The block is installed in the run sequence downstream of the controller block. The manipulated variable output (`MV`) of the controller block is interconnected to the input `In` of the SplRange block.

The neutral position (`NeutPos`) and the dead band zone (`DeadBand`) can be set by means of the corresponding parameters. `DeadBand` must be configured to be less than `NeutPos`.

`Out1` and `Out2` are adapted to the physical variable by configuring the high/low limits of `Out1` and `Out2`.

The Out1Act or Out2Act output parameter indicates (= 1) that the corresponding Out1 or Out2 output parameter is enabled if the In input value is less than (for Out1) the neutral position (NeutPos) or the In input value is greater than the neutral position (NeutPos) depending on the dead band (Deadband).

### Configuration

Use CFC editor to install the block in the OB in which the controller block runs whose manipulated variable is being processed.

There are templates (Templates) for the SplRange block for process tag types in the Advanced Process Library, one example (APL_Example_xx, xx refers to the language variant) with an application scenario for this block being:

- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for Status parameter

This block does not have the Status parameter.

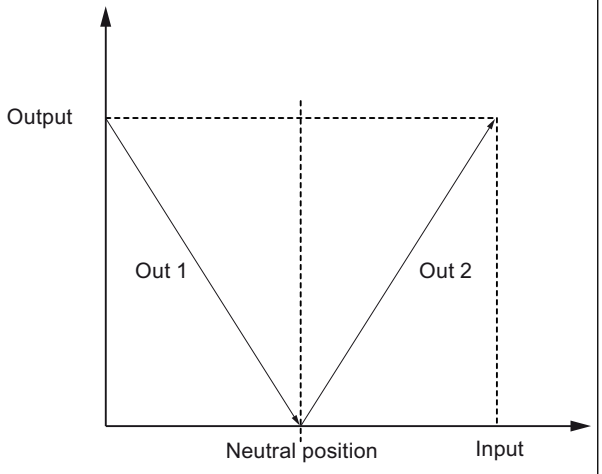
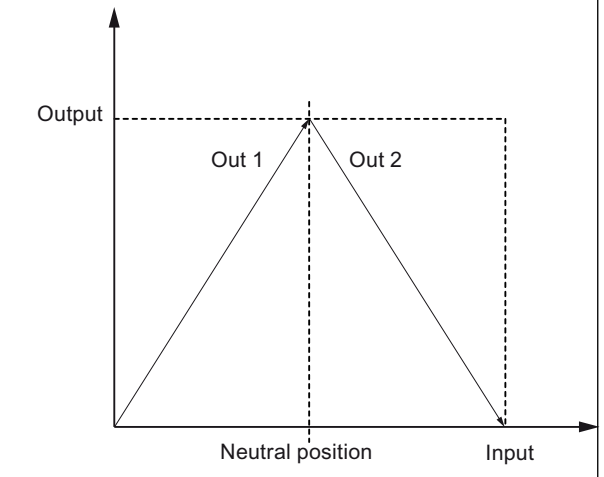
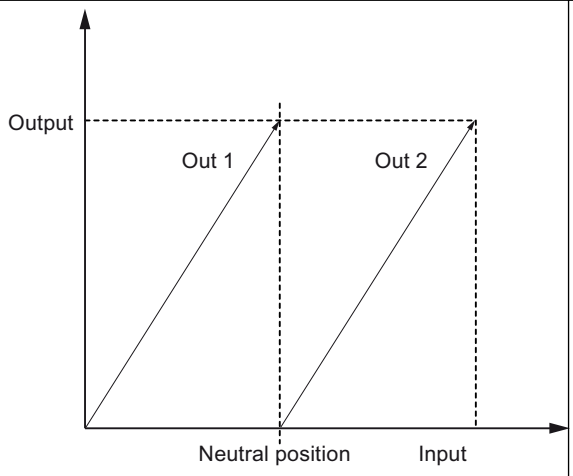
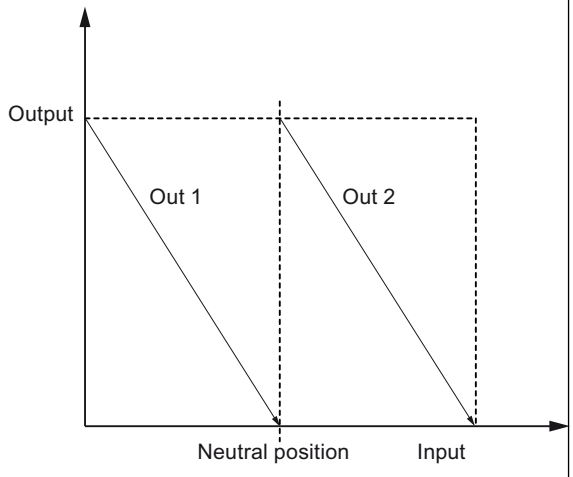
## 6.12.3 SplRange functions



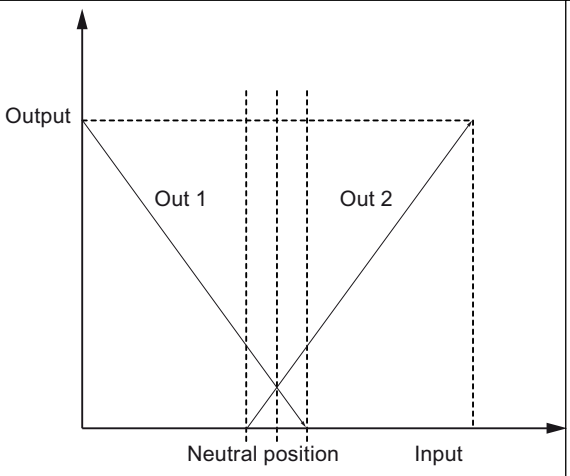


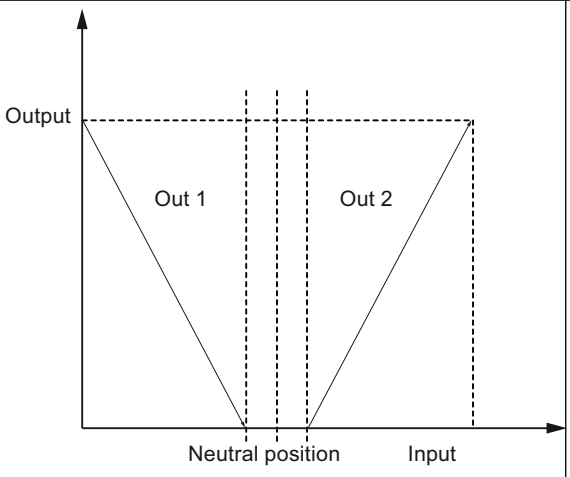
### Functions of SplRange





The functions for this block are listed below.





### Splitting of the output signal of a controller

The `In` block input can be used to split the output signal of a controller.

The table below shows the six types of signal splitting that are available:

| Case | Signal splitting | Setting the I/Os |
|---|---|---|
| 1 |  | `Out1Scale.Low` = 0.0 and `Out1Scale.High` = 100.0<br>`Out2Scale.Low` = 0.0 und `Out2Scale.High` = 100.0<br>`DeadBand` = 0.0 and `NeutPos` = 50.0 |
| 2 |  | `Out1Scale.Low` = 100.0 and `Out1Scale.High` = 0.0<br>`Out2Scale.Low` = 100.0 and `Out2Scale.High` = 0.0<br>`DeadBand` = 0.0 and `NeutPos` = 50.0 |

| Case | Signal splitting | Setting the I/Os |
|---|---|---|
| 3 |  | `Out1Scale.Low` = 100.0 and `Out1Scale.High` = 0.0<br>`Out2Scale.Low` = 0.0 and `Out2Scale.High` = 100.0<br>`DeadBand` = 0.0 and `NeutPos` = 50.0 |
| 4 |  | `Out1Scale.Low` = 0.0 and `Out1Scale.High` = 100.0<br>`Out2Scale.Low` = 100.0 and `Out2Scale.High` = 0.0<br>`DeadBand` = 0.0 and `NeutPos` = 50.0 |

| Case | Signal splitting | Setting the I/Os |
|---|---|---|
| 5 |  | `Out1Scale.Low` = 0.0 and `Out1Scale.High` = 100.0<br>`Out2Scale.Low` = 0.0 and `Out2Scale.High` = 100.0<br>`DeadBand` = -10.0 and `NeutPos` = 50.0 |
| 6 |  | `Out1Scale.Low` = 0.0 and `Out1Scale.High` = 100.0<br>`Out2Scale.Low` = 0.0 and `Out2Scale.High` = 100.0<br>`DeadBand` = 10.0 and `NeutPos` = 50.0 |

## 6.12.4 SplRange error handling

### Error handling of SplRange

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 30 | The value of `In` can no longer be displayed in the REAL number field. |

### I/Os of SplRange

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DeadBand | Width of dead band | REAL | 0.0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| In | Input value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| InScale | Limit range for the input signal | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| NeutPos | Neutral position | REAL | 50.0 |
| Out1Scale | Limit range of output 1 | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Out2Scale | Limit range of output 2 | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see SplRange error handling (Page 1221). | INT | -1 |
| Out1 | Output value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Out1Act | 1 = Output 1 is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Out2 | Output value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Out2Act | 1 = Output 2 is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

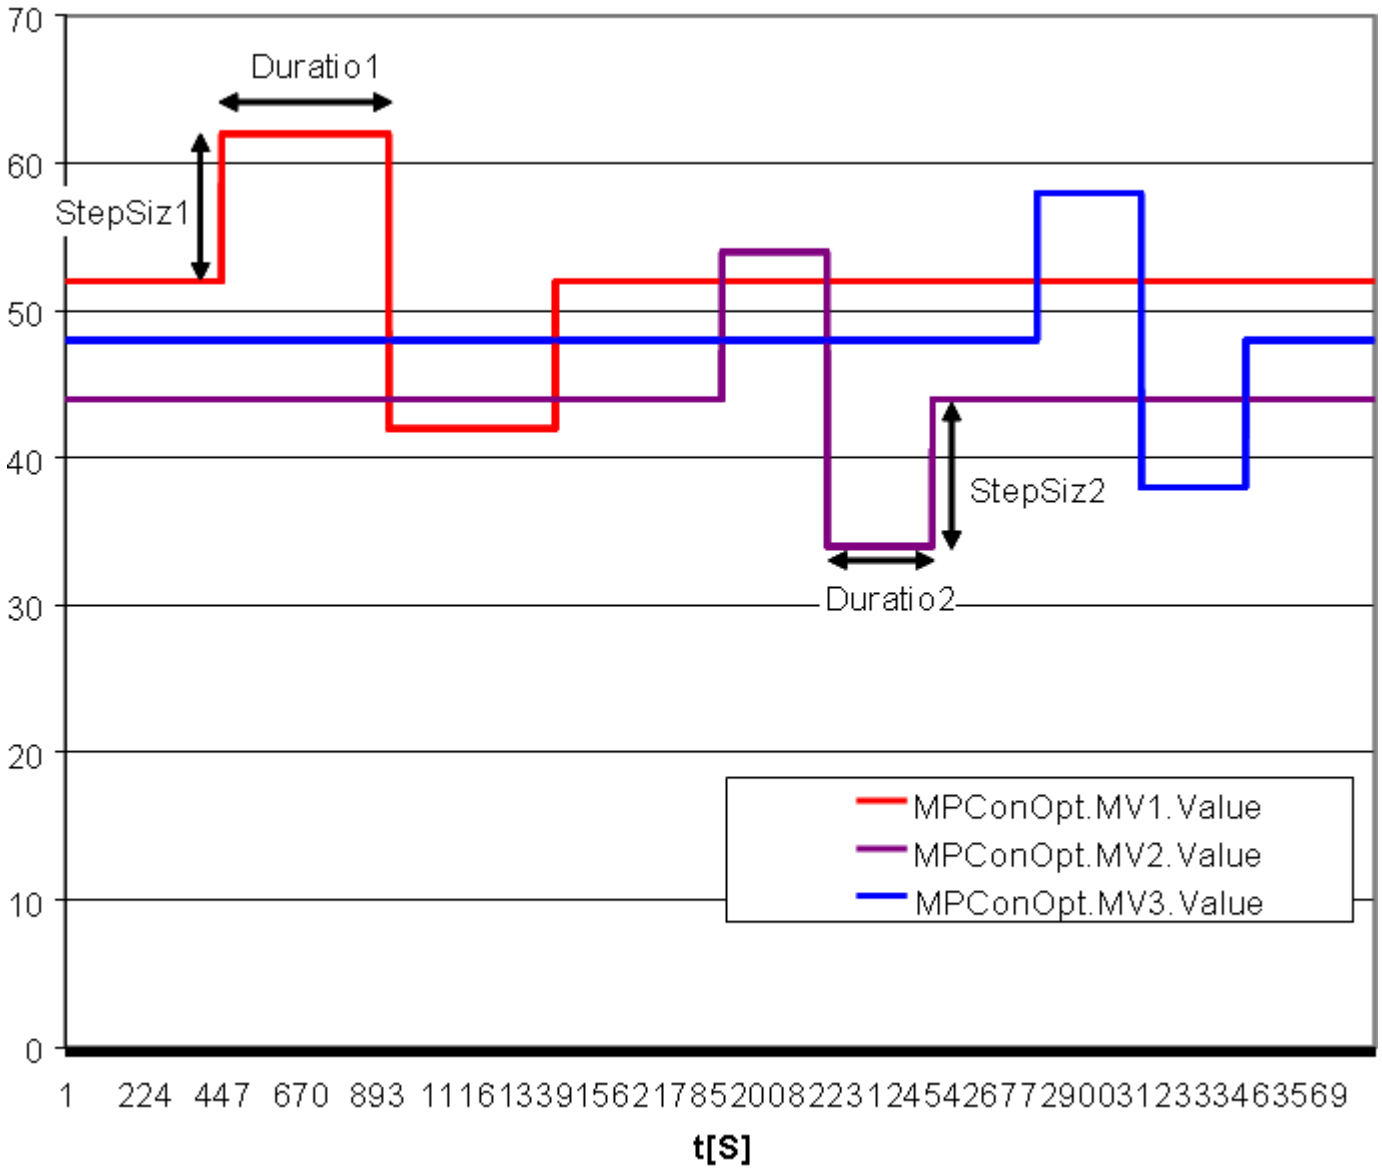
# 6.13 AutoExcitation - Process trigger for predictive controller

## 6.13.1 Description of AutoExcitation

### Object name (type + number) and family

Type + number: FB 1842

Family: Control



### Area of application of AutoExcitation

This block is used to generate suitable excitation signals for the identification of dynamic multi-variable process models for the model-based predictive controllers ModPreCon and the large predictive controller MPC10x10. It is interconnected with aModPreCon or MPC10x10 block for this purpose.

### How it works

The AutoExcitation block generates a sequence of abrupt trigger signals for the selected manipulated variables, MV1, MV2 to NumberMVs. A jump is initially made up, down, and then back to the starting point for each manipulated variable, so that the signals is symmetrical to the operating point.

The operating point taken from assigned controller via the MV1Actual...MV10Actual inputs. You set the jump height for each manipulated variable with the StepSiz1... StepSiz10 parameter and the jump duration via the Duratio1...Duratio10 parameter.

## Configuration

The AutoExcitation  block is part of the new process tag type, ModPreCon and MPC10x10. Only the new controller version has the necessary additional inputs for automatic triggering.

If the block retro-installed in an existing CFC, make sure that AutoExcitation andModPreCon or MPC10x10 are in the same OB cycle.

- Supply the AutoExcitation.MV1Actual...MV10Actual input variables with the appropriate ModPreCon.MV1...MV4 or MPC10x10.MV1...MV10 values from the controller.
- Specify the input parameter AutoExcitation.NumberMVs according to the number of manipulated variables you want to use in your MPC application. Exception: If you do not want to automatically trigger all manipulated variables of the controller, specify the number of manipulated variables to be directly triggered at the AutoExcitation.NumberMVs input parameter .
- Connect the AutoExcitation.MV1Excite...MV10Excite output variables to the appropriate ModPreCon.MV1Excite... MV4Excite or MPC10x10.MV1Excite...MV10Exciteinput variables on the controller.
- Connect the AutoExcitation.ExciteAct output variable to the ModPreCon.ExciteOn or MPC10x10.ExciteOn input variables of the controller.

## 6.13.2 AutoExcitation modes

### Operating modes of AutoExcitation

This block does not have any modes.

## 6.13.3 AutoExcitation functions

### Using AutoExcitation

Start triggering by setting the StartExcite binary input variable to the value 1 .

If you cancel triggering during ongoing operation via StartExcite =0 , the manipulated variables are reset to the original operating point.

When the Next binary input parameter = 1 , you can start the next jump manually before the planned time has expired.

The StepPhase output variable shows the current phase of the attempted jump:

0: Constant

1: Jump up

2: Jump down

3: Jump back to the operating point

The StepTime output variable indicates the remaining time in [s] until the next jump.

## 6.13.4 AutoExcitation error handling

### Overview of error numbers

The ErrorNum output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Default value when the block is installed, the block is not executed |
| 0 | There is no error. |
| 60 | One of the input parameters, Duratio1,2,3,4...10 < SampleTime or SampleTime < 0.001 |
| 61 | The trigger signals are not adopted correctly by the assigned controller. |

## 6.13.5 AutoExcitation messaging

### Messaging of AutoExcitation

This block does not offer messaging.

## 6.13.6 AutoExcitation I/Os

### I/Os of AutExcite

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Duration1...Duration10 | Duration for jump in MV1...MV10 in s | REAL | 20 |
| MV1Actual...MV10Actual | Current value of MV1...MV10 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Next* | 1 = Manual start of the next trigger change | BOOL | 0 |
| SampleTime | Sampling time in s | REAL | 1 |
| StartExcite* | 1 = Start of automatic triggering; 0= Cancel automatic triggering | BOOL | 1 |
| StepSize1...StepSize10 | Step height of MV1...MV10 | REAL | 10 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of pending error number | INT | 0 |
| ExciteAct | 1 = Automatic triggering is active | BOOL | 0 |
| MV1Excitation...MV10Excitation | Value of the trigger for MV1...MV10 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StepPhase | Phase of the jump; 0 = Constant, 1= Jump up, 2 = Jump down, 3 = Return | INT | 0 |
| StepTime | Time remaining until the next jump phase in s | REAL | 0 |

## 6.13.7 AutoExcitation block diagram

### Block diagram of AutoExcitation

A block diagram is not provided for this block.

# 6.14 LPOptim - Optimization after traversing the linear programming

## 6.14.1 Description of LPOptim

### Object name (type + number) and family

Type + number: FB1844

Family: Control or system

### Area of application of LPOptim

Optimization of a linear performance function taking into account constraints after traversing the linear programming.

The LPOptim block is used by the ModPreCon block for static operating point optimization (Page 976). However, it can also be used separately.

### Operating principle

The performance function has a linear relationship to up to four decision variables, x1...x4, with corresponding weighting factors, g1...g4 .

J = g1*x1 + g2*x2 + g3*x3 + g4*x4

The performance function is a hyper-level in a five dimensional space whose gradient direction is described by the gradient vector, Gradient = [ g1, g2, g3, g4].

The block can determine both the maximum as well as the minimum of the J performance function. A minimization problem is transformed into an equivalent maximization problem by inverting the gradient vector.

The decision variables are positive and limited by a system of up to eight linear non-equivalence constraints .

The first constraint is, for example

a11*x1+a12*x2+a13*x3+a14*x4 <= b1

All four elements of the first line from the A matrix are combined in the A1n data structure. All eight elements of the B vector are combined in the Begrenzungen data structure.

### How it works

The block operates according to the simplex procedure, i.e. based on an iterative algorithm. Due to the linear performance criterion, the solution always lies at an intersection of multiple restrictions.

### Configuration

The block can be installed in OB1 because no time-critical calculations are performed. If the block is called by ModPreCon , the user does not have to set parameters directly at LPOptim block.

## 6.14.2 LPOptim modes

### Operating modes of LPOptim

This block does not have any modes.

## 6.14.3 LPOptim functions

### Use of LPOptim

The algorithm is started with a positive edge at the Start parameter or if there is a change in one of the input variables (gradient vector and limitations), and displays the optimum variable found at the XOpt1...XOpt4 output parameters when execution is completed.

If no solution is found (non-plausible coefficient), execution is aborted with an error code.

## 6.14.4 LPOptim error handling

### Overview of error numbers

The Status output parameter can be used to display the following states:

| Status | Meaning |
|---|---|
| 0 | There is no error. |
| 10 | Unrestricted target function |
| 15 | No XOpt found |
| 20 | Infinite number of solutions |
| 35 | Unlimited permissible range |
| 40 | Configuration error |

## 6.14.5 LPOptim messaging

### Messaging

This block does not offer messaging.

## 6.14.6 LPOptim I/Os

I/Os of LPOptim

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## I/Os of LPOptim

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| J_Mini | 1= Search minimum<br>0= Search maximum | BOOL | 0 |
| Start* | 1= Start optimization calculation immediately<br>0= Start optimization calculation only if one of the input variables has changed | BOOL | 0 |
| X1 | Decision variable 1 for calculation of J_Act | REAL | 0 |

**LPOptim block diagram**

A block diagram is not provided for this block.

# 6.15 MPC10x10 - Large predictive controller

## 6.15.1 Description of MPC10x10

### Object name (type + number) and family

Type + number: FB 1920

Family: Control

### Area of application for MPC10x10

The block is used for multivariable control, similar to the ModPreCon, typically as master controller in cascade structures.

Compared to the lean multivariable controller ModPreCon, the MPC10x10 has the following functional expansions:

- Greater capacity: up to 10x10 interacting manipulated and controlled variables (compared with ModPreCon: 4x4), up to 4 measurable disturbances for a dynamic disturbance compensation (feedforward) (ModPreCon: 1). Unused MV channels can be rededicated to disturbance variables, whereby the total number of manipulated variables and disturbances is limited to 14 (ModPreCon: 5).
- Dynamic online optimization considering constraints in each sampling step. The optimization problem is resolved without constraints with ModPreCon and the manipulated variables are limited afterward. This may result in solutions that are less than optimal if several constraints are active simultaneously in automatic mode.
- Processing of (low-priority) target values for the manipulated variables, which is mainly of interest for control tasks in which there are more manipulated variables than controlled variables or in which some controlled variables do not have to be kept at an exact setpoint.
- Integrated steady state operating point optimization even for control tasks in which the number of manipulated variables does not match the number of controlled variables.

### Method of operation and area of application

The block is used for Multivariable controller (Page 2888) dynamic processes. It can handle up to ten interacting manipulated and controlled variables as well as up to four measurable disturbances.

The MPC10x10 algorithm only works for stable processes with a step response that settles to a fixed value in a finite time. If the process is unstable in one of the main transfer functions or includes an integrator (level control, for example), the corresponding partial transfer function must be stabilized with a secondary controller.

A simple P controller (proportional component only) is sufficient as a slave controller for integrating processes. It is inserted between the manipulated variable output of MPC10x10 and the input of the unstable process section, and receives the output of the integrating process section as a manipulated variable. (Unstable data links are stabilized with this approach.)

You can find an explanation of "multivariable controls" and "non-phase-minimum response" in the Help on the Advanced Process Library > Definitions.

### Note on the area of application of the controller: Longer run times

Due to the principle on which it works, the runtime of MPC10x10 is significantly longer than that of ModPreCon and obviously much longer than that for PID controllers, because very large matrices have to be multiplied in the algorithm. The runtime is also determined by the number of the process and manipulated variables in the control algorithm. This is why the MPC10x10 is unsuitable for high-speed controls and is usually used for slow, complex control tasks in which controller sample times of more than 4 s are permitted.

The computing time required on the CPU is compensated for by the fact that very slow sample times of > 20 s are used for the typical MPC10x10 applications (see Advanced control templates). The MPC10x10 is then typically located in OB30 and can be interrupted by faster OBs. Some parts of the MPC10x10 algorithm have been outsourced to auxiliary blocks due to the limitations of the address space for SIMATIC function blocks and data blocks. The MPC10x10 uses two outsourced optimization methods:

- MPC_LP_OptiFB for operating point optimization which, in turn, needs an auxiliary block MPC_LPOptiFC .
- MPC_ActSetFB

as well as auxiliary blocks for matrices that are created by the MPC Configurator and can all be identified by the prefix MPC_* in their name.

There are different forms of implementation for the matrices:

- User DBs that are filled with data by one or more FCs during initialization because large matrices cannot be pre-assigned with values in the source code for the DB:
- Data block MPC_g with initialization FCs MPC_g_FC, MPC_gb...ge;
- Data blocks MPC_ESP, MPC_Hu_FB, MPC_Hinv_FB, MPC_Omega_FB and MPC_M_FB each with a dedicated initialization function MPC_Esp_FC... as well as
- a data block MPC_RgMVi (i=1..10) for each MV with initialization FCs MPC_RgMVia_FC and MPC_RgMVib_FC.
- User DBs filled with data by the MPC10x10 during runtime: MPC_Nn, MPC_Ms, MPC_MsOld.

As user, you only have to interconnect the main function block in the CFC and need not worry about the auxiliary blocks.

The static operating point optimization is called within the MPC10x10 block in the program section in which OB1 is executed. In cyclic operation OB3x, this avoids the additional computing time required by the optimizer, the acyclic time, i.e. which is only relevant for changes to the optimizer inputs.

### Operating principle

The MPC10x10 block is a model-based predictive multivariable controller. It uses a mathematical model of the process dynamics including all interactions as part of the controller. This model allows the process response to be predicted over a defined period in the future, also known as the prediction horizon.

Based on this prediction, a performance index

$$J = \left(\vec{w} - \vec{y}\right)^T R\left(\vec{w} - \vec{y}\right) + \Delta\vec{u}^T Q \Delta\vec{u} + \left(\vec{u}_{soll} - \vec{u}\right)^T S\left(\vec{u}_{soll} - \vec{u}\right)$$

is optimized (minimized) where the following applies:

- *w* contains the time series of the future setpoints within the prediction horizon,
- *y* contains the vector of the controlled variables in the future,
- *Δu* contains the future changes of the manipulated variables within the control horizon,
- $u_{soll}$ contains the target values for the manipulated variables *u*

The control horizon is generally significantly shorter than the prediction horizon. Changes of future manipulated variables are only planned within the control horizon.

If you increase the weighting in the Q diagonal matrix, the controller moves its manipulated variables more cautiously resulting in a slower but more robust control response. Using the weighting factors in the R diagonal matrix, you specify the relative significance of the individual controlled variables. A higher weighting (priority) for a controlled variable means that this CV moves more quickly towards the setpoint and remains more accurately at the setpoint in steady state if it is not possible to achieve all setpoints precisely.

The weightings for the target values of the manipulated variables in the S matrix are typically set much lower than the weightings of the controlled variables in the R matrix so that the controller must only handle the manipulated variable target values once it has reached all primary control aims regarding the controlled variables.

The algorithm is a variant of the DMC method (**D**ynamic **M**atrix **C**ontrol), comparable to the control algorithms in so-called "full-blown" MPC software packages that were previously linked to the process control system by external PCs.

The optimization problem is solved in ongoing automatic mode in each sampling step of the controller by initially neglecting the constraints. If a constraint violation is detected within the control horizon, an iterative optimization with the so-called "active set" method takes place. Only the currently active limitations are taken into consideration during each iteration step of the optimization. Manipulated variable limitations, both absolute and relating to the gradients, are treated in the algorithm of the function block as hard constraints that must not be violated. Precise setpoints or target zones for the controlled variables are taken into account during optimization as well as possible. The target zones for the controlled variables are therefore soft constraints, which are maintained as well as possible although they cannot be guaranteed. Using a reference variable filter for future setpoint trajectories, the control response of the controller can be fine-tuned during operation.

You can achieve significant improvements in control performance when individual disturbances can be measured, for example, variations in throughput. In this case, it is a good idea to take into account a model of the influence of this disturbance on the controlled variables when predicting the controlled variables so that the controller can react preemptively to such disturbances.

## Operating point optimization

The integrated steady state operating point optimization can be used when at least one controlled variable provides certain degrees of freedom. No exact setpoint is specified for such controlled variables. Instead there is a tolerance band, e.g.

- SP2OptHiLim...SP2OptLoLim

within which the process value, CV2, must remain. These areas can be defined for any subset of the relevant controlled variables. From an economic perspective, different values within the tolerance band can be more or less favorable. With the help of the optimization function, the optimal economic point can be found within the tolerance range. This is done by defining a target function (performance criterion), which depends on the manipulated variable and controlled variable of the predictive controller. This can be, for example, the economic yield of plant operation per time unit or it may involve specific costs or energy consumption.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100) and in OB 1.

MPC10x10 and all its auxiliary blocks are provided in the block folder "MPC10x10 blocks" of the Advanced Process Library. After you have placed the block in the CFC, you still need to copy the fixed addressed global data blocks DB1 to DB22 into the project. This will make all auxiliary blocks of MPC10x10 available in the project, thereby making it executable and allowing the SCL source of the MPC configurator to be later compiled.

In contrast to the ModPreCon, only one instance of the MPC10x10 can be configured per SIMATIC CPU. The addresses of the MPC auxiliary blocks are determined during compilation of the main block by the SCL Compiler and cannot be modified afterwards. The addresses for the auxiliary blocks (DBs and FCs) used by the MPC10x10 are defined in the following symbol table. If you already have other blocks in the project assigned to the specified addresses, you need to move them.

After installation in CFC, follow the steps outlined below:

1. Excite the process with the controller in manual mode by applying a series of manipulated variable step changes. We recommend using the auxiliary function block, AutoExcitation, to generate excitation signals.
2. Record the measured data with the CFC trend display and export it to an archive file. You can also use a WinCC TagLogging TrendControl to record the data and to export the *.csv file. If the total number of manipulated and controlled variables exceeds the maximum number of trends in the CFC, you will have to use the WinCC TrendControl anyway.
3. Select the MPC10x10 instance in the CFC. Start the MPC Configurator under Edit > MPC Configurator.
   The working steps process identification, controller design and simulation of the closed control loop are executed in the MPC Configurator. You can find a detailed description of this procedure in the MPC Configurator help. You can find the help with a button in the MPC Configurator or directly under ...\Program Files (x86)\SIEMENS\STEP7\S7JMPC \s7jmpctb.chm.
4. Using the Configurator, create an SCL source code for the user data blocks (DBs) and other auxiliary blocks (FCs). The source contains all models and matrices required for an MPC10x10 instance.
5. Compile the SCL source with the S7-SCL compiler and archive the SCL source with the controller data.

Load the changes to the AS (with the option: Include user data blocks)

The values in the auxiliary blocks are applied in the controller by restarting the block by means of the input variable Restart:= true at the CFC block instance.

**Note**

During controller design in the MPC Configurator, a controller cycle time and an OB sampling time are calculated, displayed, and stored in the user data block. You yourself are responsible for ensuring that the MPC10x10 block is called in the cyclic interrupt level suitable for the OB sampling time. This is checked in the current MPC10x10 version during initialization. If the SampleTime parameter of the function block does not match the OB_SampleTime parameter of the user data block, a parameter assignment error (ErrorNum=3) is displayed. For controller cycle times greater than 5s, insert the MPC10x10 block in the OB30 and specify the appropriate cycle time for the OB30 in the hardware configuration of the SIMATIC CPU. Controller cycle times slower than 20 s cannot be set in the hardware configuration. The block would then be called every 20s and the slower sampling time automatically realized by an internal cycle reduction ratio in the block.

There are no templates for the MPC10x10 block for a process tag type in the Advanced Process Library because the controller is typically configured individually as master controller for several slave controllers.

### Startup characteristics

When the CPU starts up, the block always starts in manual mode. It is only possible to change to automatic mode when a user data block is loaded and the internal measured value memory in MPC10x10 is filled with data.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section I/Os of MPC10x10 I/Os (Page 1254)

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutAct.Value` |
| 6 | Invalid signal status |
| 7 | `ManAct.Value` |
| 8 - 9 | Not used |
| 10 | `MV1TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 11 | `MV2TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 12 | `MV3TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 13 | `MV4TrkOn.Value` AND NOT (`ManAct.Value` OR `OosAct.Value`) |
| 14 | Internal error |
| 15 | `DB_Loaded` |
| 16 | `DV_Model Available` |
| 17 | OptimAct |
| 18 | `NOT(OptimAct)` |
| 19 | Not used |
| 20 | J_Mini |
| 21 | NOT(J_Mini) |
| 22 | ExciteOn AND ManAct.Value |
| 23 | `MV5TrkOn.Value AND NOT (ManAct.Value OR OosAct.Value)` |
| 24 | `MV6TrkOn.Value` AND NOT (`ManAct.Value OR OosAct.Value`) |
| 25 | `MV7TrkOn.Value AND NOT (ManAct.Value OR OosAct.Value)` |
| 26 | `MV8TrkOn.Value` AND NOT (`ManAct.Value OR OosAct.Value`) |
| 27 | `MV9TrkOn.Value AND NOT (ManAct.Value OR OosAct.Value)` |
| 28 | `MV10TrkOn.Value` AND NOT (`ManAct.Value OR OosAct.Value`) |
| 29 | Tracking mode; i.e. at least one of the original manipulated variables (without pseudo MVs, which are used as DVs) is tracked. |
| 30 | Not allocated |
| 31 | `Feature.Bit31`: Display of the predictions in the faceplate |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MV1TargOn` |
| 1 | `MV2TargOn` |
| 2 | `MV3TargOn` |
| 3 | `MV4TargOn` |
| 4 | `MV5TargOn` |
| 5 | `MV6TargOn` |
| 6 | `MV7TargOn` |
| 7 | `MV8TargOn` |
| 8 | `MV9TargOn` |
| 9 | `MV10TargOn` |
| 10 - 30 | Not used |
| 31 | `MS_RelOp` |

## 6.15.2 MPC10x10 modes

### Operating modes of MPC10x10

The block can be operated using the following modes:

- Automatic mode (Page 79)
- Manual mode (Page 79)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

The aforementioned operating modes are valid for the block with all control channels (`MV1` ... `MV10`). Moreover, individual control channels can be tracked; see section MPC10x10 functions (Page 1243) for more information.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the section Manual and automatic mode for control blocks (Page 79) .

**Note**

In contrast to PID controllers, it is permitted to run the MPC10x10 block in "automatic mode" without its actuating signals affecting the process because there is no risk of integrator windup.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for control blocks (Page 79) .

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) .

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | `Feature.Bit5` =0 | `Feature.Bit5` =1 |
|---|---|---|
| SP1Out.ST | 16#80 | 16#60 |
| SP2Out.ST | 16#80 | 16#60 |
| SP3Out.ST | 16#80 | 16#60 |
| SP4Out.ST | 16#80 | 16#60 |
| SP5Out.ST | 16#80 | 16#60 |
| SP6Out.ST | 16#80 | 16#60 |
| SP7Out.ST | 16#80 | 16#60 |
| SP8Out.ST | 16#80 | 16#60 |
| SP9Out.ST | 16#80 | 16#60 |
| SP10Out.ST | 16#80 | 16#60 |
| SP1OpOut.ST | 16#80 | 16#60 |
| SP2OpOut.ST | 16#80 | 16#60 |
| SP3OpOut.ST | 16#80 | 16#60 |
| SP4OpOut.ST | 16#80 | 16#60 |
| SP5OpOut.ST | 16#80 | 16#60 |
| SP6OpOut.ST | 16#80 | 16#60 |
| SP7OpOut.ST | 16#80 | 16#60 |
| SP8OpOut.ST | 16#80 | 16#60 |
| SP9OpOut.ST | 16#80 | 16#60 |
| SP10OpOut.ST | 16#80 | 16#60 |
| CV1Out.ST | 16#80 | 16#60 |
| CV2Out.ST | 16#80 | 16#60 |
| CV3Out.ST | 16#80 | 16#60 |
| CV4Out.ST | 16#80 | 16#60 |
| CV5Out.ST | 16#80 | 16#60 |
| CV6Out.ST | 16#80 | 16#60 |
| CV7Out.ST | 16#80 | 16#60 |
| CV8Out.ST | 16#80 | 16#60 |
| CV9Out.ST | 16#80 | 16#60 |
| CV10Out.ST | 16#80 | 16#60 |

## 6.15.3 MPC10x10 functions

### Functions of MPC10x10

The functions for this block are listed below.

### Generating and limiting the manipulated variable

The manipulated variable MV1 ... MV4 (hereinafter referred to as MVx, x = 1 ... 10) can be generated as follows:

| ManAct | MVxTrkOn | MVx | Limit monitoring | State |
|---|---|---|---|---|
| 1 | - | Manx | ManxHiLim<br>ManxLoLim | "Manual mode", set by the operator |
| 0 | 1 | MVxTrk | MVxHiLim<br>MVxLoLim | Tracking with limitation |
| 0 | 0 | Automatic manipulated variable | MVxHiLim<br>MVxLoLim | "Automatic mode": Predictive controller algorithm |

**Remark**

If the controller is in "Out of service" mode, the output parameters MV1 ... MV10, depending on the Feature Bit (Neutral position manipulated variable takes effect at startup (Page 176)), are set to the last valid value in manual mode or the corresponding neutral position manipulated variable (SafePos1 ... SafePos10). Refer to the Out of service (Page 77) section for more on this.

The limited operating range (between MVxHiLim and MVxLoLim) is typically smaller in automatic mode than in manual mode. With regard to the limited range of validity of a linear process model for approximating a non-linear process response, this allows the stability of the closed control loop to be guaranteed within the control range in automatic mode.

The gradients of the manipulated variable (changes per second) are limited to MV1RaLim to MV10RaLim in "automatic mode". Gradient limitation applies both to the positive and negative directions.

### Tracking and limiting a manipulated variable

The block provides the standard function Tracking and limiting a manipulated variable (Page 222).

In contrast to PID controllers, tracking the manipulated variables (MV1 ... MV10) is enabled for specific channels via one of the input parameters MV1TrkOn ... MV10TrkOn. The corresponding manipulated variable is then tracked by the interconnectable input parameters MV1Trk ... MV10Trk.

### Setting the setpoint internally

With this block, the setpoint must always be set internally at the I/Os SP1 ... SP10. These are normally operated in the faceplate. In special situations, you can interconnect the setpoints but they can then no longer be changed using the faceplate.

### Setpoint tracking in manual mode

In this situation (`SP_TrackCV` = 1), the internal setpoints `SP1` ... `SP10` are tracked to the assigned process values `CV1` ... `CV10` in "manual mode". This function allows a bumpless transfer to "automatic mode". After the transfer, the setpoints can be changed by the operator again.

### Setpoint filters

The setpoint filter is the only way of changing the action of the predictive controller without having to create a new user data block with the MPC Configurator and reinitialize the controller. The specified time constant `PreFilt1` ... `PreFilt10` of the setpoint filter can be interpreted as the required settling time of this `CV` channel following a setpoint step change. As the time constant setting increases, the controller works more slowly and less aggressively. In particular, this reduces the influence of a setpoint step change in one control channel on neighboring control channels.

Internally, the MPC10x10 block works with trajectories of future setpoints that are compared with the predicted movements of the controlled variables. Without the setpoint filter, it is assumed that the current setpoint will continue to remain valid in the future within the prediction horizon. If there is a setpoint step change, this means that the full value of the new setpoint will be required in the near future although the process cannot achieve this (according to the prediction). With the setpoint filter, an asymptotic setpoint trajectory (first order) is calculated from the current process value to the required setpoint so that the required setpoint is reached in the specified time.

**Note**

The setpoint filter also comes into effect without a setpoint step if the process value deviates significantly from the setpoint due to disturbances. This means that the filter not only slows down the control response but indirectly also the response to disturbances.

The control response can only be slowed down by the setpoint filter and not accelerated; when the value is 0, the prefilter is deactivated. It is therefore advisable to set the basic controller tuning in the MPC Configurator with the "Manipulated variable move penalty" parameter and then to optimize this inside the software using the function for simulation of the closed control loop. The setpoint filter should then only be used for fine tuning of the controller action in the real-world process.

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Controlled variable (`SimCVx` , `SimCVxLi`)

### Selecting a unit of measure

The block provides the standard function Selecting a unit of measure (Page 240).

### Error signal generation and dead band

The block provides the standard function Error signal generation and dead band (Page 217).

In the predictive controller, the error signal is generated over the entire prediction horizon for each control channel as the deviation between the predicted movement of the process (starting at the current process value CV1 ... CV4) and future setpoint settings (ending at SP1 ... SP10) and used to calculate the manipulated variable.

In principle, the effect of the dead bands SP1DeadBand to SP10Deadband is the same as in a PID controller, but extends over the entire future prediction horizon. In other words, if, for example, the predicted controlled variable CV1 in the entire prediction horizon is within the band SP1 ± SP1DeadBand, the controller sees no reason whatsoever to change any manipulated variable. These are therefore also known as CV bands. In contrast to the manipulated variable limits, these are not hard constraints that need to be adhered to at all costs.

In multivariable controllers, it is advisable to make use of the fact that from the perspective of the application only some of the controlled variables need to move to a specified setpoint exactly while others only need to remain within a defined range.

A typical example would be product quality characteristics for which a tolerance band is specified. While a dead band in a PID controller tends to put stability at risk, CV bands in individual controller channels generally relieve the multivariable controller overall.

Using CV bands, the action of a soft override control can be achieved.

### Use case for error signal generation with dead band

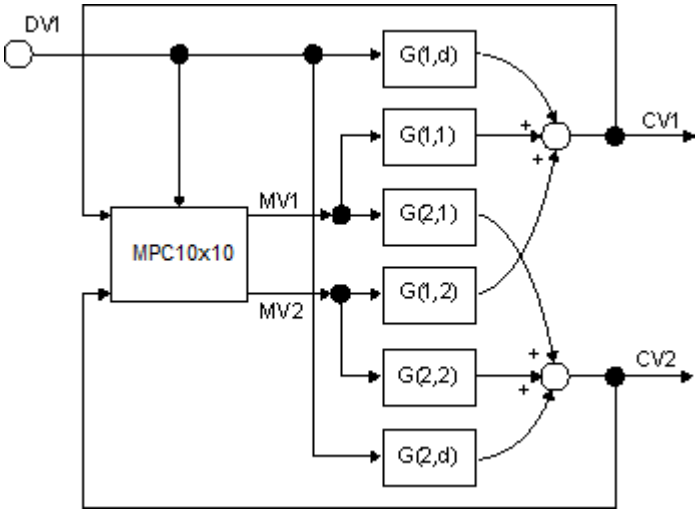
As long as the pressure in a reactor remains within the specified safety limits, the controller is interested only in product quality. However, as soon as the pressure threatens to leave the permitted range (in other words, inside the prediction horizon it moves towards an illegal value in the future), the pressure control cuts in. By weighting the controlled variables in the performance index (see MPC Configurator), the user can specify that predicted violations of the pressure limits are given a particularly high weighting.

### Predictive controller algorithm

The MPC10x10 block is derived from the familiar DMC algorithm (**D**ynamic **M**atrix **C**ontrol) .

Future changes to the manipulated variable within the control horizon are calculated from future predictive control deviations. To accomplish this, first the ideal solution is determined in each sampling step using an analytical formula without consideration of constraints. If the ideal solution comes into conflict with a constraint, an iterative optimization process is used to find a solution of the dynamic quadratic optimization problem with constraints.

Based on the principle of the receding horizon, only the first value is taken from the calculated vector of the optimum manipulated variable moves over the entire control horizon and applied to the process. In the next step, the newly arrived process values are taken into account and the calculation repeated over the entire prediction horizon.



With predictive controllers, the manipulated variable moves are based on the control deviations predicted in the future, while with a PID controller, they are based on (typically integrated) error signals of the past. This can be interpreted as a "looking ahead" strategy.

### Anti-windup

When manipulated variable limits are active, anti-windup measures are taken automatically within the controller. The prediction equations use the real limited values of the manipulated variables instead of theoretically calculated values.

### Model-based disturbance compensation

Model-based disturbance compensation can and should be used if one or more known disturbances have a strong influence on the process and their causes can be measured.

The effects of a measurable disturbance (`DV1..4` I/O) on all controlled variables `CV1 ... CV10` can be estimated when the controller is taken into manual mode. This means that no movements of the controlled variables whatsoever result from changes to the manipulated variables and all movements result from the disturbance. If the disturbance (e.g. ambient temperature) can be measured but cannot be actively adjusted, it may be necessary to search through a data archive to find the time segments in which the disturbance changed.

The identification of the transfer functions from disturbances `DV1...DV4` to all controlled variables `CV1 ... CV10` (disturbance models G(1,d) and G(2,d) in the graphic above) is performed with the MPC Configurator and is analogous to the identification of the main transfer functions (G(1,1) to G(2,2)). The measured disturbances are then linked to the `DV1...DV4` inputs of the MPC10x10 block and disturbance compensation is activated with `DV_On = 1`. As a result, the effect of the measurable disturbances is taken into account in the prediction and the controller can start counter measures in advance before the disturbance has a massive influence on the controlled variables.

Such disturbance compensation is especially effective when the disturbance is constant at times and changes from time to time. If a disturbance fluctuates constantly or oscillates, however, the feedforward control should not be enabled during operation of the controller to avoid constant oscillation of the manipulated variables, although it should be taken into account in the MPC Configurator when creating the process model.

If there is no disturbance model in the user data block, the signals at the `DV1...DV4` input are ignored.

Typical examples of measurable disturbances are inlet flows in distillation columns or throughput of continuous reactors.

### Predictive controller with more than four measurable disturbances

If you want to plan for more than four measurable disturbances in an application, but do not need all ten manipulated variable channels of the MPC10x10 block, you can dedicate the first of the previously unused MV channels for disturbance feedforwarding.

Example: You only have two control actions available, so only use MV1 and MV2. Then connect the additional measurable disturbance DV5 to the MV3Trk input parameter and set MV3TrkOn = 1. For recording of training data for the predictive controller, declare MV3Trk as the third disturbance and also use the CFC trend recorder to record the effect of changes to DV5 on all controlled variables.

Use the MPC Configurator to then determine a process model that describes the effects of DV5. However, if the disturbance variable DV5 in "automatic mode" of the controller fluctuates due to external influences, the effect of such changes is taken into consideration for predicting future process reactions through MV3Trk and predictive methods can be used to compensate this disturbance. The performance of the disturbance compensation is exactly the same as that for regular feedforward control via the input parameters DV1...DV4 and DV_On = 1.

If you want to disable this disturbance compensation in runtime with the unused MV5 manipulated variable, you need to insert a SelA02In selector block in front of the MV3Trk input. This allows you to set a constant zero for MV3Trk instead of the measured value DV5, which stops the effect of MV3 on prediction. (Due to this reassignment, MV3TrkOn must always remain 1 to prevent the controller from changing the value of MV3.)

This way, additional measurable disturbances can be selected. However, the sum of the manipulated variables and disturbances may not exceed a total number of 14.

At the output variables NumberOrigMVs, the number of original manipulated variables is displayed that can actively be influenced by the controller. The other manipulated variables (in the above example MV3) are only used for disturbance feedforward and are therefore always in tracking mode. They are referred to as pseudo MVs.

### Control of square and non-square systems

In multivariable controllers, the number of manipulated variables should ideally be the same as the number of controlled variables. This is known as a "square system". As long as constraints do not influence operation, the controller can, in principle, track all controlled variables exactly to the selected setpoints.

If there are less manipulated variables than controlled variables or if individual manipulated variables have reached their limits, degrees of freedom are lacking in the control problem. This means that it is not possible for all setpoints to be reached exactly.

The MPC10x10 algorithm then finds a compromise that can be influenced by the selection of controlled variable weightings (priorities) in the MPC Configurator: Controlled variables with higher priority will have lower control deviations.

If there are more manipulated variables than controlled variables or if some of the controlled variables are already within their setpoint bands, there are surplus degrees of freedom in the control problem.

The MPC10x10 algorithm can use these degrees of freedom to move the manipulated variable in the direction of the specified target value, whereby the weighting of the manipulated variable target value in the performance index is typically substantially less than the weighting of setpoints for the controlled variables. If the manipulated variables result in costs (e.g. mass flows of steam or other forms of energy consumption), the manipulated variable target values

can be set somewhat lower than the values previously observed at the operating point. The controller then attempts to reduce the manipulated variables (the costs) in the direction of the target values as long as the achievement of the primary control target provides some degree of freedom. In general, the advantages of the dynamic online optimization in the MPC10x10 are especially attractive for non-quadratic systems, because the restrictions of the lean algorithm of ModPreCon are overcome.

## Control of linear and non-linear systems

The MPC10x10 algorithm is based on a linear, time invariant process model. As a result, in much the same way as a PID controller, it is suitable above all for controlling non-linear systems around a fixed operating point.

Again analogous to the PID controller, there are, however, several possibilities with which the area of application can be extended in context of non-linear systems:

**Compensation functions between controller and controlled system:**

It is, for example, possible to compensate the effect of a non-linear valve characteristic curve using a polygon block between the `MV` output and the control input of the valve block. Care must be taken when implementing the manipulated variable limits. In the same way, the effect of a non-linearity at the output of the controlled system (for example a sensor characteristic curve) can be compensated by a polygon block before the `CV` input of the controller. Remember that the corresponding SP must also be equivalently transformed. In both cases, the compensation functions become part of the controlled system from the perspective of the controller. The aim is always to keep the overall response of the controlled system consisting of process and compensation elements as linear as possible.

**Trajectory control:**

This approach neatly combines the advantages of an open loop controller (Feedforward Control) with those of a closed loop controller with process value feedback (Closed Loop Control). The controller follows a previously optimized trajectory of setpoints and manipulated variables; in other words, it only needs to compensate small deviations between the stored trajectory and the current plant state. A trajectory is an optimum series of manipulated variables over time and the process values that match them. The required manipulated variables are read by means of the `MV10Traj` inputs into the MPC10x10 block and added to the values of the manipulated variable calculated by the algorithm (in automatic mode only). Among other things, the advantage of this is that the effective manipulated variable acting on the process as the sum of the trajectory and controller action is limited correctly as configured. The process values from the trajectory are linked to the corresponding setpoint specifications `SP1` ... `SP10` of the controller. As long as the process reacts exactly as planned in the trajectory, it will respond to the series of manipulated variables from the trajectory with the corresponding series of process values and the control deviation is zero. It is generally known that a non-linear dynamic process can linearized around a fixed operating point or a steady state of the system. It is also possible to linearize it around a trajectory.

## Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `DV1.ST`
- `DV4.ST`
- `CV1.ST`
- `CV2.ST`
- ...
- `CV10.ST`

### Configurable reactions using the `Feature` parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 8 | Delete history of MV and DV moves during restart (Page 201) |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 24 | Enabling local operator authorization (Page 169) |

### Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | Not used |
| 2 | 1 = Operator can switch to "Out of service" mode |
| 3 | Not used |
| 4 | Not used |
| 5 | 1 = Operator can change the setpoint 1 |
| 6 | 1 = Operator can change the manipulated variables of all channels |
| 7 | 1 = Operator can change operating high limits of the setpoints for all channels |
| 8 | 1 = Operator can change operating low limits of the setpoints for all channels |
| 9 | 1 = Operator can change the setpoint 2 |
| 10 | 1 = Operator can change the setpoint 3 |
| 11 | 1 = Operator can change the setpoint 4 |

| Bit | Function |
|---|---|
| 12 | 1 = Operator can change the setpoint filter of all channels |
| 13 - 16 | 1 = Operator can change the setpoint 5...8 |
| 17 | 1 = Operator can enable the track setpoint in "manual mode" function |
| 18 | 1 = Operator can activate the model-based disturbance compensation function |
| 19 | 1 = Operator can change the setpoint 9 |
| 20 | 1 = Operator can change the setpoint 10 |
| 21 | 1 = Operator can only activate the "Prediction Mode" function |
| 22 | 1 = Operator can change the target values of all channels |
| 23 | 1 = Operator can change the dead band parameter of all channels |
| 24 | 1 = Operator can change all parameters of the operating point optimization |
| 25 | 1 = Operator can change the simulation value `SimCV1..10` |
| 26 | 1 = Operator can activate the Simulation function |
| 27 | 1 = Operator can activate the Release for maintenance function |
| 28 | 1 = Operator can change the manipulated variable limits of all channels |
| 29 | 1 = Operator can change the gradient limits of manipulated variables of all channels |
| 30 | 1 = Operator can activate the operating point optimization |
| 31 | 1 = Operator can deactivate the operating point optimization |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Operator can activate/deactivate the `MV target` values of all channels |
| 1-15 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Release for maintenance

The block provides the standard function Release for maintenance (Page 70).

## Specifying the display area for process and setpoint values as well as operations

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

In contrast to PID controllers, there are no separate parameters for bar limits. The setpoints limits are used for all setpoint and actual value bars; manual limits are used as bar limits for all manipulated variable bars.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Integrated static operating point optimization

The integrated steady state operating point optimization can be used if no exact `SPi` setpoint is specified for at least one controlled variable (index i =1...10), but rather the `CVi` process value must remain within a tolerance range `SPiOptHiLim`...`SPiOptLoLim`. The tolerance range must, of course, be within the valid setpoint limits `SPiHiLim`...`SPiLoLim` for this control channel. The tolerance range `SPiOptHiLim`...`SPiOptLoLim` is not coupled to the operator-controlled setpoint `SPi`. If the setpoint is changed, the tolerance range is not automatically shifted. If you want to do this nevertheless, interconnect the `SPiOpOut` output parameters via two adders using the width of the tolerance range to the inputs `SPiOptHiLim` and `SPiOptLoLim`.

From an economic perspective, different values within the tolerance range can be more or less favorable. With the help of the optimization function, the optimal economic point can be found within the tolerance range.

This is done by defining a target function (performance criterion), which depends on the manipulated variable and controlled variable of the predictive controller. This can be, for example, the economic yield of plant operation per time unit or it may involve specific costs or energy consumption.

```
J= GradMV1*MV1 +GradMV2*MV2 +... +GradMV10*MV10
+GradCV1*CV1 +GradCV2*CV2 +...+GradCV10*CV10
+J0
```

You specify the individual `GradXVi` coefficients of the gradient vector as input variables at the MPC10x10 function block in the CFC or in the parameter view of the faceplate. If individual coefficients vary with time, e.g. they are dependent on current market prices, you can also interconnect these input variables. If individual manipulated or controlled variables have no influence on the performance criterion, leave the corresponding coefficients at the default value, zero.

You can use the binary `J_Mini` input parameter to specify whether the target function is to be maximized or minimized, based on whether this involves yields or costs (`J_Mini = 1` : minimization).

The term `J0` combines all contributions to the target function that do not depend on manipulated variables and controlled variables. These contributions have no effect on the optimum values of the decision variables, but are applied for calculating the current value of specified performance index according to the above-mentioned formula.

Within the controller, the terms of the target function that depend on controlled variables are converted to make their dependence on the manipulated variables visible. To do this, the steady state process model from the MPC Configurator is used.

Constraints for the controlled variables take the form of the above-mentioned tolerance ranges for setpoints. The controller takes care of adhering to the manipulated variable constraints, in any case; they do not have to be separately specified as constraints for the optimization.

Enable the optimization using the binary input variable `OptimizeOn` in the controller faceplate. The optimizer then returns setpoints within the tolerance ranges that are optimal with respect to the performance index. These setpoints are then sent to the control algorithm, which handles them in the same way as conventionally specified setpoints (with or without dead band). The operable `SP1...SP10` setpoints are not tracked to the optimized setpoints; when optimization is disabled, the old setpoints from the faceplate take effect once again. When selecting variables for archiving and graphic plotter, ensure you use the `SP1Out...SP10Out` setpoint actually in effect and not the `SP1...SP10` input variables.

The current value of the performance index is displayed at the `J_Actual` output variable.

You can find additional information about the topic of steady state operating point optimization in the online help for the MPC configurator.

### Display of the prediction of free movement

The prediction of free motion ("future without control") is a forecast for the future behavior of the process within the overall prediction horizon, under the assumption that all manipulated variables are frozen at their current values. The time length of the prediction horizon is indicated in the output parameter `PrediHorizon` in the [s] unit.

The prediction of free motion is recalculated in each sampling step within the control algorithm. If the manipulated variables are at constant values in manual mode, the prediction of the free movement is actually a realistic prediction for the future process response. It can therefore be represented graphically in the faceplate at least in terms of quality. For this purpose, five equidistant interpolation values are copied from the prediction horizon, and displayed in the standard view of the faceplate as a vertical bar next to the current process value.

Example: The prediction horizon is 1800s=30min and the current time is labeled with the index k. The prediction for k+6min, and next to it k+12min, up to k+30min then appears on the right next to the bar of the current process value. If the upper borders of each bar are virtually connected with a line (red in the picture), you can imaging the curve created by the future course of the process value over the next half hour.

In automatic mode (tracking function is switched off), the value of the manipulated variables fluctuates with each sampling step. The prediction of free movement is then only a fictional mathematical formulation within the algorithm, and not a realistic prediction for the future process response. This is why the prediction is only displayed in manual mode or in automatic mode with active tracking function. The display can be generally suppressed using `Feature.Bit31`.

### Prediction without control response

In this special "operating mode" (comparable to the block-internal simulation), the controller only monitors the process and indicates what it would like to do in the next sampling step without actively intervening in the process. This allows you as the user to build trust before "switching active" the controller the first time, i.e. actively intervening in the process.

"Prediction Mode" is activated via the binary input variable `PredictMode` or in "Parameters" in the faceplate view. Setpoints and process values are read as in normal automatic mode. The prediction of the free movement and manipulated variable change for the next sampling step

are calculated as in normal automatic mode. The starting point for the prediction of the manipulated variable for the next sampling step, however, is the current process value of the follow-up control loop at the MV1Trk...MV10Trk tracking inputs. The predicted manipulated variables are not output at the normal outputs MV1...10 but rather at the MV1Pred...MV10Pred outputs, which were especially introduced for this purpose, and are displayed in the standard view of the faceplate on the left next to MV1...10 as long as "Prediction Mode" is active.

- When the controller is in automatic mode, in "Prediction Mode" all MVi (i=1..10) are set to match the assigned MViTrk input parameters, similar to tracking mode.
- When the controller is in manual mode, all MVi are set to the desired manual values regardless of "Prediction Mode".
- When "Prediction Mode" is disabled, all MViPred always equal the respective MVi.

### Automatic process excitation for model identification

In order to determine the process model for the model predictive controller, the process must be artificially excited in order to observe its dynamic response and record it in the form of training data. This excitation signal can be specified manually in manual mode of the controller.

Alternatively, a suitable signal can be generated automatically in the form a defined, symmetrical sequence of manipulated variable steps. The trigger signals are calculated by an auxiliary function block, "AutoExcitation", which is built into the process tag type and interconnected to MPC10x10 .

Additional MV1Excite...MV10Excite input variables are required for this on the controller function block. Process excitation is performed in manual mode of the controller, because automatic mode cannot be activated before modeling. The new "Operating mode" process excitation can only be controlled via the ExciteOn input bit on the engineering system, and not on the operator station, because the CFC is needed for configuration of the AutoExcitation block. However, process excitation must be displayed on the OS in standard view at the lower left.

Manual intervention via faceplate remains possible even during process excitation. The values of the MV1Excite...MV10Excite input parameters are therefore only written event-based to the MV1Man...MV10Man values that is only if they change.

You can find additional details on automatic process excitation in the online help for the MPC configurator.

## 6.15.4 MPC10x10 error handling

### Error handling of MPC10x10

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Default value when the block is installed; this message is irrelevant. |
| 0 | There is no error. |
| 3 | Configuration error: Block is inserted in the wrong OB, cycle time of the OB is not suited for controller configuration. |
| 31 | The value of `CV1` can no longer be displayed in the real number field or is not a number. |
| 32 | The value of `CV2` can no longer be displayed in the real number field or is not a number. |
| ... | .. |
| 40 | The value of `CV10` can no longer be displayed in the real number field or is not a number. |
| 41 | The `MV_Trk1` value can no longer be displayed in the real number field or is not a number. |
| 42 | The `MV_Trk2` value can no longer be displayed in the real number field or is not a number. |
| ... | ... |
| 50 | The `MV_Trk10` value can no longer be displayed in the real number field or is not a number. |
| 51 | `AutModLi` = 1 and `ManModLi` = 1 |
| 90 | The controller matrix could not be loaded from the user data block. |

The ErrorOpt output parameter is used to output the status of the lower-level LPOptim block.

## 6.15.5 MPC10x10 messaging

### Messaging

This block does not offer messaging.

## 6.15.6 MPC10x10 I/Os

I/Os of MPC10x10

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi | 1 = Automatic mode via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp | 1 = Automatic mode via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enabled for allocation by batch control | BOOL | 0 |
| BatchID | Batch number | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| CV1...CV10 | Controlled variable 1...10 (process value) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CV1_Unit...CV10_Unit | Unit of measure for controlled variable 1...10 | INT | 1001 |
| DV_On | 1 = Activate the disturbance variable feedforward using DV | BOOL | 1 |
| DV1...DV4 | Disturbance variable 1...4 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DV1_Unit...DV4_Unit | Unit of measure for DV1...DV4 | INT | 1342 |
| DV1DeadBand...DV4DeadBand | Dead band for DV1...DV4 | REAL | 1.0 |
| DynOptOn | 1 = Activate dynamic optimization with constraints.<br>0 = Ignore constraints for optimization. | BOOL | 1 |
| ExciteOn | 1 = Automatic process trigger; MViExite input parameters are written to the MVi outputs | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Feature | I/O for additional functions (Page 1243) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1 |
| GradCV1... GradCV10 | Gradient vector for performance criterion, element (factor) for CV1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| GradMV1... GradMV10 | Gradient vector for performance criterion, element (factor) for MV1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| J_Actual_Unit | Physical unit of performance J_Actual | INT | 0 |
| J_Mini | 1 = minimize J,<br>0= maximize J | BOOL | 0 |
| J0 | Value of the performance criterion in the operating point | REAL | 0.0 |
| ManModLi | 1 = Manual mode via interconnection or SFC (effective if ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp | 1 = Manual mode via OS operator (effective if ModLiOp = 0) | BOOL | 0 |
| ModLiOp | Operating mode switchover by:<br>1 = Interconnection or SFC<br>0 = Operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp | Operator input for release for maintenance<br>1 = MS release requested | BOOL | 0 |
| MV1_Unit...MV10_Unit | Unit of measure for manipulated variable 1...10 | INT | 1342 |
| MV1Excite...MV10Excite | Default value for MV1..10 during the automatic process trigger for model generation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV1HiLi | High limit of manipulated variable MV1 | REAL | 100.0 |
| MV1LoLi | Low limit of manipulated variable MV1 | REAL | 0.0 |
| MV1Man | Manual value: Operator input for setting the manipulated variable MV1 in manual mode | REAL | 0.0 |
| MV1ManHiLim | High limit of manipulated variable MV1 in manual mode | REAL | 100.0 |
| MV1ManLoLim | Low limit of manipulated variable MV1 in manual mode | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV1RaLim | Gradient limiting of the manipulated variable MV1 [MV1_Unit/ second] | REAL | 100.0 |
| MV1TargOn...MV10TargOn | 1 = Activate MV1Target | BOOL | 1 |
| MV1Trk | Tracking value for the manipulated variable MV1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV1Traj | Trajectory value that is added to the manipulated variable MV1 | REAL | 0.0 |
| MV1TrkOn...MV10TrkOn | 1 = Tracking of manipulated variable MV1...MV10 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Allocated by SIMATIC BATCH | BOOL | 0 |
| OosLi | 1 = Out of service, via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp | 1 = Out of service, via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, to be connected with the Out output parameter of the upstream block OpStations | DWORD | 16#00000000 |
| OptimOffOp | 1 = Disable operating point optimization, normal setpoints SP1...SP10 in effect | BOOL | 0 |
| OptimOnOp | 1 = Enable operating point optimization, optimized setpoints SP1Out...SP10Out in effect | BOOL | 0 |
| OS_Perm | I/O for operating permissions (Page 1243) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| PredictMode | 1 = "Prediction only mode" enabled, prediction only, no intervention in the process | BOOL | 0 |
| PreFilt1...PreFilt10 | Settling time [s] of the setpoint filter for setpoint SP1...SP10 | REAL | 0.0 |
| Restart | 1 = Restart of the block and adoption of the data from the user block of the MPC Configurator | BOOL | 0 |
| SafePos1...SafePos10 | 1 = Safety setting for MV1...MV10 is Man1HiLim...Man10HiLim,<br>0 = Safety setting for MV1...MV10 is Man1LoLim...Man1LoLim, | BOOL | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 1.0 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate in the standard view | ANY | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate in the preview | ANY | |
| SimCV1... SimCV10 | Simulation value for control variable CV1...CV10, which is used for SimOn = 1 | REAL | 0.0 |
| SimCV1Li... SimCV10Li | Simulation value for control variable CV1...CV10, which is used for SimOnLi.Value = 1 (and SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation by:<br>1 = Interconnection or SFC<br>0 = Operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn | 1 = Enable simulation | BOOL | 0 |
| SimOnLi | 1 = Enable simulation via interconnection or SFC (if SimLiOp = 1)) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_TrkCV | 1 = Setpoints follow the CVs in manual mode and in tracking | BOOL | 0 |
| SP1...SP10 | Setpoint 1...10 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP1DeadBand... SP10DeadBand | Width (radius) of the dead band control of CV1...CV10 | REAL | 0.0 |
| SP1HiLim...SP10HiLim | Setpoint high limit 1...10 | REAL | 100.0 |
| SP1LoLim...SP10LoLim | Setpoint low limit 1...10 | REAL | 0.0 |
| SP1OptHiLim... SP10OptHiLim | High limit for optimization of setpoint 1...10 | REAL | 0.0 |
| SP1OptLoLim... SP10OptLoLim | Low limit for optimization of setpoint 1...10 | REAL | 0.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = Automatic mode is active<br>0 = Manual mode is active<br>(applies to all manipulated variable channels) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CV1Out...CV10Out | Copy CV1...CV10, preferably as output parameter | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| ErrorEndless | Error: infinite iteration loop in the dynamic optimization | BOOL | 0 |
| ErrorNum | Output of pending error number. You can find information about the error numbers that are output by this block at MPC10x10 error handling (Page 1253) | INT | -1 |
| ErrorOpt | Error number of the integrated operating point optimization function, see MPC10x10 error handling (Page 1253) | INT | 0 |
| Fut1_y1... Fut10_y5 | Prediction of free movement of CV1...CV10 for five future points in time within the prediction horizon | REAL | 0.0 |
| J_Actual | Current value of the performance criterion | REAL | 0.0 |
| Loop1Closed... Loop10Closed | 1 = MV1 is used by the algorithm for closed loop control, i.e. AutAct AND NOT MV1TrkOn<br>0 = Control loop for MV1 open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = Manual mode enabled, for all control channels | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release by OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV1...MV10 | Manipulated variable 1..10 (controller output signal) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| MV1HiAct | 1 = High limit of manipulated variable 1 reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV1LoAct | 1 = Low limit of manipulated variable 1 reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV1Pred | One-step prediction for MV1 in the "Prediction without control response" mode | REAL | 0.0 |
| MV1TargOut...MV10TargOut | Target value output (optimum value) for manipulated variable MV1...MV10 | REAL | 0.0 |
| NumberCVs | Number of control variables used | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| NumberDVs | Number of disturbances used | INT | 0 |
| NumberMVs | Number of manipulated variables used | INT | 10 |
| NumberOrigMVs | Number of original manipulated variables that are actively influenced by the controller (without pseudo MVs that are used as DVs | INT | 0 |
| OosAct | 1 = Block is "out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feed-forwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OptimAct | 1 = Operating point optimization enabled, setpoints calculated by the optimization are used<br>0 = Optimization off | BOOL | 0 |
| OS1PermLog | Display of OS_Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| OS1PermOut | Display of OS_Perm | WORD | 16#FFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| PrediHorizon | Prediction horizon [s] | REAL | 0.0 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP1OpOut...SP10OpOut | Copy of the operable setpoint 1 for step-enabling | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP1Out...SP10Out | Setpoint 1 actually used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1234) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1234) | DWORD | 16#00000000 |

## 6.15.7 MPC10x10 block diagram

### MPC10x10 block diagram

A block diagram is not provided for this block.

## 6.15.8 Operator control and monitoring

### 6.15.8.1 MPC10x10 views

#### Views of the MPC10x10 block

The block MPC10x10 provides the following views:

- MPC10x10 standard view (Page 1261)
- Trend view (Page 341)
- MPC10x10 parameter view (Page 1267)
- MPC10x10 CV parameter view (Page 1269)
- MPC10x10 MV parameter view (Page 1270)
- MPC10x10 preview (Page 1271)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MPC10x10 (Page 1274)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

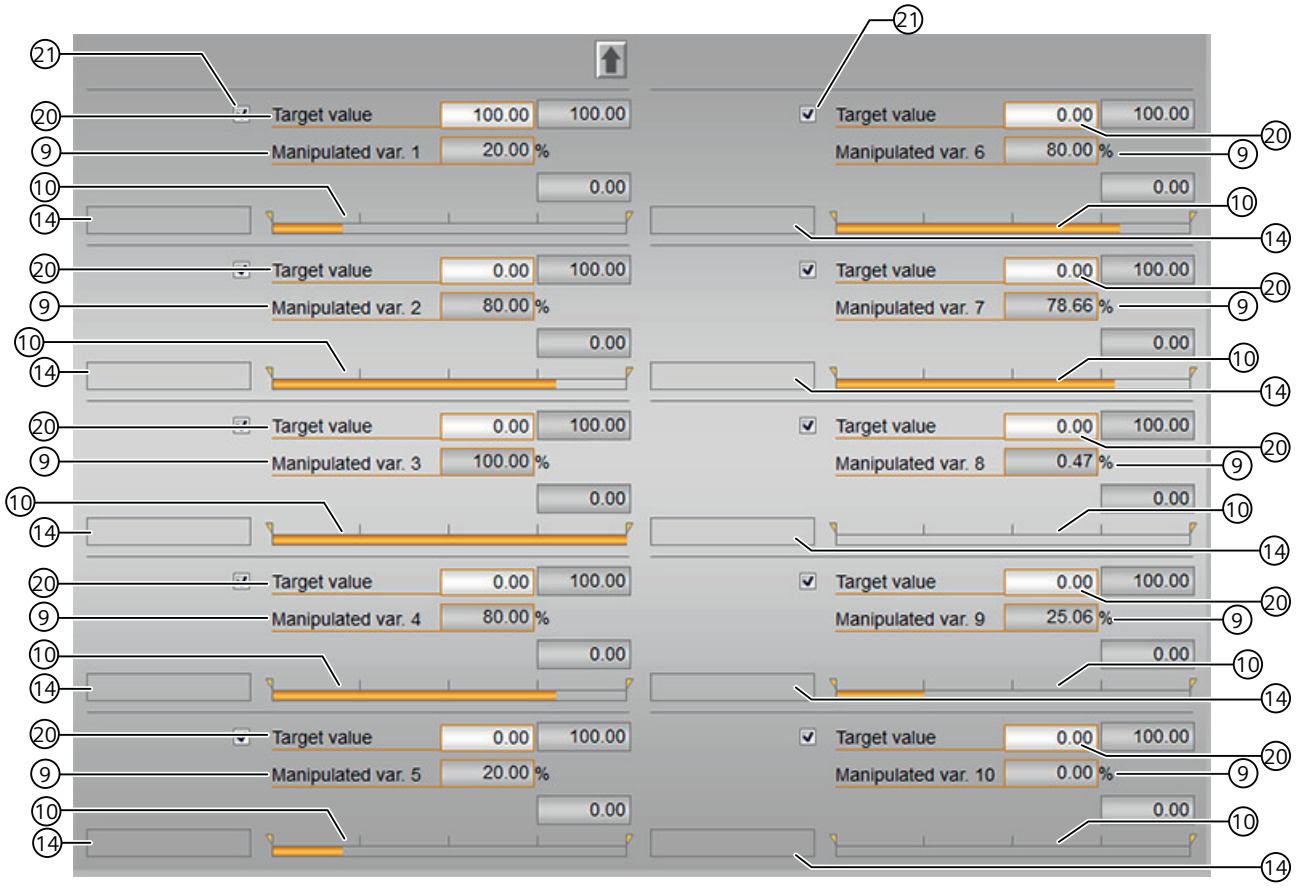
MPC10x10 trend view (Page 1273)

### 6.15.8.2 MPC10x10 standard view



#### Standard view of MPC10x10

The standard view has an upper half and a lower half. You can change between the two halves with the arrow keys. The upper half shows all available controlled variable channels with their setpoints, while the lower half shows all available manipulated variable channels.

**Upper screen half (controlled variables)**

**Lower screen half (manipulated variables)**

## (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 79)
- Automatic mode (Page 79)
- Out of service (Page 77)

For information on switching the operating mode, refer to the section

Switching operating states and operating modes (Page 289).

## (2), (3), (4) and (5) Displaying and switching for values for channels 1 to 10

This area always has the same layout for channels 1 to 10:

**(6) High and low scale range for the process value**

These values provide information on the display range for the bar graph of the process value. The scale range is defined in the engineering system. For more information refer Bar graph (Page 376).

**(7) Displaying and changing the process value including signal status**

This area shows the current process value with the corresponding signal status.

The process value is normally displayed and cannot be operated. Process values in the faceplate can only be changed within the context of internal block simulation.

In the object properties (I/Os PVx_Out > Identifier) of the block in CFC, you can specify the text to be displayed for these parameters.

**(8) Displaying and changing the setpoint including signal status**

This area shows the current setpoint with the corresponding signal status. Refer to the Changing values (Page 291) section for information on changing the setpoint.

### (11) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### (12) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on the display area for states of the block is available in the Release for maintenance (Page 70) .

### (13) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Process excitation"
  The automatic process trigger is fed forward using the upstream block AutoExcitation for recording learning data for the MPC configurator. The manipulated variable step changes are added to the manipulated values 1 to 4 according to schedule. Avoid external disturbances to the process while the process trigger is running. The manipulated variables can be changed manually while the process trigger is running.

You can find additional information on this in the section Simulating signals (Page 64).

### (14) Display area for block states

- "Internal error"
- "Invalid Signal"

### (15) Display area for block states

- "Tracking on"

### (16) Bar graph for the process value 1

There is a bar graph for the process value for every channel 1 to 10.

This area shows the current process value in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (17) Bar graph for the setpoint 1

There is a bar graph for the setpoint for every channel 1 to 10.

This area shows the current setpoint in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (18) Prediction of free movement

This area shows you the prediction of free movement in the form of a bar graph. For each channel from 1 to 10, there is a bar graph for the prediction of free movement, that is, for the future behavior of the process within the overall prediction horizon, under the assumption that all manipulated variables are frozen at their current values.

This is why the prediction of free movement is only displayed in manual mode or in automatic mode with active tracking function.

The value range of the bar graph matches the value range of the respective setpoint and current value bar.

Functions of MPC10x10 (Page 1243)

### (19) Displaying the limits

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the engineering system (ES).

### (20) Steady state operating point optimization

Activate the optimization using the button at bottom right. Activation means that the optimized setpoints SP1Out...SP4Out are actually used instead of the SP1...SP4 setpoints specified in the faceplate for closed-loop control. (The actual calculation of the optimum setpoints is not depending on this, and is only performed if one of the input variables for the optimization has changed.) The current value the economic performance index J appears in the display field below.

When optimization is enabled, the optimum setpoints are displayed on the setpoint bar as small, horizontal lines and highlighted with the abbreviation "opt.". The numerical values of the optimum setpoints are then displayed left of the input fields for the setpoints.

## Lower screen half (manipulated variables)

### (9) Displaying and changing the manipulated variable including signal status

This area shows the current manipulated variable with the corresponding signal status. Refer to the Changing values (Page 291) section for information on changing the manipulated variable. You can only make a change in manual mode.

In the object properties (I/Os MVx > Identifier) of the block in CFC, you can specify the text to be displayed for these parameters.

**(10) Bar graph for the manipulated variable with limit display**

This area shows the current manipulated variable in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES):

- Limits: `MVxHiLim` and `MVxLoLim`
- Display area: `MVxManHiLim` and `MVxManLoLim`

### (14) Display for states of the manipulated channel

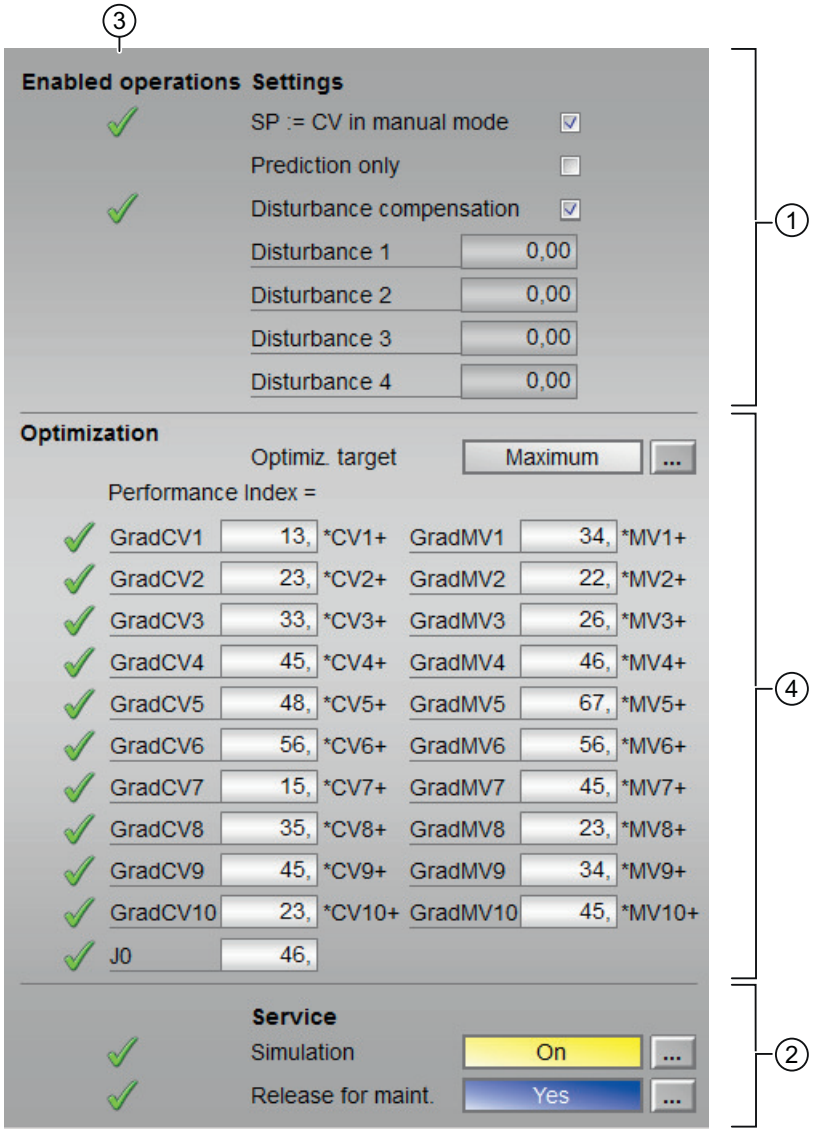
There is a display for the state of the manipulated channel for channels 1 to 10: the status display only appears if the respective channel is tracked:

- "Tracking"

### (20) Displaying and changing the target value for the manipulated variable

This area shows the current target value for the manipulated variable. Refer to the section Changing values (Page 291) for more information on changing the target value. You can make a change only in the "Automatic" mode and also only if `OptimAct` = 0. This field is not displayed in "Manual" mode.

### (21) Activate/Deactivate MV Target



When activated, `MV target` value entered by operator will be considered else target value will be tracked to the `MV value`.

### 6.15.8.3 MPC10x10 parameter view

#### Parameter view of MPC10x10

#### (1) Settings

You can activate the following functions for the controller in this area:

- "SP := CV in manual mode": ☑ Bumpless switchover from "manual mode" to "automatic mode"
- "Prediction only" activate this special "operating mode" by selecting the check box. The controller then only listens to the process and indicates what it would like to do in the next sampling step (i.e. which manipulated variables it would output in the next sampling step) without actively intervening in the process

- "Disturbance compensation": ☑ Select feedforward disturbance compensation
- "Disturbance" DV1...DV4 depending on the number of configured measurable disturbances

You cannot change the disturbance values, they can only be displayed.

In the object properties (I/Os DVx > Identifier) of the block in CFC, you can specify the text to be displayed for this parameter.

### (2) Service

You can select the following functions in this area:

- "Simulation"
- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### (3) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### (4) Optimization

**Direction of the optimization (minimize or maximize)**

By default, the optimizer seeks to maximize the performance function, in the assumption that it is dealing with economic yield. If you want to search a minimum, however, because you are dealing with costs or consumption values, click this button.

**Specification of performance index for the operating point optimization**

The performance index consists of a weighted sum of all manipulated and controlled variables. For each manipulated variable and controlled variable, enter the appropriate weighting factor, i.e. the coefficient of the gradient vector. Zero means that the value of the corresponding manipulated variable or controlled variable has no direct influence on the economic yield. If the controller has less than 10 manipulated variables or controlled variables, the irrelevant variables are hidden automatically.

J0 is the part of the performance index which does not depend on the controlled and manipulated variables of the MPC, e.g. fixed costs or costs calculated otherwise. Although this part of costs cannot be influenced during controller internal optimization, including it in the summation allows realistic numerical values to be displayed for the total costs.

MPC10x10 preview (Page 1271)

## 6.15.8.4 MPC10x10 CV parameter view

### CV parameter view for MPC10x10

The CV parameter view is a table which contains a row for each control channel:

| Channel setpoint | H range | H range optimiz. | Operator specific | Optimal setpoint | L range optimiz. | L range | Dead band | Unit | Prefilter [s] |
|---|---|---|---|---|---|---|---|---|---|
| 1 | 100,00 | 0,00 | 110,00 | 100,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 2 | 600,00 | 0,00 | 125,00 | 125,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 3 | 300,00 | 0,00 | 95,00 | 95,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 4 | 400,00 | 0,00 | 135,00 | 135,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 5 | 100,00 | 0,00 | 140,00 | 100,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 6 | 200,00 | 0,00 | 126,00 | 126,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 7 | 100,00 | 0,00 | 7,85 | 7,85 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 8 | 100,00 | 0,00 | 0,00 | 0,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 9 | 100,00 | 0,00 | 0,00 | 0,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |
| 10 | 100,00 | 0,00 | 0,00 | 0,00 | 0,00 | 0,00 | 0,00 | °C | 0,00 |

The channel number is at the far left. The physical unit applies to all values of this control channel except for the prefilter. The time constant of the prefilter is specified for all channels in seconds.

### (1) Displaying and changing the limit parameters for the setpoint

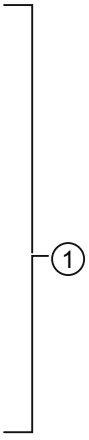
You can change the following setpoint parameters for the relevant control channel in each row:

- "H range": High limit for setpoint operation
- "H range optimization": High limit for optimizing the setpoint
- "Operator specification": Display of the setpoint specified in the standard view, cannot be operated here.

- "Dead band": Error signal generation and dead band (Page 217), Error signal generation and dead band section
- "Optimal setpoint": Calculated by the optimization, cannot be operated
- "L range optimization": Low limit for optimizing the setpoint
- "L range": Low limit for setpoint operation
- "Prefilter": TimeTrig functions (Page 2184), Setpoint filter section

The numerical values for limits are arranged from left to right in descending order. The three values per channel relevant for the optimization are highlighted in blue.

You can find additional information on this in the section Changing values (Page 291) .



The enabled operations for the setpoint parameters are displayed in the preview.

### 6.15.8.5 MPC10x10 MV parameter view

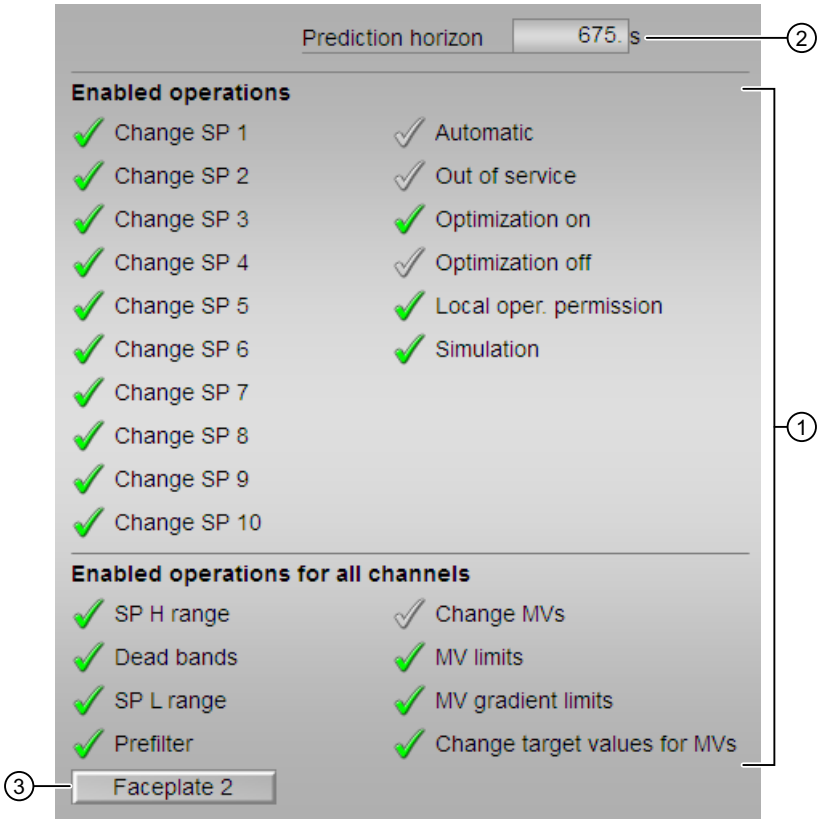
#### MV parameter view for MPC10x10

The MV parameter view is a table which contains a row for each manipulated variable channel:

| MV channel | H range | L range | Unit | Gradient [Unit/s] |
|---|---|---|---|---|
| 1 | 100,00 | 0,00 | % | 100,00 |
| 2 | 100,00 | 0,00 | % | 100,00 |
| 3 | 100,00 | 0,00 | % | 100,00 |
| 4 | 100,00 | 0,00 | % | 100,00 |
| 5 | 100,00 | 0,00 | % | 100,00 |
| 6 | 100,00 | 0,00 | % | 100,00 |
| 7 | 100,00 | 0,00 | % | 100,00 |
| 8 | 100,00 | 0,00 | % | 100,00 |
| 9 | 100,00 | 0,00 | % | 100,00 |
| 10 | 100,00 | 0,00 | % | 100,00 |

The channel number is at the far left. The physical unit applies to the high and low limit of the respective channel. The gradient is limited in the respective manipulated variable unit per second.

#### (1) Displaying and changing the limit parameters for the manipulated variable



You can change the following parameters for the manipulated variable in this area:

- "H range": Upper limit of the manipulated variable for automatic mode
- "L range": Low limit of manipulated variable for automatic mode
- "Gradient limit": Maximum (absolute) change in the manipulated variable per second

The enabled operations for the setpoint parameters are displayed in the preview.

### 6.15.8.6 MPC10x10 preview

#### Preview for MPC10x10

#### (1) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block. The lower screen half shows operator permissions which apply to all manipulated and control channels.

The upper screen half shows operator permissions which are not channel-based on the left, and channel-specific operator permissions for the individual setpoints on the right.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations for parameters are shown here:

- "Automatic": You can switch to "automatic mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Optimization on": You can switch on the optimization.
- "Optimization off": You can switch off the optimization.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator permissions (Page 285) .
- "Change SP1..10": You can change the setpoint 1..10
- "Change MVs": You can change the manipulated variables

**Note**

The OS operator must always be able to switch to "manual mode". For this reason, there is no special operator permission for switching to "manual mode" in the faceplate.

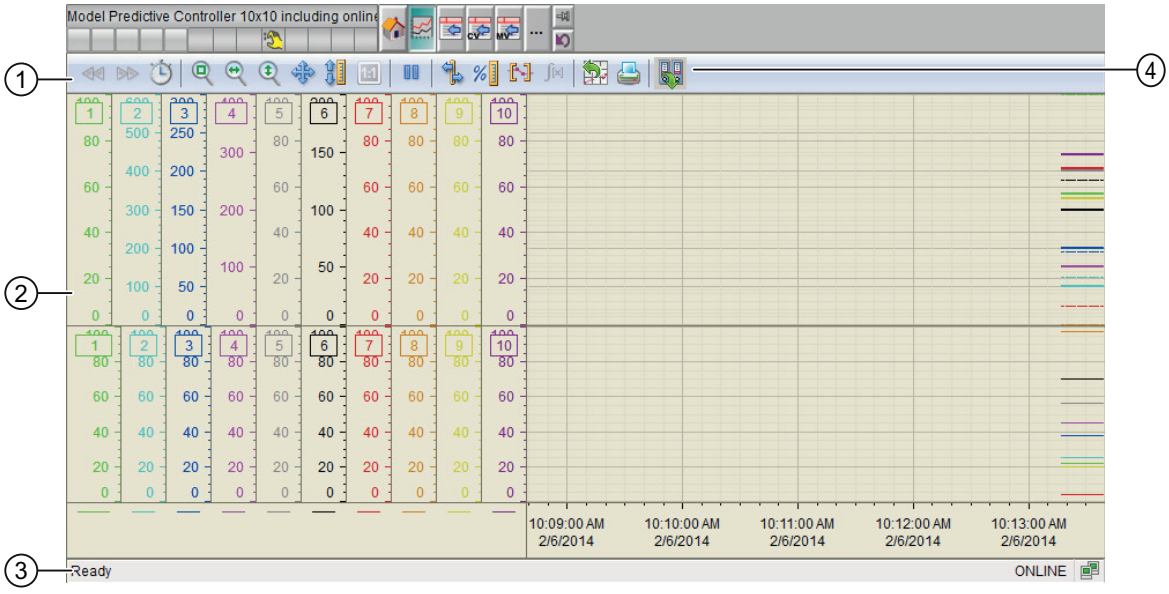
The following operator permissions apply to all manipulated channels.

- "Change MVs": You can change the manipulated variables in manual mode
- "MV limits": You can change the high and low limits for all manipulated variables.
- "MV gradient limits": You can change the gradient limits for all manipulated variables.
  The following operator permissions apply to all control channels.
  - "SP high limits": You can change the high limits for all setpoints.
  - "Dead bands": You can change the dead bands for all controlled variables.
  - "SP low limits": You can change the low limits for all setpoints.
  - "Prefilter": You can change the time constants of the prefilter for all setpoints.
- "Change target values for MVs": You can change the target values for all manipulated variables.

### (2) Prediction horizon

The prediction horizon specifies how far the controller looks into the future in its calculations. The value is set in the MPC Configurator and displayed in the faceplate for informational purposes.

### (3) Navigation button for switching to the standard view of any faceplate



Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### 6.15.8.7 MPC10x10 trend view

## MPC10x10 trend view

There is a block-specific trend view for MPC10x10 which is supplied as file @PG_APL_TrendMPC_L.pdl and which you can modify if necessary.

**(1)** Toolbar

**(2)** Display area for trends

**(3)** Status bar

**(4)** Button for switching between archive tags and online tags. The status bar shows if the trend view is working with online data or archive data.

The Export button is only visible and operable with the "Higher-level process control" operating permission.

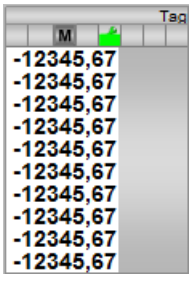
For additional information about the trend view, refer to the *WinCC Information System* Online Help.

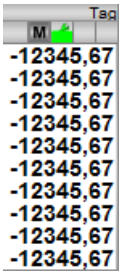
The trend view is divided into two screen halves.

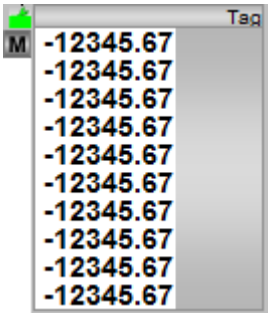
The upper screen half shows all controlled variables with their associated setpoints. The setpoint is shown in the same color as the associated process value to allow the assignment to be identified straight away. Setpoints are dashed lines, process values are bold lines. If a controlled variable is exactly on the setpoint, it hides the setpoint.

The lower screen half shows all manipulated variables.

Both screen halves use the same color sequence for the individual channels. The sequence starts at channel 1 with green (standard color for the process value with the PID controller) and then goes through the color spectrum from top to bottom as far as gray and black. From channel 7 (red), the rest of the spectrum is run through from top to bottom. Each channel has its own y-axis in the corresponding color.







### 6.15.8.8 Block icon for MPC10x10

## Block icons for MPC10x10

A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Tracking
- Memo display
- Process value (black, with and without decimal places)

The display of the tag name can be activated centrally for all block instances with the WinCC variable @APLShowTag:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | Narrow, without units |
|  | 3 | Block icon in the full display |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Operation via the block icon (Page 269)
- Block icon structure (Page 260).

# 6.16 KalFilt - State observer

## 6.16.1 Description of KalFilt

### Object name (type + number) and family

Type + number: FB 1925

Family: Control

### Area of application for KalFilt

The Kalman filter is a non-linear stochastic state observer. It forms a framework for parallel simulation of a dynamic process model, whose states are compared with real data in each cycle. During runtime, all internal state variables may be read from the model and used as a substitute for real measured values.

The state observer thus allows to determine the physical values of a process unit, which are not accessible or only measurable with high effort from other easily available measurements, for example, temperatures and mass flows.

It can therefore be used as a soft sensor, that is a piece of software that estimates values which are not measured.

In addition to its use as a state observer, it is also used as a model-based filter. The measured variables calculated from the estimated states are not subject to measurement noise and therefore generally run smoother than noisy measurements.

### How it works

#### The extended Kalman filter

The block operates as a state observer, in which the algorithm of the extended Kalman filter is implemented, and the online calculation of the internal states of non-linear dynamic systems is performed. Both, the mathematical structure of the underlying dynamic system and the properties of the stochastic disturbances must be known.

The term "filter" indicates that the algorithm is able to reduce measurement noise and other disturbances of stochastic data.

The Kalman filter is an approach to solve the general problem of estimating the states of a time-discrete process, which is described by linear stochastic differential equations and is a generalization of the classical state observer (Luenberger observer) in this respect. The estimation problem is extended to non-linear processes that result from a non-linear state space model:

$$\underline{x}_{k+1} = \underline{f}\left(\underline{x}_k, \underline{u}_k\right) + \underline{w}_k$$

$$\underline{y}_k = \underline{h}\left(\underline{x}_k\right) + \underline{v}_k$$

| Symbols | Meaning |
|---|---|
| $\underline{x}_k$ | Vector of the (inner) state variables at the time $t_k$ |
| $\underline{u}_k$ | Vector of the input variables at the time $t_k$ |
| $\underline{y}_k$ | Vector of the measurable output variables at the time $t_k$ |
| $\underline{\Phi}_k$ | Dynamic matrix (Jakobi matrix), refer to FB KalMod |
| $\underline{H}_k$ | Output matrix (Jakobi matrix), refer to FB KalMod |
| $\underline{P}_k$ | Estimation error covariance at the time $t_k$ |
| $\underline{K}_k$ | Kalman gain at the time $t_k$ |
| $\underline{Q}_k$ | Covariance of the process noise at the time $t_k$ |
| $\underline{R}_k$ | Covariance of the measurement noise at the time $t_k$ |
| $\underline{w}_k$ , $\underline{v}_k$ | Stochastic disturbances |

For the Kalman algorithm, *a priori* knowledge about the process to be observed must be provided to the block. This includes the covariance of the process noise $\underline{Q}_k$, the covariance of the observation noise $\underline{R}_k$, and the initial values (initialization) for the *a priori* state estimate $\underline{\hat{x}}_0^-$. The *a priori* estimation error covariance $\underline{P}_0^-$ is initialized with 0.

For more details on the configuration of the filter, refer to the *Kalman Configurator User Documentation*. The configuration, identification, simulation, and validation of the filter are performed in the Kalman Configurator.

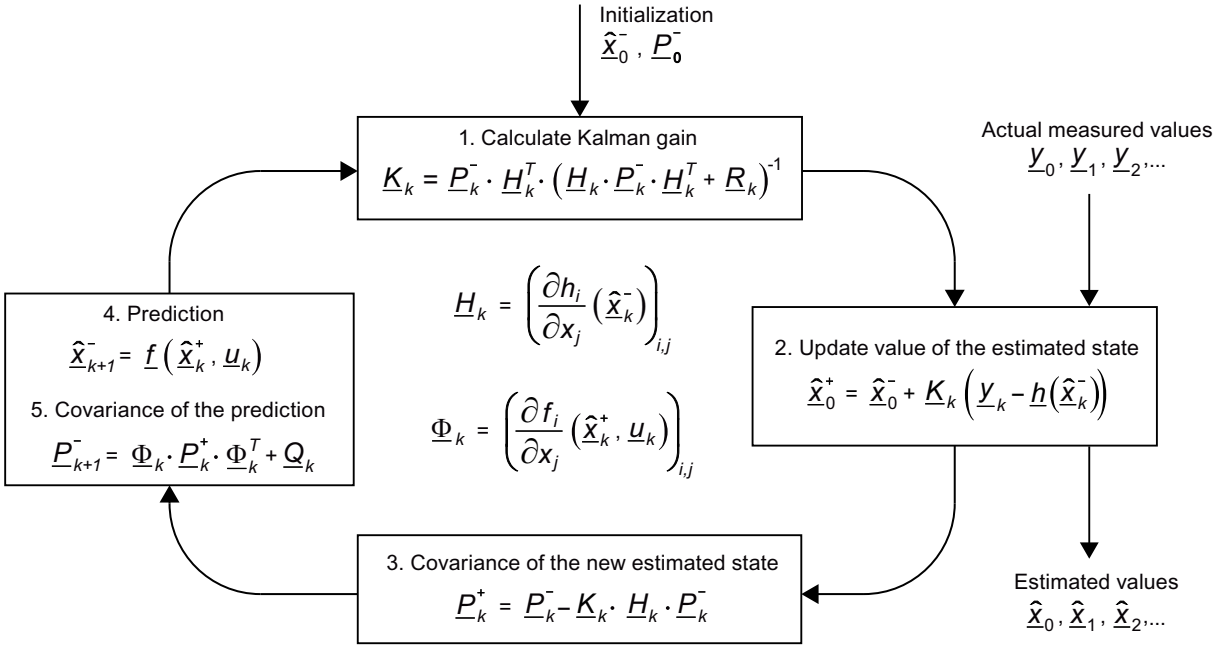


Figure 6-1 Implemented sequence of the extended Kalman filter

The sequence of the extended Kalman filter (EKF) corresponds to the linear filter: via the Kalman Gain $\underline{K}_k$ the predicted (*a priori*) state estimate $\underline{\hat{x}}_k^-$ is corrected using the actual measured values $\underline{y}_k$, which results in the corrected (*a posteriori*) state estimate $\underline{\hat{x}}_k^+$. Only two additional intermediate steps for calculating the Jacobi matrices $\underline{H}_k$ and $\underline{\Phi}_k$ are necessary for local linearization of non-linear models. The Jacobi matrices are calculated in the FB KalMod.

**Consideration of sporadic laboratory measurements**

If sporadic laboratory samples of relevant state variables are extracted from a process, the integration of these laboratory measurements in the extended Kalman filter can lead to significant improvements in estimation accuracy, since the unknown state variables can be compared with the laboratory results. The sample is taken sporadically. Once laboratory results are received, the laboratory values are provided to the EKF. The algorithm takes into account that the laboratory result is associated with a previous process state, which belongs to the past time instant where the sample was taken. For the usage of laboratory measurements, particular engineering steps are necessary. These steps are described in the section "Additional configuration tasks for inclusion of the laboratory measurements" under "Configuration".

## Operating principle

The corrected states $\underline{\hat{x}}_k^+$ (`X1`...`X15`) are used for application as a state observer. These can be used for visualization, interconnections to further calculations, or feedback for control loops.

The output variables $\underline{\hat{y}}_k^+ = \underline{h}\left(\underline{\hat{x}}_k^+\right)$ (`Y1Filt`...`Y7Filt`) calculated from the corrected states are used for application as a model-based filter.

The advantage compared to a simple low-pass filter is that the influences of the inputs are provided without additional delay to the output variables via the model. The signal status of the filtered output values `YiFilt` are based on the worst signal status of the states.

To assess the quality of the Kalman filter, the following deviations can be used:

- The deviations of the predicted output values from the measured variables:
  $\underline{e}_k^- = \underline{y}_k - \underline{h}\left(\underline{\hat{x}}_k^-\right)$ (`EY1`...`EY7`)
- The deviations of the predicted state variables from the laboratory measurements:
  $\underline{e}_{nk}^- = \underline{y}_{nk} - \underline{h}_n\left(\underline{\hat{x}}_k^-\right)$ (`EYn1`...`EYn5`)

The deviations are usually caused by modeling inaccuracies and unknown disturbances (i.e. disturbances not considered in the model).

In many applications, there are not measurable outputs that can be calculated using algebraic equations from state and input variables, and which are relevant for the practical use of the Kalman filter, for example, heat flow generated by exothermic chemical reactions or specific conversion rates in organic fermenters. These variables can be defined as non-measurable process output variables (`Z1Out`...`Z5Out`) in the Kalman configurator, for which there is a respective output equation, but no measured values.

For application of the filter block as a process simulator, the input variables `Ui` are interconnected to the actual input values to simulate the behavior of the process and get simulated measured values at the output variables `YjFilt`. Since there are no measurements for the process output variables `Yj`, the corresponding inputs at the block are connected to the output variables. The elements of the Q matrix are all set to zero, that is no model uncertainty is assumed for the simulation.

### Kalman Configurator

Using the Kalman Configurator, you can conveniently configure the process model and specify all model-specific settings for the Kalman filter. As a result, the tool generates the source code of the FB KalMod. Once you have compiled the block, you can download it to the automation system. For more details, refer to the *Kalman Configurator User Documentation*.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

Perform the following configuration tasks:

- Interconnect the input and output variables `U1`...`U7` and `Y1`...`Y7`
- Interconnect `UiLimScale`, `UiUnit` (i = 1...`NumberU`) and `YiLimScale`, `YiUnit` (i = 1...`NumberY`) and specify input limits (`UiLimScale.High/.Low`) and the measurement limits (`YiLimScale.High/.Low`)
- Specify self-explaining variable names for all configured inputs, measurable and non-measurable outputs, and state variables at the text attributes (identifiers)
- Select the associated process model in FB KalMod through `ModelNo` (1...5)
- Interconnect the initial values for the configured state variables. This connection is only necessary if the initial values are not constant, but time-varying, and a signal source for the actual values is available.
- Record measured data and configure the Kalman filter through the Kalman Configurator (refer to the *Kalman Configurator User Documentation*)

To compile the SCL sources generated by the configurator, the following user-defined data types are needed, which have to be copied from APL to the function block folder of the user project:

- UDT 43: Vector15
- UDT 44: Matrix15
- UDT 45: Kal_DB
- UDT 46: StcVector15
- UDT 47: StcMatrix15
- UDT 48: StcKalDB

The data types which you have declared must not be within this number range.

- In the "Component view" of SIMATIC Manager, right-click on the folder "Sources", select "Insert new object" and then select "External source".
- Double-click the SCL source to open/edit the code and click "Compile and load" to upload it to the CPU.
- Set the input variable `LoadParam` = 1 at the KalFilt instance in the CFC to load the model in the filter.

Additional configuration tasks for inclusion of the laboratory measurements:

- Enable bit for lab measurements (`SampleEn` = 1)
- The number of lab data (`NumberYn`) is already determined in the configurator.

Laboratory data can be inserted using the faceplate or can be provided by interconnection. Therefore, the respective signal selectors `***_LiOp` have to be set, whereby `***_LiOp` = 1 means that the link is relevant, and `***_LiOp` = 0 means that the operation in the faceplate is relevant. Both the cases are described separately as follows:

- Inserting laboratory data in the faceplate:
  - Select the signal selectors (`SaPo_LiOp` = 0, `SaRe_LiOp` = 0)
  - The operation of the faceplate to insert laboratory data is described in section KalFilt standard view (Page 1293).
- Providing laboratory data by interconnection:
  - Select the signal selectors (`SaPo_LiOp` = 1, `SaRe_LiOp` = 1)
  - At the time of taking the lab sample, set the input variable `SaPo_Ext` = 1. This command is detected via rising edge of `SaPo_Ext` and is acknowledged by setting the binary output variable `SampExtracted` = 1.
  - After laboratory analysis, provide the results to the input variables `Yn1_Ext`...`Yn5_Ext` and set the input variable `SaRe_Ext` = 1. This command is detected via rising edge of `SaRe_Ext` and is acknowledged by setting the binary output variable `LabResIncluded` = 1.
  - `Feature.Bit2` defines if the binary input variables are reset by the function block itself. If they should not be reset automatically, they have to be reset by interconnection, after the respective order was acknowledged by setting the respective binary output variable.

Diagonal elements of the covariance matrix of the measurement noise `Rn11`...`Rn55` are defined in the model FB from the Kalman Configurator.

Determining the monitoring time `TimeMon`:

- When this time has expired, waiting for the laboratory test results is terminated. It takes at least one cycle of the process model between the period when the lab sample is taken and the laboratory results are received.

The library contains the following blocks:

| Icon | Address | Data type | Comment |
|---|---|---|---|

## Startup characteristics

At the start of a run or a batch, the algorithm must be initialized and all states must be set to their initial values. This initialization is triggered by the binary input variable `Reset`, which is automatically reset after executing the initialization and is also accessible in the faceplate.

If the initial values are read from the model FB generated by the Kalman Configurator during initialization, the binary input variable `LoadParam` should be used instead, which is also automatically reset after a successful read operation, but is not accessible in the faceplate. The current values set at the corresponding input variables or in the faceplate are overwritten (for example, initial values of the states) when the parameters are loaded from the FB.

When the CPU starts up, the block is reinitialized and the parameters are loaded from the FB (in accordance with `LoadParam`).

## Status word allocation for `Status1` parameter

You can find description of each parameter in the section KalFilt I/Os (Page 1287).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct` |
| 4 | `OosLi` |
| 5 | Not used |
| 6 | `OnAct` |
| 7 | `SampleEn`, enable for introducing the laboratory values |
| 8 | `SamplePoint`, laboratory sample taken from process |
| 9 | `SampleResult`, lab results incorporated |
| 10 | Laboratory results are bad → lab results are ignored |
| 11 | Waiting period for laboratory results has expired |
| 12 | Laboratory results adapted to limits |
| 13 | `SaPo_ExtAct`, external lab sampling |
| 14 | `SaRe_ExtAct`, external lab measurement |
| 15 | Not used |
| 16 - 25 | `UserAna1` to `UserAna10` interconnected |

| Status bit | Parameter |
|---|---|
| 26 - 30 | Not used |
| 31 | Internal error |

## 6.16.2 KalFilt modes

### Operating modes of KalFilt

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | **`Feature.Bit5 =0`** | **`Feature.Bit5 =1`** |
|---|---|---|
| X1.ST | 16#80 | 16#60 |
| X2.ST | 16#80 | 16#60 |
| X3.ST | 16#80 | 16#60 |
| X4.ST | 16#80 | 16#60 |
| X5.ST | 16#80 | 16#60 |
| X6.ST | 16#80 | 16#60 |
| X7.ST | 16#80 | 16#60 |
| X8.ST | 16#80 | 16#60 |
| X9.ST | 16#80 | 16#60 |
| X10.ST | 16#80 | 16#60 |

| Output Parameters | Feature.Bit5 =0 | Feature.Bit5 =1 |
|---|---|---|
| X11.ST | 16#80 | 16#60 |
| X12.ST | 16#80 | 16#60 |
| X13.ST | 16#80 | 16#60 |
| X14.ST | 16#80 | 16#60 |
| X15.ST | 16#80 | 16#60 |
| U1Out.ST | 16#80 | 16#60 |
| U2Out.ST | 16#80 | 16#60 |
| U3Out.ST | 16#80 | 16#60 |
| U4Out.ST | 16#80 | 16#60 |
| U5Out.ST | 16#80 | 16#60 |
| U6Out.ST | 16#80 | 16#60 |
| U7Out.ST | 16#80 | 16#60 |
| Y1Out.ST | 16#80 | 16#60 |
| Y2Out.ST | 16#80 | 16#60 |
| Y3Out.ST | 16#80 | 16#60 |
| Y4Out.ST | 16#80 | 16#60 |
| Y5Out.ST | 16#80 | 16#60 |
| Y6Out.ST | 16#80 | 16#60 |
| Y7Out.ST | 16#80 | 16#60 |
| Yn1Out.ST | 16#80 | 16#60 |
| Yn2Out.ST | 16#80 | 16#60 |
| Yn3Out.ST | 16#80 | 16#60 |
| Yn4Out.ST | 16#80 | 16#60 |
| Yn5Out.ST | 16#80 | 16#60 |
| Y1Filt.ST | 16#80 | 16#60 |
| Y2Filt.ST | 16#80 | 16#60 |
| Y3Filt.ST | 16#80 | 16#60 |
| Y4Filt.ST | 16#80 | 16#60 |
| Y5Filt.ST | 16#80 | 16#60 |
| Y6Filt.ST | 16#80 | 16#60 |
| Y7Filt.ST | 16#80 | 16#60 |
| Z1Out.ST | 16#80 | 16#60 |
| Z2Out.ST | 16#80 | 16#60 |
| Z3Out.ST | 16#80 | 16#60 |
| Z4Out.ST | 16#80 | 16#60 |
| Z5Out.ST | 16#80 | 16#60 |
| SaPo_ExtAct.ST | 16#80 | 16#60 |
| SaRe_ExtAct.ST | 16#80 | 16#60 |

## 6.16.3 KalFilt functions

### Functions of KalFilt

The functions for this block are listed below.

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

- Signal status for the estimated states values `X1`...`X15`:
  - When limited (to the high or low limit), the signal status 16#78 (uncertain, process-related) is set at the relevant state estimate.
  - If the REAL value of the input or output variables is "infinity" (+#INF and -#INF) or "not a number" (+#NAN and -#NAN), the signal status 16#28 (Bad) is assigned to all state variables.
  - If a signal status of the input variables (`U`) is bad, all state variables obtain the signal status `ST_Worst`.
  - If a signal status of the output variables (`Y`) is bad, the associated covariance element of the measurement noise `R` is set to 1.0e+10 and all state variables obtain the signal status 16#68 (uncertain, device related).
  - If a signal status of the lab measured values (`Yn`) is bad or the lab value cannot be shown in the REAL number field, all lab values are ignored. The signal status of the lab measured values has no affect on the signal status `ST_Worst`.
  - In all other cases, the state estimated values have the signal status 16#80 (Good).
- The worst signal status `ST_Worst` for the block is formed from the parameters (`U1.ST` to `U7.ST`).

