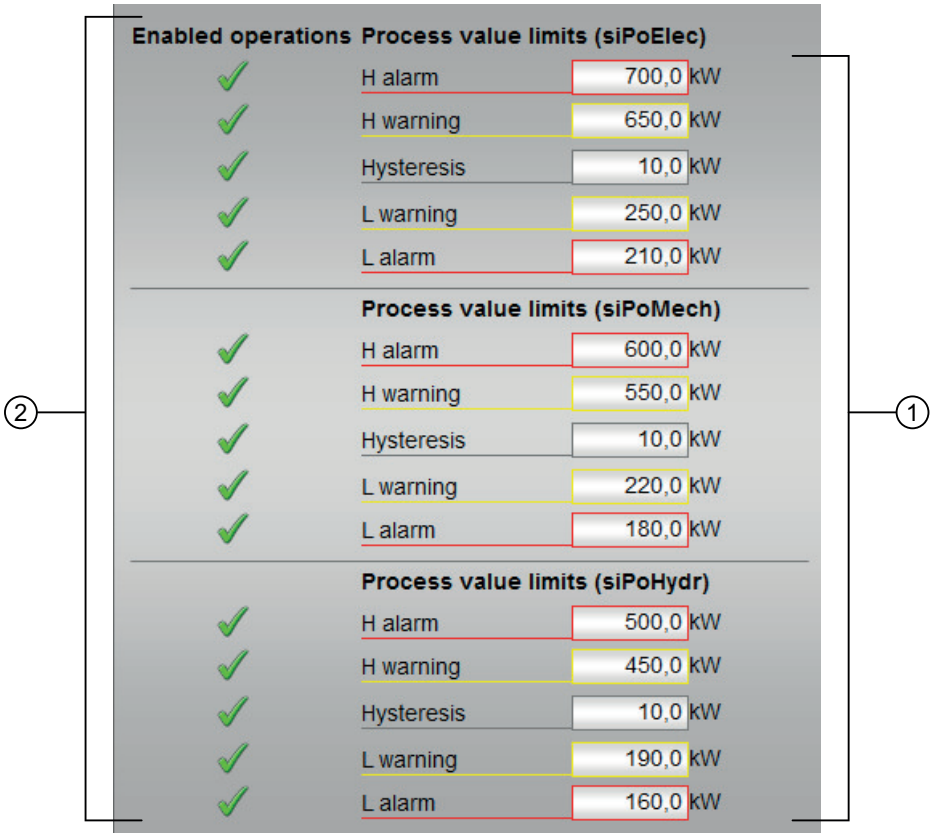
**(4) Normalized process values including signal status**
The normalized process values with the associated signal status are shown in this area:

- Input pressure (`siP_In.Value`)
- Output pressure (`siP_Out.Value`)
- Flow rate (`siFlow.Value`)
- Speed (`siSpd.Value`)
- Temperature (`siTemp.Value`)

**(5) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).



The following enabled operations are shown here:

- "Reset histogram": You can reset the block histograms.
- "Flow rate characteristic": You can change the flow rate characteristic values.
- "Delivery height characteristic": You can change the delivery height characteristic.
- "Power characteristic": You can change the power characteristic.
- "Efficiency characteristic": You can change the efficiency characteristic.
- "NPSH flow rate characteristic": You can change the flow rate characteristic values for the NPSH characteristic.
- "NPSH characteristic": You can change the NPSH characteristic.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.

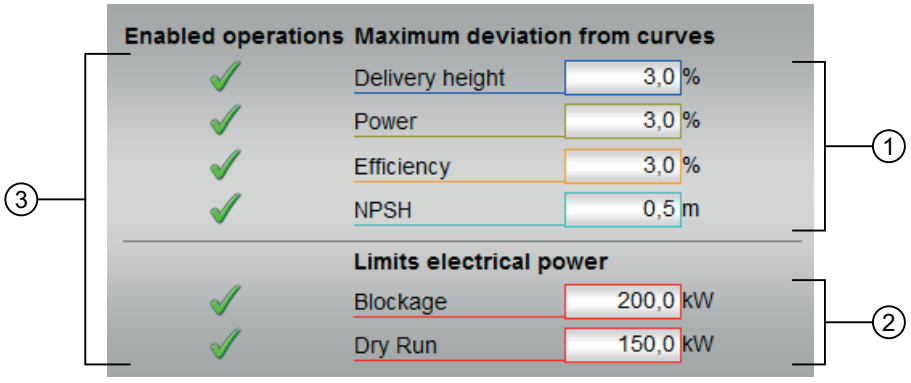
### 4.1.10.10 PumpMon limit value view

Process value limits can be set in this view:

- Electrical power
- Mechanical power
- Hydraulic power

**(1) Process value limits**
You can enter the limits for the process values in this area.

You can change the following limits:



- "H alarm": High alarm
- "H warning": High warning
- "Hysteresis"
- "L warning": Low warning
- "L alarm": Low alarm

**(2) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### 4.1.10.11 PumpMon tolerances view

**(1) Maximum deviation from the characteristic curves**
In this area, you can enter the tolerances for the deviation from the characteristic curves.

You can change the following tolerances:

- "Delivery height": Maximum deviation from the delivery height characteristic (`DelHiTol`)
- "Power": Maximum deviation from the power characteristic (`PowerTol`)
- "Efficiency": Maximum deviation from the efficiency characteristic (`EtaTol`)
- "NPSH": Maximum deviation from the NPSH characteristic (`NpshTol`)

**(2) Limits for the electrical power**
The following limits can be entered in this area:

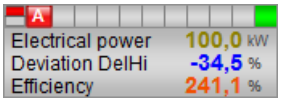
- "Blockage": Electrical power in the event of blockage (`PoBlk`)
- "Dry running": Electrical power in the event of dry running (`PoDryRun`)

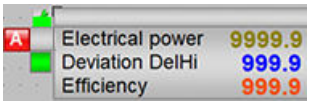
**Note**

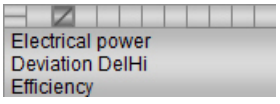
The entries apply to operation under rated conditions. With variable-speed drives, the limits are changed in accordance with the speed.

**(3) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:







- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### 4.1.10.12 Block icon for PumpMon

A block icon with the following functions is available to you:

- Process tag type
- Violations of alarm, warning, and tolerance limits
- Operating modes
- Signal status, release for maintenance
- Memo display
- Operating status of the pump
- Mechanical power
- Relative distance from the delivery height characteristic
- Efficiency

The block icon from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in full display |
|  | 2 | Block icon in full display |
|  | - | Block icon in the "Out of service" operating mode |

You can find additional information on the block icon and the operator control options in the block icon in the following sections:

- "Configuring the block icons (Page 267)"
- "Block icon structure (Page 260)"
- "Operation via the block icon (Page 269)".

# 4.2 PrDrpMon - Pressure drop monitoring

## 4.2.1 Description of PrDrpMon

### Object name (type + number) and family

Type + number: FB 1952

Family: CondMon

Number of process objects: 10 PO

### Area of application of PrDrpMon

The objective is status monitoring of plant components with the `PrDrpMon` function block within the framework of SIMATIC PCS 7 plant asset management. The monitoring concerns pressure loss of (or pressure drop to) plant components such as filters, separators, heat exchangers, pipes, etc. depending on flow, that is, monitoring of flow resistance. This type of monitoring can be useful for all plant components whose flow resistance changes in an undesirable manner during operation due to deposits, blockages, etc. This low-cost solution is based on evaluation of sensor signals that are already present in the control system and contrasts with expensive condition monitoring systems that rely on special additional sensors, such as acoustic emission or acceleration sensors.

### Mode of operation

Any limit violations in the nominal device operating range and deviations from the expected characteristic curve are visualized to the operator and made available via the block outputs for further processing. All the values can be processed further with the usual PCS 7 tools (calculations, archiving, curve recording, alarm history, etc.).

The block itself has a purely diagnostic function and, as such, does not intervene directly in the operation of the device. This means that it can be used (including as a retrofitted device) without having to worry about affecting the process. If required, active intervention (e.g., closing the input valve if there is a risk of a blockage) can be undertaken by evaluating the block outputs.

The following views are provided:

- Differential pressure characteristic curve: Display of the normalized differential pressure as a function of flow and current viscosity range with current operating point of the device.
- Various views for (one-time) input of device and medium parameters

### Configuration

Install the block in a cyclic interrupt OB (OB30 to OB38) in the CFC Editor. The block is also installed automatically in the startup OB (OB100).

### Dynamic input values

The block requires the current viscosity, the flow, and the differential pressure across the device as input data. In addition, a binary signal from a SteadyState block is needed in each case for determining the stationary state of the respective value. These signals must be provided by upstream blocks.

The following input signals must be interconnected:

- Flow of pumped media (Flow)
- Binary signal for stationary state of the flow (FlowStat)
- Input pressure (P_In)
- Binary signal for stationary state of the input pressure (P_InStat)
- Output pressure (P_Out)
- Binary signal for stationary state of the output pressure (P_OutStat)
- Viscosity (Visc)
- Stationary state of the viscosity (ViscStat)
  Instead, the viscosity can be defined as a constant value using Feature Bit 11.

### Static input values

The following data must be known and entered as static input data (most parameters can be entered via the faceplate):

- Minimum and maximum value for viscosity
- Maximum value for flow and differential pressure
- Differential pressure setpoints of different flow values for the various viscosity ranges

### Startup characteristics

Use Feature Bit 0 (Setting the startup characteristics) to define the startup characteristics for this block.

- Bit = 0: The most recently stored values are reset at startup.
- Bit = 1: The most recently used values are sent to the following output parameters at startup:
  - ActFlow1 to ActFlow15
  - ActDeltaP1 to ActDeltaP15
  - DevDeltaP
  - RelDeltaP
  - siDeltaP
  - siFlow
  - siP_In
  - siP_Out

**Note**

Additional information about `Feature.Bit0` can be found in "Set startup characteristics (Page 148)"

### Status word assignment for the `Status1` parameter

For a description of the individual parameters, refer to the section "I/Os of PrDrpMon (Page 550)".

| Status bit | Parameter |
|---|---|
| 0 - 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `OnAct.Value` |
| 6 – 10 | Not used |
| 11 | `DeltaP_Act.Value` |
| 12 | `CritDeltaP_Act.Value` |
| 13 - 27 | Not used |
| 28 | Internal error |
| 29 - 31 | Not used |

### Status word assignment for `Status2` parameter

For a description of the individual parameters, refer to the section "I/Os of PumpMon (Page 505)".

| Status bit | Parameter |
|---|---|
| 0 | Not used |
| 1 | `Feature.Bit10` |
| 2 | `Feature.Bit11` |
| 3 | `ViscMin <= Visc.Value <= ViscMax` |
| 4 | `Visc.Value < ViscMin` |
| 5 | `Visc.Value > ViscMax` |
| 6 - 31 | Not used |

### Status word assignment for `Status3` parameter

For a description of the individual parameters, refer to the section "I/Os of PumpMon (Page 505)".

| Status bit | Parameter |
|---|---|
| 0 | Not used |
| 1 | `ViscIndex = 1` |
| 2 | `ViscIndex = 2` |
| 3 | `ViscIndex = 3` |

| Status bit | Parameter |
|---|---|
| 4 | ViscIndex = 4 |
| 5 | ViscIndex = 5 |
| 6 | Visc.Value in Range 1 |
| 7 | Visc.Value in Range 2 |
| 8 | Visc.Value in Range 3 |
| 9 | Visc.Value in Range 4 |
| 10 | Visc.Value in Range 5 |
| 11 | RelDeltaP > DeltaP_Tol |
| 12 | RelDeltaP > CriticalDeltaP |
| 13 - 31 | Not used |

## 4.2.2 PrDrpMon modes

The block can be operated using the following modes:

- On
- Out of service

### "On"

General information about the "On" operating mode can be found in the section "On (Page 77)".

### "Out of service"

General information about the "Out of service" operating mode can be found in the section "Out of service (Page 77)".

## 4.2.3 PrDrpMon mode of operation

The PrDrpMon block is supplied with current process values in the CFC via the inputs Flow (flow), P_In (input pressure), P_Out (output pressure), and Visc (viscosity of the flow medium).

The binary inputs FlowStat, P_InStat, P_OutStat, and ViscStat are used to signal whether a new stationary operating point has been reached (in the case of non-constant viscosity).

### Preprocessing

The process values are normalized to SI units via the *Offs and *Fact inputs. The normalized values are output again at the output. The status signals of the process values (quality code) are not evaluated but are instead output again at the output.

- `siFlow.Value = FlowOffs + Flowfact * Flow.Value`
  (normalize to $m^3/h$)
- `siP_In.Value = P_InOffs + P_InFact * P_In.Value`
  (normalize to bar)
- `siP_Out.Value = P_OutOffs + P_OutFact * P_Out.Value`
  (normalize to bar)

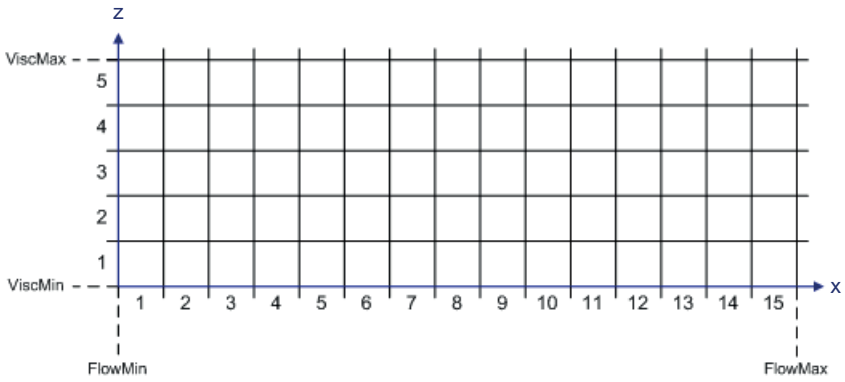
### Stationary processes

All 4 process values have a separate input for information on the stationary state of the respective process value:

| | |
|---|---|
| `FlowStat` | Stationary state of the flow |
| `P_InStat` | Stationary state of the input pressure |
| `P_OutStat` | Stationarity of the output pressure |
| `ViscStat` | Stationary state of the viscosity |

The inputs are interconnected with the `StatAct` output of the corresponding SteadyState block.

The stationary state signals for the input and output pressure are ANDed internally and then evaluated.

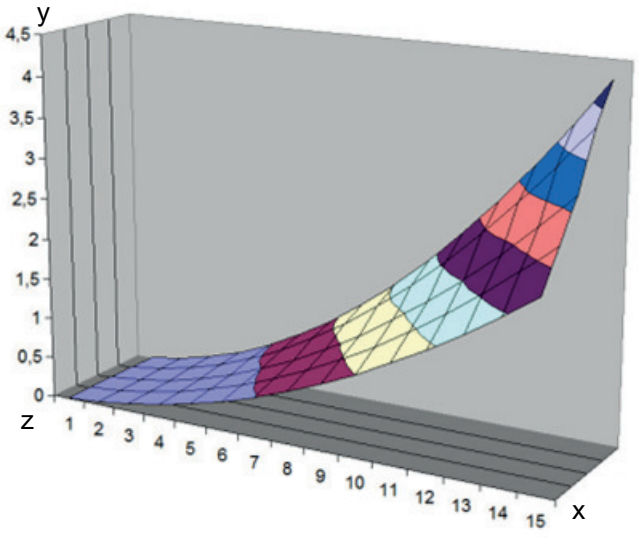


### Differential pressure characteristic field

In contrast to existing condition monitoring blocks that can display various two-dimensional characteristic fields, the `PrDrpMon`block must additionally consider a third dimension (viscosity) because the differential pressure characteristic curve is strongly dependent on it.

If the viscosity is constant enough in an application, this third dimension can also be suppressed again. In this case, `Feature.Bit11 = TRUE` must be assigned. Then only flow and differential pressure are evaluated for the characteristic field analysis.

**Note**



If the viscosity is not available as a measured value in an application, the media temperature can be interconnected by way of substitute. This changes the direction of dependency (high temperatures signify low viscosity) but this is irrelevant for the functioning of the block. For this reason, units for viscosity are also consistently omitted in the block. All labels and parameter name always refer to viscosity, however

**z** = Viscosity

**x** = Flow rate

Like for `PumpMon`, the X-dimension (Flow) is divided into 15 equal-sized areas (0 to `FlowMax`). The Y-dimension represents the pressure difference between the output pressure (`P_Out`) and input pressure (`P_In`) (0 to `DeltaP_Max`), and the Z-dimension (Visc) is divided into 5 equal-sized areas (`ViscMin` to `ViscMax`) for the characteristic field analysis. If the current measured value Visc is outside the range `ViscMin` to `ViscMax`, no points are taught or displayed. Instead, the text "`Visc < ViscMin`" or "`Visc > ViscMax`" is displayed in the standard view of the faceplate.

**x** = Flow rate ($m^3/h$)

**y** = Pressure drop (bar)

**z** = Viscosity ($m^2*s^{-1}$)

## Set differential pressure characteristic curve

For the sake of clarity, there is no three-dimensional display of the characteristic field in the faceplate. Only the sectional view belonging to the measured viscosity is calculated by the characteristic field and displayed as a two-dimensional characteristic curve.

This yields a separate two-dimensional set characteristic curve for each of the five viscosity ranges.

The interpolation points of the set differential pressure characteristic curve are written to the input parameters `Flow1`...`Flow15` and `DeltaP1`...`DeltaP15` for the display in the faceplate, depending on the currently selected viscosity range (ViscIndex).

When the viscosity range is changed (`ViscIndex`), the values of the individual interpolation points must first be saved in a static array before the static values of the new viscosity range are copied to the input parameters.

**Note**

If constant viscosity is assumed (`Feature.Bit11 = TRUE`), the `ViscStat` input is not evaluated. Only the `Flow1`...`Flow15` and `DeltaP1`...`DeltaP15` input parameters are considered.

### Automatic acquisition of the actual differential pressure characteristic curve

The actual differential pressure characteristic curve is acquired automatically depending on `Feature.Bit10`. When `Feature.Bit10 = TRUE`, a new value is acquired when all input signals are "stationary" (`FlowStat = 1`, `P_InStat = 1`, `P_OutStat = 1`, `ViscStat = 1`).

Another value is only saved when one of the four signals was "not stationary" in the meantime (e.g., `FlowStat = 0`).

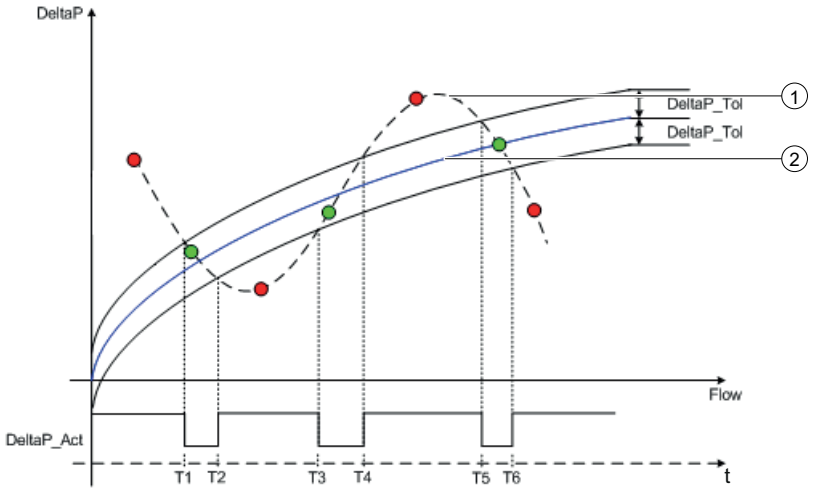
If a new measured value has been saved, the interpolation points that do not yet have a measured value will be recalculated by interpolation.

**Note**

Creeping signal changes must be detected by a corresponding setting of SteadyState.

**Note**

If constant viscosity is assumed (`Feature.Bit11 = TRUE`), the `ViscStat` input is not evaluated.



## 4.2.4 PrDrpMon functions

The functions for this block are listed below.

### Tolerance monitoring of the characteristic curves

Because the characteristic field is only expanded by individual interpolation points, an interpolation with the characteristic field is required for each comparison of the operating point, as shown in Figure 3.

For this, the four measured values around the operating point are considered in each case. An auxiliary point is calculated in each case between the two pairs that lie in the same viscosity range. These two auxiliary points are determined in such a way that they have the same flow value as the operating point. Now, it is only necessary to interpolate between the two auxiliary points in order to calculate the setpoint.

(1) Movement of the operating point over time

(2) Differential pressure characteristic

t = time

The deviation of the operating point from the two-dimensional set differential pressure characteristic curve calculated in this way is output in outputs `RelDeltaP` (relative in [%]) and `DevDeltaP` (absolute in [bar]). If the operating point exits the specified tolerance band (`DeltaP_Tol`), the `DeltaP_Act` output is set and the operating point changes from green to red in the faceplate.

The user assigns the critical relative deviation to the `CriticDeltaP` input parameter. When this parameter is reached, the functional capability of the monitored component is endangered and an immediate maintenance measure is required. In this case, the `CritDeltaP_Act` output is set to 1.

For flow values less than `MonFlowMin`, the differential pressure is not monitored. The value can be specified as a relative or static value ().

## Wear reserve

Depending on the relative deviation `RelDeltaP`, the wear reserve is calculated and output only at the `WearResDeltaP` output. The wear reserve is calculated as follows:

$$WearResDeltaP = 1 - \left( \frac{RelDeltaP}{CriticDeltaP} \right)$$

### Forming the signal status for blocks

This block has the standard function "Forming and outputting the signal status for technological blocks (Page 117)".

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `Flow.ST`
- `FlowStat.ST`
- `P_In.ST`
- `P_InStat.ST`
- `P_Out.ST`
- `P_OutStat.ST`
- `Visc.ST`
- `ViscStat.ST` (if `Feature.Bit11 = FALSE`)

The following dependencies apply to the formation of the output-side signal status:

| Signal status | Dependencies |
|---|---|
| siFlow.ST | Flow.ST |
| siP_In.ST | P_In.ST |
| siP_Out.ST | P_Out.ST |

### Selecting a unit of measurement

This block provides the standard function "Selecting a unit of measure (Page 240)".

### Configurable reactions using the `Feature`parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in section "Configurable response using the `Feature` I/O (Page 139)". The following modes of behavior are available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Setting the startup characteristics |
| 1 | Characteristics for the out of service mode |
| 6 | Minimum flow for monitoring the operating point is absolute/relative |
| 10 | Automatic acquisition of the actual differential pressure characteristic curve |
| 11 | Viscosity is constant |
| 26 | Behavior of the switching points in "Out of service" mode |
| 28 | Disabling of switching points |
| 29 | Signaling limit violation |

### Operator control permissions

This block provides the standard function "Operator control permissions (Page 285)".

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 – 9 | Not used |
| 10 | 1 = Operator can apply the actual differential pressure characteristic curve as the set characteristic curve |
| 11 | 1 = Operator can reset the actual differential pressure characteristic curve. |
| 12 | 1 = Operator can change the value for the on delay |
| 13 - 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the maximum flow value |
| 1 | 1 = Operator can change the minimum flow value |
| 2 | 1 = Operator can set the viscosity range in the parameter view to 1. |
| 3 | 1 = Operator can set the viscosity range in the parameter view to 2. |
| 4 | 1 = Operator can set the viscosity range in the parameter view to 3. |
| 5 | 1 = Operator can set the viscosity range in the parameter view to 4. |
| 6 | 1 = Operator can set the viscosity range in the parameter view to 5. |
| 7 - 14 | Not used |
| 15 | 1 = Operator can change the limit for the deviation of the differential pressure characteristic curve |
| 16 | 1 = Operator can change the critical limit for the deviation of the differential pressure characteristic curve |
| 17 | 1 = Operator can change the hysteresis for the limit for the deviation of the differential pressure characteristic curve |
| 18 - 31 | Not used |

## SIMATIC BATCH functionality

This block does not support "SIMATIC BATCH functionality".

## 4.2.5 PrDrpMon messaging

### Message behavior

The PrDrpMon block does not generate messages or maintenance alarms. It simply provides several binary message outputs that are set when the permissible deviation is exceeded. Messages may be generated for specific applications by a separate event block, and maintenance alarms by a downstream AssetMon block (included in the standard package of PCS 7). Events that are relevant for the plant operator can also be reported via interconnection of PrDrpMon message outputs to free message inputs of the associated technological block.

## 4.2.6 PrDrpMon I/Os

### I/Os of PrDrpMon

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdoptActDeltaP_Op* | 1 = Adopt the current actual differential pressure characteristic curve | BOOL | FALSE |
| BatchEn | Enable allocation | BOOL | FALSE |
| BatchID | Batch ID | DWORD | 16#0 |
| BatchName | Batch name | SRING[32] | "" |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| CriticalDeltaP | Critical relative deviation of the set differential pressure characteristic curve [%] | REAL | 50.0 |
| DeltaP1 | y value 1, differential pressure [bar] | REAL | 0.1 |
| DeltaP2 | y value 2, differential pressure [bar] | REAL | 0.4 |
| DeltaP3 | y value 3, differential pressure [bar] | REAL | 0.9 |
| DeltaP4 | y value 4, differential pressure [bar] | REAL | 1.6 |
| DeltaP5 | y value 5, differential pressure [bar] | REAL | 2.5 |
| DeltaP6 | y value 6, differential pressure [bar] | REAL | 3.6 |
| DeltaP7 | y value 7, differential pressure [bar] | REAL | 4.9 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DeltaP8 | y value 8, differential pressure [bar] | REAL | 6.4 |
| DeltaP9 | y value 9, differential pressure [bar] | REAL | 8.1 |
| DeltaP10 | y value 10, differential pressure [bar] | REAL | 10.0 |
| DeltaP11 | y value 11, differential pressure [bar] | REAL | 12.1 |
| DeltaP12 | y value 12, differential pressure [bar] | REAL | 14.4 |
| DeltaP13 | y value 13, differential pressure [bar] | REAL | 16.9 |
| DeltaP14 | y value 14, differential pressure [bar] | REAL | 19.6 |
| DeltaP15 | y value 15, differential pressure [bar] | REAL | 22.5 |
| DeltaP_Hyst | Hysteresis for the limit monitoring of the differential pressure | REAL | 5.0 |
| DeltaP_Max | Maximum differential pressure (indicates the maximum value for the y-axis) [bar] | REAL | 30.0 |
| DeltaP_Tol | Maximum deviation from the set differential pressure characteristic curve [%] | REAL | 10.0 |
| Feature | 1 = Valve open feedback signal | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Flow | Interconnectable input for the flow | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Flow1 | x value 1, flow [m³/h] | REAL | 2.0 |
| Flow2 | x value 2, flow [m³/h] | REAL | 4.0 |
| Flow3 | x value 3, flow [m³/h] | REAL | 6.0 |
| Flow4 | x value 4, flow [m³/h] | REAL | 8.0 |

| RstActDeltaP_Op* | 1 = Reset actual differential pressure characteristic curve | BOOL | FALSE |
| RunUpCyc | Number of cycles during startup (not currently evaluated) | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call of a block stored in this parameter as an additional face-plate in the standard view | ANY | - |
| SelFp2 | 1 = Call of a block stored in this parameter as an additional face-plate in the standard view | ANY | - |
| siFlowUnit | Unit of measure for the normalized flow | INT | 1349 |
| siP_Unit | Unit of measure for the normalized pressure | INT | 1137 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Stepno | Batch step number | DWORD | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| Visc | Interconnectable input for the viscosity | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ViscIndex | Index of the currently selected viscosity range for the set differential pressure characteristic curve | INT | 1 |
| ViscMax | Maximum viscosity (indicates the maximum value for the z-axis) [ViscUnit] | REAL | 500.0 |
| ViscMin | Minimum viscosity (indicates the minimum value for the z-axis) [ViscUnit] | REAL | 300.0 |
| ViscStat | Interconnectable input for the stationary state monitoring of the viscosity (SteadyState) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ViscUnit | Unit of measurement for the viscosity | INT | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActFlow1 | x value 1, actual differential pressure characteristic curve [m³/h] | REAL | 2.0 |
| ActFlow2 | x value 2, actual differential pressure characteristic curve [m³/h] | REAL | 4.0 |
| ActFlow3 | x value 3, actual differential pressure characteristic curve [m³/h] | REAL | 6.0 |
| ActFlow4 | x value 4, actual differential pressure characteristic curve [m³/h] | REAL | 8.0 |
| ActFlow5 | x value 5, actual differential pressure characteristic curve [m³/h] | REAL | 10.0 |
| ActFlow6 | x value 6, actual differential pressure characteristic curve [m³/h] | REAL | 12.0 |
| ActFlow7 | x value 7, actual differential pressure characteristic curve [m³/h] | REAL | 14.0 |
| ActFlow8 | x value 8, actual differential pressure characteristic curve [m³/h] | REAL | 16.0 |
| ActFlow9 | x value 9, actual differential pressure characteristic curve [m³/h] | REAL | 18.0 |
| ActFlow10 | x value 10, actual differential pressure characteristic curve [m³/h] | REAL | 20.0 |
| ActFlow11 | x value 11, actual differential pressure characteristic curve [m³/h] | REAL | 22.0 |
| ActFlow12 | x value 12, actual differential pressure characteristic curve [m³/h] | REAL | 24.0 |
| ActFlow13 | x value 13, actual differential pressure characteristic curve [m³/h] | REAL | 26.0 |
| ActFlow14 | x value 14, actual differential pressure characteristic curve [m³/h] | REAL | 28.0 |
| ActFlow15 | x value 15, actual differential pressure characteristic curve [m³/h] | REAL | 30.0 |
| ActDeltaP1 | y value 1, actual differential pressure characteristic curve [bar] | REAL | 0.1 |
| ActDeltaP2 | y value 2, actual differential pressure characteristic curve [bar] | REAL | 0.4 |
| ActDeltaP3 | y value 3, actual differential pressure characteristic curve [bar] | REAL | 0.9 |
| ActDeltaP4 | y value 4, actual differential pressure characteristic curve [bar] | REAL | 1.6 |
| ActDeltaP5 | y value 5, actual differential pressure characteristic curve [bar] | REAL | 2.5 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActDeltaP6 | y value 6, actual differential pressure characteristic curve [bar] | REAL | 3.6 |
| ActDeltaP7 | y value 7, actual differential pressure characteristic curve [bar] | REAL | 4.9 |
| ActDeltaP8 | y value 8, actual differential pressure characteristic curve [bar] | REAL | 6.4 |
| ActDeltaP9 | y value 9, actual differential pressure characteristic curve [bar] | REAL | 8.1 |
| ActDeltaP10 | y value 10, actual differential pressure characteristic curve [bar] | REAL | 10.0 |
| ActDeltaP11 | y value 11, actual differential pressure characteristic curve [bar] | REAL | 12.1 |
| ActDeltaP12 | y value 12, actual differential pressure characteristic curve [bar] | REAL | 14.4 |
| ActDeltaP13 | y value 13, actual differential pressure characteristic curve [bar] | REAL | 16.9 |
| ActDeltaP14 | y value 14, actual differential pressure characteristic curve [bar] | REAL | 19.6 |
| ActDeltaP15 | y value 15, actual differential pressure characteristic curve [bar] | REAL | 22.5 |
| DevDeltaP | Deviation from the set differential pressure characteristic curve [bar] | REAL | 0.0 |
| ErrorNum | Output of the existing error number. For error numbers that can be output by this block, see PrDrpMon error handling | INT | -1 |
| DeltaP_Act | 1 = Deviation from the set differential pressure characteristic curve is too large | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeltaPDrift | Indicates the deviation of the actual characteristic curve from the set characteristic curve | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MonFlowMinOut | Absolute flow value from which the differential pressure is monitored | REAL | 0.0 |
| OnAct | 1 = Block is "On" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |

### 4.2.7 PrDrpMon block diagram

A block diagram is not provided for this block.

### 4.2.8 Operator control and monitoring

#### 4.2.8.1 Views of PrDrpMon

The PumpMon block has the following views:

- PrDrpMon Standard view (Page 556)
- Parameter view (Page 559)
- Limit view (Page 558)
- Memo view (Page 338)
- Batch view (Page 336)

For general information on the faceplate and block icon, refer to the "Structure of the faceplate (Page 279)" and "Block icon structure (Page 260)" sections.

### 4.2.8.2 PrDrpMon standard view

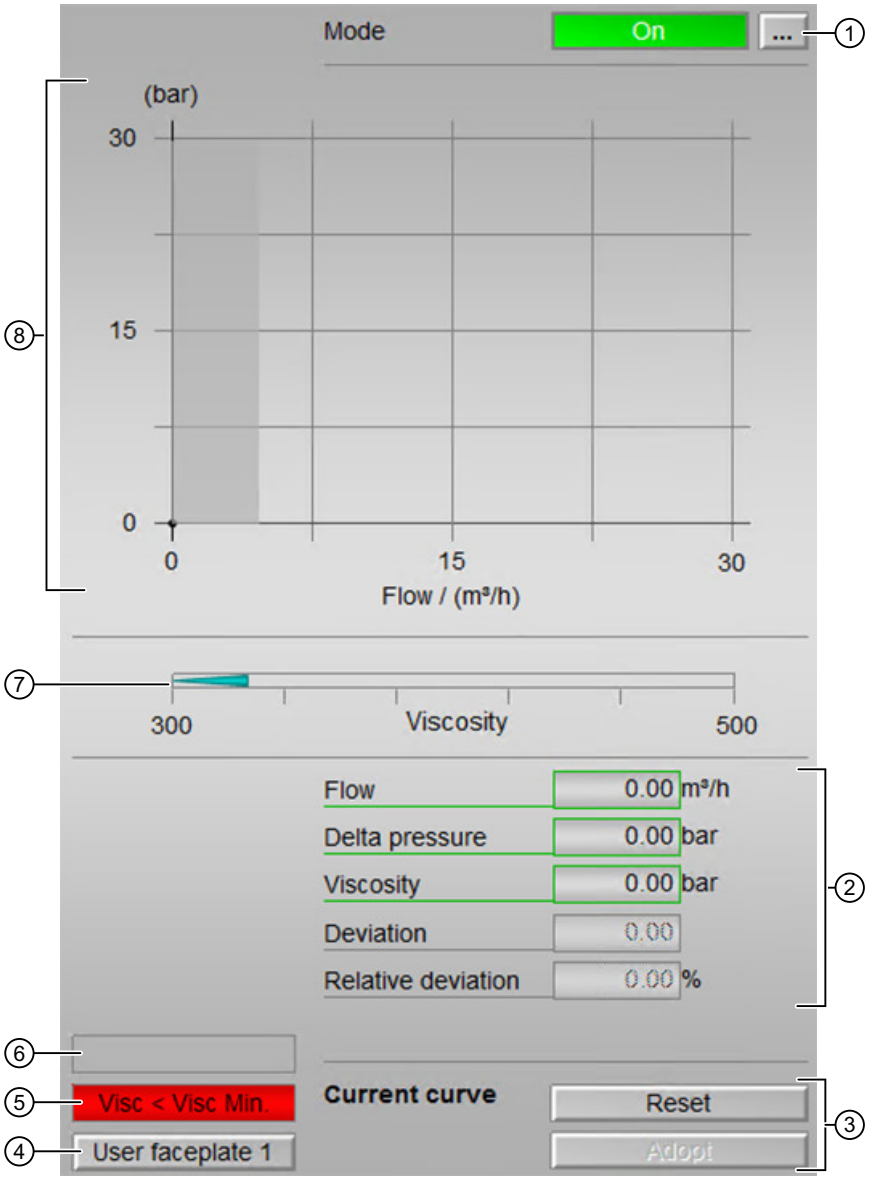

Figure 4-1 Standard view

**(1) Display and switchover of the operating mode**

This area provides information on the operating mode currently in effect. The following operating modes can be shown here:

- On
- Out of service

**(2) Display of the characteristic values**

This area shows the following values:

- Current flow (`siFlow.Value`) (Format: 9999.9)
- Current viscosity (`Visc.Value`) (Format: 999.9)
- Current calculated differential pressure (`siDeltaP.Value`) (Format: 999.9)
- Absolute deviation from the characteristic curve (`DevDeltaP`) (Format: 999.9)
- Relative deviation from the characteristic curve (`RelDeltaP`) (Format: 999.9)

**(3) Functions for the actual characteristic curve**

This area provides a button for adopting and a button for resetting the actual differential pressure characteristic curve.

When the actual characteristic curve is adopted (`AdoptActDeltaP_Op = TRUE`), the actual characteristic curve is written to the corresponding set characteristic curve.

When the actual characteristic curve is reset (`RstActDeltaP_Op = TRUE`), the actual characteristic curve is reset to zero.

**Note**

If `Feature.Bit10 = FALSE`, the buttons for adopting and resetting the actual characteristic curve are disabled.

**(4) Jump button for switching to the standard view of any faceplate**

This display is only visible when the `SelFp1` block input is interconnected.

Use this jump button to reach the standard view of the interconnected block.

**(5) Display area for block states of the characteristic values**

The current viscosity range is displayed here. The corresponding setpoints can be entered for this area in the parameter view.

If the current viscosity range falls outside the limits, "Visc < ViscMin" or "Visc > ViscMax" is displayed accordingly.

**(6) Display when tolerance limit is exceeded**

If the tolerance limit for the differential pressure of the current operating point is exceeded, this is indicated here as text "Diff > DeltaP Tol.". If the critical tolerance limit is exceeded, the text "Diff > Crit. DeltaP Tol." is displayed.

**(7) Display of current viscosity range**

The current viscosity is displayed as a horizontal bar. The scales represent the 5 viscosity ranges.

**(8) Display of actual characteristic curve with current operating point**

The interpolation points for the characteristic curve are entered in the "Characteristic parameters" view.

If the distance of the current operating point exceeds a predefined tolerance, the color of the operating point changes from green to red and a corresponding alarm is triggered (`DeltaP_Act.Value`).

The scaling of the X and Y axis is dynamic

- **X:** 0 -> FlowMax / 2 -> FlowMax
- **Y:** 0 -> DeltaP_Max / 2 -> DeltaP_Max
- The set differential pressure characteristic curve is displayed with the Flow1…Flow15 and DeltaP1…DeltaP15 parameters.
- The actual differential pressure characteristic curve is displayed with the ActFlow1… ActFlow15 and ActDeltaP1…ActDeltaP15 parameters. If Feature.Bit10 = FALSE was assigned, the actual differential pressure characteristic curve is not displayed.
- The unmonitored range (< MonFlowMin) is represented with a semi-transparent gray rectangle.

### 4.2.8.3 PrDrpMon limit view

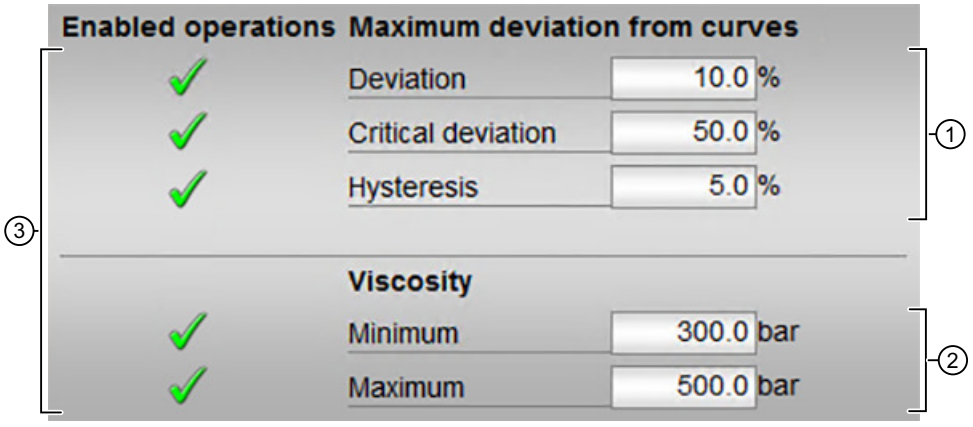

Figure 4-2 Limit value view

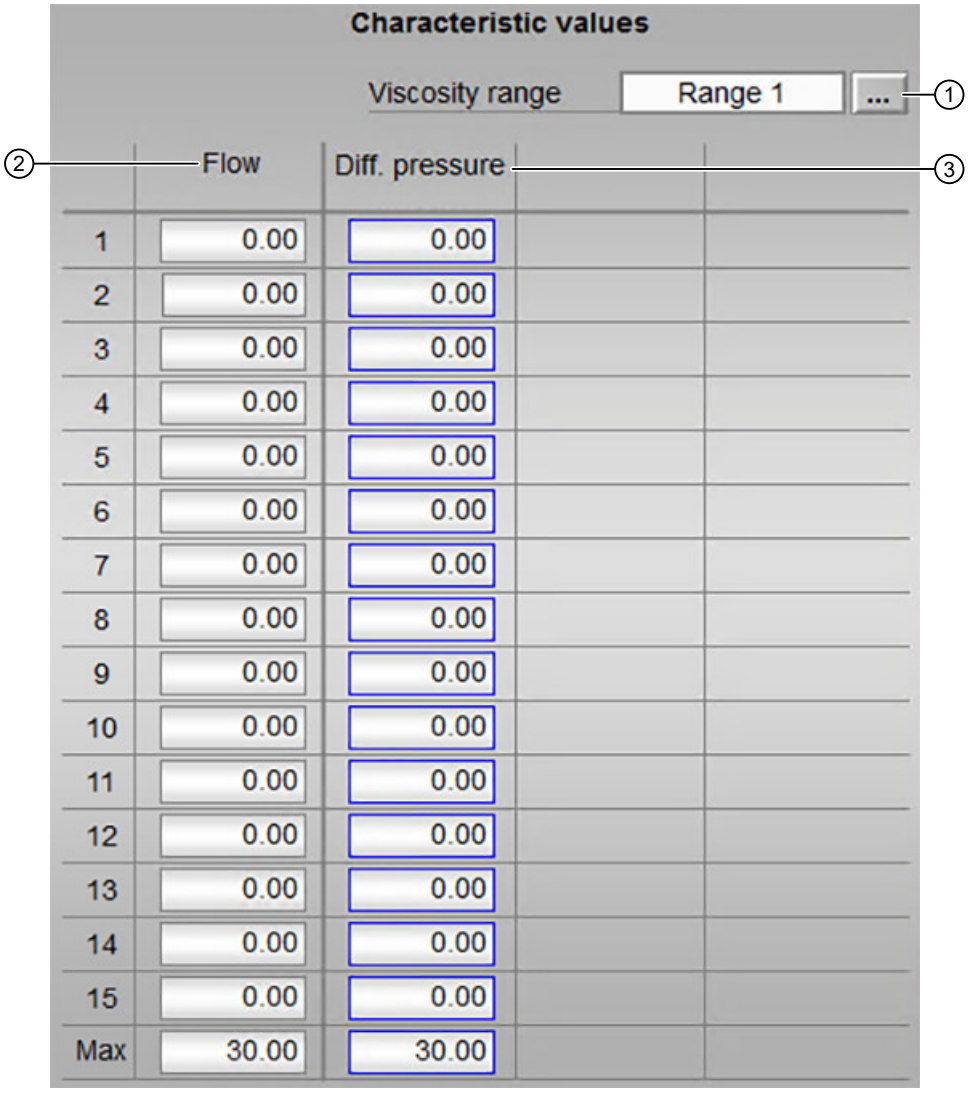
**(1) Deviations** from the characteristic curve

In this view, the maximum permitted deviation of the operating point from the set differential pressure characteristic curve DeltaP_Tolis entered (format: 999.9) and the critical relative deviation of the operating point from the set differential pressure characteristic curve CriticDeltaPis entered (format: 999.9) in [%].

Operation requires operator permission "Higher process operations".

**(2) Viscosity parameters**

In this area, the values for the minimum (ViscMin) and maximum (ViscMax) viscosity are specified (unit of measure is ViscUnit); this can also be substituted with a temperature range.



**(3) Enabled operations**

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### 4.2.8.4 PrDrpMon parameter view

**(1) Selection of the viscosity range**

The viscosity range to be assigned is selected in this area. The display field of the current viscosity range is shown with a white background.

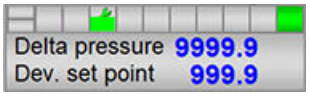
**(2) Flow parameters**

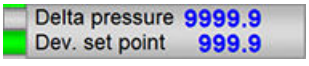
The 15 interpolation points of the flows (`Flow1` to `Flow15`) indicate the x-axis for the set differential pressure characteristic curve (format: 9999.9).

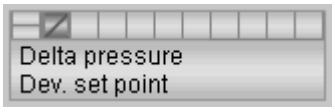
The display is made within the range 0 <= `Flow1`<= `Flow2`<=, ..., <= `Flow15`<= `FlowMax`.

In addition, the values for the maximum flow (`FlowMax`) can be specified.

**(3) Differential pressure parameters**







In this area, the differential pressure parameters `DeltaP1`to `DeltaP15`(format: 999.9) and the maximum value `DeltaP_Max`(format: 999.9) are specified. Parameters that have the value 0 are ignored in the characteristic curve.

### 4.2.8.5 Block icon for PrDrpMon

A block icon with the following functions is available to you:

- Process tag type
- Violations of alarm, warning, and tolerance limits
- Operating modes
- Signal status, release for maintenance
- Memo display
- Differential pressure
- Deviation from setpoint

The block icon from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in full display |
|  | 2 | Block icon in full display |
|  | - | Block icon in the "Out of service" operating mode |

You can find additional information on the block icon and the operator control options in the block icon in the following sections of the "PCS 7 Advanced Process Library" manual:

- "Configuring the block icons"
- "Block icon structure"
- "Operation via the block icon".

# 4.3 Valve monitoring - VlvMon

## 4.3.1 Description of VlvMon

### Object name (type + number) and family

Type + number: FB 1951

Family: CondMon

Number of process objects: 10 PO

### Area of application

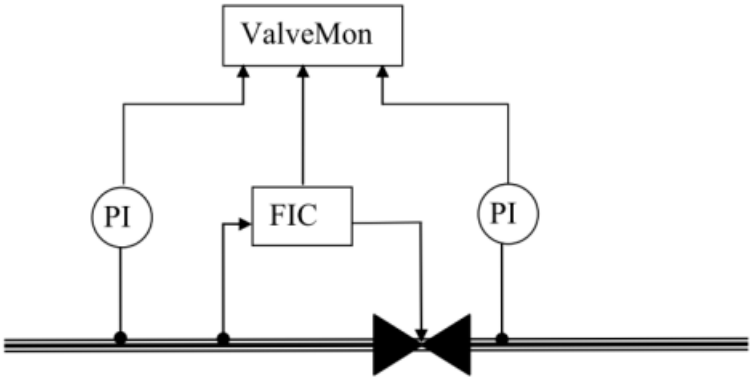
The VlvMon function block offers a low-cost solution for the monitoring and analysis of control valves (continuous action valves). Monitoring is based on the intelligent evaluation of measured values that are often already available in the control system. VlvMon can supplement the self-diagnostics of an electro-pneumatic positioner, for example Sipart PS, or replace it entirely if the positioner has no self-diagnostics or its self-diagnostics is not integrated in the process control system.

Along with pumps, valves are some of the most widely used actuators in process plants. They are subject to various symptoms of wear, such as wear (abrasion, cavitation, corrosion) of the valve plug and/or seat or caking (fouling, deposits) on the valve plug and/or seat. Their behavior during operation can be described by a valve characteristic curve. Valves are mechanical assets which, like pumps, are not registered as field devices in the process control system. However, they are typically pneumatically driven and positioned with an electro-pneumatic positioner. The positioner may be already integrated as intelligent field device in the asset management of the control system.

The status of the valve has a decisive influence on the availability and safety of the entire plant. VlvMon enables status-based monitoring of control valves using various process values. Valve malfunctions or imminent valve failures can thus be detected at an early stage. This improves maintenance planning and increases the availability of the overall plant.

The VlvMon function is used to:

- Warn of valve damage in adverse operating conditions or of wear limits being reached: Continuous operation without valve shutdown, continuous standstill, i.e. long periods of operation without valve motion risking valve caking, exceeding the max. number of strokes, exceeding the max. changes in direction.
- Provide early detection of imminent damage to valve: Deposits or caking, wear, monitoring of reaction times and flow characteristic curves.
- To optimize the valve dimensioning in the long term by means of statistical analysis of the operational data: Frequency distribution of the valve settings.



The VlvMon block can be used for each continuous action valve which can be adjusted continuously and returns the current valve position. Pure switching valves (open/closed) are not the subject of consideration. Besides basic status monitoring (monitoring of standstill time, change of direction, etc.), valve motion errors (wear, caking, etc.) are also considered.

If there are additional process values, advanced valve diagnostics can be performed (monitoring of valve characteristic curve based on differential pressure and flow rate, monitoring the supply pressure, etc.).

Relevant process values in the field of valves:

- Flow of the flowing medium
- Inlet pressure (pressure before the valve)
- Outlet pressure (pressure after the valve)
- Valve setpoint
- Valve actual position (feedback about actual valve position)
- Pressure of the compressed air supply

P&ID diagram of a control valve with associated sensors including valve monitoring:

## Mode of operation

When permissible deviations are exceeded, this is signaled to the user by the VlvMon block and made available by block outputs for further processing.

VlvMon does not offer messaging itself, but can be interconnected with the standard PCS 7 message blocks.

The block itself is designed purely for diagnostic purposes and, as such, does not intervene directly in the operation of the control valve. This means that it can be used (including as a retrofitted device) without having to worry about affecting the process. If desired, active intervention can be achieved for specific applications by evaluating the block outputs.

## Configuration

The VlvMon block is dragged from the block catalog and dropped onto the specially prepared CFC. The selection of the insert position and the OB in which the block is installed depends on the insert position of the driver block for the pressure and flow measured values. If the measurement of reaction times of the valve is a priority, both the driver blocks and VlvMon run in a correspondingly rapid cycle (about 10 times faster than the travel times of the valve). The other monitoring functions (characteristic curves, operating hours, etc.), however, are not time-critical. If the reaction times do not have to be monitored in VlvMon, it can be installed in a slow OB to save CPU resources.

The SteadyState block of the Condition Monitoring Library can be integrated to automatically detect the flow characteristic curve. The SteadyState block is used to detect steady states in a dynamic process. It analyzes an input signal and decides without delay whether this signal is steady or not. For more details, refer to the online help of the SteadyState block.

Detection of the flow characteristic curve requires a SteadyState block which must be interconnected as follows:

- Process value flow at the driver block → SteadyState `PV`
- SteadyState `StatAct` → VlvMon `FlowStat`

## Dynamic input values

For control valves with feedback of the valve position, the block requires the following process values:

- Valve setpoint (`MV`)
- Valve actual position (`Rbk`)

For extended monitoring with additional sensors:

- `Flow`
- Pressure before the valve (`P_In`)
- Pressure after the valve (`P_Out`)
- Binary signal for the compressed air supply monitoring (`SuppPres`)

The process signals are interconnected to the associated driver blocks.

## Static input values

The following data must be known and entered as static input data (most parameters can be entered via the faceplate):

- Maximum number of valve strokes (`StrokesMax`)
- Maximum number of changes of direction (`SID_Max`)
- Maximum possible flow through the valve (`FlowMax`)
- Maximum valve reaction time for a complete stroke (`T_RespMax`)
- Maximum allowable idle time without interruption (`T_Idle`)
- Maximum allowable travel time without interruption (`T_Move`)

Flow and reaction time characteristic curves can be determined automatically by the VlvMon block during ongoing plant operation. If this is not possible because no large movements are allowed during ongoing plant operation, the characteristic curves can be taken from manuals and entered manually.

### Startup characteristics

Use `Feature.Bit0` (Setting the startup characteristics) to define the startup characteristics of this block.

- **Bit = 0**: The most recently stored values are reset at startup.
- **Bit = 1:** The most recently used values are output to the following output parameters at startup:
  - `ER`
  - `FlowAct`
  - `FlowDriftAct`
  - `RespUpAct`
  - `RespDnAct`
  - `T_MoveMaxAct`
  - `T_IdleMaxAct`
  - `DeadAct`
  - `StrokesMaxAct`
  - `SID_MaxAct`
  - `ExtMoveAct`
  - `VlvPosMaxAct`
  - `VlvPosMinAct`
  - `CtrlDevMaxAct`

**Note**

Additional information about `Feature.Bit0` can be found in Set startup characteristics (Page 148)

### Status word assignment for the `Status1` parameter

For a description of the individual parameters, refer to the section I/Os of VlvMon (Page 582).

| Status bit | Parameter |
|---|---|
| 0 – 2 | `Not used` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `OnAct.Value` |

| Status bit | Parameter |
|---|---|
| 6 – 10 | Not used |
| 11 | FlowAct.Value |
| 12 | FlowDriftAct.Value |
| 13 | RespUpAct.Value |
| 14 | RespDnAct.Value |
| 15 - 16 | Not used |
| 17 | T_MoveMaxAct.Value |
| 18 | T_IdleMaxAct.Value |
| 19 | DeadAct.Value (available in a later version) |
| 20 | StrokesMaxAct.Value |
| 21 | SID_MaxAct.Value |
| 22 | ExtMoveAct.Value |
| 23 | VlvPosMaxAct.Value |
| 24 | VlvPosMinAct.Value |
| 25 | CtrlDevMaxAct.Value |
| 26 | SuppPresAct.Value |
| 27 | Not used |
| 28 | Internal error |
| 29 – 31 | Not used |

### Status word assignment for `Status2` parameter

For a description of the individual parameters, refer to the section I/Os of VlvMon (Page 582).

| Status bit | Parameter |
|---|---|
| 0 | Not used |
| 1 | Feature.Bit10 |
| 2 | Feature.Bit11 |
| 3 | Feature.Bit12 |
| 4 - 31 | Not used |

## 4.3.2 VlvMon modes

### Operating modes of VlvMon

This block can be set to the following modes:

- On
- Out of service

**"On"**

General information about the "On" operating mode can be found in On (Page 77)

**"Out of service"**

General information about the "Out of service" operating mode can be found in Out of service (Page 77)

## 4.3.3 VlvMon operating principle

The VlvMon block is supplied with the current process values in the CFC via the inputs `MV` and `Rbk`. If the flow characteristic curve is to be used, the inputs `Flow`, `P_In` (pressure before the valve) and `P_Out` (pressure after the valve) are needed.

### Preprocessing

The process values are standardized to SI units via the *`Offs` and *`Fact` inputs. The normalized values are output again at the output. The status signals of the process values (quality code) are not evaluated but are instead output again at the output.

- `siFlow.Value = FlowOffs + Flowfact * Flow.Value`
  (normalize to $m^3/h$)
- `siP_In.Value = P_InOffs + P_InFact * P_In.Value`
  (normalize to bar)
- `siP_Out.Value = P_OutOffs + P_OutFact * P_Out.Value`
  (normalize to bar)

### Flow characteristic curve

Monitoring the flow characteristic curve is the heart of the VlvMon block. This is done by setting a set characteristic curve in the block for the flow depending on the valve position. This set characteristic curve can be entered manually, but it can also be taught automatically.

To diagnose caking or damage to the interior of the valve, this set characteristic curve is compared to the current operating point and an automatic acquired actual characteristic curve. Deviations from the set characteristic curve can be explained by a change to the valve cross-section.

This flow characteristic curve consists of 20 interpolation points. For the position feedback coming from the valve, the corresponding setpoint from the characteristic curve is calculated and compared to the actual flow.

#### (1) Normalization of the flow

To monitor the flow characteristic curve, the flow must be outside the influence of the surrounding pressure. Using the two pressure sensors upstream and downstream of the control valve, the flow is therefore standardized to a standard pressure difference. Otherwise, a change

in the pump power would result in a shift of the trend, for example. For the flow standardization $F_{Norm}$, the flow is divided by the square root of the pressure difference.

$$F_{Norm}(A) = \frac{F(A, \Delta p)}{\sqrt{\Delta p}} = \alpha A \sqrt{\frac{1}{\rho/2}}$$

| | |
|---|---|
| $F_{Norm}$ | *= normalized flow rate* |
| $F$ | *= flow rate* |
| $Q$ | *= valve cross-section* |
| $\Delta p$ | *= pressure drop* |
| $\rho$ | *= medium density* |
| $\alpha$ | *= volume flow coefficient* |

**(2) Operating point monitoring**

To diagnose damage to the interior of the valve, the set flow characteristic curve is compared to the current operating point (`siFlow.Value` and `Rbk.Value`) and an automatic acquired actual characteristic curve. If the deviation of the operating point from the set trend is within the defined tolerance (`FlowTol`), the operating point lights up green. Otherwise, excessive deviation is visualized by the pixel color switching to red.

Mechanical damage and caking inside the valve result in a change of the cross-section of the valve opening. The result is an altered flow with the same valve position. If the current operating point is below the characteristic curve, the current flow is too low for the valve position and, for example, caking or blockage is indicated. If, however, the operating point is above the characteristic curve, material is missing in the valve. This may be a sign of material loss due to cavitation, rust or a fracture in the valve plug. In addition to mechanical damage, flow monitoring can also be used for early detection of blockage and routing of solids.

Operating point monitoring thus detects a temporary deviation of the set characteristic curve and outputs both the absolute deviation (`DevFlow`) as well as the percentage deviation (`RelFlow`). When the maximum percentage deviation (`FlowTol`) is exceeded, the `FlowAct` output is activated.

**(3) Automatic characteristic curve detection**

Automatic characteristic curve detection has many advantages and opens up new possibilities for monitoring. It can be used to reduce the engineering workload required to commission the VlvMon block. Characteristic curve detection during ongoing operation also makes it easier to recognize trends.

The benefits it provides can be divided into two areas:

- Commissioning: Learning in the characteristic curve in good valve state and setting the automatically detected actual characteristic curve as the set characteristic curve.
- Monitoring during production: Acquiring the actual characteristic curve for drift detection (comparison of two characteristic curves).

The block monitors the various input variables. The new measured values are collected and form the basis of an actual characteristic curve which is as up-to-date as possible. The SteadyState block is used to detect steady measured values. (See SteadyState in the online help)

The automatically detected flow characteristic curve consists of 20 interpolation points (`ActFlow1...ActFlow20`, `ActVlvPos1...ActVlvPos20`). Each interpolation point is formed from the mean of up to 5 measured values. This mean value generation reduces the influence of individual outliers and measurement inaccuracies.

In addition, this mean value generation is weighted according to the up-to-dateness of the individual measured values. New measured values therefore have a stronger influence than old ones. Considering the up-to-dateness always ensures good drift detection. The up-to-dateness of the 20 interpolation points is displayed by the corresponding dot size in the faceplate. Larger dots here represent more up-to-date measured values. This allows better evaluation of the characteristic curve by the operator.

If a valve position has not yet been reached and there is thus no measured value for this interpolation point, it is calculated by linear interpolation from the surrounding interpolation points. Its up-to-dateness is thereby set to the minimum value by the system and the corresponding point is invisible in the faceplate.

If no interpolation points have been configured for the set characteristic curve, the current actual characteristic curve can be adopted as the set characteristic curve (`Adopt_ActFlow = 1`). Individual interpolation points of the actual characteristic curve can also be used to re-adjust the set characteristic curve. If the actual characteristic curve should be detected again, the current actual characteristic curve needs to be deleted (`RstActFlowOp = 1`).

**(4) Drift detection**

Automatic characteristic curve detection provides the basis for long-term drift detection. In contrast to the operating point monitoring, it also detects deviations relating to larger ranges of valve positions and not only to the current valve position.

Here, the set characteristic curve is compared to the automatically detected actual characteristic curve. When `Feature` Bit 13 "Drift calculation flow characteristic curve active" is set, the block calculates the absolute area between the two trends and returns the percentage deviation in relation to the set characteristic curve at the `RelFlowDrift` output. If the deviation between the two trends exceeds the configured tolerance `FlowDriftTol`, the `FlowDriftAct` output is activated.

## Reaction time characteristic curves

The reaction time corresponds to the time required for a valve to move to a desired valve position (except for a dead band). It depends on the step change of the setpoint. The greater the distance to be moved, the longer the reaction time. Slow valve motion results in a long reaction time. An increasing reaction time may therefore be a sign of increased friction in the valve's interior, for example. In addition, a leak in the compressed air supply results in slower valve movement. Damage to the valve drive can also be a cause for a change in valve reaction time.

Additionally, the reaction time depends on the valve's direction of movement. Different characteristic curves can result from positive steps compared to negative steps. This is explained by the fact that the valves are often operated by compressed air in one direction and by a spring

in the other direction. These two drive systems respond differently to errors and valve damage. This makes it necessary to include two different characteristic curves.

**Note**

Reaction times are determined only for setpoint changes, meaning that reaction time monitoring does not work for valve control by a higher-level controller (e.g. a flow controller) in automatic mode with constantly variable valve setpoints. In this case, a setpoint change must occasionally be specified in manual mode of the master controller in order to check the valve reaction time.

**(1) Operating point monitoring**

To diagnose damage of the valve drive or friction problems in the valve seal, the most recently detected positive and negative setpoint change as operating point (`T_RespUp` and `StepHiUp`; `T_RespDn` and `StepHiDn`) must be compared to the corresponding set reaction time characteristic curve. If this deviation from the set trend is within the defined tolerance, the operating point lights up green. Otherwise, excessive deviation is visualized by the pixel color switching to red.

Operating point monitoring detects a temporary deviation of the set characteristic curve and calculates both the absolute deviation (`DevRespUp`, `DevRespDn`) and the percentage deviation (`RelRespUp`, `RelRespDn`). When the maximum percentage deviation `RespTol` is exceeded, the `RespAct` output is activated.

**Note**

The calculated values for the relative and absolute deviation from the set characteristic curves are not shown in the faceplate.

**(2) Automatic characteristic curve detection**

Automatic characteristic curve detection is always active. The new measured values form the basis of an actual characteristic curve which is as up-to-date as possible. The automatically detected reaction time characteristic curves consist of 20 interpolation points:

- `ActStepHiUp1`...`ActStepHiUp20`, `ActRespUp1`...`ActRespUp20` for Open
- `ActStepHiDn1`...`ActStepHiDn20`, `ActRespDn1`...`ActRespDn20` for Close

Each interpolation point is formed from the mean of up to 5 measured values. This mean value generation reduces the influence of individual outliers and measurement inaccuracies.

If a setpoint step change has not yet been reached and there is therefore no measured value for this interpolation point, it is calculated by linear interpolation from the surrounding interpolation points.

If no interpolation points have been configured for the set characteristic curve, the current actual characteristic curve can be adopted as the set characteristic curve (`Adopt_ActResp = 1`). Individual interpolation points of the actual characteristic curve can also be used to re-adjust the

set characteristic curve. If the actual characteristic curve should be detected again, the current actual characteristic curve needs to be deleted (`RstActRespOp = 1`).

**Note**

The up-to-dateness of the measured interpolation points is not evaluated for the automatically detected reaction time characteristic curves.

**(3) Control deviation**

When the valve completes its motion after a setpoint change, its final position is compared to the set position. The difference represents the steady state control deviation. A steady state control deviation can have many different causes. Problems with the drive and the power supply are just as likely as temporary mechanical impairments.

If, after reaching the set position (PosReached = TRUE), the control deviation ER exceeds the configured tolerance `CtrlDevMax` for longer than the time specified by the `T_RespMax` parameter, the `CtrlDevMaxAct` output is enabled. Monitoring is reset as soon as a new setpoint change is detected.

## Monitoring functions

**(1) Maximum time in motion**

The block monitors the time in which the valve is in constant motion. For this, the maximum time for which the valve may move without a break is specified in [min] at the `T_MoveMax` parameter.

The current timer is sent to the `T_Move` output parameter. If the current timer exceeds the maximum value, the output parameter `T_MoveMaxAct` is activated.

The function can be deactivated with `T_MoveMax = 0`.

**(2) Maximum idle time**

The block monitors the time during which the valve remain still. For this, the maximum uninterrupted time for which the valve may remain still is specified in [min] at the `T_IdleMax` parameter.

The current timer is sent to the `T_Idle` output parameter. If the current timer exceeds the maximum value, the output parameter `T_IdleMaxAct` is activated.

The function can be deactivated with `T_IdleMax = 0`.

**(3) Valve strokes**

For the number of valve strokes, the distances traveled (%) with each valve movement (positive and negative) are added together. A stroke results from 100% valve movement. It is irrelevant whether the valve movement is performed only in the same range and in small steps. Movement from 0 to 50% and back is thus counted as one stroke, as well as 5 movements from 0 to 10% and back again.

If the number of strokes exceeds the maximum number set by the StrokesMax parameter, the output parameter StrokesMaxAct is activated.

The wear reserve is output in percent at the StrokesWearRes output parameter. The wear reserve is calculated as follows:

$$StrokesWearRes = \frac{StrokesMax - Strokes}{StrokesMax} \cdot 100$$

The function can be deactivated with StrokesMax = 0.

The input parameter RstStrokesOp = TRUE sets the Strokes = 0 parameter and the measurement starts again.

**(4) Direction change**

The current number of direction changes is stored in the SID parameter.

All changes of position feedback greater than the tolerance specified with the MoveTol parameter are tested for their effective direction and compared to the last known effective direction. If there is a difference, the direction change counter is increased by 1.

If the number of direction changes exceeds the maximum number set by the SID_Max parameter, the output parameter SID_MaxAct is activated.

The wear reserve is specified at the SID_WearRes output parameter. The wear reserve is calculated as follows:

$$SID_WearRes = \frac{SID_Max - SID}{SID_Max} \cdot 100$$

The function can be deactivated with SID_Max = 0.

SID = 0 is set with the input parameter RstSID_Op = TRUE.

**(5) External movement**

When the position setpoint MV no longer changes, the current feedback position is saved. If the position feedback Rbk of the valve then changes by more than the adjustable tolerance ExtMoveTol without another setpoint change (greater than MoveTol), the output parameter ExtMoveAct is activated.

The function can be deactivated with ExtMoveTol = 0.

**(6) High and low end stop**

The block monitors the valve for the high and low end stop. The position feedback Rbk is monitored here for the adjustable position limits VlvPosMin and VlvPosMax. If a limit is violated, the output parameter VlvPosMaxAct or VlvPosMinAct is activated.

The monitoring cannot be disabled.

The VlvPosHyst parameter can be used to specify the hysteresis for the limit violation.

The values for VlvPosMin and VlvPosMax must be specified during commissioning. For this, the respective end position is approached and the measured value of the position feedback is specified at the respective parameter. VlvPosMin and VlvPosMax then define the physical end positions at the time of commissioning.

**(7) Air supply pressure monitoring**

External air supply pressure monitoring can be interconnected at the SuppPres block input. An active signal (SuppPres = TRUE) is regarded as an error here. The signal in the block is only forwarded to the output parameter SuppPresAct. The signal is not processed further.

## Histograms

The histograms show the frequency distributions of the various valve positions or setpoint step changes over the entire travel range (0 to 100%) of the valve position as a bar graph.

The RstHisOp reset input is used to reset the counters and the total counters T_HisPos, CntHisStepUp and CntHisStepDn to zero and restart them.

**(1) Histogram for valve position**

This histogram shows the frequency of the various valve positions over the full range of the valve movement.

The valve position range 0...100% is divided into 10 equal sub-ranges. Each of these sub-ranges is assigned a counter for the duration of stay:

- HisPos1 corresponds to >0-10% valve position
- HisPos2 corresponds to 10-20% valve position
- HisPos3 corresponds to 20-30% valve position
- HisPos4 corresponds to 30-40% valve position
- HisPos5 corresponds to 40-50% valve position
- HisPos6 corresponds to 50-60% valve position
- HisPos7 corresponds to 60-70% valve position
- HisPos8 corresponds to 70-80% valve position
- HisPos9 corresponds to 80-90% valve position
- HisPos10 corresponds to 90-100% valve position

There is also a counter to indicate the "closed" status.

- HisPos0 corresponds to the "closed" state (FbkCloseOut.Value = TRUE)

The T_HisPos counter is incremented with the sampling time and specifies the monitoring duration in [h]. The individual counters are incremented on the basis of the position feedback. They indicate the operating time of the component in [%] of the recording period.

**Evaluation of the histogram:**

Valves should be operated predominantly in the middle section (10-90%) of their actuator travel, not at the extremes.

- If you notice strong clusters in a range of very small openings, the dimensions of the valve are too large. In a range of very small openings, the valve characteristic curve is not reproducible, making control difficult, and there is a danger of cavitation. In addition, an almost completely closed valve is associated with greater pressure loss due to the deflection and the flow through the narrow openings.
- If you notice strong clusters in a range of very large openings, the dimensions of the valve are too small. This means that a flow controller acting upon this with its manipulated variable has little room to affect positive setpoint changes. If the valve in its fully open state actually has a smaller cross-section than that of the pipe, eddying and pressure losses occur at the joint.

**(2) Histogram for positive and negative step changes**

This histogram shows the frequency of the various setpoint step changes over the complete range of possible positive and negative steps.

**Positive valve steps:**

The valve position range `0...100%` is divided into 10 equal sub-ranges. Each of these sub-ranges is assigned a counter for the corresponding step change:

- `HisStepHiUp1` corresponds to step change 0-10%
- `HisStepHiUp2` corresponds to step change 10-20%
- `HisStepHiUp3` corresponds to step change 20-30%
- `HisStepHiUp4` corresponds to step change 30-40%
- `HisStepHiUp5` corresponds to step change 40-50%
- `HisStepHiUp6` corresponds to step change 50-60%
- `HisStepHiUp7` corresponds to step change 60-70%
- `HisStepHiUp8` corresponds to step change 70-80%
- `HisStepHiUp9` corresponds to step change 80-90%
- `HisStepHiUp10` corresponds to step change 90-100%

The `CntHisStepUp` counter is incremented with each positive step detected and indicates the total number of positive steps. The individual counters are incremented on the basis of the current step change. They provide an overview of the distribution of positive steps in relation to the total number of steps.

**Negative valve steps:**

The valve position range `100...0%` is divided into 10 equal sub-ranges. Each of these sub-ranges is assigned a counter for the corresponding step change:

- `HisStepHiDn1` corresponds to step change 0 to -10%
- `HisStepHiDn2` corresponds to step change -10 to -20%
- `HisStepHiDn3` corresponds to step change -20 to -30%
- `HisStepHiDn4` corresponds to step change -30 to -40%

- `HisStepHiDn5` corresponds to step change -40 to -50%
- `HisStepHiDn6` corresponds to step change -50 to -60%
- `HisStepHiDn7` corresponds to step change -60 to -70%
- `HisStepHiDn8` corresponds to step change -70 to -80%
- `HisStepHiDn9` corresponds to step change -80 to -90%
- `HisStepHiDn10` corresponds to step change -90 to -100%

The `CntHisStepDn` counter is incremented with each negative step detected and indicates the total number of negative steps. The individual counters are incremented on the basis of the current step change. They provide an overview of the distribution of negative steps in relation to the total number of steps.

### 4.3.4 VlvMon functions

The functions for this block are listed below.

**Analyses and characteristic curve displays of the valve data and operating states**

- Set flow characteristic curve: generated by applying the actual characteristic measured automatically after commissioning. Display of the set flow depending on the valve position with standardized flow (i.e. flow converted to standard differential pressure)
- Display of the current operating point, the absolute and percentage deviation of the operating point from the set characteristic curve.
- Actual flow characteristic curve: Determined automatically during ongoing operation. Display of the actual flow depending on the valve position with standardized flow, enables the detection of characteristic curve shifts, calculation of the percentage deviation of the actual characteristic curve compared to the set characteristic curve.
- Set reaction time characteristic curves: generated by applying the actual characteristic measured automatically after commissioning. Display of the set valve reaction time depending on the step change for positive and negative setpoint changes
- Display of the last detected positive or negative setpoint change and calculation of the absolute and percentage deviation of the step changes of the set characteristic curve.
- Actual reaction time characteristic curves: Display of the actual valve reaction time depending on the step change for positive and negative setpoint changes; enables the detection of characteristic curve shifts.
- Histogram (frequency distribution of the valve settings): Statistical evaluation of valve positions.

### Diagnostic functions for each control valve with feedback of the valve position

The block offers the following basic diagnostic functions to warn operating personnel of adverse operating conditions or of wear limits being reached. These diagnostic functions do not detect valve errors in the strict sense. However, they do help prevent valve failure. They allow for better maintenance planning and detect when a valve has exceeded its expected service life:

- Monitoring the max. allowable operating hours in continuous standstill without valve movement → caking, encrustation.
- Monitoring the max. allowable operating hours in continuous operation without valve standstill → overload.
- Monitoring the max. allowable number of valve strokes → maintenance.
- Monitoring the max. allowable number of direction changes → maintenance.

The block also recognizes a faulty valve movement using the following diagnostic procedures. Here, the setpoint given by the positioner is compared to the actual feedback of the valve. This can be used to detect wear, caking, sluggishness, increased friction and other valve movement errors:

- Detection of valve movements without position commands → air pressure leakage or external mechanical influences.
- Shifting of the high and low end position → damage to the valve plug, point of origin shifting.
- Determination of a permanent control deviation after the valve movement → indication of problems in the drive, supply voltage or the air supply.
- Monitoring of the valve response time with reference to a set response time characteristic curve for each valve movement → sluggishness, damage to the valve drive.

### Advanced diagnostic functions with additional sensors

With additional sensors that may already be installed in the valve environment, the block can perform the following advanced diagnostic functions:

*- With additional pressure transducer on inlet and outlet side as well as flow sensor:*

- Operating point monitoring of the flow characteristic curve based on a set flow characteristic curve depending on the valve position → information on changing the valve cross-section due to caking or abrasion.
- Comparison of the automatically detected actual flow characteristic curve with the set flow characteristic curve for long-term drift detection → mechanical damage to the valve plug, caking, abrasion.

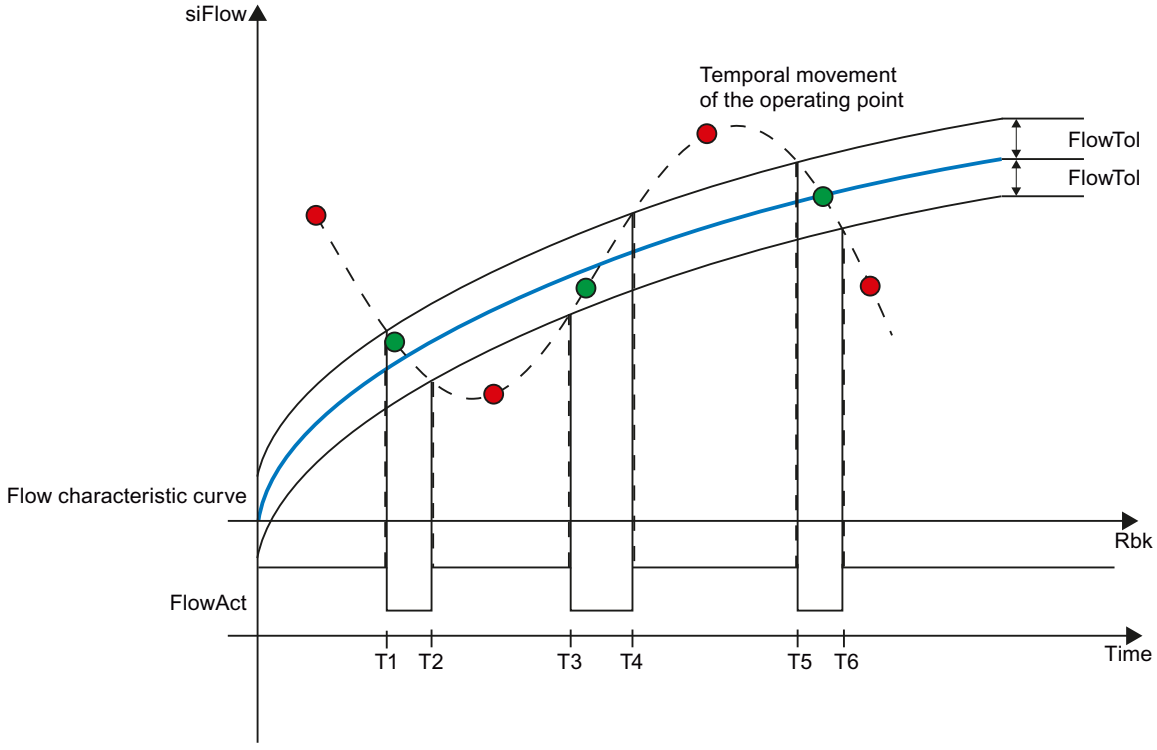
*- With additional supply compressed air sensor:*

- Monitoring the air supply pressure → leak in the compressed air supply.

### Teach functions

- Step-by-step learning of the set flow characteristic curve
- Step-by-step learning of the set reaction time characteristic curves

### Application cases / monitoring candidates



- Control valves that demonstrate above-average occurrence of malfunctions and wear.
- Control valves in which chemical deposits form.
- Control valves that have an inexplicable deviation with respect to its original flow and reaction time characteristic curves.

### Tolerance monitoring of the characteristic curves

The block monitors the deviation of the valve operating point from the flow characteristic curve and the reaction time characteristic curves for adjustable tolerances.

The functionality of the monitoring is based on the standard Limit monitoring (Page 93).

Monitoring the flow characteristic curve involves checking whether the operating point is within the tolerance range (see figure). If it is outside the tolerance range, the binary output variable FlowAct (i.e. "Flow Deviation Active") is set.

The characteristic curve monitoring for

- "Open" response time
- "Close" response time

checks whether the operating point, which is formed the most recently detected step, is within the tolerance range (see figure).

If the operating point leaves the tolerance range, the operating point in the faceplate changes its color from green to red and the corresponding output parameter is activated (`FlowAct`, `RespUpAct`, `RespDnActAct`).

## Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The signal status of the FbkCloseOut and FbkOpenOut outputs is formed from the worst signal status of the Rbk output and the corresponding feedback signal input FbkClose or FbkOpen and output.

The signal status of the valve position control deviation ER always corresponds to the signal status of the Rbk input.

The worst signal status ST_Worst for the block is formed from the following parameters:

- Rbk.ST
- Flow.ST
- P_In.ST
- P_Out.ST
- MV.ST
- FbkOpenOut.ST
- FbkCloseOut.ST

The signal states of the corresponding input measured values are used to form the signal status at the output end:

| Signal status | Derived from the signal status of the input variable |
|---|---|
| siFlow.ST | Flow.ST |
| siP_In.ST | P_In.ST |
| siP_Out.ST | P_Out.ST |

## Monitoring of feedback

This block provides the standard function Monitoring the feedbacks (Page 104).

Digital feedback signals for the "Open" and "Closed" positions are formed from the position feedback:

- Feedback for "Open" position: Rbk ≥ PosDiOpen
- Feedback for "Closed" position: Rbk ≤ PosDiClose

**Specifying control valve positions:**

There are the following positions or travel states:

- Valve closed ("Closed")
- Valve closes
- Valve open ("Open")
- Valve opens
- Valve has reached defined position

**Valve closed ("Closed")**

When the control valve reaches the "Close" position, `FbkCloseOut.Value = 1`:

- With a binary limit switch for the "Closed" position (`NoFbkClose = 0`):
  The valve is considered closed when `FbkCloseOut` is set. `FbkCloseOut` is set when `Rbk` ≤ `PosDiClose` and `FbkClose = 1`.
- Without a binary limit switch for the "Closed" position (`NoFbkClose = 1`):
  The valve is considered closed when FbkCloseOut is set. FbkCloseOut is set when Rbk ≤ PosDiClose.

**Valve closes**

If the control valve travels in the direction of the "Close" position, the `FbkClsgOut = 1` output is:

- `FbkClsgOut` is set when `MV.Value` < `RbkOut.Value` and not `PosReached.Value = 1`.

**Valve open ("Open")**

When the control valve reaches the "Open" position, the `FbkOpenOut.Value = 1` output is:

- With a binary limit switch for the "Open" position (`NoFbkOpen= 0`):
  The valve is considered open when `FbkOpenOut` is set. `FbkOpenOut` is set when `Rbk` ≥ `PosDiOpen` and `FbkOpen = 1`.
- Without a digital limit switch for the "Open" position (`NoFbkOpen = 1`):
  The valve is considered open when `FbkOpenOut` is set. `FbkOpenOut` is set when `Rbk` ≥ `PosDiOpen`.

**Valve opens**

If the control valve travels in the direction of the "Open" position, the output `FbkOpngOut = 1`:

- `FbkOpngOut` is set when `MV.Value` > `RbkOut.Value` and not `PosReached.Value = 1`.

**Valve has reached defined position**

If the control valve travels to a defined intermediate position (`MV >PosDiClose` and `MV<PosDiOpen`), the targeted position is reached when the difference `MV.Value`– `RbkOut.Value` is within the configured tolerance range ± `PosDeadBand` and therefore `ER.Value=0.0`.

If the control valve is set to the end position "Open" (`MV.Value >= PosDiOpen`), this position is reached when `ER.Value = 0.0` and also `FbkOpenOut.Value = 1`.

If the control valve is set to the end position "Open" (`MV.Value<= PosDiClose`), this position is reached when `ER.Value = 0.0` and also `FbkCloseOut.Value = 1`.

When the control valve reaches the specified position, the output `PosReached = 1` is set.

## Deactivate feedback

This block provides the standard function Disabling feedback for valves (Page 106). Feedback monitoring can be disabled separately for each feedback signal with `NoFbkOpen` or `NoFbkClose`.

### Selecting a unit of measurement

This block provides the standard function Selecting a unit of measure (Page 240).

### Configurable reactions using the "Feature" parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in section Configurable response using the Feature I/O (Page 139). The following modes of behavior are available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Setting the startup characteristics |
| 1 | Characteristics for the out of service mode |
| 10 | Flow characteristic curve active |
| 11 | "Open" response time characteristic curve active |
| 12 | "Close" response time characteristic curve active |
| 13 | Drift calculation flow characteristic curve active |
| 26 | Behavior of the switching points in "Out of service" mode |
| 28 | Disabling of switching points |
| 29 | Signaling limit violation |

### Operator control permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 – 5 | Not used |
| 6 | 1 = Operator can reset the histogram |
| 7 – 9 | Not used |
| 10 | 1 = Operator can adopt the current flow actual characteristic curve |
| 11 | 1 = Operator can reset the current flow actual characteristic curve |
| 12 | Not used |
| 13 | Not used |
| 14 | Not used |
| 15 | 1 = Operator can adopt the current reaction time actual characteristic curve |
| 16 | 1 = Operator can reset the current reaction time actual characteristic curve |
| 17 | Not used |
| 18 | Not used |
| 19 | 1 = Operator can reset the change of direction counter |

| Bit | Function |
|---|---|
| 20 | 1 = Operator can reset the stroke counter |
| 21 | Not used |
| 22 | Not used |
| 23 | 1 = Operator can change the characteristic curve values for the valve position |
| 24 | 1 = Operator can change the characteristic curve values for the flow |
| 25 | 1 = Operator can change the characteristic curve values for positive steps |
| 26 | 1 = Operator can change the characteristic curve values for negative steps |
| 27 | 1 = Operator can change the characteristic curve values for the reaction time for opening |
| 28 | 1 = Operator can change the characteristic curve value for the reaction time for closing |
| 29 | 1 = Operator can change the maximum reaction time |
| 30 – 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit for detection of a movement |
| 1 | 1 = Operator can change the limit for detection of the end position |
| 2 | 1 = Operator can change the limit for detection of an external movement |
| 3 | Not used |
| 4 | 1 = Operator can change the limit for the maximum time in motion |
| 5 | 1 = Operator can change the limit for the maximum idle time |
| 6 | 1 = Operator can change the limit for the maximum number of strokes |
| 7 | 1 = Operator can change the limit for the maximum number of changes of direction |
| 8 | Not used |
| 9 | Not used |
| 10 | Not used |
| 11 | Not used |
| 12 | Not used |
| 13 | Not used |
| 14 | Not used |
| 15 | 1 = Operator can change the limit for the deviation of the flow characteristic curve |
| 16 | 1 = Operator can change the limit for the deviation of the reaction time characteristic curve |
| 17 | Not used |
| 18 | Not used |
| 19 | Not used |
| 20 | Not used |
| 21 – 31 | Not used |

### Opening additional faceplates

You can open the standard view of the technological block (e.g. VlvAnL) interconnected to the input parameter MV using a button in the standard view of the faceplate. The interconnection makes the button in the standard view visible.

### SIMATIC BATCH functionality

This block does not support "SIMATIC BATCH functionality".

## 4.3.5 VlvMon error handling

The block overwrites the following parameters with 0 if they were configured with a negative value:

- FlowTol
- RespTol
- FlowCurveTol
- MoveTol
- ExtMoveTol
- DeadTol
- FinalTol
- StrokesMax
- SID_Max
- StepHiMax
- T_RespMax
- T_IdleMax
- T_MoveMax
- CtrlDevMax
- VlvPosHyst

### Overview of error numbers

The ErrorNum I/O can be used to output various error numbers:

| Error ID | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |

## 4.3.6 VlvMon messaging

### Message behavior

The VlvMon block does not generate messages or maintenance alarms. It simply provides several binary message outputs that are set when the permissible deviation is exceeded.

Messages may be generated for specific applications by a separate event block, and maintenance alarms by a downstream AssetMon block (included in the standard package of PCS 7). Events that are relevant for the plant operator can also be reported via interconnection of VlvMon message outputs to free message inputs of the associated VlvAnL.

## 4.3.7 I/Os of VlvMon

### I/Os of VlvMon

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Adopt_ActFlow | 1 = Adopt the current actual flow rate characteristic curve | BOOL | FALSE |
| Adopt_ActResp | 1 = Adopt the current actual response time characteristic curves | BOOL | FALSE |
| CtrlDevMax | Maximum control deviation | REAL | 0.0 |
| CycleTime | Time period in which a new measured value is used for calculation per interpolation point | TIME | T#5m |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| DeadActIn | 1 = Dead time monitoring active (available in a later version) | BOOL | FALSE |
| DeadTol | Tolerance for dead time monitoring (available in a later version) | REAL | 0.0 |
| ExtMoveTol | Tolerance for detection of an external movement | REAL | 0.0 |
| FbkClose | "1 = Valve closed feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkOpen | signal" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | 1 = Valve open feedback signal | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FinalTol | Tolerance for detecting the end position after a movement | REAL | 1.0 |
| Flow | Interconnectable input for the flow | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Flow1 | y value 1, flow [m³/h] | REAL | 1.0 |
| Flow10 | y value 10, flow [m³/h] | REAL | 100.0 |
| Flow11 | y value 11, flow [m³/h] | REAL | 121.0 |
| Flow12 | y value 12, flow [m³/h] | REAL | 144.0 |
| Flow13 | y value 13, flow [m³/h] | REAL | 169.0 |
| Flow14 | y value 14, flow [m³/h] | REAL | 196.0 |
| Flow15 | y value 15, flow [m³/h] | REAL | 225.0 |
| Flow16 | y value 16, flow [m³/h] | REAL | 256.0 |
| Flow17 | y value 17, flow [m³/h] | REAL | 289.0 |
| Flow18 | y value 18, flow [m³/h] | REAL | 324.0 |

| RespDn19 | y value 19, close response time [s] | REAL | 4.75 |
| RespDn2 | y value 2, close response time [s] | REAL | 0.5 |
| RespDn20 | y value 20, close response time [s] | REAL | 5.0 |
| RespDn3 | y value 3, close response time [s] | REAL | 0.75 |
| RespDn4 | y value 4, close response time [s] | REAL | 1.0 |
| RespDn5 | y value 5, close response time [s] | REAL | 1.25 |
| RespDn6 | y value 6, close response time [s] | REAL | 1.5 |
| RespDn7 | y value 7, close response time [s] | REAL | 1.75 |
| RespDn8 | y value 8, close response time [s] | REAL | 2.0 |
| RespDn9 | y value 9, close response time [s] | REAL | 2.25 |
| RespTol | Maximum deviation from the characteristic curves | REAL | 5.0 |
| RespUp1 | y value 1, open response time [s] | REAL | 0.5 |
| RespUp10 | y value 10, open response time [s] | REAL | 5.0 |
| RespUp11 | y value 11, open response time [s] | REAL | 5.5 |
| RespUp12 | y value 12, open response time [s] | REAL | 6.0 |
| RespUp13 | y value 13, open response time [s] | REAL | 6.5 |
| RespUp14 | y value 14, open response time [s] | REAL | 7.0 |
| RespUp15 | y value 15, open response time [s] | REAL | 7.5 |
| RespUp16 | y value 16, open response time [s] | REAL | 8.0 |
| RespUp17 | y value 17, open response time [s] | REAL | 8.5 |
| RespUp18 | y value 18, open response time [s] | REAL | 9.0 |
| RespUp19 | y value 19, open response time [s] | REAL | 9.5 |
| RespUp2 | y value 2, open response time [s] | REAL | 1.0 |
| RespUp20 | y value 20, open response time [s] | REAL | 10.0 |
| RespUp3 | y value 3, open response time [s] | REAL | 1.5 |
| RespUp4 | y value 4, open response time [s] | REAL | 2.0 |
| RespUp5 | y value 5, open response time [s] | REAL | 2.5 |
| RespUp6 | y value 6, open response time [s] | REAL | 3.0 |
| RespUp7 | y value 7, open response time [s] | REAL | 3.5 |
| RespUp8 | y value 8, open response time [s] | REAL | 4.0 |
| RespUp9 | y value 9, open response time [s] | REAL | 4.5 |
| RstActFlowOp* | 1 = Reset actual flow characteristic curve | BOOL | FALSE |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RstActRespOp* | 1 = Reset actual response time characteristic curves | BOOL | FALSE |
| RstHisOp* | 1 = Reset histograms | BOOL | FALSE |
| RstSID_Op* | 1 = Reset direction change counter | BOOL | FALSE |
| RstStrokesOp* | 1 = Reset stroke counter | BOOL | FALSE |
| RunUpCyc | Number of cycles during startup (not currently evaluated) | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SID_Max | Indicates the maximum number of direction changes | DINT | 0 |
| siFlowUnit | Unit of measure for the normalized flow | INT | 1349 |
| siP_Unit | Unit of measure for the normalized pressure | INT | 1137 |
| StepHiDn1 | x value 1, negative step change [%] | REAL | 5.0 |
| StepHiDn10 | x value 10, negative step change [%] | REAL | 50.0 |
| StepHiDn11 | x value 11, negative step change [%] | REAL | 55.0 |
| StepHiDn12 | x value 12, negative step change [%] | REAL | 60.0 |
| StepHiDn13 | x value 13, negative step change [%] | REAL | 65.0 |
| StepHiDn14 | x value 14, negative step change [%] | REAL | 70.0 |
| StepHiDn15 | x value 15, negative step change [%] | REAL | 75.0 |
| StepHiDn16 | x value 16, negative step change [%] | REAL | 80.0 |
| StepHiDn17 | x value 17, negative step change [%] | REAL | 85.0 |
| StepHiDn18 | x value 18, negative step change [%] | REAL | 90.0 |
| StepHiDn19 | x value 19, negative step change [%] | REAL | 95.0 |
| StepHiDn2 | x value 2, negative step change [%] | REAL | 10.0 |
| StepHiDn20 | x value 20, negative step change [%] | REAL | 100.0 |
| StepHiDn3 | x value 3, negative step change [%] | REAL | 15.0 |
| StepHiDn4 | x value 4, negative step change [%] | REAL | 20.0 |
| StepHiDn5 | x value 5, negative step change [%] | REAL | 25.0 |
| StepHiDn6 | x value 6, negative step change [%] | REAL | 30.0 |
| StepHiDn7 | x value 7, negative step change [%] | REAL | 35.0 |
| StepHiDn8 | x value 8, negative step change [%] | REAL | 40.0 |
| StepHiDn9 | x value 9, negative step change [%] | REAL | 45.0 |
| StepHiMax | Maximum step change (indicates the maximum value for the x-axes) | REAL | 100.0 |
| StepHiUp1 | x value 1, positive step change [%] | REAL | 5.0 |
| StepHiUp10 | x value 10, positive step change [%] | REAL | 50.0 |
| StepHiUp11 | x value 11, positive step change [%] | REAL | 55.0 |
| StepHiUp12 | x value 12, positive step change [%] | REAL | 60.0 |
| StepHiUp13 | x value 13, positive step change [%] | REAL | 65.0 |
| StepHiUp14 | x value 14, positive step change [%] | REAL | 70.0 |
| StepHiUp15 | x value 15, positive step change [%] | REAL | 75.0 |
| StepHiUp16 | x value 16, positive step change [%] | REAL | 80.0 |
| StepHiUp17 | x value 17, positive step change [%] | REAL | 85.0 |
| StepHiUp18 | x value 18, positive step change [%] | REAL | 90.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| StepHiUp19 | x value 19, positive step change [%] | REAL | 95.0 |
| StepHiUp2 | x value 2, positive step change [%] | REAL | 10.0 |
| StepHiUp20 | x value 20, positive step change [%] | REAL | 100.0 |
| StepHiUp3 | x value 3, positive step change [%] | REAL | 15.0 |
| StepHiUp4 | x value 4, positive step change [%] | REAL | 20.0 |
| StepHiUp5 | x value 5, positive step change [%] | REAL | 25.0 |
| StepHiUp6 | x value 6, positive step change [%] | REAL | 30.0 |
| StepHiUp7 | x value 7, positive step change [%] | REAL | 35.0 |
| StepHiUp8 | x value 8, positive step change [%] | REAL | 40.0 |
| StepHiUp9 | x value 9, positive step change [%] | REAL | 45.0 |
| StrokesMax | Indicates the maximum number of complete valve strokes | DINT | 0 |
| SuppPres | Connected to air supply pressure monitoring; 1 = Error | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| T_IdleMax | Indicates the maximum time for continuous standstill | DINT | 0 |
| T_MoveMax | Indicates the maximum time for continuous motion | DINT | 0 |
| T_RespMax | Maximum response time (indicates the maximum value for the y-axis) | REAL | 20.0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| VlvPos1 | x value 1, valve position | REAL | 5.0 |
| VlvPos10 | x value 10, valve position | REAL | 50.0 |
| VlvPos11 | x value 11, valve position | REAL | 55.0 |
| VlvPos12 | x value 12, valve position | REAL | 60.0 |
| VlvPos13 | x value 13, valve position | REAL | 65.0 |
| VlvPos14 | x value 14, valve position | REAL | 70.0 |
| VlvPos15 | x value 15, valve position | REAL | 75.0 |
| VlvPos16 | x value 16, valve position | REAL | 80.0 |
| VlvPos17 | x value 17, valve position | REAL | 85.0 |
| VlvPos18 | x value 18, valve position | REAL | 90.0 |
| VlvPos19 | x value 19, valve position | REAL | 95.0 |
| VlvPos2 | x value 2, valve position | REAL | 10.0 |
| VlvPos20 | x value 20, valve position | REAL | 100.0 |
| VlvPos3 | x value 3, valve position | REAL | 15.0 |
| VlvPos4 | x value 4, valve position | REAL | 20.0 |
| VlvPos5 | x value 5, valve position | REAL | 25.0 |
| VlvPos6 | x value 6, valve position | REAL | 30.0 |
| VlvPos7 | x value 7, valve position | REAL | 35.0 |
| VlvPos8 | x value 8, valve position | REAL | 40.0 |
| VlvPos9 | x value 9, valve position | REAL | 45.0 |
| VlvPosHyst | Indicates the hysteresis of the valve position [%] | REAL | 0.1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| VlvPosMax | Indicates the feedback value at the upper stop of the valve at the time of commissioning | REAL | 100.0 |
| VlvPosMin | Indicates the feedback value at the bottom stop of the valve at the time of commissioning | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AccFlowPoint 1 | y value 1, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 2 | y value 2, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 3 | y value 3, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 4 | y value 4, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 5 | y value 5, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 6 | y value 6, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 7 | y value 7, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 8 | y value 8, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 9 | y value 9, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 10 | y value 10, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 11 | y value 11, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 12 | y value 12, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 13 | y value 13, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 14 | y value 14, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 15 | y value 15, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 16 | y value 16, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 17 | y value 17, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint 18 | y value 18, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AccFlowPoint19 | y value 19, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| AccFlowPoint20 | y value 20, up-to-dateness of the actual flow characteristic curve | REAL | 1.0 |
| ActFlow1 | y value 1, actual flow characteristic curve | REAL | 1.0 |
| ActFlow2 | y value 2, actual flow characteristic curve | REAL | 2.0 |
| ActFlow3 | y value 3, actual flow characteristic curve | REAL | 3.0 |
| ActFlow4 | y value 4, actual flow characteristic curve | REAL | 4.0 |
| ActFlow5 | y value 5, actual flow characteristic curve | REAL | 5.0 |
| ActFlow6 | y value 6, actual flow characteristic curve | REAL | 6.0 |
| ActFlow7 | y value 7, actual flow characteristic curve | REAL | 7.0 |
| ActFlow8 | y value 8, actual flow characteristic curve | REAL | 8.0 |
| ActFlow9 | y value 9, actual flow characteristic curve | REAL | 9.0 |
| ActFlow10 | y value 10, actual flow characteristic curve | REAL | 10.0 |
| ActFlow11 | y value 11, actual flow characteristic curve | REAL | 11.0 |
| ActFlow12 | y value 12, actual flow characteristic curve | REAL | 12.0 |
| ActFlow13 | y value 13, actual flow characteristic curve | REAL | 13.0 |
| ActFlow14 | y value 14, actual flow characteristic curve | REAL | 14.0 |
| ActFlow15 | y value 15, actual flow characteristic curve | REAL | 15.0 |
| ActFlow16 | y value 16, actual flow characteristic curve | REAL | 16.0 |
| ActFlow17 | y value 17, actual flow characteristic curve | REAL | 17.0 |
| ActFlow18 | y value 18, actual flow characteristic curve | REAL | 18.0 |
| ActFlow19 | y value 19, actual flow characteristic curve | REAL | 19.0 |
| ActFlow20 | y value 20, actual flow characteristic curve | REAL | 20.0 |
| ActRespDn1 | y value 1, actual close response time characteristic curve [s] | REAL | 0.0 |
| ActRespDn2 | y value 2, actual close response time characteristic curve [s] | REAL | 1.0 |
| ActRespDn3 | y value 3, actual close response time characteristic curve [s] | REAL | 2.0 |
| ActRespDn4 | y value 4, actual close response time characteristic curve [s] | REAL | 3.0 |
| ActRespDn5 | y value 5, actual close response time characteristic curve [s] | REAL | 4.0 |
| ActRespDn6 | y value 6, actual close response time characteristic curve [s] | REAL | 5.0 |
| ActRespDn7 | y value 7, actual close response time characteristic curve [s] | REAL | 6.0 |
| ActRespDn8 | y value 8, actual close response time characteristic curve [s] | REAL | 7.0 |
| ActRespDn9 | y value 9, actual close response time characteristic curve [s] | REAL | 8.0 |
| ActRespDn10 | y value 10, actual close response time characteristic curve [s] | REAL | 9.0 |
| ActRespDn11 | y value 11, actual close response time characteristic curve [s] | REAL | 10.0 |
| ActRespDn12 | y value 12, actual close response time characteristic curve [s] | REAL | 11.0 |
| ActRespDn13 | y value 13, actual close response time characteristic curve [s] | REAL | 12.0 |
| ActRespDn14 | y value 14, actual close response time characteristic curve [s] | REAL | 13.0 |
| ActRespDn15 | y value 15, actual close response time characteristic curve [s] | REAL | 14.0 |
| ActRespDn16 | y value 16, actual close response time characteristic curve [s] | REAL | 15.0 |
| ActRespDn17 | y value 17, actual close response time characteristic curve [s] | REAL | 16.0 |
| ActRespDn18 | y value 18, actual close response time characteristic curve [s] | REAL | 17.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActRespDn19 | y value 19, actual close response time characteristic curve [s] | REAL | 18.0 |
| ActRespDn20 | y value 20, actual close response time characteristic curve [s] | REAL | 19.0 |
| ActRespUp1 | y value 1, actual open response time characteristic curve [s] | REAL | 0.0 |
| ActRespUp2 | y value 2, actual open response time characteristic curve [s] | REAL | 1.0 |
| ActRespUp3 | y value 3, actual open response time characteristic curve [s] | REAL | 2.0 |
| ActRespUp4 | y value 4, actual open response time characteristic curve [s] | REAL | 3.0 |
| ActRespUp5 | y value 5, actual open response time characteristic curve [s] | REAL | 4.0 |
| ActRespUp6 | y value 6, actual open response time characteristic curve [s] | REAL | 5.0 |
| ActRespUp7 | y value 7, actual open response time characteristic curve [s] | REAL | 6.0 |
| ActRespUp8 | y value 8, actual open response time characteristic curve [s] | REAL | 7.0 |
| ActRespUp9 | y value 9, actual open response time characteristic curve [s] | REAL | 8.0 |
| ActRespUp10 | y value 10, actual open response time characteristic curve [s] | REAL | 9.0 |
| ActRespUp11 | y value 11, actual open response time characteristic curve [s] | REAL | 10.0 |
| ActRespUp12 | y value 12, actual open response time characteristic curve [s] | REAL | 11.0 |
| ActRespUp13 | y value 13, actual open response time characteristic curve [s] | REAL | 12.0 |
| ActRespUp14 | y value 14, actual open response time characteristic curve [s] | REAL | 13.0 |
| ActRespUp15 | y value 15, actual open response time characteristic curve [s] | REAL | 14.0 |
| ActRespUp16 | y value 16, actual open response time characteristic curve [s] | REAL | 15.0 |
| ActRespUp17 | y value 17, actual open response time characteristic curve [s] | REAL | 16.0 |
| ActRespUp18 | y value 18, actual open response time characteristic curve [s] | REAL | 17.0 |
| ActRespUp19 | y value 19, actual open response time characteristic curve [s] | REAL | 18.0 |
| ActRespUp20 | y value 20, actual open response time characteristic curve [s] | REAL | 19.0 |
| ActStepHiDn1 | x value 1, actual close response time characteristic curve | REAL | 5.0 |
| ActStepHiDn2 | x value 2, actual close response time characteristic curve | REAL | 10.0 |
| ActStepHiDn3 | x value 3, actual close response time characteristic curve | REAL | 15.0 |
| ActStepHiDn4 | x value 4, actual close response time characteristic curve | REAL | 20.0 |
| ActStepHiDn5 | x value 5, actual close response time characteristic curve | REAL | 25.0 |
| ActStepHiDn6 | x value 6, actual close response time characteristic curve | REAL | 30.0 |
| ActStepHiDn7 | x value 7, actual close response time characteristic curve | REAL | 35.0 |
| ActStepHiDn8 | x value 8, actual close response time characteristic curve | REAL | 40.0 |
| ActStepHiDn9 | x value 9, actual close response time characteristic curve | REAL | 45.0 |
| ActStepHiDn10 | x value 10, actual close response time characteristic curve | REAL | 50.0 |
| ActStepHiDn11 | x value 11, actual close response time characteristic curve | REAL | 55.0 |
| ActStepHiDn12 | x value 12, actual close response time characteristic curve | REAL | 60.0 |
| ActStepHiDn13 | x value 13, actual close response time characteristic curve | REAL | 65.0 |
| ActStepHiDn14 | x value 14, actual close response time characteristic curve | REAL | 70.0 |
| ActStepHiDn15 | x value 15, actual close response time characteristic curve | REAL | 75.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActStepHiDn16 | x value 16, actual close response time characteristic curve | REAL | 80.0 |
| ActStepHiDn17 | x value 17, actual close response time characteristic curve | REAL | 85.0 |
| ActStepHiDn18 | x value 18, actual close response time characteristic curve | REAL | 90.0 |
| ActStepHiDn19 | x value 19, actual close response time characteristic curve | REAL | 95.0 |
| ActStepHiDn20 | x value 20, actual close response time characteristic curve | REAL | 100.0 |
| ActStepHiUp1 | x value 1, actual open response time characteristic curve | REAL | 5.0 |
| ActStepHiUp2 | x value 2, actual open response time characteristic curve | REAL | 10.0 |
| ActStepHiUp3 | x value 3, actual open response time characteristic curve | REAL | 15.0 |
| ActStepHiUp4 | x value 4, actual open response time characteristic curve | REAL | 20.0 |
| ActStepHiUp5 | x value 5, actual open response time characteristic curve | REAL | 25.0 |
| ActStepHiUp6 | x value 6, actual open response time characteristic curve | REAL | 30.0 |
| ActStepHiUp7 | x value 7, actual open response time characteristic curve | REAL | 35.0 |
| ActStepHiUp8 | x value 8, actual open response time characteristic curve | REAL | 40.0 |
| ActStepHiUp9 | x value 9, actual open response time characteristic curve | REAL | 45.0 |
| ActStepHiUp10 | x value 10, actual open response time characteristic curve | REAL | 50.0 |
| ActStepHiUp11 | x value 11, actual open response time characteristic curve | REAL | 55.0 |
| ActStepHiUp12 | x value 12, actual open response time characteristic curve | REAL | 60.0 |
| ActStepHiUp13 | x value 13, actual open response time characteristic curve | REAL | 65.0 |
| ActStepHiUp14 | x value 14, actual open response time characteristic curve | REAL | 70.0 |
| ActStepHiUp15 | x value 15, actual open response time characteristic curve | REAL | 75.0 |
| ActStepHiUp16 | x value 16, actual open response time characteristic curve | REAL | 80.0 |
| ActStepHiUp17 | x value 17, actual open response time characteristic curve | REAL | 85.0 |
| ActStepHiUp18 | x value 18, actual open response time characteristic curve | REAL | 90.0 |
| ActStepHiUp19 | x value 19, actual open response time characteristic curve | REAL | 95.0 |
| ActStepHiUp20 | x value 20, actual open response time characteristic curve | REAL | 100.0 |
| ActVlvPos1 | x value 1, actual flow characteristic curve | REAL | 0.0 |
| ActVlvPos2 | x value 2, actual flow characteristic curve | REAL | 5.0 |
| ActVlvPos3 | x value 3, actual flow characteristic curve | REAL | 10.0 |
| ActVlvPos4 | x value 4, actual flow characteristic curve | REAL | 20.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActVlvPos5 | x value 5, actual flow characteristic curve | REAL | 25.0 |
| ActVlvPos6 | x value 6, actual flow characteristic curve | REAL | 30.0 |
| ActVlvPos7 | x value 7, actual flow characteristic curve | REAL | 35.0 |
| ActVlvPos8 | x value 8, actual flow characteristic curve | REAL | 40.0 |
| ActVlvPos9 | x value 9, actual flow characteristic curve | REAL | 45.0 |
| ActVlvPos10 | x value 10, actual flow characteristic curve | REAL | 50.0 |
| ActVlvPos11 | x value 11, actual flow characteristic curve | REAL | 55.0 |
| ActVlvPos12 | x value 12, actual flow characteristic curve | REAL | 60.0 |
| ActVlvPos13 | x value 13, actual flow characteristic curve | REAL | 65.0 |
| ActVlvPos14 | x value 14, actual flow characteristic curve | REAL | 70.0 |
| ActVlvPos15 | x value 15, actual flow characteristic curve | REAL | 75.0 |
| ActVlvPos16 | x value 16, actual flow characteristic curve | REAL | 80.0 |
| ActVlvPos17 | x value 17, actual flow characteristic curve | REAL | 85.0 |
| ActVlvPos18 | x value 18, actual flow characteristic curve | REAL | 90.0 |
| ActVlvPos19 | x value 19, actual flow characteristic curve | REAL | 95.0 |
| ActVlvPos20 | x value 20, actual flow characteristic curve | REAL | 100.0 |
| CntHisStepDn | Indicates the number of negative steps | DINT | 0 |
| CntHisStepUp | Indicates the number of positive steps | DINT | 0 |
| CtrlDevMaxAct | 1 = Maximum deviation between end position reached and setpoint exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadAct | 1 = Dead time monitoring active (available in a later version) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadTolOut | Tolerance for dead time monitoring (available in a later version) | REAL | 0.0 |
| DevFlow | Deviation from the set flow characteristic curve | REAL | 0.0 |
| DevRespDn | Deviation from the set close response time characteristic curve | REAL | 0.0 |
| DevRespUp | Deviation from the set open response time characteristic curve | REAL | 0.0 |
| ER | Manipulated variable difference | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ErrorNum | Output of the existing error number. For error numbers that can be output by this block, see VlvMon error handling (Page 581). | INT | -1 |
| ExtMoveAct | 1 = External movement detected | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkCloseOut | 1 = Control valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkClsgOut | Control valve closing feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpenOut | 1 = Control valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpngOut | Control valve opening feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FinalPos | End position reached after a valve movement | REAL | 0.0 |
| FlowAct | 1 = Deviation from the set flow characteristic curve is too large | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FlowDriftAct | 1 = Deviation between set flow and actual flow characteristic curve is too large | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| HisPos0 | Indicates the time in closed status [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos1 | Indicates the duration of stay in the valve position range 0-10% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos2 | Indicates the duration of stay in the valve position range 10-20% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos3 | Indicates the duration of stay in the valve position range 20-30% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos4 | Indicates the duration of stay in the valve position range 30-40% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos5 | Indicates the duration of stay in the valve position range 40-50% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos6 | Indicates the duration of stay in the valve position range 50-60% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos7 | Indicates the duration of stay in the valve position range 60-70% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos8 | Indicates the duration of stay in the valve position range 70-80% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos9 | Indicates the duration of stay in the valve position range 80-90% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisPos10 | Indicates the duration of stay in the valve position range 90-100% [%] (with reference to T_HisPos) | REAL | 0.0 |
| HisStepHiDn1 | Indicates the number of negative steps in the step change range 0-10% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn2 | Indicates the number of negative steps in the step change range 10-20% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn3 | Indicates the number of negative steps in the step change range 20-30% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn4 | Indicates the number of negative steps in the step change range 30-40% (with reference to CntHisStepDn) | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| HisStepHiDn5 | Indicates the number of negative steps in the step change range 40-50% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn6 | Indicates the number of negative steps in the step change range 50-60% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn7 | Indicates the number of negative steps in the step change range 60-70% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn8 | Indicates the number of negative steps in the step change range 70-80% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn9 | Indicates the number of negative steps in the step change range 80-90% (with reference to CntHisStepDn) | REAL | 0.0 |
| HisStepHiDn10 | Indicates the number of negative steps in the step change range 90-100% (with reference to CntHisStepDn) | REAL | 0.0 |

## 4.3.8 VlvMon block diagram

A block diagram is not provided for this block.

## 4.3.9 VlvMon additional information

### Relationship between measuring variables and diagnosable problems

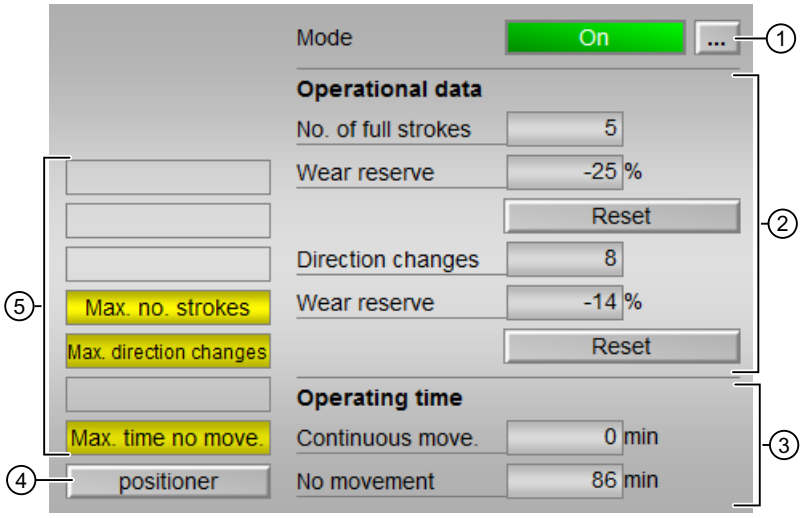
| | Flow | Pressure difference across the valve | Valve set position | Valve actual position |
|---|---|---|---|---|
| Time without movement | | | x | x |
| Time without standstill | | | x | x |
| Number of strokes | | | x | x |
| Directional reversal | | | x | x |
| External movement | | | x | x |
| Violation of high/low end stop | | | | x |

| | Flow | Pressure difference across the valve | Valve set position | Valve actual position |
|---|---|---|---|---|
| Reaction time characteristic curves | | | x | x |
| Deviation | | | x | x |
| Flow characteristic curve | x | x | | x |
| Histogram valve position | | | x | x |
| Histogram step changes | | | x | x |

Annotations:

x: Measured value required

## 4.3.10 Operator control and monitoring



### 4.3.10.1 VlvMon views

The VlvMon block provides the following views:

- Standard view of VlvMon (Page 598)
- Flow characteristic curve (Page 599)
- Reaction time characteristic curves (Page 601)
- Histogram (Page 604)
- Limit values (Page 606)
- Parameter view 1 (Page 608)
- Parameter view 2 (Page 610)
- Memo view (Page 338)
- Block icon for PumpMon (Page 612)

For general information on the faceplate and block icon, refer to the Structure of the faceplate (Page 279) and Block icon structure (Page 260).

### 4.3.10.2 VlvMon standard view

**(1) Display and switchover of operating mode**
This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On
- Out of service

**(2) Operating data**
This area shows the current number of full valve strokes (`Strokes`) and changes of direction (`SID`). In addition, the percentage of reserve for the maximum value (`StrokesWearRes`, `SID_WearRes`) is specified for the stroke and change of direction.

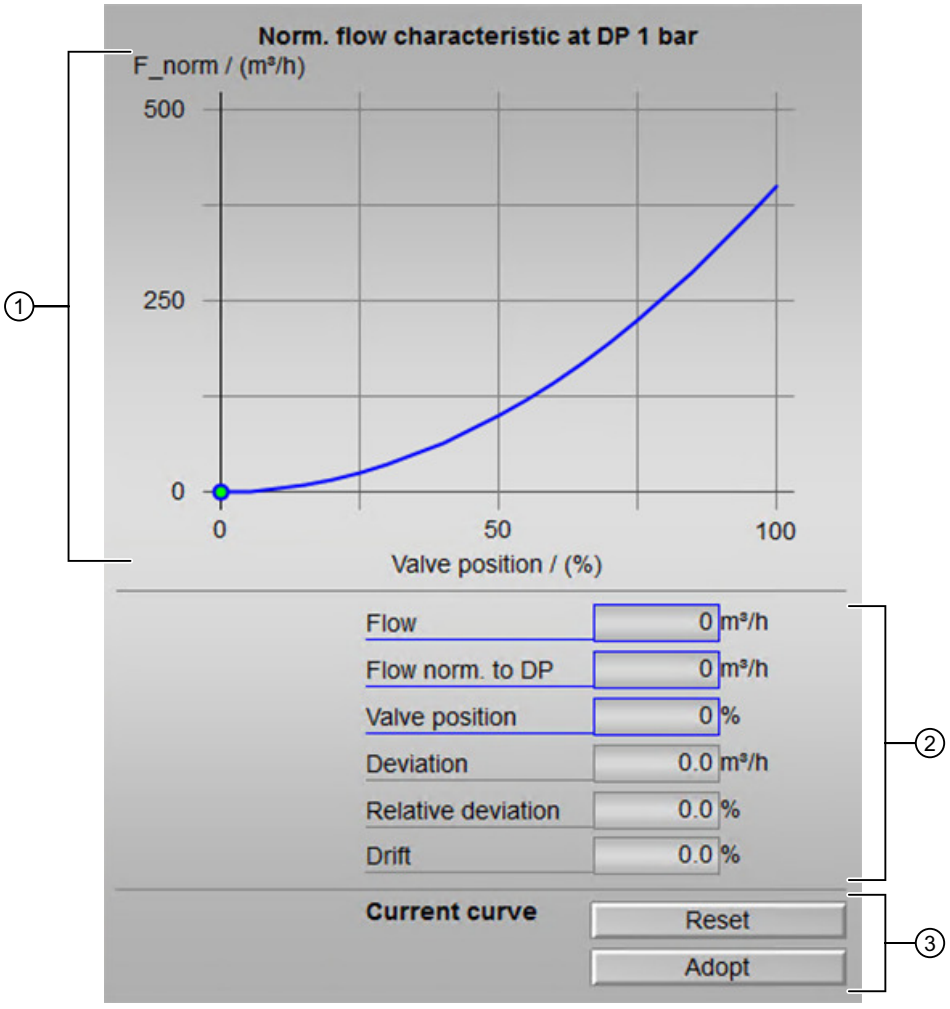
A reset button is provided in each case to reset the strokes (`RstStrokesOp`) and change of direction (`RstSID_Op`).

**(3) Operating time**

This area shows the currently calculated time of continuous movement (`T_Move`) and the continuous idle time (`T_Idle`). The values cannot be operated.

**(4) Navigation button for switching to the standard view of any faceplate**

This display is only visible when the corresponding `MV` block input is connected. Use this jump button to reach the standard view of the interconnected block.



**(5) Display area for block states**

This area provides additional information on the operating state of the block:

- External movement
- Deviation
- Supply pressure
- Max. number of strokes
- Max. direction changes

- End stop high / end stop low
- Max. idle time / max. movement time

### 4.3.10.3 VlvMon flow characteristic curve view

**(1) Display of flow characteristic curve with automatically detected actual characteristic curve**

The interpolation points for the set characteristic curve (solid blue line) are entered in the "Parameter 1" view.

The operating point continually shows the current standardized flow (`siFlow.Value`) for the current valve position (`Rbk.Value`).

If the distance between the current operating point and the set characteristic curve exceeds a specified tolerance (`FlowTol`), the color of the operating point changes from green to red and the corresponding output parameter (`FlowAct.Value`) is activated.

In addition to the set characteristic curve, the automatically detected actual characteristic curve is shown (dashed cyan line). The up-to-dateness of the characteristic curve is indicated by black dots. The larger a dot is shown, the more recent are the associated measured values. If a valve

position has not yet been approached and there is therefore no measured value for the corresponding interpolation point of the characteristic curve, no dot is shown.

The Y axis scaling is dynamic:

- Y: 0 -> `FlowMax` / 2-> `FlowMax`

The scaling of the X axis is static:

- X: 0 -> 50 % -> 100 %

**Note**

If `Feature.Bit10` "Flow characteristic curve active" = `FALSE`, the characteristic curves and the operating point are hidden.

**(2) Display of the characteristic values**

This area shows the following values:

- Flow (`Flow.Value`)
- Standardized flow (`siFlow.Value`)
- Valve position (`Rbk.Value`)
- Absolute deviation of the operating point from the set characteristic curve (`DevFlow`)
- Relative deviation of the operating point from the set characteristic curve (`RelFlow`)
- Relative deviation of the actual characteristic curve from the set characteristic curve (`RelFlowDrift`)

The values cannot be operated.

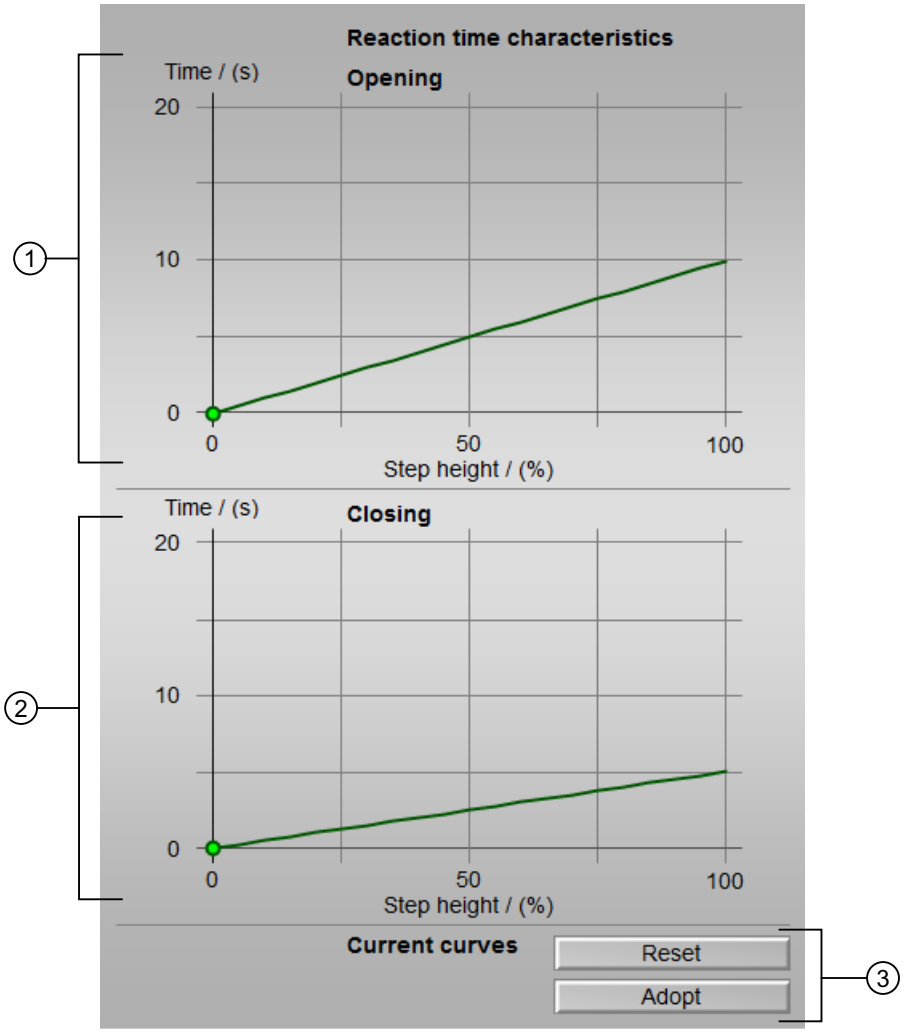
**Note**

No unit is displayed in the faceplate for the normalized flow. The unit of computation however would be $\frac{m^3/h}{\sqrt{bar}}$

**(3) Function for actual characteristic**
This area provides a button for adopting and a button for resetting the actual characteristic curve.

When the actual characteristic curve is adopted (`Adopt_ActFlow = 1`), the actual characteristic curve is written to the corresponding set characteristic curve.

- `Flow1 … Flow20 = ActFlow1 … ActFlow20`
- `VlvPos1 … VlvPos20 = ActVlvPos1 … ActVlvPos20`



When the actual characteristic curve is reset (`Rst_ActFlow = 1`), the actual characteristic curve and the associated points for displaying the up-to-dateness are reset to zero.

- `ActFlow1 … ActFlow20= 0.0`
- `ActVlvPos1 … ActVlvPos20= 0.0`
- `AccFlowPoint1 … AccFlowPoint20 = 0.0`

**Note**

If `Feature.Bit10` "Flow characteristic curve active" = `FALSE`, the buttons for adopting and resetting the actual characteristic curve are disabled.

### 4.3.10.4 VlvMon reaction time characteristic curve view

**(1) Display of the response time characteristic with automatically detected "Open" actual characteristic**
The interpolation points for the set characteristic curve (solid dark green) are entered in the "Parameter 2" view.

The operating point shows the last detected positive setpoint change (`StepHiUp`, `T_RespUp`). It remains unchanged until a new step has been detected.

If the distance between the current operating point and the set characteristic curve exceeds a specified tolerance (`RespTol`), the color of the operating point changes from green to red and the corresponding output parameter (`RespUpAct.Value`) is activated.

In addition to the set characteristic curve, the automatically detected actual characteristic curve is shown (dashed green line).

The Y axis scaling is dynamic:

- Y: 0 -> `T_RespMax` / 2 -> `T_RespMax`

The scaling of the X axis is static:

- X: 0 -> 50 % -> 100 %

**Note**

If `Feature` Bit 11 "Response time characteristic curve "Open" active" = `FALSE`, the characteristic curves and the operating point are hidden.

**(2) Display of response time characteristic curve with automatically detected actual "Close" characteristic curve**

The interpolation points for the set characteristic curve (solid dark green) are entered in the "Parameter 2" view.

The operating point shows the last detected negative setpoint change (`StepHiDn`, `T_RespDn`). It remains unchanged until a new step has been detected.

If the distance between the current operating point and the set characteristic curve exceeds a specified tolerance (`RespTol`), the color of the operating point changes from green to red and the corresponding output parameter (`RespDnAct.Value`) is activated.

In addition to the set characteristic curve, the automatically detected actual characteristic curve is shown (dashed green line).

The Y axis scaling is dynamic:

- Y: 0 -> `T_RespMax` / 2 -> `T_RespMax`

The scaling of the X axis is static:

- X: 0 -> 50 % -> 100 %

**Note**

If `Feature` Bit 12 "Response time characteristic curve "Close" active" = `FALSE`, no characteristic curves or operating point are displayed.

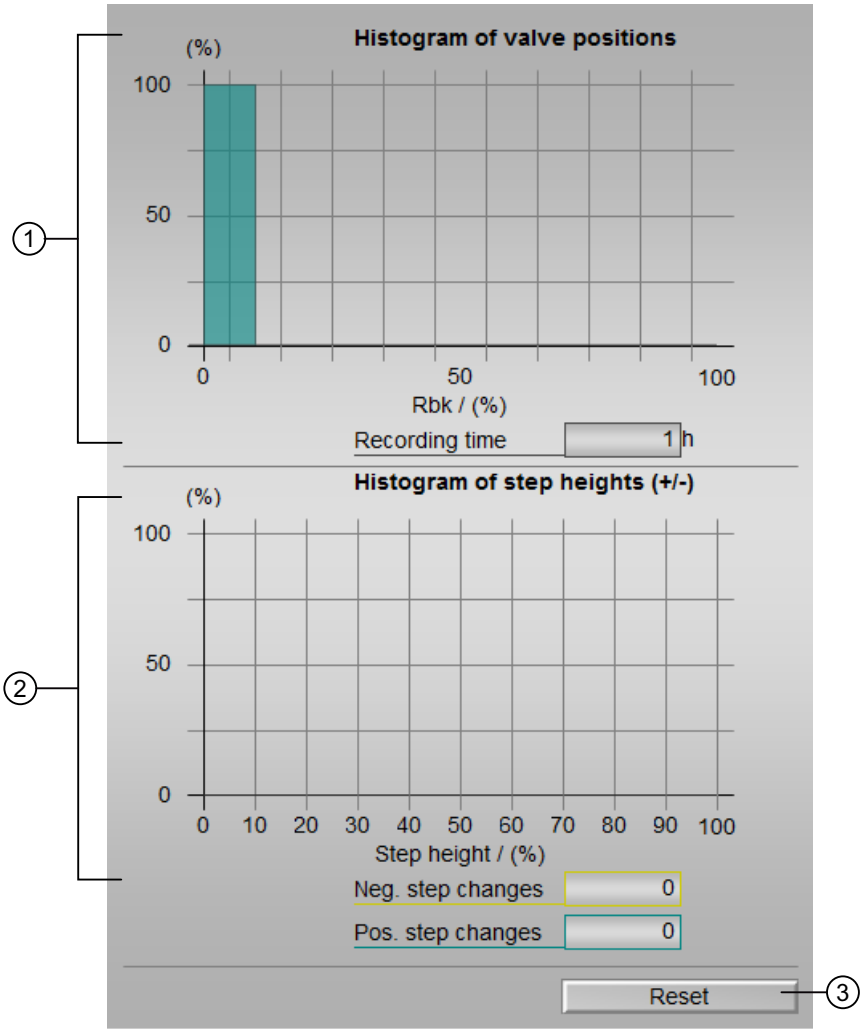
**(3) Functions for the actual characteristic curve**

This area provides a button for adopting and a button for resetting the actual characteristic curves.

When the actual characteristic curve is adopted (`Adopt_ActResp = 1`), the two actual characteristic curves are written to the corresponding set characteristic curves.

- `StepHiUp1 … StepHiUp20= ActStepHiUp1 … ActStepHiUp20`
- `RespUp1 … RespUp20= ActRespUp1 … ActRespUp20`
- `StepHiDn1 … StepHiDn20 = ActStepHiDn1 … ActStepHiDn20`
- `RespDn1 … RespDn20= ActRespDn1 … ActRespDn20`

When the actual characteristic curve is reset (`Rst_ActResp = 1`), the two actual characteristic curves are reset to zero



- `ActStepHiUp1 … ActStepHiUp20= 0.0`
- `ActRespUp1 … ActRespUp20= 0.0`
- `ActStepHiDn1 … ActStepHiDn20= 0.0`
- `ActRespDn1 … ActRespDn20= 0.0`

and the operating points are shifted to the point of origin.

**Note**

If `Feature` Bits 11 and 12 = `FALSE`, the buttons for adopting and resetting the actual characteristic curves are disabled.

### 4.3.10.5 VlvMon histogram view

The histograms show the frequency distributions of the various valve positions or setpoint step changes over the entire travel range (0 to 100%) of the valve position as a bar graph.

**(1) Histogram for valve position**

The histogram consists of a total of 11 bars. The first bar on the left of the Y axis (purple) designates the time in the closed state (`HisPos0`). The other 10 bars (cyan) divide the valve position range `0 ... 100%` into 10 equal sub-ranges. Each of these sub-ranges is assigned a counter for the duration of stay. The following rules apply:

- `HisPos1` corresponds to >0-10% valve position
- `HisPos2` corresponds to 10-20% valve position
- `HisPos3` corresponds to 20-30% valve position
- `HisPos4` corresponds to 30-40% valve position
- `HisPos5` corresponds to 40-50% valve position
- `HisPos6` corresponds to 50-60% valve position

- HisPos7 corresponds to 60-70% valve position
- HisPos8 corresponds to 70-80% valve position
- HisPos9 corresponds to 80-90% valve position
- HisPos10 corresponds to 90-100% valve position

The following applies to the counter which indicates the "closed" state:

- HisPos0 corresponds to the "closed" state (FbkCloseOut.Value = TRUE)

The scaling of the X and Y axis is static:

- X: 0 -> 50% -> 100%
- Y: 0 -> 50% -> 100%

The "Recording period:" field shows the period in [h] (T_HisPos) during which these statistics were gathered.

**(2) Histogram for step changes (+/-)**

This histogram consists of a total of 20 bars, 10 bars for positive steps (turquoise) and 10 bars for negative steps (yellow). The bars provide an overview in percentage of distribution in relation to the total number of positive and negative steps.

The valve position range 0...100% is divided into 10 equal sub-ranges. A bar is allocated to each of these sub-ranges for positive and negative steps in this range. The following applies to positive steps:

- HisStepHiUp1 corresponds to step change 0-10%
- HisStepHiUp2 corresponds to step change 10-20%
- HisStepHiUp3 corresponds to step change 20-30%
- HisStepHiUp4 corresponds to step change 30-40%
- HisStepHiUp5 corresponds to step change 40-50%
- HisStepHiUp6 corresponds to step change 50-60%
- HisStepHiUp7 corresponds to step change 60-70%
- HisStepHiUp8 corresponds to step change 70-80%
- HisStepHiUp9 corresponds to step change 80-90%
- HisStepHiUp10 corresponds to step change 90-100%

The following applies to negative steps:

- HisStepHiDn1 corresponds to step change 0 to -10%
- HisStepHiDn2 corresponds to step change -10 to -20%
- HisStepHiDn3 corresponds to step change -20 to -30%
- HisStepHiDn4 corresponds to step change -30 to -40%
- HisStepHiDn5 corresponds to step change -40 to -50%
- HisStepHiDn6 corresponds to step change -50 to -60%
- HisStepHiDn7 corresponds to step change -60 to -70%
- HisStepHiDn8 corresponds to step change -70 to -80%

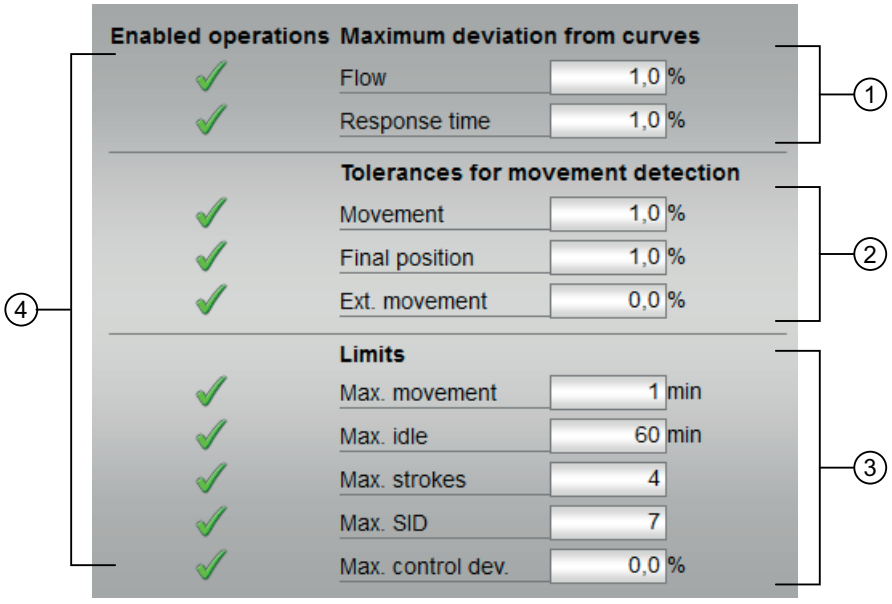
- `HisStepHiDn9` corresponds to step change -80 to -90%
- `HisStepHiDn10` corresponds to step change -90 to -100%

The scaling of the X and Y axis is static:

- X: 0 -> 50% -> 100%
- Y: 0 -> 50% -> 100%

The "No. pos. steps:" field shows the total number (`CntHisStepUp`) of positive steps.

The "No. pos. steps:" field shows the total number (`CntHisStepDN`) of negative steps.



**(3) Resetting the histogram data**

The reset button can be used to reset all the stored values to zero and restart.

**Note**

All collected statistics will be lost with this action!

### 4.3.10.6 VlvMon limit view

**(1) Maximum deviation from the characteristic curves**

In this area, you can enter the tolerances for the deviation from the characteristic curves.

You can change the following tolerances:

- "Flow:" Maximum deviation from the flow characteristic curve (`FlowTol`)
- "Response time": Maximum deviation from the reaction time characteristic curve (`RespTol`)

**(2) Tolerances for motion detection**

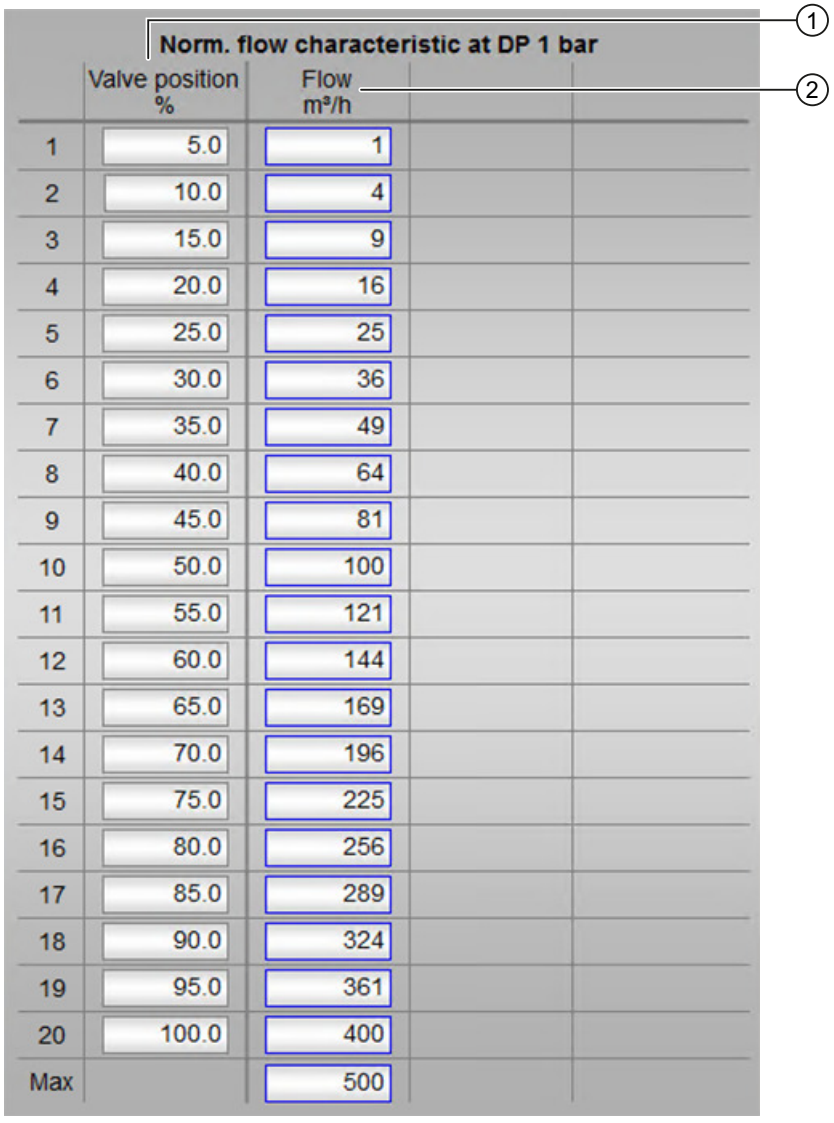
The following tolerances can be entered in this area:

- "Movement:" Tolerance for the detection of a valve movement (`MoveTol`)
- "Set position:" Tolerance for detection of the set position being reached (`FinalTol`)
- "External movement:" Tolerance for the detection of an external movement without setpoint change (`ExtMoveTol`)

**(3) Limits**

The following limits can be entered in this area:

- "Max. movement": Limit for the maximum movement time without standstill (`T_MoveMax`)
- "Max. idle": Limit for the maximum idle time without movement (`T_IdleMax`)
- "Max. number of strokes": Limit for the maximum number of full (100%) valve strokes (`StrokesMax`)
- "Max. direction changes": Limit for the maximum number of changes of direction (`SID_Max`)
- "Max. control deviation": Limit for the maximum control deviation after reaching the set position (`CtrlDevMax`)



**(4) Enabled operations**

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### 4.3.10.7 VlvMon parameter 1 view

| | Valve position % | Flow m³/h |
|---|---|---|
| 1 | 5.0 | 1 |
| 2 | 10.0 | 4 |
| 3 | 15.0 | 9 |
| 4 | 20.0 | 16 |
| 5 | 25.0 | 25 |
| 6 | 30.0 | 36 |
| 7 | 35.0 | 49 |
| 8 | 40.0 | 64 |
| 9 | 45.0 | 81 |
| 10 | 50.0 | 100 |
| 11 | 55.0 | 121 |
| 12 | 60.0 | 144 |
| 13 | 65.0 | 169 |
| 14 | 70.0 | 196 |
| 15 | 75.0 | 225 |
| 16 | 80.0 | 256 |
| 17 | 85.0 | 289 |
| 18 | 90.0 | 324 |
| 19 | 95.0 | 361 |
| 20 | 100.0 | 400 |
| Max | | 500 |

The interpolation points for the characteristic curve can be read from the data sheet and entered here.

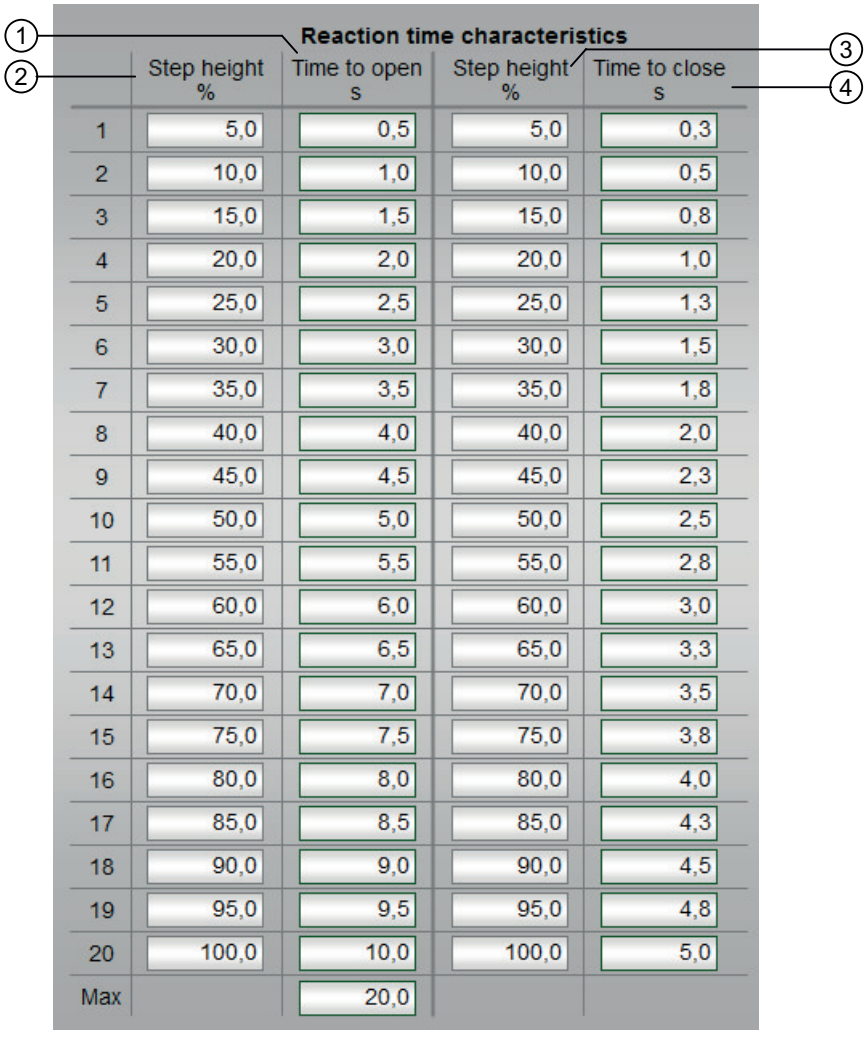
The fields for the characteristic curve interpolation points are enabled based on whether `Feature` Bit 10 "Flow characteristic curve active" is set.

**(1) Valve position parameters**

The 20 interpolation points of the valve positions provide the X axis for the flow characteristic curves. Here, each interpolation point is assigned to a valve position range. The following rules apply:

- `VlvPos1` corresponds to 0-5% valve position
- `VlvPos2` corresponds to 5-10% valve position
- `VlvPos3` corresponds to 10-15% valve position

- VlvPos4 corresponds to 15-20% valve position
- VlvPos5 corresponds to 20-25% valve position
- VlvPos6 corresponds to 25-30% valve position
- VlvPos7 corresponds to 30-35% valve position
- VlvPos8 corresponds to 35-40% valve position
- VlvPos9 corresponds to 40-45% valve position
- VlvPos10 corresponds to 45-50% valve position
- VlvPos11 corresponds to 50-55% valve position
- VlvPos12 corresponds to 55-60% valve position
- VlvPos13 corresponds to 60-65% valve position
- VlvPos14 corresponds to 65-70% valve position
- VlvPos15 corresponds to 70-75% valve position
- VlvPos16 corresponds to 75-80% valve position
- VlvPos17 corresponds to 80-85% valve position
- VlvPos18 corresponds to 85-90% valve position
- VlvPos19 corresponds to 90-95% valve position
- VlvPos20 corresponds to 95-100% valve position



The display is within the range:

```
0 <= VlvPos1 <= ... <= VlvPos20 <= 100%
```

**(2) Flow parameters**

The flow parameters Flow1 to Flow20, as well as the maximum value FlowMax, are specified in this area. Parameters that have the value 0 are ignored in the characteristic curve.

### 4.3.10.8 VlvMon parameter 2 view

| | Reaction time characteristics | | | |
|---|---|---|---|---|
| | Step height % | Time to open s | Step height % | Time to close s |
| 1 | 5,0 | 0,5 | 5,0 | 0,3 |
| 2 | 10,0 | 1,0 | 10,0 | 0,5 |
| 3 | 15,0 | 1,5 | 15,0 | 0,8 |
| 4 | 20,0 | 2,0 | 20,0 | 1,0 |
| 5 | 25,0 | 2,5 | 25,0 | 1,3 |
| 6 | 30,0 | 3,0 | 30,0 | 1,5 |
| 7 | 35,0 | 3,5 | 35,0 | 1,8 |
| 8 | 40,0 | 4,0 | 40,0 | 2,0 |
| 9 | 45,0 | 4,5 | 45,0 | 2,3 |
| 10 | 50,0 | 5,0 | 50,0 | 2,5 |
| 11 | 55,0 | 5,5 | 55,0 | 2,8 |
| 12 | 60,0 | 6,0 | 60,0 | 3,0 |
| 13 | 65,0 | 6,5 | 65,0 | 3,3 |
| 14 | 70,0 | 7,0 | 70,0 | 3,5 |
| 15 | 75,0 | 7,5 | 75,0 | 3,8 |
| 16 | 80,0 | 8,0 | 80,0 | 4,0 |
| 17 | 85,0 | 8,5 | 85,0 | 4,3 |
| 18 | 90,0 | 9,0 | 90,0 | 4,5 |
| 19 | 95,0 | 9,5 | 95,0 | 4,8 |
| 20 | 100,0 | 10,0 | 100,0 | 5,0 |
| Max | | 20,0 | | |

The interpolation points for the characteristic curves can be read from the data sheet and entered here.

The fields for the characteristic curve interpolation points (1 and 2) are enabled based on whether `Feature.Bit11` "Response time characteristic curve "Open" active" is set.

The fields for the characteristic curve interpolation points (3 and 4) are enabled based on whether `Feature.Bit12` "Response time characteristic curve "Close" active" is set.

**(1) Time UP**

The parameters `RespUp1` to `RespUp20`, as well as the maximum value `T_RespMax`, are specified in this area. Parameters that have the value 0 are ignored in the characteristic curve.

**(2) Step change UP**

The 20 interpolation points of the step change specify the x-axis for the response time characteristic curve "Open".

Here, each interpolation point is assigned to a step change range. The following rules apply:

- `StepHiUp1` corresponds to 0-5% valve step
- `StepHiUp2` corresponds to 5-10% valve step
- `StepHiUp3` corresponds to 10-15% valve step
- `StepHiUp4` corresponds to 15-20% valve step
- `StepHiUp5` corresponds to 20-25% valve step
- `StepHiUp6` corresponds to 25-30% valve step
- `StepHiUp7` corresponds to 30-35% valve step
- `StepHiUp8` corresponds to 35-40% valve step
- `StepHiUp9` corresponds to 40-45% valve step
- `StepHiUp10` corresponds to 45-50% valve step
- `StepHiUp11` corresponds to 50-55% valve step
- `StepHiUp12` corresponds to 55-60% valve step
- `StepHiUp13` corresponds to 60-65% valve step
- `StepHiUp14` corresponds to 65-70% valve step
- `StepHiUp15` corresponds to 70-75% valve step
- `StepHiUp16` corresponds to 75-80% valve step
- `StepHiUp17` corresponds to 80-85% valve step
- `StepHiUp18` corresponds to 85-90% valve step
- `StepHiUp19` corresponds to 90-95% valve step
- `StepHiUp20` corresponds to 95-100% valve step

The display is within the range:

```
0 <= StepHiUp1 <= ... <= StepHiUp20 <= 100%
```

**(3) Step change DOWN**

The 20 interpolation points of the step change provide the x-axis for the response time characteristic curve "Close".

Here, each interpolation point is assigned to a step change range. The following rules apply:

- `StepHiDn1` corresponds to 0 to -5% valve step
- `StepHiDn2` corresponds to -5 to -10% valve step
- `StepHiDn3` corresponds to -10 to -15% valve step
- `StepHiDn4` corresponds to -15 to -20% valve step
- `StepHiDn5` corresponds to -20 to -25% valve step
- `StepHiDn6` corresponds to -25 to -30% valve step
- `StepHiDn7` corresponds to -30 to -35% valve step
- `StepHiDn8` corresponds to -35 to -40% valve step

- StepHiDn9 corresponds to -40 to -45% valve step
- StepHiDn10 corresponds to -45 to -50% valve step
- StepHiDn11 corresponds to -50 to -55% valve step
- StepHiDn12 corresponds to -55 to -60% valve step
- StepHiDn13 corresponds to -60 to -65% valve step
- StepHiDn14 corresponds to -65 to -70% valve step
- StepHiDn15 corresponds to -70 to -75% valve step
- StepHiDn16 corresponds to -75 to -80% valve step
- StepHiDn17 corresponds to -80 to -85% valve step
- StepHiDn18 corresponds to -85 to -90% valve step
- StepHiDn19 corresponds to -90 to -95% valve step
- StepHiDn20 corresponds to -95 to -100% valve step

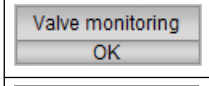
The display is within the range:

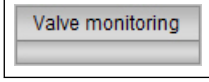
```
0 <= StepHiDn1 <= ... <= StepHiDn20 <= 100%
```

**(4) Time DOWN**

The parameters RespDn1 to RespDn20 are specified in this area. Parameters that have the value 0 are ignored in the characteristic curve.

**Note**





The maximum value of the response time characteristic curve "Open" also applies for this characteristic curve.

### 4.3.10.9 Block icon for VlvMon

A block icon with the following displays is available to you:

- Block type or process tag
- Operating modes
- Status of the valve from the view of the valve monitoring.

The block icon from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in full display in the normal state |
|  | 1 | Block icon in full display when at least one error output is active |
|  | | Block icon in the "Out of service" operating mode |

In a control panel for the plant operator, it may be useful to make valve monitoring available via a shortcut from the valve faceplate, and place the block icon for the valve monitoring in only one maintenance view of the plant.

You can find additional information about the block icon and the operator control options in the block icon in the following sections:

- "Configuring the block icons (Page 267)"
- "Block icon structure (Page 260)"
- "Operation via the block icon (Page 269)".

# 4.4 Stationary processes - SteadyState

## 4.4.1 Description of SteadyState

### Object name (type + number) and family

Type + number: FB 1955

Family: CondMon

Number of process objects: 2 PO

### Area of application

The detection of steady states of a dynamic process and the steadiness of a signal is a useful aid for the open-loop control, closed-loop control and management of processes. There are often problems which make this detection difficult. The SteadyState function block is a solution which is suitable for many such problems.

The SteadyState function block analyzes an input signal and decides online, that is, without delay, whether this signal is steady or not. This requires no complicated parameter assignment. In-depth process knowledge or detailed knowledge of the signal behavior is not necessary for the configuration.

### Configuration

The SteadyState block is dragged from the block catalog and dropped onto the specially prepared CFC. The selection of the insert position and the OB in which the block is installed depends on the insert position of the driver block for the process value to be monitored.

### Startup characteristics

Use `Feature.Bit0` (Setting the startup characteristics (Page 148)) to define the startup characteristics of this block.

- **Bit = 0:** The most recently stored values are reset at startup.
- **Bit = 1:** The most recently used values are sent to the following output parameters at startup:
  - `PV_Filtered`
  - `StatAct`

**Note**

Additional information about `Feature.Bit0` can be found in the section Setting the startup characteristics (Page 148).

### Status word assignment for the `Status1` parameter

For a description of the individual parameters, refer to the section SteadyState I/Os (Page 620).

| Status bit | Parameter |
|---|---|
| 0 – 2 | `Not used` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `Not used` |
| 6 | `OnAct.Value` |
| 7 – 27 | `Not used` |
| 28 | `Internal error` |
| 29 - 30 | `Not used` |
| 30 | `StatAct.Value` |
| 31 | `NOT StatAct.Value` |

## 4.4.2 SteadyState modes

This block can be set to the following modes:

- On
- Out of service

### "On"

General information about the "On" operating mode can be found in the section "On (Page 77)" mode.

### "Out of service"

General information about the "Out of service" operating mode can be found in the section "Out of service (Page 77)" mode.

## 4.4.3 SteadyState operating principle

### Calling OBs

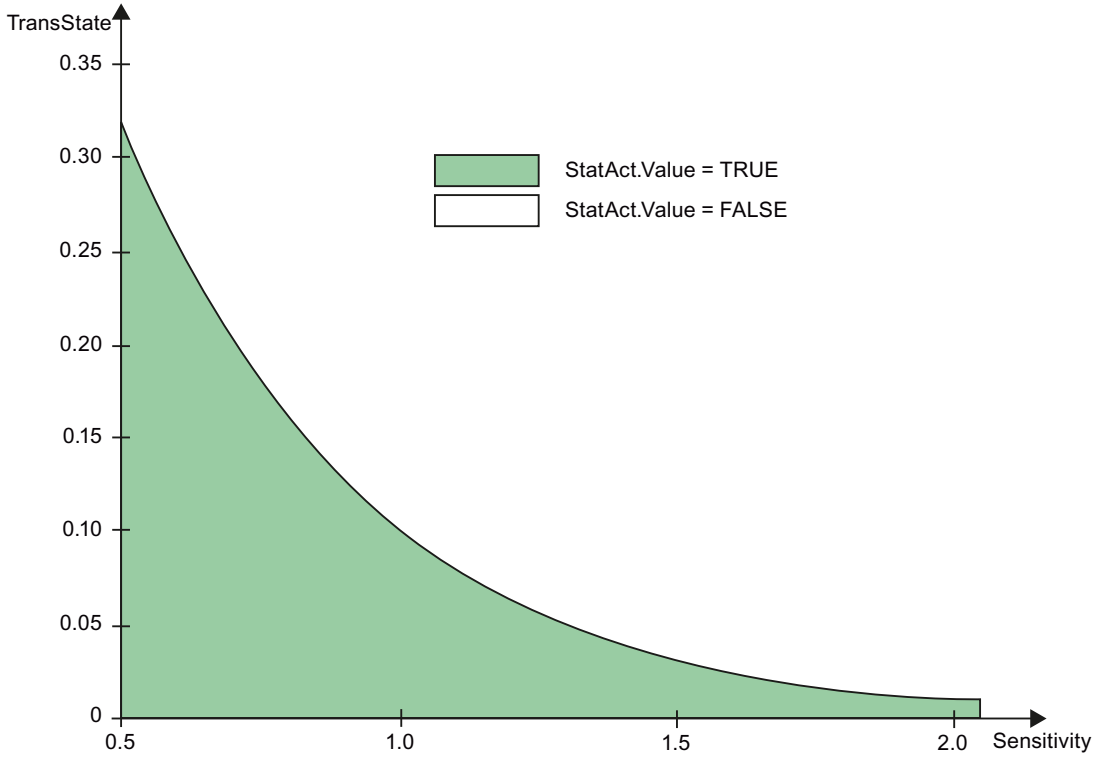
The cyclic interrupt OB into which you install the block (for example, OB32). Additionally in OB100 (see Setting the startup characteristics (Page 148)).

**Note**

The block must be installed in the same cyclic interrupt OB as the associated processing or monitoring block (e.g. MonAnL).

## Principle of Operation

The SteadyState calculation is implemented in four steps:



1. The input signal is filtered by a Kalman filter with the `TimeConstant` and displayed at the `PV_Filtered` output variable.
2. The signal is stored in a sliding time window with the length `TimeWindow`. Internally, the buffer length is limited to 1024 values. A signal is only classified as steady if it is steady throughout the entire time window.
3. The filtered signal in the sliding time window is analyzed for variances.
4. The result is provided in two forms: As a binary signal `StatAct` (`true/false`) and as an analog value `TransState`, which represents a scale for the unsteadiness (0 to 1, 0: steady, 1: completely unsteady).

The algorithm for detecting steadiness is based on a modified "Walsh transformation", in which the values in the sliding time window are tested for the presence of certain discrete frequencies.

The sensitivity of the steadiness detection can be adjusted using the `Sensitivity` tuning parameter. The default value is 1.

A steady state is detected when the following condition is satisfied:

$$TransState \leq 10^{-Sensitivity}$$

This makes it clear that with high sensitivity, the process value may move very little in order to be classified as steady.

## 4.4.4 SteadyState functions

### Detection of signal steadiness

The information as to whether a signal in the process control system is currently steady is useful for many applications.

**Applications from the field of process monitoring are:**

- The startup of steady processes is often characterized by fluctuating process variables. When these variables become steady, the process is in a steady state. Monitoring the steadiness of the relevant process variables therefore immediately indicates the end of the startup process. Example: End of the startup process of a pump when a steady flow is achieved.
- In steady processes, changing the product, a raw material or an input material results in fluctuating process variables. If the steadiness of the relevant variables is monitored, re-establishment of the steady state immediately indicates the start of the new process state. Example: Detection of a constant combustion temperature after fuel switching by monitoring the temperature of the combustion chamber or the exhaust.
- After disruption of the regular operation of a steady process, the process returns to its normal state. By monitoring the steadiness of the corresponding process variables, the cessation of the disruption is immediately detected. Example: Fluctuations in the inlet of a distillation column disrupt the head temperature. A return to a high-quality head product is indicated by the re-establishment of the steady state.

**Applications in the field of closed-loop and open-loop control are:**

- Time slices of the signal patterns containing a transition from one steady state to another steady state are useful for adjusting controller parameters. The detection of the steadiness of the variable to be controlled thereby serves to select the appropriate time slices. Example: Controller setting with SIMATIC PCS 7 PID Tuner or ModPreCon engineering tool.
- In batch processes, transition to the next basic operation in the recipe often depends on achieving certain process conditions. This situation can be indicated by the detection of the corresponding signal's steadiness . Example: A step sequence in the Sequential Function Chart (SFC) does not activate the agitator motor of a reactor for a fixed and possibly excessive period of time; instead, it stirs until the temperature in the reactor has a steady value.
- In general, switching the same process variables designed for different targets between different controllers may only be carried out in steady-state mode. This mode can be detected by monitoring the steadiness of the control variable. Only then can the switching of the controller be enabled. Example: Bumpless switching from a PI controller to a PID controller is only possible in a steady state in which the derivative component is zero.

### Detection of signal unsteadiness

The information as to whether a signal in the process control system is currently leaving steadiness has many applications.

**Applications from the field of the process monitoring are:**

- When a normally constant measured signal suddenly fluctuates, this points to a disturbance in the process or in the field device. The monitoring of the corresponding signal immediately indicates the disruption. Leaving steady state can even be detected before the signal reaches its warning or alarm limits. Example: The head temperature in the distillation column starts to fluctuate without violating the configured limits.
- Control loops designed to keep certain process variables constant can be monitored with the function block in a simple way. The detection of unsteadiness then means that the controller can no longer properly fulfill its task. Example: Monitoring of a PID controller for adherence to the steady state.
- Continuous units can be monitored for proper steady-state operation. As soon as the relevant process variables of a unit begin to fluctuate, drift or fail, the operator is notified or countermeasures are taken automatically. Example: If the head temperature of a distillation column is unsteady, the operator is immediately alerted to intervene accordingly.

## Determination of the plant status

The plant status is a criterion for a series of actions or the suppression of actions. The SteadyState function block distinguishes between "safe steady" and "not steady" states of plants or units. Applications for the binary signal in the control system are:

- Depending on the plant status, messages and alarms can be activated, suppressed or hidden. In this way, alarm surges of transient irrelevant messages can be prevented. Example: Alarm messages from the lower-level controllers are suppressed in unsteady startup or product changeover phases.
- Limits of function blocks can be changed depending on the plant status. Strict limits are often more suitable in steady-state operation than in unsteady operation. This approach considerably reduces alarm surges if a malfunction occurs. Example: A temperature value is monitored for a few degrees of deviation in steady-state normal operation. For startup phases, however, it is monitored only in accordance with the field device specification.
- Controllers or controller parameters can be selected depending on the plant status. Highly responsive controllers, which are generally not robust, are suited for steady-state operation within strict limits. In contrast, it is advisable to switch to a slower but more robust controller for startup phases or in cases of malfunction. Example: A temperature controller for startup processes is used alternately with a temperature controller for steady phases.
- Step sequences can use the current plant status, steady or not steady, as a condition for forwarding. Example: Simply reaching the setpoint temperature in a heated tank is not an adequate criterion for further action; the temperature must also be steady at this value.

## Forming the signal status for blocks

The signal status of the input signal (`PV.ST`) has no influence on the behavior of the function block.

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `PV.ST`

### Selecting a unit of measurement

This block provides the standard function "Selecting a unit of measure (Page 240)".

### Configurable reactions using the "Feature" parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in section "Configurable response using the Feature I/O (Page 139)". The following modes of behavior are available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Setting the startup characteristics |
| 1 | Characteristics for the out of service mode |

### Operator control permissions

This block provides the standard function "Operator control permissions (Page 139)".

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 – 6 | Not used |
| 7 | 1 = Operator can reset the steadiness detection |
| 8 – 12 | Not used |
| 13 | 1 = Operator can change the filter time constant |
| 14 | 1 = Operator can change the time horizon |
| 15 | 1 = Operator can change the sensitivity |
| 16 | 1 = Operator can change the amplitude band |
| 17 – 31 | Not used |

### SIMATIC BATCH functionality

This block does not support "SIMATIC BATCH functionality".

### See also

Operator control permissions (Page 285)

## 4.4.5 SteadyState error handling

### Overview of error numbers

The `ErrorNum` I/O can be used to output various error numbers:

| Error ID | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 2 | `SampleTime` parameter is too small (< 0.001) |
| 30 | The value PV can no longer be displayed in the REAL number field. |

## 4.4.6 SteadyState I/Os

### I/Os of SteadyState

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AmplBand` | Positive number that indicates the amplitude band, i.e. the range in which the observed signal varies. It is useful to specify the amplitude band if this range of variation is small compared to the absolute values of the observed signal. Otherwise, the function block monitors the absolute amplitude whereby, for example, temperature fluctuations between 418 and 422 °C are very small and therefore always appear to be steady. If, however, such fluctuations are relevant, an amplitude band of 4 would be configured in this example. | REAL | 0.0 |
| `BlkTypeInfo*` | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| `EN` | 1 = Called block is executed | BOOL | 1 |
| `Feature` | I/O for other functions (see SteadyState functions (Page 617)) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| `OnOp*` | 1 = "On" mode via operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosLi | 1 = "Out of service", via interconnection or SFC (0–1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator input | BOOL | 0 |
| OS_Perm | I/O for operator control permissions (see SteadyState functions (Page 617)) | STRUCT<br>• Bit0: BOOL<br>• Bit10: BOOL<br>• Bit31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| PV | Process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_OpScale | Limit for PV trend display of the faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| RstOp* | 1 = Reset steady state monitoring.<br>This function block immediately switches to unsteady at the output. | BOOL | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| Sensitivity | Positive number that indicates the sensitivity of the monitoring to fluctuations in the input signal. It must be between 0.1 and 10, whereby 1 is the normal value. However, even the values ½ or 2 represent a very significant change in the sensitivity; values below or above are suitable for extreme applications at best.<br>"Values greater than 1 mean that even minor changes in the signal will be classified as "unsteady"". | REAL | 1.0 |
| TimeConstant | Positive number in seconds which indicates the time constant of the low-pass filter. It is limited internally to a maximum of 10,000 sample steps based on the SampleTime parameter. A low-pass filter is applied to the input signal with the specified time constant and sent to the PV_Filtered output. | REAL | 5.0 |
| TimeWindow | Positive number in seconds that specifies how long steadiness must be observed before the block sets the corresponding StatAct output. High values thus lead to long wait times before steadiness is detected.<br>It is limited internally to a maximum of 1,024 sample steps depending on the SampleTime parameter. If more than 1,024 sampling steps are needed to monitor the signal, a clock reduction ratio is required. | REAL | 50.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

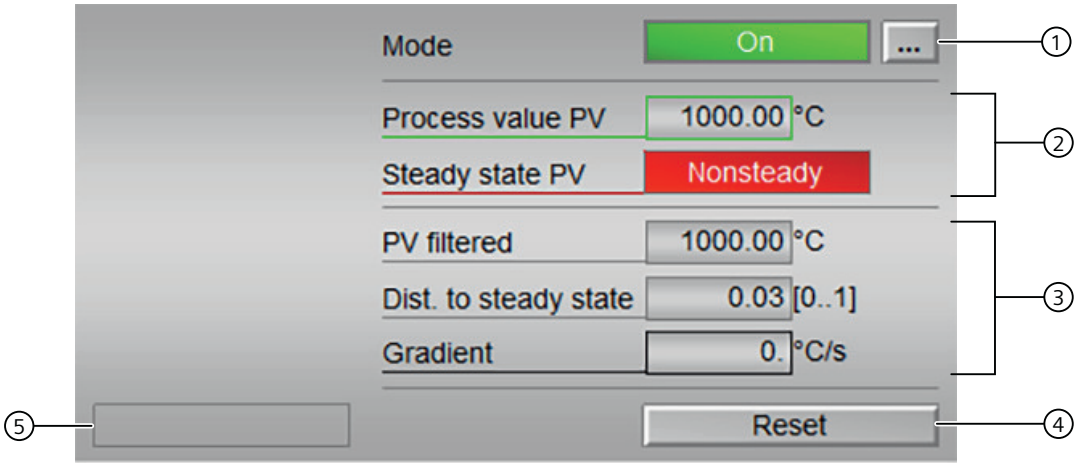
### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of the existing error number. For the error numbers that can be output by this block, see section SteadyState error handling (Page 620) | INT | -1 |
| MeanValue | Analog signal that outputs the filtered input signal averaged over the time horizon. This is the running average of the filtered input in the time window that has been selected for the TimeWindow parameter. | REAL | 0.0 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| PV_Filtered | Analog signal that outputs the filtered input signal. The filter is a low-pass filter with a time constant that has been selected for the TimeConstant parameter. | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_UnitOut | PV_Unit as output | INT | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| StatAct | A logic signal that outputs 1 if it detects steadiness of the input, otherwise 0. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word 1 | DWORD | 16#00000000 |
| TransState | Analog signal between 0 and 1, which is a measure of the unsteadiness of the signal. The closer the signal is to 0, the steadier the signal is assessed to be. | REAL | 1.0 |
| Trend | Analog signal that indicates the time derivative of the filtered input signal in the steady state, averaged over the time window. The signal is constantly 0 for non-steady input signals.<br>A trend in this respect is a slow creep, which is not yet classified as unsteady. | REAL | 0.0 |

## 4.4.7 SteadyState block diagram

A block diagram is not provided for this block.

## 4.4.8 Operator control and monitoring



### 4.4.8.1 Views of SteadyState

The SteadyState block provides the following views:

- Standard view of VlvMon (Page 623)
- Parameter view of SteadyState (Page 624)
- Trend view of SteadyState (Page 625)
- Memo view (Page 338)
- Block icon for SteadyState (Page 625)

For general information on the faceplate and block icon, refer to the "Structure of the faceplate (Page 279)" and "Block icon structure (Page 260)" section.

### 4.4.8.2 SteadyState standard view

**(1) Display and switchover of the operating mode**

This area provides information on the operating mode currently in effect. The following operating modes can be shown here:

- On
- Out of service

**(2) Process value**

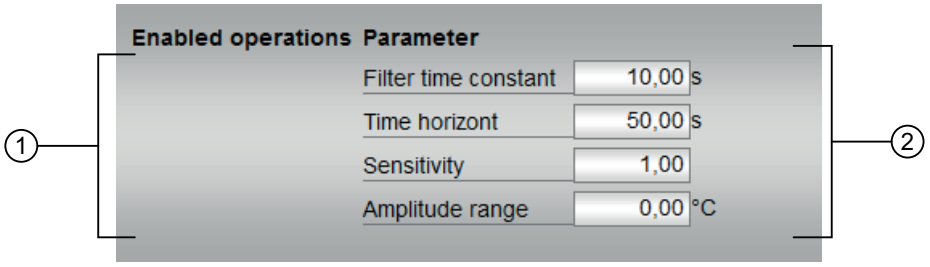
This area shows the current process value `PV` and its steady status. The status display can have the following states:

- "Steady" (green)
- "Unsteady" (red)
- No text (grey)

**(3) Further characteristic values**

In this area, the filtered process value (`PV_Filtered`), the scale of unsteadiness (`StatState`) and the gradient (`Trend`) are displayed. The values cannot be operated.

**(4) Resetting the steadiness detection**



Pressing the Reset button resets the entire steadiness detection.

**(5) Display area for block states**

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### 4.4.8.3 SteadyState parameter view

**(1) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm`).

**(2) Parameters**
The following parameters can be entered in this area:

- "Filter time constant": Time constant of the low-pass filter (`TimeConstant`)
- "Time horizon": Length of the time window for monitoring the signal (`TimeWindow`)
- "Sensitivity": Sensitivity of the monitoring to variations of the input signal (`Sensitivity`)
- "Amplitude band": Amplitude band for the monitoring (`AmplBand`)

### 4.4.8.4 SteadyState trend view

The trend view displays the process value `PV` (dark green), the filtered process value `PV_Filtered` (blue) as well as the status of the signal `StatAct` (green-red).

### 4.4.8.5 Block icon for SteadyState

A block icon with the following displays is available to you:

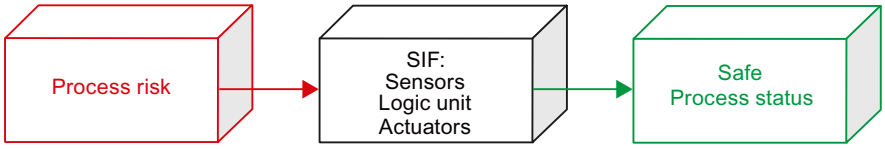
- Block type or process tag
- Operating modes
- State of the monitored signal

The block icon from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block icon in CFC | Special features |
|---|---|---|
| | 1 | Block icon in full display in steady state |
| | 1 | Block icon in full display in non-steady state |
| | 1 | Block icon in the "Out of service" operating mode |
| Steady | 2 | Block icon in full display in steady state |
| Nonsteady | 2 | Block icon in full display in non-steady state |
| | 2 | Block icon in the "Out of service" operating mode |

You can find additional information about the block icon and the operator control options in the block icon in the following sections:

- "Configuring the block icons (Page 267)"
- "Block icon structure (Page 260)"
- "Operation via the block icon (Page 269)".



# 4.5 Partial Stroke Test (PST)

## 4.5.1 Introduction

### 4.5.1.1 What is the Partial Stroke Test?

A Safety Instrumented Function (SIF) can be described as a function with which a specific Safety Integrity Level (SIL) is implemented with regard to a specific process risk. A Safety Instrumented Function normally consists of sensors, a logic unit and actuators. Only when the components of the Safety Instrumented Function operate together is the risk detected, then the process is set to a safe status. To ensure that the Safety Instrumented Function (SIF), where required, in fact functions as intended, your technical systems must be tested regularly.

A Safety Instrumented Function (SIF):

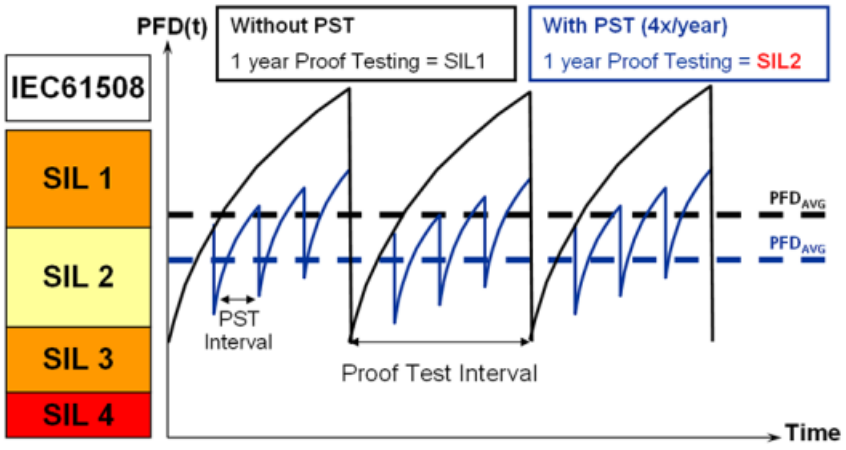
The Safety Integrity Level (SIL) achieved is derived from the average Probability of Failure on Demand (PFD) for an SIF. Failure on demand is when a device does not perform the intended function when requested. This probability of failure is defined as PFD. The PFD value is calculated on the basis of the rate of failure (λ) and the proof test interval (TI) of the device. If only the service life of one device is considered, a constant λ value can be assumed. As λ therefore has a constant valve for a given valve, the relationship between PFD and TI is directly proportional. The following applies: The greater the TI value, the greater the PFD value. This means that more frequent tests keep down the PFD value and ensure that a Safety Instrumented Function achieve the Safety Integrity Level that has been defined for it.

The actuators of a Safety Instrumented Function generally contribute most to the overall PFD value. During normal plant operation, safety shutoff valves normally stay in just one position: fully open or fully closed. These safety valves only have to perform a movement in an emergency. The fact that they do not move for long periods of time can cause the valves to block under the tough plant conditions. Regular tests are therefore required to ensure that the valve is functioning correctly and is not blocked in an emergency situation.

To test all the failure modes of a safety shutoff valve completely, it is necessary to ensure that the valve can be set to a fail-safe state. This type of test is referred to as a Full Stroke Test (FST). A Full Stroke Test normally tests the valve drive, the valve seat and, where one exists, the solenoid valve. If e.g. sealing and a short response time are required for a safety shutoff valve, these properties should also be tested in a Full Stroke Test.

Many safety shutoff valves can be tested online using a physical valve bypass. For other valves, however, the Full Stroke Test requires the process to be interrupted and causes an unwanted valve switching procedure. In these cases, the Full Stroke Test can only be performed during plant shutdown or planned maintenance when the valve can be completely opened and closed. Otherwise, costly procedures are required, e.g. using and independently testing multiple parallel valves.

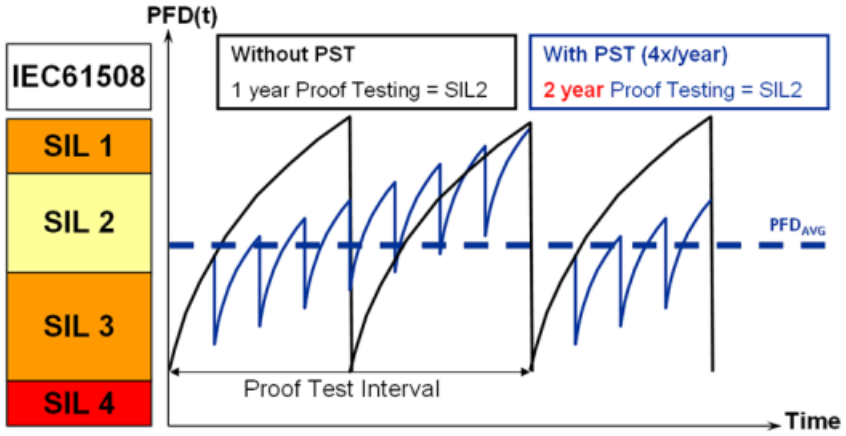
A Partial Stroke Test makes it possible to guarantee that a valve is not blocked, even when it stays in normal position, without negatively affecting the process or causing incorrect tripping. In this test, the valve normally completes a stroke of 10-20% of the full stroke. The actual stroke value of the valve depends on factors such as valve types and size, the manufacturer's recommendations and the operating conditions. After the valve has been tested in test position, it is reset to normal state. A Partial Stroke Test cannot test all the failure modes of a safety valve, but only the failure modes relating to the valve drive.



The most common error patterns in valve drive systems are listed in the following table.

| Fault description | Possible cause of error | Fault detectable? | | Fault detection |
|---|---|---|---|---|
| | | Partial Stroke Test | Full stroke/ full rotation test | |
| Solenoid valve not switching | Trip for the solenoid valve defective | Detectable | Detectable | Detection via feedback value |
| Solenoid valve not switching | Solenoid valve defective | Detectable | Detectable | Detection via feedback value |
| Valve reacts too slowly | Air line to the valve is pinched | Detectable | Detectable | Detection by monitoring the time until feedback value is given |
| Valve reacts too slowly | Valve is sluggish | Detectable | Detectable | Detection by monitoring the time until feedback value is given |
| Valve does not close or does not close completely | Valve seat pitted<br>Disk eroded | **Not** detectable | Detectable | Detection not possible via Partial Stroke Test |
| Valve does not close or does not close completely | Valve set has deposits | **Not** detectable | Detectable | Detection not possible via Partial Stroke Test |
| Valve does not close | Valve stem blocked | Detectable | Detectable | Detection via feedback value |
| Source: NAMUR Recommendation NE106, first published: 01/03/2006, Test Intervals for Safety Integrated Systems, Table 3: Most common error patterns in valve drive systems | | | | |

The diagnostic Coverage of a Proof Test (CPT) is a percentage measure for the effectiveness of a Partial Stroke Test. If the CPT value for a safety shutoff valve is 70%, for example, a Partial Stroke Test can detect 70% of all possible failure modes of the valve. A Partial Stroke Test, however, cannot test all failure modes of a safety valve, but only demonstrate that a valve is not blocked and thereby reduce the total PFD value. This contributes to maintaining the Safety Integrity Level (SIL).



The following table shows how the SIL for a Safety Instrumented Function is increased using a Partial Stroke Test by lowering the PFD value for a safety shutoff valve. The following figure shows how the safety valve only reaches SIL 1 with an annual test interval for a Full Stroke Test (Proof Test) (based on the average PFD value and the IEC 61511 guidelines). By contrast, the safety valve reaches SIL 2 with an additional Partial Stroke Test at intervals of 3 months.

Using the Partial Stroke Test to achieve a higher SIL:

The following figure shows how the required interval for the Full Stroke Test (Proof Test) can be extended by using Partial Stroke Tests, without changing the SIL. The following figure shows how the safety valve achieved SIL 2 with a Full Stroke Test interval of one year. If a Partial Stroke Test is performed at intervals of 3 months, the Full Stroke Test interval can be extended to 2 years and SIL 2 can still be achieved.

Using the Partial Stroke Test to increase the Full Stroke Test interval:

**Note**

As a Partial Stroke Test does not provide a full function check of a valve, a Proof Test must still be performed at a predefined test interval.

### 4.5.1.2 The Partial Stroke Test application

The Partial Stroke Test application contributes to the safe and reliable operation of safety shutoff valves. The application uses the S7-400 F/FH as part of the SIMATIC safety system in conjunction with an integrated valve position controller to test a pneumatic shutoff valve. Under the Partial Stroke Test solution, the position controller is used to close the valve partially to demonstrate that the valve has moved to the required position and then to reset the valve to its open position. **The safety function itself is guaranteed by a fail-safe discrete output.**

**By defining a setpoint** for the position controller **and as a result of fail-safe discrete shutoff, two separate signals are available to activate the valve's safety position**, delivering a "fail-safe" 1oo2 evaluation. According to the published report of an independent consultancy as a third-party provider, the hardware layout for the Partial Stroke Test is SIL3-capable. 2

The method used in the Partial Stroke Test application for the Partial Stroke Test is referred to as position control. It can be used for rotary slide and screw-down valves and requires the installation of an intelligent valve position controller together with a shutoff valve.

---

**Note**

This application can also be used for other drives (e.g. motor) if a feedback is available.

This application can also be used for Partial Stroke Tests even without position controller if:

1. the discrete shutoff is also actuated by the test logic
2. the binary feedback is used to simulate an analog feedback.

---

The Partial Stroke Test application contributes to the safe and reliable operation of safety shutoff valves. The application uses the S7-400 F/FH as part of the SIMATIC safety system in conjunction with an integrated valve position controller to test a pneumatic shutoff valve. Under the Partial Stroke Test solution, the position controller is used to close the valve partially to demonstrate that the valve has moved to the required position and then to reset the valve to its open position. The test is protected by a fail-safe discrete output. The output provides an independent ability to return the valve to its fail-safe position.

The analog output for the position controller in conjunction with the discrete output supplies two separate signals for safety shutoff to the drive, which together provide "fail-safe" 1oo2 evaluation. According to the published report of an independent consultancy as a third-party provider, the hardware layout for the Partial Stroke Test is SIL3-capable.

---

**Note**

The hardware report has been created by Exida and is available on request from Siemens. The applicable document details are as follows:

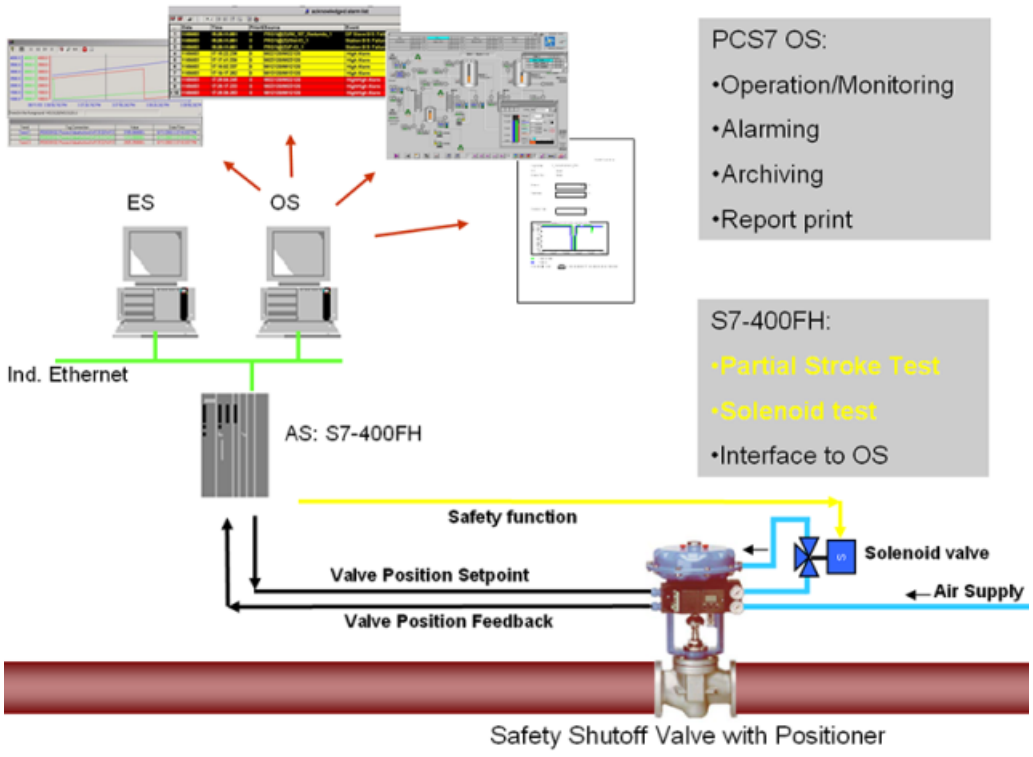
- Safety Integrity Level Verification
- Project: Final Element Configurations, Report No.: SIE 04/08-20 R001
- Version V1, Revision 1.0, October 2004
- William Goble – Rachel Amkreutz

---

The method used in the Partial Stroke Test application for the Partial Stroke Test is referred to as position control. It can be used for rotary slide and screw-down valves and requires the installation of an intelligent valve position controller together with a shutoff valve.

The PCS 7 Operator Station controls the shutoff valve during a Partial Stroke Test and records and saves the test results for documentation purposes and for prospective maintenance.

All types of valve position controllers are suitable for use with the Partial Stroke Test application. The safety component of the application defines the setpoint for the valve position and compares it to the feedback of the valve position at the time of the test.



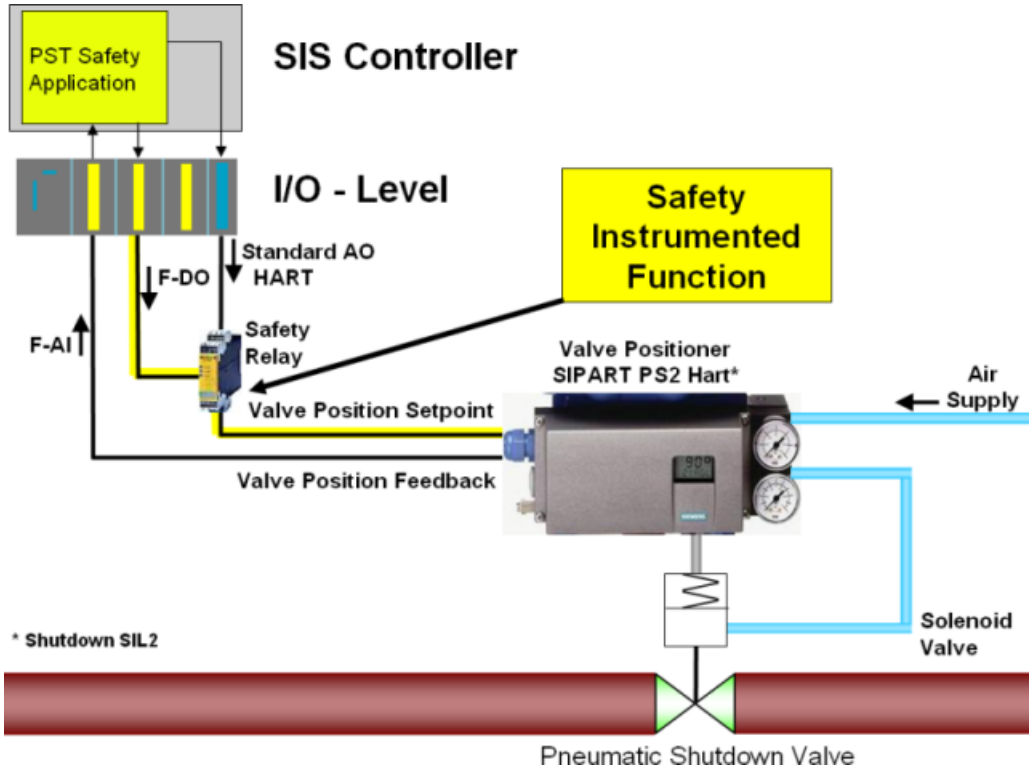
The Partial Stroke Test application includes three components (see also the following figure):

- **Partial Stroke Test engineering template:** Consists of a STEP 7 engineering template (i.e. pre-configured logic) to set up, run and monitor a Partial Stroke Test and, optionally, a solenoid valve test. This engineering template contains a CFC "chart-within-a-chart", which contains CFC charts to run the Partial Stroke Test at configured intervals. This program logic also includes PFD calculations to forecast the time period until the next required Full Stroke Test. The template has an interface to the PCS 7 Operator Station.
- **Partial Stroke Test user interface:** Consists of a block icon and a faceplate for the PCS 7 OS, visualizes the operation and status of the Partial Stroke Test and offers integrated alarm messages and event logging.
- **Partial Stroke Test test document:** Provides a pre-configured report layout for the PCS 7 OS which automatically documents the Partial Stroke Test as a printout.

The Partial Stroke Test application has the following benefits:

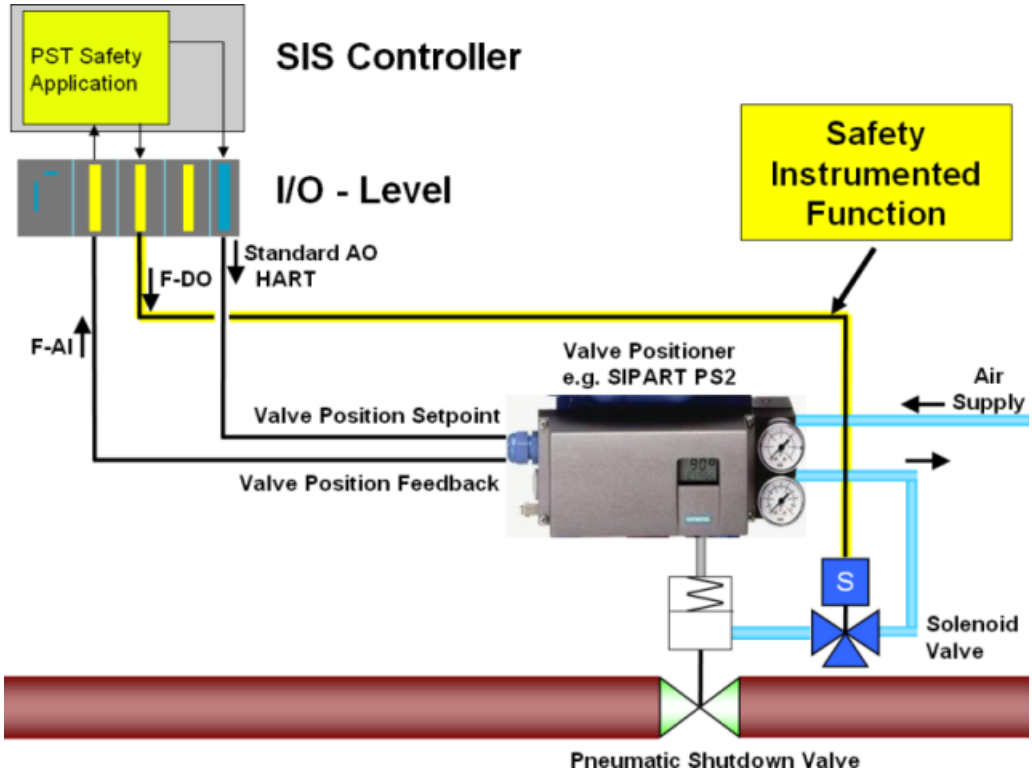
- Test safety shutoff valves with regard to various different failure modes
- Feedback for data that can be used to forecast future possible valve failures
- More flexible possibilities for testing and longer proof test interval
- Lowers the PFD value of a safety shutoff valve
- Alarm message when a Partial Stroke Test has failed or been inhibited and when a Full Stroke Test is required to achieve the specified SIL.
- Printout of test results
- Choice between manual and automatic tests

Overview of the Partial Stroke Test with S7-400FH and PCS 7:



### 4.5.1.3 Hardware overview

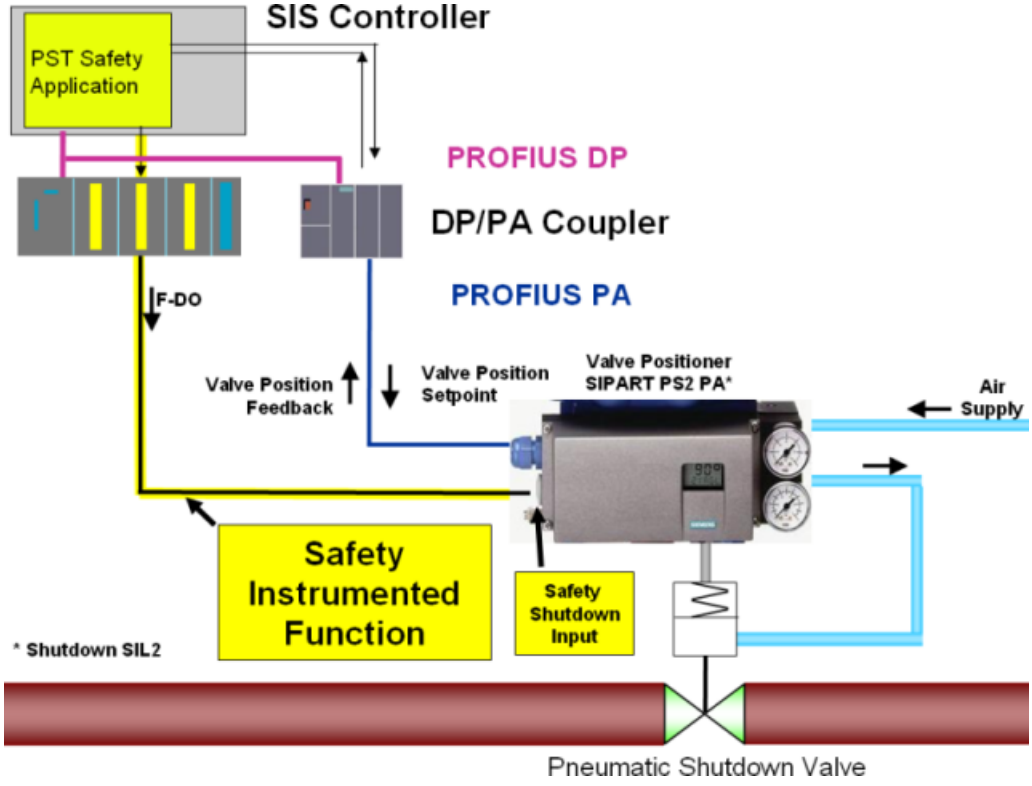
An S7-400 F/FH-CPU in conjunction with an intelligent valve position controller that supplies analog feedback data on the valve position is used for the Partial Stroke Test application. Valves that are actuated by stored energy are intended for use with the application. The valves are valves that are normally open and designed to close in the event of safety shutoff.



The following figures show two proposed arrangements of the physical system using a permanently wired valve position controller.

- Standard analog output (or standard analog output with HART) for a signal that transfers the desired valve position setpoint to the valve position controller.
- Fail-safe analog input for a signal that monitors the actual valve position
- Fail-safe discrete output for a signal that closes the valve in the event of the conditions for safety shutoff. The two possible configuration are shown in the following figures:
  - Safety relay: Interrupts the power supply to the valve position controller so that the controller interrupts the supply of compressed air to the valve

– Solenoid valve: Exhausts the air from the valve so that the spring closes the valve
Partial Stroke Test with SIPART PS2 HART for shutoff:



Partial Stroke Test with HART position controller for diagnostics only:

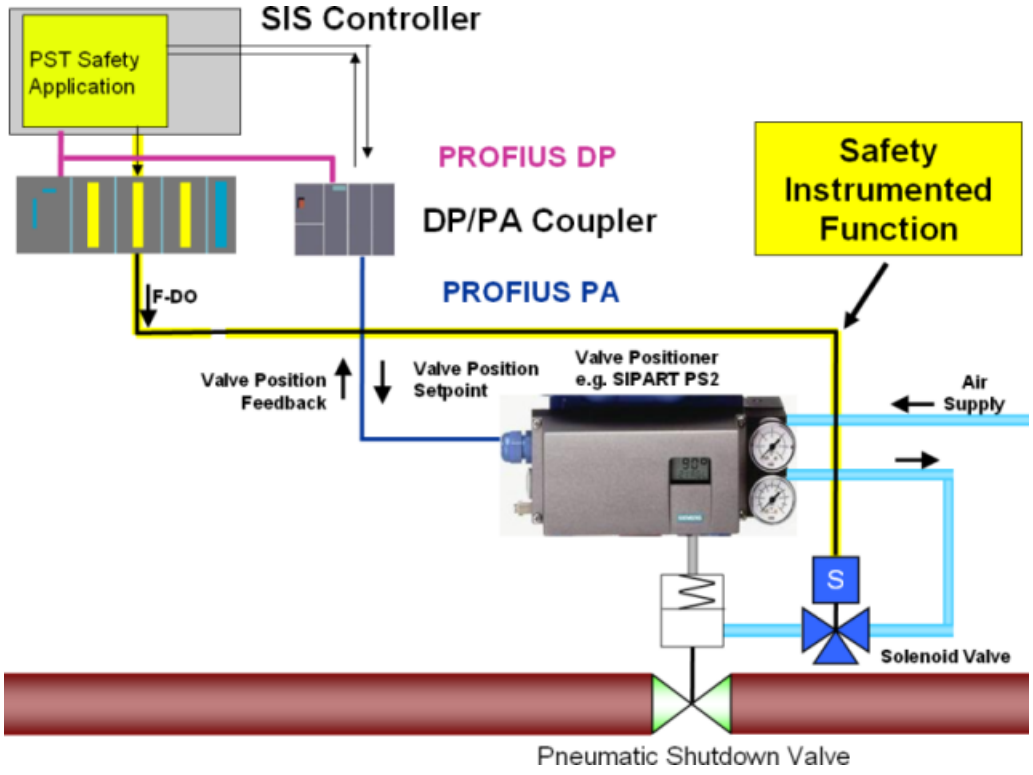
Air Supply
S
Solenoid Valve
Pneumatic Shutdown Valve

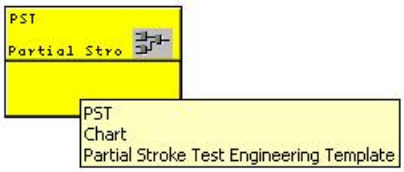


The following two figures show two proposed layouts of the physical system using position controllers and a fieldbus.

- The fieldbus transfers the desired valve position setpoint to the valve position controller and reads out the actual valve position
- Fail-safe discrete output for a signal that closes the valve in the event of the conditions for safety shutoff. The two possible configuration are shown in the following figures:
  - Input for safety shutoff: Supplies a switch-off signal to the valve position controller so that the controller interrupts the supply of compressed air to the valve

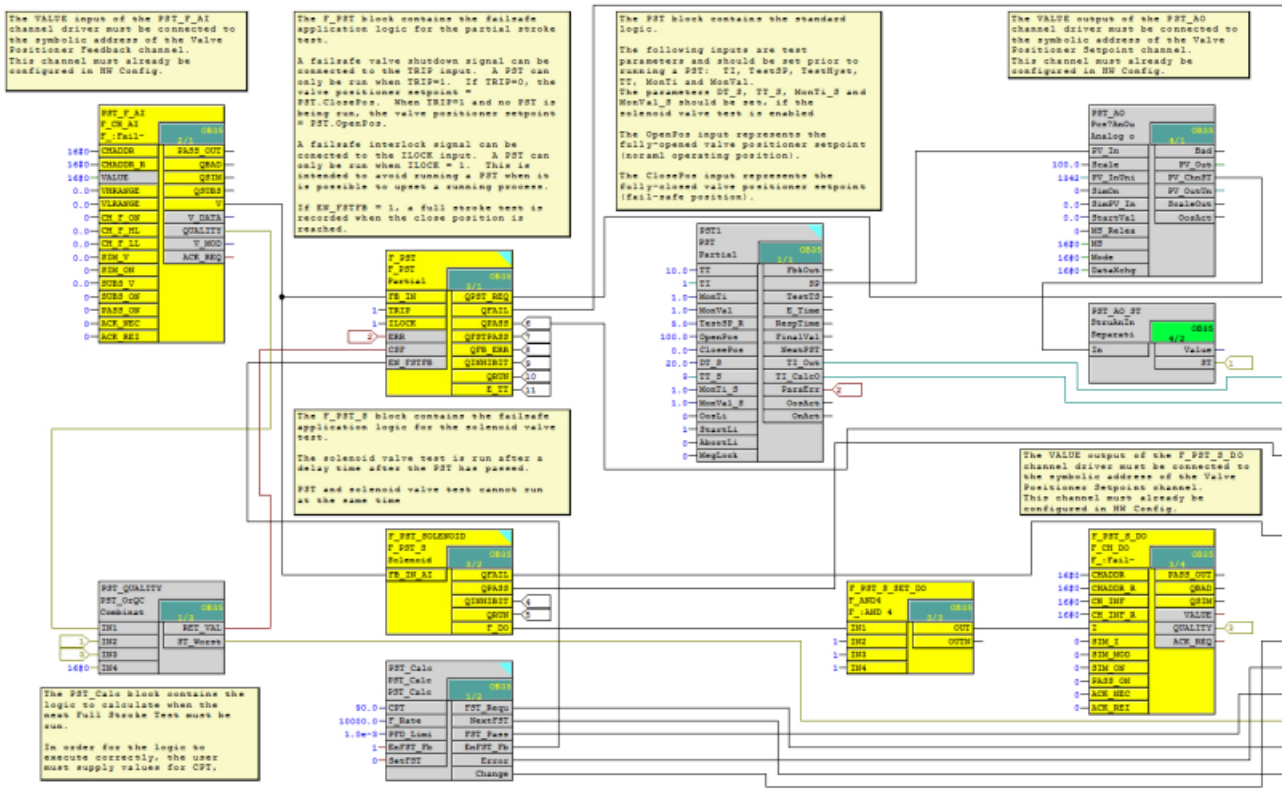
– Solenoid valve: Exhausts the air from the valve so that the spring closes the valve
Partial Stroke Test with fieldbus position controller for shutoff:

Partial Stroke Test with fieldbus position controller for diagnostics only:



Installing a position controller in a Safety Instrumented Function does not automatically render a solenoid valve unnecessary. Many applications with safety shutoff valves require a solenoid valve because ventilation by the position controller is too low to close the valve quickly. If a solenoid valve is used, it should be installed between the valve position controller and the valve drive.

If both a position controller and a solenoid valve are used, the Partial Stroke Test does not test the solenoid valve. The Partial Stroke Test application, however, includes program logic as an option to test the solenoid valve. It is up to the operator to decide whether a solenoid valve test is necessary to test the solenoid valve function at the time of the Partial Stroke Test. The failure modes of the solenoid valve frequently do not have a significant impact on the overall PFD value of the valve body. If the solenoid valve is not a significant factor, it can be test as part of the normal proof test as part of the Full Stroke Test.



### 4.5.1.4 Overview of engineering template for Partial Stroke Test

The Partial Stroke Test engineering template component consists of pre-configured STEP 7 CFC logic. The logic is encapsulated in an engineering template (a CFC "chart-within-a-chart") that can be inserted into a CFC chart. The operator instructions in the template should help the operator understand and carry out Partial Stroke Test configuration.

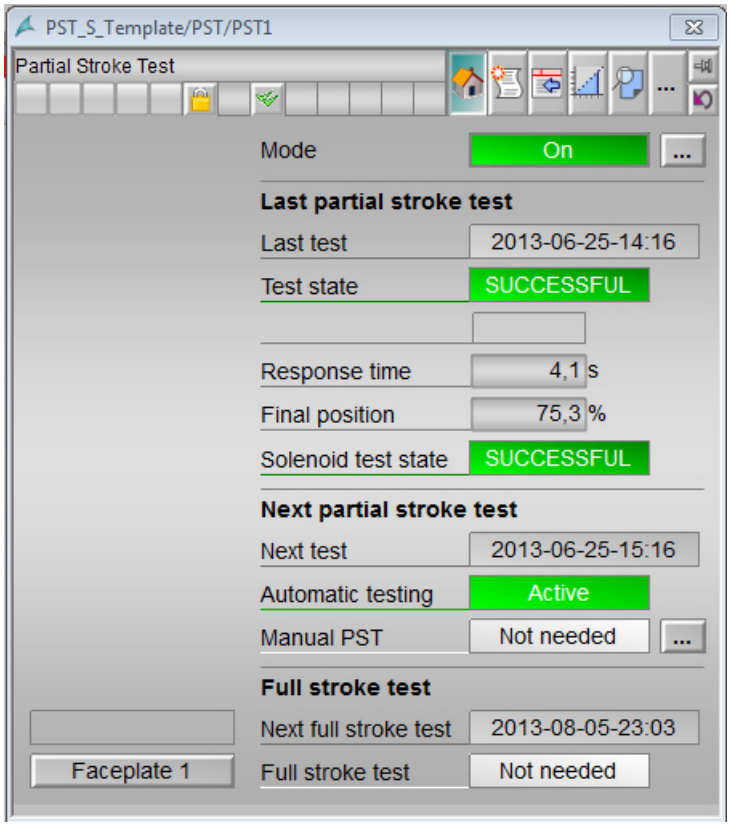
Partial Stroke Test engineering template (encapsulated logic):

Partial Stroke Test engineering template (detailed logic):

The following function blocks and functions have been created to execute the Partial Stroke Test logic:

- PST: Contains standard logic of the Partial Stroke Test; compiled SCL code
- F_PST: Contains the fail-safe logic of the Partial Stroke Test; compiled CFC charts exclusively with TÜV-certified fail-safe system function blocks
- F_PST_S: Contains the optional fail-safe logic of the solenoid valve test; compiled CFC charts exclusively with TÜV-certified fail-safe system function blocks
- PST_Calc: Contains PFD calculations to determine the time of the next Full Stroke Test; compiled SCL code
- PST_OrQC: Contains logic that evaluates the signal status of a maximum of four channel driver function blocks to determine whether there is a poor-quality signal; compiled SCL code

### 4.5.1.5 Overview of Partial Stroke Test user interface



The user interface component of the Partial Stroke Test consists of a block icon and a faceplate for the PCS 7 OS. The block icon and the faceplate can be used to visualize the Partial Stroke Test process from a PCS 7 OS console and to monitor the status and the messages for an instance of the Partial Stroke Test as well. The operator can make detailed changes to the configuration parameters and manually start tests from the faceplate with the corresponding security permissions (see AUTOHOTSPOT).

To facilitate configuration, the block icon and the faceplate are created and configured automatically at a PCS 7 OS compile when the user interface and engineering template components are used in combination.

Block icon for Partial Stroke Test:

Faceplate for Partial Stroke Test (standard view):

## 4.5.2 Usage guidelines

### 4.5.2.1 Basic rules

#### (1) Purpose of this manual

This manual provides a complete overview of the Partial Stroke Test application. The manual is intended for qualified personnel familiar with creating programs for Partial Stroke Tests and for employees who are required to configure, operate and maintain automation systems.

#### (2) Basic knowledge required

Working with this manual requires general knowledge of automation engineering. The user should be trained in the following SIMATIC technologies used in the application: STEP7, CFC, S7 F/FH systems and PCS 7 OS. The user should also be familiar with computers or devices with similar functionality (e.g. programming devices) under Windows OS.

#### (3) What is covered by this manual?

This manual applies to the Partial Stroke Test application as a component of the Condition Monitoring Library.

#### (4) Qualified Personnel

This device must only be assembled and operated by qualified personnel. Qualified personnel within the meaning of this manual are persons who are authorized in accordance with safety engineering practices and standards to operate, ground and label electric circuits, equipment and systems.

### 4.5.2.2 Safety instructions

#### (1) Certificates and approvals

As per the corresponding TÜV report, the Partial Stroke Test application operates problem-free with the Safety Instrumented Function in the proposed physical system layouts. The hardware report has been created by Exida and is available on request from Siemens.

As the setpoint for the valve position is defined by the safety instrument components of the application and compared at the time of the test to the feedback for the valve position, the test sequence is therefore safer than with a component integrated into the position controller.

The user can configure the Partial Stroke Test application to operate with safety valves by using the instructions and information in this manual. The user is responsible for checking the Partial Stroke Test logic setup with regard to the safety valves and for calculating the necessary test intervals with which a specific SIL and/or an extended proof test interval should be achieved.

### (2) Observance of the safety instructions for SIMATIC S7 F/FH Systems

The Partial Stroke Test engineering template is an engineering template based on SIMATIC S7 F/FH Systems. The user must therefore real, understand and observe all the safety instructions in the "S7 F/FH Systems - Configuration and Programming. Programming and Operating Manual".

### (3) Notes on using intelligent valve position controllers with up/down valves

If the valve is set to a fixed actuation pressure, e.g. 100 %, and is blocked e.g. due to encrustation, minor leakages may under some circumstances lead to a pressure drop in the drive. If the pressure drop is large enough to break away the encrustation, there is a risk that the critical stroke value of the valve will be exceeded.

This risk can be detected and/or avoided using the following procedures:

- The blocked valve can be detected by the Partial Stroke Test application. Sufficiently short test intervals are a precondition in this regard.
- Feeding the compressed air directly into the drive (setting in the intelligent valve position controller) prevents a pressure drop as a result of minor leakages.
- Use a pressure sensor to detect a critical (reduced) pressure.

## 4.5.3 Getting Started

### 4.5.3.1 Hardware requirements

The following hardware is required to use the Partial Stroke Test application software with PCS 7:

- A PC with CD-ROM drive
- The hardware components of the SIMATIC S7 F/FH Systems
  - S7 F/FH System CPUs (z. B. CPU417-4H) with fail-safe system license
  - Fail-safe signal modules (F-SM)

The Partial Stroke Test application is designed for valves that operate on the quiescent current principle (i.e. valves that are open in normal condition). To run the Partial Stroke Test application as intended, the following field instrumentation is also required:

- A valve position controller with analog feedback
- A safety relay or solenoid valve

**Note**

If using a relay instead of a solenoid valve, a safety relay is required under some circumstances, depending on the required SIL for the Safety Instrumented Function.

**Note**

As of the current version, the Partial Stroke Test application only supports valves that are open in normal condition (i.e. valves that are closed in fail-safe state).