### Configurable reactions using the `Feature` parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | AUTOHOTSPOT |

| Bit | Function |
|---|---|
| 2 | Resetting the commands for changing the mode (Page 172) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 24 | Enabling local operator authorization (Page 169) |

## Operator permissions

The block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch the block to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch the block to "Out of service" mode |
| 4 | Not used |
| 5 | 1 = Operator can perform a block restart |
| 6 | 1 = Operator can change `SimUi` simulation values |
| 7 | 1 = Operator can change `SimYi` simulation values |
| 8 | 1 = Operator can enter the initial values `XiStart` for state variables `X1`...`X15` |
| 9 | 1 = Operator can change the high limit `XiHiLim` for state variables `X1`...`X15` |
| 10 | 1 = Operator can change the low limits `XiLoLim` for state variables `X1`...`X15` |
| 11 | 1 = Operator can enable the simulation function |
| 12 | Not used |
| 13 | 1 = Operator can enter lab values and operate `SaPo` and `SaRe` |
| 14 | 1 = Operator can specify the maximum duration for lab data and limits for errors in lab values |
| 15 | 1 = Operator can change the scaling of the bar graph display for the estimation error in the standard view of the faceplate |
| 16 - 31 | Not used |

## 6.16.4 KalFilt error handling

### Error handling of KalFilt

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers in `ErrorNum`
- Output bit `ErrorPara` = 1
  The occurrence of an error is depicted at the faceplate using the symbol  as function block status.

### Overview of error numbers

The `ErrorNum` output parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| –1 | Predefined value when the block is inserted; the block is not executed. |
| 0 | There is no error. |
| 2 | `SampleTime` < 0.001 or required sampling time for Kalman filter is less than the cycle time of the cyclic interrupt OB in which the block is integrated. |
| 3 | FB KalFunct called internally returns an error, for example, if `ModelNo` > 5 |
| 4 | Parameter assignment error `NumberU`/`NumberY`/`NumberX`/`NumberYn`/`NumberZ`, for example, number larger than possible |
| 6 | Error loading model FB from the Kalman Configurator. The following sources of error are possible:<br>• FB is not available<br>• FB is not Kalman Configurator FB<br>• Required matrix dimensions are not supported |
| 7 | Only during startup:<br>Initial values of the state variables are out of range |
| 21 - 27 | Signal status of the input variable `U1`...`U7` is bad |
| 30 | The value of an input variable `Y1`...`Y7` or `U1`...`U7` cannot be displayed in the REAL number field |
| 31 | Matrix inversion inside the Kalman filter algorithm fails. In this case, the internal filter states will not be updated according to current measurement data, but remain at their *a priori* values. If at the next sample step, with new measurement values, the matrix-inversion works correctly again, the `ErrorNum` is set back to zero. |

I/Os of KalFilt

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameters | Description | Type | Default |
|---|---|---|---|
| BatchEn | 1 = Enable allocation for Batch control | BOOL | 0 |
| BatchID | Current batch ID | DWORD | 16#00000000 |
| BatchName | Current batch designation | STRING[32] | '' |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| EYn1Lim...EYn5Lim | Limits for the difference between lab results and associated state values | REAL | 0.0 |
| EYPScale | Scaling of the bar graph display of the estimation error in the faceplate | REAL | 100.0 |
| Feature | I/O for additional functions (Page 1284) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| LoadParam | 1 = Restart KalFilt with loading of the parameters (including the initial values for the states) from the FB | BOOL | Normal oper. |
| ModelNo | Process model number (assignment of the appropriate process model in KalFunc) | INT | 1 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp | 1=On Mode: On Mode by Operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameters | Description | Type | Default |
|---|---|---|---|
| OosOp | 1 = "Out of service", via OS operator | BOOL | 0 |
| OS_Perm | I/O for operator permissions (Page 1284) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| Q11...Q1515 | Diagonal elements of the covariance matrix *Q*, related to uncertainty of the differential equation for respective states X1... X15 | REAL | 0.0 |
| Reset | 1 = Reset the states X1...X15 to their initial values defined at the input parameters | BOOL | Normal oper. |
| R11...R77 | Diagonal elements of covariance matrix *R*, related to measurement noise of output variables Y1...Y7 | REAL | 0.0 |
| Rn11...Rn55 | Diagonal elements of covariance matrix *Rn*, related to measurement noise of lab results Yn1...Yn5 | REAL | 0.0 |
| SampleEn | Enable for sporadic laboratory measurements | BOOL | 0 |
| SampleTime | Sample time in seconds (assigned automatically) | REAL | 0.1 |
| SaPo_LiOp | Select lab sampling (internal/external):<br>1 = Via interconnection (external)<br>0 = Via operator (internal) | BOOL | 0 |
| SaPo_Int | 1 = Lab sampling internal (via operator) | BOOL | 0 |
| SaPo_Ext | 1 = Lab sampling external (via interconnection) | BOOL | 0 |
| SaRe_LiOp | Select lab result (internal/external):<br>1 = Via interconnection (external)<br>0 = Via operator (internal) | BOOL | 0 |
| SaRe_Int | 1 = Lab result internal (input by operator) | BOOL | 0 |
| SaRe_Ext | 1 = Lab result external (values comes via interconnection) | BOOL | 0 |
| SelFp1 | 1 = Call a block saved in this parameter as an additional faceplate in the standard view | ANY | |
| SelFp2 | 1 = Call a block saved in this parameter as an additional faceplate in the preview | ANY | |
| SimOn | Switch on/off of the simulation | BOOL | 0 |
| SimU1...SimU7 | Simulation values for U1...U7 | REAL | 0.0 |
| SimY1<br>...<br>SimY7 | Simulation values for Y1...Y7 | REAL | 0.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TimeMon | Monitoring time for sampling in minutes | INT | 60 |
| U1...U7 | Input variables | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| U1Unit...U7Unit | Unit for input variables U1...U7 | INT | 1342 |

| Parameters | Description | Type | Default |
|---|---|---|---|
| U1LimScale...U7LimScale | Limit of the value range and scaling for faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| UserAna1...UserAna10 | Arbitrary analog values for display in the block icon | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1Unit...UA10Unit | Unit for UserAna1...UserAna10 | INT | 1001 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| X1LimScale...X15LimScale | High and low limit for X1...X15 | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| X1Start...X15Start | Initial value for the state variables X1...X15 | REAL | 0.0 |
| X1Unit...X15Unit | Unit for the state variables X1...X15 | INT | 1001 (°K) |
| Y1...Y7 | Measurable output variables | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Y1LimScale...Y7LimScale | Limitation of the value range of Y1...Y7 and scaling for faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Y1Unit...Y7Unit | Unit for the output variables Y1...Y7 | INT | 1001 |
| Yn1_Ext...Yn5_Ext | External lab result (input for interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Yn1_Int...Yn5_Int | Internal lab result Yn1_Int...Yn5_Int (input by operator) | REAL | 0.0 |
| Yn1Unit...Yn5Unit | Unit for the lab result Yn1...Yn5 | INT | 1342 (%) |
| Yn1LimScale...Yn5LimScale | Limitation of the value range of Yn1...Yn5 and scaling for faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| Z1Unit...Z5Unit | Unit of measurement for Z1...Z5 | INT | 1001 |

## Output parameters

| Parameters | Description | Type | Default |
|---|---|---|---|
| DTimeMon | Time since extraction of lab sample in minutes | REAL | 0.0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |

| Parameters | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of pending error number. For definition of error numbers by this block, see KalFilt error handling (Page 1286). | INT | -1 |
| ErrorPara | 1= Parameter assignment error | BOOL | 0 |
| EY1...EY7 | Deviation between measured values (Y1...Y7) and prediction of the Kalman filter | REAL | 0.0 |
| EYn1...EYn5 | Deviation between lab results and prediction of the Kalman filter | REAL | 0.0 |
| EY1P_k1...EY1P_k5 | Percent deviation between measured value Y1 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EY2P_k1...EY2P_k5 | Percent deviation between measured value Y2 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EY3P_k1...EY3P_k5 | Percent deviation between measured value Y3 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EY4P_k1...EY4P_k5 | Percent deviation between measured value Y4 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EY5P_k1...EY5P_k5 | Percent deviation between measured value Y5 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EY6P_k1...EY6P_k5 | Percent deviation between measured value Y6 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EY7P_k1...EY7P_k5 | Percent deviation between measured value Y7 and prediction of the Kalman filter for 1 to 5 latest samples | REAL | 0.0 |
| EYPScaleOut | Calculated scaling of the bar representation of estimation error in the standard view of the faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| LabResIncluded | Laboratory results included | BOOL | 0 |
| NumberU | Number of input variables U | INT | 7 |
| NumberX | Number of state variables X | INT | 15 |
| NumberY | Number of output variables Y | INT | 7 |
| NumberYn | Number of lab sample variables Yn | INT | 1 |
| NumberZ | Number of non-measurable output variables Z | INT | 0 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with the settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| P11...P1515 | Diagonal elements of covariance matrix *P*, related to uncertainty of differential equation for respective states X1...X15 | REAL | 0.0 |
| SampExtracted | Laboratory sample extracted | BOOL | 0 |

| Parameters | Description | Type | Default |
|---|---|---|---|
| SaPo_ExtAct | 1 = External lab sampling is active<br>0 = Internal lab sampling is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SaRe_ExtAct | 1 = External lab results active<br>0 = Internal lab results active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word 1 | DWORD | 16#00000000 |
| Status2 | Status word 2 (not used) | DWORD | 16#00000000 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| X1...X15 | Corrected state estimation value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| U1Out...U7Out | Input variables set at the block input (copy of U1...U7) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Y1Filt...Y7Filt | Process output variables calculated based on the corrected states X1...X15 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Y1Out...Y7Out | Process output variables set at the block input (copy of Y1...Y7) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Yn1Out...Yn5Out | Lab results set at the block input | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Z1Out...Z5Out | Additional non-measurable output variables | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

**View 2**

### (1) Displaying and switching the operating mode

This area provides information on the currently active operating mode. The following operating mode can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Restarting the block

Click "Restart" to restart the Kalman filter block.

The initial values specified at the block inputs (`X1Start`...`X15Start`) can be set with `Reset`.

### (3) Display of the estimation error in process outputs

In this area, the percentage estimation errors in the existing measurement channels are displayed. These are based on the particular value range and are calculated for 5 consecutive sampling instants in the recent past. The estimation error at the current time is displayed on the far right and the most distant error in the past (5 sampling steps ago) can be seen at the far left. You can change the scaling of the bar in the parameter view (Page 1297) of the faceplate.

### (4) Sample Point

You can mark the time of extracting lab sample using "Sample Point" button (only if `SaPo_LiOp` = 0).

### (5) Sample Result

Click this button to confirm the laboratory results entered in the "TextLabDatai" fields. Refer to **(7) Laboratory results**.

### (6) Duration of Analysis

This field displays the elapsed time since the extraction of lab sample. If this is greater than the specified limit (`TimeMon`, can be changed in the parameter view), which is displayed at the upper right field, the result of the laboratory measurement is no longer used.

### (7) Laboratory results

You can enter the laboratory results (`Yni_Int`) directly in the "TextLabDatai" fields. Once they are all fully entered, the entry must be confirmed with the "Sample Result" button. The counter stops and the laboratory data are considered in the calculations of the Kalman filter. If a sample is extracted but no meaningful result can be given, a new sample extraction can be started in the faceplate. If the laboratory data is given via interconnection, the description for engineering and operation can be found in the section Additional configuration tasks for inclusion of the laboratory measurements (Page 1276).

### (8) Additional output variables

If you have output variables which cannot be measured and are calculated from *a posteriori* state estimates, you can define and enter the calculation algorithm for a maximum of 5 additional output variables (`Z1Out`...`Z5Out`) in the Kalman Configurator.

### (9) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of another function block, which is configured in the engineering system (ES).

The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, refer to the section Opening additional faceplates (Page 234).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You will find more detailed information on this in the sections Simulating signals (Page 64).

### (11) Display area for block states

This area provides additional information on the operating state of the block:

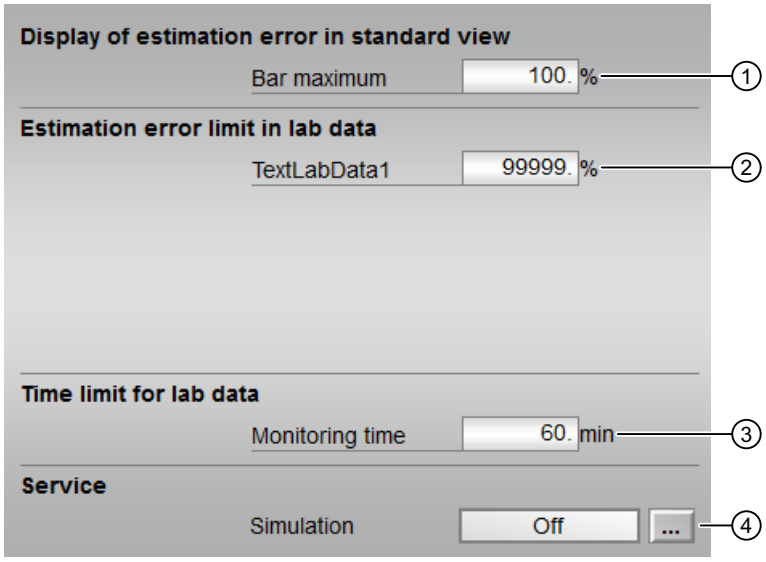
- "Sample extracted"
- "Lab results included"
- "Error in lab results"
- "Time out in analysis"
- "Lab results limited"

### (12) State variables

This area shows the current values of the estimated state variables.

### (13) Initial values

You can specify intial values for the state variables, which are used for `Reset`.



### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

## 6.16.8.3 KalFilt parameter view

### Parameter view of KalFilt

### (1) Display of estimation error in standard view

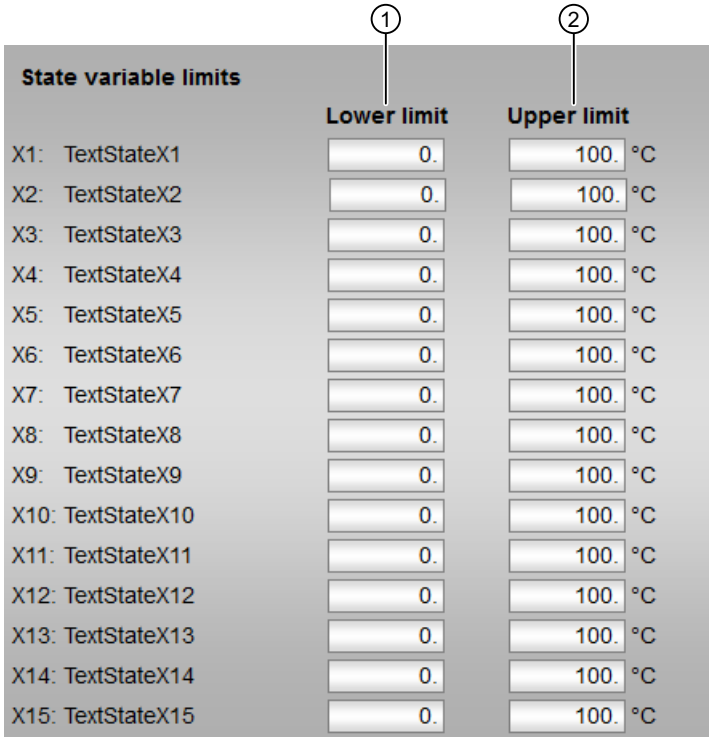
You can set the scale of the bar diagram in the "Bar maximum" (`EYPScale`) field. The bar diagram is displayed in the KalFilt standard view (Page 1293).

### (2) Estimation error limits in lab data

You can change the maximum permissible deviation of the laboratory results from the estimated state variables in the "TextLabData1" field (`EYniLim`).

If the actual error is above this value, the lab results are regarded as implausible and not used for the Kalman filter.

### (3) Duration limits in lab data



You can adjust the maximum duration for a laboratory measurement in the "Monitoring time" field.

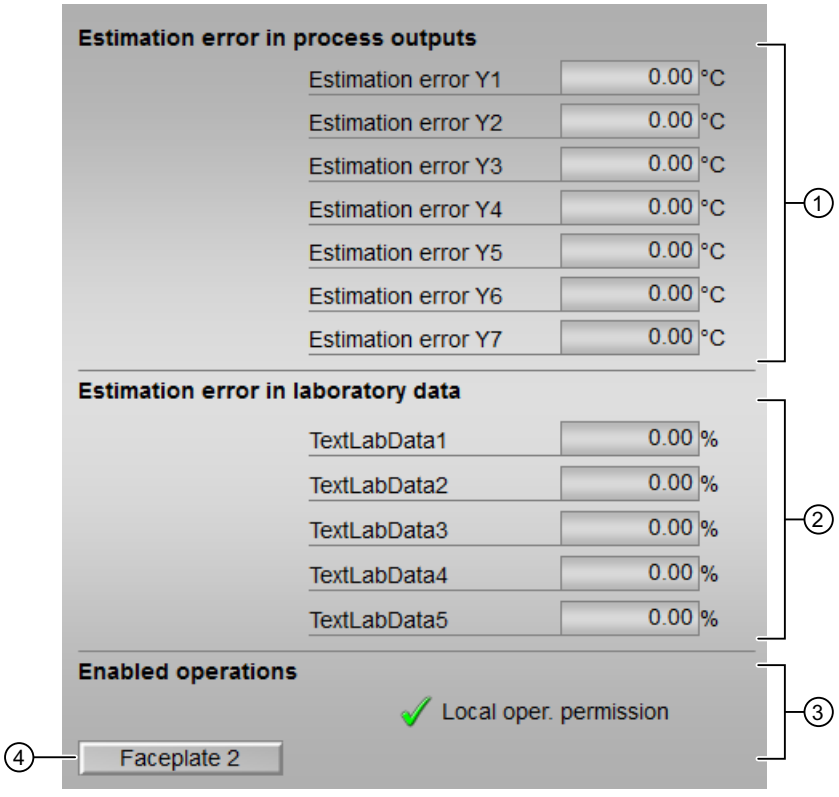
### (4) Service

You can enable and disable simulation of the block using the "Simulation" button.

## 6.16.8.4 KalFilt parameter view 2

### Parameter view 2 of KalFilt

### (1) Lower limit of state variables



You can specify the lower limit of the state variables.

### (2) Upper limit of state variables

You can specify the upper limit of the state variables.

## 6.16.8.5 KalFilt preview

### Preview of Kalfilt

### (1) Estimation error in process variables

This area shows the estimation error in the output variables. The values of the estimation error are shown in physical units in preview and as percentage in the standard view (Page 1293).

### (2) Estimation error in laboratory data

This area shows the estimation error in the laboratory results. The values of the estimation error are shown in physical units in preview and as percentage in the standard view (Page 1293).

### (3) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

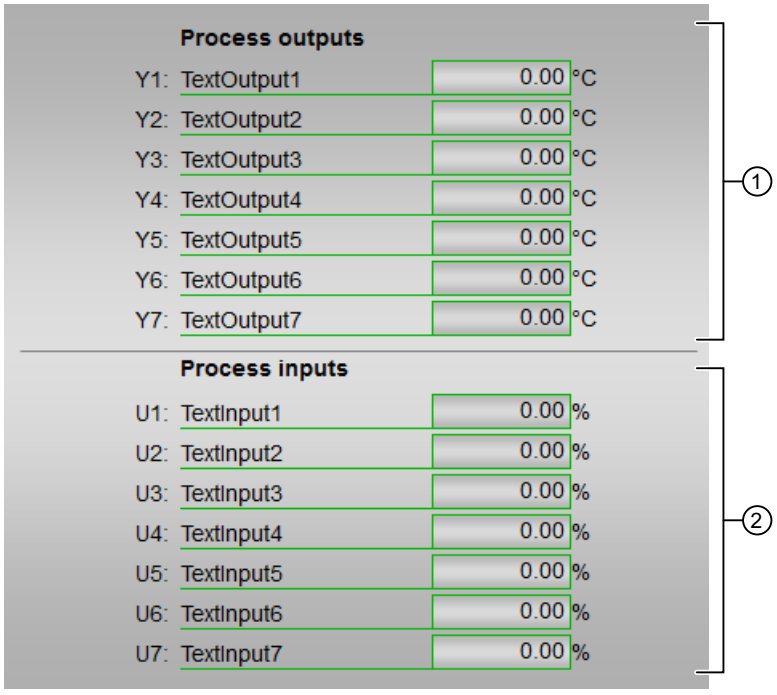
Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

The following enabled operation is shown here:

- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).

### (4) Navigation button for switching to the standard view of any faceplate



Use this navigation button to open the standard view of another function block, which is configured in the engineering system (ES).

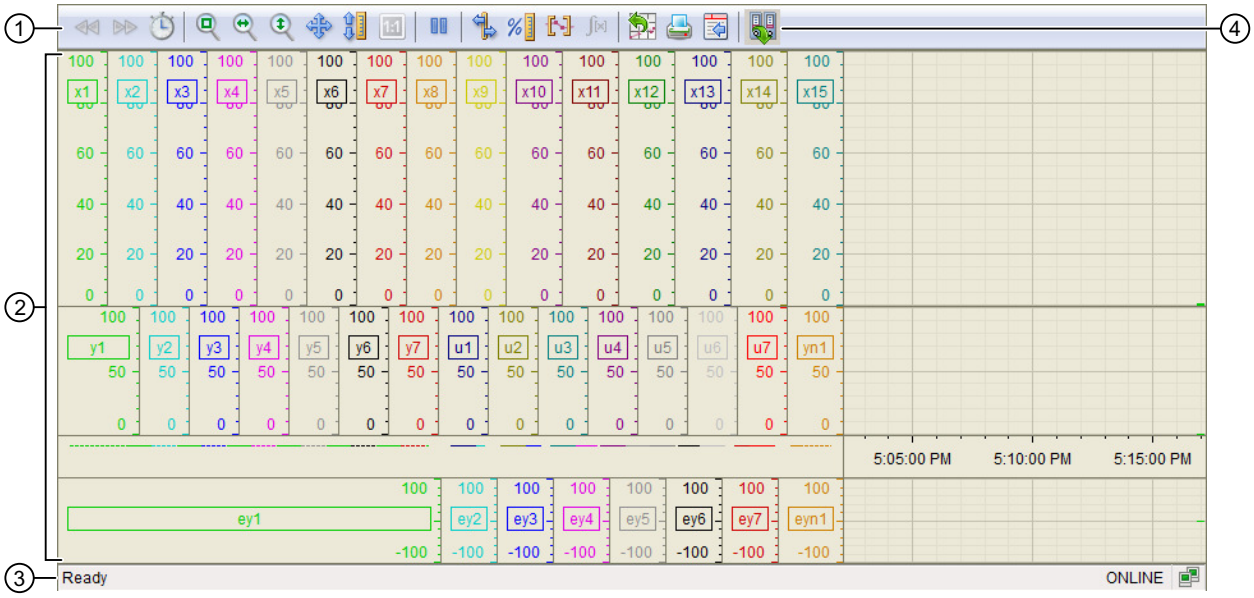
The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, refer to the section Opening additional faceplates (Page 234).

### 6.16.8.6 KalFilt measurements view

#### Measurements view of KalFilt

#### (1) Process outputs



This area displays current values of the process outputs.

#### (2) Process inputs

This area displays current values of the process inputs.

### 6.16.8.7 KalFilt trend view

#### Trend view of KalFilt

**(1)** Toolbar

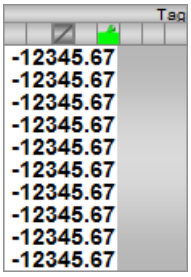
**(2)** Display area for trends

**(3)** Status bar

**(4)** Button for switching between archive tags and online tags. The status bar shows if the trend view is working with online data or archive data.

For additional information about the trend view, refer to the *WinCC Information System* Online Help.

The trend view is divided into three areas. The top area shows the state variables, the middle area shows the input and output variables, and the lower area shows the estimation errors.



### 6.16.8.8 Block icon for KalFilt

#### Block icons for KalFilt

A single block icon is available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Memo display
- User analog values 1 to 10, typically a subset of the estimated states and additional output variables (black, with and without decimal places)

The display of the tag name can be activated centrally for all block instances with the WinCC variable @APLShowTag:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon with full display for 10 freely assignable measured values:<br>`UserAna1...UserAna10` |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Operation via the block icon (Page 269)
- Block icon structure (Page 260)

# Dosing blocks

# 7

## 7.1 DoseL - Dosing device

### 7.1.1 Description of DoseL

#### Object name (type + number) and family

Type + number: FB 1809

Family: Dosage

#### Area of application for DoseL

The block is used for the following applications:

- Single-component dosing using flow measurement
- Weighing of fill/removal volume using dosing scales

#### How it works

Processing is performed discretely via a coarse/fine flow control with flow monitoring and setpoint specification. The dosing flow can be determined via a maximum of 16 cycles.

A dribbling phase and post dosing can be implemented for both processes. The input value can also be supplied from a pulse module via the `PV1CycLi` output of the Pcs7Cntx (x=1...3) channel block.

**Note**

When using a pulse module, the counted pulses per cycle must be normalized via the I/Os "Gain" and "Ti" at DoseL .

Example:

A pulse of 35 Kg per hour means that I/O "Gain" must be configured to 35 and I/O "Ti" to 3600.

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the DoseL block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Dosing (Dose_Lean) (Page 2856)
- Dosing with PA/FF devices (Dose_Lean_Fb) (Page 2857)

### Startup characteristics

Use the `Feature.Bit0` Set startup characteristics (Page 148) to define the startup characteristics of this block and `Feature2.Bit7` Use the last value following a complete download as the current value during startup of the block (Page 165).

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section DoseL I/Os (Page 1332).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 8 | `SP_ExtAct` |
| 9 | `Ctrl` |
| 10 | `Ctrl2` |
| 11 | 1 = Dosing by scale |
| 12 | 0 = Dosing by scale for filling<br>1 = Dosing by scale for removal |
| 13 | `BypProt` active |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | `DosOn` |
| 20 | `DosRelax` |
| 21 | `DosEnd` |
| 22 | `DosOff` |
| 23 | `DosPause` |
| 24 | `DosStart` |
| 25 | 1 = Post dosing |

| Status bit | Parameter |
|---|---|
| 26 | "Start" command |
| 27 | "Pause" command |
| 28 | "Continue" command |
| 29 | "Cancel" command |
| 30 | `UserAna1` interconnected |
| 31 | `UserAna2` interconnected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `DQ_AH_Act xx_Act` taking into account `Feature.Bit29` |
| 2 | `DQ_AL_Act xx_Act` taking into account `Feature.Bit29` |
| 3 | `DQ_AH_En` OR `Feature.Bit16` |
| 4 | `DQ_AL_En` OR `Feature.Bit16` |
| 5 | `DQ_AH_MsgEn` |
| 6 | `DQ_AL_MsgEn` |
| 7 | `PV_AH_Act xx_Act` taking into account `Feature.Bit29` |
| 8 | `PV_AL_Act xx_Act` taking into account `Feature.Bit29` |
| 9 | `PV_AH_En` and `Feature.Bit7` = 1 or `PV_AH_En` and flow mode OR `Feature.Bit16` |
| 10 | `PV_AL_En` and `Feature.Bit7` = 1 or `PV_AL_En` and flow mode OR `Feature.Bit16` |
| 11 | `PV_AH_MsgEn` |
| 12 | `PV_AL_MsgEn` |
| 13 | `PV_AH2_Act xx_Act` taking into account `Feature.Bit29` |
| 14 | `PV_AL2_Act xx_Act` taking into account `Feature.Bit29` |
| 15 | `PV_AH2_En` and `Feature.Bit7` = 1 or `PV_AH2_En` and flow mode OR `Feature.Bit16` |
| 16 | `PV_AL2_En` and `Feature.Bit7` = 1 or `PV_AL2_En` and flow mode OR `Feature.Bit16` |
| 17 | `PV_AH2_MsgEn` |
| 18 | `PV_AL2_MsgEn` |
| 19 | `CR_AH_Act xx_Act` taking into account `Feature.Bit29` |
| 20 | `CR_AH_En` and `Feature.Bit7` = 1 or `CR_AH_En` and flow mode OR `Feature.Bit16` |
| 21 | `CR_AH_MsgEn` |
| 22 | Display for interlocks in block icon |
| 23 | 1 = Scales tared |
| 24 | Automatic preview 1 = Dosing "On" |
| 25 | Automatic preview 1 = Dosing "Dribbling" |
| 26 | Automatic preview 1 = Dosing "End" |
| 27 | Automatic preview 1 = Dosing "Off" |

| Status bit | Parameter |
|---|---|
| 28 | Automatic preview 1 = Dosing "Pause" |
| 29 | Forcing active |
| 30 | Bypass information for display in block icon |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | "Interlock" button is enabled |
| 1 | "Permission" button is enabled |
| 2 | "Protection" button is enabled |
| 3 | `DosCancelMsgEn` |
| 4 | `Feature.Bit7` = 1 (Calculation of the flow rate for dosing by scale) |
| 5 | `Feature.Bit7` = 1 or flow mode |
| 6 | Display flow setpoint in percent |
| 7 | Display flow setpoint bar |
| 8 | Reset request in automatic mode |
| 9 | `Feature.Bit8` = 1 (Fine dosing quantity setpoint absolute) |
| 10 | `SimLiOp.Value` |
| 11 | External error generated by FaultExt or external control system fault CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 12 | 0 = Button text "Ack underdose" is visible<br>1 = Button text "Ack overdose" is visible |
| 13 | Display "Ack Dos End" block state in the standard view |
| 14 | 1= No impact of input signals on "local mode" with LocalSetting = 0 and OOS mode. |
| 15 - 17 | Not used |
| 18 | Internal error |
| 19 | Display "Forced start" |
| 20 | Display "Force abort" |
| 21 | Display "Forced pause" |
| 22 | Display "Forced continue" |
| 23 - 27 | Not used |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | 1 = Input parameter `Ctrl1ChnST` is interconnected |
| 31 | 1 = Input parameter `Ctrl2ChnST` is interconnected |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | Delay of the `DQ_AH_Tol` message |
| 9 | Delay of the `DQ_AL_Tol` message |
| 10 | Delay of the `PV_AH_Lim` message |
| 11 | Delay of the `PV_AL_Lim` message |
| 12 | Delay of the `PV_AH2_Lim` message |
| 13 | Delay of the `PV_AL2_Lim` message |
| 14 | Delay of the `CR_AH_Lim` message |
| 15 | Collection of message delays |
| 16 - 22 | Not used |
| 23 | Hidden bypass signal in Permit |
| 24 | Hidden bypass signal in interlock |
| 25 | Hidden bypass signal in Protect |
| 26 | `Feature2.Bit2`: Separate bypass signal |
| 27 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 - 31 | Not used |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 31 | Not used |

### See also

DoseL functions (Page 1312)
DoseL messaging (Page 1329)
DoseL modes (Page 1310)
DoseL error handling (Page 1327)
DoseL block diagram (Page 1348)

## 7.1.2 DoseL modes

### DoseL operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Dosing actions you can control in "local mode":

- "Start" (positive edge `StartLocal`)
- "Cancel" (`CancelLocal` = 1)
- "Pause" (`PauseLocal` = 1)
- "Continue" (`ContLocal` = 1)

If you operate the block in "local mode", control will only take place via "local" signals (input parameters `StartLocal` = 1, `CancelLocal` = 1, `PauseLocal` = 1 and `ContLocal` = 1).

**Note**

Unlike the general description, at the `LocalSetting` parameter only the values 0, 1 and 3 can be set, i.e. tracking in "local" mode is not possible with DoseL.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Dosing actions you can control in "automatic mode":

- "Start" (positive edge `StartAut`)
- "Cancel" (`CancelAut` = 1)
- "Pause" (`PauseAut` = 1)
- "Continue" (`ContAut` = 1)

## "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Dosing actions you can control in "manual mode":

- "Start" (`StartMan` = 1)
- "Cancel" (`CancelMan` = 1)
- "Pause" (`PauseMan` = 1)
- "Continue" (`ContMan` = 1)

## "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

In "Out of service" mode, if `Feature2.Bit7` =1 then Previous value of Dribbout is retained. Else if `Feature2.Bit7` =0, Dribbout value is set to 0

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit3` =1 and `Feature.Bit3` =0 is as shown below:

| Output Parameters | **`Feature.Bit3` =0** | **`Feature.Bit3` =1** |
|---|---|---|
| DosStart.ST | 16#80 | 16#60 |
| DosEnd.ST | 16#80 | 16#60 |
| DosOn.ST | 16#80 | 16#60 |
| DosRelax.ST | 16#80 | 16#60 |
| DosOff.ST | 16#80 | 16#60 |
| DosPause.ST | 16#80 | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| DQ_SP.ST | 16#80 | 16#60 |
| DQ1_SP.ST | 16#80 | 16#60 |
| DQ2_SP.ST | 16#80 | 16#60 |
| DQ_SP_Tol.ST | 16#80 | 16#60 |
| DQ_ExtOut.ST | 16#80 | 16#60 |
| DQ2_ExtOut.ST | 16#80 | 16#60 |
| DQ_Out.ST | 16#80 | 16#60 |
| DQ_AH_Act.ST | 16#XX | 16#60 |
| DQ_AL_Act.ST | 16#XX | 16#60 |
| SP.ST | 16#80 | 16#60 |
| SP1.ST | 16#80 | 16#60 |
| SP2.ST | 16#80 | 16#60 |
| SP_ExtOut.ST | 16#80 | 16#60 |
| SP2_ExtOut.ST | 16#80 | 16#60 |
| SP_ExHiAct.ST | 16#80 | 16#60 |
| SP_ExLoAct.ST | 16#80 | 16#60 |
| SP2_ExHiAct.ST | 16#80 | 16#60 |

| Output Parameters | `Feature.Bit3 =0` | `Feature.Bit3 =1` |
|---|---|---|
| SP2_ExLoAct.ST | 16#80 | 16#60 |
| PV_Out.ST | 16#80 | 16#60 |
| PV_AH_Act.ST | 16#XX | 16#60 |
| PV_AL_Act.ST | 16#XX | 16#60 |
| PV_AH2_Act.ST | 16#XX | 16#60 |
| PV_AL2_Act.ST | 16#XX | 16#60 |
| CR_AH_Act.ST | 16#XX | 16#60 |

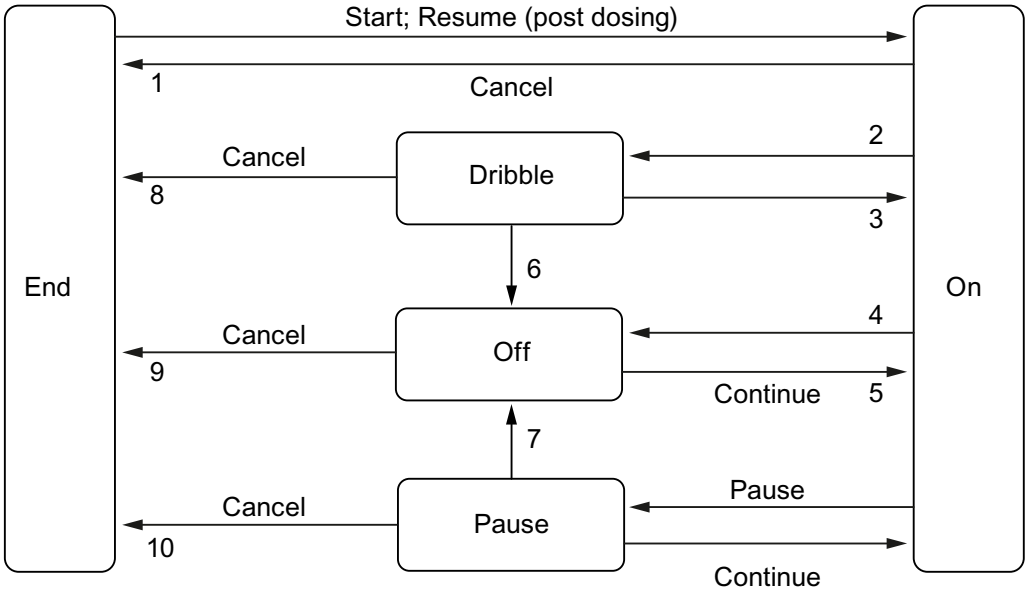
## 7.1.3 DoseL functions

### Functions of DoseL

The functions for this block are listed below.

### Status diagram



The block provides the following states:

- "End"
  If an underdosage or overdosage is identified, the status display shows the state "Ack Dos End" in the standard view.
- "On"
- "Dribbling"
- "Off"
- "Pause"

The following commands can initiate a state change:

- "Start"
- "Cancel"

- "Pause"
- "Continue"

Dosing can only be started if the dosing setpoint is greater than the current dosing quantity (`DQ_Out`) or if `Feature.Bit6` is set and no interlock is pending.

**Note**

After a start of scale dosing with `Feature.Bit14` = 1 the controls are deactivated during the scale is in taring mode (`StandStill` = 0).

However, the following status changes are also performed automatically:

| Number in graphic (top) | Function |
|---|---|
| 1 | When the dosing quantity is reached, dosing terminates (`DQ_Out` ≥ DQ_SP). |
| 2 | If the dosing quantity reaches the dribbling quantity (relative to dosing setpoint `DQ_Out` ≥ `DQ_SP` – `DribbOut`) the dribbling status becomes active. |
| 3 | Automatic post dosing in automatic mode via the `Feature.Bit12`, if an under-dosage was identified after the dribbling time (`RelaxTime`). |
| 4 | • Flow alarm (see input parameter `Feature.Bit11`) or<br>• Interlock.<br>• The dosing process of the DoseL block is set to the "Off" state with a process value status "Bad, device-related" or "Bad, process-related". The response can be set using `Feature` bit parameter assignment. |
| 5 | • The flow alarm is acknowledged (also provided via the "Continue" command if `Feature.Bit9` = 1) or<br>• The interlock is acknowledged (also provided via the "Continue" command if `Feature.Bit9` = 1).<br>• "Continue" command after underdosing. |

| Number in graphic (top) | Function |
|---|---|
| 6 | Underdosage identified after the dribbling time (`RelaxTime`).<br>Overdosage identified after the dribbling time (only with `Feature2.Bit24` = 1). |
| 7 | Interlock |
| 8 | Dribbling time (`RelaxTime`) has expired and dosing quantity is above the low tolerance limit (`DQ_Out` ≥ `DQ_SP_Tol` - `DQ_AL_Tol`) |
| 9 | The underdosage is acknowledged or the dosing quantity has been reached (`DQ_Out` ≥ `DQ_SP`) via creep flow, for example |
| 10 | Dosing quantity has been reached (`DQ_Out` ≥ `DQ_SP`) via creep flow, for example |

### Control outputs

The coarse flow (`Ctrl`) or fine flow (`Ctrl2`) control outputs are issued in the "On" status.

The coarse flow control output is active if:

- `DQ_Out` < `DQ_SP` – `DQ2_SP`

The fine flow control output is active if:

- `DQ_Out` ≥ `DQ_SP` – `DQ2_SP`
- Where `DQ_Out`: Dosing quantity actual value
- `DQ_SP`: Dosing quantity setpoint
- `DQ2_SP`: fine dosing quantity setpoint ("calculated")

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57).

In addition to the static control outputs `Ctrl`, `Ctrl2`, the block also has pulse outputs `P_Ctrl`, `P_Ctrl2`, which are dependent on the static control outputs.

### Determining the dosing quantity when using flow dosing

You can activate flow dosing using `Feature.Bit5` = 0 (Specifying the dosing type (Page 157).)

When using flow dosing, the dosing quantity is determined using the following equation:

$$DQ_Out = DQ_Out + \frac{SampleTime}{TI} \cdot \frac{(PV_Out_{alt} + PV_Out)}{2}$$

Where:

- `DQ_Out`: Dosing quantity actual value
- `SampleTime`: Sampling time [s]
- `TI`: dimensionless conversion factor for the time basis of the measured value acquisition in the time basis 1 s
- $PV_Out_{alt}$: Last value `PV_OUT`

The output parameter PV_OUT is determined using an average calculation:

$$PV_Out := \frac{PV_Out_{(t)} + PV_Out_{(t-1)} + ... + PV_Out_{(t-(n-1))}}{NumSample_{(N)}}$$

Where:

- PV_Out(t) = PV · Gain

The average calculation is only active if NumSample > 1 and NumSample ≤ 16 and serves to smooth systematically pulsating measuring signals.

**Note**

**Integration of the flow for the dosing quantity**

The integration of the flow for the dosing quantity is implemented using the trapezoid rule. Compared to the summation of rectangles rule, in which the values are simply added up, the procedural error in the case of the trapezoid rule is smaller for the determination of the numerical integral value.

The dosing quantity is determined in the "On" and "Dribbling" state. In the "End", "Off" and "Pause" states, the flow (creep flow) is determined depending on the Feature.Bit13 (Creep rate is always detected in the dosing quantity (Page 179)) and the value CR_AH_Lim. Creep flow monitoring is disabled with CR_AH_En = 0 .

### Determining the dosing quantity when dosing using scales

You can activate scale dosing via the Feature.Bit5 = 1 (Specifying the dosing type (Page 157).)

The dosing quantity is determined for a scale dosing in the "Start" state following a positive edge at the input parameter StandStill. The StandStill input parameter is a feedback signal of the scale.

The process of determining the dosing quantity stops after the dosing quantity is reset in the "End" state.

If the signal is no longer available, you need to configure StandStill with 1 permanently; the dosing quantity will then be determined right at the start of the dosing.

When weighing the fill volume (MeterType = 0), the dosing quantity is determined using the following equations:

$$DQ_Out = PV_Out - DQ_Tare$$

When weighing the removal volume (MeterType = 1):

$$DQ_Out = DQ_Tare - PV_Out$$

with PV_Out = PV · Gain

In the "Start" state, the `DQ_Tare` tare memory is set with `PV_Out` with the first positive edge of `StandStill`. With `Feature.Bit14` = 1 the dosing controls `Ctrl`, `P_Ctrl`, `Ctrl2`, `P_Ctrl2` are deactivated until the tare memory is set.

If you have permanently configured `StandStill` with 1, the tare memory is set right at the start of dosing.

**Note**

The `DQ_Out` output parameter is the dosing quantity and not the actual scale value. In the "End" state (= following resetting of the dosing quantity), nothing further is displayed, since the dosing procedure is complete. When dosing starts, the actual scale value is transferred to the tare memory, and therefore the dosing quantity always remains 0 after the start of dosing. Therefore, the actual scale value is not displayed in the "End" state.

## Calculation of the flow rate for dosing by scale

You can activate the calculation of the flow rate via the `Feature.Bit7` = 1

(Activating calculation of the flow rate for dosing by scale (Page 155)).

The flow rate for scale dosing is determined by the following equations:

$$PV_Out = (avPV(t) - avPV(t-1)) \cdot \frac{GainEff}{SampleTime}$$

with

$$avPV(t) = \frac{PV(t) + PV(t-1) + ... + PV(t-(N+1))}{NumSample(N)}$$

where `avPV(t)` = internal variable for the mean dosing quantity

## Dribbling

The "Dribbling" status is entered automatically in accordance with

- `DQ_Out` ≥ `DQ_SP` − `DribbOut`

Where:

- `DQ_Out`: Dosing quantity actual value
- `DQ_SP`: Dosing quantity setpoint
- `DribbOut`: Dribbling quantity

The dribbling quantity is specified with the input `DribbIn`.

`DribCor` = 1 can be used to automatically determine the dribbling quantity from previous dosing actions:

- `DribbOut` = `DribbOut` - (`DQ_SP` - `DQ_Out`) · `DCF` / 100

DCF represents the weighting factor of the last dosing action as a percentage and cannot be set to below 0 or above 100. DribbOut is calculated at the end of dosing or the first time an underdosage occurs, and is limited to DribbMax. Post dosing is not taken into account.

The "Dribbling" status is active for the period RelaxTime.

**Note**

Also with DribbOut = 0 the "Dribbling" status is active. If you want to deactivate the "Dribbling" status, you have to set additionally RelaxTime = 0.

When the "Enable configuration of the dribbling quantity (Page 170)" function is enabled (Feature.Bit27 = 1) and automatic determination of the dribbling quantity is disabled (DribCor = 0), the quantity can also be configured during dosing, but not in the "Dribbling" state.

After a complete download you can use the dribbling quantity from the input OldDribbOut with parameterizing Feature2.Bit7 =1.

## Overdosing/underdosing

Once the "Dribbling" state has expired, the dosing quantity is checked for overdosages or underdosages. In the "End" status, no check is performed for over- or underdosages.

An overdosage has occurred if:

- DQ_Out > DQ_SP_Tol + DQ_AH_Tol

An underdosage has occurred if:

- DQ_Out < DQ_SP_Tol - DQ_AL_Tol
- Where DQ_Out: Dosing quantity actual value
- DQ_SP_Tol: Dosing quantity setpoint for forming tolerance. This is the same as the dosing quantity setpoint (DQ_SP) before and after the check that determines overdosing/ underdosing.
- DQ_AH_Tol: High tolerance limit
- DQ_AL_Tol: Low tolerance limit

If an underdosage is identified after the "Dribbling" state, the "Off" state is entered. The underdosage can be acknowledged in "Off" state (U_AckOp = 1 or positive edge U_AckLi) and the dosing action completed, or post dosing can be started with the "Continue" command. The dosing end state display in the standard view shows "Ack Dos End".

**With** Feature2.Bit24 = 0**:**

If an overdosage is identified after the "Dribbling" state, the dosing "End" state is entered at once. A message for overdosage comes and goes in next cycle.

**With** Feature2.Bit24 = 1**:**

If an overdosage is identified after the "Dribbling" state, the "Off" state is entered. The overdosage can be acknowledged in the "Off" state (U_AckOp = 1 or positive edge U_AckLi) and the dosing action is completed.

Generally, dosages which enter the "Off" state with overdosage, have to be acknowledged.

### Post dosing

If an underdosage is detected after dribbling, post dosing can be performed using the "Continue" command. In automatic mode, `Feature.Bit12` can be used to start post dosing automatically. Post dosing is active for the period `P_DoseTime`. The block then enters the "Dribbling" state or, if that state is deactivated, the "End" state. If the conditions for the "Dribbling" or "End" states are met within the period `P_DoseTime`, the block switches to these states immediately.

Post dosing can also be carried out in the "End" state by increasing the dosing quantity setpoint and issuing the "Continue" command. Once the dosing quantity has been reset, post dosing can no longer be carried out by means of increasing the setpoint.

If the dribbling correction quantity is smaller than the dribbling quantity, dosing is started for time `P_DoseTime`. If no parameter assignment has been made for `P_DoseTime`, the coarse flow (`Ctrl`) or fine flow (`Ctrl2`) control outputs are set for one cycle.

If no parameter assignment has been made for the dribbling quantity, or the dribbling correction quantity is larger than the dribbling quantity, the dosing procedure is continued without taking time `P_DoseTime` into account.

Information on post dosing via setpoint increase:

- After the setpoint has been increased, the tolerance limits are only updated when the "Continue" command is issued. This ensures the overdosage/underdosage display remains consistent.
- Post dosing can only be carried out after a dosing procedure has been aborted if the setpoint for the dosing quantity has been increased and an actual-value quantity is present.
- In "Automatic" and "Local" modes, the "Continue" command must be issued on a positive edge to prevent unwanted dosing procedures from taking place after a setpoint increase.

**With** `Feature2.Bit24` = 0**:**

If an overdosage is identified during or after a post dosing, the dosage enters in the "End" state.

**With** `Feature2.Bit24` = 1**:**

If an overdosage is identified after a post dosing or a drain, the dosage continues to be in the "Off" state. Only with acknowledge overdosage, the block enters to the "End" state with the status display "Ack Dos End" in the standard view.

### Resetting the dosing quantity

The dosing quantity can only be reset in the "End" state using `RstDQ_Op` = 1 or positive edge `RstDQ_Li`.

The state display "Ack Dos End" is also resetted to "End".

`Feature.Bit6` can be used to reset the dosing quantity automatically when dosing starts.

### External/internal setpoint specification

This block provides the standard function Setpoint specification - internal/external (Page 136).

The block always requires the setpoint for the dosing quantity (dosing setpoint). All I/Os for the dosing setpoint start with `DQ_...`. The dosing setpoint is comprised of the coarse and fine setpoints for the coarse/fine flow control. All I/Os for the fine setpoint start with `DQ2_...`. The

coarse setpoint is generated internally from the dosing and fine setpoints and is displayed at the output with DQ1_SP. If no fine setpoint is available, the coarse setpoint is equal to the dosing setpoint.

Flow setpoints can be specified for the coarse/fine flow setpoint specification. All I/Os for the coarse flow start with SP_..., and all I/Os for the fine flow with SP2_.... The setpoint for coarse or fine flow is displayed at the output SP in the "On" status, depending on the coarse/fine flow control.

### Setpoint limitation

The setpoints are limited in the block using shared parameters:

- Coarse metering volume: DQ_HiLim, DQ_LoLim
- Fine metering volume: DQ2_HiLim, DQ2_LoLim
- Coarse flow rate: SP_HiLim, SP_LoLim
- Fine flow rate: SP2_HiLim, SP2_LoLim

If the setpoint limit is violated, external setpoints are limited to the limit you specified. If there are internal setpoints, the last valid value is output.

### Bumpless switchover from external to internal setpoint

The parameter SP_TrkExt = 1 is used so that the internal setpoint tracks the external setpoint to achieve a bumpless switchover from the external to the internal setpoint. This allows unwanted jumps at the output parameter to be avoided.

### Limit monitoring of the process value

This block provides the standard function Limit monitoring of the process value (Page 93). The calculated flow PV_Out is monitored in terms of the limit pairs PV_AH_Lim / PV_AL_Lim (coarse flow) or PV_AH2_Lim / PV_AL2_Lim (fine flow), depending on the coarse/fine flow control. Monitoring is only active in the "On" status.

The calculated flow PV_Out is monitored in terms of the limit pairs PV_AH_Lim / PV_AL_Lim (coarse flow) or PV_AH2_Lim / PV_AL2_Lim (fine flow), depending on the coarse/fine flow control. Monitoring is only active in the "On" status.

### Providing limits at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

DQ_AL_TolOut := DQ_AL_Tol;

DQ_AH_TolOut := DQ_AH_Tol;

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45). The inputs `StartForce`, `CancelForce`, `PauseForce` and `ContForce` force the block into the states "On", "End" or "Pause".

The "Pause" status can only be forced if the block is in the "On" status.

The "On" state can only be forced from the states

- "Off"
- "Pause"
- "End" if the quantity actual valve is less than the quantity setpoint.

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

The flow is simulated with `SimPV`. This input is not active in scale mode, even when the flow is formed by changing quantities (`Feature.Bit7` = 1)

You can simulate the following values:

- Flow dosing: The flow (`PV`) is specified in the setpoint view with the input (`SimPV`, `SimPV_Li`).
- Dosing using scales: The dosing quantity (`DQ_Out`) is specified in the standard view with the input (`SimDQ`, `SimDQ_Li`).

### Interlocks

This block provides the following interlocks:

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")

Refer to the section Interlocks (Page 107).

Dosing can only be started if no interlock is present. The interlock function is not active in the "Dribbling" status; nor is the activation enable active in the "On" status. An interlock in the "On" or "Pause" states will cause the block to enter the "Off" status.

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (**FaultExt**), external control system fault (**CSF**)

This block provides the possibility to pass an external error via the FaultExt parameter or an external control system fault via the CSF parameter. See DoseL error handling (Page 1327)

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- CSF
- FaultExt

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status ST_Worst for the block is formed from the following parameters:

- PV_Out.ST
- DQ_Out.ST
- DQ_SP.ST
- SP.ST
- Standstill.ST
- LocalLi.ST
- StartLocal.ST
- CancelLocal.ST
- PauseLocal.ST
- ContLocal.ST
- CtrlChnST

- Ctrl2ChnST
- StartAut.ST (only if Feature2.Bit10 = 1)
- CancelAut.ST (only if Feature2.Bit10 = 1)
- PauseAut.ST (only if Feature2.Bit10 = 1)
- ContAut.ST (only if Feature2.Bit10 = 1)
- SP_Ext.ST (only if Feature2.Bit10 = 1)

The following signal status is formed by:

| Signal status | Used status |
|---|---|
| DQ_Out.ST | Formed by the signal status PV_Out.ST. The last DQ_Out.St signal status is also included for flow dosing and the DQ_Tare.ST signal status is included for scale dosing. The worst signal status is applied. The signal status is reset with reset of the dosing quantity. |
| DQ_SP.ST | With an external setpoint DQ_Ext.ST (for DQ_HiLim.ST or DQ_LoLim.ST limit), otherwise good status |
| SP.ST | With an external setpoint SP_Ext.ST (coarse flow) / SP2_Ext.ST (fine flow) (with SP_HiLim.ST / SP_LoLim.ST or SP2_HiLim.ST / SP2_LoLim.ST limit), otherwise good status |

### Considering bad quality of automatic commands or external values

If the Feature2 bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- StartAut.ST
- CancelAut.ST
- PauseAut.ST
- ContAut.ST
- SP_Ext.ST

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Alarm delays with two time values per limit pair

This block includes the standard function alarm delay for Two time values per limit pair (Page 227).

### Display and operator input area for process values and setpoints

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Specifying the dosing type (Page 157) |
| 6 | Resetting the dosing quantity when dosing starts (Page 173) |
| 7 | Activating calculation of the flow rate for dosing by scale (Page 155) |
| 8 | Use an internal or external setpoint for the absolute fine dosing quantity (Page 164) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Stopping dosing at a flow alarm (Page 147) |
| 12 | Automatic post dosing for underdosing in automatic mode (Page 153) |
| 13 | Creep rate is always detected in the dosing quantity (Page 179) |
| 14 | Dosing controls are deactivated during scale is in taring mode (Page 205) |
| 15 | Flow setpoints in percent (Page 157) |
| 16 | Limits disabled in faceplate (Page 206) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Specifying the influence of the signal status on the dosing process (Page 158) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Enable configuration of the dribbling quantity (Page 170) |
| 28 | Disabling operating points (Page 156) |

| Bit | Function |
|---|---|
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

Comments on table:

**`Feature.Bit4`:**

- Button mode (`Feature.Bit4` = 0): The automatic commands in automatic mode are pulse signals, in other words `StartAut`, `CancelAut`, `PauseAut`, `ContAut` can be reset to 0 after switchover to the selected status. In "manual" and "local" modes, however, the automatic commands are static signals, the block state is tracked in the absence of automatic commands.
- Switch mode (`Feature.Bit4` = 1): The conditions are selected via the inputs `StartAut` (0: Cancel, 1: Start) and `PauseAut` (0: Continue, 1: Pause) with static signals.

**`Feature.Bit23`:**

**Note**

When there is a bad signal status and `Feature.Bit23` = 1 , the flow is no longer recorded in the dosing quantity in any state. The configure creep rate alarm is output.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 6 | Changes signal status of outputs in OOS (Page 208) |
| 7 | Use the last value following a complete download as the current value during startup of the block (Page 165) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |
| 24 | With acknowledge overdosage (Page 190) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can start dosing |
| 5 | 1 = Operator can pause dosing |
| 6 | 1 = Operator can continue dosing |
| 7 | 1 = Operator can cancel dosing |
| 8 | 1 = Operator can reset interlock and flow alarms |
| 9 | 1 = Operator can reset dosing quantity |
| 10 | 1 = Operator can acknowledge overdosage and underdosage |
| 11 | 1 = Operator can select external setpoints |
| 12 | 1 = Operator can select internal setpoints |
| 13 | 1 = Operator can enter dosing setpoint |
| 14 | 1 = Operator can enter dosing setpoint factor for fine dosing |
| 15 | 1 = Operator can enter flow setpoint for coarse flow |
| 16 | 1 = Operator can enter flow setpoint factor for fine flow |
| 17 | 1 = Operator can activate external/internal bumpless switchover |
| 18 | 1 = Operator can enable simulation function |
| 19 | 1 = Operator can activate the Release for maintenance function |
| 20 | Not used |
| 21 | 1 = Operator can enter dribbling quantity |
| 22 | 1 = Operator can enter maximum dribbling quantity |
| 23 | 1 = Operator can activate/deactivate automatic generation of dribbling quantity |
| 24 | 1 = Operator can enter weighting factor for generation of dribbling quantity |
| 25 | 1 = Operator can change the simulation value SimPV |
| 26 | 1 = Operator can change the simulation value SimDQ |
| 27 - 31 | Not used |

The block has the following operator permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the limit for the high alarm for `PV_OUT` (coarse flow) |
| 1 | 1 = Operator can change the limit for the low alarm for `PV_OUT` (coarse flow) |
| 2 | 1 = Operator can change the limit for the hysteresis `PV_OUT` (coarse flow) |
| 3 | 1 = Operator can change the limit for the high alarm for `PV_OUT` (fine flow) |
| 4 | 1 = Operator can change the limit for the low alarm for `PV_OUT` (fine flow) |
| 5 | 1 = Operator can change the limit for the hysteresis `PV_OUT` (fine flow) |
| 6 | 1 = Operator can change the operation high limit of the dosing setpoint |
| 7 | 1 = Operator can change the operation low limit of the dosing setpoint |
| 8 | 1 = Operator can change operation high limit of the dosing setpoint factor for fine dosing |
| 9 | 1 = Operator can change operation low limit of the dosing setpoint factor for fine dosing |

| Bit | Function |
|---|---|
| 10 | 1 = Operator can change the tolerance value for overdosage |
| 11 | 1 = Operator can change the tolerance value for Underdosage |
| 12 | 1 = Operator can change operation high limit of the flow setpoint for coarse flow |
| 13 | 1 = Operator can change operation low limit of the flow setpoint for coarse flow |
| 14 | 1 = Operator can change operation high limit of the flow setpoint for fine flow |
| 15 | 1 = Operator can change operation low limit of the flow setpoint for fine flow |
| 16 | 1 = Operator can change the dribbling time |
| 17 | 1 = Operator can change the post dosing |
| 18 | 1 = Operator can change the limit for the high alarm for `PV_OUT` (creep flow) |
| 19 | 1 = Operator can change the limit for the hysteresis for `PV_OUT` (creep flow) |
| 20 | 1 = Operator can activate / deactivate messages via `DQ_AH_MsgEn` |
| 21 | 1 = Operator can activate / deactivate messages via `DQ_AL_MsgEn` |
| 22 | 1 = Operator can activate / deactivate messages via `PV_AH_MsgEn` |
| 23 | 1 = Operator can activate / deactivate messages via `PV_AL_MsgEn` |
| 24 | 1 = Operator can activate / deactivate messages via `PV_AH2_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `PV_AL2_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `CR_AH_MsgEn` |
| 27 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### See also

Description of DoseL (Page 1305)

DoseL messaging (Page 1329)

## 7.1.4 DoseL error handling

### Error handling of DoseL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 11 | Configuration error `TI` ≤ 0 |
| 12 | Configuration error:<br>`PV_AH_Lim` < `PV_AL_Lim`<br>`PV_AH2_Lim` ≤ `PV_AL2_Lim`<br>`DQ_HiLim.Value` ≤ `DQ_LoLim.Value`<br>`DQ2_HiLim.Value` ≤ `DQ2_LoLim.Value`<br>`SP_HiLim.Value` ≤ `SP_LoLim.Value`<br>`SP2_HiLim.Value` ≤ `SP2_LoLim.Value` |
| 30 | `PV` is not a valid number |
| 31 | `PV_Out` is not a valid number |
| 32 | `DQ_Out` is not a valid number |
| 41 | The value for the `LocalSetting` I/O is not within the approved limit of 0, 1 or 3. |
| 42 | `LocalSetting` = 0 and `LocalLi` = 1 |
| 48 | `SP_LiOp` = 1 and `SP_IntLi` = 1 and `SP_ExtLi` = 1 |
| 51 | `AutModLi` = 1 and `ManModLi` = 1 and `Feature` Bit Setting switch or button mode (Page 177) = 0<br>or two I/Os are set at the same time:<br>• in "local mode" `StartLocal` (pos. edge), `CancelLocal`, `PauseLocal`, `ContLocal`when forcing states: `StartForce`, `CancelForce`, `PauseForce`, `ContForce`in "automatic mode" with pushbutton operation: `StartAut` (pos. edge), `CancelAut`, `PauseAut`, `ContAut`<br>• in "manual mode": `StartMan`, `CancelMan`, `PauseMan`, `ContMan` |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

### Invalid input signal

These errors can be output by the block, see the section Error handling (Page 128).

For the following invalid input signals, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| **Operating mode** | **Invalid input signal** | **Control reaction with** `Feature2.Bit3` = 1 |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | `StartLocal` = 1 (pos. edge) and `CancelLocal` = 1 | Dosing canceled |
| | `ContLocal` = 1 and `PauseLocal` = 1 | Dosing paused |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `StartForce` = 1 and `CancelForce` = 1 | Dosing canceled |
| | `ContForce` = 1 and `PauseForce` = 1 | Dosing paused |
| Forcing and no "local mode" | `StartForce` = 1 and `CancelForce` = 1 | Dosing canceled |
| | `ContForce` = 1 and `PauseForce` = 1 | Dosing paused |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0): `StartAut` =1 (pos. edge) and `CancelAut` =1 | Dosing canceled |
| | Pushbutton operation (`Feature.Bit4` = 0): `ContAut` = 1 and `PauseAut` = 1 | Dosing paused |
| | Pushbutton operation (`Feature.Bit4` = 0): `StartAut` = 1 (pos. edge) and `PauseAut` = 1 | Dosing paused |
| "Manual mode" and no forcing | `StartMan` = 1 and `CancelMan` = 1 | Dosing canceled |
| | `ContMan` = 1 and `PauseMan` = 1 | Dosing paused |

## 7.1.5 DoseL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system fault messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId2` | SIG 1 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a control system fault is triggered (`MsgEvId02`, SIG 1).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | Alarm - high | $$BlockComment$$<br>Overdosage |
| | SIG 2 | Alarm - low | $$BlockComment$$<br>Underdosage |
| | SIG 3 | Alarm - high | $$BlockComment$$<br>PV - High alarm limit for coarse flow violated |
| | SIG4 | Alarm - low | $$BlockComment$$<br>PV - Low alarm limit for coarse flow violated |
| | SIG 5 | Alarm - high | $$BlockComment$$<br>PV - High alarm limit for coarse flow violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>PV - Low alarm limit for fine flow violated |
| | SIG 7 | Alarm - high | $$BlockComment$$<br>PV – Creep flow too great |
| | SIG 8 | Process message - with acknowledgment | $$BlockComment$$<br>Dosing canceled |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `DQ_OUT` |
| 5 | `PV_OUT` |
| 6 | `ExtVal06` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 6 ... 8 are allocated to the parameters `ExtVa106` ... `ExtVa108` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

### Associated values for message instance `MsgEvId2`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa204` |
| 5 | `ExtVa205` |
| 6 | `ExtVa206` |
| 7 | `ExtVa207` |
| 8 | `ExtVa208` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa204` ... `ExtVa208` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 7.1.6 DoseL I/Os

I/Os of DoseL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1= "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CancelAut* | 1 = Select Cancel in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CancelForce | 1 = Force cancel | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CancelLocal | 1 = Select Cancel in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CancelMan* | 1 = Select Cancel in "manual mode" | BOOL | 0 |
| ContAut* | 1 = Select Continue in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ContForce | 1 = Force continue | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ContLocal | 1 = Select Continue in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ContMan* | 1 = Select Continue in "manual mode" | BOOL | 0 |
| CR_A_DC* | Creep flow: Delay time for incoming alarms [s] | REAL | 3.0 |
| CR_A_DG* | Creep flow: Delay time for outgoing alarms [s] | REAL | 3.0 |
| CR_AH_En | Creep flow:<br>1 = Enable high alarm | BOOL | 1 |
| CR_AH_Lim | Creep flow: Limit high alarm | REAL | 0.0 |
| CR_AH_MsgEn | Creep flow:<br>1 = Enable high alarm message | BOOL | 1 |
| CR_Hyst* | Creep flow: Hysteresis for alarm limit | REAL | 0.0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlChnST | Signal status of output channel Ctrl<br>Should be connected to an output channel block. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Ctrl2ChnST | Signal status of output channel Ctrl2<br>Should be connected to an output channel block. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| DCF | Dribbling correction [%] | REAL | 25.0 |
| DosCancelMsgEn | 1 = Cancel dosing message | BOOL | 1 |
| DQ_A_DC* | Overdosage/underdosage: Delay time for incoming alarms [s] | REAL | 0.0 |
| DQ_A_DG* | Overdosage/underdosage: Delay time for outgoing alarms [s] | REAL | 0.0 |
| DQ_AH_En | Overdosage:<br>1 = Enable high alarm | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DQ_AH_MsgEn | Overdosage:<br>1 = Enable high alarm message | BOOL | 1 |
| DQ_AH_Tol | Overdosage: Limit high alarm (relative to dosing setpoint) | REAL | 0.0 |
| DQ_AL_En | Underdosage:<br>1 = Enable low alarm | BOOL | 1 |
| DQ_AL_MsgEn | Underdosage:<br>1 = Enable low alarm message | BOOL | 1 |
| DQ_AL_Tol* | Underdosage: Limit low alarm (relative to dosing setpoint) | REAL | 0.0 |
| DQ_Ext | Dosing quantity: External setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ_HiLim | Dosing quantity: High setpoint limitation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| DQ_Int* | Dosing quantity: Internal setpoint | REAL | 0.0 |
| DQ_LoLim | Dosing quantity: Low setpoint limitation | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ_OpScale | Dosing quantity: Limit for scale in bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| DQ_Unit | Unit of measure for dosing quantity | INT | 1088 |
| DQ2_Ext | Dosing quantity: External setpoint factor for fine dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ2_HiLim* | Dosing quantity: High limitation of setpoint factor for fine dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| DQ2_Int* | Dosing quantity: Internal setpoint factor for fine dosing | REAL | 0.0 |
| DQ2_LoLim* | Dosing quantity: Low limitation of setpoint factor for fine dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DribbIn | Dribbling quantity | REAL | 0.0 |
| DribbMax | Maximum value of automatic determination of dribbling quantity | REAL | 100.0 |
| DribbCor | 1 = Automatic determination of dribbling quantity | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| ExtVa204 | Associated value 4 for messages (MsgEvID2) | ANY | |
| ExtVa205 | Associated value 5 for messages (MsgEvID2) | ANY | |
| ExtVa206 | Associated value 6 for messages (MsgEvID2) | ANY | |
| ExtVa207 | Associated value 7 for messages (MsgEvID2) | ANY | |
| ExtVa208 | Associated value 8 for messages (MsgEvID2) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions (Page 1312) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Feature2 | I/O for additional functions (Page 1312) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Gain | Gain factor | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#80 |
| Intlock | 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared<br>1 = Interlock not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is active | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signals | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| MeterType | Dosing using scales: 0=Up<br>1=Down | BOOL | 0 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgEvId2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NumSample | Number of values for average calculation | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| U_AckLi | 1 = Acknowledgement of overdosage or underdosage via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| U_AckOp* | 1 = Acknowledgement of overdosage or underdosage via operator | BOOL | 0 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OldDribbOut | Previous Dribbout Value | REAL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1312) | STRUCT<br>• Bit 0: BOOL<br>• Bit 25: BOOL<br>• Bitt 26: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1312) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| P_DoseTime* | Duration of post dosing [s] | REAL | 0.0 |
| PauseAut* | 1 = Select Pause in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PauseForce | 1 = Force pause | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PauseLocal | 1 = Select Pause in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PauseMan* | 1 = Select Pause in "manual mode" | BOOL | 0 |
| Perm_En | 1 = Activation enable (enable, Permit parameter) is active | BOOL | 1 |
| Permit | 1 = Enable for opening / closing from neutral position<br>0 = Valve activation not enabled on OS | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Prot_En | 1 = Protective interlock (protection, Protect parameter) is active | BOOL | 1 |
| Protect | 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block<br>1 = Protective interlocking not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| PV | Process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_A_DC* | Delay time for incoming PV alarms [s] when using flow dosing (coarse dosing phase) | REAL | 3.0 |
| PV_A_DG* | Delay time for outgoing PV alarms [s] when using flow dosing (coarse dosing phase) | REAL | 3.0 |
| PV_A2_DC* | Delay time for incoming PV alarms [s] when using flow dosing (fine dosing phase) | REAL | 3.0 |
| PV_A2_DG* | Delay time for outgoing PV alarms [s] when using flow dosing (fine dosing phase) | REAL | 3.0 |
| PV_AH_En | 1 = Enable PV alarm (high) limit when using flow dosing (coarse dosing phase) | BOOL | 1 |
| PV_AH_Lim | Limit PV alarm (high) when using flow dosing (coarse dosing phase) | REAL | 100.0 |
| PV_AH_MsgEn | 1 = Enable PV alarm (high) message when using flow dosing (coarse dosing phase) | BOOL | 1 |
| PV_AH2_En | 1 = Enable PV alarm (high) when using flow dosing (fine dosing phase) | BOOL | 1 |
| PV_AH2_Lim | Limit PV alarm (high) when using flow dosing (fine dosing phase) | REAL | 100.0 |
| PV_AH2_MsgEn | 1 = Enable PV alarm (high) message when using flow dosing (fine dosing phase) | BOOL | 1 |
| PV_AL_En | 1 = Enable PV alarm limit (low) when using flow dosing (coarse dosing phase) | BOOL | 1 |
| PV_AL_Lim | Limit PV alarm (low) when using flow dosing (coarse dosing phase) | REAL | 0.0 |
| PV_AL_MsgEn | 1 = Enable PV alarm (low) message when using flow dosing (coarse dosing phase) | BOOL | 1 |
| PV_AL2_En | 1 = Enable PV alarm (low) when using flow dosing (fine dosing phase) | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_AL2_Lim | Limit PV alarm (low) when using flow dosing (fine dosing phase) | REAL | 0.0 |
| PV_AL2_MsgEn | 1 = Enable PV alarm (low) message when using flow dosing (fine dosing phase) | BOOL | 1 |
| PV_Hyst* | Hysteresis for PV alarm limits when using flow dosing (coarse dosing phase) | REAL | 1.0 |
| PV_Hyst2 | Hysteresis for PV alarm limits when using flow dosing (fine dosing phase) | REAL | 1.0 |
| PV_OpScale | Limit for scale in PV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_Unit | Unit of measure for process value | INT | 1349 |
| RelaxTime* | Duration of dribbling phase [s] | REAL | 3.0 |
| RstDQ_Li | 1 = Reset dosing quantity via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstDQ_Op* | 1 = Reset dosing quantity via operator | BOOL | 0 |
| RstLi* | 1 = Reset interlock/flow monitoring via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset interlock/flow monitoring via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| SimDQ* | Dosing quantity: Value used in scale mode for SimOn = 1 | REAL | 0.0 |
| SimDQ_Li | Linkable simulation value DQ | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimPV* | Process value used in flow mode for SimOn = 1 | REAL | 0.0 |
| SimPV_Li | Process value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Ext | External flow setpoint - coarse dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExtLi | 1 = Select external setpoints via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoints via operator | BOOL | 0 |
| SP_HiLim | High limit for flow setpoint - coarse dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP_Int* | Internal flow setpoint - coarse dosing | REAL | 0.0 |
| SP_IntLi | 1 = Select internal setpoints via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoints via operator | BOOL | 0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_LoLim | Low limit for flow setpoint - coarse dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 1 |
| SP2_Ext | External flow setpoint - fine dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2_HiLim | High limit for flow setpoint - fine dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 100.0<br>• 16#80 |
| SP2_Int* | Internal flow setpoint - fine dosing | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP2_LoLim | Low limit for flow setpoint - fine dosing | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StandStill | 1 = Scales at a standstill, dosing device infeedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| StartAut* | 1 = Select Start in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartForce | 1 = Forced start | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartLocal | 1 = Select Start in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartMan* | 1 = Select Start in "manual mode" | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TI | Integral time [s] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#80 |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| | | | |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| CR_AH_Act | Creep flow: 1 = High alarm active.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl | Control output for coarse dosing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl2 | Control output for fine dosing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DosEnd | 1 = End of dosing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DosOff | 1 = Dosing off | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DosOn | 1 = Dosing on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DosPause | 1 = Dosing pause | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DosRelax | 1 = Dosing dribbling | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DosStart | 1 = Dosing started | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DQ_AH_Act | 1 = Overdosing<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| DQ_AH_TolOut | DQ_AH_Tol as output | REAL | 0.0 |
| DQ_AL_TolOut | DQ_AL_Tol as output | REAL | 0.0 |
| DQ_AL_Act | 1 = Underdosing<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | REAL | 0.0 |
| DQ_ExHiAct | Dosing quantity:<br>1 = High limit for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DQ_ExLoAct | Dosing quantity:<br>1 = Low limit for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DQ_ExtOut | Dosing quantity: External setpoint, corresponds to input parameter DQ_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ_Out | Dosing quantity | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ_SP | Dosing quantity setpoint used by block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ_SP_Tol | Setpoint for determining tolerance limits | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ_Tare | Tare memory when dosing using scales | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ1_SP | Coarse dosing quantity setpoint used by block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ2_ExHiAct | Dosing quantity:<br>1 = High limit for external setpoint factor for fine dosing has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DQ2_ExLoAct | Dosing quantity:<br>1 = Low limit for external setpoint factor for fine dosing has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DQ2_ExtOut | Dosing quantity: External setpoint factor for fine dosing [%], corresponds to input parameter DQ2_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DQ2_SP | Fine dosing quantity setpoint used by block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| DribbOut | Dribbling quantity | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see DoseL error handling (Page 1327) | INT | -1 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit or Protect) is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgAckn2 | Message acknowledgement status 2 (output ACK_STATE of second ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgErr2 | Alarm error 2 (output ERROR of second ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| MsgStat2 | Message status 2 (output STATUS of second ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Displays of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| P_Ctrl | 1 = Pulse output for coarse dosing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Ctrl2 | 1 = Pulse output for fine dosing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_AH_Act | 1 = PV high alarm enabled (coarse dosing phase).<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_AH2_Act | 1 = PV high alarm enabled (fine dosing phase).<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_AL_Act | 1 = PV low alarm enabled (coarse dosing phase).<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_AL2_Act | 1 = PV low alarm enabled (fine dosing phase).<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_OpScaleOut | PV_OpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| PV_Out | Output for process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_UnitOut | PV_Unit as output | INT | 0 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP | Active flow setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_ExHiAct | Flow for coarse dosing:<br>1 = High limit for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExLoAct | Flow for coarse dosing:<br>1 = Low limit for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOut | Flow for coarse dosing: External setpoint, corresponds to input parameter SP_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP1 | Coarse dosing flow setpoint used by block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2 | Fine dosing flow setpoint used by block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2_ExHiAct | Flow for fine dosing:<br>1 = High limit for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP2_ExLoAct | Flow for fine dosing:<br>1 = Low limit for external setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP2_ExtOut | Flow for fine dosing: External setpoint, corresponds to input parameter SP2_Ext | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1305) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1305) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1305) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1305) | DWORD | 16#00000000 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `UserAna1Out` | `UserAna1` as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| `UserAna2Out` | `UserAna2` as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |

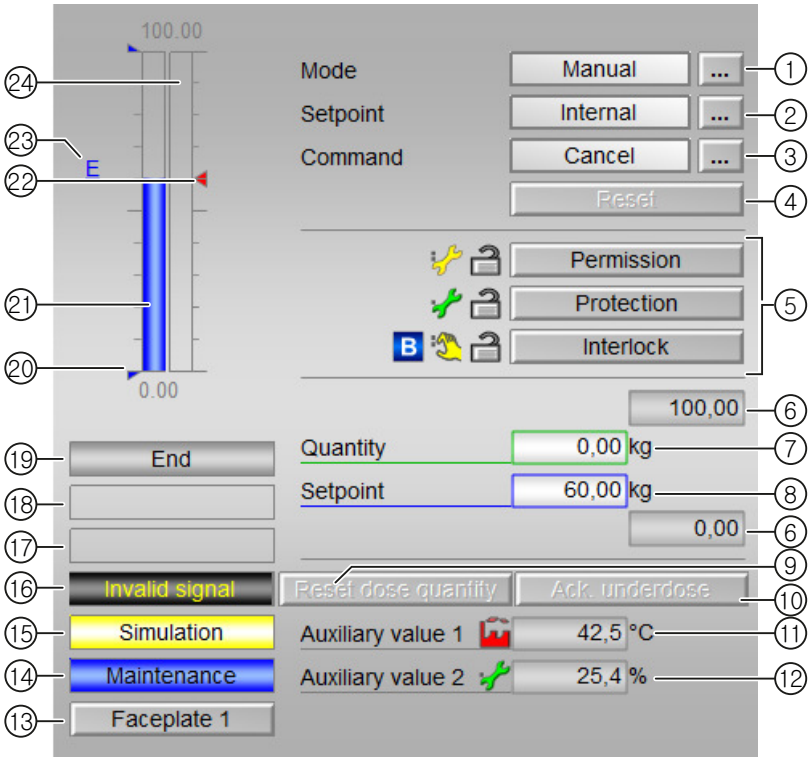
## 7.1.8 Operator control and monitoring

### 7.1.8.1 DoseL views

#### Views of the DoseL block



The block DoseL provides the following views:

- DoseL standard view (Page 1350)
- Alarm view (Page 336)
- DoseL limit view (Page 1354)
- Trend view (Page 341)
- DoseL parameter view (Page 1356)
- DoseL flow setpoint view (Page 1358)
- DoseL quantity setpoint view (Page 1361)
- DoseL preview (Page 1363)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for DoseL (Page 1366)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 7.1.8.2 DoseL standard view

**DoseL standard view**

**(1) Display and switch the operating mode**

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual mode (Page 82)
- Automatic mode (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to chapter Switching operating states and operating modes (Page 289) for information on switching the operating mode.

**(2) Displaying and changing the setpoint**

The following states can be shown and changed here:

- "Internal"
- "External"

You can find additional information on this in section Manual and automatic mode for motors, valves and dosers (Page 82).

### (3) Displaying and changing: Start, continue, pause and cancel

This area shows you the default operating state for the doser. The following states can be shown and changed here:

- "Start"
- "Continue"
- "Pause"
- "Cancel"

You can find additional information on this in section Switching operating states and operating modes (Page 289).

### (4) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in section Resetting the block in case of interlocks or errors (Page 47).

### (5) Operating range for the interlock functions of the block

You can use this button to control the interlock functions of the block. You can find additional information on this in section Interlocks (Page 107).

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (6) High and low scale range for the setpoint

This area is already set and cannot be changed.

### (7) Displaying and changing the quantity

You can find additional information on this in section Changing values (Page 291).

### (8) Displaying and changing the setpoint

You can find additional information on this in section Changing values (Page 291).

### (9) Button: Reset dose quantity

The dosing quantity can only be reset in the "End" or "Ack Dos End" state.

With resetting dose quantity also the display "Ack Dos End" is resetted to "End".

### (10) Button: Acknowledge overdosing and underdosing

Acknowledgment of overdosing and underdosing can only be made in the "Off" state.

Additional with `Feature2.Bit24` = 1:

- an acknowledgement of overdosing is possible.
- generally, overdosing or underdosing has to be acknowledged.

### (11) and (12) Display of auxiliary values

You can use this area to display two auxiliary values that have been configured in the Engineering System (ES). You can find additional information on this in section Opening additional faceplates (Page 234).

### (13) Button for switching to the standard view of any faceplate

Use this button for the standard view of a block configured in the Engineering System (ES). The visibility of this button depends on the configuration in the engineering system (ES).

You can find additional information on this in section Opening additional faceplates (Page 234).

### (14) and (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Maintenance"

You can find additional information on this in section Simulating signals (Page 64).

### (16) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Changeover error"
- "Flow"
- "Invalid Signal"

### (17) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced start"
- "Force continue"
- "Force pause"

- "Forced stop"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer: Reset of errors during Request 0/1 (Page 382)

### (18) Display area for block states

This area provides additional information on the operating state of the block:

- "Underdosed"
- "Overdosed"

### (19) Display area for block states

This area provides additional information on the operating state of the block:

- "Coarse dosing"
- "Fine dosing"
- "Relax"
- "Pause"
- "Off"
- "End"
  If an underdosage or overdosage is identified, the status display shows the state "Ack Dos End" in the standard view.
- "Taring"

### (20) Limit display for the setpoint

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the ES.

### (21) Bar graph for the setpoint

This area shows the current setpoint in the form of a bar graph. You can also see the high low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

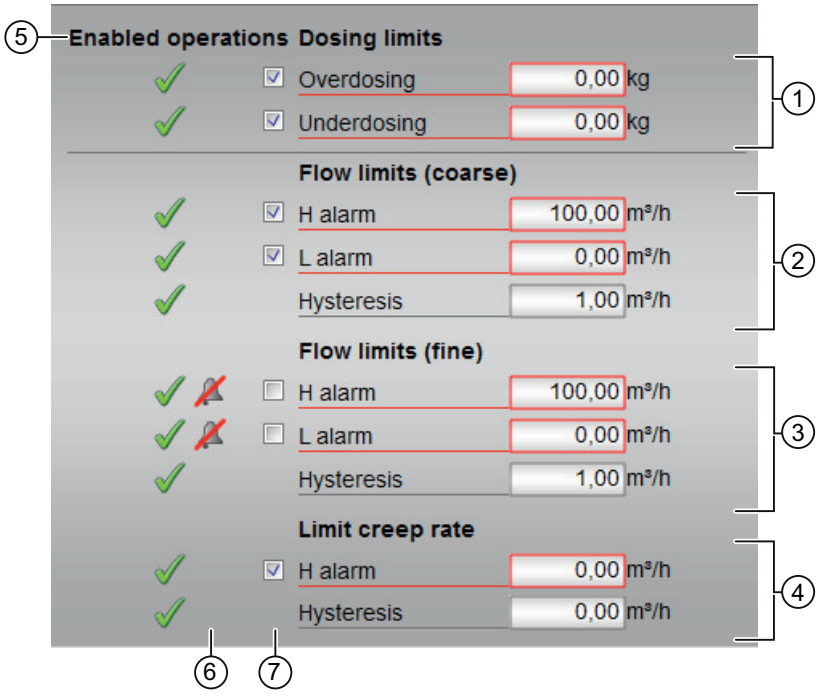
### (22) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

### (23) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".



### (24) Bar graph for the quantity

This area shows you the current quantity in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

For more information referBar graph (Page 376) section.

## 7.1.8.3 DoseL limit view

### Limit view of DoseL

**Note**

In scale mode with `Feature.Bit7` = 0, the displays **(2)**, **(3)** and **(4)** are hidden.

### (1) Displaying and changing the dosing limits

You can change the dosing limits in this area:

- "Overdosing"
- "Underdosing"

You can find additional information on this in the section Changing values (Page 291).

### (2) Displaying and changing the flow limits (coarse)

You can change the flow limits (coarse) in this area:

- "H alarm"
- "L alarm"
- "Hysteresis"

You can find additional information on this in the section Changing values (Page 291).

### (3) Displaying and changing the flow limits (fine)

You can change the flow limits (fine) in this area:

- "H alarm"
- "L alarm"
- "Hysteresis"

You can find additional information on this in the section Changing values (Page 291).

### (4) Displaying and changing the limit for the creep flow

You can change the limit for the creep rate in this area:

- "H alarm"
- "Hysteresis"

You can find additional information on this in the section Changing values (Page 291).

### (5) Enabled operation

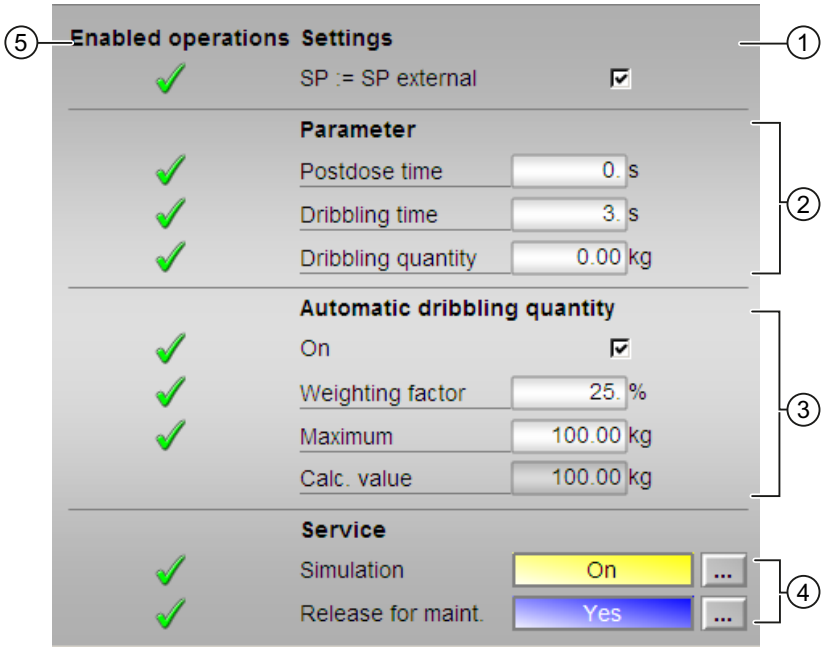
This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (6) "Message suppression/delay"

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.



Alarm delays are also displayed in this position; for more on this see section Area of application of the alarm delays (Page 225).

### (7) Suppress messages

You can enable / disable messages by setting the check mark.

## 7.1.8.4 DoseL parameter view

### Parameter view of DoseL

### (1) Settings

You can select the following functions in this area:

- "SP:=SP external": ☑ Bumpless switchover of setpoint from external to internal. The internal setpoint is tracked to the external one.

### (2) Parameter

In this area, you change parameters and therefore influence the doser. Refer also to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- "Relax time"
- "Dribble time"
- "Dribble value"

### (3) Automatic dribbling quantity

In this area, you change the automatic dribbling quantity parameters, which affects the doser. Refer also to the Changing values (Page 291) section for more on this.

You can change the parameters when the "On" check box is selected ☑.

You can influence the following parameters:

- "Weighting factor"
- "Maximum"
- "Calc. value"

### (4) Service

You can select the following functions in this area:

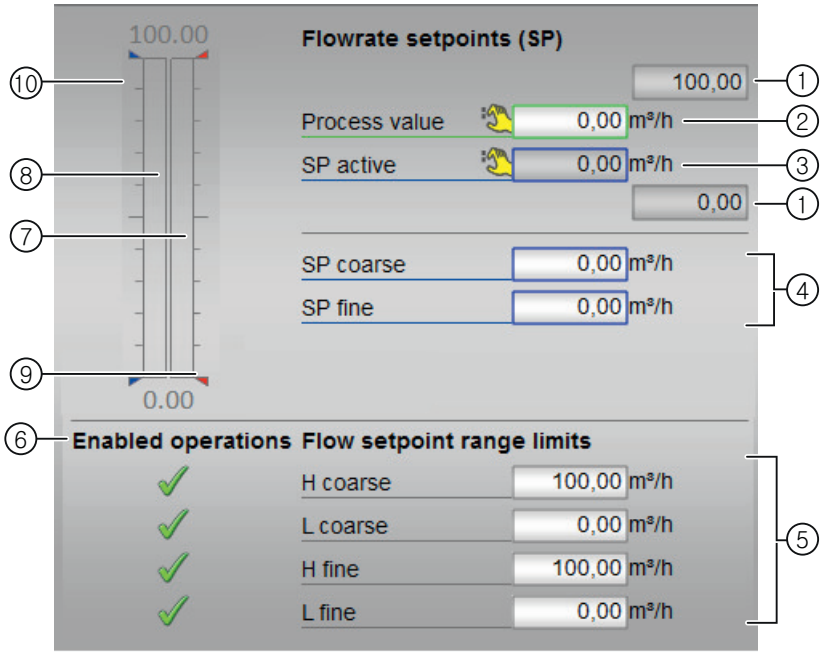
- "Simulation"
- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### (5) Enabled operations



This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### 7.1.8.5 DoseL flow setpoint view

#### Flow setpoint view for DoseL

**Note**

1.) This view cannot be selected in scale mode with `Feature.Bit7` = 0 .

2.) In scale mode with `Feature.Bit7` = 1 the displays **(3)**, **(4)**, **(5)**, **(6)** and **(8)** are hidden.

3.) If `Feature.Bit15` = 1, the display of this setpoint view changes. For further information, refer to the description below.

#### (1) High and low scale range for the process value

These values provide information on the display range for the bar graph **(7)** of the process value. The scale range is defined in the engineering system.

#### (2) Display of the process value including signal status

This area shows the current process value with the corresponding signal status.

#### (3) Displaying and changing the SP active value

You can find additional information on this in the Changing values (Page 291) section.

### (4) Additional setpoint parameters

You can change the following setpoint parameters in this area:

- "SP coarse"
- "SP fine"

You can find additional information on this in the Changing values (Page 291) section.

### (5) Displaying and changing the limits

You can change the limits in this area:

- "H coarse"
- "L coarse"
- "H fine"
- "L fine"

You can find additional information on this in the Changing values (Page 291) section.

### (6) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### (7) Bar graph for the process value

This area shows the current process value in the form of a bar graph. You can also see the high low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (8) Bar graph for the SP active setpoint

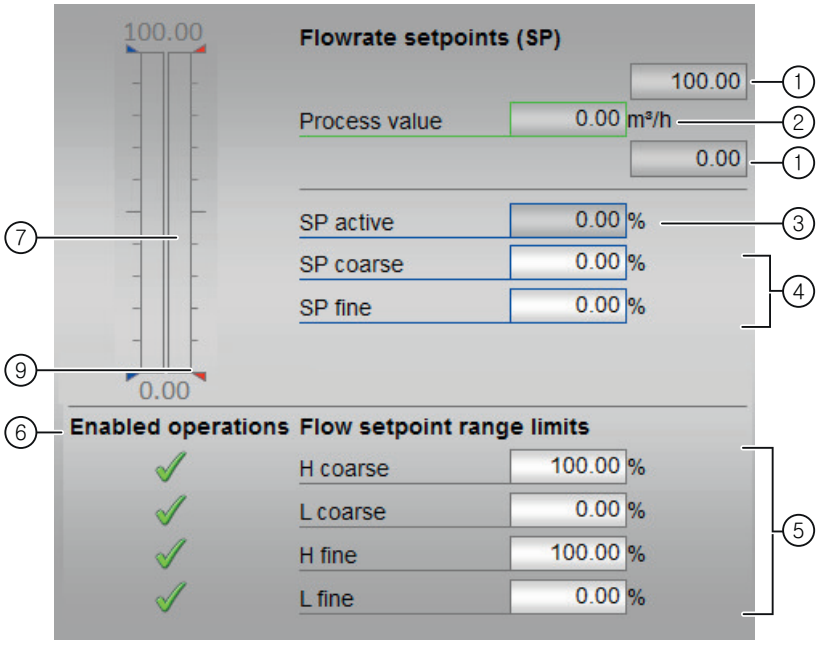
This area shows the current setpoint "SP active" in the form of a bar graph. You can also see the high low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

**Note**

If `Feature.Bit15` = 1, there are no **(8)** or **(10)** displays. For further information, refer to the description below.

### (9) Limit display

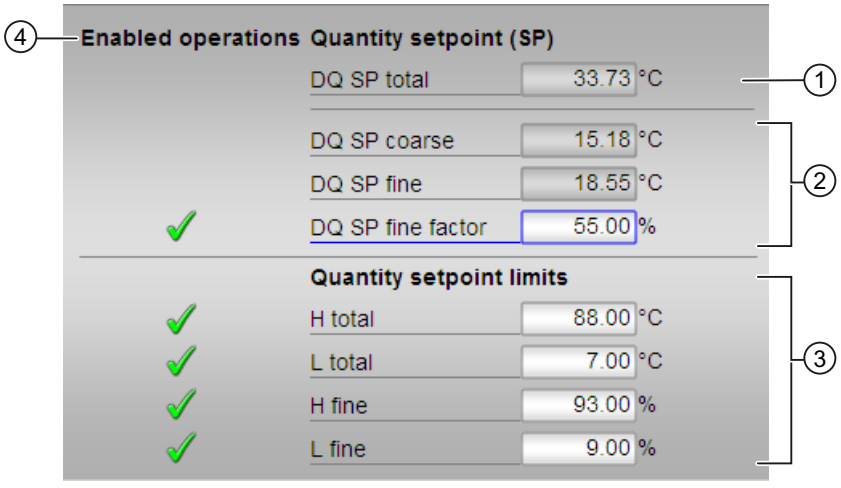
These triangles show limits for the flow limits. The flow limits are set in the limit value view.



### (10) Limit display for the setpoint

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the Engineering System (ES).

### Flow setpoint view for `Feature.Bit15` = 1



If `Feature.Bit15` = 1 , the setpoint view changes in the following ways:

- Displays **(8)** and **(10)** are omitted.
- The "SP active" value **(3)** is displayed above the area **(4)**.
- The values in the **(3)**, **(4)** and **(5)** areas contain the unit "%".

### 7.1.8.6 DoseL quantity setpoint view

#### Quantity setpoint view for DoseL

#### (1) Displaying and changing the DQ SP total setpoint

You can change the "DQ SP total" setpoint in this area.

Additional information is available in the section Changing values (Page 291).

#### (2) Displaying and changing additional setpoints

You can change the limits in this area:

- "DQ SP coarse"
- "DQ SP fine"
- "DQ SP fine factor"

Additional information is available in the section Changing values (Page 291).

**Note**

**Special note for `Feature.Bit8` = 1**

If you set this `Feature` Bit to 1, DQ SP fine is no longer displayed in the faceplate. In addition, the display of the unit for DQ SP fine factor is omitted. The input is now performed in an absolute manner.

#### (3) Displaying and changing the limits

You can change the limits in this area:

- "H total"
- "L total"

- "H fine"
- "L fine"

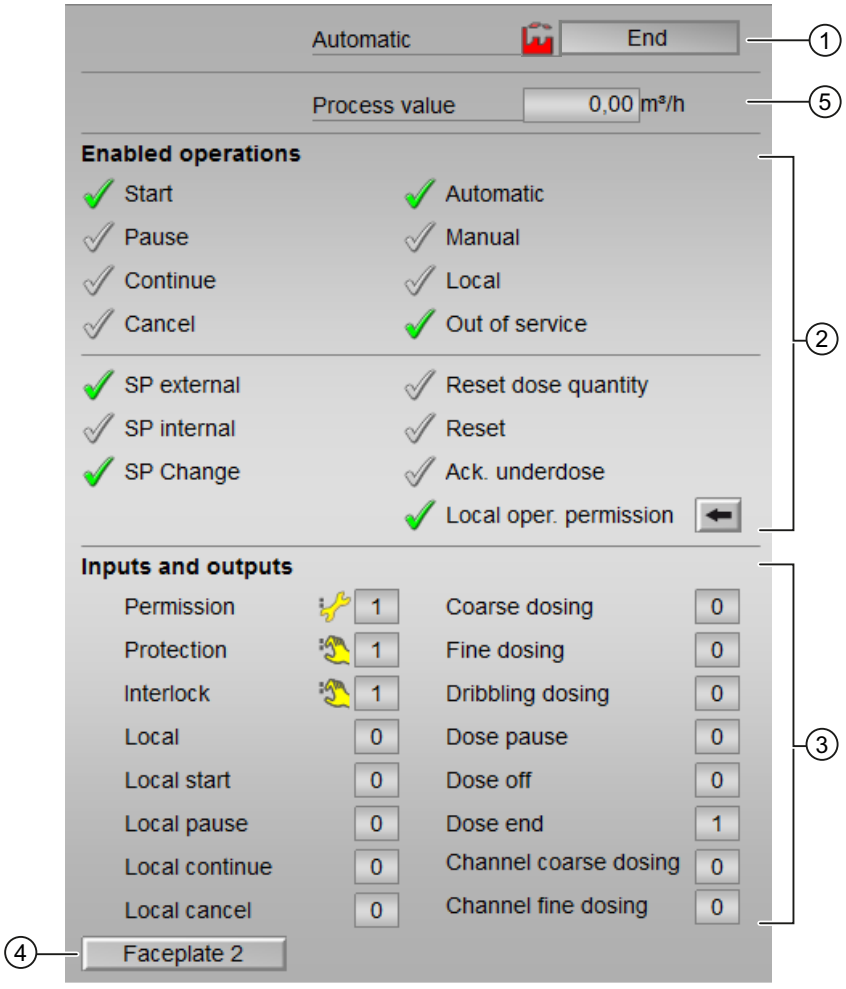
Additional information is available in the section Changing values (Page 291).

**Note**

**Special note for `Feature.Bit8` = 1**

If you set this `Feature` Bit to 1, the display of the unit for H fine and L fine is switched to the unit configured at `DQ_Unit`. The input is now performed in an absolute manner.

### (4) Enabled operations



This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### 7.1.8.7 DoseL preview

#### Preview of DoseL

#### (1) Automatic preview

This area shows you the block status after it has switched from "manual" to "automatic" mode.

If the block is in "automatic mode", the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `StartAut`
- `CancelAut`
- `PauseAut`
- `ContAut`
- `SP_Ext`

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations are shown here:

- "Start": You can start the dosing procedure
- "Pause": You can pause the dosing procedure
- "Continue": You can continue the dosing procedure after a pause or an abort.
- "Cancel": You can abort the dosing procedure
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "SP external": You can use the external setpoint
- "SP internal": You can use the internal setpoint
- "Change SP": You can change the setpoint
- "Reset dose quantity": You can reset the dosing quantity
- "Reset": You can reset the block after interlocks or errors
- "Acknowledge underdosing": You can acknowledge underdosing
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).

### (3) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission":
  - 0 = No OS release for energizing motor
  - 1 = Enable for "starting"/"stopping" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection":
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock":
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Local start": 1 = Block is started in "local mode"
- "Local pause": 1 = Dosing paused in "local mode"
- "Local continue": 1 = Dosing is continued in "local mode"
- "Local cancel": 1 = Dosing is canceled in "local mode"
- "Coarse dosing": 1 = Coarse dosing is performed
- "Fine dosing": 1 = Fine dosing is performed
- "Relax phase": 1 = Dosing procedure is in the relax phase
- "Dose pause": 1 = Dosing pause
- "Dose off": 1 = No dosing taking place
- "Dose end": 1 = Dosing is stopped
- "Channel Coarse Dosing": Signal from the output channel block for "Coarse dosing"
- "Channel Fine Dosing": Signal from the output channel block for "Fine dosing"

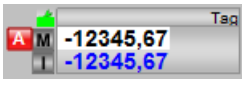
### (4) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

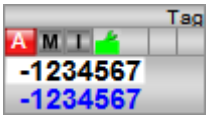
### (5) Process value

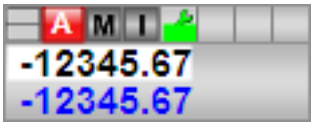
This area displays the real process value (PV).

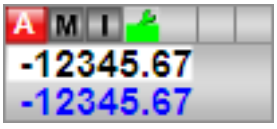


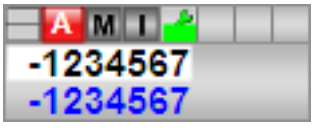
## 7.1.8.8 Block icon for DoseL

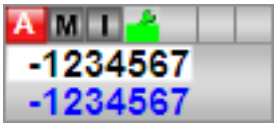
### Block symbols for DoseL











A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Internal and external setpoint specification
- Signal status, release for maintenance
- Track, force, and bypass
- Interlocks
- Memo display
- Process value (black, with and without decimal places)
- Setpoint (blue, with and without decimal places)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# Motor and valve blocks

# 8

## 8.1 Comparison of large & small blocks

### 8.1.1 MotL compared to MotS

#### Comparison of the MotL and MotS blocks

The following tables are intended to help you decide which block to use.

#### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 40%
- Runtime: ~ 25%

#### Block operating modes

| | MotL | MotS |
|---|---|---|
| Local mode (Page 86) | X | X |
| Manual mode (Page 82) | X | X |
| Automatic mode (Page 82) | X | X |
| Out of service (Page 77) | X | X |

#### Functions of the blocks

| | MotL | MotS |
|---|---|---|
| Opening additional faceplates (Page 234) | X | X |
| Operator control permissions (Page 285) | X | X |
| Limit monitoring of an additional analog value (Page 98) | X | |
| Limit monitoring with hysteresis (Page 104) | X | |
| Suppressing messages using the MsgLock parameter (Page 231) | X | X |
| Interlocks (Page 107) | X | X |
| Motor protection function (Page 106) | X | X |

| | MotL | MotS |
|---|---|---|
| Disabling interlocks (Page 111) | X | X |
| Rapid stop for motors (Page 115) | X | |
| Resetting the block in case of interlocks or errors (Page 47) | X | X |
| Outputting group errors (Page 130) | X | X |
| Outputting a signal for start readiness (Page 59) | X | X |
| Restart lock after switching off the motor (Page 1382) | X | |
| Forming the group status for interlock information (Page 113) | X | X |
| Forming and outputting the signal status for technologic blocks (Page 117) | X | X |
| Forcing operating modes (Page 45) | X | |
| Monitoring the feedbacks (Page 104) | X | X |
| Release for maintenance (Page 70) | X | X |
| Specifying warning times for control functions at motors and valves (Page 56) | X | |
| Simulating signals (Page 64) | X | X |
| Selecting a unit of measure (Page 240) | X | |
| Neutral position for motors, valves and controllers (Page 54) | X | X |
| Output signal as a static signal or pulse signal (Page 57) | X | X |
| Generating instance-specific messages (Page 230) | X | X |
| Displaying auxiliary values (Page 239) | X | |
| Time stamp | X | |
| SIMATIC BATCH functionality (Page 73) | X | |
| Labeling of buttons and text (Page 235) | X | X |
| Displaying current control signals from output channel block | X | X |
| Display active monitoring time | X | X |
| Control priority in the event of invalid or not plausible input commands (Page 186) | X | X |
| Separate monitoring time for stopping the motor (Page 180) | X | X |

## Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | MotL | MotS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | X | X |
| 1 | Reaction to the out of service mode (Page 188) | X | X |
| 2 | Resetting the commands for changing the mode (Page 172) | X | X |
| 3 | Enabling resetting of commands for the control settings (Page 172) | X | X |
| 4 | Setting switch or button mode (Page 177) | X | |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) | X | X |
| 10 | Exiting local mode (Page 189) | X | X |
| 11 | Activating the run time of feedback signals (Page 164) | X | X |
| 13 | Separate monitoring time for stopping the motor (Page 180) | X | |
| 14 | Enabling rapid stop via faceplate (Page 179) | X | |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) | X | |
| 19 | Reset even with locked state (Page 176) | X | X |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) | X | |
| 22 | Update acknowledgment and error status of the message call (Page 171) | X | |
| 24 | Enabling local operator authorization (Page 169) | X | X |
| 25 | Suppression of all messages (Page 185) | X | X |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) | X | |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) | X | X |
| 28 | Disabling operating points (Page 156) | X | |
| 29 | Signaling limit violation (Page 181) | X | |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) | X | X |
| 31 | Activating reset of protection / error in manual mode (Page 175) | X | X |

### Configurable functions using the `Feature2` parameter

| Bit number | `Feature2` bit function | MotL | MotS |
|---|---|---|---|
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) | X | X |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) | X | X |

## 8.1.2 VlvL compared to VlvS

### Comparison of the VlvL and VlvS blocks

The following tables are intended to help you decide which block to use.

### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 25%
- Runtime: ~ 20%

### Modes

| | VlvL | VlvS |
|---|---|---|
| Local mode (Page 86) | X | X |
| Manual mode (Page 82) | X | X |
| Automatic mode (Page 82) | X | X |
| Out of service (Page 77) | X | X |

### Functions

| | VlvL | VlvS |
|---|---|---|
| Opening additional faceplates (Page 234) | X | X |
| Operator control permissions (Page 285) | X | X |
| Interlocks (Page 107) | X | X |
| Disabling interlocks (Page 111) | X | X |
| Resetting the block in case of interlocks or errors (Page 47) | X | X |

| | VlvL | VlvS |
|---|---|---|
| Outputting group errors (Page 130) | X | X |
| Outputting a signal for start readiness (Page 59) | X | X |
| Forming the group status for interlock information (Page 113) | X | X |
| Forming and outputting the signal status for technologic blocks (Page 117) | X | X |
| Forcing operating modes (Page 45) | X | |
| Monitoring the feedbacks (Page 104) | X | X |
| Disabling feedback for valves (Page 106) | X | |
| Suppressing messages using the MsgLock parameter (Page 231) | X | X |
| Release for maintenance (Page 70) | X | X |
| Specifying warning times for control functions at motors and valves (Page 56) | X | |
| Simulating signals (Page 64) | X | X |
| Selecting a unit of measure (Page 240) | X | |
| Neutral position for motors, valves and controllers (Page 54) | X | X |
| Generating instance-specific messages (Page 230) | X | X |
| Displaying auxiliary values (Page 239) | X | |
| SIMATIC BATCH functionality (Page 73) | X | X |
| Output signal as a static signal or pulse signal (Page 57) | X | |
| Time stamp (Page 2046) | X | |
| Labeling of buttons and text (Page 235) | X | X |
| Displaying current control signals from output channel block | X | X |

## Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | VlvL | VlvS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | X | X |
| 1 | Reaction to the out of service mode (Page 188) | X | X |
| 2 | Resetting the commands for changing the mode (Page 172) | X | X |
| 3 | Enabling resetting of commands for the control settings (Page 172) | X | X |
| 4 | Setting switch or button mode (Page 177) | X | |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) | X | X |
| 10 | Exiting local mode (Page 189) | X | X |
| 11 | Activating the run time of feedback signals (Page 164) | X | X |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) | X | |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) | X | |
| 22 | Update acknowledgment and error status of the message call (Page 171) | X | |
| 24 | Enabling local operator authorization (Page 169) | X | X |
| 25 | Suppression of all messages (Page 185) | X | X |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) | X | X |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) | X | X |
| 31 | Activating reset of protection / error in manual mode (Page 175) | X | X |

## Configurable functions using the `Feature2` parameter

| Bit number | `Feature2` bit function | VlvL | VlvS |
|---|---|---|---|
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) | X | X |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) | X | X |

## 8.1.3 ShrdResL compared to ShrdResS

### Comparison of the ShrdResL and ShrdResS blocks

The following tables are intended to help you decide which block to use.

### Memory and runtime savings of the small block compared to the large block

You save the following resources for each instance:

- Memory space: ~ 50%
- Runtime: ~ 25%

### Parameters for channel

| | ShrdResL | ShrdResS |
|---|---|---|
| Control commands for channel | 12 | 6 |
| External setpoints for channel | 8 | 2 |
| Additional strings for channel | 2 | - |

### Functions

| | ShrdResL | ShrdResS |
|---|---|---|
| Opening additional faceplates (Page 234) | x | x |
| Operator control permissions (Page 285) | x | |
| Readiness signal (Page 1607) | x | x |
| Channel management (Page 1629) | | x |
| Channel management with parameterized priority parameter and strategy mode (Page 1607) | x | |
| Allocate/enable channel (Page 1607) | x | x |
| Enable/disable channel (Page 1607) | x | x |
| Channel prioritization (Page 1607) | x | x |
| Cascading (Page 1629) | | x |
| SIMATIC BATCH functionality (Page 73) | x | x |

### Configurable functions using the `Feature` parameter

| Bit number | `Feature` bit function | ShrdResL | ShrdResS |
|---|---|---|---|
| 0 | Set startup characteristics (Page 148) | x | x |

# 8.2 MotL - Motor (Large)

## 8.2.1 Description of MotL

### Object name (type + number) and family

Type + number: FB 1850

Family: Drives

### Area of application for MotL

The block is used for the following applications:

- Control of motors with one control signal

**Note**

This block is also available as a small block. A comparison of the MotL and MotS blocks is available in the section: MotL compared to MotS (Page 1369)

### How it works

The block is used to control motors. Various inputs are available for controlling the motor.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section MotL I/Os (Page 1394).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |

| Status bit | Parameter |
|---|---|
| 4 | `OosLi.Value` |
| 5 | 0 = `ManAct.Value`<br>1 = `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 8 | `Start.Value` |
| 9 | `Stop.Value` |
| 10 | `MonDynStopErr.Value` |
| 11 | `MonStaErr.Value` |
| 12 | `MonDynErr.Value` |
| 13 | `BypProt` |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | Trip.Value |
| 20 | Display „Forced start“ |
| 21 | Display „Forced stop“ |
| 22 | Not used |
| 23 | "Interlock" button is enabled |
| 24 | Reset request in automatic preview |
| 25 | `WarnAct.Value` or<br>`Idle Time` is active |
| 26 | Bypass information for display in block icon |
| 27 | Automatic preview for "starting" |
| 28 | Automatic preview for "stopping" |
| 29 | External error generated by FaultExt or external control system fault CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 30 | "Permission" button is enabled |
| 31 | "Protection" button is enabled |

## Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `AV_AH_Act.Value` |
| 2 | `AV_WH_Act.Value` |
| 3 | `AV_TH_Act.Value` |
| 4 | `AV_TL_Act.Value` |
| 5 | `AV_WL_Act.Value` |

| Status bit | Parameter |
|---|---|
| 6 | AV_AL_Act.Value |
| 7 | AV_AH_En OR Feature.Bit23 |
| 8 | AV_WH_En OR Feature.Bit23 |
| 9 | AV_TH_En OR Feature.Bit23 |
| 10 | AV_TL_En OR Feature.Bit23 |
| 11 | AV_WL_En OR Feature.Bit23 |
| 12 | AV_AL_En OR Feature.Bit23 |
| 13 | AV_AH_MsgEn |
| 14 | AV_WH_MsgEn |
| 15 | AV_TH_MsgEn |
| 16 | AV_TL_MsgEn |
| 17 | AV_WL_MsgEn |
| 18 | AV_AL_MsgEn |
| 19 | 1 = No impact of input signals on "local mode" with LocalSetting = 0, LocalSetting = 2, LocalSetting = 4 and OOS mode. |
| 20 | Motor is stopped |
| 21 | Motor is stopping |
| 22 | Motor is starting |
| 23 | Motor is running |
| 24 | Error in motor |
| 25 | 1 = Input parameter StartChnST is interconnected |
| 26 | Resynchronization with state "No Cmd" |
| 27 | 1 = "Permission stop" button is enabled |
| 28 | 1 = Permission stop is active |
| 29 | Hidden bypass signal in Permission stop |
| 30 | Display for interlocks in block icon |
| 31 | MS_RelOp |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Delay of the AV_AH_Lim message |
| 1 | Delay of the AV_WH_Lim message |
| 2 | Delay of the AV_TH_Lim message |
| 3 | Delay of the AV_TL_Lim message |
| 4 | Delay of the AV_WL_Lim message |
| 5 | Delay of the AV_AL_Lim message |
| 6 | Collection of message delays |
| 7 - 10 | Not used |
| 11 | Hidden bypass signal in Permit |
| 12 | Hidden bypass signal in interlock |
| 13 | Hidden bypass signal in Protect |

| Status bit | Parameter |
|---|---|
| 14 | `Feature2.Bit2`: Separate bypass signal |
| 15 - 17 | Current monitoring time is visible |
| 18 | `SimLiOp.Value` |
| 19 | 1 = Enable for rapid stop (`Feature` Bit Enabling rapid stop via faceplate (Page 179)) |
| 20 - 22 | Not used |
| 23 | Command for rapid stop |
| 24 | Output command for starting the motor |
| 25 | Output command for stopping the motor |
| 26 | Show automatic preview in the standard view |
| 27 | Internal error |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | `AV` not connected |
| 9 | Motor protection display (`Trip.Status` ≠ 16#FF) |
| 10 | 1 = Input parameter `FbkRun` is connected |
| 11 | 1 = Input parameter `FbkStop` is connected |
| 12 | Resynchronization preview for Start |
| 13 | Resynchronization preview for Stop |
| 14 | Resynchronization: Display preview |
| 15 | Resynchronization: Display small preview symbol in standard view |
| 16 - 23 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 24 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | ot used |
| 31 | Separate monitoring of shutdown of the motor (`Feature.Bit13`) |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 - 15 | Effective signal 1...16 of the message block connected via `EventTs2In` |
| 16 - 31 | Not used |

MotL error handling (Page 1390)

MotL modes (Page 1380)

## 8.2.2 MotL modes

### MotL operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Motor actions you can control in local mode:

- "Start" (`StartLocal` = 1)
- "Stop" (`StopLocal` = 1)

A motor operated in "local mode" is controlled either by "local" signals or by the feedback signals (the `FbkStart` = 1 or `FbkStop` =1 input parameter). Configuration takes place via the input parameter `LocalSetting`.