#### 4.5.3.2 Software prerequisites

The following software is required to be able to use the full scope of the software for the Partial Stroke Test engineering template and the user interface (details are provided in sections below):

The general prerequisites for SIMATIC PCS 7 apply.

**(1) Partial Stroke Test engineering template**

- S7 F systems V6.2 Upd1 and higher
- S7 F library V1.3 SP2
- PCS 7 V9.0

**(2) Partial Stroke Test user interface**

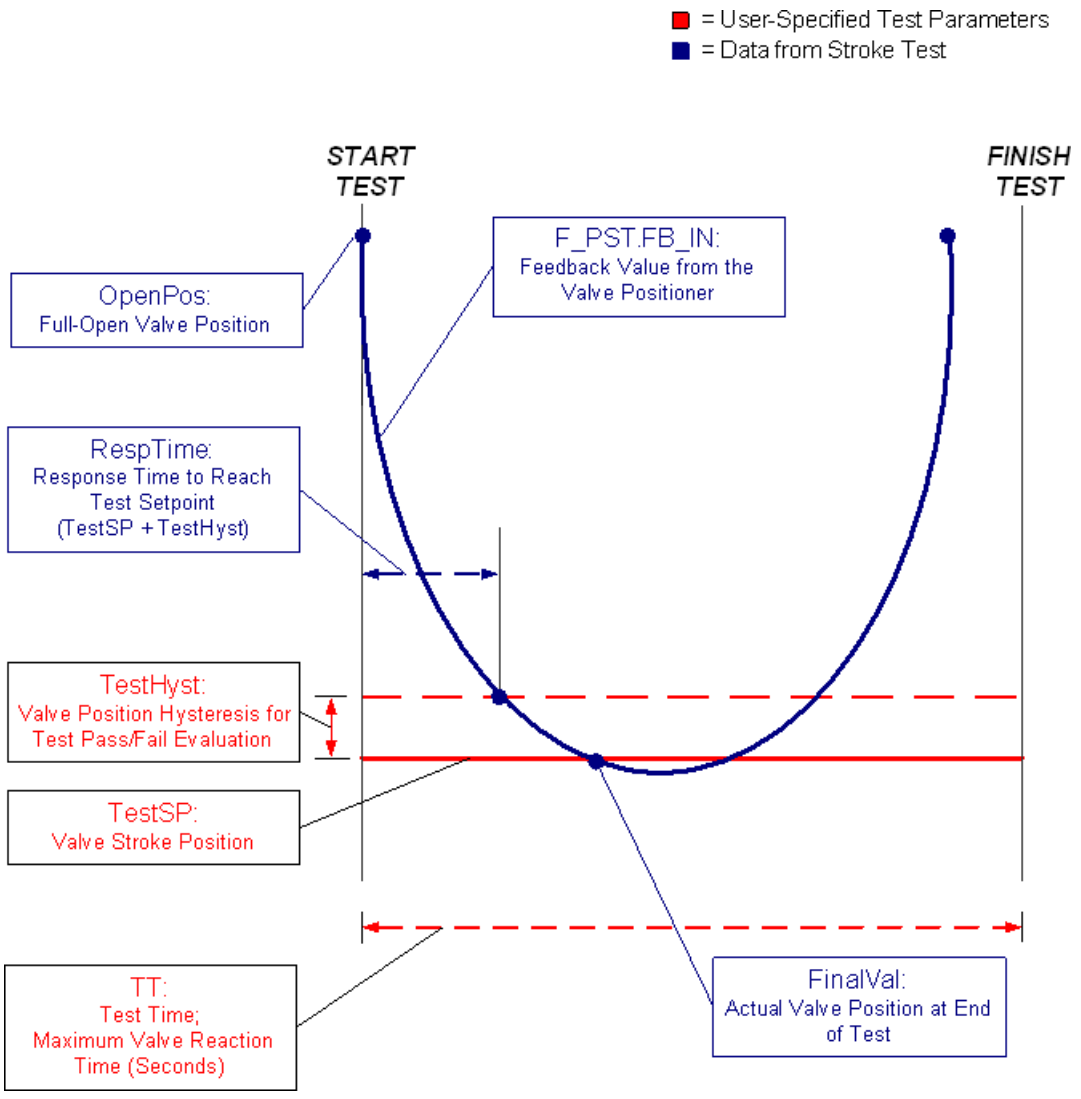
PCS 7 OS V9.0 and higher

### 4.5.4 Configuration of the engineering template

#### 4.5.4.1 Overview of Partial Stroke Test logic

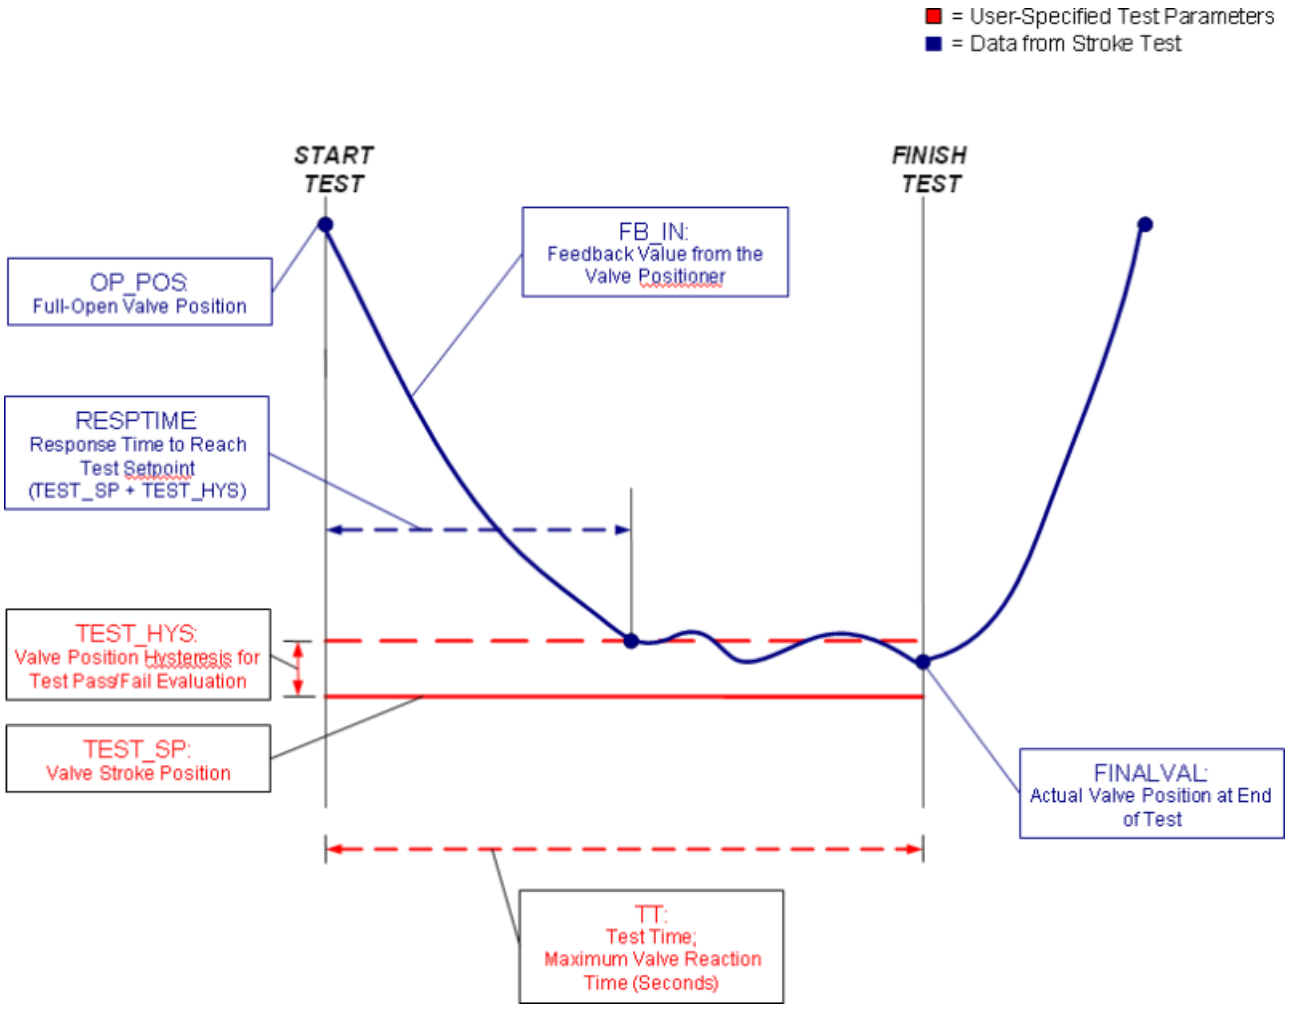
The Partial Stroke Test engineering template component consists of pre-configured CFC logic. To simplify configuration, this logic has been encapsulated in an engineering template (a CFC "chart-within-a-chart") that the user can drag and drop onto a CFC chart. The user then only has to connect the I/O channel to be used (for the feedback from the valve etc.) and specify the configuration parameters.

The engineering template for the Partial Stroke Test has the following basic performance features:



- Automatic running (at time intervals defined by the user) or manual running of Partial Stroke Tests. The system can issue a warning that a test should be run. Manual test can be started from the CFC logic itself or via the corresponding PCS 7 OS faceplate.
- Detection of whether a Partial Stroke Test, Full Stroke Test or a test outside the logic of the Partial Stroke Test application (e.g. locally at the valve position controller) has been run.
- The user can configure a valve setpoint for the test and a hysteresis used to determine the success/failure status of a Partial Stroke Test.
- The user can define the maximum time interval available to pass a Partial Stroke Test or solenoid valve test.
- The user can define a time delay between a passed Partial Stroke Test and a solenoid valve test.
- Various alarm messages that can be displayed in PCS 7 OS. Alternatively, messages can also be disabled via a disable option if no HMI is used for the Partial Stroke Test application logic

- The option for the user to monitor the valve performance. The following information is displayed for each Partial Stroke Test for this purpose:
  - Time/date of the start of test
  - Success/failure status of the test
  - Time taken to reach the desired valve position
  - Actual valve position at end of test
- Activation of the interlocking and logical enabling signals to inhibit stroke tests in cases where they are not wanted (if signal is forwarded or low signal quality is detected, with active TRIP condition or test is inhibited by a user-configured enabling signal)
- Setpoints can be varied in a user-defined range to prevent deposits in the valve housing
- The valve feedback can be monitored as early as the startup phase of the Partial Stroke Test so that early valve failure is detected
- PFD calculations to forecast the next required Full Stroke Test.



The following figures illustrate the basic functionality of the Partial Stroke Test logic. Before running a test, the user specifies the setpoint for the valve test (`TestSP`), a test hysteresis (`TestHyst`) and the maximum test running time (`TT`). When a new test is started, the setpoint of the valve position controller is set to `TestSP`, a timer is started and the feedback for the actual valve position (`F_PST.FB_IN`) is monitored. The test is passed if `F_PST.FB_IN` reaches a value below the pass threshold value. This is calculated as follows: `TestSP` + `TestHyst`. If `F_PST.FB_IN` has not passed through the success threshold value within the time interval predefined as the maximum test running time, the test has failed. At the end of a (passed or failed) test, the valve returns to its fully open position.

If a passed Partial Stroke Test is detected, the time that the valve required to pass through the threshold value `TestSP` + `TestHyst` is shown as response time (`RespTime`). The test is stopped if the value of the valve feedback is either less than `TestSP` (for display, see "Function sequence for the Partial Stroke Test (feedback value reached `TestSP`)") or if the time `TT` has passed (for display, see "Function sequence for Partial Stroke Test (feedback value reached `TestSP` + `TestHyst`)" – depending on what occurs first. At this point, `F_PST.FB_IN` is displayed and saved as the actual valve position at the end of the test (`FinalVal`). The values for `RespTime` and `FinalVal` are saved as data for prospective maintenance.

Function sequence of the Partial Stroke Test (feedback value reaches `TestSP`):

Function sequence of the Partial Stroke Test (feedback value reaches `TestSP + TestHyst`):

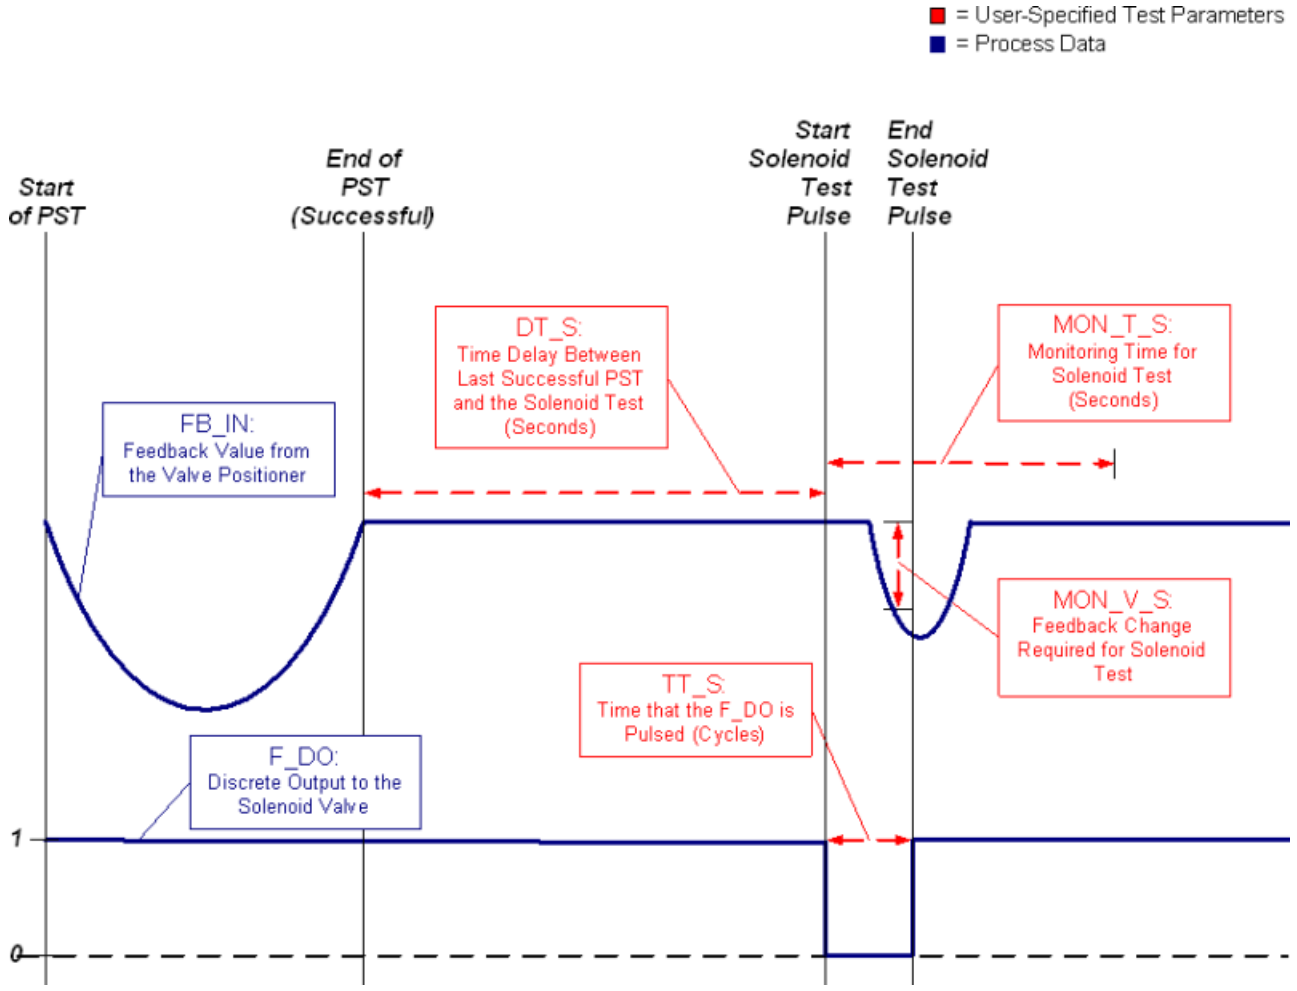
### 4.5.4.2 Logic for the solenoid valve test (optional)

If pneumatically actuated valves are used, optionally available Partial Stroke Test logic can be used for a solenoid valve test. Solenoid valve test is only relevant to hardware configurations with a solenoid valve.

The following figure shows the basic functional sequence of the logic for the solenoid valve test. If the solenoid valve test has been enabled in the configuration, it is automatically performed after a Partial Stroke Test has been passed. A delay configurable by the user occurs between the end of the Partial Stroke Test and the start of the solenoid valve test, so that the process can stabilize before the solenoid valve test. The logic for the solenoid valve test sends a fail-safe, discrete output signal as a pulse to the solenoid valve (and thereby sets it from TRUE to FALSE and then back to TRUE). The logic then monitors the feedback of the valve position controller for valve movement. For the solenoid valve test to be passed, a pre-configured stroke value has to be met within a pre-configured time interval. This stroke value cannot be a greater value, as the Partial Stroke Test that has just been passed has already confirmed that the valve has free movement. The test now checks whether the solenoid valve is fulfilling its function of interrupting the compressed air supply.

When setting up the test, the user specifies the following parameters:

- `DT_S`: Delay time between end of a passed Partial Stroke Test and start of the solenoid valve test
- `TT_S`: The test time is equal to the number of cycles for which the fail-safe output to the solenoid valve is set to 'off' by a pulse
- `MonTi_S`: The time interval within which the logic monitors the valve for a stroke movement
- `MonVal_S`: The stroke value that must be identified by the valve position controller for the solenoid valve test to be passed



The logic of the solenoid valve test is only used in certain cases. Firstly, it is only suitable for hardware configurations with solenoid valve. Whether a solenoid valve test is meaningful depends on the cycle time of the application and the response time of the valve. In particular with regard to fast-response valves, the test pulse can cause a process fault. The user is responsible for determining whether the applicable solenoid valve responds too quickly to be tested by the test logic. Prior to using the logic for the solenoid valve test, the PFD values of the solenoid valve should be checked. If the solenoid valve makes no significant contribution to the PFD of the overall valve body, it may not be necessary to test the solenoid valve regularly with the logic of the solenoid valve test.

**Note**

When defining the test running time (`TT_S`), no time interval may be chosen in which the solenoid valve test will close the valve too far and therefore cause false tripping. `TT_S` should be significantly shorter than the response time of the solenoid valve.

The logic of the solenoid valve test must not be used for fast-response valve A response of the valve that is too fast can cause false tripping.

Functional sequence of the solenoid valve test:

### 4.5.4.3 Adding the Partial Stroke Test engineering template to a STEP 7 project

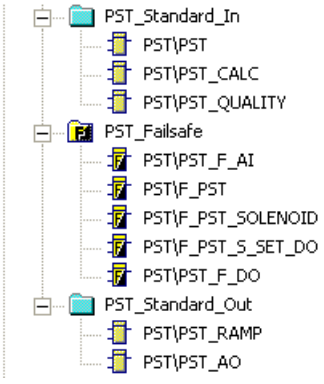
#### (1) Copy template to a CFC chart

The template can be copied to a user project in two ways.

- Copy template to the SIMATIC Manager:
  - Open the Condition Monitoring Library in the SIMATIC Manager
  - Copy the PST_Template for CFC charts into the project folder for CFC charts.
- Copy template to the CFC chart:
  - Open a CFC chart in the user project and select the library catalog. The Condition Monitoring Library is available here.
  - Select "Condition Monitoring Library" and then select "S7 program\Charts".
  - Drag the PST_Template for CFC charts to the open CFC chart.

In both cases, all blocks required to run the Partial Stroke Test application in the PLC are automatically copied to the user project.

**Note**



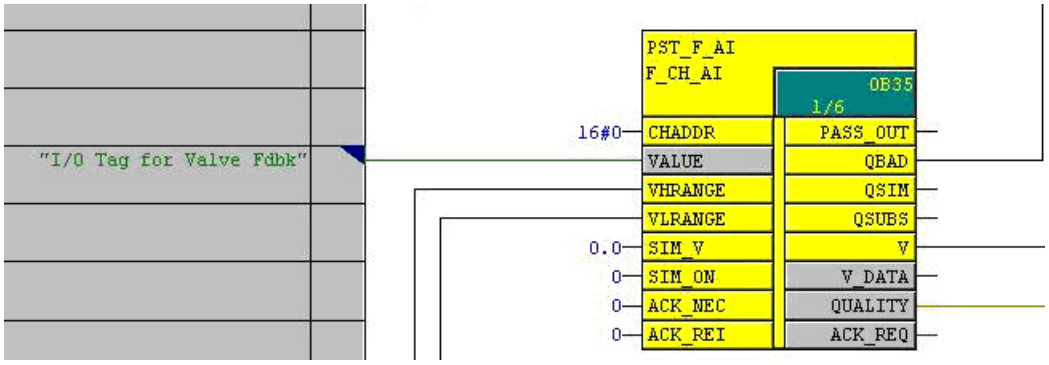
All the blocks in the Partial Stroke Test template must be run in the pre-configured sequence. This ensures that the Partial Stroke Test application logic (in terms of points in time and run sequence) functions as intended.

### (2) Set up run sequence

When the template is copied to the CFC chart, all the blocks are copied to the same runtime group. As the fail-safe program must be run in a separate runtime group, there are three runtime groups.

Open the runtime editor in the CFC chart and order the blocks as shown in the following figure.

Run sequence of the blocks in the Partial Stroke Test template:



### (3) Adjust the connections to the I/O channel drivers

The Partial Stroke Test engineering template contains three channel driver blocks:

- One F_CH_AI channel driver block for the feedback of the valve position controller
- One Pcs7AnOu block for the setpoint of the valve position controller
- The template contains a F_CH_DO channel driver block that is used to control the solenoid valve. If the Safety Instrumented Function and the corresponding channel driver block are not available, the F_CH_DO block is not required.

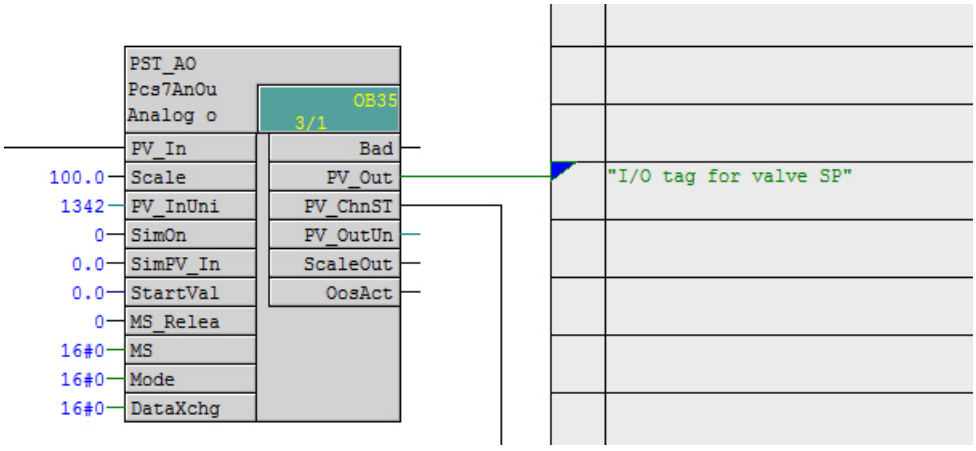
The instance name of the F_CH_AI block in the template is PST_F_AI. The PST_F_AI.VALUE input of the channel driver block must be connected to the symbolic address of the channel for the feedback of the valve position controller (see following figure). Note that this analogue input channel must initially be created in the hardware configuration.

F_CH_AI channel driver block in the Partial Stroke Test template:

The Partial Stroke Test application is designed to evaluate signals from a fail-safe analog input for the feedback of the position controller. The input for the feedback, the associated test evaluation logic and the timers for the test intervals are created with fail-safe logic to ensure that the valve stroke occurs within the configured Partial Stroke Test interval. The fail-safe logic ensures that no undiscovered error (e.g. a transient RAM error or a communications error) incorrectly results in a successful Partial Stroke Test. If this level of safety is not required for an application, the signal from a standard analog input can be used instead of a fail-safe analog input.

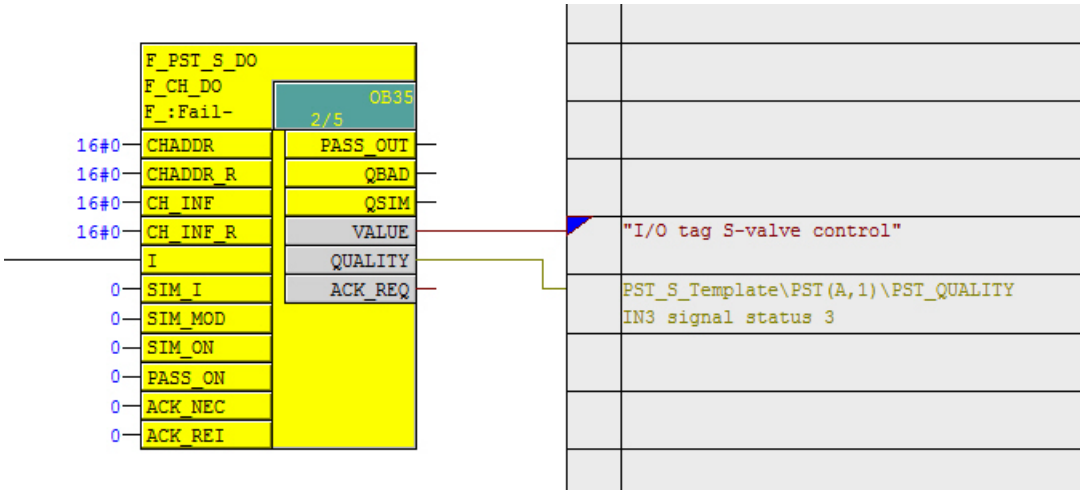
If a standard analog input signal or a PROFIBUS PA analog input signal is used, the F_CH_AI channel driver block must be deleted and replaced by a Pcs7AnIn channel driver block (for a standard analog input) or FbAnIn (for a PROFIBUS PA analog input). To do so, the user proceeds as follows:

- Delete F_CH_AI block from the CFC chart
- Add a Pcs7AnIn / FbAnIn driver block to the CFC chart and rename to PST_AI (as per the existing naming structure)
- Connect output `PST_AI.PV_Out` (Pcs7AnIn) or `PST_AI.PV_Li` (FbAnIn) to input `PST_QUALITY.IN1`
- Add a F_R_FR conversion block to the CFC chart and rename to F_PST_CONV
- Connect output `PST_AI.PV_Out` (Pcs7AnIn) or `PST_AI.PV_Li` (FbAnIn) to input `F_PST_CONV.IN`
- Connect output `F_PST_CONV.OUT` to input `F_PST.FB_IN`
- Check and if necessary change the assignment of the execution group



The instance name of the Pcs7AnOu block in the template is PST_AO. The `PST_AO.PV_Out` output of the channel driver block must be connected to the symbolic address of the channel for the setpoint of the valve position controller (see figure below). Note that this analogue output channel must initially be created in the hardware configuration. The signal does not have to be fail-safe, as the feedback signal already correctly indicates whether the test was run within the test interval.

If a PROFIBUS PA analog output is used, the Pcs7AnOu channel driver block must be deleted and replaced by a FbAnOu channel driver block. To do so, the user proceeds as follows:



- Delete the Pcs7AnOu block from the CFC chart
- Add a FbAnOu driver block to the CFC chart and rename to PST_AO (as per the existing naming structure)
- Connect output `PST_AO.PV_ChnST` to input `PST_QUALITY.IN2`

- Connect output `PST.SP` to input `PST_AO.SP_Li`
- Check and if necessary change the assignment of the execution group

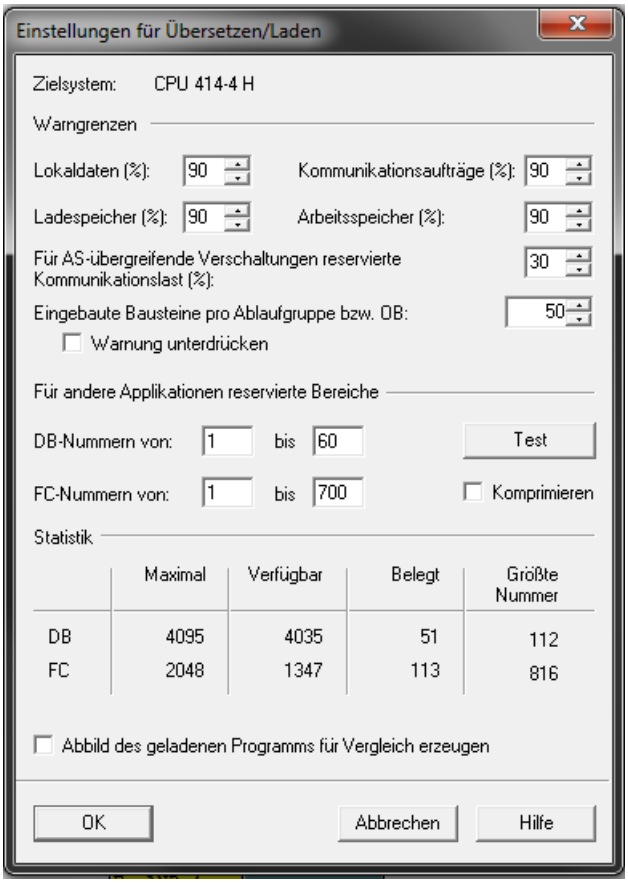
Pcs7AnOu channel driver block in the Partial Stroke Test template:

F_CH_DO channel driver block in the Partial Stroke Test template:

### 4.5.4.4 Configure blocks

Information on how to configure the individual blocks is provided in the applicable descriptions of the blocks in the "Configuration" section.

- AUTOHOTSPOT
- AUTOHOTSPOT
- Description of PST_Calc (Page 657)



- Description of PST_OrQC (Page 662)
- Description of PST_Time (Page 664)

#### 4.5.4.5 Compile and load logic of the Partial Stroke Test

After the Partial Stroke Test template has been added to a CFC chart and configured (i.e. all necessary I/O connections have been made and the test parameters F_PST, F_PST_S, PST and PST_Calc have been defined), the logic can be compiled. After compiling, the logic can be loaded to the controller.

Two notes on compiling the logic:

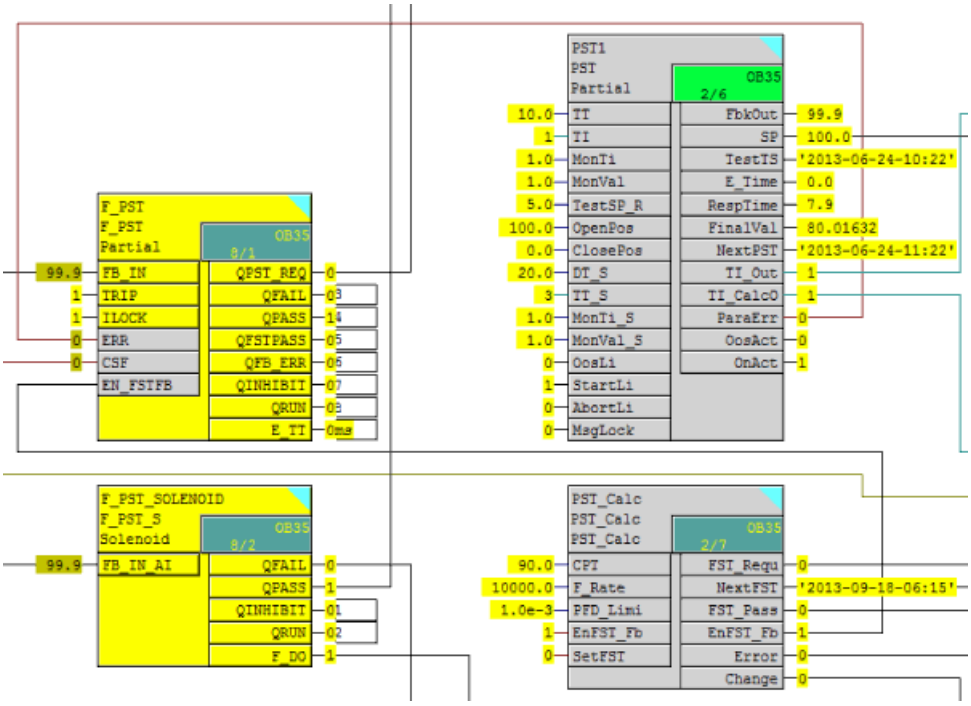
- The Partial Stroke Test engineering template uses STEP 7 functions (FCs) in a low range (i.e. FC1, "AD_DT_TM", FC2 "CONCAT", FC16 "I_STRNG", FC32 "RIGHT" etc.) by default. The number of the FCs must not be changed. For the logic to compile successfully, the user must allow FCs above number 1 to be taken into account on compile.
  To do so, proceed as following in the CFC editor: Select "Extras > Settings > Compile/Load" to open the "Settings for Compile/Load" dialog. In the "FC numbers from:" field, enter "1" for the start of the range and close the dialog with "OK" (see figure below). Then compile the logic as normal.
  Compile/load dialog in the CFC editor:

- The Partial Stroke Test engineering template contains multiple I/O channel driver blocks: For the application to function as intended, specified I/O diagnostic blocks must be created automatically and connected during compile.
  To create I/O diagnostic blocks, select "Chart > Compile > Chart as program" in the CFC editor. The "Compile program" dialog opens. Enable the "Create module driver" option and continue to compile the logic.

## 4.5.5 Working with the engineering template

### 4.5.5.1 Working with the engineering template

The engineering template can be operated and monitored in runtime mode. Open the Partial Stroke Test template in the CFC editor to view the logic details (individual blocks such as F_PST and the Partial Stroke Test block must be visible). Real-time data can be viewed in the "Debug" menu via the "Test mode" and "Monitoring on" > "Register I/Os for monitoring" menu options.



### 4.5.5.2 Display Partial Stroke Test data

Real-time data can be monitored after switching the Partial Stroke Test logic to runtime mode. The following figure shows the Partial Stroke Test logic running in monitoring mode with real-time data for the Partial Stroke Test visible. In this case, the data includes the following:

- `F_PST.QPASS = 1`; indicates that the Partial Stroke Test was passed
- `PST.TestTS = 2013-06-24-10:22`; indicates that the last Partial Stroke Test was run on June 24, 2013 at 10:22
- `PST.RespTime = 7.9`; indicates that the time for the valve position to pass through the threshold (`TestSP` + `TestHyst`) for the last Partial Stroke Test was almost 8 seconds
- `PST.FinalVal = 80.01632`; indicates that the last Partial Stroke Test ended at valve position 80.0

- `PST.NextPST = 2013-06-24-11:22`; indicates that the next Partial Stroke Test is planned for June 24, 2013 at 11:22
- `PST_Calc.NextFST = 2013-09-18-06:15`; indicates that the next Full Stroke Test is required on September 18, 2013 at 6:15 to meet the specified PFD requirements.

Partial Stroke Test logic in runtime mode:

### 4.5.5.3 Changing the values of Partial Stroke Test parameters

Any test parameters may be modified when the Partial Stroke Test logic is in runtime mode. However, subsequent changes are normally only necessary for the following Partial Stroke Test parameters:

- `TI`, interval of the automatic test
- `TestSP`, Partial Stroke Test setpoint
- `TestHyst`, hysteresis of the valve position for the success/failure result
- `TT`, Partial Stroke Test time
- `MonTi`, monitoring time for the start of the Partial Stroke Test
- `MonVal`, required change to the feedback within the time period `MonTi`

**Note**

If the value for `TI` is changed while a timer is running, the timer is fully reset. The test is then only run when the time interval of the new `TI` value is fully completed. In this case, we recommended that the user performs a manual Partial Stroke Test to cover the time interval before `TI` changes.

**Note**

If the valve closes for some reason (e.g. emergency shutdown, planned maintenance etc.) below the threshold (`ClosePos + TestHyst`), this is then only a Full Stroke Test if `PST_Calc.EnFST_Fbk = 1`. All times are reset. The PST_Calc block sets the time to the time of the next Full Stroke Test.

Otherwise, i.e. at `PST_Calc.SetFST = 1`, a Full Stroke Test is registered. Similarly in this case, all timers are reset and the PST_Calc block sets the time to the time of the next Full Stroke Test.

#### 4.5.5.4 Changing the values of solenoid valve test parameters

Normally, the following solenoid valve test parameters have to be set subsequently:

- `DT_S`, delay time for the solenoid valve test after the Partial Stroke Test has completed
- `TT_S`, time period for the solenoid valve test
- `MonTi_S`, monitoring time for the solenoid valve test
- `MonVal_S`, required change to the feedback within the time period `MonTi_S`

#### 4.5.5.5 Starting or aborting the Partial Stroke Test manually

When the Partial Stroke Test logic is in runtime mode, a Partial Stroke Test can be started or a running test can be aborted.

- To start a test, there must be a pulse for the change from 0 to 1 to input `StartLi` of the PST block. As a test can only be started when `StartLi` changes from 0 to 1, `StartLi` must be reset to 0 before a test can be requested manually.
  It is also possible to start the Partial Stroke Test from the faceplate. The I/O parameter `StartOp` is set by the faceplate and reset by the PST block after readout.
- To abort a running test, there must be a pulse for the change from 0 to 1 to input `AbortLi` of the PST block. As a test can only be aborted when `AbortLi` changes from 0 to 1, `AbortLi` must be reset to 0 before a test can be requested manually.
  It is also possible to abort the Partial Stroke Test from the faceplate. The I/O parameter `AbortOp` is set by the faceplate and reset by the PST block after readout.

### 4.5.6 F_PST

**Note**

This block is available as a part of PST template can be downloaded from the SIEMENS industry Online Support page. You can find the link in the APL V9.1 Readme (Online).

## 4.5.7 F_PST_S

**Note**

This block is available as a part of PST template can be downloaded from the SIEMENS industry Online Support page. You can find the link in the APL V9.1 Readme (Online).

## 4.5.8 PST_Calc block

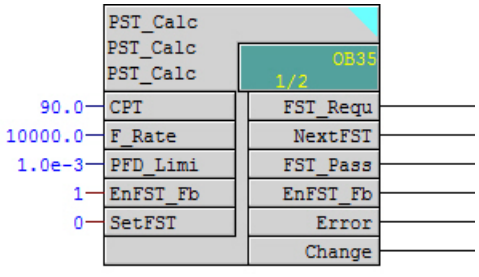
### 4.5.8.1 Description of PST_Calc

#### Object name (type + number) and family

Type + number: FB 1957

Family: CondMon

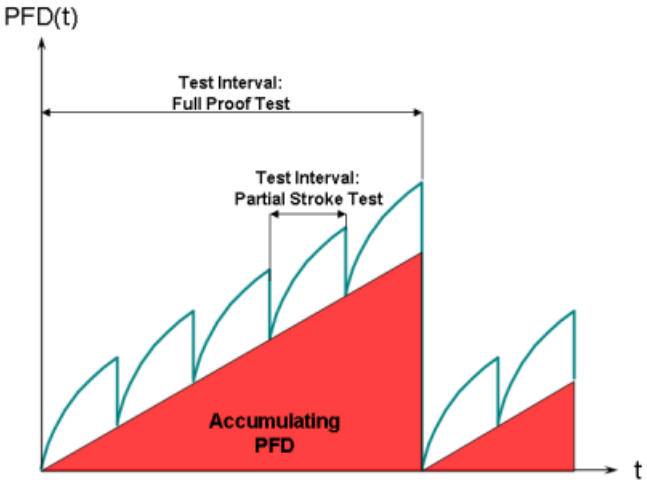
Number of process objects: 0 PO



#### Mode of operation

The PST_Calc block contains logic that calculates when the next full proof test of the valve body is required (see following figure). The Partial Stroke Test application defines this time as the date for the Full Stroke Test, but the user must specify the scope of the proof test that is required to test the entire valve body.

The block uses the data for the rate of occurrence of failure, the value for the Probability of Failure on Demand (PFDAVG) and the effect of the Partial Stroke Test to calculate the test interval to the next test required for the desired SIL level. The PST_Calc logic is responsible for the following tasks:

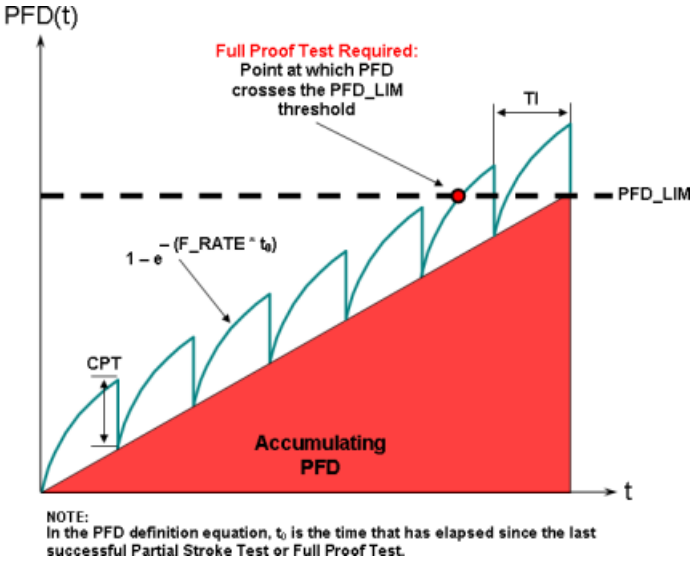


- Calculation of the running PFDAVG for the valve
- Output of a message for the user stating the next required Full Stroke Test (via PST block)
- Display of date and time at which the next Full Stroke Test is required

PST_Calc block in the valve startup test template:

A safety shutoff valve is not fully closed in a Partial Stroke Test. Not all failure modes of the valve can therefore be tested with this online test method. As already noted, the diagnostic coverage of an online proof test (CPT) is used a percentage measures of the effectiveness of a Partial Stroke Test. If the CPT value for a safety shutoff valve is 70%, for example, a Partial Stroke Test can detect 70% of all possible failure modes of the valve. Conversely, this means that 30 % of all the valve's possible failure modes cannot be tested. As these potentially undiagnosed errors accumulate, the Probability of Failure on Demand (PFDAVG) of the valve increases over time. The value for PFDAVG can only be reset to zero by a complete proof test (Full Stroke Test and associated tests), as this is the only way to achieve diagnostic coverage of 100 %. The following figure illustrates this concept:

Cumulation effect for the PFD value with the Partial Stroke Test:



After automatic tests are enabled for the first time, the PST_Calc block performs a series of calculations to determine the time of the next required full proof test (Full Stroke Test). PST_Calc calculates the curve for PFDAVG on the basis of criteria entered by the user. The PFDAVG curve for the valve is then updated when a new Partial Stroke Test or Full Stroke Test is run. This includes manually running these tests, which is also detected by the logic via monitoring of the feedback for the valve position. The PST_Calc block requires four values to calculate the next test date and time successfully:

- `TI`: The time interval between automatic Partial Stroke Tests (this input value for the PST block is transferred to the PST_Calc block)
- `CPT`: The Coverage of a Proof Test for the Partial Stroke Test
- `F_Rate`: The rate of dangerous undetected failures (λDU) for the valve
- `PFD_Limit`: The threshold value that must be met to comply with the desired SIL. If the calculated PFD value reaches the threshold value, a full proof test (Full Stroke Test) is required for the valve. This value is provided for the desired SIL in the SIL tables of the IEC 61511 standard.

The following figures illustrates the relationship between the parameters for PST_Calc.

Principle of operation of PST_Calc:

## Configuration

The inputs and outputs of the PST block that have to be parameterized by the user are described in the following two tables.

### Inputs of the PST_Calc block

| Parameter | Description | Type | Default |
|---|---|---|---|
| CPT | Effectiveness of the online proof test in percent (0 % - 100 %)<br>CPT should be set to the percentage value of the failure modes that a Partial Stroke Test covers with the test setpoint (TestSP). | REAL | 0.0 |
| F_Rate | Valve failure in time rate (FIT)<br>F_Rate defines the rate of dangerous undetected failures (λDU) for the valve body. | REAL | 100.0 |
| PFD_Limit | PFD threshold per SIL<br>PFD_Limit specifies the threshold value for PFDAVG below which the valve body must remain to achieve the desired SIL for the Safety Instrumented Function.<br>The PFDAVG values required for specified SIL levels are provided in the standard IEC 61511. | REAL | 100.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EnFST_Fbk | Enabled to record the Full Stroke Test feedback (1=enabled)<br>EnFST_Fbk allows the logic to register a Full Stroke Test solely from the valve position controller's feedback.<br>If enabled (with EnFST_Fbk=1), the logic always then registers a Full Stroke Test when the feedback indicates that the valve is fully closed (F_PST.FB_IN < (PST.ClosePos + PST.TestHyst)).<br>If disabled (with EnFST_Fbk= 0), no Full Stroke Test is registered under the same preconditions. In this case, the user can specify via the input SetFST that a Full Stroke Test has taken place. | BOOL | 1 |
| SetFST | Manual report of a Full Stroke Test (1=New Full Stroke Test)<br>When SetFST switches from 0 to 1, a new Full Stroke Test is registered. This resets the calculation of PFDAVG.<br>SetFST can be connected to the user-configured logic. As a new Full Stroke Test is only registered when SetFST switches from 0 to 1, the input has be to reset between the Full Stroke Tests. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0 u<br>• 16#80 |

## Outputs of the PST_Calc block

| Parameter | Description | Type | Default |
|---|---|---|---|
| FST_Request | Full Stroke Test required (1=Warning active)<br>FST_Request specifies the time at which a Full Stroke Test is required to maintain the desired SIL for the Safety Instrumented Function. This value is set to 1 if the time (date/time) specified by NextFST is exceeded at the current time. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NextFST | Time stamp for next Full Stroke Test<br>NextFST outputs a text string that specifies the time of the next required Full Stroke Test.<br>The Full Stroke Test must be performed at the specified time to maintain the desired SIL for the Safety Instrumented Function. | Data type: STRING [16] | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Error | Indicates invalid parameters (1=Invalid parameters)<br>The following validity checks are performed for the PST_Calc block:<br>• CPT >= 0 and CPT < 100<br>• F_Rate > 0<br>If an invalid parameter is detected, Error is set t o1.<br>PST_Calc is only calculated if automatic tests are first enabled (e.g. for PST.TI > 0) and then a Full Stroke Test is performed.<br>To reset Error and force the calculation to update, a Full Stroke Test must be performed or automatic tests must be disabled and re-enabled. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Change | Indicates parameter change (1=Parameter changed)<br>If one of the following parameter values changes between the two Full Stroke Test (where automatic tests are enabled, the block calculations are invalid and Change is set to 1:<br>• PST.TI<br>• CPT<br>• F_Rate<br>• PFD_Limit<br>PST_Calc is only calculated if automatic tests are first enabled (e.g. for PST.TI > 0) and then a Full Stroke Test is performed.<br>To reset Change and force the calculation to update, a Full Stroke Test must be performed or automatic test must be disabled and re-enabled. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

**Note**

The PST_Calc block has additional inputs and outputs that are not documented in the two above tables. These inputs and outputs are used by the Partial Stroke Test logic to transfer data between blocks and are normally hidden. The user should only define the parameters described in the table.

### 4.5.8.2 I/Os of PST_Calc

#### I/Os of PST_Calc

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

#### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CPT | Diagnostic coverage of the Partial Stroke Test [%] | REAL | 0.0 |
| EnFST_Fbk | Evaluation of the Full Stroke Test on the basis of the feedback | BOOL | 1 |
| f_FST_Passed | New passed Full Stroke Test [feedback] | UDT_F_B | |
| f_Passed | New passed Partial Stroke Test | UDT_F_B | |
| F_Rate | Valve failure in time rate [FIT] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PFD_Limit | PFD threshold value as per required SIL | REAL | 0.0 |
| SetFST | New passed Full Stroke Test (manual input) | BOOL | 0 |
| TI | Test interval [hours] | INT | 0 |

### Output parameters

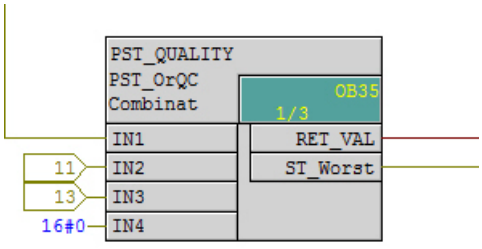
| Parameter | Description | Type | Default |
|---|---|---|---|
| Change | 1=Parameter has been changed | DigVal | |
| EnFST_FbkOut | Evaluation of the Full Stroke Test on the basis of the feedback | DigVal | |
| Error | Error in internal block | DigVal | |
| FST_Passed | Evaluation of the inputs f_FST_Passed and SetFST | DigVal | |
| FST_Request | Full Stroke Test required (1=Warning active) | DigVal | |
| NextFST | Time and date for next Full Stroke Test | STRING[16] | |

## 4.5.9 PST_OrQC block

### 4.5.9.1 Description of PST_OrQC

### Object name (type + number) and family

Type + number: FC 449



Family: CondMon

Number of process objects: 0 PO

### Mode of operation

The PST_OrQC block contains logic that evaluates the quality codes of a maximum of four driver blocks for possible poor signal quality. The block returns a single output value. The block evaluates the quality codes of the driver blocks that are used in the engineering template for the Partial Stroke Test. The result can then be connected to the CSF input of the F_PST block.

PST_OrQC block in the valve startup test template:

### Configuration

The inputs and outputs of the PST block that have to be parameterized by the user are described in the following two tables.

### Inputs of the PST_OrQC block

| Parameter | Description | Type | Default |
|---|---|---|---|
| INx | Input x (x=1..4)<br>If IN1, IN2, IN3 and IN4 are equal to 16#80, the quality of the signal is good.<br>If one of the inputs INx is not equal to 16#80, the quality of the signal is bad. | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

### Outputs of the PST_OrQC block

| Parameter | Description | Type | Default |
|---|---|---|---|
| RET_VAL | Return value of the function<br>If all the input signals return a quality code for "good", RET_VAL is set to FALSE.<br>If at least one of the inputs returns a quality code for "bad", RET_VAL is set to TRUE. | BOOL | |

## 4.5.9.2 I/Os of PST_OrQC

### I/Os of PST_OrQC

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| IN1 | Signal Status 1 | AnaVal | 16#80 |
| IN2 | Signal Status 2 | AnaVal | |
| IN3 | Signal Status 3 | AnaVal | |
| IN4 | Signal Status 4 | AnaVal | |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| RET_VAL | Return value of the function | | |
| ST_Worst | Worst signal status | BYTE | 16#80 |

## 4.5.10 PST_Time block

### 4.5.10.1 Description of PST_Time

#### Object name (type + number) and family

Type + number: FC 448

Family: CondMon

Number of process objects: 0 PO

#### Mode of operation

The PST_Time block contains logic that adds a time constant to the time stamp (of a passed test) and returns the value as a character string for display purposes.

#### Configuration

The PST_Time block is called by the PST block (within the SCL code of the PST block). The block is not visible to the user in the Partial Stroke Test engineering template, but belongs to the Partial Stroke Test application and the Condition Monitoring Library.

### 4.5.10.2 I/Os of PST_Time

#### I/Os of PST_Time

For the parameters that are not linkable, refer:Parameters that cannot be connected (Page 75)

#### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `ActTime` | Actual time<br>`ActTime` is the original time stamp. | DATE_AND_TIME | DT#90-1-1-0:0:0.000 |
| `OffsetH` | Time delay (hours)<br>`OffsetH` is the time delay in hours that is added to `ActTime`. | REAL | 0.0 |
| `OffsetMs` | Time delay (milliseconds)<br>`OffsetMs` is the time delay in milliseconds that is added to `ActTime`. | TIME | T#0s |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| RET_VAL | Return value of the function<br>RET_VAL is the sum of ActTime, OffsetH and OffsetMs after conversion to a format for character strings. | STRING[16] | |

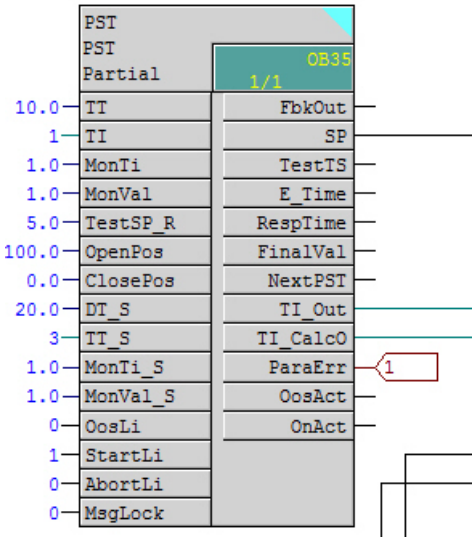
## 4.5.11 PST Block

### 4.5.11.1 Description of PST

#### Object name (type + number) and family

Type + number: FB 1956

Family: CondMon



Number of process objects: 30 PO

#### Mode of operation

The PST block contains the standard logic for the Partial Stroke Test application (see following figure). The PST logic is responsible for the following tasks:

- Acts as interface to the block icon for the Partial Stroke Test/solenoid valve test (for data transfer to/from the PCS 7 OS)
- Records the time the valve requires to reach the desired stroke setpoint during a Partial Stroke Test
- Records the feedback of the valve position controller at the end of a Partial Stroke Test
- Controls the valve position controller setpoint
- Defines the messages for Partial Stroke Test/solenoid valve test (to be used together with PCS 7 OS)

PST block in the Partial Stroke Test template:

## Configuration

The inputs and outputs of the PST block that have to be parameterized by the user are described in the I/O descriptions (AUTOHOTSPOT).

### Startup characteristics

Use `Feature.Bit0` (Setting the startup characteristics) to define the startup characteristics of this block.

- **Bit = 0:** The most recently stored values are reset at startup.
- **Bit = 1:** The most recently used values are sent to the following output parameters at startup:
  - `SP_UpRaAct`
  - `SP_DnRaAct`
  - `TripAct`
  - `PST_ReqAct`
  - `FailedAct`
  - `PassedAct`
  - `FST_PassedAct`
  - `FbkErrActAct`
  - `InhibitAct`
  - `AbortedAct`
  - `RunAct`
  - `Failed_S_Act`
  - `Passed_S_Act`
  - `Inhibit_S_Act`
  - `Run_S_Act`
  - `StartEnAct`
  - `StartEn_S_Act`

**Note**

Additional information about `Feature.Bit0` can be found in the *PCS 7 Advanced Process Library* manual.

### Status word assignment for the `Status1` parameter

For a description of the individual parameters, refer to the section AUTOHOTSPOT.

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `Not used` |
| 3 | `"Out of service" operating mode (OosAct.Value)` |
| 4 | `"Out of service" operating mode (OosLi.Value)` |
| 5 | `OnAct.Value` |

| Status bit | Parameter |
|---|---|
| 6 | MsgLock.Value |
| 7 | Started_MsgEn |
| 8 | Ended_MsgEn |
| 9 | Passed_MsgEn |
| 10 | Failed_MsgEn |
| 11 | Aborted_MsgEn |
| 12 | FbkErr_MsgEn |
| 13 | Inhibit_MsgEn |
| 14 | FST_Passed_MsgEn |
| 15 | FST_Request_MsgEn |
| 16 | PST_Request_MsgEn |
| 17 | ErrCalc_MsgEn |
| 18 | ChangeCalc_MsgEn |
| 19 | Started_S_MsgEn |
| 20 | Ended_S_MsgEn |
| 21 | Passed_S_MsgEn |
| 22 | 1 = setpoint ramp active |
| 23 | Inhibit_S_MsgEn |
| 26 | 1 = automatic test active |
| 27 | 1 = ParaErr parameter error |
| 28 | Internal Error |
| 29 | 1= Suppressed messages |
| 30 - 31 | Not used |

### Status word assignment for `Status2` parameter

For a description of the individual parameters, refer to the section AUTOHOTSPOT.

| Status bit | Parameter |
|---|---|
| 0 | Partial Stroke Test started |
| 1 | Partial Stroke Test completed |
| 2 | Not used |
| 3 | Partial Stroke Test passed |
| 4 | Partial Stroke Test failed |
| 5 | Partial Stroke Test failed because valve is blocked |
| 6 | Partial Stroke Test aborted |
| 7 | Partial Stroke Test feedback error |
| 8 | Partial Stroke Test NOT performed because trigger state not met |
| 9 | Partial Stroke Test NOT performed because enable precondition not met |
| 10 | Partial Stroke Test NOT performed because feedback is poor quality |
| 11 | Partial Stroke Test NOT performed because feedback below tolerance |
| 12 | Partial Stroke Test NOT performed because solenoid valve test is running |
| 13 | Partial Stroke Test NOT performed because parameter invalid |

| Status bit | Parameter |
|---|---|
| 14 | Full Stroke Test passed |
| 15 | Full Stroke Test required |
| 16 | Partial Stroke Test required |
| 17 | Calculation parameter assignment error |
| 18 | Calculation parameter change |
| 19 | Solenoid valve test started |
| 20 | Solenoid valve test completed |
| 21 | Solenoid valve test passed |
| 22 | Solenoid valve test failed |
| 23 | Solenoid valve test NOT performed |
| 24 | Solenoid valve test running |
| 25 | Partial Stroke Test running |
| 26 | FailedAct |
| 27 | InhibitAct |
| 28 | Solenoid valve test enabled |
| 29 | TripAct |
| 30 | ILockAct |
| 31 | Not used |

### 4.5.11.2 PST operating modes

This block can be set to the following modes:

- On
- Out of service

#### "On"

General information about the "On" operating mode can be found in the "On" section of the *"PCS 7 Advanced Process Library"* manual.

#### "Out of service"

General information about the "Out of service" operating mode can be found in the "Out of service" section of the *PCS 7 Advanced Process Library* manual.

### 4.5.11.3 PST functions

The functions for this block are listed below.

#### Forming the signal status for blocks

This block provides the standard function "Forming and outputting the signal status for technologic blocks" (see the *"PCS 7 Advanced Process Library"* manual).

The worst signal status `ST_Worst` for the block is formed from the following parameter `ST_WorstIn`. This is connected to the PST_OrQC block.

### Configurable reactions using the `Feature` parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in section "Configurable response using the Feature I/O" (see the *PCS 7 Advanced Process Library* manual). The following modes of behavior are available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Setting the startup characteristics |
| 1 | Characteristics for the out of service mode |
| 22 | Update acknowledgment and error status of the alarm call |
| 24 | Enabling local operator authorization |

### Operator control permissions

This block provides the standard function "Operator control permissions" (see the *"PCS 7 Advanced Process Library"* manual).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | 1 = Operator can switch to "Out of service" mode |
| 3 – 9 | Not used |
| 10 | 1 = User can start a manual Partial Stroke Test |
| 11 | 1 = User can abort a manual Partial Stroke Test |
| 12 | 1 = User can change the automatic test interval for the Partial Stroke Test |
| 13 | 1 = User can change the test setpoint for the Partial Stroke Test |
| 14 | 1 = User can change the position tolerance for the Partial Stroke Test |
| 15 | 1 = User can change the maximum test time for the Partial Stroke Test |
| 16 | 1 = User can change the delay time for the solenoid valve test |
| 17 | 1 = User can change the minimum position change for the solenoid valve test |
| 18 – 31 | Not used |

### Gradient limit of the setpoint

This block provides the standard function "Gradient limit of the setpoint" (see the *PCS 7 Advanced Process Library* manual). This is used to slow down the setpoint set in the valve position controller.

By default, the gradient limit effect is disabled. If the speed of the valve stroke has to be reduced by the Partial Stroke Test application by limiting the gradient, SP_DnRaLim must be set to a value greater than 0 and SP_RateOn = TRUE. Note that the speed is however only limited when a Partial Stroke Test is performed. If the valve is actuated by a logic other than the Partial Stroke Test logic (e.g. in the case of forced closing of the valve by valve trigger), speed limiting is disabled. When

using the ramp function, the TT and MonTi parameters should be adjusted so that the Partial Stroke Test is performed correctly.

**Note**

For technological reasons, it is not possible to change the parameters of "gradient limit" in the faceplate. They are only shown with their current values. A change is generally made during commissioning by direct entry in the CFC and therefore no change is normally made.

### Opening additional faceplates

You can open the standard view of the technological block (e.g. VlvAnL) interconnected to the input parameter `MV` using a button in the standard view of the faceplate. The interconnection makes the button in the standard view visible.

### SIMATIC BATCH functionality

This block has the standard function "SIMATIC BATCH functionality" (see the *"PCS 7 Advanced Process Library"* manual).

## 4.5.11.4 PST error handling

The block overwrites the following parameters with 0 if they were configured with a negative value and set the output parameter `ParaErr`:

- `TT`
- `TI`
- `MonVal`
- `MonTi`
- `TestHyst`
- `MonVal_S`
- `MonTi_S`
- `DT_S`
- `TT_S`

### Overview of error numbers

The `ErrorNum` I/O can be used to output various error numbers:

| Error ID | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 43 | TimeFactor < 0 or >2 |

### 4.5.11.5 PST reporting

#### Message behavior

The PST block contains the logic and the setup for the messages that can be displayed in the PCS 7 OS. To generate messages, `PST.MsgLock` (lock messages) must be set to 1. Thereafter, the standard settings are displayed for Partial Stroke Test application messages.

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Status message - AS | Partial stroke test started |
| | SIG 2 | Status message - AS | Partial stroke test ended: response time = @4R%4.1f@ sec |
| | SIG 3 | Status message - AS | Partial stroke test ended: test setpoint = @6R%4.1f@%, final position = @5R%4.1f@% |
| | SIG 4 | Status message - AS | Partial stroke test successful |
| | SIG 5 | AS process control message - fault | Partial stroke test failed |
| | SIG 6 | AS process control message - fault | Partial stroke test failed because valve is stuck |
| | SIG 7 | Status message - AS | Partial stroke test aborted |
| | SIG 8 | AS process control message - fault | Partial stroke test feedback error |

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | Partial stroke test NOT run: Trip state not met |
| | SIG 2 | AS process control message - fault | Partial stroke test NOT run: Permissives not met |
| | SIG 3 | AS process control message - fault | Partial stroke test NOT run: Feedback bad quality |
| | SIG 4 | AS process control message - fault | Partial stroke test NOT run: Feedback below tolerance |
| | SIG 5 | AS process control message - fault | Partial stroke test NOT run: Solenoid test is running |
| | SIG 6 | AS process control message - fault | Partial stroke test NOT run: Invalid parameter |
| | SIG 7 | Status message - AS | Full stroke test passed |
| | SIG 8 | AS process control message - fault | Full stroke test required |

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| MsgEvId3 | SIG 1 | AS process control message - fault | Partial stroke test required |
| | SIG 2 | AS process control message - fault | Parameterization error calculation |
| | SIG 3 | AS process control message - fault | Parameter change calculation |
| | SIG 4 | Status message - AS | Solenoid valve test started |
| | SIG 5 | Status message - AS | Solenoid valve test ended |
| | SIG 6 | Status message - AS | Solenoid valve test passed |
| | SIG 7 | AS process control message - fault | Solenoid valve test failed |
| | SIG 8 | AS process control message - fault | Solenoid valve test NOT run |

### Associated values for the message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `RespTime.Value` |
| 5 | `FinalVal.Value` |
| 6 | `TestSP_Out` |
| 7 | Not used |
| 8 | Not used |
| 9 | Not used |
| 10 | Not used |

### Associated values for message instance `MsgEvId2`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | Not used |
| 5 | Not used |
| 6 | Not used |
| 7 | Not used |
| 8 | Not used |

## 4.5.11.6 PST I/Os

### I/Os of PST I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Aborted_MsgEn` | 1 = Enable "Partial Stroke Test aborted" message | BOOL | 1 |
| `AbortLi` | Abort test<br>(1=Abort)<br>`AbortLi` can be connected to a user-configured logic to abort a Partial Stroke Test. During an active test (i.e. when `F_PST.QRUN` = 1), the test is aborted if `AbortLi` switches to 1. Note that a test is aborted if `AbortLi` switches from 0 to 1 (i.e. `AbortLi` must be reset between two tests). | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AbortOp` | 1 = Abort Partial Stroke Test via OS operator input | BOOL | 0 |
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | STRING[32] | '' |
| `BlkTypeInfo*` | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |

| Started_MsgEn | 1 = Enable "Partial Stroke Test started" message | BOOL | 1 |
| Started_S_MsgEn | 1 = Enable "Solenoid valve test started" message | BOOL | 1 |
| StartLi | Connectable input for manual test request<br>(1=Start test)<br>StartLi can be connected to a user-configured logic to start a Partial Stroke Test. If all test preconditions are met, a Partial Stroke Test is started when StartLi is set to 1. Note that a new test is started if StartLi switches from 0 to 1 (i.e. StartLi must be reset between two tests). | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartOp | 1 = Start Partial Stroke Test via OS operator input | BOOL | 0 |
| StepNo | Batch step number | DWORD | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| TestHyst | Hysteresis for "Test passed/failed"<br>The success/failure status of a Partial Stroke Test is determined by TestHys. For a passed test, the feedback of the valve position controller must be less than or equal to the value for (TestSP + TestHyst). | REAL | 0.0 |
| TestSP | Valve stroke position<br>TestSP is the setpoint for the valve position that is used for a Partial Stroke Test. During configuration, TestSP must be set to the value that corresponds to the supplier's recommendations for a passed Partial Stroke Test.<br>The value for TestSP should be between the values for the fully open position (OpenPos) and the fully closed position (ClosePos).<br>The Partial Stroke Test logic does not contain position limitation (which prevents the valve closing too far). The user should take this into account when specifying the value for TestSP. | REAL | 100.0 |
| TestSP_HiLim | Limit (high) of the setpoint | REAL | 100.0 |
| TestSP_LoLim | Limit (low) of the setpoint | REAL | 0.0 |
| TestSP_Range | Range for the test setpoint<br>TestSP_Range is the range in which the test setpoint TestSP fluctuates.<br>The setpoint range TestSP_Range must be less than (OpenPos - ClosePos) / 2.0. | REAL | 0.0 |
| TI | Test interval [h]<br>When TI > 0, automatic tests are enabled.<br>If TI is changed while a timer is running, the timer is fully reset (at the same time, no test is run until TI has fully completed).<br>If TI is changed while a timer is running, the user is recommended to perform a manual Partial Stroke Test to take into account the time interval before TI changed.<br>If a recommended Partial Stroke Test is not performed because it has been inhibited (because a specific start precondition has not been met), the timer for the automatic test is re-started and must complete before it is possible to attempt to start a test automatically again. | INT | 0 |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| TT | Duration of the test; maximum valve response time [s]<br>TT is the period of time that is allocated to the valve position setpoint TestSP for a Partial Stroke Test. To determine the TT value, the valve response time should be determined first via a manual stroke test (i.e. the time in which the valve normally reaches TestSP).<br>When TT = 0, a test is not possible. | REAL | 10.0 |
| TT_S | Duration of the solenoid valve test [cycles]<br>TT_S is the time period measured in cycles for which the solenoid valve receives closing pulses during a solenoid valve test.<br>For a solenoid valve test to be run, it is necessary for TT_S > 0. | INT | 3 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Abort | Abort test (1=Abort) | BOOL | 0 |
| AbortedAct | 1=Test was aborted | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Active | 1=Test active | BOOL | 0 |
| ClosePosOut | Valve position for "completely closed" | REAL | 0.0 |
| DT_S_Out | Delay time for solenoid valve test [ms] | TIME | 0ms |
| E_Time | Elapsed test time [s] | STRUCT<br>• VALUE: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ErrorNum | Output of the existing error number. For error numbers that can be output by this block, see AUTOHOTSPOT. | INT | -1 |
| Failed_S_Act | 1=Last solenoid valve test failed | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FailedAct | 1=Last test failed | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkErrAct | 1=Feedback error | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOut | Feedback signal from the valve position controller | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FinalVal | Valve actual position at end of test | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FST_PassedAct | 1=New passed Full Stroke Test | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | Quality of feedback (1=good, 0=bad) | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Inhibit_S_Act | 1=Solenoid valve test inhibited | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| InhibitAct | 1=Start was inhibited | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LockAct | Test enable signals (1=Enable test, 0=Inhibit test) | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonTi_S_Out | Monitoring time for solenoid valve test [ms] | TIME | 0ms |
| MonTiOut | Monitoring time for start Partial Stroke Test [ms] | TIME | 0ms |
| MonVal_S_Out | Change of feedback value for solenoid valve test required | REAL | 0.0 |
| MonValOut | Change in feedback value within the monitoring time required | REAL | 0. |
| MsgAckn1 | Message block 1: Output value for ACK_STATE | WORD | 16#0000 |
| MsgAckn2 | Message block 2: Output value for ACK_STATE | WORD | 16#000 |
| MsgAckn3 | Message block 3: Output value for ACK_STATE | WORD | 16#0000 |
| MsgErr1 | Message error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgErr2 | Message error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgErr3 | Message error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message block 1: Output value for STATUS | WORD | 16#0000 |
| MsgStat2 | Message block 2: Output value for STATUS | WORD | 16#0000 |
| MsgStat3 | Message block 3: Output value for STATUS | WORD | 16#0000 |
| NextPST | Time stamp for next Partial Stroke Test<br>NextPST is only used for display to the user. The logic to calculate the next required automatic Partial Stroke Test is executed by the F_PST block. | STRING[16] | '' |
| OnAct | 1 = Block is "On" | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenPosOut | Valve position for "completely open" | REAL | 0.0 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |

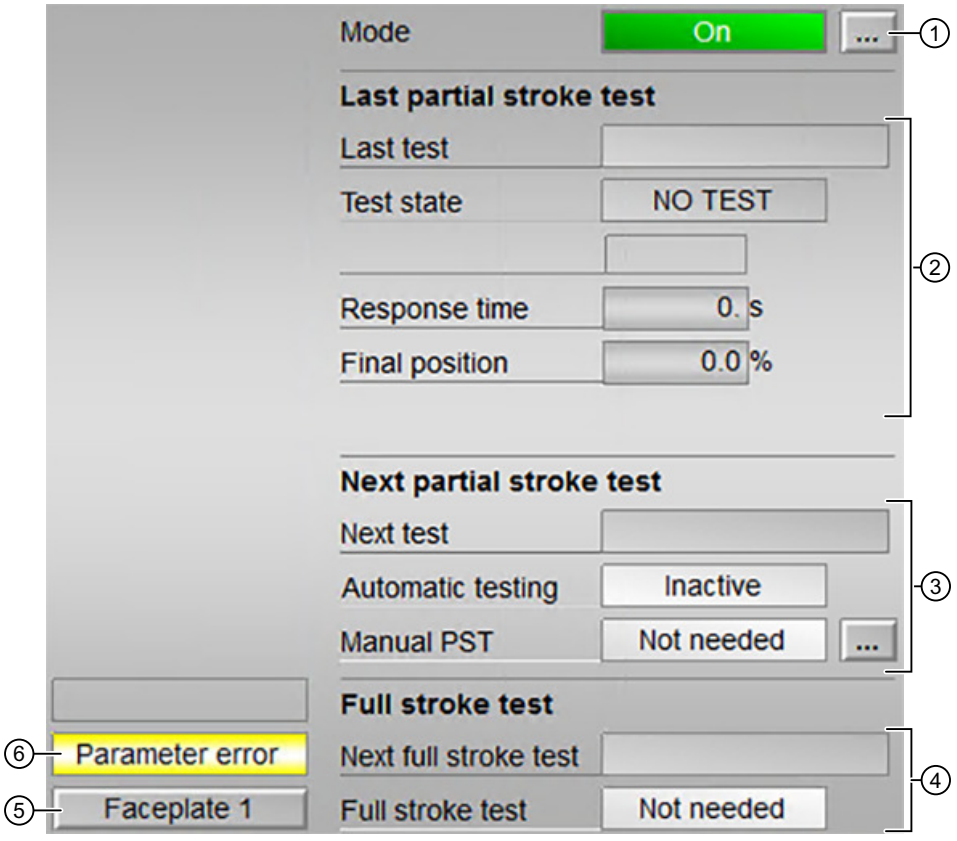
| Parameter | Description | Type | Default |
|---|---|---|---|
| ParaErr | Indicates invalid parameters<br>(1=Invalid parameters)<br>A Partial Stroke Test cannot be started if one of the test parameters (for times, values or ranges) has an invalid value. The following validity checks are run for a Partial Stroke Test:<br>• OpenPos > ClosePos<br>• TT > 0<br>• MonVal >= 0 and MonVal < (OpenPos – TestSP)<br>• MonTi >= 0 and MonTi < TT<br>• TestHyst >= 0<br>• (TestSP + TestSP_Range + TestHyst) < OpenPos and (TestSP – TestSP_Range – TestHyst) > ClosePos<br>A solenoid valve test cannot be started if one of the test parameters (for times, values or ranges) has an invalid value. The following validity checks are run for a solenoid valve test:<br>• DT_S >= 0 and DT_S < (TI – TT_S – MonTi_S)<br>• TT_S > 0 and TT_S < (TI – MonTi_S)<br>• MonVal_S >= 0 and MonVal_S < OpenPos<br>• MonTi_S >= 0 and MonTi_S < TT_S<br>If an invalid parameter is detected, ParaErr is set t o1. | BOOL | 0 |
| Passed_S_Act | 1=Last solenoid valve test passed | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PassedAct | 1=Last test passed | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PST_ReqAct | 1=Partial Stroke Test required | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RespTime | Response time until test setpoint reached [s] | STRUCT<br>• VALUE: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Run_S_Act | Solenoid valve test execution status (1=executed, 0=not executed) | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RunAct | Execution status (1=executed, 0=not executed) | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP | Setpoint of the valve position controller | STRUCT<br>• VALUE: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_DnRaAct | 1 = Negative gradient limit of the setpoint is active | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RateTarget | Target setpoint for gradient limit | REAL | 0.0 |
| SP_UpRaAct | 1 = Positive gradient limit of the setpoint is active | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Start | Manual test requirement (1=start test) | BOOL | |
| StartEn_S_Act | 1 = Solenoid valve test enabled | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartEnAct | Status: 1 = Partial Stroke Test enabled | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word | DWORD | 16#0 |
| Status2 | Status word | DWORD | 16#0 |
| TestHystOut | Valve position hysteresis for "Test passed/failed" | REAL | 0.0 |
| TestSP_HiOut | Limit (high) of the setpoint | STRUCT<br>• VALUE: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| TestSP_LoOut | Limit (low) of the setpoint | STRUCT<br>• VALUE: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TestSP_Out | Valve stroke position | REAL | 0.0 |
| TestTS | Time stamp for last test | STRING[16] | '' |
| TI_CalcOut | Test interval for PST_Calc [h] (0=no automatic tests) | INT | |
| TI_Out | Test interval [h] (0=no automatic tests) | INT | 0 |
| TripAct | Valve state after trip (1=open, 0=closed) | STRUCT<br>• VALUE: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TT_Out | Duration of the test; maximum valve response time [ms] | TIME | 0ms |
| TT_S_Out | Duration of the solenoid valve test [cycles] | INT | 0 |

### 4.5.11.7 Operator control and monitoring

#### Operator control and monitoring of the Partial Stroke Test

At runtime, the user can access the Partial Stroke Test component user interface via the PCS 7 OS. The block icon and the faceplate for the Partial Stroke Test application in this case are represented visually in the application configured and monitored in SIMATIC Manager.



#### Views of the Partial Stroke Test

The PST block has the following views:

- Standard view of PST (Page 687)
- Alarm View (Page 336)
- Parameter view (Page 689)
- Ramp view (Page 690)
- Preview (Page 691)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for PumpMon (Page 692)

For general information on the faceplate and block icon, refer to the "Structure of the faceplate (Page 279)" and "Block icon structure (Page 260)" sections.

### Partial Stroke Test standard view

**(1) Display and switchover of operating mode**
This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On
- Out of service

**(2) Last Partial Stroke Test**
This area display the result of the last performed Partial Stroke Test.

The following information is available:

- "Last test": Time of last Partial Stroke Test (`TestTS`)
- "Test status": Result of the last Partial Stroke Test
  - "NO TEST": No Partial Stroke Test has yet been performed
  - "RUNNING": A Partial Stroke Test is running now
  - "PASSED": The last Partial Stroke Test passed
  - "FAILED": The last Partial Stroke Test failed
  - "INHIBITED": The last Partial Stroke Test was inhibited
  - "ABORTED": The last Partial Stroke Test was aborted
  - "FEEDBACK ERROR": The last Partial Stroke Test had a feedback error

- "Test time": Current time period of a running Partial Stroke Test (`E_Time`). This field is only visible if "Test status" = "RUNNING".
- "Response time": Response time to reach the test setpoint during the last Partial Stroke Test (`RespTime`)
- "End position": End position when test setpoint was reached during the last Partial Stroke Test (`FinalVal`)
- "Solenoid valve status": Result of the last solenoid valve test
  - "NO TEST": No solenoid valve test has yet been performed
  - "RUNNING": A solenoid valve test is running now
  - "PASSED": The last solenoid valve test passed
  - "FAILED": The last solenoid valve test failed
  - "INHIBITED": The last solenoid valve test was inhibited

  This field is only visible if the optional visible has been enabled (`StartEn_S_Act`)

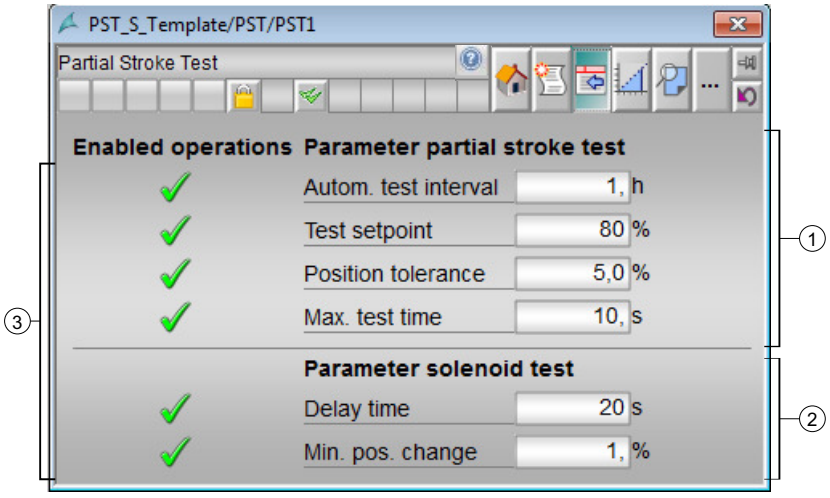
**(3) Next Partial Stroke Test**
This area displays information about the next planned Partial Stroke Test.

The following information is available:

- "Next test": Time (`NextPST`) of the next planned Partial Stroke Test (time stamp is only shown if automatic test is enabled)
- "Automatic test":
  - "Active": Calculation of the next automatic test time is enabled (`TI > 0`)
  - "Inactive": No calculation of the next test time (`TI = 0`)
- "Manual PST": Provides the ability to start or inhibit a manual Partial Stroke Test. The request status for a manual test is also displayed:
  - "Not required": A manual Partial Stroke Test is not required
  - "REQUESTED": A manual Partial Stroke Test must be performed (if "Automatic test" = "Active" and `F_PST.AUTO_EN = FALSE`)

**(4) Full Stroke Test**
This area displays information about the next Full Stroke Test that is necessary.

The following information is available:



- "Next Full Stroke Test": Indicates the time (`NextFST`) of the next required Full Stroke Test (if "Automatic test" = "Active")
- "Full Stroke Test": Indicates the request status for a Full Stroke Test:
  - "Not required": A Full Stroke Test is currently not required
  - "REQUESTED": A Full Stroke Test must be performed

**(5) Tab key for switching to the standard view of any faceplate**
This display is only visible when the corresponding `SelFp1` block input is connected. Use this jump button to reach the standard view of the interconnected block.

**(6) Display area for block states**
This area provides additional information on the operating state of the block:

- Parameter assignment error
- Internal Error

## Partial Stroke Test parameter view

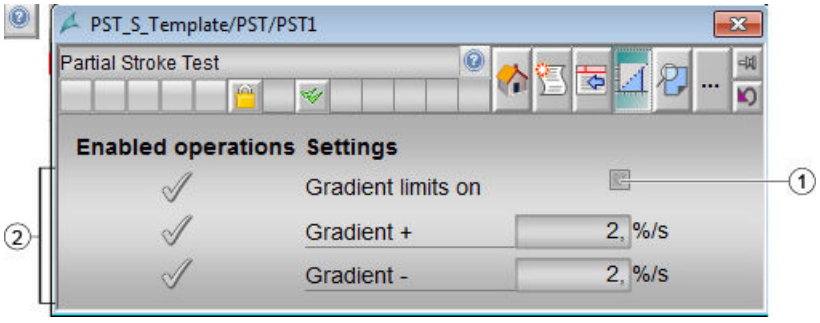
**(1) Partial Stroke Test parameters**
You can enter the parameters for the Partial Stroke Test in this area.

You can change the following parameters:

- "Automatic test interval": Indicates the test interval for automatic performance of Partial Stroke Tests in [h] (`TI`)
- "Test setpoint": Indicates the setpoint (`TestSP`)
- "Position tolerance": Indicates the position tolerance about the position setpoint (`TestHyst`)
- "Maximum test time": Indicates the maximum time period to reach the test setpoint (`TT`)

**(2) Solenoid valve test parameters**
You can enter the parameters for the optional solenoid valve test here.

You can change the following parameters if the solenoid valve test is enabled (`StartEn_S_Act`):



- "Delay time": Indicates the time delay between a passed Partial Stroke Test and the start of a solenoid valve test (`DT_S`)
- "Minimum change in position": Indicates the value of the change in position (`MonVal_S`) that is required to pass the solenoid valve test within the defined test time (`MonTi_S`).

**(3) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

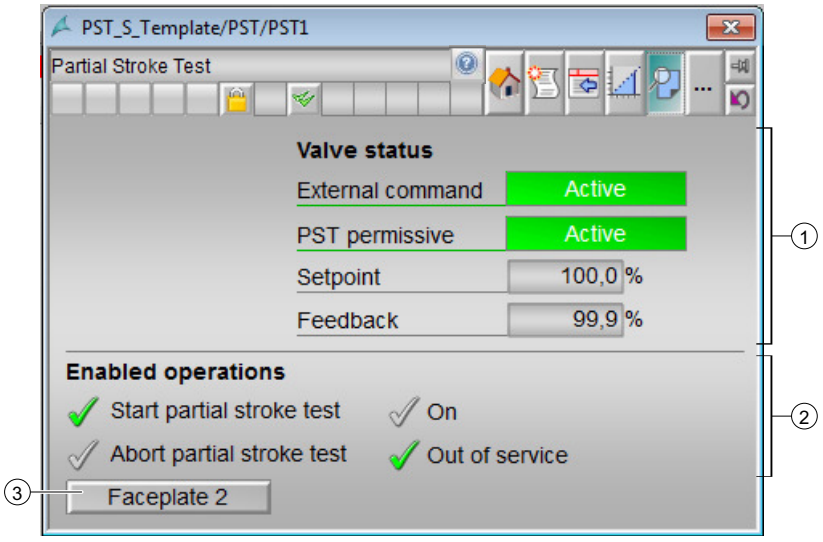
Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

## Partial Stroke Test ramp view

**(1) Enable "Gradient limit"**
The option checkbox shows you whether the "Gradient limit" is enabled and which values the "Gradient limit" has for positive and negative changes to the setpoint.

**Note**



For technological reasons, it is not possible to change the parameters of "gradient limit" in the faceplate. They are only shown with their current values. A change is generally made during commissioning by direct entry in the CFC and therefore no change is normally made.

**(2) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator can control this parameter
- **Gray check mark:** Access to this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

## Partial Stroke Test preview

**(1) "Valve status" preview area**
A preview is displayed here for the following values:

- "External command": Indicates the valve control status (`TripAct`)
- "Enable status": Indicates the status of the enable conditions for a Partial Stroke Test (`LockAct`)
- "Setpoint": Indicates the currently calculated setpoint (`SP`)
- "Read back value": Indicates the position feedback currently read back (`FbkOut`)

**(2) Enabled operations**
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark:** The OS operator may edit this parameter
- **Gray check mark:** Editing of this parameter is temporarily disabled for the OS operator due to process conditions
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`) .

The following enabled operations are shown here:

- "Start Partial Stroke Test": You may start the Partial Stroke Test.
- "Abort Partial Stroke Test": You may abort the Partial Stroke Test.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.

### Partial Stroke Test block icon

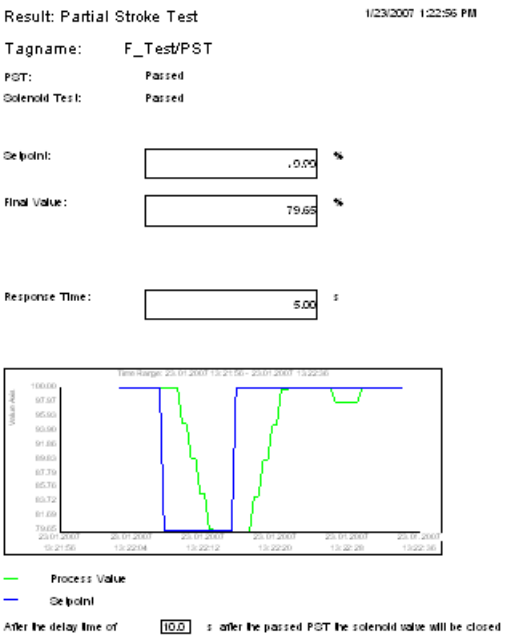
A block icon with the following displays is available to you:

- Block type or process tag
- Operating modes
- Current status of the Partial Stroke Test application.

The block icon from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in full display in the normal state |
|  | 2 | Block icon in full display in the normal state |
|  | | Block icon in the "Out of service" operating mode |

You can find additional information about the block icon and the operator control options in the block icon in the following sections:



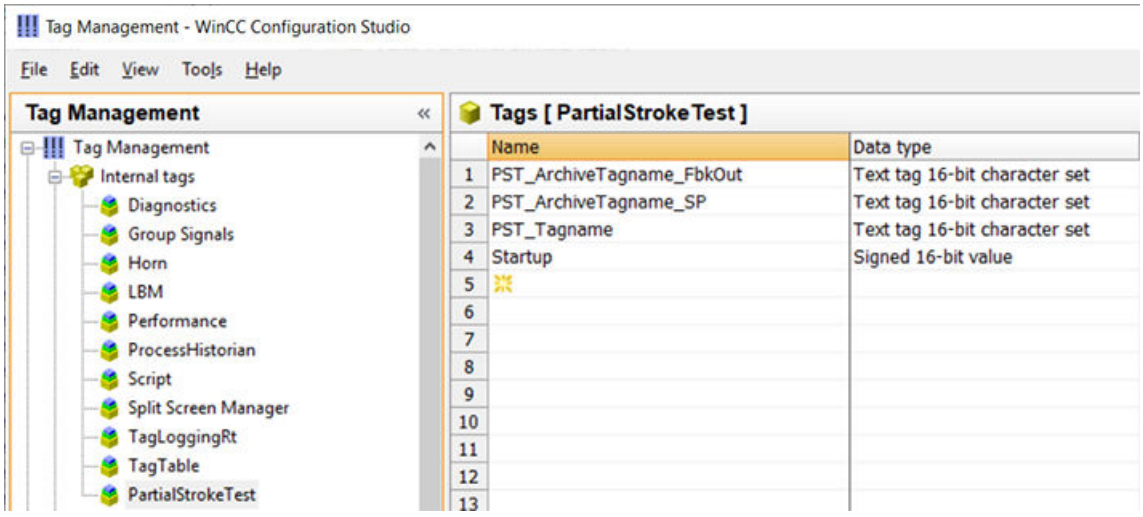
- "Configuring the block icons (Page 267)"
- "Block icon structure (Page 260)"
- "Operation via the block icon (Page 269)".

## 4.5.12 Create reports

The user has the option of creating reports after a Partial Stroke Test has been performed. The following files are provided for this purpose:

- Report layouts
  The report layouts are located in WinCC Explorer under "Report Designer\Layouts":
  - PST_DEU.RPL (German version)
  - PST_ENU.RPL (English version)
- PST.pas action for starting the print job.
  This file is located in the WinCC installation folder in the folder \WinCC\CML\PST after the Condition Monitoring Library has been installed.

Layout of the test document for the Partial Stroke Test:



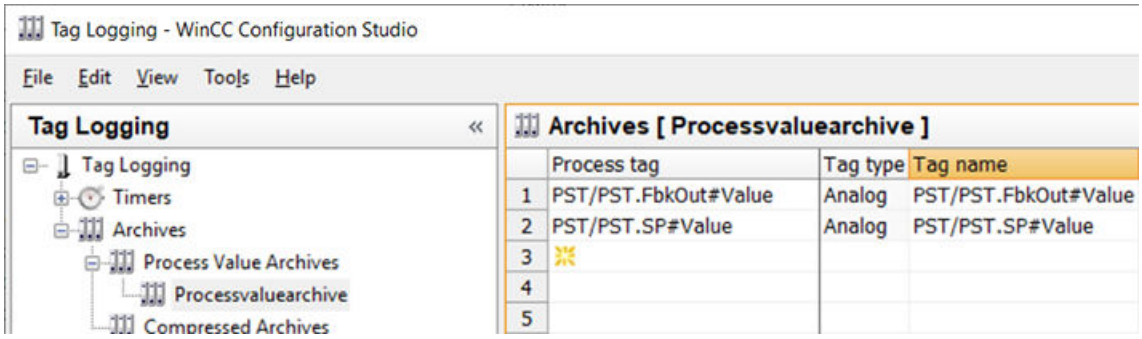
The following sections describe the procedure for configuring and activating a report for a Partial Stroke Test.

## Internal Tags

The internal tags are required to transfer the tag names and names of the archive tags to the report layout.

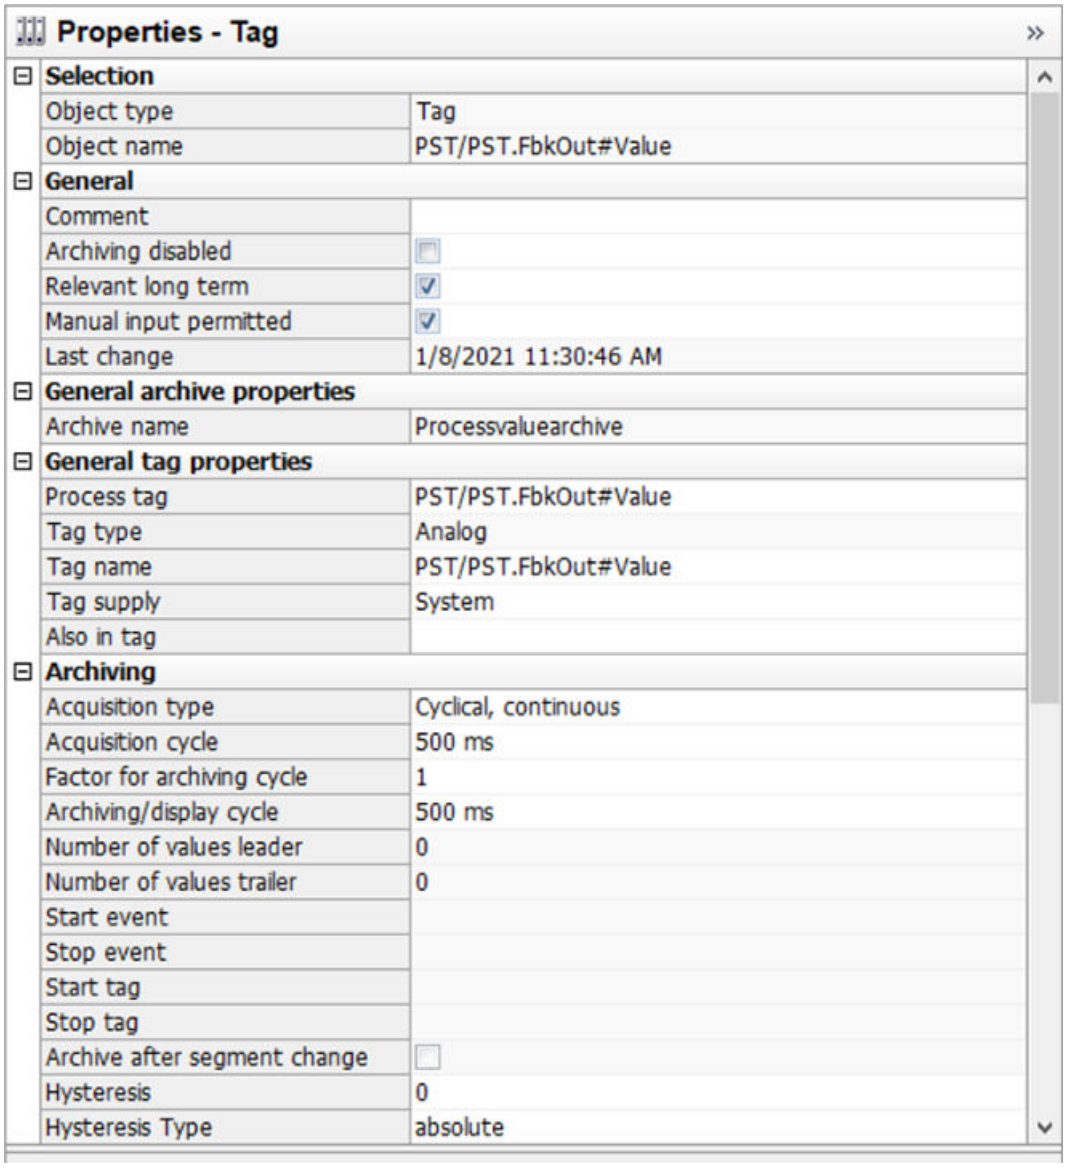
1. Open the Tag Management.
2. Add a new tag groups named "PartialStrokeTest" to the internal tags.

3. Add four tags with the below names and data types to the tag group PartialStrokeTest.
   - PST_ArchiveTagname_FbkOut - text tag 16-bit character set
   - PST_ArchiveTagname_SP - text tag 16-bit character set
   - PST_Tagname - text tag 16-bit character set
   - Startup - Signed 16-bit value
4. Assign the initial value of 2 to the "Startup" tag.



## Process tags

The report layout shows a graphic curve made up of the feedback value and the setpoint for the Partial Stroke Test that has been performed. The curve is based on data from a process data archive.

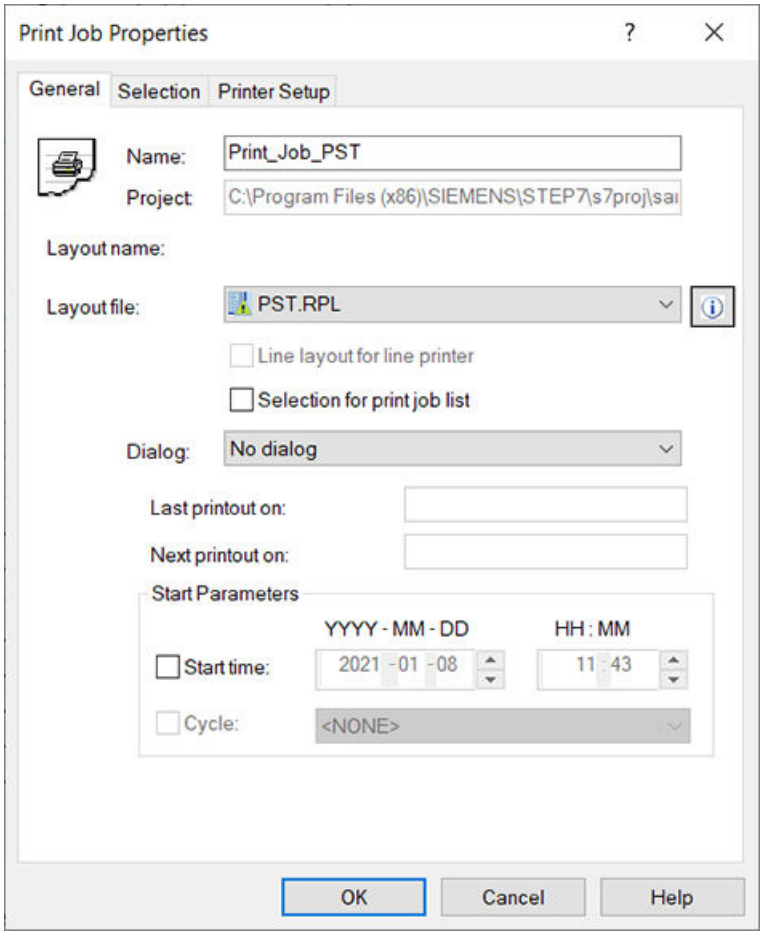


Proceed as follows to create the archive:

1. Open the Tag Logging.
2. Insert a new process value archive named **"Process value archive"**.

3. Add the `FbkOut` and `SP` tags of the PST block to the process data archive. The tag names of these process tags must not be changed!

4. The properties of the process tags must be changed.
   Set the "Archiving type" to "Cyclic, selective" in the "Archiving" tab.
   As the "Start tag", select the `.Active` I/O of the corresponding PST block.



## Creating print jobs

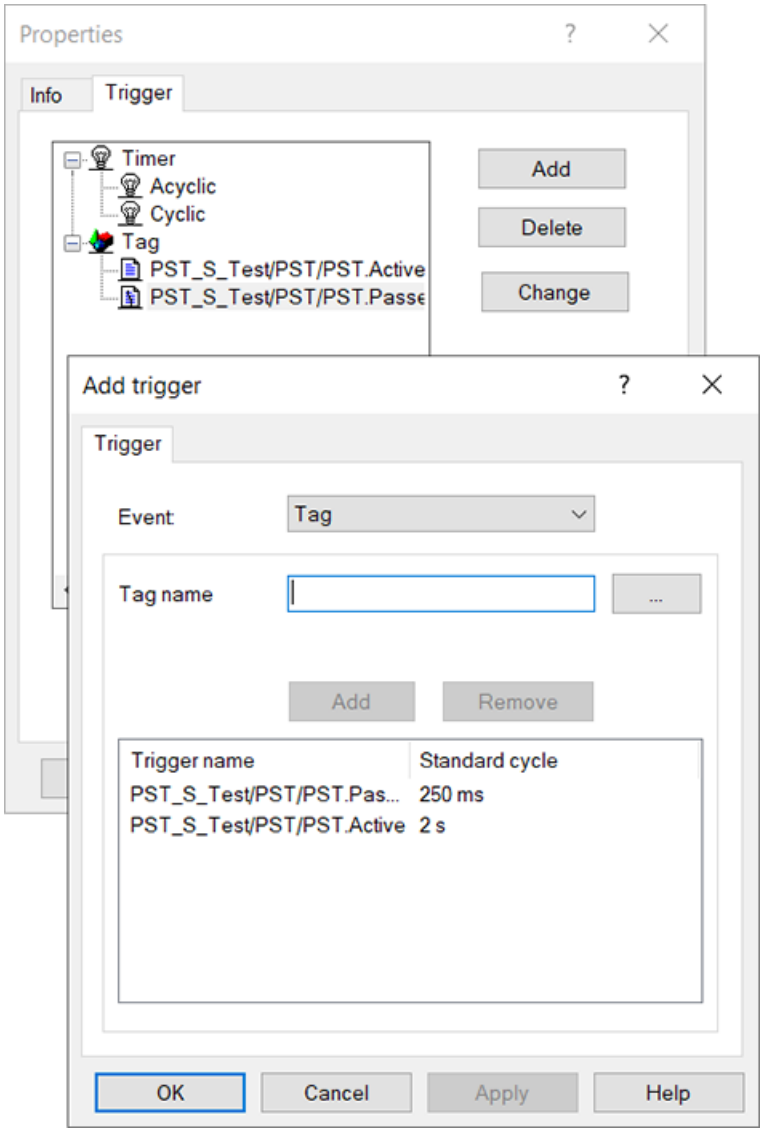
Open WinCC Explorer → "Report Designer" → "Print jobs" and add a new print job.

The print job must be configured as described below:

- Name → Print_Job_PST
- Layout → PST.rpl

For all other language versions, the names of the print jobs and the report layout can be configured freely.

## Activate print job



The print job should be started when a Partial Stroke Test and, if applicable, a solenoid valve test have been performed and complete. The global script action PST.pas that is found in the WinCC installation folder \WinCC\CML\PST is used as a template to trigger a print job for a PST instance.

The global script action PST.pas must be copied to the folder <...projectname\wincproj \OS_project_name\computer_name\PAS> and be adapted for the other PST function blocks.

Adaptations to PST.pas:

1. Open the C editor for the local action "PST.pas".
2. Define the trigger tag: Click on this icon or select "Edit" → "Info".

3. Replace the existing tags in the properties windows with the tags of the applicable Partial Stroke Test block.
   The standard cycle for the "`.PassedAct#Value`" tag must be less than or equal to the execution cycle in the CPU.

4. Change the assignment of the Partial Stroke Test tag name in the source code (circled character string) to the tag name of your PST:

```
#include "apdefap.h"

int gscAction( void )
{
BOOL active;
int startup;

char tagname[260];
char archivetagname_PST[260];

char tagname_PST[260] = "PST_S_Test/PST/PST"; // Has to be edited by user: tagname of PST

//Set tagname for report
SetTagChar ("PST_Tagname", tagname_PST);

//Set archive tagname of FbkOut for report
sprintf (archivetagname_PST, "Processvaluearchive\\%s.FbkOut#Value", tagname_PST);
//sprintf (archivetagname_PST, "Prozesswertarchiv\\%s.FbkOut#Value", tagname_PST);
SetTagChar ("PST_ArchiveTagname_FbkOut", archivetagname_PST);

//Set archive tagname of SP for report
sprintf (archivetagname_PST, "Processvaluearchive\\%s.SP#Value", tagname_PST);
//sprintf (archivetagname_PST, "Prozesswertarchiv\\%s.SP#Value", tagname_PST);
SetTagChar ("PST_ArchiveTagname_SP", archivetagname_PST);

sprintf (tagname, "%s.Active", tagname_PST);
active = GetTagBit (tagname);
startup = (int) GetTagWord ("Startup");

if (startup == 0)
        {
        if (!active)
                {
                        RPTJobPreview ("Print_Job_PST");
                        //RPTJobPrint ("Print_Job_PST");
                }
        }
else
{
        SetTagWord ("Startup", (WORD) (startup - 1));
}

return 0;
}
```

5. Adjust the function call for the print function:
   - Open "RPTJobPreview" to start the print preview, which can then be printed
   - Open "RPTJobPrint" to print the print job immediately.

# Monitoring blocks

# 5

## 5.1 Comparison of large & small blocks

### 5.1.1 MonAnL compared to MonAnS

#### Comparison of the MonAnL and MonAnS blocks

The following tables are intended to help you decide which block to use.

#### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 45%
- Runtime: ~ 30%

#### Operating modes of the blocks

| | MonAnL | MonAnS |
|---|---|---|
| On (Page 77) | X | X |
| Out of service (Page 77) | X | X |

#### Functions of the blocks

| | MonAnL | MonAnS |
|---|---|---|
| Alarm delays with two time values per limit pair (Page 227) | X | |
| Alarm delays with one time value per limit pair (Page 226) | | X |
| Limit monitoring (Page 93) | X | X |
| Suppressing messages using the MsgLock parameter (Page 231) | X | X |
| Gradient monitoring (Page 719) | X | |
| Displaying auxiliary values (Page 239) | X | |
| Forming and outputting the signal status for technologic blocks (Page 117) | X | X |

| | MonAnL | MonAnS |
|---|---|---|
| Dead band (Page 67) | X | X |
| Release for maintenance (Page 70) | X | X |
| Simulating signals (Page 64) | X | X |
| Selecting a unit of measure (Page 240) | X | X |
| Operator control permissions (Page 285) | X | X |
| Generating instance-specific messages (Page 230) | X | X |
| Display and operator input area for process values and setpoints (Page 233) | X | X |
| Opening additional faceplates (Page 234) | X | X |
| Time stamp (Page 2046) | X | |
| SIMATIC BATCH functionality (Page 73) | X | X |
| Providing PV limit at the output (Page 719) | x | |

## Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | MonAnL | MonAnS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | X | X |
| 1 | Reaction to the out of service mode (Page 188) | X | X |
| 22 | Update acknowledgment and error status of the message call (Page 171) | X | |
| 24 | Enabling local operator authorization (Page 169) | X | X |
| 25 | Suppression of all messages (Page 185) | X | X |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) | X | X |
| 28 | Disabling operating points (Page 156) | X | |
| 29 | Signaling limit violation (Page 181) | X | |

## 5.1.2 MonDiL compared to MonDiS

### Comparison of the MonDiL and MonDiS blocks

The following tables are intended to help you decide which block to use.

### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 55%
- Runtime: ~ 12%

### Operating modes of the blocks

| | MonDiL | MonDiS |
|---|---|---|
| On (Page 77) | x | x |
| Out of service (Page 77) | x | x |

### Functions of the blocks

| | MonDiL | MonDiS |
|---|---|---|
| Suppression and and reporting of signal flutter (Page 774) | x | |
| Delaying the on and off function (Page 774) | x | |
| Delaying the on function (Page 800) | | x |
| Specifying the status display for the block icon (Page 774) | x | x |
| Displaying auxiliary values (Page 239) | x | |
| Labeling of buttons and text (Page 235) | x | x |
| Generating instance-specific messages (Page 230) | x | x |
| Suppressing messages using the MsgLock parameter (Page 231) | x | x |
| Forming and outputting the signal status for technologic blocks (Page 117) | x | x |
| Release for maintenance (Page 70) | x | x |
| Simulating signals (Page 64) | x | x |

| | MonDiL | MonDiS |
|---|---|---|
| Operator control permissions (Page 285) | x | x |
| Opening additional faceplates (Page 234) | x | x |
| Time stamp (Page 2046) | x | |
| SIMATIC BATCH functionality (Page 73) | x | x |
| Group display for limit monitoring, CSF and ExtMsgx (Page 92) | x | x |

## Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | MonDiL | MonDiS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | x | x |
| 1 | Reaction to the out of service mode (Page 188) | x | x |
| 22 | Update acknowledgment and error status of the message call (Page 171) | x | |
| 24 | Enabling local operator authorization (Page 169) | x | x |
| 25 | Suppression of all messages (Page 185) | x | x |

# 5.2 AV - Displaying and monitoring additional value

## 5.2.1 Description of AV

### Object name (type + number) and family

Type + number: FB 1903

Family: Monitor

### Area of application for AV

The block is used for the following applications:

- Monitoring an additional analog value at a technologic block (motors or valves with motor).

### How it works

The block must be connected to a channel block and monitors an additional analog value. The messages of the AV block appear in the alarm view of the technologic block connected to it. Monitoring limits are configured and controlled at the technologic block.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100). The AV block and the technologic block must be installed in the same cyclic interrupt OB.

Interconnect the `AV_Tech` output parameter of the AV block to the input parameter `AV` of the technologic block in the CFC.

**Note**

Interconnection of the block to multiple technologic blocks is not permitted.

For the AV block, the Advanced Process Library contains process tag type templates; these serve as examples by providing various application scenarios for this block.

Examples of process tag types:

- Motor with an additional analog value and time-stamped signals (Motor_AV_EventTs) (Page 2863)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section AV I/Os (Page 711).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `MsgLock` |
| 4 | `AV_AH_Act.Value` |
| 5 | `AV_WH_Act.Value` |
| 6 | `AV_TH_Act.Value` |
| 7 | `AV_TL_Act.Value` |
| 8 | `AV_WL_Act.Value` |
| 9 | `AV_AL_Act.Value` |
| 10 | `AV_AH_En` |
| 11 | `AV_WH_En` |
| 12 | `AV_TH_En` |
| 13 | `AV_TL_En` |
| 14 | `AV_WL_En` |
| 15 | `AV_AL_En` |
| 16 | `AV_AH_MsgEn` |
| 17 | `AV_WH_MsgEn` |
| 18 | `AV_TH_MsgEn` |
| 19 | `AV_TL_MsgEn` |
| 20 | `AV_WL_MsgEn` |
| 21 | `AV_AL_MsgEn` |
| 22 | Delay of `AV_AH_Act` |
| 23 | Delay of `AV_WH_Act` |
| 24 | Delay of `AV_TH_Act` |
| 25 | Delay of `AV_TL_Act` |
| 26 | Delay of `AV_WL_Act` |
| 27 | Delay of `AV_AL_Act` |
| 28 - 31 | Not used |

## 5.2.2 AV modes

### AV operating modes

The block does not have any of its own operating modes.

If the interconnected technologic block is set to the "Out of service" operating mode, the AV block is also set to the "Out of service" mode. In this case `AV_Out` = `AV`.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =0 and `Feature.Bit5` =1 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| AV_Tech.ST | 16#80 | 16#60 |
| AV_AH_Act.ST | 16#XX | 16#60 |
| AV_WH_Act.ST | 16#XX | 16#60 |
| AV_TH_Act.ST | 16#XX | 16#60 |
| AV_TL_Act.ST | 16#XX | 16#60 |
| AV_WL_Act.ST | 16#XX | 16#60 |
| AV_Out.ST | 16#80 | 16#60 |
| AV_AL_Act.ST | 16#XX | 16#60 |

## 5.2.3 AV functions

### Functions of AV

The functions for this block are listed below.

### Alarm delays with two time values per limit pair

This block includes the standard function alarm delay for Two time values per limit pair (Page 227).

### Limit monitoring of an additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104). It is performed via the input parameter `AV_Hyst`.

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Forming the signal status for blocks

The worst signal status `ST_Worst` for the block is formed from the following parameter:

- `AV_Out.ST`

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

The simulation in the block AV is activated at the technological block (`SimOn` = 1). The simulation value `SimAV` for the block AV is also specified there. If internal simulation of the technological block is switched on, the output `AV_Out` has the value of `SimAV` and the status 16#60.

### Release for maintenance

The release for maintenance in the AV block is activated at the technological block (`MS_Release` = 1).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) chapter. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) (transferred to AV via AV_Tech.Mode.Bit) |
| 29 | Signaling limit violation (Page 181) (transferred to AV via AV_Tech.Mode.Bit) |

## 5.2.4 AV error handling

### Error handling of AV

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error

### Overview of error numbers

The `ErrorNum` I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |
| 30 | The value of `AV` can no longer be displayed in the REAL number field. |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

## 5.2.5 AV messaging

### Messaging

The following messages can be generated for this block:

- Process messages

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | Alarm - high | $$BlockComment$$<br>`AV` - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>`AV` - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>`AV` - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>`AV` - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>AV - Low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>`AV` - low alarm limit violated |

Explanation

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | Reserved |
| 2 | Reserved |
| 3 | Reserved |
| 4 | `AV_Out` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | Reserved |
| 9 | Reserved |
| 10 | Reserved |

The associated values 5 ... 7 are allocated to the parameters `ExtVa105` ... `ExtVa107` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 5.2.6 AV I/Os

### I/Os of AV

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AV` | Analog value | STRUCT<br>• Value:REAL<br>• ST:BYTE | -<br>• 0.0<br>• 16#80 |
| `AV_Unit` | Unit of measure for the analog value | INT | 1001 |
| `AV_A_DC*` | Delay time for incoming alarms [s] | REAL | 0.0 |
| `AV_A_DG*` | Delay time for outgoing alarms [s] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV_AH_En | 1 = Enable high alarm | BOOL | 1 |
| AV_AH_MsgEn | 1 = Enable high alarm message | BOOL | 1 |
| AV_AL_En | 1 = Enable low alarm | BOOL | 1 |
| AV_AL_MsgEn | 1 = Enable low alarm message | BOOL | 1 |
| AV_OpScale | Limit for scale in bar graph of faceplate for the analog value | STRUCT<br>• High:REAL<br>• Low:REAL | -<br>• 100.0<br>• 0.0 |
| AV_T_DC* | Delay time for incoming tolerances [s] | REAL | 0.0 |
| AV_T_DG* | Delay time for outgoing tolerances [s] | REAL | 0.0 |
| AV_TH_En | 1 = Enable high tolerance | BOOL | 0 |
| AV_TH_MsgEn | 1 = Enable high tolerance message | BOOL | 1 |
| AV_TL_En | 1 = Enable low tolerance | BOOL | 0 |
| AV_TL_MsgEn | 1 = Enable low tolerance message | BOOL | 1 |
| AV_W_DC* | Delay time for incoming warnings [s] | REAL | 0.0 |
| AV_W_DG* | Delay time for outgoing warnings [s] | REAL | 0.0 |
| AV_WH_En | 1 = Enable high warning | BOOL | 1 |
| AV_WH_MsgEn | 1 = Enable high warning message | BOOL | 1 |
| AV_WL_En | 1 = Enable low warning | BOOL | 1 |
| AV_WL_MsgEn | 1 = Enable low warning message | BOOL | 1 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| Feature | I/O for additional functions (Page 707) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV_AH_Act | 1 = High alarm active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AV_AL_Act | 1 = Low alarm active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AV_Out | Analog value output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Tech | Output parameter with which the input parameter AV of the technologic block has to be connected. This includes tags which are passed on to the technologic block for additional processing. | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#00 |
| AV_TH_Act | 1 = High tolerance active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AV_TL_Act | 1 = Low tolerance active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AV_WH_Act | 1 = High warning active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AV_WL_Act | 1 = Low warning active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see AV error handling (Page 709) | INT | -1 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 705) | DWORD | 16#00000000 |

# 5.3 MonAnL - Monitoring of an analog process tag (Large)

## 5.3.1 Description of MonAnL

### Object name (type+number) and family

Type + number: FB 1845

Family: Monitor

### Area of application for MonAnL

The block is used for the following fields of applications:

- Monitoring an analog process value
- Monitoring of the gradient of an analog process value

**Note**

This block is also available as a small block. A comparison of the MonAnL and MonAnS blocks is available in the section: MonAnL compared to MonAnS (Page 701)

### How it works

The MonAnL block is used to monitor an analog process tag and the corresponding limits. It also monitors the gradient of these signals. The block generates and outputs corresponding messages if limits are violated or if a signal gradient does not meet requirements.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the MonAnL block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring an analog process tag (AnalogMonitoring) (Page 2854)
- Monitoring of an analog process tag for PA/FF devices (AnalogMonitoring_Fb) (Page 2855)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

The output parameters PV_HysOut, PV_AH_Out, PV_WH_Out, PV_TH_Out, PV_AL_Out, PV_WL_Out and PV_TL_Out are written by the corresponding input parameters PV_Hys, PV_AH_Lim, PV_WH_Lim, PV_TH_Lim, PV_AL_Lim, PV_WL_Lim and PV_TL_Lim.

### Status word allocation for Status1 parameter

You can find a description for each parameter in section MonAnL I/Os (Page 729).

| Status bit | Parameter |
|---|---|
| 0 | Occupied |
| 1 | BatchEn |
| 2 | SimOn |
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | Not used |
| 6 | OnAct.Value |
| 7 | BypassAct.Value |
| 8 | Display of BypassAct.Value in faceplate (display and operator controls) and block icon |
| 9 | Not used |
| 10 | SimLiOp.Value |
| 11 | Delay of the PV_AH_Lim message |
| 12 | Delay of the PV_WH_Lim message |
| 13 | Delay of the PV_TH_Lim message |
| 14 | Delay of the PV_TL_Lim message |
| 15 | Delay of the PV_WL_Lim message |
| 16 | Delay of the PV_AL_Lim message |
| 17 | Collection of message delays |
| 18 - 29 | Not used |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

### Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | PV_AH_Act.Value |
| 2 | PV_WH_Act.Value |
| 3 | PV_TH_Act.Value |
| 4 | PV_TL_Act.Value |
| 5 | PV_WL_Act.Value |
| 6 | PV_AL_Act.Value |
| 7 | PV_AH_En OR Feature.Bit23 |
| 8 | PV_WH_En OR Feature.Bit23 |

| Status bit | Parameter |
|---|---|
| 9 | PV_TH_En OR Feature.Bit23 |
| 10 | PV_TL_En OR Feature.Bit23 |
| 11 | PV_WL_En OR Feature.Bit23 |
| 12 | PV_AL_En OR Feature.Bit23 |
| 13 | PV_AH_MsgEn |
| 14 | PV_WH_MsgEn |
| 15 | PV_TH_MsgEn |
| 16 | PV_TL_MsgEn |
| 17 | PV_WL_MsgEn |
| 18 | PV_AL_MsgEn |
| 19 | GradHUpAct.Value |
| 20 | GradHDnAct.Value |
| 21 | GradLAct.Value |
| 22 | GradHUpEn |
| 23 | GradHDnEn |
| 24 | GradLEn |
| 25 | GradHUpMsgEn |
| 26 | GradHDnMsgEn |
| 27 | GradLMsgEn |
| 28 | 0 = falling measured value<br>1 = rising measured value |
| 29 | 1= Suppressed messages |
| 30 | Internal error |
| 31 | MS_RelOp |

### Status word allocation for Status3 parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 - 15 | Effective signal 9..16 of the message block connected via EventTsIn |
| 16 - 31 | Not used |

MonAnL error handling (Page 726)

MonAnL modes (Page 718)

## 5.3.2 MonAnL modes

### MonAnL operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =0 and `Feature.Bit5` =1 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| PV_Out.ST | 16#80 | 16#60 |
| PV_Grad.ST | 16#80 | 16#60 |
| PV_GradPP.ST | 16#80 | 16#60 |
| PV_GradNP.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_WH_Act.ST | 16#XX | 16#60 |
| PV_TH_Act.ST | 16#XX | 16#60 |
| PV_TL_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| GradHUpAct.ST | 16#XX | 16#60 |
| GradHDnAct.ST | 16#XX | 16#60 |
| GradLAct.ST | 16#XX | 16#60 |

Description of MonAnL (Page 715)

## 5.3.3 MonAnL functions

### Functions of MonAnL

The functions for this block are listed below.

### Alarm delays with two time values

With the Separate delay times for each alarm (Page 181) function (`Feature.Bit8`), separate input parameters can be set for the alarm delay on the high and low limits.

`Feature.Bit8` = 0

This block includes the standard function alarm delay for Two time values per limit pair (Page 227).

`Feature.Bit8` = 1

This block includes the standard function alarm delay for Two time values for each individual limit (Page 228).

### Limit monitoring of the process value

This block provides the standard function Limit monitoring of the process value (Page 93).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Gradient monitoring

The PV_Grad gradient is calculated with a delay function, LagTime. This setting smoothes the jumps of the PV input value with gradient calculation.

The gradient peak values are output at the output parameters PV_GradNP (negative slope) and PV_GradPP (positive slope). They are reset as soon as the operator issues the reset command.

Thegradient PV_Grad gradient can be monitored for the following limits:

- Limit (high) for positive gradients (GradHUpLim)
- Limit (high) for negative gradients (GradHDnLim)
- Limit (low) for absolute gradients (GradLLim)

The individual monitoring functions are activated at the corresponding "Enable" parameters, e.g. GradHUpEn for activating the high gradient limit for positive gradients (GradHUpLim).

The gradient PV_Grad of the process value is calculated in units per second, per minute, or per hour, depending on the configuration of the TimeFactor:

- TimeFactor = 0: The unit of gradient limitation is Unit/Second

- TimeFactor = 1: The unit of gradient limitation is Unit/Minute

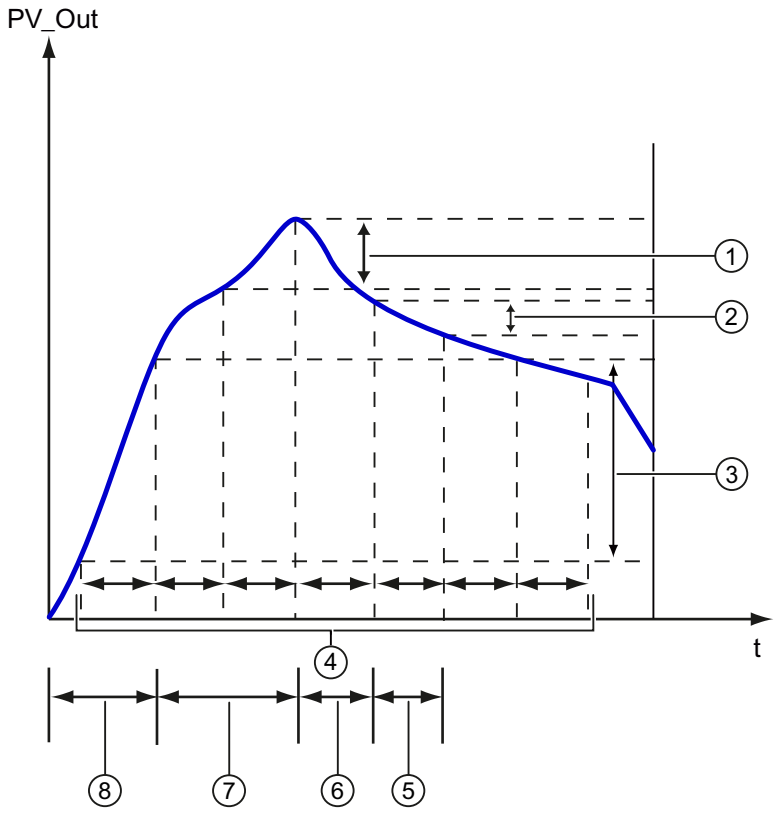
- TimeFactor = 2: Unit of gradient limitation is Unit/hour

The limits GradHUpLim, GradHDnLim and GradLLim must be entered with positive values in units per second, per minute or per hour, according to the configuration of the TimeFactor.

Reaching or exceeding the limits can be indicated and signaled at the corresponding outputs:

GradLAct: -GradLLim <= PV_Grad <= GradLLim

GradHupAct: PV_Grad is positive: PV_Grad >= GradHUpLim



GradHDnAct: PV_Grad is negative: PV_Grad <= -GradHDnLim

Messages can be output for these alarms. You activate these as follows:

- Message for alarms (high) for positive gradients: GradHUpMsgEn = 1
- Message for alarms (high) for negative gradients: GradHDnMsgEn = 1
- Message for alarms (low) for absolute gradients: GradLMsgEn = 1

## Example of generating alarms for gradient monitoring

The following example shows how alarms for gradient monitoring are generated.

| Number | Description |
|---|---|
| 1 | Gradient is negative and `PV_Grad ≤ -GradHDnLim` |
| 2 | Gradient `ABS(PV_Grad) ≤ GradLLim` |
| 3 | Gradient is positive and `PV_Grad ≥ GradHUpLim` |
| 4 | Sampling time (`SampleTime`) |
| 5 | Alarm (low) for absolute gradients |
| 6 | Alarm (high) for negative gradients |
| 7 | No alarm |
| 8 | Alarm (high) for positive gradients |

In every cycle, a value of `PV_Grad` is calculated. When this value reached the limits, the alarms are generated.

## Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Providing PV limit at the output

The following input parameters are also available at the output for making additional interconnections to other blocks:

| | |
|---|---|
| • PV_HysOut | := PV_Hyst |
| • PV_AH_Out | := PV_AH_Lim |
| • PV_WH_Out | := PV_WH_Lim |
| • PV_TH_Out | := PV_TH_Lim |
| • PV_TL_Out | := PV_TL_Lim |
| • PV_WL_Out | := PV_WL_Lim |
| • PV_AL_Out | := PV_AL_Lim |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

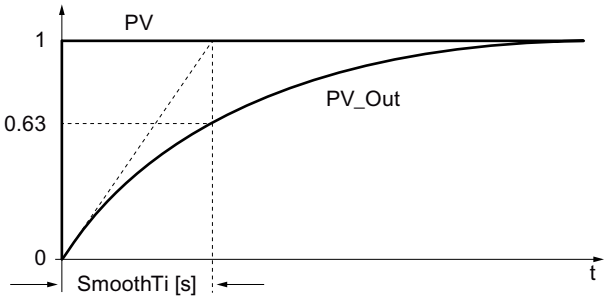
- `PV_Out.ST`

### Dead band

To suppress values that fluctuate around the zero point, this block has the standard function Dead band (Page 67).

### Smoothing PV

The block smoothes the input value `PV` using a first order time delay. This delay time can be configured with the parameter `SmoothTi`. The input of `SmoothTi` is limited to 0 to 999999 sec. The block writes back the limits if the input value is outside the limits.



The block works according to the following formula:

$PV_Out_{(n)} = PV_{(n)} + ( PV_Out_{(n-1)} - PV_{(n)} ) * e^{(-SampleTime/SmoothTi)}$

Where:

- `PV_Out` = Output value
- `SmoothTi` = Smooth time
- `SampleTime` = Sampling time
- `PV` = Input value

The formula is valid only if `SmoothTi` > 0. If `SmoothTi` = 0, the input is passed directly to the output. If the input value is outside the REAL range limits, the calculation is stopped. If the input value is inside the range limits again, the calculation is resumed automatically.

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV`, `SimPV_Li`)

### Bypass function

This block provides the standard function Bypassing signals (Page 115).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Disabling of limits

The block provides the standard function Limits disabled in faceplate (Page 206).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 8 | Separate delay times for each alarm (Page 181) |
| 9 | Substitution value is active if the block is in bypass (Page 199) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |

| Bit | Function |
|---|---|
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can activate bypass functionality |
| 5 | 1 = Operator can deactivate bypass functionality |
| 6 | 1 = Operator can change the simulation value `SimPV` |
| 7 | 1 = Operator can reset the maximum values |
| 8 | 1 = Operator can activate / deactivate messages via `GradHUpMsgEn` |
| 9 | 1 = Operator can activate / deactivate messages via `GradHDnMsgEn` |
| 10 | 1 = Operator can activate / deactivate messages via `GradLMsgEn` |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the limit (`PV`) for high alarm |
| 14 | 1 = Operator can change the limit (`PV`) for high warning |
| 15 | 1 = Operator can change the limit (`PV`) for high tolerance |
| 16 | 1 = Operator can change the limit (`PV`) for hysteresis |
| 17 | 1 = Operator can change the limit (`PV`) for low alarm |
| 18 | 1 = Operator can change the limit (`PV`) for low warning |
| 19 | 1 = Operator can change the limit (`PV`) for low tolerance |
| 20 | 1 = Operator can change the value for the high gradient limit for positive slopes (`GradHUpLim`) |
| 21 | 1 = Operator can change the value for high gradient limit for negative slopes (`GradHDnLim`) |
| 22 | 1 = Operator can change the value for the low gradient limit for positive and negative slopes (`GradLLim`) |
| 23 | 1 = Operator can change the dead band parameter `DeadBand` |
| 24 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `PV_WH_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `PV_TH_MsgEn` |

| Bit | Function |
|---|---|
| 27 | 1 = Operator can activate / deactivate messages via PV_TL_MsgEn |
| 28 | 1 = Operator can activate / deactivate messages via PV_WL_MsgEn |
| 29 | 1 = Operator can activate / deactivate messages via PV_AL_MsgEn |
| 30 | 1 = Operator can enter SmoothTi |
| 31 | Reserved |

The block has the following permissions for the OS1_Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 5.3.4 MonAnL error handling

### Error handling of MonAnL

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following error message can be generated at this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The ErrorNum I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 11 | SmoothTi < 0 or SmoothTi > 999999:<br>Due to the internal limitation to 0 or 999999 by the block, the error number has the value 11 only for one cycle. If SmoothTi is connected and is written in every cycle, the value 11 will be retained. |
| 30 | The value of PV can no longer be displayed in the REAL number field. |
| 43 | TimeFactor < 0 or TimeFactor > 2 |

### Control system fault (CSF)

An external signal can be activated via the CSF input. If this signal changes to = 1, a control system fault is triggered. Refer to the Error handling (Page 128) section for more on this.

## 5.3.5 MonAnL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId2`, SIG 2).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | Alarm - high | $$BlockComment$$<br>`PV` - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>`PV` - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>`PV` - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>`PV` - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>`PV` - low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>`PV` - low alarm limit violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>Limit (high) for positive gradients violated |
| | SIG 8 | Alarm - high | $$BlockComment$$<br>Limit (high) for negative gradients violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | Alarm - low | $$BlockComment$$<br>Limit (low) for absolute gradients violated |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | ExtVa108 |
| 9 | PV_Out.Value |
| 10 | Reserved |

The associated values 4 to 9 are allocated to the parameters ExtVa104...ExtVa108, PV_Out.Value and can be used.

Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa204 |

| Associated value | Block parameters |
|---|---|
| 5 | ExtVa205 |
| 6 | ExtVa206 |
| 7 | ExtVa207 |
| 8 | ExtVa208 |
| 9 | PV_Out.Value |
| 10 | Reserved |

The associated values 4 to 9 are allocated to the parameters ExtVa204...ExtVa208, PV_Out.Value and can be used.

Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_Hyst* | Hysteresis for PV alarm, warning and tolerance limits | REAL | 0.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_T_DC* | Delay time for incoming PV tolerance messages for overshoot/undershoot or only for undershot process values [s] | REAL | 0.0 |
| PV_T_DG* | Delay time for outgoing PV tolerance messages for overshoot/undershoot or only for undershot process values [s] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_TH_DC* | Delay time for incoming tolerance messages for overshot process values [s] | REAL | 0.0 |
| PV_TH_DG* | Delay time for outgoing tolerance messages for overshot process values [s] | REAL | 0.0 |
| PV_TH_En | 1 = Enable PV tolerance limit (high) | BOOL | 0 |
| PV_TH_Lim | Limit PV tolerance message (high) | REAL | 85.0 |
| PV_TH_MsgEn | 1 = Enable message for PV tolerance message (high) | BOOL | 1 |
| PV_TL_En | 1 = Enable PV tolerance limit (low) | BOOL | 0 |
| PV_TL_Lim | Limit PV tolerance message (low) | REAL | 15.0 |
| PV_TL_MsgEn | 1 = Activate message for PV tolerance message (low) | BOOL | 1 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_W_DC* | Delay time for incoming PV warnings for overshoot/undershoot or only for undershot process values [s] | REAL | 0.0 |
| PV_W_DG* | Delay time for outgoing PV warnings for overshoot/undershoot or only for undershot process values [s] | REAL | 0.0 |
| PV_WH_DC* | Delay time for incoming warnings for overshot process values [s] | REAL | 0.0 |
| PV_WH_DG* | Delay time for outgoing warnings for overshot process values [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| RstBypLi | 1 = Reset bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstBypOp | 1 = Reset bypass PV (via operator) | BOOL | 0 |
| RstOp* | 1 = Operator reset of the gradient's peak values | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value that is used for SimOn = 1 | REAL | 0.0 |
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| SmoothTi* | Smooth time [s] (limited to 0 to 999999) | REAL | 0.0 |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BypassAct | 1 = Bypass is activated in this block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MonAnL error handling (Page 726) | INT | -1 |
| GradHUpAct | 1 = Gradient alarm (high) for positive changes.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| GradHDnAct | 1 = Gradient alarm (high) for negative changes.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| GradLAct | 1 = Low gradient alarm.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgAckn2 | Message acknowledgement status 2 (output ACK_STATE of second ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | 1 = Alarm error 1 (output ERROR of the first ALARM_8P) | BOOL | 0 |
| MsgErr2 | 1 = Alarm error 2 (output ERROR of the second ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| MsgStat2 | Message status 2 (output STATUS of second ALARM_8P) | WORD | 16#0000 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feed-forwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1_Perm | WORD | 16#FFFF |
| OS1PermLog | Display of OS1_Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_AH_Out | PV - alarm limit (high) output | REAL | 0.0 |
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_AL_Out | PV - alarm limit (low) output | REAL | 0.0 |
| PV_Grad | Gradient value. | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_GradPP | Gradient maximum peak value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_GradNP | Gradient minimum peak value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_HysOut | Hysteresis for PV alarm, output | REAL | 0.0 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE<br>• Bit 1: BOOL of internal fill byte (Bypass information bit) | -<br>• 0.0<br>• 16#80<br>• 0 |
| PV_UnitOut | PV_Unit as output | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_TH_Act | 1 = PV tolerance message (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_TH_Out | PV tolerance limit (high) output | REAL | 0.0 |
| PV_TL_Act | 1 = PV tolerance message (low) active. You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_TL_Out | PV tolerance limit (low) output | REAL | 0.0 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WH_Out | Limit PV warning (high) output | REAL | 0.0 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WL_Out | Limit PV warning (low) output | REAL | 0.0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 715) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 715) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 715) | DWORD | 16#00000000 |
| SumMsgAct | 1 = Group message is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `UserAna1Out` | `UserAna1` as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| `UserAna2Out` | `UserAna2` as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |

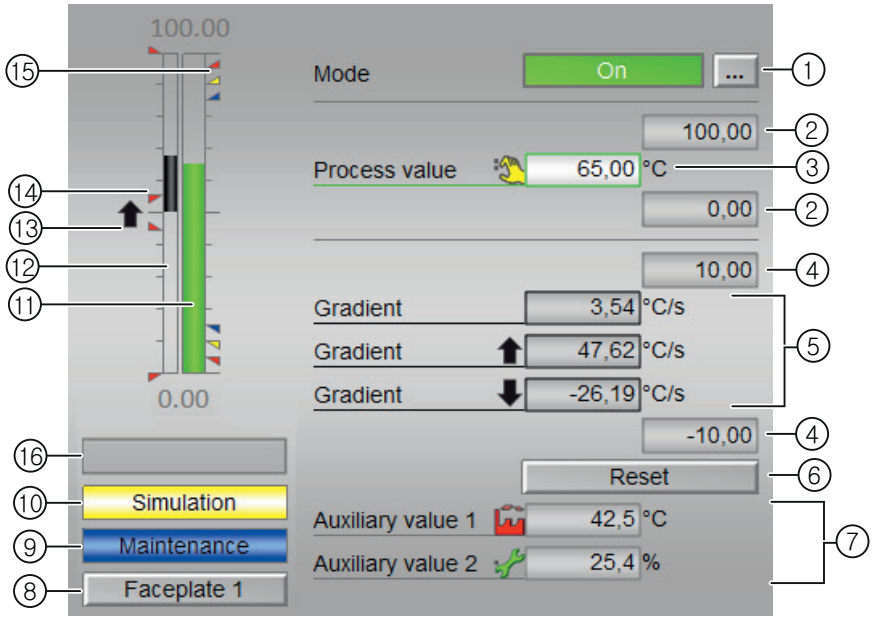
Description of MonAnL (Page 715)

## 5.3.8 Operator control and monitoring

### 5.3.8.1 MonAnL views

#### Views of the MonAnL block



The block MonAnL provides the following views:

- MonAnL standard view (Page 740)
- Alarm view (Page 336)
- MonAnL limit view (Page 743)
- Trend view (Page 341)
- MonAnL parameter view (Page 745)
- MonAnL preview (Page 746)
- MonAnL AddOn view (Page 747)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MonAnL (Page 748)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 5.3.8.2 MonAnL standard view

#### MonAnL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Bar graph (Page 376)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) High and low scale range for the process value

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the engineering system.

#### (3) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

If text is configured for this command, it is displayed as additional text and button label for command selection. Additional information is available in the section Labeling of buttons and text (Page 235).

You can change the text for the process value with the `PV_Out` parameter.

### (4) High and low scale range for the gradient value

These values provide information on the display range for the bar graph of the gradient. The scale range corresponds to 10% of the scale range for the process value: For example, once you have specified a process value scale range of 0 to 100, the scale range of the gradient will be automatically set to a value between -10 and 10.

The current gradient value is displayed when one of the following monitoring functions is activated:

- Gradient monitoring for positive changes `(GradHUpEn = 1)`
- Gradient monitoring for negative changes `(GradHDnEn = 1)`
- Gradient monitoring `(GradLEn = 1)`

### (5) Display of the gradient

This area shows the current, minimum and maximum gradient value and the rise and fall of the value. This display of the minimum and maximum gradient value functions like a min/max pointer.

The current gradient value is displayed when one of the following monitoring functions is activated:

- Gradient monitoring for positive changes `(GradHUpEn = 1)`
- Gradient monitoring for negative changes `(GradHDnEn = 1)`
- Gradient monitoring `(GradLEn = 1)`

The maximum peak gradient value is displayed when the gradient monitoring is activated for positive changes `(GradHUpEn = 1)`

The minimum peak gradient value is displayed when the gradient monitoring is activated for negative changes `(GradHDnEn = 1)`

### (6) Resetting the peak values of the gradient

You can use this button to reset the maximum or minimum peak value of the gradient (`PV_GradPP` and `PV_GradNP` output parameters).

The button is displayed when gradient monitoring is activated for positive `(GradHUpEn = 1)` or negative changes `(GradHDnEn = 1)`.

### (7) Display of auxiliary values

You can use this area to display two auxiliary values that have been configured in the engineering system. You can find additional information on this in the Displaying auxiliary values (Page 239) section.

### (8) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

### (11) Bar graph for the "process value"

This area shows the current "Process value" in the form of a bar graph. You can also see the high low limits of the bargraph's scale.The visible area in the bar graph depends on the configuration in the engineering system (ES). For more information refer Bar graph (Page 376) section.

### (12) Bar graph for the gradient

This area shows the current gradient value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

The bar graph is displayed when gradient monitoring is activated for positive `(GradHUpEn = 1)` or negative changes `(GradHDnEn = 1)`.

### (13) Display of the gradient

This display indicates the movement of the gradient up (↑) or down (↓).

Gradient monitoring is displayed when the gradient value PV_Grad ≠ 0 and one of the following monitoring functions is activated:

- Gradient monitoring for positive changes `(GradHUpEn = 1)`
- Gradient monitoring for negative changes `(GradHDnEn = 1)`
- Gradient monitoring `(GradLEn = 1)`

### (14) Display of limits in the bar graph

This area shows you the specified limits. Refer to the MonAnL limit view (Page 743) section for more on this.

The display only appears when the bar for the gradients is also displayed.

### (15) Limit display

These colored triangles show you the specified limits in the respective bar graph.

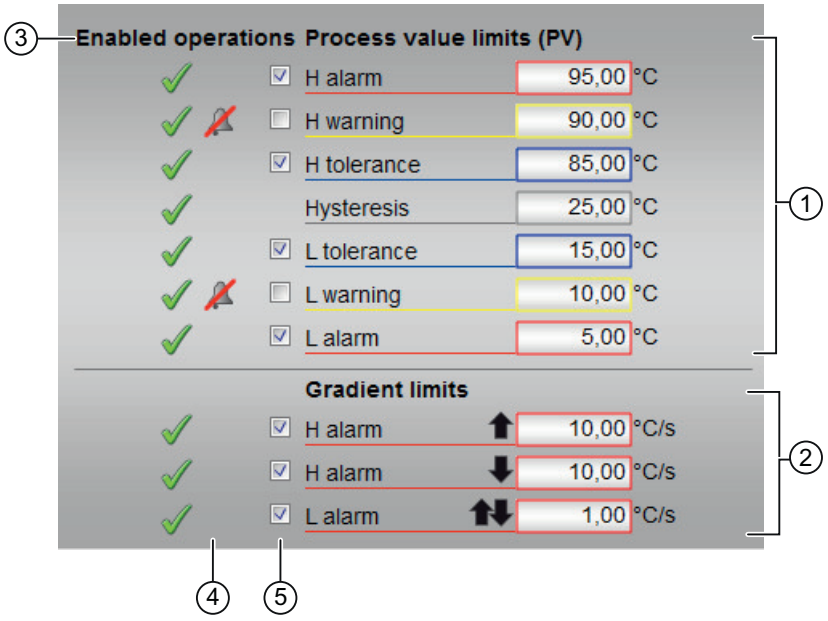
### (16) Display area for block states

This area provides additional information on the operating state of the block:

- Internal error
- Invalid Signal

### See also

On (Page 77)



## 5.3.8.3 MonAnL limit view

### Limit view of MonAnL

Several values are set in this view by default:

- Process value limits
- Gradient limits

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

### (1) Process value limits

In this area, you can enter the limits for the process value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high

- "H tolerance": Tolerance high
- "Hysteresis"
- "L tolerance": Tolerance low
- "L warning": Warning low
- "L alarm": Alarm low

**Note**

The text displayed are not valid for user-configured message classes. For more information refer Limit operation and display in the faceplate (Page 355).

### (2) Gradient limits

You can enter the gradient limits in this area. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm ⇑": Gradient for the high slope for positive changes
- "H alarm ⇓": Gradient for the high slope for negative changes
- "L alarm ⇑ ⇓": Gradient for the low slope (absolute)

### (3) Enabled operation

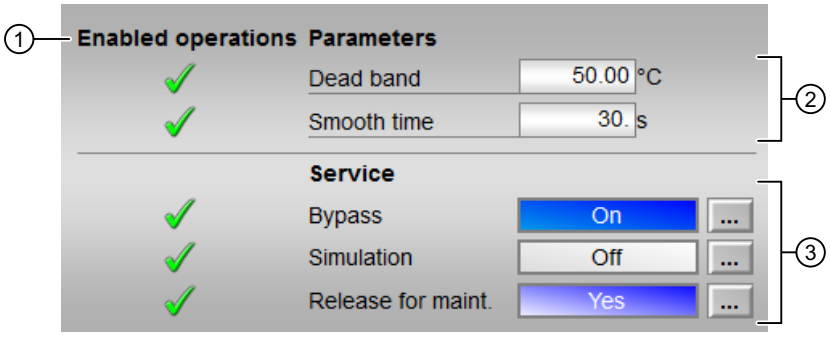
This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (4) Message suppression / delays

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.



Alarm delays are also displayed in this position; for more on this see section Area of application for alarm delays (Page 225).

### (5) Suppress messages

You can enable / disable messages by setting the check mark.

## 5.3.8.4 MonAnL parameter view

### Parameter view of MonAnL

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### (2) Parameter

You can change the following parameter in this area:

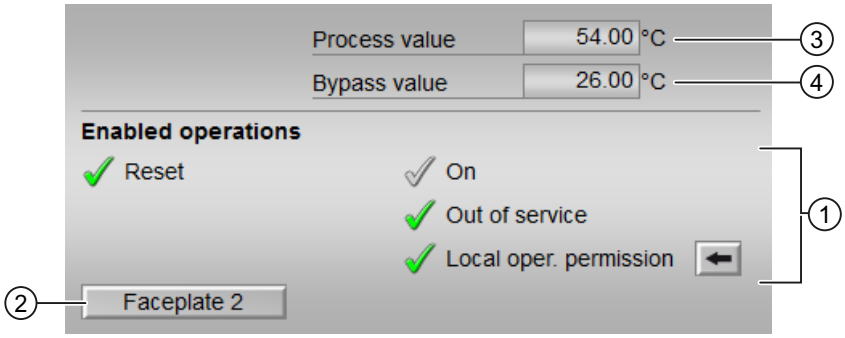
- "Dead band"
- "Smooth time"

You can find more information about this in the section Changing values (Page 291).

### (3) Service

You can select the following functions in this area:

- "Bypass"
- "Simulation"
- "Release for maintenance"



Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Bypassing signals (Page 115)
- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### 5.3.8.5 MonAnL preview

#### Preview of MonAnL

#### (1) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

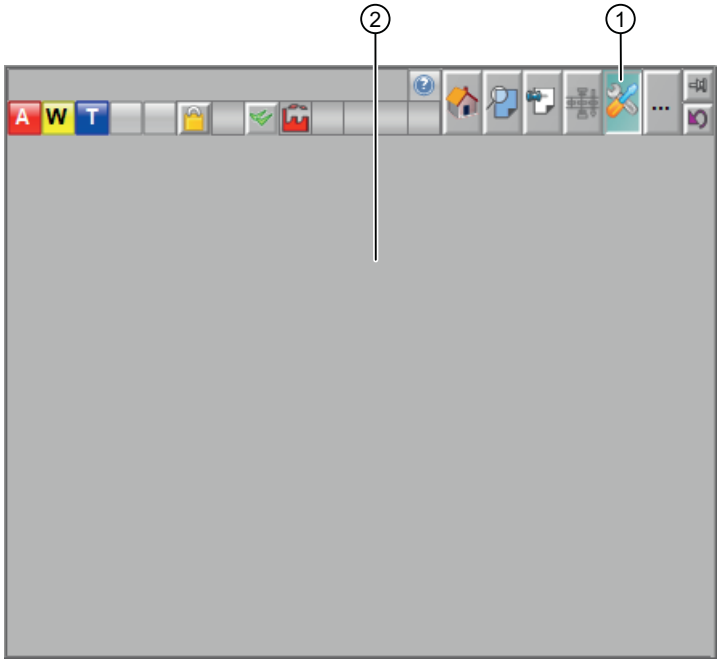
- Reset: You can reset the peak value of the gradient.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285) .

### (2) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### (3) Process value



This area displays the real process value (`PV`).

### (4) Bypass value

This area displays the bypass value (`BypPV`).

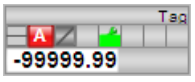
## 5.3.8.6 MonAnL AddOn view

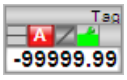
### MonAnL AddOn view

(1) AddOn view icon

(2) Work space of AddOn view: The view of the faceplate can be customized as per the operator needs.

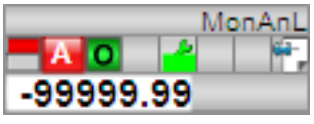
For more information, on AddOn view, refer to AUTOHOTSPOT

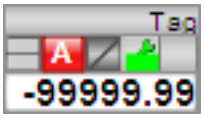


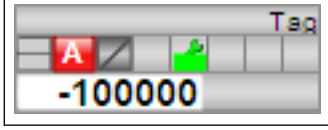


### 5.3.8.7 Block icon for MonAnL

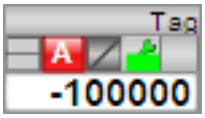
## Block symbols for MonAnL

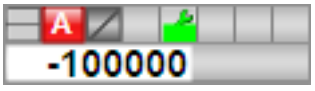


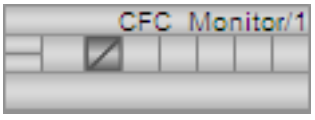




A variety of block symbols are available with the following functions:







- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Memo display
- Process value

The block symbols from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |

The block symbols from template @TemplateAPLV7.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | Block symbol in the full display |
|  | 2 | |
|  | 3 | |

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block symbol in "Out of service" mode (example with block symbol type 1) |

Additional information on the block symbol and the control options in the block symbol is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 5.4 MonAnS - Monitoring of an analog process tag (Small)

## 5.4.1 Description of MonAnS

### Object name (type + number)

Type + number: FB 1912

Family: Monitor

### Area of application for MonAnS

The block is used for the following fields of application

- Monitoring an analog process value

**Note**

This block is also available as a large block. A comparison of the MonAnL and MonAnS blocks is available in the section: MonAnL compared to MonAnS (Page 701)

### How it works

The MonAnS block is used to monitor an analog process tag and the corresponding limits. The block generates and outputs messages if any violation of limits is detected.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section MonAnS I/Os (Page 758).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |

| Status bit | Parameter |
|---|---|
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | Not used |
| 6 | OnAct.Value |
| 7 - 10 | Not used |
| 11 | Delay of the PV_AH_Lim message |
| 12 | Delay of the PV_WH_Lim message |
| 13 - 14 | Not used |
| 15 | Delay of the PV_WL_Lim message |
| 16 | Delay of the PV_AL_Lim message |
| 17 | Collection of message delays |
| 18 - 31 | Not used |

### Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | PV_AH_Act.Value |
| 2 | PV_WH_Act.Value |
| 3 - 4 | Not used |
| 5 | PV_WL_Act.Value |
| 6 | PV_AL_Act.Value |
| 7 | PV_AH_En OR Feature.Bit23 |
| 8 | PV_WH_En OR Feature.Bit23 |
| 9 - 10 | Not used |
| 11 | PV_WL_En OR Feature.Bit23 |
| 12 | PV_AL_En OR Feature.Bit23 |
| 13 | PV_AH_MsgEn |
| 14 | PV_WH_MsgEn |
| 15 - 16 | Not used |
| 17 | PV_WL_MsgEn |
| 18 | PV_AL_MsgEn |
| 19 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | Internal error |
| 31 | MS_RelOp |

MonAnS error handling (Page 755)

MonAnS messaging (Page 756)

MonAnS block diagram (Page 762)

## 5.4.2 MonAnS operating modes

### MonAnS operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =0 and `Feature.Bit5` =1 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_WH_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |

## 5.4.3 MonAnS functions

### Functions of MonAnS

The functions for this block are listed below.

### Alarm delays with one time value per limit pair

This block includes the standard function alarm delay for One time value per limit pair (Page 226).

### Limit monitoring of the process value

This block provides the standard function Limit monitoring of the process value (Page 93).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block has the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `PV_Out.ST`

### Dead band

To suppress values that fluctuate around the zero point, this block has the standard function Dead band (Page 67).

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 9 | Not used |
| 10 | 1 = Operator can change the simulation value `SimPV` |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the limit (`PV`) for high alarm |
| 14 | 1 = Operator can change the limit (`PV`) for high warning |
| 15 | Not used |
| 16 | 1 = Operator can change the limit (`PV`) for hysteresis |
| 17 | 1 = Operator can change the limit (`PV`) for low alarm |
| 18 | 1 = Operator can change the limit (`PV`) for low warning |
| 19 - 22 | Not used |
| 23 | 1 = Operator can change the dead band parameter `DeadBand` |
| 24 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `PV_AL_MsgEn` |
| 26 -27 | Not used |

| Bit | Function |
|---|---|
| 28 | 1 = Operator can activate / deactivate messages via PV_WH_MsgEn |
| 29 | 1 = Operator can activate / deactivate messages via PV_WL_MsgEn |
| 30 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 5.4.4 MonAnS error handling

### Error handling of MonAnS

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following error message can be generated at this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The ErrorNum I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 30 | The value of PV can no longer be displayed in the REAL number field. |

### Control system fault (CSF)

An external signal can be activated via the CSF input. If this signal changes to = 1, a control system fault is triggered. Refer to the Error handling (Page 128) section for more on this.

MonAnS block diagram (Page 762)

## 5.4.5 MonAnS messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 5).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>PV - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>PV - high warning limit violated |
| | SIG 3 | Warning - low | $$BlockComment$$<br>PV - low warning limit violated |
| | SIG 4 | Alarm - low | $$BlockComment$$<br>PV - low alarm limit violated |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You have the option to use two instance-specific messages for this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 7 | AS process control message - fault | $$BlockComment$$<br>External message 2 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | Reserved |
| 7 | Reserved |
| 8 | Reserved |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 5 are allocated to the parameters `ExtVa104` ... `ExtVa105` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 5.4.6 MonAnS I/Os

MonAnS I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |
| `BlkTypeInfo*` | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| `CSF` | 1 = External error (control system fault)<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `DeadBand` | Width of dead band | REAL | 0.0 |
| `EN` | 1 = Called block will be processed | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| Feature | I/O for additional MonAnS functions (Page 753) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, Description of OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for MonAnS functions (Page 753) | STRUCT<br>• Bit 0: BOOL<br>• Bit 10: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| PV* | Process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_A_DC* | Delay time for incoming PV alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_Hyst* | Hysteresis for PV alarm, warning and tolerance limits | REAL | 0.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_W_DC* | Delay time for incoming PV warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an Opening additional faceplates (Page 234) in the standard view | ANY | - |
| SimOn | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MonAnS error handling (Page 755) | INT | -1 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feed-forwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_UnitOut | PV_Unit as output | INT | 0 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Description of MonAnS (Page 750) | DWORD | 16#00000000 |
| Status2 | Description of MonAnS (Page 750) | DWORD | 16#00000000 |
| SumMsgAct | 1 = Group message is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

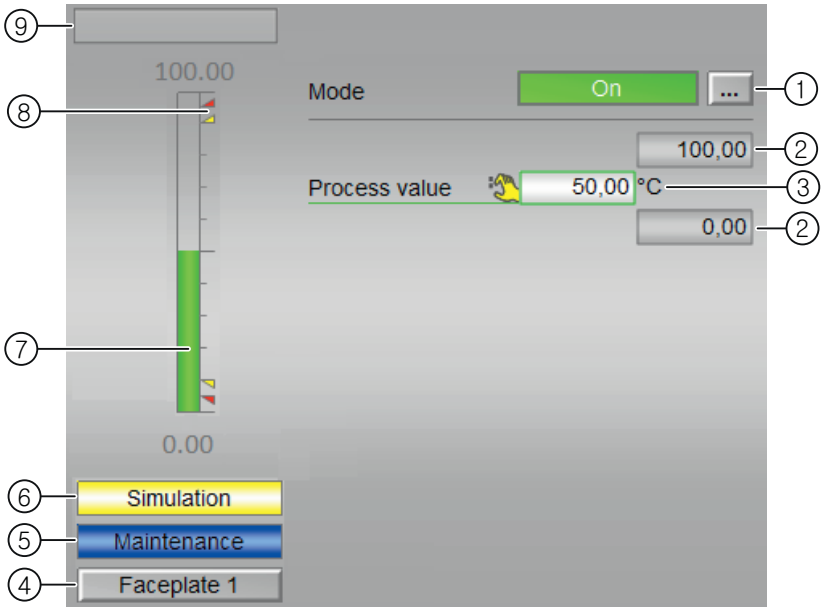
MonAnS I/Os (Page 758)

## 5.4.8 Operator control and monitoring

### 5.4.8.1 MonAnS views

### Views of the MonAnS block



The block MonAnS provides the following views:

- MonAnS standard view (Page 763)
- Alarm view (Page 336)
- MonAnS limit view (Page 765)
- Trend view (Page 341)
- MonAnS parameter view (Page 766)
- MonAnS preview (Page 767)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MonAnS (Page 768)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 5.4.8.2 MonAnS standard view

#### MonAnS standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) High and low scale range for the process value

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the engineering system.

#### (3) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

If text is configured for this command, it is displayed as additional text and button label for command selection. You can find more information about this in the section Labeling of buttons and text (Page 235).

You can change the text for the process value with the `PV_Out` parameter.

### (4) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Additional information is available in the section Opening additional faceplates (Page 234).

### (5) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

### (6) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

### (7) Bar graph for the "process value"

This area shows the current "Process value" in the form of a bar graph. You can also see the high and low limits of the bargraph's scale.The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (8) Limit display

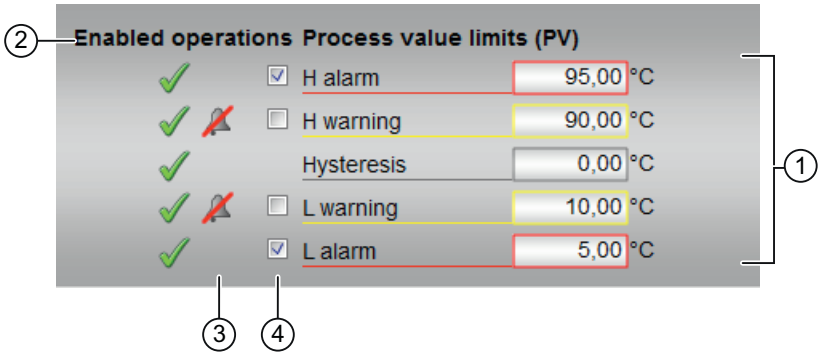
These colored triangles show you the configured limits in the respective bar graph.

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- Internal error
- "Invalid Signal"

### See also



Displaying auxiliary values (Page 239)

### 5.4.8.3 MonAnS limit view

#### Limit view of MonAnS

You can specify the process value limits in this view:

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

#### (1) Process value limits

In this area, you can enter the limits for the process value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "Hysteresis"
- "L warning": Warning low
- "L alarm": Alarm low

#### (2) Enabled operation

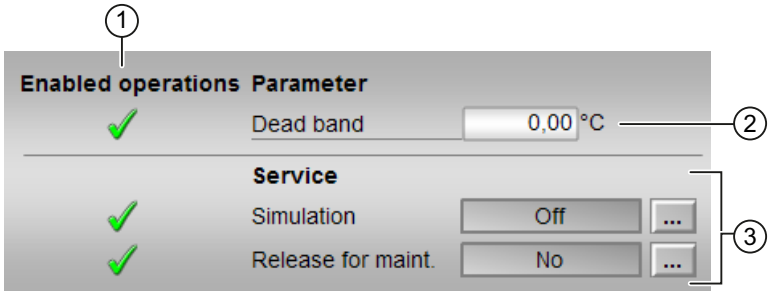
This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (3) Message suppression / delay

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.



Alarm delays are also displayed in this position; for more on this see section Area of application for alarm delays (Page 225).

### (4) Suppress messages

You can enable / disable messages by setting the check mark.

## 5.4.8.4 MonAnS parameter view

### Parameter view of MonAnS

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### (2)Parameter

You can change parameters in this area. Refer to the section Changing values (Page 291).

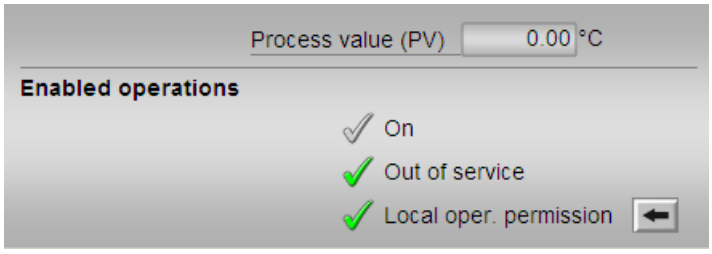
You can influence the following parameters:

- "Dead band": Width of dead band

### (3)Service

You can select the following functions in this area:

- "Simulation"
- "Release for maintenance"



Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

## 5.4.8.5 MonAnS preview

### Preview of MonAnS

### Process value

This area displays the real process value (`PV`).

### Enabled operations

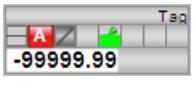
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

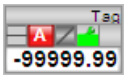
Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

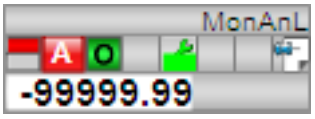
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

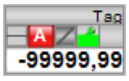


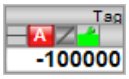


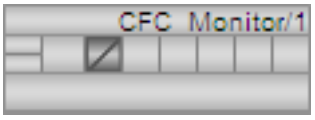
### 5.4.8.6 Block icon for MonAnS

#### Block symbols for MonAnS









A variety of block symbols are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Memo display
- Process value

The block symbols from template @TemplateAPLV8.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |

The block symbols from template @TemplateAPLV7.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | Block symbol in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | - | Block symbol in "Out of service" mode (example with type 1 block symbol) |

Additional information on the block symbol and the control options in the block symbol is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 5.5 MonDiL - Monitoring of a digital process tag (Large)

## 5.5.1 Description of MonDiL

### Object name (type + number) and family

Type + number: FB 1848

Family: Monitor

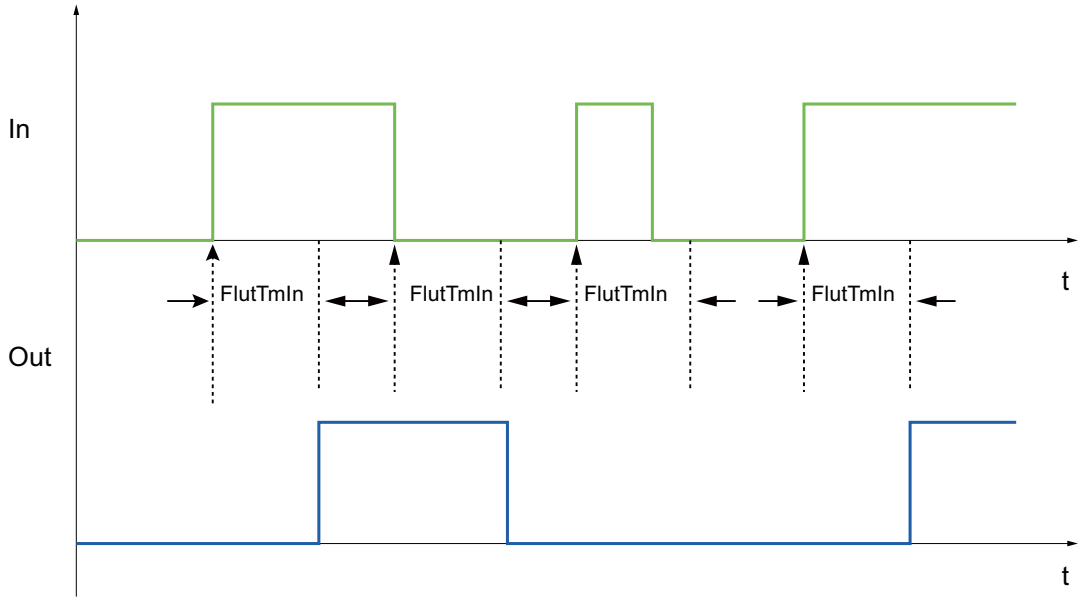
### Area of application for MonDiL

The block is used for the following applications:

- Monitoring a digital process tag

**Note**

This block is also available as a small block. A comparison of the MonDiL and MonDiS blocks is available in the section: MonDiL compared to MonDiS (Page 703)



### How it works

The MonDiL block is used to monitor a digital process tag with flutter suppression. The block reports excess flutter signals which are generated within a defined period.

The digital value to be monitored is interconnected to the `In` input parameter. Every time there is a signal change (1 - 0 or 0 - 1) the configurable timer (`FlutTmIn`) for flutter suppression is started as shown in the figure below.

When the time you have specified expires and no single change occurs, the input signal is written to the `Out` output parameter.

Set the time in the timer (`FlutTmIn`) to 0 seconds; the input signal is written directly to the output.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the MonDiL block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring of a digital process tag (DigitalMonitoring) (Page 2851)
- Monitoring a digital process tag for PA/FF devices (DigitalMonitoring_Fb) (Page 2852)

## Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block. The `Out` and `FlutAct` parameters are affected.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

## Status word allocation for `Status1` parameter

You can find a description for each parameter in section MonDiL I/Os (Page 781).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `BypassAct.Value` |

| Status bit | Parameter |
|---|---|
| 6 | `OnAct.Value` |
| 7 | `Out.Value` |
| 8 | `AlmMsgEn` |
| 9 | Display of `BypassAct.Value` in faceplate (display and operator controls) and block icon |
| 10 | `SimLiOp.Value` |
| 11 | Delay of Output set message |
| 12 - 29 | Not used |
| 30 | Auxiliary value 1 is visible |
| 31 | Auxiliary value 2 is visible |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock.Value` |
| 1 | `FlutAct.Value` |
| 2 | `FlutEn` |
| 3 | `FlutMsgEn` |
| 4 - 8 | Not used |
| 9 | `InvIn` |
| 10 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | Internal error |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 - 13 | Not used |
| 14 | Color = 11 (Background color is derived directly from `EventState`, without message classes process message and operator prompt), only for block icon type 5 |
| 15 | Color = 10 (Background color of the message instance MsgEvId1 - Message identifier SIG1) |
| 16-19 | Not used |
| 20 | Color = 6 (Violet, operator prompt) and `Out = 1` |

| Status bit | Parameter |
|---|---|
| 21 | Not used |
| 22 | Color = 5 (Pastel green, process) and `Out = 1` |
| 23 - 24 | Not used |
| 25 | Color = 4 (Black, control system) and `Out = 1` |
| 26 | Color = 9 (UCMC 6) and `Out = 1` |
| 27 | Color = 3 (Blue, tolerance / UCMC 5) and `Out = 1` |
| 28 | Color = 8 (UCMC 4) and `Out = 1` |
| 29 | Color = 2 (Yellow, warning UCMC 3) and `Out = 1` |
| 30 | Color = 7 (UCMC 2) and `Out = 1` |
| 31 | Color = 1 (Red, alarm / UCMC 1) and `Out = 1` |

Explanation:
UCMC = user-configured messages classes

**Note**

The user-configured message classes 5, 3 and 1 are displayed in the existing `Status.Bit27`, `Status.Bit29` and `Status.Bit31`.

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 15 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 16 - 31 | Not used |

### See also

MonDiL functions (Page 774)
MonDiL messaging (Page 780)
MonDiL block diagram (Page 786)
MonDiL error handling (Page 779)
MonDiL modes (Page 773)

## 5.5.2 MonDiL modes

### MonDiL operating modes

This block provides the following modes.

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### Out of service

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | **Feature.Bit5 =0** | **Feature.Bit5 =1** |
|---|---|---|
| Out.ST | 16#80 | 16#60 |

Description of MonDiL (Page 770)

## 5.5.3 MonDiL functions

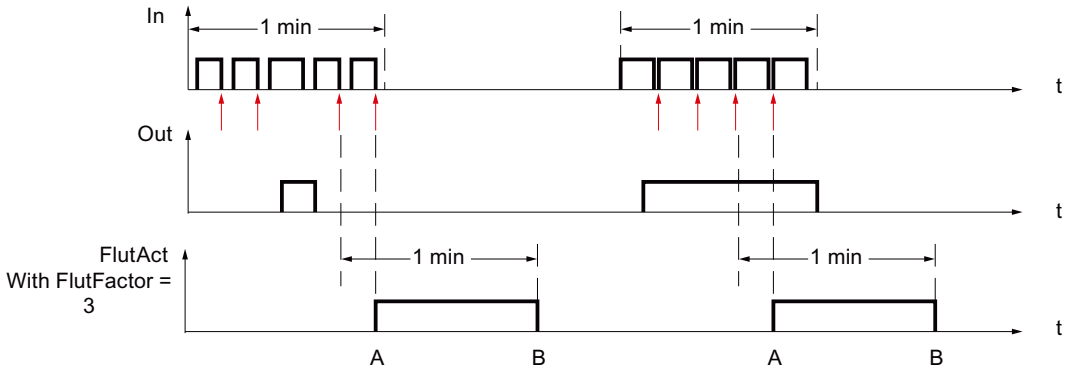
### Functions of MonDiL

The functions for this block are listed below.

### Suppression and reporting of signal flutter

The block is operated as "flutter filter". The block receives digital signals at the `In` input parameter and ideally these do not develop any flutter. The block monitors this if you activate the function via the `FlutEn` = 1 input parameter.

Use the `FlutTmIn` input parameter to set how long a continuous signal should last in order to be transferred to the process without flutter.



The preprocessed signal is sent to the process via the `Out` output parameter.

The block can be set up to report signal flutter. To do this, set parameter `FlutMsgEn` = 1. Monitoring starts at the next 0 - 1 - 0 edge transition at the input signal `In`.

Use the `FlutFactor` input parameter to specify the maximum number of signals to be filtered per minute by the block. If this maximum value is exceeded, this is indicated at the output parameter `FlutAct` by a 1. The message (`FlutAct` = 0). is cleared after the maximum value has dropped again by more than half.

### Example of the flutter suppression

You can use the `FlutFactor` input parameter to limit flutter signals to 3 per minute.

Case A:

Four flutter signals have occurred within a minute. `FlutFactor` is set to three, in other words, a maximum of three flutter signal per minute are allowed, the `FlutAct` output is set to one.

Case B:

Only one flutter signal has occurred within a minute, which corresponds to less than half the `FlutFactor`. The `FlutAct` output is reset.

### Delaying the on and off switching functions

You set delay times for setting/resetting the output using the input parameter `Out_DC` or `Out_DG`:

- `Out_DC`: delay time [s] for rising edges (0 - 1 edge)
- `Out_DG`: delay time [s] for falling edge (1 - 0 edge)

The `Out` output parameter is set/reset after expiration of the delay time.

You disable this function if you set the value of the respective parameter to 0 seconds.

### Adapting the color representation in the configured message class

You can set the background color of instance-specific texts for the block icons 2 to 5 and thereby adapt them to the configured message class. This background color is displayed when the output parameter `Out` = 1.

You set the color coding with the `Color` parameter:

| Value `Color` | Color |
|---|---|
| 0 | Old reaction |
| 1 | Red (alarm) |
| 2 | Yellow (warning) |
| 3 | Blue (tolerance) |
| 4 | Black (control system) |
| 5 | Pastel green (process) |

| Value `Color` | Color |
|---|---|
| 6 | Violet (operator prompt) |
| 7...9 | Old reaction |
| 10 | Background color of the message instance MsgEvId1 - Message identifier SIG1 |
| 11 | For block icon type 5 only, background color is derived directly from EventState without message classes process message and operator prompt [1] |

[1] This also takes into consideration the CSF input

The following colors are shown for user-configured message classes

| Value `Color` | Color |
|---|---|
| 0 | Old reaction |
| 1 | User-configured message classes 1 |
| 2 | User-configured message classes 3 |
| 3 | User-configured message classes 5 |
| 4 | Black (control system) |
| 5 | Pastel green (process) |
| 6 | Violet (operator prompt) |
| 7 | User-configured message classes 2 |
| 8 | User-configured message classes 4 |
| 9 | User-configured message classes 6 |
| 10 | Background color of the message instance MsgEvId1 - Message identifier SIG1 |
| 11 | For block icon type 5 only, background color is derived directly from EventState without message classes process message and operator prompt [1] |

[1] This also takes into consideration the CSF input

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Changing labels on buttons and text

This block provides the standard function Labeling of buttons and text (Page 235).

You can change the label for "Process value" for this block as you please. The change is made with the `FlutTmIn` parameter.

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Group display `SumMsgAct` for limit monitoring, `CSF` and `ExtMsgx`

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `In.ST`

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Value (`SimIn`, `SimInLi`)

### Bypass function

This block provides the standard function Bypassing signals (Page 115).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 9 | Substitution value is active if the block is in bypass (Page 199) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can change the delay time for rising edges (`Out_DC`) |
| 5 | 1 = Operator can change the delay time for falling edges (`Out_DG`) |
| 6 - 7 | Not used |
| 8 | 1 = Operator can activate bypass functionality |
| 9 | 1 = Operator can deactivate bypass functionality |
| 10 | 1 =Operator can change the simulation value `SimIn` |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | Not used |
| 14 | 1 = The user can input the duration for flutter suppression. |
| 15 | 1 = The user can specify the number of flutter signals that should be suppressed. |
| 16 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 5.5.4 MonDiL error handling

### Error handling of MonDiL

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)
- Flutter alarm

### Overview of error numbers

The ErrorNum I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 11 | FlutTmIn < 0 |
| 16 | FlutFactor is -ve or > 100 |

### Control system fault (CSF)

An external signal can be activated via the CSF input. If this signal changes to = 1, a control system fault is triggered. Refer to the Error handling (Page 128) section for more on this.

### Flutter alarm

An alarm is output at output FlutAct with 1 if signal flutter is detected. Refer to the functions of the block > Error handling (Page 128).

## 5.5.5 MonDiL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId1`, SIG 3).

### Process messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | Alarm - high | $$BlockComment$$<br>`Out` - Binary value set |
| | SIG 2 | Warning - high | $$BlockComment$$<br>Flutter limits violated |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa104` ... `ExtVa108` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

| Out_DC | Delay time for setting the output parameter Out for rising edges | REAL | 0.0 |
| Out_DG | Delay time for resetting the output parameter Out for falling edges | REAL | 0.0 |
| RstBypLi | 1 = Reset bypass In (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstBypOp | 1 = Reset bypass In (via operator) | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after start-up. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimIn* | Value used for SimOn = 1 | BOOL | 0 |
| SimInLi | Value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BypassAct | 1 = Bypass is activated in this block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MonDiL error handling (Page 779) | INT | -1 |
| FlutAct | 1 = Suppresses flutter signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | 1 = Alarm error 1 (output ERROR of the first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feed-forwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Out | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 770) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 770) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 770) | DWORD | 16#00000000 |
| SumMsgAct | 1 = Group message is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |

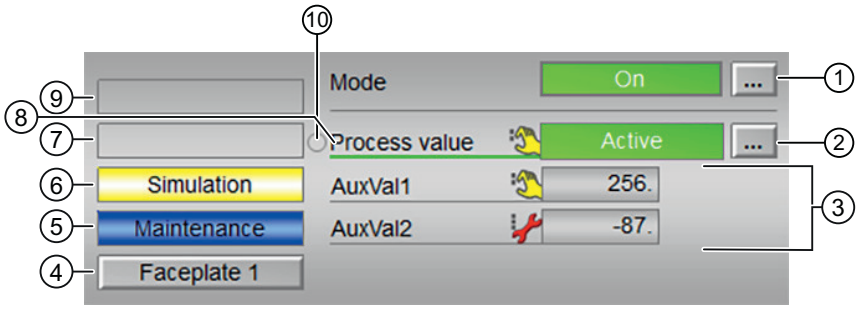
Description of MonDiL (Page 770)

## 5.5.8 Operator control and monitoring

### 5.5.8.1 MonDiL views

**Views of the MonDiL block**



The block MonDiL provides the following views:

- MonDiL standard view (Page 788)
- Alarm view (Page 336)
- Trend view (Page 341)
- MonDiL parameter view (Page 790)
- MonDiL preview (Page 792)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MonDiL (Page 793)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 5.5.8.2 MonDiL standard view

#### MonDiL standard view

#### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Display of process value enabled/disabled

This area shows you the status of the individual connected parameters.

The identifier can be changed using Text 0 / Text 1 at the output parameter `Out`.

If the block is in simulation, you can enable or disable the process value. To do this, click on the display to open the operator input area.

If text is configure for these commands, it is displayed as additional text and as button labels for command selection. You can find additional information on this in chapter Labeling of buttons and text (Page 235).

You can change the text for the process value with the `FlutTmIn` parameter.

The background color of the display can be changed using the "Color" parameter; see MonDiL functions (Page 774) under "Adapting the color representation in the configured message class".

#### (3) Display of auxiliary values

You can use this area to display two auxiliary values that have been configured in the Engineering System. You can find additional information on this in chapter Displaying auxiliary values (Page 239).

### (4) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the Engineering System (ES).

You can find additional information on this in chapter Opening additional faceplates (Page 234).

### (5) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

### (6) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Fluttering"

### (8) Displaying input values

**Changing the display:**

Follow these steps to change the displays:

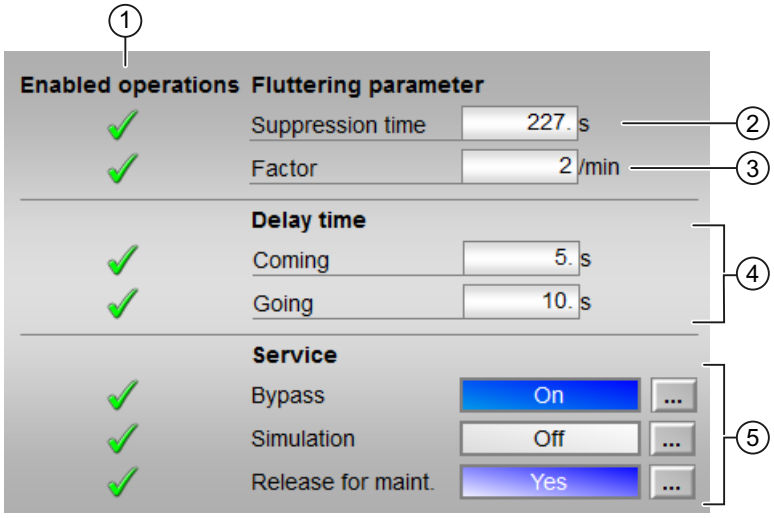
1. In the CFC, right-click the MonDiL block and select "Object Properties" from the context menu.
2. Select "I/Os" tab in the properties window.
3. In the “OS additional text” column, change the default setting for the input parameter (`FlutTmIn`) to what you want to see during runtime later.
4. In the "Identifier" column, change the default setting for the input parameter (`FlutTmIn`) to what you want to see during runtime later.
5. If both “OS additional text” and “Identifier” columns are empty, the default value is displayed in the runtime.
6. The text is used as a label and is therefore always displayed, which means it is independent of the signal status of the corresponding input (`FlutTmInx`).
7. The font size is reduced during the runtime if the input text length is greater than the label width.

**Note**

If a text is added to the "OS additional text" field of the input parameter (`FlutTmIn`), this text is displayed even if the "Identifier" text field of the same input parameter is not empty. If the "OS additional text" field of the input parameter (`FlutTmIn`) is empty, the "Identifier" text of the same input parameter is displayed.

### (9) Display area for block states

This area provides additional information on the operating state of the block:



- Internal error

### (10) Display of Inverted Input

Blank circle will be displayed when input signal In is inverted with `InvIn`.

## 5.5.8.3 MonDiL parameter view

### Parameter view of MonDiL

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### (2) Suppression time

Enter the time period during which signal flutter is suppressed. You can find additional information on this in the Changing values (Page 291) section.

### (3) Factor

Enter the number of flutter signals that can be suppressed. You can find additional information on this in the Changing values (Page 291) section.

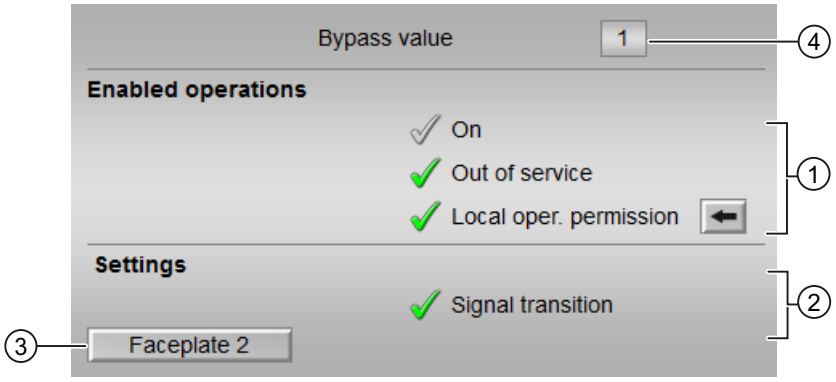
### (4) Delay time

Enter here the delay time by which the output should be set. Enter delay times here for positive ("incoming", 0 - 1 edge) and negative edges ("outgoing", 1 - 0 edge). You can find additional information on this in the Changing values (Page 291) section.

### (5) Service

You can select the following functions in this area:

- "Bypass"
- "Simulation"
- "Release for maintenance"



Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Bypassing signals (Page 115)
- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### 5.5.8.4 MonDiL preview

#### Preview of MonDiL

#### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

#### (2) Settings

- "Signal transition":
  - Activated: A message is generated with a "0 → 1" signal transition at the monitored input.
  - Deactivated: No message is generated.

#### (3) Navigation button for switching to the standard view of any faceplate

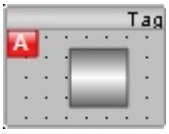
Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### (4) Bypass value

This area displays the bypass value (`BypIn`).

## 5.5.8.5 Block icon for MonDiL



### Block icons for MonDiL

A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display of the output signal
- Display configured instance-specific text for the process value (only for block icons 2 to 5). The instance-specific text for the process value can be changed using Text 0 / Text 1 at the output parameter `Out`.

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`".<br>Text in block icon can be configured via Text 1 at the `Out` output parameter. |
|  | 3 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`".<br>Text in block icon can be configured via Text 1 at the `Out` output parameter. |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 4 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`".<br>Text in block icon can be configured via Text 1 at the `Out` output parameter, a maximum of two characters are supported. |
|  | 5 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`".<br>Text in block icon can be configured via Text 1 at the `Out` output parameter. For `Color = 11`, the text background color is directly derived from EventState (but without the message classes process message and operator prompt) which also takes into consideration the CSF input. `Color = 11` is only supported by type 5. |
|  | 6 | With this block icon you can use your own e.g. emf-pictures. See "Customer-specific icons" in chapter Block icon structure (Page 260) |

**Note**

Text 1 is also used in the standard view of the faceplate in the display process value active/inactive. Long static texts must therefore be displayed on the "Process value" text using the "`FlutTmIn`" parameter (see MonDiL standard view (Page 788))

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 3 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`". |
|  | 4 | See 3 |
|  | 5 | See 3 |
|  | 6 | See 3 |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

## MonDiL6 block icon state display

The MonDiL6 block icon states are shown here:

| Symbol | Meaning |
|---|---|
|  | Active |
|  | Inactive |
|  | Out of service |

# 5.6 MonDiS - Monitoring of a digital process tag (Small)

## 5.6.1 Description of MonDiS

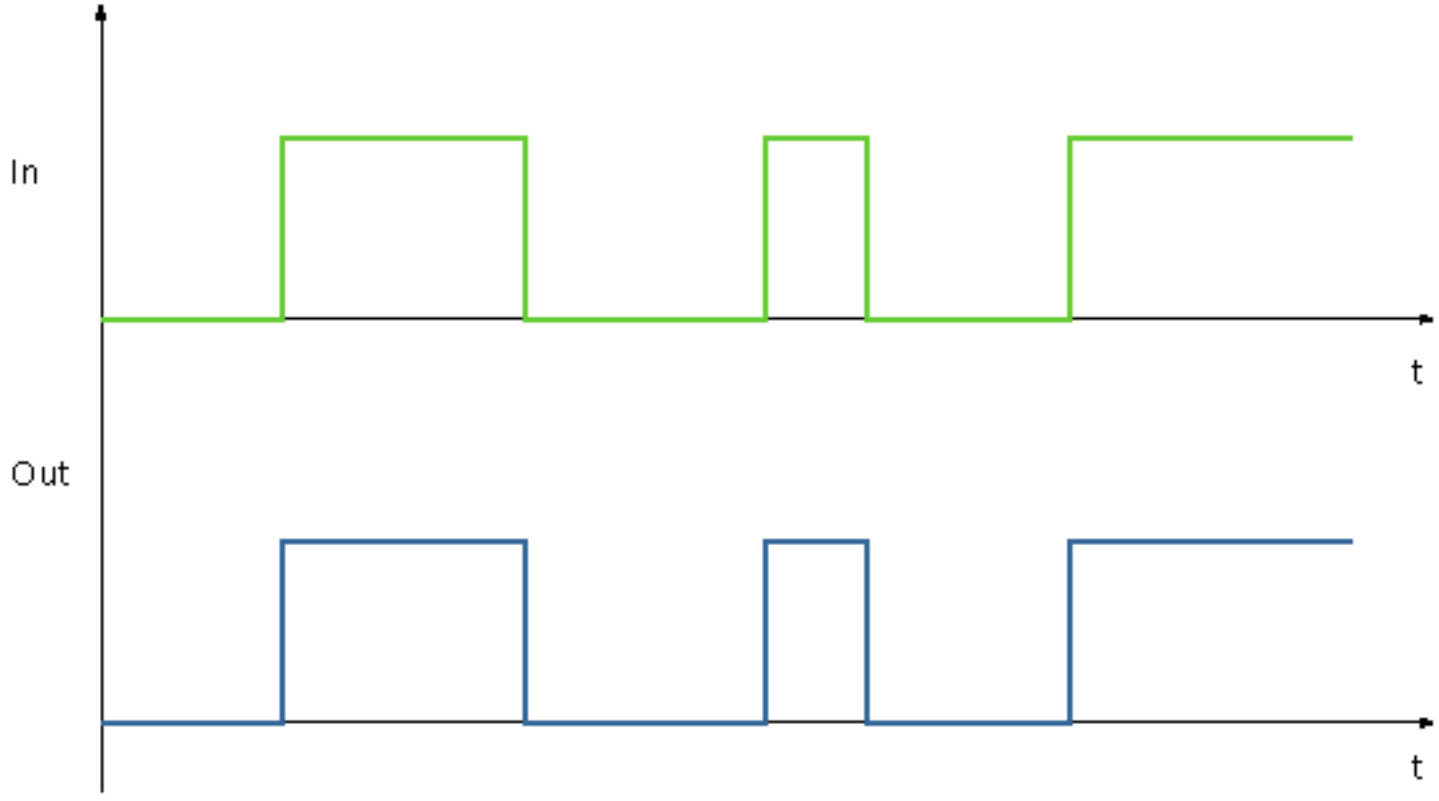
### Object name (type + number) and family

Type + number: FB 1913

Family: Monitor

### Area of application for MonDiS

The block is used for the following applications:



- Monitoring a digital process tag

**Note**

This block is also available as a large block. A comparison of the MonDiL and MonDiS blocks is available in the section: MonDiL compared to MonDiS (Page 703).

## How it works

The MonDiS is used to monitor a digital process tag. The digital value to be monitored is interconnected to the `In` input parameter. The input signal is written directly to the `Out` output parameter.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

## Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block. The `Out` parameter is affected.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

## Status word allocation for `Status1` parameter

You can find a description for each parameter in section MonDiS I/Os (Page 805).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |

| Status bit | Parameter |
|---|---|
| 2 | SimOn |
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | Not used |
| 6 | OnAct.Value |
| 7 | Out.Value |
| 8 | AlmMsgEn |
| 9 | Delay of Output set message |
| 10 - 31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock.Value |
| 1 - 8 | Not used |
| 9 | InvIn |
| 10 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | Internal error |
| 31 | MS_RelOp |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 - 13 | Not used |
| 14 | Color = 11 (Background color is derived directly from EventState, without message classes process message and operator prompt), only for block icon type 5 |
| 15 | Color = 10 (Background color of the message instance MsgEvId1 - Message identifier SIG1) |
| 16-19 | Not used |
| 20 | Color = 6 (Violet, operator prompt) and Out = 1 |
| 21 | Not used |
| 22 | Color = 5 (Pastel green, process) and Out = 1 |
| 23 - 24 | Not used |
| 25 | Color = 4 (Black, control system) and Out = 1 |
| 26 | Color = 9 (UCMC 6) and Out = 1 |
| 27 | Color = 3 (Blue, tolerance / UCMC 5) and Out = 1 |
| 28 | Color = 8 (UCMC 4) and Out = 1 |
| 29 | Color = 2 (Yellow, warning / UCMC 3) and Out = 1 |

| Status bit | Parameter |
|---|---|
| 30 | Color = 7 (UCMC 2) and `Out = 1` |
| 31 | Color = 1 (Red, alarm / UCMC 1) and `Out = 1` |

Explanation:
UCMC = user-configured messages classes

**Note**

The user-configured message classes 5, 3 and 1 are displayed in the existing `Stauts.Bit27`, `Status.Bit29` and `Status.Bit31`.

### See also

MonDiS functions (Page 800)

MonDiS error handling (Page 803)

MonDiS messaging (Page 804)

MonDiS block diagram (Page 808)

## 5.6.2 MonDiS operating modes

### MonDiS operating modes

This block provides the following modes.

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### Out of service

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | **`Feature.Bit5 =0`** | **`Feature.Bit5 =1`** |
|---|---|---|
| Out.ST | 16#80 | 16#60 |

### See also

Description of MonDiS (Page 796)

MonDiS error handling (Page 803)
MonDiS messaging (Page 804)
MonDiS I/Os (Page 805)
MonDiS block diagram (Page 808)

## 5.6.3 MonDiS functions

### Functions of MonDiS

The functions for this block are listed below.

### Delaying the on function

You set delay times for setting the output using the input parameter `Out_DC`:

- `Out_DC`: delay time [s] for rising edges (0 - 1 edge)

The `Out` output parameter is after expiration of the delay time.

You disable this function if you set the value of the respective parameter to 0 seconds.

### Adapting the color representation in the configured message class

You can set the background color of instance-specific texts for the block icons 2 to 5 and thereby adapt them to the configured message class. This background color is displayed when the output parameter `Out` = 1.

You set the color coding with the `Color` parameter:

| Value `Color` | Color |
|---|---|
| 0 | Old reaction |
| 1 | Red (alarm) |
| 2 | Yellow (warning) |
| 3 | Blue (tolerance) |
| 4 | Black (control system) |
| 5 | Pastel green (process) |
| 6 | Violet (operator prompt) |
| 7...9 | Old reaction |
| 10 | Background color of the configured message class SIG1 ("Out - setting binary output values") |
| 11 | For block icon type 5 only, background color is derived directly from EventState without message classes process message and operator prompt [1] |

[1] This also takes into consideration the CSF input

The following colors are shown for user-configured message classes

| Value `Color` | Color |
|---|---|
| 0 | Old reaction |
| 1 | User-configured message classes 1 |
| 2 | User-configured message classes 3 |
| 3 | User-configured message classes 5 |
| 4 | Black (control system) |
| 5 | Pastel green (process) |
| 6 | Violet (operator prompt) |
| 7 | User-configured message classes 2 |
| 8 | User-configured message classes 4 |
| 9 | User-configured message classes 6 |
| 10 | Background color of the configured message class SIG1 ("Out - setting binary output values") |
| 11 | For block icon type 5 only, background color is derived directly from EventState without message classes process message and operator prompt [1] |

[1] This also takes into consideration the CSF input

### Changing labels on buttons and text

This block provides the standard function Labeling of buttons and text (Page 235).

You can change the label for "Process value" for this block as you please. The change is made with the `OnOp` parameter.

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Group display `SumMsgAct` for limit monitoring, `CSF` and `ExtMsgx`

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `In.ST`

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can change the delay time for rising edges (`Out_DC`) |
| 5 - 9 | Not used |
| 10 | 1 =Operator can change the simulation value `SimIn` |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### See also

Description of MonDiS (Page 796)

MonDiS operating modes (Page 799)

MonDiS error handling (Page 803)

MonDiS messaging (Page 804)

MonDiS I/Os (Page 805)

MonDiS block diagram (Page 808)

User-configured message classes (Page 45)

## 5.6.4 MonDiS error handling

### Error handling of MonDiS

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The ErrorNum I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |

### Control system fault (CSF)

An external signal can be activated via the CSF input. If this signal changes to = 1, a control system fault is triggered. Refer to the Error handling (Page 128) section for more on this.

### See also

Description of MonDiS (Page 796)

MonDiS I/Os (Page 805)
MonDiS block diagram (Page 808)

## 5.6.5 MonDiS messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId1`, SIG 3).

### Process messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId 1` | SIG 1 | Alarm - high | $$BlockComment$$<br>`Out` - Binary value set |
| | SIG 2 | Not used | |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | Reserved |
| 7 | Reserved |
| 8 | Reserved |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 and 5 are allocated to the parameters `ExtVa104` and `ExtVa105` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 5.6.6 MonDiS I/Os

I/Os of MonDiS

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AlmMsgEn` | 1 = Alarms are output | BOOL | 1 |
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| CSF | 1 = External error (control system fault)<br>Error handling (Page 803) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Color | Color for status display in the block icon:<br>0 = Default setting<br>1 = Red (alarm)<br>2 = Yellow (warning)<br>3 = Blue (tolerance)<br>4 = Black (control system message)<br>5 = Pastel green (process message)<br>6 = Violet (operator prompt) | BYTE | 16#00 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| Feature | I/O for additional functions (Page 800) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In | Digital input value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| InvIn | Invert input In | BOOL | 0 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 800) | STRUCT<br>• Bit 0: BOOL<br>• Bit 10: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| Out_DC | Delay time for setting the output parameter Out for rising edges | REAL | 0.0 |
| RunUpCyc | Messages can be suppressed for a short time after start-up. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SimOn | 1 = Simulation on | BOOL | 0 |
| SimIn* | Value used for SimOn = 1 | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MonDiS error handling (Page 803) | INT | -1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feed-forwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| Out | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 796) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 796) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 796) | DWORD | 16#00000000 |
| SumMsgAct | 1 = Group message is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

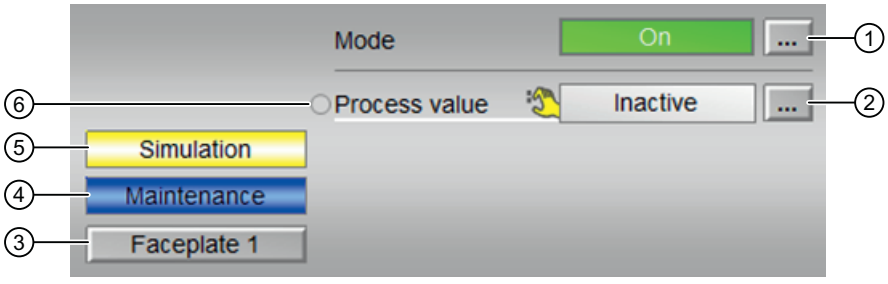
## 5.6.8 Operator control and monitoring

### 5.6.8.1 MonDiS views

#### Views of the MonDiS block



The block MonDiS provides the following views:

- MonDiS standard view (Page 809)
- Alarm view (Page 336)
- Trend view (Page 341)
- MonDiS parameter view (Page 811)
- MonDiS preview (Page 812)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MonDiS (Page 813)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 5.6.8.2 MonDiS standard view

#### MonDiS standard view

### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

### (2) Display of process value enabled/disabled

This area shows you the status of the individual connected parameters.

The identifier can be changed using Text 0 / Text 1 at the output parameter `Out`.

If the block is in simulation, you can enable or disable the process value. To do this, click on the display to open the operator input area.

If text is configure for these commands, it is displayed as additional text and as button labels for command selection. Additional information is available in the section Labeling of buttons and text (Page 235).

### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Additional information is available in the section Opening additional faceplates (Page 234).

### (4) Display area for block states

This area provides additional information on the operating state of the block:

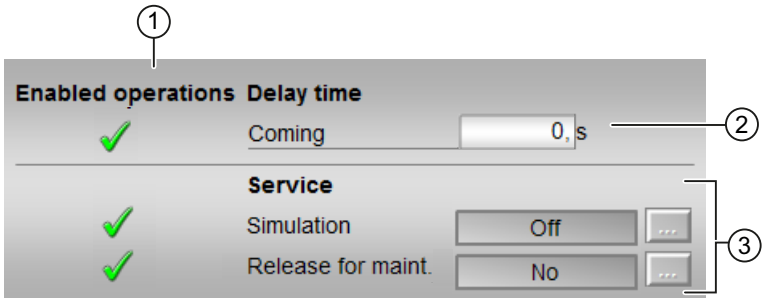
- "Maintenance"

### (5) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

### (6) Display of Inverted Input



Blank circle will be displayed when input signal In is inverted with `InvIn`

### See also

Displaying auxiliary values (Page 239)

### 5.6.8.3 MonDiS parameter view

#### Parameter view of MonDiS

#### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

#### (2) Delay time

Enter here the delay time by which the output should be set. Enter delay times here for positive ("incoming", 0 - 1 edge) edges. Additional information is available in the section Switching operating states and operating modes (Page 289).

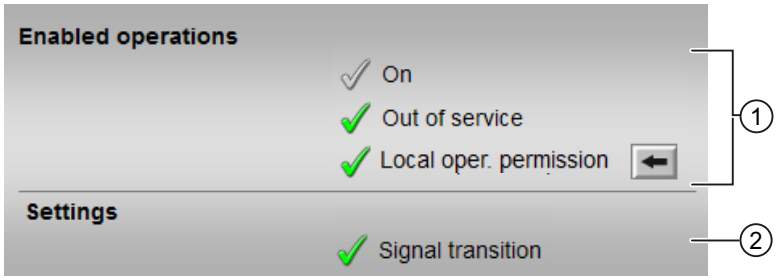
#### (3) Service

You can select the following functions in this area:

- "Simulation"
- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:



- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### See also

Changing values (Page 291)

## 5.6.8.4 MonDiS preview

### Preview of MonDiS

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

### (2) Settings

- "Signal transition":
  - Activated: A message is generated with a "0 → 1" signal transition at the monitored input.
  - Deactivated: No message is generated.

### 5.6.8.5 Block icon for MonDiS

## Block icons for MonDiS

A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display of the output signal
- Display configured instance-specific text for the process value (only for block icons 2 to 5). The instance-specific text for the process value can be changed using Text 0 / Text 1 at the output parameter `Out`.

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`". |
|  | 3 | See 2 |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 4 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`".<br>Text in block icon can be configured via Text 1 at the `Out` output parameter, a maximum of two characters are supported. |
|  | 5 | The text background color for output `Out = 1` depends on the parameter assignment of the input "Color". For `Color = 11`, the text background color is directly derived from EventState (but without the message classes process message and operator prompt) which also takes into consideration the CSF input.`Color = 11` is only supported by type 5. |

**Note**

Text 1 is also used in the standard view of the faceplate in the display process value active/inactive. Long static texts must therefore be displayed on the "Process value" text using the "`FlutTmIn`" parameter (see MonDiS standard view (Page 809))

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | The text background color for output `Out = 1` depends on the parameter assignment of the input "`Color`". |
|  | 3 | See 2 |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 5.7 MonDi08 - Monitoring 8 digital process tags

## 5.7.1 Description of MonDi08

### Object name (type + number) and family

Type + number: FB 1847

Family: Monitor

### Area of application for MonDi08

The block is used for the following applications:

- Monitoring of up to eight digital process tags

### How it works

The MonDi08 block is used to monitor up to eight digital process tags with flutter suppression.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the MonDi08 block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring eight digital process tags (Digital8Monitoring) (Page 2853)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section MonDi08 I/Os (Page 824).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |

| Status bit | Parameter |
|---|---|
| 5 | Not used |
| 6 | OnAct.Value |
| 7 | Out1.Value |
| 8 | Out2.Value |
| 9 | Out3.Value |
| 10 | Out4.Value |
| 11 | Out5.Value |
| 12 | Out6.Value |
| 13 | Out7.Value |
| 14 | Out8.Value |
| 15 - 19 | Not used |
| 20 | In1 is used |
| 21 | In2 is used |
| 22 | In3 is used |
| 23 | In4 is used |
| 24 | In5 is used |
| 25 | In6 is used |
| 26 | In7 is used |
| 27 | In8 is used |
| 28 - 31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock.Value |
| 1 | Alm1MsgEn |
| 2 | Alm2MsgEn |
| 3 | Alm3MsgEn |
| 4 | Alm4MsgEn |
| 5 | Alm5MsgEn |
| 6 | Alm6MsgEn |
| 7 | Alm7MsgEn |
| 8 | Alm8MsgEn |
| 9 | InvIn1 |
| 10 | InvIn2 |
| 11 | InvIn3 |
| 12 | InvIn4 |
| 13 | InvIn5 |
| 14 | InvIn6 |
| 15 | InvIn7 |
| 16 | InvIn8 |
| 17 - 28 | Not used |

| Status bit | Parameter |
|---|---|
| 29 | 1= Suppressed messages |
| 30 | Internal error |
| 31 | MS_RelOp |

### Status word allocation for Status3 parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 - 15 | Effective signal 9..16 of the message block connected via EventTsIn |
| 16 - 31 | Not used |

MonDi08 functions (Page 819)
MonDi08 block diagram (Page 829)
MonDi08 error handling (Page 822)
MonDi08 modes (Page 818)

## 5.7.2 MonDi08 modes

### MonDi08 operating modes

This block provides the following modes.

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### Out of service

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | `Feature.Bit5` =0 | `Feature.Bit5` =1 |
|---|---|---|
| Out1.ST | 16#80 | 16#60 |
| Out2.ST | 16#80 | 16#60 |
| Out3.ST | 16#80 | 16#60 |
| Out4.ST | 16#80 | 16#60 |
| Out5.ST | 16#80 | 16#60 |
| Out6.ST | 16#80 | 16#60 |
| Out7.ST | 16#80 | 16#60 |
| Out8.ST | 16#80 | 16#60 |

MonDi08 functions (Page 819)

Description of MonDi08 (Page 816)

## 5.7.3 MonDi08 functions

### Functions of MonDi08

The functions for this block are listed below.

### Monitoring and output of digital signals

The block is operated as "flutter filter". The block receives digital signals at the input `Inx` (x = 1 ... 8) which ideally do not develop any flutter. The block monitors these signals. Use the `FlutTmInx` (x = 1 ... 8) input to determine the duration of a continuous signal in order to transfer it to the process without flutter.

The preprocessed signal is sent to the process via the `Outx` (x = 1 ... 8) output.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `In1.ST`
- `In2.ST`
- `In3.ST`
- `In4.ST`
- `In5.ST`
- `In6.ST`
- `In7.ST`
- `In8.ST`

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 11 | Suppress MsgLock and "Out of service" mode for a connected message block (Page 202) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 24 | Enabling local operator authorization (Page 169) |

### Operator control permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 11 | Not used |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the time for flutter suppression at the `In1` input |
| 14 | 1 = Operator can change the time for flutter suppression at the `In2` input |
| 15 | 1 = Operator can change the time for flutter suppression at the `In3` input |
| 16 | 1 = Operator can change the time for flutter suppression at the `In4` input |
| 17 | 1 = Operator can change the time for flutter suppression at the `In5` input |
| 18 | 1 = Operator can change the time for flutter suppression at the `In6` input |
| 19 | 1 = Operator can change the time for flutter suppression at the `In7` input |
| 20 | 1 = Operator can change the time for flutter suppression at the `In8` input |
| 21 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Changing labels on buttons and text

This block provides the standard function Labeling of buttons and text (Page 235).

You can change the label for "Process value" for this block as you please. The change is made with the `FlutXTmIn` parameter.

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 5.7.4 MonDi08 error handling

### Error handling of MonDi08

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Flutter alarm

### Overview of error numbers

The `ErrorNum` I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 11 | Fluttering time < 0 |

### Flutter alarm

An alarm is output at output `FlutAct` with 1 if signal flutter is detected. Refer to the functions of the block > Monitoring and reporting flutter signals (Page 819).

## 5.7.5 MonDi08 messaging

### Messaging

The following messages can be generated for this block:

- Process messages
- Instance-specific messages

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId 1 | SIG 1 | Alarm - high | $$BlockComment$$ Signal change Signal 1 has occurred |
| | SIG 2 | Alarm - high | $$BlockComment$$ Signal change Signal 2 has occurred |
| | SIG 3 | Alarm - high | $$BlockComment$$ Signal change Signal 3 has occurred |
| | SIG 4 | Alarm - high | $$BlockComment$$ Signal change Signal 4 has occurred |
| | SIG 5 | Alarm - high | $$BlockComment$$ Signal change Signal 5 has occurred |
| | SIG 6 | Alarm - high | $$BlockComment$$ Signal change Signal 6 has occurred |
| | SIG 7 | Alarm - high | $$BlockComment$$ Signal change Signal 7 has occurred |
| | SIG 8 | Alarm - high | $$BlockComment$$ Signal change Signal 8 has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa104` ... `ExtVa108` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 5.7.6 MonDi08 I/Os

I/Os of MonDi08

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Alm1MsgEn` | 1 = Activate error message | BOOL | 1 |
| `Alm2MsgEn` | 1 = Activate error message | BOOL | 1 |
| `Alm3MsgEn` | 1 = Activate error message | BOOL | 1 |
| `Alm4MsgEn` | 1 = Activate error message | BOOL | 1 |
| `Alm5MsgEn` | 1 = Activate error message | BOOL | 1 |
| `Alm6MsgEn` | 1 = Activate error message | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Alm7MsgEn | 1 = Activate error message | BOOL | 1 |
| Alm8MsgEn | 1 = Activate error message | BOOL | 1 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| EN | 1 = Called block will be processed | BOOL | 1 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| Feature | I/O for additional functions (Page 819) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Flut1TmIn | Flutter time [s] | REAL | 0.0 |
| Flut2TmIn | Flutter time [s] | REAL | 0.0 |
| Flut3TmIn | Flutter time [s] | REAL | 0.0 |
| Flut4TmIn | Flutter time [s] | REAL | 0.0 |
| Flut5TmIn | Flutter time [s] | REAL | 0.0 |
| Flut6TmIn | Flutter time [s] | REAL | 0.0 |
| Flut7TmIn | Flutter time [s] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Flut8TmIn | Flutter time [s] | REAL | 0.0 |
| In1 | Binary input In1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In2 | Binary input In2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In3 | Binary input In3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In4 | Binary input In4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In5 | Binary input In5 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In6 | Binary input In6 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In7 | Binary input In7 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In8 | Binary input In8 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| InvIn1 | Invert input In1 | BOOL | 0 |
| InvIn2 | Invert input In2 | BOOL | 0 |
| InvIn3 | Invert input In3 | BOOL | 0 |
| InvIn4 | Invert input In4 | BOOL | 0 |
| InvIn5 | Invert input In5 | BOOL | 0 |
| InvIn6 | Invert input In6 | BOOL | 0 |
| InvIn7 | Invert input In7 | BOOL | 0 |
| InvIn8 | Invert input In8 | BOOL | 0 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 819) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MonDi08 error handling (Page 822) | INT | -1 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | 1 = Alarm error 1 (output ERROR of the first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out1 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out2 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out3 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out4 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out5 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out6 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out7 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out8 | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 816) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 816) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 816) | DWORD | 16#00000000 |

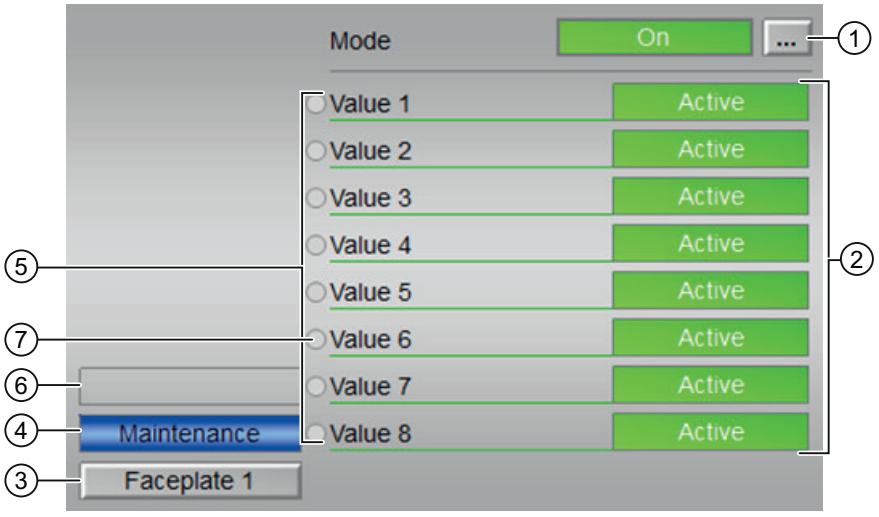
## 5.7.8 Operator control and monitoring

### 5.7.8.1 MonDi08 views

### Views of the MonDi08 block



The block MonDi08 provides the following views:

- MonDi08 standard view (Page 830)
- Alarm view (Page 336)
- Trend view (Page 341)
- MonDi08 parameter view (Page 832)
- MonDi08 preview (Page 833)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MonDi08 (Page 834)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 5.7.8.2 MonDi08 standard view

#### MonDi08 standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) Display of the status for each parameter

This display is only visible when the corresponding block input is connected.

This area shows you the status of the individual parameters available.

You can determine the names for the connected parameters using the `S7_String` attribute at the corresponding input parameter. A default text is displayed if you enter nothing here.

You can change the text for value 1 ... 8 with the `FlutXTmIn` parameter.

Additional information is available in the section Labeling of buttons and text (Page 235).

#### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### (4) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

### (5) Displaying input values

**Changing the display:**

Follow these steps to change the displays:

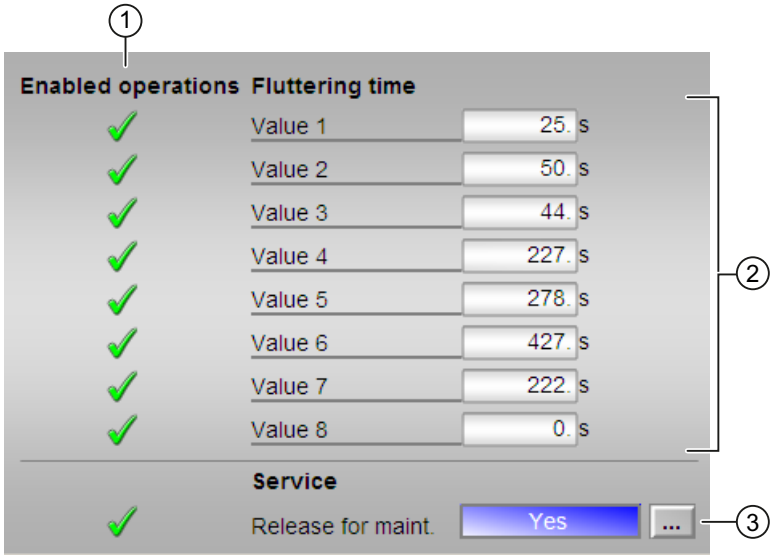
1. In the CFC, right-click the MonDi08 block and select "Object Properties" from the context menu.
2. Select "I/Os" tab in the properties window.
3. In the “OS additional text” column, change the default setting for the input parameter (`FlutXTmIn`, where x = 1...8) to what you want to see during runtime later.
4. In the "Identifier" column, change the default setting for the input parameter (`FlutXTmIn`, where x = 1...8) to what you want to see during runtime later.
5. If both “OS additional text” and “Identifier” columns are empty, the default value is displayed in the runtime.
6. The text is used as a label and is therefore always displayed, which means it is independent of the signal status of the corresponding input (`FlutXTmIn`, where x = 1...8).
7. The font size is reduced during the runtime if the input text length is greater than the label width.