`LocalSetting` =2,4: The control outputs are tracked to the feedbacks.

All two feedbacks are available and plausible means that always only one feedback is active. The corresponding control output is tracked:

```
Start = FbkRun
```

```
StopCtrl = FbkStop
```

When both feedbacks are false then the drive is between of two positions. In this case no monitoring is started. When two feedbacks are active, then they are not plausible. In this case the static monitoring counter starts. In both cases "all feedbacks are reset" or "not plausible feedbacks" with `Feature2Bit21` =1 all the control outputs are set to false (No command state) else control outputs will be hold.

If one feedback is available it is always plausible.

| NoFbkRun =0 (default) | NoFbkStop =0 |
|---|---|
| `Start = FbkRun`<br>`StopCtrl = NOT FbkRun` | `Start = NOT FbkStop`<br>`StopCtrl = FbkStop` |

When all feedbacks are not available the control outputs will be hold.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Motor actions you can control in auto mode:

- "Start" (`StartAut` = 1)
- "Stop" (`StopAut` = 1)

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Motor actions you can control in manual mode:

- "Start" (`StartMan` = 1)
- "Stop" (`StopMan` = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the Out of service (Page 77) section.

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkRunOut.ST | 16#80 | 16#60 |
| Run.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |
| AV_Out.ST | 16#80 | 16#60 |

## 8.2.3 MotL functions

### Functions of MotL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can start the motor |
| 6 | Not used |
| 7 | 1 = Operator can reset the motor |
| 8 | 1 = Operator can define or change the monitoring time for startup |
| 9 | 1 = Operator can define the monitoring time for the status |
| 10 | 1 = Operator can enable the monitoring time function (Bit 8 - 9) |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the high limit (`AV`) for the alarm |
| 14 | 1 = Operator can change the high limit (`AV`) for the warning |
| 15 | 1 = Operator can change the high limit (`AV`) for the tolerance |
| 16 | 1 = Operator can change the limit (`AV`) for hysteresis |

| Bit | Function |
|---|---|
| 17 | 1 = Operator can lower the limit (AV) for the alarm |
| 18 | 1 = Operator can lower the limit (AV) for the warning |
| 19 | 1 = Operator can lower the limit (AV) for the tolerance |
| 20 | 1 = Operator can activate / deactivate messages via AV_AH_MsgEn |
| 21 | 1 = Operator can activate / deactivate messages via AV_WH_MsgEn |
| 22 | 1 = Operator can activate / deactivate messages via AV_TH_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via AV_TL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via AV_WL_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via AV_AL_MsgEn |
| 26 | 1 = Operator can change the simulation value SimAV |
| 27- 29 | Not used |
| 30 | 1 = Operator can define the monitoring time for stopping |
| 31 | 1 = Operator can execute the rapid stop |

The block has the following permissions for the OS1_Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Limit monitoring of an additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104).

### Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Interlocks

This block provides the following interlocks:

- Activation enable
- Interlock without reset ("Interlock")

- Interlock with reset ("Protection")
- Permission for stop ("Permission stop")

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Rapid stop for motors

This block provides the standard function Rapid stop for motors (Page 115).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See MotL error handling (Page 1390)

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `Trip`
- `MonDynErr`
- `MonStaErr`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Restart lock after switching off the motor

After switching off or stopping the motor, it can only be restarted after the time set with the `IdleTime` input parameter.

When the "Stop" command is given, the motor goes immediately into "Stop" mode, and `IdleTime`starts after the feedback (`FbkRun` = 0) is given. The motor cannot be started again until the `IdleTime` has expired.

The `IdleTime` parameter can be set independently of the `MonTiDynamic` parameter.

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `LocalLi.ST`
- `StartLocal.ST`
- `StopLocal.ST`
- `Trip.ST`
- `FbkRunOut.ST`
- `AV_Out.ST`
- `StartChn.ST`
- `StartAut.ST` (only if `Feature2.Bit10` = 1)
- `StopAut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (motor stop) in the "Automatic" mode:

- `StartAut.ST`
- `StopAut.ST`

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).

The following states can be enforced:

- "Start" (`StartForce`)
- "Stop" (`StopForce`)

### Feedback monitoring

This block provides the standard functio

### Disabling feedback

This block provides the standard function of Disabling feedback for valve and motors (Page 106). Feedback monitoring can be deactivated separately for each feedback with `NoFbkRun` or `NoFbkStop` as required.

The output signals of feedback are tracked by the control and the other available feedbacks:

| NoFbkRun | NoFbkStop | Comment |
|---|---|---|
| 0 | 1 | **Default:**<br>`FbkRunOut = FbkRun;`<br>`FbkStopOut = StopCtrl AND NOT FbkRun;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkRunOut = FbkRun;`<br>`FbkStopOut = NOT FbkRun;` |
| 0 | 0 | `FbkRunOut = FbkRun;`<br>`FbkStopOut = FbkStop;` |
| 1 | 0 | `FbkRunOut = Start AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkRunOut = NOT FbkStop;`<br>`FbkStopOut = FbkStop;` |
| 1 | 1 | `FbkRunOut = Start;`<br>`FbkStopOut = StopCtrl;` |

When all feedbacks are not available, the position is on hold after a switch to local mode with `LocalSetting` =2/4.

### Using StopCtrl with mode "No Cmd"

This block provides the standard function Control with output StopCtrl and state “No Cmd” (Page 214)

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56).

You can generate warning signals when, for example, motors are started. Warning signals can be generated in the following modes:

- Manual mode (Page 82) (`WarnTiMan` input parameter)
- Automatic mode (Page 82) (`WarnTiAut` input parameter)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a motor is started, then this is displayed at the output parameter with `WarnAct` = 1. The motor then starts after the set warning time has expired and `WarnAct` then goes back to 0.

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Additional value (`SimAV`, `SimAV_Li`)

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the control outputs are tracked as follow:

**NoFbkRun =0, NoFbkStop =1 (default):**

Start := FbkRun;

StopCtrl := NOT FbkRun;

**NoFbkRun =0, NoFbkStop =0:**

Plausible feedback positions (FbkRun =1, FbkStop =0 or FbkRun =0, FbkStop =1) are tracked as control position.

Start := FbkRun;

StopCtrl := FbkStop;

In case there are no plausible feedback positions (FbkRun =0, FbkStop =0 or FbkRun =1, FbkStop =1) the control position depends on Feature2 Bit21.

- Feature2 Bit21 =0 (default): Control position are not changed.
- Feature2 Bit21 =1: Control position becomes "No Cmd" Start := 0; StopCtrl := 0;

**NoFbkRun =1, NoFbkStop =0:**

Start := NOT FbkStop;

StopCtrl := FbkStop;

With other combinations of **NoFbkRun**, **NoFbkStop** the controls are not changed.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 14 | Enabling rapid stop via faceplate (Page 179) |

| Bit | Function |
|---|---|
| 13 | Separate monitoring time for stopping the motor (Page 180) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In pushbutton operation (Bit 4 = 0) the automatic commands in "automatic" mode are latching, in other words `StartAut`, `StopAut` can be reset to 0 after changing the control. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

In switching mode (Bit 4 = 1), the control is selected with the static signal `StartAut`. If `StartAut` input is not set the motor is stopped. Control via `StopAut` is not needed. If the "Activate command reset for control" function (Bit 3 = 1) is also activated, the `StartAut` input is reset to the neutral position after evaluation in the block.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 21 | Control with output StopCtrl and state “No Cmd” (Page 214) |

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- `StartMan`
- `StopMan`
- `RapidStp`

## 8.2.4 MotL error handling

### Error handling of MotL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Control system fault (CSF)
- Invalid or not plausible input commands

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 41 | The value for the LocalSetting I/O is not within the approved limit of 0 to 4. |
| 42 | LocalSetting = 0 or LocalSetting = 3 or LocalSetting = 4 and LocalLi = 1 |
| 51 | StartLocal = 1 and StopLocal = 1<br>StartAut = 1 and StopAut = 1<br>AutModLi = 1 and ManModLi = 1<br>StartForce = 1 and StopForce = 1 |
| 52 | LocalAct = 1 and LocalSetting = 2 or 4 and SimOn = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| Operating mode | Invalid or not plausible input commands | Control reaction with Feature2.Bit3 = 1 |
|---|---|---|
| Local: Localsetting = 1 or Localsetting = 3 | Pushbutton operation for local mode (Feature2.Bit4 = 0):<br>StartLocal = 1 and StopLocal = 1 | Motor is stopped |
| Local: Localsetting = 1 or Localsetting = 3 and forcing | StartForce = 1 and StopForce = 1 | |
| Forcing and no "local mode" | StartForce = 1 and StopForce = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (Feature.Bit4 = 0):<br>StartAut = 1 and StopAut = 1 | |
| "Manual mode" and no forcing | StopMan = 1 and StartMan = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

Description of MotL (Page 1376)

## 8.2.5 MotL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Motor feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>Motor protection triggered |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId1`, SIG 3).

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | ExtVa108 |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters ExtVa104 ... ExtVa108 , and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 8.2.6 MotL I/Os

I/Os of MotL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| AV | Input additional analog value, to be connected to AV_Tech of the AV block | ANY | |
| AV_AH_Lim | Limit high alarm | REAL | 95.0 |
| AV_AL_Lim | Limit low alarm | REAL | 5.0 |
| AV_Hyst | Hysteresis for alarm, warning and tolerance limits | REAL | 1.0 |
| AV_TH_Lim | Limit high tolerance | REAL | 85.0 |
| AV_TL_Lim | Limit low tolerance | REAL | 15.0 |
| AV_WH_Lim | Limit high warning | REAL | 90.0 |
| AV_WL_Lim | Limit low warning | REAL | 10.0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| EventTs2In | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTs2In input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkRun | 1= Motor feedback running | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkStop | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1382)<br><br>Separate monitoring time for stopping the motor | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 13: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1382) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| IdleTime* | Wait time for restart in [s] | REAL | 5.0 |
| Intlock | 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared<br>1 = Interlock not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is active | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors  Motors: Stop is the neutral position | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MonTiDynamic* | Monitoring time for feedback errors or feedback start error after successful operation in [s] | REAL | 3.0 |
| MonTiDyStop* | Monitoring time for feedback stop errors after successful operation in [s] | REAL | 3.0 |
| MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoFbkRun | 1= Motor feedback running not present | BOOL | 0 |
| NoFbkStop | 1= Motor feedback stopped not present | BOOL | 1 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1382)<br>1 = Operator can set or change the monitoring time for "Control: Start"<br>1 = Operator can set or change the monitoring time for "Control: Stop" | STRUCT<br>• Bit 0: BOOL<br>• Bit 8: BOOL<br>• Bit 20: BOOL<br>• Bit 30: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1382) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| Permit | 1 = OS activation enable for motor<br>0 = No OS release for energizing motor | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermitSafePos | 1=Motor stop is allowed | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL<br>(Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermSf_En | 1=Permit stop enabled | BOOL | 1 |
| Perm_En | 1 = Activation enable (enable, Permit parameter) is active | BOOL | 1 |
| Protect | 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block<br>1 = Protective interlocking not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Prot_En | 1 = Protective interlock (protection, Protect parameter) is active | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RapidStp* | Rapid stop for the motor:<br>0 = Motor On<br>1 = Motor Off | BOOL | 0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimAV* | Additional value used for SimOn = 1 | REAL | 0.0 |
| SimAV_Li | Additional analog value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| StartAut* | 1 = Starting the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartChnST | Signal status of output channel Start<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| StartForce | 1 = Force motor start | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartLocal | 1 = Starting the motor in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartMan* | 1 = Starting the motor in "manual mode" | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stopping the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopForce | 1 = Force motor stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopLocal | 1 = Stopping the motor in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stopping the motor in "manual mode" | BOOL | 0 |
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| WarnTiAut | Prewarning of motor start in "automatic mode" in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan | Prewarning of motor start in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AV_OpScale | Limit for scale in AV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| AV_Out | Output additional analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Unit | Unit of measure for additional analog value | INT | 0 |
| CurrMon | Remaining monitoring time [s] | DINT | 0 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MotL error handling (Page 1390) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkRunOut | 1= Motor feedback running | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkStopOut | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit, Protect) or Trip is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynErr | 1 = Feedback error or feedback start error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonDynStopErr | 1 = Feedback stop error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | WORD | 16#FFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Stop | 0 = Pulse signal for stopping the motor | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| P_Start | 1 = Pulse signal for starting the motor | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| R_StpAct | 1 = Rapid stop of the motor is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Run | 1 = Motor is running | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Start | 1 = Control of motor: started | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word 1 (Page 1376) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1376) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1376) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1376) | DWORD | 16#00000000 |
| Stop | 1 = Motor stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopCtrl | Control output to Stop the motor (go to Safe position) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TripOut | Trip as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| WarnAct | 1 = Prewarning for motor start active (parameters WarnTiAut and WarnTiMan) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |

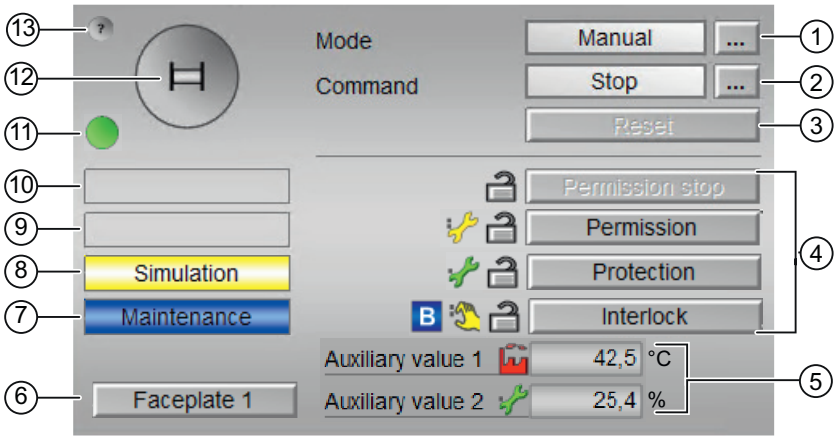
## 8.2.8 Operator control and monitoring

### 8.2.8.1 MotL views

### Views of the MotL block



The MotL block provides the following views:

- MotL standard view (Page 1405)
- Alarm view (Page 336)
- Limit view of motors (Page 328)
- Trend view (Page 341)
- Parameter view for motors and valves (Page 320)
- MotL preview (Page 1408)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MotL (Page 1412)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.2.8.2 MotL standard view

#### MotLstandard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Starting and stopping the motor

This area shows you the default operating state for the motor. The following states can be shown and executed here:

- "Start"
- "Stop"
- "Rapid stop"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operator control and display area for interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (6) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (9) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Motor protection"
- "External error"
- "Status error"
- "Control error"
- "Internal error"
- "Changeover error"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced start"
- "Forced stop"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (11) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the motor would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (12) Status display of the motor

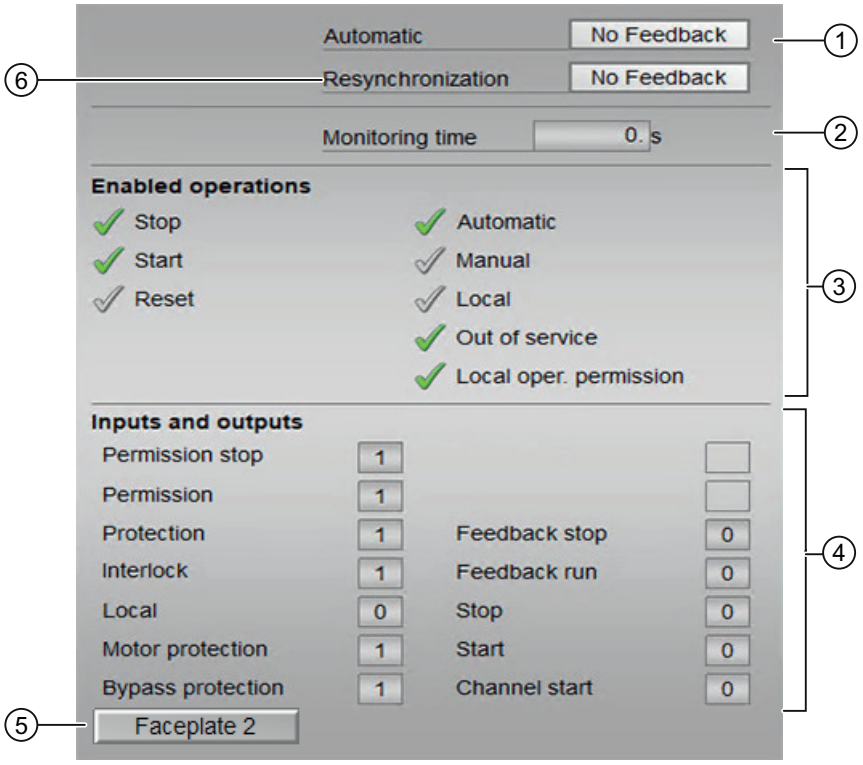
The current status of the motor is graphically displayed here.

You can find more information about this in section Block icon for MotL (Page 1412).

### (13) Mini preview for Resynchronization

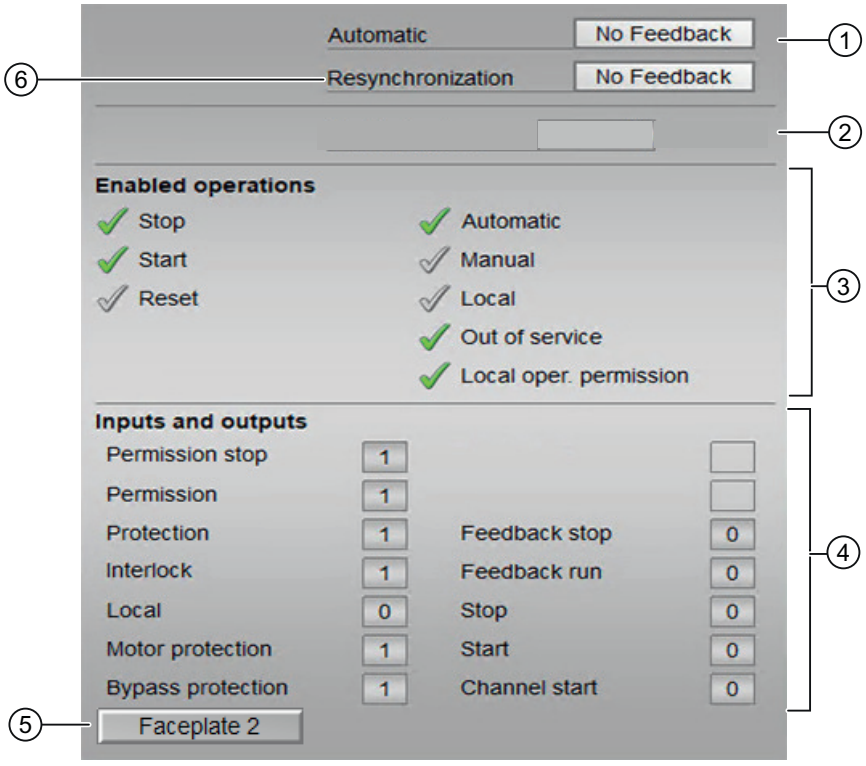
Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:



- Start
- Stop
- No Cmd

**Note**



Mini preview for resynch is visible only if resynchronization command is different to control output value.

## 8.2.8.3 MotL preview

### Preview of MotL

Display of the current monitoring time is visible.

Display of the remaining monitoring time is not visible.

## (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `StartAut`
- `StopAut`

### (2) Monitoring time

The remaining "Monitoring time" is displayed in this area.

### (3) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Stop": You can stop the motor.
  If the text is configured for this command, it is also displayed in brackets. For more informtaion, see section Labeling of buttons and text (Page 235).
- "Start": You can start the motor.
  If the text is configured for this command, it is also displayed in brackets. For more informtaion, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the motor after interlocks or errors.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).
- "Monitoring time": Display of the remaining monitoring time.

### (4) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission":
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "starting"/"stopping" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection":
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Local stop": 1 = Stopping the motor in "local mode"
- "Local start": 1 = Starting the motor in "local mode"
- "Feedback run →": 1 = Motor has started and is running
- "Feedback stop" : 1 = Motor has stopped
- "Stop": 1 = Stop motor
- "Start": 1 = Start motor
- "Channel Start": Signal from the output channel block "Start"
- "Permission stop": 1 = Motor can not be stopped in manual (by operator) or automatic (by logic) mode

### (5) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more informtaion, see section Opening additional faceplates (Page 234).

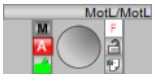
### (6) Resynchronization

Displays the Resynchronization state and Resynchronization Signal status based on feedback value.

## 8.2.8.4 Block icon for MotL

### Block symbols for MotL

A variety of block symbols are available with the following functions:



- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Motor state display

The block symbols from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 4 | |
|  | 5 | |
|  | 6 | |

The block symbols from template @TemplateAPLV7.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | Block symbol in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | 9 | |
|  | 10 | |
|  | - | Block symbol in "Out of service" mode (example with type 1 block symbol) |

Additional information on the block symbol and the control options in the block symbol is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Motor state display

The following motor states are shown here:

| Symbol | Meaning |
|---|---|
|  | Motor started (motor symbol changes) |
|  | The motor is running |
|  | Motor stopped (motor symbol changes) |
|  | Motor idle |
|  | Error at motor (monitoring error, motor protection) |
|  | Motor out of service |
|  | “No Cmd” State |

# 8.3 MotS - Motor (Small)

## 8.3.1 Description of MotS

### Object name (type + number)

Type + number: FB 1910

Family: Drives

### Area of application for MotS

The block is used for the following applications:

- Controlling motors

**Note**

This block is also available as a large block. A comparison of the MotL and MotS blocks is available in the section: MotL compared to MotS (Page 1369)

### How it works

The block is used to control motors. Various inputs are available for controlling the motor.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation

For a description of the individual parameters, see the section MotS I/Os (Page 1426).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |

| Status bit | Parameter |
|---|---|
| 4 | `OosLi.Value` |
| 5 | 0 = `ManAct.Value`<br>1 = `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | `LockAct.Value` |
| 8 | `Start.Value` |
| 9 | Motor is stopped |
| 10 | Not used |
| 11 | `MonStaErr.Value` |
| 12 | `MonDynErr.Value` |
| 13 | `BypProt` |
| 14 | Invalid signal status |
| 15 | Not used |
| 16 | 1 = `Intlock` is active |
| 17 - 18 | Not used |
| 19 | `Trip` |
| 20 - 22 | Not used |
| 23 | "Interlock" button is enabled |
| 24 | Reset request in automatic preview |
| 25 | Not used |
| 26 | Bypass information for display in block icon |
| 27 | Automatic preview for "starting" |
| 28 | Automatic preview for "stopping" |
| 29 | External error generated by FaultExt or external control system fault CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 30 - 31 | Not used |

## Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 - 18 | Not used |
| 19 | 1 = No impact of input signals on "local mode" when `LocalSetting` = 0, `LocalSetting` = 2 and OOS mode. |
| 20 | Motor is stopped |
| 21 | Motor is stopping |
| 22 | Motor is starting |
| 23 | Motor is running |
| 24 | Error in motor |
| 25 | 1 = Input parameter `StartChnST` is interconnected |
| 26 - 29 | Not used |

| Status bit | Parameter |
|---|---|
| 30 | Display for interlocks in block icon |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 - 11 | Not used |
| 12 | Hidden bypass signal in interlock |
| 13 | Not used |
| 14 | `Feature2.Bit2`: Separate bypass signal |
| 15 - 23 | Not used |
| 24 | Output command for "starting" the motor |
| 25 | Output command for "stopping" the motor |
| 26 | Show automatic preview in the standard view |
| 27 | Internal error |
| 28 | `GrpErr.Value` |
| 29 | Enable for "starting" the motor |
| 30 | Not used |
| 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 8 | Not used |
| 9 | `Trip` not connected |
| 10 | Do not connect `FbkOutRun` |
| 11 - 31 | Not used |

MotS functions (Page 1419)
MotS error handling (Page 1424)
MotS modes (Page 1418)

## 8.3.2 MotS modes

### MotS operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

**Note**

**"Local mode" for the block MotS**

In contrast to the "Large" blocks, it is only possible to perform settings in this block `LocalSetting` with 0 or 2. A "local operation" is accordingly possible only via the internal tracking of the feedback value.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Motor actions you can control in auto mode:

- "Start" (`StartAut` = 1)
- "Stop" (`StopAut` = 1)

**Note**

**Information about the "Small" block**

This "Small" block works with pushbutton operation. The automatic commands are therefore latching, in other words, `OpenAut`, `CloseAut` can be reset to 0 after the control is changed. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Motor actions you can control in "manual mode":

- "Start" (`StartMan` = 1)
- "Stop" (`StopMan` = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkRunOut.ST | 16#80 | 16#60 |
| Run.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |

## 8.3.3 MotS functions

### Functions of MotS

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can start the motor |
| 6 | Not used |
| 7 | 1 = Operator can reset the motor |
| 8 | 1 = Operator can define the monitoring time for startup |
| 9 | Not used |
| 10 | 1 = Operator can activate the monitoring time function (Bit 8) |
| 11 | 1 = Operator can enable functional simulation |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Button labels

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- `StartMan`
- `StopMan`

## Interlocks

This block provides the following interlocks:

- Interlock without reset (interlock)

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

## Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See MotS error handling (Page 1424).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `Trip`
- `MonDynErr`
- `MonStaErr`
- `FaultExt`

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `LocalLi.ST`
- `Trip.ST`
- `FbkRunOut.ST`
- `StartChn.ST`

- `StartAut.ST` (only if `Feature2.Bit10` = 1)
- `StopAut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (motor stop) in the "Automatic" mode:

- `StartAut.ST`
- `StopAut.ST`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Output signal as a static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |

| Bit | Function |
|---|---|
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

## 8.3.4 MotS error handling

### Error handling of MotS

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Control system fault (CSF)
- Invalid input signals

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers.

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not 0 or 2 |
| 42 | `LocalSetting` = 0 and `LocalLi` = 1 |
| 51 | `StartAut` = 1 and `StopAut` = 1, `AutModLi` = 1 and `ManModLi` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid input signals

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid input signals, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| Operating mode | Invalid input signals | Control reaction with `Feature2.Bit3` =1 |
|---|---|---|
| "Automatic mode" | `StartAut` = 1 and `StopAut` = 1 | Motor is stopping |
| "Manual mode" | `StopMan` = 1 and `StartMan` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.3.5 MotS messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Motor feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>Motor protection triggered |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 3).

### Instance-specific messages

You have the option to use two instance-specific messages for this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment.

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 - 10 | Reserved |

The associated values 4 ... 5 are allocated to the parameters ExtVa104 ... ExtVa105 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 8.3.6 MotS I/Os

I/Os of MotS

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkRun | Feedback for starting is present:<br>1 = Start<br>0 = Stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Feature | I/O for additional functions (Page 1419) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1419) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Intlock | 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared<br>1 = Interlock not activated | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is active | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonTiDynamic* | Monitoring time for feedback errors after operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1419) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimOn | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| StartAut* | 1 = Starting the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StartChnST | Signal status of output channel Start<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| StartMan* | 1 = Starting the motor in "manual mode" | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stopping the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stopping the motor in "manual mode" | BOOL | 0 |
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MotS error handling (Page 1424) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkRunOut | Feedback for starting is present:<br>1 = Start<br>0 = Stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock or Trip is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynErr | 1 = Feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |

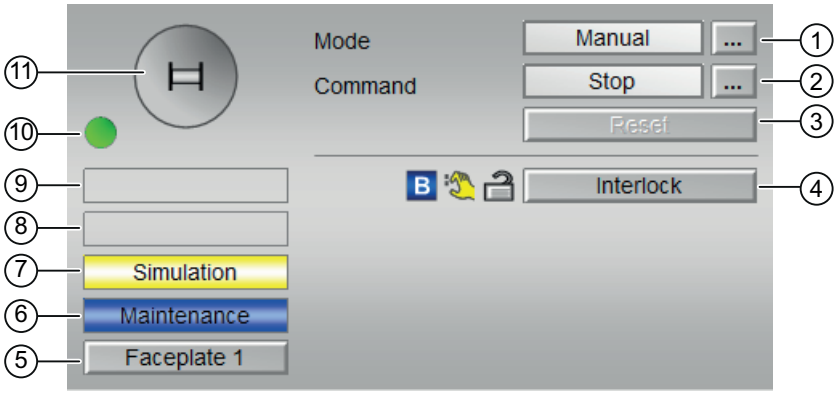
MotS error handling (Page 1424)

## 8.3.8 Operator control and monitoring

### 8.3.8.1 MotS views

**Views of the MotS block**



The block MotS provides the following views:

- MotS standard view (Page 1433)
- Alarm view (Page 336)
- Trend view (Page 341)
- Parameter view for motors and valves (Page 320)
- MotS preview (Page 1436)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MotS (Page 1438)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.3.8.2 MotS standard view

#### MotSstandard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Starting and stopping the motor

This area shows you the default operating state for the motor. The following states can be shown and executed here:

- "Start"
- "Stop"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operator control and display area for the interlock function of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock function of the block. You can find additional information on this in the section Interlocks (Page 107).

The following is displayed in addition to the button:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (6) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in the section Simulating signals (Page 64).

### (8) Display area for block states

This area provides additional information on the operating state of the block (from high to low according to priority):

- "Motor protection"
- "External error"
- "Status error"
- "Control error"
- "Internal error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (subsection "Invalid input signals") and Motor protection function (Page 106).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

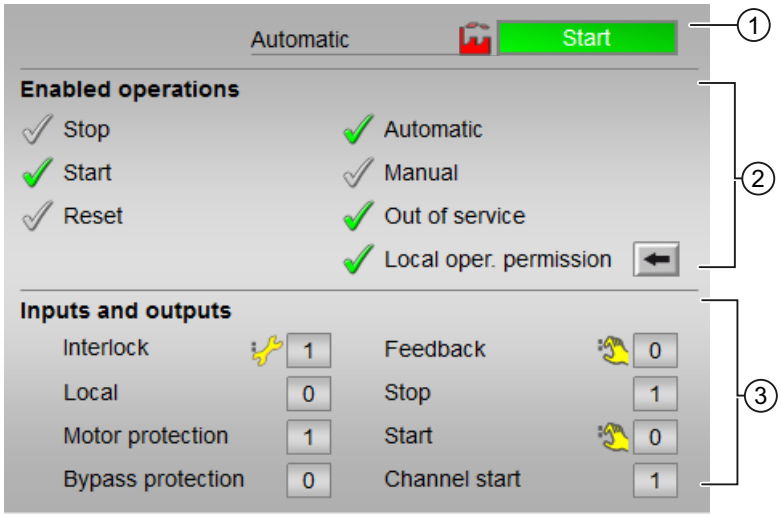
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer: Reset of errors during Request 0/1 (Page 382)

### (10) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the motor would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (11) Status display of the motor



The current status of the motor is graphically displayed here:

- Green: Motor is running
- Gray: Motor idle
- Red: A fault has occurred

You can find additional information on this in the section Block icon for MotS (Page 1438).

### 8.3.8.3 MotS preview

#### Preview of MotS

#### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `StartAut`
- `StopAut`

#### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Stop": You can stop the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Start": You can start the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the motor after interlocks or errors.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section sedtion Operator control permissions (Page 285).

### (3) Displaying current control signals

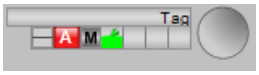
This area shows the most important parameters for this block with the current selection:

- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Feedback →": 1 = Motor has started and is running
- "Stop": 1 = Stop motor
- "Start": 1 = Start motor
- "Channel Start": Signal from the output channel block for "Start"

### 8.3.8.4 Block icon for MotS

#### Block symbols for MotS



A variety of block symbols are available with the following functions:

- Process tag type
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Motor state display

The block symbols from template @TemplateAPLV9.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |

The block symbols from template @TemplateAPLV7.PDL:

| Symbols | Selection of the block symbol in CFC | Special features |
|---|---|---|
|  | 1 | Block symbol in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | - | Block symbol in "Out of service" mode (example with type 1 block symbol) |

Additional information on the block symbol and the control options in the block symbol is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Motor state display

The following motor states are shown here:

| Symbol | Meaning |
|---|---|
|  | Motor started (motor symbol changes) |
| | The motor is running |
| | Motor stopped (motor symbol changes) |
| | Motor idle |
|  | Error at motor (monitoring error, motor protection) |

# 8.4 MotRevL - Reversible motor

## 8.4.1 Description of MotRevL

### Object name (type + number) and family

Type + number: FB 1851

Family: Drives

### Area of application for MotRevL

The block is used for the following applications:

- Control of reversible motors

### How it works

The block is used to control reversible motors. Various inputs are available for controlling the motor.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the MotRevL block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- Reversing motor (MotorReversible) (Page 2861)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section MotRevL I/Os (Page 1463).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |

| Status bit | Parameter |
|---|---|
| 4 | OosLi.Value |
| 5 | 0 = ManAct.Value<br>1 = AutoAct.Value |
| 6 | LocalAct.Value |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 8 | Fwd.Value |
| 9 | Motor is stopped |
| 10 | Rev.Value |
| 11 | MonStaErr.Value |
| 12 | MonDynErr.Value |
| 13 | BypProt |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = Intlock is active |
| 17 | 1 = Permit is active |
| 18 | 1 = Protect is active |
| 19 | Trip.Value |
| 20 | Display „Forced forward“ |
| 21 | Display „Forced stop“ |
| 22 | Display „Forced reverse“ |
| 23 | "Interlock" button is enabled |
| 24 | Reset request in automatic preview |
| 25 | WarnAct.Value or<br>IdleTime active |
| 26 | Bypass information for display in block icon |
| 27 | Automatic preview for forward mode |
| 28 | Automatic preview for "stopping" |
| 29 | Automatic preview for reverse mode |
| 30 | "Permission" button is enabled |
| 31 | "Protection" button is enabled |

### Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | AV_AH_Act.Value |
| 2 | AV_WH_Act.Value |
| 3 | AV_TH_Act.Value |
| 4 | AV_TL_Act.Value |
| 5 | AV_WL_Act.Value |
| 6 | AV_AL_Act.Value |

| Status bit | Parameter |
|---|---|
| 7 | AV_AH_En OR Feature.Bit23 |
| 8 | AV_WH_En OR Feature.Bit23 |
| 9 | AV_TH_En OR Feature.Bit23 |
| 10 | AV_TL_En OR Feature.Bit23 |
| 11 | AV_WL_En OR Feature.Bit23 |
| 12 | AV_AL_En OR Feature.Bit23 |
| 13 | AV_AH_MsgEn |
| 14 | AV_WH_MsgEn |
| 15 | AV_TH_MsgEn |
| 16 | AV_TL_MsgEn |
| 17 | AV_WL_MsgEn |
| 18 | AV_AL_MsgEn |
| 19 | 1 = No impact of input signals on "local mode" with LocalSetting = 0, LocalSetting = 2, LocalSetting = 4 and OOS mode. |
| 20 | Motor is stopped |
| 21 | Motor stops in forward mode |
| 22 | Motor stops in reverse mode |
| 23 | Motor starts in forward mode |
| 24 | Motor runs in forward mode |
| 25 | Motor starts in reverse mode |
| 26 | Motor runs in reverse mode |
| 27 | Error when stopping motor |
| 28 | Error in forward mode of motor |
| 29 | Error in reverse mode of motor |
| 30 | Display for interlocks in block icon |
| 31 | MS_RelOp |

### Status word allocation for Status3 parameter

| Status bit | Parameter |
|---|---|
| 0 | Delay of the AV_AH_Lim message |
| 1 | Delay of the AV_WH_Lim message |
| 2 | Delay of the AV_TH_Lim message |
| 3 | Delay of the AV_TL_Lim message |
| 4 | Delay of the AV_WL_Lim message |
| 5 | Delay of the AV_AL_Lim message |
| 6 | Collection of message delays |
| 7 | Resynchronization preview for Forward |
| 8 | Resynchronization preview for Reverse |
| 9 | Resynchronization preview for Stop |
| 10 | Resynchronization: Display preview |
| 11 | Resynchronization: Display small preview symbol in standard view |

| Status bit | Parameter |
|---|---|
| 12 | 1 = "Permission stop" button is enabled |
| 13 | 1 = Permission stop is active |
| 14 | Resynchronization with state “No Cmd” |
| 15 | Current monitoring time is visible |
| 16 | `MonDynStopErr.Value` |
| 17 | Not used |
| 18 | `SimLiOp.Value` |
| 19 | 1 = Enable for rapid stop (`Feature` Bit Enabling rapid stop via faceplate (Page 179)) |
| 20 | 1 = Input parameter `FwdChnST` is interconnected |
| 21 | 1 = Input parameter `RevChnST` is interconnected |
| 22 | Not used |
| 23 | Command for rapid stop |
| 24 | Command for starting → the motor |
| 25 | Command for starting ← the motor |
| 26 | Show automatic preview in the standard view |
| 27 | Internal error |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal `3` of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | `AV` not connected |
| 9 | Motor protection display (`Trip.Status` ≠ 16#FF) |
| 10 | 1 = Input parameter `FbkFwd` is connected |
| 11 | 1 = Input parameter `FbkRev` is connected |
| 12 - 19 | Effective signal 1...8 of the message block connected via `EventTs2In` |
| 20 | 1 = Input parameter `FbkStop` is connected |
| 21 | Not used |
| 22 | External error generated by FaultExt or external control system fault from CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 23 | Hidden bypass signal in Permit |

| Status bit | Parameter |
|---|---|
| 24 | Hidden bypass signal in interlock |
| 25 | Hidden bypass signal in Protect |
| 26 | `Feature2.Bit2`: Separate bypass signal |
| 27 | `Feature2.Bit16`: Separate interlock for each direction or position |
| 28 | Hidden bypass signal in Permit Reverse |
| 29 | Hidden bypass signal in Interlock Reverse |
| 30 | Hidden bypass signal in Protect Reverse |
| 31 | Separate monitoring of shutdown of the motor (`Feature.Bit13`) |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9...16 of the message block connected via `EventTsIn` |
| 8 - 15 | Effective signal 9...16 of the message block connected via `EventTs2In` |
| 16 | The permission button for "Forward" is enabled |
| 17 | The permission button for "Reverse" is enabled |
| 18 | The interlock button for "Forward" is enabled |
| 19 | The Interlock button for "Reverse" is enabled |
| 20 | The protection button "Forward" is enabled |
| 21 | The protection button "Reverse" is enabled |
| 22 | 1 = Permission button "Reverse" is active |
| 23 | 1 = Interlock button "Reverse" is active |
| 24 | 1 = Protection button "Reverse" is active |
| 25 - 31 | Not used |
| 29 | 1= Suppressed messages |
| 30 - 31 | Not used |

### See also

MotRevL functions (Page 1447)
MotRevL messaging (Page 1461)
MotRevL block diagram (Page 1474)
MotRevL error handling (Page 1457)
MotRevL modes (Page 1445)

## 8.4.2 MotRevL modes

### MotRevL operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Motor actions you can control in local mode:

- "Starting in forward" (`FwdLocal` = 1)
- "Starting in reverse" (`RevLocal` = 1)
- "Stopping" (`StopLocal` = 1)

A motor operated in "local mode" is controlled either by "local" signals or by the feedback signals (input parameters `FbkFwd` = 1, `FbkRev` = 1 or `FbkStop` =1) . Configuration takes place via the input parameter `LocalSetting`.

`LocalSetting` =2,4: The control outputs are tracked to the feedbacks.

All three feedbacks are available and plausible means that always only one feedback is active. The corresponding control output is tracked:

```
Fwd = FbkFwd,
Rev = FbkRev,
StopCtrl = FbkStop.
```

When all feedbacks are false then the drive is between of two positions. In this case no monitoring is started. When two feedbacks are active, then they are not plausible. In this case the static monitoring counter starts. In both cases “all feedbacks are reset” or “not plausible feedbacks” with `Feature2Bit21` =1 all the control outputs are set to false (No command state) else control outputs are hold.

If two feedbacks are available then they are always plausible besides they are both active.

| `NoFbkStop =1` (default) | `NoFbkFwd =1` | `NoFbkRev =1` |
|---|---|---|
| `Fwd = FbkFwd,`<br>`Rev = FbkRev,`<br>`StopCtrl = NOT FbkFwd AND NOT FbkRev` | `Fwd = NOT FbkStop AND NOT FbkRev`<br>`Rev = FbkRev,`<br>`StopCtrl = FbkStop` | `Fwd = FbkFwd,`<br>`Rev = NOT FbkStop AND NOT FbkFwd`<br>`StopCtrl = FbkStop` |

When they are not plausible the control outputs will be hold.

When only one feedback is available the concerned control output is tracked. The other control outputs are hold if the available feedback is false.

| `NoFbkStop =0` | `NoFbkFwd =0` | `NoFbkRev =0` |
|---|---|---|
| `StopCtrl = FbkStop,` `Fwd,Rev` are hold if `FbkStop =0` | `Fwd = FbkFwd,` `StopCtrl,Rev` are hold if `FbkFwd =0` | `Rev = FbkRev,` `StopCtrl,Fwd` are hold if `FbkRev =0` |

When all feedbacks are not available the control outputs will be hold.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Motor actions you can control in auto mode:

- "Starting in forward" (`FwdAut` = 1)
- "Starting in reverse" (`RevAut` = 1)
- "Stopping" (`StopAut` = 1)

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Motor actions you can control in "manual mode":

- "Starting in forward" (`FwdMan` = 1)
- "Starting in reverse" (`RevMan` = 1)
- "Stopping" (`StopMan` = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkFwdOut.ST | 16#80 | 16#60 |
| FbkRevOut.ST | 16#80 | 16#60 |
| RunFwd.ST | 16#80 | 16#60 |
| RunRev.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |
| AV_Out.ST | 16#80 | 16#60 |

## 8.4.3 MotRevL functions

### Functions of MotRevL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can start the motor in forward |
| 6 | 1 = Operator can start the motor in reverse |
| 7 | 1 = Operator can reset the motor |
| 8 | 1 = Operator can define or change the monitoring time for startup |
| 9 | 1 = Operator can define the monitoring time for the status |
| 10 | 1 = Operator can enable the monitoring time function (Bit 8 - 9) |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the high limit (`AV`) for the alarm |
| 14 | 1 = Operator can change the high limit (`AV`) for the warning |
| 15 | 1 = Operator can change the high limit (`AV`) for the tolerance |
| 16 | 1 = Operator can change the limit (`AV`) for hysteresis |

| Bit | Function |
|---|---|
| 17 | 1 = Operator can lower the limit (AV) for the alarm |
| 18 | 1 = Operator can lower the limit (AV) for the warning |
| 19 | 1 = Operator can lower the limit (AV) for the tolerance |
| 20 | 1 = Operator can activate / deactivate messages via AV_AH_MsgEn |
| 21 | 1 = Operator can activate / deactivate messages via AV_WH_MsgEn |
| 22 | 1 = Operator can activate / deactivate messages via AV_TH_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via AV_TL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via AV_WL_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via AV_AL_MsgEn |
| 26 | 1 =Operator can change the simulation value SimAV |
| 27 - 29 | Not used |
| 30 | 1 = Operator can define the monitoring time for stopping |
| 31 | 1 = Operator can execute the rapid stop |

The block has the following permissions for the OS1Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Restart lock after changing direction of rotation or switching off the motor

Use the input parameter IdleTime to enter a restart lock for changing the direction of rotation or restarting the motor. Use the Feature Bit Enabling direct changeover between forward and reverse (Page 156) to define how the change is to take place. When the "Stop" command is given, the motor goes immediately into "Stop" mode, and IdleTime starts after the feedback (FbkFwd and FbkRev = 0) is given. The motor cannot be started again until the IdleTime has expired.

The IdleTime parameter can be set independently of the MonTiDynamic parameter.

### Limit monitoring of an additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104). It is performed via the input parameter AV_Hyst.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Interlocks

This block provides the following interlocks:

**`Feature2.Bit16` = 0:**

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")
- Permission for stop ("Permission stop")

**`Feature2.Bit16` = 1:**

- Activation enable forward
- Activation enable reverse
- Interlock forward without reset ("Interlock forward")
- Interlock reverse without reset ("Interlock reverse")
- Interlock forward with reset ("Protection interlock forward")
- Interlock reverse with reset ("Protection interlock reverse")

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

### Rapid stop for motors

This block provides the standard function Rapid stop for motors (Page 115).

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See MotRevL error handling (Page 1457).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `Trip`
- `MonDynErr`
- `MonStaErr`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `FbkFwdOut.ST`
- `FbkRevOut.ST`
- `LocalLi.ST`
- `FwdLocal.ST`
- `StopLocal.ST`
- `RevLocal.ST`
- `Trip.ST`
- `AV_Out.ST`
- `FwdChn.ST`
- `RevChn.ST`
- `FwdAut.ST` (only if `Feature2.Bit10` = 1)

- RevAut.ST (only if Feature2.Bit10 = 1)
- StopAut.ST (only if Feature2.Bit10 = 1)

### Considering bad quality of automatic commands or external values

If the Feature2 bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (motor stop) in the "Automatic" mode:

- FwdAut.ST
- RevAut.ST
- StopAut.ST

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).

The following states can be enforced:

- "Start in forward" (FwdForce)
- "Start in reverse" (RevForce)
- "Stop" (StopForce)

**Note**

The Feature Bit Enabling direct changeover between forward and reverse (Page 156) for this block has no function with forced operating states. The motor can always be reversed directly.

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

### Disabling feedback

This block provides the standard function for Disabling feedback for valve and motors (Page 106).

Feedback monitoring can be deactivated separately for each feedback with NoFbkFwd or NoFbkRev or NoFbkStop as required.

The output signals of feedback are tracked by the control and the other available feedbacks:

| NoFbkFwd | NoFbkRev | NoFbkStop | Comment |
|---|---|---|---|
| 0 | 0 | 1 | **Default:**<br>`FbkFwdOut = FbkFwd;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = StopCtrl AND NOT FbkFwd AND NOT FbkRev;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkFwdOut = FbkFwd;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = NOT FbkFwd AND NOT FbkRev;` |
| 1 | 0 | 1 | `FbkFwdOut = Fwd AND NOT FbkRev;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = StopCtrl AND NOT FbkRev;` |
| 0 | 1 | 1 | `FbkFwdOut = FbkFwd;`<br>`FbkRevOut = Rev AND NOT FbkFwd;`<br>`FbkStopOut = StopCtrl AND NOT FbkFwd;` |
| 1 | 1 | 1 | `FbkFwdOut = Fwd;`<br>`FbkRevOut = Rev;`<br>`FbkStopOut = StopCtrl;` |
| 1 | 0 | 0 | `FbkFwdOut = FbkFwd;`<br>`FbkRevOut = Rev AND NOT FbkFwd AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkFwdOut = FbkFwd;`<br>`FbkRevOut = NOT FbkFwd AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;` |

| NoFbkFwd | NoFbkRev | NoFbkStop | Comment |
|---|---|---|---|
| 0 | 1 | 0 | FbkFwdOut = FbkFwd;<br>FbkRevOut = Rev AND NOT FbkFwd AND NOT FbkStop;<br>FbkStopOut = FbkStop;<br>**Local mode with LocalSetting =2/4:**<br>FbkFwdOut = FbkFwd;<br>FbkRevOut = NOT FbkFwd AND NOT FbkStop;<br>FbkStopOut = FbkStop |
| 0 | 0 | 0 | FbkFwdOut = FbkFwd;<br>FbkRevOut = FbkRev;<br>FbkStopOut = FbkStop; |
| 1 | 1 | 0 | FbkFwdOut = Fwd AND NOT FbkStop;<br>FbkRevOut = Rev AND NOT FbkStop;<br>FbkStopOut = FbkStop; |

When all feedbacks are not available the position is hold after a switch to local mode with `LocalSetting` =2/4.
When 2 of 3 feedbacks are not available the position is hold after a switch to local mode with `LocalSetting` =2/4.

### Using StopCtrl with mode "No Cmd"

This block provides the standard function Control with output StopCtrl and state “No Cmd” (Page 214)

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56).

You can generate warning signals when, for example, motors are started. Warning signals can be generated in the following modes:

- Manual mode (Page 82) (`WarnTiMan` input parameter)
- Automatic mode (Page 82) (`WarnTiAut` input parameter)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a motor is started, then this is displayed at the output parameter with `WarnAct` = 1. The motor then starts after the set warning time has expired and `WarnAct` then goes back to 0.

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Additional value (`SimAV`, `SimAV_Li`)

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the controls are tracked as follow:

**NoFbkFwd =0, NoFbkRev =0, NoFbkStop =1 (default):**

Fwd := FbkFwd;

Rev := FbkRev;

StopCtrl := NOT FbkFwd AND NOT FbkRev;

In case if there are no plausible feedback positions (FbkFwd =1, FbkRev =1) the controls are not changed.

**NoFbkFwd =0, NoFbkRev =0, NoFbkStop =0:**

Plausible feedback positions (only one feedback signal is active) are tracked as control position.

Fwd := FbkFwd;

Rev := FbkRev;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (two or three feedback signals are active) the control position depends on Feature2 Bit21.

- Feature2 Bit21 =0 (default): Control position is not changed.
- Feature2 Bit21 =1: Control position becomes "No Cmd" Fwd := 0; Rev := 0; StopCtrl := 0;

**NoFbkFwd =0, NoFbkRev =1, NoFbkStop =0:**

Fwd := FbkFwd AND NOT FbkStop;

Rev := NOT FbkFwd AND NOT FbkStop;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (FbkFwd =1, FbkStop =1) the controls are not changed.

**NoFbkFwd =1, NoFbkRev =0, NoFbkStop =0:**

Fwd := NOT FbkRev AND NOT FbkStop;

Rev := FbkRev AND NOT FbkStop;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (FbkRev =1, FbkStop =1) the controls are not changed.

With other combinations of **NoFbkFwd**, **NoFbkRev**, **NoFbkStop** the controls are not changed.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 7 | Enabling direct changeover between forward and reverse (Page 156) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 13 | Separate monitoring time for stopping the motor (Page 180) |
| 14 | Enabling rapid stop via faceplate (Page 179) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |

| Bit | Function |
|---|---|
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In pushbutton operation (Bit 4 = 0) the automatic commands in "automatic" mode are latching; in other words, `FwdAut`, `RevAut`, `StopAut` can be reset to 0 after changing the control. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

In switching mode (Bit 4 = 1), control is selected with the static signals `FwdAut`, `RevAut`. If `FwdAut`, `RevAut` inputs are not set, the motor is stopped. Control via `StopAut` is not needed. If the "Activate command reset for control" function (Bit 3 = 1) is also enabled, the inputs `FwdAut`, `RevAut` are reset to the neutral position after evaluation in the block.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 16 | Separate interlock for each direction, position, or speed (Page 180) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |

| Bit | Function |
|---|---|
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 21 | Control with output StopCtrl and state "No Cmd" (Page 214) |

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `FwdMan`
- `RevMan`
- `StopMan`
- `RapidStp`

## 8.4.4 MotRevL error handling

### Error handling of MotRevL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Invalid or not plausible input commands
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not within the approved limit of 0 to 4. |
| 42 | `LocalSetting` = 0 or `LocalSetting` = 3 or `LocalSetting` = 4 and `LocalLi` = 1 |
| 51 | `FwdLocal` = 1 and `StopLocal` = 1 and `Feature2.Bit4` = 0<br>`RevLocal` = 1 and `StopLocal` = 1 and `Feature2.Bit4` = 0<br>`FwdLocal` = 1 and `RevLocal` = 1<br>`FwdLocal` = 1 and `Rev` = 1 and `Feature.Bit7` = 1<br>`RevLocal` = 1 and `Fwd` = 1 and `Feature.Bit7` = 1<br>`FwdAut` = 1 and `StopAut` = 1 and `Feature.Bit4` = 0<br>`RevAut` = 1 and `StopAut` = 1 and `Feature.Bit4` = 0<br>`FwdAut` = 1 and `RevAut` = 1<br>`FwdAut` = 1 and `Rev` = 1 and `Feature.Bit7` = 1<br>`RevAut` = 1 and `Fwd` = 1 and `Feature.Bit7` = 1<br>`AutModLi` = 1 and `ManModLi` = 1<br>`FwdForce` = 1 and `StopForce` = 1<br>`RevForce` = 1 and `StopForce` = 1<br>`FwdForce` = 1 and `RevForce` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 or 4 and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| Operating mode | Invalid or not plausible input commands | Control reaction with `Feature2.Bit3` =1 |
|---|---|---|

| | | |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | Pushbutton operation for local mode (`Feature2.Bit4` = 0):<br>`FwdLocal` = 1 and `RevLocal` = 1 or<br>`FwdLocal` = 1 and `StopLocal` = 1 or<br>`StopLocal` = 1 and `RevLocal` = 1<br>Switching mode (`Feature2.Bit4` = 1):<br>`FwdLocal` = 1 and `RevLocal` = 1<br>Enabling direct changeover between forward and reverse (`Feature.Bit7` = 1):<br>`FwdLocal` = 1 and `Rev` = 1 or<br>`RevLocal` = 1 and `Fwd` = 1 | Motor is stopped |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `FwdForce` = 1 and `RevForce` = 1 or<br>`FwdForce` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `RevForce` = 1 | |
| Forcing and no "local mode" | `FwdForce` = 1 and `RevForce` = 1 or<br>`FwdForce` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `RevForce` = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0):<br>`FwdAut` = 1 and `RevAut` = 1 or<br>`FwdAut` = 1 and `StopAut` = 1 or<br>`StopAut` = 1 and `RevAut` = 1<br>Switching mode (`Feature.Bit4` = 1):<br>`FwdAut` = 1 and `RevAut` = 1<br>Enabling direct changeover between forward and reverse (`Feature.Bit7` = 1):<br>`FwdAut` = 1 and `Rev` = 1 or<br>`RevAut` = 1 and `Fwd` = 1 | |
| "Manual mode" and no forcing | `FwdMan` = 1 and `RevMan` = 1 or<br>`FwdMan` = 1 and `StopMan` = 1 or<br>`StopMan` = 1 and `RevMan` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.4.5 MotRevL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Motor feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>Motor protection triggered |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId1`, SIG 3).

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | ExtVa108 |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters ExtVa104 ... ExtVa108 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 8.4.6 MotRevL I/Os

I/Os of MotRevL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1 = "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| AV | Input additional analog value, to be connected to AV_Out of the AV block | ANY | |
| AV_AH_Lim | Limit high alarm | REAL | 95.0 |
| AV_AL_Lim | Limit low alarm | REAL | 5.0 |
| AV_Hyst | Hysteresis for alarm, warning and tolerance limits | REAL | 1.0 |
| AV_TH_Lim | Limit high tolerance | REAL | 85.0 |
| AV_TL_Lim | Limit low tolerance | REAL | 15.0 |
| AV_WH_Lim | Limit high warning | REAL | 90.0 |
| AV_WL_Lim | Limit low warning | REAL | 10.0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| EventTs2In | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTs2In input parameter serves to interconnect the EventTsOut output parameter of the EventTs,Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkFwd | 1= Motor feedback running forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkRev | 1= Motor feedback running reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkStop | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1447)<br>1 = Separate monitoring time for stopping the motor | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 13: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1447) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FwdAut* | 1 = Activating forward mode of motor in automatic mode | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FwdChnST | Signal status of output channel Fwd<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FwdForce | 1 = Forcing activation of motor forward mode | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FwdLocal | 1 = Activation of forward motor operation in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FwdMan* | 1 = Activation of forward motor operation in "manual mode" | BOOL | 0 |
| IdleTime* | Wait time for change of direction or restart in [s] | REAL | 5.0 |
| Intlock | 0 = Interlock / interlock **Motor Forward** is activated Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock / interlock **Motor Forward** is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Intl_En | 1 = Interlock / **Interlock Motor Forward** (interlock, Intlock parameter) is activated | BOOL | 1 |
| IntlRev | 0 = Interlock Motor Reverse is activated. Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock Motor Reverse is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| IntlRevEn | 1 = Interlock Motor Reverse (interlock, IntlRev parameter) is activated | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Characteristics of Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors  Motors: Stop is the neutral position | BOOL | 1 |
| MonTiDynamic* | Monitoring time for feedback errors  or feedback start error after successful operation in [s] | REAL | 3.0 |
| MonTiDyStop* | Monitoring time for feedback stop errors after successful operation in [s] | REAL | 3.0 |
| MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | 1 = Release for maintenance via OS operator | BOOL | 0 |
| NoFbkFwd | 1= Motor Feedback running forward not present | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| NoFbkRev | 1= Motor Feedback running reverse not present | BOOL | 0 |
| NoFbkStop | 1= Motor feedback stopped not present | BOOL | 1 |
| `Occupied` | 1 = In use by a batch | BOOL | 0 |
| `OosLi` | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `OosOp*` | 1 = "Out of service", via OS operator | BOOL | 0 |
| `OpSt_In` | Input parameter for local operator authorization, connected with the `Out` output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| `OS_Perm` | I/O for operator permissions (Page 1447)<br><br>1 = Operator can set or change the monitoring time for "Control: Start"<br><br>1 = Operator can set or change the monitoring time for "Control: Stop" | STRUCT<br>• Bit 0: BOOL<br>• Bit 8: BOOL<br>• Bit 20: BOOL<br>• Bit 30: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| `OS1Perm` | I/O for operator permissions (Page 1447) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| `Permit` | 1 = Activation enable / **Activation enable Motor Forward**<br>0 = No activation enable for motor/**Motor Forward** | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| `Perm_En` | 1 = Activation enable / **(activation enable Motor Forward** (enable, Permit parameter)is activated | BOOL | 1 |
| `PermRev` | 1 = Activation enable Motor Reverse<br>0 = No activation enable Motor Reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermitSafePos | 1=Motor stop is allowed | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | |
| PermSf_En | 1=Permit stop enabled | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermRevEn | 1 = Activation enable Motor Reverse(enable, PermRev parameter) is activated | BOOL | 1 |
| Protect | 0 = Protective interlock / **protective interlock Motor Forward** is activated. Once the interlock condition has cleared, the block must be reset<br>1 = Protective interlock / **protective interlock Motor Forward** is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Prot_En | 1 = Protective interlock / **protective interlock Motor Forward** (protection, Protect parameter) is activated | BOOL | 1 |
| ProtRev | 0 = Protective interlock Motor Reverse is activated. Once the interlock condition has cleared, the block must be reset<br>1 = Protective interlock Motor Reverse is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| ProtRevEN | 1 = Protective interlock Motor Reverse (protection, ProtRev parameter) is activated | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RapidStp* | Rapid stop for the motor:<br>0 = Motor On<br>1 = Motor Off | BOOL | 0 |
| RevAut* | 1 = Activation of reverse motor operation in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RevChnST | Signal status of output channel Rev<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| RevForce | 1 = Force activation of reverse motor operation | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RevLocal | 1 = Activation of reverse motor operation in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RevMan* | 1 = Activation of reverse motor operation in "manual mode" | BOOL | 0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimAV* | Additional value used for SimOn = 1 | REAL | 0.0 |
| SimAV_Li | Additional analog value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stop the motor in automatic mode | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopForce | 1 = Force motor stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopLocal | 1 = Stopping the motor in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stopping the motor in "manual mode" | BOOL | 0 |
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| WarnTiAut* | Prewarning of motor start in automatic mode in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan* | Prewarning of motor start in manual mode in [s] | REAL | 0.0 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AV_OpScale | Limit for scale in AV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| AV_Out | Output additional analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Unit | Unit of measure for additional analog value | INT | 0 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CurrMon | Remaining monitoring time [s] | DINT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MotRevL error handling (Page 1457) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkFwdOut | 1= Motor feedback running forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkRevOut | 1= Motor feedback running reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkStopOut | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Fwd | 1 = Control of motor forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlRevOut | IntlRev as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit, Protect) or Trip is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynErr | 1 = Feedback error or feedback start error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonDynStopErr | 1 = Feedback stop error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | WORD | 16#FFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| PermRevOut | PermRev as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtRevOut | ProtRev as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Fwd | 1 = Pulse signal for starting the motor in forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rev | 1 = Pulse signal for starting the motor in reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Stop | 0 = Pulse signal for stopping the motor | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| R_StpAct | 1 = Rapid stop of the motor is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Rev | 1 = Control of motor: Reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RunFwd | 1 = Motor is running forwards | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RunRev | 1 = Motor is running in reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word 1 (Page 1440) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1440) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1440) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1440) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1440) | DWORD | 16#00000000 |
| Stop | 1 = Motor stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopCtrl | Control output to Stop the motor (go to Safe position) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| TripOut | Trip as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |
| WarnAct | 1 = Prewarning for motor start active (parameters WarnTiAut and WarnTiMan) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

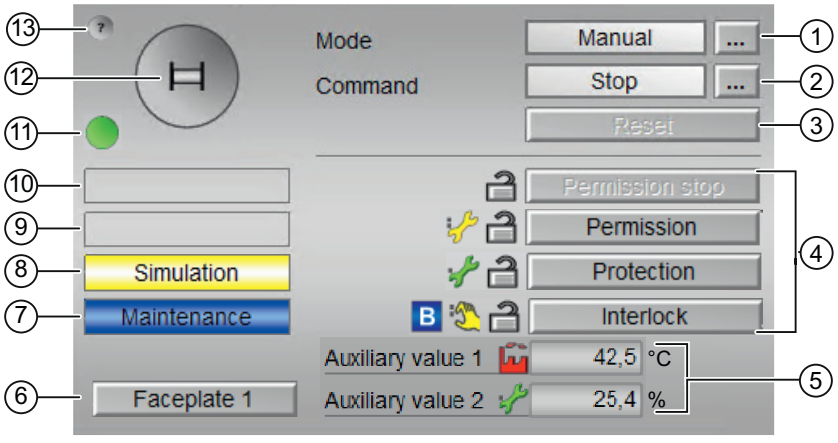
## 8.4.8 Operator control and monitoring

### 8.4.8.1 MotRevL views

#### Views of the MotRevL block



The block MotRevL provides the following views:

- MotRevL standard view (Page 1475)
- Alarm view (Page 336)
- Limit view of motors (Page 328)
- Trend view (Page 341)
- Parameter view for motors and valves (Page 320)
- MotRevL preview (Page 1479)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MotRevL (Page 1485)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.4.8.2 MotRevL standard view

#### MotRevL standard view

### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

See also the section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Starting and stopping the motor

This area shows you the default operating state for the motor. The following states can be shown and executed here:

- "Start→ "
- "Start ←"
- "Stop"
- "Rapid stop"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (6) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Motor protection"
- "External error"
- "Status error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced stop"
- "Forced start →"
- "Forced start ←"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (11) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the motor would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (12) Status display of the motor

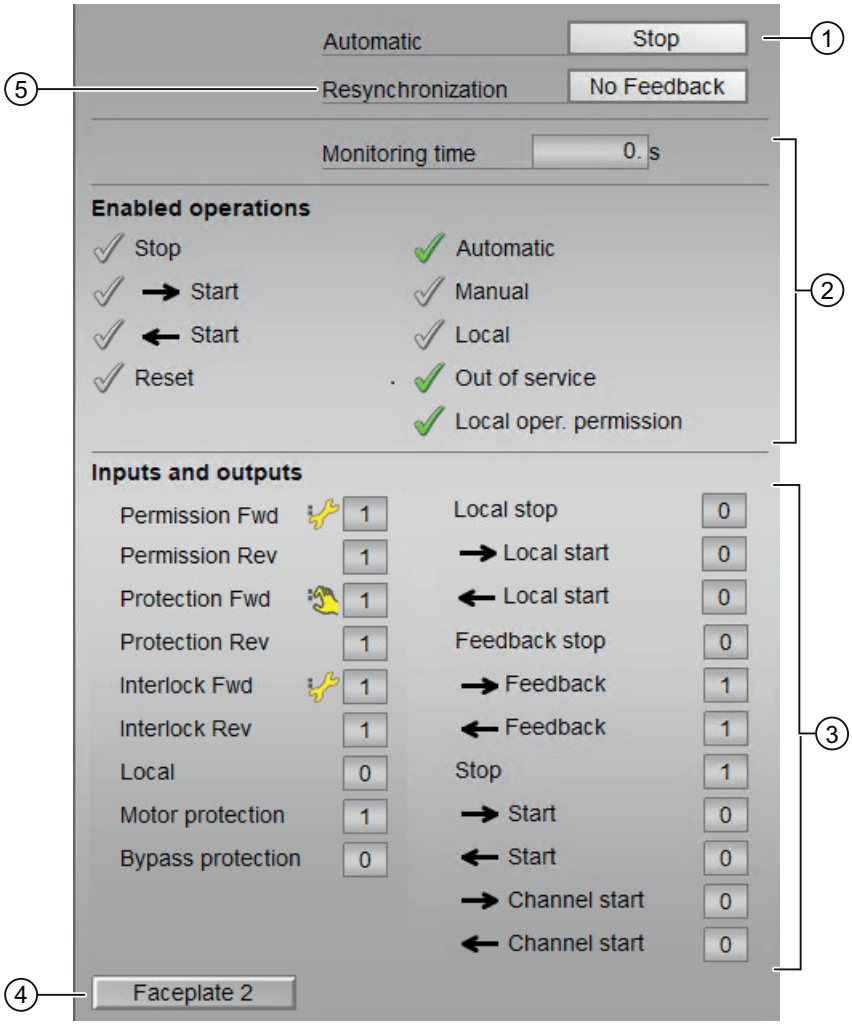
The current status of the motor is graphically displayed here.

You can find more information about this in section Block icon for MotRevL (Page 1485).

### (13) Mini preview for Resynchronization

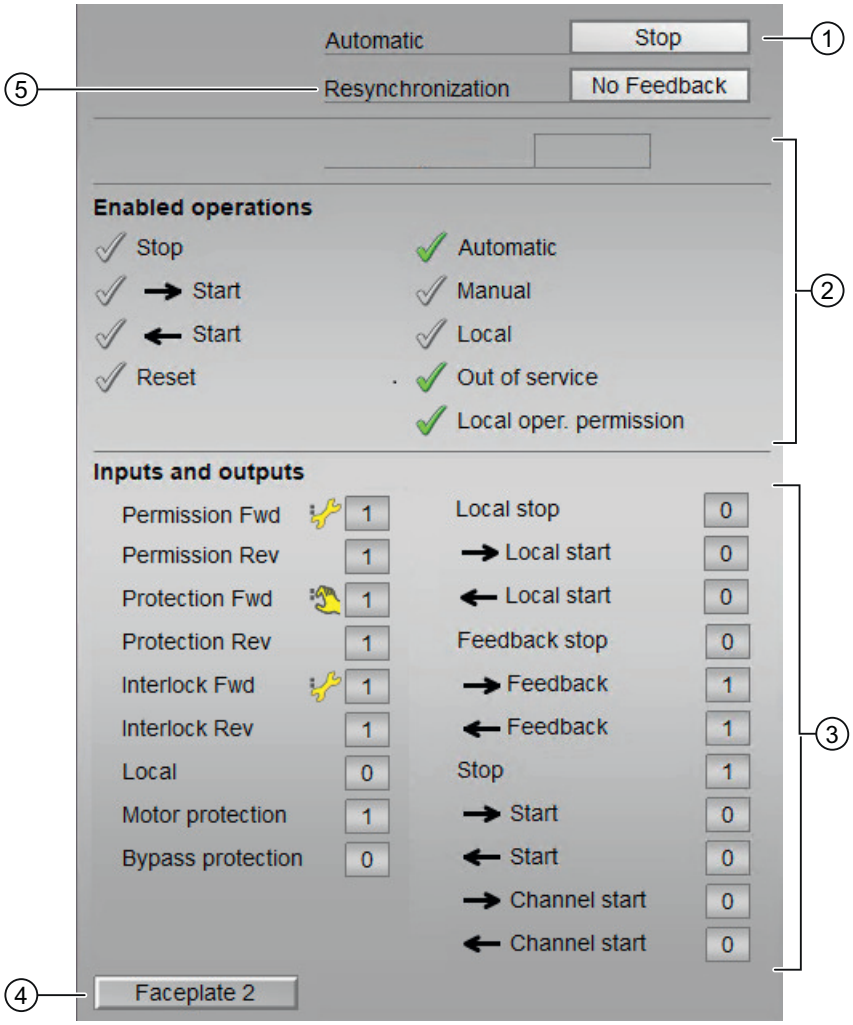
Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:



- Fwd
- Rev
- Stop
- No Cmd

**Note**



Mini preview for resynch is visible only if resynchronization command is different to control output value.

### 8.4.8.3 MotRevL preview

**Preview of MotRevL**

Display of the current monitoring time is visible.

Display of the current monitoring time is not visible.

### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `FwdAut`
- `RevAut`
- `StopAut`

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Stop": You can stop the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Start →": You can start the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Start ←": You can start the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the motor after interlocks or errors.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.

- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. For more information, see section Operator control permissions (Page 285).
- "Monitoring time": Display of the remaining monitoring time.

### (3) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission":
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "starting"/"stopping" from the neutral position
- "Enable" (`Feature2.Bit16` **=0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "Start" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Enable Fwd" (`Feature2.Bit16` **=1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "Start forward" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Enable Rev" (`Feature2.Bit16` **=1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "Start reverse" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection":
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you must reset the block
  - 1 = "Good" state

- "Protection" (`Feature2.Bit16` **=0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you must reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection Fwd" (`Feature2.Bit16` **=1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you must reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection Rev" (`Feature2.Bit16` **=1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you must reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state
- "Interlock" (`Feature2.Bit16` **=0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock Fwd" (`Feature2.Bit16` **=1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Interlock Rev" (`Feature2.Bit16` **=1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Local stop": 1 = Stopping the motor in "local mode"
- "Local start →": 1 = Starting the motor in "local mode"
- "Local start ←": 1 = Starting the motor in "local mode"
- "Feedback →": 1 = Motor has started and is running
- "Feedback ←": 1 = Motor has started and is running
- "Feedback stop" : 1 = Motor has stopped
- "Stop": 1 = Stop motor
- "Start →": 1 = Start motor
- "Start ←": 1 = Start motor
- "Channel Start →": Signal from the output channel block for "Start"
- "Channel Start ←": Signal from the output channel block for "Start"
- "Permission stop": 1 = Motor can not be stopped in manual (by operator) or automatic (by logic) mode

### (4) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, see section Opening additional faceplates (Page 234).

### (5) Resynchronization

Displays the Resynchronization state and Resynchronization Signal status based on feedback value.

### 8.4.8.4 Block icon for MotRevL

## Block icons for MotRevL

A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Motor state display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Direction display inverted to symbol 1 |
|  | 4 | Direction display inverted to symbol 2 |
|  | 5 | "M" symbol with small direction display |
|  | 6 | "M" symbol with small direction display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | 9 | |
|  | 10 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Motor state display

The following motor states are shown here:

| Icon | Meaning |
|---|---|
|  | Motor started (motor symbol changes) |
|  | The motor is running |
|  | Motor stopped (motor symbol changes) |
|  | Motor idle |
|  | Error at motor (monitoring error, motor protection) |
|  | Motor out of service |
|  | “No Cmd” State |

# 8.5 MotSpdCL - Controllable reversible motor

## 8.5.1 Description of MotSpdCL

### Object name (type + number) and family

Type + number: FB 1854

Family: Drives

### Area of application for MotSpdCL

The block is used for the following applications:

- Control of motors with two directions of rotation and different speeds
- Control of a device feed (optionally configurable via `Feature` bit)

### How it works

The block is used to control reversible motors for different speeds. Various inputs are available for controlling the motor.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the MotSpdCL block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

**Note**

At a warm restart with the `Feature` Bit set to 0, the block is switched to manual mode and the setpoint is set to internal and to 0.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

For a description of the individual parameters, see the section MotSpdCL I/Os (Page 1518).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | 0 = `ManAct.Value`<br>1 = `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon<br>In case of `Feature2.Bit16 =1` then a closed padlock is displayed if Interlock forward or Interlock reverse is active. |
| 8 | `Fwd.Value` |
| 9 | `SimLiOp.Value` |
| 10 | `Rev.Value` |
| 11 | `MonStaErr.Value` |
| 12 | `MonDynErr.Value` |
| 13 | `BypProt` |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | `Trip` |
| 20 | Display „Forced forward“ |
| 21 | Display „Forced stop“ |
| 22 | Display „Forced reverse“ |
| 23 | "Interlock" button is enabled |
| 24 | Reset request in automatic preview |
| 25 | `WarnAct.Value` or<br>`IdleTime` active |
| 26 | Bypass information for display in block icon |
| 27 | Automatic preview for forward mode |
| 28 | Automatic preview for "stopping" |
| 29 | Automatic preview for reverse mode |
| 30 | "Permission" button is enabled |
| 31 | "Protection" button is enabled |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `AV_AH_Act.Value` |
| 2 | `AV_WH_Act.Value` |
| 3 | `AV_TH_Act.Value` |
| 4 | `AV_TL_Act.Value` |
| 5 | `AV_WL_Act.Value` |
| 6 | `AV_AL_Act.Value` |
| 7 | `AV_AH_En` OR `Feature.Bit23` |
| 8 | `AV_WH_En` OR `Feature.Bit23` |
| 9 | `AV_TH_En` OR `Feature.Bit23` |
| 10 | `AV_TL_En` OR `Feature.Bit23` |
| 11 | `AV_WL_En` OR `Feature.Bit23` |
| 12 | `AV_AL_En` OR `Feature.Bit23` |
| 13 | `AV_AH_MsgEn` |
| 14 | `AV_WH_MsgEn` |
| 15 | `AV_TH_MsgEn` |
| 16 | `AV_TL_MsgEn` |
| 17 | `AV_WL_MsgEn` |
| 18 | `AV_AL_MsgEn` |
| 19 | 1 = No impact of input signals on "local mode" with `LocalSetting` = 0, `LocalSetting` = 2, `LocalSetting` = 4 and OOS mode. |
| 20 | Motor is stopped |
| 21 | Motor stops in forward mode |
| 22 | Motor stops in reverse mode |
| 23 | Motor starts in forward mode |
| 24 | Motor runs in forward mode |
| 25 | Motor starts in reverse mode |
| 26 | Motor runs in reverse mode |
| 27 | Error when "stopping" the motor |
| 28 | Error in forward mode of motor |
| 29 | Error in reverse mode of motor |
| 30 | `SP_ExtAct.Value` |
| 31 | Display for interlocks in block icon |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | 1 = SP ramp active |
| 1 | `RbkWH_Act.Value` |
| 2 | Delay of the `AV_AH_Lim` message |
| 3 | Delay of the `AV_WH_Lim` message |

| Status bit | Parameter |
|---|---|
| 4 | RbkWL_Act.Value |
| 5 | Delay of the AV_TH_Lim message |
| 6 | Delay of the AV_TL_Lim message |
| 7 | RbkWH_En OR Feature.Bit23 |
| 8 | Delay of the AV_WL_Lim message |
| 9 | Delay of the AV_AL_Lim message |
| 10 | RbkWL_En OR Feature.Bit23 |
| 11 | Delay of the RbkWH_Lim message |
| 12 | Delay of the RbkWL_Lim message |
| 13 | Collection of message delays |
| 14 | RbkWH_MsgEn |
| 15 | Current monitoring time is visible |
| 16 | MonDynStopErr.Value |
| 17 | RbkWL_MsgEn |
| 18 | Motor is stopped |
| 19 | 1 = Enable for rapid stop (Feature Bit Enabling rapid stop via faceplate (Page 179)) |
| 20 | SP_RmpModTime |
| 21 | SP_RmpOn |
| 22 | SP_UpRaAct, SP_DnRaAct limits enabled for gradient mode (SP_RateOn = 1) |
| 23 | Command for "rapid stop" of the motor |
| 24 | Command for "starting" → the motor |
| 25 | Command for "starting" ← the motor |
| 26 | Show automatic preview in the standard view |
| 27 | RdyToStart.Value |
| 28 | GrpErr.Value |
| 29 | MS_RelOp |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

## Status word allocation for Status4 parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via EventTsIn |
| 1 | Effective signal 2 of the message block connected via EventTsIn |
| 2 | Effective signal 3 of the message block connected via EventTsIn |
| 3 | Effective signal 4 of the message block connected via EventTsIn |
| 4 | Effective signal 5 of the message block connected via EventTsIn |
| 5 | Effective signal 6 of the message block connected via EventTsIn |
| 6 | Effective signal 7 of the message block connected via EventTsIn |
| 7 | Effective signal 8 of the message block connected via EventTsIn |
| 8 | AV not connected |
| 9 | Motor protection display (Trip.Status ≠ 16#FF) |

| Status bit | Parameter |
|---|---|
| 10 | 1 = Input parameter FbkFwd is connected |
| 11 | 1 = Input parameter FbkRev is connected |
| 12 | 1 = Setpoint difference high limit violated (ER_AH_Act.Value) |
| 13 | 1 = Setpoint difference low limit violated (ER_AL_Act.Value) |
| 14 | ER_AH_En OR Feature.Bit23 |
| 15 | ER_AL_En OR Feature.Bit23 |
| 16 | 1 = Report setpoint difference high limit violation (ER_AH_MsgEn) |
| 17 | 1 = Report setpoint difference low limit violation (ER_AL_MsgEn) |
| 18 | 1 = Monitoring of setpoint difference "SP - Rbk" activated |
| 19 | DvFdAct.Value Device feed ON |
| 20 | NOT DvFdAct.Value Device feed OFF |
| 21 | Feature.Bit15 Frequency converter with separate device feed (Page 162) |
| 22 | External error generated by FaultExt or external control system fault from CSF with set Feature.Bit18 Activating error state for external process control error CSF (Page 162) |
| 23 | Hidden bypass signal in Permit |
| 24 | Hidden bypass signal in interlock |
| 25 | Hidden bypass signal in Protect |
| 26 | Feature2.Bit2: Separate bypass signal |
| 27 | Feature.Bit16: Setpoint specification with separate display area and custom unit (Page 182) |
| 28 | 1 = Input parameter FwdChnST is interconnected |
| 29 | 1 = Input parameter RevChnST is interconnected |
| 30 | 1 = Input parameter SP_OutChnS is interconnected |
| 31 | Separate monitoring of shutdown of the motor (Feature.Bit13) |

### Status word allocation for Status5 parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via EventTsIn |
| 8 | Delay of the ER_AH_Lim message |
| 9 | Delay of the ER_AL_Lim message |
| 10 | Not used |
| 11 | 1= Suppressed messages |
| 12 | 1 = Input parameter FbkStop is connected |
| 13 - 15 | Not used |
| 16 | 1 = Input parameter SP_LiRmpTime is not interconnected (SP_LiRmpTime.ST = 16#FF) |
| 17 - 26 | Effective signal 1...16 of the message block connected via EventTs2In |
| 27 | Internal error |
| 28-31 | Effective signal 1...16 of the message block connected via EventTs2In |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 | Resynchronization preview for Forward |
| 1 | Resynchronization preview for Reverse |
| 2 | Resynchronization preview for Stop |
| 3 | Resynchronization: Display preview |
| 4 | Resynchronization: Display small preview symbol in standard view |
| 5 | Not used |
| 6 | Resynchronization with state "No Cmd" |
| 7 - 11 | Not used |
| 12 | `Feature2 bit 16`: Separate interlock for each direction or position |
| 13 | Hidden bypass signal in Permit Reverse |
| 14 | Hidden bypass signal in Interlock Reverse |
| 15 | Hidden bypass signal in Protect Reverse |
| 16 | "Permission Forward" button is enabled |
| 17 | "Permission Reverse " button is enabled |
| 18 | "Interlock Forward " button is enabled |
| 19 | "Interlock Reverse " button is enabled |
| 20 | "Protect Forward " button is enabled |
| 21 | "Protect Reverse " button is enabled |
| 22 | 1 = Permission Reverse is active |
| 23 | 1 = Intlock Reverse is active |
| 24 | 1 = Protect Reverse is active |
| 25 | 1 = "Permission stop" button is enabled |
| 26 | 1 = Permission stop is active |
| 27 | Hidden bypass signal in Permission stop |
| 28-31 | Not used |

MotSpdCL functions (Page 1496)
MotSpdCL modes (Page 1494)

## 8.5.2 MotSpdCL modes

### MotSpdCL operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) .

Motor actions you can control in local mode:

- "Starting in forward" (`FwdLocal` = 1)
- "Starting in reverse" (`RevLocal` = 1)
- "Stopping" (`StopLocal` = 1)

A motor operated in "local mode" is controlled either by "local" signals or by the feedback signals (input parameters `FbkFwd` = 1, `FbkRev` = 1 or `FbkStop` =1/). Configuration takes place via the input parameter `LocalSetting`.

`LocalSetting` =2,4: The control outputs are tracked to the feedbacks.

All three feedbacks are available and plausible means that always only one feedback is active. The corresponding control output is tracked:

```
Fwd = FbkFwd,
Rev = FbkRev,
StopCtrl = FbkStop.
```

When all feedbacks are false then the drive is between of two positions. In this case no monitoring is started. When two feedbacks are active, then they are not plausible. In this case the static monitoring counter starts. In both cases “all feedbacks are reset” or “not plausible feedbacks” with `Feature2Bit21` =1 all the control outputs are set to false (No command state) else control outputs are hold.

If two feedbacks are available then they are always plausible besides they are both active.

| `NoFbkStop =1` (default) | `NoFbkFwd =1` | `NoFbkRev =1` |
|---|---|---|
| `Fwd = FbkFwd,`<br>`Rev = FbkRev,`<br>`StopCtrl = NOT FbkFwd AND NOT FbkRev` | `Fwd = NOT FbkStop AND NOT FbkRev`<br>`Rev = FbkRev,`<br>`StopCtrl = FbkStop` | `Fwd = FbkFwd,`<br>`Rev = NOT FbkStop AND NOT FbkFwd`<br>`StopCtrl = FbkStop` |

When they are not plausible the control outputs will be hold.

When only one feedback is available the concerned control output is tracked. The other control outputs are hold if the available feedback is false.

| NoFbkStop =0 | NoFbkFwd =0 | NoFbkRev =0 |
|---|---|---|
| StopCtrl = FbkStop,<br>Fwd,Rev are hold if FbkStop =0 | Fwd = FbkFwd,<br>StopCtrl,Rev are hold if FbkFwd =0 | Rev = FbkRev,<br>StopCtrl,Fwd are hold if FbkRev =0 |

When all feedbacks are not available the control outputs will be hold.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) .

Motor actions you can control in auto mode:

- "Starting in forward" (FwdAut = 1)
- "Starting in reverse" (RevAut = 1)
- "Stopping" (StopAut = 1)

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Motor actions you can control in "manual mode":

- "Starting in forward" (FwdMan = 1)
- "Starting in reverse" (RevMan = 1)
- "Stopping" (StopMan = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with Feature2.Bit1 =0 and Feature2.Bit1 =1 is as shown below:

| Output Parameters | **Feature2.Bit1 =0** | **Feature2.Bit1 =1** |
|---|---|---|
| DvFdAct.ST | 16#80 | 16#60 |
| FbkFwdOut.ST | 16#80 | 16#60 |
| FbkRevOut.ST | 16#80 | 16#60 |
| RunFwd.ST | 16#80 | 16#60 |
| RunRev.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |
| Starting.ST | 16#80 | 16#60 |

| Output Parameters | `Feature2.Bit1` =0 | `Feature2.Bit1` =1 |
|---|---|---|
| Stoping.ST | 16#80 | 16#60 |
| SP_Out.ST | 16#80 | 16#60 |
| SP_Out2.ST | 16#80 | 16#60 |
| SP_ExtAct.ST | 16#80 | 16#60 |
| RbkOut.ST | 16#80 | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| ER.ST | 16#80 | 16#60 |
| ER_AH_Act.ST | 16#XX | 16#60 |
| ER_AL_Act.ST | 16#XX | 16#60 |
| AV_Out.ST | 16#80 | 16#60 |

**Note**

In case of external setpoint value specification, the block switches to internal setpoint value specification.

Description of MotSpdCL (Page 1488)

## 8.5.3 MotSpdCL functions

### Functions of MotSpdCL

The functions for this block are listed below.

### Alarm delays with two time values per limit pair

This block has the standard alarm delay function for Two time values per limit pair (Page 227) limit monitoring of the feedback.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can start the motor in forward |
| 6 | 1 = Operator can start the motor in reverse |
| 7 | 1 = Operator can reset the motor |
| 8 | 1 = Operator can define or change the monitoring time for startup |
| 9 | 1 = Operator can define the monitoring time for the status |
| 10 | 1 = Operator can activate the monitoring time |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the limit (AV) for high alarm |
| 14 | 1 = Operator can change the limit (AV) for high warning |
| 15 | 1 = Operator can change the limit (AV) for high tolerance |
| 16 | 1 = Operator can change the limit (AV) for hysteresis |
| 17 | 1 = Operator can change the limit (AV) for low alarm |
| 18 | 1 = Operator can change the limit (AV) for low warning |
| 19 | 1 = Operator can change the limit (AV) for low tolerance |
| 20 | 1 = Operator can enable the bumpless switchover from external to internal SP_TrkExt |
| 21 | 1 = Operator can change the internal setpoint SP_Int |
| 22 | 1 = Operator can switch the setpoint to "external" SP_ExtOp |
| 23 | 1 = Operator can switch the setpoint to "internal" SP_IntOp |
| 24 | 1 = Operator can enable the setpoint's gradient limitation function SP_RateOn |
| 25 | 1 = Operator can change the setpoint's high limit for the ramp SP_UpRaLim |
| 26 | 1 = Operator can change the setpoint's low limit for the ramp SP_DnRaLim |
| 27 | 1 = Operator can enable the setpoint ramp function SP_RmpOn |
| 28 | 1 = Operator can switch between the time value or the value for the ramp SP_RmpModTime |
| 29 | 1 = Operator can change the ramp time SP_RmpTime |
| 30 | 1 = Operator can change the target setpoint SP_RmpTarget for the setpoint ramp |
| 31 | 1 = Operator can enable rapid stop |

The block has the following permissions for the OS1Perm parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can change the limit (Rbk) for high warning |
| 2 | Not used |

| Bit | Function |
|---|---|
| 3 | 1 = Operator can change the limit (Rbk) for hysteresis |
| 4 | Not used |
| 5 | 1 = Operator can change the limit (Rbk) for low warning |
| 6 | 1 = Operator can change the limit (setpoint difference) ER_AH_Lim for the high alarm |
| 7 | 1 = Operator can change the hysteresis (setpoint difference) ER_Hyst |
| 8 | 1 = Operator can change the limit (setpoint difference) ER_AL_Lim for the low alarm |
| 9 | 1 = Operator can change the simulation value SimRbk |
| 10 | 1 = Operator can activate the device infeed DvFdOnMan |
| 11 | 1 = Operator can deactivate the device infeed DvFdOffMan |
| 12 | 1 =Operator can change the simulation value SimAV |
| 13 | 1 = Operator can change the derivative gain parameter ER_AH_DFac |
| 14 | 1 = Operator can change the derivative gain parameter ER_AL_DFac |
| 15 - 19 | Not used |
| 20 | 1 = Operator can activate / deactivate messages via AV_AH_MsgEn |
| 21 | 1 = Operator can activate / deactivate messages via AV_WH_MsgEn |
| 22 | 1 = Operator can activate / deactivate messages via AV_TH_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via AV_TL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via AV_WL_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via AV_AL_MsgEn |
| 26 | 1 = Operator can activate / deactivate messages via RbkWH_MsgEn |
| 27 | 1 = Operator can activate / deactivate messages via RbkWL_MsgEn |
| 28 | 1 = Operator can activate / deactivate messages via ER_AH_MsgEn |
| 29 | 1 = Operator can activate / deactivate messages via ER_AL_MsgEn |
| 30 | 1 = Operator can define the monitoring time for stopping |
| 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Restart lock after changing direction of rotation or switching off the motor

Use the input parameter IdleTime to enter a restart lock for changing the direction of rotation or restarting the motor. Use the Feature Bit Enabling direct changeover between forward and reverse (Page 156) to define how the change is to take place. When the "Stop" command is given, the motor goes immediately into Stop mode and IdleTime starts after the feedback (FbkFwd and FbkRev = 0) is given. The motor cannot be started again until the IdleTime has expired.

The IdleTime parameter can be set independently of the MonTiDynamic parameter.

### Limit monitoring of an additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring of the feedback

The block provides the standard function Limit monitoring of the feedback (Page 101). This limit monitoring is only active when the motor has started.

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104). It is performed via the input parameter `AV_Hyst`.

### Providing limits at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

`ER_AH_LimOut` := `ER_AH_Lim`;

`ER_AL_LimOut` := `ER_AL_Lim`;

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### External/internal setpoint specification

The block provides the standard function Setpoint specification - internal/external (Page 136).

### Setpoint adaption in motor stop and starting

With `Feature2.Bit7` = 1; Define the setpoint after stop and start of the motor (Page 198), the setpoint can be set to a stop value and after start of the motor, the setpoint can be set to a minimal value (`SP_LoLim`).

### Setpoint limitation

Limit the setpoint using the parameters:

- `SP_HiLim` (top)
- `SP_LoLim` (bottom)

Limit violations are displayed at the SP_HiAct and SP_LoAct output parameters with a 1.

With Feature2.Bit7 = 1; Define the setpoint after stop and start of the motor (Page 198), the lower limit value of the setpoint SP_LoLim will be limited to SP_Off and in case of violation, SP_LoLim will be written back to SP_Off.

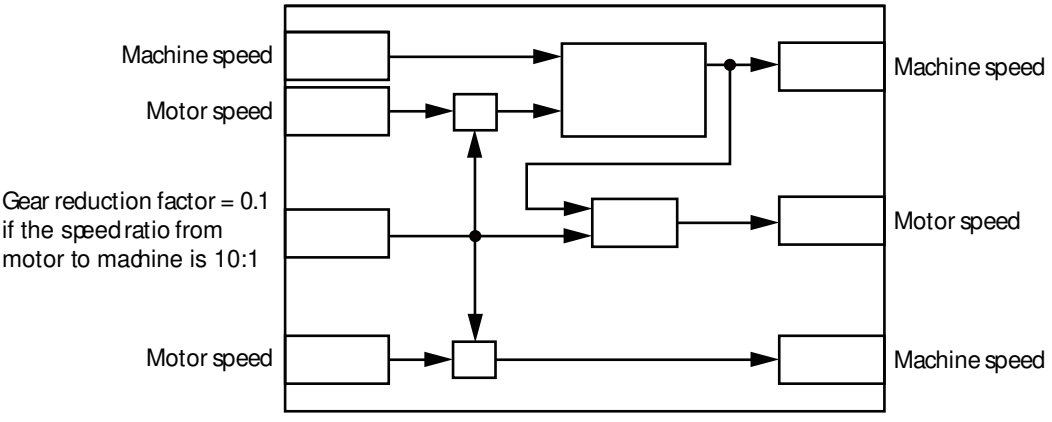
### Gradient limit of the setpoint

The block provides the standard function Gradient limit of the setpoint (Page 132).

### Using setpoint ramp

The block provides the standard function Using setpoint ramp (Page 131).

### Gear reduction or setpoint adaptation with factor



With the parameter FactGR, a factor can be entered for gear reduction. It affects the outputs SP_Out, SP_Out2, and RbkOut:

- SP_Out = FactGR * SP_Ext if the setpoint is external (SP_ExtAct = 1)
- SP_Out2 parameter:
  - If FactGR <> 0.0 then SP_Out2 = SP_Out / FactGR
  - If FactGR = 0.0 then SP_Out2 = SP_Out

As a result, the readback value will also be adjusted:

RbkOut = FactGR * Rbk

Below is an example for the gear reduction from motor speed to machine speed in the ratio 10:1.

The factor FactGR can also be used for adapting the range in percentage.

### Formation of the difference between setpoint and position feedback

The block always forms the difference between setpoint and position feedback:

ER.Value = SP_Out - RbkOut.Value.

### Limit monitoring of the setpoint difference

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102).

To transmit the messages, you need to enable `Feature.Bit5` Alarm setpoint difference (Page 182).

When the function activated, the message configuration should be adapted as follows:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 7 | Alarm - high | $$BlockComment$$<br>`ER` - high alarm limit `SP - Rbk` violated |
| | SIG 8 | Alarm - low | $$BlockComment$$<br>`ER` - low alarm limit `SP - Rbk` violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Interlocks

This block provides the following interlocks:

`Feature2` bit 16 = 0:

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")
- Permission for stop ("Permission stop")

`Feature2` bit 16 = 1:

- Activation enable forward
- Activation enable reverse
- Interlock forward without reset ("Interlock forward ")
- Interlock reverse without reset ("Interlock reverse ")
- Interlock forward with reset ("Protection interlock forward ")
- Interlock reverse with reset ("Protection interlock reverse ")

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

### Rapid stop for motors

This block provides the standard function Rapid stop for motors (Page 115).

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See MotSpdCL error handling (Page 1512).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `Trip`
- `MonDynErr`
- `MonStaErr`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `FbkFwdOut.ST`
- `FbkRevOut.ST`

- LocalLi.ST
- FwdLocal.ST
- StopLocal.ST
- RevLocal.ST
- Trip.ST
- AV_Out.ST
- RbkOut.ST
- SP_Out.ST
- FwdChn.ST
- RevChn.ST
- SP_OutChn.ST
- FwdAut.ST (only if Feature2.Bit10 = 1)
- RevAut.ST (only if Feature2.Bit10 = 1)
- StopAut.ST (only if Feature2.Bit10 = 1)
- SP_Ext.ST (only if Feature2.Bit10 = 1)

The signal status of the SP_Out output parameter is always equivalent to the signal status of input parameter SP_Ext or SP_Int, depending on how the setpoint is specified. If the internal setpoint SP_Int is used, the signal status is always output as 16#80.

In case of Feature.Bit10 = 1, SP_Ext.ST influences ST_Worst independent of setpoint specification.

### Considering bad quality of automatic commands or external values

If the Feature2 bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (motor stop) in the "Automatic" mode:

- FwdAut.ST
- RevAut.ST
- StopAut.ST
- SP_Ext.ST

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).

The following states can be enforced:

- "Start in forward" (`FwdForce`)
- "Start in reverse" (`RevForce`)
- "Stop" (`StopForce`)

**Note**

The `Feature` bit Enabling direct changeover between forward and reverse (Page 156) for this block has no function with forced operating states. The motor can always be reversed directly.

## Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

## Disabling feedback

This block provides the standard function for Disabling feedback for valve and motors (Page 106).

Feedback monitoring can be deactivated separately for each feedback with `NoFbkFwd` or `NoFbkRev` or `NoFbkStop` as required.

The output signals of feedback are tracked by the control and the other available feedbacks:

| NoFbkFwd | NoFbkRev | NoFbkStop | Comment |
|---|---|---|---|
| 0 | 0 | 1 | **Default:**<br>`FbkFwdOut = FbkFwd;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = StopCtrl AND NOT FbkFwd AND NOT FbkRev;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkFwdOut = FbkFwd;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = NOT FbkFwd AND NOT FbkRev;` |
| 1 | 0 | 1 | `FbkFwdOut = Fwd AND NOT FbkRev;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = StopCtrl AND NOT FbkRev;` |

| NoFbkFwd | NoFbkRev | NoFbkStop | Comment |
|---|---|---|---|
| 0 | 1 | 1 | `FbkFwdOut = FbkFwd;`<br>`FbkRevOut = Rev AND NOT FbkFwd;`<br>`FbkStopOut = StopCtrl AND NOT FbkFwd;` |
| 1 | 1 | 1 | `FbkFwdOut = Fwd;`<br>`FbkRevOut = Rev;`<br>`FbkStopOut = StopCtrl;` |
| 1 | 0 | 0 | `FbkFwdOut = Fwd AND NOT FbkRev AND NOT FbkStop;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = FbkStop;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkFwdOut = NOT FbkRev AND NOT FbkStop;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = FbkStop;` |
| 0 | 1 | 0 | `FbkFwdOut = FbkFwd;`<br>`FbkRevOut = Rev AND NOT FbkFwd AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkFwdOut = FbkFwd;`<br>`FbkRevOut = NOT FbkFwd AND NOT FbkStop;`<br>`FbkStopOut = FbkStop` |
| 0 | 0 | 0 | `FbkFwdOut = FbkFwd;`<br>`FbkRevOut = FbkRev;`<br>`FbkStopOut = FbkStop;` |
| 1 | 1 | 0 | `FbkFwdOut = Fwd AND NOT FbkStop;`<br>`FbkRevOut = Rev AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;` |

When all feedbacks are not available the position is hold after a switch to local mode with `LocalSetting` =2/4.
When 2 of 3 feedbacks are not available the position is hold after a switch to local mode with `LocalSetting` =2/4.

### Using StopCtrl with mode "No Cmd"

This block provides the standard function Control with output StopCtrl and state “No Cmd” (Page 214)

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56).

You can generate warning signals when, for example, motors are started. Warning signals can be generated in the following modes:

- Manual mode (Page 82) (`WarnTiMan` input parameter)Automatic mode (Page 82) (`WarnTiAut` input parameter)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a motor is started, then this is displayed at the output parameter with `WarnAct` = `1`. The motor then starts after the set warning time has expired and `WarnAct` then goes back to 0 .

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Additional value (`SimAV`, `SimAV_Li`)
- Position feedback (`SimRbk`, `SimRbkLi`)

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Specifying the display and operator input area for process values and setpoints during operation

This block features the standard function Display and control fields for process values and setpoints (Page 233).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Delay alarm for control deviation at setpoint step changes

The block provides the standard function Delay alarm for control deviation at setpoint step changes (Page 216).

### Disabling of limits

The block provides the standard function Limits disabled in faceplate (Page 206).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the controls are tracked as follow:

**NoFbkFwd =0, NoFbkRev =0, NoFbkStop =1 (default):**

Fwd := FbkFwd;

Rev := FbkRev;

StopCtrl := NOT FbkFwd AND NOT FbkRev;

In case if there are no plausible feedback positions (FbkFwd =1, FbkRev =1) the controls are not changed.

**NoFbkFwd =0, NoFbkRev =0, NoFbkStop =0:**

Plausible feedback positions (only one feedback signal is active) are tracked as control position.

Fwd := FbkFwd;

Rev := FbkRev;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (two or three feedback signals are active) the control position depends on Feature2 Bit21.

- Feature2 Bit21 =0 (default): Control position is not changed.
- Feature2 Bit21 =1: Control position becomes "No Cmd" Fwd := 0; Rev := 0; StopCtrl := 0;

**NoFbkFwd =0, NoFbkRev =1, NoFbkStop =0:**

Fwd := FbkFwd AND NOT FbkStop;

Rev := NOT FbkFwd AND NOT FbkStop;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (FbkFwd =1, FbkStop =1) the controls are not changed.

**NoFbkFwd =1, NoFbkRev =0, NoFbkStop =0:**

Fwd := NOT FbkRev AND NOT FbkStop;

Rev := FbkRev AND NOT FbkStop;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (FbkRev =1, FbkStop =1) the controls are not changed.

Analog Readback value:

SP_Out := Rbk; SP_Out is tracked and limited to SP_HiLim and SP_LoLim.

With other combinations of **NoFbkFwd**, **NoFbkRev**, **NoFbkStop** the controls are not changed.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Alarm setpoint difference (Page 182) |
| 6 | Ramp rate calculation (Page 191) |
| 7 | Enabling direct changeover between forward and reverse (Page 156) |
| 8 | Inverter enable (Page 201) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 12 | Gradient limitation with time duration (Page 197) |
| 13 | Separate monitoring time for stopping the motor (Page 180) |

| Bit | Function |
|---|---|
| 14 | Enabling rapid stop via faceplate (Page 179) |
| 15 | Frequency converter with separate device feed (Page 162) |
| 16 | Setpoint specification with separate display area and custom unit (Page 182) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In pushbutton operation (Bit 4 = 0) , the automatic commands in "automatic" mode are latching; in other words, `FwdAut`, `RevAut`, `StopAut` can be reset to 0 after changing the control. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

In switching mode (Bit 4 = 1), control is selected with the static signals `FwdAut`, `RevAut`. If `FwdAut`, `RevAut` inputs are not set, the motor is stopped. Control via `StopAut` is not needed. If the "Activate command reset for control" function (Bit 3 = 1) is also enabled, the inputs `FwdAut`, `RevAut` are reset to the neutral position after evaluation in the block.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 6 | Operator can change the setpoint via faceplate also in the "Local" mode (Page 197) |
| 7 | Define the setpoint after stop and start of the motor (Page 198) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |

| Bit | Function |
|---|---|
| 12 | Disable limit act output when limit value message is disabled (Page 209) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 16 | Separate interlock for each direction, position, or speed (Page 180) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 21 | Control with output StopCtrl and state “No Cmd” (Page 214) |

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `FwdMan`
- `RevMan`
- `StopMan`
- `RapidStp`

### Controlling a device infeed or an inverter enable

The function is activated via `Feature.Bit15` Frequency converter with separate device feed (Page 162) and specified via `Feature.Bit8` Inverter enable (Page 201).

When the function is activated, the motor can be started in two steps:

- Switch on device infeed or inverter enable first, then start the motor

When the "device infeed" function is activated, the motor can also be started directly:
The device infeed is also activated when starting in forward or reverse. The frequency converter automatically determines the correct sequence. The activation of the device infeed for starting the motor can be performed in the automatic, manual and local operating modes with local setting 1 or 3, or by forcing.

With local setting 2 or 4, the controls are tracked based on feedback signals regardless of the status of the device infeed or the inverter enable.

With motors without device infeed or inverter enable (`Feature.Bit15` = 0 default), the `DvFdAct.Value` control is always zero.

Separate activation/deactivation of the device infeed or the inverter enable is performed in manual mode using `DvFdOnMan` and `DvFdOffMan` via the standard view of the faceplate. In automatic mode, activation/deactivation is performed via the input signals `DvFdOnAut` or `DvFdOffAut`. The `Feature.Bit3` (activate reset of commands for control) and 4 (set switch or pushbutton operation) are also based on the automatic inputs `DvFdOnAut` and `DvFdOffAut`.

The following table shows the effects on MotSpdCL block when parameterizing device infeed and inverter enable:

| **MotSpdCL specification** | **Effect on MotSpdCL block when parameterizing device infeed**<br>**`Feature.Bit8` = 0** | **Effect on MotSpdCL block when parameterizing inverter enable**<br>**`Feature.Bit8` = 1** |
|---|---|---|
| Motor start - dependent (`Fwd` = 1 or `Rev` = 1) | Device infeed is activated (`DvFdAct` = 1) | Inverter enable remains unchanged |
| Motor stop (`Fwd` = 0 and `Rev` = 0) | Device infeed remains unchanged | Inverter enable remains unchanged |
| Activate device infeed or inverter enable (`DvFdAct` = 1) | Motor control remains unchanged | Motor control remains unchanged |
| Deactivate device infeed or inverter enable (`DvFdAct` = 0) | Motor control is reset (`Fwd` = 0, `Rev` = 0) | Motor control remains unchanged |
| Monitoring the feedback signals (`FbkFwd`, `FbkRev`) | Feedback signals are monitored for motor controls (`Fwd`, `Rev`) | Feedback signals are monitored for motor controls and the inverter enable:<br>(`Fwd` and `DvFdAct`), (`Rev` and `DvFdAct`) |
| Monitoring fault, external fault, motor protection, or interlock | Motor control is reset (`Fwd` = 0, `Rev` = 0)<br>Device infeed remains unchanged | Motor control is reset (`Fwd` = 0, `Rev` = 0)<br>Inverter enable remains unchanged |
| Limit value monitoring of the feedback<br>Limit value monitoring of the setpoint difference | Only active when:<br>`Fwd` = 1 or `Rev` = 1 | Only active if the inverter enable is also activated:<br>`Fwd` = 1 or `Rev` = 1;<br>And `DvFdAct` = 1 |

Commands for starting the motor have higher priority than commands for a device infeed or the inverter enable.

**⚠ DANGER**

**Separate switching on/off of the device infeed**

With switch mode (`Feature.Bit4` = 1) and deactivated control reset (`Feature.Bit3` = 0), the `DvFdOnAut` input is also set for controlling the device infeed or the inverter enable when starting in forward or in reverse in automatic mode.

## 8.5.4 MotSpdCL error handling

### Error handling of MotSpdCL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Control system fault (CSF)
- Invalid or not plausible input commands

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not within the approved limit of 0 to 4. |
| 42 | `LocalSetting` = 0 or `LocalSetting` = 3 or `LocalSetting` = 4 and `LocalLi` = 1 |

| Error number | Meaning of the error number |
|---|---|
| 51 | FwdLocal = 1 and StopLocal = 1 and Feature2.Bit4 = 0<br>RevLocal = 1 and StopLocal = 1 and Feature2.Bit4 = 0<br>FwdLocal = 1 and RevLocal = 1<br>FwdLocal = 1 and Rev = 1 and Feature.Bit7 = 0<br>RevLocal = 1 and Fwd = 1 and Feature.Bit7 = 0<br>FwdAut = 1 and StopAut = 1 and Feature.Bit4 = 0<br>RevAut = 1 and StopAut = 1 and Feature.Bit4 = 0<br>FwdAut = 1 and RevAut = 1<br>FwdAut = 1 and Rev = 1 and Feature.Bit7 = 0<br>RevAut = 1 and Fwd = 1 and Feature.Bit7 = 0<br>AutModLi = 1 and ManModLi = 1<br>FwdForce = 1 and StopForce = 1<br>RevForce = 1 and StopForce = 1<br>FwdForce = 1 and RevForce = 1<br>SP_LiOp = 1 and SP_IntLi = 1 and SP_ExtLi = 1<br>DvFdOnMan and DvFdOffMan and Feature.Bit15<br>DvFdOnAut and DvFdOffAut and Feature.Bit15 |
| 52 | LocalAct = 1 and LocalSetting = 2 or 4 and SimOn = 1 |

**Note**

The relationship of the pushbutton/switch mode Feature.Bit4 is not taken into account

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| **Operating mode** | **Invalid or not plausible input commands** | **Control reaction with** `Feature2.Bit3` = 1 |
|---|---|---|

| | | |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | Pushbutton operation for local mode (`Feature2.Bit4` = 0):<br>`FwdLocal` = 1 and `RevLocal` = 1 or<br>`FwdLocal` = 1 and `StopLocal` = 1 or<br>`StopLocal` = 1 and `RevLocal` = 1<br>Switching mode (`Feature2.Bit4` = 1):<br>`FwdLocal` = 1 and `RevLocal` = 1<br>Enabling direct changeover between forward and reverse (`Feature.Bit7` = 1):<br>`FwdLocal` = 1 and `Rev` = 1 or `RevLocal` = 1 and `Fwd` = 1 | Motor is stopped |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `FwdForce` = 1 and `RevForce` = 1 or<br>`FwdForce` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `RevForce` = 1 | |
| Forcing and no "local mode" | `FwdForce` = 1 and `RevForce` = 1 or<br>`FwdForce` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `RevForce` = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0):<br>`FwdAut` = 1 and `RevAut` = 1 or<br>`FwdAut` = 1 and `StopAut` = 1 or<br>`StopAut` = 1 and `RevAut` = 1<br>Switching mode (`Feature.Bit4` = 1):<br>`FwdAut` = 1 and `RevAut` = 1<br>Enabling direct changeover between forward and reverse (`Feature.Bit7` = 1):<br>`FwdAut` = 1 and `Rev` = 1 or `RevAut` = 1 and `Fwd` = 1 | |
| "Manual mode" and no forcing | `FwdMan` = 1 and `RevMan` = 1 or<br>`FwdMan` = 1 and `StopMan` = 1 or<br>`StopMan` = 1 and `RevMan` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.5.5 MotSpdCL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | PLC process control message - Failure | $$BlockComment$$<br>Motor feedback error |
| | SIG 2 | PLC process control message - Failure | $$BlockComment$$<br>Motor protection triggered |
| | SIG 3 | PLC process control message - Failure | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1,, a process control fault is triggered (`MsgEvId1`, SIG 3).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 4 | Warning - high | $$BlockComment$$<br>Rbk - high warning limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>Rbk - low warning limit violated |
| | SIG 7 | Alarm - high | Only with Feature Bit5 =1:<br>$$BlockComment$$<br>ER - high warning limit violated |
| | SIG 8 | Alarm - low | Only with Feature Bit5 =1:<br>$$BlockComment$$<br>ER - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

With Feature Bit5 =1 SIG 7 and SIG 8 are used for monitoring the difference ER = SP – Rbk. Message class and Event need to be adapted.

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 6 | PLC process control message - Failure | $$BlockComment$$<br>External message 1 |
| | SIG 7 | PLC process control message - Failure | Only with Feature Bit5 =0 (default): $$BlockComment$$<br>External message 2 |
| | SIG 8 | PLC process control message - Failure | Only with Feature Bit5 =0 (default): $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment.

With Feature Bit5 =0 SIG 7 and SIG 8 are used for the inputs ExtMsg2.Value and ExtMsg3.Value. Message class and Event need to be adapted.