**Note**

If a text is added to the "OS additional text" field of the input parameter (`FlutXTmIn`, where x = 1...8), this text is displayed even if the "Identifier" text field of the same input parameter is not empty. If the "OS additional text" field of the input parameter (`FlutXTmIn`, where x = 1...8) is empty, the "Identifier" text of the same input parameter is displayed.

### (6) Display area for block states

This area provides additional information on the operating state of the block:



- Internal error

### (7) Display of Inverted Input

Blank circle will be displayed when input signal In is inverted with `InvIn`

### 5.7.8.3 MonDi08 parameter view

#### Parameter view of MonDi08

#### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

#### (2) Area for entering the flutter time

Use this area to set the time period to determine how long a continuous signal should last in order for it to be transferred to the process without flutter.

Refer to the Changing values (Page 291) section for more on this.

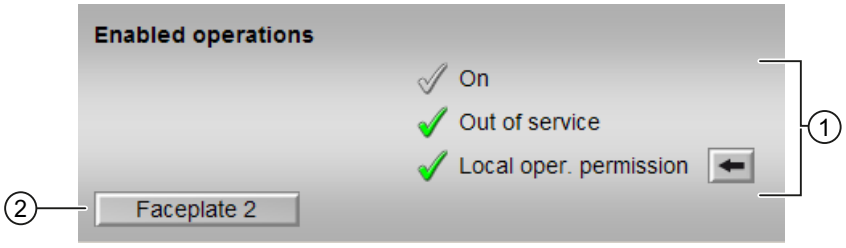
You can determine the names for the connected parameters using the `S7_String` attribute at the corresponding input parameter. A default text is displayed if you enter nothing here.

You can change the text for value 1 ... 8 with the `FlutXTmIn` parameter.

Additional information is available in the section Labeling of buttons and text (Page 235).

### (3) Service

You can select the following function in this area:



- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the Release for maintenance (Page 70) section.

## 5.7.8.4 MonDi08 preview

### Preview of MonDi08

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

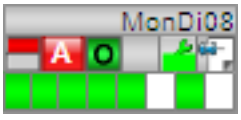
### (2) Navigation button for switching to the standard view of any faceplate

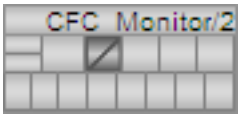
Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### 5.7.8.5 Block icon for MonDi08

#### Block symbols for MonDi08





A variety of block symbols are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display of the output signal

The block symbols from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | |

The block symbols from template @TemplateAPLV7.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | Block symbol in the full display |
|  | 2 | |
|  | - | Block symbol in "Out of service" mode (example with type 1 block symbol) |

Additional information on the block symbol and the control options in the block symbol is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# Controller blocks

# 6

## 6.1 Comparison of large & small blocks

### 6.1.1 PIDConL compared to PIDConS

#### Comparison of the PIDConL and PIDConS blocks

The following tables are intended to help you decide which block to use.

#### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 45%
- Runtime: ~ 40%

#### Block operating modes

| | PIDConL | PIDConS |
|---|---|---|
| Manual mode (Page 79) | X | X |
| Automatic mode (Page 79) | X | X |
| Program mode for controllers (Page 85) | X | |
| Out of service (Page 77) | X | X |

#### Functions of the blocks

| | PIDConL | PIDConS |
|---|---|---|
| Generating and limiting the manipulated variable | X | X |
| Tracking and limiting a manipulated variable (Page 222) | X | X |
| Tracking and limiting a manipulated variable (Page 222) | X | X |
| Neutral position for motors, valves and controllers (Page 54) | X | X |
| Outputting group errors (Page 130) | X | X |
| Outputting a signal for start readiness (Page 59) | X | X |

| | PIDConL | PIDConS |
|---|---|---|
| "Actuator active" information | X | X |
| Limit monitoring of the feedback (Page 101) | X | |
| Setpoint specification - internal/ external (Page 136) | X | X |
| Setpoint limiting for external setpoints (Page 222) | X | X |
| Gradient limit of the setpoint (Page 132) | X | |
| Using setpoint ramp (Page 131) | X | |
| Tracking setpoint in manual mode (Page 222) | X | X |
| Simulating signals (Page 64) | X | X |
| Limit monitoring of the process value (Page 93) | X | X |
| Alarm delays with two time values per limit pair | | |
| Alarm delay with one time value per limit pair | X | X |
| Error signal generation and dead band (Page 217) | X | X |
| Delay alarm for control deviation at setpoint step changes (Page 216) | X | |
| Limit monitoring of error signal | X | |
| Inverting control direction (Page 217) | X | |
| Physical standardization of setpoint, manipulated variable and process value | X | |
| Selecting a unit of measure (Page 240) | X | X |
| PID algorithm | X | X |
| Structure segmentation at controllers (Page 224) | X | |
| Anti-windup (Page 1024) | X | X |
| Feedforwarding and limiting disturbance variables (Page 223) | X | |
| Using control zones (Page 220) | X | |
| Forming and outputting the signal status for technologic blocks (Page 117) | X | X |
| Operator control permissions (Page 285) | X | X |
| Release for maintenance (Page 70) | X | X |
| Generating instance-specific messages (Page 230) | X | X |

| | PIDConL | PIDConS |
|---|---|---|
| Suppressing messages using the MsgLock parameter (Page 231) | X | X |
| Display and operator input area for process values and setpoints (Page 233) | X | X |
| Opening additional faceplates (Page 234) | X | X |
| SIMATIC BATCH functionality (Page 73) | X | X |
| Time stamp | X | |
| Dead band is temporarily disabled (Page 152) | X | |
| Labeling of buttons and text (Page 235) | X | |
| Displaying current control signals from output channel block | X | X |
| Interlocks (Page 107) | X | |
| Disabling interlocks (Page 111) | X | |

## Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | PIDConL | PIDConS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | X | X |
| 1 | Reaction to the out of service mode (Page 188) | X | X |
| 2 | Resetting the commands for changing the mode (Page 172) | X | X |
| 4 | Setting switch or button mode (Page 177) | X | |
| 12 | Control zone with specified I component (Page 171) | X | |
| 13 | Control zone with frozen I component (Page 171) | X | |
| 14 | External control deviation (Page 161) | X | |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) | X | X |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) | X | X |
| 18 | Disabling bumpless switchover to automatic mode for controllers (Page 183) | X | |
| 22 | Update acknowledgment and error status of the message call (Page 171) | X | |
| 24 | Enabling local operator authorization (Page 169) | X | X |

| Bit number | `Feature` bit function | PIDConL | PIDConS |
|---|---|---|---|
| 25 | Suppression of all messages (Page 185) | X | X |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) | X | X |
| 28 | Disabling operating points (Page 156) | X | |
| 29 | Signaling limit violation (Page 181) | X | |
| 30 | Dead band is temporarily disabled (Page 152) | X | |

# 6.2 ConPerMon - Monitoring of the control performance of control loops

## 6.2.1 Description of ConPerMon

### Object name (type + number) and family

Type + number: FB 1805

Family: Control

### Area of application for ConPerMon

The block is used for the following applications:

- Permanent monitoring of control performance of control loops for early detection of problems as they develop

The block calculates:

- Stochastic characteristics of the control performance with the process in a steady state
  - Mean value, variance and standard deviation of controlled variable
  - Mean value of the manipulated variable and control deviation
  - Control performance index
  - Estimated steady state process gain
- Deterministic characteristics of the control performance with step changes in the setpoint
  - Response time and settling time and the settling ratio
  - Overshoot absolute and relative to the step height

Other statistical and graphic evaluations of the signals in the control loop over longer, freely selectable periods are available in the faceplate of the ConPerMon block.

In an overview representation of a plant or unit, you can obtain a clear picture of the status of all control loops based on ConPerMon block icons (indicator light function).

The aim is to detect problems as they develop and to focus the attention of the user on the control loops in a plant that are no longer operating correctly.

### How it works

The ConPerMon block evaluates the setpoint and process value signals and the manipulated variable of the PID controller in a sliding time window. The mode of the controller is also taken into account.

With the process in a steady state, the detected stochastic characteristics are compared with the reference values obtained during commissioning. If there is a step change in the setpoint, the stochastic characteristics are by definition irrelevant and are temporarily frozen. Instead, the monitoring of the deterministic characteristics is automatically activated.

If the control performance falls below a defined limit a message is generated. This is also the case when a defined limit for overshoot is exceeded when there is a step change in the setpoint.

## Configuration

Each PID controller has a ConPerMon block assigned to it that is installed in the same CFC chart and interconnected with the controller. This already takes place with the corresponding process tag types.

You can open the standard view for the ConPerMon block from the standard view of a controller (for example PIDConL). Additional information on this topic is available in the section Opening additional faceplates (Page 234).

After successful commissioning and optimization of the PID controller to be monitored, the ConPerMon block is initialized while the process is in a steady state and it stores the corresponding characteristic values as reference values.

Follow the steps outlined below:

- Change the PID controller you want to monitor to automatic mode and set the setpoint to the typical operating point. This operating status is intended to represent the normal operation of the process; in other words, the entire plant/unit should be running under production conditions. Monitor the process with a trend writer (CFC trend in the Engineering-System or WinCC Online-Trend-Control on the Operator Station) and wait until the process has settled
- To specify the length `TimeWindow` of the sliding time window, monitor the `PV_Variance` block output of the ConPerMonblock in a trend. The time window should be long enough to keep the variance fairly constant in the relevant decimal places. If the selected time window is too short in relation to the time constants in the control loop and the disturbance signal spectrum, the variance will have too much noise and no useful information.
  If the selected time window is too long, it takes longer before any deterioration of the control performance is detected by the ConPerMon block. It also takes longer following a step change in the setpoint before the monitoring of the stochastic characteristics can be resumed. A good starting value for the `TimeWindow` parameter is 10 times as long as the longest process time constant or 20 times as long as the reset time of the PID controller.
- If the controller
  - is set perfectly,
  - has achieved a steady state,
  - the time window has been defined and filled with values from the steady state,

  the ConPerMon block can be initialized. You do this by clicking the "Initialize" button in the parameter view of the ConPerMon faceplate or by setting the `InitRefVar` = 1 parameter in the CFC block. This saves the `PV_Variance` parameter in the current time window as a reference value for calculating the control performance in the block along with reference values for manipulated variable and process variable.

The **C**ontrol **P**erformance **I**ndex CPI should now be approximately at 100% and therefore indicate that the control loop is operating correctly. Due to stochastic fluctuations, the CPI can also temporarily exceed the 100% mark. If, however, the CPI drops by a significant amount over a longer period, this indicates deterioration of the control performance.

For more detailed information on interpreting the calculation results of the block, refer to the section ConPerMon functions (Page 845).

**Note**

If the length of the time window is changed during runtime, the CPI will temporarily deviate considerably from its old value and then gradually settle to the new steady value. It is advisable to reinitialize the ConPerMon block after the CPI value has settled to a constant level.

The ConPerMon faceplate is opened from the faceplate of the assigned PID controller so that the ConPerMonicon pictures do not need to be installed separately in each OS picture. It is, in fact, advisable to group all ConPerMon block icons of a plant or unit in one overview picture at the appropriate hierarchy level.

You can expand this overview picture with the trend display of the control performance of all control loops over a longer time to allow you to recognize gradual deterioration (for example reflecting wear and tear). You can also display a further view of the message archive (WinCC AlarmLogging Control) as a hit list sorted according to the frequency in which they occur. In this list, the control loops that caused the most alarms will be shown at the top.

For the ConPerMon block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)

## Startup characteristics

When the CPU starts up, the block is reinitialized but the stored reference values are retained. The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

**Note**

For ConPerMon, the default value of `RunUpCyc` is set very high (32000). You must adapt it to your own process by taking into account the freely selectable signal inputs `ExtMsg1..3`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section ConPerMon I/Os (Page 860)

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `PID_AutAct.Value` |
| 6 | `OnAct.Value` |
| 7 | Not used |
| 8 | Internal error |
| 9-14 | Not used |
| 15 | `CPI_Suppress` |
| 16 - 31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `OvsAH_Act.Value` |
| 2 | `OvsWH_Act.Value` |
| 3 - 4 | Not used |
| 5 | `CPI_WL_Act.Value` |
| 6 | `CPI_AL_Act.Value` |
| 7 | `OvsAH_En` OR `Feature.Bit31` |
| 8 | `OvsWH_En` OR `Feature.Bit31` |
| 9 - 10 | Not used |
| 11 | `CPI_WL_En` OR `Feature.Bit31` |
| 12 | `CPI_AL_En` OR `Feature.Bit31` |
| 13 | `OvsAH_MsgEn` |
| 14 | `OvsWH_MsgEn` |
| 15 - 16 | Not used |
| 17 | `CPI_WL_MsgEn` |
| 18 | `CPI_AL_MsgEn` |
| 19 | Delay of the `CPI_WL_Lim` message |
| 20 | Delay of the `CPI_AL_Lim` message |
| 21 | Collection of message delays |
| 22 - 23 | Not used |
| 24 | 1= Suppressed messages |
| 25 - 31 | Not used |

## 6.2.2 ConPerMon modes

### ConPerMon operating modes

The block can be operated using the following modes

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

Description of ConPerMon (Page 841)

## 6.2.3 ConPerMon functions

### Functions of ConPerMon

The functions for this block are listed below.

### Monitoring of stochastic characteristics of the control performance

The mean value of a variable relating to an ergodic stochastic process (Page 2886) can be determined from a sliding time window with the length n = `TimeWindow` / `SampleTime`, for example, for the controlled variable y = `PV`:

$$\bar{y} = \frac{1}{n}\sum_{i=1}^{n} y(i)$$

A recursive formulation of this calculation is included in the MeanTime block that is called by the ConPerMonblock. Most steady-state time series can be considered as being ergodic so that the expected value can be estimated by averaging over a window of finite length.

The mean control deviation is `ER_Mean` = `SP` - `PV_Mean`. A mean steady-state control deviation ≠ 0 at a constant setpoint is an indication of problems in the control loop if the controller has I component. You should then check the following potential causes:

- The actuator does not have sufficient capacity. As a result, the controller's actuating signal constantly approaches its limit. This can be caused by unsuitably dimensioned actuators or may simply by wear and tear.
- The manipulated variable demanded by the controller does not take effect in the process, for example because the actuator is defective.

If a steady-state reference operating point (`MV_Ref`, PV_Ref) is known, this can be used to estimate the current mean steady state gain of a linear process model if it is assumed that only disturbances without mean value have an effect:

$$\mathrm{StatGain} = \frac{\mathrm{PV}_{\mathrm{Mean}} - \mathrm{PV}_{\mathrm{Ref}}}{\mathrm{MV}_{\mathrm{Mean}} - \mathrm{MV}_{\mathrm{Ref}}}$$

Normally the reference operating point is obtained during the initialization of the ConPerMon block. Estimation of the steady state gain is then, however, impossible precisely at this operating point. As an alternative, you can also enter the reference values `PV_Ref` and `MV_Ref` manually at the appropriate block inputs. Typical steady-state operating points are often known in advance, for example

- Flow control: `PV` = 0 for `MV` = 0, in other words, valve closed,
- Temperature control: `PV` = `PV_Ambient` for `MV` = 0, in other words, ambient temperature

If the steady state gain changes gradually as time progresses, this is an indication of wear phenomena in the process, such as deposits on heat exchangers, valves or shutters, failing efficiency of process plant, etc.

If, for example, a temperature regulation circuit is closed by a heat exchanger and a deposit forms on the exchanger surfaces, the heat transfer coefficient, and consequently the process gain, is reduced. Within certain limits, this can be compensated by a closed control loop (so that the controller initially disregards the problem). Although the original control loop dynamics can be restored (to a certain extent) by suitable increase of the controller gain as the pollution increases, it is advisable to eliminate the cause of the problem; in other words, to clean the heat exchanger.

If the estimated steady state gain changes suddenly and temporarily, this tends to point to an external disturbance. This may be a normal occurrence in the operation of the process. If, however, these occurrences become more frequent, it is worth finding out the cause.

Due to the approach, the variance `PV_Variance` as second moment requires the calculation of differences of each current measured value from (constant !) mean value:

- `Feature.Bit8` = 0 (default), approximate calculation with reduced computing power consumption:

$$\sigma_y^2 = \frac{1}{n}\left(\sum_{i=1}^{n} y^2(i)\right) - \overline{y}^2$$

- `Feature.Bit8` = 1, more exact calculation corresponding to mathematical definition of variance:

$$\sigma_y^2 = \frac{1}{n-1}\sum_{i=1}^{n}\left(y(i) - \overline{y}\right)^2$$

The standard deviation

$$PV_StdDev = \sigma_y = \sqrt{\sigma_y^2}$$

as the square root of the variance is easier to interpret because it has the same physical unit as the measured value.

The control performance index CPI (**C**ontrol **P**erformance **I**ndex) in the unit [%] describes the current variance of the controlled variable relative to a reference variance (benchmark). It is defined as

$$\varsigma = \frac{\sigma_{ref}^2}{\sigma_y^2} 100\%$$

The CPI moves in the $0 < \varsigma \leq 100\%$ range. If the current variance corresponds to the benchmark, the index reaches the value 100. If, by contrast, the current variance becomes larger, the control performance index decreases accordingly. Ideally, the benchmark is obtained in a defined good state of the control loop and stored when the ConPerMon block is initialized. It does not matter if the CPI temporarily reaches values somewhat higher than 100%. A CPI > 100% only means that the variance of the controlled variable is currently somewhat lower than in the reference state. Other alternatives for determining the benchmark will be explained in a separate .

If you consider the calculated CPI signal to be too strongly affected by noise, you can smooth it using the integrated low pass filter (parameter `CPI_FiltFactor`) with the filter time constant `TimeWindow · CPI_FiltFactor`.

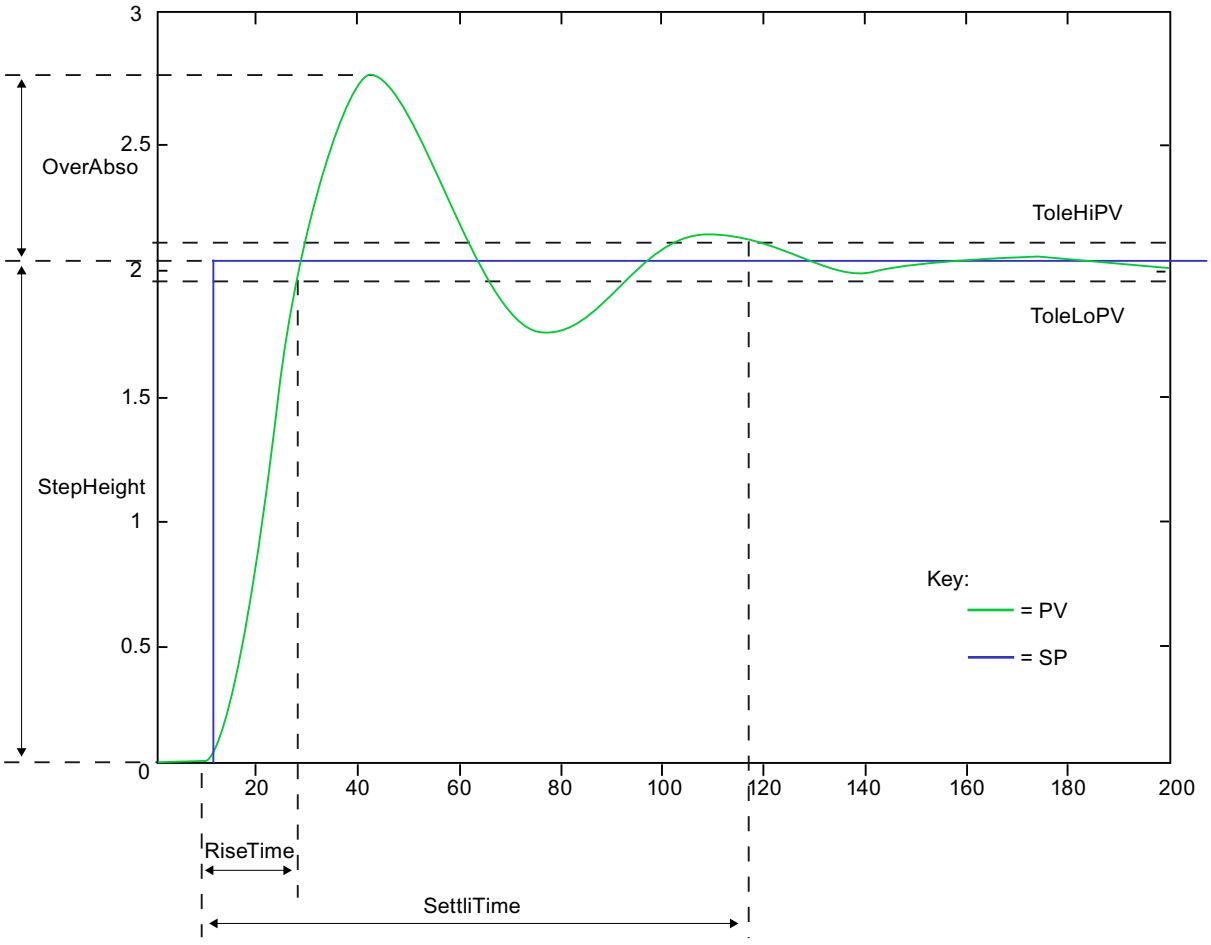
The disadvantage of these stochastic characteristics is that they assume an ergodic (Page 2886) or steady state in the process - at least in a statistical sense. Each step change in the standpoint in a controller is an elementary violation of this requirement and leads temporarily to incorrect statements of the stochastic characteristics, for example variances increasing too much. The basic principle of the combined approach implemented in the ConPerMonblock is to use both stochastic and deterministic characteristics for the control performance and to select the suitable characteristics automatically depending on the operating state.

If a step change in the setpoint is detected in a control loop, the ConPerMon block freezes the CPIvalue and automatically suppresses all messages relating to this. As a user, you can also force the suppression of the messages manually via the `ManSupprCPI` = 1 binary input. This setting is useful to avoid false alarms when known disturbances occur, for example at a load change in a

Conti process (Page 2887) or a dosing procedure in a Batch process (Page 2881). In such cases the variance of the controlled variable usually rises momentarily. This should not be interpreted as a worsening of the control performance.

### Monitoring of deterministic characteristics of the control performance

Assessment of the control performance based on the response to a step change in the setpoint is relatively simple. In the sense of automatic monitoring, the ConPerMon block is capable of determining the essential characteristics of the control performance directly from the signal changes so that when necessary a message or an alarm can be generated automatically by the system.



The first thing to look for is always the overshoot if it is present and clearly distinct from the noise level. For a positive step response,

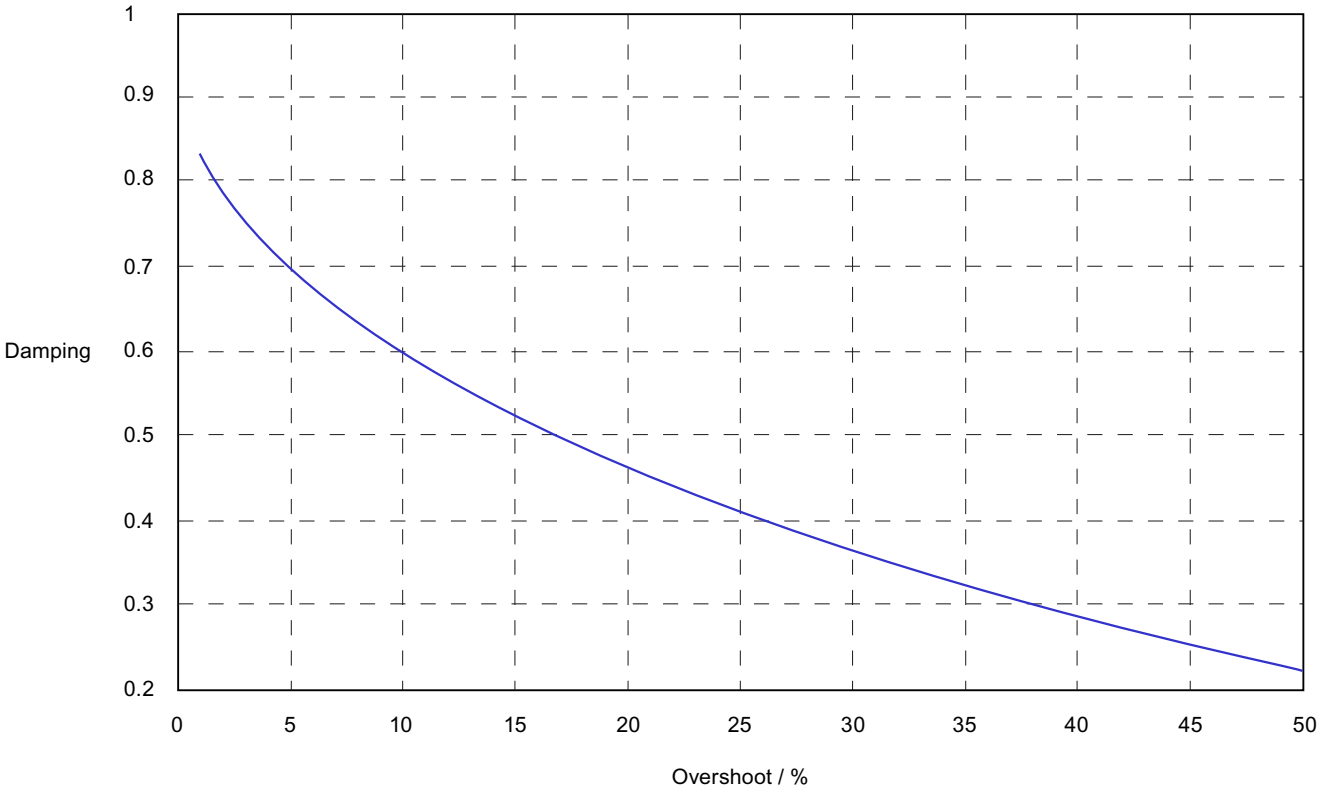
`OverAbso` = max(`PV`) - `SP` > 0

is output where is for a negative step response (step response down), and negative values

`OverAbso` = min(`PV`) - `SP` < 0

are also output. For normalization, the absolute overshoot is related to the height of the step change in the setpoint and is therefore always positive. The relative overshoot (`Overshoot`) as a percentage is a measure of the damping of the control loop. If this is more than 20 or 30%, the loop gain (gain of the controller multiplied by the gain of the control system) is generally too high either because the controller was badly set from the beginning or because the properties of the control system have changed over the course of time. If overshoot is significantly too high, the control loop is generating weakly damped oscillations in the plant. The block sends a message to this effect if the relative overshoot is above a specified limit.

In every control loop, there is a general correlation between overshoot and phase reserve: The higher the overshoot, the lower the phase reserve. If the response of the closed control loop can be described approximately by a 2nd order transfer function



$$g_{cl}(s) = \frac{PV(s)}{SP(s)} = \frac{1}{\frac{1}{\omega_0^2}s^2 + 2\frac{\delta}{\omega_0}s + 1}$$

the following relationships are known:

- If $\delta \geq 1$ , the overshoot is equal to zero and the settling response is asymptotic.
- If $\delta < 1$ , overshoot and oscillations occur.

The damping of the closed loop can be determined approximately from the overshoot:

$$\delta = \frac{-\ln\left(\frac{\text{Overshoot}}{100\%}\right)}{\sqrt{\ln^2\left(\frac{\text{Overshoot}}{100\%}\right) + \pi^2}}$$

An optimum controller setting typically aims for overshoot between 5 and 25%, which means damping between 0.7 and 0.4.

If overshoot is too high, it is often helpful to reduce the gain of the controller.

While overshoot primarily serves to check controller gain, there is a further characteristic that provides information on the setting of the I component: If the setting of the reset time is unsuitable, the process value will creep towards the new setpoint following a step change in the setpoint. The ratio to the `RiseTime` is relevant, and not the absolute value of the `SettliTime`. If the settling ratio, in other words the quotient of the rise time and settling time, is less than approximately 25%, it can generally be assumed that the reset time of the controller is too slow. To determine the rise time and settling time, a 3σ tolerance band is placed around the setpoint and is also displayed in the faceplate of the ConPerMon block. The absolute values of the settling time and rise time can be assessed in terms of the concrete requirements of the process control for a specific application.

During a step change in the setpoint, larger mathematical variances of the controlled variable are bound to occur compared with the steady state so that generating alarms due to the variance limits being exceeded needs to be suppressed until the settling process has neared completion following the step change in the setpoint. The calculated deterministic characteristics are then output and the stochastic evaluation is reactivated.

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Alternatives for determining the benchmark

During planned commissioning of a plant with integrated ConPerMon, following controller optimization, the ConPerMon block is initialized for every control loop and the calculated variance stored as the benchmark for calculating the CPI.

As an alternative, a benchmark can be set via the `RefVarExt` input parameter by setting the `RefVarExtOn` = 1 input parameter. There are various ways of obtaining numeric values for the benchmark:

- Take the lowest variance that was ever measured in this control loop since the initialization of the ConPerMon block. This is displayed at the `PV_VarMin` output parameter. This value is only useful when the control loop has been in a stable and desirable operating state for a longer period of time at least once since the initialization of the ConPerMon block.
- Take the variance of the control loop with a theoretical minimum variance controller as can be obtained based on archived data using another supplier's CPM application. This depends only on the process dead time and the disturbance model. This form of CPI is known as the Harris index and represents a lower barrier that can generally not be reached by a PID controller which is why CPI seldom reaches the value 100% even by well tuned controllers. Low CPI values provide the first indication that the controller settings could be improved. You should, however, bear in mind that the minimum variance is only a theoretically achievable value and that the minimum variance controller has characteristics that are not desired in the real application, for example extremely high manipulated variable amplitudes. With minimum variance-based CPI, therefore, it is not worth making every effort to bring this as close as possible to 100%

### Cascade control

In a cascade control, you should only use the ConPerMon block for the primary controller and not for the secondary controller. The ConPerMon block cannot make any useful statements about the control performance of the secondary controller because

- the variance of the process value in the secondary control loop depends directly on the variance of the setpoint that is set as the manipulated variable by the primary controller,
- there are neither operating phases with a constant setpoint nor defined step changes in the setpoint.

Apart from this, from the perspective of process control, the primary control loop is, of course, the one whose control performance should be monitored while the control performance of the secondary loop is of secondary importance. It is nevertheless advisable to set the secondary controller carefully before optimization and monitoring of the primary controller is started because a poor response by the secondary controller cannot be compensated by the primary controller.

For additional information, read about the process tag template Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840).

### Split-range control

The split-range function block contains two separate (static) characteristics for both actuators. Any significant difference between the two actuators in terms of performance (in other words, different steady state gains for heating and cooling) can be compensated by setting different gradients for the characteristics, so that the controller is presented with a linear process response (regardless of the sign) as far as possible. It this does not work, the control performance will differ slightly in the two areas. The initialization of the ConPerMon block should then be performed in the worse area to avoid error alarms.

For additional information, read about the process tag template Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833).

### PID controller with gain scheduler

The aim of gain scheduling is to achieve consistent control performance over the entire operating range. If this does not work perfectly, the initialization of the ConPerMon block should be performed in an operating point with worse control performance to avoid error alarms. We recommend that you expand the alarm limits somewhat at the ConPerMon block: permit lower `CPI`s and higher overshoot.

For additional information, read about the process tag template PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825).

### Override control

For change-over control, different controllers are active depending on the process state; their control performances differ, of course. We recommend using control loop monitoring only for the primary controller, and to suppress it using the `ManSuprCPI` input parameter if limit controlling is activated.

For additional information, read about the process tag template Override control (Page 2846).

### Feedforward control

The task of feedforward control is to avoid or at least to reduce degradation of the control performance caused by a measurable disturbance variable. Control loop monitoring therefore can basically be used as it is used for simple control loop. When the disturbance variable is quiet for a time and then acts up for a brief period, the resulting fluctuations of the control performance cannot be ruled out. The reason behind it is that feedforward control represents a model-based intervention, and a model is never a perfect reflection of reality.

For additional information, read about the process tag template PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827).

### Smith predictor

The Smith predictor enables higher control performance than a simple PI controller in control loops with dead time. Control loop monitoring therefore can basically be used as it is used for simple control loop. If the dead time changes during ongoing operation, control performance will most likely go down.

For additional information, read about the process tag template PID controller with Smith predictor (SmithPredictorControl) (Page 2830).

### Ratio control

With ratio controlling, the control loop monitoring should only be used in the primary control loop if the setpoints are to be determined for combined components from the actual value of the primary component. In this case, you can expect continuous setpoint changes in the control loops for the combined components - similar to sequential control loop of a cascade. If the setpoints for combined components are to be determined from the setpoint of the primary component, the lower-level control loops can be monitored as well.

For additional information, read about the process tag template Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836).

### Multivariable controller

The mathematical concept of the ConPerMon block is intended for monovariable control loops. If the variance in a control loop is found to be too high, the block cannot determine whether the actual cause is within the control loop or whether influences are being brought in due to interactions from the outside. If, therefore, you notice strong interactions between various control loops in your plant or even use multivariable controllers, the information provided by the ConPerMon block should be treated with caution.

It can nevertheless make sense to equip a multivariable controller such as the ModPreCon block with control loop monitoring to establish whether the control performance achieved during commissioning of the controller is also retained in runtime. In this case, each controller channel of the multivariable controller has a separate ConPerMon block. Several additional logic functions need to be configured upstream from the `ManSuprCPI` input parameter as shown in the corresponding sample project Predictive control of a 2x2 multi-variable controlled system (ModPreConSim) (Page 2879):

- If one or more other channels for the multivariable controller is in a non-steady state (for example, step change in the setpoint) indicated by the `CPI_SupRoot` = 1 output parameter, the temporarily increased variance cannot be avoided in this controller channel and should not cause a CPI message.
- If one or more other channels of the multivariable controller have higher variances (poor control performance) indicated by the corresponding output `CPI_WrnAct` = 1, due to the interaction, these variances also cause a higher variance in this controller channel that cannot be avoided and should not lead to a CPI warning. It is possible to find the actual cause of a disturbance in a multivariable system as follows: The channel that first detects higher variances, set the alarm while subsequent alarms in adjacent channels are suppressed.

  **Note**

  In the case of multivariables, the estimated steady state gains from the monovariable observation are irrelevant. By setting the input parameter `StGainValid` = 0, this status is also displayed in the faceplate as "Uncertain, process related".

If a PID controllers is remotely controlled in program mode (Page 85), it should be treated similar to a secondary controller for a cascade connection in regard to control performance monitoring, i.e. monitoring is usually impractical in this case.

If program mode is the typical operating mode of the controller involved, the corresponding ConPerMon block can be completely removed. If the controller involved is often used in automatic mode, however, monitoring can be temporarily disabled during program mode by connecting the output parameter `AdvCoAct` of the PIDConL block to the input parameter `ManSupprCPI` of the ConPerMon block.

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status for the block is formed from the following parameters:

- `SP_Mon.ST`
- `PV_Mon.ST`
- `MV_Mon.ST`
- `ER_Mean.ST`
- In addition, the ConPerMon block has the following special functions for determining status values:
- If you use a step controller without position feedback, there is no manipulated variable that you could interconnect with the input parameter `MV_Mon`. Unlike most other input parameters `MV_Mon`does not have the preset signal status "Uncertain, process related" (16#78). If there is no interconnected value, this status is transferred to the calculated output parameters `MV_Mean` and `StatGain`.
- `StGainValid`: Set this input to 0 if you use a multivariable controller or observe strong interactions between neighboring control loops. This gives the calculated output parameter `StatGain` the signal status "Uncertain, process related". If known disturbances affect your process, for example dosing procedures in a batch process, you can also set this input temporarily using the recipe control.
- Under normal circumstances the output parameter `StatGain` accepts the worse signal status of `PV_Mon` and `MV_Mon`. Other possible causes of uncertain status for `StatGain` are:
  - the process is currently very close to the reference operating point, or
  - the process is currently in transition, e.g. step change in the setpoint.
- The signal status of the CPI output parameter is dependent on output parameter `CPI_Suppress`: If `CPI_Suppress` = 1, the control performance index CPI is uncertain. Apart from this, the CPI can also become uncertain in occasional situations when there are numeric problems in the calculation of the variance. Under normal circumstances the CPI signal status is the same as the `PV_Mon` signal status.
- The signal status of the `OverAbso` output parameter is set to invalid when step changes in the setpoint are evaluated whose step change height is too low in relation to the noise level.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 8 | Variants of CPI calculation (Page 202) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 31 | Limits disabled in faceplate (Page 206) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 12 | Disable limit act output when limit value message is disabled (Page 209) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 - 1 | Not used |
| 2 | 1 = Operator can switch to "Out of service" mode |
| 3 - 27 | Not used |
| 28 | 1 = Operator can initialize the block |
| 29 | 1 = Operator may input a value for the time window, the reference value for the controlled variable and the reference value of the manipulated variable |
| 30 | 1 = Operator can abort the evaluation of the step response |
| 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (overshoot) for high alarm |
| 1 | 1 = Operator can change the limit (process value) for the high warning |
| 2 | Not used |
| 3 | 1 = Operator may change a value for the `CPI` hysteresis. |
| 4 | Not used |
| 5 | 1 = Operator can change the limit (control performance index `CPI`) for the low warning |

| Bit | Function |
|---|---|
| 6 | 1 = Operator can change the limit (control performance index CPI) for the low alarm |
| 7 | 1 = Operator can activate / deactivate messages via CPI_WL_MsgEn |
| 8 | 1 = Operator can activate / deactivate messages via CPI_AL_MsgEn |
| 9 | 1 = Operator can activate / deactivate messages via OvsAH_MsgEn |
| 10 | 1 = Operator can activate / deactivate messages via OvsWH_MsgEn |
| 7 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Alarm delays with a time value for all limits

The block provides the standard function One time value for all limits (Page 226).

This function is used only for monitoring the control performance index CPI.

### Limit operation and display in the faceplate

This block provides the standard function Limit operation and display in the faceplate (Page 355).

### Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

### Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 6.2.4 ConPerMon error handling

### Error handling of ConPerMon

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 2 | `SampleTime` < 0.001 |
| 10 | `TimeWindow` < 20 · `SampleTime` |

## 6.2.5 ConPerMon messaging

### Messaging

If the control performance falls below a defined limit a message is generated. This is also the case when a defined limit for overshoot is exceeded when there is a step change in the setpoint.

If the CPI temporarily falls below the configured warning and alarm limits, it is not necessary to trigger an alarm immediately. The main aim of the control loop monitoring is to signal the need for maintenance or optimization measures in individual control loops. With the alarm delay, you can make sure that an alarm is triggered only after the cause exists for longer than a configured period `AlmDelay`.

The following messages can be generated for this block:

- Process messages
- Instance-specific messages

**Note**

For ConPerMon, the default value of `RunUpCyc` is set very high (32000). You must adapt it to your own process by taking into account the freely selectable signal inputs `ExtMsg1..3`.

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvID` | SIG 1 | Alarm - high | $$BlockComment$$<br>Overshoot - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>Overshoot - high warning limit violated |
| | SIG 3 | Warning - low | $$BlockComment$$<br>`CPI` - low warning limit violated |
| | SIG 4 | Alarm - low | $$BlockComment$$<br>`CPI` - low alarm limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvID | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@5%x@ |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@6%x@ |
| | SIG 7 | AS process control message - fault | $$BlockComment$$<br>External message 3<br>Status 16#@7%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvID**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | CPI (Control Performance Index) |
| 5 | ExtMsg1.ST |
| 6 | ExtMsg2.ST |
| 7 | ExtMsg3.ST |
| 8 | ExtVa108 |
| 9 | ExtVa109 |
| 10 | Reserved |

The associated values 8 ... 9 are allocated to the parameters ExtVa108 ... ExtVa109 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 6.2.6 ConPerMon I/Os

I/Os of ConPerMon

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AlmDelay | Alarm delay time [s] for monitoring the control performance index CPI<br>0 = Alarm delay deactivated | REAL | 0.0 |
| BatchEn | 1 = Enable allocation for batch control | BOOL | 0 |
| BatchID | Current batch ID | DWORD | 16#00000000 |
| BatchName | Current batch designation | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BreakSuppress | 1 = Manually cancel suppression of the control performance alarm during a step response | BOOL | 0 |
| CPI_AlmHyst | Alarm hysteresis of the control performance index [%] | REAL | 5.0 |
| CPI_AL_En | 1 = Activate alarm (low) for monitoring of control performance | BOOL | 1 |
| CPI_AL_Lim | Low alarm limit for control performance [%] | REAL | 30.0 |
| CPI_FiltFactor | Low pass filter for CPI, filter time constant = TimeWindow · CPI_FiltFactor | REAL | 1.0 |
| CPI_WL_En | 1 = Activate warning (low) for monitoring of control performance | BOOL | 1 |
| CPI_WL_Lim | Low warning limit for control performance [%] | REAL | 50.0 |
| CPI_AL_MsgEn | 1 = Activate alarm message for:<br>Low limit for control performance | BOOL | 0 |
| CPI_WL_MsgEn | 1 = Activate warning message for:<br>Low limit for control performance | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa108 | Associated value 8 for messages (MsgEvID) | ANY | |
| ExtVa109 | Associated value 9 for messages (MsgEvID) | ANY | |
| Feature | I/O for additional functions (Page 845) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| InitRefVar | 1 = Initialization of the block.<br>The benchmark of the controlled variable variance and the reference values of the controlled variable and manipulated variable are measured in the steady state. | BOOL | 0 |
| LoopClosed | 1 = Control loop is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManSupprCPI | 1 = Manual suppression of the CPI calculation and message, e.g. during known disturbances | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgEvID | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Mon | Manipulated variable of the controller for monitoring | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#78 |
| MV_Ref | Reference value of the manipulated variable | REAL | 0.0 |
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosLi | 1 = Edge transition (0-1) = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 845) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 845) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OvsAH_En | 1 = Activate alarm (high) for overshoot | BOOL | 1 |
| OvsAH_Lim | Overshoot alarm limit [%] | REAL | 25.0 |
| OvsAH_MsgEn | 1 = Enable alarm message for overshoot | BOOL | 0 |
| OvsWH_En | 1 = Activate warning (high) for overshoot | BOOL | 1 |
| OvsWH_Lim | Overshoot warning limit [%] | REAL | 20.0 |
| OvsWH_MsgEn | 1 = Enable warning message for overshoot | BOOL | 0 |
| PV_Mon | Controlled variable for monitoring | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Ref | Reference value for controlled variable | REAL | 0.0 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| RefVarExt | Reference value for PV_Variance in control loop "good" status | REAL | 0.0 |
| ReVaExOn | 1 = Use the external reference value of RefVarExt | BOOL | 0 |
| RefVariance | Variance of controlled variable in control loop "good" status | REAL | 100.0 |
| RunUpCyc | Number of start cycles in which messages are suppressed | INT | 32000 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SettlingTimer | Settling time for the adjustment of the dead band | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_Mon | Setpoint of the corresponding controller for monitoring | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StGainValid | 0 = Output parameter StatGain systematically invalid, e.g. for multi-variable processes | BOOL | 1 |
| TimeWindow | Width of the sliding time window [s] for statistical evaluations | REAL | 120.0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OSs | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CPI | Control performance index | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CPI_AL_Act | 1 = Alarm due to control performance is active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CPI_Suppress | 1 = Message for the control performance index is suppressed; retain last valid CPI value | BOOL | 1 |
| CPI_SuRoot | 1= CPI message suppression was triggered in this control loop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CPI_WL_Act | 1 = Warning due to control performance is active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER_Mean | Mean value of the error signal in the time window [PV_Unit] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see ConPerMon error handling (Page 857) | INT | -1 |
| MsgAckn | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Message error (output ERROR of ALARM_8P) | BOOL | 0 |
| MsgStatus | Message status (output STATUS of ALARM_8P) | WORD | 16#0000 |
| MV_Mean | Mean value of the manipulated variable in the time window [MV_Unit] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| O_MS_Ext | Reserved | DWORD | 0 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OverAbso | Absolute overshoot of the step response [PV_Unit] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Overshoot | Relative overshoot of the step response with respect to the step change height [%] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OvsAH_Act | 1 = Alarm due to overshoot is active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OvsWH_Act | 1 = Warning due to overshoot is active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Mean | Mean value of the controlled variable in the time window [PV_Unit] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_StdDev | Standard deviation of the controlled variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_ToleHi | Limit (high) of the 3σ band around the setpoint | REAL | 0.0 |
| PV_ToleLo | Limit (low) of the 3σ band around the setpoint | REAL | 0.0 |
| PV_Variance | Variance of the controlled variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_VarMin | Minimum observed value of the process variance (slave pointer) | REAL | 10000.0 |
| RefStdDev | Standard deviation of controlled variable in control loop "good" status | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RiseTime | Rise time of the step response [s] | REAL | 0.0 |
| SettliDeadBand | Settling time for the adjustment of the dead band | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SettlRatio | Ratio = Rise time/settling time · 100% | REAL | 0.0 |
| SettliTime | Settling time of the step response [s] | REAL | 0.0 |
| StatGain | Steady-state process gain [PV_Unit / MV_Unit] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 841) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Status2` | Status word 2 (Page 841) | DWORD | 16#00000000 |
| `StepPhase` | Phase of the step response:<br>0 = Waiting<br>1 = Rising<br>2 = Overshoot<br>3 = Settled | INT | 0 |

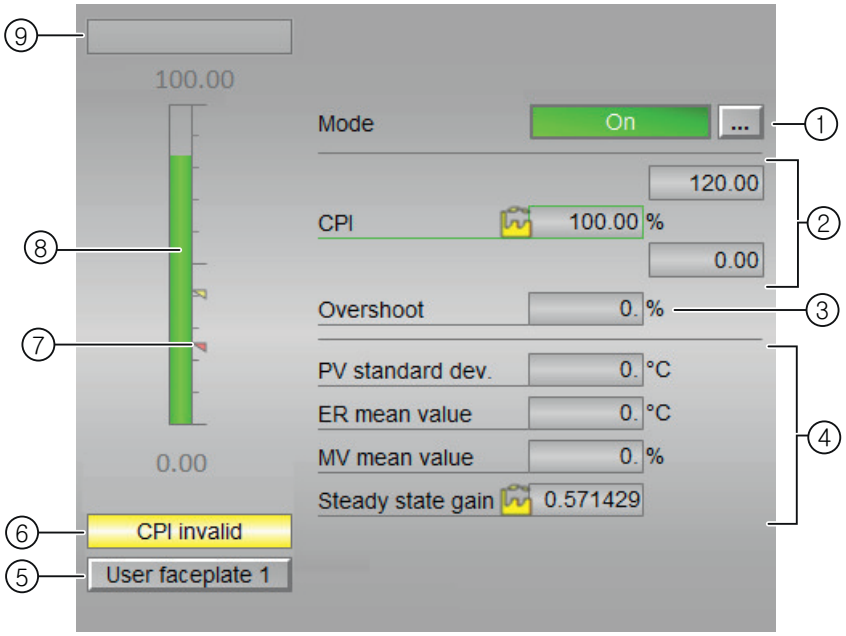
## 6.2.8 Operator control and monitoring

### 6.2.8.1 ConPerMon views

### Views of the ConPerMon block

The block ConPerMon provides the following views:



- ConPerMon standard view (Page 867)
- Alarm view (Page 336)

- ConPerMon limit view (Page 869)
- Trend view (Page 341)
- ConPerMon parameter view (Page 870)
- ConPerMon preview (Page 871)
- Memo view (Page 338)
- Batch view (Page 336)
- ConPerMon setpoint view (Page 872)
- Block icon for ConPerMon (Page 874)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 6.2.8.2 ConPerMon standard view

#### ConPerMon standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

### (2) Display area for control performance

This area shows the current control performance index.

### (3) Display area for the overshoot

This area shows you the relative overshoot based on a step change [%].

### (4) Display area for the static evaluation of the current time window (`TimeWindow`)

This area shows you the statistical evaluation of the current time window. The following values are evaluated:

- "PV standard dev.": Standard deviation of the controlled variable
- "ER mean value": Mean value of the control deviation
- "MV mean value": Mean value of the manipulated variable
- "Steady state gain": Steady-state process gain

### (5) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. You can also see the high low limits of the bargraph's scale. The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the Opening additional faceplates (Page 234) section for more on this.

### (6) Display for CPI valid / CPI invalid

This area shows you if the control performance index is valid or invalid:

- "CPI invalid": Control performance is invalid

You set the limits for the control performance index in the limits views, depending on the configuration in the engineering system (ES).

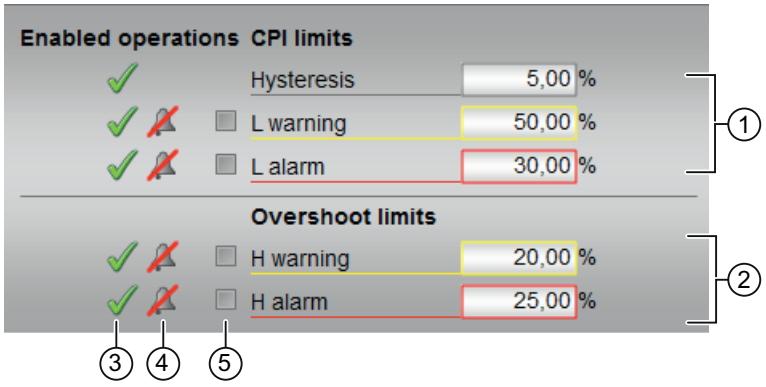
### (7) Limit display

These colored triangles show you the configured limits in the respective bar graph.

### (8) Bar graph for control performance index

This area shows you the current CPI control performance index in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

For more information, refer: Bar graph (Page 376)



### (9) Display area for block states

This area provides additional information on the operating state of the block:

- Internal error
- Invalid Signal

## 6.2.8.3 ConPerMon limit view

### Limit view of ConPerMon

### (1) CPI limits

In this area, you can enter the limits for the CPI control performance index. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "Hysteresis"
- "L warning": Warning low
- "L alarm": Alarm low

### (2) Overshoot limits

In this area, you can enter the limits for the overshoot. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H warning": Warning high
- "H alarm": Alarm high

### (3) Enabled operation

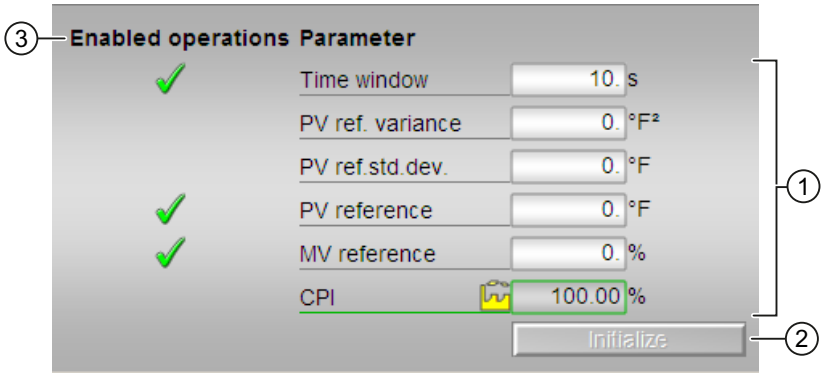
This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (4) "Message suppression/delay"

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.



Alarm delays are also displayed in this position; for more on this see section Area of application of the alarm delays (Page 225).

### (5) Suppress messages

You can enable / disable messages by setting the check mark.

## 6.2.8.4 ConPerMon parameter view

### Parameter view of ConPerMon

### (1) Parameter

In this area, you change parameters and therefore influence the controller. Refer to the Changing values (Page 291) section for more on this.

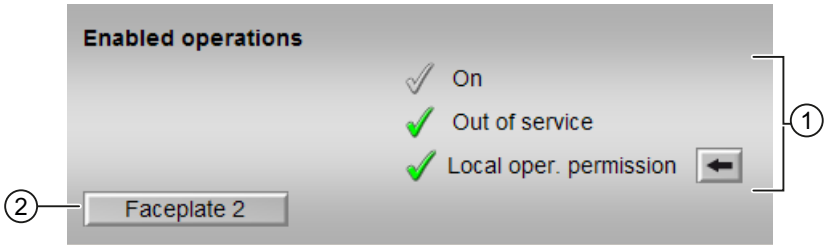
You can influence the following parameters:

- "Time window": Set the time window here, in which the statical evaluation for the following values is to be performed:
  - Standard deviation of the controlled variable
  - Mean value of the control deviation
  - Mean value of the manipulated variable
  - Steady-state process gain
- "PV reference": Reference value for controlled variable
- "MV reference": Reference value of the manipulated variable

### (2) Initialize button

Clicking this button initializes the block. The benchmark of the controlled variable variance and the reference values of the controlled variable and manipulated variable are measured in the steady state.

### (3) Enabled operations



This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

## 6.2.8.5 ConPerMon preview

### Preview of ConPerMon

### (1) Enabled operations

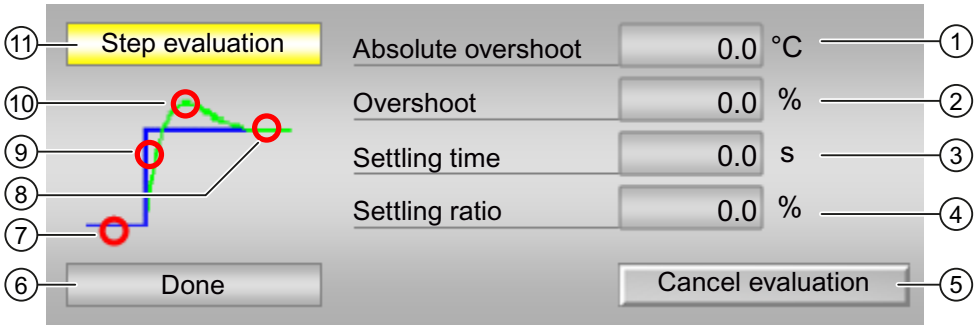
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. You can find more information about this in the section titled: Operator control permissions (Page 285)



### (2) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Additional information is available in the section Opening additional faceplates (Page 234).

## 6.2.8.6 ConPerMon setpoint view

### Setpoint view of ConPerMon

### (1) Absolute overshoot

The absolute overshoot is given in the physical unit of the actual value.

### (2) Overshoot

Output of the relative overshoot base on a step change.

### (3) Settling time

Settling time of the step response in seconds.

### (4) Settling time ratio

The settling time ratio is formed from the ramp time by the settling time.

### (5) Cancel evaluation button

You can use the button to show the evaluation of the step response.

**Note**

The "Cancel evaluation" button is operable when **all** of the following conditions are met:

- Operator permission level = 2 (Higher-level process control)
- Parameter `OS_Perm.Bit30` = 1 (Operator can abort the evaluation of the step response)

### (6), (7), (8), (9) and (10): Status of the step response

The following states are shown here:

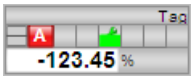
- (6) Textual display of the states
- (7) "Idle": steady state
- (8) "Steady-state": i.e. the actual value is located within the tolerance band of the setpoint
- (9) "Rising phase": from the initial state to the first time the setpoint is reached
- (10) "Overshoot"

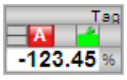
### (11) Display: Evaluation of the step response in progress:

- "Step evaluation"
- "Constant PV"

### See also

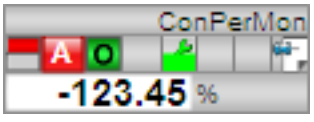
ConPerMon standard view (Page 867)
ConPerMon limit view (Page 869)
ConPerMon parameter view (Page 870)





### 6.2.8.7 Block icon for ConPerMon

## Block icons for ConPerMon



A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits
- Operating modes
- Signal status, release for maintenance
- Memo display
- Process value (black, with and without decimal places)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

# 6.3 FmCont - Interface to module FM 355

## 6.3.1 Description of FmCont

### Object name (type + number) and family

Type + number: FB 1818

Family: Control

### Area of application for FmCont

The block is used for the following applications:

- Fixed setpoint control
- Cascade control
- Ratio control
- Split-range control

### How it works

Block FmCont is used to interface the `FM 355` controller modules.

FmCont can be used for the C (continuous controllers) and S (step and pulse controllers) module types. It contains the algorithms of the setpoint ramp, the setpoint rise limitation, and the limit monitoring of the process value, the control deviation, and the position feedback. Limit monitoring is not used on the module. The control function itself (e.g. PID algorithm) is processed on the module.

You can use the FmCont block to monitor all relevant process values and to change all relevant controller parameters.

Application examples of the FM 355 and detailed descriptions of the associated input and output parameters can be found in the manual for the FM 355. controller module.

Process values such as temperatures, levels and flows can be controlled. However, pressure processes which are not excessively fast are also possible.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100). Set the input parameter `LogAddr` to the module address from HW Config and the input parameter `Channel` to the desired controller channel (1 ... 4).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The parameter `CoordNo` is set
- The in/out parameter `Mode` is interconnected to the corresponding `OMODE_xx` output parameter of the MOD block.

- The parameter FM 355 is set in accordance with the module type C/S
- The in/out parameter EnCoord is interconnected to the output EN_CO_x of the FM_CO block of the Basis Library (x = number of the rack)
- The output parameter EnCoNum is interconnected to the input ENCOx_yy of the FmCont block (x = number of the rack, yy = coordination number).

For the control loop monitoring to work as planned in the trend view of the controller faceplates, the

S7_xarchive:='Value,shortterm;'

attributes in the process tag types for control loops at the controller function block must be set for the following tags:

- Input parameters:
  - CPI_In
- Output parameters
  - MV
  - MV_HiAct
  - MV_LoAct
  - LoopClosed
  - SP
  - PV_Out
  - PV_ToleHi
  - PV_ToleLo

## Startup characteristics

Use the Feature startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at RunUpCyc.

## Status word allocation for Status1 parameter

For a description of the individual parameters, see the section I/Os of FmCont (Page 897)

| Status bit | Parameter |
|---|---|
| 0 | Occupied |
| 1 | BatchEn |
| 2 | SimOn |
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | AutAct.Value |
| 6 | Invalid signal status |
| 7 | ManAct.Value |

| Status bit | Parameter |
|---|---|
| 8 | SP_ExtAct.Value |
| 9 | MV_SafeOn.Value AND NOT OosAct.Value |
| 10 | MV_TrkOn.Value AND NOT (ManAct.Value OR OosAct.Value OR MV_SafeAct.Value) |
| 11 | MV.Value > ManLoLim for continuous or pulse controller<br>NOT FbkClosed.Value for step controller with/without position feedback |
| 12 | Open.Value |
| 13 | Close.Value |
| 14 | Stop.Value |
| 15 | FbkOpnOut.Value |
| 16 | FbkClsOut.Value |
| 17 | SimOn AND ManAct |
| 18 | MV_SafeOn.Value |
| 19 | AdvCoAct.Value |
| 20 | 1 = Input parameter Rbk is not interconnected (RbkOut.ST = 16#FF) |
| 21 | NegGain.Value |
| 22 | MV_FmTrkAct.Value AND NOT (OosAct.Value OR MV_SafeAct.Value) |
| 23 - 24 | Not used |

| 31 | MS_RelOp |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 | Delay of the PV_AH_Lim message |
| 9 | Delay of the PV_WH_Lim message |
| 10 | Delay of the PV_TH_Lim message |
| 11 | Delay of the PV_TL_Lim message |
| 12 | Delay of the PV_WL_Lim message |
| 13 | Delay of the PV_AL_Lim message |
| 14 | Delay of the ER_AH_Lim message |
| 15 | Delay of the ER_AL_Lim message |
| 16 | Collection of message delays |
| 17 - 19 | Not used |

| Status bit | Parameter |
|---|---|
| 20 | 1= Suppressed messages |
| 21 - 23 | Not used |
| 24 | Internal error |
| 25-26 | Not used |
| 27 | `SP_UpRaAct`, `SP_DnRaAct` limits enabled for gradient mode (`SP_RateOn = 1`) |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | `SimLiOp.Value` |
| 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 31 | Not used |

## 6.3.2 FmCont modes

### FmCont operating modes

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Program mode for controllers"

General information on "Program mode for controllers" is available in the section Program mode for controllers (Page 85).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| RbkOut.ST | 16#XX | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| FbkOpnOut.ST | 16#80 | 16#60 |
| FbkClsOut.ST | 16#80 | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| SP.ST | 16#80 | 16#60 |
| SP_ExtOut.ST | 16#80 | 16#60 |
| PV.ST | 16#80 | 16#60 |
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_TH_Act.ST | 16#XX | 16#60 |
| PV_TL_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| PV_ToleHi.ST | 16#XX | 16#60 |
| PV_ToleLo.ST | 16#XX | 16#60 |
| ER.ST | 16#80 | 16#60 |
| ER_AH_Act.ST | 16#XX | 16#60 |
| ER_AL_Act.ST | 16#XX | 16#60 |

## 6.3.3 FmCont functions

### Functions of FmCont

The functions for this block are listed below.

### Module types

FmCont can be used for the C (continuous controllers) and S (step controllers with and without position feedback and pulse controllers) module types. You can use the following parameters to identify which module type and controller type has been set:

| FM 355 | StepCon | WithRbk | Module type, controller type |
|---|---|---|---|
| 1 or C | - | - | FM 355 C: Continuous controller |
| 0 or S | 1 | 1 | FM 355 S: Step controller with position feedback |
| 0 or S | 1 | 0 | FM 355 S: Step controller without position feedback |
| 0 or S | 0 | - | FM 355 S: Pulse controller |

You must set input parameter `StepCon` if you want to set the step controller with/without position feedback as the controller type.

### Generating manipulated variables for continuous controllers, step controllers with position feedback, or pulse controllers

The manipulated variable MV and the actuating signals Open, Close and Stop are generated as follows

| MV_Safe-On | MV_FmTrk On | ManAct | MV_TrkOn | AdvCoAct AND NOT AdvCo-ModSP | MV = | Manipu-lated varia-ble limit | State | Open, Close, Stop |
|---|---|---|---|---|---|---|---|---|
| 1 | - | - | - | - | MV_Safe | MV_HiLim<br>MV_LoLim | Tracking to safety value | **Cont. controller:** Open, Close, Stop = 0<br>**Step controller with position feedback:** Depending on Rbk and MV, the output signals Open, Close and Stop are generated using the algorithm of a positioner.<br>**Pulse controller:** Depending on MV, the output signals Open and Close are generated using the algorithm of a pulse controller (Stop = 0). |
| 0 | 1 | - | - | - | Prepared FM analog input | MV_HiLim<br>MV_LoLim | Tracking to an FM analog input | |
| 0 | 0 | 1 | - | - | Man | ManHiLim<br>ManLoLim | Manual mode, set by the operator | |
| 0 | 0 | 0 | 1 | - | MV_Trk | MV_HiLim<br>MV_LoLim | Tracking to block input MV_Trk | |
| 0 | 0 | 0 | 0 | 1 | AdvCoMV | MV_HiLim<br>MV_LoLim | Higher-level program mode | |
| 0 | 0 | 0 | 0 | 0 | P_Part + I_Part + D_Part + FFwd | MV_HiLim<br>MV_LoLim | Automatic mode (PID algorithm) | |

### Generating actuating signals for step controllers without position feedback (WithRbk = 0)

The manipulated variable signals `Open`, `Close` and `Stop` can be generated as follows:

| ManAct | Open, Close, Stop | State |
|---|---|---|
| 1 | The output signals are generated using input signals `OpenOp`/`Li`, `CloseOp`/`Li` or `StopOp`/`Li` | Manual mode, set by the operator |
| 0 | The output signals are generated using PID output variables `P_Part`, `I_Part`, `D_Part` and `FFwd` | Automatic mode (PID algorithm) |

### Tracking and limiting a manipulated variable (cont. controller, step controller with position feedback and pulse controller)

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

### Neutral position

The controller modules have their own mechanism for feedforwarding a safety value (see manual for Temperature Controller FM 355-2 or manual for Controller Module FM 355).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `ModErr`
- `ParFM_Err`
- `PerACCErr`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### "Actuator active" information

For continuous and pulse controllers: If the manipulated variable `MV` is greater than the minimum manual limit `ManLoLim`, this is recognized as actuator active.

For step controllers: If the parameter `FbkClosed` = 0 , this is recognized as "Actuator active".

This status can be used to indicate a customized symbol in the process image, for example, and is saved in the status word (see Status word section in Description of FmCont (Page 876)).

### Limit monitoring of position feedback (cont. controller, step controller with position feedback and pulse controller)

The block provides the standard function Limit monitoring of the feedback (Page 101).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### External/internal setpoint specification

The block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint limiting for external setpoints

The block provides the standard function Setpoint limiting for external setpoints (Page 222).

### Gradient limit of the setpoint

The block provides the standard function Gradient limit of the setpoint (Page 132).

### Using setpoint ramp

The block provides the standard function Using setpoint ramp (Page 131).

### Tracking setpoint in manual mode

The block provides the standard function Tracking setpoint in manual mode (Page 222).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV`, `SimPV_Li`)
- Position feedback (`SimRbk`, `SimRbkLi`)

**Note**

The simulated process value `SimPV` only affects alarm processing and not the PID algorithm in the control module.

### Limit monitoring of the process value

The block provides the standard function Limit monitoring of the process value (Page 93).

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

### Limit monitoring of error signal

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102).

### Inverting control direction

The block provides the standard function Inverting control direction (Page 217).

### Physical standardization of setpoint, manipulated variable and process value

Controller gain `Gain` is entered either using a physical variable or as standardized value.

- `Gain` as a physical variable:
  The standardized variables retain their default values:
  - `NormPV.High` = 100 and `NormPV.Low` = 0
  - `NormMV.High` = 100 and `NormMV.Low` = 0

  For step controllers with/without position feedback and pulse controllers, the values of `NormMV.High` and `NormMV.Low` are not taken into account. The algorithm uses default values 0 and 100 for internal calculations.
  The effective gain is: `GainEff` = `Gain`
- Entering a standardized `Gain` (dimensionless):
  Change the standardized variables to the actual range of the process values and manipulated variables.
  - Internal and external setpoints; the process value and corresponding parameters are entered according to the physical measuring range of the process value.

  Continuous controller, pulse controller:
  - The manual value, the tracking value of the manipulated variable, feedforward control and the corresponding parameters are set according to the physical measuring range of the manipulated variable.

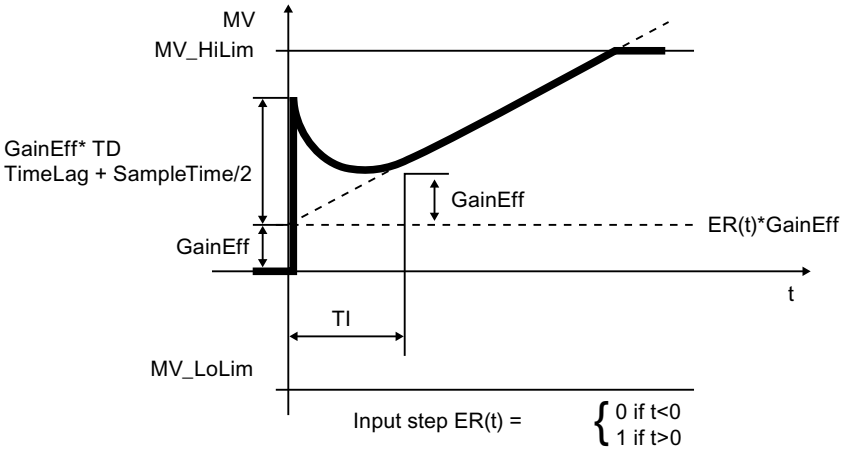
  Step controller with position feedback:
  - The manual parameter, the tracking value of the manipulated variable, feedforward control and the corresponding parameters are entered as a percentage 0 ... 100.

  Step controller without position feedback:
  - No physical measuring range available.

  The effective gain is:
  - Step controller with/without position feedback:
    `GainEff` = 100.0 / (`NormPV.High` - `NormPV.Low`) · `Gain`
  - Continuous controller, pulse controller:
    `GainEff` = (`NormMV.High` - `NormMV.Low`) / (`NormPV.High` - `NormPV.Low`) · `Gain`

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).



## PID algorithm

The manipulated variable is generated in automatic mode according to the following algorithm:

MV = GainEff · (1 + 1 / (TI · s) + (TD · s) / (1 + TD / DiffGain · s)) · ER

Where: s = Complex number

The following step response occurs:

**Note**

This formula describes a standard application where the P, I and D components are activated and the P and D components are not in the feedback circuit (PropSel = 1, TI ≠ 0, D_InSel = 0 and P_FbkSel = 0).

The D component delay is derived from TD / DiffGain.

- The P component can be shut down by PropSel = 0 .
- The I component can be shut down by TI = 0 .
- The D component can be shut down by TD = 0 .

## Structure segmentation at controllers

The PID controller algorithm of FM 355 features structure segmentation. It is activated via the P_FbkSel and D_InSel parameters. The precise functionality is described in the FM 355 manual.

## Anti-windup

The PID control algorithm of FM 355 has an anti-windup function. The I component is frozen or tracked after the manipulated variable has reached its limits (MV_HiLim or MV_LoLim).

## Feedforwarding and limiting disturbance variables

The block provides a function for activating the disturbance variable feedforward. The precise functionality is described in the FM 355 manual.

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the setpoint value SP:
  The signal status of the SP output parameter is always equivalent to the signal status of input parameter SP_Ext or SP_Int, depending on how the setpoint is specified. If the internal setpoint SP_Int is used, the signal status is always output as 16#80.
- Signal status for PV_Out, RbkOut, Open, Close, Stop:
  The signal status is always 16#60 when simulation is activated.
  When the ModErr.Value, ChFM_Err, ParFM_Err module error occurs, the signal status of PV_Out is always 16#0. RbkOut is always 16#0 for step controllers with position feedback
  Otherwise, the following applies:
  ```
  PV_Out.ST: 16#80
  Step controller: RbkOut.ST: = 16#80
  Continuous controller or pulse controller: RbkOut.ST: = Rbk.ST
  Open.ST := 16#80;
  Close.ST := 16#80;
  Stop.ST := 16#80;
  ```
- Signal status of the error signal ER:
  The signal status of output parameter ER is obtained from the worst signal status of the two output parameters PV_Out and SP and is output. The signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation.
  Signal status for FbkOpnOut, FbkClsOut:
  ```
  FbkOpnOut.ST := FbkOpened.ST;
  FbkClsOut.ST := FbkClosed.ST;
  ```
- Signal status for the manipulated variable MV:
  The status signal from the output parameter MV is always set to 16#80 in "manual mode" and for step controllers without position feedback.
  In "automatic mode", the signal status for continuous controllers or pulse controllers is formed from the following parameters:
  RbkOut.STFFwdOut.STER.STWith step controllers, the FbkOpnOut.STFbkClsOut.STparameters are also included. The signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation.
- Worst signal status:
  The worst signal status ST_Worst for the block is formed from:
  - PV_Out.ST;
  - SP:ST;
  - FFwdOut.ST;
  - RbkOut.ST;

  With step controllers (FM355 = 0, StepCon = 1), the following are also included:
  - FbkOpnOut.ST;
  - FbkClsOut.ST;

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6 | Ramp rate calculation (Page 191) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | SP following PV in open loop has no priority over SP_Ext and SP limits (Page 193) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 31 | Limits disabled in faceplate (Page 206) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" `AutModOp` |
| 1 | 1 = Operator can switch to "manual mode" `ManModOp` |
| 2 | 1 = Operator can switch to "Out of service" mode `OosOp` |
| 3 | 1 = Operator can switch to "program mode" `AdvCoEn` |
| 4 | 1 = Operator can switch the setpoint to "external" `SP_ExtOp` |
| 5 | 1 = Operator can switch the setpoint to "internal" `SP_IntOp` |
| 6 | 1 = Operator can change the internal setpoint `SP_Int` |

| Bit | Function |
|---|---|
| 7 | Continuous controllers, pulse controllers or step controllers with position feedback:<br>1 = Operator can change the manual parameter `Man`<br>Step controller without position feedback:<br>1 = Operator can change the manual operation signals `OpenOp`, `StopOp`, `CloseOp` |
| 8 | 1 = Operator can change operation high limit of the setpoint `SP_InHiLim` |
| 9 | 1 = Operator can change operation low limit of the setpoint `SP_InLoLim` |
| 10 | 1 = Operator can change the operation high limit of the manipulated variable `ManHiLim` |
| 11 | 1 = Operator can change the operation low limit of the manipulated variable `ManLoLim` |
| 12 | 1 = Operator can enable the setpoint's gradient limitation function `SP_RateOn` |
| 13 | 1 = Operator can change the setpoint's high limit for the ramp `SP_UpRaLim` |
| 14 | 1 = Operator can change the setpoint's low limit for the ramp `SP_DnRaLim` |
| 15 | 1 = Operator can switch between the time value or the value for the ramp `SP_RmpModTime` |
| 16 | 1 = Operator can change the ramp time `SP_RmpTime` |
| 17 | 1 = Operator can change the target setpoint `SP_RmpTarget` for the setpoint ramp |
| 18 | 1 = Operator can enable the setpoint ramp function `SP_RmpOn` |
| 19 | Not used |
| 20 | 1 = Operator can enable the track setpoint in manual mode function `SP_TrkPV` |
| 21 | 1 = Operator can enable the bumpless switchover from external to internal `SP_TrkExt` |
| 22 | 1 = Operator can change the gain parameter `Gain` |
| 23 | 1 = Operator can change the integral time parameter `TI` |
| 24 | 1 = Operator can change the derivative time parameter `TD` |
| 25 | 1 = Operator can change the derivative gain parameter `DiffGain` |
| 26 | 1 = Operator can change the dead band parameter `DeadBand` |
| 27 | Not used |
| 28 | 1 = Operator can change the integral time parameter `MotorTime` |
| 29 | 1 = Operator can change the integral time parameter `PulseTime` |
| 30 | 1 = Operator can change the integral time parameter `BreakTime` |
| 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (process value) `PV_AH_Lim` for the high alarm |
| 1 | 1 = Operator can change the limit (process value) `PV_WH_Lim` for the high warning |
| 2 | 1 = Operator can change the limit (process value) `PV_TH_Lim` for the high tolerance |
| 3 | 1 = Operator can change the hysteresis (process value) `PV_Hyst` |
| 4 | 1 = Operator can change the limit (process value) `PV_TL_Lim` for the low tolerance |
| 5 | 1 = Operator can change the limit (process value) `PV_WL_Lim` for the low warning |
| 6 | 1 = Operator can change the limit (process value) `PV_AL_Lim` for the low alarm |
| 7 | 1 = Operator can change the limit (error signal) `ER_AH_Lim` for the high alarm |
| 8 | 1 = Operator can change the hysteresis (error signal) `ER_Hyst` |
| 9 | 1 = Operator can change the limit (error signal) `ER_AL_Lim` for the low alarm |
| 10 | 1 = Operator can change the limit (position feedback) `RbkWH_Lim` for the high warning |
| 11 | 1 = Operator can change the hysteresis (position feedback) `RbkHyst` |

| Bit | Function |
|---|---|
| 12 | 1 = Operator can change the limit (position feedback) RbkWL_Lim for the low warning |
| 13 | 1 = Operator can open the valve |
| 14 | 1 = Operator can close the valve |
| 15 | 1 = Operator can stop the valve |
| 16 | 1 = Operator can activate the Simulation function SimOn |
| 17 | 1 = Operator can activate the Release for maintenance function MS_RelOp |
| 18 | 1 = Operator can activate / deactivate messages via PV_AH_MsgEn |
| 19 | 1 = Operator can activate / deactivate messages via PV_WH_MsgEn |
| 20 | 1 = Operator can activate / deactivate messages via PV_TH_MsgEn |
| 21 | 1 = Operator can activate / deactivate messages via PV_TL_MsgEn |
| 22 | 1 = Operator can activate / deactivate messages via PV_WL_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via PV_AL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via ER_AH_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via ER_AL_MsgEn |
| 26 | 1 = Operator can activate / deactivate messages via RbkWH_MsgEn |
| 27 | 1 = Operator can activate / deactivate messages via RbkWL_MsgEn |
| 28 | 1 = Operator can change the simulation value SimPV |
| 29 | 1 = Operator can change the simulation value SimRbk |
| 30 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Release for maintenance

The block provides the standard function Release for maintenance (Page 70).

### Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

### Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `OpenOp`
- `StopOp`
- `CloseOp`

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

EventTs functions (Page 2046)

## 6.3.4 FmCont error handling

### Error handling of FmCont

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

## Overview of error numbers

The ErrorNum I/O can be used to output various error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 30 | The value of PV can no longer be displayed in the REAL number field. |
| 31 | The value of SP_Ext can no longer be displayed in the REAL number field. |
| 33 | The value of MV_Trk can no longer be displayed in the REAL number field. |
| 35 | The value of Rbk can no longer be displayed in the REAL number field. |
| 36 | The value of MV can no longer be displayed in the REAL number field. |
| 50 | The controller cannot be switched to program mode, because program mode with default setpoint (AdvCoModSP = 0) is not possible for step controllers without position feedback (WithRbk = 0). |
| 51 | AutModLi = 1 and ManModLi = 1<br>SP_LiOp = 1 and SP_IntLi = 1 and SP_ExtLi = 1<br>OpenLi = 1 and StopLi = 1<br>CloseLi = 1 and StopLi = 1<br>OpenLi = 1 and CloseLi = 1 |
| 59 | = 1, "Gain is negative" |
| 60 | \|TI\| < SampleTime / 2 |
| 61 | \|TD\| < SampleTime |
| 62 | DiffGain < 1 or DiffGain > 10 |
| 63 | TD / DiffGain < SampleTime / 2 |
| 64 | PropFacSP < 0 or PropFacSP > 1 |
| 66 | NormPV_High = NormPV_Low |
| 67 | MotorTime < SampleTime |
| 68 | PulseTime < SampleTime |
| 69 | BreakTime < SampleTime |
| 70 | Channel < 1 or Channel > 4 |
| 71 | (D_InSel < 0 or D_InSel > 4) and D_InSel ≠ 17 |

## Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 6.3.5 FmCont messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId2` | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId2`, SIG 6).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>PV - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>PV - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>PV - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>PV - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>PV - low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>PV - low alarm limit violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>ER - high alarm limit violated |
| | SIG 8 | Alarm - low | $$BlockComment$$<br>ER - low alarm limit violated |
| MsgEvId2 | SIG 7 | Warning - high | $$BlockComment$$<br>Rbk - high warning limit violated |
| | SIG 8 | Warning - low | $$BlockComment$$<br>Rbk - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@5%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@6%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 3<br>Status 16#@7%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 4<br>Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | Process value `PV_Out` |
| 5 | Control deviation `ER` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | Not allocated |
| 9 | Not allocated |
| 10 | Not allocated |

The associated values 6 ... 7 are allocated to the parameters `ExtVa106` ... `ExtVa107` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance `MsgEvId2`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | Position feedback `RbkOut` |
| 5 | Signal status `ExtMsg1` |
| 6 | Signal status `ExtMsg2` |
| 7 | Signal status `ExtMsg3` |
| 8 | Signal status `ExtMsg4` |
| 9 | `ExtVa209` |
| 10 | `ExtVa210` |

The associated values 9 ... 10 are allocated to the parameters `ExtVa209` ... `ExtVa210` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### 6.3.6 FmCont I/Os

I/Os of FmCont

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

#### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AccMode* | 1 = Transfer of operating parameters SubN1_ID, SubN2_ID, RackNo, SlotNo and Channel to internal processing | BOOL | 1 |
| AdvCoEn | 1 = Enable "program mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoModSP | Type of "program mode":<br>1 = Setpoint specification<br>0 = Manipulated variable specification | BOOL | 1 |
| AdvCoMstrOn | Activate (0-1) or deactivate (1-0) "program mode" via edge transition | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoMV | Specified value from the external program.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | REAL | 0.0 |
| AdvCoOn* | 1 = Enable "program mode" via faceplate.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | BOOL | 0 |
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation for batch control | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BreakTime* | Minimum break duration [s] | REAL | 1.0 |
| Channel | Controller channel number (1..4) | INT | 1 |
| CloseLi* | 1 = Close via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseOp* | 1 = Close via operator | BOOL | 0 |
| CoordNo | Coordination number | INT | 0 |
| CPI_In | Input for control performance index, which is calculated by the assigned ConPerMon block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| D_InSel* | Input for differentiator:<br>0 = Error signal<br>1..4 = Channel 1..4<br>17 = Actual value to feedback | INT | 0 |
| DeadBand* | Width of dead band | REAL | 0.0 |
| DiffGain* | Gain of differentiator [1...10] DiffGain = TD/(delay time of D component) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 5.0<br>• 16#80 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ER_A_DC* | Delay for incoming alarms during error signal monitoring | REAL | 0.0 |
| ER_A_DG* | Delay for outgoing alarms during error signal monitoring | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AH_Lim | Alarm limit (high) for error signal monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for error signal monitoring | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_AL_En | 1 = Activate alarm (low) for error signal monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for error signal monitoring | REAL | -100.0 |
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for error signal monitoring | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for error signal | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | Binary input for freely selectable message 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa209 | Associated value 9 for messages (MsgEvID2) | ANY | |
| ExtVa210 | Associated value 10 for messages (MsgEvID2) | ANY | |
| FbkClosed | Low limit stop signal of position feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#80 |
| FbkOpened | High limit stop signal of position feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Feature | I/O for additional functions (Page 882) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FM355 | Module type:<br>0: FM 355 S; 1: FM 355 C | BOOL | 0 |
| FuzOptOn* | Fuzzy optimization | BOOL | 0 |
| Gain* | Proportional gain<br>Gain.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| LogAddr | Logical address FM 355 | INT | 0 |
| Man* | Manual specification for the manipulated variable | REAL | 0.0 |
| ManHiLim* | Limit (high) for manual parameter Man | REAL | 100.0 |
| ManLoLim* | Limit (low) for manual parameter Man | REAL | 0.0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| Mode | Operating mode | DWORD | 16#00000000 |
| ModLiOp | Operating mode switchover between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MotorTime* | Motor actuating time [s] | REAL | 30.0 |
| MS | Maintenance status | DWORD | 0 |
| MS_Release | Release for maintenance (interconnected with MS_Release of the technology block) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ms_Ext | External maintenance status. For more information, refer to the MS_Ext (Page 2463) parameter section under information on using channel blocks. | DWORD | 0 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvID1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgEvID2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_FmTrkOn | 1 = Manipulated variable tracking in the FM | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiLim* | Limit (high) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| MV_LoLim* | Limit (low) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_OpScale | OS display range for manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_Safe* | Neutral position manipulated variable | REAL | 0.0 |
| MV_SafeOn | 1 = Neutral position manipulated variable MV_Safe at output MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Trk* | Tracking value for the manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| NegGain* | 0 = Effective proportional gain GainEff is positive<br>1 = Effective proportional gain GainEff is negative | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NormMV | Manipulated variable range (MV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| NormPV | Process value range (PV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Occupied | Occupied by batch control | BOOL | 0 |
| OosLi | Edge transition (0-1) = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OP_Sel* | Operation via OP<br>0 = "Off" (P bus)<br>1 = "On" (K bus) | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpenLi* | 1 = Open via interconnection or CFC | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| OpenOp* | 1 = Open via operator | BOOL | 0 |
| OptimEn | 1 = Enable optimization of PID parameters by PID tuner | BOOL | 0 |
| OptimOcc | 1 = Optimization running | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 882) | STRUCT | - |
| | | • Bit 0: BOOL | • 1 |
| | | • ... | • 1 |
| | | • Bit 31: BOOL | • 1 |
| OS1Perm | I/O for operator permissions (Page 882) | STRUCT | - |
| | | • Bit 0: BOOL | • 1 |
| | | • Bit 18: BOOL | • 1 |
| | | • Bit 19: BOOL | • 1 |
| | | • Bit 31: BOOL | • 1 |
| P_FbkSel* | 1 = P component in feedback | BOOL | 0 |
| PropSel* | 1 = Activate P component | BOOL | 1 |
| PulseTime* | Minimum pulse duration [s] | REAL | 1.0 |
| PV_A_DC* | Delay time for incoming PV alarms [s] | REAL | 0.0 |
| PV_A_DG* | Delay time for outgoing PV alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_Hyst | Hysteresis for PV alarm, warning and tolerance limits | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT | - |
| | | • High: REAL | • 100.0 |
| | | • Low: REAL | • 0.0 |
| PV_T_DC* | Delay time for incoming PV tolerance messages [s] | REAL | 0.0 |
| PV_T_DG* | Delay time for outgoing PV tolerance messages [s] | REAL | 0.0 |
| PV_TH_En | 1 = Enable PV tolerance limit (high) | BOOL | 0 |
| PV_TH_Lim | Limit PV tolerance message (high) | REAL | 85.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_TH_MsgEn | 1 = Enable message for PV tolerance message (high) | BOOL | 1 |
| PV_TL_En | 1 = Enable PV tolerance limit (low) | BOOL | 0 |
| PV_TL_Lim | Limit PV tolerance message (low) | REAL | 15.0 |
| PV_TL_MsgEn | 1 = Activate message for PV tolerance message (low) | BOOL | 1 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_W_DC* | Delay time for incoming PV warnings [s] | REAL | 0.0 |
| PV_W_DG* | Delay time for outgoing PV warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| RackNo | Rack number | BYTE | 16#FF |
| Rbk* | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 1 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 100.0 |
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 1 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 0.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |
| RefStdDevIn | Reference value of PV standard deviation (sigma) in defined "good" state of control loop | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| S_RbkOnPIDTun | Simulation of position feedback on;<br>For PCS 7 PID tuner only | BOOL | 0 |
| S_RbkPIDTun | Simulated position feedback | REAL | 50.0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SlotNo | Slot number | BYTE | 16#FF |
| SP_DnRaLim | Limit (low) for the gradient of the set-point [SP_Unit/s] | REAL | 100.0 |
| SP_ExHiLim* | Limit (high) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_ExLoLim* | Limit (low) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Ext* | External setpoint of - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi* | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_InHiLim* | Limit (high) of internal setpoint | REAL | 100.0 |
| SP_InLoLim* | Limit (low) of internal setpoint | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_IntLi* | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RateOn* | 1 = Activate limitation of setpoint gradients | BOOL | 0 |
| SP_RmpModTime | 1 = Use time (SP_RmpTime) for setpoint ramp,<br>0 = Use gradient | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |
| SP_RmpTime* | Time for setpoint ramp [s] from current SP up to SP_RmpTarget | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 1 |
| SP_TrkPV | 1 = Setpoint follows PV in "manual mode" and with tracking | BOOL | 0 |
| SP_UpRaLim | Gradient limit (high) for the setpoint [SP_Unit/s] | REAL | 100.0 |
| StepCon | Controller type in the FM 355 S:<br>0 = Pulse controller<br>1 = Step controller | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopLi* | 1 = Stop via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopOp* | 1 = Stop via operator | BOOL | 0 |
| SubN1_ID | ID of the primary DP master system | BYTE | 16#FF |
| SubN2_ID | ID of the redundant DP master system | BYTE | 16#FF |
| TD* | Derivative time [s]<br>TD.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| TextRef | Text reference | WORD | 0 |
| TI* | Integral time [s]<br>TI.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### In/out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| EnCoord | Current coordination number | STRUCT<br>• CO_ACT : INT | -<br>• 0 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoAct | 1 = "Program mode" enabled.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoRdy | 1 = "Program mode" available | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutAct | 1 = "Automatic mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ChFM_Err | 1 = Channel error on the module | BOOL | 0 |
| Close | Control output:<br>1 = Closed is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| EnCoNum | Coordination number | BYTE | 16#00 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_AH_Act | 1 = Alarm limit (high) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ER_AL_Act | 1 = Alarm limit (low) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ErrorNum | Output of pending error number; for error numbers that can be output by this block, see FmCont error handling (Page 892) | INT | -1 |
| FbkClsOut | 1 = Low limit stop of the position feedback reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpnOut | 1 = High limit stop of the position feedback reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FFwdOut | Disturbance variable generated in the FM | STRUCT<br>Value: REAL<br>ST: BYTE | -<br>0.0<br>16#80 |
| FuzCon | Controller type:<br>0 = PID controller<br>1 = Fuzzy controller | BOOL | 0 |
| FuzOptAct | 1 = Optimization of fuzzy controller active | BOOL | 0 |
| FuzSP_PV_Act | Fuzzy controller display:<br>Setpoint < actual value | BOOL | 0 |
| GainEff | Effective proportional gain depends on NegGain, Gain, NormPV, and NormMV | REAL | 1.0 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LoopClosed | 1 = Control loop closed<br>0 = Control loop open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| ManARW_Act | 1 = Tracking mode or anti-reset windup by secondary controller | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManHiOut | Limit (high) for "manual mode", corresponds to input parameter ManHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| ManLoOut | Limit (low) for "manual mode", corresponds to input parameter ManLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ModErr | 1 = Module error | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgAckn2 | Message acknowledgement status 2 (output ACK_STATE of second ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgErr2 | Alarm error 2 (output ERROR of second ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| MsgStat2 | Message status 2 (output STATUS of second ALARM_8P) | WORD | 16#0000 |
| MV | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_FmTrkAct | 1 = Track manipulated variable in the FM enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_SafeAct | 1 = Neutral position manipulated variable of the FM enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_SpliA | Manipulated variable A of split-range function | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_SpliB | Manipulated variable B of split-range function | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_UnitOut | Unit of measure for manipulated variable, for interconnecting to the MV_Unit input parameter of the ConPerMon block | INT | 0 |
| MV_Visible | 1 = MV display visible<br>Evaluated by block icon | BOOL | 0 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Open | Control output:<br>1 = Open is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS_Perm1 | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| ParFM_Err | 1 = Direct parameter-assignment error of the FM or input Channel configured incorrectly | BOOL | 0 |
| PerAccErr | 1 = I/O access error | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV | Process value of the module | STRUCT<br>• Value: REAL<br>• ST:BYTE | -<br>• 0.0<br>• 16#80 |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_TH_Act | 1 = PV tolerance message (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_TL_Act | 1 = PV tolerance message (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_ToleHi | Limit (high) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_ToleLo | Limit (low) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_UnitOut | Unit of measure for process value, for interconnecting to the PV_Unit input parameter of the ConPerMon block | INT | 0 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkOut | Output for position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkVisible | 1 = Rbk display visible<br>Evaluated by block icon | BOOL | 0 |
| RbkWH_Act | 1 = Warning (high) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RetValue | Return value of WRREC / RDREC | WORD | 16#0000 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExHiAct | 1 = Limit (high) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExLoAct | 1 = Limit (low) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOut | External setpoint, corresponds to input parameter SP_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_InHiOut | Limit (high) for SP_Int corresponds to input parameter SP_InHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_InLoOut | Limit (low) for SP_Int corresponds to input parameter SP_InLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_RateTarget | Target setpoint for the gradient limitation | REAL | 0.0 |
| SP_UpRaAct | Positive gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| SplitRange | 1 = Split-range function has been activated | BOOL | 0 |
| Status1 | Status word 1 (Page 876) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 876) | DWORD | 16#00000000 |
| Status3 | Status word 2 (Page 876) | DWORD | 16#00000000 |
| Stop | Control output:<br>1 =Stopped is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SumMsgAct | 1 = Active hardware interrupt | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| WithRbk | Controller type:<br>0 = Step controller without position feedback<br>1 = Step controller with position feedback | BOOL | 0 |

## 6.3.8 Operator control and monitoring

### 6.3.8.1 FmCont views

#### Views of the FmCont block

The block FmCont provides the following views:

- FM controllers standard view (analog) (Page 294)
- FM controllers standard view (pulse controller) (Page 298)
- FM controllers standard view (step controller with position feedback) (Page 302)
- FM controllers standard view (step controller without position feedback) (Page 306)
- Alarm view (Page 336)
- Limit view of FM controllers (Page 322)
- Trend view (Page 341)
- Ramp view (Page 334)
- Parameter view of FM controllers (Page 318)
- Preview of FM controllers (Page 331)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icons for PID and FM controller (Page 269)

Refer to the Structure of the faceplate (Page 279) and Block icon structure (Page 260) sections for general information about the faceplate and block icon.

# 6.4 FmTemp - Interface to temperature controller modules FM 355-2

## 6.4.1 Description of FmTemp

### Object name (type + number) and family

Type + number: FB 1819

Family: Control

### Area of application for FmTemp

The block is used for the following applications:

- Fixed setpoint control
- Cascade control
- Ratio control
- Split-range control

### How it works

Block FmTemp is used to interface the FM 355-2 temperature controller modules.

FmTemp can be used for the C (continuous controllers) and S (step and pulse controllers) module types. It contains the algorithms of the setpoint ramp, the setpoint rise limitation, and the limit monitoring of the process value, the control deviation, and the position feedback. Limit monitoring is not used on the module.

The control function itself (e.g. PID algorithm) is processed on the module. You can use the FmTemp block to monitor all relevant process values and to change all relevant controller parameters.

Application examples of the FM 355-2 and detailed descriptions of the associated input and output parameters can be found in the manual of the FM 355-2. temperature controller.

It is primarily used for controlling temperature processes, but can also control level and flow processes which are not excessively fast, for example.

Module FM 355-2 features online optimization of the PID parameters. You can set the corresponding parameters for performing online optimization in the CFC chart at block FmTemp .

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100). Set the input `LogAddr` to the module address from HW Config and the input `Channel` to the desired controller channel (0 ... 3)..

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The parameter CoordNo is set
- The in/out parameter Mode is interconnected to the corresponding OMODE_xx output parameter of the MOD block.
- The parameter FM 355_2 is set in accordance with the module type C/S
- The in/out parameter EnCoord is interconnected to the output EN_CO_x of the FM_CO block of the Basis Library (x = number of the rack)
- The output EnCoNum is interconnected to the input ENCOx_yy of the FM_CO block (x = number of the rack, yy = coordination number).

For the control loop monitoring to work as planned in the trend view of the controller faceplates, the

S7_xarchive:='Value, shortterm;'

attributes in the process tag types for control loops at the controller function block must be set for the following tags:

- Input parameters:
  - CPI_In
- Output parameters
  - MV
  - MV_HiAct
  - MV_LoAct
  - LoopClosed
  - SP
  - PV_Out
  - PV_ToleHi
  - PV_ToleLo

## Startup characteristics

Use the Feature Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at RunUpCyc.

## Status word allocation for Status1 parameter

You can find a description for each parameter in section FmTemp I/Os (Page 938).

| Status bit | Parameter |
|---|---|
| 0 | Occupied |
| 1 | BatchEn |
| 2 | SimOn |

| Status bit | Parameter |
|---|---|
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | AutAct.Value |
| 6 | Invalid signal status |
| 7 | ManAct.Value |
| 8 | SP_ExtAct.Value |
| 9 | MV_SafeOn.Value |
| 10 | MV_TrkOn.Value |
| 11 | MV.Value > ManLoLim for continuous or pulse controller<br>NOT FbkClosed.Value for step controller with/without position feedback |
| 12 | Open.Value |
| 13 | Close.Value |
| 14 | Stop.Value |
| 15 | FbkOpened.Value |
| 16 | FbkClosed.Value |
| 17 | SimOn AND ManAct |
| 18 | SimOn AND ManAct |
| 19 | AdvCoAct |
| 20 | 1 = Input parameter Rbk is not interconnected (RbkOut.ST = 16#FF) |
| 21 | NegGain |
| 22 - 26 | Not used |
| 27 | AdvCoModSP |
| 28 | 1 = Analog controller (FM 355_2 = 1) |
| 29 | 1 = Pulse controller (FM 355_2 = 0 AND StepCon = 0) |
| 30 | 1 = Step controller with position feedback<br>(FM 355_2 = 0 AND StepCon = 1 AND WithRbk = 1 ) |
| 31 | 1 = Step controller without position feedback<br>(FM 355_2 = 0 AND StepCon = 1 AND WithRbk = 0 ) |

### Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | PV_AH_Act.Value |
| 2 | PV_WH_Act.Value |
| 3 | PV_TH_Act.Value |
| 4 | PV_TL_Act.Value |
| 5 | PV_WL_Act.Value |
| 6 | PV_AL_Act.Value |
| 7 | PV_AH_En OR Feature.Bit31 |
| 8 | PV_WH_En OR Feature.Bit31 |
| 9 | PV_TH_En OR Feature.Bit31 |

| Status bit | Parameter |
|---|---|
| 10 | PV_TL_En OR Feature.Bit31 |
| 11 | PV_WL_En OR Feature.Bit31 |
| 12 | PV_AL_En OR Feature.Bit31 |
| 13 | PV_AH_MsgEn |
| 14 | PV_WH_MsgEn |
| 15 | PV_TH_MsgEn |
| 16 | PV_TL_MsgEn |
| 17 | PV_WL_MsgEn |
| 18 | PV_AL_MsgEn |
| 19 | ER_AH_Act.Value |
| 20 | ER_AL_Act.Value |
| 21 | ER_AH_En OR Feature.Bit31 |
| 22 | ER_AL_En OR Feature.Bit31 |
| 23 | ER_AH_MsgEn |
| 24 | ER_AL_MsgEn |
| 25 | RbkWH_Act.Value |
| 26 | RbkWL_Act.Value |
| 27 | RbkWH_En OR Feature.Bit31 |
| 28 | RbkWL_En OR Feature.Bit31 |
| 29 | RbkWH_MsgEn |
| 30 | RbkWL_MsgEn |
| 31 | MS_RelOp |

### Status word allocation for Status3 parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 | Delay of the PV_AH_Lim message |
| 9 | Delay of the PV_WH_Lim message |
| 10 | Delay of the PV_TH_Lim message |
| 11 | Delay of the PV_TL_Lim message |
| 12 | Delay of the PV_WL_Lim message |
| 13 | Delay of the PV_AL_Lim message |
| 14 | Delay of the ER_AH_Lim message |
| 15 | Delay of the ER_AL_Lim message |

| Status bit | Parameter |
|---|---|
| 16 | Collection of message delays |
| 17 - 19 | Not used |
| 20 | 1= Suppressed messages |
| 21 - 23 | Not used |
| 24 | Internal error |
| 25-26 | Not used |
| 27 | `SP_UpRaAct`, `SP_DnRaAct` limits enabled for gradient mode (`SP_RateOn = 1`) |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | `SimLiOp.Value` |
| 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 31 | Not used |

FmTemp block diagram (Page 956)

## 6.4.2 FmTemp modes

### FmTemp operating modes

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Program mode for controllers"

General information on "Program mode for controllers" is available in the section Program mode for controllers (Page 85).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| RbkOut.ST | 16#80 | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| FbkOpnOut.ST | 16#80 | 16#60 |
| FbkClsOut.ST | 16#80 | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| SP.ST | 16#80 | 16#60 |

## 6.4.3 FmTemp functions

### Functions of FmTemp

The functions for this block are listed below.

### Module types

FmTemp can be used for the C (continuous controllers) and S (step controllers with and without position feedback and pulse controllers) module types. You can use the following parameters to identify which module type and controller type has been set:

| FM 355 | StepCon | WithRbk | Module type, controller type |
|---|---|---|---|
| 1 or C | - | - | FM 355-2 C: Continuous controller |
| 0 or S | 1 | 1 | FM 355-2 S: Step controller with position feedback |
| 0 or S | 1 | 0 | FM 355-2 S: Step controller without position feedback |
| 0 or S | 0 | - | FM 355-2 S: Pulse controller |

### Generating manipulated variables for continuous controllers, step controllers with position feedback, or pulse controllers

The manipulated variable MV and the actuating signals Open, Close and Stop are generated as follows:

| MV_Safe-On | MV_FMTrk On | ManAct | MV_TrkOn | AdvCoAct AND NOT AdvCo-ModSP | MV = | Manipu-lated variable limit | State | Open, Close, Stop |
|---|---|---|---|---|---|---|---|---|
| 1 | - | - | - | - | MV_Safe | MV_HiLim<br>MV_LoLim | Tracking to safety value | **Cont. controller:** Open, Close, Stop = 0<br>**Step controller with position feedback:** Depending on Rbk and MV, the output signals Open, Close and Stop are generated using the algorithm of a positioner.<br>**Pulse controller:** Depending on MV, the output signals Open and Close are generated using the algorithm of a pulse controller (Stop = 0). |
| 0 | 1 | - | - | - | Prepared FM analog input | MV_HiLim<br>MV_LoLim | Tracking to an FM analog input | |
| 0 | 0 | 1 | - | - | Man | ManHiLim<br>ManLoLim | Manual mode, set by the operator | |
| 0 | 0 | 0 | 1 | - | MV_Trk | MV_HiLim<br>MV_LoLim | Tracking to block input MV_Trk | |
| 0 | 0 | 0 | 0 | 1 | AdvCoMV | MV_HiLim<br>MV_LoLim | Higher-level program mode | |
| 0 | 0 | 0 | 0 | 0 | P_Part + I_Part + D_Part + FFwd | MV_HiLim<br>MV_LoLim | Automatic mode (PID algorithm) | |

### Generating actuating signals for step controllers without position feedback (WithRbk = 0)

The manipulated variable signals `Open`, `Close` and `Stop` can be generated as follows:

| ManAct | Open, Close, Stop | State | ManAct |
|---|---|---|---|
| 1 | The output signals are generated using input signals `OpenOp`/`Li`, CloseOp/`Li` or `StopOp`/`Li` | Manual mode, set by the operator | 1 |
| 0 | The output signals are generated using PID output variables `P_Part`, `I_Part`, `D_Part` and `FFwd` | Automatic mode (PID algorithm) | 0 |

### Tracking and limiting a manipulated variable (cont. controller, step controller with position feedback and pulse controller)

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

### Neutral position

The controller modules have their own mechanism for feedforwarding a safety value (see manual for Temperature Controller FM 355-2).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `ModErr`
- `ParFM_Err`
- `PerAccErr`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### "Actuator active" information

For continuous and pulse controllers: If the manipulated variable `MV` is greater than the minimum manual limit `ManLoLim`, this is recognized as actuator active.

For step controllers: If the parameter `FbkClosed` = 0 , this is recognized as "Actuator active".

This status can be used to indicate a customized symbol in the process image, for example, and is saved in the status word (see Status word section in Description of FmTemp (Page 916)).

### Limit monitoring of position feedback (cont. controller, step controller with position feedback and pulse controller)

The block provides the standard function Limit monitoring of the feedback (Page 101).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### External/internal setpoint specification

The block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint limiting for external setpoints

The block provides the standard function Setpoint limiting for external setpoints (Page 222).

### Limitation of rate of change of setpoint

The block provides the standard function Gradient limit of the setpoint (Page 132).

### Using setpoint ramp

The block provides the standard function Using setpoint ramp (Page 131).

### Tracking setpoint in manual mode

The block provides the standard function Tracking setpoint in manual mode (Page 222).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV`, `SimPV_Li`)
- Position feedback (`SimRbk`, `SimRbkLi`)

**Note**

The simulated process value `SimPV` only affects alarm processing and not the PID algorithm in the control module.