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa104` ... `ExtVa108` , and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 8.5.6 MotSpdCL I/Os

I/Os of MotSpdCL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AddOn` | AddOn block connector for device specific view | ANY | - |
| `AutModLi*` | 1 = "Automatic mode" via interconnection or SFC (controlled by `ModLiOp` = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AutModOp*` | 1 = "Automatic mode" via operator (controlled by `ModLiOp` = 0) | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV | Input additional analog value, to be connected to AV_Tech of the AV block | ANY | |
| AV_AH_Lim | Limit high alarm | REAL | 95.0 |
| AV_AL_Lim | Limit low alarm | REAL | 5.0 |
| AV_Hyst | Hysteresis for alarm, warning and tolerance limits | REAL | 1.0 |
| AV_TH_Lim | Limit high tolerance | REAL | 85.0 |
| AV_TL_Lim | Limit low tolerance | REAL | 15.0 |
| AV_WH_Lim | Limit high warning | REAL | 90.0 |
| AV_WL_Lim | Limit low warning | REAL | 10.0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DvFdOnAut* | 1 = Activation of device infeed in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DvFdOffAut* | 1 = Deactivation of device infeed in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DvFdOnMan* | 1 = Activation of device infeed in "manual mode" | BOOL | 0 |
| DvFdOffMan* | 1 = Deactivation of device infeed in "manual mode" | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_A_DC* | Reserved | REAL | 0.0 |
| ER_A_DG* | Reserved | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for setpoint difference monitoring | BOOL | 1 |
| ER_AH_DFac* | Delay factor at the positive setpoint step changes for incoming alarms at the error signal monitoring ER_AH_Lim | REAL | 0.0 |
| ER_AH_Lim | Alarm limit (high) for setpoint difference monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for setpoint difference monitoring Messages are only output if you have also enabled the Feature.Bit5 Alarm setpoint difference (Page 182). | BOOL | 1 |
| ER_AL_DFac* | Delay factor at the negative setpoint step changes for incoming alarms at the error signal monitoring ER_AL_Lim | REAL | 0.0 |
| ER_AL_En | 1 = Activate alarm (low) for setpoint difference monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for setpoint difference monitoring | REAL | -100.0 |
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for setpoint difference monitoring Messages are only output if you have also enabled the Feature.Bit5 Alarm setpoint difference (Page 182). | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for error signal | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EventTs2In | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTs2In input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| FactGR | Gear reducing factor | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#80 |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkFwd | 1= Motor feedback running forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkRev | 1= Motor feedback running reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkStop | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| `Feature` | I/O for additional functions (Page 1496)<br>1 = Separate monitoring time for stopping the motor<br>1 = Setpoint with own scale and unit of the parameter | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 13: BOOL<br>• Bit 16: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0<br>• 0<br>• 0 |
| `Feature2` | I/O for additional functions (Page 1496) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| `FwdAut*` | 1 = Activation of forward motor operation in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FwdChnST` | Signal status of output channel for `Fwd`<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| `FwdForce` | 1 = Forcing activation of motor forward mode | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FwdLocal` | 1 = Activation of forward motor operation in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FwdMan*` | 1 = Activation of forward motor operation in "manual mode" | BOOL | 0 |
| `IdleTime*` | Wait time for change of direction or restart in [s] | REAL | 5.0 |
| `Intlock` | 0 = Interlock / Interlock Open is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock / Interlock Forward is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| `Intl_En` | 1 = Parameter `Intlock` is enabled | BOOL | 1 |
| `IntlRev` | 0 = Interlock Reverse is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock Reverse is deactivated. | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| IntlRevEn | 1 = Parameter IntlRev is enabled | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Characteristics of Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors  Motors: Stop is the neutral position | BOOL | 1 |
| MonTiDynamic* | Monitoring time for feedback errors or feedback start error after successful operation in [s] | REAL | 3.0 |
| MonTiDyStop* | Monitoring time for feedback stop errors after successful operation in [s] | REAL | 3.0 |
| MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoFbkFwd | 1= Motor Feedback running forward not present | BOOL | 0 |
| NoFbkRev | 1= Motor Feedback running reverse not present | BOOL | 0 |
| NoFbkStop | 1= Motor feedback stopped not present | BOOL | 1 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1496)<br>1 = Operator can set or change the monitoring time for "Control: Start" | STRUCT<br>• Bit 0: BOOL<br>• Bit8: BOOL<br>• Bit 10: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1496)<br>1 = Operator can set or change the monitoring time for "Control: Stop" | STRUCT<br>• Bit 0: BOOL<br>• Bit 9: BOOL<br>• Bit 30: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| Permit | 1 = Activation enable / Activation Forward enable<br>0 = No activation enable / No activation Forward enable | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| PermitSafePos | 1=Motor stop is allowed | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermSf_En | 1=Permit stop enabled | BOOL | 1 |
| Perm_En | 1 = Parameter Permit enable | BOOL | 1 |
| PermRev | 1 = Activation Reverse enable0 = No activation Reverse enable | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| PermRevEn | 1 = Parameter PermRev is enabled | BOOL | 1 |
| Protect | 0 = Protective interlock / protective interlock Forward is activated.<br>Once the interlock condition has cleared, the block must be reset<br>1 = Protective interlock / protective interlock Forward is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| Prot_En | 1 = Parameter Protect enable | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ProtRev | 0 = Protective interlock Reverse is activated.<br>Once the interlock condition has cleared, the block must be reset<br>1 = Protective interlock Reverse is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| ProtRevEn | 1 = Parameter ProtRev enable | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RapidStp* | Rapid stop for the motor:<br>0 = Motor On<br>1 = Motor Off | BOOL | 0 |
| Rbk | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkW_DC* | Delay time for incoming warnings [s] | REAL | 0.0 |
| RbkW_DG* | Delay time for outgoing warnings [s] | REAL | 0.0 |
| RbkHyst | Hysteresis for warning limits | REAL | 1.0 |
| RbkOpScale | Limit for scale in bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| RbkUnit | Unit of measure for additional analog value | INT | 0 |
| RbkUnitOut | RbkUnit as output | INT | 0 |
| RbkOpScaleOut | RbkOpScale as output | STRUCT<br>• High: REAL<br>• Low: REAL | <br>• 100.0<br>• 0.0 |
| RbkWH_En | 1 = Enable high warning | BOOL | 1 |
| RbkWH_Lim | Limit high warning | REAL | 90.0 |
| RbkWH_MsgEn | 1 = Enable high warning message | BOOL | 1 |
| RbkWL_En | 1 = Enable low warning | BOOL | 1 |
| RbkWL_Lim | Limit low warning | REAL | 10.0 |
| RbkWL_MsgEn | 1 = Enable low warning message | BOOL | 1 |
| RevAut* | 1 = Activation of reverse motor operation in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RevChnST | Signal status of output channel for Rev<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| RevForce | 1 = Force activation of reverse motor operation | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RevLocal | 1 = Activation of reverse motor operation in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RevMan* | 1 = Activation of reverse motor operation in "manual mode" | BOOL | 0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| SimAV* | Additional value used for SimOn = 1 | REAL | 0.0 |
| SimAV_Li | Additional analog value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_DnRaLim* | Limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 100.0 |
| SP_Ext | external setpoint - (to interconnection) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_ExtLi | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtOp* | 1 = Select external setpoint (via operator) | BOOL | 0 |
| SP_HiLim | Limit (high) of setpoint | REAL | 100.0 |
| SP_LoLim* | Limit (low) of setpoint;<br>if Feature2.Bit7 = 1<br>then SP_LoLim is limited and written back to SP_Off. | REAL | 0.0 |
| SP_Int* | Internal setpoint for operation | REAL | 1.0 |
| SP_IntLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntOp* | 1 = Select internal setpoint (via operator) | BOOL | 1 |
| SP_LiDnRaLim | Linkable limit (low) for the gradient of the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiOp | Select setpoint source (internal/external):<br>1 = Via interconnection<br>0 = Via operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_LiRmpTime | Linkable time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_LiUpRaLim | Linkable gradient limit (high) for the setpoint [Unit/(Time unit)]<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_Off | Setpoint if the motor is off | REAL | 0.0 |
| SP_OpScale | SP bar limit display for OS | ScaVal | |
| SP_OutChnST | Signal status of output channel SP_Out<br>Should be connected to an output channel block | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| SP_RateOn* | 1 = Activate limitation of setpoint gradients | BOOL | 0 |
| SP_RmpModTime | 1 = Use time values (SP_RmpTime, SP_LiRmpTime)<br>0 = Use gradient limits (SP_DnRaLim, SP_LiDnRaLim, SP_UpRaLim, SP_LiUpRaLim) | BOOL | 0 |
| SP_RmpOn* | 1 = Activate setpoint ramp to target setpoint SP_RmpTarget | BOOL | 0 |
| SP_RmpTarget* | Target setpoint for setpoint ramp | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP_RmpTime* | Time [Time unit] for setpoint ramp from current SP up to SP_RmpTarget or time [Time unit] for gradient limitation in ramp mode duration<br>Time unit depends on TimeFactor | REAL | 0.0 |
| SP_TrkExt | 1 = Bumpless switchover from external to internal setpoint active | BOOL | 0 |
| SP_Unit | Operator inputs | INT | 0 |
| SP_UpRaLim* | Gradient limit (high) for the setpoint [Unit/(Time unit)] Time unit depends on TimeFactor | REAL | 100.0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stopping the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopForce | 1 = Force motor stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopLocal | 1 = Stopping the motor in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stopping the motor in "manual mode" | BOOL | 0 |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| WarnTiAut* | Prewarning of motor start in "automatic mode" in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan* | Prewarning of motor start in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AV_OpScale | Limit for scale in AV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| AV_Out | Output additional analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Unit | Unit of measure for additional analog value | INT | 0 |
| DvFdAct | 1 = Device infeed enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CurrMon | Remaining monitoring time [s] | DINT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Error signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_A_DCOut | Effective delay time [s] for incoming alarms at the error signal monitoring | REAL | 0.0 |
| ER_AH_Act | 1 = Alarm limit (high) for control deviation violated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_AL_Act | 1 = Alarm limit (low) for control deviation violated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ER_AH_LimOut | ER_AH_Lim as output | REAL | 0.0 |
| ER_AL_LimOut | ER_AL_Lim as output | REAL | 0.0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MotSpdCL error handling (Page 1512) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkFwdOut | 1= Motor feedback running forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkRevOut | 1= Motor feedback running reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkStopOut | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Fwd | 1 = Control of motor forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlRevOut | IntlRev as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit, Protect) or Trip is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MonDynErr | 1 = Feedback error or feedback start error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonDynStopErr | 1 = Feedback stop error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| P_Fwd | 1 = Pulse signal for starting the motor in forward | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rev | 1 = Pulse signal for starting the motor in reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Stop | 0 = Pulse signal for stopping the motor | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| PermRevOut | PermRev as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtRevOut | ProtRev as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| R_StpAct | 1 = Rapid stop of the motor is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkOut | Output of readback value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Rev | 1 = Control of motor: Reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RunFwd | 1 = Motor is running forwards | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RunRev | 1 = Motor is running in reverse | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_DnRaAct | 1 = Negative gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtAct | 1 = External setpoint is active<br>0 = Internal setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_HiAct | 1 = Limit (high) for setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_LoAct | 1 = Limit (low) for setpoint has been reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_Out | Setpoint used by controller | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_Out2 | Additional setpoint, without gear reducing factor | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP_RateTarget | Target setpoint for the gradient limitation | REAL | 0.0 |
| SP_UpRaAct | 1 = Positive gradient limiting of setpoint is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_RemRT | Remaining ramp time of the setpoint | REAL | 0.0 |
| Starting | 1 = Motor will start | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word 1 (Page 1488) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1488) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1488) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1488) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1488) | DWORD | 16#00000000 |
| Status6 | Status word 6 (Page 1488) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Stop | 1 = Motor is stopping | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopCtrl | Control output to Stop the motor (go to Safe position) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Stopping | 1 = Motor will stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TripOut | Trip as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |
| WarnAct | 1 = Prewarning for motor start active (parameters WarnTiAut and WarnTiMan) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

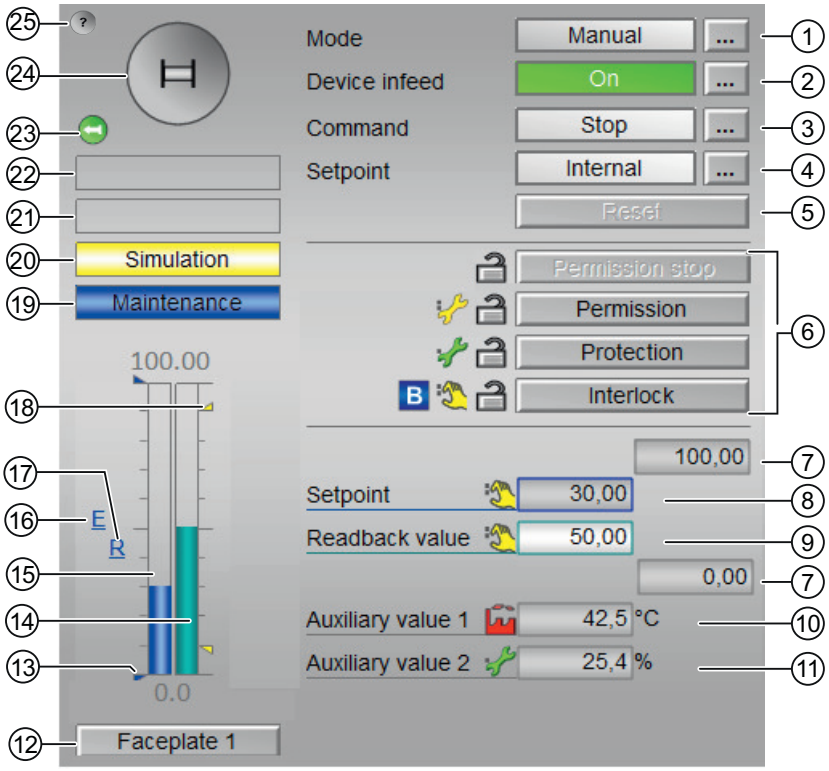
## 8.5.8 Operator control and monitoring

### 8.5.8.1 MotSpdCL views

### Views of the MotSpdCL block



The block MotSpdCL provides the following views:

- MotSpdCL standard view (Page 1536)
- Alarm view (Page 336)
- Limit view of motors (Page 328)
- MotSpdCL limit view for readback values (Page 1546)
- Trend view (Page 341)
- Ramp view (Page 334)
- MotSpdCL parameter view (Page 1548)
- MotSpdCL preview (Page 1542)
- MotSpdCL AddOn view (Page 1552)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MotSpdCL (Page 1552)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.5.8.2 MotSpdCL standard view

#### MotSpdCL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

See also the section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Separate switching on/off of the device infeed or the inverter enable

This area shows you the default operating state for the device infeed or the inverter enable. The following states can be shown and executed here:

- "On"
- "Off"

If the inverter enable is parameterized (`Feature.Bit15` = 1 and `Feature.Bit8` = 1), the text "Device infeed" is replaced by "Inverter enable".

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. You can find additional information on this in the section Labeling of buttons and text (Page 235).

### (3) Starting and stopping the motor

This area shows you the default operating state for the variable motor. The following states can be shown and executed here:

- "Start |→"
- "Start ←|"
- "Stop"
- "Rapid stop"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. You can find more information about this in section Labeling of buttons and text (Page 235).

### (4) Switching the setpoint internal/external

This area shows how to specify the setpoint. The setpoint can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the setpoint specification.

You can find additional information on this in the section Setpoint specification - internal/ external (Page 136).

### (5) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (6) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (7) High and low scale range for the setpoint

This area is already set and cannot be changed.

### (8) Display and change the setpoint including signal status

This area shows the current setpoint with the corresponding signal status.

Refer to the Changing values (Page 291) section for information on changing the setpoint. The setpoint specification also needs to be set to "Internal" for this block.

### (9) Displaying the readback value

This area shows you the current readback value with the corresponding signal status.

### (10) and (11) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (12) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (13) Displaying the limits

These triangles show the `SP_HiLim` and `SP_LoLim` setpoint limits configured in the engineering system (ES).

### (14) Bar graph for the readback value

This area shows you the current readback value in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (15) Bar graph for the setpoint

This area shows the current setpoint in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (16) Display of external setpoint

This display [E] is only visible when you have selected "Internal" setpoint specification. It shows the external setpoint that would apply if you were to change the setpoint specification to "external".

### (17) Display for the target setpoint of the setpoint ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (18) Limit display

These colored triangles show you the configured limits in the respective bar graph.

For more information, refer: Bar graph (Page 376)

### (19) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this topic is available in sections Release for maintenance (Page 70) Display area for block states.

### (20) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (21) Display area for block states

This area provides additional information on the operating state of the block:

- "Motor protection"
- "External error"
- "Status error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (22) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced stop"
- "Forced start |→"
- "Forced start ←|"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)
- "SP ramp active"

You can find additional information on this in the section Forcing operating modes (Page 45).

### (23) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the motor would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (24) Status display of the motor

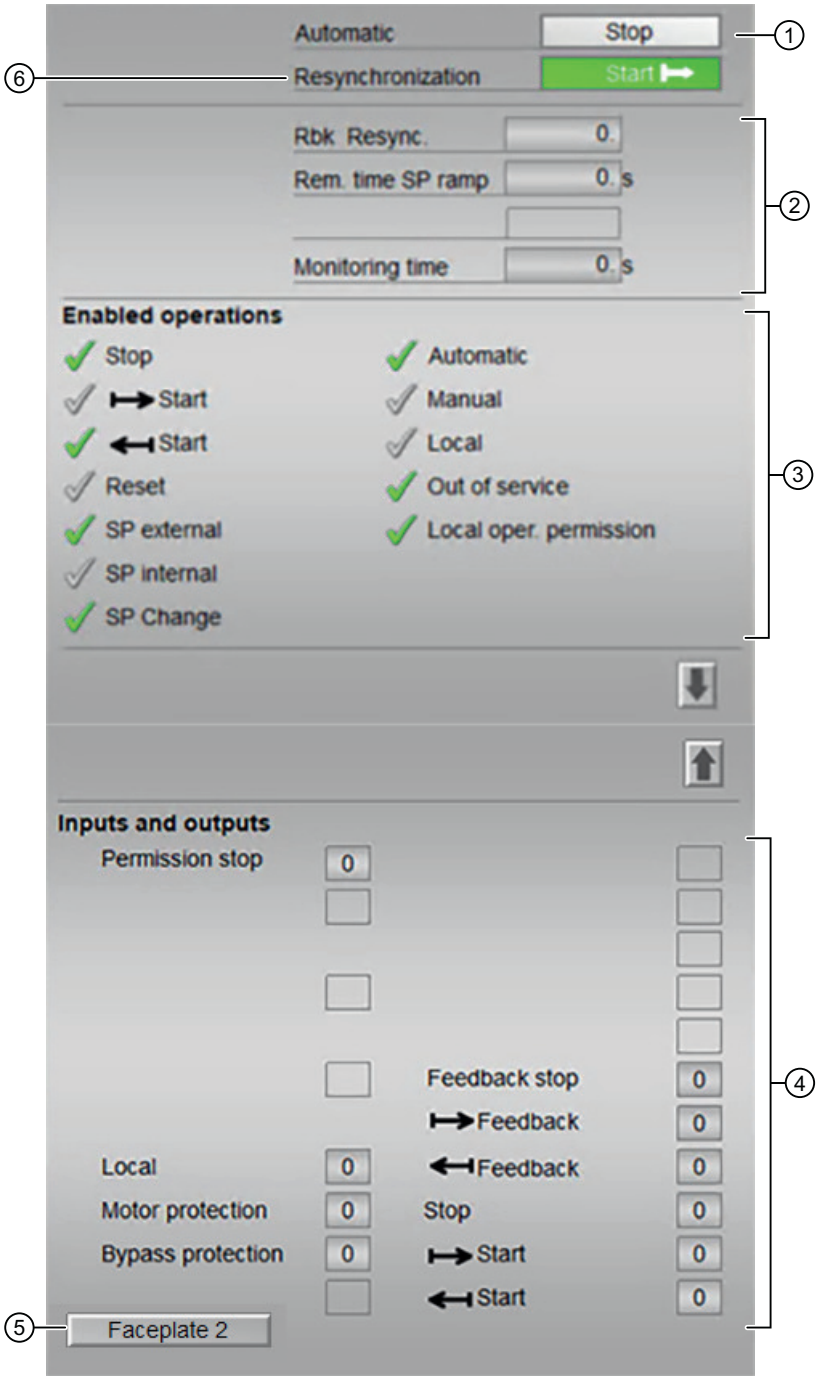
The current status of the motor is graphically displayed here.

You can find more information about this in section Block icon for MotSpdCL (Page 1552)

### (25) Mini preview for Resynchronization

Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:



- Fwd
- Rev
- Stop
- No Cmd

**Note**

Mini preview for resynch is visible only if resynchronization command is different to control output value.

### 8.5.8.3 MotSpdCL preview

**Preview of MotSpdCL**

### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `FwdAut`
- `RevAut`
- `StopAut`
- `SP_Ext`

### (2) Preview area

This area shows you a preview of the following values:

- "Rem. time SP ramp" : Remaining time to reach the ramp target value.
- "Channel Setpoint": Setpoint from the output channel block.
- "Monitoring time": Display of the remaining monitoring time.
- "Rbk Resync": Shows the input Rbk value for Resynchronization

### (3) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Stop": You can stop the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Start |→ ": You can start the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Start ←|": You can start the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the motor after interlocks or errors.
- "SP external": You can feedforward the external setpoint.
- "SP internal": You can feedforward the internal setpoint.
- "Change SP": You can change the setpoint.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).
- "Device infeed On": You can activate the device infeed
- "Device infeed Off": You can deactivate the device infeed

### (4) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission" (`Feature2.Bit16` =0):
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "opening"/"closing" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- " Permission Fwd" (`Feature2.Bit16` =1):
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "Start forward" from the neutral position

- " Permission Rev" (`Feature2.Bit16` =1):
  This display is only visible when the corresponding block input is connected.
  - 0 = No OS release for energizing motor
  - 1 = Enable for "Start reverse" from the neutral position
  - to reset the block
  - 1 = "Good" state
- "Protection" (`Feature2.Bit16` =0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection Fwd" (`Feature2.Bit16` =1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state
- "Protection Rev" (`Feature2.Bit16` =1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state
- "Interlock" (`Feature2.Bit16` =0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock Fwd" (`Feature2.Bit16` =1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state
- "Interlock Rev" (`Feature2.Bit16` =1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Local stop": 1= Block is operated in "local mode"
- "Local start |→": 1= Block is operated in a controlled manner in "local mode"
- "Local start ←|": 1= Block is operated in a controlled manner in "local mode"
- "Feedback |→": 1 = Motor has started and is running
- Feedback←|: 1 = Motor has started and is running
- "Feedback stop" : 1 = Motor has stopped
- "Stop": 1 = Stop motor
- "Start | →" 1 = Start motor
- "Start ←|": 1 = Start motor
- "Device infeed": 1 = Enable device infeed
- "Channel Start →":Signal from the output channel block for "Start"
- "Channel Start ←":Signal from the output channel block for "Start"
- "Permission stop": 1 = Motor can not be stopped in manual (by operator) or automatic (by logic) mode

**(5) Navigation button for switching to the standard view of any faceplate**

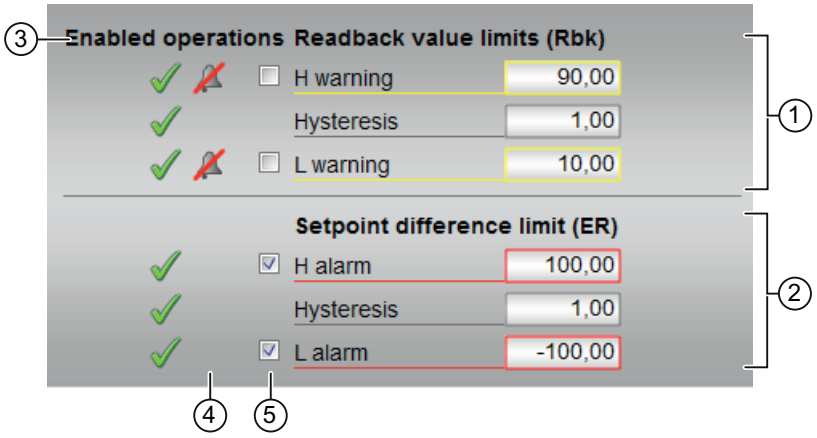
This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, see section Opening additional faceplates (Page 234).

**(6) Resynchronization**

Displays the Resynchronization state and Resynchronization Signal status based on feedback and readback values.



### 8.5.8.4 MotSpdCL limit view for readback values

**Limit view for readback values of MotSpdCL**

Several values are set in this view by default:

- Readback value limits

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

### (1) Displaying and changing the limits for the readback value

In this area, you can enter the limits for the readback value. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H warning": Warning high
- "Hysteresis"
- "L warning": Warning low

### (2) Displaying and changing the limits for the setpoint difference

In this area, you can enter the limits for the setpoint difference. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "Hysteresis"
- "L alarm": Alarm low

### (3) Enabled operation

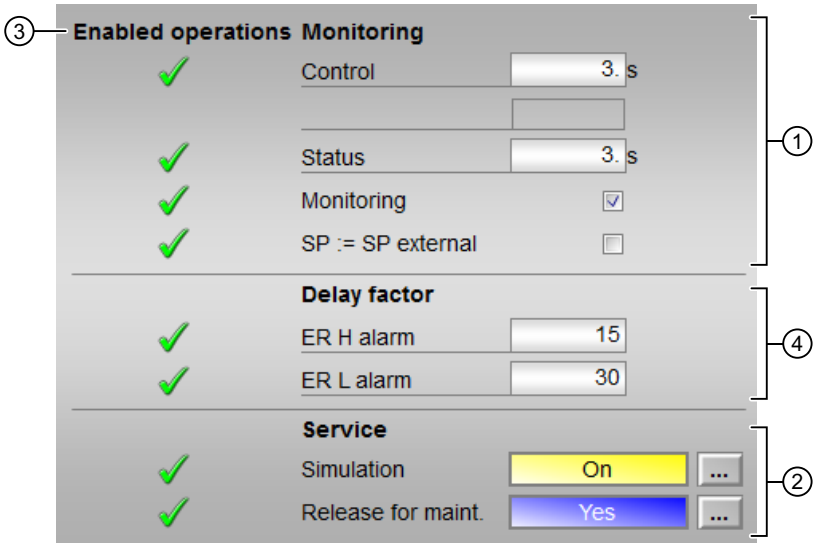
This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

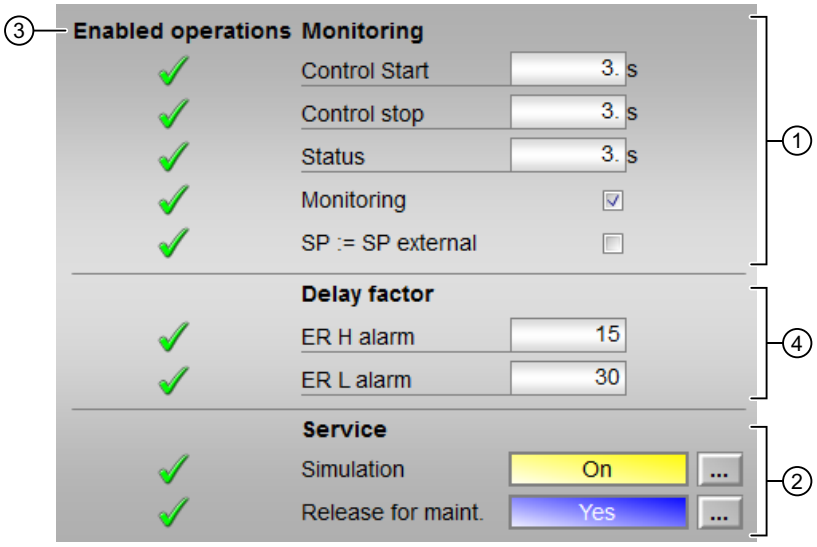
### (4) "Message suppression/delay"

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.



Alarm delays are also displayed in this position; for more on this see section Area of application of the alarm delays (Page 225).

### (5) Suppress messages



You can enable / disable messages by setting the check mark.

## 8.5.8.5 MotSpdCL parameter view

### Parameter view of MotSpdCL

Parameter view of MotSpdCL with `Feature.Bit13` = 0

Parameter view of MotSpdCL with `Feature.Bit13` = 1

## (1) Monitoring

In this area, you change parameters and therefore influence the motor. Refer to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- `Feature.Bit13` **= 0**
  - "Control": Monitoring time during startup and shutdown of the motor (dynamic)
- `Feature.Bit13` **= 1**
  - "Control stop": Monitoring time during shutdown of the motor (dynamic)
  - "Control start": Monitoring time during startup of the motor (dynamic)

**"Status" monitoring**

You can monitor time during permanent operation of the motor (static).

**Enable monitoring**

You can enable monitoring by selecting the check box (☑)

You can find additional information on this in the section Monitoring the feedbacks (Page 104).

**Activating bumpless switchover**

"SP := SP external": ☑ Bumpless switchover of setpoint from external to internal. The internal setpoint is tracked to the external one.

### (2) Service

You can select the following functions in this area:

- Simulation
- Release for maintenance

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### (3) Enabled operation

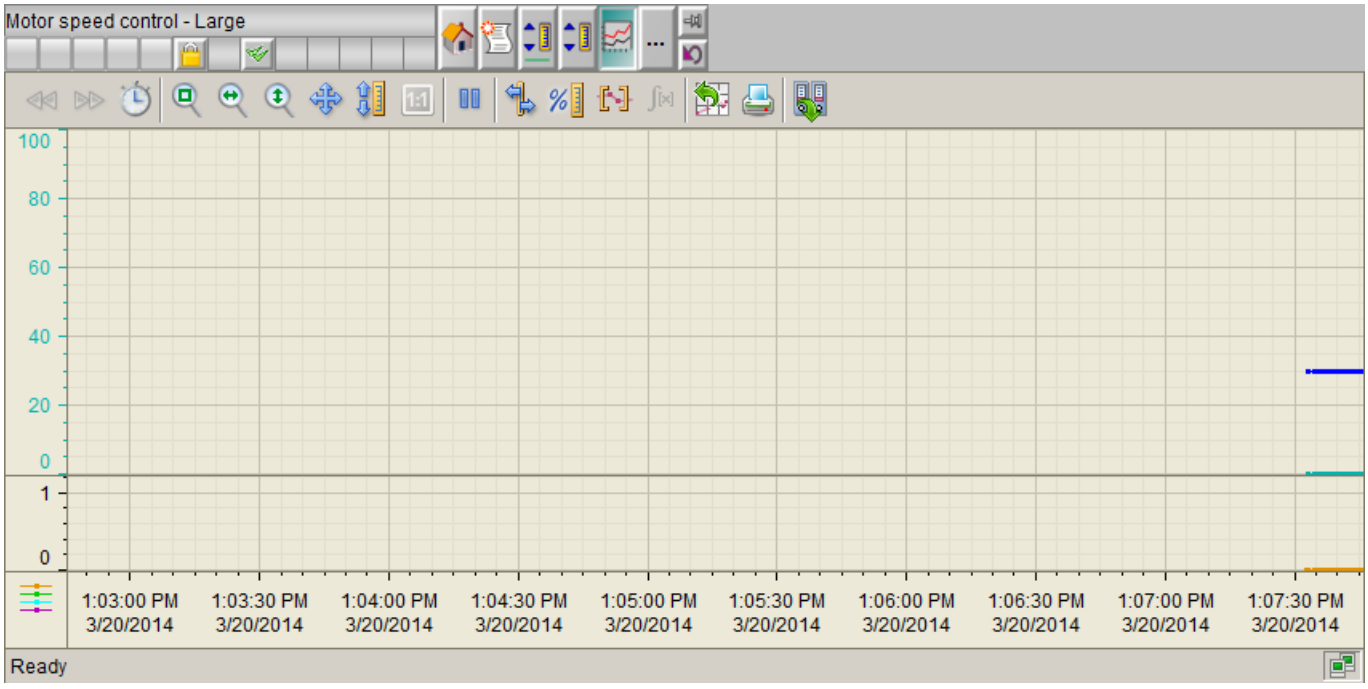
This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

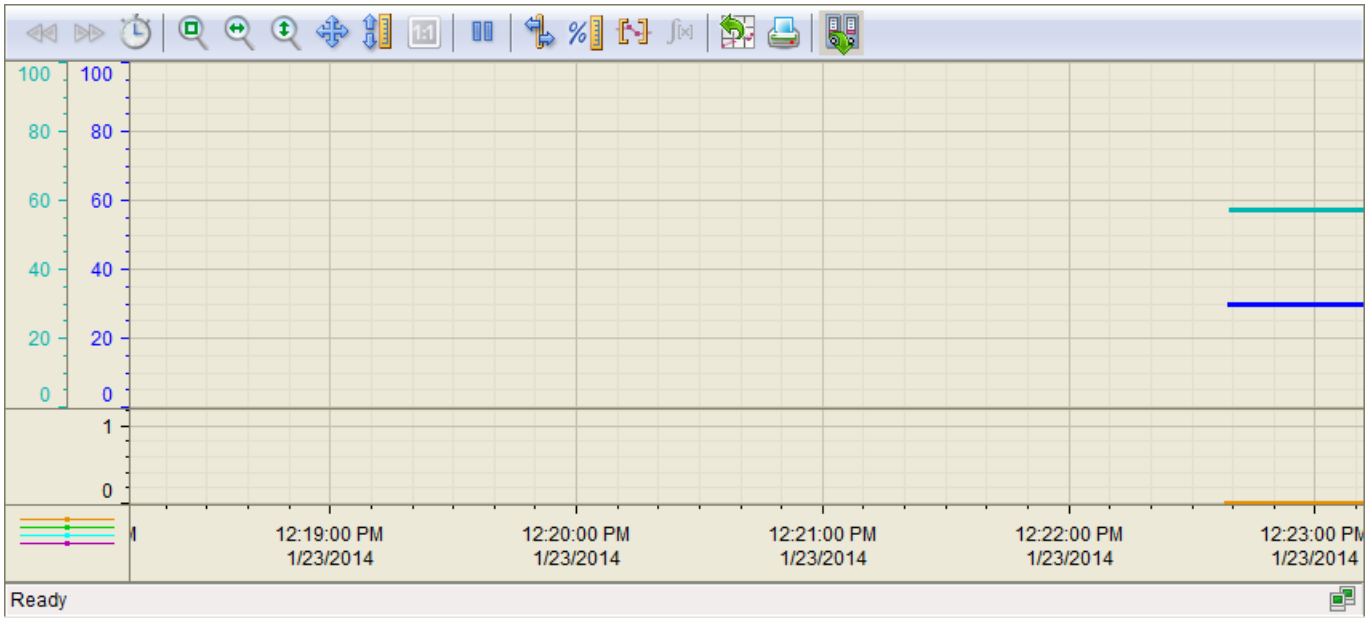
### (4) Delay factor

In this area, you can change the following parameters:



- "ER H alarm": Delay factor at the positive setpoint step changes for incoming alarms at the control deviation monitoring `ER_AH_Lim`.
- "ER L alarm": Delay factor at the negative setpoint step changes for incoming alarms at the control deviation monitoring `ER_AL_Lim`.

## 8.5.8.6 MotSpdCL trend view

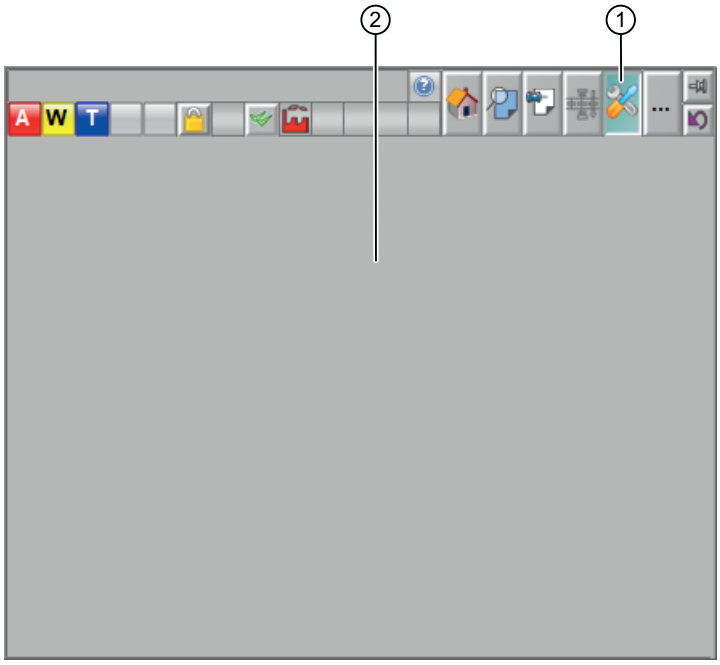


### Trend view of MotSpdCL

You can find general information in section Trend view (Page 341).

Depending on `Feature.Bit16` (process value with separate scale range) either one or two value axes are shown in the trend view.

- Process value with separate scale range



- Process value without separate scale range

**Note**

This function only has an effect when `SP_Out` is configured in "TrendConfiguration1" and `PV_In` is configured in "TrendConfiguration2" in the block icon (default).

### 8.5.8.7 MotSpdCL AddOn view

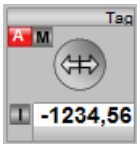
#### MotSpdCL AddOn view

(1) AddOn view icon

(2) Work space of AddOn view: The view of the faceplate can be customized as per the operator needs.

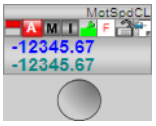
For more information, on AddOn view, refer to AddOn View for function blocks (Page 343)

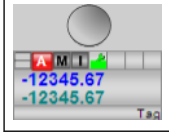
### 8.5.8.8 Block icon for MotSpdCL



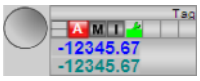
#### Block icons for MotSpdCL

A variety of block icons are available with the following functions:





- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Internal and external setpoint specification
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display



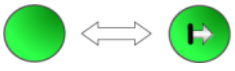
- Motor state display
- Setpoint (blue, with decimal places)
- Feedback value (green, with decimal places)

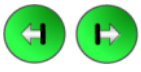
The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Direction display inverted to symbol 1 |
|  | 4 | Direction display inverted to symbol 2 |
|  | 5 | "M" symbol with small direction display |
|  | 6 | "M" symbol with small direction display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |





| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Motor state display

The following motor states are shown here:

| Icon | Meaning |
|---|---|
|  | Motor started (motor symbol changes) |
|  | The motor is running |
|  | Motor stopped (motor symbol changes) |
|  | Motor idle |
|  | Error at motor (monitoring error, Motor protection) |

| Icon | Meaning |
|---|---|
|  | Motor out of service |
|  | “No Cmd” State |

# 8.6 MotSpdL - Two-speed motor

## 8.6.1 Description of MotSpdL

### Object name (type + number) and family

Type + number: FB 1856

Family: Drives

### Area of application for MotSpdL

The block is used for the following applications:

- Control of two-speed motors

### How it works

The block is used to control motors with two speeds. Various inputs are available for controlling the motor. You can add monitoring of a maximum of two feedbacks produced by the contactor relay and a switching mode with which the speed change can be performed.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB3x). The block is also installed automatically in the startup OB (OB100).

Further addressing is not required.

For the MotSpdL block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- Two-speed motor (Motor2Speed) (Page 2860)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section MotSpdL I/Os (Page 1578).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |

| Status bit | Parameter |
|---|---|
| 2 | SimOn |
| 3 | OosAct.Value |
| 4 | OosLi.Value |
| 5 | 0 = ManAct.Value<br>1 = AutoAct.Value |
| 6 | LocalAct.Value |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon<br><br>In case of Feature2.Bit16 = 1 then a closed padlock is displayed if Interlock Open OR Interlock Close is active. |
| 8 | Spd1.Value |
| 9 | Motor is stopped |
| 10 | Spd2.Value |
| 11 | MonStaErr.Value |
| 12 | MonDynErr.Value |
| 13 | BypProt |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = Intlock is active |
| 17 | 1 = Permit is active |
| 18 | 1 = Protect is active |
| 19 | Trip.Value |
| 20 | Display „Forced speed1“ |
| 21 | Display „Forced stop“ |
| 22 | Display „Forced speed2“ |
| 23 | "Interlock" button is enabled |
| 24 | Reset request in automatic preview |
| 25 | WarnAct:Value,<br>IdleTime or<br>SwOverTi active |
| 26 | Bypass information for display in block icon |
| 27 | Automatic preview for (Speed1) |
| 28 | Automatic preview for (Stop) |
| 29 | Automatic preview for (Speed2) |
| 30 | "Permission" button is enabled |
| 31 | "Protection" button is enabled |

## Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock |
| 1 | AV_AH_Act.Value |

| Status bit | Parameter |
|---|---|
| 2 | AV_WH_Act.Value |
| 3 | AV_TH_Act.Value |
| 4 | AV_TL_Act.Value |
| 5 | AV_WL_Act.Value |
| 6 | AV_AL_Act.Value |
| 7 | AV_AH_En OR Feature.Bit23 |
| 8 | AV_WH_En OR Feature.Bit23 |
| 9 | AV_TH_En OR Feature.Bit23 |
| 10 | AV_TL_En OR Feature.Bit23 |
| 11 | AV_WL_En OR Feature.Bit23 |
| 12 | AV_AL_En OR Feature.Bit23 |
| 13 | AV_AH_MsgEn |
| 14 | AV_WH_MsgEn |
| 15 | AV_TH_MsgEn |
| 16 | AV_TL_MsgEn |
| 17 | AV_WL_MsgEn |
| 18 | AV_AL_MsgEn |
| 19 | 1 = No impact of input signals on "local mode" with LocalSetting = 0, 2, 4 |
| 20 | Motor is stopped |
| 21 | Motor stops at speed 1 |
| 22 | Motor stops at speed 2 |
| 23 | Motor starts at speed 1 |
| 24 | Motor running at speed 1 |
| 25 | Motor starts at speed 2 |
| 26 | Motor running at speed 2 |
| 27 | Error when stopping motor |
| 28 | Error with motor speed 1 |
| 29 | Error with motor speed 2 |
| 30 | Display for interlocks in block icon |
| 31 | MS_RelOp |

### Status word allocation for Status3 parameter

| Status bit | Parameter |
|---|---|
| 0 | Delay of the AV_AH_Lim message |
| 1 | Delay of the AV_WH_Lim message |
| 2 | Delay of the AV_TH_Lim message |
| 3 | Delay of the AV_TL_Lim message |
| 4 | Delay of the AV_WL_Lim message |
| 5 | Delay of the AV_AL_Lim message |
| 6 | Collection of message delays |
| 7 | Resynchronization preview for Speed1 |

| Status bit | Parameter |
|---|---|
| 8 | Resynchronization preview for Speed2 |
| 9 | Resynchronization preview for Stop |
| 10 | Resynchronization: Display preview |
| 11 | Resynchronization: Display small preview symbol in standard view |
| 12 - 13 | Not used |
| 14 | Resynchronization with state “No Cmd” |
| 15 | Current monitoring time is visible |
| 16 | `MonDynStopErr.Value` |
| 17 | Not used |
| 18 | `SimLiOp.Value` |
| 19 | 1 = Enable for rapid stop (`Feature` Bit Enabling rapid stop via faceplate (Page 179)) |
| 20 | 1 = Input parameter `Spd1ChnST` is interconnected |
| 21 | 1 = Input parameter `Spd2ChnST` is interconnected |
| 22 | Not used |
| 23 | Command for rapid stop |
| 24 | Command for starting > the motor |
| 25 | Command for starting >> the motor |
| 26 | Show automatic preview in the standard view |
| 27 | Internal error |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

## Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal `6` of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | `AV` not connected |
| 9 | Motor protection display (`Trip.Status` ≠ 16#FF) |
| 10 | 1 = Input parameter `FbkSpd1` is connected |
| 11 | 1 = Input parameter `FbkSpd2` is connected |
| 12 | 1 = Input parameter FbkStop is connected |
| 13 - 21 | Not used |

| Status bit | Parameter |
|---|---|
| 22 | External error generated by FaultExt or external control system fault CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 23 | Hidden bypass signal in Permit |
| 24 | Hidden bypass signal in interlock |
| 25 | Hidden bypass signal in Protect |
| 26 | `Feature2.Bit2`: Separate bypass signal |
| 27 | `Feature2.Bit16`: Separate interlock for each direction, speed or position |
| 28 | Hidden bypass signal in Permit Close |
| 29 | Hidden bypass signal in Interlock Close |
| 30 | Hidden bypass signal in Protect Close |
| 31 | Separate monitoring of shutdown of the motor (`Feature.Bit13`) |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 15 | Not used |
| 16 | "Permission Open" button is enabled |
| 17 | "Permission Close" button is enabled |
| 18 | "Interlock Open" button is enabled |
| 19 | "Interlock Close" button is enabled |
| 20 | "Protect Open" button is enabled |
| 21 | "Protect Close" button is enabled |
| 22 | 1 = Permission Close is active |
| 23 | 1 = Intlock Close is active |
| 24 | 1 = Protect Close is active |
| 25 | 1 = "Permission stop" button is enabled |
| 26 | 1 = Permission stop is active |
| 27 | Hidden bypass signal in Permission stop |
| 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 - 31 | Not used |

MotSpdL functions (Page 1563)

MotSpdL messaging (Page 1577)

MotSpdL block diagram (Page 1590)

MotSpdL error handling (Page 1574)

MotSpdL modes (Page 1561)

## 8.6.2 MotSpdL modes

### MotSpdL modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions. This includes, for example, the parameters for mode changes.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Motor actions you can control in local mode:

- starting with speed 1 (`Spd1Local` = 1)
- starting with speed 2 (`Spd2Local` = 1)
- stopping (`StopLocal` = 1).

A motor operated in "local" mode is controlled either by "local" signals (input parameters `Spd1Local` = 1, `Spd2Local` = 1 and `StopLocal` = 1) or feedback signals (input parameters `FbkSpd1` = 1, `FbkSpd2` = 1 or `FbkStop` =1). Configuration takes place via the input parameter `LocalSetting`.

`LocalSetting` =2,4: The control outputs are tracked to the feedbacks.

All three feedbacks are available and plausible means that always only one feedback is active. The corresponding control output is tracked:

```
Spd1 = FbkSpd1,
Spd2 = FbkSpd2,
StopCtrl = FbkStop.
```

When all feedbacks are false then the drive is between of two positions. In this case no monitoring is started. When two feedbacks are active at the same time, then they are not plausible. In this case the static monitoring counter starts. In both cases "all feedbacks are reset" or "not plausible feedbacks" with `Feature2Bit21` =1 all the control outputs are set to false (No command state) else control outputs will be hold.

If two feedbacks are available then they are always plausible besides they are both active.

| NoFbkStop =1 (default) | NoFbkSp1 =1 | NoFbkSp2 =1 |
|---|---|---|
| `Spd1 = FbkSpd1,`<br>`Spd2 = FbkSpd2,`<br>`StopCtrl = NOT FbkSpd1 AND NOT FbkSpd2` | `Spd1 = NOT FbkStop AND NOT FbkSpd2`<br>`Spd2 = FbkSpd2,`<br>`StopCtrl = FbkStop` | `Spd1 = FbkSpd1,`<br>`Spd2 = NOT FbkStop AND NOT FbkSpd1`<br>`StopCtrl = FbkStop` |

When they are not plausible the control outputs will be hold.

When only one feedback is available the concerned control output is tracked. The other control outputs are hold if the available feedback is false.

| NoFbkStop =0 | NoFbkSp1 =0 | NoFbkSp2 =0 |
|---|---|---|
| `StopCtrl = FbkStop,` `Spd1,Spd2` are hold if `FbkStop =0` | `Spd1= FbkSpd1,` `StopCtrl,Spd2` are hold if `FbkSpd1=0` | `Spd2 = FbkSpd2,` `StopCtrl, Spd1` are hold if `FbkSpd2=0` |

When all feedbacks are not available the control outputs will be hold.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Motor actions you can control in auto mode:

- starting with speed 1 (`Spd1Aut` = 1)
- starting with speed 2 (`Spd2Aut` = 1)
- stopping (`StopAut` = 1).

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Motor actions you can control in "manual mode":

- starting with speed 1 (`Spd1Man` = 1)
- starting with speed 2 (`Spd2Man` = 1)
- stopping (`StopMan` = 1).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkSpd1Out.ST | 16#80 | 16#60 |
| FbkSpd2Out.ST | 16#80 | 16#60 |
| RunSpd1.ST | 16#80 | 16#60 |
| RunSpd2.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |
| Starting.ST | 16#80 | 16#60 |

| Output Parameters | Feature2.Bit1 =0 | Feature2.Bit1 =1 |
|---|---|---|
| Stoping.ST | 16#80 | 16#60 |
| AV_Out.ST | 16#80 | 16#60 |

## 8.6.3 MotSpdL functions

### Functions of MotSpdL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can start the motor at speed 1 |
| 6 | 1 = Operator can start the motor at speed 2 |
| 7 | 1 = Operator can reset the motor |
| 8 | 1 = Operator can define or change the monitoring time for startup |
| 9 | 1 = Operator can define the monitoring time for the status |
| 10 | 1 = Operator can activate the monitoring time function (Bit 8 - 9) |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |

| Bit | Function |
|---|---|
| 13 | 1 = Operator can change the limit (AV) for high alarm |
| 14 | 1 = Operator can change the limit (AV) for high warning |
| 15 | 1 = Operator can change the limit (AV) for high tolerance |
| 16 | 1 = Operator can change the limit (AV) for hysteresis |
| 17 | 1 = Operator can change the limit (AV) for low alarm |
| 18 | 1 = Operator can change the limit (AV) for low warning |
| 19 | 1 = Operator can change the limit (AV) for low tolerance |
| 20 | 1 = Operator can activate / deactivate messages via AV_AH_MsgEn |
| 21 | 1 = Operator can activate / deactivate messages via AV_WH_MsgEn |
| 22 | 1 = Operator can activate / deactivate messages via AV_TH_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via AV_TL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via AV_WL_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via AV_AL_MsgEn |
| 26 | 1 = Operator can change the simulation value SimAV |
| 27 - 29 | Not used |
| 30 | 1 = Operator can define the monitoring time for stopping |
| 31 | 1 = Operator can execute the rapid stop |

The block has the following permissions for the OS1Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Restart lock after switching off the motor

After switching off or stopping the motor, it can only be restarted after the time set with the IdleTime input parameter. When the "Stop" command is given, the motor goes immediately into "Stop" mode, and IdleTime starts after the feedback (FbkSpd1 and FbkSpd2 = 0) is given. The motor cannot be started again until the IdleTime has expired.

The IdleTime parameter can be set independently of the MonTiDynamic parameter.

### Limit monitoring of an additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Interlocks

This block provides the following interlocks:

`Feature2.Bit16` = 0:

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")
- Permission for stop ("Permission stop")

`Feature2.Bit16` = 1:

- Activation enable speed1
- Activation enable speed2
- Interlock speed1 without reset ("Interlock speed1")
- Interlock speed2 without reset ("Interlock speed2")
- Interlock open with reset ("Protection interlock speed1")
- Interlock close with reset ("Protection interlock speed2")

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

### Rapid stop for motors

This block provides the standard function Rapid stop for motors (Page 115).

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (FaultExt), external control system fault (CSF)

This block provides the possibility to pass an external error via the FaultExt parameter or an external control system fault via the CSF parameter. See MotSpdL error handling (Page 1574).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- CSF
- Trip
- MonDynErr
- MonStaErr
- FaultExt

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status ST_Worst for the block is formed from the following parameters:

- FbkSpd1Out.ST
- FbkSpd2Out.ST
- LocalLi.ST
- Spd1Local.ST
- StopLocal.ST
- Spd2Local.ST
- Trip.ST
- AV_Out.ST
- Spd1Chn.ST
- Spd2Chn.ST
- Spd1Aut.ST (only if Feature2.Bit10 = 1)

- `Spd2Aut.ST` (only if `Feature2.Bit10` = 1)
- `StopAut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position (motor stop) in the "Automatic" mode:

- `Spd1Aut.ST`
- `Spd2Aut.ST`
- `StopAut.ST`

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).

The following states can be enforced:

- Speed 1 (`Spd1Force`)
- Speed 2 (`Spd2Force`)
- Stop (`StopForce`)

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

### Disabling feedback

This block provides the standard function for Disabling feedback for valve and motors (Page 106).

Feedback monitoring can be deactivated separately for each feedback with `NoFbkSpd1` or `NoFbkSpd2` or `NoFbkStop` as required.

The output signals of feedback are tracked by the control and the other available feedbacks:

| NoFbkSpd1 | NoFbkSpd2 | NoFbkStop | Comment |
|---|---|---|---|
| 0 | 0 | 1 | **Default:**<br>`FbkSpd1Out = FbkSpd1;`<br>`FbkSpd2Out = FbkSpd2;`<br>`FbkStopOut = StopCtrl AND NOT FbkSpd1 AND NOT FbkSpd2;`<br>**Local mode with Local-Setting =2/4:**<br>`FbkSpd1Out = FbkSpd1;`<br>`FbkSpd2Out = FbkSpd2;`<br>`FbkStopOut = NOT FbkSpd1 AND NOT FbkSpd2;` |
| 1 | 0 | 1 | `FbkSpd1Out = Spd1 AND NOT FbkSpd2;`<br>`FbkSpd2Out = FbkSpd2;`<br>`FbkStopOut = StopCtrl AND NOT FbkSpd2;` |
| 0 | 1 | 1 | `FbkSpd1Out = FbkSpd1;`<br>`FbkSpd2Out = Spd2 AND NOT FbkSpd1;`<br>`FbkStopOut = StopCtrl AND NOT FbkSpd1;` |
| 1 | 1 | 1 | `FbkSpd1Out = Spd1;`<br>`FbkSpd2Out = Spd2;`<br>`FbkStopOut = StopCtrl;` |

| NoFbkSpd1 | NoFbkSpd2 | NoFbkStop | Comment |
|---|---|---|---|
| 1 | 0 | 0 | `FbkFwdOut = Spd1 AND NOT FbkSpd2 AND NOT FbkStop;`<br>`FbkSpd2Out = FbkSpd2;`<br>`FbkStopOut = FbkStop;`<br>**Local mode with Local-Setting =2/4:**<br>`FbkSpd1Out = NOT FbkSpd2 AND NOT FbkStop;`<br>`FbkSpd2Out = FbkSpd2;`<br>`FbkStopOut = FbkStop;` |
| 0 | 1 | 0 | `FbkSpd1Out = FbkSpd1;`<br>`FbkSpd2Out = Spd2 AND NOT FbkSpd1 AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;`<br>**Local mode with Local-Setting =2/4:**<br>`FbkSpd1Out = FbkSpd1;`<br>`FbkSpd2Out = NOT FbkSpd1 AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;` |
| 0 | 0 | 0 | `FbkSpd1Out = FbkSpd1;`<br>`FbkSpd2Out = FbkSpd2;`<br>`FbkStopOut = FbkStop;` |
| 1 | 1 | 0 | `FbkSpd1Out = Spd1 AND NOT FbkStop;`<br>`FbkSpd2Out = Spd2 AND NOT FbkStop;`<br>`FbkStopOut = FbkStop;` |

### Using StopCtrl with mode "No Cmd"

This block provides the standard function Control with output StopCtrl and state “No Cmd” (Page 214)

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56).

You can generate warning signals when, for example, motors are started. Warning signals can be generated in the following modes:

- Manual mode (Page 82) (`WarnTiMan` input parameter)
- Automatic mode (Page 82) (`WarnTiAut` input parameter)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a motor is started, then this is displayed at the output parameter with `WarnAct` = 1. The motor then starts after the set warning time has expired and `WarnAct` then goes back to 0.

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

### Step control mode for the speed change

Use the input parameter `SwiOverTi` and the `Feature.Bit5` (Specifying switching mode (Page 178)) to specify how the motor is to carry out the speed change.

In so doing use the input parameter `SwiOverTi` to adjust the switching time. You have the following options:

- Switching on and off occurs immediately
- Switching on via speed 1
- Switching off via speed 1

**Switching on and off occurs immediately:** This setting enables you to switch directly from the "Off" state to speed 2 or from speed 2 (`Spd2`) to "Off".

**Switching on via speed 1:** The speed change from the "Off" condition to speed 2 (`Spd2`) is accomplished via speed 1 (`Spd1`) and after expiration of the time at the parameter `SwiOverTi`.

**Switching off via speed 1:** The speed change from speed 2 (`Spd2`) to the "Off" state is accomplished via speed 1 (`Spd1`) and after expiration of the time at parameter `SwiOverTi`.

| Step control mode | **SwiOverTi** | **Feature.Bit5** |
|---|---|---|
| Switching on and off occurs immediately | = 0.0 | 0/1 |
| Switching on only via speed 1 | > 0.0 | 0 |
| Switching on and off via speed 1 | > 0.0 | 1 |

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Additional value (`SimAV`, `SimAV_Li`)

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the controls are tracked as follow:

**NoFbkSpd1 =0, NoFbkSpd2 =0, NoFbkStop =1 (default):**

Spd1 := FbkSpd1;

Spd2 := FbkSpd2;

StopCtrl := NOT FbkSpd1 AND NOT FbkSpd2;

In case if there are no plausible feedback positions (FbkSpd1 =1, FbkSpd2 =1) the controls are not changed.

**NoFbkSpd1 =0, NoFbkSpd2 =0, NoFbkStop =0:**

Plausible feedback positions (only one feedback signal is active) are tracked as control position.

Spd1 := FbkSpd1;

Spd2 := FbkSpd2;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (two or three feedback signals are active) the control position depends on Feature2 Bit21.

- Feature2 Bit21 =0 (default): Control position is not changed.
- Feature2 Bit21 =1: Control position becomes "No Cmd" Spd1 := 0; Spd2 := 0; StopCtrl := 0;

**NoFbkSpd1 =0, NoFbkSpd2 =1, NoFbkStop =0:**

Spd1 := FbkSpd1 AND NOT FbkStop;

Spd2 := NOT FbkSpd1 AND NOT FbkStop;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (FbkSpd1 =1, FbkStop =1) the controls are not changed.

**NoFbkFwd =1, NoFbkRev =0, NoFbkStop =0:**

Spd1 := NOT FbkSpd2 AND NOT FbkStop;

Spd2 := FbkSpd2 AND NOT FbkStop;

StopCtrl := FbkStop;

In case if there are no plausible feedback positions (FbkSpd2 =1, FbkStop =1) the controls are not changed.

With other combinations of **NoFbkSpd1**, **NoFbkSpd2**, **NoFbkStop** the controls are not changed.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Specifying switching mode (Page 178) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 13 | Separate monitoring time for stopping the motor (Page 180) |
| 14 | Enabling rapid stop via faceplate (Page 179) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |

| Bit | Function |
|---|---|
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In pushbutton operation (Bit 4 = 0) the automatic commands in "automatic" mode are latching, in other words `Spd1Aut`, `Spd2Aut`, `StopAut` can be reset to 0 after changing the control. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

In switching mode (Bit 4 = 1), control is selected with the static signals `Spd1Aut`, `Spd2Aut`. If `Spd1Aut`, `Spd2Aut` inputs are not set, the motor is stopped. Control via `StopAut` is not needed. If the "Activate command reset for control" function (Bit 3 = 1) is also enabled, the inputs `Spd1Aut`, `Spd2Aut` are reset to the neutral position after evaluation in the block.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 16 | Separate interlock for each direction, position, or speed (Page 180) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 21 | Control with output StopCtrl and state “No Cmd” (Page 214) |

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `Spd1Man`
- `Spd2Man`
- `StopMan`
- `RapidStp`

## 8.6.4 MotSpdL error handling

### Error handling of MotSpdL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Invalid or not plausible input commands
- Control system fault (CSF)

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value for the LocalSetting I/O is not within the approved limit of 0 to 4. |
| 42 | LocalSetting = 0 or LocalSetting = 3 or LocalSetting = 4 and LocalLi = 1 |
| 51 | Spd1Local = 1 and StopLocal = 1<br>Spd2Local = 1 and StopLocal = 1<br>Spd1Local = 1 and Spd2Local = 1<br>Spd1Aut = 1 and StopAut = 1<br>Spd2Aut = 1 and StopAut = 1<br>Spd1Aut = 1 and Spd2Aut = 1<br>AutModLi = 1 and ManModLi = 1<br>Spd1Force = 1 and StopForce = 1<br>Spd2Force = 1 and StopForce = 1<br>Spd1Force = 1 and Spd2Force = 1 |
| 52 | LocalAct = 1 and LocalSetting = 2 or 4 and SimOn = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| **Operating mode** | **Invalid or not plausible input commands** | **Control reaction with** `Feature2.Bit3` =1 |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | Pushbutton operation for local mode (`Feature2.Bit4` = 0):<br>`Spd1Local` = 1 and `Spd2Local` = 1 or<br>`Spd1Local` = 1 and `StopLocal` = 1 or<br>`StopLocal` = 1 and `Spd2Local` = 1<br>Switching mode (`Feature2.Bit4` = 1):<br>`Spd1Local` = 1 and `Spd2Local` = 1 | Motor is stopped |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `Spd1Force` = 1 and `Spd2Force` = 1 or<br>`Spd1Force` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `Spd2Force` = 1 | |
| Forcing and no "local mode" | `Spd1Force` = 1 and `Spd2Force` = 1 or<br>`Spd1Force` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `Spd2Force` = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0):<br>`Spd1Aut` = 1 and `Spd2Aut` = 1 or<br>`Spd1Aut` = 1 and `StopAut` = 1 or<br>`StopAut` = 1 and `Spd2Aut` = 1<br>Switching mode (`Feature.Bit4` = 1):<br>`Spd1Aut` = 1 and `Spd2Aut` = 1 | |
| "Manual mode" and no forcing | `Spd1Man` = 1 and `Spd2Man` = 1 or<br>`Spd1Man` = 1 and `StopMan` = 1 or<br>`StopMan` = 1 and `Spd2Man` = 1 | |

## Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

Description of MotSpdL (Page 1556)

MotSpdL messaging (Page 1577)

## 8.6.5 MotSpdL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Motor feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>Motor protection triggered |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 3).

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa104` ... `ExtVa108` and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 8.6.6 MotSpdL I/Os

I/Os of MotSpdL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

Table 8-1

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AutModLi*` | 1 = "Automatic mode" via interconnection or SFC (controlled by `ModLiOp` = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AutModOp*` | 1 = "Automatic mode" via operator (controlled by `ModLiOp` = 0) | BOOL | 0 |
| `AV` | Input additional analog value, to be connected to `AV_Tech` of the AV block | ANY | |
| `AV_AH_Lim` | Limit high alarm | REAL | 95.0 |
| `AV_AL_Lim` | Limit low alarm | REAL | 5.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV_Hyst | Hysteresis for alarm, warning and tolerance limits | REAL | 1.0 |
| AV_TH_Lim | Limit high tolerance | REAL | 85.0 |
| AV_TL_Lim | Limit low tolerance | REAL | 15.0 |
| AV_WH_Lim | Limit high warning | REAL | 90.0 |
| AV_WL_Lim | Limit low warning | REAL | 10.0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CSF | 1 = External error (control system faultError handling (Page 128)) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkSpd1 | 1= Motor feedback running Speed1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkSpd2 | 1= Motor feedback running Speed2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkStop | 1= Motor feedback stoped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1563)<br>1 = Separate monitoring time for stopping the motor | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 13: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1563) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| IdleTime* | Wait time for restart of motor in [s] | REAL | 5.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Intlock | 0 = Interlock / Interlock open is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock / Interlock open is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| Intl_En | 1 = Parameter Intlock is enabled. | BOOL | 1 |
| IntlSp2 | 0 = Interlock close is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock close is deactivated. | BOOL | 1 |
| IntlSp2En | 1 = Parameter IntlSp2 is enabled. | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors  Motors: Stop is the neutral position | BOOL | 1 |
| MonTiDynamic* | Monitoring time for feedback errors  or feedback start error after successful operation in [s] | REAL | 3.0 |
| MonTiDyStop* | Monitoring time for feedback stop errors after successful operation in [s] | REAL | 3.0 |
| MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MS_RelOp | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | 1 = Release for maintenance via OS operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| NoFbkSp1 | 1= Motor Feedback running Speed1 not present | BOOL | 0 |
| NoFbkSp2 | 1= Motor Feedback running Speed2 not present | BOOL | 0 |
| NoFbkStop | 1= Motor Feedback stopped not present | BOOL | 1 |
| `Occupied` | 1 = In use by a batch | BOOL | 0 |
| `OosLi` | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `OosOp*` | 1 = "Out of service", via OS operator | BOOL | 0 |
| `OpSt_In` | Input parameter for local operator authorization, connected with the `Out` output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| `OS_Perm` | I/O for operator permissions (Page 1563)<br>1 = Operator can set or change the monitoring time for "Control: Start"<br>1 = Operator can set the monitoring time for "Control:Stop" | STRUCT<br>• Bit 0: BOOL<br>• Bit 8: BOOL<br>• Bit 20: BOOL<br>• Bit 30: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| `OS1Perm` | I/O for operator permissions (Page 1563) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| `Permit` | 1 = Activation enable / Activation open enable.<br>0 = No activation enable / No activation open enable. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| PermitSafePos | 1=Motor stop is allowed | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermSf_En | 1=Permit stop enabled | BOOL | 1 |
| `Perm_En` | 1 = Parameter `Permit` enable | BOOL | 1 |
| `PermSp2` | 1 = Activation Close enable<br>0 = No activation Close enable | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| `PermSp2En` | 1 = Parameter `PermSp2` is enabled | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Protect | 0 = Protective interlock / Protective interlock open is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock / Protective interlock open is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| Prot_En | 1 = Parameter Protect enable | BOOL | 1 |
| ProtSp2 | 0 = Protective interlock close is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock close is deactivated. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| ProtSp2En | 1 = Parameter ProtSp2 enable | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RapidStp* | Rapid stop for the motor:<br>0 = Motor On<br>1 = Motor Off | BOOL | 0 |
| Spd1Aut* | 1 = Activation of motor speed 1 in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Spd2Aut* | 1 = Activation of motor speed 2 in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Spd1ChnST | Signal status of output channel for Fwd<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Spd2ChnST | Signal status of output channel for Rev<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Spd1Force | 1 = Force activation of motor speed 1 in "manual mode" or in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Spd2Force | 1 = Force activation of motor speed 2 in "manual mode" or in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Spd1Local | 1 = Activation of motor speed 1 in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Spd2Local | 1 = Activation of motor speed 2 in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Spd1Man* | 1 = Activation of motor speed 1 in "manual mode" | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Spd2Man* | 1 = Activation of motor speed 2 in "manual mode" | BOOL | 0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimAV* | Additional value used for SimOn = 1 | REAL | 0.0 |
| SimAV_Li | Additional analog value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stopping the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopForce | 1 = Force motor stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopLocal | 1 = Stopping the motor in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stopping the motor in "manual mode" | BOOL | 0 |
| SwOverTi* | Time for speed change | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| WarnTiAut* | Prewarning of motor start in "automatic mode" in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan* | Prewarning of motor start in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AV_OpScale | Limit for scale in AV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| AV_Out | Output additional analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Unit | Unit of measure for additional analog value | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `CSF_Out` | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `CurrMon` | Remaining monitoring time [s] | DINT | 0 |
| `ENO` | 1 = Block algorithm completed without errors | BOOL | 0 |
| `ErrorNum` | Output of pending error number. For error numbers that can be output by this block, see MotSpdL error handling (Page 1574) | INT | -1 |
| `FaultExtOut` | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkSpd1Out` | 1= Motor feedback running Speed1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkSpd2Out` | 1= Motor feedback running Speed1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkStopOut | 1= Motor feedback stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `GrpErr` | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `IntlockOut` | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `IntlSp2Out` | IntlSp2 as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `LocalAct` | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `LockAct` | 1 = Interlock (`Intlock`, `Permit`, `Protect`) or `Trip` is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `ManAct` | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MonDynErr | 1 = Feedback error or feedback start error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonDynStopErr | 1 = Feedback stop error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | WORD | 16#FFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Spd1 | 1 = Pulse signal for starting the motor with speed 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Spd2 | 1 = Pulse signal for starting the motor with speed 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Stop | 0 = Pulse signal for stopping the motor | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermitOut | Permit as Output | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT | - |
| | | • Value: BOOL | • 1 |
| | | • ST: BYTE | • 16#FF |
| PermSp2Out | PermSp2 as Output | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| ProtectOut | Protect as Output | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| ProtSp2Out | ProtSp2 as Output | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| R_StpAct | 1 = Rapid stop of the motor is active | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| RunSpd1 | 1 = Motor running at speed 1 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| RunSpd2 | 1 = Motor running at speed 2 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| SimAct | 1 = Simulation Active | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Spd1 | 1 = Control of motor: Speed 1 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| Spd2 | 1 = Control of motor: Speed 2 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Starting | 1 = Motor will start | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Status1 | Status word 1 (Page 1556) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1556) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1556) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1556) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1556) | DWORD | 16#00000000 |
| Stop | 1 = Motor is stopping | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopCtrl | Control output to Stop the motor (go to Safe position) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Stoping | 1 = Motor will stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TripOut | Trip as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |
| WarnAct | 1 = Prewarning for motor start active (parameters WarnTiAut and WarnTiMan) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

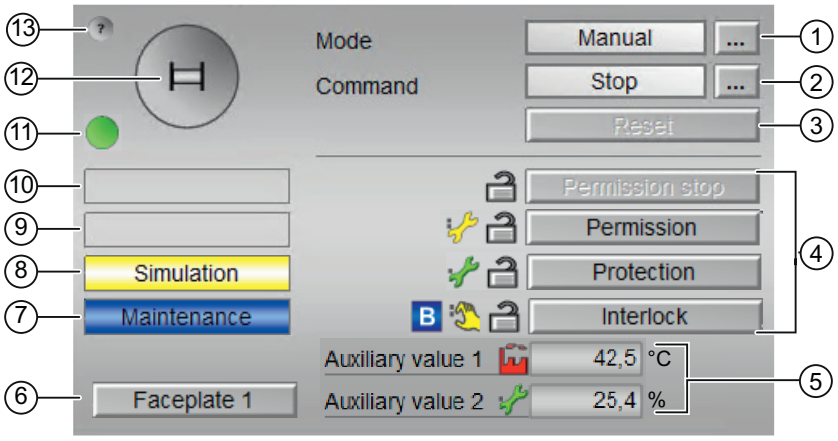
## 8.6.8 Operator control and monitoring

### 8.6.8.1 MotSpdL views

### Views of the MotSpdL block



The block MotSpdL provides the following views:

- MotSpdL standard view (Page 1591)
- Alarm view (Page 336)
- Limit view of motors (Page 328)
- Trend view (Page 341)
- Parameter view for motors and valves (Page 320)
- MotSpdL preview (Page 1595)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for MotSpdL (Page 1600)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.6.8.2 MotSpdL standard view

#### MotSpdL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Starting and stopping the motor

This area shows you the default operating state for the motor. The following states can be shown and executed here:

- "Start >"
- "Start >>"
- "Stop"
- "Rapid stop"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (6) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Motor protection"
- "External error"
- "Status error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced stop"
- "Forced start >"
- "Forced start >>"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (11) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the motor would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (12) Status display of the motor

The current status of the motor is graphically displayed here.

You can find more information about this in section Block icon for MotSpdL (Page 1600).

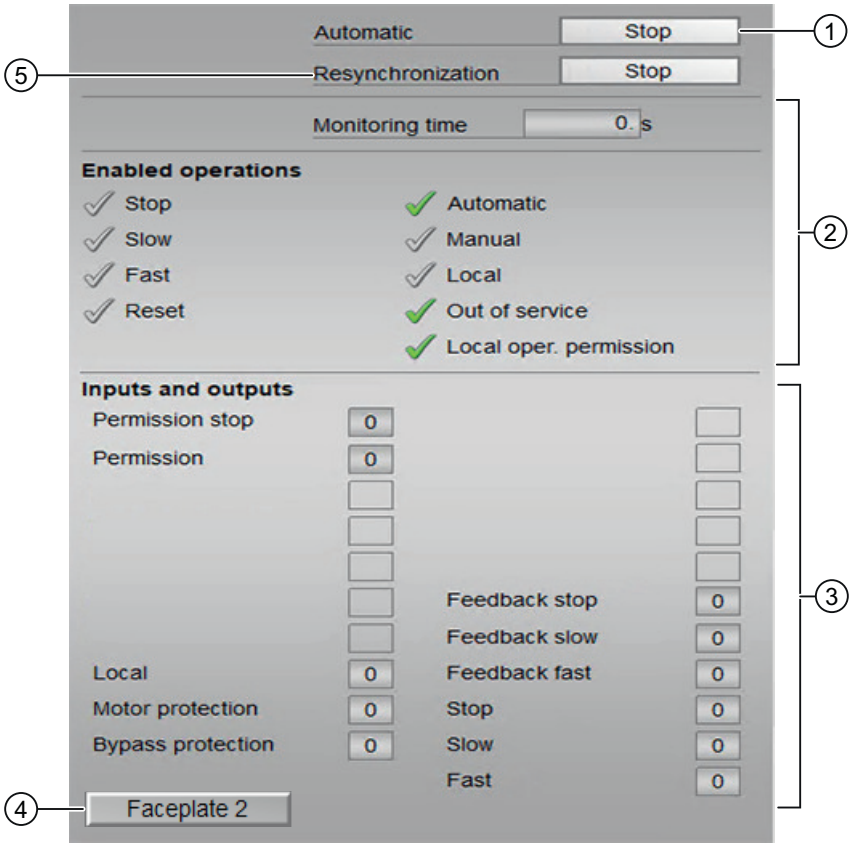
### (13) Mini preview for Resynchronization

Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:

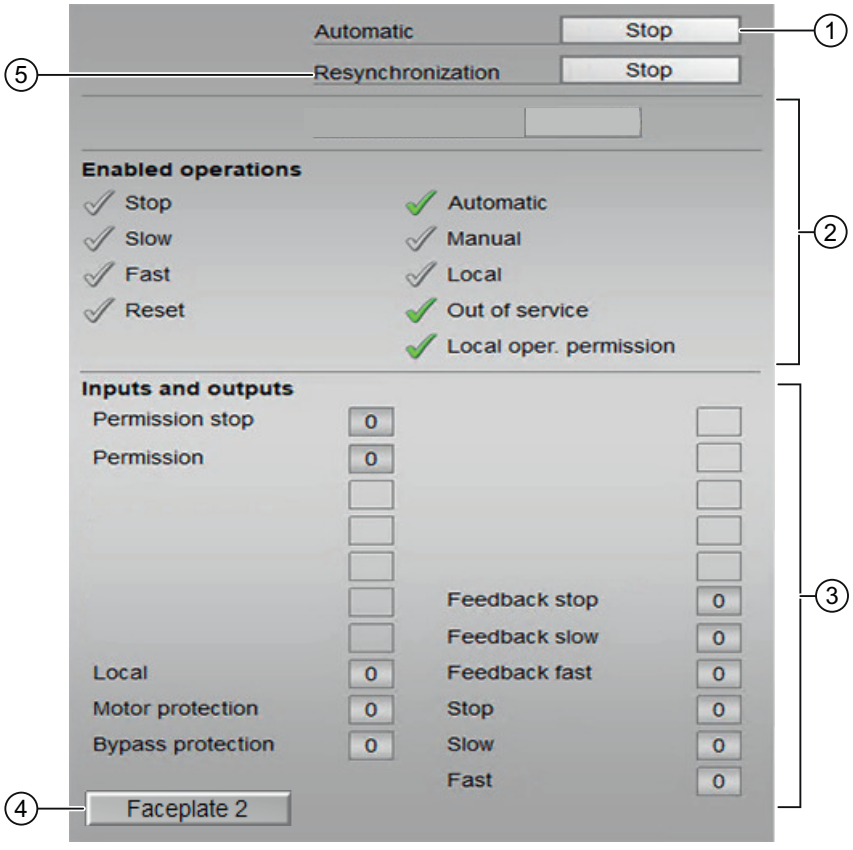
- Spd1
- Spd2
- Stop
- No Cmd

**Note**



Mini preview for resynch is visible only if resynchronization command is different to control output value.

## See also



Functions of the blocks (Page 45)

### 8.6.8.3 MotSpdL preview

**Preview of MotSpdL**

Display of the current monitoring time is visible.

Display of the current monitoring time is not visible.

### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `Spd1Aut`
- `Spd2Aut`
- `StopAut`

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Stop": You can stop the motor.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Slow": You can start the motor in the "slow" state.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Fast": You can start the motor in the "fast" state.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the motor after interlocks or errors.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. For more information, see section Operator control permissions (Page 285).
- "Monitoring time": Display of the remaining monitoring time.

### (3) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission" (`Feature2.Bit16` **= 0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "slow"/"fast" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission slow" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "slow" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission fast" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "fast" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection" (`Feature2.Bit16` **= 0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection slow" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Protection fast" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock" (`Feature2.Bit16` **= 0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock slow" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock fast" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Local stop": 1 = Stopping the motor in "local mode"
- "Local slow": 1 = Starting the motor in "local mode", slow
- "Local fast": 1 = Starting the motor in "local mode", fast
- "Feedback slow": 1 = Motor has started and is running slow
- "Feedback fast": 1 = Motor has started and is running fast
- "Feedback stop" : 1 = Motor has stopped

- "Stop": 1 = Stop motor
- "Slow": 1 = Motor is running slow
- "Fast": 1 = Motor is running fast
- "Channel Slow": Signal from the output channel block for "Slow"
- "Channel Fast": Signal from the output channel block for "Fast"
- "Permission stop": 1 = Motor can not be stopped in manual (by operator) or automatic (by logic) mode

**(4) Navigation button for switching to the standard view of any faceplate**

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, see section Opening additional faceplates (Page 234).

**(5) Resynchronization**

Displays the Resynchronization state and Resynchronization Signal status based on feedback value.

### 8.6.8.4 Block icon for MotSpdL

**Properties of the MotSpdLblock icon**

A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Motor state display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | "M" symbol with small speed display |
|  | 6 | "M" symbol with small speed display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 9 | |
|  | 10 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Motor state display

The following motor states are shown here:

| Symbol | Meaning |
|---|---|
|  | Motor started (motor symbol changes) |
|  | The motor is running |
|  | Motor stopped (motor symbol changes) |
|  | Motor idle |
|  | Error at motor (monitoring error, motor protection) |
|  | Motor out of service |
|  | “No Cmd” State |

# 8.7 ShrdResL - Multiplexer for shared resources (Large)

## 8.7.1 Description of ShrdResL

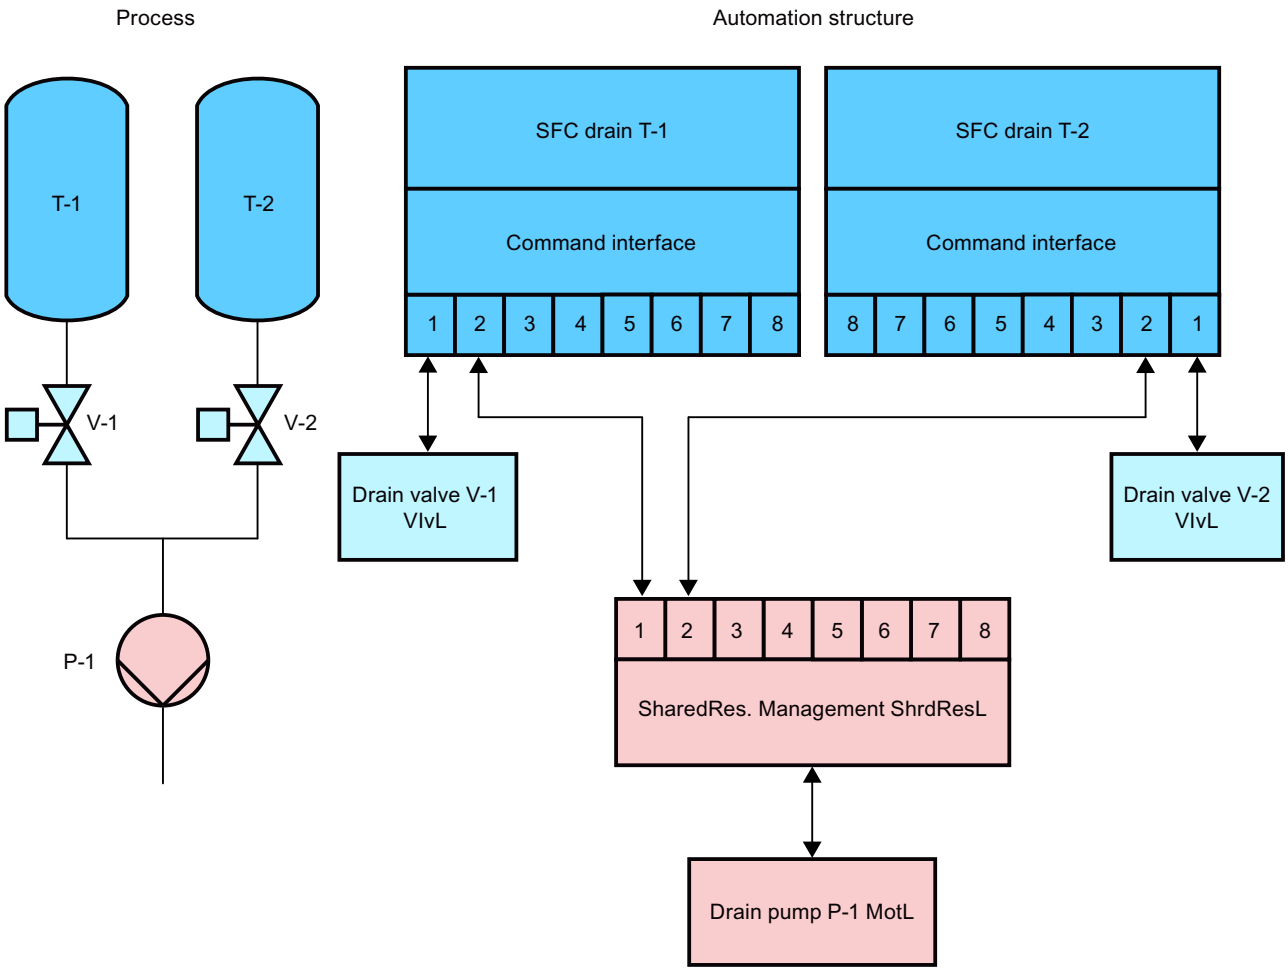
### Object name (type + number) and family

Type + number: FB 1917

Family: Drives

### Area of application for ShrdResL

The block is used for the following application:



- Organize individual requests for downstream block from upstream applications.

### How it works

The block coordinates the access from up to eight SFC step sequencers to a technological block of the families "Drives" or "Dose".These blocks include:

- Motors
- Valves
- Dosers

The block has eight channels, each with a standardized command interface.

In case of multiple allocation requests, the channel to be allocated depends on the priority of each channel and a strategy mode which coordinates the sequence of the allocated channels.

As soon as a channel is allocated, its command interface is aligned in accordance with the command interface at the output.

**Note**

A cascading of channels is not possible.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

## Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in the section ShrdResL I/Os (Page 1614).

| Status bit | Parameter |
|---|---|
| 0 | `ReadyIn`, Readiness signal of the interconnected technological block |
| 1 | `ChnEn_1` |
| 2 | `ChnEn_2` |
| 3 | `ChnEn_3` |
| 4 | `ChnEn_4` |
| 5 | `Ready`, Channel allocation is possible |
| 6 | `ActChnNo` = 1, 1 = Channel 1 is enabled |
| 7 | `ActChnNo` = 2, 1 = Channel 2 is enabled |
| 8 | `ActChnNo` = 3, 1 = Channel 3 is enabled |
| 9 | `ActChnNo` = 4, 1 = Channel 4 is enabled |
| 10 | `MultiOcc`, 1 = Request for more than one channel |
| 11 | Not used |
| 12 | `BatchEn` |
| 13 | `Occupied` |
| 14 - 16 | Not used |
| 17 | `NxtChnNo` = 1, 1 = Channel 1 is the next allocated channel |
| 18 | `NxtChnNo` = 2, 1 = Channel 2 is the next allocated channel |
| 19 | `NxtChnNo` = 3, 1 = Channel 3 is the next allocated channel |
| 20 | `NxtChnNo` = 4, 1 = Channel 4 is the next allocated channel |
| 21 | `BaEn_1` |
| 22 | `BaEn_2` |
| 23 | `BaEn_3` |
| 24 | `BaEn_4` |
| 25 | `Occ_1` |
| 26 | `Occ_2` |
| 27 | `Occ_3` |
| 28 | `Occ_4` |
| 29 - 30 | Not used |
| 31 | Internal error |

### Status word allocation for `Status2` parameter

You can find a description for each parameter in the section ShrdResL I/Os (Page 1614).

| Status bit | Parameter |
|---|---|
| 0 | Not used |
| 1 | `ChnEn_5` |
| 2 | `ChnEn_6` |
| 3 | `ChnEn_7` |
| 4 | `ChnEn_8` |

| Status bit | Parameter |
|---|---|
| 5 | Not used |
| 6 | `ActChnNo` = 5, 1 = Channel 5 is enabled |
| 7 | `ActChnNo` = 6, 1 = Channel 6 is enabled |
| 8 | `ActChnNo` = 7, 1 = Channel 7 is enabled |
| 9 | `ActChnNo` = 8, 1 = Channel 8 is enabled |
| 10 - 16 | Not used |
| 17 | `NxtChnNo` = 5, 1 = Channel 5 is the next allocated channel |
| 18 | `NxtChnNo` = 6, 1 = Channel 6 is the next allocated channel |
| 19 | `NxtChnNo` = 7, 1 = Channel 7 is the next allocated channel |
| 20 | `NxtChnNo` = 8, 1 = Channel 8 is the next allocated channel |
| 21 | `BaEn_5` |
| 22 | `BaEn_6` |
| 23 | `BaEn_7` |
| 24 | `BaEn_8` |
| 25 | `Occ_5` |
| 26 | `Occ_6` |
| 27 | `Occ_7` |
| 28 | `Occ_8` |
| 29 - 31 | Not used |

ShrdResL I/Os (Page 1614)
ShrdResL block diagram (Page 1619)

## 8.7.3 ShrdResL functions

### Functions of ShrdResL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

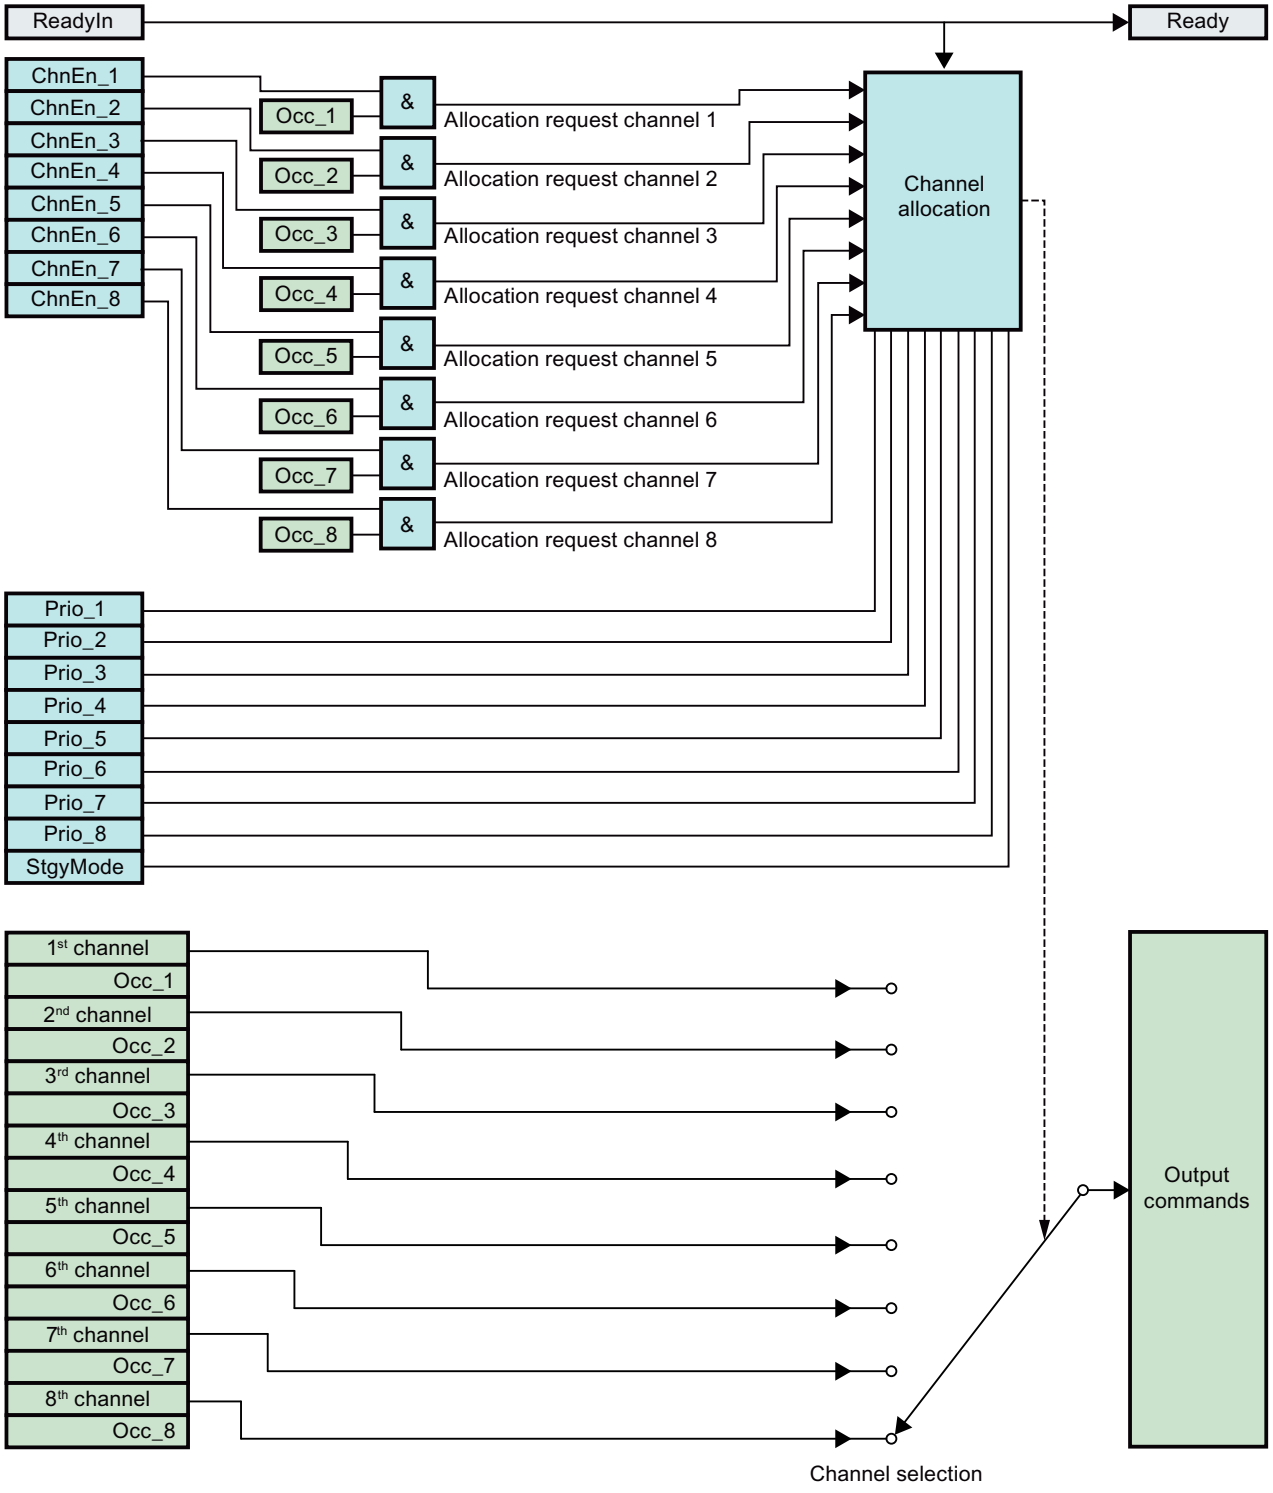
| Bit | Function |
|---|---|
| 0 - 5 | Not used |
| 6 | 1 = Operator can change the priority of channel 1 |
| 7 | 1 = Operator can change the priority of channel 2 |
| 8 | 1 = Operator can change the priority of channel 3 |
| 9 | 1 = Operator can change the priority of channel 4 |
| 10 | 1 = Operator can change the priority of channel 5 |
| 11 | 1 = Operator can change the priority of channel 6 |
| 12 | 1 = Operator can change the priority of channel 7 |
| 13 | 1 = Operator can change the priority of channel 8 |
| 14 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bit:



| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |

### Readiness signal

In order to assign one of the channels, the ready signal must be `ReadyIn` = 1 and at least one channel enable must be `ChnEn_x` = 1 (x = 1 to 8). The ready signal is output at the `Ready` output.

## Channel management

Overview of the channel management:

### Allocate/enable channel

A channel can only be allocated if the readiness signal (`ReadyIn` = 1) and the respective channel enabling is available for the allocation `ChnEn_x` = 1.

With `ChnEn_x` = 0, the channel x is disabled and cannot be allocated.

The allocation request of a channel by the upstream application is accomplished via the input `Occ_x`. In case of multiple requests, the channel allocation function stores the requests in a buffer and calculates the allocated channel number with the help of the channel priorities `Prio_x` (x = 1 to 8) and the strategy mode `StgyMode`.

Each channel has its own priority. It can be parameterized at the inputs `Prio_x` (x = 1 to 8).

The strategy mode defines the order of storing the requests in the buffer.

| Strategy 1 | Strategy 2 | Parameter value of `StgyMode` |
|---|---|---|
| First In First Out | Order | 0 |
| First In First Out | Maximum Priority; in case equal request Order is used | 1 |
| First In First Out | Minimum Priority; in case equal request Order is used | 2 |
| Last In First Out | Order | 3 |
| Last In First Out | Maximum Priority; in case equal request Order is used | 4 |
| Last In First Out | Minimum Priority; in case equal request Order is used | 5 |
| Maximum Priority | Order | 6 |
| Maximum Priority | First In First Out | 7 |
| Maximum Priority | Last In First Out | 8 |
| Minimum Priority | Order | 9 |
| Minimum Priority | First In First Out | 10 |
| Minimum Priority | Last In First Out | 11 |

The allocation request will be evaluated with **Strategy 1**. If after the first evaluation, there are equal requests, the **Strategy 2** will be evaluated. This happens in the following cases:

- Two or more requests are in the same cycle and **Strategy 1** is "First In First Out" or "Last In First Out".
- Two or more requests have the same priority and **Strategy 1** is "Maximum Priority" or "Minimum Priority".

The parameterization "Order" in **Strategy 2** means that the priority of the request depends on the channel number:

- Channel 1 has the highest priority
- Channel 8 has the lowest priority

If **Strategy 2** is "Maximum Priority" or "Minimum Priority" and if after the evaluation, there are equal requests, the channel allocation is calculated with "Order".

The applied commands are aligned in accordance with the output command interface.

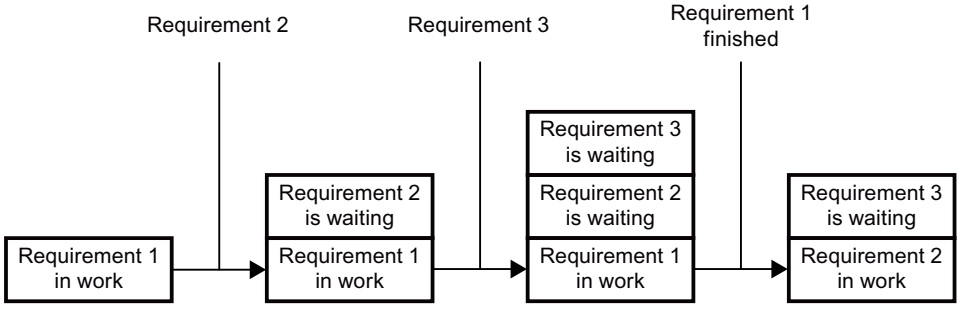
The number of the allocated channel is displayed at the output `ActChnNo` (INT format). If no channel is allocated, the output is 0.

### Enable/disable channel

If the allocated channel disabling via `Occ_x` = 0 or via `ChnEn_x` = 0, the next channel in the allocation request buffer is automatically switched to the command outputs. If there is no other allocation request (every `Occ_x` = 0), the commands of the output interface are resetted to the default values.

### Channel prioritization

Channel 1 has the highest priority, channel 4 has the lowest. If the input `Occ_x` is set at multiple enabled channels, the channel with the highest priority is allocated and the output `MultiOcc` = 1 is set.

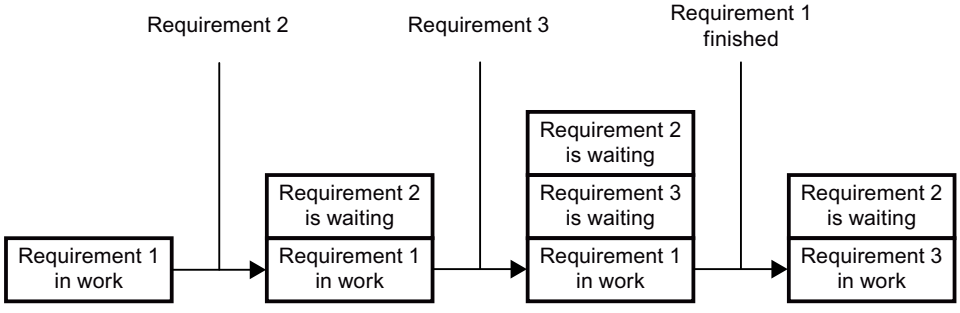


### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Example for "First In First Out" Strategy mode (`StgyMode` = 0, 1, or 2)

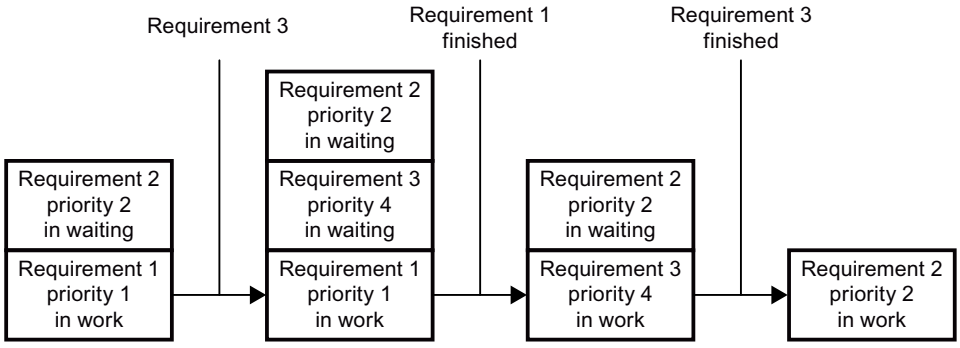
The requirement which is issued for the longest duration will be released first.



The requirements that are coming in the same cycle will be evaluated after **Strategy 2**.

### Example for "Last In First Out" Strategy mode (`StgyMode` = 3, 4, or 5)

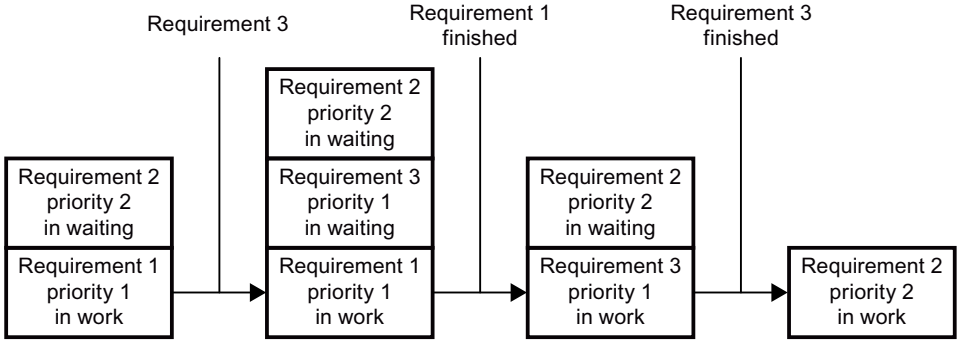
The requirement which is issued for the shortest duration will be released first.



The requirements that are coming in the same cycle will be evaluated after **Strategy 2**.

### Example for "Maximum Priority" Strategy mode (`StgyMode` = 6, 7, or 8)

The requirement with the highest priority will be released first.



The requirements that are coming in the same cycle will be evaluated after **Strategy 2**.

### Example for "Minimum Priority" Strategy mode (`StgyMode` = 9, 10, or 11)

The requirement with the lowest priority will be released first.

The requirements that are coming in the same cycle will be evaluated after **Strategy 2**.

## 8.7.4 ShrdResL error handling

### ShrdResL error handling

Please refer to the section Error handling (Page 128) in the basic instructions.

The following error can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed. |
| 0 | There is no error. |
| 49 | Wrong strategy mode number:<br>`StgyMode` < 0 or `StgyMode` > 11 |

| UserStatus2 | Freely assignable bits for use in PCS 7 OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActChnNo | Displays the allocated channel | INT | 0 |
| AutMod | 1= "Automatic mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| Ctrl01 | Control command 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ... | ... | ... | ... |
| Ctrl12 | Control command 12 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlW1 | Available user control word 1 | DWORD | 16#00000000 |
| CtrlW2 | Available user control word 2 | DWORD | 16#00000000 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of the current error number. For error numbers that can be outputted by this block, see ShrdResL error handling (Page 1613) | INT | -1 |
| NxtChnNo | Next occupied channel number | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ManMod | 1 = "Manual mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ModLi | 1 = Control via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MultiOcc | 1 = More than one channel request is present | BOOL | 0 |
| Occupied | 1 = Occupied<br>Is also used as a control signal for the channel allocation. | BOOL | 0 |
| Ready | 1 = Active readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstLi | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtLi | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP1Ext | External setpoint 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ... | ... | ... | ... |
| SP8Ext | External setpoint 8 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Status1 | Status word 1 (Page 1603) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1603) | DWORD | 16#00000000 |
| StepNo | Step number | DWORD | 16#00000000 |
| Strng1 | Additional string 1 | S7-String | |
| Strng2 | Additional string 2 | S7-String | |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |

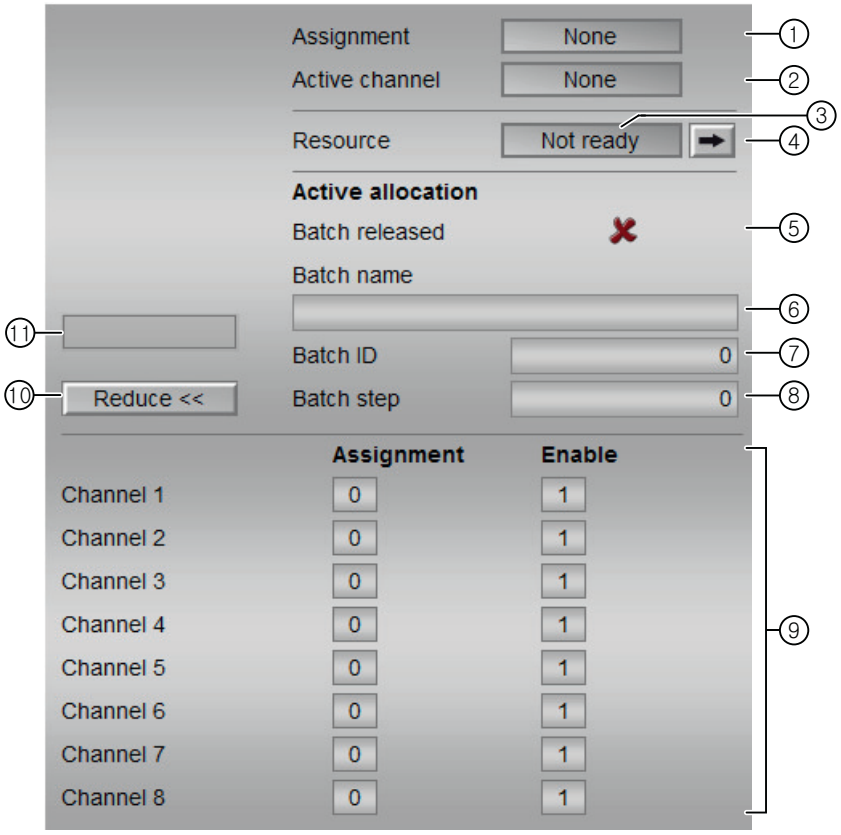
## 8.7.8 Operator control and monitoring

### 8.7.8.1 ShrdResL views

### Views of the ShrdResL block



The block ShrdResL provides the following views:

- ShrdResL standard view (Page 1620)
- ShrdResL general preview (Page 1622)
- ShrdResL preview (Page 1622)
- ShrdResL parameter view (Page 1624)
- Memo view (Page 338)
- Block icon for ShrdResL (Page 1625)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.7.8.2 ShrdResL standard view

#### ShrdResL standard view

#### (1) Allocation

The allocation status is displayed in this area:

- "None": Display for all `Occ_1`...`Occ_4` = 0 and `Occupied` = 0
- "Requested": Display for one of `Occ_1`...`Occ_4` = 1 and `Occupied` = 0
- "Active": Display for `Occupied` = 1

#### (2) Active channel

The channel number of the active channel is displayed in this area.

If the text is configured for this command (Text 1 in the object properties), it is displayed as additional text and button label for command selection. Additional information is available in the section Labeling of buttons and text (Page 235).

### (3) Resource

The status of the enable signal is displayed in this area:

- "Idle": Display for `ReadyIn` = 1
- "Not ready": Display for `ReadyIn` = 0

### (4) Jump key to standard view of any faceplate

This display is only visible when the corresponding block input is interconnected.

Use this navigation button to jump to the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find more information on this in the section Opening additional faceplates (Page 234).

### (5) Release batch

This area displays if the block is released for operation via SIMATIC BATCH (`BatchEn` = 1).

### (6) Batch name

This area displays the name of the batch that is currently running (`Batchname`).

### (7) Batch ID

This area displays the identification number of the batch that is currently running (`BatchID`).

### (8) Batch step

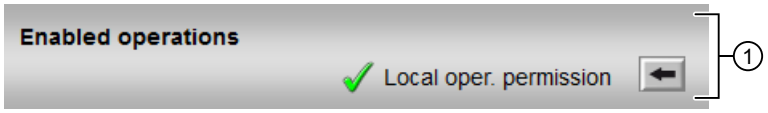
This area displays the step number of the batch that is currently running (`StepNo`).

### (9) Display channel 1 to 8

This area is only visible when the **(10)** "Expand" button is pressed.

The "Allocation" and "Release" status of the channels 1 to 8 are displayed in this area.

The next channel for allocation, which is in waiting position, is marked with a yellow exclamation mark.



### (11) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

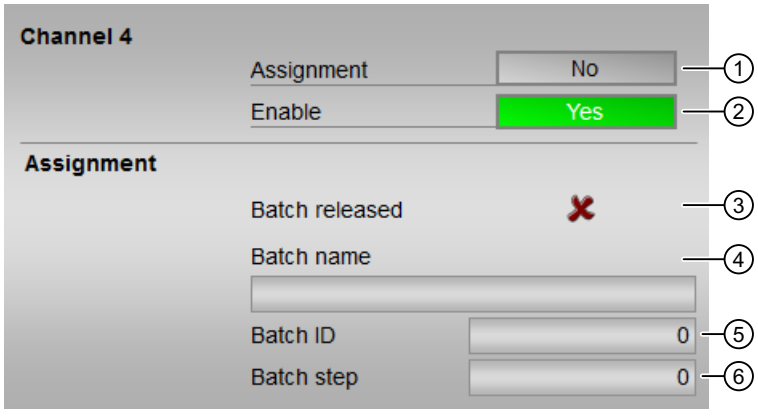
### 8.7.8.3 ShrdResL general preview

#### ShrdResL general preview

#### (1) Enabled operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:



- **Green check mark**: The OS operator can control this parameter.
- **Gray check mark**: The OS operator cannot control this parameter at this time due to the process.
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm`).

The following enabled operation is shown here:

- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).

### 8.7.8.4 ShrdResL preview

#### ShrdResL preview

Each of the eight channels has its own preview. The previews of the individual channels are identical. The preview shown in this graphic is of channel 4.

### (1) Allocation

The allocation status of the channel is displayed in this area.

- "No": Display for `Occ_1` = 0
- "Requested": Display for `Occ_1` = 1and `ActChnNo` = 0
- "Active": Display for `ActChnNo` = 1

### (2) Enable

The status of the enable is displayed in this area.

- "Yes": Display for `ChnEn` = 1
- "No": Display for `ChnEn` = 0

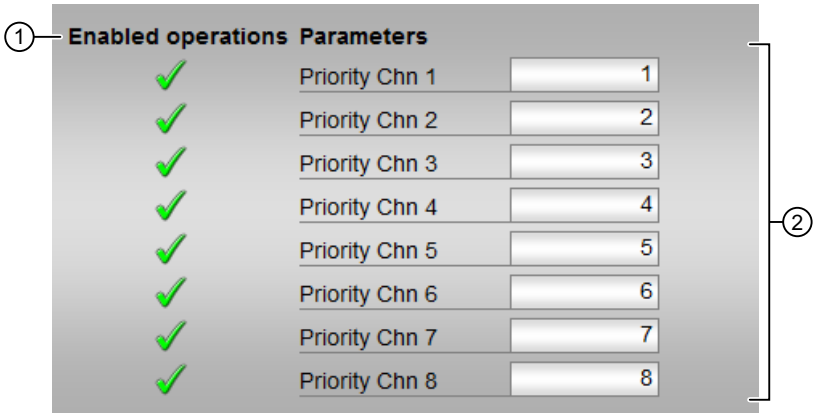
### (3) Release batch

This area displays if the block is released for operation via SIMATIC BATCH (`BatchEn` = 1).

### (4) Batch name

This area displays the name of the batch that is currently running (`Batchname`).

### (5) Batch ID



This area displays the identification number of the batch that is currently running (`BatchID`).

### (6) Batch step

This area displays the step number of the batch that is currently running (`StepNo`).

### 8.7.8.5 ShrdResL parameter view

#### Parameter view of ShrdResL

#### (1) Enabled operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for operation enable:

- **Green check mark**: The OS operator can control this parameter.
- **Gray check mark**: The OS operator cannot control this parameter at this time due to the process.
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm`).

#### (2) Parameters

In this area, you can change the parameters and thereby influence the behavior of ShrdResL. You can find more information on this in the section Changing values (Page 291).

You can influence the following parameters:

- "Priority Chn 1": Priority for channel 1
- "Priority Chn 2": Priority for channel 2
- "Priority Chn 3": Priority for channel 3
- "Priority Chn 4": Priority for channel 4
- "Priority Chn 5": Priority for channel 5
- "Priority Chn 6": Priority for channel 6
- "Priority Chn 7": Priority for channel 7
- "Priority Chn 8": Priority for channel 8

### 8.7.8.6 Block icon for ShrdResL

## Block icons for ShrdResL

A variety of block icons are available with the following functions:

- Display active channel
- Process tag type (2 only)
- Memo display (2 only)
- Fixed text (language dependent, 2 only)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

# 8.8 ShrdResS - Multiplexer for shared resources (Small)

## 8.8.1 Description for ShrdResS

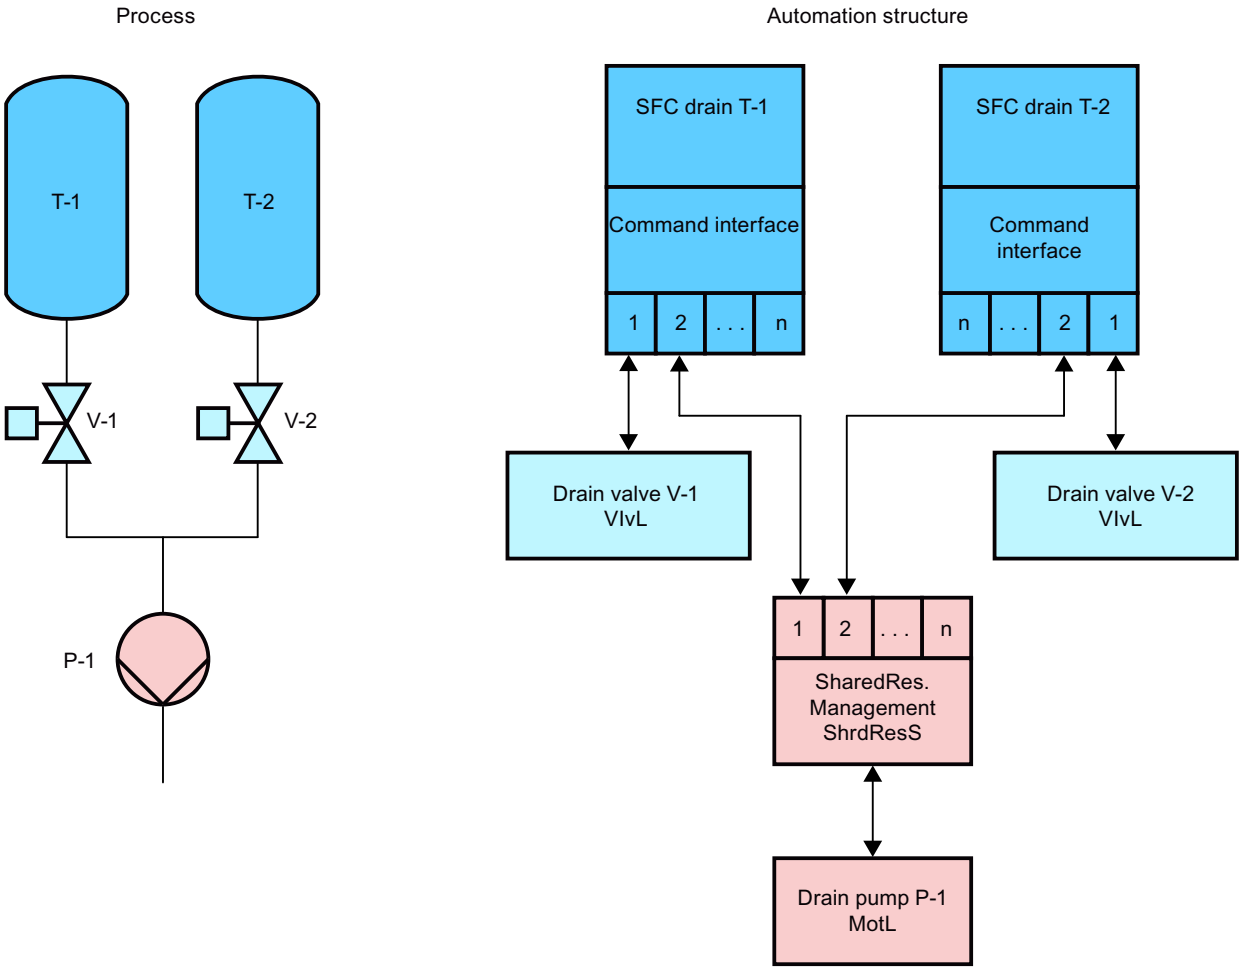
### Object name (type + number) and family

Type + number: FB 1914

Family: Drives

### Area of application for ShrdResS

The block is used for the following applications:



- Organize individual requests for downstream block from upstream applications

### How it works

The block coordinates the access from up to four SFC step sequencers to a technologic block of the families "Drives" or "Dose". These blocks include:

- Motors
- Valves
- Dosers

The block has four channels, each with a standardized command interface.

The block can be cascaded via the fourth channel so that accesses via more than four upstream applications are possible. Use the cascade by interconnecting the output parameter `CasOut` of the first block to the input parameter `CasIn` of the second block. The output interface of the upstream block is then used as channel 4 for the second block.

As soon as a channel is allocated, its command interface is aligned 1-to-1 with the command interface at the output.

The channel with the lower number always has priority with shared allocation. Cascaded blocks are always allocated to channel 4 of the upstream block; they are then in 4th place.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

## Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

You can find a description for each parameter in section ShrdResS I/Os (Page 1633).

| Status bit | Parameter |
|---|---|
| 0 | `ReadyIn`, readiness signal of the interconnected technologic block |
| 1 | `ChnEn_1` |
| 2 | `ChnEn_2` |
| 3 | `ChnEn_3` |
| 4 | `ChnEn_4` |
| 5 | `Ready`, channel allocation is possible |
| 6 | `ActChnNo` = 1, 1 = Channel 1 enabled |
| 7 | `ActChnNo` = 2, 1 = Channel 2 enabled |
| 8 | `ActChnNo` = 3, 1 = Channel 3 enabled |
| 9 | `ActChnNo` = 4, 1 = Channel 4 enabled |
| 10 | `MultiOcc`, 1 = Request for more than one channel |
| 11 | `Cascaded`, 1 = 4. Channel is cascaded |
| 12 | `BatchEn` |
| 13 | `Occupied` |
| 14 - 20 | Not used |
| 21 | `BaEn_1` |
| 22 | `BaEn_2` |
| 23 | `BaEn_3` |
| 24 | `BaEn_4` |
| 25 | `Occ_1` |
| 26 | `Occ_2` |
| 27 | `Occ_3` |
| 28 | `Occ_4` |
| 29 - 31 | Not used |

### Status word allocation for `Status1` parameter

| Status bit | Parameter |
|---|---|
| 31 | Internal error |

ShrdResS block diagram (Page 1641)

## 8.8.3 ShrdResS functions

### Functions of ShrdResS

The functions for this block are listed below.

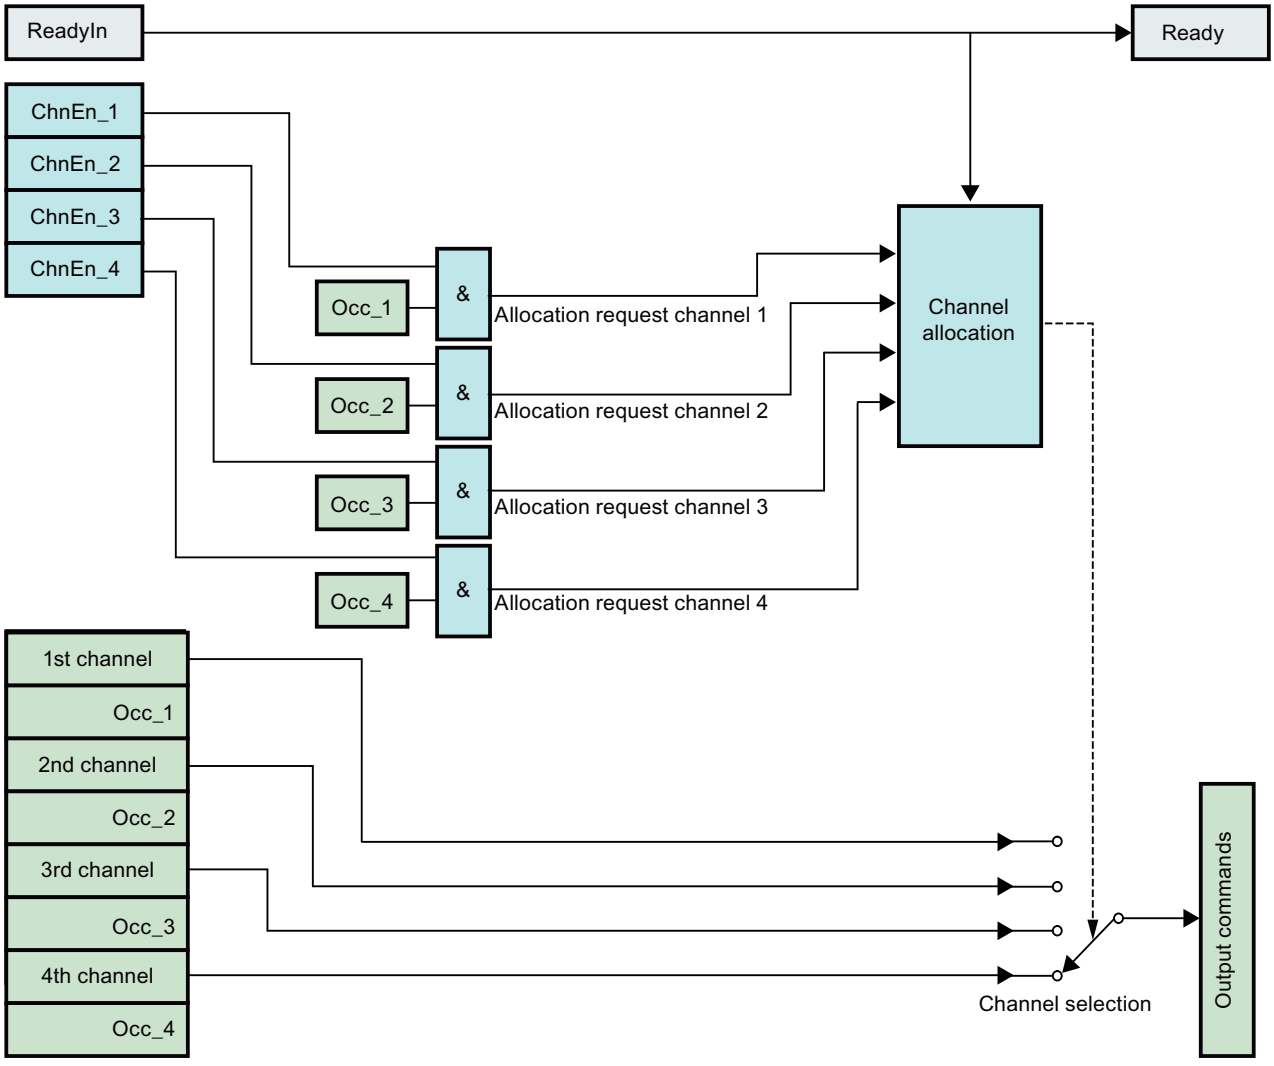
### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

If the block is cascaded, the standard view of the ShrdResS block interconnected to `CasIn` can be opened in addition to the freely configured faceplate.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:



| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |

### Readiness signal

In order to assign one of the channels, the ready signal must be `ReadyIn` = 1 and at least one channel enable must be `ChnEn_x = 1` (x = 1...4) . The ready signal is output at the `Ready` output.

## Channel management

Overview of the channel management

## Allocate/enable channel

A channel can only be allocated if the readiness signal (`ReadyIn` = 1) and the respective channel enabling is available for the allocation `ChnEn_x` = 1.

With `ChnEn_x` = 0 the channel x is disabled and cannot be allocated.

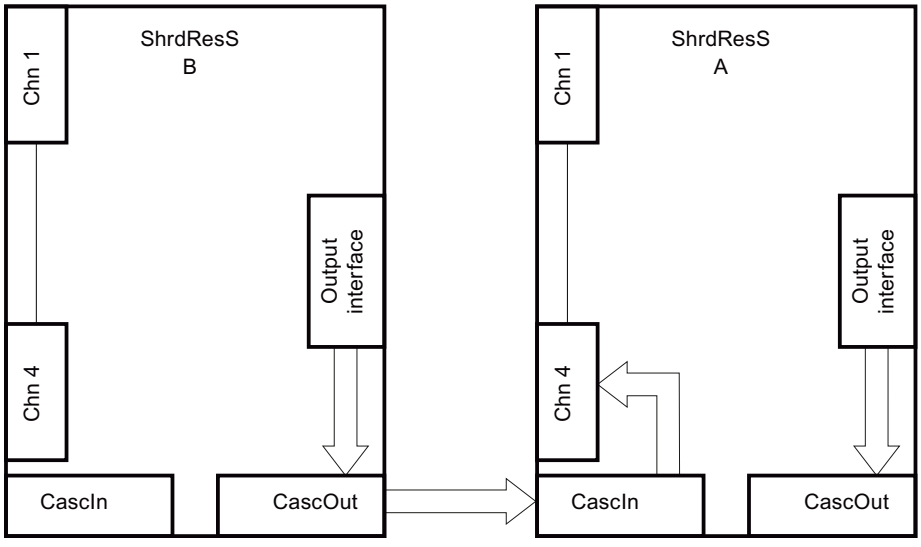
The allocation of a channel by the upstream application is accomplished via the input `Occ_x`. As long as this input is 1, the channel is allocated and enabled. The applied commands are aligned 1-to-1 with the output command interface.

The number of the allocated channel is displayed at the output `ActChnNo` (INT format). If no channel is allocated, the output is 0.

### Enable/disable channel

If no channel enabling via `Occ_x` = 0 occurs or if the channel is disabled via `ChnEn_x` = 0, the next highest priority channel is automatically switched to the command outputs. If there is no other allocation request (every `Occ_x` = 0), the commands of the output interface are reset to the default values.

### Channel prioritization



Channel 1 has the highest priority, channel 4 has the lowest. If the input `Occ_x` is set at multiple enabled channels, the channel with the highest priority is allocated and the output `MultiOcc` = 1 is set.

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Cascading

For cascading, the output `CasOut` of a ShrdResS block B must be connected with the input `CasIn` of the downstream ShrdResS block A. Therefore, the fourth channel of the downstream block ShrdResS A is allocated by the ShrdResS B block connected to `CasIn`. The command interface of the fourth channel is tracked in this case to the output interface of the connected ShrdResS B block.

Any values applied via interconnection at the 4th channel of block A are not taken into account in the block code during cascading.

## 8.8.4 ShrdResS error handling

### ShrdResS error handling

Please refer to the section Error handling (Page 128) in the basic instructions.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block will not be processed |
| 0 | There is no error. |
| 40 | Interconnection error on `CasIn`, incorrect block type interconnected |

| ModLi_4* | 1 = Control via interconnection or SFC for channel 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occ_1 | 1 = Occupied<br>Is also used as a control signal for the channel allocation for channel 1 | BOOL | 0 |
| Occ_2 | 1 = Occupied<br>Is also used as a control signal for the channel allocation for channel 2 | BOOL | 0 |
| Occ_3 | 1 = Occupied<br>Is also used as a control signal for the channel allocation for channel 3 | BOOL | 0 |
| Occ_4* | 1 = Occupied<br>Is also used as a control signal for the channel allocation for channel 4 | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ReadyIn | Readiness signal:<br>1 = Signal for channel enabling active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstLi_1* | 1 = Resetting via interconnection for channel 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstLi_2* | 1 = Resetting via interconnection for channel 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstLi_3* | 1 = Resetting via interconnection for channel 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstLi_4* | 1 = Resetting via interconnection for channel 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SelFpRes | Selection for faceplate resource | ANY | |
| SP_Ex_1 | 1 = Select external setpoint (via interconnection) for channel 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_Ex_2 | 1 = Select external setpoint (via interconnection) for channel 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_Ex_3 | 1 = Select external setpoint (via interconnection) for channel 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_Ex_4 | 1 = Select external setpoint (via interconnection) for channel 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_In_1* | 1 = Select internal setpoint (via interconnection) for channel 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_In_2* | 1 = Select internal setpoint (via interconnection) for channel 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_In_3* | 1 = Select internal setpoint (via interconnection) for channel 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_In_4* | 1 = Select internal setpoint (via interconnection) for channel 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SP1Ext_1* | 1. External setpoint for channel 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2Ext_1* | 2. External setpoint for channel 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP1Ext_2* | 1. External setpoint for channel 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2Ext_2* | 2. External setpoint for channel 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP1Ext_3* | 1. External setpoint for channel 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2Ext_3* | 2. External setpoint for channel 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP1Ext_4* | 1. External setpoint for channel 4 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2Ext_4* | 2. External setpoint for channel 4 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StepNo_1 | Step number for channel 1 | DWORD | 16#00000000 |
| StepNo_2 | Step number for channel 2 | DWORD | 16#00000000 |
| StepNo_3 | Step number for channel 3 | DWORD | 16#00000000 |
| StepNo_4 | Step number for channel 4 | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ActChnNo | Displaying the allocated channel | INT | 0 |
| AutMod | 1= "Automatic mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Cascaded | 1 = Block is cascaded | BOOL | 0 |
| CasOut | 1 = Output parameter for cascade formation, to be interconnected with the input parameter CasIn of the following ShrdResS block | DWORD | 16#00000000 |
| Ctrl01 | 1. Control command | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl02 | 2. Control command | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl03 | 3. Control command | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl04 | 4. Control command | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl05 | 5. Control command | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl06 | 6. Control command | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlW1 | 1. Available user control word | DWORD | 16#00000000 |
| CtrlW2 | 2. Available user control word | DWORD | 16#00000000 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see ShrdResS error handling (Page 1632) | INT | -1 |
| ManMod | 1 = "Manual mode" via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ModLi | 1 = Control via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MultiOcc | 1 = More than one channel request is present | BOOL | 0 |
| Occupied | 1 = Occupied<br>Is also used as a control signal for the channel allocation | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Ready | 1 = Active readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstLi | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_ExtLi | 1 = Select external setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP_IntLi | 1 = Select internal setpoint (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SP1Ext | 1. External setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SP2Ext | 2. External setpoint | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Status1 | Status word 1 (Page 1626) | DWORD | 16#00000000 |
| StepNo | Step number | DWORD | 16#00000000 |

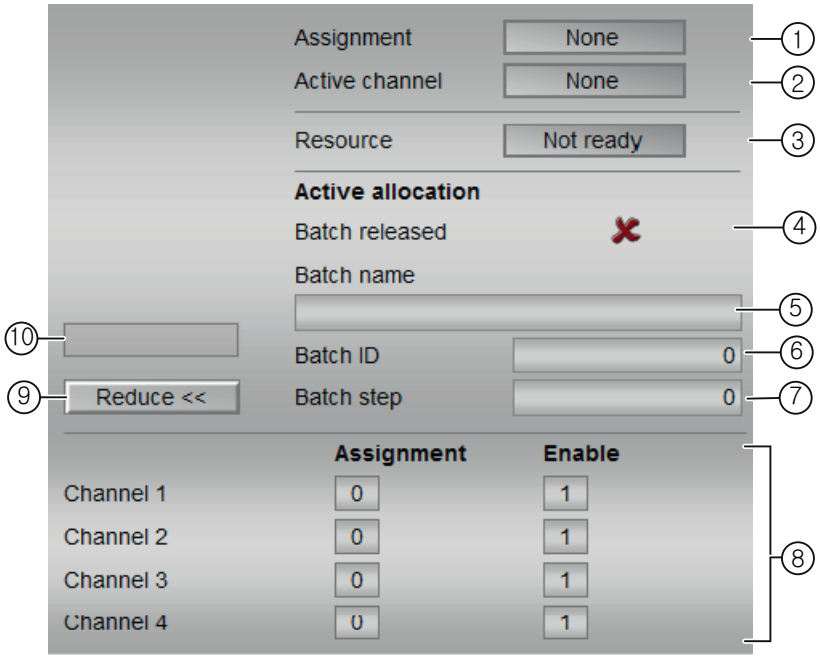
## 8.8.8 Operator control and monitoring

### 8.8.8.1 ShrdResS views

#### Views of the ShrdResS block



The block ShrdResS provides the following views:

- ShrdResS standard view (Page 1642)
- ShrdResS preview (Page 1644)
- Memo view (Page 338)
- Block icon for ShrdResS (Page 1645)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.8.8.2 ShrdResS standard view

#### ShrdResS standard view

### (1) Allocation

The allocation status is displayed in this area.

- "None": Display for `Status1.Bit 10 = 0` and `Status1.Bit 13 = 0`
- "Requested": Display for `Status1.Bit 10 = 1` and `Status1.Bit 13 = 0`
- "Active": Display for `Status1.Bit 13 = 1`

### (2) Active channel

The channel number of the active channel is displayed in this area.

If text is configured for this command (Text 1 in the object properties), it is displayed as additional text and button label for command selection. Additional information is available in the section Labeling of buttons and text (Page 235).

Use the ← button to switch to the standard view of the connected `CasIn` block.

Use the → button to switch to the standard view of the connected `CasOut` block.

### (3) Resource

The status of the general enable signal is displayed in this area.

- "Idle": Display for `ReadyIn = 1`
- "Not ready": Display for `ReadyIn = 0`

Use the → button to switch to the standard view of the connected `SelFpRes` block.

### (4) Release batch:

This area shows you if the block is released for operation via SIMATIC BATCH (`BatchEn = 1`).

### (5) Batch name

This area shows the name of the batch that is currently running (`Batchname`).

### (6) Batch ID

This area shows the identification number of the batch that is currently running (`BatchID`).

### (7) Batch step

This area shows you the step number of the batch that is currently running (`StepNo`).

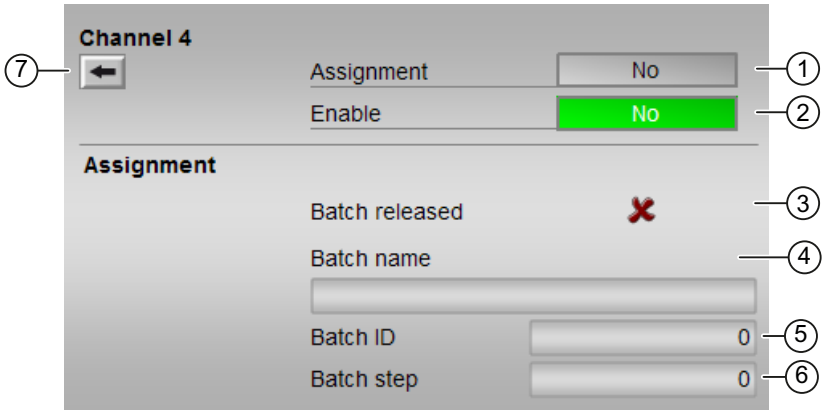
### (8) Display channel 1-4

This area is only visible when the **(9)** "Expand" button is pressed.

The "Allocation" und "Release" status of channels 1-4 are displayed in this area.

### (9) Expand / Collapse

This button enables or disables the display area **(8)**. The label of the button changes accordingly.



### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

## 8.8.8.3 ShrdResS preview

### ShrdResS preview

Each of the four channels has its own preview. The previews of the individual channels are identical except for number **(7)** . The preview described here is based on channel 4.

### (1) Allocation

The allocation status of the channel is displayed in this area.

- "No": Display for `Occ_1 = 0`
- "Requested": Display for `Occ_1 = 1` and `ActChnNo = 0`
- "Active": Display for `ActChnNo = 1`

### (2) Enable

The status of the enable is displayed in this area.

- "Yes": Display for `ChnEn = 1`
- "No": Display for `ChnEn = 0`

**(3) Release batch:**

This area shows you if the block is released for operation via SIMATIC BATCH (`BatchEn = 1`).

**(4) Batch name**

This area shows the name of the batch that is currently running (`Batchname`).

**(5) Batch ID**

This area shows the identification number of the batch that is currently running (`BatchID`).

**(6) Batch step**

This area shows you the step number of the batch that is currently running (`StepNo`).

**(7) Button ←**

Use the ← button to switch to the standard view of the cascaded ShrdResS block. This button is only available for channel 4.

### 8.8.8.4 Block icon for ShrdResS

**Block icons for ShrdResS**

A variety of block icons are available with the following functions:

- Display active channel
- Process tag type (2 only)
- Memo display (2 only)
- Fixed text (language dependent, 2 only)

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

# 8.9 Vlv2WayL - Two-way valve

## 8.9.1 Description of Vlv2WayL

### Object name (type + number) and family

Type + number: FB 1897

Family: Drives

### Area of application for Vlv2WayL

The block is used for the following applications:

- Control of multi-way valves with up to three switching positions. One of these positions is the neutral position (de-energized position)
- Control of three individual valves (valve network) to implement a 2-way valve circuit with neutral position (de-energized position)

### How it works

The multi-way valve (or valve network) is controlled via position 0 (neutral position), position 1 (way 1), or position 2 (way 2). Various inputs are available for controlling the positions.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the Vlv2WayL block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- Two-way valve (Valve2Way) (Page 2866)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section Vlv2WayL I/Os (Page 1664).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 8 | "Open"/"Closed" command for `V0` |
| 9 | "Open"/"Closed" command for `V1` |
| 10 | "Open"/"Closed" command for `V2` |
| 11 | Feedback error without control change |
| 12 | Feedback error due to control change |
| 13 | `BypProt` active |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | Display „Force Pos0“ |
| 20 | Display „Force Pos1“ |
| 21 | Display „Force Pos2“ |
| 22 | Feedback for Pos0 OK |
| 23 | Feedback for Pos1 OK |
| 24 | Feedback for Pos2 OK |
| 25 | Feedback for current position OK |
| 26 | Automatic preview Pos0 |
| 27 | Automatic preview Pos1 |
| 28 | Automatic preview Pos2 |
| 29 | `SafeV0` |
| 30 | `SafeV1` |
| 31 | `SafeV2` |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | Forcing active |

| Status bit | Parameter |
|---|---|
| 2 | Display for interlocks in block icon |
| 3 | `WarnAct.Value` |
| 4 | External error generated by FaultExt or external control system fault from CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 5 | For the status display error in the valve |
| 6 | Current monitoring time `P0` is visible |
| 7 | Current monitoring time `V0` is visible |
| 8 | Current monitoring time `V1` is visible |
| 9 | Current monitoring time `V2` is visible |
| 10 | Current monitoring time `P1` is visible |
| 11 | Current monitoring time `P2` is visible |
| 12 | 1 = Input parameter `FbkP1` is connected and `Feature.Bit12` = 1 |
| 13 | 1 = Input parameter `FbkP2` is connected and `Feature.Bit12` = 1 |
| 14 | 1 = Input parameter `FbkP0` is connected |
| 15 | 1 = Input parameter `FbkV0` is connected and `Feature.Bit12` = 0 |
| 16 | 1 = Input parameter `FbkV1` is connected and `Feature.Bit12` = 0 |
| 17 | 1 = Input parameter `FbkV2` is connected and `Feature.Bit18` = 0 |
| 18 | Reset request in automatic |
| 19 | 1 = No impact of input signals on "local mode" with `LocalSetting` = 0, `LocalSetting` = 2, `LocalSetting` = 4 and OOS mode. |
| 20 | `CtrlV0.Value` |
| 21 | `CtrlV1.Value` |
| 22 | `CtrlV2.Value` |
| 23 | `FbkV0Out.Value` |
| 24 | `FbkV1Out.Value` |
| 25 | `FbkV2Out.Value` |
| 26 | `FbkP0Out.Value` |
| 27 | Feedback `V0` (`FbkV0`), for OS display only |
| 28 | Feedback `V1` (`FbkV1`), for OS display only |
| 29 | Feedback `V2` (`FbkV2`), for OS display only |
| 30 | Bypass information for display in block icon |
| 31 | `MS_RelOp` |

## Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | "Interlock" button is enabled |
| 1 | "Permission" button is enabled |
| 2 | "Protection" button is enabled |
| 3 | `Pos0Out` |
| 4 | Travel in position 0 |
| 5 | Monitoring error in position 0 |

| Status bit | Parameter |
|---|---|
| 6 | `Pos1Out` |
| 7 | Travel in position 1 |
| 8 | Monitoring error in position 1 |
| 9 | `Pos2Out` |
| 10 | Travel in position 2 |
| 11 | Monitoring error in position 2 |
| 12 | Preview position 0 control `CtrlV0` |
| 13 | Preview position 0 control `CtrlV1` |
| 14 | Preview position 0 control `CtrlV2` |
| 15 | Preview position 1 control `CtrlV0` |
| 16 | Preview position 1 control `CtrlV1` |
| 17 | Preview position 1 control `CtrlV2` |
| 18 | Preview position 2 control `CtrlV0` |
| 19 | Preview position 2 control `CtrlV1` |
| 20 | Preview position 2 control `CtrlV2` |
| 21 | Preview for automatic control `CtrlV0` |
| 22 | Preview for automatic control `CtrlV1` |
| 23 | Preview for automatic control `CtrlV2` |
| 24 | `UserAna1` interconnected |

Resetting the block in case of interlocks or errors (Page 47)

## 8.9.2 Vlv2WayL modes

### Vlv2WayL operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Valve actions you can control in "local mode":

- Travel to neutral position (`Pos0Local` = 1)
- Moving to position 1 (`Pos1Local` = 1)
- Moving to position 2 (`Pos2Local` = 1).

A block operated in "local mode" is controlled either by "local" signals (input parameters `Pos0Local` = 1, `Pos1Local` = 1 and `Pos2Local` = 1) or by feedback signals (input parameters

`FdbV0`, `FdbV1`, `FdbV2` and `FdbP0`; if no position can be assigned, the last valid position is accepted). Configuration takes place via the input parameter `LocalSetting`.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Valve actions you can control in "automatic mode":

- Travel to neutral position (`Pos0Aut` = 1)
- Moving to position 1 (`Pos1Aut` = 1)
- Moving to position 2 (`Pos2Aut` = 1).

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Valve actions you can control in "manual mode":

- Travel to neutral position (`Pos0Man` = 1)
- Moving to position 1 (`Pos1Man` = 1)
- Moving to position 2 (`Pos2Man` = 1).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkV0Out.ST | 16#80 | 16#60 |
| FbkV1Out.ST | 16#80 | 16#60 |
| FbkV2Out.ST | 16#80 | 16#60 |
| FbkP0Out.ST | 16#80 | 16#60 |
| FbkP1Out.ST | 16#80 | 16#60 |
| FbkP2Out.ST | 16#80 | 16#60 |
| Pos0.ST | 16#80 | 16#60 |
| Pos1.ST | 16#80 | 16#60 |
| Pos2.ST | 16#80 | 16#60 |

Description of Vlv2WayL (Page 1647)

## 8.9.3 Vlv2WayL functions

### Functions of Vlv2WayL

The functions for this block are listed below.

### Defining valve positions for individual valves

The control outputs for position 1 and position 2 can be selected individually with `DefPos1` and `DefPos2`:

| Route 1 or route 2 | Control outputs | | |
|---|---|---|---|
| **`DefPos1` or `DefPos2`** | **Valve `V0` (`CtrlV0`)** | **Valve `V1` (`CtrlV1`)** | **Valve `V2` (`CtrlV2`)** |
| 0 | closed | closed | closed |
| 1 | closed | closed | open |
| 2 | closed | open | closed |
| 3 | closed | open | open |
| 4 | open | closed | closed |
| 5 | open | closed | open |
| 6 | open | open | closed |
| 7 | open | open | open |

Position 0 is the neutral position (de-energized state) and cannot be configured. In position 0 all control outputs are de-energized (`CtrlVx` = 0).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57). In addition to the static control outputs `CtrlV0`, `CtrlV1`, `CtrlV2`, `Pos0Out`, `Pos1Out`, `Pos2Out`, the block also has pulse outputs `P_CtrlV0`, `P_CtrlV1`, `P_CtrlV2`, `P_CtrlP0`, `P_CtrlP1`, `P_CtrlP2` which are output depending on the static control outputs.

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54). The neutral position (de-energized state) is set individually using parameters `SafeV0`, `SafeV1`, `SafeV2` for each valve (`CtrlV0`, `CtrlV1`, `CtrlV2`):

- `SafeVx` = 0 means that at `CtrlVx` = 0 the valve drive closes and at `CtrlVx` = 1 it opens (de-energized state is "closed")
- `SafeVx` = 1 means that at `CtrlVx` = 0 the valve drive opens and at `CtrlVx` = 1 it closes(de-energized state is "open")

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56). The warning signal is output before the valve moves into position 1 or position 2 . No warning signal is output for position 0 (neutral position).

You can generate warning signals when, for example, valves open. Warning signals can be generated in the following modes:

- Manual and automatic mode for motors, valves and dosers (Page 82) (Input parameter `WarnTiMan`)
- Manual and automatic mode for motors, valves and dosers (Page 82) (Input parameter `WarnTiAut`)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a valve opens then, this is displayed at the output parameter with `WarnAct` = 1. The valve then opens after the set warning time has expired and `WarnAct` then returns to 0.

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

The monitoring of the feedback signal is dependent on `Feature.Bit12` "Position feedback signals are active (Page 179)".

### Valve feedback signals are active (`Feature.Bit12` = 0):

Startup characteristic monitoring is individually set up for every output signal `CtrlV0`, `CtrlV1`, `CtrlV2` via parameters `MonTiV0Dynamic`, `MonTiV1Dynamic` and `MonTiV2Dynamic` and is set for position 0 via `MonTiP0Dynamic`. The parameter `MonTiStatic` monitors compliance with the position.

The position feedback signals (FbkP1, FbkP2) are not used to monitor the control outputs.

**Note**

The monitoring function does not take into consideration the neutral positions (SafeV0, SafeV1, SafeV2), which means the feedback messages FbkV0, FbkV1, FbkV2 must correspond to the CtrlV0, CtrlV1, CtrlV2 controls (e.g., CtrlV0 = 1 means the feedback FbkV0 is monitored for "1").

FbkP0 must not occur for positions 1 or 2; at position 0, FbkV0, FbkV1 and FbkV2 must not occur.

If there are several feedback messages for position 0 (e.g. with a valve network), these must be combined using an upstream AND block at FbkP0.

### Position feedback signals are active (Feature.Bit12 = 1):

Startup characteristic monitoring is individually set up for the position feedback signals Pos1Out and Pos2Out via the parameters MonTiP1Dynamic and MonTiVP2Dynamic and for position 0 via MonTiP0Dynamic. The MonTiStatic parameter monitors compliance with the position.

The position feedback signals FbkP0, FbkP1 and FbkP2 are used to monitor the output signals Pos0Out, Pos1Out and Pos2Out.

**Note**

The separate valve feedback signals(FbkV0, FbkV1, FbkV2) are not used to monitor the control outputs.

### Disabling feedback

This block provides the standard function Disabling feedback for valves (Page 106). Feedback monitoring can be deactivated separately for each feedback with NoFbkV0, NoFbkV1, NoFbkV2, NoFbkP0, NoFbkP1, NoFbkP2.

### Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45). The inputs Pos0Force, Pos1Force, Pos2Force force the block into position 0, position 1 or position 2.

### Simulating signals

This block provides the standard function Simulating signals (Page 64)

### Interlocks

This block provides the following interlocks:

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")

Refer to the Interlocks (Page 107) section for more on this.

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See Vlv2WayL error handling (Page 1660)

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `MonDynV0` only with valve feedback signals (`Feature.Bit12` = 0)
- `MonDynV1` only with valve feedback signals (`Feature.Bit12` = 0)
- `MonDynV2` only with valve feedback signals (`Feature.Bit12` = 0)
- `MonDynP0`
- `MonDynP1`only with position feedback signals (`Feature.Bit12` = 1)
- `MonDynP2`only with position feedback signals (`Feature.Bit12` = 1)
- `MonStaV0`
- `MonStaV1`
- `MonStaV2`
- `MonStaP0`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `FbkV0Out.ST` only with valve feedback signals (`Feature.Bit12` = 0)
- `FbkV1Out.ST` only with valve feedback signals (`Feature.Bit12` = 0)
- `FbkV2Out.ST` only with valve feedback signals (`Feature.Bit12` = 0)
- `FbkP0Out.ST`
- `FbkP1Out.ST`only with position feedback signals (`Feature.Bit12` = 1)
- `FbkP2Out.ST`only with position feedback signals (`Feature.Bit12` = 1)
- `LocalLi.ST`
- `Pos0Local.ST`
- `Pos1Local.ST`
- `Pos2Local.ST`
- `V0P0ChnST.ST`
- `V1P1ChnST.ST`
- `V2P2ChnST.ST`
- `Pos0Aut.ST` (only if `Feature2.Bit10` = 1)
- `Pos1Aut.ST` (only if `Feature2.Bit10` = 1)
- `Pos2Aut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- `Pos0Aut.ST`
- `Pos1Aut.ST`
- `Pos2Aut.ST`

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can switch to position 0 |
| 5 | 1 = Operator can switch to position 1 |
| 6 | 1 = Operator can switch to position 2 |
| 7 | 1 = Operator can reset the valve |
| 8 | 1 = Operator can define the monitoring time for startup |
| 9 | 1 = Operator can define the monitoring time for the end position |
| 10 | 1 = Operator can activate the monitoring time function (Bit 8 - 9) |
| 11 | Not used |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable reactions with the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 12 | Position feedback signals are active (Page 179) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In pushbutton operation (Bit 4 = 0) the automatic commands in "automatic mode" are latching, in other words `Pos0Aut`, `Pos1Aut`, `Pos2Aut` can be reset to 0 after switching to the selected position. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the position is tracked.

In switching mode (Bit 4 = 1) positions 1 and 2 are selected by static signals via inputs `Pos1Aut` and `Pos2Aut`. If inputs `Pos1Aut` and `Pos2Aut` are not set, the block switches to position 0. Control via `Pos0Aut` is not needed.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |

| Bit | Function |
|---|---|
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and "Out of service" mode for a connected message block (Page 202) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `Pos0Man`
- `Pos1Man`
- `Pos2Man`

## 8.9.4 Vlv2WayL error handling

### Vlv2WayL error handling

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Control system fault (CSF)
- Invalid or not plausible input commands

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not within the approved limit of 0 to 4. |
| 42 | `LocalSetting` = 0 and `LocalLi` = 1 |
| 51 | For `ModLiOp` = 1:<br>• `AutModLi` = 1 and `ManModLi` = 1<br>If "local mode" is enabled:<br>• `Pos0Local` = 1 and `Pos1Local` = 1<br>• `Pos0Local` = 1 and `Pos2Local` = 1<br>• `Pos1Local` = 1 and `Pos2Local` = 1<br>If "automatic mode" is enabled:<br>• `Pos0Aut` = 1 and `Pos1Aut` = 1<br>• `Pos0Aut` = 1 and `Pos2Aut` = 1<br>• `Pos1Aut` = 1 and `Pos2Aut` = 1<br>Generally:<br>• `Pos0Force` = 1 and `Pos1Force` = 1<br>• `Pos0Force` = 1 and `Pos2Force` = 1<br>• `Pos1Force` = 1 and `Pos2Force` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 or 4 and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| **Operating mode** | **Invalid or not plausible input commands** | **Control reaction with `Feature2.Bit3` = 1** |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | Pushbutton operation for local mode (`Feature2.Bit4` = 0):<br>`Pos1Local` = 1 and `Pos2Local` = 1 or<br>`Pos1Local` = 1 and `Pos0Local` = 1 or<br>`StopLocal` = 1 and `Pos2Local` = 1<br>Switching mode (`Feature2.Bit4` = 1):<br>`Pos1Local` = 1 and `Pos2Local` = 1 | Valve is set to Pos0. |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `Pos1Force` = 1 and `Pos2Force` = 1 or<br>`Pos1Force` = 1 and `Pos0Force` = 1 or<br>`Pos0Force` = 1 and `Pos2Force` = 1 | |
| Forcing and no "local mode" | `Pos1Force` = 1 and `Pos2Force` = 1 or<br>`Pos1Force` = 1 and `Pos0Force` = 1 or<br>`Pos0Force` = 1 and `Pos2Force` = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0):<br>`Pos1Aut` = 1 and `Pos2Aut` = 1 or<br>`Pos1Aut` = 1 and `Pos0Aut` = 1 or<br>`Pos0Aut` = 1 and `Pos2Aut` = 1<br>Switching mode (`Feature.Bit4` = 1):<br>`Pos1Aut` = 1 and `Pos2Aut` = 1 | |
| "Manual mode" and no forcing | `Pos1Man` = 1 and `Pos0Man` = 1 or<br>`Pos1Man` = 1 and `Pos0Man` = 1 or<br>`Pos0Man` = 1 and `Pos2Man` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.9.5 Vlv2WayL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Position 0 feedback error (neutral position) |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>Position 1 or 2 feedback error |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 3).

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa104` ... `ExtVa108` , and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

I/Os of Vlv2WayL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AutModLi*` | 1= "Automatic mode" via:<br>Interconnection or SFC (controlled via `ModLiOp` = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AutModOp*` | 1 = "Automatic mode" via operator (controlled by `ModLiOp` = 0) | BOOL | 0 |
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BypProt | 1 = Bypassing interlock in "local mode" and in "simulation" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| DefPos1 | Output signal parameter setting for position 1 | INT | 3 |
| DefPos2 | Output signal parameter setting for position 2 | INT | 6 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkP0 | 1 = Feedback for position 0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#FF |
| FbkP1 | 1 = Feedback for position 1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#FF |
| FbkP2 | 1 = Feedback for position 2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#FF |
| FbkV0 | 1 = Feedback for control output CtrlV0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#FF |
| FbkV1 | 1 = Feedback for control output CtrlV1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#FF |
| FbkV2 | 1 = Feedback for control output CtrlV2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1653) | STRUCT<br>• Bit:0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1653) | STRUCT<br>• Bit:0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Intlock | 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared<br>1 = Interlock not activated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is active | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signals | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = "Manual mode" via OS operator (controlled by ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors | BOOL | 1 |
| MonTiP0Dynamic* | Monitoring time for position 0 after operation in [s] | REAL | 3.0 |
| MonTiP1Dynamic* | Monitoring time for position 1 after operation in [s] | REAL | 3.0 |
| MonTiP2Dynamic* | Monitoring time for position 2 after operation in [s] | REAL | 3.0 |
| MonTiV0Dynamic* | Monitoring time for feedback errors FdbV0 after operation in [s] | REAL | 3.0 |
| MonTiV1Dynamic* | Monitoring time for feedback errors FdbV1 after operation in [s] | REAL | 3.0 |
| MonTiV2Dynamic* | Monitoring time for feedback errors FdbV2 after operation in [s] | REAL | 3.0 |
| MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoFbkP0 | 1 = Feedback for position 0 not present | BOOL | 0 |
| NoFbkP1 | 1 = Feedback for position 1 not present | BOOL | 0 |
| NoFbkP2 | 1 = Feedback for position 2 not present | BOOL | 0 |
| NoFbkV0 | 1 = Feedback for control output CtrlV0 not present | BOOL | 0 |
| NoFbkV1 | 1 = Feedback for control output CtrlV1 not present | BOOL | 0 |
| NoFbkV2 | 1 = Feedback for control output CtrlV2 not present | BOOL | 0 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1653) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| Permit | 1 = Enable for opening / closing from neutral position<br>0 = Valve activation not enabled on OS | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Perm_En | 1 = Activation enable (enable, Permit parameter) is active | BOOL | 1 |
| Pos0Aut* | 1 = Select position 0 in "automatic mode" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos0Force | 1 = Force position 0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos0Local | 1 = Select position 0 in "local mode" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos0Man* | 1 = Select position 0 in "manual mode" | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Pos1Aut* | 1 = Select position 1 in "automatic mode" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos1Force | 1 = Force position 1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos1Local | 1 = Select position 1 in "local mode" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos1Man* | 1 = Select position 1 in "manual mode" | BOOL | 0 |
| Pos2Aut* | 1 = Select position 2 in "automatic mode" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos2Force | 1 = Force position 2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos2Local | 1 = Select position 2 in "local mode" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos2Man* | 1 = Select position 2 in "manual mode" | BOOL | 0 |
| Protect | 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block<br>1 = Protective interlocking not activated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Prot_En | 1 = Protective interlock (protection, Protect parameter) is active | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafeV0 | Neutral position for valve V0 (CtrlV0):<br>1= Open<br>0 = Closed | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SafeV1 | Neutral position for valve V1 (CtrlV1):<br>1= Open<br>0 = Closed | BOOL | 0 |
| SafeV2 | Neutral position for valve V2 (CtrlV2):<br>1= Open<br>0 = Closed | BOOL | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| V0P0ChnST | Signal status of output channel for CtrlV0 or Pos0Out<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| V1P1ChnST | Signal status of output channel for CtrlV1 or Pos1Out<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| V2P2ChnST | Signal status of output channel for CtrlV2 or Pos2Out<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| WarnTiAut | Prewarning for valve movement into position 1 or position 2 in "automatic mode" in [s] | REAL | 0.0 |
| WarnTiMan | Prewarning for valve movement into position 1 or position 2 in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CtrlV0 | Control output V0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| CtrlV1 | Control output V1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| CtrlV2 | Control output V2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| CurrMonP0 | Remaining monitoring time P0 [s] | DINT | 0 |
| CurrMonP1 | Remaining monitoring time P1 [s] | DINT | 0 |
| CurrMonP2 | Remaining monitoring time P2 [s] | DINT | 0 |
| CurrMonV0 | Remaining monitoring time V0 [s] | DINT | 0 |
| CurrMonV1 | Remaining monitoring time V1 [s] | DINT | 0 |
| CurrMonV2 | Remaining monitoring time V2 [s] | DINT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see Vlv2WayL error handling (Page 1660) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkP0Out | Feedback from position 0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| FbkP1Out | Feedback from position 1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| FbkP2Out | Feedback from position 2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| FbkV0Out | Control output feedback CtrlV0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| FbkV1Out | Control output feedback CtrlV1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| FbkV2Out | Control output feedback CtrlV2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit or Protect) is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 1<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MonDynP0 | 1 = Feedback error for position 0 due to a control change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonDynP1 | 1 = Feedback error for position 1 due to a control change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonDynP2 | 1 = Feedback error for position 2 due to a control change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonDynV0 | 1 = Feedback error for FdbV0 due to control change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonDynV1 | 1 = Feedback error for FdbV1 due to control change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonDynV2 | 1 = Feedback error for FdbV2 due to control change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonStaP0 | 1 = Feedback error for position 0 due to an unexpected feedback change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonStaP1 | 1 = Feedback error for position 1 due to an unexpected feedback change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonStaP2 | 1 = Feedback error for position 2 due to an unexpected feedback change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonStaV0 | 1 = Feedback error FdbV0 due to unexpected feedback change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonStaV1 | 1 = Feedback error FdbV1 due to unexpected feedback change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MonStaV2 | 1 = Feedback error FdbV2 due to unexpected feedback change | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "out of service" | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| P_CtrlP0 | 1 = Pulse signal for moving the valve to position 0 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| P_CtrlP1 | 1 = Pulse signal for moving the valve to position 1 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| P_CtrlP2 | 1 = Pulse signal for moving the valve to position 2 | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| P_CtrlV0 | 1 = Pulse signal for moving the valve to route 0 (V0) | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| P_CtrlV1 | 1 = Pulse signal for moving the valve to route 1 (V1) | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| P_CtrlV2 | 1 = Pulse signal for moving the valve to route 2 (V2) | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Pos0 | 1 = Pos0 is reached | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Pos1 | 1 = Pos1 is reached | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos2 | 1 = Pos2 is reached | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos0Out | 1 = Position 0 is active | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos1Out | 1 = Position 1 is active | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Pos2Out | 1 = Position 2 is active | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1647) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1647) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1647) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1647) | DWORD | 16#00000000 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `UserAna2Out` | `UserAna2` as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| `WarnAct` | 1 = Prewarning for valve movement to position 1 or position 2 enabled (parameter `WarnTiAut` and `WarnTiMan`) | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |

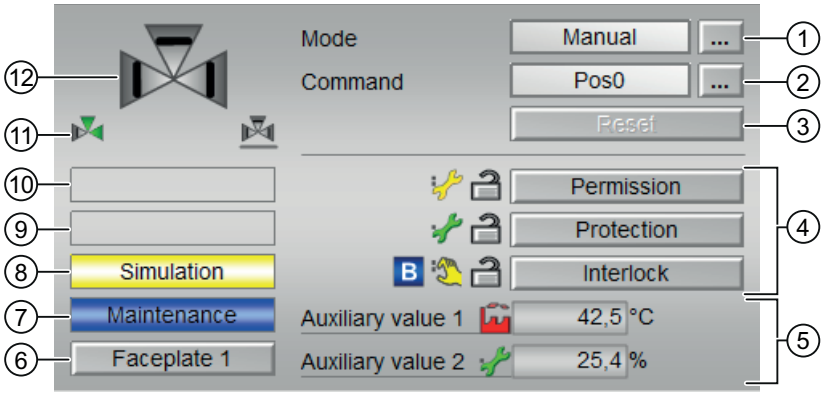
## 8.9.8 Operator control and monitoring

### 8.9.8.1 Vlv2WayL views

#### Views of the Vlv2WayL block



The block Vlv2WayL provides the following views:

- Vlv2WayL standard view (Page 1677)
- Alarm view (Page 336)
- Trend view (Page 341)
- Vlv2WayL parameter view (Page 1681)
- Vlv2WayL preview (Page 1683)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for Vlv2WayL (Page 1688)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.9.8.2 Vlv2WayL standard view

#### Vlv2WayL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)

- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Selecting the position for 2-way valve

This area shows you the default operating state for the valve. The following states can be shown and executed here:

- "Pos0"
- "Pos1"
- "Pos2"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (6) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "External error"
- "End position error"
- "Control error"
- "Internal error"
- "Changeover error"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Force Pos0"
- "Force Pos1"
- "Force Pos2"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (11) Automatic preview

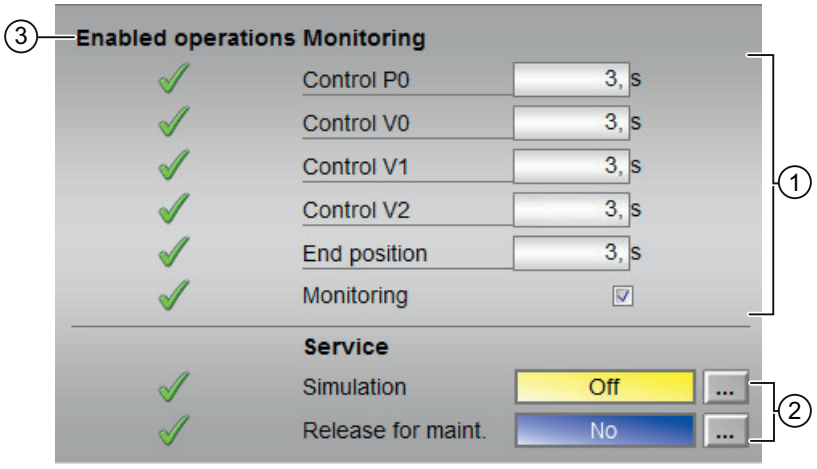
This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the valve would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (12) Status display of the valve

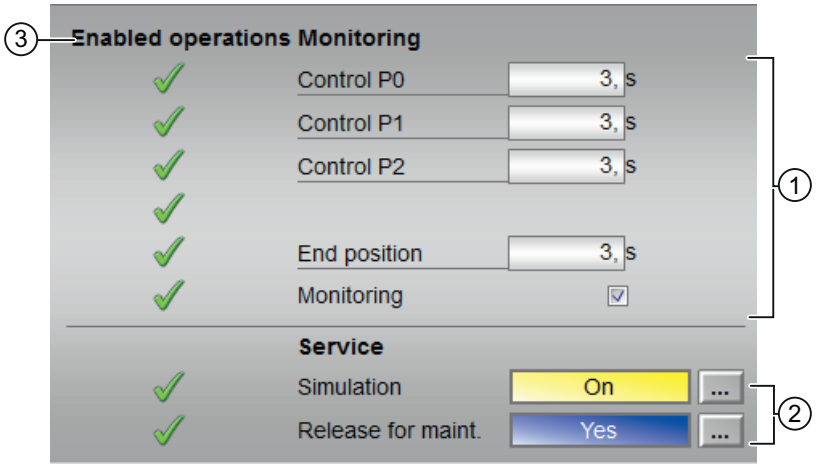
You can find additional information on this in the section Block icon for Vlv2WayL (Page 1688).

### (13) Neutral position of the valve



The neutral position of the valve is shown here.

If the neutral position of the valve is "Closed" (SafePos = 0), a gray valve is shown.



If the neutral position of the valve is "Open" (SafePos = 0), a green valve is shown.

### 8.9.8.3 Vlv2WayL parameter view

#### Parameter view of Vlv2WayL

Two-way valve with separate valve feedback signals (`Feature.Bit12` = 0)

Two-way valve with position feedback signals (`Feature.Bit12` = 1)

#### (1) Monitoring

In this area, you change parameters and therefore influence the valve. Refer to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- "Control P0": Monitoring time while "opening"/"closing" the valve
- "Control P1": Monitoring time while "opening"/"closing" the valve
- "Control P2": Monitoring time while "opening"/"closing" the valve

- "Control V0": Monitoring time while "opening"/"closing" the valve
- "Control V1": Monitoring time while "opening"/"closing" the valve
- "Control V2": Monitoring time while "opening"/"closing" the valve
- "End position": Monitoring time for maintaining the valve position

**Enable monitoring**

You can enable monitoring by selecting the check box (☑)

You can find additional information on this in the section Monitoring the feedbacks (Page 104).

### (2) Service

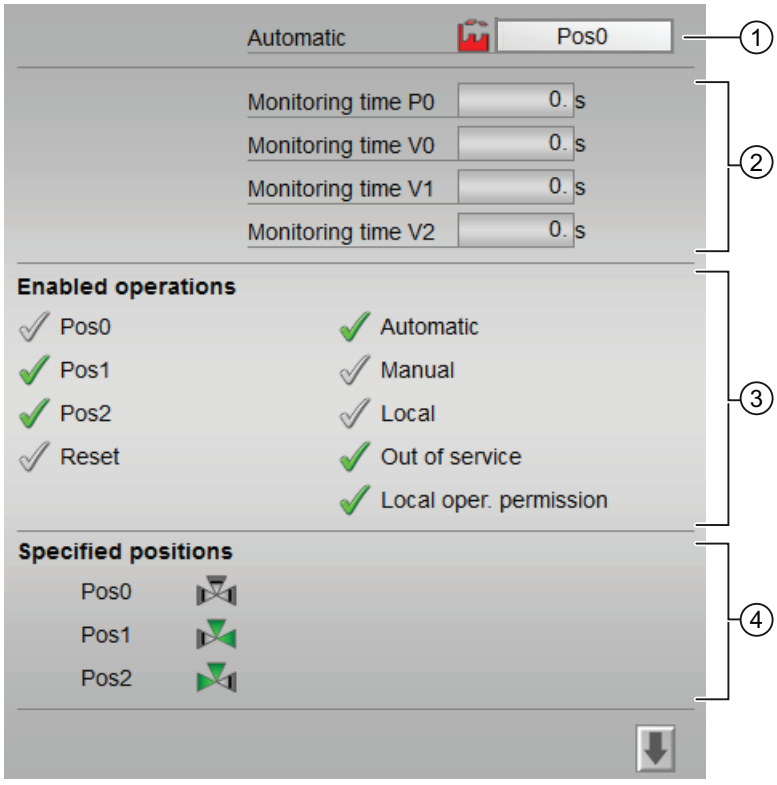
You can select the following functions in this area:

- "Simulation"
- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

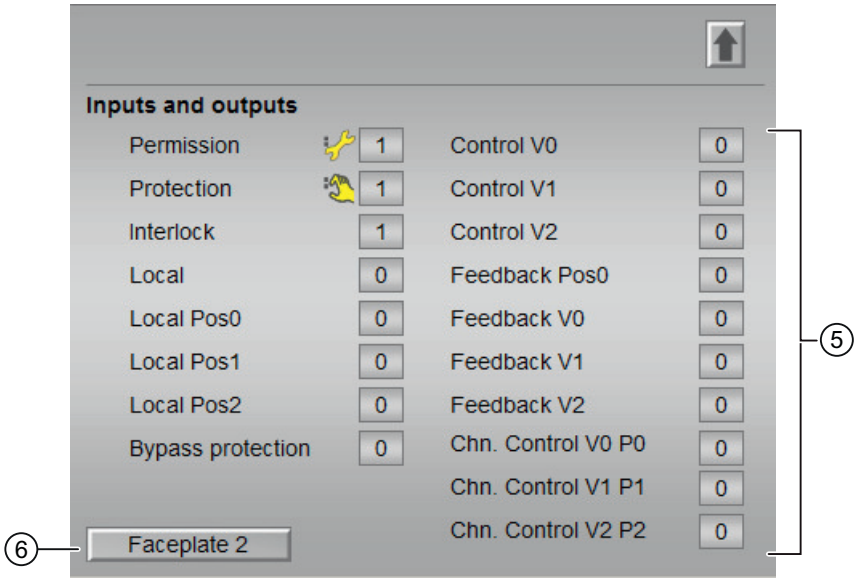
### (3) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.



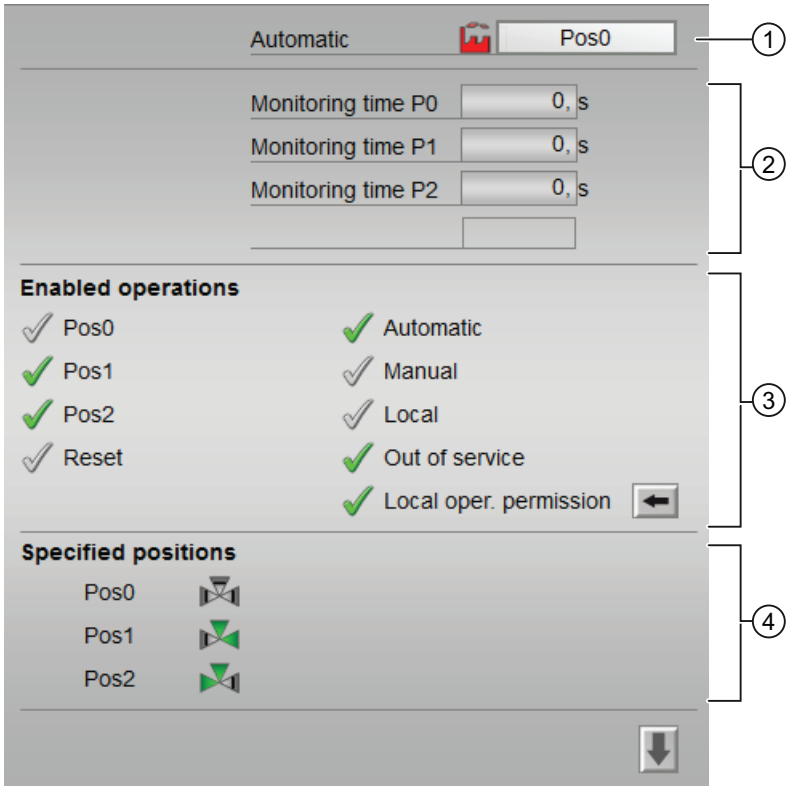
Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

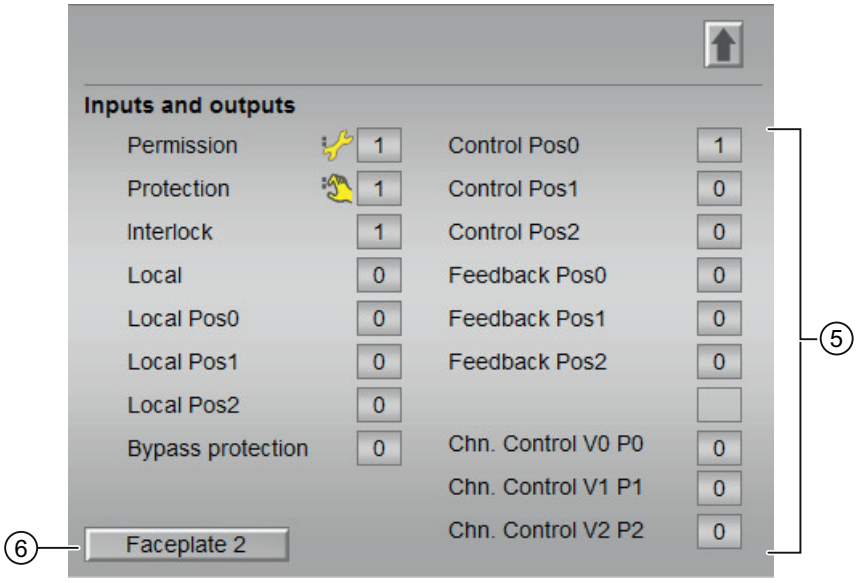


### 8.9.8.4 Vlv2WayL preview

#### Preview of Vlv2WayL



Two-way valve with single value feedback signals (`Feature.Bit12` = 0)



The preview has an upper half and a lower half. You can change between the two halves with the arrow keys.

Two-way valve with position feedback signals (`Feature.Bit12` = 1)

The preview has an upper half and a lower half. You can change between the two halves with the arrow keys.

## (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `Pos0Aut`
- `Pos1Aut`
- `Pos2Aut`

## (2) Preview area

The following enabled operations are shown here:

- "Monitoring time `P0`": Display of the remaining monitoring time `P0` (`Feature.Bit12` = 1)
- "Monitoring time `P1`": Display of the remaining monitoring time `P1` (`Feature.Bit12` = 1)
- "Monitoring time `P2`": Display of the remaining monitoring time `P2` (`Feature.Bit12` = 1)
- "Monitoring time `V0`": Display of the remaining monitoring time `V0` (`Feature.Bit12` = 0)

- "Monitoring time `V1`": Display of the remaining monitoring time `V1` (`Feature.Bit12` = 0)
- "Monitoring time `V2`": Display of the remaining monitoring time `V2` (`Feature.Bit12` = 0)

### (3) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Pos0": You can set the valve to position 0.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Pos1": You can set the valve to position 1.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Pos2": You can set the valve to position 2.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the valve if errors occur.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).

### (4) Specified Position

Preview of the valve positions, as configured in the engineering system (ES).

### (5) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission":
  This display is only visible when the corresponding block input is connected.
  - 0 = Valve activation not enabled on OS
  - 1 = Enable for "starting"/"stopping" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection":
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Local Pos0": 1 = Block was set to position 0 in "local mode"
- "Local Pos1": 1 = Block was set to position 1 in "local mode"
- "Local Pos2": 1 = Block was set to position 2 in "local mode"
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"

Control and feedback signals with `Feature.Bit12` = 0

- "Control Pos0": 1 = Control signal for the position 0
- "Control V0": 1 = Control signal for the valve 0
- "Control V1": 1 = Control signal for the valve 1
- "Control V2": 1 = Control signal for the valve 2
- "Feedback Pos0": 1 = Valve is in position 0
- "Feedback V0": 1 = Feedback if valve 0 was opened
- "Feedback V1": 1 = Feedback if valve 1 was opened
- "Feedback V2": 1 = Feedback if valve 2 was opened

Control and feedback signals with `Feature.Bit12` = 1

- "Control Pos0": 1 = Control signal for the position 0
- "Control Pos1": 1 = Control signal for the position 1
- "Control Pos2": 1 = Control signal for the position 2
- "Feedback Pos0": 1 = Valve is in position 0
- "Feedback Pos1": 1 = Valve is in position 1
- "Feedback Pos2": 1 = Valve is in position 2

Control signals of the output channel block

- "Channel control V0 P0": Control signal for V0 or P0 of the output channel block
- "Channel control V1 P1": Control signal for V1 or P1 of the output channel block
- "Channel control V2 P2": Control signal for V2 or P2 of the output channel block

**(6) Navigation button for switching to the standard view of any faceplate**

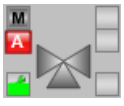
This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

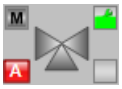
For more information, see section Opening additional faceplates (Page 234).

### 8.9.8.5 Block icon for Vlv2WayL

**Properties of the Vlv2WayLblock icon**



A variety of block icons are available with the following functions:



- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as the control system fault
- Operating modes
- Signal status, release for maintenance
- Forcing states
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Valve status display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | |
|  | 4 | |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | 9 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 10 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Valve status display

The following valve states are shown here:

| Icon | Meaning |
|---|---|
|  | Valve open |
|  | Error at valve |
|  | Valve is opening |
|  | Valve closed |
|  | Valve is closing |

# 8.10 VlvL - Valve (Large)

## 8.10.1 Description of VlvL

### Object name (type + number) and family

Type + number: FB 1899

Family: Drives

### Area of application for VlvL

The block is used for the following applications:

- Controlling a valve in two positions ("open"/"closed") with adjustable neutral position

**Note**

This block is also available as a small block. A comparison of the VlvL and VlvS blocks is available in the section: VlvL compared to VlvS (Page 1372)

### How it works

The valve is opened or closed by a control signal. The signal 0 corresponds to the de-energized state (neutral position) of the valve.

The control is monitored by the "open"/"close" (feedback) signals. Missing feedback can be derived from the control in the block.

Various inputs are available for control purposes. The next sections provide more detailed information on configuration, operating principles, visualization and operation.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the VlvL block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- Valve (Valve_Lean) (Page 2865)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section VlvL I/Os (Page 1707).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon |
| 8 | "Open"/"Closed" command (1 = "Open") |
| 9 | `FbkOpenOut.Value` |
| 10 | `FbkCloseOut.Value` |
| 11 | Feedback error without control change |
| 12 | Feedback error due to control change |
| 13 | `BypProt` |
| 14 | Invalid signal status |
| 15 | Mode switchover error |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | Display „Forced open“ |
| 20 | Display „Forced close“ |
| 21 | `Force` |
| 22 | Automatic preview (1 = "Open") |
| 23 | Bumpless switchover to "automatic mode" enabled |
| 24 | `SafePos` |
| 25 | `UserAna1` interconnected |
| 26 | `UserAna2` interconnected |
| 27 | `WarnAct.Value` |
| 28 | For the Error status display in the Closed valve |
| 29 | For the Error status display in the Opened valve |
| 30 | External error generated by FaultExt or external control system fault from CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 31 | 1 = Input parameter `CtrlChnST` is interconnected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | Not used |
| 2 | Display for interlocks in block icon |
| 3 - 11 | Not used |
| 12 | Resynchronization preview for Open |
| 13 | Resynchronization preview for Close |
| 14 | Resynchronization: Display preview |
| 15 | Resynchronization: Display small preview symbol in standard view |
| 16 | 1 = Input parameter `FbkClose` is connected |
| 17 | 1 = Input parameter `FbkOpen` is connected |
| 18 | Reset request in automatic |
| 19 | 1 = No impact of input signals on "local mode" with `LocalSetting` = 0, `LocalSetting` = 2, `LocalSetting` = 4 and OOS mode. |
| 20 | 1 = Valve open |
| 21 | 1 = Valve closed |
| 22 | 1 = Valve opens |
| 23 | 1 = Valve closes |
| 24 | Resynchronization with state "No Cmd" |
| 25 - 29 | Not used |
| 30 | Bypass information for display in block icon |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | "Interlock" button is enabled |
| 9 | "Permission" button is enabled |
| 10 | "Protection" button is enabled |
| 11 | Hidden bypass signal in Permit |
| 12 | Hidden bypass signal in interlock |
| 13 | Hidden bypass signal in Protect |
| 14 | `Feature2.Bit2`: Separate bypass signal |
| 15 | Current monitoring time is visible |

| Status bit | Parameter |
|---|---|
| 16 | 1 = " Permit neutral pos." button is enabled |
| 17 | 1 = Permission SafePos is active |
| 18 | Hidden bypass signal in Permission SafePos |
| 19 - 25 | Not used |
| 26 | Show automatic preview in the standard view |
| 27 | Not used |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | Not used |
| 31 | Internal error |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 31 | Not used |

VlvL error handling (Page 1703)

VlvL modes (Page 1694)

Resetting the block in case of interlocks or errors (Page 47)

## 8.10.2 VlvL modes

### VlvL operating modes

The block supports all standard modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Valve actions you can control in "local mode":

- "Open" (`OpenLocal` = 1)
- "Close" (`CloseLocal` = 1)

A block operated in "local mode" is controlled either by "local" signals or by feedback signals (input parameters `FbkOpen`, `FbkClose` or `FbkStop`; if no position can be assigned, the last valid position is accepted). Configuration takes place via the input parameter `LocalSetting`.

`LocalSetting` =2,4: The control outputs are tracked to the feedbacks.

All two feedbacks are available and plausible means that always only one feedback is active. The corresponding control output is tracked:

```
Ctrl = FbkOpen XOR SafePos
```

```
StopCtrl = FbkClose XOR SafePos
```

When both feedbacks are false then the drive is between of two positions. In this case no monitoring is started. When two feedbacks are active at the same time, then they are not plausible. In this case the static monitoring counter starts. In both cases "all feedbacks are reset" or "not plausible feedbacks" with `Feature2Bit21` =1 all the control outputs are set to false (No command state) else control outputs will be hold.

If one feedback is available it is always plausible.

| NoFbkClose =0 | NoFbkOpen =0 |
|---|---|
| `Ctrl = NOT (FbkClose XOR SafePos)`<br>`StopCtrl = FbkClose XOR SafePos` | `Ctrl = FbkOpen XOR SafePos`<br>`StopCtrl = NOT (FbkOpen XOR SafePos)` |

When all feedbacks are not available the control outputs will be hold.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Valve actions you can control in "automatic mode":

- "Open" (`OpenAut` = 1)
- "Close" (`CloseAut` = 1)

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Valve actions you can control in "manual mode":

- "Open" (`OpenMan` = 1)
- "Close" (`CloseMan` = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkOpenOut.ST | 16#80 | 16#60 |
| FbkCloseOut.ST | 16#80 | 16#60 |
| Opened.ST | 16#80 | 16#60 |
| Closed.ST | 16#80 | 16#60 |
| Opening.ST | 16#80 | 16#60 |
| Closing.ST | 16#80 | 16#60 |

VlvL error handling (Page 1703)

VlvL functions (Page 1696)

## 8.10.3 VlvL functions

### Functions of VlvL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |

| Bit | Function |
|---|---|
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can open the valve |
| 5 | 1 = Operator can close the valve |
| 6 | 1 = Operator can reset the valve |
| 7 | 1 = Operator can define the monitoring time for startup |
| 8 | 1 = Operator can define the monitoring time for the end position |
| 9 | 1 = Operator can activate the monitoring time function (Bit 7 - 8) |
| 10 | 1 = Operator can enable function simulation |
| 11 | 1 = Operator can activate the Release for maintenance function |
| 12 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Interlocks

This block provides the following interlocks:

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")
- Permission for safe position (“Permit neutral pos.”)

Refer to the Interlocks (Page 107) section for more on this.

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See VlvL error handling (Page 1703)

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `MonDynErr`
- `MonStaErr`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status ST_Worst for the block is formed from the following parameters:

- `FbkOpenOut.ST`
- `FbkCloseOut.ST`
- `LocalLi.ST`
- `OpenLocal.ST`
- `CloseLocal.ST`
- `CtrlChn.ST`
- `OpenAut.ST` (only if `Feature2.Bit10` = 1)
- `CloseAut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- `OpenAut.ST`
- `CloseAut.ST`

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).
Inputs `OpenForce` and `CloseForce` force the block to open or close.

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104). Startup characteristics are monitored by setting parameter`MonTiDynamic`. The parameter `MonTiStatic` monitors compliance with the position.

### Disabling feedback

This block provides the standard function for Disabling feedback for valve and motors (Page 106).

Feedback monitoring can be deactivated separately for each feedback with `NoFbkOpen` or `NoFbkClose` as required.

The output signals of feedback are tracked by the control and the other available feedbacks:

| NoFbkOpen | NoFbkClose | Comment |
|---|---|---|
| 0 | 0 | **Default:**<br>`FbkOpenOut = FbkOpen;`<br>`FbkCloseOut = FbkClose;` |
| 0 | 1 | `FbkOpenOut = FbkOpen;`<br>`FbkCloseOut = (StopCtrl XOR SafePos) AND NOT FbkOpen;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkOpenOut = FbkOpen;`<br>`FbkCloseOut = NOT FbkOpen;` |
| 1 | 0 | `FbkOpenOut = (Ctrl XOR SafePos) AND NOT FbkClose;`<br>`FbkCloseOut = FbkClose;`<br>**Local mode with LocalSetting =2/4:**<br>`FbkOpenOut = NOT FbkClose;`<br>`FbkCloseOut = FbkClose;` |
| 1 | 1 | `FbkOpenOut = Ctrl XOR SafePos;`<br>`FbkCloseOut = StopCtrl XOR SafePos;` |

When all feedbacks are not available, the position is on hold after a switch to local mode with `LocalSetting` =2/4.

### Disabling feedback

This block provides the standard function Disabling feedback for valves (Page 106). Feedback monitoring can be deactivated separately for each feedback with `NoFbkOpen` or `NoFbkClose` as required.

### Using StopCtrl with mode "No Cmd"

This block provides the standard function Control with output StopCtrl and state “No Cmd” (Page 214)

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56). The warning signal is output before the valve moves away from the neutral position. No signal is output for movement to the neutral position.

You can generate warning signals when, for example, valves open. Warning signals can be generated in the following modes:

- Manual and automatic mode for motors, valves and dosers (Page 82) (Input parameter `WarnTiMan`)
- Description of VlvL (Page 1691) (Input parameter `WarnTiAut`)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a valve opens then, this is displayed at the output parameter with `WarnAct` = 1. The valve then opens after the set warning time has expired and `WarnAct` then returns to 0.

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54). The neutral position (de-energized state) is set using the `SafePos` parameter.

- `SafePos` = 0 means that at `Ctrl` = 0 the valve drive closes and at `Ctrl` = 1 it opens (de-energized state is "closed")
- `SafePos` = 1 means that at `Ctrl` = 0 the valve drive opens and at `Ctrl` = 1 it closes (de-energized state is "open")

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

## Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the control outputs are tracked as follow:

**NoFbkOpen =0, NoFbkClose =0 (default):**

Plausible feedback positions (FbkOpen =1, FbkClose =0 or FbkOpen =0, FbkClose =1) are tracked as control position.

**SafePos =0:** Ctrl := FbkOpen; StopCtrl := FbkClose;

**SafePos =1:** Ctrl := FbkClose; StopCtrl := FbkOpen;

In case if there are no plausible feedback positions (FbkOpen =0, FbkClose =0 or FbkOpen =1, FbkClose =1) the control position depends on Feature2 Bit21.

- Feature2 Bit21 =0 (default): Control position is not changed.
- Feature2 Bit21 =1: Control position becomes "No Cmd" Ctrl := 0; StopCtrl := 0;

**NoFbkOpen =1, NoFbkClose =0:**

**SafePos =0:** Ctrl := NOT FbkClose; StopCtrl := FbkClose;

**SafePos =1:** Ctrl := FbkClose; StopCtrl := NOT FbkClose;

**NoFbkOpen =0, NoFbkClose =1:**

**SafePos =0:** Ctrl := NOT FbkOpen; StopCtrl := FbkOpen;

**SafePos =1:** Ctrl := FbkOpen; StopCtrl := NOT FbkOpen;

With other combinations **NoFbkOpen =1**, **NoFbkClose =1** the controls are not changed

## Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |

| Bit | Function |
|---|---|
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In pushbutton operation (Bit 4 = 0) the automatic commands in "automatic" mode are latching, in other words `OpenAut`, `CloseAut` can be reset to zero after changing the control. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

In switching mode (Bit 4 = 1), the control is selected with the static signal `OpenAut`. If input `OpenAut` is not set the valve is closed. Control via `CloseAut` is not needed. If the "Activate command reset for control" function (Bit 3 = 1) is also activated, the `OpenAut` input is reset to the neutral position after evaluation in the block.

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |
| 21 | Control with output StopCtrl and state “No Cmd” (Page 214) |

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57). In addition to the static control output `Out`, the block also has pulse outputs `P_Open`, `P_Close`, which are dependent on the static control output.

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `OpenMan`
- `CloseMan`

## 8.10.4 VlvL error handling

### Error handling of VlvL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Invalid or not plausible input commands
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not within the approved limit of 0 to 4. |
| 42 | `LocalSetting` = 0 or `LocalSetting` = 3 or `LocalSetting` = 4 and `LocalLi` = 1 |
| 51 | `AutModLi` = 1 and `ManModLi` = 1<br>`OpenLocal` = 1 and `CloseLocal` = 1<br>`OpenAut` = 1 and `CloseAut` = 1<br>`OpenForce` = 1 and `CloseForce` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 or `4` and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block. Refer to the Error handling (Page 128) section for more on this.

### Invalid or not plausible input commands

This error can be output by the block. Refer to the Error handling (Page 128) section for more on this.

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| **Operating mode** | **Invalid or not plausible input commands** | **Control reaction with `Feature2.Bit3` = 1** |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | Pushbutton operation for local mode (`Feature2.Bit4` = 0):<br>`OpenLocal` = 1 and `CloseLocal` = 1 | Valve is set to its neutral position. |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `OpenForce` = 1 and `CloseForce` = 1 | |
| Forcing and no "local mode" | `OpenForce` = 1 and `CloseForce` = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature2.Bit4` = 0):<br>`OpenAut` = 1 and `CloseAut` = 1 | |
| "Manual mode" and no forcing | `OpenMan` = 1 and `CloseMan` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.10.5 VlvL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 2).

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | ExtVa106 |
| 7 | ExtVa107 |
| 8 | ExtVa108 |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters ExtVa104 ... ExtVa108 and can be used. See the "Process Control System PCS 7 - Engineering System" manual.

## 8.10.6 VlvL I/Os

I/Os of VlvL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1= "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 1) | BOOL | 0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BypProt | 1 = Bypassing interlock is active in "local mode" and in simulation | BOOL | 0 |
| CloseAut* | 1 = Select Close valve in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseForce | 1 = Force valve closure | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CloseLocal | 1 = Select Close valve in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseMan* | 1 = Select Close valve in "manual mode" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlChnST | Signal status of output channel Ctrl<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| EN | 1 = Called block will be processed | BOOL | 1 |
| EventTsIn | For interconnecting data between a technological block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs block. When this interconnection is configured, the messages of the EventTs block are displayed on the OS in the alarm view of the technological block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvID1) | ANY | |
| ExtVa107 | Associated value 7 for messages (MsgEvID1) | ANY | |
| ExtVa108 | Associated value 8 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkOpen | 1 = Valve open feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkClose | 1 = Valve closed feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1696) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1696) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Intlock | 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared<br>1 = Interlock not activated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is active | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1= "Manual mode" via: OS operator (controlled via ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors | BOOL | 1 |
| MonTiDynamic* | Monitoring time after operation in [s] | REAL | 3.0 |
| MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoFbkClose | 1 = No feedback present for "valve closed" | BOOL | 0 |
| NoFbkOpen | 1 = No feedback present for "valve open" | BOOL | 0 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpenAut* | 1 = Select Open valve in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenForce | 1 = Force valve opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenLocal | 1 = Select Open valve in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenMan* | 1 = Select Open valve in "manual mode" | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1696) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| Permit | 1 = Enable for opening / closing from neutral position<br>0 = Valve activation not enabled on OS | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermitSafePos | 1=Valve SafePos allowed | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermSf_En | 1=Permit SafePos enabled | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Perm_En | 1 = Activation enable (enable, Permit parameter) is active | BOOL | 1 |
| Protect | 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block<br>1 = Protective interlocking not activated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Prot_En | 1 = Protective interlock (protection, Protect parameter) is active | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | Neutral position for valve:<br>1= Open<br>0 = Closed | BOOL | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | - |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| WarnTiAut | Prewarning of valve movement from neutral position in "automatic mode" in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan | Prewarning of valve movement from neutral position in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| Closed | 1 = Valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Closing | 1 = Valve is closing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ctrl | Control output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopCtrl | Control output go to SafePos | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CurrMon | Remaining monitoring time [s] | DINT | 0 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see VlvL error handling (Page 1703) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkCloseOut | Valve closed feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpenOut | Valve open feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit or Protect) is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynErr | 1 = Feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opened | 1 = Valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opening | 1 = Valve is opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| P_Close | 1 = Pulse signal to close valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Open | 1 = Pulse signal to open valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>ST: BYTE | -<br>• 1<br>• 16#FF |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1691) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1691) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1691) | DWORD | 16#00000000 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |
| WarnAct | 1 = Prewarning for valve movement away from neutral position active (parameters WarnTiAut and WarnTiMan) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

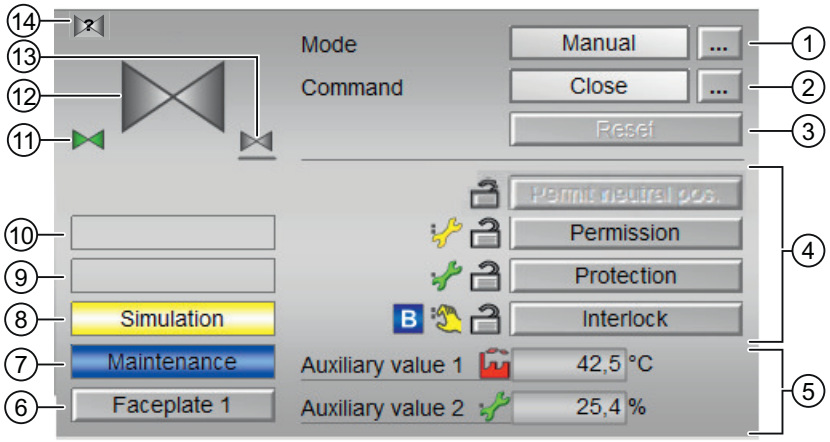
## 8.10.8 Operator control and monitoring

### 8.10.8.1 VlvL views

#### Views of the VlvL block



The block VlvL provides the following views:

- VlvL standard view (Page 1717)
- Alarm view (Page 336)
- Trend view (Page 341)
- Parameter view for motors and valves (Page 320)
- VlvL preview (Page 1721)
- Memo view (Page 338)
- Batch view (Page 336)
- VlvL block icon (Page 1725)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.10.8.2 VlvL standard view

#### VlvL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Opening and closing the valve

This area shows you the default operating state for the valve. The following states can be shown and executed here:

- "Open"
- "Close"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

#### (3) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (6) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "External error"
- "End position error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced open"
- "Forced close"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (11) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the valve would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (12) Status display of the valve

The current status of the valve is graphically displayed here.

You can find more information about this in section VlvL block icon (Page 1725)

### (13) Neutral position of the valve

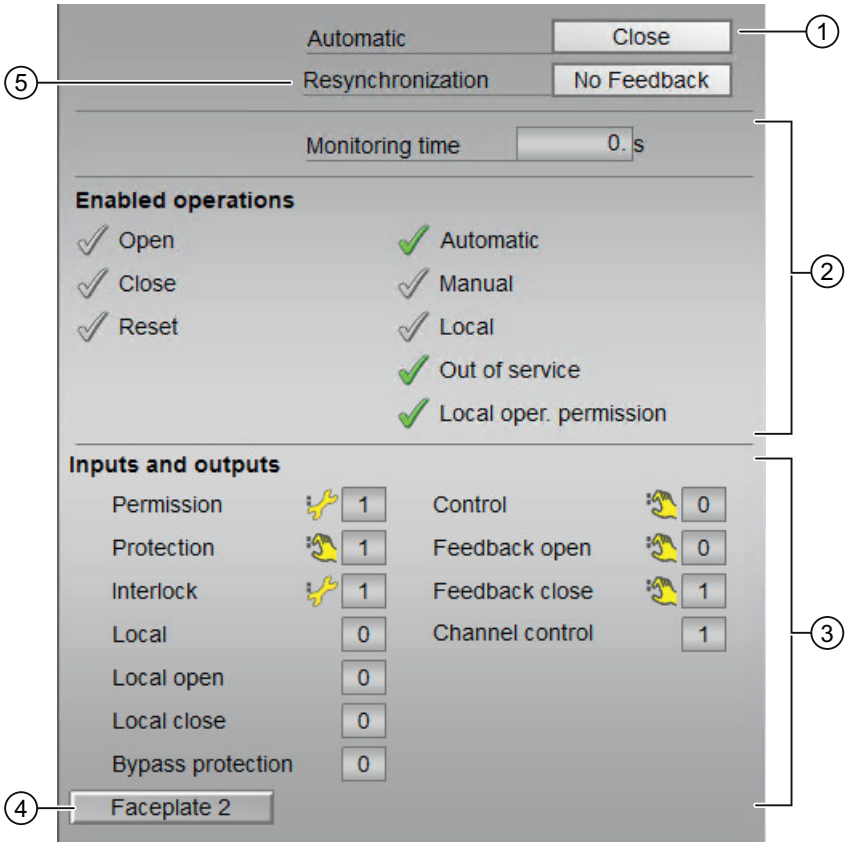
Display the neutral position for the valve:

- If the neutral position of the valve is "Closed" (`SafePos` = 0), , a gray valve is shown.
- If the neutral position of the valve is "Open" (`SafePos` = 1), a green valve is shown.

### (14) Mini preview for Resynchronization

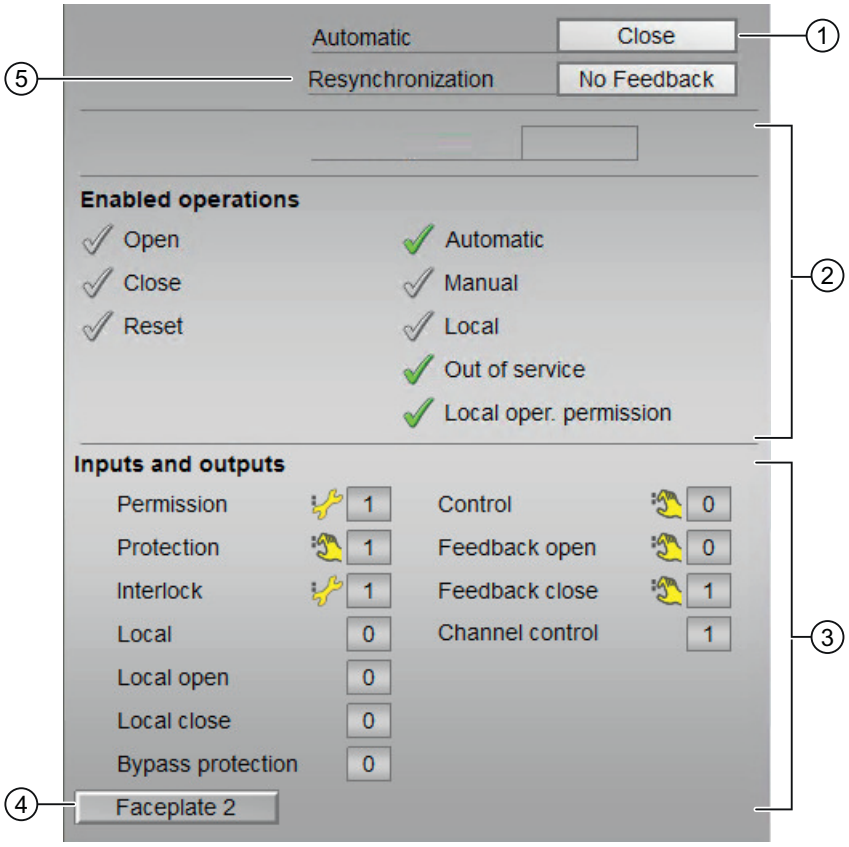
Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:



- Open
- Close
- No Cmd

**Note**



Mini preview for resync is visible only if resynchronization command is different to control output value.

### 8.10.8.3 VlvL preview

**Preview of VlvL**

Display of the current monitoring time is visible.

Display of the current monitoring time is not visible.

### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `OpenAut`
- `CloseAut`

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Open": You can open the valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Close": You can close the valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the valve if interlocks or errors occur.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).
- "Monitoring time": Display of the remaining monitoring time.

### (3) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission":
  This display is only visible when the corresponding block input is connected.
  - 0 = Valve activation not enabled on OS
  - 1 = Enable for "opening"/"closing" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permit neutral pos" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = prevents stop command to the motor
  - 1 = prevents the control in safe position direction

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection":
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Local open": 1 = Opening the valve in "local mode"
- "Local close": 1 = Closing the valve in "local mode"
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Control": Display for valve control:
  - 0 = Valve is closing
  - 1 = Valve is opening
- "Feedback open": 1 = Valve is open

- "Feedback close": 1 = Valve is closed
- "Channel Control": Control signal of the output channel block

### (4) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

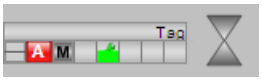
For more information, see section Opening additional faceplates (Page 234).

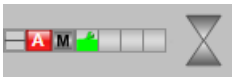
### (5) Resynchronization

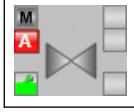
Displays the Resynchronization state and Resynchronization Signal status based on feedback value.

## 8.10.8.4 VlvL block icon

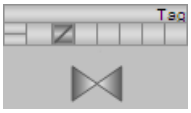
### Block icons for VlvL







A variety of block icons are available with the following functions:



- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Forcing states
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Valve status display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Non-rotating block icon |
|  | 4 | Non-rotating block icon |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | 9 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 10 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Valve status display

The following valve states are shown here:

| Icon | Meaning |
|---|---|
|  | Valve open |
|  | Valve closed |
|  | Error at valve |
|  | Valve is opening |
|  | Valve is closing |
|  | Valve closed |
|  | Valve is closing |
|  | "No Cmd" state Symbol |

# 8.11 VlvS - Valve (small)

## 8.11.1 Description of VlvS

### Object name (type + number) and family

Type + number: FB 1911

Family: Drives

### Area of application for VlvS

The block is used for the following applications:

- Controlling a valve in two positions ("open"/"closed") with adjustable neutral position

**Note**

This block is also available as a large block. A comparison of the VlvL and VlvS blocks is available in the section: VlvL compared to VlvS (Page 1372)

### How it works

The valve is opened or closed by a control signal. The signal 0 corresponds to the de-energized state (neutral position) of the valve.

The control is monitored by the "open"/"close" (feedback) signals. Missing feedback can be derived from the control in the block.

Various inputs are available for control purposes. The next sections provide more detailed information on configuration, operating principles, visualization and operation.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section VlvS I/Os (Page 1739).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value = 1; ManAct.Value = 0` |
| 6 | `LocalAct.Value` |
| 7 | `LockAct.Value` |
| 8 | "Open"/"Closed" command (1 = "Open") |
| 9 | `FbkOpenOut.Value` |
| 10 | `FbkCloseOut.Value` |
| 11 | Feedback error without control change |
| 12 | Feedback error due to control change |
| 13 | `BypProt` |
| 14 | Invalid signal status |
| 15 | Not used |
| 16 | 1 = `Intlock` is active |
| 17 - 21 | Not used |
| 22 | Automatic preview (1 = "Open") |
| 23 | Not used |
| 24 | `SafePos` |
| 25 - 27 | Not used |
| 28 | For the Error status display in the Closed valve |
| 29 | For the Error status display in the Opened valve |
| 30 | External error generated by FaultExt or external control system fault CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 31 | 1 = Input parameter `CtrlChnST` is interconnected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | Not used |
| 2 | Display for interlocks in block icon |
| 3 - 15 | Not used |
| 16 | 1 = Input parameter `FbkClose` is interconnected |
| 17 | 1 = Input parameter `FbkOpen` is interconnected |
| 18 | Reset request in automatic |

| Status bit | Parameter |
|---|---|
| 19 | 1 = No impact of input signals on "local mode" when `LocalSetting` = 0, `LocalSetting` = 2 and OOS mode. |
| 20 | 1 = Valve open |
| 21 | 1 = Valve closed |
| 22 | 1 = Valve opens |
| 23 | 1 = Valve closes |
| 24 - 29 | Not used |
| 30 | Bypass information for display in block icon |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Not used |
| 8 | "Interlock" button is enabled |
| 9 - 11 | Not used |
| 12 | Hidden bypass signal in interlock |
| 13 | Not used |
| 14 | `Feature2.Bit2`: Separate bypass signal |
| 15 - 25 | Not used |
| 26 | Show automatic preview in the standard view |
| 27 | Not used |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | Not used |
| 31 | Internal error |

### See also

VlvS modes (Page 1731)
VlvS functions (Page 1732)
VlvS error handling (Page 1736)
VlvS reporting (Page 1738)
VlvS block diagram (Page 1745)

## 8.11.2 VlvS modes

### VlvS operating modes

The block supports all standard modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

**Note**

**"Local mode" for the block VlvS**

In contrast to the "Large" blocks, it is only possible to perform settings in this block `LocalSetting` with 0, 2 and 5.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Valve actions you can control in "automatic mode":

- "Open" (`OpenAut` = 1)
- "Close" (`CloseAut` = 1)

**Note**

**Information about the "Small" block**

This "Small" block works with pushbutton operation. The automatic commands are therefore latching, in other words, `OpenAut` and `CloseAut` can be reset to 0 after the control is changed. In "manual" and "local" modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Valve actions you can control in "manual mode":

- "Open" (`OpenMan` = 1)
- "Close" (`CloseMan` = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkOpenOut.ST | 16#80 | 16#60 |
| FbkCloseOut.ST | 16#80 | 16#60 |
| Opened.ST | 16#80 | 16#60 |
| Closed.ST | 16#80 | 16#60 |
| Opening.ST | 16#80 | 16#60 |
| Closing.ST | 16#80 | 16#60 |

## 8.11.3 VlvS functions

### Functions of VlvS

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can open the valve |
| 5 | 1 = Operator can close the valve |
| 6 | 1 = Operator can reset the valve |
| 7 | 1 = Operator can define the monitoring time for startup |
| 8 | Not used |
| 9 | 1 = Operator can activate the monitoring time function (Bit 7) |
| 10 | 1 = Operator can switch to Simulation |
| 11 | 1 = Operator can activate the Release for maintenance function |
| 12 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Button labels

This block provides the standard function Labeling of buttons and text (Page 235)

Instance-specific text can be configured for the following parameters:

- `OpenMan`
- `CloseMan`

## Interlocks

This block provides the following interlocks:

- Interlock without reset ("Interlock")

Refer to the Interlocks (Page 107) section for more on this.

## Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

## Resetting the block in case of interlocks

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See VlvS error handling (Page 1736)

### Group error

This block provides the standard function Outputting group errors (Page 130)

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `MonDynErr`
- `MonStaErr`
- `FaultExt`

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54). The neutral position (de-energized state) is set using the `SafePos` parameter.

- `SafePos = 0` means that at `Ctrl = 0` the valve drive closes and at `Ctrl = 1` it opens (de-energized state is "closed")
- `SafePos = 1` means that at `Ctrl = 0` the valve drive opens and at `Ctrl = 1` it closes (de-energized state is "open")

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status ST_Worst for the block is formed from the following parameters:

- `FbkOpenOut.ST`
- `FbkCloseOut.ST`
- `LocalLi.ST`
- `CtrlChn.ST`
- `OpenAut.ST` (only if `Feature2.Bit10` = 1)
- `CloseAut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- `OpenAut.ST`
- `CloseAut.ST`

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104). Startup characteristics are monitored by setting parameter`MonTiDynamic`. The parameter `MonTiStatic` monitors compliance with the position.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 25 | Suppression of all messages (Page 185) |

| Bit | Function |
|---|---|
| 27 | Interlock display with LocalSetting 2 or 5 (Page 189) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS  (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 8.11.4 VlvS error handling

### Error handling of VlvS

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error

- Invalid input signals
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not within the valid limit of 0, 2 or 5 |
| 42 | `LocalSetting` = 0 and `LocalLi` = 1 |
| 51 | `AutModLi` = 1 and `ManModLi` = 1<br>`OpenAut` = 1 and `CloseAut` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 or 5 and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid input signals

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid input signals, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| Operating mode | Invalid input signals | Control reaction with `Feature2.Bit3` =1 |
|---|---|---|
| "Automatic mode" | `OpenAut` = 1 and `CloseAut` = 1 | Valve is set to its neutral position. |
| "Manual mode" | `OpenMan` = 1 and `CloseMan` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.11.5 VlvS reporting

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId1`, SIG 2).

### Instance-specific messages

You have the option to use two instance-specific messages for this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 3 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External message 2 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance MsgEvId1

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 - 10 | Reserved |

The associated values 4 ... 5 are allocated to the parameters ExtVa104 ... ExtVa105 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

## 8.11.6 VlvS I/Os

I/Os of VlvS

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1= "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp | 1 = "Automatic mode" via operator (controlled by ModLiOp = 1) | BOOL | 0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BypProt | 1 = Bypassing interlock is active in "local mode" and in simulation | BOOL | 0 |
| CloseAut* | 1 = Select Close valve in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseMan* | 1 = Select Close valve in "manual mode" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlChnST | Signal status of output channel Ctrl<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvID1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvID1) | ANY | |
| FaultExt | 1 = External error<br>Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpen | 1 = Valve open feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FbkClose | 1 = Valve closed feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1732) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1732) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Intlock | 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared<br>1 = Interlock not activated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Interlock without reset (interlock, Intlock parameter) is active | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = Manual mode via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1 = Manual mode via: OS operator (controlled via ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Monitor | 1 = Feedback monitoring | BOOL | 1 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors | BOOL | 1 |
| MonTiDynamic* | Monitoring time after operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpenAut* | 1 = Select Open valve in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenMan* | 1 = Select Open valve in "manual mode" | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1732) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SafePos | Neutral position for valve:<br>1= Open<br>0 = Closed | BOOL | 0 |
| SimOn | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| Ctrl | Control output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Closed | 1 = Valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Closing | 1 = Valve is closing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see VlvS error handling (Page 1736) | INT | -1 |
| FaultExtOut | FaultExt at output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkCloseOut | Valve closed feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpenOut | Valve open feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LockAct | 1 = Interlock is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynErr | 1 = Feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opened | 1 = Valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opening | 1 = Valve is opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1728) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1728) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1728) | DWORD | 16#00000000 |

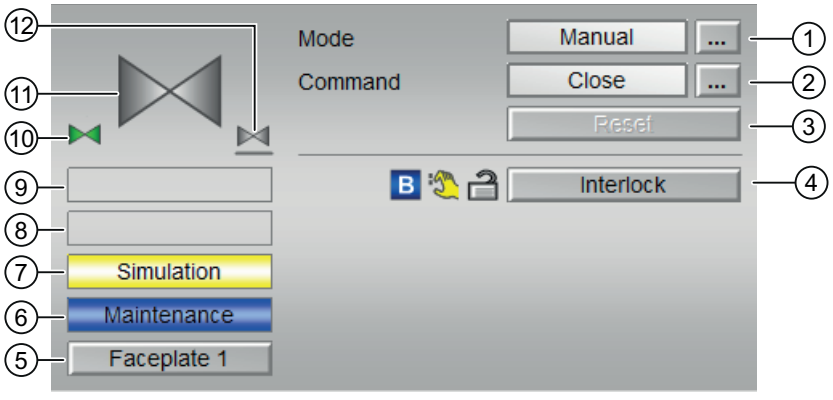
## 8.11.8 Operator control and monitoring

### 8.11.8.1 VlvS views

#### Views of the VlvS block



The block VlvS provides the following views:

- VlvS standard view (Page 1746)
- Alarm view (Page 336)
- Trend view (Page 341)
- Parameter view for motors and valves (Page 320)
- VlvS preview (Page 1749)
- Memo view (Page 338)
- Batch view (Page 336)
- VlvS block icon (Page 1751)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 8.11.8.2 VlvS standard view

#### VlvS standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)

- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Opening and closing the valve

This area shows you the default operating state for the valve. The following states can be shown and executed here:

- "Open"
- "Close"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocks (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (6) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in the section Simulating signals (Page 64).

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "External error"
- "End position error"
- "Control error"
- "Internal error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer: Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (10) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the valve would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (11) Status display of the valve

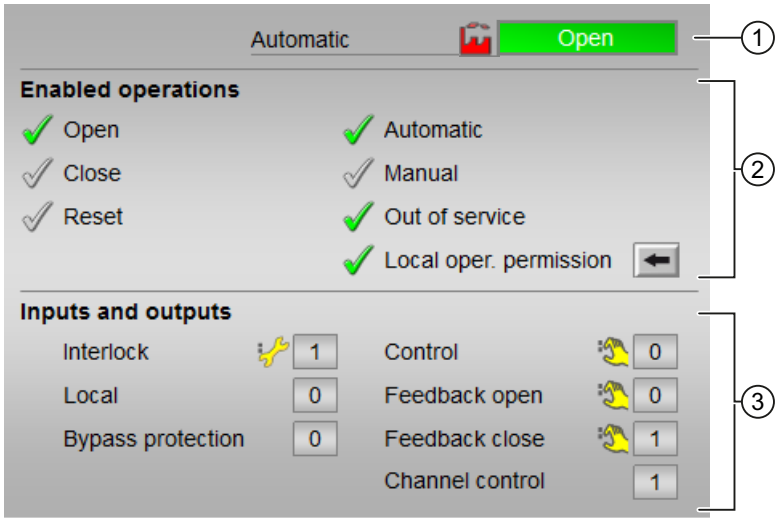
The current status of the valve is graphically displayed here.

- Green: Valve is open
- Gray: Valve is closed
- Red: Fault at valve

You can find more information about this in section VlvS block icon (Page 1751).

### (12) Neutral position of the valve

Display the neutral position for the valve:



- If the neutral position of the valve is "Closed" (`SafePos` = 0), , a gray valve is shown.
- If the neutral position of the valve is "Open" (`SafePos` = 1), a green valve is shown.

### See also

Displaying auxiliary values (Page 239)

## 8.11.8.3 VlvS preview

### Preview of VlvS

### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `OpenAut`
- `CloseAut`

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Open": You can open the valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Close": You can close the valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the valve if interlocks or errors occur.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. For more information, see section Labeling of buttons and text (Page 235).

### (3) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Interlock":
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Control": Display for valve control:
  - 0 = Valve is closing
  - 1 = Valve is opening
- "Feedback open": 1 = Valve is open
- "Feedback close": 1 = Valve is closed
- "Channel Control": Control signal of the output channel block

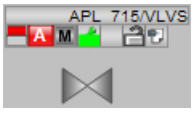
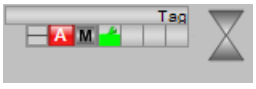
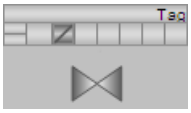
## 8.11.8.4 VlvS block icon

### Block icons for VlvS







A variety of block icons are available with the following functions:

- Process tag type
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Valve status display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Non-rotating block icon |
|  | 4 | Non-rotating block icon |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

### Valve status display

The following valve states are shown here:

| Symbol | Meaning |
|---|---|
|  | Valve open |
|  | Valve closed |
|  | Error at valve |
|  | Valve is opening |
|  | Valve is closing |
|  | Valve closed |
|  | Valve is closing |

# 8.12 VlvMotL - Motor valve

## 8.12.1 Description of VlvMotL

### Object name (type + number) and family

Type + number: FB 1900

Family: Drives

### Area of application for VlvMotL

The block is used for the following applications:

- Motor valve control

### How it works

Various operating modes are available for controlling the motor-driven valve. This functionality allows you to set specific valve states. All changes of modes or states and faults occurring in this context are monitored, visualized in the faceplate and reported to the operator. Operators with suitable permissions can use the block icon and the faceplate to view the current states of the motor-driven valve and to operate it.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the VlvMotL block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Motor valve (ValveMotor) (Page 2867)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

After a startup without control (`Open`, `Close` = 0)", no monitoring of the feedback signals `FbkOpen` and `FbkClose` takes place during the `V_MonTiStatic` time. Changes to `FbkOpen` and `FbkClose` are applied. This means that the feedback is monitored again, also in stop state.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section VlvMotL I/Os (Page 1778).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon<br>With `Feature2.Bit16` = 1, a closed padlock is displayed if "Interlock Open" or "Interlock Close" is active. |
| 8 | `Open.Value` |
| 9 | Motor is stopped |
| 10 | `Close.Value` |
| 11 | Torque shutdown enabled (`TorqOpen` or `TorqClose` = 1)<br>When the seal valve function is enabled, the torque shutoff is only active if the `TorqClose` signal is enabled before the valve feedback. |
| 12 | `WarnAct.Value` or<br>`IdleTime` active |
| 13 | Feedback error without control change |
| 14 | Feedback error due to control change |
| 15 | `Mode Switch Fail` |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | `Trip.Value` |
| 20 | Display „Forced open“ |
| 21 | Display „Forced stop“ |
| 22 | Display „Forced close“ |
| 23 | "Interlock" button is enabled |
| 24 | 0 = Display neutral position "Closed" Display "Closed" for representation of neutral position in `SafePos` = 0 or 2<br>1 = Display "Opened" for representation of neutral position in `SafePos` = 1 or 2 |
| 25 | 1 = Display "Intermediate" for representation of neutral position in `SafePos` = 2 |
| 26 | Bypass information for display in block icon |
| 27 | Bypass enabled (`BypProt` = 1) and `Local.Act` = 1 or `SimOn` = 1 |
| 28 | Invalid signal status |
| 29 | 0 = closed<br>1 = open |
| 30 | "Permission" button is enabled |
| 31 | "Protection" button is enabled |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `AV_AH_Act.Value` |
| 2 | `AV_WH_Act.Value` |
| 3 | `AV_TH_Act.Value` |
| 4 | `AV_TL_Act.Value` |
| 5 | `AV_WL_Act.Value` |
| 6 | `AV_AL_Act.Value` |
| 7 | `AV_AH_En` OR `Feature.Bit23` |
| 8 | `AV_WH_En` OR `Feature.Bit23` |
| 9 | `AV_TH_En` OR `Feature.Bit23` |
| 10 | `AV_TL_En` OR `Feature.Bit23` |
| 11 | `AV_WL_En` OR `Feature.Bit23` |
| 12 | `AV_AL_En` OR `Feature.Bit23` |
| 13 | `AV_AH_MsgEn` |
| 14 | `AV_WH_MsgEn` |
| 15 | `AV_TH_MsgEn` |
| 16 | `AV_TL_MsgEn` |
| 17 | `AV_WL_MsgEn` |
| 18 | `AV_AL_MsgEn` |
| 19 | 1 = No impact of input signals on "local mode" with `LocalSetting` = 0, `LocalSetting` = 2, `LocalSetting` = 4 and OOS mode. |
| 20 | 1 = Valve closes |
| 21 | 1 = Valve closed |
| 22 | 1 = Valve stopped |
| 23 | 1 = Valve opens |
| 24 | 1 = Valve open |
| 25 | For the Error status display in the Closed valve |
| 26 | For the Error status display in the Opened valve |
| 27 | Automatic preview for "opening" |
| 28 | Automatic preview for "closing" |
| 29 | Automatic preview for "stopping" |
| 30 | Display for interlocks in block icon |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | `M_MonStaErr.Value` |
| 1 | `M_MonDynErr.Value` |
| 2 | `V_MonStaErr.Value` |
| 3 | `V_MonDynErr.Value` |

| Status bit | Parameter |
|---|---|
| 4 | `M_MonStopErr.Value` |
| 5 | 1 = "Permit neutral pos." or " Permission stop" button is enabled |
| 6 | 1 = Permission SafePos / Stop is active |
| 7 | Not used |
| 8 | Reset request in automatic |
| 9 | External error generated by FaultExt or external control system fault from CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 10 | Hidden bypass signal in Permission SafePos / Stop |
| 11 | Motor protection display (`Trip.Status` ≠ 16#FF) |
| 12 | 1 = Input parameter `FbkClose` is connected |
| 13 | 1 = Input parameter `FbkClosing` is connected |
| 14 | 1 = Input parameter FbkOpen is connected |
| 15 | 1 = Input parameter `FbkOpening` is connected |
| 16 | 1 = Input parameter `TorOpen` is connected |
| 17 | 1 = Input parameter `TorClose` is connected |
| 18 | `SimLiOp.Value` |
| 19 | 1 = Enable for "rapid stop"(`Feature` Bit Enabling rapid stop via faceplate (Page 179)) |
| 20 | 1 = Input parameter `OpenChnST` is interconnected |
| 21 | 1 = Input parameter `CloseChnST` is interconnected |
| 22 | Not used |
| 23 | Command for "rapid stop" |
| 24 | "Open"/"Stop" command |
| 25 | "Close"/"Stop" command |
| 26 | Show automatic preview in the standard view |
| 27 | Internal error |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | Auxiliary value 1 visible |
| 31 | Auxiliary value 2 visible |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal `8` of the message block connected via `EventTsIn` |
| 8 | `AV` not connected |

| Status bit | Parameter |
|---|---|
| 9 | Delay of the `AV_AH_Lim` message |
| 10 | Delay of the `AV_WH_Lim` message |
| 11 | Delay of the `AV_TH_Lim` message |
| 12 | Delay of the `AV_TL_Lim` message |
| 13 | Delay of the `AV_WL_Lim` message |
| 14 | Delay of the `AV_AL_Lim` message |
| 15 | Collection of message delays |
| 16 | "Permission Open" button is enabled |
| 17 | "Permission Close" button is enabled |
| 18 | "Interlock Open" button is enabled |
| 19 | "Interlock Close" button is enabled |
| 20 | "Protection Open" button is enabled |
| 21 | "Protection Close" button is enabled |
| 22 | 1 = "Permission Close" is active |
| 23 | Hidden bypass signal in Permit |
| 24 | Hidden bypass signal in interlock |
| 25 | Hidden bypass signal in Protect |
| 26 | `Feature2.Bit2`: Separate bypass signal |
| 27 | 1 = "Interlock Close" is active |
| 28 | 1 = "Protection Close" is active |
| 29 | Current motor monitoring time is visible |
| 30 | Current valve monitoring time is visible |
| 31 | Separate monitoring of shutdown of the motor (`Feature.Bit13`) |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 | 1 = Valve still closes (`Status2.Bit20`) but the motor is not running |
| 9 | 1 = Valve still opens (`Status2.Bit23`) but the motor is not running |
| 10 | Hidden bypass signal in "Permission Close" |
| 11 | Hidden bypass signal in "Interlock Close" |
| 12 | Hidden bypass signal in "Protection Close" |
| 13 | `Feature2.Bit16` Separate interlock for each direction, position, or speed (Page 180) |
| 14 | 1= Suppressed messages |
| 15 | Not used |
| 16 - 31 | Effective signal 1...16 of the message block connected via `EventTs2In` |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 | Resynchronization: Valve Open |
| 1 | Resynchronization: Valve Close |
| 2 | Resynchronization: Valve Stop |
| 3 | Resynchronization: Motor Opening |
| 4 | Resynchronization: Motor Closing |
| 5 | Resynchronization: Motor Stopped |
| 6 | Resynchronization: Display preview |
| 7 | Resynchronization: Display small preview symbol in standard view |
| 8 | Resynchronization preview view for Valve/Motor open |
| 9 | Resynchronization preview view for Valve/Motor close |
| 10 | Resynchronization preview view for Valve/Motor Stop |
| 11 - 31 | Not used |

## 8.12.2 VlvMotL modes

### VlvMotL operating modes

The block supports all standard modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

Motor valve actions you can control in "local mode"

- "Open" (`OpenLocal` = 1)
- "Close" (`CloseLocal` = 1)
- "Stop" (`StopLocal` = 1).