### Limit monitoring of the process value

The block provides the standard function Limit monitoring of the process value (Page 93).

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

### Limit monitoring of error signal

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102).

### Inverting control direction

The block provides the standard function Inverting control direction (Page 217).

### Physical standardization of setpoint, manipulated variable and process value

Controller gain `Gain` is entered either using a physical variable or as standardized value.

- `Gain` as a physical variable:
  The standardized variables retain their default values:
  - `NormPV.High` = 100 and `NormPV.Low` = 0
  - `NormMV.High` = 100 and `NormMV.Low` = 0

  For step controllers with/without position feedback and pulse controllers, the values of `NormMV.High` and `NormMV.Low` are not taken into account. The algorithm uses default values 0 and 100 for internal calculations.
  The effective gain is: `GainEff` = `Gain`
- Entering a standardized `Gain` (dimensionless):
  Change the standardized variables to the actual range of the process values and manipulated variables.
  - Internal and external setpoints; the process value and corresponding parameters are entered according to the physical measuring range of the process value.

  Continuous controller, pulse controller:
  - The manual value, the tracking value of the manipulated variable, disturbance variable feedforward and the corresponding parameters are set according to the physical measuring range of the manipulated variable.

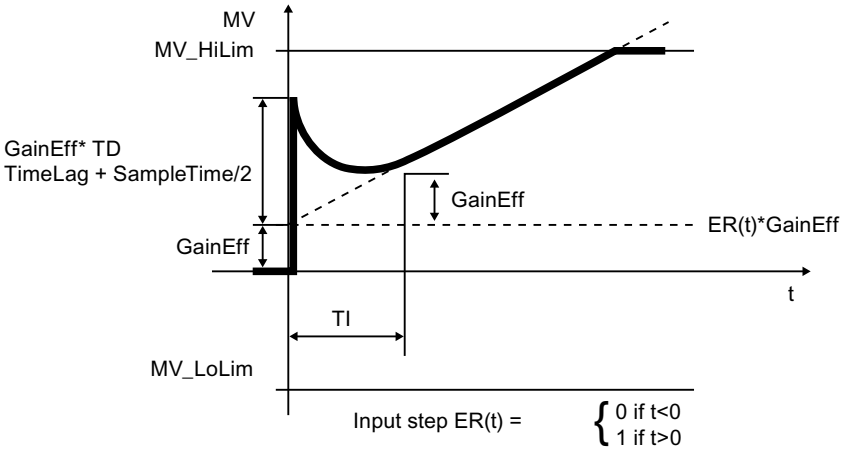
  Step controller with position feedback:
  - The manual parameter, the tracking value of the manipulated variable, disturbance variable feedforward and the corresponding parameters are entered as a percentage 0 ... 100.

  Step controller without position feedback:
  - No physical measuring range available.

  The effective gain is:
  - Step controller with/without position feedback:
    `GainEff` = 100.0 / (`NormPV.High` - `NormPV.Low`) · `Gain`
  - Continuous controller, pulse controller:
    `GainEff` = (`NormMV.High` - `NormMV.Low`) / (`NormPV.High` - `NormPV.Low`) · `Gain`

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).



### PID algorithm

The manipulated variable is generated in automatic mode according to the following algorithm:

`MV` = `GainEff` · (1 + 1 / (`TI` · s) + (`TD` · s) / (1 + `TD` / `DiffGain` · s)) · `ER`

Where: s = Complex number

The following step response occurs:

**Note**

This formula describes a standard application where P, I and D components are activated and the P and D components are not in the feedback circuit (`PropSel` = 1, `TI` ≠ 0, `D_InSel` = 0 and `PropFacSP` = 1).

The D component delay is derived from `TD` / `DiffGain`.

- The P component can be shut down by `PropSel` = 0 .
- The I component can be shut down by `TI` = 0 .
- The D component can be shut down by `TD` = 0 .

### Structure segmentation at controllers

The PID controller algorithm of FM 355 features structure segmentation. It is activated via the `PropFacSel` and `D_InSel` parameters. The precise functionality is described in the FM 355 manual.

### Online optimization of the PID controller parameters

- Optimization sequence
  The optimization sequence is as follows:
  - Create a steady state
  - Set PID_On = 1 (if PID parameters are required)
  - Assign parameters of TunD_MV / TunC_MVLMN
  - Set TunOn = 1 (phase 1, preparing for optimization)
  - Start the optimization using a step change in the setpoint or by setting TunStart

  If you have not made any configuration errors, the controller optimization is now in phase 2 and StatusH is 0.
  - When the point of inflection has been reached (PHASE ≥ 3) evaluate the diagnostics display at the StatusH parameter. Phase 0 is reached in a few cycles for process type I and the optimization is completed in full. For process types II and III, the optimization goes to phase 7 (checking the process type). If StatusH > 20000 , an estimation error has occurred or the point of inflection has not been reached. In this case, repeat the procedure.
- Result
  - Once optimization is complete, the parameters PropFacSP, GAIN, TI, TD, DiffGain, ConZone are updated (both for the module and at FmTemp). Furthermore, the PI or PID parameter sets are saved on the FM 355-2.
  - The precise procedure is described in the FM 355-2 manual of the temperature controller module.
- Permanent backup of optimized controller parameters
  - Save, compile and download the hardware configuration; the optimized controller parameters are now in the system data block (SDB).
  - Transfer the modified parameters to the offline data management of the CFC via Chart > Readback.

### Anti-windup

The PID control algorithm of FM 355 has an anti-windup function. The I component is frozen or tracked after the manipulated variable has reached its limits (MV_HiLim or MV_LoLim).

### Feedforwarding and limiting disturbance variables

The block provides a function for activating the disturbance variable feedforward. The precise functionality is described in the FM 355-2 manual.

### Control zone

The block provides the standard function Using control zones (Page 220).

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the setpoint value SP:
  The signal status of the SP output parameter is always equivalent to the signal status of input parameter SP_Ext or SP_Int, depending on how the setpoint is specified. If the internal setpoint SP_Int is used, the signal status is always output as 16#80.
- Signal status for PV_Out, RbkOut, Open, Close, Stop:
  When the manipulated value (for example, substitute value, simulation, last valid value) is activated, the signal status is always 16#60.
  When the ModErr.Value, ChFM_Err, ParFM_Err module error occurs, the signal status of PV_Out is always 16#0. RbkOut is always 16#0 for step controllers with position feedback
  Otherwise, the following applies:

```
PV_Out.ST: 16#80
Step controller: RbkOut.ST: = 16#80
Continuous controller or pulse controller: RbkOut.ST: = Rbk.ST
Open.ST := 16#80;
Close.ST := 16#80;
Stop.ST := 16#80;
```

- Signal status of the error signal ER:
  The signal status of output parameter ER is obtained from the worst signal status of the two output parameters PV_Out and SP and is output. The signal status 16#60 (external manipulated value - for example, substitute value, simulation, last valid value) is suppressed because the block acts as a sink with external simulation.
  Signal status for FbkOpnOut, FbkClsOut:

```
FbkOpnOut.ST := FbkOpened.ST;
FbkClsOut.ST := FbkClosed.ST;
```

- Signal status for the manipulated variable `MV`:
  The status signal from the output parameter `MV` is always set to `16#80` in "manual mode" and for step controllers without position feedback.
  In "automatic mode", the signal status for continuous controllers or pulse controllers is formed from the following parameters:
  `RbkOut.STFFwdOut.STER.ST`With step controllers, the `FbkOpnOut.STFbkClsOut.ST`parameters are also included. The signal status `16#60` (external manipulated value - for example, substitute value, simulation, last valid value) is suppressed because the block acts as a sink with an external manipulated value (for example, substitute value, simulation, last valid value).
- Worst signal status:
  The worst signal status `ST_Worst` for the block is formed from:
  - `PV_Out.ST;`
  - `SP:ST;`
  - `FFwdOut.ST;`
  - `RbkOut.ST;`

  With step controllers (FM355-2 = 0, StepCon = 1), the following are also included:
  - `FbkOpnOut.ST;`
  - `FbkClsOut.ST;`

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6 | Ramp rate calculation (Page 191) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | SP following PV in open loop has no priority over SP_Ext and SP limits (Page 193) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 31 | Limits disabled in faceplate (Page 206) |

### Configurable reactions using the Feature2 parameter

| Bit | Function |
|---|---|
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" AutModOp |
| 1 | 1 = Operator can switch to "manual mode" ManModOp |
| 2 | 1 = Operator can switch to "Out of service" mode OosOp |
| 3 | 1 = Operator can switch to "program mode" AdvCoEn |
| 4 | 1 = Operator can switch the setpoint to "external" SP_ExtOp |
| 5 | 1 = Operator can switch the setpoint to "internal" SP_IntOp |
| 6 | 1 = Operator can change the internal setpoint SP_Int |
| 7 | Continuous controllers, pulse controllers or step controllers with position feedback:<br>1 = Operator can change the manual parameter Man<br>Step controller without position feedback:<br>1 = Operator can change the manual operation signals OpenOp, StopOp, CloseOp |
| 8 | 1 = Operator can change operation high limit of the setpoint SP_InHiLim |
| 9 | 1 = Operator can change operation low limit of the setpoint SP_InLoLim |
| 10 | 1 = Operator can change the operation high limit of the manipulated variable ManHiLim |
| 11 | 1 = Operator can change the operation low limit of the manipulated variable ManLoLim |
| 12 | 1 = Operator can enable the setpoint's gradient limitation function SP_RateOn |
| 13 | 1 = Operator can change the setpoint's high limit for the ramp SP_UpRaLim |
| 14 | 1 = Operator can change the setpoint's low limit for the ramp SP_DnRaLim |
| 15 | 1 = Operator can switch between the time value or the value for the ramp SP_RmpModTime |
| 16 | 1 = Operator can change the ramp time SP_RmpTime |
| 17 | 1 = Operator can change the target setpoint SP_RmpTarget for the setpoint ramp |
| 18 | 1 = Operator can enable the setpoint ramp function SP_RmpOn |
| 19 | Not used |
| 20 | 1 = Operator can enable the track setpoint in manual mode function SP_TrkPV |
| 21 | 1 = Operator can enable the bumpless switchover from external to internal SP_TrkExt |
| 22 | 1 = Operator can change the gain parameter Gain |
| 23 | 1 = Operator can change the integral time parameter TI |
| 24 | 1 = Operator can change the derivative time parameter TD |
| 25 | 1 = Operator can change the derivative gain parameter DiffGain |
| 26 | 1 = Operator can change the dead band parameter DeadBand |
| 27 | 1 = Operator can change the control zone parameter ConZone |
| 28 | 1 = Operator can change the integral time parameter MotorTime |

| Bit | Function |
|---|---|
| 29 | 1 = Operator can change the integral time parameter `PulseTime` |
| 30 | 1 = Operator can change the integral time parameter `BreakTime` |
| 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (process value) `PV_AH_Lim` for the high alarm |
| 1 | 1 = Operator can change the limit (process value) `PV_WH_Lim` for the high warning |
| 2 | 1 = Operator can change the limit (process value) `PV_TH_Lim` for the high tolerance |
| 3 | 1 = Operator can change the hysteresis (process value) `PV_Hyst` |
| 4 | 1 = Operator can change the limit (process value) `PV_TL_Lim` for the low tolerance |
| 5 | 1 = Operator can change the limit (process value) `PV_WL_Lim` for the low warning |
| 6 | 1 = Operator can change the limit (process value) `PV_AL_Lim` for the low alarm |
| 7 | 1 = Operator can change the limit (error signal) `ER_AH_Lim` for the high alarm |
| 8 | 1 = Operator can change the hysteresis (error signal) `ER_Hyst` |
| 9 | 1 = Operator can change the limit (error signal) `ER_AL_Lim` for the low alarm |
| 10 | 1 = Operator can change the limit (position feedback) `RbkWH_Lim` for the high warning |
| 11 | 1 = Operator can change the hysteresis (position feedback) `RbkHyst` |
| 12 | 1 = Operator can change the limit (position feedback) `RbkWL_Lim` for the low warning |
| 13 | 1 = Operator can open the valve |
| 14 | 1 = Operator can close the valve |
| 15 | 1 = Operator can stop the valve |
| 16 | 1 = Operator can activate the Simulation function `SimOn` |
| 17 | 1 = Operator can activate the Release for maintenance function `MS_RelOp` |
| 18 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 19 | 1 = Operator can activate / deactivate messages via `PV_WH_MsgEn` |
| 20 | 1 = Operator can activate / deactivate messages via `PV_TH_MsgEn` |
| 21 | 1 = Operator can activate / deactivate messages via `PV_TL_MsgEn` |
| 22 | 1 = Operator can activate / deactivate messages via `PV_WL_MsgEn` |
| 23 | 1 = Operator can activate / deactivate messages via `PV_AL_MsgEn` |
| 24 | 1 = Operator can activate / deactivate messages via `ER_AH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `ER_AL_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `RbkWH_MsgEn` |
| 27 | 1 = Operator can activate / deactivate messages via `RbkWL_MsgEn` |
| 28 | 1 = Operator can change the simulation value `SimPV` |
| 29 | 1 = Operator can change the simulation value `SimRbk` |
| 30 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Release for maintenance

The block provides the standard function Release for maintenance (Page 70).

### Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `OpenOp`
- `StopOp`
- `CloseOp`

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

## 6.4.4 FmTemp error handling

### Error handling of FmTemp

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 30 | The value of `PV` can no longer be displayed in the REAL number field. |
| 31 | The value of `SP_Ext` can no longer be displayed in the REAL number field. |
| 33 | The value of `MV_Trk` can no longer be displayed in the REAL number field. |
| 35 | The value of `Rbk` can no longer be displayed in the REAL number field. |
| 36 | The value of `MV` can no longer be displayed in the REAL number field. |
| 50 | The controller cannot be switched to program mode, because program mode with default setpoint (`AdvCoModSP` = 0) is not possible for step controllers without position feedback (`WithRbk` = 0). |
| 51 | `AutModLi` = 1 and `ManModLi` = 1<br>`SP_LiOp` = 1 and `SP_IntLi` = 1 and `SP_ExtLi` = 1<br>`OpenLi` = 1 and `StopLi` = 1<br>`CloseLi` = 1 and `StopLi` = 1<br>`OpenLi` = 1 and `CloseLi` = 1 |
| 59 | = 1, "Gain is negative" |
| 60 | \|`TI`\| < `SampleTime` / 2 |
| 61 | \|`TD`\| < `SampleTime` |
| 62 | `DiffGain` < 1 or `DiffGain` > 10 |
| 63 | `TD` / `DiffGain` < `SampleTime` / 2 |
| 64 | `PropFacSP` < 0 or `PropFacSP` > 1 |
| 66 | `NormPV_High` = `NormPV_Low` |
| 67 | `MotorTime` < `SampleTime` |

| Error number | Meaning of the error number |
|---|---|
| 68 | PulseTime < SampleTime |
| 69 | BreakTime < SampleTime |
| 70 | Channel < 0 or Channel > 3 |
| 71 | (D_InSel < 0 or D_InSel > 4) and D_InSel ≠ 17 |
| 74 | ConZone < 0.0<br>FM 355-2 sets the output ParFM_Err = 1 |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 6.4.5 FmTemp messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId2`, SIG 6).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | Alarm - high | $$BlockComment$$<br>`PV` - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>`PV` - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>`PV` - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>`PV` - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>`PV` - low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>`PV` - low alarm limit violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>`ER` - high alarm limit violated |
| | SIG 8 | Alarm - low | $$BlockComment$$<br>`ER` - low alarm limit violated |
| `MsgEvId2` | SIG 7 | Warning - high | $$BlockComment$$<br>`Rbk` - high warning limit violated |
| | SIG 8 | Warning - low | $$BlockComment$$<br>`Rbk` - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@5%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@6%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 3<br>Status 16#@7%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 4<br>Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | Process value PV_Out |
| 5 | Control deviation ER |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | Not allocated |
| 9 | Not allocated |
| 10 | Not allocated |

The associated values 6 ... 7 are allocated to the parameters ExtVa106 ... ExtVa107 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |

| Associated value | Block parameters |
|---|---|
| 4 | Position feedback `RbkOut` |
| 5 | Signal status `ExtMsg1` |
| 6 | Signal status `ExtMsg2` |
| 7 | Signal status `ExtMsg3` |
| 8 | Signal status `ExtMsg4` |
| 9 | `ExtVa209` |
| 10 | `ExtVa210` |

The associated values 9 ... 10 are allocated to the parameters `ExtVa209` ... `ExtVa210` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

I/Os of FmTemp

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AccMode*` | 1 = Transfer of operating parameters `SubN1_ID`, `SubN2_ID`, `RackNo`, `SlotNo` and `Channel` to internal processing | BOOL | 1 |
| `AdvCoEn` | 1 = Enable "program mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AdvCoModSP` | Type of "program mode":<br>1 = Setpoint specification<br>0 = Manipulated variable specification | BOOL | 1 |
| `AdvCoMstrOn` | Activate (0-1) or deactivate (1-0) "program mode" via edge transition | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoMV | Specified value from the external program.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | REAL | 0.0 |
| AdvCoOn* | 1 = Enable "program mode" via faceplate.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | BOOL | 0 |
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation for batch control | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BreakTime* | Minimum break duration [s] | REAL | 1.0 |
| Channel | Controller channel number (0..3) | INT | 0 |
| CloseLi* | 1 = Close via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseOp* | 1 = Close via operator | BOOL | 0 |
| ConZone* | Control zone | REAL | 0.0 |
| CoordNo | Coordination number | INT | 0 |
| CPI_In | Input for control performance index, which is calculated by the assigned ConPerMon block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| D_InSel* | Input for differentiator:<br>0 = Error signal<br>1..4 = Channel 0..3<br>17 = Actual value to feedback | INT | 0 |
| DeadBand* | Width of dead band | REAL | 0.0 |
| DiffGain* | Gain of differentiator [1..10] DiffGain = TD / (delay time of D component) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 5.0<br>• 16#80 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ER_A_DC* | Delay for incoming alarms during error signal monitoring | REAL | 0.0 |
| ER_A_DG* | Delay for outgoing alarms during error signal monitoring | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AH_Lim | Alarm limit (high) for error signal monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AL_En | 1 = Activate alarm (low) for error signal monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for error signal monitoring | REAL | -100.0 |
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for error signal monitoring | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for error signal | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | Binary input for freely selectable message 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa209 | Associated value 9 for messages (MsgEvID2) | ANY | |
| ExtVa210 | Associated value 10 for messages (MsgEvID2) | ANY | |
| FbkClosed | Low limit stop signal of position feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpened | High limit stop signal of position feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions (Page 922) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FM355_2 | Module type:<br>0: FM 355-2 S;<br>1: FM 355-2 C | BOOL | 0 |
| Gain* | Proportional gain<br>Gain.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| LoadPID* | Load optimized PI/PID parameters | BOOL | 0 |
| LogAddr | Logical address FM 355 | INT | 0 |
| Man* | Manual specification for the manipulated variable | REAL | 0.0 |
| ManHiLim* | Limit (high) for manual parameter Man | REAL | 100.0 |
| ManLoLim* | Limit (low) for manual parameter Man | REAL | 0.0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| Mode | Operating mode | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ModLiOp | Operating mode switchover between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MotorTime* | Motor actuating time [s] | REAL | 30.0 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MS | Maintenance status | DWORD | 0 |
| MS_Release | Release for maintenance (interconnected with MS_Release of the technology block) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ms_Ext | External maintenance status. For more information, refer to the MS_Ext (Page 2463) parameter section under information on using channel blocks. | DWORD | 0 |
| MsgEvID1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgEvID2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_FmTrkOn | 1 = Manipulated variable tracking in the FM | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiLim* | Limit (high) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| MV_LoLim* | Limit (low) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_OpScale | OS display range for manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_Safe* | Neutral position manipulated variable | REAL | 0.0 |
| MV_SafeOn | 1 = Neutral position manipulated variable MV_Safe at output MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Trk* | Tracking value for the manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| NegGain* | 0 = Effective proportional gain GainEff is positive<br>1 = Effective proportional gain GainEff is negative | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NormMV | Manipulated variable range (MV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| NormPV | Process value range (PV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Occupied | Occupied by batch control | BOOL | 0 |
| OosLi | Edge transition (0-1) = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpenLi* | 1 = Open via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenOp* | 1 = Open via operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 922) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 922) | STRUCT<br>• Bit 0: BOOL<br>• Bit 18: BOOL<br>• Bit 19: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| PID_On* | 1 = PID mode on | BOOL | 0 |
| PropFacSP* | Applying the P component to the feedback [0..1].<br>0 = P component fully in feedback | REAL | 1.0 |
| PropSel* | 1 = Activate P component | BOOL | 1 |
| PulseTime* | Minimum pulse duration [s] | REAL | 1.0 |
| PV_A_DC* | Delay time for incoming PV alarms [s] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_A_DG* | Delay time for outgoing PV alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_Hyst | Hysteresis for PV alarm, warning and tolerance limits | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_T_DC* | Delay time for incoming PV tolerance messages [s] | REAL | 0.0 |
| PV_T_DG* | Delay time for outgoing PV tolerance messages [s] | REAL | 0.0 |
| PV_TH_En | 1 = Enable PV tolerance limit (high) | BOOL | 0 |
| PV_TH_Lim | Limit PV tolerance message (high) | REAL | 85.0 |
| PV_TH_MsgEn | 1 = Enable message for PV tolerance message (high) | BOOL | 1 |
| PV_TL_En | 1 = Enable PV tolerance limit (low) | BOOL | 0 |
| PV_TL_Lim | Limit PV tolerance message (low) | REAL | 15.0 |
| PV_TL_MsgEn | 1 = Activate message for PV tolerance message (low) | BOOL | 1 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_W_DC* | Delay time for incoming PV warnings [s] | REAL | 0.0 |
| PV_W_DG* | Delay time for outgoing PV warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| RackNo | Rack number | BYTE | 16#FF |
| RatioFac* | Ratio factor | REAL | 0.0 |
| Rbk* | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 1 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 100.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 1 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 0.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |
| RefStdDevIn | Reference value of PV standard deviation (sigma) in defined "good" state of control loop | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SavePar* | 1 = Save PID controller parameters | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SlotNo | Slot number | BYTE | 16#FF |
| SP_DnRaLim | Limit (low) for the gradient of the setpoint [SP_Unit/s] | REAL | 100.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_ExHiLim* | Limit (high) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_ExLoLim* | Limit (low) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Ext* | External setpoint of - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi* | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_InHiLim* | Limit (high) of internal setpoint | REAL | 100.0 |
| SP_InLoLim* | Limit (low) of internal setpoint | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |
| SP_IntLi* | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RateOn* | 1 = Activate limitation of setpoint gradients | BOOL | 0 |
| SP_RmpModTime | 1 = Use time (SP_RmpTime) for setpoint ramp,<br>0 = Use gradient | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |
| SP_RmpTime* | Time for setpoint ramp [s] from current SP up to SP_RmpTarget | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 1 |
| SP_TrkPV | 1 = Setpoint follows PV in "manual mode" and with tracking | BOOL | 0 |
| SP_UpRaLim | Gradient limit (high) for the setpoint [SP_Unit/s] | REAL | 100.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| StopLi* | 1 = Stop via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopOp* | 1 = Stop via operator | BOOL | 0 |
| SubN1_ID | ID of the primary DP master system | BYTE | 16#FF |
| SubN2_ID | ID of the redundant DP master system | BYTE | 16#FF |
| TD* | Derivative time [s]<br>TD.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| TextRef | Text reference | WORD | 0 |
| TI* | Integral time [s]<br>TI.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#FF |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| TunC_MV* | Delta manipulated variable for cooling optimization | REAL | -20.0 |
| TunC_Start* | Start cooling optimization | BOOL | 0 |
| TunD_MV* | Delta manipulated variable for process trigger | REAL | 20.0 |
| TunOn* | Enable controller optimization | BOOL | 0 |
| TunStart* | Start controller optimization | BOOL | 0 |
| UndoPar* | Undo controller parameter changes | BOOL | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## In/out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| EnCoord | Current coordination number | STRUCT<br>• CO_ACT : INT | -<br>• 0 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoAct | 1 = "Program mode" enabled.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoRdy | 1 = "Program mode" available | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutAct | 1 = "Automatic mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ChFM_Err | 1 = Channel error on the module | BOOL | 0 |
| Close | Control output:<br>1 = Closed is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| EnCoNum | Coordination number | BYTE | 16#00 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_AH_Act | 1 = Alarm limit (high) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ER_AL_Act | 1 = Alarm limit (low) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of pending error number, for error numbers that can be output by this block, see FmTemp error handling (Page 934) | INT | -1 |
| FFwdOut | Disturbance variable generated in the FM | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| FbkClsOut | 1 = Low limit stop of the position feedback reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpnOut | 1 = High limit stop of the position feedback reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GainEff | Effective proportional gain depends on NegGain, Gain, NormPV, and NormMV | REAL | 1.0 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LoopClosed | 1 = Control loop closed<br>0 = Control loop open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| ManARW_Act | 1 = Tracking mode or anti-reset windup by secondary controller | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManHiOut | Limit (high) for "manual mode", corresponds to input parameter ManHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| ManLoOut | Limit (low) for "manual mode", corresponds to input parameter ManLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ModErr | 1 = Module error | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 0 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgAckn2 | Message acknowledgement status 2 (output ACK_STATE of second ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgErr2 | Alarm error 2 (output ERROR of second ALARM_8P) | BOOL | 0 |

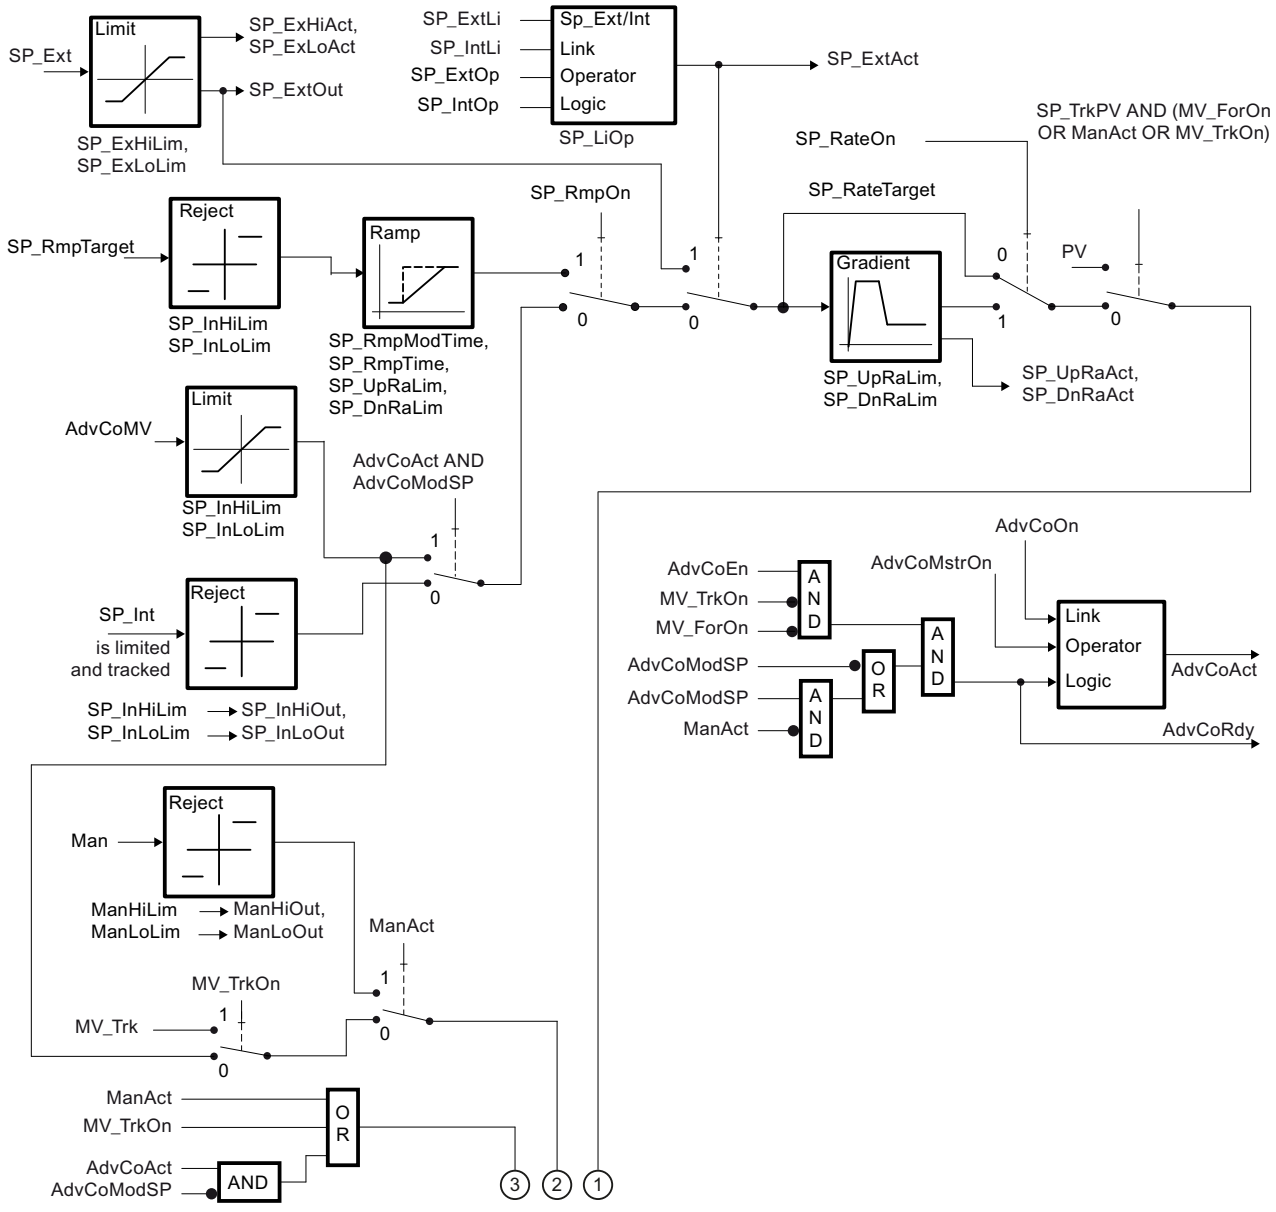
| MV | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_FmTrkAct | 1 = Track manipulated variable in the FM enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_SafeAct | 1 = Neutral position manipulated variable of the FM enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_SpliA | Manipulated variable A of split-range function | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_SpliB | Manipulated variable B of split-range function | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_UnitOut | Unit of measure for manipulated variable, for interconnecting to the MV_Unit input parameter of the ConPerMon block | INT | 0 |
| MV_Visible | 1 = MV display visible<br>Is evaluated by the block icon | BOOL | 0 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Open | Control output<br>1 = Open is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS_Perm1 | DWORD | 16#FFFFFFFF |
| ParFM_Err | 1 = Direct parameter-assignment error of the FM or input Channel configured incorrectly | BOOL | 0 |
| PerAccErr | 1 = I/O access error | BOOL | 0 |
| Phase | Phase of auto-tuning [0..7] | INT | 0 |
| PV | Process value of the module | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>0.0<br>16#80 |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_TH_Act | 1 = PV tolerance message (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_TL_Act | 1 = PV tolerance message (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_ToleHi | Limit (high) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_ToleLo | Limit (low) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_UnitOut | Unit of measure for process value, for interconnecting to the PV_Unit input parameter of the ConPerMon block | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29(Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkOut | Output for position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RetValue | Return value of WRREC / RDREC | WORD | 16#0000 |
| RbkVisible | 1 = Rbk display visible<br>Is evaluated by the block icon | BOOL | 0 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExHiAct | 1 = Limit (high) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExLoAct | 1 = Limit (low) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOut | External setpoint, corresponds to input parameter SP_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_InHiOut | Limit (high) for SP_Int corresponds to input parameter SP_InHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_InLoOut | Limit (low) for SP_Int corresponds to input parameter SP_InLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_RateTarget | Target setpoint for the gradient limitation | REAL | 0.0 |
| SP_UpRaAct | Positive gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SplitRange | 1 = Split-range function has been activated | BOOL | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 916) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 916) | DWORD | 16#00000000 |
| Status3 | Status word 2 (Page 916) | DWORD | 16#00000000 |
| StatusC | Status of cooling optimization | INT | 0 |
| StatusD | Status of controller design | INT | 0 |
| StatusH | Status of heating optimization | INT | 0 |



| Parameter | Description | Type | Default |
|---|---|---|---|
| StepCon | 1 = Step controller | BOOL | 0 |
| Stop | Control output:<br>1 =Stopped is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SumMsgAct | 1 = Active hardware interrupt | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TunAct | 1 = Optimization running | BOOL | 0 |
| WithRbk | Controller type:<br>0 = Step controller without position feedback<br>1 = Step controller with position feedback | BOOL | 0 |
| ZoneTun | Controller channels grouped in one zone for parallel optimization | WORD | 16#0000 |

## 6.4.8 Operator control and monitoring

### 6.4.8.1 FmTemp views

#### Views of the FmTemp block

The block FmTemp provides the following views:

- FM controllers standard view (analog) (Page 294)
- FM controllers standard view (pulse controller) (Page 298)
- FM controllers standard view (step controller with position feedback) (Page 302)
- FM controllers standard view (step controller without position feedback) (Page 306)
- Alarm view (Page 336)
- Limit view of FM controllers (Page 322)
- Trend view (Page 341)
- Parameter view of FM controllers (Page 318)
- Preview of FM controllers (Page 331)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icons for PID and FM controller (Page 269)

Refer to the Structure of the faceplate (Page 279) and Block icon structure (Page 260) sections for general information about the faceplate and block icon.

# 6.5 GainSched - Adapting parameter values for a PID controller

## 6.5.1 Description of GainSched

### Object name (type + number) and family

Type + number: FB 1820

Family: Control

### Area of application for GainSched

The block is used for the following applications:

- Continuous adaptation of the parameter values of a PID controller to the current operating point of a non-linear process
- Controller gain
- Integral action time
- Derivative action time

### How it works

If your process requires different PID controller parameters due to its non-linear response at different operating points, you can store optimum parameter sets for up to three different operating points in theGainSched block in the form of a table ("timetable"). The current operating point is represented by a continuously measurable variable X, typically by the actual value of the controller itself. The block ensures that the suitable optimum parameters `Gain`(j), `TI`(j) and `TD`(j) are made available to the controller for each operating point X(j).

If the process is between two operating points, the parameters are calculated by linear interpolation between the optimum values of the two nearest operating points. This allows a bumpless, continuous adaptation of the controller parameters while the process moves from one operating point to another.

The block should be considered a supplementary function for a PID controller to improve the control performance of the PID controller in non-linear processes. The GainSched faceplate is called from the parameter view of the corresponding PID controller using the "Gain scheduler" button.

In contrast to all other function blocks, the GainSched block is implemented as a CFC chart and is generated with the "Compile chart as block type" function. The source chart "`FbGainSchedLim`" is supplied with the library so that you have more options open to you:

- You can use the precompiled function block GainSched from the library if the standard functionality is adequate for your needs.
- If you require special additional functions for gain scheduling in your application (for example more than three operating points, additional logic functions for selecting the parameters), you will need to modify the CFC source chart and compile it as a block type with a different FB number.

If the current value of input parameter X is below the lowest value X1 in the table or above the highest value X3, precisely the controller parameters which are specified at the relevant boundary point X1 or X3 in the table are output.

## Configuration

The GainSched block is placed in the same CFC chart as the assigned controller and interconnected with it as shown in the corresponding template: The output parameters Link2Gain, Link2TI and Link2TD are connected to the inputs Gain, TI and TD of the PID controller. The input X of GainSched is supplied with the measured value for the operating point, typically with the same value as PV of the controller.

You can open the standard view for the GainSched block from the parameter view of a controller (for example PIDConL). Additional information on this topic is available in the section Opening additional faceplates (Page 234).

To specify the parameters for gain scheduling, run separate controller optimizations at each of the intended operating points, for example with a tool such as the PID tuner. Use amplitudes as small as possible to excite the process to capture the approximately linear response in the area of the operating point under investigation. The optimum parameter values calculated by the PID tuner are entered in the relevant row belonging to the operating point in the table of the GainSched block. The table is clearly displayed in the standard view of the faceplate. Make sure that the numeric values are also permanently stored in the data management of the engineering system by reading back the numeric values of the parameters from AS to the ES or entering them manually at the inputs of the CFC block.

For the GainSched block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)

## Gain scheduling for batch processes

A typical area of application for gain scheduling is in batch processes that, in contrast to continuous processes, cannot be linearized around a fixed operating point because they need to be moved backwards and forwards between different operating points during the course of the batch. Here, there are three application scenarios:

- The controller parameters depend on a single continuously measurable variable that is representative of the operating point, for example, the reactor temperature. This is the normal use case for the GainSched block: The management of the controller parameters is handled in the block and is independent of batch recipes.
- The controller parameters depend on a continuously measurable variable that is representative of the operating point, but there is also a dependency on the materials used in the reaction. Suitable parameter sets for gain scheduling can then be anchored in the recipe and transferred by SIMATIC BATCH to the GainSched block.

- The controller parameters depend only the current phase of the batch. They can then be written directly from the Batch package to the PID controller and no gain scheduling block is necessary. The disadvantage of this is that there is bump in the controller parameters at the transfer from one phase to the next. The controller should be put into manual mode temporarily at the time of the transfer to avoid a bump in the manipulated variable.
- The recipe only specifies which of the controller parameter sets 1 ... 3 is currently required from the GainSched block. The numerical values of the parameter, however, are not anchored in the recipe. In this case input variable `X` of the GainSched block can then be used as the number of the required data record and assigned by the recipe instead of being linked with a measurable process variable. In this case, there are only three discrete values for `X` and the precautions against a change of controller parameters with bump outlined above must be taken because the interpolation abilities of the GainSched block are not used.

In general, it is not necessary to manage the batch parameters (batch number, batch name, etc.) in the GainSched block because the block does not generate any separate messages and there is always a 1-to-1 relationship with a controller block that knows the batch parameters.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 6.5.2 GainSched modes

### GainSched modes

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)

### "Automatic mode"

In "automatic mode" (`ManParOn` = 0) the controller parameters are determined through a polygon in accordance with the settings in the "automatic" area of the parameter view.

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Manual mode"

In "manual mode" (`ManParOn` = 1) the controller parameters correspond to the settings in the "manual" area.

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for control blocks (Page 79).

## 6.5.3 GainSched functions

### Functions of GainSched

The functions for this block are listed below.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 24 | Enabling local operator authorization (Page 169) |

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

## 6.5.6 GainSched I/Os

### GainSched I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Gain1 | PID gain for operating point 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Gain2 | PID gain for operating point 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Gain3 | PID gain for operating point 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| GainOp | PID gain: Input for "manual mode" | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Feature | I/O for additional functions (Page 962) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| ManParOn | 1 = input of PID parameters in "manual mode"<br>0 = use the planned controller parameters from the table | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_In | Input parameter for local operating permission, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| TD_Op | PID derivative action time [s]: Manual input for the operator | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| TD1 | PID derivative action time [s] for operating point 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TD2 | PID derivative action time [s] for operating point 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TD3 | PID derivative action time [s] for operating point 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TI_Op | PID integral action time [s]: Manual input for the operator | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TI1 | PID integral action time [s] for operating point 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TI2 | PID integral action time [s] for operating point 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| TI3 | PID integral action time [s] for operating point 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| X | Process value that defines the operating point | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| X1 | Operating point 1 (support point) for X | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| X2 | Operating point 2 (support point) for X | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| X3 | Operating point 3 (support point) for X | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| X_Unit | Unit of measure for the operating point | INT | 1001 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| Link2Gain | Calculated controller gain | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Link2TD | Calculated integral action time | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Link2TI | Calculated derivative action time | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Parameter used to hide operator controls in the faceplate | DWORD | 16#00000000 |

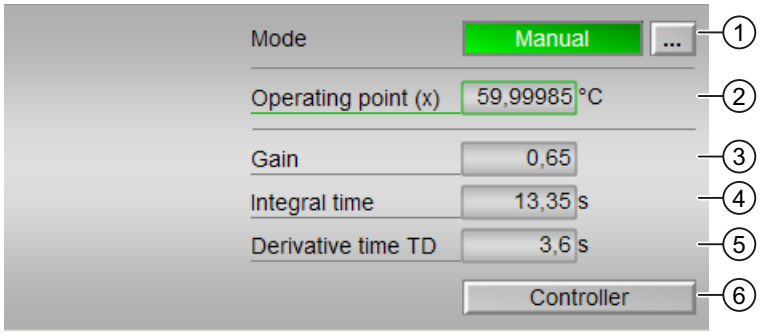
### 6.5.8.1 GainSched views

#### Views of the GainSched block



The GainSched block provides the following views:

- GainSched standard view (Page 967)
- GainSched parameter view (Page 968)
- GainSched preview (Page 969)
- Memo view (Page 338)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 6.5.8.2 GainSched standard view

#### GainSched standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

In "manual mode", you can specify the values on the OS in the parameter view of this block; they are then output directly via the corresponding output parameters.

In "automatic mode", an interpolation is performed through the interpolation points, which can also be specified in the parameter view.

### (2) Displaying the operating point (X)

Currently used operating point.

### (3) Displaying the gain

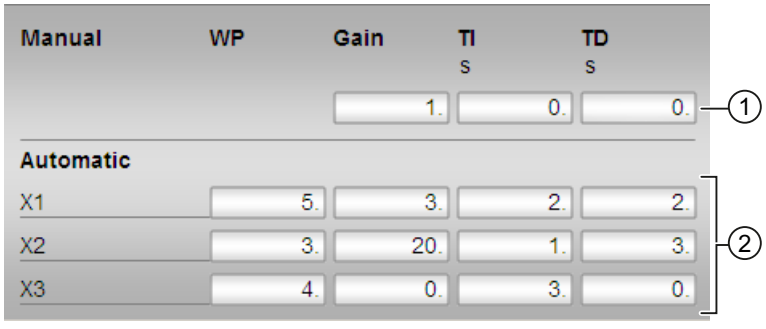
The controller gain currently output at the `Link2Gain` output parameter.

### (4) Displaying the integration time `TI`

Integration time currently output at the `Link2TI` output parameter.

### (5) Displaying and changing the derivative time `TD`

Derivative time currently output at the `Link2TD` output parameter.



### (6) Navigation button to GainSched block

Use this navigation button to reach the standard view of a controller block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Additional information is available in the section Opening additional faceplates (Page 234).

## 6.5.8.3 GainSched parameter view

### Parameter view of GainSched

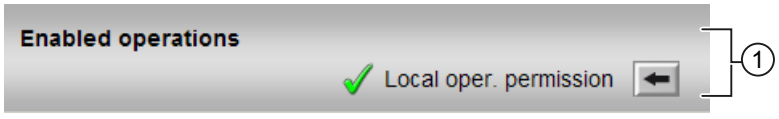
### (1) Displaying and changing the values for the controller parameters in "manual mode"

This is where you enter the values for the parameters to be used in "manual mode" at the corresponding output parameters of the block:

- "Gain": Input parameter `GainOp`
- "TI": Integration time, input parameter `TI_Op`
- "TD": Derivative time, input parameter `TD_Op`

Refer to the section titled Changing values (Page 291) for information on changing the values.

### (2) Displaying and changing the values for the controller parameters in "automatic mode"



This is where you enter the values for the parameters to be used in "automatic mode" for the interpolation (max. 3 values):

- "X1": Operating point 1, input parameter `X1`
- "X2": Operating point 2, input parameter `X2`
- "X3": Operating point 3, input parameter `X3`
- "Gain": Input parameter `Gain1` ... `Gain3`
- "TI": Integration time, input parameter `TI1` ... `TI3`
- "TD": Derivative time, input parameter `TD1` ... `TD3`

Refer to the section titled Changing values (Page 291) for information on changing the values.

## 6.5.8.4 GainSched preview

### Preview of GainSched

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations are shown here:

- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

# 6.6 ModPreCon - Model predictive controller

## 6.6.1 Description of ModPreCon

### Object name (type + number) and family

Type + number: FB 1843

Family: Control

### Area of application for ModPreCon

The block is used in much the same way as a PIDConL block for the following applications:

- Fixed setpoint control
- Cascade control
- Ratio control
- Split-range control

In contrast to the PID controllers, this is a multivariable controller.

Compared to Advanced Process Library V7.1.4, the new version provides the following functional enhancements:

- Integrated static operating point optimization,
- Prediction without control response and display of the prediction of the free motion,
- Automatic process trigger for model identification,
- Verification of the sampling time.

### Method of operation and area of application

The block is used for multivariable control (Page 2888) of dynamic processes. It can handle up to four dependent manipulated and controlled variables as well as a measurable disturbance.

In special situations, the ModPreCon block can also be used for particularly difficult dynamic, single-variable controls. It is better than a PID controller, for example, in systems with non-minimum phase (Page 2889) or a strongly oscillating response.

The ModPreCon algorithm only works for stable processes with a step response that settles to a fixed value in a finite time. If the process is unstable in one of the main transfer functions or includes an integrator (level control, for example), the corresponding partial transfer function must be stabilized with a secondary controller.

A simple P controller (proportional component only) is sufficient as a subordinate controller for integrating processes. It is inserted between the manipulated variable output from ModPreCon and the input of the unstable process section, and receives the output of the integrating process section as a manipulated variable. (Unstable data links are stabilized with this approach.)

You can find an explanation of "multivariable controls" and "non-phase-minimum response" in the Help on the Advanced Process Library > Definitions.

## Note on the area of application of the controller: Longer run times

Due to the principle on which they work, the runtime for multivariable controllers is significantly longer than that for PID controllers, because the matrix calculations in the algorithm are much more complex. The runtime is also determined by the number of the process and manipulated variables in the control algorithm. This is why the multivariable controller is unsuited for rapid control and is usually used for slow, complex control tasks.

The computation time required on the CPU is compensated for by the fact that very slow sample times of > 20s are used for the typical ModPreCon applications (see Advanced control templates). The ModPreCon is then typically in OB30 and can be interrupted by faster OBs.

Optimization is called within the ModPreCon block in the program section in which OB1 is executed. In cyclic operation (OB3x), this avoids the additional computing time required by the optimizer, the acyclic time, i.e. which is only relevant for changes to the optimizer inputs. The calculation time load caused by the ModPreCon block is hardy more with optimization than it is for ModPreCon without optimization.

### Operating principle

The ModPreCon block is a model-based predictive multivariable controller. It uses a mathematical model of the process dynamics including all interactions as part of the controller. This model allows the process response to be predicted over a defined period in the future, also known as the prediction horizon.

Based on this prediction, a performance index

$$J = (\vec{w} - \vec{y})^T \cdot R \cdot (\vec{w}-\vec{y}) + \Delta\vec{u}^T \cdot Q \, \Delta\vec{u}$$

is optimized (minimized) where the following applies:

- w contains the time series of the future setpoints,
- y contains the vector of the controlled variables in the future,
- Δu contains the future changes to the manipulated variable.

If you increase the weighting in the Q diagonal matrix, the controller moves its manipulated variables more cautiously resulting in a slower but more robust control response. Using the weighting factors in the R diagonal matrix, you specify the relative significance of the individual controlled variables. A higher weighting (priority) for a controlled variable means that this CV moves more quickly towards the setpoint and remains more accurately at the setpoint in steady state if it is not possible to achieve all setpoints precisely.

The algorithm is a variant of the DMC procedure (**D**ynamic **M**atrix **C**ontrol) in which the optimization problem is solved in the design phase ignoring the constraints. The function block itself contains the analytical solution of the optimization problem. Manipulated variable limitations, both absolute and relating to the gradients, are treated in the algorithm of the function block as hard constraints that must not be violated. This means that precise setpoints or target zones for the controlled variables are taken into account during optimization as well as possible. The target zones for the controlled variables are therefore soft limits, which are maintained as well as possible although they cannot be guaranteed. Using a reference variable filter for future setpoint settings, the control response of the controller can be fine-tuned during operation.

You can achieve significant improvements in control performance when individual disturbances can be measured, for example variations in throughput. In this case, it is a good idea to take into account a model of the influence of this disturbance on the controlled variables when predicting the controlled variables so that the controller can react preemptively to such disturbances.

**Operating point optimization**

The integrated static operating point optimization can be used when at least one controlled variable provides certain degrees of freedom. No exact setpoint is specified for such controlled variables. Instead there is a tolerance band, e.g.

SP2OptHiLim...SP2OptLoLim

within which the process value, CV2, must remain. These areas can be defined for any subset of the relevant controlled variables. From an economic perspective, different values within the tolerance range can be more or less favorable. With the help of the optimization function, the optimal economic point can be found within the tolerance range. This is done by defining a target function (performance criterion), which depends on the manipulated variable and controlled variable of the predictive controller. This can be, for example, the economic yield of plant operation per time unit or it may involve specific costs or energy consumption.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

After installation in CFC, follow the steps outlined below:

1. Excite the process with the controller in manual mode by applying a series of manipulated variable step changes.
2. Record the measured data with the CFC trend display and export it to an archive file.
3. Select the ModPreCon instance in the CFC. Start the MPC Configurator with the command Edit > MPC Configurator. The working steps process identification, controller design and simulation of the closed control loop are executed in the MPC Configurator. You can find a detailed description of this procedure in the MPC Configurator help. You can find the help with a button in the MPC Configurator or directly under ...\Program Files (x86)\SIEMENS \STEP7\S7JMPC\s7jmpctb.chm. (the last letter is the language code).
4. Using the Configurator, create an SCL source code for the user data block (DB). It contains the models and matrices required for a ModPreCon instance.

5. Compile the SCL source code in the engineering system and download it to the AS.
6. Enter the number of the data block at the DB_No input parameter of the ModPreCon block. The values are adopted in the controller by restarting the block using the Restart input parameter.

**Note**

During controller design in the MPC Configurator, a controller cycle time and an OB sampling time are calculated, displayed, and stored in the user data block. You yourself are responsible for the ModPreCon block being called in the cyclic interrupt level suitable for the OB sampling time. This is checked in the current ModPreCon version during initialization. If the SampleTime parameter of the function block does not match the OB_SampleTime parameter of the user data block, a parameter assignment error (ErrorNum=3) is displayed. For controller cycle times greater than 5 s, specify the ModPreCon block in the OB30 and specify the appropriate cycle time for the OB30 in the hardware configuration of the Simatic CPU. Controller cycle times slower than 20 s cannot be set in the hardware configuration. The block would then be called every 20s and the slower sampling time automatically realized by an internal cycle reduction ratio in the block.

For the ModPreCon block, the Advanced Process Library contains a template for a process tag type as examples and there is an example project (where APL_Example_xx, xx designates the language variant) containing various application cases for this block. Several application cases are simulated in the example project and serve to explain how the block works.

Example of a process tag type:

- Model-based predictive control (you can find additional information on this in the Help on Advanced Process Library > PCS 7 Advanced Process Control Templates > Process tag types > Model-based predictive control (ModPreCon))

Application cases in example project:

- Predictive control of a 2x2 multi-variable controlled system (you can find additional information on this in the Help on Advanced Process Library > PCS 7 Advanced Process Control Templates > Example project APL_Example_xx > Predictive control of a 2x2 multi-variable controlled system)
- Predictive control of a non-linear process (you can find additional information on this in the Help on Advanced Process Library > PCS 7 Advanced Process Control Templates > Example project APL_Example_xx > Predictive control of a non-linear process)

## Startup characteristics

When the CPU starts up, the block always starts in manual mode. It is only possible to change to automatic mode when a user data block is loaded and the internal measured value memory in ModPreCon is filled with data.

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

You can find additional information on the `Feature` bit "Set startup characteristics" in the Help on Advanced Process Library > Basics of APL > Selectable block response> Set startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section ModPreCon I/Os (Page 990)

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutAct.Value` |
| 6 | Invalid signal status |
| 7 | `ManAct.Value` |
| 8 - 9 | Not used |
| 10 | `MV1TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 11 | `MV2TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 12 | `MV3TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 13 | `MV4TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 14 | Internal error |
| 15 | `DB_Loaded` |
| 16 | `DV_Model Available` |
| 17 | OptimAct |
| 18 | `NOT(OptimAct)` |
| 19 | `SimOn AND ManAct` |
| 20 | J_Mini |
| 21 | NOT(J_Mini) |
| 22 | ExciteOn AND ManAct.Value |
| 23-30 | Not allocated |
| 31 | `Feature.Bit31`: Display of the predictions in the faceplate |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 - 30 | Not used |
| 31 | `MS_RelOp` |

## 6.6.2 ModPreCon modes

### Operating modes of ModPreCon

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

The aforementioned operating modes are valid for the block with all control channels (`MV1` ... `MV4`). Moreover, individual control channels can be tracked; see chapter ModPreCon functions (Page 976) for more information.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

**Note**

In contrast to PID controllers, it is permitted to run the ModPreCon block in "automatic mode" without its actuating signals affecting the process because there is no risk of integrator windup.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | `Feature.Bit5` =0 | `Feature.Bit5` =1 |
|---|---|---|
| SP1Out.ST | 16#XX | 16#60 |
| SP2Out.ST | 16#XX | 16#60 |

| Output Parameters | `Feature.Bit5 =0` | `Feature.Bit5 =1` |
|---|---|---|
| SP3Out.ST | 16#XX | 16#60 |
| SP4Out.ST | 16#XX | 16#60 |
| SP1OpOut.ST | 16#XX | 16#60 |
| SP2OpOut.ST | 16#XX | 16#60 |
| SP3OpOut.ST | 16#XX | 16#60 |
| SP4OpOut.ST | 16#XX | 16#60 |
| CV1Out.ST | 16#80 | 16#60 |
| CV2Out.ST | 16#80 | 16#60 |
| CV3Out.ST | 16#80 | 16#60 |
| CV4Out.ST | 16#80 | 16#60 |

## 6.6.3 ModPreCon functions

### Functions of ModPreCon

The functions for this block are listed below.

### Generating and limiting the manipulated variable

The manipulated variable `MV1` ... `MV4` (hereinafter referred to as `MVx`, x = 1 ... 4) can be generated as follows:

| ManAct | MVxTrkOn | MVx | Limit monitoring | State |
|---|---|---|---|---|
| 1 | - | `Manx` | `ManxHiLim`<br>`ManxLoLim` | "Manual mode", set by the operator |
| 0 | 1 | `MVxTrk` | `MVxHiLim`<br>`MVxLoLim` | Tracking with limitation |
| 0 | 0 | Automatic manipulated variable | `MVxHiLim`<br>`MVxLoLim` | "Automatic mode": Predictive controller algorithm |

Remark

If the controller is in "Out of service" mode, the output parameters `MV1` ... `MV4`, depending on the `Feature` Bit (Neutral position manipulated variable takes effect at startup (Page 176)), are set to the last valid value in manual mode or the corresponding neutral position manipulated

variable (SafePos1 ... SafePos4). Refer to the Out of service (Page 77) section for more on this.

The limited operating range (between MVxHiLim and MVxLoLim) is typically smaller in automatic mode than in manual mode. With regard to the limited range of validity of a linear process model for approximating a non-linear process response, this allows the stability of the closed control loop to be guaranteed within the control range in automatic mode.

The gradients of the manipulated variable (changes per second) are limited to MV1RaLim to MV4RaLim in "automatic mode". Gradient limitation applies both to the positive and negative directions.

### Tracking and limiting a manipulated variable

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

In contrast to PID controllers, tracking the manipulated variables (MV1 ... MV4) is enabled for specific channels via one of the input parameters MV1TrkOn ... MV4TrkOn. The corresponding manipulated variable is then tracked by the interconnectable input parameters MV1Trk ... MV4Trk.

### Setting the setpoint internally

With this block, the setpoint must always be set internally at the I/Os SP1 ... SP4. These are normally operated in the faceplate. In special situations, you can interconnect the setpoints but they can then no longer be changed using the faceplate.

### Setpoint tracking in manual mode

In this situation (SP_TrackCV = 1), the internal setpoints SP1 ... SP4 are tracked to the assigned process values CV1 ... CV4 in "manual mode". This function allows a bumpless transfer to "automatic mode". After the transfer, the setpoints can be changed by the operator again.

### Setpoint filters

The setpoint filter is the only way of changing the action of the predictive controller without having to create a new user data block with the MPC Configurator and reinitialize the controller. The specified time constant PreFilt1 ... PreFilt4 of the setpoint filter can be interpreted as the required settling time of this CV channel following a setpoint step change. As the time constant setting increases, the controller works more slowly and less aggressively. In particular, this reduces the influence of a setpoint step change in one control channel on neighboring control channels.

Internally, the ModPreCon block works with sets of future setpoints that are compared with the predicted movements of the controlled variables. Without the setpoint filter, it is assumed that the current setpoint will continue to remain valid in the future within the prediction horizon. If there is a setpoint step change, this means that the full value of the new setpoint will be required in the near future although the process cannot achieve this (according to the prediction). With the setpoint filter, an asymptotic setpoint trajectory (first order) is calculated from the current

process value to the required setpoint so that the required setpoint is reached in the specified time.

**Note**

The setpoint filter also comes into effect without a setpoint step if the process value deviates significantly from the setpoint due to disturbances. This means that the filter not only slows down the control response but indirectly also the response to disturbances.

The control response can only be slowed down by the setpoint filter and not accelerated; when the value is 0, the prefilter is deactivated. It is therefore advisable to set the basic controller action in the MPC Configurator with the "Manipulated variable change penalty" parameter and then to optimize this in the software using the function for simulation of the closed control loop. The setpoint filter should then only be used for fine tuning of the action in the operational system.

**Note**

Do not select an excessively long filter time constant. Values that are greater than the control horizon of the predictive controller (s. ModPreCon user DB, header comment of the SCL source: "control horizon" times "controller sample time" in seconds) can have undesirable effects when the dead band is used at the same time. If you wish to dramatically slow down the reaction of the controller, it is better to use the penalty of the manipulated variable changes in the MPC Configurator.

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Controlled variable (`SimCVx` , `SimCVxLi`)

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

In the predictive controller, the error signal is generated over the entire prediction horizon for each control channel as the deviation between the predicted movement of the process (starting at the current process value `CV1` ... `CV4`) and future setpoint settings (ending at `SP1` ... `SP4`) and used to calculate the manipulated variable.

In principle, the effect of the dead bands `SP1DeadBand` to `SP4Deadband` is the same as in a PID controller, but extends over the entire future prediction horizon. In other words, if, for example, the predicted controlled variable `CV1` in the entire prediction horizon is within the band `SP1` ± `SP1DeadBand`, the controller sees no reason whatsoever to change any manipulated variable. These are therefore also known as `CV` bands. In contrast to the manipulated variable limits, these are not hard constraints that need to be adhered to at all costs.

In multivariable controllers, it is advisable to make use of the fact that from the perspective of the application only some of the controlled variables need to move to a specified setpoint exactly while others only need to remain within a defined range.

A typical example would be quality characteristics for which a tolerance band is specified. While a dead band in a PID controller tends to put stability at risk, CV bands in individual controller channels generally relieve the multivariable controller overall.

Using CV bands, the action of a soft override control can be achieved.

### Use case for error signal generation with dead band

As long as the pressure in a reactor remains within the set safety limits, the controller is interested only in product quality. However, as soon as the pressure threatens to leave the permitted range (in other words, in the prediction it moves towards an illegal value in the future), the pressure control cuts in. By weighting the controlled variables in the performance index (see MPC Configurator), the user can specify that predicted violations of the pressure limits are given a particularly high weighting.

### Predictive controller algorithm

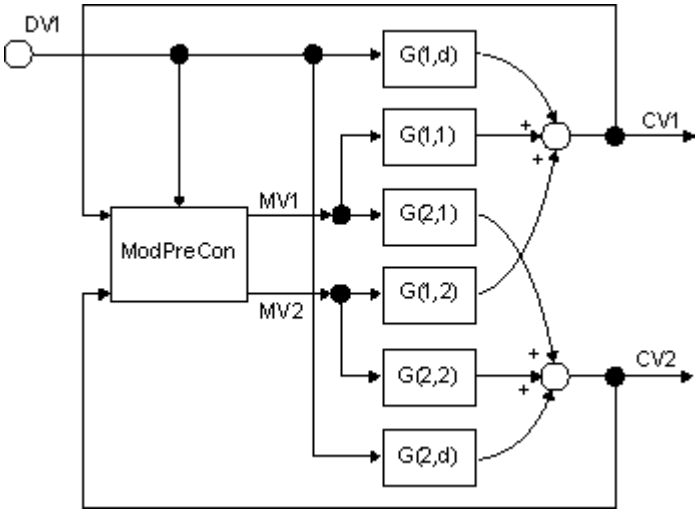
The ModPreCon block is derived from the familiar DMC algorithm (**D**ynamic **M**atrix **C**ontrol) . Future changes to the manipulated variable within the control horizon are calculated according to the formula:

$$\Delta\underline{\vec{u}} = \underline{C} \cdot (\underline{\vec{w}} - \underline{\vec{f}})$$

Where:

- w contains the time series of the future setpoints
- f contains the predicted free movement of the controlled variables (with constant manipulated variables) in the future
- C is the constant controller matrix calculated by the MPC Configurator. C includes both the process model and the weighting of the manipulated variable changes and the controlled variables from the performance index of the optimization.

Based on the principle of the receding horizon, only the first value is taken from the vector of the optimum manipulated variable changes over the entire control horizon and applied to the process. In the next step, the newly arrived process values are taken into account and the calculation repeated over the entire prediction horizon.



With predictive controllers, the manipulated variable changes are based on the control deviations predicted in the future, while with a PID controller, they are based on error signal of the past (possibly also integrated). This can be interpreted as a "looking ahead" strategy.

### Anti-windup

When manipulated variable limits are active, anti-windup measures are taken automatically within the controller. The prediction equations use the real limited values of the manipulated variable instead of theoretically calculated values.

### Model-based disturbance compensation

Model-based disturbance compensation can and should be used when a known disturbance has a strong influence on the process and its cause can be measured.

The effects of a measurable disturbance (`DV1` I/O) on all controlled variables `CV1` ... `CV4` can be estimated when the controller is taken into manual mode. This means that no movements of the controlled variables whatsoever result from changes to the manipulated variable and all movements result from the disturbance. If the disturbance can be measured but cannot be actively adjusted, it may be necessary to search through a data archive to find the time segments in which the disturbance changed.

The identification of the transfer functions from the disturbance variable `DV1` to all controlled variables `CV1` ... `CV4` (disturbance model, in the graphic above G(1.d) and G(2.d)) is performed with the MPC Configurator and is analogous to the identification of the main transfer functions (G(1.1) to G(2.2)). The measured disturbance variable is then switched to the `DV1` input of the ModPreCon block and disturbance compensation is activated with `DV_On` = 1. As a result, the effect of the measurable disturbance is taken into account in the prediction and the controller can start counter measures in advance before the disturbance can have a massive influence on the controlled variables.

Such disturbance compensation is especially effective when the disturbance is constant in sections and changes from time to time. If a disturbance changes constantly or oscillates, however, the feedforward control is not enabled during operation of the controller to avoid constant oscillation of the manipulated variables, although it should be taken into account in the MPC Configurator when creating the process model.

If there is no disturbance model in the user data block, the `DV1` input is ignored.

Typical examples of measurable disturbances are inlet volumes in distillation columns or throughput of continuous reactors.

### Predictive controller with more than one measurable disturbance

If you want to plan for more than one measurable disturbance in an application, but do not need all four disturbances from the ModPreCon block, you can dedicate the first of the previously unused control channels for disturbance variable feedforwarding.

Example: You only have two control actions available, so only use MV1 and MV2. Then connect the additional measurable disturbance variable DV2 to the MV3Trk input parameter and set MV3TrkOn = 1. For recording training data for the predictive controller, declare MV3Trk as the third disturbance and also use the CFC trend recorder to record the effect of changes to DV2 on all controlled variables.

Use the MPC Configurator to then determine a process model that describes the effects of DV2. However, if the DV2 in "automatic mode" of the controller changes due to external influences, the effect of such change is taken into consideration for predicting future process reactions through MV3Trk, and predictive methods can be used to compensate. The performance of the disturbance compensation is exactly the same as that for regular feedforward control via the input parameters DV and DV_On = 1.

If you want to disable this disturbance compensation in runtime with the unused MV3 manipulated variable, you need to insert a MV3Trk a selector block in front of the SelA02In input. This allows you to set a constant zero for MV3Trk instead of the measured value DV2, which stops the effect of MV3 on prediction. (Due to this reassignment, MV3TrkOn must always remain 1 to prevent the controller from changing the value of MV3.)

This way, up to four measurable disturbances can be selected. However, the sum of the manipulated variables and disturbances may not exceed a total number of five.

### Control of square and non-square systems

In multivariable controllers, the number of manipulated variables should ideally be the same as the number of controlled variables. This is known as a "square system". As long as constraints do not influence operation, the controller can, in principle, track all controlled variables exactly to the selected setpoints.

If there are less manipulated variables than controlled variables, or individual manipulated variables have reached their limits, there is no freedom in the control problem. This means that it is not possible for all setpoints to be reached exactly.

The ModPreCon algorithm then finds a compromise that can be influenced by the selection of controlled variable weights (priorities) in the MPC Configurator: Controlled variables with higher priority will have lower control deviations.

**Note**

Since the ModPreCon block is a lean predictive controller algorithm without online optimization, there can be no general guarantee that the compromise found is optimum in a mathematical sense; in other words, it is the minimum of the fit function taking into account the manipulated variable limits. In most practical situations, however, the controller finds sensible compromises.

The static operating point optimization it not a dynamic online optimization in this sense, i.e. it does not change anything in the above-mentioned restriction.

If there are more manipulated variables than controlled variables or if some of the controlled variables are already within their setpoint bands, there is surplus freedom in the control problem. A lean predictive controller algorithm, however, cannot recognize this situation explicitly and use the free manipulated variables for optimization. The ModPreCon block therefore moves all manipulated variables to values that meet the aims in terms of controlled variables and then leaves them there. In some situations, however, it can be useful to provide the

controller with more manipulated variables than controlled variables, for example when the effect of individual manipulated variables is too restricted.

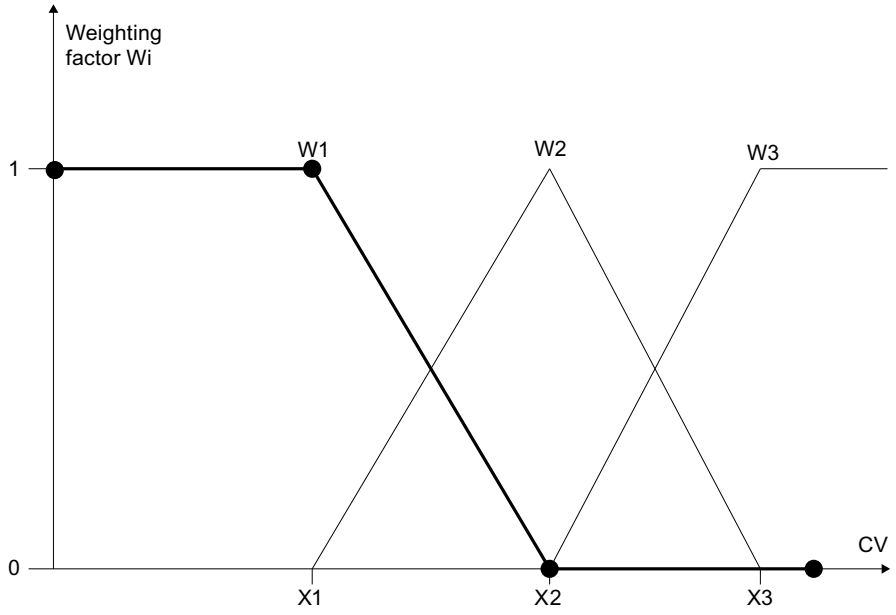
Another approach is to define the excess manipulated variables as pseudo controlled variables at the same time. You do this by assigning a setpoint with low priority to the pseudo controlled variables. The controller then attempts to achieve the important control aims as first priority and, at the same time, attempts to reach certain ideal values for the individual manipulated variables.

## Control of linear and non-linear systems

The ModPreCon algorithm is based on a linear, time invariant process model. As a result, in much the same way as a PID controller, it is suitable above all for controlling non-linear systems around a fixed operating point.

Again analogous to the PID controller, there are, however, several possibilities with which the area of application can be extended with non-linear systems:

**Compensation functions between controller and controlled system:**



It is, for example, possible to compensate the effect of a non-linear valve characteristic curve using a polygon block between the `MV` output and the control input of the valve block. Care must be taken when implementing the manipulated variable limits. In the same way, the effect of a non-linearity at the output of the controlled system (for example a sensor characteristic curve) can be compensated by a polygon block before the `CV` input of the controller. Remember that the corresponding SP must also be transformed accordingly. In both cases, the compensation functions become part of the controlled system from the perspective of the controller. The aim is always to keep the overall response of the controlled system consisting of process and compensation elements as linear as possible.

**Multimodel control:**

This approach is related to the basic idea of operating-point-based parameter control with PID controllers. Since the model parameter of the ModPreCon block cannot be modified in runtime, however, the control strategy for selecting the suitable parameter set becomes a control strategy for selecting the suitable model.

Several ModPreCon instances with different models for different operating points run at the same time. The local optimal models are determined by starting the process at the various operating points with small amplitudes, so that only the reaction of the non-linear process in the ambience of this operating point is registered.

The final manipulated variable for each manipulated variable is formed as a weighted mean value of the manipulated variables proposed by the controller instances. (It is recommended that experiments for starting the process for the MPC Configurator are only performed after implementing the functions for adding the manipulated variables, in order to ensure that the same conditions applicable when the model is in operation actually take effect.)

The weighting factors 0 ... 1 are formed in the same way as the membership functions known from fuzzy logic so that the sum of all weights is always one and each controller has the highest weighting at its own operating point. A polygon with 4 or 5 interpolation points is used to calculate each individual weighting factor. The weighting factors are calculated based on a specific measurable `PV` variable of the process, which is representative for the operating point of the process. This can be one of the `CVx` controlled variables, although it does not have to be. The abscissa of the interpolation points of all polygons is selected in such a way that they cover the entire value range of `PV` in order to avoid extrapolation errors.

One should note in this regard that the only non-linear effects in the full multi-variable control loop that can be modeled are those that correlate exactly to a representative `PV` variable. This approach is therefore not suitable for cases in which individual partial transfer functions demonstrate non-linear effects that depend on various, totally independent variables.

To ensure the stability of the overall control loop, all subcontrollers must be at least stable at all operating points. In contrast to PID controllers however, an MPC is not affected by windup problems if it temporarily runs in "automatic mode" but cannot intervene in the real process (weighting factor zero).

One of the controller instances is defined as the main controller and shown in the operator faceplate on the OS. All others are connected in such a way that they adopt the operating mode ("manual"/"automatic mode") and the setpoints from the main controller. The manual manipulated variables are passed to the secondary controller via the tracking inputs. This means that no operator intervention is required on secondary controllers.

**Note**

The manipulated variables of the main controller can be used when switching from automatic to manual mode. If the process was in the operating range of a secondary controller beforehand, the current manipulated variables in the process can deviate significantly. In this case, you should apply the actual manipulated values in effect by manual input in the faceplate of the primary controller.

You can find an example for multi-model controlling in the example project of Advanced Process Library under Predictive control of a non-linear process (ModPreConNonLinSim) (Page 2879).

**Trajectory control:**

This approach neatly combines the advantages of an open loop controller (Feedforward Control) with those of a closed loop controller with process value feedback (Closed Loop Control). The controller follows a previously optimized trajectory of setpoints and manipulated variables; in other words, it only needs to compensate small deviations between the stored trajectory and the current plant state. A trajectory is an optimum series of manipulated variables over time and the process values that match them. The required manipulated variables are read via the inputs `MV1Traj` ... `MV4Traj` into the ModPreCon block and added to the values of the manipulated variable calculated by the algorithm (in automatic mode only). Among other things, the advantage of this is that the effective manipulated variable acting on the process can be configured and is limited to the sum of the trajectory and controller action. The process values from the trajectory are switched to the corresponding setpoint specifications `SP1` ... `SP4` of the controller. As long as the process reacts exactly as planned in the trajectory, it will respond to the series of manipulated variables from the trajectory with the corresponding series of process values and the control deviation is zero. It is generally known that a non-linear dynamic process can linearized around a fixed operating point or a steady state of the system. It is also possible to linearize it around a trajectory.

## Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `DV1.ST`
- `CV1.ST`
- `CV2.ST`
- `CV3.ST`
- `CV4.ST`

## Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 8 | Delete history of MV and DV moves during restart (Page 201) |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |

| Bit | Function |
|---|---|
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 24 | Enabling local operator authorization (Page 169) |

## Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | Not used |
| 2 | 1 = Operator can switch to "Out of service" mode |
| 3 | Not used |
| 4 | Not used |
| 5 | 1 = Operator can change the setpoint 1 |
| 6 | 1 = Operator can change the manipulated variables of all channels |
| 7 | 1 = Operator can change operating high limits of the setpoints for all channels |
| 8 | 1 = Operator can change operating low limits of the setpoints for all channels |
| 9 | 1 = Operator can change the setpoint 2 |
| 10 | 1 = Operator can change the setpoint 3 |
| 11 | 1 = Operator can change the setpoint 4 |
| 12 | 1 = Operator can change the setpoint filter of all channels |
| 13 - 16 | Not used |
| 17 | 1 = Operator can enable the track setpoint in "manual mode" function |
| 18 | 1 = Operator can activate the model-based disturbance compensation function |
| 19 | 1 = Operator can enable the function "Prediction without control response" |
| 20 - 22 | Not used |
| 23 | 1 = Operator can change the dead band parameter of all channels |
| 24 | 1 = Operator can change the tuning parameters |
| 25 | 1 = Operator can change the simulation value SimPV1..4 |
| 26 | 1 = Operator can activate the Simulation function |
| 27 | 1 = Operator can activate the Release for maintenance function |
| 28 | 1 = Operator can change the manipulated variable limits of all channels |
| 29 | 1 = Operator can change the gradient limits of manipulated variables of all channels |
| 30 | 0 = Operator can set the integrated static operating point optimization |
| 31 | 1 = Operator can set the integrated static operating point optimization |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Release for maintenance

The block provides the standard function Release for maintenance (Page 70).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

In contrast to PID controllers, there are no separate parameters for bar limits. The setpoints limits are used for all setpoint and actual value bars; manual limits are used as bar limits for all manipulated variable bars.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Integrated static operating point optimization

The integrated static operating point optimization can be used if no exact SPi setpoint is specified for at least one controlled variable (index i =1...4), but rather the CVi process value must remain within a tolerance range SPiOptHiLim...SPiOptLoLim. The tolerance range must, of course, be within the valid setpoint limits SPiHiLim...SPiLoLim for this control channel. The tolerance range SPiOptHiLim...SPiOptLoLim is not coupled to the operator-controlled setpoint SPi. If the setpoint is changed, the tolerance range is not automatically shifted. If you want to do this nevertheless, interconnect the SPiOpOut output parameters via two adders to the width of the tolerance range at the inputs SPiOptHiLim and SPiOptLoLim.

From an economic perspective, different values within the tolerance range can be more or less favorable. With the help of the optimization function, the optimal economic point can be found within the tolerance range.

This is done by defining a target function (performance criterion), which depends on the manipulated variable and controlled variable of the predictive controller. This can be, for example, the economic yield of plant operation per time unit or it may involve specific costs or energy consumption.

J= GradMV1*MV1 +GradMV2*MV2 +GradMV3*MV3 +GradMV4*MV4

+GradCV1*CV1 +GradCV2*CV2 +GradCV3*CV3 +GradCV4*CV4

+J0

You specify the individual GradXVi coefficients of the gradient vector as input variables at the ModPreCon function block in the CFC or in the parameter view of the faceplate. If individual coefficients vary with time, e.g. they are dependent on current market prices, you can also interconnect these input variables. If individual manipulated or controlled variables have no influence on the performance criterion, leave the corresponding coefficients at the default value, zero.

You can use the binary J_Mini input parameter to specify whether the target function is to be maximized or minimized, based on whether this involves yields or costs (J_Mini = 1 : minimization).

The term J0 combines all contributions to the target function that do not depend on manipulated variables and controlled variables. These contributions have no effect on the optimum values in the decision variables, but are applied for calculating the current value of employed performance criterion similar to the above-mentioned formula.

Within the controller, the terms of the target function that depend on manipulated variables are converted to make their dependence on the controlled variables visible. To do this, the inverse stationary process model from the MPC Configurator is used. This requires that the number of manipulated variables matches the number of controlled variables. If the number of manipulated variables does not match the number of controlled variables, the largest possible square submodel in the matrix of the transfer functions is truncated from the top left. If there are more manipulated variables than controlled variables, for example, only the first manipulated variables are used, in accordance with the number of controlled variables.

Constraints for the controlled variables take the form of the above-mentioned tolerance ranges for setpoints. The controller takes care of adhering to the manipulated variable limits, in any case; they do not have to separately specified as constraints for the optimization.

Enable the optimization using the binary input variable OptimizeOn in the controller faceplate. The optimizer then returns setpoints within the tolerance ranges that are optimal for the performance criterion. These setpoints are then sent to the control algorithm, which handles them in the same way as conventionally specified setpoints (with or without dead band). The operable SP1...SP4 setpoints are not tracked to the optimized setpoints; when optimization is disabled, the old setpoints from the faceplate take effect once again. When selecting variables for archiving and graphic plotter, ensure you use the SP1Out...SP4Out setpoint actually in effect and not the SP1...SP4. input variables.

The current value of the performance criterion is displayed at the J_Actual output variables.

You can find additional information about the topic of static operating point optimization in the online help for the MPC configuration editor.

### Display of the prediction of free movement

The prediction of free motion is a forecast for the future behavior of the process within the overall prediction horizon, under the assumption that all manipulated variables are frozen at their current values. The time length of the prediction horizon is indicated in the output parameter PrediHorizon in the [s] unit.

The prediction of free motion is recalculated in each sampling step within the control algorithm. If the manipulated variables is to a constant value in manual mode, the prediction of the free movement is actually a realistic prediction for the future process response. It can therefore be represented graphically in the faceplate at least in terms of quality. For this purpose, five equidistant interpolation values are copied from the prediction horizon, and displayed in the standard view of the faceplate as a vertical bar next to the current process value.

Example: The prediction horizon is 1800s=30min and the current time is labeled with the index k. The prediction for k+6min, and next to it k+12min, up to k+30min then appears on the right next to the bar of the current process value. If the upper border of the bar is conceptually connected with a line (red in the picture red), you can imaging the curve created by the future course of the process value over the next half hour.

In automatic mode (tracking function is switched off), the value of the manipulated variables changes with each sampling step. The prediction of free movement is then only a fictional mathematical formulation within the algorithm, and not a realistic prediction for the future process response. This is why the prediction is only displayed in manual mode or in automatic mode with active tracking function. The display can be generally suppressed using `Feature.Bit31`.

### Prediction without control response

In this special "operating mode" (comparable to the block-internal simulation), the controller only monitors the process and indicates what it would like to do in the next sampling step without actively intervening in the process. This allows you as the user to build trust before "switching active" the controller the first time, i.e. actively intervening in the process.

"Prediction Mode" is activated via the binary input variable PredictMode or in "Parameters" in the faceplate view. Setpoints and process values are read as in normal automatic mode. The prediction of the free movement and manipulated variable change for the next sampling step are calculated as in normal automatic mode. The starting point for the prediction of the manipulated variable for the next sampling step, however, is the current process value of the follow-up control loop at the MV1Trk...MV4Trk tracking inputs. The predicted manipulated variables are not output at the normal outputs MV1...4, but rather at the MV1Pred...MV4Pred outputs, which were especially introduced for this purpose, and are displayed in the standard view of the faceplate on the left next to MV1...4, as long as "Prediction Mode" is active.

- When the controller is in automatic mode, in "Prediction Mode" all MVi (i=1..4) are set to match the assigned MViTrk input parameters, similar to tracking mode.
- When the controller in manual mode, all MVi are set to the desired manual values regardless of "Prediction Mode".
- When "Prediction Mode" is disabled, all MViPred always equal the assigned MVi.

### Automatic process trigger for model identification

In order to determine the process model for the model predictive controller, the process must be artificially triggered in order to observe its dynamic response and record it in the form of training data. This trigger can be specified manually in manual mode of the controller.

Alternatively, a suitable trigger signal can be generated automatically in the form a defined, symmetrical sequence of manipulated variable jumps. The trigger signals are calculated by an auxiliary function block, "AutoExcitation", which is built into the process tag type and interconnected with ModPreCon .

Additional MV1Excite...MV4Excite input variables are required for this on the controller. Process triggering performed in manual mode of the controller, because automatic mode cannot be activated before modeling. The new process trigger "operating mode" can only be controlled via the ExciteOn input bit on the Engineering System, and not on the operator station, since the CFC is needed for data recording in any case. However, process triggering must be displayed on the OS in standard view at the lower left.

Manual intervention per faceplate remains possible even during the triggering. The values of the MV1Excite...MV4Excite input parameters are therefore only written to the MV1Man...MV4Man manual values event-based, but only if they change.

You can find additional details on automatic process triggering in the online help for the MPC configuration editor.

## 6.6.4 ModPreCon error handling

### Error handling of ModPreCon

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Default value when the block is installed; this message is irrelevant. |
| 0 | There is no error. |
| 3 | Configuration error: Block is inserted in the wrong OB, cycle time of the OB is not suited for controller configuration. |
| 32 | The value of `CV1` can no longer be displayed in the real number field or is not a number. |
| 33 | The value of `CV2` can no longer be displayed in the real number field or is not a number. |
| 34 | The value of `CV3` can no longer be displayed in the real number field or is not a number. |
| 35 | The value of `CV4` can no longer be displayed in the real number field or is not a number. |
| 36 | The `MV_Trk1` value can no longer be displayed in the real number field or is not a number. |
| 37 | The `MV_Trk2` value can no longer be displayed in the real number field or is not a number. |
| 38 | The `MV_Trk3` value can no longer be displayed in the real number field or is not a number. |
| 39 | The `MV_Trk4` value can no longer be displayed in the real number field or is not a number. |

| Error number | Meaning of the error number |
|---|---|
| 51 | `AutModLi` = 1 and `ManModLi` = 1 |
| 90 | The controller matrix could not be loaded from the user data block. |

The ErrorOpt output parameter is used to output the status of the lower-level LPOptim block. See ModPreCon I/Os (Page 990) for more.

| MV3_Unit | Unit of measure for manipulated variable 3 | INT | 1342 |
| MV3Excite | MV3 for automatic process trigger | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV3HiLim | High limit of manipulated variable MV3 | REAL | 100.0 |
| MV3LoLim | Low limit of manipulated variable MV3 | REAL | 0.0 |
| MV3Man* | Manual value: Operator input for setting the manipulated variable MV3 in manual mode | REAL | 0.0 |
| MV3ManHiLim | High limit of manipulated variable MV3 in manual mode | REAL | 100.0 |
| MV3ManLoLim | Low limit of manipulated variable MV3 in manual mode | REAL | 0.0 |
| MV3RaLim | Gradient limit of the manipulated variable MV3 per sampling step | REAL | 100.0 |
| MV3Traj | Trajectory value that is added to the manipulated variable MV3 | REAL | 0.0 |
| MV3Trk | Tracking value for the manipulated variable MV3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV3TrkOn | 1 = Tracking of manipulated variable MV3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV4_Unit | Unit of measure for manipulated variable 4 | INT | 1342 |
| MV4Excite | MV4 for automatic process trigger | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV4HiLim | High limit of manipulated variable MV4 | REAL | 100.0 |
| MV4LoLim | Low limit of manipulated variable MV4 | REAL | 0.0 |
| MV4Man* | Manual value: Operator input for setting the manipulated variable MV4 in manual mode | REAL | 0.0 |
| MV4ManHiLim | High limit of manipulated variable MV4 in manual mode | REAL | 100.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV4ManLoLim | Low limit of manipulated variable MV4 in manual mode | REAL | 0.0 |
| MV4RaLim | Gradient limit of the manipulated variable MV4 per sampling step | REAL | 100.0 |
| MV4Traj | Trajectory value that is added to the manipulated variable MV4 | REAL | 0.0 |
| MV4Trk | Tracking value for the manipulated variable MV4 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV4TrkOn | 1 = Tracking of manipulated variable MV4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Allocated by SIMATIC BATCH | BOOL | 0 |
| OosLi | 1 = Out of service, via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = Out of service, via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations | DWORD | 16#00000000 |
| OptimOffOp | 1 = Disable optimization, normal setpoints SP1...SP4 in effect | BOOL | 0 |
| OptimOnOp | 1 = Enable optimization, optimized setpoints SP1Out ... SP4Out in effect | BOOL | 0 |
| OS_Perm | I/O for operator permissions | STRUCT<br>• Bit 0: BOOL<br>• Bit 25: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| PredictMode | 1 = "Prediction mode" enabled, prediction only, no intervention in the process | BOOL | 0 |
| PreFilt1 | Settling time [s] of the setpoint filter for setpoint SP1 | REAL | 0.0 |
| PreFilt2 | Time constant [s] of the setpoint filter for setpoint SP2 | REAL | 0.0 |
| PreFilt3 | Time constant [s] of the setpoint filter for setpoint SP3 | REAL | 0.0 |
| PreFilt4 | Time constant [s] of the setpoint filter for setpoint SP4 | REAL | 0.0 |
| Restart* | 1 = Restart of the block and adoption of the data from the user block that is entered at the input parameter DB_No | BOOL | 1 |
| SafePos1 | Neutral position for MV1 | BOOL | 0 |
| SafePos2 | Neutral position for MV2 | BOOL | 0 |
| SafePos3 | Neutral position for MV3 | BOOL | 0 |
| SafePos4 | Neutral position for MV4 | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 1.0 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate in the preview | ANY | - |
| SimCV1* | Controlled variable CV1 (process value) which is used with SimOn = 1 | REAL | 0.0 |
| SimCV2* | Controlled variable CV2 (process value) which is used with SimOn = 1 | REAL | 0.0 |
| SimCV3* | Controlled variable CV3 (process value) which is used with SimOn = 1 | REAL | 0.0 |
| SimCV4 | Controlled variable CV4 (process value) which is used with SimOn = 1 | REAL | 0.0 |
| SimCV1Li | Controlled variable CV1 (process value) that is used for SimOnLi.Value = 1 (SimLiOp.Value =1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SimCV2Li | Controlled variable CV2 (process value) that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SimCV3Li | Controlled variable CV3 (process value) that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SimCV4Li | Controlled variable CV4 (process value) that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SP_TrkCV | 1 = Setpoints follow the CVs in manual mode and in tracking | BOOL | 0 |
| SP1* | Setpoint 1<br>SP1.ST=FF: Operable in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP1DeadBand | Width of the dead band control of CV1 | REAL | 0.0 |
| SP1HiLim | High limit for setpoint 1 | REAL | 100.0 |
| SP1LoLim | Low limit for setpoint 1 | REAL | 0.0 |
| SP1OptHiLim | High limit for optimization of setpoint 1 | REAL | 100.0 |
| SP1OptLoLim | Low limit for optimization of setpoint 1 | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP2* | Setpoint 2<br>SP2.ST=FF: Operable in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP2DeadBand | Width of the dead band control of CV2 | REAL | 0.0 |
| SP2HiLim | High limit for setpoint 2 | REAL | 100.0 |
| SP2LoLim | Low limit for setpoint 2 | REAL | 0.0 |
| SP2OptHiLim | High limit for optimization of setpoint 2 | REAL | 100.0 |
| SP2OptLoLim | Low limit for optimization of setpoint 2 | REAL | 0.0 |
| SP3* | Setpoint 3<br>SP3.ST=FF: Operable in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP3DeadBand | Width of the dead band control of CV3 | REAL | 0.0 |
| SP3HiLim | High limit for setpoint 3 | REAL | 100.0 |
| SP3LoLim | Low limit for setpoint 3 | REAL | 0.0 |
| SP3OptHiLim | High limit for optimization of setpoint 3 | REAL | 100.0 |
| SP3OptLoLim | Low limit for optimization of setpoint 3 | REAL | 0.0 |
| SP4* | Setpoint 4<br>SP4.ST=FF: Operable in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP4DeadBand | Width of the dead band control of CV4 | REAL | 0.0 |
| SP4HiLim | High limit for setpoint 4 | REAL | 100.0 |
| SP4LoLim | Low limit for setpoint 4 | REAL | 0.0 |
| SP4OptHiLim | High limit for optimization of setpoint 4 | REAL | 100.0 |
| SP4OptLoLim | Low limit for optimization of setpoint 4 | REAL | 0.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = Automatic mode is active<br>0 = Manual mode is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CV1Out | Output of manipulated variable 1 (process value) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CV2Out | Output of manipulated variable 2 (process value) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CV3Out | Output of manipulated variable 3 (process value) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CV4Out | Output of manipulated variable 4 (process value) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. You can find information via the error numbers that are output by this block at ModPreCon error handling (Page 989) | INT | -1 |
| ErrorOpt | Error number of the integrated optimization function, see the description of function block LPOptim | INT | 0 |
| Fut1_y1... Fut1_y5 | Prediction of free movement of CV1 for five future points in time within the prediction horizon | REAL | 0 |
| Fut2_y1... Fut2_y5 | Prediction of free movement of CV2 for five future points in time within the prediction horizon | REAL | 0 |
| Fut3_y1... Fut3_y5 | Prediction of free movement of CV3 for five future points in time within the prediction horizon | REAL | 0 |
| Fut4_y1... Fut4_y5 | Prediction of free movement of CV4 for five future points in time within the prediction horizon | REAL | 0 |
| J_Actual | Current value of the performance criterion | REAL | 0 |
| Loop1Closed | 1 = Control loop for CV1 closed<br>0 = Control loop for CV1 open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Loop2Closed | 1 = Control loop for CV2 closed<br>0 = Control loop for CV2 open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Loop3Closed | 1 = Control loop for CV3 closed<br>0 = Control loop for CV3 open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Loop4Closed | 1 = Control loop for CV4 closed<br>0 = Control loop for CV4 open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ManAct | 1 = Manual mode active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release by OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV1 | Control variable 1 (control signal) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV1HiAct | 1 = High limit of manipulated variable 1 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV1LoAct | 1 = Low limit of manipulated variable 1 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV1Pred | One-step prediction for MV1 in the "Prediction without control response" mode | REAL | 0 |
| MV2 | Manipulated variable 2 (control signal) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV2HiAct | 1 = High limit of manipulated variable 2 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV2LoAct | 1 = Low limit of manipulated variable 2 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV2Pred | One-step prediction for MV2 in the "Prediction without control response" mode | REAL | 0 |
| MV3 | Manipulated variable 3 (control signal) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV3HiAct | 1 = High limit of manipulated variable 3 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV3LoAct | 1 = Low limit of manipulated variable 3 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV3Pred | One-step prediction for MV3 in the "Prediction without control response" mode | REAL | 0 |
| MV4 | Manipulated variable 4 (control signal) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV4HiAct | 1 = High limit of manipulated variable 4 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV4LoAct | 1 = Low limit of manipulated variable 4 reached or exceeded | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV4Pred | One-step prediction for MV4 in the "Prediction without control response" mode | REAL | 0 |
| NumberCVs | Number of controlled variables (process values) used | INT | 0 |
| NumberDVs | Number of disturbances used | INT | 0 |
| NumberMVs | Number of manipulated variables used | INT | 4 |
| OosAct | 1 = Block is "out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OptimAct | 1 = Optimization is active | BOOL | 0 |
| OptimAvailable | 1 = Optimization available, 0 = Optimization not available, because old user data block is loaded | BOOL | 0 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| PrediHorizon | Prediction horizon [s] | REAL | 0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP1OpOut | Copy of the operable setpoint 1 for step-enabling | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2OpOut | Copy of the operable setpoint 2 for step-enabling | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP3OpOut | Copy of the operable setpoint 3 for step-enabling | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP4OpOut | Copy of the operable setpoint 4 for step-enabling | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP1Out | Setpoint 1 used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2Out | Setpoint 2 used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP3Out | Setpoint 3 used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP4Out | Setpoint 4 used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 | DWORD | 16#00 |
| Status2 | Status word 2 | DWORD | 16#00 |

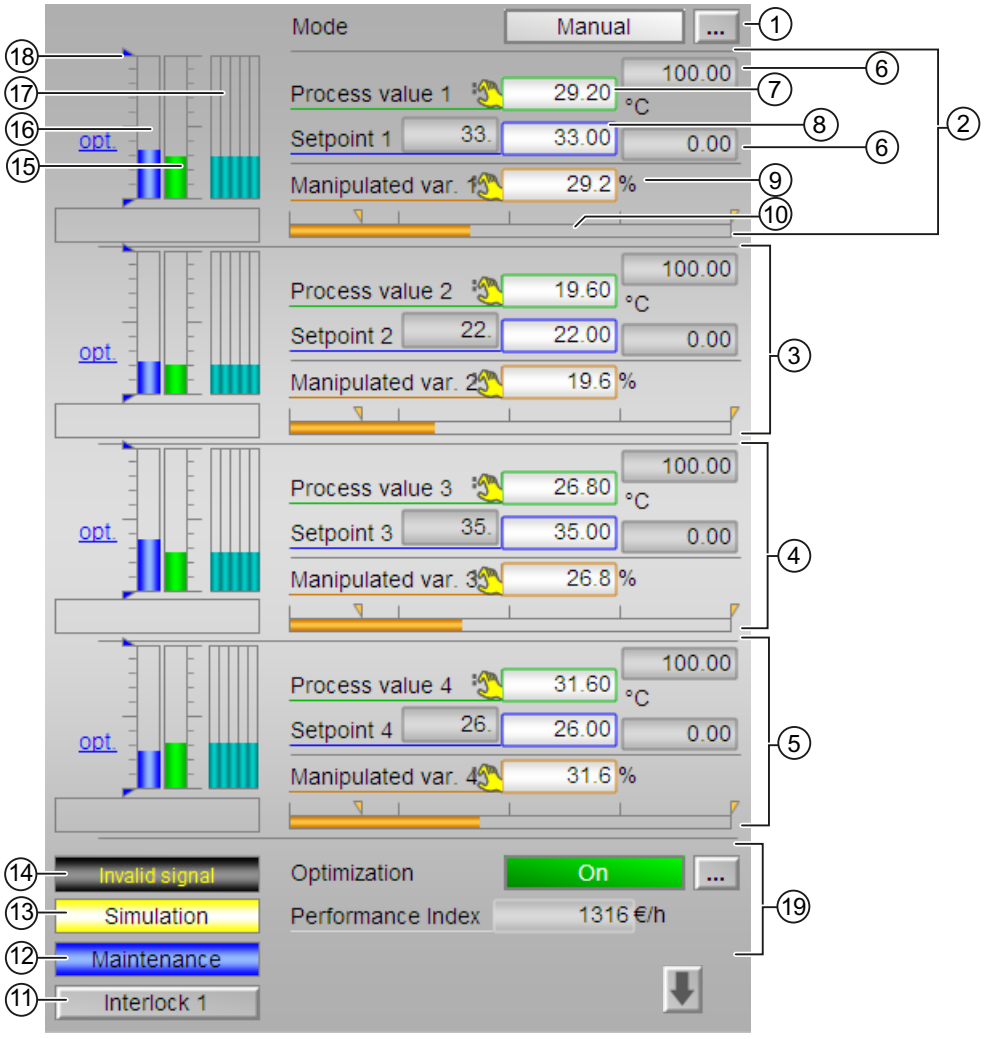
## 6.6.8 Operator control and monitoring

### 6.6.8.1 ModPreCon views

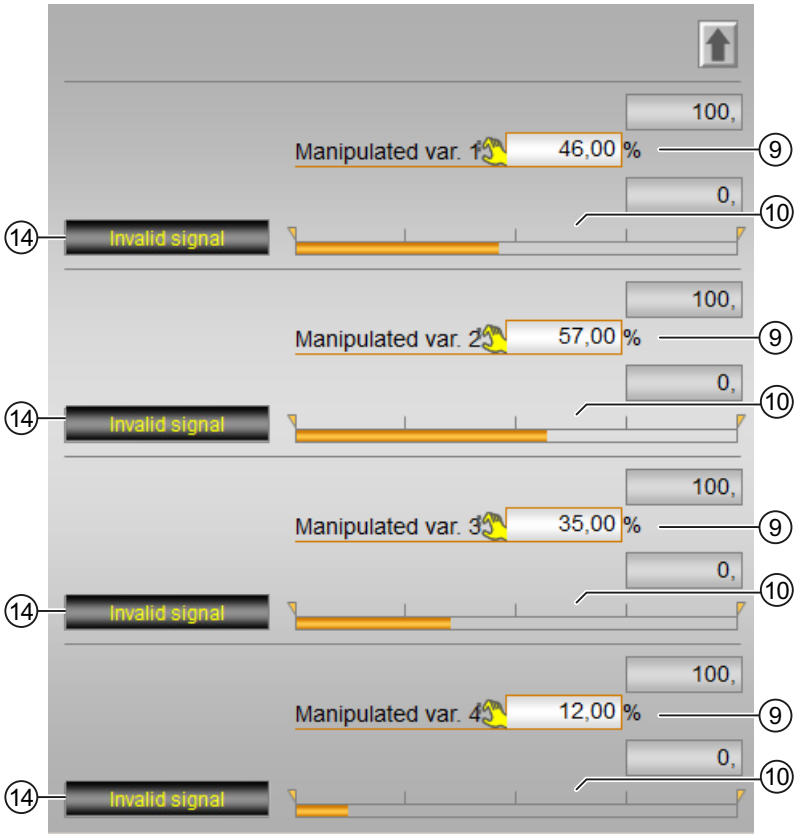
#### Views of the ModPreCon block

The block ModPreCon provides the following views:

- ModPreCon standard view (Page 1003)
- ModPreCon trend view (Page 1013)
- ModPreCon parameter view (Page 1008)
- ModPreCon parameter view channel 1 to 4 (Page 1010)
- ModPreCon preview (Page 1011)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for ModPreCon (Page 1014)



Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.



#### See also

Trend view (Page 341)

### 6.6.8.2 ModPreCon standard view

## ModPreCon standard view

The standard view has an upper half and a lower half. You can change between the two halves with the arrow keys. The upper half shows all available controlled variable channels with their setpoints, while the lower half shows all available manipulated variable channels.

**Upper screen half (controlled variables)**

## (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

## (2), (3), (4) and (5) Displaying and switching for values for channels 1 to 4

This area always has the same layout for channels 1 to 4:

**(6) High and low scale range for the process value**

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the engineering system.

**(7) Displaying and changing the process value including signal status**

This area shows the current process value with the corresponding signal status.

In the object properties (I/Os PVx_Out > Identifier) of the block in CFC, you can specify the text to be displayed for these parameters.

**(8) Displaying and changing the setpoint including signal status**

This area shows the current setpoint with the corresponding signal status. Refer to the Changing values (Page 291) section for information on changing the setpoint.

### (11) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (12) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (13) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Process excitation"
  The automatic process trigger is fed forward using the upstream block AutoExcitation for recording learning data for the MPC configurator. The manipulated variable step changes are added to the manipulated values 1 to 4 according to schedule. Avoid external disturbances to the process while the process trigger is running. The manipulated variables can be changed manually while the process trigger is running.

You can find additional information on this in the section Simulating signals (Page 64).

### (14) Display area for block states

- "Internal error"
- "Invalid Signal"

### (15) Display area for block states

- "Tracking on"

### (16) Bar graph for the process value 1

There is a bar graph for the process value for every channel 1 to 4.

This area shows the current process value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (17) Bar graph for the setpoint 1

There is a bar graph for the setpoint for every channel 1 to 4.

This area shows the current setpoint in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (18) Prediction of free movement

This area shows you the prediction of free movement in the form of a bar graph. For each channel from 1 to 4, there is a bar graph for the prediction of free movement, that is, for the future behavior of the process within the overall prediction horizon, under the assumption that all manipulated variables are frozen at their current values.

This is why the prediction of free movement is only displayed in manual mode or in automatic mode with active tracking function.

The value range of the bar graph matches the value range of the assigned setpoint and current value bar.

ModPreCon functions (Page 976)

### (19) Displaying the limits

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the engineering system (ES).

### (20) Static operating point optimization

Activate the optimization using the button at bottom right. Activation means that the optimized setpoints SP1Out...SP4Out are actually used instead of the SP1...SP4 setpoints specified in the faceplate for the closed-loop control. (The actual calculation of the optimum setpoints depends on this, and is only performed if one of the input variables for the optimization has changed.) The current value the economic performance criterion J appears in the display field below.

When optimization is enabled, the optimum setpoints are displayed on the setpoint bar as small, horizontal lines and highlighted with the abbreviation "opt.". The numerical values of the optimum setpoints are then displayed left of the input fields for the setpoints.

**Lower screen half (manipulated variables)**

### (9) Displaying and changing the manipulated variable including signal status

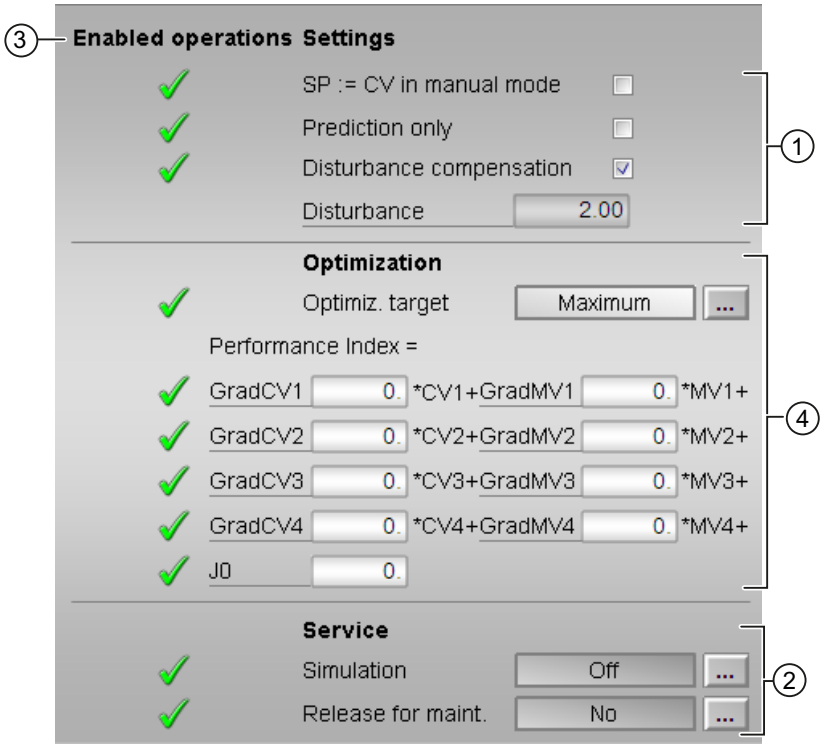
This area shows the current manipulated variable with the corresponding signal status. Refer to the Changing values (Page 291) section for information on changing the manipulated variable. You can only make a change in manual mode.

In the object properties (I/Os MVx > Identifier) of the block in CFC, you can specify the text to be displayed for these parameters.

### (10) Bar graph for the manipulated variable with limit display

This area shows the current manipulated variable in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES):

- Limits: `MVxHiLim` and `MVxLoLim`
- Display area: `MVxManHiLim` and `MVxManLoLim`



### (14) Display for block states

There is a display for the states of the block for every channel 1 to 4:

- "Tracking"

### 6.6.8.3 ModPreCon parameter view

#### Parameter view of ModPreCon

#### (1) Settings

You can activate the following functions for the controller in this area:

- "SP := CV in manual mode": ☑ Bumpless switchover from "manual mode" to "automatic mode"
- "Prediction only" activate this special "operating mode" by selecting the check box. The controller then only listens in on the process and indicates what it would like to do in the next sampling step without actively intervening in the process
- "Disturbance compensation": ☑ Select disturbance feedforward
- "Disturbance variable"

You cannot change the disturbance variable, it can only be displayed.