A block operated in "local mode" is controlled either by "local" signals or by feedback signals (input parameters `FbkOpen` and `FbkClose`; if no position can be assigned, the last valid position is accepted). Configuration takes place via the input parameter `LocalSetting`.

`LocalSetting` =2,4: The motor controls and the valve position are tracked to the feedbacks.

With `Feature Bit12` =0 (motor feedback available)

```
Open = FbkOpening
```

```
Close = FbkClosing
```

```
StopCtrl = NOT FbkOpening AND NOT FbkClosing
```

When both feedbacks are switched off, the motor controls will be tracked to stop.

When both feedbacks are active (not plausible), the motor controls will be hold and the static monitoring counter starts.

When valve is in end position the motor feedbacks are monitored to stop.

The valve position is tracked to the valve feedbacks.

Valve position open = `FbkOpen`

Valve position close = `FbkClose`

Valve position intermediate = `NOT FbkClose AND NOT FbkOpen`

The valve feedbacks are monitored to not plausibility (`FbkOpen AND FbkClose`) and of reaching the end position after starting the motor.

When a valve feedback is not available (`NoFbkOpen, NoFbkClose`) the reaching of end position is adapted by a time delay of V_MonTiDynamic.

With `Feature Bit12` =1 (no motor feedback available)

The motor controls are always switched to stop.

```
Open = false
```

```
Close = false
```

```
StopCtrl = true
```

The valve position is tracked to the valve feedbacks.

Valve position open = `FbkOpen`

Valve position close = `FbkClose`

Valve position intermediate = `NOT FbkClose AND NOT FbkOpen`

The valve feedbacks are monitored to not plausibility (`FbkOpen AND FbkClose`).

If only one feedback is available it is always plausible.

| NoFbkOpen =0 | NoFbkClose =0 |
|---|---|
| Valve position open = FbkOpen<br>Valve position close = NOT FbkOpen<br>If FbkOpen becomes inactive after a delay of V_MonTiDynamic the valve position is closed. | Valve position open = NOT FbkClose<br>Valve position close = FbkClose If FbkClose becomes inactive after a delay of V_MonTiDynamic the valve position is opend. |

It is not possible to switch in intermediate position.

When all feedbacks are not available the valve position will be hold.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

Motor valve actions you can control in "automatic mode":

- "Open" (OpenAut = 1)
- "Close" (CloseAut = 1)
- "Stop" (StopAut = 1)

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

Motor valve actions you can control in "manual mode":

- "Open" (OpenMan = 1)
- "Close" (CloseMan = 1)
- "Stop" (StopMan = 1)

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with Feature2.Bit1 =0 and Feature2.Bit1 =1 is as shown below:

| Output Parameters | Feature2.Bit1 =0 | Feature2.Bit1 =1 |
|---|---|---|
| FbkOpenOut.ST | 16#80 | 16#60 |
| FbkCloseOut.ST | 16#80 | 16#60 |
| FbkOpngOut.ST | 16#80 | 16#60 |
| FbkClsgOut.ST | 16#80 | 16#60 |
| Opened.ST | 16#80 | 16#60 |
| Closed.ST | 16#80 | 16#60 |

| Output Parameters | `Feature2.Bit1` =0 | `Feature2.Bit1` =1 |
|---|---|---|
| Opening.ST | 16#80 | 16#60 |
| Closing.ST | 16#80 | 16#60 |
| Stop.ST | 16#80 | 16#60 |
| AV_Out.ST | 16#80 | 16#60 |

**Note**

In "Out of service" mode feedbacks signal status will be set to simulation after moving the valve to the safe position when `Feature2.bit1=1`.

## 8.12.3 VlvMotL functions

### Functions of VlvMotL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can open the valve |

| Bit | Function |
|---|---|
| 6 | 1 = Operator can close the valve |
| 7 | 1 = Operator can reset the valve |
| 8 | 1 = Operator can define the monitoring time for the valve startup |
| 9 | 1 = Operator can define the monitoring time for the end position of the valve |
| 10 | 1 = Operator can enable the monitoring time function of the valve (Bit 8 - 9) |
| 11 | 1 = Operator can define or change the monitoring time for startup |
| 12 | 1 = Operator can define the monitoring time for the motor status |
| 13 | 1 = Operator can enable the monitoring time function of the motor (Bit 8 - 9) |
| 14 | 1 = Operator can activate the Simulation function |
| 15 | 1 = Operator can activate the Release for maintenance function |
| 16 | 1 = Operator can change the limit (`AV`) for high alarm |
| 17 | 1 = Operator can change the limit (`AV`) for high warning |
| 18 | 1 = Operator can change the limit (`AV`) for high tolerance |
| 19 | 1 = Operator can change the limit (`AV`) for hysteresis |
| 20 | 1 = Operator can change the limit (`AV`) for low alarm |
| 21 | 1 = Operator can change the limit (`AV`) for low warning |
| 22 | 1 = Operator can change the limit (`AV`) for low tolerance |
| 23 | 1 = Operator can activate / deactivate messages via `AV_AH_MsgEn` |
| 24 | 1 = Operator can activate / deactivate messages via `AV_WH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `AV_TH_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `AV_TL_MsgEn` |
| 27 | 1 = Operator can activate / deactivate messages via `AV_WL_MsgEn` |
| 28 | 1 = Operator can activate / deactivate messages via `AV_AL_MsgEn` |
| 29 | 1 = Operator can change the simulation value `SimAV` |
| 30 | 1 = Operator can define the monitoring time for stopping |
| 31 | 1 = Operator can execute the rapid stop |

The block has the following permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Restart lock after changing direction of rotation or switching off the motor

Use the input parameter `IdleTime` to enter a restart lock for changing the direction of rotation or restarting the motor. When the "Stop" command is given, the motor goes immediately into "Stop" mode, and `IdleTime` starts after the feedback (`FbkOpening` and `FbkClosing` = 0) is given. The motor cannot be started again (open or close) until the `IdleTime` has expired.

### Limit monitoring of an additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104). It is performed via the input parameter `AV_Hyst`.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Interlocks

This block provides the following interlocks:

- `Feature2.Bit16` = 0
  - Activation enable ("Permission")
  - Interlock without reset ("Interlock")
  - Interlock with reset ("Protection")
  - Permission for safe position (“Permit neutral pos.” or “Permission stop”)
- `Feature2.Bit16` = 1
  - Activation enable Open ("Permission Open")
  - Activation enable Close ("Permission Close")
  - Interlock open without reset ("Interlock Open")
  - Interlock close without reset ("Interlock Close")
  - Interlock open with reset ("Protection Open")
  - Interlock close with reset ("Protection Close")

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

### Rapid stop for motors

This block provides the standard function Rapid stop for motors (Page 115).

### Torque monitoring

The block provides torque monitoring.

The signals of the torque monitoring switches are interconnected to input parameters `TorqOpen` and `TorqClose` for opening and closing the motor valve.

An active torque shutdown is displayed in the parameter either by the value 0 or by the signal status 16#00 or 16#28.

If the torque shutdown is active, the motor is stopped. You have the option of moving the valve in the opposite direction.

If, for example, the torque shutdown is active when the valve opens, you can still close the valve.

Active torque shutoff appears in the standard view of the display area for block states.

When the "Seal valve" function is enabled via `Feature.Bit8`, the torque shutoff for the closing `TorqClose` is also evaluated (see section Sealing the valve).

### Reset of motor control after valve end position has been reached

After a motor control in the direction of one of the end positions, open or closed, the valve is opened or closed accordingly. After the end position is reached, the block is notified of this via the `FbkOpen` or `FbkClose` input. The `Feature` bit Motor stop in end position depends only on the corresponding feedback signal (Page 199) can affect the dependencies of the feedback signals to downscale the motor in the end position.

**Note**

If you deactivate one of the valve feedback signals via the inputs `NoFbkOpen, NoFbkClose,` the corresponding valve feedback signal `FbkOpen`, `FbkClose` for the motor switch off in the end position is no longer evaluated. After the valve monitoring time `V_MonTiDynamic` has expired, the corresponding output of the valve feedback signal `FbkOpenOut`, `FbkCloseOut` is set and the associated motor control `Open`, `Close` is reset again. The motor feedback signals are also monitored when the valve feedback signals are switched off.

In the case of missing valve feedback signals, the corresponding signals of the torque monitoring with the inputs `TorqOpen` or `TorqClose` must be used.

### Sealing the valve

The function is activated via `Feature.Bit8` Sealing the valve (Page 187). The seal valve function combines the query of the end position CLOSED via the input parameter `FbkClose` with the limit violation of the configured torque via the input parameter `TorqClose`. This ensures that the valve is completely sealed.

The valve is only considered completely sealed when the feedback for the end position CLOSE has been received (0->1) and the torque cutoff for Closed is enabled. The torque shutoff should

not come before the feedback in this case. The `FbkCloseOut` output shows whether the valve is sealed:

`FbkCloseOut := FbkClose.Value has been received (0->1)`

And "Torque shutoff closed is enabled"

And "Torque shutoff closed is enabled" did not come before `FbkClose` (0->1)

"Torque shutoff closed is enabled" means that `TorqClose = 0` or the signal status is `16#00` or `16#28`.

When "Torque shutoff closed is enabled" comes before the end position feedback closed, this is displayed in the faceplate in the standard view and the motor stops. Opening the valve is still possible.

**Note**

The command text for Close in the standard view and preview can be changed to Seal in the CFC at the `CloseMan` parameter in Text 1. See Section Labeling of buttons and text (Page 235)

### Disabling interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See VlvMotL error handling (Page 1774)

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `Trip`
- `V_MonDynErr`
- `V_MonStaErr`
- `M_MonDynErr`
- `M_MonStaErr`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Control loop is open (CascaCut)

The output CascaCut indicates whether the control loop within this block is open. In the open control loop, the master controller must be set to tracking mode to avoid until windup behavior. If you use this block in a cascade structure, then connect the output CascaCut to the input MV_TrkOn of the master controller.

CascaCut is active in the following cases:

- Block is not in automatic mode
- Force function is active
- Motor protection is active
- Interlock is active
- Monitoring error is active

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status for the block is formed from the following parameters:

- FbkClsgOut.ST
- FbkOpngOut.ST
- FbkOpenOut.ST
- FbkCloseOut.ST
- LocalLi.ST
- OpenLocal.ST
- StopLocal.ST
- TorqClose.ST
- CloseLocal.ST
- Trip.ST
- TorqOpen.ST
- AV_Out.ST
- OpenChn.ST
- CloseChn.ST

- `OpenAut.ST` (only if `Feature2.Bit10` = 1)
- `CloseAut.ST` (only if `Feature2.Bit10` = 1)
- `StopAut.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- `OpenAut.ST`
- `CloseAut.ST`
- `StopAut.ST`

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).
Inputs `OpenForce` and `CloseForce` and `StopForce`force the block to open, close or stop.

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

The `FbkOpen` and `FbkClose` feedback is monitored for the valve; the `FbKOpening` and `FbkClosing` feedback is monitored for the motor.

The monitoring of the feedback for the valve will not be active if it was stopped during opening or closing.

#### Monitoring valve feedback

The monitoring of valve feedback is set using the parameter `V_Monitor`.

Startup characteristics are monitored by setting parameter `V_MonTiDynamic`. The parameter `V_MonTiStatic` monitors compliance with the position.

Feedback errors are displayed at the corresponding parameters `V_MonDynErr` and/or `V_MonStaErr`.

**Note**

After the motor valve stops in the intermediate position or end position or after a startup without control (`Open`, `Close` = 0)" or a stop after a monitoring error, no monitoring of the feedback signals `FbkOpen` and `FbkClose` takes place during the `V_MonTiStatic` time. Changes to `FbkOpen` and `FbkClose` are applied. This means that the feedback is monitored again, also in stop state.

**Note**

When the "Seal valve" function is enabled via `Feature.Bit8`, the torque shutoff for closing `TorqClose` is also evaluated (see section Sealing the valve (Page 187)).

**Monitoring the motor feedback**

The monitoring of motor feedback is set using the parameter M_Monitor.

Startup characteristics are monitored by setting parameterM_MonTiDynamic. The parameter M_MonTiStatic monitors compliance with the position.

Feedback errors are displayed at the corresponding parameters M_MonDynErr and/or M_MonStaErr.

## Disabling feedback

This block provides the standard function Disabling feedback for valves (Page 106). Feedback monitoring can be deactivated separately for each feedback with NoFbkOpen or NoFbkClose as required.

## Tracking the valve position after a motor stop or after a startup

Because of vibration or mass inertia after a motor stop the block tracks the valve position for the time V_MonTiStatic. During this time the static feedback monitoring is not active. The monitoring starts after the time V_MonTiStatic.

- Motor is stopped in end position open (FbkOpen =1, FbkClose =0):
  Open and intermediate position will be tracked.
  FbkOpen =1, FbkClose =0: valve goes to open position
  FbkOpen =0, FbkClose =0: valve goes to intermediate position
- Motor is stopped in intermediate position (FbkOpen =0, FbkClose =0):
  Open, Close and intermediate position can be tracked.
  FbkOpen =1, FbkClose =0: valve goes to open position
  FbkOpen =0, FbkClose =0: valve goes to intermediate position
  FbkOpen =0, FbkClose =1: valve goes to close position
- Motor is stopped in end position close (FbkOpen =0, FbkClose =1):
  Close and intermediate position can be tracked.
  FbkOpen =1, FbkClose =0: valve goes to open position
  FbkOpen =0, FbkClose =0: valve goes to intermediate position

Because of preparing the feedback signals after startup the block tracks the valve position for the time V_MonTiStatic.

- Open, Close and intermediate position can be tracked.
  FbkOpen =1, FbkClose =0: valve goes to open position
  FbkOpen =0, FbkClose =0: valve goes to intermediate position
  FbkOpen =0, FbkClose =1: valve goes to close position

**Note**

After resetting the block, in the case of interlocks or errors, the valve position will always be tracked, depending on FbkOpen and FbkClose.

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56).

You can generate warning signals when, for example, valves open. Warning signals can be generated in the following modes:

- Manual and automatic mode for motors, valves and dosers (Page 82) (Input parameter `WarnTiMan`)
- Manual and automatic mode for motors, valves and dosers (Page 82) (Input parameter `WarnTiAut`)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut`. If, for example, a valve opens, this is displayed at the output parameter with `WarnAct` = 1. The valve then opens after the set warning time has expired and `WarnAct` then returns to 0.

A corresponding warning is not output if the warning times (`WarnTiMan` or `WarnTiAut`) are specified with a smaller value than the `SampleTime` parameter.

**Note**

The warning is activated for each actuation that causes the motor to start, even if this means that the valve is moved to the neutral position

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Additional value (`SimAV`, `SimAV_Li`)

In the case of internal simulation with immediate tracking of feedback, it is possible to simulate a position between the open and closed state (`FbkOpenOut` = `FbkCloseOut` = 0) by means of a stop command.

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

### Output signal as a pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57). In addition to the static control outputs `Open` and `Close`, the block also has pulse outputs `P_Open`, `P_Close`, and `P_Stop`, which are dependent on the static control output.

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Disabling of limits

The block provides the standard function Limits disabled in faceplate (Page 206).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the controls are tracked as follow:

**Valve**

**NoFbkOpen =0, NoFbkClose =0:**

Plausible feedback positions are tracked as control position. In case of not plausible feedback positions the controls are not changed.

**NoFbkOpen =0, NoFbkClose =1:**

If FbkOpen is active, position open is controlled. Else position close is controlled. Stop position is not possible.

**NoFbkOpen =1, NoFbkClose = 0:**

If FbkClose is active, position close is controlled. Else position open is controlled. Stop position is not possible.

**NoFbkOpen =1, NoFbkClose =1:**

Control position is not changed.

**Motor**

**Motor feedbacks are present** Feature Bit 12 =0:

Open := FbkOpening AND NOT FbkClosing AND valve position is not open;

Close := FbkClosing AND NOT FbkOpening AND valve position is not close;

StopCtrl := NOT FbkOpening AND NOT FbkClosing;

In case if there are no plausible motor feedbacks (FbkOpening =1, FbkClosing =1) the motor goes to stop control.

**Motor feedbacks are not present** Feature Bit 12 =1:

The motor goes to stop control:

Open := false;

Close := false;

StopCtrl := true;

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 8 | Sealing the valve (Page 187) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 12 | Motor feedback is not available (Page 168) |
| 13 | Separate monitoring time for stopping the motor (Page 180) |
| 14 | Enabling rapid stop via faceplate (Page 179) |
| 15 | Motor stop in end position depends only on the corresponding feedback signal (Page 199) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In switching mode (Bit 4 = 1), control is selected with the static signals `OpenAut` and `CloseAut`. If the `OpenAut` and `CloseAut` inputs are not set, the motor is stopped. Control via `StopAut` is not needed. If the "Activate command reset for control" function (Bit 3 = 1) is activated, the inputs `OpenAut` and `CloseAut` are reset to 0 after evaluation in the block.

### Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 16 | Separate interlock for each direction, position, or speed (Page 180) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- `OpenMan`
- `CloseMan`

- StopMan
- RapidStp

### Outputs for status of drive

The block has the following outputs to indicate the status of the drives. In the CFC plan, this information can be further interconnected:

| | |
|---|---|
| Closed =1 | Motor is stopped:<br>Open, Close, FbkClsgOut, FbkOpngOut =0<br>Valve is in position closed: FbkCloseOut =1 |
| Opened =1 | Motor is stopped:<br>Open, Close, FbkClsgOut, FbkOpngOut =0<br>Valve is in position opened: FbkOpenOut =1 |
| Closing =1 | Motor drives in direction of position closed:<br>Close, FbkClsgOut =1 |
| Opening =1 | Motor drives in direction of position opened:<br>Open, FbkOpngOut =1 |
| Stop =1 | Motor is stopped and position is reached:<br>Open, Close, FbkClsgOut, FbkOpngOut =0 |

**Note**

The outputs for status of drive are only can be active if there is no monitoring error:

MonDynErr =0, MonStaErr =0

## 8.12.4 VlvMotL error handling

### Error handling of VlvMotL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Invalid or not plausible input commands
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value for the `LocalSetting` I/O is not within the approved limit of 0 to 4. |
| 42 | `LocalSetting` = 0 or `LocalSetting` = 3 or `LocalSetting` = 4 and `LocalLi` = 1 |
| 51 | `OpenLocal` = 1 and `StopLocal` = 1<br>`CloseLocal` = 1 and `StopLocal` = 1<br>`OpenLocal` = 1 and `CloseLocal` = 1<br>`OpenAut` = 1 and `StopAut` = 1<br>`CloseAut` = 1 and `StopAut` = 1<br>`OpenAut` = 1 and `CloseAut` = 1<br>`AutModLi` = 1 and `ManModLi` = 1<br>`OpenForce` = 1 and `StopForce` = 1<br>`CloseForce` = 1 and `StopForce` = 1<br>`OpenForce` = 1 and `CloseForce` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 or 4 and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be kept or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| **Operating mode** | **Invalid or not plausible input commands** | **Control reaction with `Feature2.Bit3` = 1** |
|---|---|---|
| Local: `Localsetting` = 1 or `Localsetting` = 3 | Pushbutton operation for local mode (`Feature2.Bit4` = 0):<br>`OpenLocal` = 1 and `CloseLocal` = 1 or<br>`OpenLocal` = 1 and `StopLocal` = 1 or<br>`StopLocal` = 1 and `CloseLocal` = 1<br>Switching mode (`Feature2.Bit4` = 1):<br>`OpenLocal` = 1 and `CloseLocal` = 1 | Motor is started in valve neutral position direction. |
| Local: `Localsetting` = 1 or `Localsetting` = 3 and forcing | `OpenForce` = 1 and `CloseForce` = 1 or<br>`OpenForce` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `CloseForce` = 1 | |
| Forcing and no "local mode" | `OpenForce` = 1 and `CloseForce` = 1 or<br>`OpenForce` = 1 and `StopForce` = 1 or<br>`StopForce` = 1 and `CloseForce` = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0):<br>`OpenAut` = 1 and `CloseAut` = 1 or<br>`OpenAut` = 1 and `StopAut` = 1 or<br>`StopAut` = 1 and `CloseAut` = 1<br>Switching mode (`Feature.Bit4` = 1):<br>`OpenAut` = 1 and `CloseAut` = 1 | |
| "Manual mode" and no forcing | `OpenMan` = 1 and `CloseMan` = 1 or<br>`OpenMan` = 1 and `StopMan` = 1 or<br>`StopMan` = 1 and `CloseMan` = 1 | |

## Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.12.5 VlvMotL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages

### Process control fault

The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Motor feedback error |
| | SIG 2 | AS process control message - fault | $$BlockComment$$<br>Motor protection triggered |
| | SIG 3 | AS process control message - fault | $$BlockComment$$<br>Valve feedback error |
| | SIG 4 | AS process control message - fault | $$BlockComment$$<br>External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter `CSF`. If it changes to `CSF` = 1, a process control fault is triggered (`MsgEvId1`, SIG 4).

### Instance-specific messages

You can use up to three instance-specific messages with this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 5 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 6 | AS process control message - fault | $$BlockComment$$<br>External message 2 |
| | SIG 7 | AS process control message - fault | $$BlockComment$$<br>External message 3 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |
| 6 | `ExtVa106` |
| 7 | `ExtVa107` |
| 8 | `ExtVa108` |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters `ExtVa104` ... `ExtVa108` , and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

|---|---|---|---|
| FbkClose | 1 = Valve closed feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkClosing | 1 = Valve closing feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkOpen | 1 = Valve open feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkOpening | 1 = Valve opening feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1762)<br>1 = Separate monitoring time for stopping the motor | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 13: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0<br>• 0 |
| Feature2 | I/O for additional functions (Page 1762) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| IdleTime* | Wait time for change of direction or restart in [s] | REAL | 5.0 |
| Intlock | 0 = Interlock / interlock Open is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock / interlock Open is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Parameter Intlock is enabled | BOOL | 1 |
| IntlCls | 0 = Interlock Close is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock Close is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| IntlClsEn | 1 = Parameter IntlCls is enabled | BOOL | 1 |
| LocalLi | 1 = Activate "local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LocalSetting | Properties for the Local mode (Page 86) | INT | 0 |
| ManModLi* | 1 = Manual mode via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1= "Manual mode" via: OS operator (controlled via ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Switchover of operating mode between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors | BOOL | 1 |
| MonTiDynamic* | Monitoring time for feedback errors or feedback start error after successful operation in [s] | REAL | 3.0 |
| MonTiDyStop* | Monitoring time for feedback stop errors after successful operation in [s] | REAL | 3.0 |
| M_Monitor | 1 = Motor feedback monitoring | BOOL | 1 |
| M_MonTiDynamic* | Motor monitoring time after operation in [s] | REAL | 3.0 |
| M_MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp | 1 = Release for maintenance via OS operator | BOOL | 0 |
| NoFbkClose | 1 = No feedback present for "valve closed" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoFbkOpen | 1 = No feedback present for "valve open" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpenAut* | 1 = Select Open valve in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenChnST | Signal status of output channel for Open<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| OpenForce | 1 = Force valve opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenLocal | 1 = Select Open valve in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenMan* | 1 = Select Open valve in "manual mode" | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, to be connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator permissions (Page 1762)<br>1 = Operator can set or change the monitoring time for "Control: Start"<br>1 = Operator can set or change the monitoring time for "Control: Stop" | STRUCT<br>• Bit 0: BOOL<br>• Bit11: BOOL<br>• Bit 20: BOOL<br>• Bit 30: BOOL | -<br>• 1<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 1762) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| Permit | 1 = Activation / activation Open is activated<br>0 = Activation / activation Open is deactivated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermitSafePos | 1=Valve SafePos / Stop allowed | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermSf_En | 1=Permit SafePos / Stop enabled | BOOL | 1 |
| Perm_En | 1 = Parameter Permit is enabled | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermCls | 1 = Activation Close is activated<br>0 = Activation Close is deactivated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermClsEn | 1 = Parameter PermCls is enabled | | |
| Protect | 0 = Protective interlock / protective interlock Open is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock / protective interlock Open is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Prot_En | 1 = Parameter Protect is enabled | BOOL | 1 |
| ProtCls | 0 = Protective interlock Close is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock Close is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| ProtClsEn | 1 = Parameter ProtCls is enabled | BOOL | 1 |
| PulseWidth* | Pulse width of control signal [s] | REAL | 3.0 |
| RapidStp* | Rapid stop for the motor<br>0 = Motor On<br>1 = Motor Off | BOOL | 0 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | Neutral position for valve:<br>0 = Closed<br>1 = Open<br>2 = Stop (valve can be in position Closed, Opened or Intermediate) | INT | 2 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SimAV* | Additional value used for SimOn = 1 | REAL | 0.0 |
| SimAV_Li | Additional analog value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1= Simulation per interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stopping the motor in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopForce | 1 = Force motor stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopLocal | 1 = Stopping the motor in "local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stopping the motor in "manual mode" | BOOL | 0 |
| TorqOpen | 0 = Torque shutdown active when opening<br>1 = "Good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| TorqClose | 0 = Torque shutdown active when closing<br>1 = "Good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| V_Monitor | 1 = Valve feedback monitoring | BOOL | 1 |
| V_MonTiDynamic* | Valve monitoring time after operation in [s] | REAL | 5.0 |
| V_MonTiStatic* | Monitoring time for valve feedback errors without operation in [s] | REAL | 5.0 |
| WarnTiAut* | Prewarning of valve movement from neutral position in "automatic mode" in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan* | Prewarning of valve movement from neutral position in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AV_OpScale | Limit for scale in AV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| AV_Out | Output additional analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Unit | Unit of measure for additional analog value | INT | 0 |
| CascaCut | Cascade connection:<br>1 = Control chain from master controller to secondary valve is interrupted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Close | Control output<br>1= Close valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Closed | 1 = Valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Closing | 1 = Valve is closing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CurrMonV | Remaining valve monitoring time [s] | DINT | 0 |
| CurrMonM | Remaining motor monitoring time [s] | DINT | 0 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see VlvMotL error handling (Page 1774) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkCloseOut | Valve closed feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkClsgOut | Valve closing feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpenOut | Valve open feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpngOut | Valve opening feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlClsOut | IntlCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LockAct | 1 = Interlock (Intlock, Permit, Protect) or Trip is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynErr | 1 = Feedback error or feedback start error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| MonDynStopErr | 1 = Feedback stop error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| M_MonDynErr | 1 = Motor feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| M_MonStaErr | 1 = Motor feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgment status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Open | Control output:<br>1 = Open the valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opened | 1 = Valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opening | 1 = Valve is opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1_Perm | WORD | 16#FFFF |
| OS1PermLog | Display of OS1_Perm with settings changed by the block algorithm | WORD | 16#FFFF |
| P_Close | 1 = Pulse signal to close valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Open | 1 = Pulse signal to open valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Stop | 0 = Pulse signal for stopping the valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>ST: BYTE | -<br>• 1<br>• 16#FF |
| PermClsOut | PermCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtClsOut | ProtCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| R_StpAct | 1 = Rapid stoProtClsOutp of the motor is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1754) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1754) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1754) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1754) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1754) | DWORD | 16#00000000 |
| Status6 | Status word 6 (Page 1754) | DWORD | 16#00000000 |
| Stop | 1 = Motor is stopped independent of position | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TripOut | Trip as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| V_MonDynErr | 1 = Valve feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| V_MonStaErr | 1 = Valve feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| StopCtrl | Control output go to SafePos | BOOL | 0 |
| WarnAct | 1 = Prewarning for valve movement away from neutral position active (parameters WarnTiAut and WarnTiMan) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

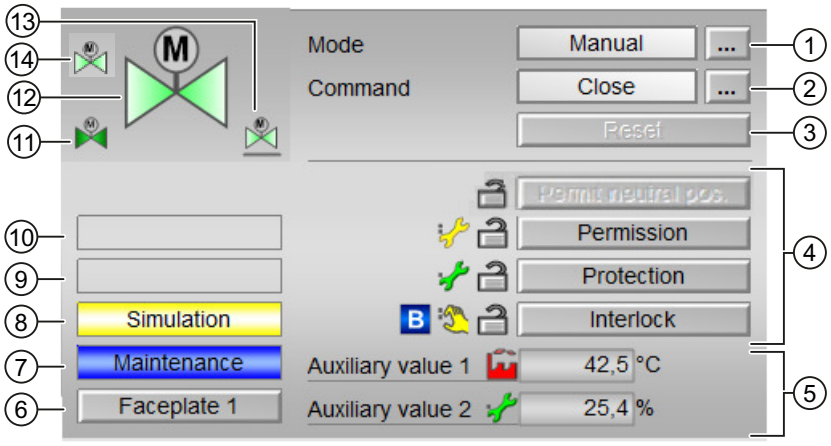
## 8.12.8 Operator control and monitoring

### 8.12.8.1 VlvMotL views

### Views of the VlvMotL block

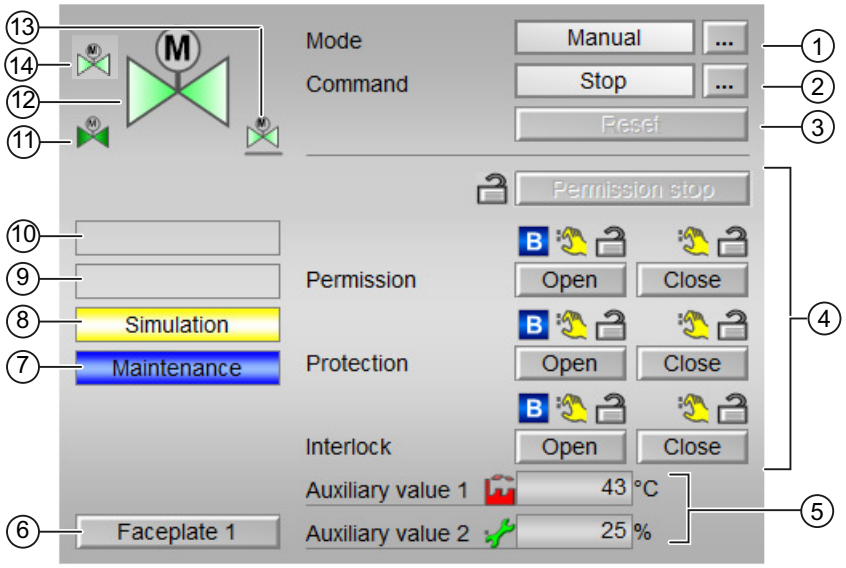
The VlvMotL block provides the following views:

- VlvMotL standard view (Page 1792)
- Limit view of motors (Page 328)
- Alarm view (Page 336)



- Trend view (Page 341)
- VlvMotL parameter view (Page 1797)
- VlvMotL preview (Page 1799)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for VlvMotL (Page 1805)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.



### 8.12.8.2 VlvMotL standard view

#### VlvMotL standard view

With `Feature2.Bit16` = 0:

With `Feature2.Bit16` = 1:

## (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

## (2) Open, close and stop the motor valve

This area shows you the default operating state for the motor valve. The following states can be shown and executed here:

- "Open"
- "Close"
- "Stop"
- "Rapid stop"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (4) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (5) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system. You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (6) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (7) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (8) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Motor protection"
- "External error"
- "Torque active"
- "End position error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104) , Error handling (Page 128) (section "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced open"
- "Forced close"
- "Forced stop"
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find additional information on this in the section Forcing operating modes (Page 45).

### (11) Automatic preview

This display is only visible in "manual mode", in "local mode", or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the valve would assume if you switched from "manual" or "local" mode to "automatic mode", or performed a reset to "automatic mode".

### (12) Status display of the motor valve

The current status of the motor valve is graphically displayed here.

You can find more information about this in section Block icon for VlvMotL (Page 1805)

### (13) Neutral position of the valve

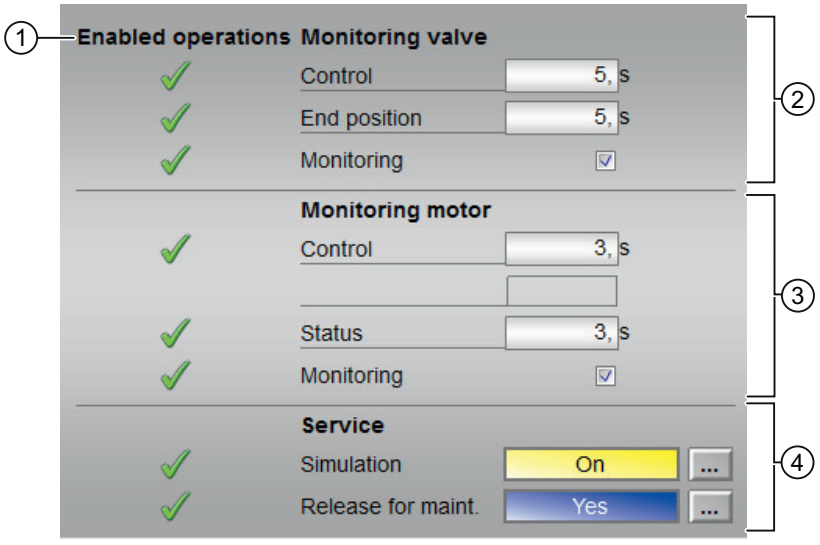
This representation shows the neutral position for the valve:

- Green: Neutral position is "Open"  or neutral position is “Stop” and valve is opened
- Gray: Neutral position is "Closed" or neutral position is “Stop” and valve is closed
- Light green: Neutral position is "Stop" and valve is in intermediate position

### (14) Mini preview for Resynchronization

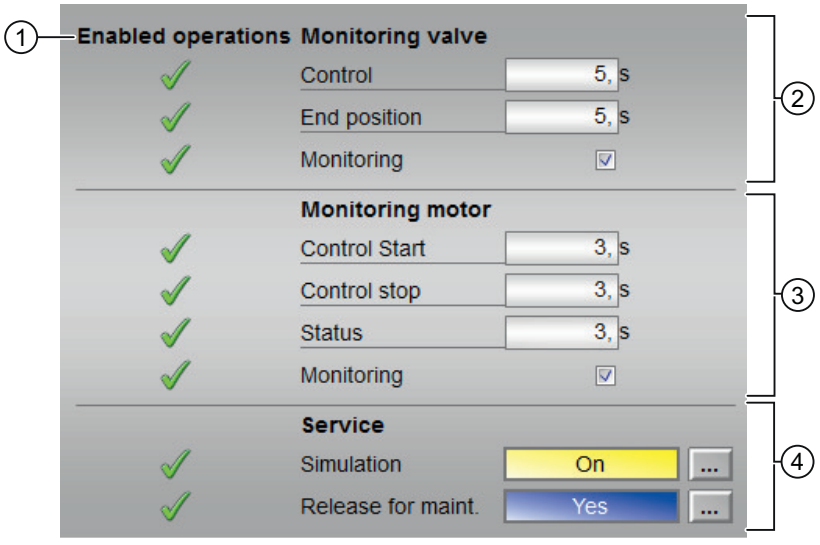
Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:



- Open
- Close
- Intermediate

**Note**



Mini preview for resynch is visible only if resynchronization command is different to control output value.

### 8.12.8.3 VlvMotL parameter view

#### Parameter view of VlvMotL

Parameter view for VlvMotL with `Feature.Bit13` = 0

Parameter view for VlvMotL with `Feature.Bit13` = 1

#### (1) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### (2) Monitoring valve

In this area, you change parameters and therefore influence the valve. You can find additional information on this in the section Changing values (Page 291).

You can influence the following parameters:

- "Control": Monitoring time for the valve run time (dynamic)
- "End position": Monitoring time for maintaining the valve position (static)
- "Monitoring":
  You can enable monitoring by selecting the check box (☑)
  You can find additional information on this in the section Monitoring the feedbacks (Page 104).

### (3) Monitoring motor

In this area, you change parameters and therefore influence the motor. You can find additional information on this in the section Changing values (Page 291).

You can influence the following parameters:

`Feature.Bit13` **= 0**

- "Control": Monitoring time during startup and shutdown of the motor (dynamic)
- "Status": Monitoring time during permanent operation of the motor (static)

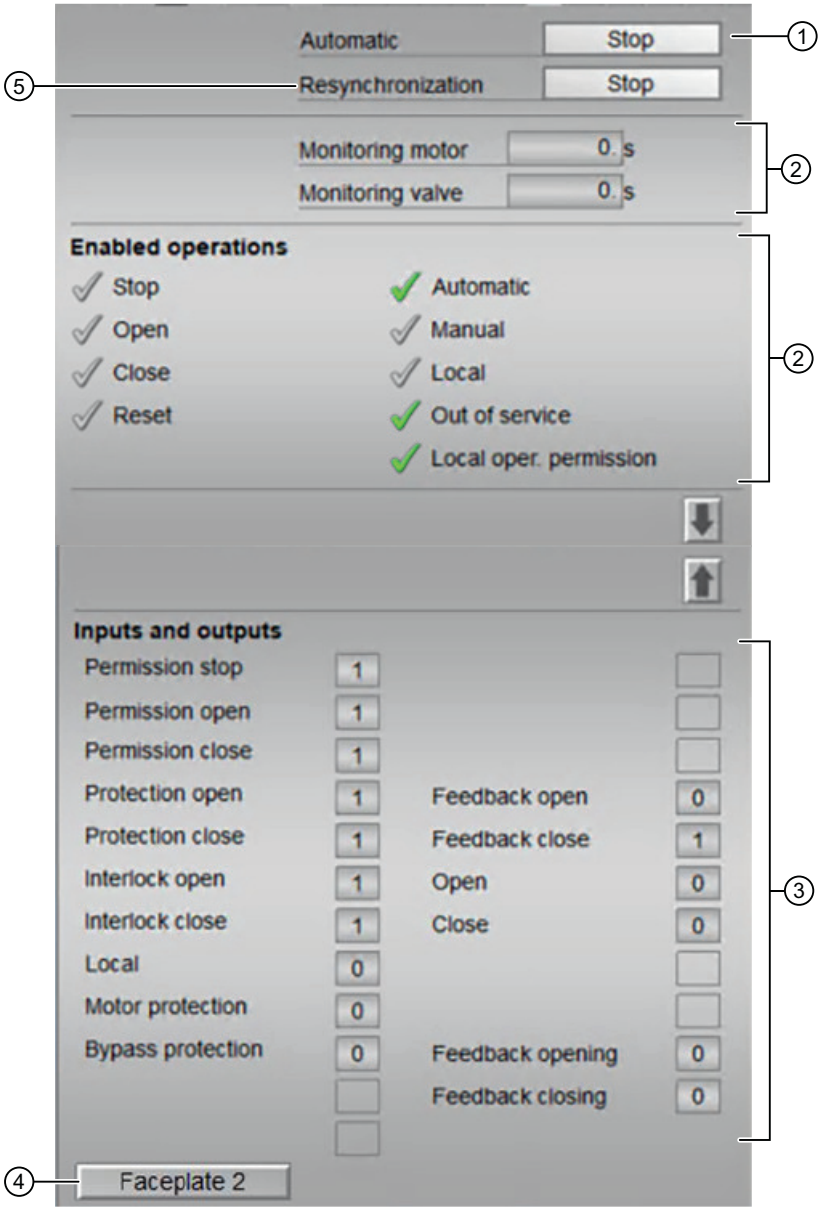
`Feature.Bit13` **= 1**

- "Control start": Monitoring time during startup of the motor (dynamic)
- "Control stop": Monitoring time during shutdown of the motor (dynamic)
- "Status": Monitoring time during permanent operation of the motor (static)
- "Monitoring":
  You can enable monitoring by selecting the check box (☑)
  You can find additional information on this in the section Monitoring the feedbacks (Page 104).

### (4) Service

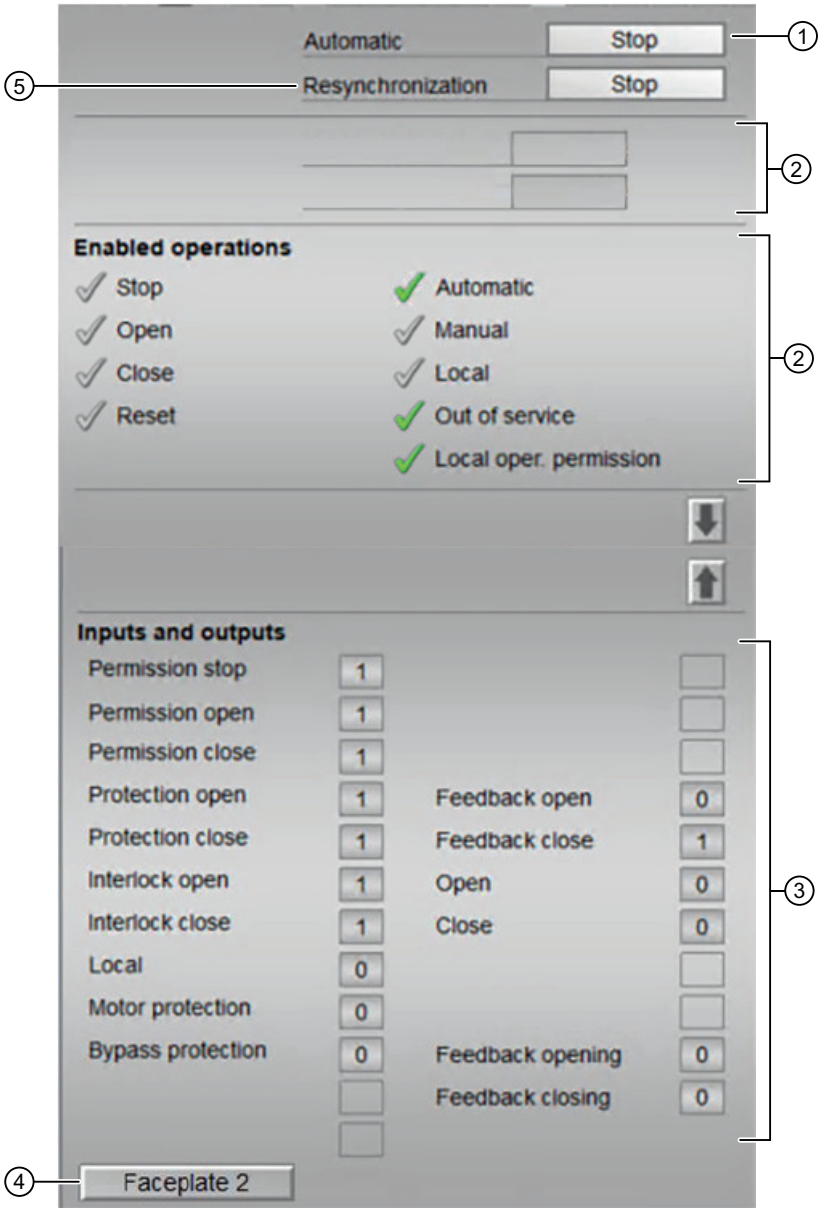
You can select the following functions in this area:

- "Simulation"
- "Release for maintenance" (with display for a maintenance request)



You can find additional information on this in the section Switching operating states and operating modes (Page 289).

You can find information on this area in the section:



- Simulating signals (Page 64)
- Release for maintenance (Page 70)

### 8.12.8.4 VlvMotL preview

**Preview of VlvMotL**

Display of the current monitoring time of the motor/valve is visible.

Display of the current monitoring time of the motor/valve is not visible.

### (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".
- If the valve is in the end position and the automatic stop command is active, the automatic preview does not show the current status "Closed", but the active automatic command "Stop".

This area also displays the worst signal status of the following automatic commands:

- `OpenAut`
- `CloseAut`
- `StopAut`

### (2) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Stop": You can stop the motor of the valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Open": You can open the motor valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Close": You can close the motor valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the motor valve if interlocks or errors occur.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.

- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. You can find additional information on this in the section Operator control permissions (Page 285).
- "Monitoring motor": Display of the remaining monitoring time of the motor.
- "Monitoring valve": Display of the remaining monitoring time of the valve.

### (3) Displaying current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "opening"/"closing" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission Open" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "open" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission Close" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "close" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permit neutral pos" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Prevents the control in safe position direction
  - 1 = prevents the stop command

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Protection Open" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection Close" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permit neutral pos" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Prevents the control in safe position direction
  - 1 = prevents the stop command

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock Open" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock Close" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"
- "Torque opening": 0 = Torque shutdown when opening
- "Torque closing": 0 = Torque shutdown when closing
- "Local stop": 1 = Stopping the motor valve in "local mode"
- "Local open": 1 = Opening the motor valve in "local mode"
- "Local close": 1 = Closing the motor valve in "local mode"
- "Feedback open": 1 = Motor valve is open
- "Feedback close": 1 = Motor valve is closed
- "Open": 1 = Motor valve is opened
- "Close": 1 = Motor valve is closed
- "Channel Open": Signal from the output channel block for "Open"
- "Channel Close": Signal from the output channel block for "Close"
- "Feedback opening": 1 = Motor valve is opening
- "Feedback closing": 1 = Motor valve is closing

### (4) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, see section Opening additional faceplates (Page 234).

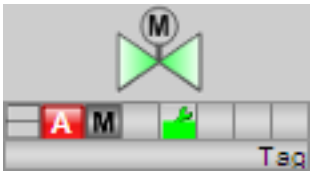
### (5) Resynchronization

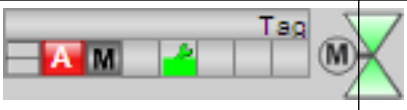
Displays the Resynchronization state and Resynchronization Signal status based on feedback value.

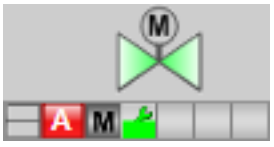
- When motor feedbacks are not present (`Feature.Bit12` = 1) - Resynchronization preview is based on valve feedbacks.
- When motor feedbacks are present (`Feature.Bit12` = 0) - Resynchronization preview is based on motor feedbacks.

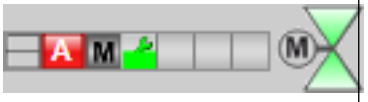
### 8.12.8.5 Block icon for VlvMotL

#### Block icons for VlvMotL









A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Displays for bypassing interlocks
- Interlocks
- Memo display
- Valve status display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Non-rotating block icon |
|  | 4 | Non-rotating block icon |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | 9 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 10 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Valve status display

The following valve states are shown here:

| Icon | Meaning |
|---|---|
|  | Valve open |
|  | Valve closed |
|  | Error at valve |
|  | Valve is opening |
|  | Valve is closing |
|  | Valve stop |
|  | Valve closed |
|  | Valve is closing |

# 8.13 VlvAnL - Control valve

## 8.13.1 Description of VlvAnL

### Object name (type + number) and family

Type + number: FB 1896

Family: Drives

### Area of application for VlvAnL

The block is used for the following applications:

- Control of an analog control valve and positioner with adjustable neutral position
- Control of an optional auxiliary valve for regulating the auxiliary power of the control valve

### How it works

The control valve is brought to a specified position using and analog activation signal. The activation signal can be formed by a ramp function in this case.

The block forms the manipulated variable error from the difference between the activation signal and the acquired position feedback and can monitor it for adherence to high and low limits.

The control valve is monitored for the "Open"/"Closed" position. The block can be connected with a digital limit switch for this purpose. The block can generate the digital position signals itself through the adjustable limits for the "Open"/"Closed" position.

Missing feedback can be derived from the control in the block.

Various inputs are available for control purposes. The next sections provide more detailed information on configuration, operating principles, visualization and operation.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

For the VlvAnL block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Control valve (VlvAnL) (Page 2868)
- Control valve for PA/FF devices (ValveAnalog_Fb) (Page 2869)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

If `Feature` Bit Set startup characteristics (Page 148) = 0, the following applies to the startup characteristics:

- `Feature.Bit16` = 0 closes the main valve
- With `Feature.Bit16` = 1 the main valve is moved into the neutral position

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section VlvAnL I/Os (Page 1835).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0: Open padlock in the block icon<br>1: Closed padlock in the block icon<br><br>In case of `Feature2.Bit16` = 1 then a closed padlock is displayed if Interlock Open OR Interlock Close is active. |
| 8 | Control valve "Open"/"Closed" command (0 = "Closed", 1 ="Open") |
| 9 | `FbkOpenOut.Value` control valve |
| 10 | `FbkCloseOut.Value` control valve |
| 11 | 1 = Feedback error control valve without control change |
| 12 | 1 = Feedback error control valve due to control change |
| 13 | `BypProt` |
| 14 | 1 = Invalid signal status |
| 15 | 1 = Mode changeover error |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | Display "Forced open" |
| 20 | Display "Forced stop" |
| 21 | 1 = `Force` |
| 22 | Automatic preview of auxiliary valve (1 = "Open") |
| 23 | 1 = Bumpless switchover to "automatic mode" enabled |
| 24 | 1 = Actuator active (`PosDiClose` < `MV` <`PosDiOpen`) |
| 25 | `UserAna1` interconnected |

| Status bit | Parameter |
|---|---|
| 26 | `UserAna2` interconnected |
| 27 | Auxiliary valve "Open"/"Closed" command (0 =" Closed", 1 = "Open") |
| 28 | `FbkOpenAuxVOut.Value` (auxiliary valve) |
| 29 | `FbkCloseAuxVOut.Value` (auxiliary valve) |
| 30 | 1 = Feedback error auxiliary valve without control change |
| 31 | 1 = Feedback error auxiliary valve due to control change |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | 1 = `MsgLock` message suppression active |
| 1 | 1 = "Open" and "Close" commands deactivated (command line not visible) |
| 2 | 1 = Display for interlocks in block icon |
| 3 | 1 = Display "Opened" for representation of neutral position in `SafePos` = 1 or 2 |
| 4 | 1 = Display "Closed" for representation of neutral position in `SafePos` = 0 or 2 |
| 5 | 1 = Display "Intermediate" for representation of neutral position in `SafePos` = 2 |
| 6 | 1 = Operator can reset the valve |
| 7 | `WarnAct.Value` |
| 8 | 1 = External manipulated variable active (`MV_ExtAct.Value`) |
| 9 | 1 = Forced manipulated variable (`MV_Forced`) is output without limit at output `MV` |
| 10 | 1 = Tracking of manipulated variables `MV`, `MV_TrkOn.Value` = 1 and `MV_ForOn.Value` = 0 |
| 11 | 1 = Manipulated variable greater than limit (low) for manipulated variable `MV` (`MV.Value` > `ManLoLim`) |
| 12 | 1 = Input parameter `Rbk` is not interconnected (`RbkOut.ST` = 16#FF) |
| 13 | 1 = Input parameter `FbkAuxVClose` is connected |
| 14 | 1 = Input parameter `FbkAuxVOpen` is connected |
| 15 | 1 = Input parameter `FbkClose` is connected |
| 16 | 1 = Input parameter `FbkOpen` is connected |
| 17 | For the Error status display in the Closed valve |
| 18 | Reset request in automatic |
| 19 | 1 = No impact of input signals on "local mode" with `LocalSetting` = 0, `LocalSetting` = 2, `LocalSetting` = 4 and OOS mode. |
| 20 | 1 = Control valve open |
| 21 | 1 = Control valve closed |
| 22 | 1 = Control valve opening |
| 23 | 1 = Control valve closing |
| 24 | 1 = Control valve in intermediate position ("Stop") |
| 25 | 1 = Position reached |
| 26 | Control of valve, open auxiliary valve |
| 27 | Control of valve, close auxiliary valve |
| 28 | 1 = Control valve is in intermediate position |
| 29 | For the Error status display in the Opened valve |

| Status bit | Parameter |
|---|---|
| 30 | 1 = Bypass information for display in block icon |
| 31 | `MS_RelOp` |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | Effective signal 1 of the message block connected via `EventTsIn` |
| 1 | Effective signal 2 of the message block connected via `EventTsIn` |
| 2 | Effective signal 3 of the message block connected via `EventTsIn` |
| 3 | Effective signal 4 of the message block connected via `EventTsIn` |
| 4 | Effective signal 5 of the message block connected via `EventTsIn` |
| 5 | Effective signal 6 of the message block connected via `EventTsIn` |
| 6 | Effective signal 7 of the message block connected via `EventTsIn` |
| 7 | Effective signal 8 of the message block connected via `EventTsIn` |
| 8 | 1 = "Interlock" button is enabled |
| 9 | 1 = "Permission" button is enabled |
| 10 | 1 = "Protection" button is enabled |
| 11 | 1 = Manipulated variable difference high limit violated (`ER_AH_Act.Value`) |
| 12 | 1 = Manipulated variable difference low limit violated (`ER_AL_Act.Value`) |
| 13 | `ER_AH_En` OR `Feature.Bit23` |
| 14 | `ER_AL_En` OR `Feature.Bit23` |
| 15 | 1 = Report manipulated variable difference high limit violation (`ER_AH_MsgEn`) |
| 16 | 1 = Report manipulated variable difference low limit violation (`ER_AL_MsgEn`) |
| 17 | 1 = Readback value high limit violated (`RbkWH_Act.Value`) |
| 18 | 1 = Readback value low limit violated (`RbkWL_Act.Value`) |
| 19 | `RbkWH_En` OR `Feature.Bit23` |
| 20 | `RbkWL_En` OR `Feature.Bit23` |
| 21 | 1 = Report readback value high limit violation (`RbkWH_MsgEn`) |
| 22 | 1 = Report readback value low limit violation (`RbkWL_MsgEn`) |
| 23 | 1 = Automatic preview control valve "Open" |
| 24 | 1 = Automatic preview control valve "Closed" |
| 25 | 1 = Automatic preview control valve "Stop" |
| 26 | 1 = Show automatic preview in the standard view |
| 27 | 1 = Auxiliary valve present |
| 28 | `GrpErr.Value` |
| 29 | `RdyToStart.Value` |
| 30 | `MV_UpRaAct`, `MV_DnRaAct` limits enabled for gradient mode (`MV_RateOn = 1`) |
| 31 | `SimLiOp.Value` |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | External error generated by FaultExt or external control system fault CSF with set `Feature.Bit18` Activating error state for external process control error CSF (Page 162) |
| 1 | Delay of the `ER_AH_Lim` message |
| 2 | Delay of the `ER_AL_Lim` message |
| 3 | Delay of the `RbkWH_Lim` message |
| 4 | Delay of the `RbkWL_Lim` message |
| 5 | Collection of message delays |
| 6 | 1 = MV ramp active |
| 7 | Resynchronization preview for Open |
| 8 | Resynchronization preview for Close |
| 9 | Resynchronization preview for Stop |
| 10 | Resynchronization: Display preview |
| 11 | Resynchronization: Display small preview symbol in standard view |
| 12 | 1 = Open operation disabled |
| 13 | 1 = Close operation disabled |
| 14 | 1 = Operator MV input in open direction is not allowed |
| 15 | 1 = Operator MV input in close direction is not allowed |
| 16 - 18 | Not used |
| 19 | `Feature2.Bit16`: Separate interlock for each direction, speed or position |
| 20 | Hidden bypass signal in Permit Close |
| 21 | Hidden bypass signal in Interlock Close |
| 22 | Hidden bypass signal in Protect Close |
| 23 | Hidden bypass signal in Permit |
| 24 | Hidden bypass signal in interlock |
| 25 | Hidden bypass signal in Protect |
| 26 | `Feature2.Bit2`: Separate bypass signal |
| 27 | 1 = Input parameter `MV_ChnST` is interconnected |
| 28 | 1 = Input parameter `CtrlChnST` is interconnected |
| 29 | Current monitoring time is visible |
| 30 | Current auxiliary valve monitoring time is visible |
| 31 | Internal error |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 9..16 of the message block connected via `EventTsIn` |
| 8 - 15 | Not used |
| 16 | "Permission Open" button is enabled |
| 17 | "Permission Close" button is enabled |
| 18 | "Interlock Open" button is enabled |

| Status bit | Parameter |
|---|---|
| 19 | "Interlock Close" button is enabled |
| 20 | "Protect Open" button is enabled |
| 21 | "Protect Close" button is enabled |
| 22 | 1 = Permission Close is active |
| 23 | 1 = Intlock Close is active |
| 24 | 1 = Protect Close is active |
| 25 | 1 = " Permit neutral pos." button is enabled |
| 26 | 1 = Permission SafePos is active |
| 27 | Hidden bypass signal in Permission SafePos |
| 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | `MV_TrkOn.Value` |
| 31 | Not used |

VlvAnL block diagram (Page 1850)

## 8.13.2 VlvAnL modes

### VlvAnL operating modes

The block can be operated using the following modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

The block supports the local modes 2 and 4. Therefore, the control settings for the block are also made based on internal adjustment of the feedback value.

Main valve:

If the readback value is connected /available (`Rbk.ST <> 16#FF`) and the two feedback signals are available the analog main control and the valve position is tracked.

```
MV = Rbk;
```

Valve position open `= (Rbk >= PosDiOpen) AND FbkOpen`

Valve position close `= (Rbk <= PosDiClose) AND FbkClose`

In end position the readback value and the feedback signal are monitored of plausibility.

When readback value is not available only the feedbacks determine the valve position.

When feedback signals are not available only the readback value determines the valve position.

When readback value and feedback signals values are not available the valve position is hold.

Auxiliary valve:

`LocalSetting =2,4`: The control outputs are tracked to the feedbacks.

All two feedbacks are available and plausible means that always only one feedback is active. The control output is tracked:

`Ctrl = NOT (FbkAuxVOpen XOR SafePosAux);` when `FbkAuxVOpen =1, Ctrl = FbkAuxVClose XOR SafePosAux;` when `FbkAuxVClose =1`

When both feedbacks are false then the drive is between of two positions. In this case no monitoring is started. When two feedbacks are active at the same time, then they are not plausible. In this case the static monitoring counter starts.

If one feedback is available it is always plausible.

| NoFbk`AuxV`Open =1 | NoFbk`AuxV`Close =1 |
|---|---|
| `Ctrl = NOT (FbkCloseAuxV XOR SafePosAux)` | `Ctrl = FbkOpenAuxV XOR SafePosAux` |

When all feedbacks are not available the control outputs will be hold.

You can find general information on "Local mode", switching modes and Bumpless switchover in the Local mode (Page 86) section.

## "Automatic mode"

You can find general information on "Automatic mode", switching modes and Bumpless switchover in the Manual and automatic mode for motors, valves and dosers (Page 82) section.

**With auxiliary valve**

In "automatic mode", the automatic commands affect the auxiliary valve, which you can

- "Open" (`OpenAut` = 1)
- "Close" (`CloseAut` = 1)

**Without auxiliary valve**

In "automatic mode", the automatic commands affect the control valve, which you can

- "Open" (`OpenAut` = 1)
- "Close" (`CloseAut` = 1)

**Note**

If no auxiliary valve is configured, no internal manipulated variable specifications can be made in "automatic mode". Manipulated variable specification is set to external when the mode is switched to "automatic".

## "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

**With auxiliary valve:**

In "manual mode", the operator actions affect the auxiliary valve, which you can:

- "Open" (`OpenMan` = 1)
- "Close" (`CloseMan` = 1)

**Note**

If no auxiliary valve is configured, no external manipulated variable specifications can be made in the manual operating mode. With an internal manipulated value, the switchover from "automatic mode" to "manual mode" is bumpless. With an external manipulated value, the switchover is bumpless only if `MV_TrkExt` = 1 is parameterized.

**Without auxiliary valve:**

In "manual mode", the operator actions affect the control valve, which you can:

- "Open" (`OpenMan` = 1)
- "Close" (`CloseMan` = 1)

**Note**

If no auxiliary valve is configured, no external manipulated variable specifications can be made in the manual operating mode. Manipulated variable specification is set to internal when the mode is switched to manual. The switching is bumpless depending on the parameter `MV_TrkExt`.

## "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkAuxVOpenOut.ST | 16#80 | 16#60 |
| FbkAuxVCloseOut.ST | 16#80 | 16#60 |
| FbkOpenOut.ST | 16#80 | 16#60 |
| FbkCloseOut.ST | 16#80 | 16#60 |
| FbkOpngOut.ST | 16#80 | 16#60 |
| FbkClsgOut.ST | 16#80 | 16#60 |
| Opened.ST | 16#80 | 16#60 |
| Closed.ST | 16#80 | 16#60 |
| Opening.ST | 16#80 | 16#60 |
| Closing.ST | 16#80 | 16#60 |
| AuxOpened.ST | 16#80 | 16#60 |
| AuxClosed.ST | 16#80 | 16#60 |
| AuxOpning.ST | 16#80 | 16#60 |
| AuxClsing.ST | 16#80 | 16#60 |
| RbkOut.ST | 16#XX | 16#60 |
| RbkWH_Act.ST | 16#XX | 16#60 |
| RbkWL_Act.ST | 16#XX | 16#60 |
| PosReached.ST | 16#80 | 16#60 |
| ER.ST | 16#80 | 16#60 |
| ER_AH_Act.ST | 16#XX | 16#60 |
| ER_AL_Act.ST | 16#XX | 16#60 |

## 8.13.3 VlvAnL functions

### Functions of VlvAnL

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Interlocks

This block provides the following interlocks:

**`Feature2.Bit16` = 0:**

- Activation enable
- Interlock without reset ("Interlock")
- Interlock with reset ("Protection")
- Permission for safe position ("Permit neutral pos.")

In case of nondirectionally interlock also the auxiliary valve controls to neutral position.

**`Feature2.Bit16` = 1:**

- Activation enable Open
- Activation enable Close
- Interlock open without reset ("Interlock open")
- Interlock close without reset ("Interlock close")
- Interlock open with reset ("Protection interlock open")
- Interlock close with reset ("Protection interlock close")

In case of directionally interlock the auxiliary valve controls do not change.

Refer to the section Interlocks (Page 107) as well as Influence of the signal status on the interlock (Page 112).

### Resetting the block in case of interlocks or errors

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External error (`FaultExt`), external control system fault (`CSF`)

This block provides the possibility to pass an external error via the `FaultExt` parameter or an external control system fault via the CSF parameter. See, VlvAnL error handling (Page 1832).

### Group error

This block provides the standard function Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `MonDynErr`
- `MonStaErr`

- MonDynAuxVErr
- MonStaAuxVErr
- FaultExt

### Outputting a signal for start readiness

This block provides the standard function Outputting a signal for start readiness (Page 59).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

### Simulating signals

This block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Position feedback (SimRbk, SimRbkLi)

### Using a manipulated variable ramp

The block provides the standard function Using a manipulated variable ramp (Page 133).

This function is ignored with tracking and forced tracking.

### Gradient limiting of the manipulated variable

This block provides the standard function Gradient limiting of the manipulated variable (Page 134).

**Note**

This function is ignored with tracking, forced tracking, forced operating states and travel to the neutral position.

### Tracking and limiting a manipulated variable

You can correct the manipulated variable output to the tracking value MV_Trk or the manipulated variable feedback Rbk to realize Bumpless switchover. To track the manipulated variable output, you have to set the parameter MV_TrkOn = 1.

If the parameter is MV_TrkRbk = 0, the manipulated variable output is corrected to the tracking value MV_Trk. The manipulated variable output MV is limited to the MV_HiLim and MV_LoLim parameters.

If the parameter is MV_TrkRbk = 1, the manipulated variable output is tracked to the position feedback Rbk. There are no limits here.

The "Tracking" text is displayed additionally in the standard view of the faceplate.

### Forming the group status for interlocks

This block provides the standard function Forming the group status for interlock information (Page 113).

### Control loop is open (CascaCut)

The CascaCut output indicates whether the control loop within this block is open. In the open control loop, the master controller must be set to tracking mode to avoid until windup behavior. If you use this block in a cascade structure, then connect the output CascaCut to the input MV_TrkOn of the master controller.

CascaCut is active in the following cases:

- Auxiliary valve is closed
- Block is not in external MV mode
- Tracking function is active
- Force function is active
- Motor protection is active
- Interlock is active
- Monitoring error is active

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The signal status of the output for the manipulated variable feedback RbkOut always corresponds to the signal status of the Rbk input or when the block is in simulation, the signal status of the 16#60 output.

The signal status of the FbkCloseOut and FbkOpenOut outputs is fetched and sent from the worst signal status from the RbkOut output and the corresponding feedback signal inputs FbkClose and FbkOpen.

The signal status of the manipulated variable output MV always corresponds to the signal status of the input parameter MV_Ext or MV_Int, depending on how the setpoint is specified. If the internal manipulated variable MV_Int is used, the signal status is always output as 16#80.

The signal status of manipulated variable difference ER is fetched and sent from the worst signal status of the two outputs RbkOut and MV.

The worst signal status ST_Worst for the block is formed from the following parameters:

- FbkOpenOut.ST
- FbkCloseOut.ST
- FbkAuxVOpenOut.ST
- FbkAuxVCloseOut.ST
- RbkOut.ST
- LocalLi.ST

- `MV_Chn.ST`
- `CtrlChn.ST`
- `OpenAut.ST` (only if `Feature2.Bit10` = 1)
- `CloseAut.ST` (only if `Feature2.Bit10` = 1)
- `MV_Ext.ST` (only if `Feature2.Bit10` = 1)

### Considering bad quality of automatic commands or external values

If the `Feature2` bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- `OpenAut.ST`
- `CloseAut.ST`
- `MV_Ext.ST`

### Forcing operating modes

This block provides the standard function Forcing operating modes (Page 45).

**Note**

If `OpenForce` =1, the high range limit `MV_HiLim` is the output and if `CloseForce` =1, the low range limit `MV_LoLim` is the output that is available at the output `MV`.

If the block is operated with an auxiliary valve, the commands `OpenForce` and `CloseForce` additionally effect the auxiliary valve. With `CloseForce` = 1, the auxiliary valve is closed and the rest position of the control valve is triggered, independent of the output `MV`.

A configured ramp limit has no effect.

### Feedback monitoring

This block provides the standard function Monitoring the feedbacks (Page 104).

Digital feedback signals for the "Open" and "Closed" positions are formed from the position feedback:

- Feedback for "Open" position: `Rbk` ≥ `PosDiOpen`
- Feedback for "Closed" position: `Rbk` ≤ `PosDiClose`

**Specifying control valve positions:**

There are the positions:

- Valve closed ("Closed")
- Valve closes
- Valve open ("Open")

- Valve opens
- Valve has reached defined position

**Valve closed ("Closed")**

When the control valve reaches the "Close" position, the output is `FbkCloseOut.Value` = 1:

- With a binary limit switch for the "Close" position (`NoFbkClose` = 0):
  The valve is considered closed when `FbkCloseOut` is set. `FbkCloseOut` is set when `Rbk` ≤ `PosDiClose` and `FbkClose` = 1.
- Without a binary limit switch for the "Close" position (`NoFbkClose` = 1):
  The valve is considered closed when `FbkCloseOut` is set. `FbkCloseOut` is set when `Rbk` ≤ `PosDiClose`.

**Valve closes**

If the control valve travels in the direction of the "Close" position, the output is `FbkClsgOut = 1`:

- `FbkClsgOut` is set when `MV.Value < RbkOut.Value` and not when `PosReached.Value = 1` .

**Valve open ("Open")**

When the control valve reaches the "Open" position, the output is `FbkOpenOut.Value = 1`:

- With a binary limit switch for the "Open" position (`NoFbkOpen = 0`):
  The valve is considered open when `FbkOpenOut` is set. `FbkOpenOut` is set when `Rbk` ≥ `PosDiOpen` and `FbkOpen = 1`.
- Without a binary limit switch for the "Open" position (`NoFbkOpen = 1`):
  The valve is considered open when `FbkOpenOut` is set. `FbkOpenOut` is set, when `Rbk` ≥ `PosDiOpen`.

**Valve opens**

If the control valve travels in the direction of the "Open" position, the output is `FbkOpngOut` = 1:

- `FbkOpngOut` is set when `MV.Value > RbkOut.Value` and is not `PosReached.Value = 1`.

**Valve has reached defined position**

If the control valve is sent to a specified intermediate position (`MV` > `PosDiClose` and `MV` < `PosDiOpen`), the targeted position is reached when the difference `MV.Value – RbkOut.Value` is within the configured tolerance range ± `PosDeadBand` and therefore `ER.Value = 0.0`.

If the control valve is set to the end position "Open" (`MV.Value >= PosDiOpen`), this position is reached when `ER.Value = 0.0` and also `FbkOpenOut.Value = 1`.

If the control valve is set to the end position "Closed" (`MV.Value <= PosDiClose`), this position is reached when `ER.Value = 0.0` and also `FbkCloseOut.Value = 1`.

When the control valve reaches the specified position, the `PosReached` = 1 output is set.

**Dynamic monitoring**

The monitoring is based on the effective feedback signals `FbkOpenOut` and `FbkCloseOut` and not directly on the feedback inputs `FbkOpen` and `FbkClose`.

A dynamic monitoring error is generated if:

- The "Close" end position is targeted (`MV` ≤ `PosDiClose`) and this position (`FbkCloseOut`) is not reached within the monitoring time `MonTiDynamic`.
- The "Close" end position is targeted (`MV` ≤ `PosDiClose`) and the feedback of the binary limit switch `FbkClose` is already within the control range.
- The "Open" position is targeted (`MV` ≥ `PosDiOpen`) and this position (`FbkOpenOut`) is not reached within the monitoring time `MonTiDynamic`.
- The "Open" end position is targeted (`MV` ≥ `PosDiOpen`) and the feedback for the binary limit switch `FbkOpen` is already within the control range.
- A further intermediate position is controlled and this position is not reached (`PosReached` = 0) within the monitoring time `MonTiDynamic`.

**Static monitoring**

The monitoring is based on the effective feedback signals `FbkOpenOut` and `FbkCloseOut` and not on the feedback inputs `FbkOpen` and `FbkClose`.

A static monitoring error is generated if:

- The "Close" end position (`FbkCloseOut` = 1) is abandoned without a command having been issued beforehand, and the monitoring time `MonTiStatic` has expired.
- The "Close" end position is reached (`FbkCloseOut` = 1), the feedback of the binary limit switch `FbkClose` is gone, and monitoring time `MonTiStatic` has expired.
- The "Open" end position (`FbkOpenOut` = 1) is abandoned without a command having been issued beforehand and the monitoring time `MonTiStatic` has expired.
- The "Open" end position is reached (`FbkOpenOut` = 1), the feedback of the binary limit switch `FbkOpen` is gone, and monitoring time `MonTiStatic` has expired.
- The valve is in intermediate position and with constant `MV`, the analog feedback `Rbk` has been changed so much that the position is no longer reached (`PosReached` = 0) and the monitoring time `MonTiStatic` has expired.

## Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

## Monitoring the feedback for the auxiliary valve

The auxiliary valve provides dynamic and static monitoring of the feedback. No special monitoring time can be configured for overseeing the retention of the end position of the auxiliary valve. If the end position is exited without the corresponding command, a "monitoring runtime error" is reported after expiration of the time configured under "Control".

Monitoring is disabled by default and no connections are displayed.

The following parameters can be used to monitor the auxiliary valve

| Parameter | Function |
|---|---|
| FbkAuxVOpen | 1 = Auxiliary valve open feedback signal |
| FbkAuxVClose | 1 = Auxiliary valve closed feedback signal |
| NoFbkAuxVOpen | 1 = No feedback present for Auxiliary valve open (default = 1) |
| NoFbkAuxVClose | 1 = No feedback present for Auxiliary valve closed (default = 1) |
| MonitorAuxV | 1 = Feedback monitoring of the auxiliary valve (default = 0) |
| MonAuxVTime | Monitoring time after auxiliary valve operation in [s] |
| MonDynAuxVErr | Dynamic monitoring error pending |
| MonStaAuxVErr | Static monitoring error pending |

Otherwise, the monitoring works like the monitoring function of the control valve.

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function Neutral position for motors, valves and controllers (Page 54).

The neutral position (de-energized state) for the auxiliary valve is set using the `SafePosAux` parameter.

- `SafePosAux` = 0 means that the auxiliary valve closes with `Ctrl` = 0 and opens with `Ctrl` = 1.
- `SafePosAux` = 1 means that the auxiliary valve opens with `Ctrl` = 0 and closes with `Ctrl` = 1 .

The setting is made with the `SafePos` parameter for the control valve.

- `SafePos` = 0 The control valve is in the "closed" position (`MV.Value` = `MV_LoLim`)
- `SafePos` = 1 The control valve is in the "open" position (`MV.Value` = `MV_HiLim`)
- `SafePos` = 2 The control valve's rest position is "Stop" (`MV.Value` = `RbkOut`, if `Rbk.ST` <> 16 # FF, otherwise MV.Value remains unchanged)

The control valve is brought to the neutral position when the `FbkAuxVCloseOut` = 1 control valve is closed.

### Generating instance-specific messages

This block provides the standard function Generating instance-specific messages (Page 230).

### Disabling of limits

The block provides the standard function Limits disabled in faceplate (Page 206).

## Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

**Resynch Main Valve**

MV =Rbk; MV is tracked and limited to MV_HiLim and MV_LoLim.

Depending on the feedback input signals and the readback input value the valve state is calculated and set as the feedback output signals**:**

MV =MV_HiLim if FbkOpen And (Rbk >= PosDiOpen)

MV =MV_LoLim if FbkClose And (Rbk <= PosDiClose)

If both feedback signals are not available (NoFbkOpen =1, NoFbkClose =1) only Rbk is considered. If only one feedback and no readback value is available an intermediate position cannot be tracked. Either a feedback signal or a readback value has to be available else resynchronization holds the controls.

**Resynch Auxiliary Valve**

**NoFbkAuxVOpen =0, NoFbkAuxVClose =0:**

**SafePosAux =0:** Ctrl := FbkAuxVOpen AND NOT FbkAuxVClose;

**SafePosAux =1:** Ctrl := FbkAuxVClose AND NOT FbkAuxVOpen;

If there are no plausible feedback positions (FbkAuxVOpen =0, FbkAuxVClose =0 or FbkAuxVOpen =1, FbkAuxVClose =1) the control position is not changed.

**NoFbkAuxVOpen =1, NoFbkAuxVClose =0:**

**SafePosAux =0:** Ctrl := NOT FbkAuxVClose;

**SafePosAux =1:** Ctrl := FbkAuxVClose;

**NoFbkAuxVClose =1, NoFbkAuxVOpen =0:**

**SafePosAux =0:** Ctrl := FbkAuxVOpen;

**SafePosAux =1:** Ctrl := NOT FbkAuxVOpen;

With other combinations **NoFbkAuxVOpen =1, NoFbkAuxVClose =1 (default)** the control position of resynchronization is not changed.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Control via auxiliary valve (Page 182) |
| 6 | Disabling opening and closing (Page 169) |
| 7 | Ramp rate calculation (Page 191) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 12 | Gradient limitation with time duration (Page 197) |
| 15 | Neutral position manipulated variable takes effect with "out of service" operating mode (Page 177) |
| 16 | Neutral position manipulated variable takes effect at startup (Page 176) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

**With auxiliary valve (`Feature.Bit5` = 1):**

In this case the automatic commands `OpenAut` and `CloseAut` control the auxiliary valve

In pushbutton operation (Bit 4 = 0) the automatic commands in automatic mode are latching, in other words `OpenAut`, and `CloseAut`, can be reset to 0 after changing the control. In manual and local modes, however, the automatic commands are not saved and in the absence of automatic commands the automatic control is tracked.

In switching mode (Bit 4 = 1), control is selected with the static signals `OpenAut`. If input `OpenAut` is not set the auxiliary valve is closed. Control via `CloseAut` is not needed. If the

"Activate command reset for control settings" function (Bit 3 = 1) is activated, the `OpenAut` input is reset to the neutral position after evaluation in the block.

**Without auxiliary valve (`Feature.Bit5` = 0):**

The analog valve is opened or closed in automatic mode with the automatic commands `OpenAut` and `CloseAut`. If `OpenAut` and CloseAut are reset, the output MV is set to `MV_Ext`. For "Activate command reset for control settings" (Bit 3 = 1), `OpenAut` and CloseAut are reset and the control elements are self-locking. This means the output `MV` is only set to `MV_Ext` after a change of `MV_Ext`. Control via switch or button mode (bit 4) does not affect the behavior of `OpenAut` and `CloseAut`.

## Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |
| 16 | Separate interlock for each direction, position, or speed (Page 180) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |

## Displaying auxiliary values

This block provides the standard function Displaying auxiliary values (Page 239).

## Alarm delays with two time values per limit pair

This block has the standard alarm delay function Two time values per limit pair (Page 227) for limit monitoring of the feedback and limit monitoring of the manipulated variable difference.

The function here relates solely to the limits of the manipulated variable difference.

## Digital feedback from the readback value

This block forms a digital position feedback for "Closed" and "Open" from the configured operating points of the position feedback values `PosDiClose` and `PosDiOpen`.

## Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "automatic mode" |
| 1 | 1 = Operator can switch to "manual mode" |
| 2 | 1 = Operator can switch to "local mode" |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can open the valve |
| 5 | 1 = Operator can close the valve |
| 6 | 1 = Operator can reset the valve |
| 7 | 1 = Operator can define the monitoring time for startup |
| 8 | 1 = Operator can define the monitoring time for the end position |
| 9 | 1 = Operator can enable the monitoring the control valve feedback function (Bit 7 - 8) |
| 10 | 1 = Operator can activate the Simulation function |
| 11 | 1 = Operator can activate the Release for maintenance function |
| 12 | 1 = Operator can change the simulation value `SimRbk` |
| 13 - 23 | Not used |
| 24 | 1 = Operator can define the monitoring time of the auxiliary valve for startup |
| 25 | Not used |
| 26 | 1 = Operator can enable the monitoring the auxiliary valve feedback function (Bit 24) |
| 27 - 31 | Not used |

The block has the following operator permissions for the `OS1Perm` parameter:

| Bit | Function |
|---|---|
| 0 - 3 | Not used |
| 4 | 1 = Operator can switch the manipulated variable to "external" `MV_ExtOp` |
| 5 | 1 = Operator can switch the manipulated variable to "internal" `MV_IntOp` |
| 6 | Not used |
| 7 | 1 = Operator can change the manual manipulated variable `MV_Int` |
| 8 - 9 | Not used |
| 10 | 1 = Operator can change the operation high limit of the manipulated variable `MV_HiLim` |
| 11 | 1 = Operator can change the operation low limit of the manipulated variable `MV_LoLim` |
| 12 | 1 = Operator can enable the manipulated variable's gradient limitation function `MV_RateOn` |
| 13 | 1 = Operator can change the manipulated variable's high limit for the ramp `MV_UpRaLim` |
| 14 | 1 = Operator can change the manipulated variable's low limit for the ramp `MV_DnRaLim` |
| 15 | 1 = Operator can switch between the time value or the value for the ramp (`MV_RmpModTime`) |
| 16 | 1 = Operator can change the ramp time `MV_RmpTime` |
| 17 | 1 = Operator can change the target manipulated variable `MV_RmpTarget` for the manipulated variable ramp |

| Bit | Function |
|---|---|
| 18 | 1 = Operator can enable the manipulated variable ramp function MV_RmpOn |
| 19 | Not used |
| 20 | 1 = Operator can enable the track manipulated variable function in tracking mode MV_TrkRbk |
| 21 | 1 = Operator can enable the bumpless switchover from external to internal MV_TrkExt |
| 22 | 1 = Operator can activate / deactivate messages via ER_AH_MsgEn |
| 23 | 1 = Operator can activate / deactivate messages via ER_AL_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via RbkWH_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via RbkWL_MsgEn |
| 26 | 1 = Operator can change the limit (manipulated variable difference) for the high alarm ER_AH_Lim |
| 27 | 1 = Operator can change the hysteresis (manipulated variable difference) ER_Hyst |
| 28 | 1 = Operator can change the limit (manipulated variable difference) for the low alarm ER_AL_Lim |
| 29 | 1 = Operator can change the limit (position feedback) for the high warning RbkWH_Lim |
| 30 | 1 = Operator can change the hysteresis (position feedback) RbkHyst |
| 31 | 1 = Operator can change the hysteresis (position feedback) for low warning RbkWL_Lim |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

## Generation of manipulated variables

The manipulated variable MV is formed as follows:

| MV_ForOn | CloseForce | OpenForce | ManAct | AutAct | LocalAct | MV_TrkOn | MV_TrkRbk | MV_ExtAct | MV = | Limit | State |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 0 | 0 | – | – | – | – | – | – | MV_Forced | none | Forced tracking without limit |
| – | 1 | 0 | – | – | – | – | – | – | MV_OpScale.Low | MV_OpScale.Low | Forced close |
| – | 0 | 1 | – | – | – | – | – | – | MV_OpScale.High | MV_OpScale.High | Forced open |
| 0 | 0 | 0 | 1 | 0 | 0 | 0 | – | 0 | MV_Int | MV_HiLim MV_LoLim | Manual mode with internal manipulated variable |
| 0 | 0 | 0 | 1 | 0 | 0 | 0 | – | 1 | MV_ExtOut | MV_HiLim MV_LoLim | Manual mode with external manipulated variable and limit |
| 0 | 0 | 0 | 0 | 1 | 0 | 0 | – | 0 | MV_Int | MV_HiLim MV_LoLim | Automatic with internal manipulated variable and limit |

| MV_ For On | Close Force | OpenF orce | Man Act | Aut Act | Local Act | MV_ Trk On | MV_ Trk Rbk | MV_ Ext Act | MV = | Limit | State |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 1 | 0 | 0 | – | 1 | MV_ExtOut | MV_HiLim MV_LoLim | Automatic with external manipulated variable and limit |
| 0 | 0 | 0 | – | – | 0 | 1 | 0 | – | MV_Trk | MV_HiLim MV_LoLim | Tracking with limitation |
| 0 | 0 | 0 | 0 | – | 0 | 1 | 1 | – | Rbk | none | Tracking to position feedback without limit |
| 0 | 0 | 0 | 0 | 0 | 1 | – | – | – | Rbk | None | Local mode with tracking to position feedback without limit |

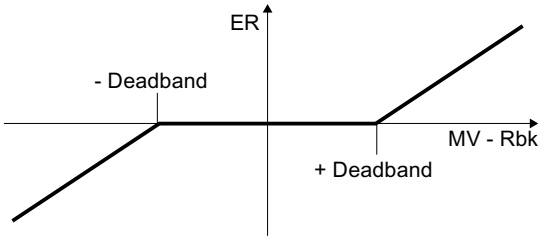
### "Actuator active" information

- The following applies for PosReached.Value = 0:
  With PosDiClose < MV < PosDiOpen, the control valve is detected as active and Bit 24 is set in Status1.
- The following applies for PosReached.Value = 1:
  Status1.Bit 24 = 0

This status can be used to indicate a customized symbol in the process image, for example, and is saved in the status word (see Status word section in Description of VlvAnL (Page 1808)).

### General function "MV difference"

The manipulated variable difference is sent to the ER output and is calculated with the following formula:



ER = MV - Rbk

If ER is within the dead band, ER = 0 is set and the manipulated variable is considered reached.

### Manipulated variable difference generation and dead band

The manipulated variable difference is formed by the effective manipulated variable MV and the position feedback Rbk, and sent to the ER output. A dead band can be set at the PosDeadBand input:

- PosDeadBand = 0 Dead band is disabled
- PosDeadBand ≠ 0 Dead band is enabled

### Limit monitoring of manipulated variable and error signal

The block provides the standard function Limit monitoring of setpoint, manipulated variable and control deviation (Page 102).

Monitoring is disabled in the following situations:

- The auxiliary valve is closed
- The control valve is in the neutral position

### Providing limits at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

```
ER_AH_LimOut := ER_AH_Lim;
ER_AL_LimOut := ER_AL_Lim;
```

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Specifying warning times for control functions at motors and valves

This block provides the standard function Specifying warning times for control functions at motors and valves (Page 56).

The warning time affect the analog manipulated variable `MV`. The output is updated only with the specification of a new manipulated variable after the warning time has expired.

Warning time is ignored in tracking `MV_TrkOn` = 1 and in forced tracking `MV_ForOn`.

### Disabling feedback

This block provides the standard function Disabling feedback for valves (Page 106).

This function is available for both the control valve and auxiliary valve. The feedback for the auxiliary valve is disabled by default, connections are not displayed.

The disable setting is made with the `NoFbkOpen` and `NoFbkClose` parameters for the control valve.

The disable setting is made with the `NoFbkAuxVOpen` and `NoFbkAuxVClose` parameters for the auxiliary valve.

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### Button labels

This block provides the standard function Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- `OpenMan`
- `CloseMan`

### Outputs for status of drive

The block has the following outputs to indicate the status of the drives. In the CFC plan, this information can be further interconnected:

| | |
|---|---|
| Closed =1 | Valve is in position closed:<br>`MV` <= `PosDiClose`, (`RbkOut` <= `PosDiClose`) AND `FbkClose` =1 |
| Opened =1 | Valve is in position opened:<br>`MV` >= `PosDiOpen`, (`RbkOut` >= `PosDiOpen`) AND `FbkOpen` =1 |
| Closing =1 | Control is in position closed and feedbacks are not in position closed:<br>`MV` <= `PosDiClose`, (`RbkOut` > `PosDiClose`) OR `FbkClose` =0 |
| Opening =1 | Control is in position opened and feedbacks are not in position opened:<br>`MV` >= `PosDiOpen`, (`RbkOut` < `PosDiOpen`) OR `FbkOpen` =0 |
| Stop =1 | Control and feedbacks are in same position. Position is reached. |

**Note**

The outputs for status of drive are only can be active if there is no monitoring error:

`MonDynErr` =0, `MonStaErr` =0

## 8.13.4 VlvAnL error handling

### Error handling of VlvAnL

Refer to section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Invalid input signals
- Control system fault (CSF)

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 41 | The value of the `LocalSetting` connection is outside the valid range. Valid values are 0, 2 and 4 |
| 42 | `LocalSetting` = 0 or `LocalSetting` = 4 and `LocalLi` = 1 |
| 51 | `AutModLi` = 1 and `ManModLi` = 1<br>`OpenAut` = 1 and `CloseAut` = 1<br>`OpenForce` = 1 and `CloseForce` = 1<br>`MV_LiOp` = 1 and `MV_IntLi` = 1 and `MV_ExtLi` = 1; Only when using auxiliary valve (`Feature.Bit5 = 1`) |
| 52 | `LocalSetting` = 2 or 4 and `SimOn` = 1 |

### Mode switchover error

This error can be output by the block, see the section Error handling (Page 128).

### Invalid input signals

This error can be output by the block, see the section Error handling (Page 128).

For the following invalid input signals, the control output can be kept or switched to the neutral position. This depends on the function  control priority for invalid input command (Page 186).

| **Operating mode** | **Invalid input signals** | **Control reaction with `Feature2.Bit3` = 1** |
|---|---|---|
| Forcing | `OpenForce` = 1 and `CloseForce` = 1 | Valve without auxiliary valve (`Feature.Bit5` = 0):<br>Valve is set to its neutral position.<br><br>Valve with auxiliary valve (`Feature.Bit5` = 1):<br>Valve is set to its neutral position. |
| "Automatic mode" and no forcing | Pushbutton operation (`Feature.Bit4` = 0):<br>`OpenAut` = 1 and `CloseAut` = 1 | |
| "Manual mode" and no forcing | `OpenMan` = 1 and `CloseMan` = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. A control system fault is triggered if this signal changes to 1. Refer to the Error handling (Page 128) section for more on this.

## 8.13.5 VlvAnL messaging

### Messaging

The following messages can be generated for this block:

- Process control fault
- Instance-specific messages
- Process messages

### Process control fault

- The following control system error messages can be output:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 1 | AS process control message - fault | $$BlockComment$$<br>Feedback error |
| | SIG 6 | AS process control message - fault | External error has occurred |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to input parameter CSF. If it changes to CSF = 1, a process control fault is triggered (MsgEvId1, SIG 6).

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 2 | Alarm - high | $$BlockComment$$<br>ER - high alarm limit violated |
| | SIG 3 | Alarm - low | $$BlockComment$$<br>ER - low alarm limit violated |
| | SIG 4 | Warning - high | $$BlockComment$$<br>Rbk - high warning limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>Rbk - low warning limit violated |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Instance-specific messages

You have the option to use one or two instance-specific messages for this block.

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG 7 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 8 | AS process control message - fault | $$BlockComment$$<br>External message 2 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |

| Associated value | Block parameters |
|---|---|
| 3 | BatchID |
| 4 | ExtVal04 |
| 5 | ExtVal05 |
| 6 | ExtVal06 |
| 7 | ExtVa107 |
| 8 | ExtVa108 |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 ... 8 are allocated to the parameters ExtVa104 ... ExtVa108 and can be used. Additional information is available in the "Process Control System PCS 7 - Engineering System" manual.

I/Os of VlvAnL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameter

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutModLi* | 1= "Automatic mode" via interconnection or SFC (controlled by ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutModOp* | 1 = "Automatic mode" via operator (controlled by ModLiOp = 0) | BOOL | 0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BypProt | 1 = Bypassing interlock is active in "local mode" and in simulation | BOOL | 0 |
| CloseAut* | 1 = Select Close valve in "automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseForce | 1 = Force valve closure | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseMan* | 1 = Select Close valve in "manual mode" | BOOL | 0 |
| CSF | 1 = External error (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlChnST | Signal status of output channel for Ctrl<br>Should be connected to an output channel block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ER_A_DC* | Delay for incoming alarms during manipulated variable difference monitoring | REAL | 0.0 |
| ER_A_DG* | Delay for outgoing alarms during manipulated variable difference monitoring | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for manipulated variable difference monitoring | BOOL | 1 |
| ER_AH_Lim | Alarm limit (high) for manipulated variable difference monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Activate messages for alarm (high) for manipulated variable difference monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for manipulated variable difference monitoring | REAL | -100.0 |
| ER_AL_En | 1 = Activate alarm (low) for manipulated variable difference monitoring | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ER_AL_MsgEn | 1 = Activate messages for alarm (low) for manipulated variable difference monitoring | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for manipulated variable difference monitoring | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTsIn input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| PermCls | 1 = Activation close enable<br>0 = No activation close enable | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| PermClsEn | 1 = Parameter PermCls is enabled | BOOL | 1 |
| Perm_En | 1 = Parameter Permit enable | BOOL | 1 |
| Permit | 1 = Activation enable / Activation open enable.<br>0 = No activation enable / No activation open enable. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermitSafePos | 1=Valve SafePos allowed | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL<br>(Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermSf_En | 1=Permit SafePos enabled | BOOL | 1 |
| PosDeadBand | Dead band for forming manipulated variable difference | REAL | 0.1 |
| PosDiClose | Limit for control valve position "closed" | REAL | 5.0 |
| PosDiOpen | Limit for control valve position "open" | REAL | 95.0 |
| ProtCls | 0 = Protective interlock close is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock close is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 1<br>• 16#FF |
| ProtClsEn | 1 = Parameter ProtCls enable | BOOL | 1 |
| Prot_En | 1 = Parameter Protect enabled | BOOL | 1 |
| Protect | 0 = Protective interlock / protective interlock open is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock / protective interlock open is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE | -<br>• 1<br>• 16#FF |
| Rbk | Position feedback for display on OS | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkW_DC* | Delay time for incoming warnings [s] | REAL | 0.0 |
| RbkW_DG* | Delay time for outgoing warnings [s] | REAL | 0.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 0 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 90.0 |
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 0 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 10.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | Neutral position for control valve:<br>0 = Closed<br>1 = Open<br>2 = Stop (valve can be in position Closed, Opened or Intermediate) | INT | 0 |
| SafePosAux | Neutral position for auxiliary valve:<br>1= Open<br>0 = Closed | BOOL | 0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimRbk* | Position feedback used for SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| WarnTiAut | Prewarning of valve movement in automatic mode in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan | Prewarning of valve movement in manual mode in [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode", "Local mode" or "Out of service" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AuxClosed | 1 = Auxiliary valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AuxClsing | 1 = Auxiliary valve is closing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AuxOpened | 1 = Valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AuxOpning | 1 = Auxiliary valve is opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CascaCut | Cascade connection:<br>1 = Control chain from master controller to secondary valve is interrupted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Closed` | 1 = Valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `Closing` | 1 = Valve is closing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `Ctrl` | Control output for auxiliary valve (depends on `SafePosAuxV`) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `CurrMon` | Remaining monitoring time [s] | DINT | 0 |
| `CurrMonAuxV` | Remaining auxiliary valve monitoring time [s] | DINT | 0 |
| `ENO` | 1 = Block algorithm completed without errors | BOOL | 0 |
| `ER` | Manipulated variable difference | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `ER_AH_Act` | 1 = Alarm limit (high) for manipulated variable difference violated.<br>You can change the reaction for this parameter with `Feature.Bit28` (Disabling operating points (Page 156)) and with `Feature.Bit29` (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `ER_AL_Act` | 1 = Alarm limit (low) for manipulated variable difference violated.<br>You can change the reaction for this parameter with `Feature.Bit28` (Disabling operating points (Page 156)) and with `Feature.Bit29` (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `ER_AH_LimOut` | ER_AH_Lim as output | REAL | 0.0 |
| `ER_AL_LimOut` | ER_AL_Lim as output | REAL | 0.0 |
| `ErrorNum` | Output of pending error number. For error numbers that can be output by this block, see VlvAnL error handling (Page 1832) | INT | -1 |
| `FaultExtOut` | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkAuxVCloseOut` | 1 = Auxiliary valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `FbkAuxVOpenOut` | 1 = Auxiliary valve open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkCloseOut` | 1 = Control valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkClsgOut` | Control valve closing feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkOpenOut` | 1 = Control valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `FbkOpngOut` | Control valve opening feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `GrpErr` | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `IntlockOut` | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `IntlClsOut` | IntlCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `LocalAct` | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `LockAct` | 1 = Interlock (`Intlock`, `Permit` or `Protect`) is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `ManAct` | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| `MonDynAuxVErr` | 1 = Feedback error auxiliary valve due to output change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `MonDynErr` | 1 = Feedback error control valve due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MonStaAuxVErr | 1 = Feedback error from auxiliary valve due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonStaErr | 1 = Feedback error from control valve due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message acknowledgement status 1 (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Alarm error 1 (output ERROR of first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (output STATUS of first ALARM_8P) | WORD | 16#0000 |
| MV | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_DnRaAct | Positive limit (low) for manipulated variable is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_ExtAct | 1 = External manipulated variable active<br>0 = Internal manipulated variable active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_ExtOut | Output for external manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_RateTarget | Target manipulated variable for the gradient limitation | REAL | 0.0 |
| MV_UnitOut | Unit of measure for manipulated variable | INT | 0 |
| MV_UpRaAct | Positive limit (high) for manipulated variable is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_RemRT | Remaining ramp time of the manipulated variable | REAL | 0.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opened | 1 = Valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opening | 1 = Valve is opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePosOut | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>ST: BYTE | -<br>• 1<br>• 16#FF |
| PermClsOut | PermCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtClsOut | ProtCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PosReached | 1 = Control valve has reached specified position | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RbkOut | Position feedback output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Active start readiness | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1808) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1808) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1808) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1808) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1808) | DWORD | 16#00000000 |
| Stop | 1 = Valve is stopped | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |
| StopCtrl | Control output go to SafePos | BOOL | 0 |
| WarnAct | 1 = Prewarning for control valve movement away from neutral position active (parameters WarnTiAut and WarnTiMan)) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

"local", "automatic", or "manual" mode"

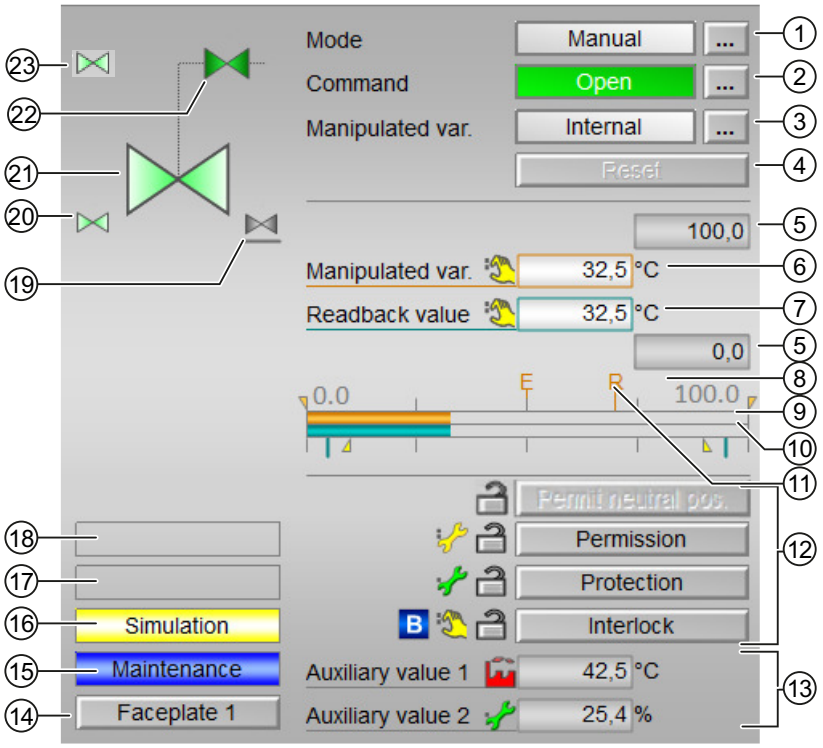
## 8.13.8 Operator control and monitoring

### 8.13.8.1 VlvAnL views

#### Views of the VlvAnL block

The VlvAnL block provides the following views:

- VlvAnL standard view with auxiliary valve (Page 1852)
- VlvAnL standard view without auxiliary valve (Page 1857)
- VlvAnL limit view (Page 1863)
- Alarm view (Page 336)
- Trend view (Page 341)
- VlvAnL parameter view (Page 1871)
- VlvAnL preview (Page 1865)
- Memo view (Page 338)
- Batch view (Page 336)
- Ramp view (Page 334)
- Block icon for VlvAnL (Page 1872)



Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

#### See also

Parameter view for motors and valves (Page 320)

### 8.13.8.2 VlvAnL standard view with auxiliary valve

#### Standard view with auxiliary valve of VlvAnL

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Opening, closing and stopping the control valve

This area shows you the default operating state for the valve. The following states can be shown and executed here:

- "Open"
- "Close"
- "Stop" (display only, no operation possible)

"Close"/"open" command relates to the auxiliary valve.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (3) Displaying and switching the default manipulated variable

This area shows how to specify the manipulated variable. The manipulated variable can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the setpoint specification.

### (4) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (5) High and low scale range for the manipulated variable

These values provide information on the display range for the bar graph of the manipulated variable. The scale range is defined in the engineering system. For more information refer Bar graph (Page 376).

### (6) Displaying and changing the manipulated variable including signal status:

This area shows the current manipulated variable with the corresponding signal status.

The manipulated variable can only be changed by

- Internal manipulated variable specification (`MV_ExtAct` = 0) and
- An opened auxiliary valve (due to the dependency on the standard function Neutral position for motors, valves and controllers (Page 54))

For more information on changing the manipulated variable, refer to section Changing values (Page 291).

### (7) Display of the position feedback including signal status

This area shows the current feedback of the manipulated variable with the corresponding signal status.

### (8) Display for the target manipulated variable of the manipulated variable ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (9) Bar graph for the manipulated variable

This area shows the current manipulated variable in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (10) Bar graph for position feedback

This area shows the current position feedback in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

The limits for the "open" and "close" positions are shown with 2 green lines.

### (11) Display of external manipulated variable

This display [E] is only visible when you have selected "Internal" manipulated variable specification. It shows the external manipulated variable that would apply if you were to change the manipulated variable specification to "External".

### (12) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

  If there is a bypass, it is displayed instead of the signal status.

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (13) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (14) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the section Opening additional faceplates (Page 234) for more on this.

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (16) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in the section Simulating signals (Page 64).

### (17) Display area for block states

This area provides additional information on the operating state of the block:

- "External error"
- "End position error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104), Error handling (Page 128) (section "Invalid input signals" and "Mode changeover error").

### (18) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced open" (`OpenForce`)
- "Forced close" (`CloseForce`)
- "Forced tracking" (`MV_ForOn`)
- "Tracking" (`MV_TrkOn`)
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer: Reset of errors during Request 0/1 (Page 382)
- "MV ramp active"

You can find additional information on this in the section Forcing operating modes (Page 45).

### (19) Representation of neutral position

This representation shows the neutral position for the control valve:

- **Green:** Neutral position is "Open"
- **Gray:** Neutral position is "Closed"
- **Light green:** Neutral position is "Stop"

### (20) Automatic preview

This display is only visible in "manual mode", in "local mode" or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the valve would assume if you switched from "manual" or "local" mode to "automatic mode" or performed a reset to "automatic mode".

| Mode | Discription |
|---|---|
|  | Open: The control output will go to position open: `MV >= PosDiOpen` |
|  | Close: The control output will go to position close: `MV <= PosDiClose` |
|  | Stop: The control output will go to intermediate position: `PosDiClose < MV < PosDiOpen` |

The `OpenAut`, `CloseAut` commands switch on the energy for the valve.

The symbols are only visible if the new position is different to the actual position.

### (21) Status display of the control valve

You can find more information about this in section Block icon for VlvAnL (Page 1872).

### (22) Picture of auxiliary valve

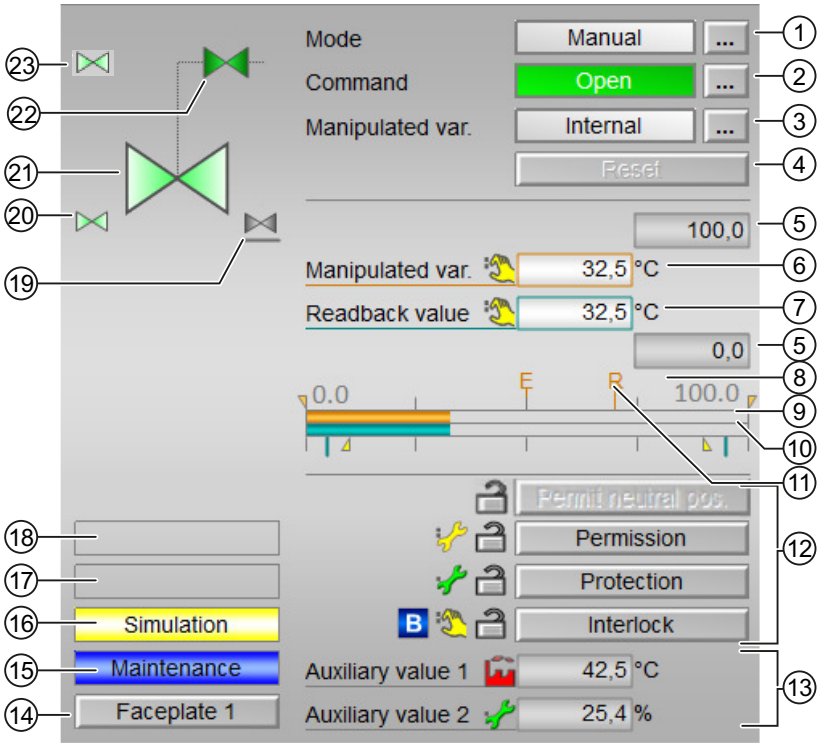
The small auxiliary valve and the associated line are only shown when the control valve has an additional auxiliary valve and it can be controlled. This can be configured with `Feature.Bit5` on the block.

The current status of the auxiliary valve is graphically displayed here.

### (23) Mini preview for Resynchronization

Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:



- Open
- Close
- Intermediate

**Note**

Mini preview for resynch is visible only if resynchronization command is different to control output value.

## 8.13.8.3 VlvAnL standard view without auxiliary valve

### Standard view without auxiliary valve of VlvAnL

### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

### (2) Opening, closing and stopping the control valve

This area shows you the default operating state for the valve. The following states can be shown and executed here:

- "Open"
- "Close"
- "Stop" (display only, no operation possible)

"Close"/"Open" command relates to the control valve.

The "Open" command sets the manipulated variable equal to the high limit of the control range (`MV_OpScale.High`).

The "Close" command sets the manipulated variable equal to the low limit of the control range (`MV_OpScale.Low`)

If there is no auxiliary valve (`Feature.Bit5` = 0), the command line can be completely hidden with `Feature.Bit6`.

- 0: (default) line is displayed
- 1: Command line hidden.

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (3) Displaying and switching the default manipulated variable

This area shows how to specify the manipulated variable. The manipulated variable can be specified as follows:

- By the application ("External", CFC/SFC)
- By the user directly in the faceplate ("Internal").

If there is no auxiliary valve, the specification of the manipulated variable depends on the mode, "manual" or "automatic". You cannot switch between "internal" and "external" here in this case.

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the setpoint specification.

### (4) Resetting the block

Click "Reset" for interlocks or errors. You can find additional information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (5) High and low scale range for the manipulated variable

These values provide information on the display range for the bar graph of the manipulated variable. The scale range is defined in the engineering system. For more information refer Bar graph (Page 376).

### (6) Displaying and changing the manipulated variable including signal status:

This area shows the current manipulated variable with the corresponding signal status.

The manipulated variable can only be changed by internal manipulated variable specification (`MV_ExtAct` = 0).

For more information on changing the manipulated variable, refer to section Changing values (Page 291).

### (7) Display of the position feedback including signal status

This area shows the current feedback of the manipulated variable with the corresponding signal status.

### (8) Display for the target manipulated variable of the manipulated variable ramp

This display [R] shows the target setpoint and is only visible if you have enabled ramp generation in the Ramp view (Page 334).

### (9) Bar graph for the manipulated variable

This area shows the current manipulated variable in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (10) Bar graph for position feedback

This area shows the current position feedback in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

The limits for the "open" and "close" positions are shown with 2 green lines.

### (11) Display of external manipulated variable

This display [E] is only visible when you have selected "Internal" manipulated variable specification. It shows the external manipulated variable that would apply if you were to change the manipulated variable specification to "External".

### (12) Operating range for the interlock functions of the block

This display is only visible when the corresponding block input is connected.

You can use this button to control the interlock functions of the block. You can find additional information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

  If there is a bypass, it is displayed instead of the signal status.

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (13) Display of auxiliary values

This display is only visible when the corresponding block input is connected.

You can use this area to display two auxiliary values that have been configured in the engineering system (ES). You can find additional information on this in the section Displaying auxiliary values (Page 239).

### (14) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

See also the section Opening additional faceplates (Page 234) for more on this.

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

Additional information on this is available in section Release for maintenance (Page 70) Display area for block states.

### (16) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Delay"

You will find more detailed information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (17) Display area for block states

This area provides additional information on the operating state of the block:

- "External error"
- "End position error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Invalid Signal"

Additional information on these errors is available in the sections Monitoring the feedbacks (Page 104), Error handling (Page 128) (section "Invalid input signals" and "Mode changeover error").

### (18) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced open" (`OpenForce`)
- "Forced close" (`CloseForce`)
- "Forced tracking" (`MV_ForOn`)
- "Tracking" (`MV_TrkOn`)
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer: Reset of errors during Request 0/1 (Page 382)
- "MV ramp active"

You can find additional information on this in the section Forcing operating modes (Page 45).

### (19) Representation of neutral position

This representation shows the neutral position for the control valve:

- **Green:** Neutral position is "Open" or neutral position is “Stop” and valve is opened
- **Gray:** Neutral position is "Closed" or neutral position is “Stop” and valve is closed
- **Light green:** Neutral position is "Stop" and valve is in intermediate position

### (20) Automatic preview

This display is only visible in "manual mode", in "local mode" or with a reset request in "automatic mode", when the current output signals are not identical to the control in "automatic mode".

The display shows what state the valve would assume if you switched from "manual" or "local" mode to "automatic mode" or performed a reset to "automatic mode".

| Mode | Discription |
|---|---|
|  | Open: The control output will go to position open: `MV >= PosDiOpen` |
|  | Close: The control output will go to position close: `MV <= PosDiClose` |
|  | Stop: The control output will go to intermediate position: `PosDiClose < MV < PosDiOpen` |

The `OpenAut`, `CloseAut` commands set the MV control to open or close position.

The symbols are only visible if the new position is different to the actual position.

### (21) Picture of control valve

The current status of the control valve is graphically displayed here.

You can find more information about this in section Block icon for VlvAnL (Page 1872).

### (22) Picture of auxiliary valve

The small auxiliary valve and the associated line are only shown when the control valve has an additional auxiliary valve and it can be controlled. This can be configured with `Feature.Bit5` on the block.

The current status of the auxiliary valve is graphically displayed here.

### (23) Mini preview for Resynchronization

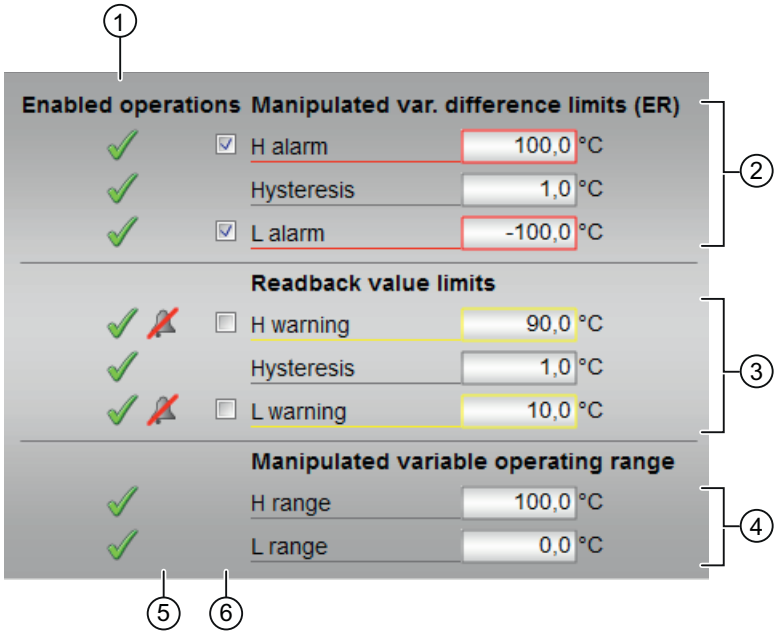
Displays the Resynchronization state and Resynchronization Signal status based on feedback and readback values.

The mini preview displays the following states:

- Open
- Close
- Intermediate

**Note**

Mini preview for resynch is visible only if resynchronization command is different to control output value.



### 8.13.8.4 VlvAnL limit view

#### Limit view of VlvAnL

Several values are set in this view by default:

- Manipulated variable difference limits
- Readback value limits
- Manipulated variable operating range

The toolbars of the faceplate and the block icon indicate when the limits are reached or violated.

#### (1) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

#### (2) Manipulated variable difference limits

In this area, you can enter the limits for the manipulated variable error. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "Hysteresis"
- "L alarm": Alarm low

### (3) Readback value limits (MV)

In this area, you can enter the limits for the readback value (position feedback). Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H warning": Warning high
- "Hysteresis"
- "L warning": Warning low

### (4) Manipulated variable operating range (MV)

In this area, you can enter the limits for the manipulated variable operation range. Refer to the Changing values (Page 291) section for more on this.

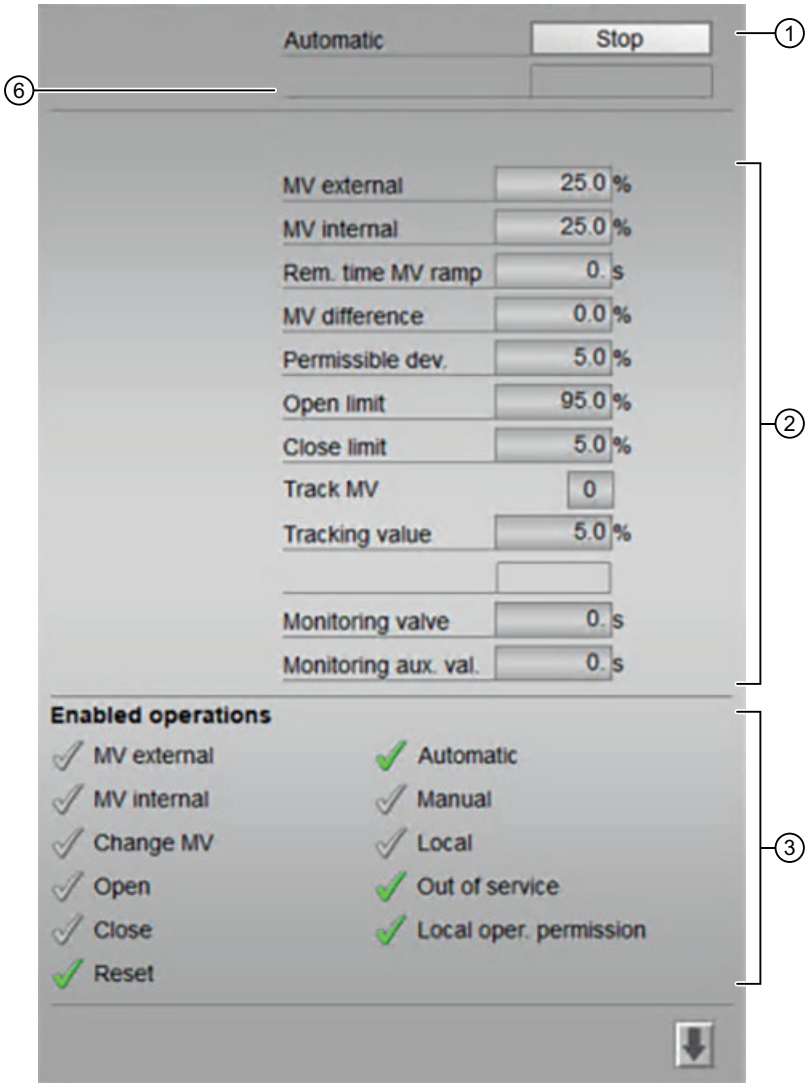
You can change the following limits:

- "H range": Range limit high
- "L range": Range limit low

### (5) Message suppression / delay

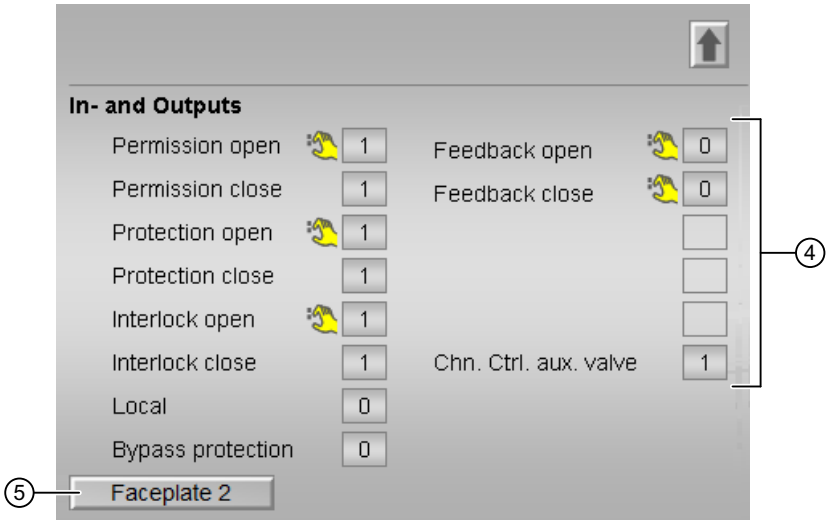
Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

Alarm delays are also displayed in this position; for more on this see section



Area of application of the alarm delays (Page 225).

### (6) Suppress messages



You can enable / disable messages by setting the check mark.

### 8.13.8.5 VlvAnL preview

**Preview of VlvAnL**

The preview has an upper half and a lower half. You can change between the two halves with the arrow keys.

## (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

If the block is in "Automatic" mode, the current block state is displayed.

| Mode | Discription |
|---|---|
| Open | Automatic commands will open the valve or valve is already opened: `MV >= PosDiOpen` |
| Close | Automatic commands will close the valve or valve is already closed: `MV <= PosDiClose` |
| Stop | Automatic commands will set the valve to intermediate position or valve is already in intermediate position: `PosDiOpen <= MV <= PosDiClose` |

**Note**

If the valve is closed and interlock locking is active (SafePos=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".

This area also displays the worst signal status of the following automatic commands:

- `OpenAut`
- `CloseAut`
- `MV_Ext`

### (2) Preview area

- "Manipulated variable external": Display current external manipulated variable (`MV_ExtOut`).
- "Manipulated variable internal": Display current internal manipulated variable (`MV_Int`).
- "Rem. time MV ramp": Remaining time to reach the ramp target value.
- "Manipulated variable difference": Current manipulated variable error (`ER`)
- "Permissible dev.": Permissible ± deviation (`PosDeadBand`) of manipulated variable that is output. If the manipulated variable feedback `Rbk` is within this range, the manipulated variable is considered reached.
- "Open limit": Limit (`PosDiOpen`) for forming the "Control valve Open" signal (`FbkOpenOut`). If the position feedback reaches this limit, the control valve is open.
- "Close limit": Limit (`PosDiClose`) for forming the "Control valve Closed" signal (`FbkCloseOut`). If the position feedback reaches this limit, the control valve is closed.
- "Manipulated variable tracking": (`MV_TrkOn` = 1) manipulated variable is corrected to the tracking value. Tracking value for the effective manipulated variable for "Track manipulated variable"
- "Channel MV" Display of the manipulated variable by the output channel block
- "Auxiliary valve monitoring" Display of the remaining monitoring time of the auxiliary valve.
- "Monitoring valve" Display of the remaining monitoring time of the valve.
- "Rbk Resync": Shows the input Rbk value for Resynchronization

### (3) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Manipulated variable external": You can enable external manipulated variable specification
- "Manipulated variable internal": You can enable internal manipulated variable specification
- "Change MV": You can change the manipulated variable
- "Open": You can open the valve. The display always relates to the auxiliary valve and control valve. Neither the auxiliary valve nor the control valve can be opened if there is no enable. For the control valve this means: If a new manipulated variable is greater than the current valve position, this new manipulated variable take effect.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Close": You can close the valve. The display always relates to the auxiliary valve and control valve. Neither the auxiliary valve nor the control valve can be closed if there is no enable. For the control valve this means: If a new manipulated variable is less than the current valve position, this new manipulated variable does not take effect and the control valve retains its position.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Reset": You can reset the valve if interlocks or errors occur.
- "Automatic": You can switch to "automatic mode".
- "Manual": You can switch to "manual mode".
- "Local": You can switch to "local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the OpStations block. For more information, see section Operator control permissions (Page 285).

### (4) Inputs and outputs

This area shows the most important parameters for this block with the current selection.

- "Permission" (`Feature2.Bit16` **= 0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "opening"/"closing" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission open" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "open" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission close" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "close" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Permit neutral pos" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = prevents stop command to the motor
  - 1 = prevents the control in safe position direction

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection" (`Feature2.Bit16` **= 0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is in effect; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection open" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is in effect; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection close" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is in effect; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock" (`Feature2.Bit16` **= 0**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock open" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Interlock close" (`Feature2.Bit16` **= 1**):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (LocalLi) is active
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypassing interlock in "local mode" and in "simulation"

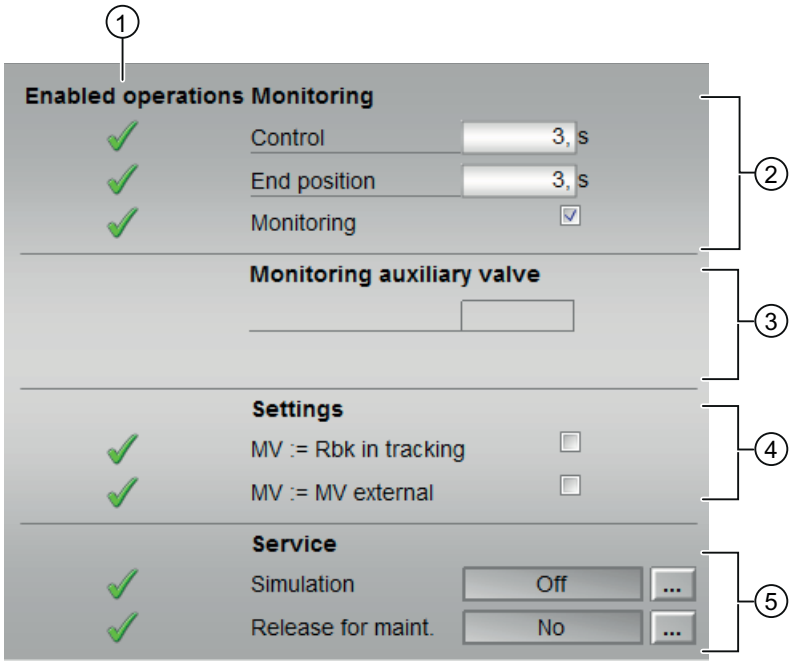
Since, depending on the configuration, the block itself forms the digital feedback signals internally via the "Open" and "Closed" positions, the following reaction results from the "Feedback open" and "Feedback closed" signals.

- Control valve:
  - "Feedback open": The display is derived from the `FbkOpenOut` output. However, this output is formed from the configured limit for the "Open" position.
  - "Feedback close": The display is derived from the `FbkCloseOut` output. However, this output is formed from the configured limit for the "Closed" position.
- "Control auxiliary valve": only visible when there is a auxiliary valve
  - Control binary control `Ctrl.Out`
  - "Feedback open auxiliary valve": `FbkAuxVOpenOut`.
  - "Feedback closed auxiliary valve": `FbkAuxCloseOut`.
  - "Channel Control auxiliary valve": Signal for controlling the auxiliary valve by the output channel block

### (5) Navigation button for switching to the standard view of any faceplate

This display is only visible when the corresponding block input is connected.

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).



For more information, see section Opening additional faceplates (Page 234).

### (6) Resynchronization

Displays the Resynchronization state and Resynchronization Signal status based on feedback and readback values.

### 8.13.8.6 VlvAnL parameter view

#### Parameter view of VlvAnL

#### (1) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

#### (2) Monitoring

In this area, you change parameters and therefore influence the control valve. Refer to the Changing values (Page 291) section for more on this.

You can influence the following parameters:

- "Control": Monitoring time during opening and closing of the control valve (dynamic)
- "End position": Monitoring time of the end position of the control valve (static)

**Enable monitoring**

You can enable monitoring by selecting the check box (☑)

You can find additional information on this in the section Monitoring the feedbacks (Page 104).

### (3) Monitoring auxiliary valve

As under **(2)** Monitoring, but only visible when there is an auxiliary valve. Only one common monitoring time can be entered for dynamic and static monitoring.

### (4) Settings

- `MV` = `Rbk` in tracking mode: Correction is performed with the position feedback `Rbk` instead of the `MV_Trk` tracking value. The switchover from "Track manipulated variable" (`MV_TrkOn` = 1) to "Do not track manipulated variable" is bumpless (`MV_TrkOn` = 0).
  Set `MV_TrkRbk` parameter.
- `MV` = `MV` extern: Bumpless switchover of manipulated variable from external to internal. The internal manipulated variable is tracked to the external one.
  Set `MV_TrkExt` parameter.

### (5) Service

You can select the following functions in this area:

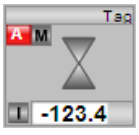
- "Simulation"
- "Release for maintenance" (with display for a maintenance request)

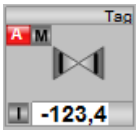
Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Simulating signals (Page 64)
- Release for maintenance (Page 70)

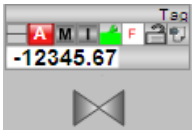
## 8.13.8.7 Block icon for VlvAnL

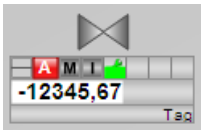




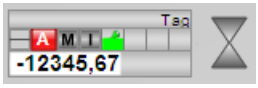
### Block icons for VLvAnL

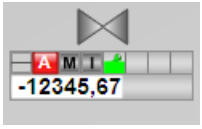
A variety of block icons are available with the following functions:

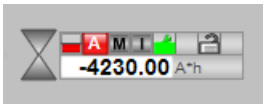


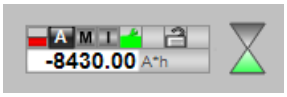


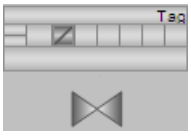
- Limits (high/low)
- Alarm violation. Warning and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Forcing states
- Displays for bypassing interlocks











- Interlocks
- Valve status display
- Display of feedback value (white, with decimal places)
- Operation of the manipulated variable
- Process tag type
- External/internal manipulated variable specification
- Memo display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Non-rotating block icon |
|  | 4 | Non-rotating block icon |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Valve status display

The following valve states are shown here:

| Icon | Meaning |
|---|---|
|  | Valve open |
|  | Valve closed |
|  | Error at valve |
|  | Valve is opening |

| Icon | Meaning |
|---|---|
|  | Valve is closing |
|  | Valve stopped |
|  | Valve closed |
|  | Valve is closing |

# 8.14 VlvPosL - Valve positioner

## 8.14.1 Description of VlvPosL

### Object name (type + number) and family

Type + number: FB 1918

Family: Drives

### Area of application for VlvPosL

The block is used for the following application:

- Control of a motor valve with analog position feedback.

### How it works

Various operating modes are available for controlling the motorized valve. This enables you to change the valve states individually. All changes of modes or states, as well as errors occurring in this context, are monitored, visualized in the faceplate and reported to the operator. Operators with suitable permissions can use the block icon and the faceplate to view the current state of the motorized valve and operate it.

The motor valve with analog position feedback can be controlled via binary signals such as "Open", "Close", or "Stop" or via analog manipulated variable signals. An internal position controller is activated when analog manipulated variable signals are used. This enables even motor valves with delayed reaction in their position feedback to be position controlled.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

Following startup, the messages are suppressed for the number of cycles assigned in the `RunUpCyc` parameter.

After a startup without control (`Open, Close` = 0) no monitoring of the feedback signals `FbkOpen` and `FbkClose` takes places during the `V_MonTiStatic` time. Changes to `FbkOpen` and `FbkClose` are applied. This means that the feedback is monitored again even in the stop state.

### Status word assignment for `Status1` parameter

You can find a description of the individual parameters in the section VlvPosL I/Os (Page 1912).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `AutoAct.Value` |
| 6 | `LocalAct.Value` |
| 7 | 0 = Open padlock in the block icon<br>1 = Closed padlock in block icon<br>With `Feature2.Bit16` = 1, a closed padlock is displayed if "Interlock Open" or "Interlock Close" is active. |
| 8 | `Open.Value` |
| 9 | Motor is stopped |
| 10 | `Close.Value` |
| 11 | Torque shutoff enabled (`TorqOpen` or `TorqClose` = 1)<br>When the seal valve function is enabled, the torque shutoff is only active when the `TorqClose` signal is active before the valve feedback. |
| 12 | `WarnAct.Value` |
| 13 | Feedback error without control change |
| 14 | Feedback error due to control change |
| 15 | Mode switch fail |
| 16 | 1 = `Intlock` is active |
| 17 | 1 = `Permit` is active |
| 18 | 1 = `Protect` is active |
| 19 | Displays forced operating state in the block icon: Force |
| 20 | Not used |
| 21 | 1 = Position control is active |
| 22 | 1 = Position control is not active |
| 23 | "Interlock" button is enabled |
| 24 | 0 = Display neutral position "Closed" Display "Closed" for representation of neutral position in `SafePos` = 0 or 2<br>1 = Display "Opened" for representation of neutral position in `SafePos` = 1 or 2 |
| 25 | 1 = Display "Intermediate" for representation of neutral position in `SafePos` = 2 |
| 26 | Bypass information for display in block icon |
| 27 | Bypass active (`BypProt` = 1) and `Local.Act` = 1 or `SimOn` = 1 |
| 28 | Invalid signal status |
| 29 | 0 = Closed<br>1 = Open |
| 30 | "Permission" button is enabled |
| 31 | "Protection" button is enabled |

### Status word assignment for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock` |
| 1 | `AV_AH_Act.Value` |
| 2 | `AV_WH_Act.Value` |
| 3 | `AV_TH_Act.Value` |
| 4 | `AV_TL_Act.Value` |
| 5 | `AV_WL_Act.Value` |
| 6 | `AV_AL_Act.Value` |
| 7 | `AV_AH_En` OR `Feature.Bit23` |
| 8 | `AV_WH_En` OR `Feature.Bit23` |
| 9 | `AV_TH_En` OR `Feature.Bit23` |
| 10 | `AV_TL_En` OR `Feature.Bit23` |
| 11 | `AV_WL_En` OR `Feature.Bit23` |
| 12 | `AV_AL_En` OR `Feature.Bit23` |
| 13 | `AV_AH_MsgEn` |
| 14 | `AV_WH_MsgEn` |
| 15 | `AV_TH_MsgEn` |
| 16 | `AV_TL_MsgEn` |
| 17 | `AV_WL_MsgEn` |
| 18 | `AV_AL_MsgEn` |
| 19 | 1 = No impact of input signals on "local mode" with `LocalSetting` = 0, `LocalSetting` = 2, `LocalSetting` = 4 and OOS mode. |
| 20 | 1 = Valve is closing |
| 21 | 1 = Valve is closed |
| 22 | 1 = Valve is stopped |
| 23 | 1 = Valve is opening |
| 24 | 1 = Valve is open |
| 25 | For the error status display in the closed valve |
| 26 | For the error status display in the opened valve |
| 27 | Automatic preview for "Open" |
| 28 | Automatic preview for "Close" |
| 29 | Automatic preview for "Stop" |
| 30 | Display for interlocks in block icon |
| 31 | `MS_RelOp` |

### Status word assignment for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | `M_MonStaErr.Value` |
| 1 | `M_MonDynErr.Value` |
| 2 | `V_MonStaErr.Value` |
| 3 | `V_MonDynErr.Value` |

| Status bit | Parameter |
|---|---|
| 4 | M_MonStopErr.Value |
| 5 | Automatic preview for "Position Control" on |
| 6 | Automatic preview for "Position Control" off |
| 7 | Torque shutoff opening enabled |
| 8 | Torque shutoff closing enabled |
| 9 | External fault generated by FaultExt or external control system fault CSF with set Feature.Bit18 Activating error state for external process control error CSF (Page 162) |
| 10 | Vibration successfully completed – Reset required |
| 11 | Display motor protection (Trip status, Trip.ST ≠ 16#FF) |
| 12 | 1 = Input parameter FbkClose is interconnected |
| 13 | 1 = Input parameter FbkClosing is interconnected |
| 14 | 1 = Input parameter FbkOpen is interconnected |
| 15 | 1 = Input parameter FbkOpening is interconnected |
| 16 | 1 = Input parameter TorOpen is interconnected |
| 17 | 1 = Input parameter TorClose is interconnected |
| 18 | SimLiOp.Value |
| 19 | 1 = Enable for rapid stop (Feature.Bit14 Enabling rapid stop via faceplate (Page 179)) |
| 20 | 1 = Input parameter OpenChnST is interconnected |
| 21 | 1 = Input parameter CloseChnST is interconnected |

### Status word assignment for Status5 parameter

| Status bit | Parameter |
|---|---|
| 0 - 7 | Effective signal 1 to 8 of the message block connected via EventTsIn |
| 8 - 15 | Effective signal 9 to 16 of the message block connected via EventTsIn |
| 16 | AV is not connected |
| 17 | Delay of the message AV_AH_Lim |
| 18 | Delay of the message AV_WH_Lim |
| 19 | Delay of the message AV_TH_Lim |
| 20 | Delay of the message AV_TL_Lim |
| 21 | Delay of the message AV_WL_Lim |
| 22 | Delay of the message AV_AL_Lim |
| 23 | Collection of the message delays |
| 24 | 1 = High limit of the manipulated variable difference is violated (ER_AH_Act.Value) |
| 25 | 1 = Low limit of the manipulated variable difference is violated (ER_AL_Act.Value) |
| 26 | 1 = High limit of the readback value is violated (RbkWH_Act.Value) |
| 27 | 1 = Low limit of the readback value is violated (RbkWL_Act.Value) |

| Status bit | Parameter |
|---|---|
| 28 | 1 = Valve still closes (`Status2.Bit20`) but the motor is not running |
| 29 | 1 = Valve still opens (`Status2.Bit23`) but the motor is not running |
| 30 | `MV_TrkOn.Value` |
| 31 | Not used |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 - 15 | Effective signal 1 to 16 of the message block connected via `EventTs2In` |
| 16 | Hidden bypass signal in "Permission Close" |
| 17 | Hidden bypass signal in "Interlock Close" |
| 18 | Hidden bypass signal in "Protection Close" |
| 19 | "Permission Open" button is enabled |
| 20 | "Permission Close" button is enabled |
| 21 | "Interlock Open" button is enabled |
| 22 | "Interlock Close" button is enabled |
| 23 | "Protection Open" button is enabled |
| 24 | "Protection Close" button is enabled |
| 25 | 1 = "Permission Close" is active |
| 26 | 1 = "Interlock Close" is active |
| 27 | 1 = "Protection Close" is active |
| 28 | 1 = "Permit neutral pos." or " Permission stop" button is enabled |
| 29 | 1 = Permission SafePos / Stop is active |
| 30 | Hidden bypass signal in Permission SafePos / Stop |
| 31 | Not used |

### Status word allocation for `Status7` parameter

| Status bit | Parameter |
|---|---|
| 0 | 1 = Open operation disabled |
| 1 | 1 = Close operation disabled |
| 2 | Resynchronization: Valve Open |
| 3 | Resynchronization: Valve Close |
| 4 | Resynchronization: Valve Stop |
| 5 | Resynchronization: Motor Opening |
| 6 | Resynchronization: Motor Closing |
| 7 | Resynchronization: Motor Stopped |
| 8 | Resynchronization: Display preview |
| 9 | Resynchronization: Display small preview symbol in standard view |
| 10 | 1 = Operator MV input in open direction is not allowed |
| 11 | 1 = Operator MV input in close direction is not allowed |

| Status bit | Parameter |
|---|---|
| 12 | Resynchronization preview view for Valve/Motor open |
| 13 | Resynchronization preview view for Valve/Motor close |
| 14 | Resynchronization preview view for Valve/Motor Stop |
| 15 - 31 | Not used |

## 8.14.2 VlvPosL modes

### VlvPosL operating modes

The block supports all standard operating modes:

- Local mode (Page 86)
- Automatic mode (Page 82)
- Manual mode (Page 82)
- Out of service (Page 77)

The next section provides additional block-specific information relating to the general descriptions.

### "Local mode"

You can find general information on "Local mode", switching modes, and bumpless switchover in the section Local mode (Page 86).

When you put a block into "Local mode", it is controlled either by "Local" signals or by feedback signals. With `LocalSetting` = 1 or 3, you can control the motor valve with the following "Local" signals:

- "Open" (`OpenLocal` = 1)
- "Close" (`CloseLocal` = 1)
- "Stop" (`StopLocal` = 1)

The feedback signals `FbkOpening`, `FbkClosing`, `FbkOpen`, `FbkClose`, and the analog readback `Rbk` will be monitored.

With `LocalSetting` = 2 or 4, the control outputs `Open`, `Close` and `StopCtrl` and the internal status `Opened`/`Closed`/`Stop` of the block will be tracked.

In the case where motor feedback signals are available (`Feature.Bit12` = 0), the control outputs `Open`, `Close` and `StopCtrl` will be tracked from the motor feedback signals `FbkOpening` and `FbkClosing`. The valve feedback signals `FbkOpen`, `FbkClose`, and the analog readback `Rbk` will be monitored.

In the case where no motor feedback signals are available (`Feature.Bit12` = 1), the internal status `Opened`/`Closed`/`Stop` of the block will be tracked from the valve feedback signals `FbkOpen`, `FbkClose`, and the analog readback `Rbk`. It will only be monitored if the analog readback and valve feedback signals are not suitable together.

If no position can be identified, the last valid position is assumed.

In local mode position control is switched off and manipulated value `MV_Out` is tracked to `MV_Scale.High`, `MV_Scale.Low`, `RbkOut`.

### "Automatic mode"

You can find general information on "Automatic mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

You can control the motor valve in "Automatic mode" with analog position feedback:

- "Open" (`OpenAut` = 1)
- "Close" (`CloseAut` = 1)
- "Stop" (`StopAut` = 1)

Position control is terminated with "Open", "Close", or "Stop". It is enabled again with:

- "Activate position control" (`PosOnAut` = 1)

For position control, the motor valve is controlled via the `Open` and `Close` outputs such that the manipulated variable `MV` and position feedback `Rbk` come into agreement.

### "Manual mode"

You can find general information on "Manual mode", switching modes and bumpless switchover in the section Manual and automatic mode for motors, valves and dosers (Page 82).

You can control the motor valve in "Manual mode" with analog position feedback:

- "Open" (`OpenMan` = 1)
- "Close" (`CloseMan` = 1)
- "Stop" (`StopMan` = 1)

Position control is terminated with "Open", "Close", or "Stop". It is enabled again with:

- "Activate position control" (`PosOnMan` = 1)

For position control, the motor valve is controlled via the `Open` and `Close` outputs such that the manual value `Man` and position feedback `Rbk` come into agreement.

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature2.Bit1` =0 and `Feature2.Bit1` =1 is as shown below:

| Output Parameters | **`Feature2.Bit1` =0** | **`Feature2.Bit1` =1** |
|---|---|---|
| FbkOpenOut.ST | 16#80 | 16#60 |
| FbkCloseOut.ST | 16#80 | 16#60 |
| FbkOpngOut.ST | 16#80 | 16#60 |
| FbkClsgOut.ST | 16#80 | 16#60 |
| Opened.ST | 16#80 | 16#60 |
| Closed.ST | 16#80 | 16#60 |
| Opening.ST | 16#80 | 16#60 |

## 8.14.3 VlvPosL functions

### Functions of VlvPosL

The functions for this block are listed below.

### Motor valve control

The motor valve is controlled via the Open and Close outputs or via the pulse outputs P_Open, P_Close, and P_Stop. The outputs are set by either of the following methods:

- Directly via the corresponding inputs:
  - OpenMan, CloseMan, and StopMan in manual mode
  - OpenAut, CloseAut, and StopAut in automatic mode
  - OpenLocal, CloseLocal, and StopLocal in local mode
  - OpenForce, CloseForce, and StopForce for the force operating states function. The position control is switched off. The analog control output MV_Out is tracked:
    OpenXxx: MV_Scale.High
    CloseXxx: MV_Scale.Low
    StopXxx: Rbk_Out
    with Xxx: Man,Aut,Local,Force
- Calculated by a position controller which controls the position feedback signal Rbk to a specified manipulated variable MV_Out. Depending of mode and function MV_Out is calculated by the following inputs:
  - Man in manual mode
  - MV in automatic mode
  - MV_Trk when „Tracking function (MV_TrkOn =1)“ is active.
  - MV_Force when „Forcing function for analog value (MV_ForOn =1)“ is active.

Position control is switched on by:

- PosOnMan in manual mode
- PosOnAut in automatic mode
- MV_ForOn for the force operating states functions.

Position control is switched off by:

- direct control via the command inputs OpenX, CloseX, StopX (see above)
- after a switch to Local Mode
- after a switch to Out of Service mode
- after a monitoring error of the feedbacks FbkOpen,FbkClose,Rbk

In the local mode, the manipulated variable is always tracked to the position feedback.

For direct control via the Open, Close, Stop inputs above, position control is terminated and must be reactivated via the PosOn inputs.

### Motor valve control with position control

When controlling with enabled position control PosAct = 1, the motor valve is moved to the desired valve position using the specified analog manipulated variable.

Depending on the mode and function, the effective analog manipulated variable `MV_Out` is specified by:

| FaultExt<br>CLS<br>+FB18<br>Trip<br>RapidStp | MV_ForOn | Permit Intlock Protect ...Cls | ManAct | MV_TrkOn | MV_Out<br>Open, Close are calculated from position controller | Limits | Comment |
|---|---|---|---|---|---|---|---|
| 1 | - | - | - | - | `FaultExt,CLS+FB8:`<br>Depending on rest position:<br>`SafePos = 0:`<br>`MV_Out = MV_LoLim`<br>`SafePos = 1:`<br>`MV_Out = MV_HiLim`<br>`SafePos = 2:`<br>`MV_Out = RbkOut`<br>`Trip, RapidStp:`<br>`MV_Out = RbkOut` | `MV_HiLim`<br>`MV_LoLim` | External fault, Motor protection, Rapid stop |
| 0 | 1 | - | - | - | `MV_Out = MV_Forced` | none | Forced tracking |

| 0 | 0 | 0 | `0`<br>`AutAct` = 1 | 0 | `MV` | `MV_HiLim`<br>`MV_LoLim` | Automatic mode |

Functions like sealing, torque monitoring or vibrations are not included in the table.

### Motor valve control without position control

The commands for the controlling of motor valve are inputed over `OpenX, CloseX, StopX` (see above). The analog manipulated value output `MV_Out` is tracking:

| FaultExt<br>CLS<br>+FB18<br>Trip<br>Rap-<br>idStp | OpenForce<br>CloseForce<br>StopForce | Permit Intlock<br>Protect ...Cls | OpenX<br>CloseX<br>StopX | Open, Close<br>MV_Out is tracking | Limits, Range | Comment |

The manipulated variable is then held and can be monitored | `MV_Scale.High`<br>`MV_Scale.Low` | Manual mode<br>Automatic mode<br>Local mode<br>X: Man<br>Aut<br>Local |

Functions like sealing, torque monitoring or vibrations are not included in the table.

If the motor valve is in "Out Of Service" mode (OOS), the analog position control is switched off. The controls Open and Close are set depending on the parameters SafePos, Rbk, FbkOpen, and FbkClose. Accordingly, the output MV_Out is tracked to MV_HiLim, MV_LoLim or RbkOut. The control outputs Open and Close are used to put the valve into its target position. If the target position is lost, then the control outputs are set again.

### Limiting the manipulated variable MV_Out

If position control is on (PosAct =1) the manipulated variable is limited by MV_HiLim and MV_LoLim and output at MV_Out. Reaching the limit is displayed at MV_HiAct =1 for the high limit and MV_LoAct =1 for the low limit.

**Note**

If position control is off (PosAct =0) or forcing is active over OpenForce, CloseForce, StopForce or MV_ForOn (independent of position control) the MV_Out is not limited and the outputs MV_HiAct, MV_LoAct are set to false.

### Deadband for position control

The manipulated variable difference MV_Out – RbkOut is controlled by a deadband width (DeadBand) and displayed at the ER output.

Depending on the parameter DeadBand and the difference (MV_Out – RbkOut) the following cases can occur:

- **(MV_Out – RbkOut) > DeadBand:**
  ER = (MV_Out – RbkOut) – DeadBand
- **(MV_Out – RbkOut) < (–1* DeadBand):**
  ER = (MV_Out – RbkOut) + DeadBand
- **Otherwise:**
  ER = 0.0

The internal position controller is set with the following parameters:

- Gain: Controller gain
- MotorTime: Motor runtime from closed to fully open valve
- TmLag: Delay time caused, for example, by lag of the motor valve when switching on and off.

The pulse output is formed by a three-step element with hysteresis and set with the following parameters:

- PulseTime: Minimum pulse length of the outputs Open or Close
- BreakTime: Mminimum pulse break between two pulse outputs of Open or Close

**Note**

PulseTime and BreakTime are limited to SampleTime. If they are smaller parameterized than SampleTime they will be written back to the input with the value of SampleTime.

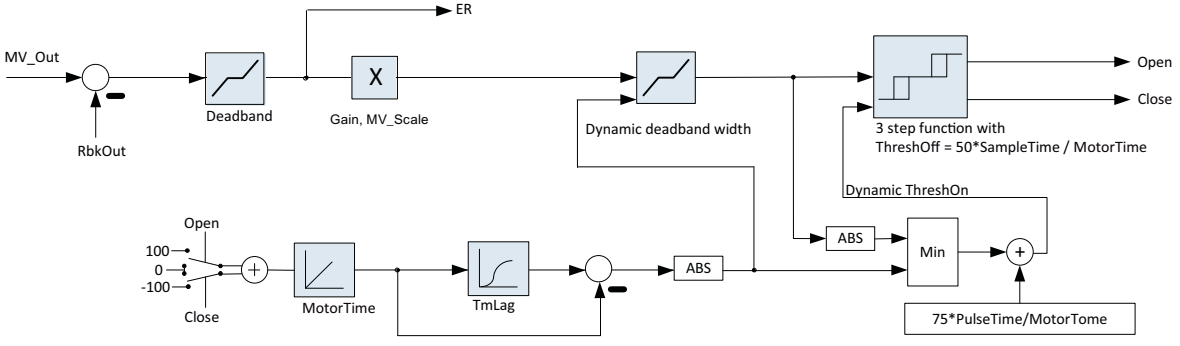
PulseTime and BreakTime values which are too large, can reduce the precision of position control.

The effective trip threshold and response threshold of the three-step element is displayed at the `ThreshOff` and `ThreshOn` output parameters.

The `PosReached` output shows whether the specified position has been reached. This is the case when:

- Intermediate position:
  `PosRbkHys` >= ABS (`MV_Out` - `RbkOut`)
- End position open:
  `MV_Out` >= `PosDiOpen` AND `RbkOut` >= `PosDiOpen` AND `FbkOpenOut` AND NOT `FbkCloseOut`
- End position closed:
  `MV_Out` <= `PosDiClose` AND `RbkOut` <= `PosDiClose` AND `FbkCloseOut` AND NOT `FbkOpenOut`

**Note**



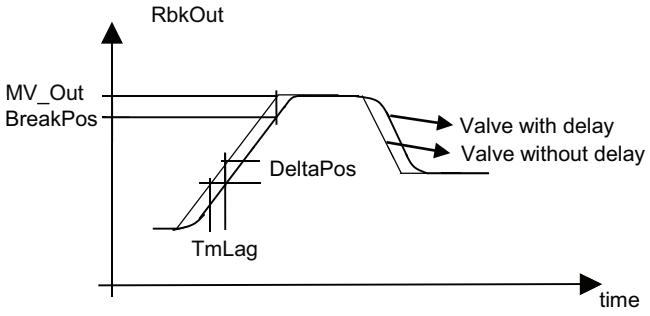
For the end positions "`PosDiOpen`" and "`PosDiClose`", the hysteresis and deadband also apply.

If the position is reached, the control and feedback signals of the motor are reset with the following values:

- `Open` = 0
- `Close` = 0
- `FbkOpngOut` = 0
- `FbkClsgOut` = 0

### Position control for control valves with delay behavior

The purpose of the position control is to move the valve to a specified control valve position by switching on and off as few times as possible at the `Open` and `Close` outputs.



The control difference between the output `MV_Out` and the position feedback signal `RbkOut` can be amplified at the `Gain` parameter.

Small control differences are suppressed at the dead band using the `DeadBand` parameter. As a rule, the preset values `Gain` = 1 and `DeadBand` = 0 can be retained.

At second dead zone, the dead zone width is dynamically formed as a function of `TmLag`. `TmLag` represents a delay time that can occur when the control valve moves.

If `TmLag` =0, the dynamic is switched off and the result is a dead zone width of zero.

Derived from the binary outputs `Open`, `Close`, and the time constant `MotorTime`, `TmLag` (the dynamic dead band width) is calculated as a difference between a delayed and an undelayed motor valve. This ensures that the pulses are switched off via `Open` and `Close` on time to reach the specified valve position without overshoot.

For example: The calculation of `Open` and `Close` to avoid overshoot is done as follows:

`DeltaPos` = 100% * `TmLag` / `MotorTime`

- Case A: `MV_Out` > `RbkOut`: `BreakPos` = `MV_Out` – `DeltaPos`
- Case B: `MV_Out` < `RbkOut`: `BreakPos` = `MV_Out` + `DeltaPos`
  - `DeltaPos` is the distance to the target position.
  - `BreakPos` is the calculated feedback position before reaching the target position where the control outputs `Open` and `Close` switch off in time in order to avoid overshoot.

A three step function with hysteresis is used to calculate the binary control outputs `Open` and `Close`, from the manipulated variable difference `ER`. The number of pulses required to reach a preset valve position is further reduced by an adaptive response threshold of the three step function. The dynamic behavior is also switched off with `TmLag` = 0. The position control is switched off after a monitoring error.

## Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

## Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the parameter `OS_Perm`:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can switch to "Automatic mode" |
| 1 | 1 = Operator can switch to "Manual mode" |
| 2 | 1 = Operator can switch to "Local mode" |
| 3 | 1 = Operator can switch to "Out of service mode" |

| Bit | Function |
|---|---|
| 4 | 1 = Operator can stop the motor |
| 5 | 1 = Operator can open the valve |
| 6 | 1 = Operator can close the valve |
| 7 | 1 = Operator can trigger rapid stop for motors |
| 8 | 1 = Operator can activate position control |
| 9 | 1 = Operator can reset the valve |
| 10 | 1 = Operator can change the manual value `Man` |
| 11 | 1 = Operator can change the simulation value `SimRbk` |
| 12 | 1 = Operator can define the valve monitoring time for control |
| 13 | 1 = Operator can define the valve monitoring time for end position |
| 14 | 1 = Operator can activate the function valve monitoring time (bits 12 and 13) |
| 15 | 1 = Operator can define the motor monitoring time for control start or stop |
| 16 | 1 = Operator can define the monitoring time for control stop |
| 17 | 1 = Operator can define the motor monitoring time for status |
| 18 | 1 = Operator can activate the function motor monitoring time (bits 15,16, and 17) |
| 19 | 1 = Operator can define the readback monitoring time |
| 20 | 1 = Operator can activate the function readback monitoring time (bit 19) |
| 21 | Not used |
| 22 | 1 = Operator can change proportional gain of the position control |
| 23 | Not used |
| 24 | 1 = Operator can set the delay time of the motor valve |
| 25 | 1 = Operator can set the deadband width of the manipulated variable difference |
| 26 | 1 = Operator can set the motor run time |
| 27 | 1 = Operator can set the minimum pulse duration |
| 28 | 1 = Operator can set the minimum break duration |
| 29 | Not used |
| 30 | 1 = Operator can activate the "Simulation" function |
| 31 | 1 = Operator can activate the "Release for maintenance" function |

The block has the following permissions for the parameter `OS1Perm`:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can change the high operating limit of the manipulated variable `MV_HiLim` |
| 1 | 1 = Operator can change the low operating limit of the manipulated variable `MV_LoLim` |
| 2 | Not used |
| 3 | 1 = Operator can enable/disable messages via `ER_AH_MsgEn` |
| 4 | 1 = Operator can enable/disable messages via `ER_AL_MsgEn` |
| 5 | 1 = Operator can enable/disable messages via `RbkWH_MsgEn` |
| 6 | 1 = Operator can enable/disable messages via `RbkWL_MsgEn` |
| 7 | 1 = Operator can change the limit (manipulated variable difference) for the high alarm `ER_AH_Lim` |
| 8 | 1 = Operator can change the hysteresis (manipulated variable difference) `ER_Hyst` |
| 9 | 1 = Operator can change the limit (manipulated variable difference) for the low alarm `ER_AL_Lim` |

| Bit | Function |
|---|---|
| 10 | 1 = Operator can change the limit (position feedback) for the high warning RbkWH_Lim |
| 11 | 1 = Operator can change the hysteresis (position feedback) RbkHyst |
| 12 | 1 = Operator can change the hysteresis (position feedback) for the low warning RbkWL_Lim |
| 13 | Not used |
| 14 | 1 = Operator can change the simulation value SimAV |
| 15 | 1 = Operator can change the limit (AV) for the high alarm |
| 16 | 1 = Operator can change the limit (AV) for the high warning |
| 17 | 1 = Operator can change the limit (AV) for the high tolerance |
| 18 | 1 = Operator can change the limit (AV) for the hysteresis |
| 19 | 1 = Operator can change the limit (AV) for the low alarm |
| 20 | 1 = Operator can change the limit (AV) for the low warning |
| 21 | 1 = Operator can change the limit (AV) for the low tolerance |
| 22 | 1 = Operator can enable / disable messages via AV_AH_MsgEn |
| 23 | 1 = Operator can enable / disable messages via AV_WH_MsgEn |
| 24 | 1 = Operator can enable / disable messages via AV_TH_MsgEn |
| 25 | 1 = Operator can enable / disable messages via AV_TL_MsgEn |
| 26 | 1 = Operator can enable / disable messages via AV_WL_MsgEn |
| 27 | 1 = Operator can enable / disable messages via AV_AL_MsgEn |
| 28 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm, OS1Perm as a parameter, you have to reset the corresponding OS_Perm, OS1Perm bit.

### Limit monitoring for additional analog value

This block provides the standard function Limit monitoring of an additional analog value (Page 98).

### Limit monitoring with hysteresis

This block provides the standard function Limit monitoring with hysteresis (Page 104). This is done using the input parameter AV_Hyst.

### Providing limits at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

```
ER_AH_LimOut := ER_AH_Lim;
ER_AL_LimOut := ER_AL_Lim;
```

### Suppress messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Interlocks

This block provides the following interlocks:

- `Feature2.Bit16` = 0
  - Activation enable ("Permission")
  - Interlock without reset ("Interlock")
  - Interlock with reset ("Protection")
  - Permission for safe position (“Permit neutral pos.” or “Permission stop”)
- `Feature2.Bit16` = 1
  - Activation enable Open ("Permission Open")
  - Activation enable Close ("Permission Close")
  - Interlock open without reset ("Interlock Open")
  - Interlock close without reset ("Interlock Close")
  - Interlock open with reset ("Protection Open")
  - Interlock close with reset ("Protection Close")

For more on this, see the sections Interlocks (Page 107) and Influence of the signal status on the interlock (Page 112).

When an interlock is pending and position control is enabled, the block remains in position control. The following manipulated variables are controlled based on the configured neutral position for an interlock with/without reset:

| `SafePos` | Manipulated variable |
|---|---|
| 0: Closed | `MV_Out` = `MV_LoLim` |
| 1: Opened | `MV_Out` = `MV_HiLim` |
| 2: Stopped | `MV_Out` = `RbkOut` |

**Note**

The neutral position cannot be reached if the limit `MV_HiLim` is not configured greater than or equal to `PosDiOpen` or `MV_LoLim` is not configured less than or equal to `PosDiClose`.

With VlvPosL in position control, the neutral position is reached when:

| `SafePos` | Neutral position is reached when |
|---|---|
| 0: Closed | `PosReached` = 1, `FBkOpenOut` = 0, `FBkCloseOut` = 1 |
| 1: Opened | `PosReached` = 1, `FBkOpenOut` = 1, `FBkCloseOut` = 0 |
| 2: Stopped | `PosReached` = 1, independent of `FBkOpenOut`, `FBkCloseOut` |

If VlvPosL is in the neutral position, it can only leave this position when an activation enable is set.

### Motor protection function

This block provides the standard function Motor protection function (Page 106).

When motor protection is pending and position control is enabled, the block remains in position control. The manipulated variable is tracked to the feedback value (`MV_Out` = `RbkOut`) and with this, the motor is in the stop state.

### Rapid stop for motors

This block provides the standard function Rapid stop for motors (Page 115).

When rapid stop is pending and position control is enabled, the block remains in position control. The manipulated variable is tracked to the feedback value (`MV_Out` = `RbkOut`) and with this, the motor is in the stop state.

### Torque monitoring

This block provides torque monitoring.

The signals of the torque monitoring switches are interconnected to the input parameters `TorqOpen` to open the motor valve and `TorqClose` to close the motor valve.

- `TorqOpen` / `TorqClose` (`Value` =1 and `ST`<>16#00, 16#28): Torque in good state
- `TorqOpen` (`Value` =0 or `ST`=16#00, 16#28): Torque increased in direction Up
- `TorqClose` (`Value` =0 or `ST`=16#00, 16#28): Torque increased in direction Closed

Using `Feature2.Bit6` (Vibration), you can define how to proceed in automatic mode when torque is active. If `Feature.Bit8` is set, the parameter `TorqClose` is also considered for the function "Sealing the valve".

**Vibration is deactivated (`Feature2.Bit6` = 0)**

If one of the two torques `TorqOpen` or `TorqClose` is activated, a running motor is stopped in the corresponding direction and the position control is switched off. You can still move the valve in the opposite direction. If both the torques are activated, the motor valve can no longer be moved.

An active torque is displayed in the standard view as "Torque active" in the display area for block states.

**Vibration is activated (`Feature2.Bit6` =1) and VlvPosL is in automatic mode**

Depending on whether the position control is switched on, the attempts of vibration refer to the parameter `VibrWidth` in seconds or the parameter `VibrPerc` in percent.

- **Vibration with position control switched off (`PosAct` =0)**
  - If a torque occurs to one of the end positions during a control, the motor runs in the opposite direction for `VibrWidth` seconds.
  - If the torque normalizes again after `VibrWidth` seconds, the motor is controlled in the originally desired direction. When the torque comes active again, the motor runs in the opposite direction again for `VibrWidth` seconds. This procedure is repeated for a maximum of `VibrNo` times.
- **Vibration with position control switched on (`PosAct` =1)**
  - If a torque occurs to a new valve position `MV` during control, the motor runs back to the position `MV_Out` = `RbkOut` - (`MV_HiLim` - `MV_LoLim`) / 100.0 * `VibrPerc` in the opposite direction.
  - If the torque has normalized again after reaching to this position, the control takes place in the originally desired position `MV`. When the torque is switched off again, the motor valve runs back by `VibrPerc` percent. This procedure is repeated a maximum of `VibrNo` times.

If the function vibration is activated, "Vibrate enabled" is displayed in the display area of the standard view.

After `VibrNo` attempts of reverse moving and control again to the original position without reaching this position because of an active torque, the motor stops and position control is switched off. You must reset the block so that vibration can be reactivated.

If the torque does not normalize during the reverse moving, the motor stops and the position control is switched off.

**Note**

The function vibration tries to release a blockage by repeatedly moving the motor valve back and forth against it. This is only suitable for certain types of blockages, such as clearing branches or chunks of wood from weir valves.

### Sealing the valve

This function is enabled using `Feature.Bit8` Sealing the valve (Page 187). The seal valve function combines the query of the end position "Closed" via the input parameter `FbkClose` and `Rbk` with the limit violation of the configured torque via the input parameter `TorqClose`. This ensures that the valve is completely closed.

The valve is only considered completely closed when the feedback for the end position "Close" has been received (0->1), the position feedback `Rbk` is smaller than or equal to `PosDiClose`, and the torque shutdown for "Closed" is enabled. The torque shutoff should not come before the

feedback in this case. The FbkCloseOut output shows whether the valve is sealed tight with the following conditions:

- FbkCloseOut:= FbkClose.Value AND RbkOut.Value <= PosDiClose has come in (0->1)
- "Torque shutoff closed is enabled"
- "Torque shutoff closed is enabled" did not come before FbkCloseOut (0->1)

"Torque shutoff closed enabled" means TorqClose = 0 or the signal status is 16#00 or 16#28.

When "Torque shutoff closed is enabled" comes before the end position feedback closed, this is displayed in the faceplate in the standard view and the motor stops. Opening the valve is still possible.

**Note**

The command text for Close in the standard view and preview can be changed to Seal in the CFC at the CloseMan parameter in Text 1. See section Labeling of buttons and text (Page 235).

### Disable interlocks

This block provides the standard function Disabling interlocks (Page 111).

### Resetting the block in case of interlocks

This block provides the standard function Resetting the block in case of interlocks or errors (Page 47).

### External fault (FaultExt), External control system fault (CSF)

This block provides the possibility to pass an external fault via the FaultExt parameter or an external control system fault via the CSF parameter. See VlvPosL error handling (Page 1908).

When an external fault or control system fault is pending (Feature.Bit18 = 1) and position control is enabled, the block remains in position control. The following manipulated variable is set based on the configured neutral position:

| SafePos | Manipulated variable |
|---|---|
| 0: Closed | MV_Out = MV_LoLim |
| 1: Opened | MV_Out = MV_HiLim |
| 2: Stopped | MV_Out = RbkOut |

**Note**

The neutral position cannot be reached if the limit MV_HiLim is not configured greater than or equal to PosDiOpen or MV_LoLim is not configured less than or equal to PosDiClose.

### Group error

This block provides the standard function, Outputting group errors (Page 130).

The following parameters are taken into consideration when forming the group error:

- `CSF`
- `Trip`
- `V_MonDynErr`
- `V_MonStaErr`
- `M_MonDynErr`
- `M_MonStaErr`
- `RbkMonDynErr`
- `RbkMonStaErr`
- `FaultExt`

### Outputting a signal for start readiness

This block provides the standard function, Outputting a signal for start readiness (Page 59).

### Forming the group status for interlocks

This block provides the standard function, Forming the group status for interlock information (Page 113).

### Control loop is open (`CascaCut`)

The `CascaCut` output indicates whether the control loop within this block is open. In the open control loop, the master controller must be set to tracking mode to avoid until windup behavior. If you use this block in a cascade structure, then connect the output `CascaCut` to the input `MV_TrkOn` of the master controller.

`CascaCut` is active in the following cases:

- Block is not in automatic mode
- Force function is active
- Motor protection is active
- Interlock is active
- Tracking function is active
- Position control is off
- Monitoring error is active

### Forming the signal status for blocks

This block provides the standard function, Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status for the block is formed from the following parameters:

- FbkClsgOut.ST
- FbkOpngOut.ST
- FbkOpenOut.ST
- FbkCloseOut.ST
- RbkOut.ST
- LocalLi.ST
- OpenLocal.ST
- StopLocal.ST
- CloseLocal.ST
- Trip.ST
- TorqOpen.ST
- TorqClose.ST
- AV_Out.ST
- OpenChn.ST
- CloseChn.ST
- OpenAut.ST (only if Feature2.Bit10 = 1)
- CloseAut.ST (only if Feature2.Bit10 = 1)
- StopAut.ST (only if Feature2.Bit10 = 1)
- MV.ST (only if Feature2.Bit10 = 1)
- PosOnAut.ST (only if Feature2.Bit10 = 1)
- MV_Out.ST

### Considering bad quality of automatic commands or external values

If the Feature2 bit Considering bad quality of automatic commands or external values (Page 200) is set to 1 and one of the following parameters has bad signal status (16#00 or 16#28), the block goes to the neutral position in the "Automatic" mode:

- OpenAut.ST
- CloseAut.ST
- StopAut.ST
- MV.ST
- PosOnAut.ST

## Forcing operating modes

This block provides the standard function, Forcing operating modes (Page 45). The inputs `OpenForce`, `CloseForce`, and `StopForce` force the block to open, close, or stop, respectively. When any of these inputs is set, then the activated position control `PosAct` is terminated and you must separately reactivate it.

With `MV_ForOn` = 1, position control is enabled and set to the manipulated variable `MV_Forced`. The inputs `OpenForce`, `CloseForce` and `StopForce` have higher priority over `MV_ForOn`.

## Feedback monitoring

This block provides the standard function, Monitoring the feedbacks (Page 104).

The `FbkOpen` and `FbkClose` feedback is monitored for the valve; the `FbKOpening` and `FbkClosing` feedback is monitored for the motor.

The monitoring of the feedback for the valve will not be active if it was stopped during opening or closing.

### Monitoring valve feedback

The monitoring of valve feedback is set using the parameter `V_Monitor`.

Startup characteristics are monitored by setting parameter `V_MonTiDynamic`. The parameter `V_MonTiStatic` monitors compliance with the position.

Feedback errors are displayed at the corresponding parameters `V_MonDynErr` and/or `V_MonStaErr`.

**Note**

After the motor valve stops in the intermediate position or end position or after a startup without control (`Open`, `Close` = 0)" or a stop after a monitoring error, no monitoring of the feedback signals `FbkOpen` and `FbkClose` takes place during the `V_MonTiStatic` time. Changes to `FbkOpen` and `FbkClose` are applied. This means that the feedback is monitored again, also in stop state.

**Note**

When the "Seal valve" function is enabled via `Feature.Bit8`, the torque shutoff for closing `TorqClose` is also evaluated (see section Sealing the valve (Page 187)).

### Monitoring the motor feedback

The monitoring of motor feedback is set using the parameter `M_Monitor`.

Startup characteristics are monitored by setting parameter`M_MonTiDynamic`. The parameter `M_MonTiStatic` monitors compliance with the position.

Feedback errors are displayed at the corresponding parameters `M_MonDynErr` and/or `M_MonStaErr`.

### Monitoring valve feedback

The monitoring of valve feedback is set using the V_Monitor parameter.

Startup characteristics are monitored by setting the V_MonTiDynamic parameter. When starting the motor valve, the current position feedback Rbk is taken into consideration and is included in the calculation of the monitoring time as follows:

Monitoring of the position feedback is switched on (RbkMonitor =1):

- Monitoring time = V_MonTiDynamic – MotorTime + Abs(MV_Out - RbkOut) * MotorTime/(MV_Scale.High-MV_Scale.Low)

**Note**

The dynamic monitoring time V_MonTiDynamic should be greater than motor actuating time MotorTime.

Monitoring of the position feedback is switched off (RbkMonitor =0):

- Open or close motor valve: Monitoring time = V_MonTiDynamic

Monitoring of the position feedback Rbk with activated position control can be set separately using RbkMonitor, RbkMonTi.

The V_MonTiStatic parameter sets the compliance with the valve position.

Feedback errors are displayed at the corresponding parameters V_MonDynErr or V_MonStaErr.

The valve travel range is divided into three ranges for monitoring:

- Valve open: RbkOut ≥ PosDiOpen
- Valve in intermediate position: PosDiClose < RbkOut < PosDiOpen
- Valve closed: RbkOut ≤ PosDiClose

To monitor the end positions, the FbkOpenOut and FbkCloseOut outputs are formed as follows:

When the motor valve reaches the "Open" position, the output is FbkOpenOut = 1:

- With a binary limit switch for the "Open" position (NoFbkOpen = 0):
  The valve is considered open if FbkOpenOut is set. FbkOpenOut is set if RbkOut ≥ PosDiOpen and FbkOpen = 1.
- Without binary end switch for the position "Open" (NoFbkOpen = 1):
  The valve is considered open if FbkOpenOut is set. FbkOpenOut is set if RbkOut ≥ PosDiOpen.

When the motor valve reaches the "Closed" position, the output is FbkCloseOut = 1:

- With a binary limit switch for the "Closed" position (NoFbkClose = 0):
  The valve is considered closed if FbkCloseOut is set. FbkCloseOut is set if RbkOut ≤ PosDiClose and FbkClose = 1.
- Without binary end switch for the position "Closed" (NoFbkClose = 1):
  The valve is considered closed if FbkCloseOut is set. FbkCloseOut is set if RbkOut ≤ PosDiClose.

**Note**

After the motor valve stops in the intermediate position or end position or after a CPU startup without control (`Open`, `Close` = 0), no monitoring of the feedback signals `FbkOpen`, `FbkClose` and `Rbk` takes place during the time `V_MonTiStatic`. Changes to `FbkOpen`, `FbkClose` and `Rbk` are applied to `FbkOpenOut` and `FbkCloseOut`. After the time `V_MonTiStatic`, the feedbacks are monitored again, also in the stop state.

**Note**

When the "Seal valve" function is enabled by means of `Feature.Bit8`, the torque shutoff for the closing `TorqClose` is also evaluated (see section Sealing the valve (Page 187)).

### Monitoring the motor feedback

The monitoring of motor feedback is set using the `M_Monitor` parameter.

Startup characteristics are monitored by setting the `M_MonTiDynamic` parameter; the `M_MonTiStatic` parameter monitors maintenance of the position.

Feedback errors are displayed at the corresponding parameters `M_MonDynErr` or `M_MonStaErr`.

### Monitoring of the position feedback Rbk

The monitoring of position feedback `Rbk` is set using the `RbkMonitor` parameter.

The monitoring of the startup characteristics is set at the `RbkMonTi` parameter. The effective monitoring time is calculated as follows:

- Monitoring time = ABS($MV_Out_n$ - $MV_Out_{n-1}$) * `MotorTime`/(`MV_Scale.High`–`MV_Scale.Low`) + `RbkMonTi`
  $MV_Out_n$: Current manipulated variable to be reached
  $MV_Out_{n-1}$: Last manipulated variable reached

The valve position is reached when the following condition is met:
`PosRbkHys` >= ABS(`MV_Out` - `RbkOut.Value`)

Feedback errors are displayed at the corresponding parameters `RbkMonDynErr` or `RbkMonStaErr`.

### Release for maintenance

This block provides the standard function, Release for maintenance (Page 70).

### Specify warning times for control functions

This block provides the standard function, Specifying warning times for control functions at motors and valves (Page 56).

You can generate warning signals when, for example, valves open. Warning signals can be generated in the following modes:

- Manual and automatic mode for motors, valves and dosers (Page 82) (input parameter `WarnTiMan`)
- Manual and automatic mode for motors, valves and dosers (Page 82) (input parameter `WarnTiAut`)

You specify the warning times in seconds using the input parameters `WarnTiMan` and `WarnTiAut` . If, for example, a valve opens, this is displayed at the output parameter with `WarnAct` = 1. The valve then opens after the set warning time has expired and `WarnAct` then returns to 0.

A corresponding warning is not outputted if the values specified for the warning times (`WarnTiMan` or `WarnTiAut`) are lower than the `SampleTime` parameter.

**Note**

The warning is activated for each actuation that causes the motor to start, even if this means that the valve is moved to the neutral position.

A parameterized warning time (`WarnTiMan`, `WarnTiAut`) is not active in the position control mode.

### Simulating signals

This block provides the standard function, Simulating signals (Page 64).

You can simulate the following values:

- Additional value (`SimAV`, `SimAV_Li`)

With internal simulation with immediate tracking of feedback, it is possible to simulate a position between the open and closed state (`FbkOpenOut` = `FbkCloseOut` = 0) by means of a stop command.

### Select unit of measure

This block provides the standard function, Selecting a unit of measure (Page 240).

### Neutral position

This block provides the standard function, Neutral position for motors, valves and controllers (Page 54).

### Output signal as pulse signal or static signal

This block provides the standard function Output signal as a static signal or pulse signal (Page 57). In addition to the static control outputs `Open` and `Close`, the block also has pulse outputs `P_Open`, `P_Close`, and `P_Stop`, which are dependent on the static control output.

### Generate instance-specific messages

This block provides the standard function, Generating instance-specific messages (Page 230).

### Resynchronization

This block provides the standard function Resynchronization (Page 258).

Resynchronization is switched on over feature bits:

| | |
|---|---|
| Feature2 Bit17 =1 | Resynchronization after CPU startup |
| Feature2 Bit18 =1 | Resynchronization after Simulation or after Out of service |
| Feature2 Bit19 =1 | Resynchronization after control system fault |
| Feature2 Bit20 =1 | Resynchronization with 0->1 trigger at StateTrkOn input |

If there are no restrictions the control outputs are tracked as follow:

**Valve position**

**NoFbkOpen =0, NoFbkClose =0:**

Valve position open: Status7.Bit2 := FbkOpen AND (Rbk >= PosDiOpen);

Valve position close: Status7.Bit3 := FbkClose AND (Rbk <= PosDiClose);

valve position intermediate: Status7.Bit4 := NOT Status7.Bit2 AND NOT Status7.Bit3;

If both valve feedback signals are not available (NoFbkOpen =1, NoFbkClose =1) only the readback value is relevant. The analog readback value is always available at VlvPosL.

**Position control is off (PosAct =0):**

**Motor controls**

**Motor feedbacks are present** Feature Bit 12 =0:

Open := FbkOpening AND NOT FbkClosing AND valve position is not open;

Close := FbkClosing AND NOT FbkOpening AND valve position is not close;

StopCtrl := NOT FbkOpening AND NOT FbkClosing;

In case if there are no plausible motor feedbacks (FbkOpening =1, FbkClosing =1) the motor goes to stop control.

**Motor feedbacks are not present** Feature Bit 12 =1:

The motor goes to stop control:

Open := false;

Close := false;

StopCtrl := true;

**Analog Readback value:**

MV_Out := Rbk; MV_Out is tracked and limited to MV_Scale.

**Position control is on (PosAct =1):**

Motor controls:

Depending on the resulting difference “MV_Out – Rbk” during “Tracking of State” the control outputs Open, Close, P_Open, P_Close are calculated.

Analog Readback value:

MV_Out := Rbk;

MV_Out is tracked and limited to MV_HiLim and MV_LoLim.

### Configurable reactions using the `Feature` parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Enabling resetting of commands for the control settings (Page 172) |
| 4 | Setting switch or button mode (Page 177) |
| 8 | Sealing the valve (Page 187) |
| 9 | Resetting via input signals in the event of interlocking (Protection) or errors (Page 174) |
| 10 | Exiting local mode (Page 189) |
| 11 | Activating the run time of feedback signals (Page 164) |
| 12 | Motor feedback is not available (Page 168) |
| 13 | Separate monitoring time for stopping the motor (Page 180) |
| 14 | Enabling rapid stop via faceplate (Page 179) |
| 17 | Enabling bumpless switchover to automatic mode for valves, motors, and dosers (Page 184) |
| 18 | Activating error state for external process control error CSF (Page 162) |
| 19 | Reset even with locked state (Page 176) |
| 20 | Disable calculation of impulse control in LocalSetting 2 and 4 (Page 200) |
| 21 | Enable bumpless switchover to "Automatic" mode for operator only (Page 183) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 27 | Interlock display with LocalSetting 2 or 4 (Page 189) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |
| 31 | Activating reset of protection / error in manual mode (Page 175) |

In switching mode (`Feature.Bit4` = 1), the control is selected with the static signals `OpenAut` and `CloseAut`. If the `OpenAut` and `CloseAut` inputs are not set, the motor is stopped. Control via `StopAut` is not required. If the "Enable reset of commands for control" function

(`Feature.Bit3` = 1) is also enabled, the `OpenAut` and `CloseAut` inputs are reset to 0 after evaluation in the block.

In switching mode (`Feature.Bit4` = 1), the `PosOnAut` control acts as a switch. The "Enable resetting of commands for control" function (`Feature.Bit3` = 1) has no influence on `PosOnAut`.

### Display auxiliary values

This block provides the standard function, Displaying auxiliary values (Page 239).

### Configurable reactions using the `Feature2` parameter

| Bit | Function |
|---|---|
| 1 | Changes signal status of outputs in OOS (Page 208) |
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 3 | Control priority in the event of invalid or not plausible input commands (Page 186) |
| 4 | Setting switch or button mode for local commands (Page 195) |
| 5 | Evaluation of the signal status of the interlock signals (Page 153) |
| 6 | Vibrate after torque monitoring (Page 190) |
| 8 | Forcing commands in the Local mode (Page 198) |
| 9 | Button mode with triggered local control commands (Page 209) |
| 10 | Considering bad quality of automatic commands or external values (Page 200) |
| 11 | Suppress MsgLock and “Out of service” mode for a connected message block (Page 202) |
| 12 | Disable limit act output when limit value message is disabled (Page 209) |
| 13 | Resetting the Pending Error in Local Mode 1 and 3 (Page 210) |
| 16 | Separate interlock for each direction, position, or speed (Page 180) |
| 17 | Resynchronization after startup (Page 213) |
| 18 | Resynchronization after out of service or after simulation (Page 213) |
| 19 | Resynchronization after CSF (Page 214) |
| 20 | Resynchronization with StateTrkOn input (Page 214) |

### Connection of the time-stamped messages from EventTs or Event16Ts

This block provides the standard function Connection of the time-stamped messages from EventTs or Event16Ts (Page 233).

### SIMATIC BATCH functionality

This block provides the standard function, SIMATIC BATCH functionality (Page 73).

### Disable feedback

This block provides the standard function, Disabling feedback for valves (Page 106). Feedback monitoring can be disabled separately for each feedback signal with `NoFbkOpen` or `NoFbkClose`.

### Labeling of buttons

This block provides the standard function, Labeling of buttons and text (Page 235).

Instance-specific text can be configured for the following parameters:

- `OpenMan`
- `CloseMan`
- `StopMan`
- `RapidStp`

### Outputs for status of drive

The block has the following outputs to indicate the status of the drives. In the CFC plan, this information can be further interconnected:

| | |
|---|---|
| Closed =1 | Motor is stopped:<br>`Open`, `Close`, `FbkClsgOut`, `FbkOpngOut` =0<br>Valve is in position closed:<br>(`RbkOut` <= `PosDiClose`) AND `FbkClose` =1, `MV_Out` <= `PosDiClose` |
| Opened =1 | Motor is stopped:<br>`Open`, `Close`, `FbkClsgOut`, `FbkOpngOut` =0<br>Valve is in position opened:<br>(`RbkOut` >= `PosDiOpen`) AND `FbkOpen` =1, `MV_Out` >= `PosDiOpen` |
| Closing =1 | Motor drives in direction of position closed:<br>`Close`, `FbkClsgOut` =1 |
| Opening =1 | Motor drives in direction of position opened:<br>`Open`, `FbkOpngOut` =1 |
| Stop =1 | Motor is stopped and position is reached:<br>`Open`, `Close`, `FbkClsgOut`, `FbkOpngOut` =0 |

**Note**

The outputs for status of drive are only can be active if there is no monitoring error:

`MonDynErr` =0, `MonStaErr` =0

## 8.14.4 VlvPosL error handling

### Error handling of VlvPosL

For troubleshooting all blocks, see also the Error handling (Page 128) section in the basics.

The following errors can be displayed for this block:

- Error numbers
- Mode switchover error
- Invalid or not plausible input commands
- Control system fault (`CSF`)

### Overview of error numbers

The `ErrorNum` parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Pre-defined value when inserting the block; the block is not executed. |
| 0 | No error pending. |
| 41 | The value for the `LocalSetting` connection is not within the valid limit of 0 to 4. |
| 42 | `LocalSetting` = 0 or `LocalSetting` = 3 or `LocalSetting` = 4 and `LocalLi` = 1 |
| 51 | `OpenLocal` = 1 and `StopLocal` = 1<br>`CloseLocal` = 1 and `StopLocal` = 1<br>`OpenLocal` = 1 and `CloseLocal` = 1<br>`OpenAut` = 1 and `StopAut` = 1<br>`CloseAut` = 1 and `StopAut` = 1<br>`OpenAut` = 1 and `CloseAut` = 1<br>`PosOnAut` = 1 and `StopAut` = 1<br>`PosOnAut` = 1 and `OpenAut` = 1<br>`PosOnAut` = 1 and `CloseAut` = 1<br>`AutModLi` = 1 and `ManModLi` = 1<br>`OpenForce` = 1 and `StopForce` = 1<br>`CloseForce` = 1 and `StopForce` = 1<br>`OpenForce` = 1 and `CloseForce` = 1 |
| 52 | `LocalAct` = 1 and `LocalSetting` = 2 or 4 and `SimOn` = 1 |

### Mode switchover error

This error can be outputted by the block, see section Error handling (Page 128).

### Invalid or not plausible input commands

This error can be outputted by the block, see section Error handling (Page 128).

For the following invalid or not plausible input commands, the control output can be stopped or switched to the neutral position. This depends on the function Control priority in the event of invalid or not plausible input commands (Page 186).

| Operating mode | Invalid or not plausible input commands | Control reaction with **Feature2.Bit3 = 1** |
|---|---|---|
| Local: Localsetting = 1<br>or Localsetting = 3 | Pushbutton operation for local mode (Feature2.Bit4 = 0):<br>OpenLocal = 1 and CloseLocal = 1 or<br>OpenLocal = 1 and StopLocal = 1 or<br>StopLocal = 1 and CloseLocal = 1<br>Switching mode (Feature2.Bit4 = 1):<br>OpenLocal = 1 and CloseLocal = 1 | Motor is started in valve neutral position direction. |
| Local: Localsetting = 1<br>or Localsetting = 3 and forcing | OpenForce = 1 and CloseForce = 1 or<br>OpenForce = 1 and StopForce = 1 or<br>StopForce = 1 and CloseForce = 1 | |
| Forcing and no "Local mode" | OpenForce = 1 and CloseForce = 1 or<br>OpenForce = 1 and StopForce = 1 or<br>StopForce = 1 and CloseForce = 1 | |
| "Automatic mode" and no forcing | Pushbutton operation (Feature.Bit4 = 0):<br>OpenAut = 1 and CloseAut = 1 or<br>OpenAut = 1 and StopAut = 1 or<br>StopAut = 1 and CloseAut = 1 or<br>StopAut = 1 and PosOnAut = 1 or<br>CloseAut = 1 and PosOnAut = 1 or<br>OpenAut = 1 and PosOnAut = 1<br><br>Switch mode (Feature.Bit4 = 1):<br>OpenAut = 1 and CloseAut = 1 or<br>CloseAut = 1 and PosOnAut = 1 or<br>OpenAut = 1 and PosOnAut = 1 | |
| "Manual mode" and no forcing | OpenMan = 1 and CloseMan = 1 or<br>OpenMan = 1 and StopMan = 1 or<br>StopMan = 1 and CloseMan = 1 | |

### Control system fault (CSF)

An external signal can be activated via the CSF input. If this signal CSF.Value = 1, a control system fault is triggered. For more information on this, see section Error handling (Page 128).

## 8.14.5 VlvPosL messaging

### Message characteristics

The following messages can be generated for this block:

- Control system fault
- Process messages
- Instance-specific messages

### Control system fault

The following control system fault messages can be outputted:

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG1 | AS control system message - fault | $$BlockComment$$<br>Motor feedback error |
| | SIG2 | AS control system message - fault | $$BlockComment$$<br>Motor protection triggered |
| | SIG3 | AS control system message - fault | $$BlockComment$$<br>Valve feedback error |
| | SIG4 | AS control system message - fault | $$BlockComment$$<br>External fault has occurred |

**Explanation**:

$$BlockComment$$: Content of the instance-specific comment

You can interconnect an external fault (signal) to the input parameter `CSF`. If this `CSF` = 1, a control system fault is triggered (`MsgEvId1`, SIG4).

### Process messages

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG1 | Alarm - high | $$BlockComment$$<br>ER - Alarm high limit violated |
| | SIG2 | Alarm - low | $$BlockComment$$<br>ER - Alarm low limit violated |
| | SIG3 | Warning - high | $$BlockComment$$<br>Rbk - High warning limit violated |
| | SIG4 | Warning - low | $$BlockComment$$<br>Rbk - Low warning limit violated |

### Instance-specific messages

You can use up to four instance-specific messages with this block.

| Message instance | Message ID | Message class | Event |
|---|---|---|---|
| MsgEvId1 | SIG5 | AS control system message - fault | $$BlockComment$$<br>External message 1 |
| | SIG6 | AS control system message - fault | $$BlockComment$$<br>External message 2 |
| MsgEvId2 | SIG5 | AS control system message - fault | $$BlockComment$$<br>External message 3 |
| | SIG6 | AS control system message - fault | $$BlockComment$$<br>External message 4 |

**Explanation**:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for the message instance **MsgEvId1**

| Associated value | Block parameter |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |
| 4 | ExtVa104 |
| 5 | ExtVa105 |
| 6 | ExtVa106 |
| 7 | Reserved |
| 8 | Reserved |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 to 6 are assigned to the parameters ExtVa104 to ExtVa106, and are usable. For more information on this, refer to the manual "*Process Control System PCS 7 - Engineering System*".

### Associated values for the message instance `MsgEvId2`

| Associated value | Block parameter |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa204` |
| 5 | `ExtVa205` |
| 6 | `ExtVa206` |
| 7 | Reserved |
| 8 | Reserved |
| 9 | Reserved |
| 10 | Reserved |

The associated values 4 to 6 are assigned to the parameters `ExtVa204` to `ExtVa206`, and are usable. For more information on this, refer to the manual "*Process Control System PCS 7 - Engineering System*".

## 8.14.6 VlvPosL I/Os

I/Os of VlvPosL

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AutModLi*` | 1= "Automatic mode" via interconnection or SFC (controlled via `ModLiOp` = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `AutModOp*` | 1 = "Automatic mode" via operator (controlled via `ModLiOp` = 1) | BOOL | 0 |
| `AV` | Input additional analog value, to be connected to `AV_Tech` of the `AV` block | ANY | |
| `AV_AH_Lim` | Limit high alarm | REAL | 95.0 |
| `AV_AL_Lim` | Limit low alarm | REAL | 5.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV_Hyst | Hysteresis for alarm, warning and tolerance limits | REAL | 1.0 |
| AV_TH_Lim | Limit high tolerance | REAL | 85.0 |
| AV_TL_Lim | Limit low tolerance | REAL | 15.0 |
| AV_WH_Lim | Limit high warning | REAL | 90.0 |
| AV_WL_Lim | Limit low warning | REAL | 10.0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7 string | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BlkTypeData* | This input can not be edit or linked and is for internal usage only! | | |
| BreakTime* | Minimum break duration [s] | REAL | 1.0 |
| BypProt | 1 = Bypass interlock is enabled in "Local mode" and in simulation | BOOL | 0 |
| CloseAut* | 1 = Select Close valve in "Automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseChnST | Signal status of the output channel of Close.<br>It should be connected to an output channel block. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| CloseForce | 1 = Force Close valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseLocal | 1 = Select Close valve in "Local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CloseMan* | 1 = Select Close valve in "Manual mode" | BOOL | 0 |
| CSF | 1 = External fault (control system fault) Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DeadBand | Deadband for forming the output ER | REAL | 0.1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block is executed | BOOL | 1 |
| ER_A_DC* | Delay for incoming alarms during monitoring of the manipulated variable difference | REAL | 0.0 |
| ER_A_DG* | Delay for outgoing alarms during monitoring of the manipulated variable difference | REAL | 0.0 |
| ER_AH_En | 1 = Activate alarm (high) for manipulated variable difference monitoring | BOOL | 1 |
| ER_AH_Lim | Alarm limit (high) for manipulated variable difference monitoring | REAL | 100.0 |
| ER_AH_MsgEn | 1 = Enable messages for alarm (high) for manipulated variable difference monitoring | BOOL | 1 |
| ER_AL_Lim | Alarm limit (low) for manipulated variable difference monitoring | REAL | -100.0 |
| ER_AL_En | 1 = Activate alarm (low) for manipulated variable difference monitoring | BOOL | 1 |
| ER_AL_MsgEn | 1 = Enable messages for alarm (low) for manipulated variable difference monitoring | BOOL | 1 |
| ER_Hyst | Alarm hysteresis for manipulated variable difference monitoring | REAL | 1.0 |
| EventTsIn | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>Input parameter EventTsIn is used to interconnect output parameter EventTsOut of the EventTs, Event16TS block. When this interconnection is configured, the messages of the EventTs, Event16TS block are displayed and can also be acknowledged on the OS in the message view of the technological block. | ANY | |
| EventTs2In | For interconnecting data between a technology block and the message blocks EventTs, Event16Ts.<br>The EventTs2In input parameter serves to interconnect the EventTsOut output parameter of the EventTs, Event16Ts block. When this interconnection is configured, the messages of the EventTs, Event16Ts block are displayed on the OS in the alarm view of the technology block and can also be acknowledged there. | ANY | |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg3 | Binary input for freely selectable message 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg4 | Binary input for freely selectable message 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvId1) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvId1) | ANY | |
| ExtVa106 | Associated value 6 for messages (MsgEvId1) | ANY | |
| ExtVa204 | Associated value 4 for messages (MsgEvId2) | ANY | |
| ExtVa205 | Associated value 5 for messages (MsgEvId2) | ANY | |
| ExtVa206 | Associated value 6 for messages (MsgEvId2) | ANY | |
| FaultExt | 1 = External fault Error handling (Page 128) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkClose | 1 = Valve closed feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkClosing | 1 = Valve closing feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkOpen | 1 = Valve open feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| FbkOpening | 1 = Valve opening feedback signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| Feature | I/O for additional functions (Page 1884) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Feature2 | I/O for additional functions (Page 1884) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Gain | Position control gain | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 1.0<br>• 16#FF |
| Intlock | 0 = Interlock / Interlock Open is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock / Interlock Open is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Intl_En | 1 = Parameter Intlock is enabled | BOOL | 1 |
| IntlCls | 0 = Interlock Close is activated.<br>Once the interlock condition has cleared, the block can be operated without reset.<br>1 = Interlock Close is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| IntlClsEn | 1 = Parameter IntlCls is enabled | BOOL | 1 |
| LocalLi | 1 = Activate "Local mode" via plant signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalOp* | 1 = "Local mode" via operator | BOOL | 0 |
| LocalSetting | Properties for Local mode (Page 86) | INT | 0 |
| Man* | Manipulated variable in "manual mode" | REAL | 0.0 |
| ManModLi* | 1 = "Manual mode" via interconnection or SFC (controlled via ModLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManModOp* | 1= "Manual mode" via: OS operator (controlled via ModLiOp = 0) | BOOL | 1 |
| ModLiOp | Toggle operation between:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MonSafePos | 1 = Go to neutral position in the event of monitoring errors | BOOL | 1 |
| MotorTime* | Motor actuating time [s] | REAL | 30.0 |
| M_Monitor | 1 = Motor feedback monitoring | BOOL | 1 |
| M_MonTiDynamic* | Monitoring time for feedback errors or feedback start errors after successful operation in [s] | REAL | 3.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| M_MonTiStatic* | Monitoring time for feedback errors without operation in [s] | REAL | 3.0 |
| M_MonTiStop* | Monitoring time for feedback stop errors after successful operation in [s] | REAL | 3.0 |
| MS_RelOp* | 1= Release for maintenance via OS operator | BOOL | 0 |
| MsgEvId1 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgEvId2 | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>For more on this, refer to the section Suppressing messages using the MsgLock parameter (Page 231). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV | Manipulated variable in "automatic mode" | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_Forced | Forced manipulated variable that is not limited and has top priority | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_ForOn | 1 = Output forced manipulated variable MV_Forced unlimited at output MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_HiLim | Limit (high) for manipulated variable MV | REAL | 100.0 |
| MV_LoLim | Limit (low) for manipulated variable MV | REAL | 0.0 |
| MV_OpScale | OS display range for the manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_Scale | Range for the manipulated variable MV | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| MV_Trk | Tracking value for manipulated variable MV | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_TrkOn | 1 = Tracking of manipulated variable MV | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Unit | Unit of measure for manipulated variable | INT | 1342 |
| NoFbkClose | 1 = No feedback present for "valve closed" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoFbkOpen | 1 = No feedback present for "valve open" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Occupied | 1 = Occupied by a batch | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpenAut* | 1 = Select Open valve in "Automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenChnST | Signal status of the output channel of Open.<br>It should be connected to an output channel block. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| OpenForce | 1 = Force Open valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenLocal | 1 = Select Open valve in "Local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpenMan* | 1 = Select Open valve in "Manual mode" | BOOL | 0 |
| OpSt_In | Input parameter for local operator permission, to be connected with the Out output parameter of the upstream block OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for Operator control permissions (Page 285) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for Operator control permissions (Page 285) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| Permit | 1 = Activation / activation Open is activated<br>0 = Activation / activation Open is deactivated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermitSafePos | 1=Valve SafePos / Stop allowed | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PermSf_En | 1=Permit SafePos / Stop enabled | BOOL | 1 |
| Perm_En | 1 = Parameter Permit is enabled | BOOL | 1 |
| PermCls | 1 = Activation Close is activated<br>0 = Activation Close is deactivated | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| PermClsEn | 1 = Parameter PermCls is enabled | BOOL | 1 |
| PosDiClose | Limit for control valve position "closed" | REAL | 5.0 |
| PosDiOpen | Limit for control valve position "open" | REAL | 95.0 |
| PosOnAut | 1 = Select Activate position control in "Automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PosOnMan | 1 = Select Activate position control in "Manual mode" | BOOL | 0 |
| PosRbkHys | allowable variation from preset position;<br>should be greater than the parameter DeadBand | REAL | 0.1 |
| Protect | 0 = Protective interlock / protective interlock Open is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock / protective interlock Open is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| Prot_En | 1 = Parameter Protect is enabled | BOOL | 1 |
| ProtCls | 0 = Protective interlock Close is activated.<br>Once the interlock condition has cleared, the block must be reset.<br>1 = Protective interlock Close is deactivated. | STRUCT<br>• Value:BOOL<br>• ST:BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 1<br>• 16#FF<br>• 0 |
| ProtClsEn | 1 = Parameter ProtCls is enabled | BOOL | 1 |
| PulseTime | Minimum pulse duration [s] | REAL | 1.0 |
| PulseWidth* | Pulse width of the control signal [s] | REAL | 3.0 |
| RapidStp* | Rapid stop for the motor<br>0 = Motor On<br>1 = Motor off | BOOL | 0 |
| Rbk | Position feedback | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkHyst | Alarm hysteresis for position feedback | REAL | 1.0 |
| RbkMonitor | 1 = Position feedback monitoring | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RbkMonTi | Monitoring time for the position feedback in [s] | REAL | 5.0 |
| RbkW_DC* | Delay time for incoming warnings [s] | REAL | 0.0 |
| RbkW_DG* | Delay time for outgoing warnings [s] | REAL | 0.0 |
| RbkWH_En | 1 = Enable warning (high) for position feedback | BOOL | 0 |
| RbkWH_Lim | Limit for position feedback of warning (high) | REAL | 90.0 |
| RbkWH_MsgEn | 1 = Enable messages for warning (high) for position feedback | BOOL | 1 |
| RbkWL_En | 1 = Enable warning (low) for position feedback | BOOL | 0 |
| RbkWL_Lim | Limit for position feedback of warning (low) | REAL | 10.0 |
| RbkWL_MsgEn | 1 = Enable messages for warning (low) for position feedback | BOOL | 1 |
| RstLi* | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SafePos | Neutral position for valve:<br>0 = Closed<br>1 = Open<br>2 = Stop (valve can be in position Closed, Opened or Intermediate) | INT | 2 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an Opening additional faceplates (Page 234) in the standard view | ANY | - |
| SelFp2 | Call a block saved in this parameter as an Opening additional faceplates (Page 234) in the preview | ANY | - |
| SimAV* | Additional value used with SimOn = 1 | REAL | 0.0 |
| SimAV_Li | Additional analog value used with SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled via SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimRbk* | Position feedback used with SimOn = 1 | REAL | 0.0 |
| SimRbkLi | Position feedback used with SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| StopAut* | 1 = Stop the motor in "Automatic mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopForce | 1 = Force motor stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopLocal | 1 = Stop the motor in "Local mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StopMan* | 1 = Stop the motor in "Manual mode" | BOOL | 0 |
| TmLag | Delay time of the LeadLag filter [s] | REAL | 0.0 |
| TorqClose | 0 = Torque shutdown active when closing<br>1 = Good state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| TorqOpen | 0 = Torque shutdown active when opening<br>1 = Good state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| Trip | 1 = Motor is in "good" state | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#FF |
| UA1unit | Unit of measure for analog auxiliary value 1 | INT | 0 |
| UA2unit | Unit of measure for analog auxiliary value 2 | INT | 0 |
| UserAna1 | Analog auxiliary value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserAna2 | Analog auxiliary value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |
| VibrNo | Vibration number if TorqOpen or TorqClose | INT | 3 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| VibrPerc | Vibration Width [%] if TorqOpen or TorqClose (in analog mode) | REAL | 5.0 |
| VibrWidth | Vibration Width [s] if TorqOpen or TorqClose (in binary mode) | REAL | 3.0 |
| V_Monitor | 1 = Valve feedback monitoring | BOOL | 1 |
| V_MonTiDynamic* | Valve monitoring time after operation in [s] | REAL | 30.0 |
| V_MonTiStatic* | Monitoring time for valve feedback errors without operation in [s] | REAL | 5.0 |
| WarnTiAut* | Prewarning of valve movement in "automatic mode" in [s] | REAL | 0.0 |
| StateTrkOn | Initiate tracking of state | BOOL | 0 |
| WarnTiMan* | Prewarning of valve movement in "manual mode" in [s] | REAL | 0.0 |

* Values can be written back to these inputs during execution of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AutAct | 1 = "Automatic mode" enabled<br>0 = "Manual mode" is enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AutoST | 1 = Worst signal status of automatic commands | BYTE | 16#80 |
| AV_OpScale | Limit for scale in AV bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| AV_Out | Output additional analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| AV_Unit | Unit of measure for additional analog value | INT | 0 |
| CascaCut | Cascade connection:<br>1 = Control chain from master controller to secondary valve is interrupted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Close | Control output<br>1= Close valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Closed | 1 = Valve is closed | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Closing | 1 = Valve is closing | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CurrMonM | Remaining motor monitoring time [s] | DINT | 0 |
| CurrMonRbk | Remaining monitoring time of position feedback [s] | DINT | 0 |
| CurrMonV | Remaining valve monitoring time [s] | DINT | 0 |
| CSF_Out | CSF as Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER | Difference of the manipulated variable MV_Out and the position feedback RbkOut in consideration of the parameter DeadBand | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ER_AH_Act | 1 = Alarm limit (high) for manipulated variable difference violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ER_AL_Act | 1 = Alarm limit (low) for manipulated variable difference violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ER_AH_LimOut | ER_AH_Lim as output | REAL | 0.0 |
| ER_AL_LimOut | ER_AL_Lim as output | REAL | 0.0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see the section VlvPosL error handling (Page 1908) | INT | -1 |
| FaultExtOut | FaultExt as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkCloseOut | Valve closed feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkClsgOut | Valve closing feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpenOut | Valve open feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FbkOpngOut | Valve opening feedback | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| GrpErr | 1 = Group error pending | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| IntlockOut | Intlock as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| IntlClsOut | IntlCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LocalAct | 1 = "Local mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| LockAct | 1 = Interlock (Intlock, Permit, Protect) or Trip is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ManAct | 1 = "Manual mode" enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| M_MonDynErr | 1 = Feedback error or feedback start error of the motor due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| M_MonStaErr | 1 = Motor feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| M_MonStopErr | 1 = Feedback stop error of the motor due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance:<br>1 = Enable for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1 | Message - acknowledgment status 1 (ACK_STATE output of the first ALARM_8P) | WORD | 16#0000 |
| MsgAckn2 | Message - acknowledgment status 2 (ACK_STATE output of the first ALARM_8P) | WORD | 16#0000 |
| MsgErr1 | Message error 1 (ERROR output of the first ALARM_8P) | BOOL | 0 |
| MsgErr2 | Message error 2 (ERROR output of the first ALARM_8P) | BOOL | 0 |
| MsgStat1 | Message status 1 (STATUS output of the first ALARM_8P) | WORD | 16#0000 |
| MsgStat2 | Message status 2 (STATUS output of the first ALARM_8P) | WORD | 16#0000 |
| MV_HiAct | 1 = Limit (high) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MV_LoAct | 1 = Limit (low) of manipulated variable violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MV_Aut | Manipulated variable in automatic mode | REAL | 0.0 |
| MV_Out | Manipulated variable | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| MV_UnitOut | Unit of measure for manipulated variable | INT | 0 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Open | Control output:<br>1 = Open the valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opened | 1 = Valve is open | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opening | 1 = Valve is opening | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the input parameter OpSt_In for further interconnection with other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS1PermOut | Display of OS1Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS1PermLog | Display of OS1Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| PosAct | Position control is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PosReached | 1 = Control valve has reached specified position | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Close | 1 = Pulse signal to close valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Open | 1 = Pulse signal to open valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| P_Rst | 1= Pulse output for reset<br>The parameter persists for one cycle after a reset. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Stop | 0 = Pulse signal for stopping the valve | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| PermitOut | Permit as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PermitSafePos-Out | PermitSafePos as output | STRUCT<br>• Value: BOOL<br>ST: BYTE | -<br>• 1<br>• 16#FF |
| PermClsOut | PermCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtectOut | Protect as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ProtClsOut | ProtCls as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| R_StpAct | 1 = Rapid stop of the motor is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkMonDynErr | 1 = Position feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkMonStaErr | 1 = Position feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkOut | Position feedback output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| RbkWH_Act | 1 = Warning (high) enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RbkWL_Act | 1 = Warning (low) enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RdyToReset | 1 = Ready for reset via RstLi input or commands in "local", "automatic", or "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyToStart | 1 = Ready to start | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation Active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1876) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1876) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1876) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1876) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1876) | DWORD | 16#00000000 |
| Status6 | Status word 6 (Page 1876) | DWORD | 16#00000000 |
| Status7 | Status word 7 (Page 1876) | DWORD | 16#00000000 |
| Stop | 1 = Motor is stopped and position is reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SumMsgAct | 1 = Active hardware interrupt | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ThreshOff | Trip threshold of the three-step element | REAL | 0.0 |
| ThreshOn | Response threshold of the three-step element | REAL | 0.0 |
| TripOut | Trip as Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UA1unitOut | UA1 as output | INT | 0 |
| UA2unitOut | UA2 as output | INT | 0 |
| UserAna1Out | UserAna1 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| UserAna2Out | UserAna2 as output | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| V_MonDynErr | 1 = Valve feedback error due to control change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| V_MonStaErr | 1 = Valve feedback error due to unexpected feedback change | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ResyncST | Worst Signal Status of inputs for resynchronization | BYTE | 16#80 |
| StopCtrl | Control output go to SafePos | BOOL | 0 |
| WarnAct | 1 = Prewarning for control valve movement away from active (WarnTiAut and WarnTiMan parameters) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

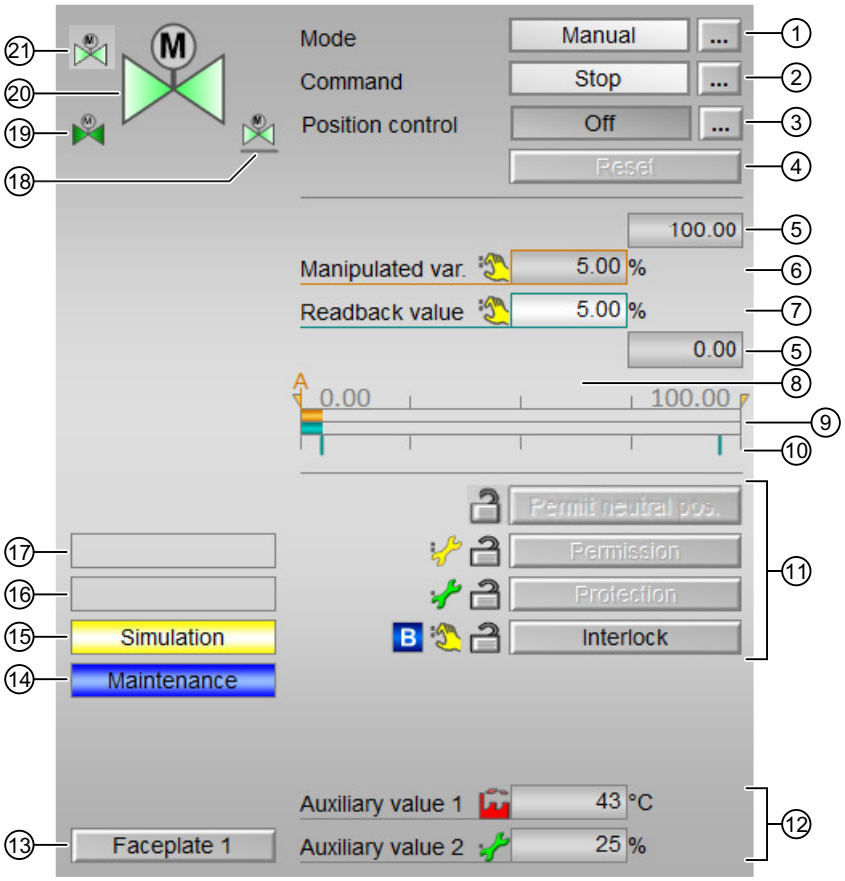
## 8.14.8 Operator control and monitoring

### 8.14.8.1 VlvPosL views

#### Views of the VlvPosL block



The VlvPosL block provides the following views:

- VlvPosL standard view (Page 1930)
- Limit view of motors (Page 328)
- VlvPosL limit value view (Page 1935)
- Alarm view (Page 336)
- Trend view (Page 341)
- VlvPosL parameter view (Page 1937)
- VlvPosL preview (Page 1941)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for VlvPosL (Page 1947)

You can find general information about the faceplate and block icon in the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260).

### 8.14.8.2 VlvPosL standard view

#### Standard view of VlvPosL

#### (1) Display and switch the operating mode

This area displays the current operating mode of the block. The following operating modes can be shown here:

- Manual and automatic mode for motors, valves and dosers (Page 82)
- Local mode (Page 86)
- Out of service (Page 77)

For information on switching the mode, see section Switching operating states and operating modes (Page 289).

### (2) Open, close and stop the motor valve

This area displays the default operating state for the motor valve. The following states can be shown and executed here:

- "Open"
- "Close"
- "Stop"
- "Rapid stop"

Analog positioning mode is terminated if one of these commands is executed. Positioning mode can be reactivated using the **(3)** button.

For information on switching the mode, see section Switching operating states and operating modes (Page 289).

If the text is configured for these commands, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (3) Activate positioning at an analog manipulated variable

This area shows you the default operating state for positioning to the analog manipulated variable. The following states can be shown here:

- "On"
- "Off"

Only the positioning mode is activated here:

- "On"

Positioning mode is terminated when the motor valve is operated using the **(2)** button.

### (4) Reset the block

Click "Reset" in the event of interlocks or errors. You can find more information on this in the section Resetting the block in case of interlocks or errors (Page 47).

### (5) High and low scale range for the manipulated variable

These values provide information on the display range for the bar graph of the manipulated variable. The scale range is defined in the engineering system.

### (6) Display and change the manipulated variable including signal status

This area shows the current manipulated variable with the corresponding signal status.

The manipulated variable can only be changed in manual mode and active position control.

You can find more information about changing the manipulated variable in the section Changing values (Page 291).

### (7) Display for position feedback including signal status

This area shows the current feedback of the manipulated variable with the corresponding signal status.

### (8) Display of the manipulated variable for automatic mode

The display [A] is only visible when the block is not in automatic mode. In Automatic mode, it is displayed when it needs to be reset or when tracking or forced tracking is enabled.

This display shows the manipulated variable that would apply if you were to switch to automatic mode or if you were to reset in automatic mode or disable tracking or forced tracking.

### (9) Bar display for manipulated variable

This area shows the current manipulated variable in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (10) Bar display for position feedback

This area shows the current position feedback in the form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

The limits for the "open" and "closed" positions are shown with 2 green lines.

For more information, refer: Bar graph (Page 376)

### (11) Area for operating the interlock functions of the block

This display is only visible when the corresponding block input is interconnected.

You can use these buttons to control the interlock functions of the block. You can find more information on this in the section Interlocking functions (Page 107).

The following is displayed in addition to the buttons:

- Interlock status (see Forming the group status for interlock information (Page 113)), for example:

- Signal status (see Forming and outputting the signal status for technologic blocks (Page 117)), for example:

- Bypass information (see Forming the group status for interlock information (Page 113)):

If the text is configured for the interlocks, it is displayed as status text and as button labels for command selection. For more information, see section Labeling of buttons and text (Page 235).

### (12) Display for auxiliary values

This display is only visible when the corresponding block input is interconnected.

You can use this area to display two auxiliary values that have been configured in the engineering system. You can find more information on this in the section Displaying auxiliary values (Page 239).

### (13) Jump key to standard view of any faceplate

This display is only visible when the corresponding block input is interconnected.

Use this navigation button to jump to the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find more information on this in the section Opening additional faceplates (Page 234).

### (14) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

You can find more information on this in the section Release for maintenance (Page 70) display area for block states.

### (15) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"
- "Time delay"

You can find more information on this in the sections Simulating signals (Page 64) and Display of delay times (Page 288).

### (16) Display area for block states

This area provides additional information on the operating state of the block:

- "Motor protection"
- "External error"
- "Vibrate enabled"
- "End position error"
- "Control error"
- "Internal error"
- "Changeover error"
- "Torque active"
- "Invalid Signal"

You can find more information on this in the sections Monitoring the feedbacks (Page 104), Error handling (Page 128) (headings "Invalid input signals" and "Mode switchover error") and Motor protection function (Page 106).

### (17) Display area for block states

This area provides additional information on the operating state of the block:

- "Forced open" (`OpenForce`)
- "Forced closed" (`CloseForce`)
- "Forced stop" (`StopForce`)
- "Forced tracking" (`MV_ForOn`)
- "Tracking" (`MV_TrkOn`)
- "Request 0/1": Reset is expected but reset is not possible from faceplate. For more details, refer:Reset of errors during Request 0/1 (Page 382)

You can find more information on this in the section Forcing operating modes (Page 45).

### (18) Neutral position of the valve

This representation shows the neutral position for the valve:

- **Green**: Neutral position is "Open" or neutral position is “Stop” and valve is opened
- **Gray**: Neutral position is "Closed" or neutral position is “Stop” and valve is closed
- **Light green**: Neutral position is "Stop" and valve is in intermediate position

### (19) Automatic preview

This display is only visible in "Manual mode", in "Local mode", or with a reset request in "Automatic mode", when the current output signals are not identical to the control in "Automatic mode".

The display shows what state the valve would assume if you switched from "Manual" or "Local" mode to "Automatic mode", or performed a reset to "Automatic mode".

| Mode | Discription |
|---|---|
|  | Open: Automatic commands will open the motor valve. If position control is On or is switched on by automatic command, the Automatic `MV_Aut` is in open position. |
|  | Close: Automatic commands will close the motor valve. If position control is On or is switched on by automatic command, the Automatic `MV_Aut` is in close position. |
|  | Stop: Automatic commands will stop the motor valve or move it in another intermediate position. If position control is On or is switched on by automatic command, the Automatic `MV_Aut` is in intermediate position. |

The symbols are only visible if the position is not reached.

### (20) Status display of the motor valve

The current status of the motor valve is graphically displayed here.

You can find more information on this in the section Block icon for VlvPosL (Page 1947).

### (21) Mini preview for Resynchronization

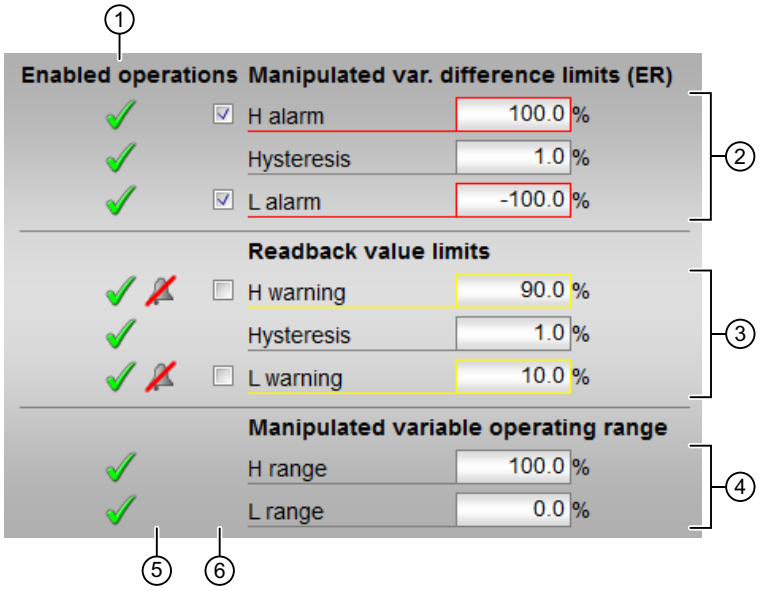
Displays the mini preview for Resynchronizing the signal state.

The mini preview displays the following states:

- Open
- Close
- Intermediate

**Note**

Mini preview for resynch is visible only if resynchronization command is different to control output value.



## 8.14.8.3 VlvPosL limit value view

### Limit view of VlvPosL

Several values are set in this view by default:

- Manipulated variable difference limits
- Readback value limits
- Manipulated variable operating range

The toolbar of the faceplate and the block icon indicate when the limits are reached or violated.

### (1) Enabled operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for operation enable:

- **Green check mark**: The OS operator can control this parameter
- **Gray check mark**: The OS operator cannot control this parameter at this time due to the process
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (2) Limits of the manipulated variable difference

In this area, you can enter the limits for the manipulated variable difference. For more on this, see section Changing values (Page 291).

You can change the following limits:

- "H alarm": Alarm high
- "Hysteresis"
- "L alarm": Alarm low

### (3) Readback value limits (`Rbk`)

In this area, you can enter the limits for the readback value (position feedback). For more on this, see section Changing values (Page 291).

You can change the following limits:

- "H warning": Warning high
- "Hysteresis"
- "L warning": Warning low

### (4) Manipulated variable operating range

In this area, you can enter the limits for the manipulated variable operation range. For more on this, see section Changing values (Page 291).

You can change the following limits:

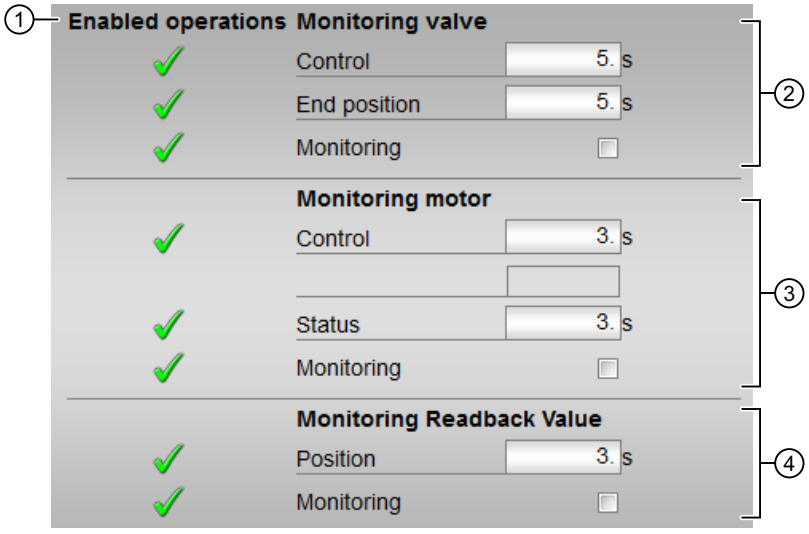
- "H range": Range limit high
- "L range": Range limit low

### (5) Message suppression / delay

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when you install the block (all `xx_MsgEn` parameters are assigned the default value 1). Messages can only be outputted if limit monitoring of the additional analog value has been enabled.

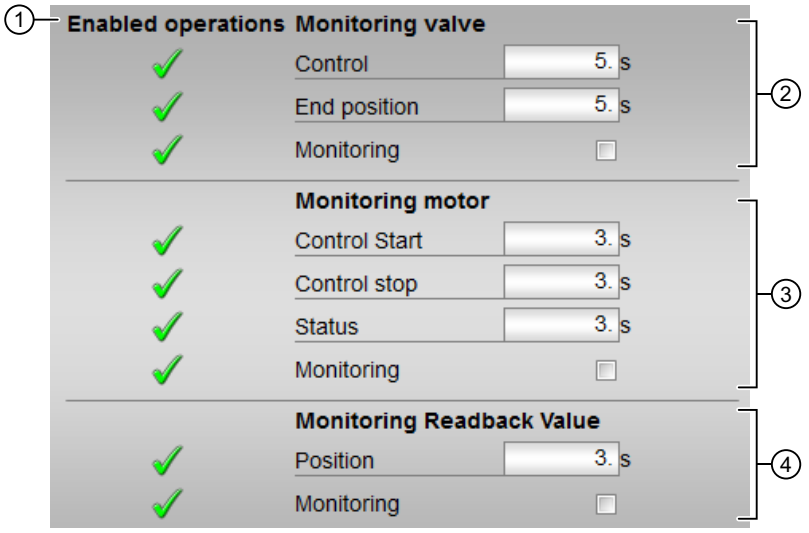
Alarm delays are also displayed in this position; for more on this, see section Area of application of the alarm delays (Page 225).

### (6) Suppress messages



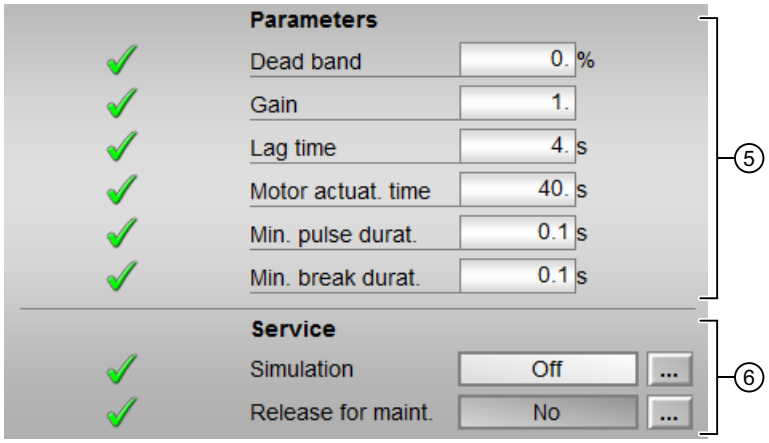
You can enable/disable messages by setting the check mark.

## 8.14.8.4 VlvPosL parameter view



### Parameter view of VlvPosL

The parameter has an upper half and a lower half. You can navigate between the two halves with the arrow keys.



Upper half of the parameter view of VlvPosL with `Feature.Bit13` = 0:

Upper half of the parameter view of VlvPosL with `Feature.Bit13` = 1:

Lower half of the parameter view of VlvPosL:

## (1) Enabled operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for operation enable:

- **Green check mark**: The OS operator can control this parameter.
- **Gray check mark**: The OS operator cannot control this parameter at this time due to the process.
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

## (2) Monitor valve

In this area, you can change parameters and thereby influence the valve. You can find more information on this in the section Changing values (Page 291).

You can influence the following parameters:

- "Control": Monitoring time while "Opening"/"Closing" the valve (dynamic)
- "End position": Monitoring time for maintaining the valve position (static)

### Enable monitoring

You can enable monitoring by selecting the check box (☑).

You can find more information on this in the section Monitoring the feedbacks (Page 104).

## (3) Monitor motor

In this area, you change parameters and thereby influence the motor. You can find more information on this in the section Changing values (Page 291).

You can influence the following parameters:

- "Control": Monitoring time during startup and stopping of the motor (dynamic) `Feature.Bit13` = 0
- "Control start": Monitoring time during startup of the motor (dynamic) `Feature.Bit13` = 1
- "Control stop": Monitoring time during stopping of the motor (dynamic) `Feature.Bit13` = 1
- "Status": Monitoring time during permanent operation of the motor (static)

**Enable monitoring**

You can enable monitoring by selecting the check box (☑).

You can find more information on this in the section Monitoring the feedbacks (Page 104).

### (4) Monitoring the valve position

In this area, you change parameters and thereby influence the valve. You can find more information on this in the section Changing values (Page 291).

You can influence the following parameter:

- "Position": Monitoring time for the valve

**Enable monitoring**

You can enable monitoring by selecting the check box (☑).

You can find more information on this in the section Monitoring the feedbacks (Page 104).

### (5) "Parameters"

In this area, you change parameters and thereby influence the controller. For more on this, see section Changing values (Page 291).

You can influence the following parameters:

- "Deadband": Width of deadband
- "Gain": Gain
- "Delay": Delay time in [s]
- "Motor actuating time": Motor actuating time [s]
- "Minimum pulse duration": Minimum pulse duration [s]
- "Minimum break duration": Minimum break duration [s]

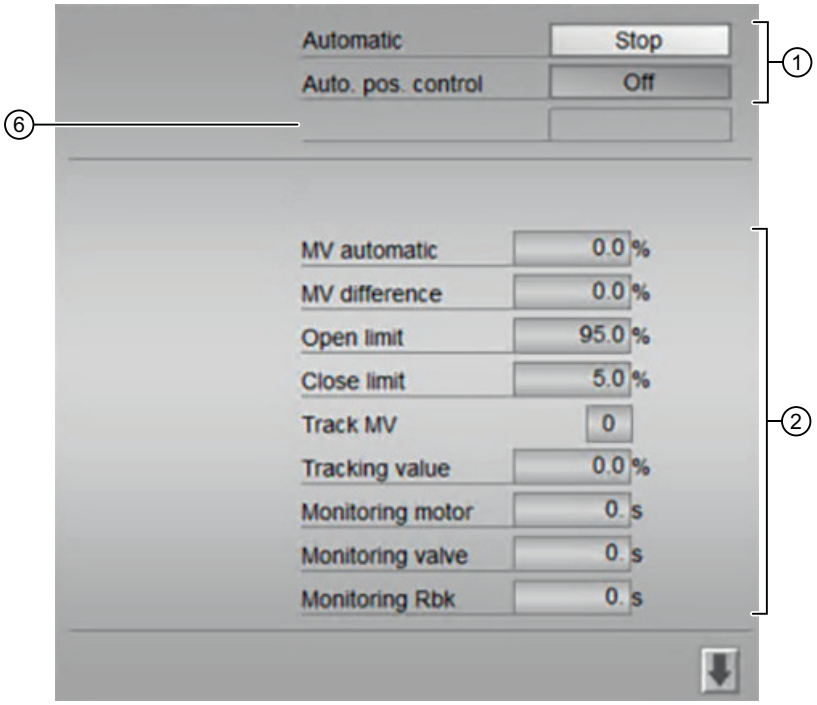
### (6) Service

You activate the following functions in this area:

- "Simulation"
- "Release for maintenance" (with display for maintenance demanded)

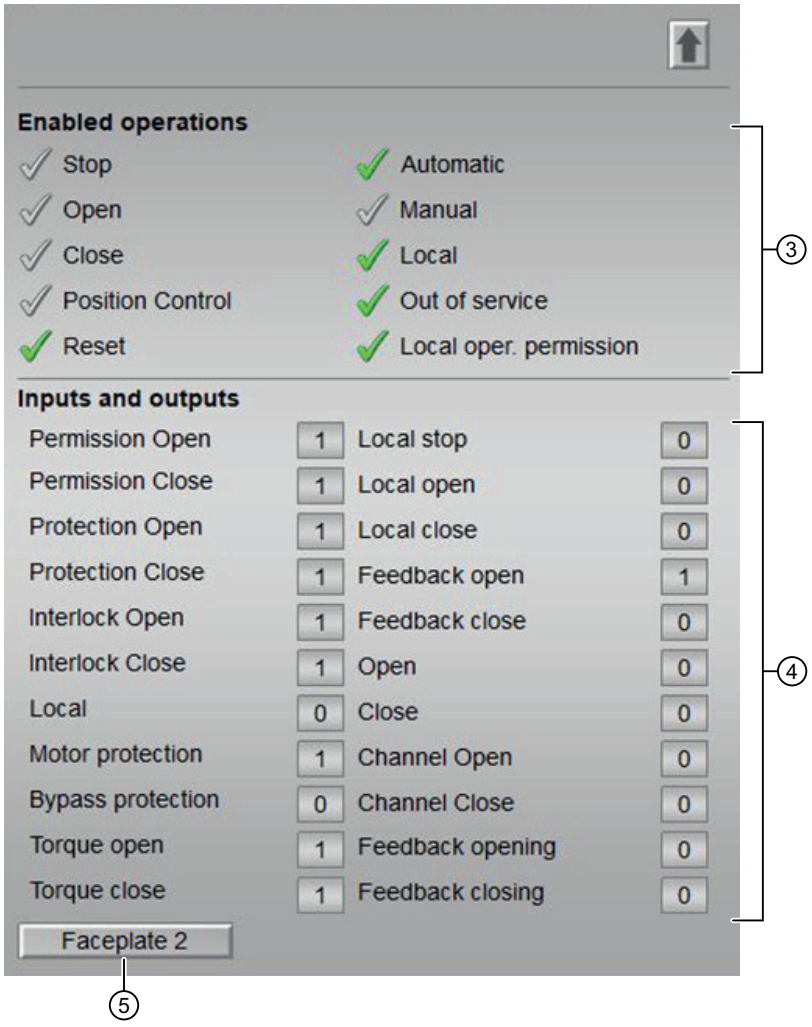
You can find more information on this in the section Switching operating states and operating modes (Page 289).