In the object properties (I/Os DV1 > Identifier) of the block in CFC, you can specify the text to be displayed for this parameter.

#### (2) Service

You can select the following functions in this area:

- "Simulation"
- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### (3) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

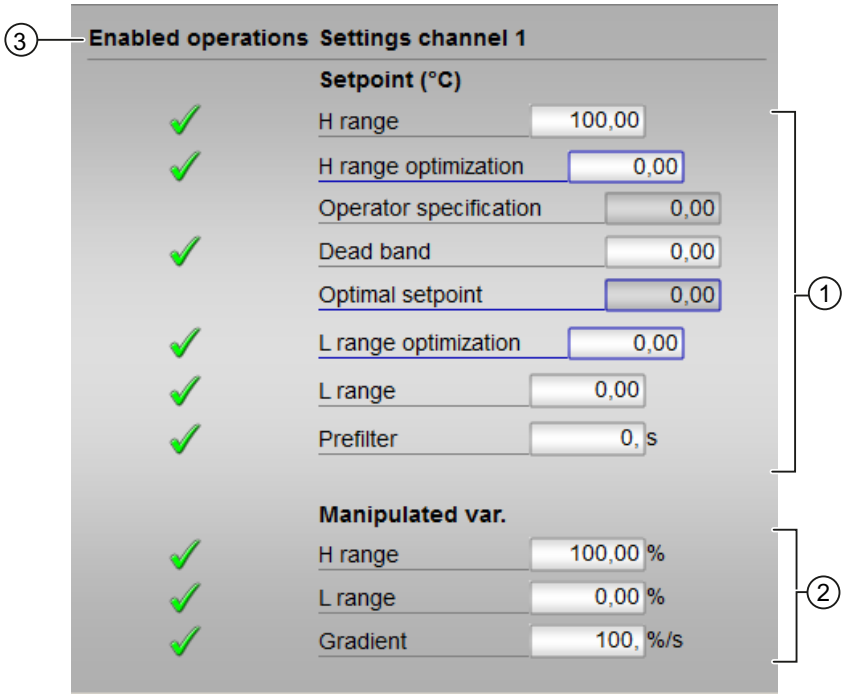
Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### (4) Optimization

**Direction of the optimization (minimize or maximize)**

By default, the optimizer seeks to maximize the performance function, in the assumption that it is dealing with economic yield. If you want to search a minimum, however, because you are dealing with costs or consumption values, click this button.



**Specification of performance criterion for the operating point optimization**

The performance criterion consists of a weighted sum of all manipulated and controlled variables. For each manipulated variable and controlled variable, enter the appropriate weighting factor, i.e. the coefficient of the gradient vector. Zero means that the value of the corresponding manipulated variable or controlled variable no direct influence on the economic yield. If the controller has less than four manipulated variables or controlled variables, the irrelevant variables are hidden automatically.

### 6.6.8.4 ModPreCon parameter view channel 1 to 4

#### Parameter view channel 1 to 4 for ModPreCon

The layout of the parameter view for channels 1 to 4 is always identical:

#### (1) Displaying and changing the limit parameters for the setpoint

You can change the following parameters for the setpoint in this area:

- "H range": High limit for setpoint operation
- "H range optimization": High limit for optimizing the setpoint
- "Operator input": Display of the setpoint entered in the standard view, cannot be operated here.
- "Dead band": Dead band (Page 67), Error signal generation and dead band section
- "Optimal setpoint": Calculated by the optimization, cannot be operated
- "L range optimization": Low limit for optimizing the setpoint
- "L range": Low limit for setpoint operation
- "Prefilter": ModPreCon functions (Page 976), Setpoint filter section

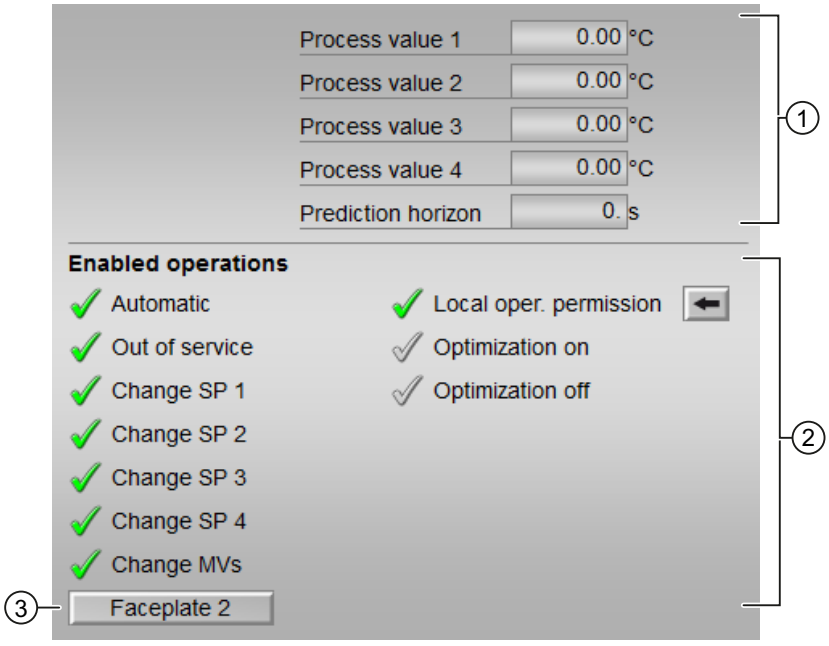
You can find additional information on this in the section Changing values (Page 291) .

### (2) Displaying and changing the limit parameters for the manipulated variable

You can change the following parameters for the manipulated variable in this area:

- "H range": Upper limit of the manipulated variable for automatic mode
- "L range": Low limit of manipulated variable for automatic mode
- "Gradient limit": Maximum (absolute) change in the manipulated variable per sampling step

### (3) Enabled operation



This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

## 6.6.8.5 ModPreCon preview

### Preview for ModPreCon

### (1) Process value

This area displays the real process values (`PVx`) and the prediction horizon.

In the object properties (I/Os PVxOut > Identifier) of the block in CFC, you can specify the text to be displayed for these parameters.

**Prediction horizon**

The prediction horizon specifies how far the controller looks into the furutre of its calculation.

### (2) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

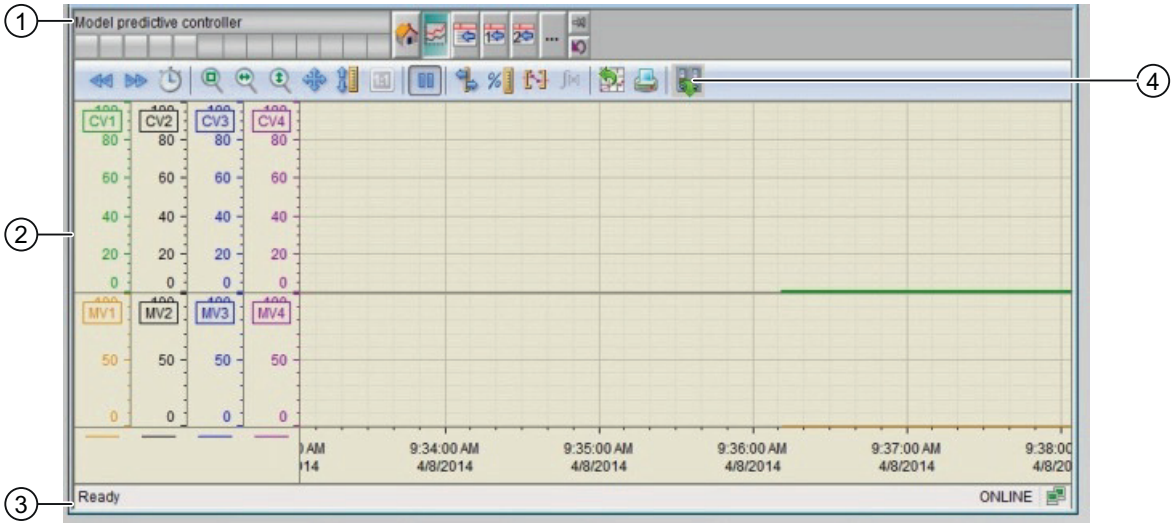
The following enabled operations for parameters are shown here:

- "Automatic": You can switch to "automatic mode".
- "Out of service": You can switch to "Out of service" operating mode.
- " "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285) .
- "Change SP1": You can change the setpoint 1
- "Change SP2": You can change the setpoint 2
- "Change SP3": You can change the setpoint 3
- "Change SP4": You can change the setpoint 4
- "Change MVs": You can change the manipulated variables

**Note**

The OS operator must always be able to switch to "manual mode". That is why the switch to "manual mode" is not shown here in the faceplate.

### (3) Navigation button for switching to the standard view of any faceplate



Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### 6.6.8.6 ModPreCon trend view

## ModPreCon trend view

There is a block-specific trend view for ModPreCon which is supplied as file @PG_APL_TrendMPC.pdl and which you can modify if necessary.

**(1)** Toolbar

**(2)** Display area for trends

**(3)** Status bar

**(4)** Button for switching between archive tags and online tags. The status bar shows if the trend view is working with online data or archive data.

The Export button is only visible and operable with the "Higher-level process control" operating permission.

For additional information about the trend view, refer to the *WinCC Information System* Online Help.

The trend view is divided into two screen halves.

The upper screen half shows all controlled variables with their associated setpoints. The setpoint is shown in the same color as the associated process value to allow the assignment to be identified straight away. Setpoints are dashed lines, process values are bold lines. If a controlled variable is exactly on the setpoint, it hides the setpoint.

The lower screen half shows all manipulated variables.

Both screen halves use the same color sequence for the individual channels. The sequence starts at channel 1 with green (standard color for the process value with the PID controller) and then goes through the color spectrum from top to bottom as far as gray and black. Each channel has its own y-axis in the corresponding color.

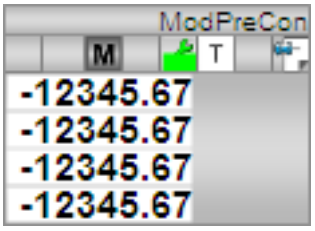
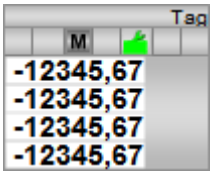
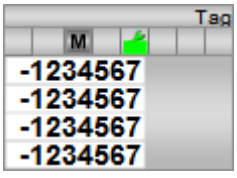
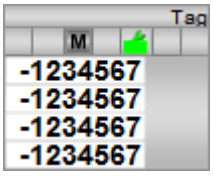
## 6.6.8.7 Block icon for ModPreCon

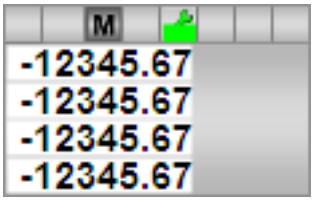
### Block icons for ModPreCon

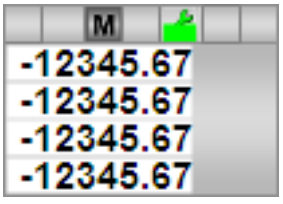


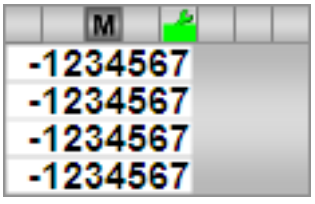




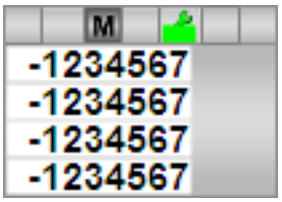








A variety of block icons are available with the following functions:



- Process tag type
- Operating modes
- Signal status, release for maintenance
- Tracking
- Memo display
- Process value (black, with and without decimal places)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 6.7 PIDConL - Continuous PID controller (Large)

## 6.7.1 Description of PIDConL

### Object name (type + number) and family

Type and number: FB 1874

Family: Control

### Area of application for PIDConL

The block is used for the following applications:

- Fixed setpoint control
- Cascade control
- Ratio control
- Split-range control
- Smith predictor closed-loop control
- Override control (override)

### How it works

The block is a PID controller with continuous output signal (manipulated variable). It is used to activate a final controlling element with continuous action input.

The block functions following the PID algorithm with a delayed D component and an integrator with double precision.

The block is suitable for controlling sluggish control loops, for example, for temperatures and filling levels, and high-speed control loops, for example, for flow rates and speed. For a given CPU, a compromise has to be made between the number of controllers and the frequency with which the individual controllers have to be processed. The faster the modulated control loops are, i.e. the more frequently the manipulated variables have to be calculated per time unit, the lower the number of controllers that can be installed.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the control loop monitoring to work as planned in the trend view of the controller faceplates, the

```
S7_xarchive:='Value, shortterm;'
```

attributes in the process tag types for control loops at the controller function block must be set for the following tags:

- Input parameters:
  - CPI_In
- Output parameters
  - MV
  - MV_HiAct
  - MV_LoAct
  - LoopClosed
  - SP
  - PV_Out
  - PV_ToleHi
  - PV_ToleLo

For the PIDConL block, the Advanced Process Library contains templates for process tag types as examples and there is a example project (APL_Example_xx, xx designates the language variant) containing different application cases for this block. Several application cases are simulated in the example project and serve to explain how the block works.

Examples of process tag types:

- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- Override control (Page 2846)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- PID controller for PA/FF devices (PIDControl_Lean_Fb) (Page 2821)

Application cases in example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)
- Cascade control of temperature by using the heat flow (CascadeSim) (Page 2873)
- Control loop monitoring for simulation with colored noise (ConPerMonSim) (Page 2875)
- Feedforward control to compensate a measurable disturbance variable (DisturbCompSim) (Page 2875)
- Operating point-oriented adaptation of parameters (gain scheduling) for non-linear processes (GainSchedSim) (Page 2876)

- Override control on a pipeline (OverrideSim) (Page 2877)
- Smith predictor for a dead time system (SmithPredictorSim) (Page 2877)
- Filtering of noisy measured values in a control loop (SigSmoothSim) (Page 2877)

### Startup characteristics

Use the `Feature` bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

The following output parameters are written with the corresponding input parameters:

- `PV_HysOut`
- `PV_AH_Out`
- `PV_WH_Out`
- `PV_TH_Out`
- `PV_AL_Out`
- `PV_WL_Out`
- `PV_TL_Out`

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section PIDConL I/Os (Page 1039).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutAct.Value` |
| 6 | Invalid signal status |
| 7 | `ManAct.Value` |
| 8 | `SP_ExtAct.Value` |
| 9 | `MV_ForOn.Value` |
| 10 | `MV_TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value` OR `MV_ForOn.Value`) |
| 11 | `MV.Value` > `ManLoLim` |
| 12 | `SimLiOp.Value` |
| 13 | "Interlock" button is enabled OR `Intlock.ST` ≠ 16#FF |
| 14 | 0 = Open padlock in the block icon<br>1 = Closed padlock in block icon |
| 15 - 17 | Not used (can be set to 1 if `Intl.Status` = 16#60) |
| 18 | `SimOn` AND `ManAct` |

| Status bit | Parameter |
|---|---|
| 19 | AdvCoAct |
| 20 | 1 = Input parameter Rbk is not interconnected (RbkOut.ST = 16#FF) |
| 21 | NegGain |
| 22 | 1 = SP ramp active |
| 23 | OptimEn |
| 24 | OptimOcc |
| 25 | Not used (can be set to 1 if Intl.Status = 16#60) |
| 26 | Display of BypassAct.Value in faceplate (display and operator controls) and block icon |
| 27 | AdvCoModSP |
| 28 | Not used (can be set to 1 if Intl.Status = 16#60) |
| 29 | BypProt |
| 30 | Dead band is temporarily disabled |
| 31 | Bypass information for display in block icon |

### Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | PV_AH_Act.Value |
| 2 | PV_WH_Act.Value |
| 3 | PV_TH_Act.Value |
| 4 | PV_TL_Act.Value |
| 5 | PV_WL_Act.Value |
| 6 | PV_AL_Act.Value |
| 7 | PV_AH_En OR Feature.Bit31 |
| 8 | PV_WH_En OR Feature.Bit31 |
| 9 | PV_TH_En OR Feature.Bit31 |
| 10 | PV_TL_En OR Feature.Bit31 |
| 11 | PV_WL_En OR Feature.Bit31 |
| 12 | PV_AL_En OR Feature.Bit31 |
| 13 | PV_AH_MsgEn |
| 14 | PV_WH_MsgEn |
| 15 | PV_TH_MsgEn |
| 16 | PV_TL_MsgEn |
| 17 | PV_WL_MsgEn |
| 18 | PV_AL_MsgEn |
| 19 | ER_AH_Act.Value |
| 20 | ER_AL_Act.Value |
| 21 | ER_AH_En OR Feature.Bit31 |
| 22 | ER_AL_En OR Feature.Bit31 |
| 23 | ER_AH_MsgEn |

| Status bit | Parameter |
|---|---|
| 24 | ER_AL_MsgEn |
| 25 | RbkWH_Act.Value |
| 26 | RbkWL_Act.Value |
| 27 | RbkWH_En OR Feature.Bit31 |
| 28 | RbkWL_En OR Feature.Bit31 |
| 29 | RbkWH_MsgEn |
| 30 | RbkWL_MsgEn |
| 31 | MS_RelOp |

### Status word allocation for Status3 parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 | Delay of the PV_AH_Lim message |
| 9 | Delay of the PV_WH_Lim message |
| 10 | Delay of the PV_TH_Lim message |
| 11 | Delay of the PV_TL_Lim message |
| 12 | Delay of the PV_WL_Lim message |
| 13 | Delay of the PV_AL_Lim message |
| 14 | Delay of the ER_AH_Lim message |
| 15 | Delay of the ER_AL_Lim message |
| 16 | Collection of message delays |
| 17 | BypassAct.Value |
| 18 - 19 | Not used |
| 20 | 1= Suppressed messages |
| 21 - 23 | Not used |
| 24 | Feature2.Bit2: Separate bypass signal |
| 25 | Hidden bypass signal in Intlock |
| 26 | LockAct.Value |
| 27 | SP_UpRaAct, SP_DnRaAct limits enabled for gradient mode (SP_RateOn = 1) |
| 28 | GrpErr.Value |
| 29 | RdyToStart.Value |
| 30 | 1 = Input parameter MV_ChnST is interconnected |
| 31 | Internal error |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 28 | Not used |
| 29 | 1 = Input parameter `SP_LiRmpTime` is not interconnected (`SP_LiRmpTime.ST = 16#FF`) |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

PIDConL modes (Page 1022)

## 6.7.2 PIDConL modes

### PIDConL operating modes

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) section.

### "Program mode for controllers"

General information on "Program mode for controllers" is available in the section Program mode for controllers (Page 85).

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =0 and `Feature.Bit5` =1 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| RbkOut.ST | 16#80 | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| SP.ST | 16#80 | 16#60 |
| SP_ExtOut.ST | 16#80 | 16#60 |
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_WH_Act.ST | 16#XX | 16#60 |
| PV_TH_Act.ST | 16#XX | 16#60 |
| PV_TL_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| PV_ToleHi.ST | 16#80 | 16#60 |
| PV_ToleLo.ST | 16#80 | 16#60 |
| ER.ST | 16#80 | 16#60 |
| ER_AH_Act.ST | 16#XX | 16#60 |
| ER_AL_Act.ST | 16#XX | 16#60 |

**Note**

The status of `RbkOut` will be 16#FF without Rbk. when `Feature.Bit5` = 0.

Description of PIDConL (Page 1017)

## 6.7.3 PIDConL functions

### Functions of PIDConL

The functions for this block are listed below.

### Generation of manipulated variables

The manipulated variable `MV` can be generated as follows:

| MV_For-On | Int-lock | ManAct | MV_Trk On | AdvCoAct AND NOT AdvCoModSP | MV = | Limit monitoring | State |
|---|---|---|---|---|---|---|---|
| 1 | - | - | - | - | `MV_Forced` | none | Forced tracking through constraint without limitation |
| 0 | 1 | - | - | - | Neutral position: depends on `SafePos`, `SafePos2` | none | Interlock state |
| 0 | 0 | 1 | - | - | `Man` | `ManHiLim` `ManLoLim` | Manual mode, set by the operator |
| 0 | 0 | 0 | 1 | - | `MV_Trk` | `MV_HiLim` `MV_LoLim` | Tracking with limitation |
| 0 | 0 | 0 | 0 | 1 | `AdvCoMV` | `MV_HiLim` `MV_LoLim` | Higher-level program mode |
| 0 | 0 | 0 | 0 | 0 | `P_Part` + `I_Part` + `D_Part` + `FFwd` | `MV_HiLim` `MV_LoLim` | Automatic mode (PID algorithm) |

If the controller is in "out of service" mode, the output parameter `MV` is set to the last valid value in manual mode or the neutral position manipulated variable depending on the `Feature` Bit (Neutral position manipulated variable takes effect at startup (Page 176)). Refer to the Out of service (Page 77) section for more on this.

### Tracking and limiting a manipulated variable

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

Tracking has a higher priority than interlock in this block.

### Neutral position

The block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### "Actuator active" information

If the manipulated variable `MV` is greater than the minimum manual limit `ManLoLim`, this is recognized as actuator active. This status can be used to indicate a customized symbol in the process image, for example, and is saved in the status word (see Status word section in Description of PIDConL (Page 1017)).

### Limit monitoring of position feedback

The block provides the standard function Limit monitoring of the feedback (Page 101).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### External/internal setpoint specification

The block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint limiting for external setpoints

The block provides the standard function Setpoint limiting for external setpoints (Page 222).

### Gradient limit of the setpoint

The block provides the standard function Gradient limit of the setpoint (Page 132).

### Using setpoint ramp

The block provides the standard function Using setpoint ramp (Page 131).

### Tracking setpoint in manual mode

The block provides the standard function Tracking setpoint in manual mode (Page 222).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV, SimPV_Li`)
- Position feedback (`SimRbk, SimRbkLi`)

### Bypass function

This block provides the standard function Bypassing signals (Page 115).

### Limit monitoring of the process value

The block provides the standard function Limit monitoring of the process value (Page 93) with the alarm delay type Two time values per limit pair (Page 227). With the `Feature` Bit Separate delay times for each alarm (Page 181), the alarm delay type Two time values for each individual limit (Page 228) can be activated.

### Providing limits at the output

For further connections to the other blocks, the following input parameters are also displayed with the corresponding output parameters:

- `PV_HysOut` := `PV_Hyst`
- `PV_AH_Out` := `PV_AH_Lim`
- `PV_WH_Out` := `PV_WH_Lim`
- `PV_TH_Out` := `PV_TH_Lim`
- `PV_TL_Out` := `PV_TL_Lim`
- `PV_WL_Out` := `PV_WL_Lim`
- `PV_AL_Out` := `PV_AL_Lim`
- `ER_AH_LimOut` := `ER_AH_Lim`
- `ER_AL_LimOut` := `ER_AL_Lim`

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

The `Feature.Bit14` can be used to feedforward an external error signal `ER_Ext`. When the external error signal is activated, `ER_Ext` affects both the dead band and the error signal alarm generation.

### Delay alarm for control deviation at setpoint step changes

The block provides the standard function Delay alarm for control deviation at setpoint step changes (Page 216).

### Limit monitoring of error signal

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102). The monitoring of error signal works with the alarm delay type Two time values per limit pair (Page 227). With the `Feature` Bit Separate delay times for each alarm (Page 181), the alarm delay type Two time values for each individual limit (Page 228) can be activated.

### Inverting control direction

The block provides the standard function Inverting control direction (Page 217).

### Physical standardization of setpoint, manipulated variable and process value

Controller gain `Gain` is entered either using a physical variable or as standardized value.

`Gain` as a physical variable:

The standardized variables retain their default values:

- `NormPV.High` = 100 and `NormPV.Low` = 0
- `NormMV.High` = 100 and `NormMV.Low` = 0

The effective gain is:

`GainEff` = `Gain`

Entering a standardized `Gain` (dimensionless):

Change the standardized variables to the actual range of the process values and manipulated variables.

- Internal and external setpoints; the process value and corresponding parameters are entered according to the physical measuring range of the process value.
- The manual value, the tracking value of the manipulated variable, feedforward control and the corresponding parameters are set according to the physical measuring range of the manipulated variable.

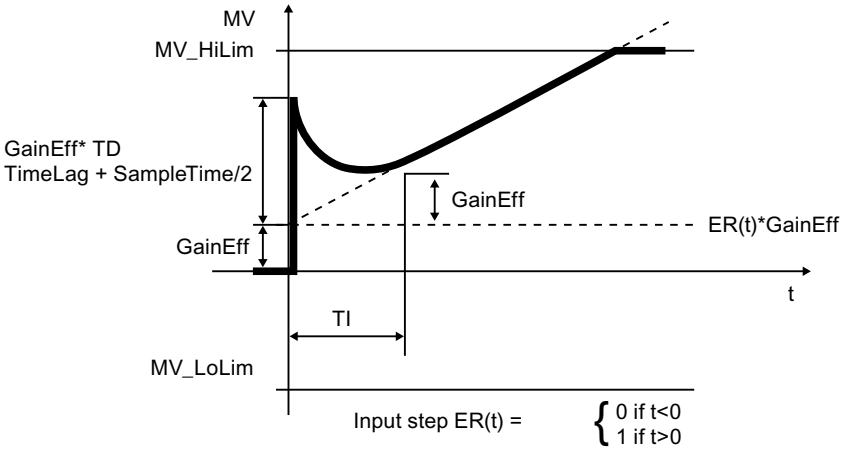
The effective gain is:

`GainEff` = (`NormMV.High` - `NormMV.Low`) / (`NormPV.High` - `NormPV.Low`) · `Gain`

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### PID algorithm



The manipulated variable is generated in automatic mode according to the following algorithm:

`MV` = `GainEff` · (1 + 1 / (`TI` · s) + (`TD` · s) / (1 + `TD` / `DiffGain` · s)) · `ER`

Where:

s = Complex number

The following step response occurs:

**Note**

The formula describes a standard application where P, I and D components are activated and the P and D components are not in the feedback circuit (`PropSel` = `1`, `TI` <> `0` and `IntSel` = `1`, `TD` <> `0` and `DIffSel` = `1`, `DiffToFbk` = `0` and `PropFacSP` = 1).

The D component delay is derived from `TD` / `DiffGain`.

- The P component is displayed at the `P_Part` I/O and can be deactivated using `PropSel` = 0 .
- The I component is displayed at the I_Part I/O and can be deactivated using `TI = 0` or IntSel = 0. In deactivated state, I_Part is specified by MV_Offset and added to the manipulated variable. Make a selection for this value so that the remaining control deviation equals zero at the control loop's typical operating point, at least. `IntSel` is used for temporary deactivation of the I component. The I component is not reactivated until `TI <> 0` and `IntSel = 1`. After the I component is activated, the integrator continues working starting from `MV_Offset`.
- The D component is displayed at the `D_Part` I/O and can be deactivated using `TD` = 0 or `DiffSel` = `0`.

### Structure segmentation at controllers

The block provides the standard function Structure segmentation at controllers (Page 224).

### Anti-windup

The controller has an anti-windup function. The I component is frozen after the manipulated variable has reached limits (`MV_HiLim` or `MV_LoLim`).

### Feedforwarding and limiting disturbance variables

The block provides the standard function Feedforwarding and limiting disturbance variables (Page 223).

### Control zone

The block provides the standard function Using control zones (Page 220).

### Control loop is open (CascaCut)

The CascaCut output indicates whether the control loop within this block is open. In the open control loop, the master controller must be set to tracking mode to avoid until windup behavior. If you use this block in a cascade structure, then connect the output CascaCut to the input MV_TrkOn of the master controller.

CascaCut is active in the following cases:

- Block is not in automatic mode
- MV program mode is active
- Setpoint is not in external mode
- Interlock is active

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the process value PV_Out:
  The signal status of the output parameter PV_Out always corresponds to the signal status of input parameter PV or, if the block is in simulation mode, 16#60.
- Signal status for the setpoint value SP:
  The signal status of the SP output parameter is always equivalent to the signal status of input parameter SP_Ext or SP_Int, depending on how the setpoint is specified. If the internal setpoint SP_Int is used, the signal status is always output as 16#80.
- Signal status of the error signal ER:
  The signal status of output parameter ER is obtained from the worst signal status of the two output parameters PV_Out and SP and is output.
  The signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation.
  If the external error signal is activated (Feature.Bit14 = 1), the signal status of ER_Ext.ST is applied.
- Signal status for the manipulated variable MV:
  The signal status of output parameter MV is obtained in "automatic mode" or in "program mode" with default setpoint from the worst signal status of the two parameters FFwd and ER and is output. In "manual mode", the signal status is output as good. The signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation. In "manual mode", the signal status is output as good.

- Signal status for position feedback `RbkOut`:
  The signal status of `RbkOut` always corresponds to the signal status of input parameter `Rbk` or, if the block is in simulation mode, `16#60`.
- Worst signal status:
  The worst signal status `ST_Worst` for the block is formed from the following parameters:
  `Feature.Bit14` = 1 (external error signal)
  - `ER_Ext.ST`;
  - `FFwd.ST`;
  - `RbkOut.ST`;
  - `MV_ChnST.ST`;

  `Feature.Bit14` = 0 (external error signal)
  - `SP.ST`;
  - `PV_Out.ST`;
  - `FFwd.ST`;
  - `RbkOut.ST`;
  - `MV_ChnST.ST`;

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6 | Ramp rate calculation (Page 191) |
| 8 | Separate delay times for each alarm (Page 181) |
| 9 | Substitution value is active if the block is in bypass (Page 199) |
| 11 | Gradient limitation with time duration (Page 197) |
| 12 | Control zone with specified I component (Page 171) |
| 13 | Control zone with frozen I component (Page 171) |
| 14 | External control deviation (Page 161) |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 18 | Disabling bumpless switchover to automatic mode for controllers (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | SP following PV in open loop has no priority over SP_Ext and SP limits (Page 193) |
| 24 | Enabling local operator authorization (Page 169) |

| Bit | Function |
|---|---|
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Dead band is temporarily disabled (Page 152) |
| 31 | Limits disabled in faceplate (Page 206) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" `AutModOp` |
| 1 | 1 = Operator can switch to "manual mode" `ManModOp` |
| 2 | 1 = Operator can switch to "Out of service" mode `OosOp` |
| 3 | 1 = Operator can switch to "program mode" `AdvCoEn` |
| 4 | 1 = Operator can switch the setpoint to "external" `SP_ExtOp` |
| 5 | 1 = Operator can switch the setpoint to "internal" `SP_IntOp` |
| 6 | 1 = Operator can change the internal setpoint `SP_Int` |
| 7 | 1 = Operator can change the manual parameter `Man` |
| 8 | 1 = Operator can change operation high limit of the setpoint `SP_InHiLim` |
| 9 | 1 = Operator can change operation low limit of the setpoint `SP_InLoLim` |
| 10 | 1 = Operator can change the operation high limit of the manipulated variable `ManHiLim` |
| 11 | 1 = Operator can change the operation low limit of the manipulated variable `ManLoLim` |
| 12 | 1 = Operator can enable the setpoint's gradient limitation function `SP_RateOn` |
| 13 | 1 = Operator can change the setpoint's high limit for the ramp `SP_UpRaLim` |
| 14 | 1 = Operator can change the setpoint's low limit for the ramp `SP_DnRaLim` |
| 15 | 1 = Operator can switch between the time value or the value for the ramp `SP_RmpModTime` |
| 16 | 1 = Operator can change the ramp time `SP_RmpTime` |
| 17 | 1 = Operator can change the target setpoint `SP_RmpTarget` for the setpoint ramp |
| 18 | 1 = Operator can enable the setpoint ramp function `SP_RmpOn` |
| 19 | 1 = Operator can permit the PID optimization function `OptimEn` |
| 20 | 1 = Operator can enable the track setpoint in "manual mode" function `SP_TrkPV` |

| Bit | Function |
|---|---|
| 21 | 1 = Operator can enable the bumpless switchover from external to internal `SP_TrkExt` |
| 22 | 1 = Operator can change the gain parameter `Gain` |
| 23 | 1 = Operator can change the integral time parameter `TI` |
| 24 | 1 = Operator can change the derivative time parameter `TD` |
| 25 | 1 = Operator can change the derivative gain parameter `DiffGain` |
| 26 | 1 = Operator can change the dead band parameter `DeadBand` |
| 27 | 1 = Operator can change the control zone parameter `ConZone` |
| 28 | 1 = Operator can change the derivative gain parameter `ER_AH_DFac` |
| 29 | 1 = Operator can change the derivative gain parameter `ER_AL_DFac` |
| 30 | Not used |
| 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (process value) `PV_AH_Lim` for the high alarm |
| 1 | 1 = Operator can change the limit (process value) `PV_WH_Lim` for the high warning |
| 2 | 1 = Operator can change the limit (process value) `PV_TH_Lim` for the high tolerance |
| 3 | 1 = Operator can change the hysteresis (process value) `PV_Hyst` |
| 4 | 1 = Operator can change the limit (process value) `PV_TL_Lim` for the low tolerance |
| 5 | 1 = Operator can change the limit (process value) `PV_WL_Lim` for the low warning |
| 6 | 1 = Operator can change the limit (process value) `PV_AL_Lim` for the low alarm |
| 7 | 1 = Operator can change the limit (error signal) `ER_AH_Lim` for the high alarm |
| 8 | 1 = Operator can change the hysteresis (error signal) `ER_Hyst` |
| 9 | 1 = Operator can change the limit (error signal) `ER_AL_Lim` for the low alarm |
| 10 | 1 = Operator can change the limit (position feedback) `RbkWH_Lim` for the high warning |
| 11 | 1 = Operator can change the hysteresis (position feedback) `RbkHyst` |
| 12 | 1 = Operator can change the limit (position feedback) `RbkWL_Lim` for the low warning |
| 13 | Not Used |
| 14 | 1 = Operator can activate bypass functionality |
| 15 | 1 = Operator can deactivate bypass functionality |
| 16 | 1 = Operator can activate the Simulation function `SimOn` |
| 17 | 1 = Operator can activate the Release for maintenance function `MS_RelOp` |
| 18 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 19 | 1 = Operator can activate / deactivate messages via `PV_WH_MsgEn` |
| 20 | 1 = Operator can activate / deactivate messages via `PV_TH_MsgEn` |
| 21 | 1 = Operator can activate / deactivate messages via `PV_TL_MsgEn` |
| 22 | 1 = Operator can activate / deactivate messages via `PV_WL_MsgEn` |
| 23 | 1 = Operator can activate / deactivate messages via `PV_AL_MsgEn` |
| 24 | 1 = Operator can activate / deactivate messages via `ER_AH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `ER_AL_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `RbkWH_MsgEn` |
| 27 | 1 = Operator can activate / deactivate messages via `RbkWL_MsgEn` |

| Bit | Function |
|---|---|
| 28 | 1 = Operator can change the simulation value SimPV |
| 29 | 1 = Operator can change the simulation value SimRbk |
| 30 | 1 = Operator can activate the derivative action to the feedback path DiffToFbk |
| 31 | 1 = Operator can change the proportional action to the feedback path PropFacSP |

The block has the following permissions for the OS2Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

## Interlocks

This block provides the following interlocks:

- Interlock without reset ("Interlock")

If interlock is active without forcing (MV_ForOn =0) the manipulated value MV.Value is set to the neutral position value ( Neutral position for motors, valves and controllers (Page 54) ).

You can find additional information on this in the section Interlocks (Page 107).

## Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

## Release for maintenance

The block provides the standard function Release for maintenance (Page 70)

## Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

## Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

## Button labels

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- AutModOp
- ManModOp
- AdvCoOn
- OosOp
- SP_ExtOp
- SP_IntOp

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

## 6.7.4 PIDConL error handling

### Error handling of PIDConL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

## Overview of error numbers

The ErrorNum output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 30 | The value of PV can no longer be displayed in the REAL number field. |
| 31 | The value of SP_Ext can no longer be displayed in the REAL number field. |
| 32 | The value of FFwd can no longer be displayed in the REAL number field. |
| 33 | The value of MV_Trk can no longer be displayed in the REAL number field. |
| 34 | The value of MV_Forced can no longer be displayed in the REAL number field. |
| 35 | The value of Rbk can no longer be displayed in the REAL number field. |
| 36 | The value of MV can no longer be displayed in the REAL number field. |
| 51 | AutModLi = 1 and ManModLi = 1<br>SP_LiOp = 1 and SP_IntLi = 1 and SP_ExtLi = 1 |
| 52 | Feature.Bit30 = 1 and MeanMV.ST = 16#78 |
| 59 | = 1, "Gain is negative" |
| 60 | \|TI\| < SampleTime / 2 |
| 61 | \|TD\| < SampleTime |
| 62 | DiffGain < 1 or DiffGain > 10 |
| 63 | TD / DiffGain < SampleTime / 2 |
| 64 | PropFacSP < 0 or PropFacSP > 1 |
| 66 | NormPV_High = NormPV_Low |
| 74 | ConZone < 0.0 |

## Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 6.7.5 PIDConL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId2` | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId2`, SIG 6).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>PV - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>PV - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>PV - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>PV - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>PV - low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>PV - low alarm limit violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>ER - high alarm limit violated |
| | SIG 8 | Alarm - low | $$BlockComment$$<br>ER - low alarm limit violated |
| MsgEvId2 | SIG 7 | Warning - high | $$BlockComment$$<br>Rbk - high warning limit violated |
| | SIG 8 | Warning - low | $$BlockComment$$<br>Rbk - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@5%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@6%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 3<br>Status 16#@7%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 4<br>Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | Process value PV_Out |
| 5 | Control deviation ER |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | Not allocated |
| 9 | Not allocated |
| 10 | Not allocated |

The associated values 6 ... 7 are allocated to the parameters ExtVa106 ... ExtVa107 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | Position feedback RbkOut |
| 5 | Signal status ExtMsg1 |
| 6 | Signal status ExtMsg2 |
| 7 | Signal status ExtMsg3 |
| 8 | Signal status ExtMsg4 |
| 9 | ExtVa209 |
| 10 | ExtVa210 |

The associated values 9 ... 10 are allocated to the parameters ExtVa209 ... ExtVa210 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 6.7.6 PIDConL I/Os

I/Os of PIDConL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoEn | 1 = Enable "program mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoOn* | 1 = Enable "program mode" via faceplate.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | BOOL | 0 |
| AdvCoModSP | Type of "program mode":<br>1 = Setpoint specification<br>0 = Manipulated variable specification | BOOL | 1 |
| AdvCoMstrOn | Activate (0-1) or deactivate (1-0) "program mode" via edge transition | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoMV | Specified value from the external program.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | REAL | 0.0 |
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation for batch control | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Interlock bypass during simulation | BOOL | 0 |
| BypLiOp | 1 = Bypass commands via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypLock | 1 = Bypass activation or deactivation is locked for operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypPV | Substitution value if block is in bypass | REAL | 0.0 |
| BypPVLi | 1 = Select bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypPVOp | 1 = Select bypass PV (via operator) | BOOL | 0 |
| ConZone | Width of control zone | REAL | 0.0 |
| CPI_In | Input for control performance index, which is calculated by the assigned ConPerMon block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadBand | Width of dead band | REAL | 0.0 |
| DiffGain | Gain of differentiator [1..10] DiffGain = TD / (delay time of D component) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 5.0<br>• 16#80 |
| DiffSel | 1 = D component activated | BOOL | 1 |
| DiffToFbk | 1 = D component is placed in the feedback | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ER_A_DC* | Delay time for incoming ER high/low or only low alarms [s] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_AH_DC* | Delay time for incoming ER high alarms [s] | REAL | 0.0 |
| ER_A_DG* | Delay time for outgoing ER high/low or only low alarms [s] | REAL | 0.0 |
| ER_AH_DG* | Delay time for outgoing ER high alarms [s] | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AH_DFac* | Delay factor at positive setpoint step changes for incoming alarms at the error signal monitoring ER_AH_Lim | REAL | 0.0 |
| ER_AH_Lim | Alarm limit (high) for error signal monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AL_DFac* | Delay factor at negative setpoint step changes for incoming alarms at the error signal monitoring ER_AL_Lim | REAL | 0.0 |
| ER_AL_En | 1 = Activate alarm (low) for error signal monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for error signal monitoring | REAL | -100.0 |
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for error signal monitoring | BOOL | 1 |
| ER_Ext | External error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_Hyst | Alarm hysteresis for error signal | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | 1 = Binary input for freely selectable message 1 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | 1 = Binary input for freely selectable message 2 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg3 | 1 = Binary input for freely selectable message 3 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | 1 = Binary input for freely selectable message 4 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa209 | Associated value 9 for messages (MsgEvID2) | ANY | |
| ExtVa210 | Associated value 10 for messages (MsgEvID2) | ANY | |
| Feature | I/O for additional functions (Page 1024) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1024) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FFwd* | Input for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| FFwdHiLim | Limit (high) for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| FFwdLoLim | Limit (low) for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• -100.0<br>• 16#80 |
| Gain | Proportional gain<br>Gain.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is in effect | BOOL | 1 |
| IntHoldNeg | 1 = Integrator cannot run in negative direction | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| IntHoldPos | 1 = Integrator cannot run in positive direction | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Intlock | 0 = Interlock without reset is in effect<br>Once the interlock condition has cleared, the block can be operated without reset<br>1 = Interlock not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| IntSel | 1 = I component activated | BOOL | 1 |
| Man* | Manual specification for the manipulated variable | REAL | 0.0 |
| ManHiLim | Limit (high) for manual parameter Man | REAL | 100.0 |
| ManLoLim | Limit (low) for manual parameter Man | REAL | 0.0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Operating mode switchover between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvID1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgEvID2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Hotspot-Text (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_ChnST | Signal status of output channel for MV<br>Should be connected to an output channel block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| MV_Forced* | Forced manipulated variable that is not limited and assumes top priority | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_ForOn | 1 = Output forced manipulated variable MV_Forced unlimited at output MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiLim | Limit (high) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_LoLim | Limit (low) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Mean | Mean value of the MV in the time window | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| MV_Offset | Manipulated variable for ER=0, operating point for controller with deactivated I component | REAL | 0.0 |
| MV_OpScale | OS display range for manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_SafePos | Manipulated variable neutral position | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Trk* | Tracking value for the manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| NegGain | 0 = Effective proportional gain GainEff is positive<br>1 = Effective proportional gain GainEff is negative | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NormMV | Manipulated variable range (MV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| NormPV | Process value range (PV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OptimEn* | 1 = Enable optimization of PID parameters by PID tuner | BOOL | 0 |
| OptimOcc* | 1 = Optimization running | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1024) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1024) | STRUCT<br>• Bit 0: BOOL<br>• Bit 18: BOOL<br>• Bit 19: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| OS2Perm | I/O for operator permissions (Page 1024) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| PropFacSP | Applying the P component to the feedback [0..1].<br>0 = P component fully in feedback | REAL | 1.0 |
| PropSel | 1 = Activate P component | BOOL | 1 |
| PV* | Process value (controlled variable) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_A_DC* | Delay time for incoming PV high/low or only low alarms [s] | REAL | 0.0 |
| PV_AH_DC* | Delay time for incoming PV high alarms [s] | REAL | 0.0 |
| PV_A_DG* | Delay time for outgoing PV high/low or only low alarms [s] | REAL | 0.0 |
| PV_AH_DG* | Delay time for outgoing PV high alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_Hyst | Hysteresis for PV alarm, warning and tolerance limits | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_T_DC* | Delay time for incoming PV high/low or only low tolerance messages [s] | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_TH_DC* | Delay time for incoming PV high tolerance messages [s] | REAL | 0.0 |
| PV_T_DG* | Delay time for outgoing PV high/low or only low tolerance messages [s] | REAL | 0.0 |
| PV_TH_DG* | Delay time for outgoing PV high tolerance messages [s] | REAL | 0.0 |
| PV_TH_En | 1 = Enable PV tolerance limit (high) | BOOL | 0 |
| PV_TH_Lim | Limit PV tolerance message (high) | REAL | 85.0 |
| PV_TH_MsgEn | 1 = Enable message for PV tolerance message (high) | BOOL | 1 |
| PV_TL_En | 1 = Enable PV tolerance limit (low) | BOOL | 0 |
| PV_TL_Lim | Limit PV tolerance message (low) | REAL | 15.0 |
| PV_TL_MsgEn | 1 = Enable message for tolerance message (low) | BOOL | 1 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_W_DC* | Delay time for incoming PV high/low or only low warnings [s] | REAL | 0.0 |
| PV_WH_DC* | Delay time for incoming PV high warnings [s] | REAL | 0.0 |
| PV_W_DG* | Delay time for outgoing PV high/low or only low warnings [s] | REAL | 0.0 |
| PV_WH_DG* | Delay time for outgoing PV high warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| Rbk* | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 1 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 100.0 |
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 1 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 0.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RefStdDevIn | Reference value of PV standard deviation (sigma) in defined "good" state of control loop | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| RstBypLi | 1 = Reset bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstBypOp | 1 = Reset bypass PV (via operator) | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | 1 = Neutral position (Page 54) for controller manipulated variable is ManHiLim<br>0 = Neutral position for controller manipulated variable is ManLoLim | BOOL | 0 |
| SafePos2 | Neutral position for controller manipulated variable:<br>0 = SafePos is valid<br>1 = Neutral position is MV_SafePos<br>2 = Neutral position is last manipulated variable (stop) | INT | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SettliTime | Settling time [s] of the control loop determined by the ConPerMon block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#78 |
| SettliFactor | Factor to increase the settling time to adjust the dead band | REAL | 2.0 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Vale: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaLim* | Limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| SP_ExHiLim | Limit (high) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_ExLoLim | Limit (low) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Ext* | external setpoint - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi* | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_InHiLim | Limit (high) of internal setpoint | REAL | 100.0 |
| SP_InLoLim | Limit (low) of internal setpoint | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |
| SP_IntLi* | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 0 |
| SP_LiDnRaLim | Linkable limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_LiRmpTime | Linkable time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiUpRaLim | Linkable gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_RateOn* | 1 = Activate limitation of setpoint gradients | BOOL | 0 |
| SP_RmpModTime | 1 = Use time values (SP_RmpTime, SP_LiRmpTime)<br>0 = Use gradient limits (SP_DnRaLim, SP_LiDnRaLim, SP_UpRaLim, SP_LiUpRaLim) | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |
| SP_RmpTime* | Time [Time unit] for setpoint ramp from current SP up to SP_RmpTarget or time [Time unit] for gradient limitation in ramp mode duration.<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 1 |
| SP_TrkPV | 1 = Setpoint follows PV in "manual mode" and with tracking | BOOL | 0 |
| SP_UpRaLim* | Gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TD | Derivative time [s]<br>TD.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| TI | Integral time [s]<br>TI.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#FF |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>Value: REAL<br>ST: BYTE | <br>0.0<br>16#FF |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>Value: REAL<br>ST: BYTE | <br>0.0<br>16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoAct | 1 = "Program mode" enabled.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoRdy | 1 = "Program mode" available | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutAct | 1 = "Automatic mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypassAct | 1 = Bypass is activated in this block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CascaCut | Cascade connection:<br>1 = Control chain from primary to secondary controller is interrupted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DynDeadBand | Dynamic dead band | REAL | 0.0 |
| D_Part | D component of PID algorithm | REAL | 0.0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_A_DCOut | Effective delay time [s] for incoming alarms at the error signal monitoring | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_AH_Act | 1 = Alarm limit (high) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ER_AL_Act | 1 = Alarm limit (low) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ER_AL_LimOut | ER_AL_Lim as output | REAL | 0.0 |
| ER_AH_LimOut | ER_AH_Lim as output | REAL | 0.0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see PIDConL error handling (Page 1034) | INT | -1 |
| FFwdHiAct | 1 = Limit (high) for additive disturbance variable activation violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FFwdLoAct | 1 = Limit (low) for additive disturbance variable activation violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GainEff | Effective proportional gain depends on NegGain, Gain, NormPV, and NormMV | REAL | 1.0 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| I_Part | I component of PID algorithm | REAL | 0.0 |
| LockAct | 1 = Interlock is in effect | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LoopClosed | 1 = Control loop closed<br>0 = Control loop open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ManHiOut | Limit (high) for "manual mode", corresponds to input parameter ManHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| ManLoOut | Limit (low) for "manual mode", corresponds to input parameter ManLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgAckn2 | Message acknowledgement status 2 (output ACK_STATE of second ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | 1 = Alarm error 1 (output ERROR of the first ALARM_8P) | BOOL | 0 |
| MsgErr2 | 1 = Alarm error 2 (output ERROR of the second ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| MsgStat2 | Message status 2 (output STATUS of second ALARM_8P) | WORD | 16#0000 |
| MV | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_UnitOut | Unit of measure for manipulated variable, for interconnecting to the MV_Unit input parameter of the ConPerMon block | INT | 0 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS2PermOut | Display of OS2_Perm | WORD | 16#FFFF |
| OS2PermLog | Display of OS2_Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| PhaseDeadBand | Phase for the dynamic adjustment of the dead band<br>0: Dead band enabled<br>1: Dead band disabled<br>2: Settling time | INT | 0 |
| P_Part | P component of PID algorithm | REAL | 0.0 |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_AH_Out | PV - High alarm limit output | REAL | 0.0 |
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_AL_Out | PV - Low alarm limit output | REAL | 0.0 |
| PV_HysOut | PV - Alarm hysteresis output | REAL | 0.0 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE<br>• Bit 1: BOOL of internal fill byte (Bypass information bit) | -<br>• 0.0<br>• 16#80<br>• 0 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_TH_Act | 1 = PV tolerance message (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_TH_Out | PV - High tolerance limit output | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_TL_Act | 1 = PV tolerance message (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_TL_Out | PV - Low tolerance limit output | REAL | 0.0 |
| PV_ToleHi | Limit (high) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_ToleLo | Limit (low) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WH_Out | PV - High warning limit output | REAL | 0.0 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WL_Out | PV - Low warning limit output | REAL | 0.0 |
| PV_UnitOut | Unit of measure for process value, for interconnecting to the PV_Unit input parameter of the ConPerMon block | INT | 0 |
| RbkOut | Output for position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RbkWL_Act | 1 = Warning (low) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SettlingTimer | Settling time for a closed control loop | REAL | 0.0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExHiAct | 1 = Limit (high) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExLoAct | 1 = Limit (low) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

### Calculation of the output parameter ER_A_DCOut

ER_A_DC is assigned by default to the output before a setpoint change.

ER_A_DCOut = ER_A_DC

In the case of a setpoint change in the positive direction during automatic mode, the output is calculated as follows:

ER_A_DCOut = Maximum (ER_A_DC, ER_AH_DFac * Setpoint difference)

In the case of a setpoint change in the negative direction during automatic mode, the output is calculated as follows:

ER_A_DCOut = Maximum (ER_A_DC, -1*ER_AH_DFac * Setpoint difference)

When the control circuit has stabilized again, meaning

(ER_AL_Lim + ER_Hyst) <= ER <= (ER_AH_Lim – ER_Hyst)

and the delay time for outgoing alarms ER_A_DG has expired, the output is reset again to ER_A_DC: ER_A_DCOut = ER_A_DC

### Activating and deactivating the function:

The function is deactivated (default) when the following applies: ER_AH_DFac = 0.0 and ER_AL_DFac = 0.0

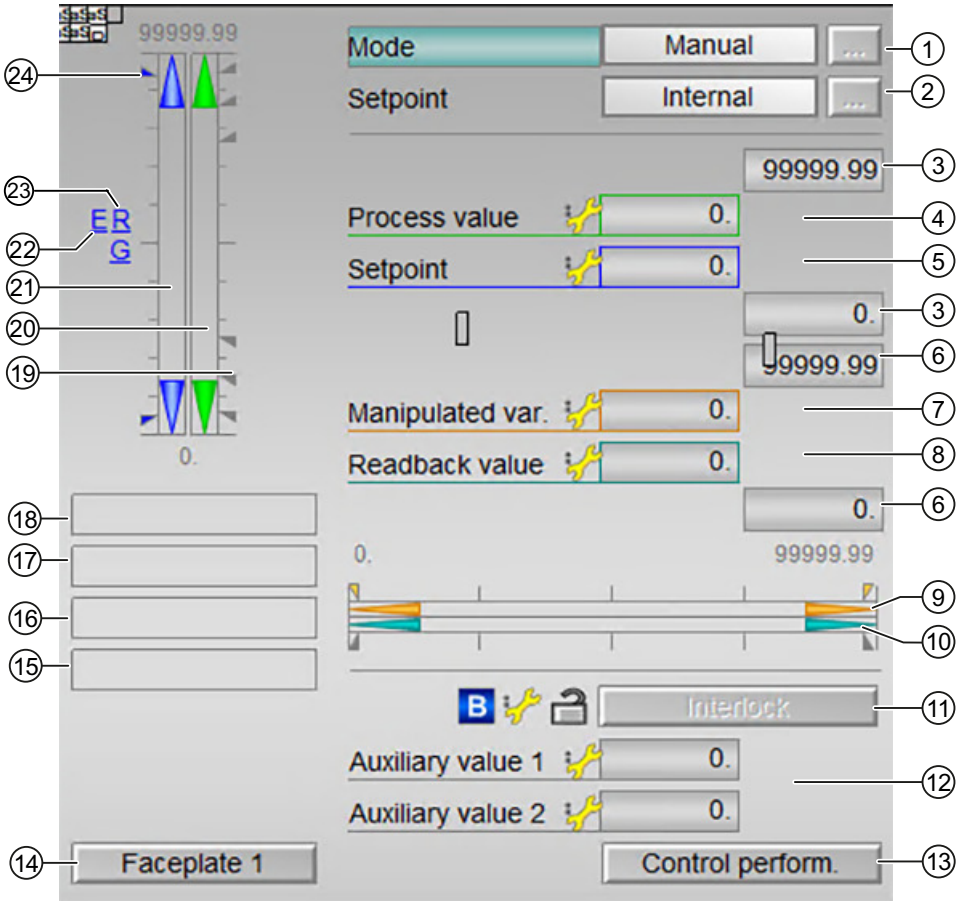
## 6.7.8 Operator control and monitoring

### 6.7.8.1 PIDConL views

#### Views of the PIDConL block



The block PIDConL provides the following views:

- PIDConL, PIDConS and PIDConR standard views (Page 1061)
- Alarm view (Page 336)
- Limit view of PID controllers (Page 325)
- Trend view (Page 341)
- Ramp view (Page 334)
- Parameter view of PID controllers (Page 315)
- PIDConL, PIDConS and PIDConR previews (Page 1066)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icons for PID and FM controller (Page 269)

Refer to the Structure of the faceplate (Page 279) and Block icon structure (Page 260) sections for general information about the faceplate and block icon.

### 6.7.8.2 PIDConL, PIDConS and PIDConR standard views

#### PIDConL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85) (not with PIDConS)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Displaying and switching the setpoint

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the setpoint specification.

You can find additional information on this in the section Setpoint specification - internal/ external (Page 136).

**Note**

With the PIDConR block, this area is only visible if you have set the `Feature` Bit Switching operator controls for external setpoint to visible (Page 154) to 1.

### (3) High and low scale range for the process value

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the engineering system. For more information refer Bar graph (Page 376) section.

### (4) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

### (5) Displaying and changing the setpoint including signal status

This area shows the current setpoint with the corresponding signal status.

Refer to the Changing values (Page 291) section for information on changing the setpoint. The setpoint specification also needs to be set to "Internal" for this block.

### (6) High and low scale range for the setpoint

This area is already set and cannot be changed.

### (7) Displaying and changing the manipulated variable including signal status

This area shows the current manipulated variable with the corresponding signal status.

Refer to the Changing values (Page 291) section for information on changing the manipulated variable. You can only make a change in manual mode.

### (8) Display of the position feedback including signal status

This display is only visible when the corresponding block input is connected.

This area shows the current feedback of the manipulated variable with the corresponding signal status.

### (9) Bar graph for the manipulated variable

This area shows the current manipulated variable in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (10) Bar graph for position feedback

This display is only visible when the corresponding block input is connected.

This area shows the current position feedback in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (11) Operator control and display area for interlock functions of the block (not with PIDConS)

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (12) Display for auxiliary values

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find more information on this in the section Displaying auxiliary values (Page 239).

**Note**

Auxiliary values are available only in `PIDConL` and `PIDConR`

### (13) Navigation button for the standard view of the ConPerMon block

Use this navigation button to open the standard view of the ConPerMon block. The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the section Opening additional faceplates (Page 234) for more on this.

### (14) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the section Opening additional faceplates (Page 234) for more on this.

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (16) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in the section Simulating signals (Page 64).

### (17) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (18) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Optimizing"
- "Tracking"
- "Forced tracking"
- "Load SP"
- "SP ramp active"

### (19) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

### (20) Bar graph for the process value

This area shows the current process value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (21) Bar graph for the setpoint

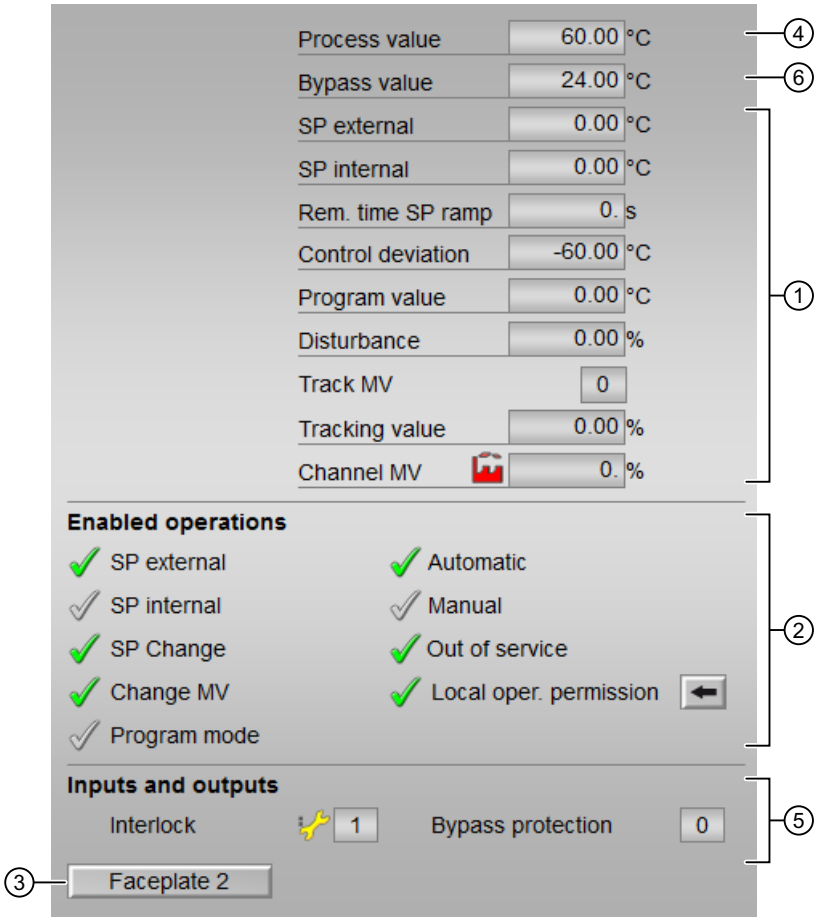
This area shows the current setpoint in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (22) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (23) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).



### (24) Limit display for the setpoint

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the engineering system (ES).

### 6.7.8.3 PIDConL, PIDConS and PIDConR previews

#### Preview of PIDConL

The preview shows you the parameters that you, as an OS operator, can control. You cannot control anything in this view, however.

#### (1) Preview area

This area shows you a preview for the following values:

- "SP external": currently applicable external setpoint
  - With the PIDConR block, this area is only visible if you have set the `Feature` Bit Switching operator controls for external setpoint to visible (Page 154) to 1
- "SP internal": currently applicable internal setpoint
- "Rem. time SP ramp" : Remaining time to reach the ramp target value (not with PIDConS)
- "Error signal": Current control deviation
- "Program value": Default value for program mode (not with PIDConS)
- "Disturbance variable": Additive value for feedforward control (not with PIDConS)

- "Track MV": Track manipulated variable (value is 1)
- "Tracking value": effective manipulated variable for "Track manipulated variable"
- "Channel MV": Display of the manipulated variable by the output channel block

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations are shown here:

- "SP external": You can feedforward the external setpoint.
- "SP internal": You can feedforward the internal setpoint.
- "Change SP": You can change the setpoint.
- "Change MV": You can change the manipulated variable.
- "Program mode": You can switch to "program mode". (not with PIDConS)
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).

### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the section Opening additional faceplates (Page 234) for more on this.

### (4) Process value

This area displays the real process value (`PV`).

### (5) Inputs and outputs

This area shows the following parameters:

- "Interlock" (not with PIDConS):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock deact." (not with PIDConS):
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"

### (6) Bypass value

This area displays the bypass value (`BypPV`).

# 6.8 PIDConS - Continuous PID controller (Small)

## 6.8.1 Description of PIDConS

### Object name (type + number) and family

Type and number: FB 1830

Family: Control

### Area of application for PIDConS

The block is used for the following applications:

- Fixed setpoint control

### How it works

The block is a PID controller with continuous output signal (manipulated variable). It is used to activate a final controlling element with continuous action input.

The block functions following the PID algorithm with a delayed D component and an integrator with double precision.

The block is suitable for controlling sluggish control loops, for example, for temperatures and filling levels, and high-speed control loops, for example, for flow rates and speed. For a given CPU, a compromise has to be made between the number of controllers and the frequency with which the individual controllers have to be processed. The faster the modulated control loops are, i.e. the more frequently the manipulated variables have to be calculated per time unit, the lower the number of controllers that can be installed.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the control loop monitoring to work as planned in the trend view of the controller faceplates, the

```
S7_xarchive:='Value, shortterm;'
```

attributes in the process tag types for control loops at the controller function block must be set for the following tags:

- Input parameters:
  - `CPI_In`
- Output parameters
  - `MV`
  - `MV_HiAct`
  - `MV_LoAct`
  - `LoopClosed`
  - `SP`
  - `PV_Out`
  - `PV_ToleHi`
  - `PV_ToleLo`

There are no templates for the PIDConS block for process tag types or simulated use cases in the example project (APL_Example_xx, xx represents the language variant). However, you can replace PIDConL with PIDConS in the following process tag types and use cases.

Examples of process tag types:

- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)

Application cases in example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)
- Control loop monitoring for simulation with colored noise (ConPerMonSim) (Page 2875)
- Operating point-oriented adaptation of parameters (gain scheduling) for non-linear processes (GainSchedSim) (Page 2876)
- Filtering of noisy measured values in a control loop (SigSmoothSim) (Page 2877)

### Startup characteristics

Use the `Feature` bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section PIDConS I/Os (Page 1082).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |

| Status bit | Parameter |
|---|---|
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | AutAct.Value |
| 6 | Invalid signal status |
| 7 | ManAct.Value |
| 8 | SP_ExtAct.Value |
| 9 | 1 = Input parameter MV_ChnST is interconnected |
| 10 | MV_TrkOn.Value AND NOT (ManAct.Value OR OosAct.Value) |
| 11 | MV.Value > MV_LoLim.Value |
| 12 - 17 | Not used |
| 18 | SimOn AND ManAct |
| 19 | Not used |
| 20 | 1 = Input parameter Rbk is not interconnected (Rbk.ST = 16#FF) |
| 21-22 | Not used |
| 23 | OptimEn |
| 24 | OptimOcc |
| 25 - 30 | Not used |
| 31 | Internal error |

## Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | PV_AH_Act.Value |
| 2 | PV_WH_Act.Value |
| 3-4 | Not used |
| 5 | PV_WL_Act.Value |
| 6 | PV_AL_Act.Value |
| 7 | PV_AH_En OR Feature.Bit31 |
| 8 | PV_WH_En OR Feature.Bit31 |
| 9-10 | Not used |
| 11 | PV_WL_En OR Feature.Bit31 |
| 12 | PV_AL_En OR Feature.Bit31 |
| 13 | PV_AH_MsgEn |
| 14 | PV_WH_MsgEn |
| 15-16 | Not used |
| 17 | PV_WL_MsgEn |
| 18 | PV_AL_MsgEn |
| 19 | Delay of the PV_AH_Lim message |
| 20 | Delay of the PV_WH_Lim message |
| 21 | Delay of the PV_WL_Lim message |
| 22 | Delay of the PV_AL_Lim message |

| Status bit | Parameter |
|---|---|
| 23 | Collection of message delays |
| 24 | 1= Suppressed messages |
| 25-28 | Not used |
| 29 | `GrpErr.Value` |
| 30 | `RdyToStart.Value` |
| 31 | `MS_RelOp` |

PIDConS messaging (Page 1080)

PIDConS block diagram (Page 1091)

## 6.8.2 PIDConS modes

### PIDConS operating modes

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) chapter.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the Manual and automatic mode for control blocks (Page 79) chapter.

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) chapter.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =0 and `Feature.Bit5` =1 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| SP_ExtAct.ST | 16#80 | 16#60 |
| SP.ST | 16#80 | 16#60 |
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_WH_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| PV_ToleHi.ST | 16#80 | 16#60 |
| PV_ToleLo.ST | 16#80 | 16#60 |
| ER.ST | 16#80 | 16#60 |

PIDConS I/Os (Page 1082)

## 6.8.3 PIDConS functions

### Functions of PIDConS

The functions for this block are listed below.

### Generation of manipulated variables

The manipulated variable MV can be generated as follows:

| ManAct | MV_TrkOn | AdvCoAct AND NOT AdvCoModSP | MV = | Limit monitoring | State |
|---|---|---|---|---|---|
| 1 | - | - | Man | MV_HiLim<br>MV_LoLim | Manual mode, set by the operator |
| 0 | 1 | - | MV_Trk | MV_HiLim<br>MV_LoLim | Tracking with limitation |
| 0 | 0 | 0 | P_Part<br>+ I_Part<br>+ D_Part | MV_HiLim<br>MV_LoLim | Automatic mode (PID algorithm) |

If the controller is in "out of service" mode, the output parameter MV is set to the last valid value in manual mode or the neutral position manipulated variable depending on the Feature Bit (Neutral position manipulated variable takes effect at startup (Page 176)). Refer to the Out of service (Page 77) section for more on this.

### Tracking and limiting a manipulated variable

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

### Neutral position

The block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- CSF

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### "Actuator active" information

If the manipulated variable MV is greater than the minimum manual limit MV_LoLim.Value, this is recognized as actuator active. This status can be used to indicate a customized symbol in the process image, for example, and is saved in the status word (see Status word section in Description of PIDConS (Page 1069)).

### External/internal setpoint specification

The block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint limitation

With this function, you can limit the setpoint to a range by means of the parameters `SP_HiLim` (high limit) and `SP_LoLim` (low limit). If the setpoint lies outside the range defined by you, it is limited to the valid range.

If the setpoint is at or above the limit `SP_HiLim`, this is displayed at the output `SP_HiAct = 1`.

If the setpoint is at or below the limit `SP_LoLim`, this is displayed at the output `SP_LoAct = 1`

### Tracking setpoint in manual mode

The block provides the standard function Tracking setpoint in manual mode (Page 222).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV`)

### Limit monitoring of the process value

The block provides the standard function Limit monitoring of the process value (Page 93).

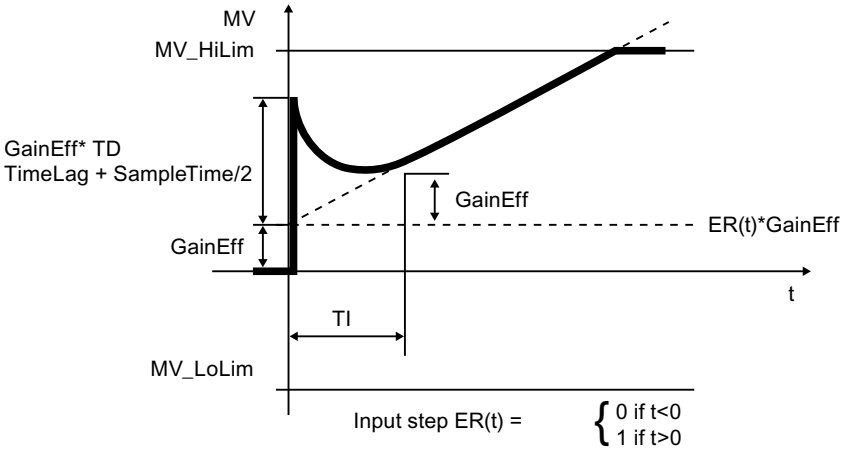
### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### PID algorithm



The manipulated variable is generated in automatic mode according to the following algorithm:

$MV = GainEff \cdot (1 + (1 / (TI \cdot s) + (TD \cdot s) / (1 + TD / DiffGain \cdot s)) \cdot ER$

Where:

s = Complex number

The following step response occurs:

**Note**

The formula describes a standard application where P, I and D components are activated and the P and D components are not in the feedback circuit (`PropSel = 1, TI <> 0, DiffToFbk = 0` and `PropFacSP = 1`).

The D component delay is derived from `TD` / `DiffGain`.

- The P component is displayed at the `P_Part` I/O and can be deactivated using `PropSel` = 0 .
- The I component is displayed at the `I_Part` I/O and can be deactivated using `TI` = 0 .
- The D component is displayed at the `D_Part` I/O and can be deactivated using `TD` = 0 .

## Anti-windup

The controller has an anti-windup function. The I component is frozen after the manipulated variable has reached limits (`MV_HiLim` or `MV_LoLim`).

## Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the process value `PV_Out`:
  The signal status of the output parameter `PV_Out` always corresponds to the signal status of input parameter `PV` or, if the block is in simulation mode, 16#60.
- Signal status for the setpoint value `SP`:
  The signal status of the `SP` output parameter is always equivalent to the signal status of the input parameter `SP_Ext` or `SP_Int`, depending on how the setpoint is specified. If the internal setpoint `SP_Int` is used, the signal status is always outputted as `16#80`.
- Signal status of the error signal `ER`:
  The signal status of output parameter `ER` is obtained from the worst signal status of the two output parameters `PV_Out` and `SP`, and is outputted.
  The signal status `16#60` (external simulation) is suppressed because the block acts as a sink with external simulation.

- Signal status for the manipulated variable MV:
  The signal status of output parameter MV is formed in "Automatic mode" from the error signal ER and output. In "manual mode", the signal status is output as good. The signal status 16#60 (external simulation) is suppressed because the block acts as a sink with external simulation. In "manual mode", the signal status is output as good.
- Worst signal status:
  The worst signal status ST_Worst for the block is formed from SP, PV_Out, MV_ChnST and Rbk .

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 4 | Not used. |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6-14 | Not used. |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 17 - 22 | Not used. |
| 23 | SP following PV in open loop has no priority over SP_Ext and SP limits (Page 193) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 - 30 | Not used. |
| 31 | Limits disabled in faceplate (Page 206) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" AutModOp |
| 1 | 1 = Operator can switch to "manual mode" ManModOp |
| 2 | 1 = Operator can switch to "Out of service" mode OosOp |
| 3 | 1 = Operator can switch the setpoint to "external" SP_ExtOp |
| 4 | 1 = Operator can switch the setpoint to "internal" SP_IntOp |
| 5 | 1 = Operator can change the internal setpoint SP_Int |

| Bit | Function |
|---|---|
| 6 | 1 = Operator can change the manual parameter `Man` |
| 7 | 1 = Operator can change the high operation limit of the setpoint `SP_HiLim` |
| 8 | 1 = Operator can change the low operation limit of the setpoint `SP_LoLim` |
| 9 | 1 = Operator can change the operation high limit of the manipulated variable `ManHiLim` |
| 10 | 1 = Operator can change the operation low limit of the manipulated variable `ManLoLim` |
| 11 | 1 = Operator can permit the PID optimization function `OptimEn` |
| 12 | 1 = Operator can enable the track setpoint in "manual mode" function `SP_TrkPV` |
| 13 | 1 = Operator can enable the bumpless switchover from external to internal `SP_TrkExt` |
| 14 | 1 = Operator can change the gain parameter `Gain` |
| 15 | 1 = Operator can change the integral time parameter `TI` |
| 16 | 1 = Operator can change the derivative time parameter `TD` |
| 17 | 1 = Operator can change the derivative gain parameter `DiffGain` |
| 18 | 1 = Operator can change the dead band parameter `DeadBand` |
| 19 | 1 = Operator can change the limit (process value) `PV_AH_Lim` for the high alarm |
| 20 | 1 = Operator can change the limit (process value) `PV_WH_Lim` for the high warning |
| 21 | 1 = Operator can change the hysteresis (process value) `PV_Hyst` |
| 22 | 1 = Operator can change the limit (process value) `PV_WL_Lim` for the low warning |
| 23 | 1 = Operator can change the limit (process value) `PV_AL_Lim` for the low alarm |
| 24 | 1 = Operator can activate the Simulation function `SimOn` |
| 25 | 1 = Operator can activate the Release for maintenance function `MS_RelOp` |
| 26 | 1 = Operator can change the simulation value `SimPV` |
| 27 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 28 | 1 = Operator can activate / deactivate messages via `PV_WH_MsgEn` |
| 29 | 1 = Operator can activate / deactivate messages via `PV_WL_MsgEn` |
| 30 | 1 = Operator can activate / deactivate messages via `PV_AL_MsgEn` |
| 31 | Not used |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Release for maintenance

The block provides the standard function Release for maintenance (Page 70)

### Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 6.8.4 PIDConS error handling

### Error handling of PIDConS

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 30 | The value of `PV` can no longer be displayed in the REAL number field. |
| 31 | The value of `SP_Ext` can no longer be displayed in the REAL number field. |
| 33 | The value of `MV_Trk` can no longer be displayed in the REAL number field. |
| 35 | The value of `Rbk` can no longer be displayed in the REAL number field. |
| 36 | The value of `MV` can no longer be displayed in the REAL number field. |
| 51 | `AutModLi` = 1 and `ManModLi` = 1<br>`SP_LiOp` = 1 and `SP_IntLi` = 1 and `SP_ExtLi` = 1 |
| 60 | \|`TI`\| < `SampleTime` / 2 |
| 61 | \|`TD`\| < `SampleTime` |
| 62 | `DiffGain` < 1 or `DiffGain` > 10 |
| 63 | `TD` / `DiffGain` < `SampleTime` / 2 |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the section Error handling (Page 128).

## 6.8.5 PIDConS messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system fault messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 5).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>PV - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>PV - high warning limit violated |
| | SIG 3 | Warning - low | $$BlockComment$$<br>PV - low warning limit violated |
| | SIG 4 | Alarm - low | $$BlockComment$$<br>PV - low alarm limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You have the option of using one or two instance-specific messages for this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@8%x@ |
| | SIG 7 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@9%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | Process value `PV_Out` |
| 5 | Control deviation `ER` |
| 6 | Signal status `ExtMsg1` |
| 7 | Signal status `ExtMsg2` |
| 8 | `ExtVa108` |
| 9 | `ExtVa109` |
| 10 | Not allocated |

The associated values 8 ... 9 are allocated to the parameters `ExtVa108` ... `ExtVa109` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 6.8.6 PIDConS I/Os

I/Os of PIDConS

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AutModLi*` | 1 = "Automatic mode" via interconnection or SFC (controlled by `ModLiOp` = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AutModOp*` | 1 = "Automatic mode" via operator (controlled by `ModLiOp` = 0) | BOOL | 0 |
| `BatchEn` | 1 = Enable allocation for batch control | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of block-type<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| CPI_In | Input for control performance index, which is calculated by the assigned ConPerMon block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| CSF | 1 = External error (control system fault)<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadBand | Width of dead band | REAL | 0.0 |
| DiffGain | Gain of differentiator [1..10] DiffGain = TD / (delay time of D component) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 5.0<br>• 16#80 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtMsg1 | 1 = Binary input for freely selectable message 1 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | 1 = Binary input for freely selectable message 2 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| ExtVa109 | Associated value 9 for messages (MsgEvID1) | ANY | |
| Feature | I/O for additional PIDConS functions (Page 1073) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Gain | Proportional gain<br>Gain.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| IntHoldNeg | 1 = Integrator cannot run in negative direction | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| IntHoldPos | 1 = Integrator cannot run in positive direction | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Man* | Manual specification for the manipulated variable | REAL | 0.0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Operating mode switchover between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvID1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_ChnST | Signal status of output channel for MV<br>Should be connected to an output channel block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| MV_HiLim | Limit (high) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| MV_LoLim | Limit (low) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Offset | Manipulated variable for ER=0, operating point for controller with deactivated I component | REAL | 0.0 |
| MV_OpScale | OS display range for manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_SafePos | Manipulated variable neutral position | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Trk* | Tracking value for the manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OptimEn* | 1 = Enable optimization of PID parameters by PID tuner | BOOL | 0 |
| OptimOcc* | 1 = Optimization running | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permission (Page 1073) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1073) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| PropSel | 1 = Activate P component | BOOL | 1 |
| PV* | Process value (controlled variable) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_A_DC* | Delay time for incoming PV alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_Hyst | Hysteresis for PV alarm, warning and tolerance limits | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_W_DC* | Delay time for incoming PV warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| Rbk* | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | 1 = Neutral position (Page 54) for controller manipulated variable is MV_HiLim<br>0 = Neutral position for controller manipulated variable is MV_LoLim | BOOL | 0 |
| SafePos2 | Neutral position for control valve:<br>0 = SafePos is valid<br>1 = Neutral position is MV_SafePos<br>2 = Neutral position is last manipulated variable (stop) | INT | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |
| SP_Ext* | external setpoint - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi* | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_HiLim | Limit (high) of internal SP | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 100.0<br>• 16#80 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |
| SP_IntLi* | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_LoLim | Limit (low) of internal SP | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_TrkPV | 1 = Setpoint follows PV in "manual mode" and with tracking | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TD | Derivative time [s]<br>TD.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| TI | Integral time [s]<br>TI.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| D_Part | D component of PID algorithm | REAL | 0.0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see PIDConS error handling (Page 1079) | INT | -1 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| I_Part | I component of PID algorithm | REAL | 0.0 |
| LoopClosed | 1 = Control loop closed<br>0 = Control loop open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_UnitOut | Unit of measure for manipulated variable, for interconnecting to the MV_Unit input parameter of the ConPerMon block | INT | 0 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1_Perm | WORD | 16#FFFF |
| OS1PermLog | Display of OS1_Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| P_Part | P component of PID algorithm | REAL | 0.0 |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_ToleHi | Limit (high) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_ToleLo | Limit (low) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_UnitOut | Unit of measure for process value, for interconnecting to the PV_Unit input parameter of the ConPerMon block | INT | 0 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_HiOut | Limit (high) for SP corresponds to input parameter SP_HiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_LoOut | Limit (low) for SP corresponds to input parameter SP_LoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1069) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1069) | DWORD | 16#00000000 |

## 6.8.8 Operator control and monitoring

### 6.8.8.1 PIDConS views

#### Views of the PIDConS block

The block PIDConS provides the following views:

- PIDConL, PIDConS and PIDConR standard views (Page 1061)
- Alarm view (Page 336)
- Limit view of PID controllers (Page 325)
- Trend view (Page 341)
- Parameter view of PID controllers (Page 315)
- PIDConL, PIDConS and PIDConR previews (Page 1066)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icons for PID and FM controller (Page 269)

Refer to the Structure of the faceplate (Page 279) and Block icon structure (Page 260) chapters for general information about the faceplate and block icon.

# 6.9 PIDConR - Continuous PID controller with external reset

## 6.9.1 Description of PIDConR

### Object name (type + number) and family

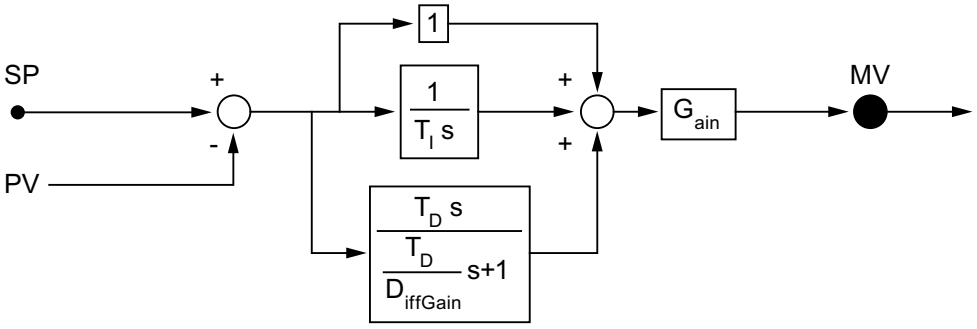
Type + number: FB 1875

Family: Control

### Area of application for PIDConR

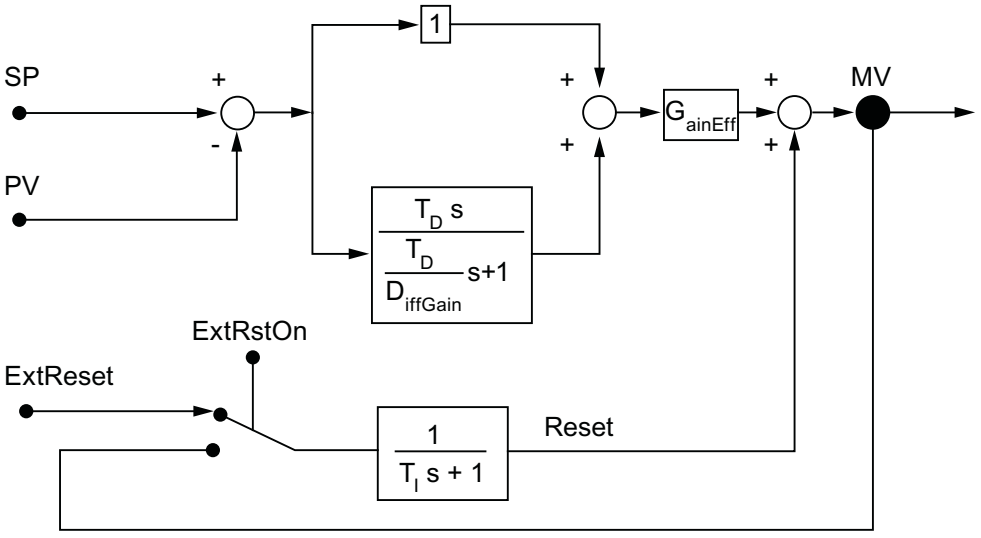
The block is used for the following applications:

- Fixed setpoint control
- Cascade control
- Ratio control
- Split-range control
- Smith predictor closed-loop control
- Override control (override)



Unlike PIDConL, the PIDConR permits an external reset and satisfies the special requirements of the US market.

### How it works



The block is a PID controller with continuous output signal (manipulated variable). It is used to activate a final controlling element with continuous action input.

The block functions following the PID algorithm with a delayed D component and an integrator with double precision. Its particular feature is that it is an incremental control algorithm with a serial-interactive structure. Incremental means that the current manipulated variable is calculated from the old manipulated variable of the last sampling step. In place of the old manipulated variable, an output point for the manipulated variable calculation (external reset) can be specified externally by interconnection. The difference between the parallel controller structure of the PIDConL and the serial-interactive structure of the PIDConR is shown in the next two diagrams.

**PIDConL**

**PIDConR**

The block is suitable for controlling sluggish control loops, for example, for temperatures and filling levels, and high-speed control loops, for example, for flow rates and speed. For a given CPU, a compromise has to be made between the number of controllers and the frequency with which the individual controllers have to be processed. The faster the modulated control loops are, i.e. the more frequently the manipulated variables have to be calculated per time unit, the lower the number of controllers that can be installed.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the control loop monitoring to work as planned in the trend view of the controller faceplates, the

```
S7_xarchive:='Value, shortterm;'
```

attributes in the process tag types for control loops at the controller function block must be set for the following tags:

- Input parameters:
  - CPI_In
- Output parameters
  - MV
  - MV_HiAct
  - MV_LoAct
  - LoopClosed
  - SP
  - PV_Out
  - PV_ToleHi
  - PV_ToleLo

For the PIDConR block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Cascade control with PIDConR (CascadeR) (Page 2843)
- Override control with PIDConR (OverrideR) (Page 2848)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Ratio control with PIDConR (RatioR) (Page 2839)

**Note**

The meaning of the controller parameters of both structures is different for all controller parameter settings with a D component. If you want to transfer parameter values from one structure to another, they have to be converted according to the formula in the PIDConR function .

### Startup characteristics

Use the Feature Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at RunUpCyc.

The following output parameters are written with the corresponding input parameters:

- PV_HysOut
- PV_AH_Out
- PV_WH_Out
- PV_TH_Out
- PV_AL_Out

- PV_WL_Out
- PV_TL_Out

### Status word allocation for Status1 parameter

You can find a description for each parameter in section PIDConR I/Os (Page 1121).

| Status bit | Parameter |
|---|---|
| 0 | Occupied |
| 1 | BatchEn |
| 2 | SimOn |
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | AutAct.Value |
| 6 | Invalid signal status |
| 7 | ManAct.Value |
| 8 | SP_ExtAct.Value |
| 9 | MV_ForOn.Value |
| 10 | MV_TrkOn.Value AND NOT (ManAct.Value OR OosAct.Value OR MV_ForOn.Value) |
| 11 | MV.Value > ManLoLim |
| 12 | SimLiOp.Value |
| 13 | "Interlock" button is enabled OR Intlock.ST ≠ 16#FF |
| 14 | 0 = Open padlock in the block icon<br>1 = Closed padlock in block icon |
| 15 | SP_LoadOn.Value |
| 16 | SP_LoadOn.Value AND NOT (MV_TrkOn.Value OR OosAct.Value OR MV_ForOn.Value) |
| 17 | Feature.Bit19 |
| 18 | Feature.Bit21 |
| 19 | AdvCoAct |
| 20 | 1 = Input parameter Rbk is not interconnected (RbkOut.ST = 16#FF) |
| 21 | NegGain |
| 22 | 1 = SP ramp active |
| 23 | OptimEn |
| 24 | OptimOcc |
| 25 | Not used |
| 26 | Display of BypassAct.Value in faceplate (display and operator controls) and block icon |

| 28 | SimOn AND ManAct |
| 29 | BypProt |
| 30 | Dead band is temporarily disabled |
| 31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `PV_AH_Act.Value` |
| 2 | `PV_WH_Act.Value` |
| 3 | `PV_TH_Act.Value` |
| 4 | `PV_TL_Act.Value` |
| 5 | `PV_WL_Act.Value` |
| 6 | `PV_AL_Act.Value` |
| 7 | `PV_AH_En` OR `Feature.Bit31` |
| 8 | `PV_WH_En` OR `Feature.Bit31` |
| 9 | `PV_TH_En` OR `Feature.Bit31` |
| 10 | `PV_TL_En` OR `Feature.Bit31` |
| 11 | `PV_WL_En` OR `Feature.Bit31` |
| 12 | `PV_AL_En` OR `Feature.Bit31` |
| 13 | `PV_AH_MsgEn` |
| 14 | `PV_WH_MsgEn` |
| 15 | `PV_TH_MsgEn` |
| 16 | `PV_TL_MsgEn` |
| 17 | `PV_WL_MsgEn` |
| 18 | `PV_AL_MsgEn` |
| 19 | `ER_AH_Act.Value` |
| 20 | `ER_AL_Act.Value` |
| 21 | `ER_AH_En` OR `Feature.Bit31` |
| 22 | `ER_AL_En` OR `Feature.Bit31` |
| 23 | `ER_AH_MsgEn` |
| 24 | `ER_AL_MsgEn` |
| 25 | `RbkWH_Act.Value` |
| 26 | `RbkWL_Act.Value` |
| 27 | `RbkWH_En` OR `Feature.Bit31` |
| 28 | `RbkWL_En` OR `Feature.Bit31` |
| 29 | `RbkWH_MsgEn` |
| 30 | `RbkWL_MsgEn` |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |

| Status bit | Parameter |
|---|---|
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | Delay of the `PV_AH_Lim` message |
| 9 | Delay of the `PV_WH_Lim` message |
| 10 | Delay of the `PV_TH_Lim` message |
| 11 | Delay of the `PV_TL_Lim` message |
| 12 | Delay of the `PV_WL_Lim` message |
| 13 | Delay of the `PV_AL_Lim` message |
| 14 | Delay of the `ER_AH_Lim` message |
| 15 | Delay of the `ER_AL_Lim` message |
| 16 | Delay of the `RbkWH_Lim` message |
| 17 | `BypassAct.Value` |
| 18 | Collection of message delays |
| 19 | Delay of the `RbkWL_Lim` message |
| 20 | 1= Suppressed messages |
| 21 - 23 | Not used |
| 24 | `Feature2.Bit2`: Separate bypass signal |
| 25 | Hidden bypass signal in Intlock |
| 26 | `LockAct.Value` |
| 27 | `SP_UpRaAct`, `SP_DnRaAct` limits enabled for gradient mode (`SP_RateOn = 1`) |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | 1 = Input parameter `MV_ChnST` is interconnected |
| 31 | Internal error |

## Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 28 | Not used |
| 29 | 1 = Input parameter `SP_LiRmpTime` is not interconnected (`SP_LiRmpTime.ST = 16#FF`) |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

## 6.9.2 PIDConR modes

### Operating modes of PIDConR

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

In "manual mode", the control settings for the device are made manually by the operator. The operator decides how to change the block's manipulated variable (output signal).

In "automatic mode", the controller's manipulated variable is calculated automatically by the block algorithm.

### Changing between operating modes

The switchover between manual and automatic modes takes place as shown in the following schematic:

**Switchover by using faceplates:** The switchover between operating modes is carried out in the standard view of the faceplate. In the function block, the parameters `ManModOp` for "manual mode" and `AutModOp` for "automatic mode" are used.

**Switchover via interconnection (CFC or SFC instance):** The switchover between the operating modes is carried out by means of interconnection on the function block.

**Note**

You can access the variable parameters `AutModOp` and `ManModOp` from a normal SFC (in contrast to the instance of an SFC type). The SFC can thus change the operating mode without revoking the access rights of the operator.

## Points to note for this block

With PIDConR the switchover between operating modes via interconnectable input parameters follows a different logic than that used for other controller blocks. This logic is oriented towards the special requirements of the US market. The basic approach is to issue the controller with certain commands by interconnection using an individual input parameter. The commands issued by interconnection take priority over the entries in the faceplate, i.e. if such a command input is made, the associated operator controls are locked in the faceplate:

- If the interconnectable `AutExtSet` = 1 input parameter is set, the controller goes into "automatic mode" with an external setpoint. This is also known as the "cascade" operating mode.
- If the interconnectable `AutIntSet` = 1 input parameter is set, the controller goes into "automatic" mode with internal setpoint. `AutIntSet` has higher priority than`AutExtSet`. For more information about the internal and external setpoint, refer to section PIDConR functions (Page 1103).
- If the interconnectable input parameter `ManSet` = 1 is set, the controller goes into "manual" mode. This command has higher priority than `AutIntSet` and `AutExtSet`.
- If one of the interconnectable input parameters `MV_Close` or `MV_Open` is set, the controller also goes into "manual" operating mode and performs the corresponding command.

The `ModLiOp`, `ManModLi` and `AutModLi` input parameters are not therefore present in PIDConR.

## Switchover from automatic mode to manual mode

When changing over from "automatic mode" to "manual mode", the last valid control settings (**M**anipiulated **V**alue `MV`) for the controller set in "automatic mode" remain valid until you change the control settings manually.

## Switchover from manual mode to automatic mode

The switchover from manual to automatic mode can take place with or without the internal setpoint tracking the process value. You specify this behavior on the `SP_TrkPV` I/O, which can also be operated from the faceplate in the parameter view (Option "`SP` : = `PV` in Manual").

### Switchover with tracked internal setpoint

(`SP_TrkPV` = 1) means that in "manual" mode the setpoint (`SP`) tracks the process variable (`PV`). This results in bumpless switchover, which means the manipulated variable remains constant after switching back to "automatic mode" until the setpoint (`SP`) is changed or the process value (`PV`) changes.

### Switchover without tracked internal setpoint

(`SP_TrkPV` = 0) means that the setpoint does not track the actual value in manual mode and that the block immediately recalculates the manipulated variable based on the setpoint and process value (`PV`) when the mode is changed. PIDConR only offers **switchover without P step**: During switchover, the I action (reset) of the controller is set in such a way that the switchover is carried out without a P step (virtually bumpless referring to the manipulated variable). In case of a large control deviation, when switching from the manual mode to the automatic mode, it may happen that the integral action is set far outside the manipulated variable limits. See

`Feature` bit With accelerated return of the integral action from the manipulated variable limit (Page 193).

### Reaction of signals when operating mode is changed

Using the `Feature` Bit Resetting the commands for changing the mode (Page 172), you can specify whether the block automatically resets the signal for changing the operating mode.

### "Program mode for controllers"

You can find general information about the "Program mode for controller" in the section Program mode for controllers (Page 85).

In case of a large control deviation, when switching from the program mode with manipulated variable specification to the automatic mode, it may happen that the integral action is set far outside the manipulated variable limits. See `Feature` bit With accelerated return of the integral action from the manipulated variable limit (Page 193).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =0 and `Feature.Bit5` =1 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| RbkOut.ST | 16#80 | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| SP.ST | 16#80 | 16#60 |
| SP_ExtOut.ST | 16#80 | 16#60 |
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_WH_Act.ST | 16#XX | 16#60 |
| PV_TH_Act.ST | 16#XX | 16#60 |
| PV_TL_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| PV_ToleHi.ST | 16#80 | 16#60 |
| PV_ToleLo.ST | 16#80 | 16#60 |
| ER.ST | 16#80 | 16#60 |
| ER_AH_Act.ST | 16#XX | 16#60 |
| ER_AL_Act.ST | 16#XX | 16#60 |

**Note**

The status of `RbkOut` will be 16#FF without Rbk. when `Feature.Bit5` = 0.

## 6.9.3 PIDConR functions

### Functions of PIDConR

The functions for this block are listed below.

### Generation of manipulatedvariables

The manipulated variable `MV` can be generated as follows:

| MV_ForOn | MV_BumpOn | MV_Close | MV_Open | Man-Act | MV_TrkOn | Adv-CoAct AND NOT AdvCo-ModSP | MV = | Limit monitoring | State |
|---|---|---|---|---|---|---|---|---|---|
| 1 | - | - | - | - | - | - | `MV_Forced` | none | Forced tracking through constraint without limitation |
| 0 | 1 | - | - | - | - | - | `MV_Bump` | Manual mode:<br>`ManHiLim`<br>`ManLoLim`<br>Automatic mode:<br>`MV_HiLim`<br>`MV_LoLim` | Sudden manipulation of the manipulated variable |
| 0 | 0 | 1 | - | - | - | - | `ManLoLim` | `ManHiLim`<br>`ManLoLim` | Close by interconnection |

| MV_ForOn | MV_BumpOn | MV_Close | MV_Open | Man-Act | MV_TrkOn | Adv-CoAct AND NOT AdvCo-ModSP | MV = | Limit monitoring | State |
|---|---|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 1 | - | - | - | ManHiLim | ManHiLim<br>ManLoLim | Open by interconnection |
| 0 | 0 | 0 | 0 | 1 | - | - | Man | ManHiLim<br>ManLoLim | Manual mode, set by the OS operator or via the ManSet = 1 command |
| 0 | 0 | 0 | 0 | 0 | 1 | - | MV_Trk | MV_HiLim<br>MV_LoLim | Tracking with limitation |
| 0 | 0 | 0 | 0 | 0 | 0 | 1 | AdvCoMV | MV_HiLim<br>MV_LoLim | Higher-level program mode |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | PID.OUT + FFwd | MV_HiLim<br>MV_LoLim | Automatic mode (PID algorithm) |

If the controller is in "out of service" mode, the output parameter MV is set to the last valid value in manual mode or the neutral position manipulated variable depending on the Feature Bit Neutral position manipulated variable takes effect at startup (Page 176). Refer to the Out of service (Page 77) section for more on this.

The PIDConR offers the following special ways of influencing the generation of manipulated variables via interconnectable input parameters. The commands issued by interconnection take priority over the entries in the faceplate, i.e. if such a command input is made, the associated operator controls are locked in the faceplate.

**MV_BumpOn** is used for sudden manipulation of the manipulated variable and has a similar effect to MV_ForOn, the difference being that the appropriate limits are applied. If MV_BumpOn = 1 is set in "automatic mode", the MV_Bump manipulated variable is written in a limited manner between MV_HiLim and MV_LoLim to output MV. If MV_BumpOn = 1 is set in "manual mode", the MV_Bump manipulated variable is written in a limited manner between ManHiLim and ManLoLim to output MV. If MV_BumpOn is reset to 0, the controller returns to its previous mode.

**MV_Close** is used to close the adjustment valve. MV_Close = 1 switches the controller to "manual mode" with manipulated variable MV = ManLoLim. If MV_Close is reset to 0, the controller remains in "manual mode".

**MV_Open** is used to open the adjustment valve. MV_Open = 1 switches the controller to "manual mode" with manipulated variable MV = ManHiLim. If MV_Open is reset to 0, the controller remains in "manual mode".

These commands have higher priority than "automatic mode", but lower priority than forced tracking by MV_ForOn.

For meshed controller structures, such as a cascade control and closed-loop control with the PIDConR block, the ExtReset input parameter is used with ExtRstOn = 1 rather than MV_Trk with MV_TrkOn = 1 (also refer to the process tag types Cascade control with PIDConR (CascadeR) (Page 2843) and Override control with PIDConR (OverrideR) (Page 2848)).

### Displaying additional information relating to the manipulated variable on the output

The manual manipulated variable limitations ManLoLim and ManHiLim are copied to the ManLoOut and ManHiOut output parameters so that they can be further interconnected to the secondary controller as setpoint limits SP_ExtLoLim and SP_ExtHiLim. If you want to use the same limit pairs for "manual" and "automatic" mode, you can interconnect output parameters ManLoOut and ManHiOut to input parameters MV_LoLim and MV_HiLim of the same block and thereby control the limits for manipulated variable limitation in the faceplate. In most cases, a valve's complete control range can be passed through in "manual" mode. You can then further interconnect the ManLoOut and ManHiOut output parameters to the LoScale and HiScale input parameters of the assigned analog output channel block. Caution: If the valves have an open neutral position (SafePos = 1), this interconnection must be crossed over: LoScale = ManHiOut and HiScale = ManLoOut. On the controller, 0% is always interpreted as the valve being closed and 100% as the valve being open, but the channel block then issues a control signal of 0% for a 100% controller manipulated variable.

### Tracking and limiting a manipulated variable

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

In case of a large control deviation, when disabling the tracking or forced tracking function and switching to the automatic mode, it may happen that the integral action is set far outside the manipulated variable limits. See Feature bit With accelerated return of the integral action from the manipulated variable limit (Page 193).

Tracking has a higher priority than interlock in this block.

### Neutral position

The block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- CSF

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### "Actuator active" information

If the manipulated variable MV is greater than the minimum manual limit ManLoLim, this is recognized as actuator active. This status can be used to display a custom symbol in the process image, for example, and is stored in the status word (you can find additional information under "Status word" in the Description of PIDConR (Page 1094) section).

### Limit monitoring of position feedback

The block provides the standard function Limit monitoring of the feedback (Page 101).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### External/internal setpoint specification

This input of setpoints is carried out either using a CFC/SFC program or using the faceplate (operator). The operator can specify an internal setpoint value (`SP_Int`) or a higher-level open-loop control will specify an external setpoint value (`SP_Ext`).

#### Setpoint specification internally and externally using faceplate

With PIDConR, the setpoint signal source is selected via the faceplate at the SP_IntOp = 1 parameter for the internal setpoint specification SP_ExtOp = 1 for external setpoint specification, just as it is with other controllers.

**Note**

In contrast to the other controllers, with PIDConR you can only switch to external setpoint specification via SP_ExtOp = 1 in automatic mode or in the program SP mode.

#### Setpoint specification internally and externally using interconnection

With PIDConR the switchover between internal and external setpoint via interconnectable input parameters follows a different logic than that used for other controller blocks. This logic is oriented towards the special requirements of the US market.

The setpoint signal source (internal/external) can be selected by interconnection along with selection of the operating mode using the `AutIntSet` input parameter for automatic with an internal setpoint and `AutExtSet` for automatic with an external setpoint (additional information is available in the PIDConR modes (Page 1100) section). The commands issued by interconnection take priority over the entries in the faceplate, i.e. if such a command input is made, the associated operator controls are locked in the faceplate. Input parameters `SP_LiOp`, `SP_ExtLi` and `SP_IntLi` on PIDConR are not therefore needed.

The PIDConR also offers a special way of influencing the setpoint specification via interconnectable input parameters. Loading setpoints. If the `SP_LoadOn` = 1 input parameter is set, the controller goes into "automatic" mode. The value of the `SP_Load` input parameter is limited according to an internal setpoint and used for control purposes. If the parameter `SP_LoadOn` changes back from 1 to 0, the controller remains in "automatic" mode and sets the default setpoint back to the internal setpoint.

Loading a setpoint via `SP_LoadOn` takes priority over all other forms of setpoint specification.

### Bumpless switchover from external to internal setpoint

The parameter `SP_TrkExt` = 1 is used so that the internal setpoint tracks the external setpoint to achieve a bumpless switchover from the external to the internal setpoint. This allows unwanted jumps at the output parameter to be avoided.

### Bumpless switchover between internal and external setpoint with PID initialization

With `Feature.Bit14` With PID initialization if mode SP intern extern changes (Page 207)you can make a bumpless switchover between internal and external setpoint. During switchover the PID algorithm will be initialized.

### Setpoint limiting for external setpoints

The block provides the standard function Setpoint limiting for external setpoints (Page 222).

### Gradient limit of the setpoint

The block provides the standard function Gradient limit of the setpoint (Page 132).

### Using setpoint ramp

The block provides the standard function Using setpoint ramp (Page 131).

### Tracking setpoint in manual mode

The block provides the standard function Tracking setpoint in manual mode (Page 222).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV`, `SimPV_Li`)
- Position feedback (`SimRbk`, `SimRbkLi`)

### Bypass function

This block provides the standard function Bypassing signals (Page 115).

### Limit monitoring of the process value

The block provides the standard function Limit monitoring of the process value (Page 93) with the alarm delay type Two time values for each individual limit (Page 228).

The PIDConR is the only block to have separate input parameters for the alarm delay at the high and low limits. Delay alarm for control deviation at setpoint step changes (Page 216)

### Providing limits at the output

For further connections to the other blocks, the following input parameters are also displayed with the corresponding output parameters:

- `PV_HysOut` := `PV_Hyst`
- `PV_AH_Out` := `PV_AH_Lim`
- `PV_WH_Out` := `PV_WH_Lim`
- `PV_TH_Out` := `PV_TH_Lim`
- `PV_TL_Out` := `PV_TL_Lim`
- `PV_WL_Out` := `PV_WL_Lim`
- `PV_AL_Out` := `PV_AL_Lim`
- `ER_AH_LimOut` := `ER_AH_Lim`
- `ER_AL_LimOut` := `ER_AL_Lim`

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

### Delay alarm for control deviation at setpoint step changes

The block provides the standard function Delay alarm for control deviation at setpoint step changes (Page 216)

### Limit monitoring of error signal

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102). The monitoring of error signal works with the alarm delay type Two time values per limit pair (Page 227). With the `Feature` Bit Separate delay times for each alarm (Page 181), the alarm delay type Two time values for each individual limit (Page 228) can be activated.

### Inverting control direction

The block provides the standard function Inverting control direction (Page 217).

### Physical standardization of setpoint, manipulated variable and process value

Controller gain `Gain` is entered either using a physical variable or as standardized value.

`Gain` as a physical variable [`MV_Unit` / `PV_Unit`]:

The standardized variables retain their default values:

- `NormPV.High` = 100 and `NormPV.Low` = 0
- `NormMV.High` = 100 and `NormMV.Low` = 0

The effective gain is:

`GainEff` = `Gain`

Entering a standardized `Gain` (dimensionless):

Change the standardized variables to the actual range of the process values and manipulated variables.

- Internal and external setpoints; the process value and corresponding parameters are entered according to the physical measuring range of the process value.
- The manual value, the tracking value of the manipulated variable, disturbance variable feedforward and the corresponding parameters are set according to the physical measuring range of the manipulated variable.

The effective gain is:

`GainEff` = (`NormMV.High` - `NormMV.Low`) / (`NormPV.High` - `NormPV.Low`) · `Gain`

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### PID algorithm

The manipulated variable is generated in automatic mode according to the following algorithm:

For more information refer to "How it works" in Description of PIDConR (Page 1094)

$$MV = G_{ainEff}\left[1+\frac{T_D s}{\frac{T_D}{D_{iffGain}}s+1}\right](SP-PV)+Reset$$

$$Reset = \left(\frac{1}{T_I s+1}\right) MV, \qquad \text{ExtRstOn = 0}$$

$$Reset = \left(\frac{1}{T_I s+1}\right) \text{ExtReset}, \qquad \text{ExtRstOn = 1}$$

Where:

s = complex number of the Laplace transformation

This formula describes a standard application where P, I and D component is activated

The D component delay is derived from `TD` / `DiffGain`.

- The P component can be deactivated by `PropSel` = 0 .
- The I component can be deactivated by `IntSel` = 0 . The `MV_Offset` input parameter can then be used to add a constant value to the manipulated variable. Select this value such that the remaining control deviation equals zero at least at the control loop's typical operating point.
- The D component can be deactivated by `TD` = 0 or `DiffSel` = `1`.

**Note**

The formula describes a standard application where P, I and D components are activated and the D component is in the feedback circuit, while the P component is formed by the error signal (`PropSel` = `1`, `TI` <> `0` and `IntSel` = `1`, `TD` <> `0` and `DiffSel` = `1`, `DiffToFbk` = `1`, and `PropFacSP` = `1`).

If you set the `Feature` Bit Enabling bumpless change to the proportional gain, derivative time and amplification of the differentiator (Page 183) to 1, changes in the proportional gain `Gain` are carried out in a bumpless manner in "automatic" mode by converting the internal reset.

If the GainSched block is linked to the controller, you have to make the parameter settings for the `Feature` Bit Enabling bumpless change to the proportional gain, derivative time and amplification of the differentiator (Page 183) with 0.

The PID core algorithm is implemented in the PIDKernR function block which in turn calls a series of auxiliary functions for the 64-bit arithmetic. Every edge transition on the `InitPid` input parameter forces initialization equations to be carried out by PIDKernR. In so doing, the internal reset is calculated such that the `MV` output does not suffer a P step.

During initialization in the automatic mode with a large control deviation, it may happen that the integral action is set far outside the manipulated variable limits. See `Feature` bit With accelerated return of the integral action from the manipulated variable limit (Page 193).

**Note**

The meaning of the controller parameters with PIDConR is different to that with the other PID controllers for all controller parameter settings with a D component. If you want to transfer parameter values from one kind of controller to another, they have to be converted using the following formulas. The calculation is based on an ideal transfer function without a delay in the D component, and all three control channels are applied to the `ER` = `SP` - `PV` control deviation.

Parallel controller structure (for example, PIDConL):

$$MV = G_{ainEff}\left(1+\frac{1}{T_I s}+T_D s\right)ER$$

The parameters of the serial-interactive controller structure (PIDConR):

$$MV = G'_{ainEff}\left(1+T'_D s\right)\left(1+\frac{1}{T'_I s}\right)ER$$

These parameters are marked using a speech mark. Both controllers calculate the same manipulated variable if the parameter values of the serial-interactive structure are determined by the following substitution:

$$G'_{ainEff} = \alpha G_{ainEff} \ , \quad T'_I = \alpha T_I \ , \quad T'_D = \frac{1}{\alpha} T_D$$

where $\alpha$ is the conversion factor:

$$\alpha = \frac{1}{2} \pm \sqrt{\frac{1}{4} - \frac{T_D}{T_I}}$$

The argument of the square root is negative and the conversion is impossible if:

$$\frac{T_D}{T_I} > \frac{1}{4}$$

In such cases, the output of PIDConL cannot be exactly replicated by PIDConR. In all other cases, there are two solutions for $\alpha$ and therefore two parameter sets that will generate the same control action of the ideal controller structures. The conversion in the other direction, from serial-interactive to parallel controller structure is always possible by:

$$\alpha = \frac{T'_I}{T'_I + T'_D}$$

You can see that the conversion factor only equals one if $T_D = 0$.

In PID-Tuner, the conversion for ideal controller structures is performed automatically before downloading of parameters to the PIDConR function block. The first of the two possible solutions (plus square root) is used. If the argument of the square root is negative, it will be set to zero, which implies that PIDConR control performance may deteriorate slightly.

### Structure segmentation at controllers

The block provides the standard function Structure segmentation at controllers (Page 224).

### Use output point for the manipulated variable calculation (external reset)

For the `ExtResOn` = 0 input parameter (default setting), the starting point for the manipulated variable calculation within the block is taken from manipulated variable `MV`. In other words, this is the manipulated variable of the last sampling step. If `ExtResOn` = 1, the `ExtReset` start parameter is used. This is used in particular for networked control structures, such as cascade or transfer control.

### Anti-windup

A controller with incremental algorithm (external reset) inherently has an anti-windup reaction because the starting point for the manipulated variable calculation (external reset value) is limited provided it is taken internally from manipulated variable `MV` or is taken from another signal source with limitation. If the starting point for the manipulated variable calculation (external reset value) is at the limit (`MV_HiLim` or `MV_LoLim`), the I component is automatically frozen.

### Feedforwarding and limiting disturbance variables

The block provides the standard function Feedforwarding and limiting disturbance variables (Page 223).

### Control loop is open (`CascaCut`)

The `CascaCut` output indicates whether the control loop within this block is open. In the open control loop, the master controller must be set to tracking mode to avoid until windup behavior. If you use this block in a cascade structure, then connect the output `CascaCut` to the input `MV_TrkOn` of the master controller.

`CascaCut` is active in the following cases:

- Block is not in automatic mode
- `MV` program mode is active
- Setpoint is not in external mode
- Interlock is active

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the process value `PV_Out`:
  The signal status of the output parameter `PV_Out` always corresponds to the signal status of input parameter `PV` or, if the block is in simulation mode, 16#60.
- Signal status for the setpoint value `SP`:
  The signal status of the SP output parameter is always equivalent to the signal status of input parameter `SP_Ext` or `SP_Int`, depending on how the setpoint is specified. If the internal setpoint `SP_Int` is used, the signal status is always output as 16#80.
- Signal status of the error signal `ER`:
  The signal status of output parameter `ER` is obtained from the worst signal status of the two output parameters `PV_Out` and `SP` and is output. The signal status `16#60` (external simulation) is suppressed because the block acts as a sink with external simulation.
- Signal status for the manipulated variable `MV`:
  The signal status of output parameter `MV` is obtained in "automatic mode" or in "program mode" with default setpoint from the worst signal status of the two parameters `FFwd` and `ER` and is output. In "manual mode", the signal status is output as good. The signal status `16#60` (external simulation) is suppressed because the block acts as a sink with external simulation. In "manual mode", the signal status is output as good.

- Signal status for position feedback `RbkOut`:
  The signal status of `RbkOut` always corresponds to the signal status of input parameter `Rbk` or, if the block is in simulation mode, `16#60`.
- Worst signal status:
  The worst signal status `ST_Worst` for the block is formed from the following parameters:
  - `SP.ST`;
  - `PV_Out.ST`;
  - `FFwd.ST`;
  - `RbkOut.ST`;
  - `MV_ChnST.ST`;

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6 | Ramp rate calculation (Page 191) |
| 8 | Separate delay times for each alarm (Page 181) |
| 9 | Substitution value is active if the block is in bypass (Page 199) |
| 11 | Gradient limitation with time duration (Page 197) |
| 14 | With PID initialization if mode SP intern extern changes (Page 207) |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 17 | With accelerated return of the integral action from the manipulated variable limit (Page 193) |
| 19 | Enabling program mode (Page 170) |
| 20 | Enabling bumpless change to the proportional gain, derivative time and amplification of the differentiator (Page 183) |
| 21 | Switching operator controls for external setpoint to visible (Page 154) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | SP following PV in open loop has no priority over SP_Ext and SP limits (Page 193) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Dead band is temporarily disabled (Page 152) |
| 31 | Limits disabled in faceplate (Page 206) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 11 | Suppress MsgLock and "Out of service" mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" `AutModOp` |
| 1 | 1 = Operator can switch to "manual mode" `ManModOp` |
| 2 | 1 = Operator can switch to "Out of service" mode `OosOp` |
| 3 | 1 = Operator can switch to "program mode" `AdvCoOn` |
| 4 | 1 = Operator can switch the setpoint to "external" `SP_ExtOp` |
| 5 | 1 = Operator can switch the setpoint to "internal" `SP_IntOp` |
| 6 | 1 = Operator can change the internal setpoint `SP_Int` |
| 7 | 1 = Operator can change the manual parameter `Man` |
| 8 | 1 = Operator can change operation high limit of the setpoint `SP_InHiLim` |
| 9 | 1 = Operator can change operation low limit of the setpoint `SP_InLoLim` |
| 10 | 1 = Operator can change the operation high limit of the manipulated variable `ManHiLim` |
| 11 | 1 = Operator can change the operation low limit of the manipulated variable `ManLoLim` |
| 12 | 1 = Operator can enable the setpoint's gradient limitation function `SP_RateOn` |
| 13 | 1 = Operator can raise the gradient limit `SP_UpRaLim` of the setpoint |
| 14 | 1 = Operator can lower the gradient limit `SP_DnRaLim` of the setpoint |
| 15 | 1 = Operator can switch between the time value or the gradient value for specifying the ramp `SP_RmpModTime` |
| 16 | 1 = Operator can change the ramp time `SP_RmpTime` |
| 17 | 1 = Operator can change the target setpoint `SP_RmpTarget` for the setpoint ramp |
| 18 | 1 = Operator can enable the setpoint ramp function `SP_RmpOn` |
| 19 | 1 = Operator can permit the PID optimization function `OptimEn` |
| 20 | 1 = Operator can enable the track setpoint in manual mode function `SP_TrkPV` |
| 21 | 1 = Operator can enable the bumpless switchover from external to internal `SP_TrkExt` |
| 22 | 1 = Operator can change the gain parameter `Gain` |
| 23 | 1 = Operator can change the integral time parameter `TI` |
| 24 | 1 = Operator can change the derivative time parameter `TD` |
| 25 | 1 = Operator can change the derivative gain parameter `DiffGain` |
| 26 | 1 = Operator can change the dead band parameter `DeadBand` |
| 27 | Not used |

| Bit | Function |
|---|---|
| 28 | 1 = Operator can change the derivative gain parameter ER_AH_DF |
| 29 | 1 = Operator can change the derivative gain parameter ER_AL_DF |
| 30 - 31 | Not used |

The block has the following permissions for the OS1Perm parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (process value) PV_AH_Lim for the high alarm |
| 1 | 1 = Operator can change the limit (process value) PV_WH_Lim for the high warning |
| 2 | 1 = Operator can change the limit (process value) PV_TH_Lim for the high tolerance |
| 3 | 1 = Operator can change the hysteresis (process value) PV_Hyst |
| 4 | 1 = Operator can change the limit (process value) PV_TL_Lim for the low tolerance |
| 5 | 1 = Operator can change the limit (process value) PV_WL_Lim for the low warning |
| 6 | 1 = Operator can change the limit (process value) PV_AL_Lim for the low alarm |
| 7 | 1 = Operator can change the limit (error signal) ER_AH_Lim for the high alarm |
| 8 | 1 = Operator can change the hysteresis (error signal) ER_Hyst |
| 9 | 1 = Operator can change the limit (error signal) ER_AL_Lim for the low alarm |
| 10 | 1 = Operator can change the limit (position feedback) RbkWH_Lim for the high warning |
| 11 | 1 = Operator can change the hysteresis (position feedback) RbkHyst |
| 12 | 1 = Operator can change the limit (position feedback) RbkWL_Lim for the low warning |
| 13 | Not Used |
| 14 | 1 = Operator can activate bypass functionality |
| 15 | 1 = Operator can deactivate bypass functionality |
| 16 | 1 = Operator can activate the Simulation function SimOn |
| 17 | 1 = Operator can activate the Release for maintenance function MS_RelOp |
| 18 | 1 = Operator can activate / deactivate messages via PV_AH_MsgEn |
| 19 | 1 = Operator can activate / deactivate messages via PV_WH_MsgEn |
| 20 | 1 = Operator can activate / deactivate messages via PV_TH_MsgEn |
| 21 | 1 = Operator can activate / deactivate messages via PV_TL_MsgEn |
| 22 | 1 = Operator can activate / deactivate messages via PV_WL_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via PV_AL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via ER_AH_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via ER_AL_MsgEn |
| 26 | 1 = Operator can activate / deactivate messages via RbkWH_MsgEn |
| 27 | 1 = Operator can activate / deactivate messages via RbkWL_MsgEn |
| 28 | 1 = Operator can change the simulation value SimPV |
| 29 | 1 = Operator can change the simulation value SimRbk |
| 30 | 1 = Operator can activate the derivative action to the feedback path DiffToFbk |
| 31 | 1 = Operator can change the proportional action to the feedback path PropFacSP |

The block has the following permissions for the OS2Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Interlocks

This block provides the following interlocks:

- Interlock without reset ("Interlock")

You can find additional information on this in the section Interlocks (Page 107).

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Release for maintenance

The block provides the standard function Release for maintenance (Page 70).

### Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- AutModOp
- ManModOp
- AdvCoOn
- OosOp
- SP_ExtOp
- SP_IntOp

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

## 6.9.4 PIDConR error handling

### Error handling of PIDConR

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |

| Error number | Meaning of the error number |
|---|---|
| 30 | The value of PV can no longer be displayed in the REAL number field. |
| 31 | The value of SP_Ext can no longer be displayed in the REAL number field. |
| 32 | The value of FFwd can no longer be displayed in the REAL number field. |
| 33 | The value of MV_Trk can no longer be displayed in the REAL number field. |
| 34 | The value of MV_Forced can no longer be displayed in the REAL number field. |
| 35 | The value of Rbk can no longer be displayed in the REAL number field. |
| 36 | The value of MV can no longer be displayed in the REAL number field. |
| 51 | AutModLi = 1 and ManModLi = 1<br>SP_LiOp = 1 and SP_IntLi = 1 and SP_ExtLi = 1 |
| 52 | Feature.Bit30 = 1 and MeanMV.ST = 16#78 |
| 59 | = 1 "Gain is negative" |
| 60 | \|TI\| < SampleTime / 2 |
| 61 | \|TD\| < SampleTime |
| 62 | DiffGain < 1 or DiffGain > 10 |
| 63 | TD / DiffGain < SampleTime / 2 |
| 64 | PropFacSP < 0 or PropFacSP > 1 |
| 66 | NormPV_High = NormPV_Low |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 6.9.5 PIDConR messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId2, SIG 6).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>PV - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>PV - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>PV - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>PV - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>PV - low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>PV - low alarm limit violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>ER - high alarm limit violated |
| | SIG 8 | Alarm - low | $$BlockComment$$<br>ER - low alarm limit violated |
| MsgEvId2 | SIG 7 | Warning - high | $$BlockComment$$<br>Rbk - high warning limit violated |
| | SIG 8 | Warning - low | $$BlockComment$$<br>Rbk - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@5%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@6%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 3<br>Status 16#@7%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 4<br>Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | Process value PV_Out |
| 5 | Control deviation ER |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | Not allocated |
| 9 | Not allocated |
| 10 | Not allocated |

The associated values 6 ... 7 are allocated to the parameters ExtVa106 ... ExtVa107 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |

| Associated value | Block parameters |
|---|---|
| 4 | Position feedback RbkOut |
| 5 | Signal status ExtMsg1 |
| 6 | Signal status ExtMsg2 |
| 7 | Signal status ExtMsg3 |
| 8 | Signal status ExtMsg4 |
| 9 | ExtVa209 |
| 10 | ExtVa210 |

The associated values 9 ... 10 are allocated to the parameters ExtVa209 ... ExtVa210 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

I/Os of PIDConR

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoEn | 1 = Enable "program mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoOn* | 1 = Enable "program mode" via faceplate.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | BOOL | 0 |
| AdvCoModSP | Type of "program mode":<br>1 = Setpoint specification<br>0 = Manipulated variable specification | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoMstrOn | 1 = Enable (0-1) or disable (1-0) "program mode" via edge transition | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoMV | Specified value from the external program.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | REAL | 0.0 |
| AutExtSet* | 1 = Activate "automatic" mode with external setpoint by interconnection (SP = SP_Ext) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutIntSet* | 1 = Activate "automatic" mode with internal setpoint by interconnection (SP = SP_Op).<br>AutIntSet has higher priority thanAutExtSet. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic" mode via operator | BOOL | 0 |
| BatchEn | 1 = Enable allocation for batch control | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Interlock bypass during simulation | BOOL | 0 |
| BypLiOp | 1 = Bypass commands via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypLock | 1 = Bypass activation or deactivation is locked for operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypPV | Substitution value if block is in bypass | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BypPVLi | 1 = Select bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypPVOp | 1 = Select bypass PV (via operator) | BOOL | 0 |
| CPI_In | Input for control performance index, which is calculated by the assigned ConPerMon block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| CSF | 1 = External error (control system fault)<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadBand | Width of dead band | REAL | 0.0 |
| DiffGain | Gain of differentiator<br>[1..10] DiffGain = TD / (delay time of D component) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 5.0<br>• 16#80 |
| DiffSel | 1 = D component activated | BOOL | 1 |
| DiffToFbk* | 1 = D component is placed in the feedback | BOOL | 1 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ER_A_DC* | Delay time for incoming ER high/low or only low alarms [s] | REAL | 0.0 |
| ER_AH_DC* | Delay time for incoming ER high alarms [s] | REAL | 0.0 |
| ER_AH_DFac* | Delay factor at positive setpoint step changes for incoming alarms at the error signal monitoring ER_AH_Lim | REAL | 0.0 |
| ER_A_DG* | Delay time for outgoing ER high/low or only low alarms [s] | REAL | 0.0 |
| ER_AH_DG* | Delay time for outgoing ER high alarms [s] | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AH_Lim | Alarm limit (high) for error signal monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AL_DFac* | Delay factor at negative setpoint step changes for incoming alarms at the error signal monitoring ER_AL_Lim | REAL | 0.0 |
| ER_AL_En | 1 = Activate alarm (low) for error signal monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for error signal monitoring | REAL | -100.0 |
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for error signal monitoring | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for error signal | REAL | 1.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | 1 = Binary input for freely selectable message 1 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | 1 = Binary input for freely selectable message 2 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | 1 = Binary input for freely selectable message 3 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | 1 = Binary input for freely selectable message 4 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtReset | Value to which a reset is made if ExtRstOn = 1. | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ExtRstOn | 1 = Reset externally | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa209 | Associated value 9 for messages (MsgEvID2) | ANY | |
| ExtVa210 | Associated value 10 for messages (MsgEvID2) | ANY | |
| Feature | I/O for additional functions (Page 1103) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 20: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Feature2 | I/O for additional functions (Page 1103) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FFwd* | Input for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| FFwdHiLim | Limit (high) for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| FFwdLoLim | Limit (low) for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• -100.0<br>• 16#80 |
| Gain | Proportional gain<br>Gain.ST = 16#FF: Enabled in face-plate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| InitPid* | InitPid edge transitions result in the PID algorithm's initialization equations being carried out. Is used, for example, for SP changes without MV jumps | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is in effect | BOOL | 1 |
| Intlock | 0 = Interlock without reset is in effect<br>Once the interlock condition has cleared, the block can be operated without reset<br>1 = Interlock not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| IntSel | 1 = I component activated | BOOL | 1 |
| Man* | Manual specification for the manipulated variable | REAL | 0.0 |
| ManHiLim | Limit (high) for manual parameter Man | REAL | 100.0 |
| ManLoLim | Limit (low) for manual parameter Man | REAL | 0.0 |
| ManModOp* | 1 = "Manual" mode via OS operator | BOOL | 1 |
| ManSet* | 1 = Activate "manual" mode via interconnection.<br>ManSet has higher priority thanAutIntSet. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvID1 | Message number (assigned automatically) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgEvID2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Bump* | Default value for controller output MV if MV_BumpOn = 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_BumpOn | 1 = Set controller output MV:= MV_Bump without (!) taking the controller into "manual" mode. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_ChnST | Signal status of output channel for MV<br>Should be connected to an output channel block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| MV_Close | 1 = Close adjustment valve by interconnection, i.e. MV:= MV_LoLim<br>MV_Close has higher priority than MV_Open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Forced* | Forced manipulated variable that is not limited and assumes top priority | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_ForOn | 1 = Output forced manipulated variable MV_Forced unlimited at output MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiLim | Limit (high) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| MV_Mean | Mean value of the MV in the time window | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| MV_LoLim | Limit (low) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Offset | Manipulated variable for ER=0, operating point for controller with deactivated I component | REAL | 0.0 |
| MV_Open | 1 = Open adjustment valve by interconnection, i.e. MV:= MV_HiLim<br>MV_Open has higher priority than MV_TrkOn | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_OpScale | OS display range for manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_SafePos | Manipulated variable neutral position | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Trk* | Tracking value for the manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| NegGain | 0 = Effective proportional gain GainEff is positive<br>1 = Effective proportional gain GainEff is negative | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NormMV | Manipulated variable range (MV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| NormPV* | Process value range (PV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Occupied | Occupied by batch control | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OptimEn* | 1 = Enable optimization of PID parameters by PID tuner | BOOL | 0 |
| OptimOcc* | 1 = Optimization running | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1103) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS1Perm | I/O for operator permissions (Page 1103) | STRUCT<br>• Bit 0: BOOL<br>• Bit 18: BOOL<br>• Bit 19:BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| OS2Perm | I/O for operator permissions | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| PropFacSP | Applying the P component to the feedback [0..1].<br>0 = P component fully in feedback | REAL | 1.0 |
| PropSel* | 1 = Activate P component | BOOL | 1 |
| PV* | Process value (controlled variable) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_AH_DC* | Delay time for incoming PV high alarms [s] | REAL | 0.0 |
| PV_AH_DG* | Delay time for outgoing PV high alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_AL_DC* | Delay time for incoming PVlow alarms [s] | REAL | 0.0 |
| PV_AL_DG* | Delay time for outgoing PV low alarms [s] | REAL | 0.0 |
| PV_Hyst | Hysteresis for PV alarm, warning and tolerance limits | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_TH_DC* | Delay time for incoming PV high tolerance messages [s] | REAL | 0.0 |
| PV_TH_DG* | Delay time for outgoing PV high tolerance messages [s] | REAL | 0.0 |
| PV_TH_En | 1 = Enable PV tolerance limit (high) | BOOL | 0 |
| PV_TH_Lim | Limit PV tolerance message (high) | REAL | 85.0 |
| PV_TH_MsgEn | 1 = Enable message for PV tolerance message (high) | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_TL_DC* | Delay time for incoming PV low tolerance messages [s] | REAL | 0.0 |
| PV_TL_DG* | Delay time for outgoing PV low tolerance messages [s] | REAL | 0.0 |
| PV_TL_En | 1 = Enable PV tolerance limit (low) | BOOL | 0 |
| PV_TL_Lim | Limit PV tolerance message (low) | REAL | 15.0 |
| PV_TL_MsgEn | 1 = Activate message for PV tolerance message (low) | BOOL | 1 |
| PV_WH_DC* | Delay time for incoming PV high warnings [s] | REAL | 0.0 |
| PV_WH_DG* | Delay time for outgoing PV high warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_DC* | Delay time for incoming PV low warnings [s] | REAL | 0.0 |
| PV_WL_DG* | Delay time for outgoing PV low warnings [s] | REAL | 0.0 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| Rbk* | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkW_DC* | Delay time for incoming Rbk warnings [s] | REAL | 0.0 |
| RbkW_DG* | Delay time for outgoing Rbk warnings [s] | REAL | 0.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 1 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 100.0 |
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 1 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 0.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |
| RefStdDevIn | Reference value of PV standard deviation (sigma) in defined "good" state of control loop | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RstBypLi | 1 = Reset bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstBypOp | 1 = Reset bypass PV (via operator) | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | 1 = Neutral position (Page 54) for controller manipulated variable is ManHiLim<br>0 = Neutral position for controller manipulated variable is ManLoLim | BOOL | 0 |
| SafePos2 | Neutral position for controller manipulated variable:<br>0 = SafePos is valid<br>1 = Neutral position is MV_SafePos<br>2 = Neutral position is last manipulated variable (stop) | INT | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SettliFactor | Factor to increase the settling time to adjust the dead band | REAL | 2.0 |
| SettliTime | Settling time [s] of the control loop determined by the ConPerMon block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#78 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaLim* | Limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| SP_ExHiLim | Limit (high) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_ExLoLim | Limit (low) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Ext* | external setpoint - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_InHiLim | Limit (high) of internal setpoint | REAL | 100.0 |
| SP_InLoLim | Limit (low) of internal setpoint | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 0 |
| SP_LiDnRaLim | Linkable limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiRmpTime | Linkable time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiUpRaLim | Linkable gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_Load* | Defined setpoint, if SP_LoadOn = 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_LoadOn* | 1 = Take controller into "automatic mode" with internal setpoint and set setpoint at SP:= SP_Load.<br>This kind of setpoint specification has maximum priority. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RateOn* | 1 = Activate limitation of setpoint gradients | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_RmpModTime | 1 = Use time values (SP_RmpTime, SP_LiRmpTime)<br>0 = Use gradient limits (SP_DnRaLim, SP_LiDnRaLim, SP_UpRaLim, SP_LiUpRaLim) | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |
| SP_RmpTime* | Time [Time unit] for setpoint ramp from current SP up to SP_RmpTarget or time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 1 |
| SP_TrkPV | 1 = Setpoint follows PV in "manual mode" and with tracking | BOOL | 0 |
| SP_UpRaLim* | Gradient limit (high) for the setpoint [Unit/(Time unit)]Time unit depends on TimeFactor | REAL | 100.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TD | Derivative time [s]<br>TD.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| TI | Integral time [s]<br>TI.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#FF |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>Value: REAL<br>ST: BYTE | <br>0.0<br>16#FF |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>Value: REAL<br>ST: BYTE | <br>0.0<br>16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoAct | 1 = "Program mode" enabled.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoRdy | 1 = "Program mode" available | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutAct | 1 = "Automatic mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypassAct | 1 = Bypass is activated in this block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CascaCut | Cascade connection:<br>1 = Control chain from primary to secondary controller is interrupted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DynDeadBand | Dynamic dead band | REAL | 0.0 |
| PhaseDeadBand | Phase for the dynamic adjustment of the dead band<br>0: Dead band enabled<br>1: Dead band disabled<br>2: Settling time | INT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_A_DCOut | Effective delay time [s] for incoming alarms at the error signal monitoring | REAL | 0.0 |
| ER_AH_Act | 1 = Alarm limit (high) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_AL_Act | 1 = Alarm limit (low) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ER_AH_LimOut | ER_AH_Lim as output | REAL | 0.0 |
| ER_AL_LimOut | ER_AL_Lim as output | REAL | 0.0 |
| ErrorNum* | Output of pending error number.<br>For error numbers that can be output by this block, see PIDConR error handling (Page 1117) | INT | -1 |
| FFwdHiAct | 1 = Limit (high) for additive disturbance variable activation violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| PV_TL_Act | 1 = PV tolerance message (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_TL_Out | PV - Low tolerance limit output | REAL | 0.0 |
| PV_ToleHi | Limit (high) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_ToleLo | Limit (low) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_UnitOut | Unit of measure for process value, for interconnecting to the PV_Unit input parameter of the ConPerMon block | INT | 0 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WH_Out | PV - High warning limit output | REAL | 0.0 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WL_Out | PV - Low warning limit output | REAL | 0.0 |
| RbkOut | Output for position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SettlingTimer | Settling time for a closed control loop | REAL | 0.0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExHiAct | 1 = Limit (high) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExLoAct | 1 = Limit (low) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOut | External setpoint, corresponds to input parameter SP_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_InHiOut | Limit (high) for SP_Int corresponds to input parameter SP_InHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_InLoOut | Limit (low) for SP_Int corresponds to input parameter SP_InLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_RateTarget | Target setpoint for the gradient limitation | REAL | 0.0 |
| SP_UpRaAct | Positive gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RemRT | Remaining ramp time of the setpoint | REAL | 0.0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1094) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1094) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1094) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1094) | DWORD | 16#00000000 |
| SumMsgAct | 1 = Active hardware interrupt | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserAna1Out | UserAna1 as output | STRUCT | |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#FF |
| UserAna2Out | UserAna2 as output | STRUCT | |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#FF |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Calculation of the output parameter ER_A_DCOut

ER_A_DC is assigned by default to the output before a setpoint change.

ER_A_DCOut = ER_A_DC

In the case of a setpoint change in the positive direction during automatic mode, the output is calculated as follows:

ER_A_DCOut = Maximum (ER_A_DC, ER_AH_DFac * Setpoint difference)

In the case of a setpoint change in the negative direction during automatic mode, the output is calculated as follows:

ER_A_DCOut = Maximum (ER_A_DC, -1*ER_AH_DFac * Setpoint difference)

When the control circuit has stabilized again, meaning

(ER_AL_Lim + ER_Hyst) <= ER <= (ER_AH_Lim – ER_Hyst)

and the delay time for outgoing alarms ER_A_DG has expired, the output is reset again to ER_A_DC: ER_A_DCOut = ER_A_DC

### Activating and deactivating the function:

The function is deactivated (default) when the following applies: ER_AH_DFac = 0.0 and ER_AL_DFac = 0.0

### Views of the PIDConR block

This block has the same views as the PIDConL block. Refer to the section Operator control and monitoring (Page 1060) of the PIDConL block.

# 6.10 PIDStepL - Step controller

## 6.10.1 Description of PIDStepL

### Object name (type + number) and family

Type + number: FB 1878

Family: Control

### Area of application for PIDStepL

The block is used for the following applications:

- Fixed setpoint control
- Cascade control
- Ratio control
- Split-range control
- Smith predictor closed-loop control
- Override control (override)

Note on restricting the area of application: The block is not intended for pulse-duration modulation. Examples of applications: Temperature control with electric heater, which can switched on an off via a (semiconductor) relay. The heating power required by the controller, for example 80%, is output in the form of binary pulses, whereby the duration of the on pulses in this case is four times as long as the pause duration. Such control is built with a combination of a continuous controller (such as PIDConL) and the pulse generator module PULSEGEN from the CFC library ELEM_400.

### How it works

The block is a PID step controller with binary output signals (manipulated variable signals). It is used to control integral action actuators (e.g. valves driven by motors).

The block functions following the PID algorithm with a delayed D component and an integrator with double precision.

The step controller can function both with and without a position feedback for the valve position.

The block is suitable for controlling sluggish control loops, for example, for temperatures and filling levels, and high-speed control loops, for example, for flow rates and speed. For a given CPU, a compromise has to be made between the number of controllers and the frequency with which the individual controllers have to be processed. The faster the modulated control loops are, i.e. the more frequently the manipulated variables have to be calculated per time unit, the lower the number of controllers that can be installed.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the control loop monitoring to work as planned in the trend view of the controller faceplates, the

`S7_xarchive:='Value, shortterm;'`

attributes in the process tag types for control loops at the controller function block must be set for the following tags:

- Input parameters:
  - `CPI_In`
- Output parameters
  - `MV`
  - `MV_HiAct`
  - `MV_LoAct`
  - `LoopClosed`
  - `SP`
  - `PV_Out`
  - `PV_ToleHi`
  - `PV_ToleLo`

For the PIDStepL block, the Advanced Process Library contains templates for process tag types as examples and there is a example project (APL_Example_xx, xx designates the language variant) containing different application cases for this block.

Several process tag types are simulated in the example project and serve to explain the block function.

Examples of process tag types:

- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)

## Startup characteristics

Use the Feature Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section PIDStepL I/Os (Page 1163).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutAct.Value` |
| 6 | Invalid signal status |
| 7 | `ManAct.Value` |
| 8 | `SP_ExtAct.Value` |
| 9 | `MV_ForOn.Value` |
| 10 | `MV_TrkOn.Value` |
| 11 | NOT `RbkClosed.Value` |
| 12 | `Open.Value` |
| 13 | `Close.Value` |
| 14 | `Stop.Value` |
| 15 | `FbkOpened.Value` |
| 16 | `FbkClosed.Value` |
| 17 | `SimLiOp.Value` |
| 18 | `SimOn` AND `ManAct` |
| 19 | `AdvCoAct` |
| 20 | 1 = Input parameter `Rbk` is not interconnected (`RbkOut.ST` = 16#FF) |
| 21 | `NegGain` |
| 22 | 1 = SP ramp active |
| 23 | `OptimEn` |
| 24 | `OptimOcc` |
| 25 | Not used |
| 26 | Display of `BypassAct.Value` in faceplate (display and operator controls) and block icon |
| 27 | `AdvCoModSP` |
| 28 | 1 = Input parameter `OpenChnST` is interconnected |
| 29 | 1 = Input parameter `CloseChnST` is interconnected |
| 30 | 1 = Input parameter `StopChnST` is interconnected |
| 31 | `WithRbk` = 1 (Step controller with position feedback) |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `PV_AH_Act.Value` |
| 2 | `PV_WH_Act.Value` |

| Status bit | Parameter |
|---|---|
| 3 | PV_TH_Act.Value |
| 4 | PV_TL_Act.Value |
| 5 | PV_WL_Act.Value |
| 6 | PV_AL_Act.Value |
| 7 | PV_AH_En OR Feature.Bit31 |
| 8 | PV_WH_En OR Feature.Bit31 |
| 9 | PV_TH_En OR Feature.Bit31 |
| 10 | PV_TL_En OR Feature.Bit31 |
| 11 | PV_WL_En OR Feature.Bit31 |
| 12 | PV_AL_En OR Feature.Bit31 |
| 13 | PV_AH_MsgEn |
| 14 | PV_WH_MsgEn |
| 15 | PV_TH_MsgEn |
| 16 | PV_TL_MsgEn |
| 17 | PV_WL_MsgEn |
| 18 | PV_AL_MsgEn |
| 19 | ER_AH_Act.Value |
| 20 | ER_AL_Act.Value |
| 21 | ER_AH_En OR Feature.Bit31 |
| 22 | ER_AL_En OR Feature.Bit31 |
| 23 | ER_AH_MsgEn |
| 24 | ER_AL_MsgEn |
| 25 | RbkWH_Act.Value |
| 26 | RbkWL_Act.Value |
| 27 | RbkWH_En OR Feature.Bit31 |
| 28 | RbkWL_En OR Feature.Bit31 |
| 29 | RbkWH_MsgEn |
| 30 | RbkWL_MsgEn |
| 31 | MS_RelOp |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 | Delay of the PV_AH_Lim message |

| Status bit | Parameter |
|---|---|
| 9 | Delay of the PV_WH_Lim message |
| 10 | Delay of the PV_TH_Lim message |
| 11 | Delay of the PV_TL_Lim message |
| 12 | Delay of the PV_WL_Lim message |
| 13 | Delay of the PV_AL_Lim message |
| 14 | Delay of the ER_AH_Lim message |
| 15 | Delay of the ER_AL_Lim message |
| 16 | Collection of message delays |
| 17 | BypassAct.Value |
| 18 - 19 | Not used |
| 20 | 1= Suppressed messages |
| 21 - 26 | Not used |
| 27 | SP_UpRaAct, SP_DnRaAct limits enabled for gradient mode (SP_RateOn = 1) |
| 28 | GrpErr.Value |
| 29 | RdyToStart.Value |
| 30 | Not used |
| 31 | Internal error |

### Status word allocation for Status4 parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via EventTsIn |
| 8 - 28 | Not used |
| 29 | 1 = Input parameter SP_LiRmpTime is not interconnected (SP_LiRmpTime.ST = 16#FF) |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

## 6.10.2 PIDStepL modes

### PIDStepL modes

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the section Manual and automatic mode for control blocks (Page 79).

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for control blocks (Page 79).

### "Program mode for controllers"

You can find general information about the "Program mode for controller" in the section Program mode for controllers (Page 85).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | `Feature.Bit5` =0 | `Feature.Bit5` =1 |
|---|---|---|
| Open.ST | 16#80 | 16#60 |
| Close.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |
| RbkOut.ST | 16#80 | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| SP.ST | 16#80 | 16#60 |
| SP_ExtOut.ST | 16#80 | 16#60 |

| Output Parameters | Feature.Bit5 =0 | Feature.Bit5 =1 |
|---|---|---|
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_WH_Act.ST | 16#XX | 16#60 |
| PV_TH_Act.ST | 16#XX | 16#60 |
| PV_TL_Act.ST | 16#XX | 16#60 |
| PV_WL_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| PV_ToleHi.ST | 16#80 | 16#60 |
| PV_ToleLo.ST | 16#80 | 16#60 |
| ER.ST | 16#80 | 16#60 |
| ER_AH_Act.ST | 16#XX | 16#60 |
| ER_AL_Act.ST | 16#XX | 16#60 |

**Note**

The status of `RbkWH_Act` and `RbkWL_Act` will be 16#80 without Rbk.

## 6.10.3 PIDStepL functions

### Functions of PIDStepL

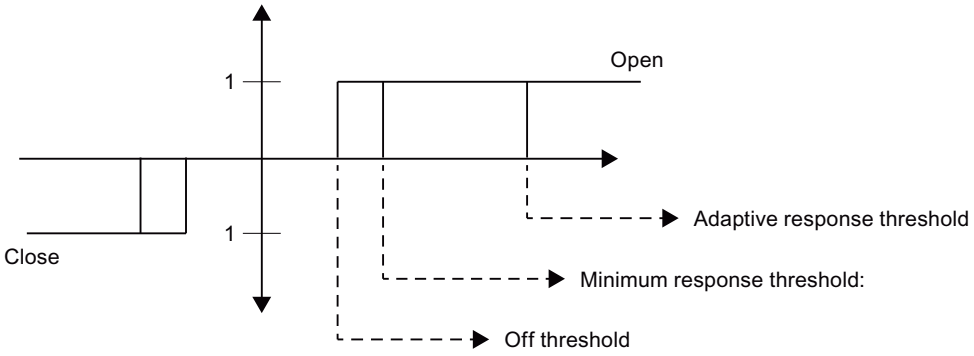
The functions for this block are listed below.

### Generation of manipulated variables with position feedback (`WithRbk` = 1)

The manipulated variable `MV` and therefore the actuating signals `Open`, `Close` and `Stop` can be generated as follows:

| MV_ForOn | ManAct | MV_TrkOn | AdvCoAct AND NOT AdvCoModSP | MV = | Limit monitoring | State | Open, Close, Stop |
|---|---|---|---|---|---|---|---|
| 1 | - | - | - | `MV_Forced` | none | Forced tracking through constraint without limitation | Depending on `Rbk` and `MV`, the output signals `Open`, `Close` and `Stop` are generated using the algorithm of a positioner. |
| 0 | 1 | - | - | `Man` | `ManHiLim` `ManLoLim` | Manual mode, set by the operator | |
| 0 | 0 | 1 | - | `MV_Trk` | `MV_HiLim` `MV_LoLim` | Tracking with limitation | |
| 0 | 0 | 0 | 1 | `AdvCoMV` | `MV_HiLim` `MV_LoLim` | Higher-level program mode | |
| 0 | 0 | 0 | 0 | `P_Part` + `I_Part` + `D_Part` + `FFwd` | `MV_HiLim` `MV_LoLim` | Automatic mode (PID algorithm) | |

If the controller is in "out of service" mode, the output parameter `MV` is set to the last valid value in manual mode or the neutral position manipulated variable depending on the `Feature` Bit (Neutral position manipulated variable takes effect at startup (Page 176)). Refer to the Out of service (Page 77) section for more on this.



### Generation of actuating signal without position feedback (`WithRbk` = 0)

The manipulated variable `MV` can be generated as follows:

| ManAct | Open, Close, Stop | State |
|---|---|---|
| 1 | The output signals are generated using the input signals:<br>`Feature.Bit7` = 0<br>`ModLiOp` = 0: `OpenOp`, `CloseOp` or `StopOp`<br>`ModLiOp` = 1: `OpenLi`, `CloseLi` or `StopLi`<br>`Feature.Bit7` = 1<br>`CtrlLiOp` = 0: `OpenOp`, `CloseOp` or `StopOp`<br>`CtrlLiOp` = 1: `OpenLi`, `CloseLi` or `StopLi` | Manual mode |
| 0 | The output signals are generated using PD output variables `P_Part`, `D_Part` and `FFwd` | Automatic mode (PID algorithm) |

If the controller is in "out of service" mode, the output parameter `MV` is set to the last valid value in manual mode or the neutral position manipulated variable depending on the `Feature` Bit (Neutral position manipulated variable takes effect at startup (Page 176)). Refer to the Out of service (Page 77) section for more on this.

### Three-position element with hysteresis and pulse generation

The difference (`MV - Rbk`) for a step controller with position feedback forms the input for the three-position element. The difference for step controllers without position feedback is formed from the output of the PD block and an internal feedback, which is weighted by the common integration of the position signal Open/Close `MotorTime` and the I-component weighted by `TI` (see block diagram).

You can calculate the response threshold of the three position element as follows:

- Minimum response threshold: `100.0 * Max(PulseTime, SampleTime) / MotorTime`
- Off threshold: `0.5 * 110.0 / MotorTime * SampleTime;`

Using "`ThrAdaOn`" you can turn on an adaption of the response threshold to reduce the switching frequency. This only affects the closed control loop (automatic operation without tracking) and is limited to:

- Down: Minimum response threshold
- Up: 10

The currently effective response threshold can be read at the output "`ThesOn`".

The pulse generation after the three position element ensures that `PulseTime` and `BreakTime` are maintained during pulse generation.

### Tracking and limiting a manipulated variable

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

**Note**

This function is only available to you if position feedback is enabled for the controller (`WithRbk` = 1).

### Neutral position

The block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming group errors:

- `CSF`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### "Actuator active" information

If the parameter `FbkClosed` = 0, this is recognized as "Actuator active". This status can be used to indicate a customized symbol in the process image, for example, and is saved in the status word (see Status word section in Description of PIDStepL (Page 1141)).

### Limit monitoring of position feedback

The block provides the standard function Limit monitoring of the feedback (Page 101).

**Note**

This function is only available to you if position feedback is enabled for the controller (`WithRbk` = 1).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### External/internal setpoint specification

The block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint limiting for external setpoints

The block provides the standard function Setpoint limiting for external setpoints (Page 222).

### Gradient limit of the setpoint

The block provides the standard function Gradient limit of the setpoint (Page 132).

### Using setpoint ramp

The block provides the standard function Using setpoint ramp (Page 131).

### Tracking setpoint in manual mode

The block provides the standard function Tracking setpoint in manual mode (Page 222).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Process value (`SimPV, SimPV_Li`)
- Position feedback (`SimRbk, SimRbkLi`)

### Bypass function

This block provides the standard function Bypassing signals (Page 115).

### Limit monitoring of the process value

The block provides the standard function Limit monitoring of the process value (Page 93).

### Providing limits at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

`ER_AH_LimOut` := `ER_AH_Lim`

`ER_AL_LimOut` := `ER_AL_Lim`

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

### Limit monitoring of error signal

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102).

### Inverting control direction

The block provides the standard function Inverting control direction (Page 217).

### Physical standardization of setpoint, manipulated variable and process value

Controller gain `Gain` is entered either using a physical variable or as standardized value.

`Gain` as a physical variable:

The standardized variables retain their default values:

- `NormPV.High` = 100 and `NormPV.Low` = 0

The effective gain is:

`GainEff` = `Gain`

Entering a standardized `Gain` (dimensionless):

Change the standardized variables to the actual range of the process values and manipulated variables.

- Internal and external setpoints; the process value and corresponding parameters are entered according to the physical measuring range of the process value.
- The manual parameter, the tracking value of the manipulated variable, feedforward control and the corresponding parameters are entered as a percentage 0...100.

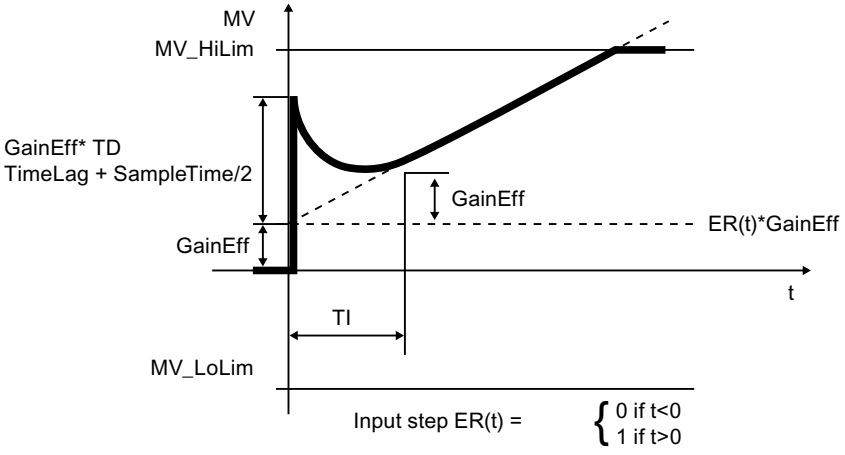
The effective gain is:

`GainEff` = 100.0 / (`NormPV.High` - `NormPV.Low`) · `Gain`

## Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

## PID algorithm



The manipulated variable is generated in automatic mode according to the following algorithm:

`MV` = `GainEff` · (1 + 1 / (`TI` · s) + (`TD` · s) / (1 + `TD` / `DiffGain` · s)) · `ER`

Where:

s = Complex number

The following step response occurs:

**Note**

The formula describes a standard application where P, I and D components are activated and the P and D components are not in the feedback circuit (`PropSel` = 1, `TI` <> 0, `DiffToFbk` = 0 `and IntSel` = 1, `DiffToFbk` = 0 and `PropFacSP` = 1).

The D component delay is derived from TD / DiffGain.

- The P component is at the P_Part I/O and can be deactivated using PropSel = 0 .
- The I component is displayed at the I_Part I/O and can be deactivated using TI = 0 or IntSel = 0. In deactivated state, I_Part is specified by MV_Offset and added to the manipulated variable. Make a selection for this value so that the remaining control deviation equals zero at the control loop's typical operating point, at least. IntSel is used for temporary deactivation of the I component. The I component is not reactivated until TI <> 0 and IntSel = 1. After the I component is activated, the integrator continues working starting from MV_Offset.
- The D component is displayed at the D_Part I/O and can be deactivated using TD = 0 or DiffSel = 0.

### Structure segmentation at controllers

The block provides the standard function Structure segmentation at controllers (Page 224).

### Anti-windup

The controller has an anti-windup function. The I component is frozen after the manipulated variable has reached limits (MV_HiLim or MV_LoLim).

### Feedforwarding and limiting disturbance variables

The block provides the standard function Feedforwarding and limiting disturbance variables (Page 223).

### Control loop is open (CascaCut)

The CascaCut output indicates whether the control loop within this block is open. In the open control loop, the master controller must be set to tracking mode to avoid until windup behavior. If you use this block in a cascade structure, then connect the output CascaCut to the input MV_TrkOn of the master controller.

CascaCut is active in the following cases:

- Block is not in automatic mode
- Setpoint is not in external mode
- Force or Tracking function is active

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the process value `PV_Out`:
  The signal status of the output parameter `PV_Out` always corresponds to the signal status of input parameter `PV` or, if the block is in simulation mode, 16#60.
- Signal status for the setpoint value `SP`:
  The signal status of the `SP` output parameter is always equivalent to the signal status of input parameter `SP_Ext` or `SP_Int`, depending on how the setpoint is specified. If the internal setpoint `SP_Int` is used, the signal status is always output as 16#80.
- Signal status of the error signal `ER`:
  The signal status of output parameter `ER` is obtained from the worst signal status of the two output parameters `PV_Out` and `SP` and is output.
  The signal status `16#60` (external simulation) is suppressed because the block acts as a sink with external simulation.
- Signal status for position feedback `RbkOut`:
  The signal status of `RbkOut` always corresponds to the signal status of input parameter `Rbk` or, if the block is in simulation mode, `16#60`. `RbkOut` is always `16#80` for step controllers without position feedback.
- Signal status for the manipulated variable `MV`:
  The signal status of output parameter `MV` is obtained in "automatic mode" from the worst signal status of the following parameters and is output:
  `ER.STFFwd.STFbkOpened.STFbkClosed.STRbkOut.ST`The signal status `16#60` (external simulation) is suppressed because the block acts as a sink with external simulation.
  In "manual mode" and for step controllers without position feedback, the signal status is always output as good.

- Signal status for `Open`, `Close`, `Stop`:
  The signal status is `16#60` when simulation is activated; otherwise, it is always `16#80`.
- Worst signal status:
  The worst signal status `ST_Worst` for the block is formed from the following parameters:
  - `SP.ST`;
  - `PV_Out.ST`;
  - `FFwd.ST`;
  - `FbkOpened.ST`;
  - FbkClosed.ST;
  - `RbkOut.ST`;
  - `OpenChnST.ST`;
  - `CloseChnST.ST`;
  - `StopChnST.ST`;

**Note**

The `RbkOut.ST` parameter is always 16#80for a step controller without position feedback (`WithFbk` = 0) .

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6 | Ramp rate calculation (Page 191) |
| 7 | Use connectable inputs OpenLi, StopLi, CloseLi with CtrlLiOp (Page 212) |
| 9 | Substitution value is active if the block is in bypass (Page 199) |
| 11 | Gradient limitation with time duration (Page 197) |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 18 | Disabling bumpless switchover to automatic mode for controllers (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | SP following PV in open loop has no priority over SP_Ext and SP limits (Page 193) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |

| Bit | Function |
|---|---|
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 31 | Limits disabled in faceplate (Page 206) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" `AutModOp` |
| 1 | 1 = Operator can switch to "manual mode" `ManModOp` |
| 2 | 1 = Operator can switch to "Out of service" mode `OosOp` |
| 3 | 1 = Operator can switch to "program mode" `AdvCoEn` |
| 4 | 1 = Operator can switch the setpoint to "external" `SP_ExtOp` |
| 5 | 1 = Operator can switch the setpoint to "internal" `SP_IntOp` |
| 6 | 1 = Operator can change the internal setpoint `SP_Int` |
| 7 | 1 = Operator can change the manual parameter `Man` (`WithRbk` = 1) |
| 8 | 1 = Operator can change operation high limit of the setpoint `SP_InHiLim` |
| 9 | 1 = Operator can change operation low limit of the setpoint `SP_InLoLim` |
| 10 | 1 = Operator can change the operation high limit of the manipulated variable `ManHiLim` |
| 11 | 1 = Operator can change the operation low limit of the manipulated variable `ManLoLim` |
| 12 | 1 = Operator can enable the setpoint's gradient limitation function `SP_RateOn` |
| 13 | 1 = Operator can change the setpoint's high limit for the ramp `SP_UpRaLim` |
| 14 | 1 = Operator can change the setpoint's low limit for the ramp `SP_DnRaLim` |
| 15 | 1 = Operator can switch between the time value or the value for the ramp `SP_RmpModTime` |
| 16 | 1 = Operator can change the ramp time `SP_RmpTime` |
| 17 | 1 = Operator can change the target setpoint `SP_RmpTarget` for the setpoint ramp |
| 18 | 1 = Operator can enable the setpoint ramp function `SP_RmpOn` |
| 19 | 1 = Operator can permit the PID optimization function `OptimEn` |
| 20 | 1 = Operator can enable the track setpoint in "manual mode" function `SP_TrkPV` |
| 21 | 1 = Operator can enable the bumpless switchover from external to internal `SP_TrkExt` |
| 22 | 1 = Operator can change the gain parameter `Gain` |
| 23 | 1 = Operator can change the integral time parameter `TI` |
| 24 | 1 = Operator can change the derivative time parameter `TD` |

| Bit | Function |
|---|---|
| 25 | 1 = Operator can change the derivative gain parameter `DiffGain` |
| 26 | 1 = Operator can change the dead band parameter `DeadBand` |
| 27 | 1 = Operator can activate bypass functionality |
| 28 | 1 = Operator can change the integral time parameter `MotorTime` |
| 29 | 1 = Operator can change the integral time parameter `PulseTime` |
| 30 | 1 = Operator can change the integral time parameter `BreakTime` |
| 31 | 1 = Operator can deactivate bypass functionality |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit (process value) `PV_AH_Lim` for the high alarm |
| 1 | 1 = Operator can change the limit (process value) `PV_WH_Lim` for the high warning |
| 2 | 1 = Operator can change the limit (process value) `PV_TH_Lim` for the high tolerance |
| 3 | 1 = Operator can change the hysteresis (process value) `PV_Hyst` |
| 4 | 1 = Operator can change the limit (process value) `PV_TL_Lim` for the low tolerance |
| 5 | 1 = Operator can change the limit (process value) `PV_WL_Lim` for the low warning |
| 6 | 1 = Operator can change the limit (process value) `PV_AL_Lim` for the low alarm |
| 7 | 1 = Operator can change the limit (error signal) `ER_AH_Lim` for the high alarm |
| 8 | 1 = Operator can change the hysteresis (error signal) `ER_Hyst` |
| 9 | 1 = Operator can change the limit (error signal) `ER_AL_Lim` for the low alarm |
| 10 | 1 = Operator can change the limit (position feedback) `RbkWH_Lim` for the high warning |
| 11 | 1 = Operator can change the hysteresis (position feedback) `RbkHyst` |
| 12 | 1 = Operator can change the limit (position feedback) `RbkWL_Lim` for the low warning |
| 13 | 1 = Operator can open the valve: `OpenOp` (`WithRbk` = 0) |
| 14 | 1 = Operator can close the valve: `CloseOp` (`WithRbk` = 0) |
| 15 | 1 = Operator can stop the valve: `StopOp` (`WithRbk` = 0) |
| 16 | 1 = Operator can activate the Simulation function `SimOn` |
| 17 | 1 = Operator can activate the Release for maintenance function `MS_RelOp` |
| 18 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 19 | 1 = Operator can activate / deactivate messages via `PV_WH_MsgEn` |
| 20 | 1 = Operator can activate / deactivate messages via `PV_TH_MsgEn` |
| 21 | 1 = Operator can activate / deactivate messages via `PV_TL_MsgEn` |
| 22 | 1 = Operator can activate / deactivate messages via `PV_WL_MsgEn` |
| 23 | 1 = Operator can activate / deactivate messages via `PV_AL_MsgEn` |
| 24 | 1 = Operator can activate / deactivate messages via `ER_AH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `ER_AL_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `RbkWH_MsgEn` |
| 27 | 1 = Operator can activate / deactivate messages via `RbkWL_MsgEn` |
| 28 | 1 = Operator can change the simulation value `SimPV` |
| 29 | 1 = Operator can change the simulation value `SimRbk` |
| 18 - 29 | Not used |

| Bit | Function |
|---|---|
| 30 | 1 = Operator can activate the derivative action to the feedback path `DiffToFbk` |
| 31 | 1 = Operator can change the proportional action to the feedback path `PropFacSP` |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Release for maintenance

The block provides the standard function Release for maintenance (Page 70).

### Generating instance-specific messages

The block provides the standard function Generating instance-specific messages (Page 230) without the time stamp function in the I/O.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `OpenOp`
- `StopOp`
- `CloseOp`

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

## 6.10.4 PIDStepL error handling

### Error handling of PIDStepL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 30 | The value of `PV` can no longer be displayed in the REAL number field. |
| 31 | The value of `SP_Ext` can no longer be displayed in the REAL number field. |
| 32 | The value of `FFwd` can no longer be displayed in the REAL number field. |
| 33 | The value of `MV_Trk` can no longer be displayed in the REAL number field. |
| 34 | The value of `MV_Forced` can no longer be displayed in the REAL number field. |
| 35 | The value of `Rbk` can no longer be displayed in the REAL number field. |
| 36 | The value of `MV` can no longer be displayed in the REAL number field. |
| 50 | The controller cannot be switched to program mode, because program mode with default setpoint (`AdvCoModSP` = 0) is not possible for step controllers without position feedback (`WithRbk` = 0). |

| Error number | Meaning of the error number |
|---|---|
| 51 | AutModLi = 1 and ManModLi = 1<br>SP_LiOp = 1 and SP_IntLi = 1 and SP_ExtLi = 1<br>OpenLi = 1 and StopLi = 1<br>CloseLi = 1 and StopLi = 1<br>OpenLi = 1 and CloseLi = 1 |
| 59 | = 1 "Gain is negative" |
| 60 | \|TI\| < SampleTime / 2 |
| 61 | \|TD\| < SampleTime |
| 62 | DiffGain < 1 or DiffGain > 10 |
| 63 | TD / DiffGain < SampleTime / 2 |
| 64 | PropFacSP < 0 or PropFacSP > 1 |
| 66 | NormPV_High = NormPV_Low |
| 67 | MotorTime < SampleTime |
| 68 | PulseTime < SampleTime |
| 69 | BreakTime < SampleTime |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 6.10.5 PIDStepL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId2, SIG 6).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>PV - high alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>PV - high warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>PV - high tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>PV - low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>PV - low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>PV - low alarm limit violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>ER - high alarm limit violated |
| | SIG 8 | Alarm - low | $$BlockComment$$<br>ER - low alarm limit violated |
| MsgEvId2 | SIG 7 | Warning - high | $$BlockComment$$<br>Rbk - high warning limit violated |
| | SIG 8 | Warning - low | $$BlockComment$$<br>Rbk - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to four instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External message 1<br>Status 16#@5%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 2<br>Status 16#@6%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 3<br>Status 16#@7%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 4<br>Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | Process value PV_Out |
| 5 | Control deviation ER |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | Not allocated |
| 9 | Not allocated |
| 10 | Not allocated |

The associated values 6 ... 7 are allocated to the parameters ExtVa106 ... ExtVa107 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |

| Associated value | Block parameters |
|---|---|
| 4 | Position feedback RbkOut |
| 5 | Signal status ExtMsg1 |
| 6 | Signal status ExtMsg2 |
| 7 | Signal status ExtMsg3 |
| 8 | Signal status ExtMsg4 |
| 9 | ExtVa209 |
| 10 | ExtVa210 |

The associated values 9 ... 10 are allocated to the parameters ExtVa209 ... ExtVa210 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 6.10.6 PIDStepL I/Os

I/Os of PIDStepL

For the parameters that are not linkable, refer:Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoEn | 1 = Enable "program mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoOn* | 1 = Enable "program mode" via faceplate.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | BOOL | 0 |
| AdvCoModSP | Type of "program mode":<br>1 = Setpoint specification<br>0 = Manipulated variable specification | BOOL | 1 |
| AdvCoMstrOn | Activate (0-1) or deactivate (1-0) "program mode" via edge transition | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoMV | Specified value from the external program.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | REAL | 0.0 |
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation for batch control | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of block-type<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BreakTime | Minimum break duration [s] | REAL | 1.0 |
| BypLiOp | 1 = Bypass commands via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypLock | 1 = Bypass activation or deactivation is locked for operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypProt | Bypass Protection in Sim Modes | BOOL | 0 |
| BypPV | Substitution value if block is in bypass | REAL | 0.0 |
| BypPVLi | 1 = Select bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypPVOp | 1 = Select bypass PV (via operator) | BOOL | 0 |
| CloseChnST | Output channel state of Close<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CloseLi* | 1 = Close via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseOp* | 1 = Close via operator | BOOL | 0 |
| CPI_In | Input for control performance index, which is calculated by the assigned ConPerMon block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| CSF | 1 = External error (control system fault)<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadBand | Width of dead band | REAL | 0.0 |
| DiffGain | Gain of differentiator [1..10] DiffGain = TD / (delay time of D component) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 5.0<br>• 16#FF |
| DiffSel | 1 = D component activated | BOOL | 1 |
| DiffToFbk | 1 = D component is placed in the feedback | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ER_A_DC* | Delay for incoming alarms during error signal monitoring | REAL | 0.0 |
| ER_A_DG* | Delay for outgoing alarms during error signal monitoring | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AH_Lim | Alarm limit (high) for error signal monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for error signal monitoring | BOOL | 1 |
| ER_AL_En | 1 = Activate alarm (low) for error signal monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for error signal monitoring | REAL | -100.0 |
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for error signal monitoring | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for error signal | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg1 | 1 = Binary input for freely selectable message 1 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | 1 = Binary input for freely selectable message 2 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | 1 = Binary input for freely selectable message 3 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | 1 = Binary input for freely selectable message 4 is used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa209 | Associated value 9 for messages (MsgEvID2) | ANY | |
| ExtVa210 | Associated value 10 for messages (MsgEvID2) | ANY | |
| FbkClosed | Low limit stop signal of position feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#80 |
| FbkOpened | High limit stop signal of position feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions (Page 1147) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FFwd* | Input for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| FFwdHiLim | Limit (high) for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| FFwdLoLim | Limit (low) for additive disturbance variable activation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• -100.0<br>• 16#80 |
| Gain | Proportional gain<br>Gain.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| IntHoldNeg | 1 = Integrator cannot run in negative direction | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| IntHoldPos | 1 = Integrator cannot run in positive direction | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Intlock | Reserved | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| Intl_En | Reserved | BOOL | 1 |
| IntSel | 1 = I component activated | BOOL | 1 |
| Man* | Manual specification for the manipulated variable | REAL | 0.0 |
| ManHiLim | Limit (high) for manual parameter Man | REAL | 100.0 |
| ManLoLim | Limit (low) for manual parameter Man | REAL | 0.0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Operating mode switchover between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MotorTime | Motor actuating time [s] | REAL | 30.0 |
| MS_RelOp* | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvID1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgEvID2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Forced* | Forced manipulated variable that is not limited and assumes top priority | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_ForOn | 1 = Output forced manipulated variable MV_Forced unlimited at output MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiLim | Limit (high) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| MV_LoLim | Limit (low) for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Offset | Manipulated variable for ER = 0, operating point for controller with deactivated I component | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_Trk* | Tracking value for the manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NegGain | 0 = Effective proportional gain GainEff is positive<br>1 = Effective proportional gain GainEff is negative | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NormPV | Process value range (PV) for standardizing the proportional gain (GAIN) | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpenChnST | Output channel state of Open<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| OpenLi* | 1 = Open via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenOp* | 1 = Open via operator | BOOL | 0 |
| OptimEn* | 1 = Enable optimization of PID parameters by PID tuner | BOOL | 0 |
| OptimOcc* | 1 = Optimization running | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1147) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1147) | STRUCT<br>• Bit 0: BOOL<br>• Bit 18: BOOL<br>• Bit 19: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| PropFacSP | Applying the P component to the feedback [0..1]. 0 = P component fully in feedback | REAL | 1.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PropSel | 1 = Activate P component | BOOL | 1 |
| PulseTime | Minimum pulse duration [s] | REAL | 1.0 |
| PV* | Process value (controlled variable) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Unit | Unit of measure for process value | INT | 1001 |
| PV_A_DC* | Delay time for incoming PV alarms [s] | REAL | 0.0 |
| PV_A_DG* | Delay time for outgoing PV alarms [s] | REAL | 0.0 |
| PV_AH_En | 1 = Enable PV alarm limit (high) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) | REAL | 95.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) | BOOL | 1 |
| PV_AL_Lim | PV alarm limit (low) | REAL | 5.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message | BOOL | 1 |
| PV_Hyst | Hysteresis for PV alarm, warning and tolerance limits | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_T_DC* | Delay time for incoming PV tolerance messages [s] | REAL | 0.0 |
| PV_T_DG* | Delay time for outgoing PV tolerance messages [s] | REAL | 0.0 |
| PV_TH_En | 1 = Enable PV tolerance limit (high) | BOOL | 0 |
| PV_TH_Lim | Limit PV tolerance message (high) | REAL | 85.0 |
| PV_TH_MsgEn | 1 = Enable message for PV tolerance message (high) | BOOL | 1 |
| PV_TL_En | 1 = Enable PV tolerance limit (low) | BOOL | 0 |
| PV_TL_Lim | Limit PV tolerance message (low) | REAL | 15.0 |
| PV_TL_MsgEn | 1 = Activate message for PV tolerance message (low) | BOOL | 1 |
| PV_Unit | Unit of measure for process value | INT | 1001; °C |
| PV_W_DC* | Delay time for incoming PV warnings [s] | REAL | 0.0 |
| PV_W_DG* | Delay time for outgoing PV warnings [s] | REAL | 0.0 |
| PV_WH_En | 1 = Enable PV warning limit (high) | BOOL | 1 |
| PV_WH_Lim | Limit PV warning (high) | REAL | 90.0 |
| PV_WH_MsgEn | 1 = Enable PV warning (high) message | BOOL | 1 |
| PV_WL_En | 1 = Enable PV warning limit (low) | BOOL | 1 |
| PV_WL_Lim | Limit PV warning (low) | REAL | 10.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_WL_MsgEn | 1 = Enable PV warning (low) message | BOOL | 1 |
| Rbk* | Position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 1 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 100.0 |
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 1 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 0.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |
| RefStdDevIn | Reference value of PV standard deviation (sigma) in defined "good" state of control loop | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#78 |
| RstBypLi | 1 = Reset bypass PV (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstBypOp | 1 = Reset bypass PV (via operator) | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| S_RbkOnPIDTun | Simulation of position feedback on;<br>For PCS 7 PID tuner only | BOOL | 0 |
| S_RbkPIDTun* | Simulated position feedback | REAL | 50.0 |
| SafePos | Neutral position (Page 54) for step controller actuating signals:<br>0 = Close<br>1 = Open<br>2 = Stop | INT | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used for SimOn = 1 | REAL | 0.0 |
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaLim* | Limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| SP_ExHiLim | Limit (high) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_ExLoLim | Limit (low) for external setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Ext* | External setpoint of - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi* | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_InHiLim | Limit (high) of internal setpoint | REAL | 100.0 |
| SP_InLoLim | Limit (low) of internal setpoint | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 0.0 |
| SP_IntLi* | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 0 |
| SP_LiDnRaLim | Linkable limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_LiRmpTime | Linkable time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiUpRaLim | Linkable gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_RateOn* | 1 = Activate limitation of setpoint gradients | BOOL | 0 |
| SP_RmpModTime | 1 = Use time values (SP_RmpTime, SP_LiRmpTime)<br>0 = Use gradient limits (SP_DnRaLim, SP_LiDnRaLim, SP_UpRaLim, SP_LiUpRaLim) | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |
| SP_RmpTime* | Time [Time unit] for setpoint ramp from current SP up to SP_RmpTarget or time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 1 |
| SP_TrkPV | 1 = Setpoint follows PV in "manual mode" and with tracking | BOOL | 0 |
| SP_UpRaLim* | Gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopChnST | Output channel state of Stop<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| StopLi* | 1 = Stop via interconnection or CFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopOp* | 1 = Stop via operator | BOOL | 0 |
| TD | Derivative time in [s]<br>TD.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| ThrAdaOn | Adaptation of threshold<br>0 = Hold constant | BOOL | 1 |
| TI | Integral time [s]<br>TI.ST = 16#FF: Enabled in faceplate | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>Value: REAL<br>ST: BYTE | <br>0.0<br>16#FF |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>Value: REAL<br>ST: BYTE | <br>0.0<br>16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus 2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| WithRbk | 1 = Feedback value available for the manipulated variable | BOOL | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AdvCoAct | 1 = "Program mode" enabled.<br>The parameter is available on the WinCC OPC server to be read by external APC programs. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AdvCoRdy | 1 = "Program mode" available | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutAct | 1 = "Automatic mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypassAct | 1 = Bypass is activated in this block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CascaCut | Cascade connection:<br>1 = Control chain from primary to secondary controller is interrupted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Close | Control output:<br>1 = Closed is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| D_Part | D component of PID algorithm | REAL | 0.0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_AH_Act | 1 = Alarm limit (high) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ER_AL_Act | 1 = Alarm limit (low) for control deviation violated.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ER_AH_LimOut | ER_AH_Lim as output | REAL | 0.0 |
| ER_AL_LimOut | ER_AL_Lim as output | REAL | 0.0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see PIDStepL error handling (Page 1159) | INT | -1 |
| FFwdHiAct | 1 = Limit (high) for additive disturbance variable activation violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FFwdLoAct | 1 = Limit (low) for additive disturbance variable activation violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GainEff | Effective proportional gain depends on NegGain, Gain, NormPV, and NormMV | REAL | 1.0 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Reserved | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| I_Part | I component of PID algorithm | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LoopClosed | 1 = Control loop closed<br>0 = Control loop open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| ManHiOut | Limit (high) for "manual mode", corresponds to input parameter ManHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| ManLoOut | Limit (low) for "manual mode", corresponds to input parameter ManLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MS_Release | Release for maintenance: 1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgAckn2 | Message acknowledgement status 2 (output ACK_STATE of second ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | 1 = Alarm error 1 (output ERROR of the first ALARM_8P) | BOOL | 0 |
| MsgErr2 | 1 = Alarm error 2 (output ERROR of the second ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| MsgStat2 | Message status 2 (output STATUS of second ALARM_8P) | WORD | 16#0000 |
| MV | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Open | Control output:<br>1 = Open is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| P_Part | P component of PID algorithm | REAL | 0.0 |
| PV_AH_Act | 1 = PV alarm (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_AL_Act | 1 = PV alarm (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE<br>• Bit 1: BOOL of internal fill byte (Bypass information bit) | -<br>• 0.0<br>• 16#80<br>• 0 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_TH_Act | 1 = PV tolerance message (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_TL_Act | 1 = PV tolerance message (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_ToleHi | Limit (high) of 3-sigma band around the set-point is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_ToleLo | Limit (low) of 3-sigma band around the setpoint is calculated when a ConPerMon block is connected | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_UnitOut | Unit of measure for process value, for interconnecting to the PV_Unit input parameter of the ConPerMon block | INT | 0 |
| PV_WH_Act | 1 = PV warning (high) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| PV_WL_Act | 1 = PV warning (low) active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| RbkOut | Output for position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) for position feedback active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_ExHiAct | 1 = Limit (high) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExLoAct | 1 = Limit (low) for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOut | External setpoint, corresponds to input parameter SP_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_InHiOut | Limit (high) for SP_Int corresponds to input parameter SP_InHiLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_InLoOut | Limit (low) for SP_Int corresponds to input parameter SP_InLoLim | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_RateTarget | Target setpoint for the gradient limitation | REAL | 0.0 |
| SP_UpRaAct | Positive gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RemRT | Remaining ramp time of the setpoint | REAL | 0.0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1141) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1141) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1141) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1141) | DWORD | 16#00000000 |
| Stop | Control output:<br>1 =Stopped is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SumMsgAct | 1 = Active hardware interrupt | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Threson | Adaptive threshold [%] | REAL | 0.0 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |

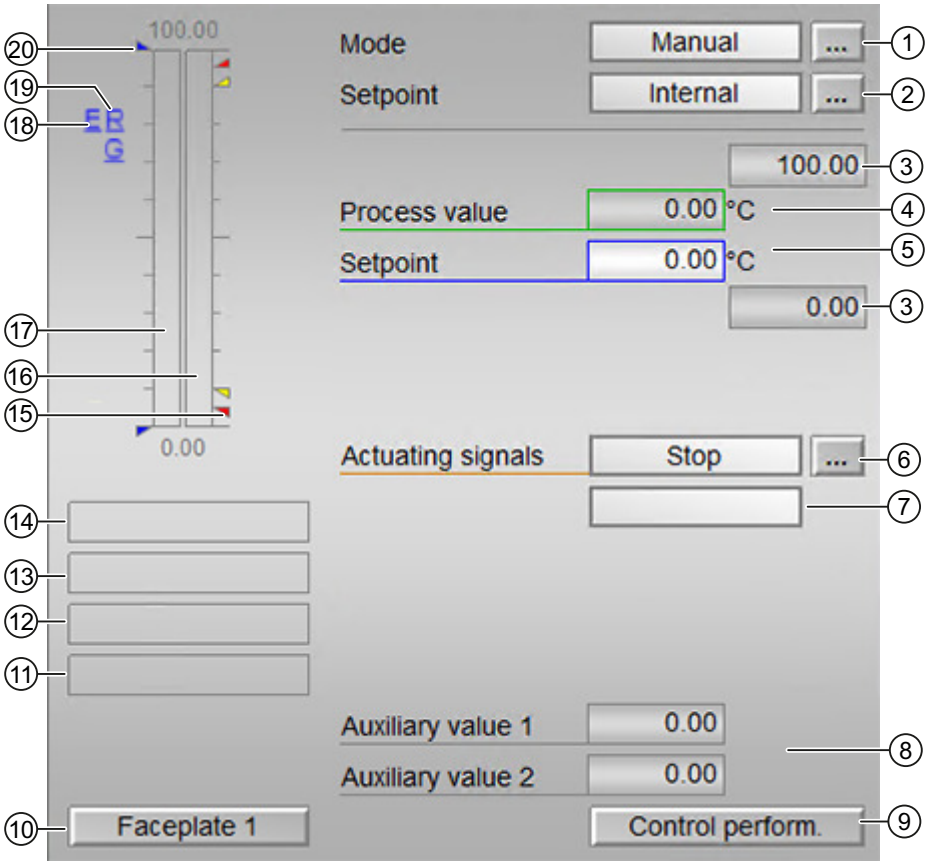
## 6.10.8 Operator control and monitoring

### 6.10.8.1 PIDStepL views

#### Views of the PIDStepL block



The block PIDStepL provides the following views:

- PIDStepL standard view without position feedback (Page 1185)
- PIDStepL standard view with position feedback (Page 1189)
- Alarm view (Page 336)
- Limit view of PID controllers (Page 325)
- Trend view (Page 341)
- Ramp view (Page 334)
- Parameter view of PID controllers (Page 315)
- PIDStepL preview (Page 1193)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icons for PID and FM controller (Page 269)

Refer to the Structure of the faceplate (Page 279) and Block icon structure (Page 260) sections for general information about the faceplate and block icon.

### 6.10.8.2 PIDStepL standard view without position feedback

#### PIDStepL standard view without position feedback

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

### (2) Displaying and switching the setpoint

This area shows how to specify the setpoint. The setpoint can specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the setpoint specification.

You can find additional information on this in the Setpoint specification - internal/external (Page 136) section.

### (3) High and low scale range for the process value

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the Engineering System (ES). For more information refer Bar graph (Page 376) section.

### (4) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

### (5) Displaying and changing the setpoint including signal status

This area shows the current setpoint with the corresponding signal status.

Refer to the Changing values (Page 291) section for information on changing the setpoint. The setpoint specification also needs to be set to "Internal" for this block.

### (6) Displaying and changing manipulated variables

This area shows you the currently valid manipulated variable. Refer to the Switching operating states and operating modes (Page 289) section for information on changing the manipulated variable.

The following manipulated variables can be selected:

- "Open"
- "Stop"
- "Close"

If text is configured for these commands, it is displayed as status text and as button labels for command selection. You can find more information about this in the Section Labeling of buttons and text (Page 235).

### (7) Displaying the feedback

The following feedback can be displayed:

- "Open"
- "Closed"

If text is configured for these commands, it is displayed as status text and as button labels for command selection. You can find more information about this in the Section Labeling of buttons and text (Page 235).

### (8) Display for auxiliary values

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find more information on this in the section Displaying auxiliary values (Page 239).

### (9) Navigation button for switching to the standard view of the ConPerMon block

Use this navigation button to reach the standard view of the ConPerMon block. The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the Opening additional faceplates (Page 234) section for more on this.

### (10) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### (11) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on the display area for states of the block is available in section Release for maintenance (Page 70).

### (12) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in the Simulating signals (Page 64) section.

### (13) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (14) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Optimization"
- "Tracking"
- "Forced tracking"
- "SP ramp active"

### (15) Limit display

These colored triangles show you the configured limits in the respective bar graph.

### (16) Bar graph for the process value

This area shows the current process value in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

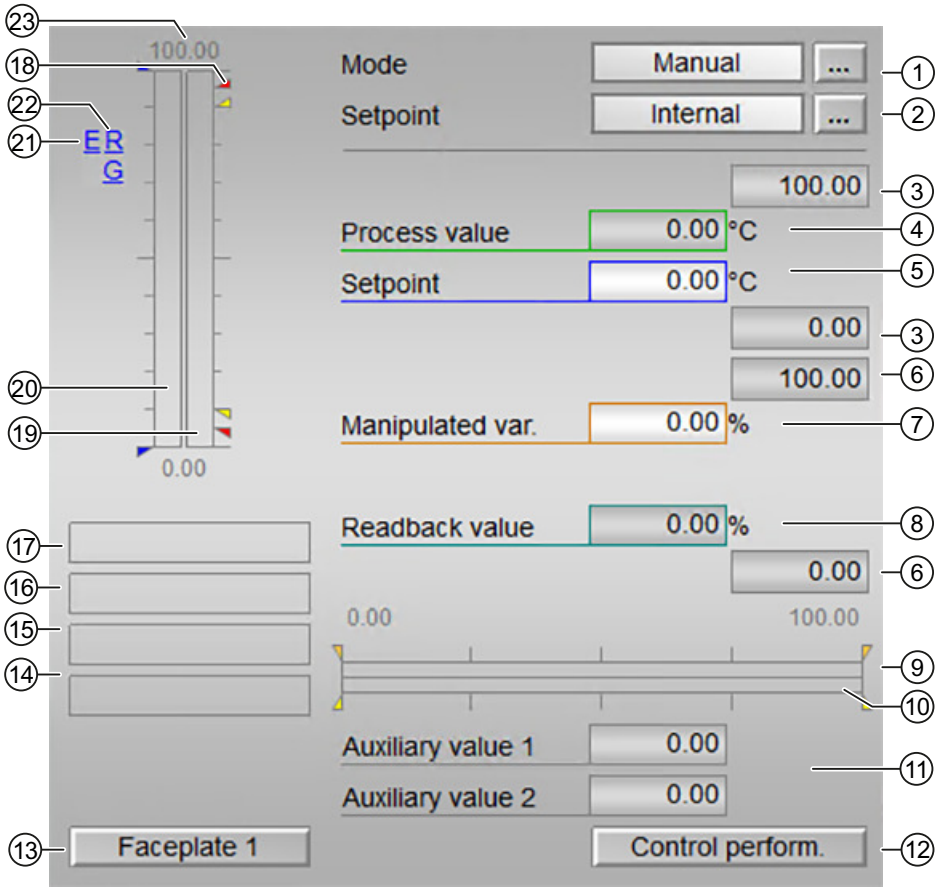
### (17) Bar graph for the setpoint

This area shows the current setpoint in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (18) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (19) Display for the target setpoint of the setpoint ramp



This display [R] shows you the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (20) Displaying the limits

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the Engineering System (ES).

### 6.10.8.3 PIDStepL standard view with position feedback

**PIDStepL standard view with position feedback**

**(1) Display and switch the operating mode**

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Program mode for controllers (Page 85)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Display and switch the setpoint specification

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) chapter for information on switching the setpoint specification.

You can find additional information on this in section Setpoint specification - internal/external (Page 136).

### (3) High and low scale range for the process value

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the Engineering System (ES). For more information referBar graph (Page 376) section.

### (4) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

### (5) Display and change the setpoint including signal status

This area shows the current setpoint with the corresponding signal status.

Refer to the Changing values (Page 291) chapter for information on changing the setpoint. The setpoint specification also needs to be set to "Internal" for this block.

### (6) High and low limits of the manipulated variable

You can only display and change a manipulated variable in "manual mode".

### (7) Displaying and changing the manipulated variable

You can only display and change a manipulated variable in "manual mode".

### (8) Displaying the feedback

This display is only visible when the corresponding block input is interconnected.

The following feedback can be displayed:

- "Open"
- "Closed"

### (9) Bar graph for the manipulated variable

The bar graph for the manipulated variable is only available in manual mode. You can also see the high and low limits of the bargraph's scale.

### (10) Bar graph for the readback value

This display is only visible when the corresponding block input is interconnected. You can also see the high and low limits of the bargraph's scale.

The bar graph for the readback value is only available in manual mode.

### (11) Display for auxiliary values

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find more information on this in the section Displaying auxiliary values (Page 239).

### (12) Button for switching to the standard view of the ConPerMon block

Use this button for the standard view of the ConPerMon block. The visibility of this button depends on the configuration in the engineering system (ES).

Refer also to chapter Opening additional faceplates (Page 234) for more on this.

### (13) Button for switching to the standard view of any faceplate

Use this button for the standard view of a block configured in the Engineering System (ES). The visibility of this button depends on the configuration in the engineering system (ES).

You can find additional information on this in section Opening additional faceplates (Page 234).

### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in chapter Release for maintenance (Page 70) Display area for block states.

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in section Simulating signals (Page 64).

### (16) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal errorl"
- "Invalid Signal"

### (17) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Optimization"
- "Tracking"
- "Forced tracking"
- "SP ramp active"

### (18) Limit display

These colored triangles show you the configured limits in the respective bar graph.

### (19) Bar graph for the process value

This area shows the current process value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (20)Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

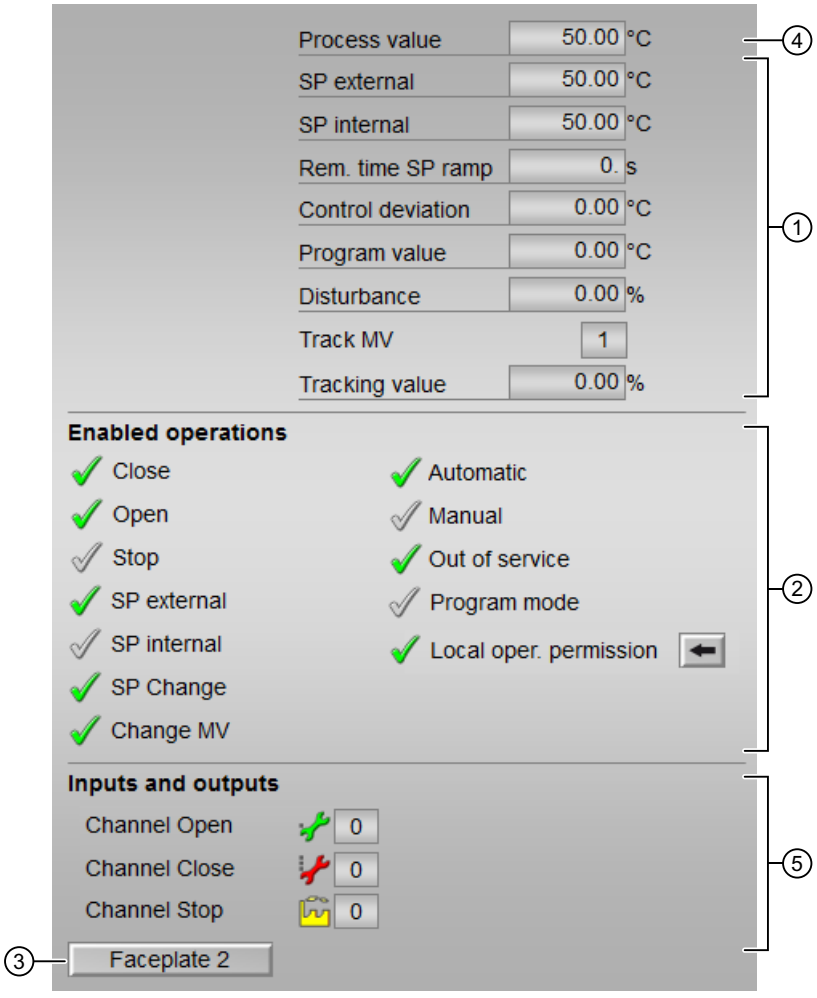
### (21) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (22) Bar graph for the setpoint

This area shows the current setpoint in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (23) Displaying the limits



These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the Engineering System (ES).

### See also

Labeling of buttons and text (Page 235)

### 6.10.8.4 PIDStepL preview

#### Preview of PIDStepL

#### (1) Preview area

This area shows you a preview for the following values:

- "SP external": currently applicable external setpoint
- "SP internal": currently applicable internal setpoint
- "Rem. time SP ramp": Remaining time to reach the ramp target value.
- "Error signal": Current control deviation
- "Program value": specified value for program mode
- "Disturbance variable": additive value for feedforward control

- "Track MV": Track manipulated variable (value is 1)
- "Tracking value": effective manipulated variable for "Track manipulated variable"

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Close": You can select the manipulated variable "Close". If text is configured for this command, it is also displayed in brackets. You can find additional information on this in the section Labeling of buttons and text (Page 235) .
- "Open": You can select the manipulated variable "Open". If text is configured for this command, it is also displayed in brackets. You can find additional information on this in the section Labeling of buttons and text (Page 235) .
- "Stop": You can select the manipulated variable "Stop". If text is configured for this command, it is also displayed in brackets. You can find additional information on this in the section Labeling of buttons and text (Page 235) .
- "SP external": You can feedforward the external setpoint.
- "SP internal": You can feedforward the internal setpoint.
- "Change SP": You can change the setpoint.
- "Change MV": You can change the manipulated variable.
- "Program mode": You can switch to "program mode".
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285) .

### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### (4) Process value

This area displays the real process value (PV).

### (5) Display of the current control signal

This area shows the most important parameters for this block with the current selection

- "Channel Open": Signal from the output channel block for "Open"
- "Channel Close": Signal from the output channel block for "Close"
- "Channel Stop": Signal from the output channel block for "Stop"

# 6.11 Ratio - Ratio controlling

## 6.11.1 Description of Ratio

### Object name (type + number) and family

Type + number: FB 1883

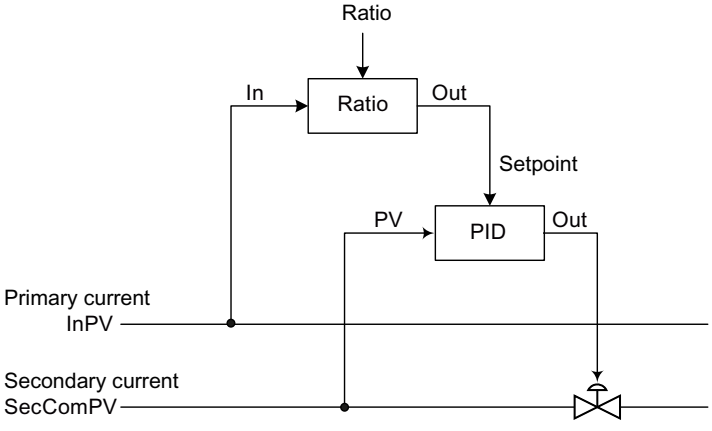
Family: Control

### Area of application for Ratio

The block is used for the following applications:

- Forming a ratio

### How it works



The block is used to create a ratio, for example, in a ratio control. It is also used to set elements (for example, synchronization control loop), or to influence the reference variable of a cascade.

The block operates according to the equation: `Out` = `In` · `RatioOut` + `Offset`

Where:

- `RatioOut` is either the value from `RatioInt` or `RatioExt`
- `Offset` is the offset value that should be added to the output value

`In` is based on the interconnection whereas `RatioOut` is selected based on the internal/ external selection.

Also refer to the Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836) section for information on calculating the current ratio.

### Configuring OBs

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

The description for each parameter can be found in the Ratio I/Os (Page 1202) section.

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 | Not used |
| 8 | `RatExtAct.Value` |
| 9 | `RatLoAct.Value` |
| 10 | `RatHiAct.Value` |
| 11 | `OutLoAct.Value` |
| 12 | `OutHiAct.Value` |
| 13 | `RatTrkExt` |
| 14 | `SimLiOp.Value` |
| 15 - 29 | Not used |
| 30 | Invalid signal |
| 31 | Internal error |

## 6.11.2 Ratio modes

### Ratio operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

The last valid value is provided at the `Out` output in this operating mode. The `OutHiAct`, `OutLoAct`, `RatHiAct`and `RatLoAct`output parameters are reset.

Description of Ratio (Page 1196)

## 6.11.3 Ratio functions

### Functions of Ratio

The functions for this block are listed below.

### Internal or external ratio

You can use the RatLiOp parameter to specify if the ratio should be specified internally or externally:

- RatLiOp = 0: The ratio (RatioInt) is specified by the operator. The operator can decide if the specification should be made internally (RatIntOp = 1) or externally (RatExtOp = 1) .
- RatLiOp = 1: The ratio (RatioExt) is specified by an interconnection. The interconnection is used to determine if the specification should be made internally (RatIntLi = 1) or externally (RatExtLi = 1) .

### Bumpless switchover from external to internal ratio

The parameter RatTrkExt = 1 is used so that the internal ratio tracks the external setpoint to achieve a bumpless switchover from the external to the internal ratio. This allows unwanted jumps at the output parameter to be avoided.

### Limiting the ratio

The ratio is limited by the RatHiLim parameter (high) or RatLoLim parameter (low).

The external ratio RatioExt is limited to the value you have specified if a limit is violated. This is then also used to form the output value Out. If these limits are reached or violated RatioHiAct or RatioLoAct are also set to 1.

The internal ratio RatioInt is checked against the value you have specified. If a value is outside the specified limit, it is reset to the most recent valid value.

### Limiting the output value

The output value is limited by the OutHiLim parameter (high) or OutLoLim parameter (low).

The OutHiAct or OutLoAct output parameter is set to 1 as soon as the output value has reached or exceeded the limits

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Analog input value (SimIn, SimInLi)

### Display and operator input area for process values and setpoints

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can switch to external |
| 5 | 1 = Operator can switch to internal |
| 6 | 1 = Operator can specify the internal ratio |
| 7 - 9 | Not used |
| 10 | 1 =Operator can change the simulation value `SimIn` |
| 11 | 1 = Operator can switch to "Simulation" mode |
| 12 | 1 = Operator can enable bumpless switchover |
| 13 | Not used |
| 14 | 1 = Operator can change `RatHiLim` |
| 15 | 1 = Operator can change `RatLoLim` |
| 16 | 1 = Operator can change `OutHiLim` |
| 17 | 1 = Operator can change `OutLoLim` |
| 18 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Forming and outputting signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` is formed from the following parameters:

- `Out.ST`
- `SecComPV.ST`
- `InPV.ST`
- `RatioExt.ST`
- `Offset.ST`

The signal status of the `Out` output parameter corresponds to the input parameter `In`.

The signal status of the current ratio calculation corresponds to the status of the input parameter `SecComPV`.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 24 | Enabling local operator authorization (Page 169) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 6.11.4 Ratio error handling

### Ratio error handling

Refer to section Error handling (Page 128) for basic instructions on how to troubleshoot all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when implementing the block; block will not be processed. |
| 0 | No active fault |
| 30 | The input value of `In` can no longer be displayed in the REAL number field. |
| 51 | `RatLiOp` = 1 and `RatExtLi` = 1 and `RatInLi` = 1 |

### I/Os of Ratio

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of block-type<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 1198) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In | Analog input | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| InPV | Input for process variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| InUnit | Unit of measure for input parameter In | INT | 1001 |
| Offset | Offset | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operating permission, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS_Perm | I/O for operator control permissions (Page 1198) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OutHiLim | High limit for output value | REAL | 100.0 |
| OutLoLim | Low limit for output value | REAL | 0.0 |
| RatExtLi | 1 = Select external ratio (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RatExtOp* | 1 = Select external ratio (via operator) | BOOL | 0 |
| RatHiLim | High limit | REAL | 100.0 |
| RatIntLi | 1 = Select internal ratio (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RatIntOp* | 1 = Select internal ratio (via operator) | BOOL | 1 |
| RatioExt | External ratio | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#80 |
| RatioInt* | Internal ratio | REAL | 1.0 |
| RatioUnit | Unit of measure for the RationInt, RatioExt input parameter or RatioPV (output parameter) | INT | 0 |
| RatLiOp | Select ratio source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RatLoLim | Low limit | REAL | 0.0 |
| RatOpScale | Limit for scale in bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| RatTrkExt | 1 = Bumpless switchover from external to internal ratio active | BOOL | 0 |
| SecComPV* | Process value of secondary component | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SecComUnit | Unit of measure for input parameter SecComPV | INT | 1001 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimIn* | Analog input value used for SimOn = 1 | REAL | 0.0 |
| SimInLi | Value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see Ratio error handling (Page 1201) | INT | -1 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| Out | Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OutHiAct | 1 = High limit overshoot | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OutHiLmOut | Output of high limit | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OutLoAct | 1 = Low limit overshoot | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutLoLmOut | Output of low limit | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RatExtAct | 1 = External ratio used<br>0 = Internal ratio used | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RatHiAct | 1 = Limit (high) for ratio active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RatioPV | Current ratio | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RatioOut | Applied ratio (RatioInt or RatioExt) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RatOpScaleOut | RatOpScale as output | STRUCT<br>High: REAL<br>Low: REAL | |
| RatLoAct | 1 = Limit (low) for ratio active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RatioUnitOut | RatioUnit as output | INT | 0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status | Status word (Page 1196) | DWORD | 16#00000000 |

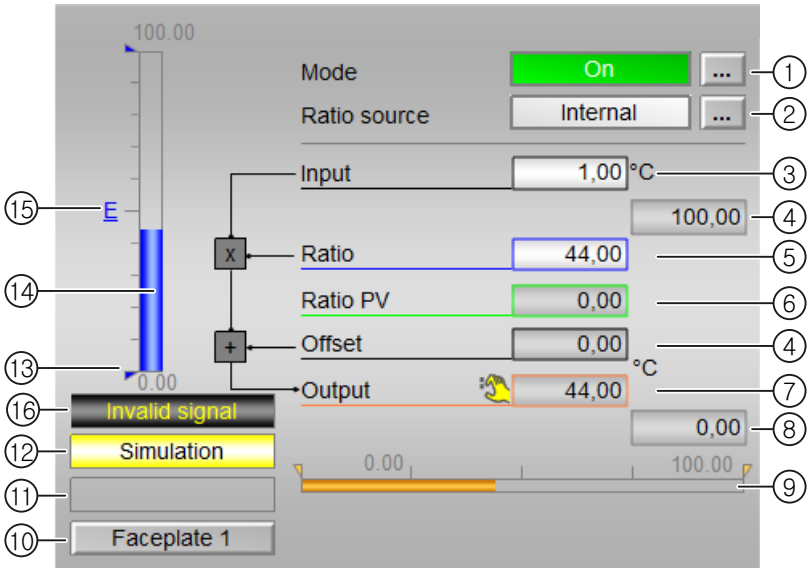
## 6.11.8 Operator control and monitoring

### 6.11.8.1 Ratio views

### Views of the Ratio block



The block Ratio provides the following views:

- Ratio standard view (Page 1208)
- Trend view (Page 341)
- Ratio parameter view (Page 1211)
- Ratio preview (Page 1212)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for Ratio (Page 1213)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 6.11.8.2 Ratio standard view

#### Ratio standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) Displaying and switching the ratio source

This area shows you the currently valid signal source for the ratio setpoint. The following signal sources can be shown here:

- "External"
- "Internal"

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the signal source.

#### (3) Displaying the input value

The faceplate is a schematic representation of the function of the Ratio block as a signal flow chart:

Output = Input · Ratio + `Offset`

The input is typically the flow setpoint or actual value of the primary component of a ratio controller.

### (4) High and low scale range for the ratio

The scale range is based on the bar graph for the ratio specification. For more information refer Bar graph (Page 376) section.

### (5) Displaying and switching the default ratio

This area shows you the currently valid specification for the ratio.

The ratio source **(2)** needs to be set to "internal" in order to change this value.

Refer to the Changing values (Page 291) section for information on changing this value.

### (6) Displaying the ratio `PV`

This area shows you the current ratio actual value with the corresponding signal status, i.e. the ratio of the actually measured `PV` from the active controller. The task of the ratio controller is to set the flow of all components so that the actual ratio approximates the specified ratio as closely as possible.

### (7) Display of the `Offset`

This area shows the current `Offset`.

### (8) Displaying the output value

This area shows the current output value `Out`, which typically serves as the setpoint for the flow of the secondary component.

### (9) Bar graph for the output

This display graphically represents the output value with the limits set in the Engineering System (ES) (orange triangles, output parameters `OutHiLmOut` and `OutLoLmOut`). You can also see the high and low limits of the bargraph's scale.

### (10) Displaying the limit

This status display is based on the limit of the output value `Out`.

### (11) Display area for block states

This area shows if the output value has violated the range limits:

- "Output ≥ HL"
- "Output ≤ LL"

You can set the range limits in the parameter view (Page 1211) of the block.

### (12) Display area for block states

This area provides additional information on the operating state of the block:

- Simulation

You can find additional information on this in the Simulating signals (Page 64) section.

### (13) Display of the limits for the ratio

This blue triangle shows the configured range limits for the ratio.

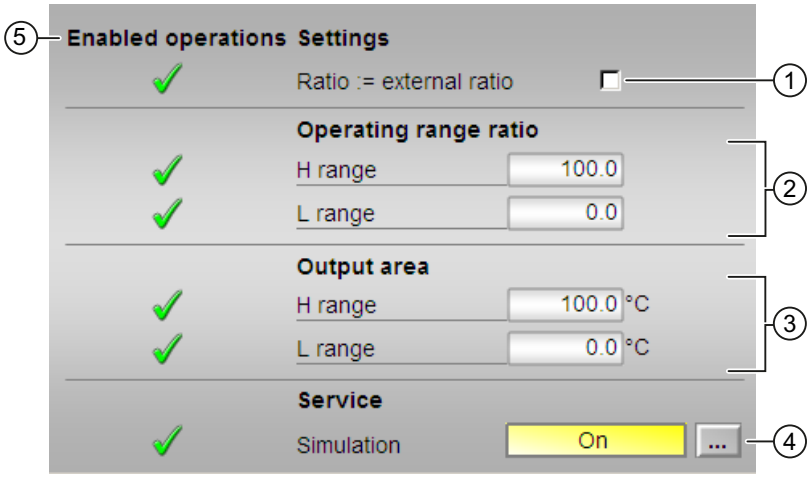
### (14) Bar graph for the default ratio

This area shows you the currently valid specification for the ratio in the form of a bar graph. The visible area in the bar graph depends on the configuration of the ratio in the engineering system (ES). You can also see the high and low limits of the bargraph's scale.

### (15) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (16) Display area for block states



This area provides additional information on the operating state of the block:

- Internal error
- Invalid Signal

You can find additional information on this in Error handling (Page 128) section.

### 6.11.8.3 Ratio parameter view

#### Parameter view of Ratio

#### (1) Settings Ratio := external ratio

When the check box is selected ☑, the ratio is bumplessly switched from external to internal. The internal ratio value is tracked to the external one.

#### (2) Operating range ratio

This is where you specify the operating range for the ratio (input parameters `RatHiLim` or `RatLoLim`). The range is indicated by a blue triangle in the standard view of the bar graph.

#### (3) Range for output value

This is where you specify the operating range for the output value (input parameters `OutHiLmOut` or `OutLoLmOut`).

#### (4) Service

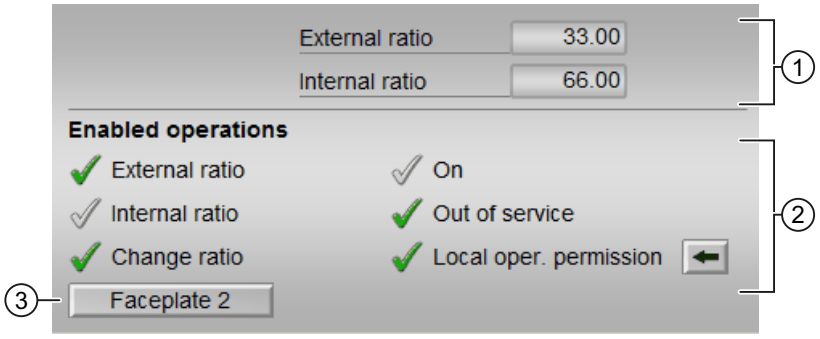
You can select the following functions in this area:

- "Simulation"

You can find information about this in the following chapters:

- Switching operating states and operating modes (Page 289)
- Simulating signals (Page 64)
- Release for maintenance (Page 70).

### (5) Enabled operations



This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

## 6.11.8.4 Ratio preview

### Preview of Ratio

### (1) Preview area

This area shows you a preview for the following values:

- "External ratio": currently applicable external ratio
- "Internal ratio": currently applicable internal ratio

### (2) Enabled operations

This area shows all operations for which special operating permissions are assigned. They depend on the configuration in the Engineering System (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter at all due to the configured AS operating permissions (`OS_Perm` or `OS1Perm`).

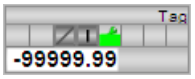
The following enabled operations are shown here:

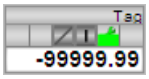
- "Ratio external": You can change the external ratio.
- "Ratio internal": You can change the internal ratio.
- "Change ratio": You can change the ratio.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in chapter Operator control permissions (Page 285).

**(3) Navigation button for switching to the standard view of any faceplate**

Use this navigation button to reach the standard view of a block configured in the Engineering System (ES). The visibility of this navigation button depends on the configuration in the Engineering System (ES).

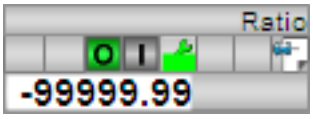
You can find additional information on this in chapter Opening additional faceplates (Page 234).

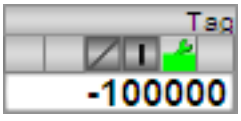


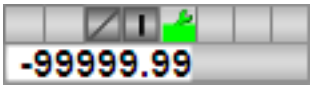


### 6.11.8.5 Block icon for Ratio

**Block icons for Ratio**







A variety of block icons are available with the following functions:

- Process tag type
- Display of the ratio
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits
- Operating modes
- Internal and external setpoint specification
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

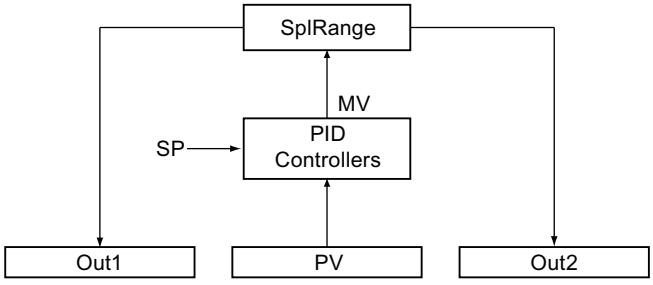
# 6.12 SplRange - Signal splitter

## 6.12.1 Description of SplRange

### Object name (type + number) and family

Type + number: FC 372

Family: Control



### Area of application for SplRange

The block is used for the following applications:

- Splitting the output signal of a PID controller

### How it works

The block is used to split signals output coming from a PID controller. You can use this controller to control two valves, for example.

The output parameters are calculated as follows:

`Out1` = `Out1Scale.Low` + ((`NeutPos` - `DeadBand` - `In`) / (`NeutPos` - `DeadBand` - `InScale.Low`)) · (`Out1Scale.High` - `Out1Scale.Low`)

`Out2` = `Out2Scale.Low` + ((`NeutPos` + `DeadBand` - `In`) / (`NeutPos` + `DeadBand` - `InScale.High`)) · (`Out2Scale.High` - `Out2Scale.Low`)

The neutral position (`NeutPos`) forms the reference point for selecting the individual splitter profiles. For details, refer to the SplRange functions (Page 1218) section.

Refer to SplRange I/Os (Page 1222) to learn the meaning of the parameters.