You can find information on this area in the sections:



- Simulating signals (Page 64)
- Release for maintenance (Page 70)

## 8.14.8.5 VlvPosL preview



### Preview of VlvPosL

The preview has an upper half and a lower half. You can navigate between the two halves with the arrow keys.

Upper half of the preview of VlvPosL:

Lower half of the preview of VlvPosL:

## (1) Automatic preview

This area shows you the block status after it has switched from the "Manual" mode or "Local" mode to the "Automatic" mode.

| Mode | Discription |
|---|---|
| Open | Automatic commands will open the motor valve or valve is already opened. If position control is On or is switched on by automatic command, the automatic `MV_Aut` is in open position. |
| Close | Automatic commands will close the motor valve or valve is already closed. If position control is On or is switched on by automatic command, the Automatic `MV_Aut` is in close position. |
| Stop | Automatic commands will stop the motor valve or the automatic `MV_Aut` move it in another intermediate position. If position control is On or is switched on by automatic command, the automatic `MV_Aut` is in intermediate position. |

If the block is in "Automatic" mode, the current block state is displayed.

**Note**

- If the valve is closed and interlock locking is active (`SafePos`=0 Close), the automatic preview does not show the current status "Closed", instead it shows the active automatic command "Open".

This area also displays the worst signal status of the following automatic commands:

- `OpenAut`
- `CloseAut`
- `StopAut`
- `PosOnAut`
- `MV`

### (2) Preview area

- "MV Automatic": Display of the current automatic manipulated variable (`MV_Aut`). It depends on tracking (`MV_TrkOn, MV_Trk`) and is limited (`MV_HiLim, MV_LoLim`).
- "MV difference": Current manipulated variable difference (`ER`).
- "Open limit": Limit (`PosDiOpen`) for forming the "Control valve open" signal (`FbkOpenOut`). If the position feedback reaches this limit, the control valve is open.
- "Close limit": Limit (`PosDiClose`) for forming the "Control valve closed" signal (`FbkCloseOut`). If the position feedback reaches this limit, the control valve is closed.
- "Manipulated variable tracking": (`MV_TrkOn` = 1) Manipulated variable is tracked to the tracking value.
- "Tracking value": Effective manipulated variable for "Track manipulated variable"
- "Monitoring motor": Display of the remaining monitoring time of the motor. This display is only visible when monitoring is activated.
- "Monitor valve": Display of the remaining monitoring time of the valve. This display is only visible when monitoring is activated.
- "Monitoring Rbk": Display of the remaining monitoring time for the position feedback. This display is only visible when monitoring is activated.
- "Rbk Resync": Shows the input Rbk value for Resynchronization

### (3) Enabled operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for operation enable:

- **Green check mark**: The OS operator can control this parameter.
- **Gray check mark**: The OS operator cannot control this parameter at this time due to the process.
- **Red cross**: The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

The following enabled operations are shown here:

- "Stop": You can stop the motor of the valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Open": You can open the motor valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Close": You can close the motor valve.
  If the text is configured for this command, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Position Control": You can switch on the position control.
- "Reset": You can reset the motor valve if interlocks or errors occur.
- "Automatic": You can switch to "Automatic mode".
- "Manual": You can switch to "Manual mode".
- "Local": You can switch to "Local mode".
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to change to the standard view of the OpStations block. For more information, see section Operator control permissions (Page 285).

### (4) Display current control signals

This area shows the most important parameters for this block with the current selection:

- "Permission" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "opening"/"closing" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permission Open" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "open" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Permission Close" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Motor valve activation not enabled on OS
  - 1 = Enable for "close" from the neutral position

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Permit neutral pos" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Prevents the control in safe position direction
  - 1 = prevents the stop command

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection Open" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Protection Close" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Protective interlocking is effective; once the interlocking condition has disappeared, you will have to reset the block
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock" (`Feature2.Bit16` = 0):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).

- "Interlock Open" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Interlock Close" (`Feature2.Bit16` = 1):
  This display is only visible when the corresponding block input is connected.
  - 0 = Interlocking without reset is active; you can operate the block without reset once the interlocking condition has disappeared
  - 1 = "Good" state

  If the text is configured for the interlocks, it is also displayed in brackets. For more information, see section Labeling of buttons and text (Page 235).
- "Local": 1 = Control signal for "Local mode" (`LocalLi`) is active
- "Motor protection": 1 = Motor is in "good" state
- "Interlock deact.":
  - 0 = Bypass disabled
  - 1 = Bypass interlock in "Local mode" and in simulation
- "Torque opening": 0 = Torque shutoff when opening
- "Torque closing": 0 = Torque shutoff when closing
- "Local stop": 1 = Stop the motor valve in "Local mode"
- "Local open": 1 = Open the motor valve in "Local mode"
- "Local close": 1 = Close the motor valve in "Local mode"
- "Feedback open": 1 = Motor valve is opened
- "Feedback closed": 1 = Motor valve is closed
- "Open": 1 = Motor valve is opening
- "Close": 1 = Motor valve is closing
- "Channel Open": Signal from the output channel block for "Open"
- "Channel Close": Signal from the output channel block for "Close"
- "Feedback opening": 1 = Motor valve is opening
- "Feedback closing": 1 = Motor valve is closing

### (5) Jump key to standard view of any faceplate

This display is only visible when the corresponding block input is interconnected.

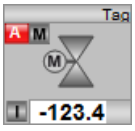
Use this navigation button to jump to the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

For more information, see section Opening additional faceplates (Page 234).

### (6) Resynchronization

Displays the Resynchronization state and Resynchronization Signal status based on feedback and readback values.

- When motor feedbacks are not present (`Feature.Bit12` = 1) - Resynchronization preview is based on valve feedbacks.
- When motor feedbacks are present (`Feature.Bit12` = 0) - Resynchronization preview is based on motor feedbacks.



## 8.14.8.6 Block icon for VlvPosL

### Block icons for VlvPosL

A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits as well as control system faults
- Operating modes
- Signal status, release for maintenance
- Forcing states
- Operating the manipulated variable in manual mode
- Display of active position control
- Display of the position feedback (white, with decimal places)
- Display for bypassing interlocks
- Interlocks
- Memo display
- Valve status display

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 3 | Non-rotating block icon |
|  | 4 | Non-rotating block icon |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269)

## Valve status display

The following valve states are shown here:

| Icon | Meaning |
|---|---|
|  | Valve open |
|  | Valve closed |
|  | Error at valve |
|  | Valve is opening |
|  | Valve is closing |
|  | Valve is stopping |
|  | Valve closed |
|  | Valve is closing |

# Interlock blocks

# 9

## 9.1 Intlk02 - Interlock display with 2 input signals

### 9.1.1 Description of Intlk02

#### Object name (type + number) and family

Type + number: FB 1824

Family: Interlck

#### Area of application for Intlk02

The block is used for the following applications:

- Standardized interlock with display

#### How it works

The block is used to calculate a standardized interlock that can be displayed on the OS. A maximum of 2 input signals can be supplied to the block. They are linked using selectable binary logic. The signal status of the output signal is also determined. You can assign an analog value with the signal status and unit to each input value for display in the faceplate.

The current state is displayed at the `Out` output parameter:

- `Out` = 0: Interlock
- `Out` = 1: "Good" state

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Intlk02 block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Dosing (Dose_Lean) (Page 2856)
- Dosing with PA/FF devices (Dose_Lean_Fb) (Page 2857)
- Two-speed motor (Motor2Speed) (Page 2860)
- Reversing motor (MotorReversible) (Page 2861)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Two-way valve (Valve2Way) (Page 2866)

- Motor valve (ValveMotor) (Page 2867)
- Control valve (VlvAnL) (Page 2868)
- Control valve for PA/FF devices (ValveAnalog_Fb) (Page 2869)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section Intlk02 I/Os (Page 1957).

| Status bit | Parameter |
|---|---|
| 0 | 1 = `Logic` = OR |
| 1 | 1 = `Logic` = AND |
| 2 | Not used |
| 3 | Result of logic operation `Out.Value` |
| 4 | 1 = At least one input value is excluded. See the section Excluding input values in Intlk02 functions (Page 1952). |
| 5 | 1 = All input values are excluded |
| 6 | 1 = No input value is interconnected or `NotUsed.Value` |
| 7 | Status display for simulation |
| 8 | Status display for not interlocked |
| 9 | Status display for interlocked |
| 10 | Activate `OS_Perm` bits |
| 11 | `Feature.Bit2`: Separate evaluation for excluded and simulated interlock signals. |
| 12 | Internal error |
| 13-29 | Not used |
| 30 | `Occupied` |
| 31 | `BatchEn` |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01.Value` |
| 1 | `In02.Value` |
| 2 - 31 | Not used |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | `InvIn01` |
| 1 | `InvIn02` |
| 2 - 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` with inversion |
| 1 | `In02` with inversion |
| 2 - 15 | Not used |
| 16 | Bypass `In01` (via interconnection) |
| 17 | Bypass `In02` (via interconnection) |
| 18 - 31 | Not used |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 | `BypIn01` |
| 1 | `BypIn02` |
| 2 - 15 | Not used |
| 16 | In01 hidden bypass information |
| 17 | In02 hidden bypass information |
| 18 - 31 | Not used |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` not connected |
| 1 | `In02` not connected |
| 2 - 31 | Not used |

### Status word allocation for `Status7` parameter

| Status bit | Parameter |
|---|---|
| 0 | `AV01` not connected |
| 1 | `AV02` not connected |
| 2 - 31 | Not used |

#### Status word allocation for `Status8` parameter

Identical to `FirstIn`.

Intlk02 error handling (Page 1956)
Intlk02 functions (Page 1952)
Description of Intlk02 (Page 1949)

### 9.1.3 Intlk02 functions

#### Functions of Intlk02

The functions for this block are listed below.

#### Handling non-connected inputs

Inputs which are not interconnected are not evaluated. They are not displayed in the faceplate either.

**Special situation:** If no inputs are connected, the output value is defined using the `DefaultOut` parameter. The signal status is set to 16#FF.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234). However, only one additional faceplate can be called up using `SelFp1 = 1`.

### First-in detection for interlock blocks

This block provides the standard function Recording the first signal for interlock blocks (Page 58). Note that a signal status change only has an effect on the first-in detection when the `Feature` bit Evaluation of signal status (Page 152) and the input `FirstInEn` is set.

The response to deactivation via the `FirstInEn` input can be influenced by `Feature` bit First-in detection response to deactivation (Page 187).

**Note**

This function can only be executed in the faceplate with "process control" operating permission.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for interlock blocks (Page 124).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `Out.ST`

### Bypass

**Note**

Bypassing the interlock means that the interlock signal (input signal) is excluded from the logic of the interlock block, in other words, this signal is ignored in the logic operation.

This function can only be executed in the faceplate with "high-level operating permission".

You can bypass interlock signals as follows:

- From operator over faceplate (`BypInx` = 1):
  Independent `BypLix` or `Inx.Bit1` are connected and enabled, the operator can bypass or reset bypass the interlock input signal.
- By connecting `BypLix` in CFC (`BypLix.Value` = 1, `BypLix.ST` <> `16#FF`)
  Follow this if interlock signals are connected to outputs, which has no bypass information bit. Refer to section Bypassing signals (Page 115).
- By bypass information bit in the connected interlock signal `Inx.Bit1`. For this the corresponding enable bit (`BypEn.Inx` = 1) and `Feature.Bit2` Separate evaluation for excluded and simulated interlock signals (Page 162) are to be set. Follow this if the interlock signals are connected to outputs which has the bypass information bit. Refer to section Bypassing signals (Page 115).

The following table shows the possibilities to switch on/off the bypass of an interlock signal:

| BypLix.ST <> 16#FF | BypEn.Inx AND Feature.Bit2 | Interpretation |
|---|---|---|
| - | - | Only operator: `BypInx` |
| x | - | Input `BypLix` and operator |
| - | x | Bypass bit in Interlock input `Inx.Bit1` and operator |
| x | x | "`BypLix.Value OR Inx.Bit1`" and operator |

A value change of the used bypass signal `(BypLix.Value, Inx.Bit1)` tracks the input `BypInx` for faceplate and actualizes the bypass value. You can always operate the bypass over faceplate if no change of the used connected bypass inputs is active in block cycle.

**Note**

After a change of the parameterization in CFC (bypass via information bit `Bit1` in the interlock signals or bypass via interconnection separate inputs `BypLix`), a corresponding trigger of the bypass value must be made for the change to take effect.

You can also use both connected bypass inputs (`BypLix.Value, Inx.Bit1`) for one interlock input signal. Have a look that all prerequisites are fulfilled. Then with a change of `BypLix.Value` or `Inx.Bit1` the bypass of an interlock input `BypInx` is set to "`BypLix.Value OR Inx.Bit1`". Both inputs are to be false to reset the bypass. After that operator can change bypass over faceplate again.

The following symbol in standard view indicates a bypass request signal from the connected parameter.

- `Inx.Bit1 =1`: Output `Out.Bit1` of an interlock block,
  Output from a technological block with bypass functionality
- `BypLix.Value =1`: Output from a connected block

The following symbol in standard view indicates whether the interlock input signal is in bypass:

At the outputs `Byp01Act`... `Byp02Act`, you can see whether the corresponding input interlock signal is bypassed (`BypxAct` =`BypInx`).

You can reset all the bypass of interlock signals as follows:

- From operator over faceplate (`RstBypOp` = 0 -> 1)
- Over CFC linkable parameter (`RstBypLi` = 0 -> 1)

**Special situation:** If all input parameters are bypassed, the output value is defined using the `DefaultOut` parameter.

The output BypAct displays the information if there is an operated or connected bypass available.

```
BypAct.Value = BypIn01 OR BypInx …
                       OR In01.Bit1 OR Inx.Bit1 …
                       OR BypLi1.Value OR BypLix.Value …
```

**Note**

Do not connect the input BypLix with the output BypAct from an interlock block as BypAct is calculated from the internal bypass signal information and is only for display bypass and not for operate a bypass of an interlock input.

The bypass information Out.Bit1 and the status Out.ST depends on Feature.Bit2:

**Feature.Bit2 = 0:**

Out.Bit1 = 0, Bypass information bit is not active and reset.
A bypassed interlock input, which is switch-relevant, sets the status of Out.ST to Simulation.

**Feature.Bit2 = 1:**

Out.Bit1 = BypAct.Value, Bypass information bit is active and tracked.
A bypassed interlock input has no influence on the status of Out.ST

## Operating permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can exclude values |
| 1 | 1 = Operator can reset the exclusion of input values |
| 2 | 1 = Operator can reset the recording of the first signal |
| 3 - 15 | Not used |
| 16 | 1 = Operator can set or reset the exclusion of input value In01 |
| 17 | 1 = Operator can set or reset the exclusion of input value In02 |
| 18 – 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the chapter Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Activate OS_Perm bits (Page 168)<br>0 = `OS_Perm` bits 16...17 inactive (evaluation only in faceplate)<br>1 = `OS_Perm` bits 16...17 active (evaluation only in faceplate) |
| 21 | First-in detection response to deactivation (Page 187) |
| 23 | Evaluation of signal status (Page 152) |
| 24 | Enabling local operator authorization (Page 169) |
| 31 | Activating recording of the first signal (Page 161) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 9.1.4 Intlk02 error handling

### Error handling of Intlk02

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 13 | The parameter `Logic` has not been set to 0 or 1. |

## 9.1.6 Intlk02 I/Os

I/Os of Intlk02

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV01 | Analog value of In01 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| AV02 | Analog value of In02 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| AV01_Unit | Unit of measure for AV01 | INT | 0 |
| AV02_Unit | Unit of measure for AV02 | INT | 0 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BypIn01* | 1 = Input In01 is not used | BOOL | 0 |
| BypIn02* | 1 = Input In02 is not used | BOOL | 0 |
| BypLi01 | Bypass In01 (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| BypLi02 | Bypass In02 (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| DefaultOut | Output value for cases where all inputs are excluded or not interconnected. Refer to the section Intlk02 functions (Page 1952) of the block. | BOOL | 1 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 1952) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| FirstInEn | First-in detection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| In01 | Input In01 | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#FF<br>• 0 |
| In02 | Input In02 | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#FF<br>• 0 |
| InvIn01 | Invert input In01 | BOOL | 0 |
| InvIn02 | Invert input In02 | BOOL | 0 |
| Logic | Logical operation:<br>0 = Logical OR<br>1 = Logical AND | INT | 0 |
| NotUsed | 1 = Block is not used (only for display in the faceplate). You can find additional information on this in the section Interlock blocks standard view (Page 310) / Color of the field. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OS_Perm | I/O for operating permissions (Page 1952) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| RstBypOp* | 1 = Reset via BypIn01and BypIn02 | BOOL | 0 |
| RstLi | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Data type | Default |
|---|---|---|---|
| BypAct | 1 = Bypass active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Byp01Act | 1 = Bypass of input 01 is active | BOOL | 0 |
| Byp02Act | 1 = Bypass of input 02 is active | BOOL | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see Intlk02 error handling (Page 1956). | INT | -1 |
| FirstIn | Bit-coded number of the first signal that has resulted in a change at the output | DWORD | 16#00000000 |
| OpSt_Out | Value of the OpSt_In input parameter for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| Out | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1949) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1949) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1949) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1949) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1949) | DWORD | 16#00000000 |
| Status6 | Status word 6 (Page 1949) | DWORD | 16#00000000 |
| Status7 | Status word 7 (Page 1949) | DWORD | 16#00000000 |
| Status8 | Status word 8 (Page 1949) | DWORD | 16#00000000 |

## 9.1.8 Operator control and monitoring

### 9.1.8.1 Interlock block views

### Views of the blocks Intlk02, Intlk04, Intlk08, Intlk16

The blocks provide the following views:

- Interlock blocks standard view (Page 310)
- Preview of interlock blocks (Page 333)
- Batch view (Page 336)
- Block icon for interlock blocks (Page 272)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

# 9.2 Intlk04 - Interlock display with 4 input signals

## 9.2.1 Description of Intlk04

### Object name (type + number) and family

Type + number: FB 1825

Family: Interlck

### Area of application for Intlk04

The block is used for the following applications:

- Standardized interlock with display

### How it works

The block is used to calculate a standardized interlock that can be displayed on the OS. A maximum of 4 input signals can be supplied to the block. They are linked using selectable binary logic. The signal status of the output signal is also determined. You can assign an analog value with the signal status and unit to each input value for display in the faceplate.

The current state is displayed at the `Out` output parameter:

- `Out` = 0: Interlock
- `Out` = 1: "Good" state

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Intlk02 (Intlk04) block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Refer to Description of Intlk02 (Page 1949) for more information.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section Intlk04 I/Os (Page 1970).

| Status bit | Parameter |
|---|---|
| 0 | 1= `Logic` = OR |
| 1 | 1 = `Logic` = AND |
| 2 | Not used |

| Status bit | Parameter |
|---|---|
| 3 | Result of logic operation `Out.Value` |
| 4 | 1 = At least one input value is excluded. See the section Excluding input values in Intlk04 functions (Page 1965). |
| 5 | 1 = All input values are excluded |
| 6 | 1 = No input value is interconnected or `NotUsed.Value` |
| 7 | Status display for simulation |
| 8 | Status display for not interlocked |
| 9 | Status display for interlocked |
| 10 | Not used |
| 11 | `Feature.Bit2`: Separate evaluation for excluded and simulated interlock signals |
| 12 | Internal error |
| 13-29 | Not used |
| 30 | `Occupied` |
| 31 | `BatchEn` |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01.Value` |
| 1 | `In02.Value` |
| 2 | `In03.Value` |
| 3 | `In04.Value` |
| 4 - 31 | Not used |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | `InvIn01` |
| 1 | `InvIn02` |
| 2 | `InvIn03` |
| 3 | `InvIn04` |
| 4 - 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` with inversion |
| 1 | `In02` with inversion |
| 2 | `In03` with inversion |
| 3 | `In04` with inversion |
| 4 - 15 | Not used |
| 16 | Bypass `In01` (via interconnection) |

| Status bit | Parameter |
|---|---|
| 17 | Bypass `In02` (via interconnection) |
| 18 | Bypass `In03` (via interconnection) |
| 19 | Bypass `In04` (via interconnection) |
| 20 - 31 | Not used |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 | `BypIn01` |
| 1 | `BypIn02` |
| 2 | `BypIn03` |
| 3 | `BypIn04` |
| 4 - 15 | Not used |
| 16 | In01hidden bypass information |
| 17 | In02hidden bypass information |
| 18 | In03hidden bypass information |
| 19 | In04hidden bypass information |
| 20-31 | Not used |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` not connected |
| 1 | `In02` not connected |
| 2 | `In03` not connected |
| 3 | `In04` not connected |
| 4 - 31 | Not used |

### Status word allocation for `Status7` parameter

| Status bit | Parameter |
|---|---|
| 0 | `AV01` not connected |
| 1 | `AV02` not connected |
| 2 | `AV03` not connected |
| 3 | `AV04` not connected |
| 4 - 31 | Not used |

### Status word allocation for `Status8` parameter

Identical to `FirstIn`.

Intlk04 functions (Page 1965)
Description of Intlk04 (Page 1962)

## 9.2.3 Intlk04 functions

### Functions of Intlk04

The functions for this block are listed below.

### Inversion of logic signals

You can invert the input signals by setting the input parameter `InvInx` for the input concerned to `Inx` = 1, e.g. for input `In01` set the I/O `InvIn01`.

The inversion is displayed in the faceplate. If you invert signals using any other method this is not shown in the faceplate.

## Bypass

**Note**

Bypassing the interlock means that the interlock signal (input signal) is excluded from the logic of the interlock block, in other words, this signal is ignored in the logic operation.

This function can only be executed in the faceplate with "high-level operating permission".

You can bypass interlock signals as follows:

- From operator over faceplate (`BypInx` = 1):
  Independent `BypLix` or `Inx.Bit1` are connected and enabled, the operator can bypass or reset bypass the interlock input signal.
- By connecting `BypLix` in CFC (`BypLix.Value` = 1, `BypLix.ST` <> `16#FF`)
  Follow this if interlock signals are connected to outputs, which has no bypass information bit. Refer to sectionBypassing signals (Page 115).
- By bypass information bit in the connected interlock signal `Inx.Bit1`. For this the corresponding enable bit (`BypEn.Inx = 1`) and `Feature.Bit2` Separate evaluation for excluded and simulated interlock signals (Page 162) are to be set. Follow this if the interlock signals are connected to outputs which has the bypass information bit. Refer to sectionBypassing signals (Page 115).

The following table shows the possibilities to switch on/off the bypass of an interlock signal:

| BypLix.ST <> 16#FF | BypEn.Inx AND Feature.Bit2 | Interpretation |
|---|---|---|
| - | - | Only operator: `BypInx` |
| x | - | Input `BypLix` and operator |
| - | x | Bypass bit in Interlock input `Inx.Bit1` and operator |
| x | x | "`BypLix.Value OR Inx.Bit1`" and operator |

A value change of the used bypass signal `(BypLix.Value, Inx.Bit1)` tracks the input `BypInx` for faceplate and actualizes the bypass value. You can always operate the bypass over faceplate if no change of the used connected bypass inputs is active in block cycle.

**Note**

After a change of the parameterization in CFC (bypass via information bit `Bit1` in the interlock signals or bypass via interconnection separate inputs `BypLix`), a corresponding trigger of the bypass value must be made for the change to take effect.

You can also use both connected bypass inputs (`BypLix.Value, Inx.Bit1`) for one interlock input signal. Have a look that all prerequisites are fulfilled. Then with a change of `BypLix.Value` or `Inx.Bit1` the bypass of an interlock input `BypInx` is set to "`BypLix.Value OR Inx.Bit1`". Both inputs are to be false to reset the bypass. After that operator can change bypass over faceplate again.

The following symbol in standard view indicates a bypass request signal from the connected parameter.

- `Inx.Bit1 =1`: Output `Out.Bit1` of an interlock block,
  Output from a technological block with bypass functionality
- `BypLix.Value =1`: Output from a connected block

The following symbol in standard view indicates whether the interlock input signal is in bypass:

At the outputs `Byp01Act`... `Byp02Act`, you can see whether the corresponding input interlock signal is bypassed (`BypxAct` =`BypInx`).

You can reset all the bypass of interlock signals as follows:

- From operator over faceplate (`RstBypOp` = 0 -> 1)
- Over CFC linkable parameter (`RstBypLi` = 0 -> 1)

**Special situation:** If all input parameters are bypassed, the output value is defined using the `DefaultOut` parameter.

The output `BypAct` displays the information if there is an operated or connected bypass available.

```
BypAct.Value = BypIn01 OR BypInx …
                       OR In01.Bit1 OR Inx.Bit1 …
                       OR BypLi1.Value OR BypLix.Value …
```

**Note**

Do not connect the input `BypLix` with the output `BypAct` from an interlock block as `BypAct` is calculated from the internal bypass signal information and is only for display bypass and not for operate a bypass of an interlock input.

The bypass information `Out.Bit1` and the status `Out.ST` depends on `Feature.Bit2`:

**`Feature.Bit2` = 0:**

`Out.Bit1` = 0, Bypass information bit is not active and reset.
A bypassed interlock input, which is switch-relevant, sets the status of `Out.ST` to Simulation.

**`Feature.Bit2` = 1:**

`Out.Bit1` = `BypAct.Value`, Bypass information bit is active and tracked.
A bypassed interlock input has no influence on the status of `Out.ST`

## Handling non-connected inputs

Inputs which are not interconnected are not evaluated. They are not displayed in the faceplate either.

**Special situation:** If no inputs are connected, the output value is defined using the `DefaultOut` parameter. The signal status is set to 16#FF.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234). However, only one additional faceplate can be called up using `SelFp1` = 1.

### First-in detection for interlock blocks

This block provides the standard function Recording the first signal for interlock blocks (Page 58). Note that a signal status change only has an effect on the first-in detection when the `Feature` bit Evaluation of signal status (Page 152) and the input `FirstInEn` is set.

The response to deactivation via the `FirstInEn` input can be influenced by `Feature` bit First-in detection response to deactivation (Page 187).

**Note**

This function can only be executed in the faceplate with "process control" operating permission.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for interlock blocks (Page 124).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `Out.ST`

### Operating permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can exclude values |
| 1 | 1 = Operator can reset the exclusion of input values |
| 2 | 1 = Operator can reset the recording of the first signal |
| 3 - 15 | Not used |
| 16 | 1 = Operator can set or reset the exclusion of input value In01 |
| 17 | 1 = Operator can set or reset the exclusion of input value In02 |
| 18 | 1 = Operator can set or reset the exclusion of input value In03 |
| 19 | 1 = Operator can set or reset the exclusion of input value In04 |
| 20 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable reactions using the `Feature` I/O

You can find an overview of all reactions provided by the `Feature` parameter in the chapter Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Activate OS_Perm bits (Page 168)<br>0 = `OS_Perm` bits 16...17 inactive (evaluation only in faceplate)<br>1 = `OS_Perm` bits 16...17 active (evaluation only in faceplate) |
| 21 | First-in detection response to deactivation (Page 187) |
| 23 | Evaluation of signal status (Page 152) |
| 24 | Enabling local operator authorization (Page 169) |
| 31 | Activating recording of the first signal (Page 161) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 9.2.4 Intlk04 error handling

### Error handling of Intlk04

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 13 | The parameter `Logic` has not been set to 0 or 1. |

## 9.2.8 Operator control and monitoring

### 9.2.8.1 Interlock block views

#### Views of the blocks Intlk02, Intlk04, Intlk08, Intlk16

The blocks provide the following views:

- Interlock blocks standard view (Page 310)
- Preview of interlock blocks (Page 333)
- Batch view (Page 336)
- Block icon for interlock blocks (Page 272)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

# 9.3 Intlk08 - Interlock display with 8 input signals

## 9.3.1 Description of Intlk08

### Object name (type + number) and family

Type + number: FB 1826

Family: Interlck

### Area of application of Intlk08

The block is used for the following applications:

- Standardized interlock with display

### How it works

The block is used to calculate a standardized interlock that can be displayed on the OS. A maximum of 8 input signals can be supplied to the block. They are linked using selectable binary logic. The signal status of the output signal is also determined. You can assign an analog value with the signal status and unit to each input value for display in the faceplate.

The current state is displayed at the `Out` output parameter:

- `Out` = 0: Interlock
- `Out` = 1: "Good" state

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Intlk02 (Intlk08) block, the Advanced Process Library contains process tag type templates; these serve as examples by providing various application scenarios for this block.

Refer to Description of Intlk02 (Page 1949) for more information.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section Intlk08 I/Os (Page 1985).

| Status bit | Parameter |
|---|---|
| 0 | 1 = `Logic` = OR |
| 1 | 1 = `Logic` = AND |
| 2 | Not used |

| Status bit | Parameter |
|---|---|
| 3 | Result of logic operation `Out.Value` |
| 4 | 1 = At least one input value is excluded. See the section Excluding input values in Intlk08 functions (Page 1980) |
| 5 | 1 = All input values are excluded |
| 6 | 1 = No input value is interconnected or `NotUsed.Value` |
| 7 | Status display for simulation |
| 8 | Status display for not interlocked |
| 9 | Status display for interlocked |
| 10 | `Feature.Bit5` |
| 11 | `Feature.Bit2`: Separate evaluation for excluded and simulated interlock signals |
| 12 | Internal error |
| 13-29 | Not used |
| 30 | `Occupied` |
| 31 | `BatchEn` |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01.Value` |
| 1 | `In02.Value` |
| 2 | `In03.Value` |
| 3 | `In04.Value` |
| 4 | `In05.Value` |
| 5 | `In06.Value` |
| 6 | `In07.Value` |
| 7 | `In08.Value` |
| 8 - 31 | Not used |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | `InvIn01` |
| 1 | `InvIn02` |
| 2 | `InvIn03` |
| 3 | `InvIn04` |
| 4 | `InvIn05` |
| 5 | `InvIn06` |
| 6 | `InvIn07` |
| 7 | `InvIn08` |
| 8 - 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` with inversion |
| 1 | `In02` with inversion |
| 2 | `In03` with inversion |
| 3 | `In04` with inversion |
| 4 | `In05` with inversion |
| 5 | `In06` with inversion |
| 6 | `In07` with inversion |
| 7 | `In08` with inversion |
| 8 - 15 | Not used |
| 16 | Bypass `In01` (via interconnection) |
| 17 | Bypass `In02` (via interconnection) |
| 18 | Bypass `In03` (via interconnection) |
| 19 | Bypass `In04` (via interconnection) |
| 20 | Bypass `In05` (via interconnection) |
| 21 | Bypass `In06` (via interconnection) |
| 22 | Bypass `In07` (via interconnection) |
| 23 | Bypass `In08` (via interconnection) |
| 24 - 31 | Not used |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 | `BypIn01` |
| 1 | `BypIn02` |
| 2 | `BypIn03` |
| 3 | `BypIn04` |
| 4 | `BypIn05` |
| 5 | `BypIn06` |
| 6 | `BypIn07` |
| 7 | `BypIn08` |
| 8 - 15 | Not used |
| 16 - 23 | `In01..IN08` hidden bypass information |
| 24 - 31 | Not used |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` not connected |
| 1 | `In02` not connected |
| 2 | `In03` not connected |

| Status bit | Parameter |
|---|---|
| 3 | `In04` not connected |
| 4 | `In05` not connected |
| 5 | `In06` not connected |
| 6 | `In07` not connected |
| 7 | `In08` not connected |
| 8 - 31 | Not used |

### Status word allocation for `Status7` parameter

| Status bit | Parameter |
|---|---|
| 0 | `AV01` not connected |
| 1 | `AV02` not connected |
| 2 | `AV03` not connected |
| 3 | `AV04` not connected |
| 4 | `AV05` not connected |
| 5 | `AV06` not connected |
| 6 | `AV07` not connected |
| 7 | `AV08` not connected |
| 8 - 31 | Not used |

### Status word allocation for `Status8` parameter

Identical to `FirstIn`.

Intlk08 error handling (Page 1984)
Intlk08 functions (Page 1980)
Description of Intlk08 (Page 1976)

## 9.3.3 Intlk08 functions

### Functions of Intlk08

The functions for this block are listed below.

### Logic operators

Use the `Logic` input to specify the logic operator that the block should employ when determining the interlock state. Make the following settings:

- `Logic` = 0: OR
- `Logic` = 1: AND

### Inversion of logic signals

You can invert the input signals by setting the input parameter `InvInx` for the input concerned to `Inx` = 1 , e.g. for input `In01` set the I/O `InvIn01`.

The inversion is displayed in the faceplate. If you invert signals using any other method, this is not shown in the faceplate.

### Bypass

**Note**

Bypassing the interlock means that the interlock signal (input signal) is excluded from the logic of the interlock block, in other words, this signal is ignored in the logic operation.

This function can only be executed in the faceplate with "high-level operating permission".

You can bypass interlock signals as follows:

- From operator over faceplate (`BypInx` = 1):
  Independent `BypLix` or `Inx.Bit1` are connected and enabled, the operator can bypass or reset bypass the interlock input signal.
- By connecting `BypLix` in CFC (`BypLix.Value` = 1, `BypLix.ST` <> `16#FF`)
  Follow this if interlock signals are connected to outputs, which has no bypass information bit. Refer to sectionBypassing signals (Page 115).
- By bypass information bit in the connected interlock signal `Inx.Bit1`. For this the corresponding enable bit (`BypEn.Inx` = 1) and `Feature.Bit2` Separate evaluation for excluded and simulated interlock signals (Page 162) are to be set. Follow this if the interlock signals are connected to outputs which has the bypass information bit. Refer to sectionBypassing signals (Page 115).

The following table shows the possibilities to switch on/off the bypass of an interlock signal:

| BypLix.ST <> 16#FF | BypEn.Inx AND Feature.Bit2 | Interpretation |
|---|---|---|
| - | - | Only operator: `BypInx` |
| x | - | Input `BypLix` and operator |
| - | x | Bypass bit in Interlock input `Inx.Bit1` and operator |
| x | x | "`BypLix.Value OR Inx.Bit1`" and operator |

A value change of the used bypass signal `(BypLix.Value, Inx.Bit1)` tracks the input `BypInx` for faceplate and actualizes the bypass value. You can always operate the bypass over faceplate if no change of the used connected bypass inputs is active in block cycle.

**Note**

After a change of the parameterization in CFC (bypass via information bit `Bit1` in the interlock signals or bypass via interconnection separate inputs `BypLix`), a corresponding trigger of the bypass value must be made for the change to take effect.

You can also use both connected bypass inputs (`BypLix.Value, Inx.Bit1`) for one interlock input signal. Have a look that all prerequisites are fulfilled. Then with a change of `BypLix.Value` or `Inx.Bit1` the bypass of an interlock input `BypInx` is set to "`BypLix.Value OR Inx.Bit1`". Both inputs are to be false to reset the bypass. After that operator can change bypass over faceplate again.

The following symbol in standard view indicates a bypass request signal from the connected parameter.

- `Inx.Bit1 =1`: Output `Out.Bit1` of an interlock block,
  Output from a technological block with bypass functionality
- `BypLix.Value =1`: Output from a connected block

The following symbol in standard view indicates whether the interlock input signal is in bypass:

At the outputs `Byp01Act`... `Byp02Act`, you can see whether the corresponding input interlock signal is bypassed (`BypxAct` =`BypInx`).

You can reset all the bypass of interlock signals as follows:

- From operator over faceplate (`RstBypOp` = 0 -> 1)
- Over CFC linkable parameter (`RstBypLi` = 0 -> 1)

**Special situation:** If all input parameters are bypassed, the output value is defined using the `DefaultOut` parameter.

The output `BypAct` displays the information if there is an operated or connected bypass available.

```
BypAct.Value = BypIn01 OR BypInx …
                        OR In01.Bit1 OR Inx.Bit1 …
                        OR BypLi1.Value OR BypLix.Value …
```

**Note**

Do not connect the input `BypLix` with the output `BypAct` from an interlock block as `BypAct` is calculated from the internal bypass signal information and is only for display bypass and not for operate a bypass of an interlock input.

The bypass information `Out.Bit1` and the status `Out.ST` depends on `Feature.Bit2`:

**`Feature.Bit2` = 0:**

`Out.Bit1` = 0, Bypass information bit is not active and reset.
A bypassed interlock input, which is switch-relevant, sets the status of `Out.ST` to Simulation.

**`Feature.Bit2` = 1:**

`Out.Bit1` = `BypAct.Value`, Bypass information bit is active and tracked.
A bypassed interlock input has no influence on the status of `Out.ST`

## Handling non-connected inputs

Inputs which are not interconnected are not evaluated. They are not displayed in the faceplate either.

**Special situation:** If no inputs are connected, the output value is defined using the `DefaultOut` parameter. The signal status is set to 16#FF.

## Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234). However, only one additional faceplate can be called up using `SelFp1` = 1 .

### First-in detection for interlock blocks

This block provides the standard function Recording the first signal for interlock blocks (Page 58). Note that a signal status change only has an effect on the first-in detection when the `Feature` bit Evaluation of signal status (Page 152) and the input FirstInEn is set.

The response to deactivation via the `FirstInEn` input can be influenced by `Feature` bit First-in detection response to deactivation (Page 187).

**Note**

This function can only be executed in the faceplate with "process control" operating permission.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for interlock blocks (Page 124).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `Out.ST`

### Operating permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can exclude values |
| 1 | 1 = Operator can reset the exclusion of input values |
| 2 | 1 = Operator can reset the recording of the first signal |
| 3 - 15 | Not used |
| 16 | 1 = Operator can set or reset the exclusion of input value In01 |
| 17 | 1 = Operator can set or reset the exclusion of input value In02 |
| 18 | 1 = Operator can set or reset the exclusion of input value In03 |
| 19 | 1 = Operator can set or reset the exclusion of input value In04 |
| 20 | 1 = Operator can set or reset the exclusion of input value In05 |
| 21 | 1 = Operator can set or reset the exclusion of input value In06 |
| 22 | 1 = Operator can set or reset the exclusion of input value In07 |
| 23 | 1 = Operator can set or reset the exclusion of input value In08 |
| 24 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the chapter Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Activate OS_Perm bits (Page 168)<br>0 = `OS_Perm` bits 16...17 inactive (evaluation only in faceplate)<br>1 = `OS_Perm` bits 16...17 active (evaluation only in faceplate) |
| 21 | First-in detection response to deactivation (Page 187) |
| 23 | Evaluation of signal status (Page 152) |
| 24 | Enabling local operator authorization (Page 169) |
| 31 | Activating recording of the first signal (Page 161) |

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 9.3.4 Intlk08 error handling

### Error handling of Intlk08

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 13 | The parameter `Logic` has not been set to 0 or 1 |

| RstOp* | 1 = Reset via operator | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BypAct | 1 = Bypass active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Byp01Act | 1 = Bypass of input 01 is active | BOOL | 0 |
| Byp02Act | 1 = Bypass of input 02 is active | BOOL | 0 |
| Byp03Act | 1 = Bypass of input 03 is active | BOOL | 0 |
| Byp04Act | 1 = Bypass of input 04 is active | BOOL | 0 |
| Byp05Act | 1 = Bypass of input 05 is active | BOOL | 0 |
| Byp06Act | 1 = Bypass of input 06 is active | BOOL | 0 |
| Byp07Act | 1 = Bypass of input 07 is active | BOOL | 0 |
| Byp08Act | 1 = Bypass of input 08 is active | BOOL | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see Intlk08 error handling (Page 1984) | INT | -1 |
| FirstIn | Bit-coded number of the first signal that has resulted in a change at the output | DWORD | 16#00000000 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| Out | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |

## 9.3.8 Operator control and monitoring

### 9.3.8.1 Interlock block views

### Views of the blocks Intlk02, Intlk04, Intlk08, Intlk16

The blocks provide the following views:

- Interlock blocks standard view (Page 310)
- Preview of interlock blocks (Page 333)
- Batch view (Page 336)
- Block icon for interlock blocks (Page 272)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

# 9.4 Intlk16 - Interlock display with 16 input signals

## 9.4.1 Description of Intlk16

### Object name (type + number) and family

Type + number: FB 1827

Family: Interlck

### Area of application for Intlk16

The block is used for the following applications:

- Standardized interlock with display

### How it works

The block is used to calculate a standardized interlock that can be displayed on the OS. A maximum of 16 input signals can be supplied to the block. They are linked using selectable binary logic. The signal status of the output signal is also determined. You can assign an analog value with the signal status and unit to each input value for display in the faceplate.

The current state is displayed at the `Out` output parameter:

- `Out` = 0: Interlock
- `Out` = 1: "Good" state

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Intlk02 (Intlk16) block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Refer to Description of Intlk02 (Page 1949) for more information.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section Intlk16 I/Os (Page 2003).

| Status bit | Parameter |
|---|---|
| 0 | 1 = `Logic` = OR |
| 1 | 1 = `Logic` = AND |
| 2 | Not used |

| Status bit | Parameter |
|---|---|
| 3 | Result of logic operation `Out.Value` |
| 4 | 1 = At least one input value is excluded. See the section Excluding input values in Intlk16 functions (Page 1997) |
| 5 | 1 = All input values are excluded |
| 6 | 1 = No input value is interconnected or `NotUsed.Value` |
| 7 | Status display for simulation |
| 8 | Status display for not interlocked |
| 9 | Status display for interlocked |
| 10 | Not used |
| 11 | `Feature.Bit2`: Separate evaluation for excluded and simulated interlock signals |
| 12 | Internal error |
| 13-29 | Not used |
| 30 | `Occupied` |
| 31 | `BatchEn` |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01.Value` |
| 1 | `In02.Value` |
| 2 | `In03.Value` |
| 3 | `In04.Value` |
| 4 | `In05.Value` |
| 5 | `In06.Value` |
| 6 | `In07.Value` |
| 7 | `In08.Value` |
| 8 | `In09.Value` |
| 9 | `In10.Value` |
| 10 | `In11.Value` |
| 11 | `In12.Value` |
| 12 | `In13.Value` |
| 13 | `In14.Value` |
| 14 | `In15.Value` |
| 15 | `In16.Value` |
| 16 - 31 | Not used |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | `InvIn01` |
| 1 | `InvIn02` |
| 2 | `InvIn03` |

| Status bit | Parameter |
|---|---|
| 3 | InvIn04 |
| 4 | InvIn05 |
| 5 | InvIn06 |
| 6 | InvIn07 |
| 7 | InvIn08 |
| 8 | InvIn09 |
| 9 | InvIn10 |
| 10 | InvIn11 |
| 11 | InvIn12 |
| 12 | InvIn13 |
| 13 | InvIn14 |
| 14 | InvIn15 |
| 15 | InvIn16 |
| 16 - 31 | Not used |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0 | In01 with inversion |
| 1 | In02 with inversion |
| 2 | In03 with inversion |
| 3 | In04 with inversion |
| 4 | In05 with inversion |
| 5 | In06 with inversion |
| 6 | In07 with inversion |
| 7 | In08 with inversion |
| 8 | In09 with inversion |
| 9 | In10 with inversion |
| 10 | In11 with inversion |
| 11 | In12 with inversion |
| 12 | In13 with inversion |
| 13 | In14 with inversion |
| 14 | In15 with inversion |
| 15 | In16 with inversion |
| 16 | Bypass In01 (via interconnection) |
| 17 | Bypass In02 (via interconnection) |
| 18 | Bypass In03 (via interconnection) |
| 19 | Bypass In04 (via interconnection) |
| 20 | Bypass In05 (via interconnection) |
| 21 | Bypass In06 (via interconnection) |
| 22 | Bypass In07 (via interconnection) |
| 23 | Bypass In08 (via interconnection) |

| Status bit | Parameter |
|---|---|
| 24 | Bypass `In09` (via interconnection) |
| 25 | Bypass `In10` (via interconnection) |
| 26 | Bypass `In11` (via interconnection) |
| 27 | Bypass `In12` (via interconnection) |
| 28 | Bypass `In13` (via interconnection) |
| 29 | Bypass `In14` (via interconnection) |
| 30 | Bypass `In15` (via interconnection) |
| 31 | Bypass `In16` (via interconnection) |

### Status word allocation for `Status5` parameter

| Status bit | Parameter |
|---|---|
| 0 | `BypIn01` |
| 1 | `BypIn02` |
| 2 | `BypIn03` |
| 3 | `BypIn04` |
| 4 | `BypIn05` |
| 5 | `BypIn06` |
| 6 | `BypIn07` |
| 7 | `BypIn08` |
| 8 | `BypIn09` |
| 9 | `BypIn10` |
| 10 | `BypIn11` |
| 11 | `BypIn12` |
| 12 | `BypIn13` |
| 13 | `BypIn14` |
| 14 | `BypIn15` |
| 15 | `BypIn16` |
| 16 - 31 | `In01`..`In16`hidden bypass information |

### Status word allocation for `Status6` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In01` not connected |
| 1 | `In02` not connected |
| 2 | `In03` not connected |
| 3 | `In04` not connected |
| 4 | `In05` not connected |
| 5 | `In06` not connected |
| 6 | `In07` not connected |
| 7 | `In08` not connected |
| 8 | `In09` not connected |

| Status bit | Parameter |
|---|---|
| 9 | `In10` not connected |
| 10 | `In11` not connected |
| 11 | `In12` not connected |
| 12 | `In13` not connected |
| 13 | `In14` not connected |
| 14 | `In15` not connected |
| 15 | `In16` not connected |
| 16 - 31 | Not used |

### Status word allocation for `Status7` parameter

| Status bit | Parameter |
|---|---|
| 0 | `AV01` not connected |
| 1 | `AV02` not connected |
| 2 | `AV03` not connected |
| 3 | `Av04` not connected |
| 4 | `AV05` not connected |
| 5 | `AV06` not connected |
| 6 | `AV07` not connected |
| 7 | `AV08` not connected |
| 8 | `AV09` not connected |
| 9 | `AV10` not connected |
| 10 | `AV11` not connected |
| 11 | `AV12` not connected |
| 12 | `AV13` not connected |
| 13 | `AV14` not connected |
| 14 | `AV15` not connected |
| 15 | `AV16` not connected |
| 16 - 31 | Not used |

### Status word allocation for `Status8` parameter

Identical to `FirstIn`.

Description of Intlk16 (Page 1992)

## 9.4.3 Intlk16 functions

### Functions of Intlk16

The functions for this block are listed below.

### Logic operators

Use the `Logic` input to specify the logic operator that the block should employ when determining the interlock state. Make the following settings:

- `Logic` = 0: OR
- `Logic` = 1: AND

### Inversion of logic signals

You can invert the input signals by setting the input parameter `InvInx` for the input concerned to `Inx` = 1, e.g. for input `In01` set the I/O `InvIn01`.

The inversion is displayed in the faceplate. If you invert signals using any other method, this is not shown in the faceplate.

## Bypass

**Note**

Bypassing the interlock means that the interlock signal (input signal) is excluded from the logic of the interlock block, in other words, this signal is ignored in the logic operation.

This function can only be executed in the faceplate with "high-level operating permission".

You can bypass interlock signals as follows:

- From operator over faceplate (`BypInx` = 1):
  Independent `BypLix` or `Inx.Bit1` are connected and enabled, the operator can bypass or reset bypass the interlock input signal.
- By connecting `BypLix` in CFC (`BypLix.Value` = 1, `BypLix.ST` <> `16#FF`)
  Follow this if interlock signals are connected to outputs, which has no bypass information bit. Refer to sectionBypassing signals (Page 115).
- By bypass information bit in the connected interlock signal `Inx.Bit1`. For this the corresponding enable bit (`BypEn.Inx` = 1) and `Feature.Bit2` Separate evaluation for excluded and simulated interlock signals (Page 162) are to be set. Follow this if the interlock signals are connected to outputs which has the bypass information bit. Refer to sectionBypassing signals (Page 115).

The following table shows the possibilities to switch on/off the bypass of an interlock signal:

| BypLix.ST <> 16#FF | BypEn.Inx AND Feature.Bit2 | Interpretation |
|---|---|---|
| - | - | Only operator: `BypInx` |
| x | - | Input `BypLix` and operator |
| - | x | Bypass bit in Interlock input `Inx.Bit1` and operator |
| x | x | "`BypLix.Value OR Inx.Bit1`" and operator |

A value change of the used bypass signal `(BypLix.Value, Inx.Bit1)` tracks the input `BypInx` for faceplate and actualizes the bypass value. You can always operate the bypass over faceplate if no change of the used connected bypass inputs is active in block cycle.

**Note**

After a change of the parameterization in CFC (bypass via information bit `Bit1` in the interlock signals or bypass via interconnection separate inputs `BypLix`), a corresponding trigger of the bypass value must be made for the change to take effect.

You can also use both connected bypass inputs (`BypLix.Value, Inx.Bit1`) for one interlock input signal. Have a look that all prerequisites are fulfilled. Then with a change of `BypLix.Value` or `Inx.Bit1` the bypass of an interlock input `BypInx` is set to "`BypLix.Value OR Inx.Bit1`". Both inputs are to be false to reset the bypass. After that operator can change bypass over faceplate again.

The following symbol in standard view indicates a bypass request signal from the connected parameter.

- `Inx.Bit1 =1`: Output `Out.Bit1` of an interlock block,
  Output from a technological block with bypass functionality
- `BypLix.Value =1`: Output from a connected block

The following symbol in standard view indicates whether the interlock input signal is in bypass:

At the outputs `Byp01Act`... `Byp02Act`, you can see whether the corresponding input interlock signal is bypassed (`BypxAct` =`BypInx`).

You can reset all the bypass of interlock signals as follows:

- From operator over faceplate (`RstBypOp` = 0 -> 1)
- Over CFC linkable parameter (`RstBypLi` = 0 -> 1)

**Special situation:** If all input parameters are bypassed, the output value is defined using the `DefaultOut` parameter.

The output `BypAct` displays the information if there is an operated or connected bypass available.

```
BypAct.Value = BypIn01 OR BypInx …
                       OR In01.Bit1 OR Inx.Bit1 …
                       OR BypLi1.Value OR BypLix.Value …
```

**Note**

Do not connect the input `BypLix` with the output `BypAct` from an interlock block as `BypAct` is calculated from the internal bypass signal information and is only for display bypass and not for operate a bypass of an interlock input.

The bypass information `Out.Bit1` and the status `Out.ST` depends on `Feature.Bit2`:

**`Feature.Bit2` = 0:**

`Out.Bit1` = 0, Bypass information bit is not active and reset.
A bypassed interlock input, which is switch-relevant, sets the status of `Out.ST` to Simulation.

**`Feature.Bit2` = 1:**

`Out.Bit1 = BypAct.Value`, Bypass information bit is active and tracked.
A bypassed interlock input has no influence on the status of `Out.ST`

## Handling non-connected inputs

Inputs which are not interconnected are not evaluated. They are not displayed in the faceplate either.

**Special situation:** If no inputs are connected, the output value is defined using the `DefaultOut` parameter. The signal status is set to 16#FF.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234). However, only one additional faceplate can be called up using `SelFp1` = 1 .

### First-in detection for interlock blocks

This block provides the standard function Recording the first signal for interlock blocks (Page 58). Note that a signal status change only has an effect on the first-in detection when the `Feature` bit Evaluation of signal status (Page 152) and the input FirstInEn is set.

The response to deactivation via the `FirstInEn` input can be influenced by `Feature` bit First-in detection response to deactivation (Page 187).

**Note**

This function can only be executed in the faceplate with "process control" operating permission.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for interlock blocks (Page 124).

The worst signal status `ST_Worst` for the block is formed from the following parameter:

- `OUT.ST`

### Operating permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | 1 = Operator can exclude values |
| 1 | 1 = Operator can reset the exclusion of input values |
| 2 | 1 = Operator can reset the recording of the first signal |
| 3 - 15 | Not used |
| 16 | 1 = Operator can set or reset the exclusion of input value In01 |
| 17 | 1 = Operator can set or reset the exclusion of input value In02 |
| 18 | 1 = Operator can set or reset the exclusion of input value In03 |
| 19 | 1 = Operator can set or reset the exclusion of input value In04 |
| 20 | 1 = Operator can set or reset the exclusion of input value In05 |
| 21 | 1 = Operator can set or reset the exclusion of input value In06 |
| 22 | 1 = Operator can set or reset the exclusion of input value In07 |
| 23 | 1 = Operator can set or reset the exclusion of input value In08 |
| 24 | 1 = Operator can set or reset the exclusion of input value In09 |
| 25 | 1 = Operator can set or reset the exclusion of input value In10 |
| 26 | 1 = Operator can set or reset the exclusion of input value In11 |

| Bit | Function |
|---|---|
| 27 | 1 = Operator can set or reset the exclusion of input value In12 |
| 28 | 1 = Operator can set or reset the exclusion of input value In13 |
| 29 | 1 = Operator can set or reset the exclusion of input value In14 |
| 30 | 1 = Operator can set or reset the exclusion of input value In15 |
| 31 | 1 = Operator can set or reset the exclusion of input value In16 |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the chapter Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 2 | Separate evaluation for excluded and simulated interlock signals (Page 162) |
| 5 | Activate OS_Perm bits (Page 168)<br>0 = `OS_Perm` bits 16...17 inactive (evaluation only in faceplate)<br>1 = `OS_Perm` bits 16...17 active (evaluation only in faceplate) |
| 21 | First-in detection response to deactivation (Page 187) |
| 23 | Evaluation of signal status (Page 152) |
| 24 | Enabling local operator authorization (Page 169) |
| 31 | Activating recording of the first signal (Page 161) |

## SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 9.4.4 Intlk16 error handling

### Error handling of Intlk16

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 13 | The parameter `Logic` has not been set to 0 or 1. |

| Logic | Logical operation:<br>0 = Logical OR<br>1 = Logical AND | INT | 0 |
| NotUsed | 1 = Block is not used (only for display in the faceplate). You can find additional information on this in the section Interlock blocks standard view (Page 310) / Color of the field. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS_Perm | I/O for operating permissions (Page 1997) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| RstBypOp* | 1 = Reset inputs BypIn01 to BypIn16 | BOOL | 0 |
| RstLi | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| SelFp1 | Call a block saved in this parameter as Opening additional faceplates (Page 234) in standard view | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BypAct | 1 = Bypass active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Byp01Act | 1 = Bypass of input 01 is active | BOOL | 0 |
| Byp02Act | 1 = Bypass of input 02 is active | BOOL | 0 |
| Byp03Act | 1 = Bypass of input 03 is active | BOOL | 0 |
| Byp04Act | 1 = Bypass of input 04 is active | BOOL | 0 |
| Byp05Act | 1 = Bypass of input 05 is active | BOOL | 0 |
| Byp06Act | 1 = Bypass of input 06 is active | BOOL | 0 |
| Byp07Act | 1 = Bypass of input 07 is active | BOOL | 0 |
| Byp08Act | 1 = Bypass of input 08 is active | BOOL | 0 |
| Byp09Act | 1 = Bypass of input 09 is active | BOOL | 0 |
| Byp10Act | 1 = Bypass of input 10 is active | BOOL | 0 |
| Byp11Act | 1 = Bypass of input 11 is active | BOOL | 0 |
| Byp12Act | 1 = Bypass of input 12 is active | BOOL | 0 |
| Byp13Act | 1 = Bypass of input 13 is active | BOOL | 0 |
| Byp14Act | 1 = Bypass of input 14 is active | BOOL | 0 |
| Byp15Act | 1 = Bypass of input 15 is active | BOOL | 0 |
| Byp16Act | 1 = Bypass of input 16 is active | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Out | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE<br>• Bit 1: BOOL (Bypass information bit) | -<br>• 0<br>• 16#80<br>• 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 1992) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 1992) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 1992) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 1992) | DWORD | 16#00000000 |
| Status5 | Status word 5 (Page 1992) | DWORD | 16#00000000 |
| Status6 | Status word 6 (Page 1992) | DWORD | 16#00000000 |
| Status7 | Status word 7 (Page 1992) | DWORD | 16#00000000 |
| Status8 | Status word 8 (Page 1992) | DWORD | 16#00000000 |

## 9.4.8 Operator control and monitoring

### 9.4.8.1 Interlock block views

#### Views of the blocks Intlk02, Intlk04, Intlk08, Intlk16

The blocks provide the following views:

- Interlock blocks standard view (Page 310)
- Preview of interlock blocks (Page 333)
- Batch view (Page 336)
- Block icon for interlock blocks (Page 272)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

# 9.5 FirstIn - Transform output Intlck FirstIn for message associated value

## 9.5.1 Description of FirstIn

### Object name (type + number) and family

Type + number: FC 1929

Family: Interlck

### Area of application for FirstIn

The block is used for the following applications:

- To generate an external message that can be seen in the technological block.
- To generate an external message from EventTs or Event16Ts block.

### How it works

FirstIn block works only with the combination of a technological block that has `ExtMsgx` and `ExtValxx` input parameters.

The block generates messages requiring acknowledgment that appear in the alarm view of the interconnected technological block.

The block must be connected to a technological block. Messages of the interconnected technological blocks are displayed in the message view.

FirstIn block also works with EventTs and Event16Ts blocks to generate an external message. External signals of FirstIn block should be connected with EventTs or Event16Ts block. When a fault occurs, EventTs or Event16Ts block is triggered and the message can be viewed in the interconnected technological block.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

Connect the following output parameters with the input parameters as indicated in the following table:

| Output parameter | | Input parameter | |
|---|---|---|---|
| **Parameter name** | **Block** | **Parameter name** | **Block** |
| `FirstIn` | Interlock | `FirstIn` | FirstIn |
| `Out` | Interlock | `Interlock` | Technological |
| `FirstInAct` | FirstIn | `ExtMsgx` | Technological |
| `ExtVa1FI` | FirstIn | `ExtValxx` | Technological |
| `ExtVa2FI` | FirstIn | `ExtValxx` | Technological |

For example:

- Output parameters `ExtVa1FI` and `ExtVa2FI` are connected to the input parameters `ExtVa104` and `ExtVa108` respectively.
- Output parameter `FirstInAct` is connected to the input parameter `ExtMsg2`.

In the PCS 7 special message property of the external message 2 signal, add the following syntax:

"@4%s@@8%s@".

**With EventTs/Event16Ts blocks:**

You can connect FirstIn block with the block EventTs or Event16Ts. Connect the input parameters `ExtVaxxx` (`ExtVal01`...`ExtVal03` in case of EventTs block and `ExtVal01`...`ExtVa106` in case of Event16Ts block) with the output parameters `ExtVa1FI` or `ExtVa2FI` of the FirstIn block.

The output parameter `FirstInAct` of the FirstIn block should be connected with any `Inx` input parameters of the EventTs/Event16Ts blocks.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# Message blocks 10

## 10.1 Event - Creating messages

### 10.1.1 Description of Event

#### Object name (type + number) and family

Type + number: FB 1811

Family: Report

#### Area of application for Event

The block is used for the following applications:

- Generation of messages requiring acknowledgment

#### How it works

The block is used to simultaneously output up to eight different messages that require acknowledgment.

The individual messages are assigned to the monitored signals via the inputs and the messages released or blocked depending on the process status data. If a change is made to one or more of the monitored signals enabled for reporting, a message is output.

The signals to be monitored are interconnected with inputs `In1` ... `In8`. Each `Inx` signal can also be inverted via input `InvInx`. A message is output if a signal value is changed (but taking inversion into account).

Each input is assigned a separate message text. A message received at input `In5`, for example, is output with the message text for the SIG 5 signal.

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

Further addressing is not required.

#### Startup characteristics

During startup, the message block suppresses all messages. The duration (number of cycles) of message suppression is set at the `RunUpCyc` parameter. During restart (OB100) an internal counter that is initialized with this value decrements each time the block is executed. Messages are not generated if the counter value does not equal zero.

Messages whose alarm delay has not elapsed during this period are then output.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section Event I/Os (Page 2025).

| Status bit | Parameter |
|---|---|
| 0 | `In1.Value` |
| 1 | `In2.Value` |
| 2 | `In3.Value` |
| 3 | `In4.Value` |
| 4 | `In5.Value` |
| 5 | `In6.Value` |
| 6 | `In7.Value` |
| 7 | `In8.Value` |
| 8 | `InvIn1` |
| 9 | `InvIn2` |
| 10 | `InvIn3` |
| 11 | `InvIn4` |
| 12 | `InvIn5` |
| 13 | `InvIn6` |
| 14 | `InvIn7` |
| 15 | `InvIn8` |
| 16 | `In1` with inversion |
| 17 | `In2` with inversion |
| 18 | `In3` with inversion |
| 19 | `In4` with inversion |
| 20 | `In5` with inversion |
| 21 | `In6` with inversion |
| 22 | `In7` with inversion |
| 23 | `In8` with inversion |
| 24 | `In1` not connected |
| 25 | `In2` not connected |
| 26 | `In3` not connected |
| 27 | `In4` not connected |
| 28 | `In5` not connected |
| 29 | `In6` not connected |
| 30 | `In7` not connected |
| 31 | `In8` not connected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In1MsgEn` |
| 1 | `In2MsgEn` |
| 2 | `In3MsgEn` |
| 3 | `In4MsgEn` |
| 4 | `In5MsgEn` |
| 5 | `In6MsgEn` |
| 6 | `In7MsgEn` |
| 7 | `In8MsgEn` |
| 8 | `AV1` not connected |
| 9 | `AV2` not connected |
| 10 | `AV3` not connected |
| 11 | `AV4` not connected |
| 12 | `AV5` not connected |
| 13 | `AV6` not connected |
| 14 | `AV7` not connected |
| 15 | `AV8` not connected |
| 16 | Active signal 1 for messages |
| 17 | Active signal 2 for messages |
| 18 | Active signal 3 for messages |
| 19 | Active signal 4 for messages |
| 20 | Active signal 5 for messages |
| 21 | Active signal 6 for messages |
| 22 | Active signal 7 for messages |
| 23 | Active signal 8 for messages |
| 24 | `MsgLock` |
| 25 | `Occupied` |
| 26 | `BatchEn` |
| 27 | Batch - parameter exists |
| 28 - 31 | Not used |

## 10.1.2 Event modes

### Event operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

Description of Event (Page 2017)

## 10.1.3 Event functions

### Functions of Event

The functions for this block are listed below.

### Activation and deactivation of messages

Set the I/Os `In1MsgEn` to `In8MsgEn` accordingly to activate or deactivate the messages applied to inputs `In1` to `In8`. All messages are activated by default.

To deactivate messages received at I/O `In4`, for example, you set I/O `In4MsgEn` = 0 accordingly.

You can deactivate all messages via I/O `MsgLock` = 1 .

### Delay of alarms

You can delay the alarms indicating signal changes.

For incoming alarms (signal change 0 - 1), set the delay at parameter `AlmOnDly`; for outgoing alarms (signal change 1 - 0) set it at parameter `AlmOffDly`.

Enter 0 or a negative value to deactivate the delay.

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Operator control permissions

The block has the following Operator control permissions (Page 285) for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 31 | Not used |

This block does not have a faceplate yet; the operator control permissions have already been assigned in the planning phase for these faceplates.

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 8 | Reporting with BATCH parameters (Page 167) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 27 | Selecting values associated with messages (Page 167) |

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The block determines the worst signal status via all interconnected binary and analog inputs, and outputs this value at `ST_Worst`.

- `In1`

etc. to

- `In8`
- `AV1`

etc. to

- `AV8`

## 10.1.4 Event error handling

### Error handling of Event

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |

Description of Event (Page 2017)

## 10.1.5 Event messaging

### Messaging

Messages which can be acknowledged are generated using ALARM_8P. The block uses the PMC communication channel and has 8 digital inputs and 8 associated values.

Every edge transition detected for one or more digital inputs results in a message. The associated values are assigned consistently to the message at the time of edge evaluation. All 8 signals are assigned a common message number, which is split at the OS into 8 messages. The Engineering System (ES) assigns the message number automatically by calling the message server.

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId` | SIG 1 | AS process control message - error | Text 1 |
| | SIG 2 | AS process control message - error | Text 2 |
| | SIG 3 | AS process control message - error | Text 3 |
| | SIG 4 | AS process control message - error | Text 4 |
| | SIG 5 | AS process control message - error | Text 5 |
| | SIG 6 | AS process control message - error | Text 6 |
| | SIG 7 | AS process control message - error | Text 7 |
| | SIG 8 | AS process control message - error | Text 8 |

You can change the message class and the event to meet your needs at the block type and/or block instance.

Depending on `Feature.Bit27` "Select message associated values", either the signal status or the associated analog value is written as message associated value ( `Feature.Bit8` = 0).

### Associated values for message instance `MsgEvId` (`Feature.Bit27` = 0)

| Associated value | Block parameters |
|---|---|
| 1 | `In1.ST` |
| 2 | `In2.ST` |
| 3 | `In3.ST` |
| 4 | `In4.ST` |
| 5 | `In5.ST` |
| 6 | `In6.ST` |
| 7 | `In7.ST` |
| 8 | `In8.ST` |
| 9 | Not allocated |
| 10 | Not allocated |

### Associated values for message instance `MsgEvId` (`Feature.Bit27` = 1)

| Associated value | Block parameters |
|---|---|
| 1 | `AV1.Value` |
| 2 | `AV2.Value` |
| 3 | `AV3.Value` |
| 4 | `AV4.Value` |
| 5 | `AV5.Value` |
| 6 | `AV6.Value` |
| 7 | `AV7.Value` |
| 8 | `AV8.Value` |
| 9 | Not allocated |
| 10 | Not allocated |

### The batch information is transmitted with `Feature.Bit8` = 1:

The first three associated values are described as follows and are followed by the signal status of the input signal or the associated analog value, depending on `Feature.Bit27` "Selecting message associated values":

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchId |
| 4 | In1.ST / AV1.Value |
| 5 | In2.ST / AV2.Value |
| 6 | In3.ST / AV3.Value |
| 7 | In4.ST / AV4.Value |
| 8 | In5.ST / AV5.Value |

| Associated value | Block parameters |
|---|---|
| 9 | In6.ST / AV6.Value |
| 10 | In7.ST / AV7.Value |

Enter the batch ID @1%s@ under "Properties - Block - Special properties - Messages extended - Message texts block".

### I/Os of Event

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AlmOnDly | Alarm delay time [s] for signal transition 0 → 1 | REAL | 0.0 |
| AlmOffDly | Alarm delay time [s] for signal transition 1 → 0 | REAL | 0.0 |
| AV1 | Message associated value for In1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| AV1_Unit | Unit for AV1 | INT | 0 |
| AV2 | Message associated value for In2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| AV2_Unit | Unit for AV2 | INT | 0 |
| AV3 | Message associated value for In3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AV3_Unit | Unit for AV3 | INT | 0 |
| AV4 | Message associated value for In4 | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#FF |
| AV4_Unit | Unit for AV4 | INT | 0 |
| AV5 | Message associated value for In5 | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#FF |
| AV5_Unit | Unit for AV5 | INT | 0 |
| AV6 | Message associated value for In6 | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#FF |
| AV6_Unit | Unit for AV6 | INT | 0 |
| AV7 | Message associated value for In7 | STRUCT | - |

| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#FF |
| In3MsgEn | 1 = Activate message for input In3 | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| In4 | Input In4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In4MsgEn | 1 = Activate message for input In4 | BOOL | 1 |
| In5 | Input In5 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In5MsgEn | 1 = Activate message for input In5 | BOOL | 1 |
| In6 | Input In6 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In6MsgEn | 1 = Activate message for input In6 | BOOL | 1 |
| In7 | Input In7 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In7MsgEn | 1 = Activate message for input In7 | BOOL | 1 |
| In8 | Input In8 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| In8MsgEn | 1 = Activate message for input In8 | BOOL | 1 |
| InvIn1 | 1 = Invert input In1 | BOOL | 0 |
| InvIn2 | 1 = Invert input In2 | BOOL | 0 |
| InvIn3 | 1 = Invert input In3 | BOOL | 0 |
| InvIn4 | 1 = Invert input In4 | BOOL | 0 |
| InvIn5 | 1 = Invert input In5 | BOOL | 0 |
| InvIn6 | 1 = Invert input In6 | BOOL | 0 |
| InvIn7 | 1 = Invert input In7 | BOOL | 0 |
| InvIn8 | 1 = Invert input In8 | BOOL | 0 |
| MS_RelOp | 1 = Release for maintenance by OS operator | BOOL | 0 |
| MsgEvId | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>Refer also to the Suppressing messages using the MsgLock parameter (Page 231) section for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS_Perm | I/O for operator control permissions (Page 2020) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUp-Cyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | RESERVED | ANY | |
| SelFp2 | RESERVED | ANY | |
| StepNo | Batch step number | DWORD | 16#00 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see Event error handling (Page 2022) | INT | -1 |
| MsgAckn | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Alarm error (output ERROR of ALARM_8) | BOOL | 0 |
| MsgStat | Alarm status (output STATUS of ALARM_8P) | WORD | 16#0000 |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| ST_Worst | Worst signal status | BYTE | 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Status1 | Status word 1 (Page 2017) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 2017) | DWORD | 16#00000000 |

# 10.2 EventNck - Generating messages without acknowledgment

## 10.2.1 Description of EventNck

### Object name (type + number) and family

Type + number: FB 1904

Family: Report

### Area of application for EventNck

The block is used for the following applications:

- Generation of messages not requiring acknowledgment

### How it works

The block is used to simultaneously output up to eight different messages that do not require acknowledgment.

The individual messages are assigned to the monitored signals via the inputs and the messages released or blocked depending on the process status data. If a change is made to one or more of the monitored signals enabled for reporting, a message is output.

The signals to be monitored are interconnected with inputs `In1` to `In8`. Each `Inx` signal can also be inverted via input `InvInx`. A message is output if a signal value is changed (but taking inversion into account).

Each input is assigned a separate message text. A message received at input `In5`, for example, is output with the message text for the SIG 5 signal.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

Further addressing is not required.

### Startup characteristics

During startup, the message block suppresses all messages. The duration (number of cycles) of message suppression is set at the `RunUpCyc` parameter. During restart (OB100) an internal counter that is initialized with this value decrements each time the block is executed. Messages are not generated if the counter value does not equal zero.

Messages whose alarm delay has not elapsed during this period are then output.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section EventNck I/Os (Page 2037).

| Status bit | Parameter |
|---|---|
| 0 | `In1.Value` |
| 1 | `In2.Value` |
| 2 | `In3.Value` |
| 3 | `In4.Value` |
| 4 | `In5.Value` |
| 5 | `In6.Value` |
| 6 | `In7.Value` |
| 7 | `In8.Value` |
| 8 | `InvIn1` |
| 9 | `InvIn2` |
| 10 | `InvIn3` |
| 11 | `InvIn4` |
| 12 | `InvIn5` |
| 13 | `InvIn6` |
| 14 | `InvIn7` |
| 15 | `InvIn8` |
| 16 | `In1` with inversion |
| 17 | `In2` with inversion |
| 18 | `In3` with inversion |
| 19 | `In4` with inversion |
| 20 | `In5` with inversion |
| 21 | `In6` with inversion |
| 22 | `In7` with inversion |
| 23 | `In8` with inversion |
| 24 | `In1` not connected |
| 25 | `In2` not connected |
| 26 | `In3` not connected |
| 27 | `In4` not connected |
| 28 | `In5` not connected |
| 29 | `In6` not connected |
| 30 | `In7` not connected |
| 31 | `In8` not connected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `In1MsgEn` |
| 1 | `In2MsgEn` |
| 2 | `In3MsgEn` |

| Status bit | Parameter |
|---|---|
| 3 | `In4MsgEn` |
| 4 | `In5MsgEn` |
| 5 | `In6MsgEn` |
| 6 | `In7MsgEn` |
| 7 | `In8MsgEn` |
| 8 | `AV1` not connected |
| 9 | `AV2` not connected |
| 10 | `AV3` not connected |
| 11 | `AV4` not connected |
| 12 | `AV5` not connected |
| 13 | `AV6` not connected |
| 14 | `AV7` not connected |
| 15 | `AV8` not connected |
| 16 | Active signal 1 for messages |
| 17 | Active signal 2 for messages |
| 18 | Active signal 3 for messages |
| 19 | Active signal 4 for messages |
| 20 | Active signal 5 for messages |
| 21 | Active signal 6 for messages |
| 22 | Active signal 7 for messages |
| 23 | Active signal 8 for messages |
| 24 | `MsgLock` |
| 25 - 31 | Not used |

## 10.2.2 EventNck modes

### EventNck modes

The block provides the following modes:

- On (Page 77)
- Out of service (Page 77)

**"On"**

General information on the "On" mode is available in the section On (Page 77).

**"Out of service"**

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

**See also**

EventNck block diagram (Page 2041)

## 10.2.3 EventNck functions

**Functions of EventNck**

The functions for this block are listed below.

**Activation and deactivation of messages**

Set the I/Os `In1MsgEn` ... `In8MsgEn` accordingly to enable or disable the messages applied to inputs `In1` ... `In8`. All messages are activated by default.

To deactivate messages received at I/O `In4`, for example, you set I/O `In4MsgEn` = 0 accordingly.

You can deactivate all messages via I/O `MsgLock` = 1.

**Delay of alarms**

You can delay the alarms indicating signal changes.

For incoming alarms (signal change 0 - 1), set the delay at parameter `AlmOnDly`; for outgoing alarms (signal change 1 - 0) set it at parameter `AlmOffDly`.

Enter 0 or a negative value to deactivate the delay.

**Suppressing messages using the `MsgLock` parameter**

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Operator control permissions

The block has the following Operator control permissions (Page 285) for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 31 | Not used |

This block does not have a faceplate yet; the operator control permissions have already been assigned in the planning phase for these faceplates.

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 27 | Selecting values associated with messages (Page 167) |

### Forming the signal status for blocks

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The block determines the worst signal status via all interconnected binary and analog inputs, and outputs this value at `ST_Worst`.

- `In1`

etc. to

- `In8`
- `AV1`

etc. to

- AV8

## 10.2.4 EventNck error handling

### Error handling of EventNck

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |

### See also

EventNck block diagram (Page 2041)

## 10.2.5 EventNck messaging

### Messaging

Messages not requiring acknowledgment are generated with NOTIFY_8P . The block uses the PMC communication channel and has 8 digital inputs and 10 associated values.

Every edge transition detected for one or more digital inputs results in a message. The associated values are assigned consistently to the message at the time of edge evaluation. All 8 signals are assigned a common message number, which is split at the OS into 8 messages. The Engineering System (ES) assigns the message number automatically by calling the message server.

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId` | SIG 1 | Operating message – without acknowledgment | Text 1 |
| | SIG 2 | Operating message – without acknowledgment | Text 2 |
| | SIG 3 | Operating message – without acknowledgment | Text 3 |
| | SIG 4 | Operating message – without acknowledgment | Text 4 |
| | SIG 5 | Operating message – without acknowledgment | Text 5 |
| | SIG 6 | Operating message – without acknowledgment | Text 6 |
| | SIG 7 | Operating message – without acknowledgment | Text 7 |
| | SIG 8 | Operating message – without acknowledgment | Text 8 |

You can change the message class and the event to meet your needs at the block type and/or block instance.

### Associated values for message instance `MsgEvId`

You can use the `Feature` Bit Selecting values associated with messages (Page 167) to define whether the signal status of the signal or the associated analog value is to be used as the associated value for the message.

| Associated value | Block parameters |
|---|---|
| 1 | `In1.ST` |
| 2 | `In2.ST` |
| 3 | `In3.ST` |
| 4 | `In4.ST` |

| Associated value | Block parameters |
|---|---|
| 5 | `In5.ST` |
| 6 | `In6.ST` |
| 7 | `In7.ST` |
| 8 | `In8.ST` |
| 9 | Not allocated |
| 10 | Not allocated |

### Associated values for message instance `MsgEvId`

| Associated value | Block parameters |
|---|---|
| 1 | `AV1.Value` |
| 2 | `AV2.Value` |
| 3 | `AV3.Value` |
| 4 | `AV4.Value` |
| 5 | `AV5.Value` |
| 6 | `AV6.Value` |
| 7 | `AV7.Value` |
| 8 | `AV8.Value` |
| 9 | Not allocated |
| 10 | Not allocated |

## 10.2.6 EventNck I/Os

### I/Os of EventNck

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AlmOnDly | Alarm delay time [s] for signal transition 0 → 1 | REAL | 0.0 |
| AlmOffDly | Alarm delay time [s] for signal transition 1 → 0 | REAL | 0.0 |
| AV1 | Message associated value for In1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see EventNck error handling (Page 2035). | INT | -1 |
| MsgErr | 1 = Alarm error (output ERROR of NOTIFY_8P) | BOOL | 0 |
| MsgStat | Alarm status (output STATUS of NOTIFY_8P) | WORD | 16#0000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 2030) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 2030) | DWORD | 16#00000000 |

# 10.3 EventTs - Creating messages with time stamp

## 10.3.1 Description of EventTs

### Object name (type + number) and family

Type + number: FB 1812

Family: Report

### Area of application for EventTs

The block is used for the following applications:

- Generating messages which have to be acknowledged for time-stamped signals

### How it works

The block must be linked to a channel block and monitors up to eight different binary signals. From these, it generates time-stamped messages requiring acknowledgment that appear in the alarm view of the technological block to which it is connected.

The individual messages are assigned to the monitored signals via the inputs and the messages released or blocked depending on the process status data. If a change is made to one or more of the monitored signals enabled for reporting, a message is output containing a time stamp for the signal change.

`EventTs` can operate independently or in combination with one of the technological blocks that has the `EventTsIn` or `EventTs2In` input parameter. When this interconnection is configured, the messages of the `EventTs` block are displayed in the OS of the alarm view of the technological block and can also be acknowledged there. The following functions are controlled by the technological block:

- Switching to "Out of service" mode and switching back to "On" mode: `OosAct`, `OnAct`
- Release for maintenance: MS_Release
- Suppressing messages using the `MsgLock` parameter
- Batch parameters: `BatchEn`, `BatchID`, `BatchName`, `StepNo`, `Occupied`

**Note**

The `EventTs` instance must be newly created between deleting the interconnection of `EventTs` and the technological block and a delta download.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100) and in OB1 because of the time stamp.

If the EventTs operates together with a technological block, interconnect the output parameter EventTsOut of the EventTs block and the input parameter EventTsIn or EventTs2In of the technological block in the CFC.

Depending on how the time stamp is generated, the signals to be monitored for this are interconnected at inputs In1 ... In8 or InTS1 ... InTS8. Each Inx or InTSx signal can also be inverted via input Invx. A message is output if a signal value is changed (but taking inversion into account).

Each input is assigned a separate message text. A message received at input InTS5, for example, is output with the message text for the SIG 5 signal.

Configuration of the alarms for negative edges 1 → 0 in HW Config only effects the signal inputs InTS1 ... InTS8 of EventTs.

If TimeStrampOn = 0 , meaning the inputs In1 ... In8 are used, you will have to set the input Invx = 1 to generate an alarm 1 → 0 at input Inx for a negative edge.

**Note**

Interconnection of the block to multiple technological blocks is not permitted.

For the EventTs block, the Advanced Process Library contains process tag type templates; these serve as examples by providing various application scenarios for this block.

Examples of process tag types:

- Motor with an additional analog value and time-stamped signals (Motor_AV_EventTs) (Page 2863)

## Startup characteristics

During startup, the message block suppresses all messages. The duration (number of cycles) of message suppression is set at the RunUpCyc parameter. During restart (OB100) an internal counter that is initialized with this value decrements each time the block is executed. Messages are not generated if the counter value does not equal zero.

## Status word allocation for Status1 parameter

You can find a description for each parameter in section EventTs I/Os (Page 2052).

| Status bit | Parameter |
|---|---|
| 0 | Active signal 1 |
| 1 | Active signal 2 |
| 2 | Active signal 3 |
| 3 | Active signal 4 |
| 4 | Active signal 5 |
| 5 | Active signal 6 |
| 6 | Active signal 7 |
| 7 | Active signal 8 |
| 8 | InvIn1 |
| 9 | InvIn2 |

| Status bit | Parameter |
|---|---|
| 10 | InvIn3 |
| 11 | InvIn4 |
| 12 | InvIn5 |
| 13 | InvIn6 |
| 14 | InvIn7 |
| 15 | InvIn8 |
| 16 | Active signal 1 with inversion |
| 17 | Active signal 2 with inversion |
| 18 | Active signal 3 with inversion |
| 19 | Active signal 4 with inversion |
| 20 | Active signal 5 with inversion |
| 21 | Active signal 6 with inversion |
| 22 | Active signal 7 with inversion |
| 23 | Active signal 8 with inversion |
| 24 | Active signal 1 not connected |
| 25 | Active signal 2 not connected |
| 26 | Active signal 3 not connected |
| 27 | Active signal 4 not connected |
| 28 | Active signal 5 not connected |
| 29 | Active signal 6 not connected |
| 30 | Active signal 7 not connected |
| 31 | Active signal 8 not connected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | In1MsgEn |
| 1 | In2MsgEn |
| 2 | In3MsgEn |
| 3 | In4MsgEn |
| 4 | In5MsgEn |
| 5 | In6MsgEn |
| 6 | In7MsgEn |
| 7 | In8MsgEn |
| 8 | Effective signal 1 for message |
| 9 | Effective signal 2 for message |
| 10 | Effective signal 3 for message |
| 11 | Effective signal 4 for message |
| 12 | Effective signal 5 for message |
| 13 | Effective signal 6 for message |
| 14 | Effective signal 7 for message |
| 15 | Effective signal 8 for message |

| Status bit | Parameter |
|---|---|
| 16 | MsgLock |
| 17 - 24 | Not used |
| 25 | Occupied |
| 26 | BatchEn |
| 27 | Batch - parameter exists |
| 28 - 31 | Not used |

EventTs error handling (Page 2048)

EventTs functions (Page 2046)

EventTs modes (Page 2045)

## 10.3.2 EventTs modes

### EventTs operating modes

The block provides the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

Description of EventTs (Page 2042)

## 10.3.3 EventTs functions

### Functions of EventTs

The functions for this block are listed below.

### Activation and deactivation of messages

You can set the I/Os `InMsgEn1` ... `InMsgEn8` to individually enable or disable the messages applied to inputs `In1` ... `In8` or `InTS1` ... `InTS8`. All messages are activated by default.

To deactivate messages received at I/O `InTS4`, for example, you set I/O `InMsgEn4` = 0 accordingly.

You can deactivate all messages via I/O `MsgLock` = 1 .

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Time stamp as associated value of a message

You can use input `TimeStampOn` to select how the time stamp for the signals of EventTs will be generated:

- If you want to use the high-precision time stamp from the I/O devices, set `TimeStampOn` = 1. Interconnect one of the `InTSx` inputs with output `TS_Out` of block Pcs7DiIT.
- If you want to use the time stamp from the CPU, set `TimeStampOn` = 0. Interconnect one of the `Inx` inputs with output `PV_Out` of block Pcs7DiIT or with an appropriate output of a different block.

For additional time stamp properties, refer to the description of the standard function Time stamp (Page 231).

### Signal status as associated value of a message

The signal status as an associated value of the message is output for every signal, as is the time stamp.

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Operator permissions

The block has the following Operator control permissions (Page 285) for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 31 | Not used |

This block does not have a faceplate yet; the operator permissions have already been assigned in the planning phase for these faceplates.

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable functions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 8 | Reporting with BATCH parameters (Page 167) |
| 9 | Enable external message (Page 200) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |

### Displaying and outputting the signal status

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The block determines the worst signal status via all interconnected binary inputs (according to `TimeStampOn`) and outputs this value at `ST_Worst`.

- `TimeStampOn` = 0
  - `In1`

  etc. to

  - `In8`
- `TimeStampOn` = 1
  - `InTS1`

  etc. to

  - `InTS8`

## 10.3.4 EventTs error handling

### Error handling of EventTs

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |

Description of EventTs (Page 2042)

## 10.3.5 EventTs messaging

### Messaging

Messages which can be acknowledged are generated using ALARM_8P. The ALARM_8P has 8 digital inputs and 10 associated values. Every edge transition detected for one or more digital inputs results in a message. The associated values are assigned consistently to the message at the time of edge evaluation. All 8 signals are assigned a common message number, which is split at the OS into 8 messages. The Engineering System (ES) assigns the message number automatically by calling the message server.

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId 1` | SIG 1 | AS process control message - fault | $$BlockComment$$ `InTS1` Status 16#@1%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$ `InTS2` Status 16#@2%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$ `InTS3` Status 16#@3%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$ `InTS1` Status 16#@4%x@ |
| | SIG 5 | AS process control message - fault | $$BlockComment$$ `InTS5` Status 16#@5%x@ |
| | SIG 6 | AS process control message - fault | $$BlockComment$$ `InTS6` Status 16#@6%x@ |
| | SIG 7 | AS process control message - fault | $$BlockComment$$ `InTS7` Status 16#@7%x@ |
| | SIG 8 | AS process control message - fault | $$BlockComment$$ `InTS8` Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

The following applies for `TimeStampOn` = 0 : 16#@n%x@ (n = 1 ... 8): The value contains the signal status of `In1` ... `In8`

The following applies for `TimeStampOn` = 1 : 16#@n%x@ (n = 1 ... 8): Statement on the validity of the time stamp from `InTS0` ... `InTS8`. If the value is 80, the time stamp is formed by the I/O. If the value is ≠ 80, the time stamp of the I/O is invalid; the time stamp is generated by the CPU as a substitute and is therefore not exact.

You can change the message class and the event to meet your needs at the block type and/or block instance.

### Associated values for message instance **MsgEvId**

| Associated value | Block parameters |
|---|---|
| 1 | `TimeStampOn` = 0: `In1.ST` |
| 2 | `TimeStampOn` = 0: `In2.ST` |
| 3 | `TimeStampOn` = 0: `In3.ST` |
| 4 | `TimeStampOn` = 0: `In4.ST` |
| 5 | `TimeStampOn` = 0: `In5.ST` |
| 6 | `TimeStampOn` = 0: `In6.ST` |
| 7 | `TimeStampOn` = 0: `In7.ST` |
| 8 | `TimeStampOn` = 0: `In8.ST` |
| 9 | Not allocated |
| 10 | Not allocated |

### Associated values for message instance **MsgEvId**

| Associated value | Block parameters |
|---|---|
| 1 | `TimeStampOn` = 1: `InTS1.ST` |
| 2 | `TimeStampOn` = 1: `InTS2.ST` |
| 3 | `TimeStampOn` = 1: `InTS3.ST` |
| 4 | `TimeStampOn` = 1: `InTS4.ST` |
| 5 | `TimeStampOn` = 1: `InTS5.ST` |
| 6 | `TimeStampOn` = 1: `InTS6.ST` |
| 7 | `TimeStampOn` = 1: `InTS7.ST` |
| 8 | `TimeStampOn` = 1: `InTS8.ST` |
| 9 | Not allocated |
| 10 | Not allocated |

### The batch information is transmitted with `Feature.Bit8` =1:

The first three associated values are described as follows and are followed by the signal status of the input signals or the validity of the time stamp depending on `TimeStampOn`:

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchId |
| 4 | In1.ST / InTS1.ST |
| 5 | In2.ST / InTS2.ST |
| 6 | In3.ST / InTS3.ST |
| 7 | In4.ST / InTS4.ST |
| 8 | In5.ST / InTS5.ST |
| 9 | In6.ST / InTS6.ST |

The tenth associated value is not available.

Enter the batch ID @1%s@ under "Properties - Block - Special properties - Messages extended - Message texts block".

The associated values in the process messages (event) must be incremented by 3:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId 1` | SIG 1 | AS process control message - fault | $$BlockComment$$ `InTS1` Status 16#@4%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$ `InTS2` Status 16#@5%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$ `InTS3` Status 16#@6%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$ `InTS1` Status 16#@7%x@ |
| | SIG 5 | AS process control message - fault | $$BlockComment$$ `InTS5` Status 16#@8%x@ |
| | SIG 6 | AS process control message - fault | $$BlockComment$$ `InTS6` Status 16#@9%x@ |
| | SIG 7 | AS process control message - fault | $$BlockComment$$ `InTS7` Status[1] |
| | SIG 8 | AS process control message - fault | $$BlockComment$$ `InTS8` Status[1] |

[1] You cannot specify a separate associated value here.

| InTS8 | Signal 8 with I/O-device time stamp | ANY | |
| Inv1 | 1 = Invert input In1 or InTS1 | BOOL | 0 |
| Inv2 | 1 = Invert input In2 or InTS2 | BOOL | 0 |
| Inv3 | 1 = Invert input In3 or InTS3 | BOOL | 0 |
| Inv4 | 1 = Invert input In4 or InTS4 | BOOL | 0 |
| Inv5 | 1 = Invert input In5 or InTS5 | BOOL | 0 |
| Inv6 | 1 = Invert input In6 or InTS6 | BOOL | 0 |
| Inv7 | 1 = Invert input In7 or InTS7 | BOOL | 0 |
| Inv8 | 1 = Invert input In8 or InTS8 | BOOL | 0 |
| MsgEn1 | 1 = Activate message for input In1 or InTS1 | BOOL | 1 |
| MsgEn2 | 1 = Activate message for input In2 or InTS2 | BOOL | 1 |
| MsgEn3 | 1 = Activate message for input In3 or InTS3 | BOOL | 1 |
| MsgEn4 | 1 = Activate message for input In4 or InTS4 | BOOL | 1 |
| MsgEn5 | 1 = Activate message for input In5 or InTS5 | BOOL | 1 |
| MsgEn6 | 1 = Activate message for input In6 or InTS6 | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MsgEn7 | 1 = Activate message for input In7 or InTS7 | BOOL | 1 |
| MsgEn8 | 1 = Activate message for input In8 or InTS8 | BOOL | 1 |
| MsgEvId | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp | 1 = Release for maintenance by OS operator | BOOL | 0 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OS_Perm | I/O for EventTs functions (Page 2046) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | RESERVED | ANY | |
| SelFp2 | RESERVED | ANY | |
| StepNo | Batch step number | DWORD | 16#00 |
| TimeStampOn | 0 = Use time stamp of the CPU<br>1 = Use time stamp of the I/O devices | BOOL | 0 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Outputs

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see EventTs error handling (Page 2048) | INT | -1 |
| EventTsOut | For maneuvering of data between a technological block and the message blocks EventTs, Event16Ts. | STRUCT | |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Message error (output ERROR of ALARM_8P) | BOOL | 0 |
| MsgStat | Message status (output STATUS of ALARM_8P) | WORD | 16#0000 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 2042) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 2042) | DWORD | 16#00000000 |

# 10.4 Event16Ts - Creating 16 messages with time stamp

## 10.4.1 Description of Event16Ts

### Object name (type + number) and family

Type + number: FB 1887

Family: Report

### Area of application for Event16Ts

The block is used for the following applications:

- Generating messages which have to be acknowledged for time-stamped signals

For Event16Ts block, use the templates for the process tag types of the EventTs block in the Advanced Process Library as examples with various use cases. Replace the EventTs block with the Event16Ts block.

### How it works

The block monitors up to sixteen different binary signals, connect the block to a channel block.

The block generates time-stamped messages requiring acknowledgment that appear in the alarm view of the technological block to which it is connected.

The individual messages are assigned to the monitored signals via the inputs and the messages released or blocked depending on the process status data. If a change is made to one or more of the monitored signals enabled for reporting, a message is output containing a time stamp for the signal change.

`Event16Ts` can operate independently or in combination with one of the technological blocks that has the `EventTsIn` or `EventTs2In` input parameter. When the interconnection is configured, the messages of the `Event16Ts` block are displayed in the OS of the alarm view of the technological block and you can also acknowledge the messages. The following functions are controlled by the technological block:

- Switching to "Out of service" mode and switching back to "On" mode: `OosAct`, `OnAct`
- Release for maintenance: MS_Release
- Suppressing messages using the `MsgLock` parameter
- Batch parameters: `BatchEn`, `BatchID`, `BatchName`, `StepNo`, `Occupied`

**Note**

The `Event16Ts` instance must be newly created between deleting the interconnection of `Event16Ts` and the technological block and a delta download.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100) and in OB1 because for time stamping.

If the `Event16Ts` operates together with a technological block, interconnect the output parameter `EventTsOut` of the `Event16Ts` block and the input parameter `EventTsIn` or `EventTs2In` of the technological block in the CFC.

Depending on how the time stamp is generated, the signals to be monitored for this are interconnected at inputs `In1` ... `In16` or `InTS1` ... `InTS16`. Each `Inx` or `InTSx` signal can also be inverted via input `Invx`. If a signal value changes taking inversion into account, a message is output.

**Note**

1. The input parameters `ExtVal01`, `ExtVal02`, and `ExtVal03` will be used for `In1`...`In8` and `InTS1`...`InTS8`.
2. The input parameters `ExtVal04`, `ExtVal05`, and `ExtVal06` will be used for `In9`...`In16` and `InTS9`...`InTS16`.

Each input is assigned a separate message text. A message received at input `InTS5`, for example, is output with the message text for the SIG 5 signal.

Configuration of the alarms for negative edges 1 → 0 in HW Config only effects the signal inputs `InTS1` ... `InTS16` of Event16Ts.

If `TimeStrampOn` = 0 , meaning the inputs `In1` ... `In16` are used, you will have to set the input `Invx` = 1 to generate an alarm 1 → 0 at input `Inx` for a negative edge.

**Note**

Interconnection of the block to multiple technological blocks is not permitted.

For the Event16Ts block, the Advanced Process Library contains templates for process tag types as an example with various application scenarios for this block.

Examples of process tag types:

- Motor with an additional analog value and time-stamped signals (Motor_AV_EventTs) (Page 2863)

## Startup characteristics

During startup, the message block suppresses all messages. The duration (number of cycles) of message suppression is set at the `RunUpCyc` parameter. During restart (OB100) an internal counter that is initialized with this value decrements each time the block is executed. Messages are not generated if the counter value does not equal zero.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section I/Os of Event16Ts.

| Status bit | Parameter |
|---|---|
| 0 | Active signal 1 with inversion |
| 1 | Active signal 2 with inversion |
| 2 | Active signal 3 with inversion |
| 3 | Active signal 4 with inversion |
| 4 | Active signal 5 with inversion |
| 5 | Active signal 6 with inversion |
| 6 | Active signal 7 with inversion |
| 7 | Active signal 8 with inversion |
| 8 | Active signal 9 with inversion |
| 9 | Active signal 10 with inversion |
| 10 | Active signal 11 with inversion |
| 11 | Active signal 12 with inversion |
| 12 | Active signal 13 with inversion |
| 13 | Active signal 14 with inversion |
| 14 | Active signal 15 with inversion |
| 15 | Active signal 16 with inversion |
| 16 | Active signal 1 not connected |
| 17 | Active signal 2 not connected |
| 18 | Active signal 3 not connected |
| 19 | Active signal 4 not connected |
| 20 | Active signal 5 not connected |
| 21 | Active signal 6 not connected |
| 22 | Active signal 7 not connected |
| 23 | Active signal 8 not connected |
| 24 | Active signal 9 not connected |
| 25 | Active signal 10 not connected |
| 26 | Active signal 11 not connected |
| 27 | Active signal 12 not connected |
| 28 | Active signal 13 not connected |
| 29 | Active signal 14 not connected |
| 30 | Active signal 15 not connected |
| 31 | Active signal 16 not connected |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | Active signal 1 |
| 1 | Active signal 2 |
| 2 | Active signal 3 |

| Status bit | Parameter |
|---|---|
| 3 | Active signal 4 |
| 4 | Active signal 5 |
| 5 | Active signal 6 |
| 6 | Active signal 7 |
| 7 | Active signal 8 |
| 8 | Active signal 9 |
| 9 | Active signal 10 |
| 10 | Active signal 11 |
| 11 | Active signal 12 |
| 12 | Active signal 13 |
| 13 | Active signal 14 |
| 14 | Active signal 15 |
| 15 | Active signal 16 |
| 16 | InvIn1 |
| 17 | InvIn2 |
| 18 | InvIn3 |
| 19 | InvIn4 |
| 20 | InvIn5 |
| 21 | InvIn6 |
| 22 | InvIn7 |
| 23 | InvIn8 |
| 24 | InvIn9 |
| 25 | InvIn10 |
| 26 | InvIn11 |
| 27 | InvIn12 |
| 28 | InvIn13 |
| 29 | InvIn14 |
| 30 | InvIn15 |
| 31 | InvIn16 |

### Status word allocation for `Status3` parameter

| Status bit | Parameter |
|---|---|
| 0 | In1MsgEn |
| 1 | In2MsgEn |
| 2 | In3MsgEn |
| 3 | In4MsgEn |
| 4 | In5MsgEn |
| 5 | In6MsgEn |
| 6 | In7MsgEn |
| 7 | In8MsgEn |
| 8 | In9MsgEn |

| Status bit | Parameter |
|---|---|
| 9 | In10MsgEn |
| 10 | In11MsgEn |
| 11 | In12MsgEn |
| 12 | In13MsgEn |
| 13 | In14MsgEn |
| 14 | In15MsgEn |
| 15 | In16MsgEn |
| 16 | Effective signal 1 for message |
| 17 | Effective signal 2 for message |
| 18 | Effective signal 3 for message |
| 19 | Effective signal 4 for message |
| 20 | Effective signal 5 for message |
| 21 | Effective signal 6 for message |
| 22 | Effective signal 7 for message |
| 23 | Effective signal 8 for message |
| 24 | Effective signal 9 for message |
| 25 | Effective signal 10 for message |
| 26 | Effective signal 11 for message |
| 27 | Effective signal 12 for message |
| 28 | Effective signal 13 for message |
| 29 | Effective signal 14 for message |
| 30 | Effective signal 15 for message |
| 31 | Effective signal 16 for message |

### Status word allocation for `Status4` parameter

| Status bit | Parameter |
|---|---|
| 0-7 | Not used |
| 8 - 15 | Not used |
| 16 | `MsgLock` |
| 7 - 24 | Not used |
| 25 | `Occupied` |
| 26 | `BatchEn` |
| 27 | Batch - parameter exists |
| 28 - 31 | Not used |

Event16Ts functions (Page 2062)
Event16Ts operating modes (Page 2062)

## 10.4.2 Event16Ts operating modes

### Event16Ts operating modes

The block provides the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

Event16Ts functions (Page 2062)
Description of Event16Ts (Page 2057)

## 10.4.3 Event16Ts functions

### Functions of Event16Ts

The functions for this block are listed below.

### Activation and deactivation of messages

You can set the I/Os `InMsgEn1` ... `InMsgEn8` to individually enable or disable the messages applied to inputs `In1` ... `In8` or `InTS1` ... `InTS8`. All messages are activated by default.

To deactivate messages received at I/O `InTS4`, for example, you set I/O `InMsgEn4` = 0 accordingly.

You can deactivate all messages via I/O `MsgLock` = 1 .

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Time stamp as associated value of a message

You can use input `TimeStampOn` to select how the time stamp for the signals of Event16Ts will be generated:

- If you want to use the high-precision time stamp from the I/O devices, set `TimeStampOn` = 1. Interconnect one of the `InTSx` inputs with output `TS_Out` of block Pcs7DiIT.
- If you want to use the time stamp from the CPU, set `TimeStampOn` = 0. Interconnect one of the `Inx` inputs with output `PV_Out` of block Pcs7DiIT or with an appropriate output of a different block.

For additional time stamp properties, refer to the description of the standard function Time stamp (Page 231).

### Signal status as associated value of a message

The signal status as an associated value of the message is output for every signal, as is the time stamp.

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Operator permissions

The block has the following Operator control permissions (Page 285) for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 - 31 | Not used |

This block does not have a faceplate yet; the operator permissions have already been assigned in the planning phase for these faceplates.

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Configurable functions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 8 | Reporting with BATCH parameters (Page 167) |
| 9 | Enable external message (Page 200) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |

### Displaying and outputting the signal status

The block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The block determines the worst signal status via all interconnected binary inputs (according to `TimeStampOn`) and outputs this value at `ST_Worst`.

- `TimeStampOn` = 0
  - `In1`

  etc. to

  - `In16`
- `TimeStampOn` = 1
  - `InTS1`

  etc. to

  - `InTS16`

## 10.4.4 Event16Ts error handling

### Error handling of EventTs

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |

## 10.4.5 Event16Ts messages

### Messaging

Messages which can be acknowledged are generated using ALARM_8P. The ALARM_8P has 8 digital inputs and 10 associated values. Every edge transition detected for one or more digital inputs results in a message. The associated values are assigned consistently to the message at the time of edge evaluation. All 8 signals are assigned a common message number, which is split at the OS into 8 messages. The Engineering System (ES) assigns the message number automatically by calling the message server.

### Process messages (MsgEvId1)

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | $$BlockComment$$ `InTS1` Status 16#@1%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$ `InTS2` Status 16#@2%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$ `InTS3` Status 16#@3%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$ `InTS4` Status 16#@4%x@ |
| | SIG 5 | AS process control message - fault | $$BlockComment$$ `InTS5` Status 16#@5%x@ |
| | SIG 6 | AS process control message - fault | $$BlockComment$$ `InTS6` Status 16#@6%x@ |
| | SIG 7 | AS process control message - fault | $$BlockComment$$ `InTS7` Status 16#@7%x@ |
| | SIG 8 | AS process control message - fault | $$BlockComment$$ `InTS8` Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

The following applies for `TimeStampOn` = 0 : 16#@n%x@ (n = 1 ... 8): The value contains the signal status of `In1` ... `In8`

The following applies for `TimeStampOn` = 1 : 16#@n%x@ (n = 1 ... 8): Statement on the validity of the time stamp from `InTS0` ... `InTS8`. If the value is 80, the time stamp is formed by the I/O. If the value is ≠ 80, the time stamp of the I/O is invalid; the time stamp is generated by the CPU as a substitute and is therefore not exact.

You can change the message class and the event to meet your needs at the block type and/or block instance.

### Process messages (MsgEvId2)

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | SIG 1 | AS process control message - fault | $$BlockComment$$ InTS9 Status 16#@1%x@ |
| | SIG 2 | AS process control message - fault | $$BlockComment$$ InTS10 Status 16#@2%x@ |
| | SIG 3 | AS process control message - fault | $$BlockComment$$ InTS11 Status 16#@3%x@ |
| | SIG 4 | AS process control message - fault | $$BlockComment$$ InTS12 Status 16#@4%x@ |
| | SIG 5 | AS process control message - fault | $$BlockComment$$ InTS13 Status 16#@5%x@ |
| | SIG 6 | AS process control message - fault | $$BlockComment$$ InTS14 Status 16#@6%x@ |
| | SIG 7 | AS process control message - fault | $$BlockComment$$ InTS15 Status 16#@7%x@ |
| | SIG 8 | AS process control message - fault | $$BlockComment$$ InTS16 Status 16#@8%x@ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

The following applies for TimeStampOn = 0 : 16#@n%x@ (n = 1 ... 8): The value contains the signal status of In9 ... In16

The following applies for TimeStampOn = 1 : 16#@n%x@ (n = 1 ... 8): Statement on the validity of the time stamp from InTS9 ... InTS16. If the value is 80, the time stamp is formed by the I/O. If the value is ≠ 80, the time stamp of the I/O is invalid; the time stamp is generated by the CPU as a substitute and is therefore not exact.

You can change the message class and the event to meet your needs at the block type and/or block instance.

### Associated values for message instance MsgEvId1

| Associated value | Block parameters |
|---|---|
| 1 | TimeStampOn = 0: In1.ST |
| 2 | TimeStampOn = 0: In2.ST |
| 3 | TimeStampOn = 0: In3.ST |
| 4 | TimeStampOn = 0: In4.ST |
| 5 | TimeStampOn = 0: In5.ST |
| 6 | TimeStampOn = 0: In6.ST |
| 7 | TimeStampOn = 0: In7.ST |
| 8 | TimeStampOn = 0: In8.ST |
| 9 | Not allocated |
| 10 | Not allocated |

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | TimeStampOn = 1: In9.ST |
| 2 | TimeStampOn = 1: In10.ST |
| 3 | TimeStampOn = 1: In11.ST |
| 4 | TimeStampOn = 1: In12.ST |
| 5 | TimeStampOn = 1: In13.ST |
| 6 | TimeStampOn = 1: In14.ST |
| 7 | TimeStampOn = 1: In15.ST |
| 8 | TimeStampOn = 1: In16.ST |
| 9 | Not allocated |
| 10 | Not allocated |

### Associated values for message instance **MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | TimeStampOn = 0: InTS1.ST |
| 2 | TimeStampOn = 0: InTS2.ST |
| 3 | TimeStampOn = 0: InTS3.ST |
| 4 | TimeStampOn = 0: InTS4.ST |
| 5 | TimeStampOn = 0: InTS5.ST |
| 6 | TimeStampOn = 0: InTS6.ST |
| 7 | TimeStampOn = 0: InTS7.ST |
| 8 | TimeStampOn = 0: InTS8.ST |
| 9 | Not allocated |
| 10 | Not allocated |

### Associated values for message instance **MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | TimeStampOn = 0: InTS9.ST |
| 2 | TimeStampOn = 0: InTS10.ST |
| 3 | TimeStampOn = 0: InTS11.ST |
| 4 | TimeStampOn = 0: InTS12.ST |
| 5 | TimeStampOn = 0: InTS13.ST |
| 6 | TimeStampOn = 0: InTS614.ST |
| 7 | TimeStampOn = 0: InTS15.ST |
| 8 | TimeStampOn = 0: InTS16.ST |
| 9 | Not allocated |
| 10 | Not allocated |

### The batch information is transmitted with `Feature.Bit8` =1:

The first three associated values are described as follows and are followed by the signal status of the input signals or the validity of the time stamp depending on `TimeStampOn`:

**MsgEvId1**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchId |
| 4 | In1.ST / InTS1.ST |
| 5 | In2.ST / InTS2.ST |
| 6 | In3.ST / InTS3.ST |
| 7 | In4.ST / InTS4.ST |
| 8 | In5.ST / InTS5.ST |
| 9 | In6.ST / InTS6.ST |

**MsgEvId2**

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchId |
| 4 | In7.ST / InTS7.ST |
| 5 | In8ST / InTS8.ST8 |
| 6 | In9.ST / InTS9.ST |
| 7 | In10.ST / InTS10.ST |
| 8 | In11.ST / InTS11.ST |
| 9 | I12.ST / InTS12.ST |

The tenth associated value is not available.

Enter the batch ID @1%s@ under "Properties - Block - Special properties - Messages extended - Message texts block".

The associated values in the process messages (event) must be incremented by 3:

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | $$BlockComment$$ `InTS1` Status 16#@4%x@ |

I/Os of EventTs

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Inputs

| Parameter | Description | Type | Default |
|---|---|---|---|
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-string | |
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `Feature` | I/O for additional functions (Page 2062) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| `ExtVal01` | External message 1 | ANY | |
| `ExtVal02` | External message 2 | ANY | |
| `ExtVal03` | External message 3 | ANY | |
| `ExtVal04` | External message 4 | ANY | |
| `ExtVal05` | External message 5 | ANY | |
| `ExtVal06` | External message 6 | ANY | |
| `In1..In16` | Signal 1..16 for CPU time stamp | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#FF |
| `InTS1..InTS16` | Signal 1..16 with I/O-device time stamp | ANY | |
| `Inv1..Inc16` | 1 = Invert input `In1..In16` or `InTS1..InTS16` | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `MsgEn1..MsgEn16` | 1 = Activate message for input `In1..In16` or `InTS1..InTS16` | BOOL | 1 |
| `MsgEvId1` | Message number (assigned automatically) | DWORD | 16#00000000 |
| `MsgEvId2` | Message number (assigned automatically) | DWORD | 16#00000000 |
| `MsgLock` | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `MS_RelOp` | 1 = Release for maintenance by OS operator | BOOL | 0 |
| `Occupied` | 1 = In use by a batch | BOOL | 0 |
| `OnOp*` | 1 = "On" mode via operator | BOOL | 0 |
| `OosLi` | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `OosOp*` | 1 = "Out of service", via OS operator | BOOL | 0 |
| `OS_Perm` | I/O for Event16Ts functions (Page 2062) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| `RunUpCyc` | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| `SampleTime` | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| `SelFp1` | RESERVED | ANY | |
| `SelFp2` | RESERVED | ANY | |
| `StepNo` | Batch step number | DWORD | 16#00000000 |
| `TimeStampOn` | 0 = Use time stamp of the CPU<br>1 = Use time stamp of the I/O devices | BOOL | 0 |
| `UserStatus` | First freely assignable bits for use in OS | BYTE | 16#00000000 |
| `UserStatus2` | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Outputs

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see Event16Ts error handling (Page 2065) | INT | -1 |
| EventTsOut | For maneuvering of data between a technological block and the message blocks EventTs, Event16Ts. | STRUCT | |
| MS_Release | Release for maintenance:<br>1 = Release for OS operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn1..MsgAckn2 | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr1..MsgErr2 | 1 = Message error (output ERROR of ALARM_8P) | BOOL | 0 |
| MsgStat1..MsgStat2 | Message status (output STATUS of ALARM_8P) | WORD | 16#0000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 2057) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 2057) | DWORD | 16#00000000 |
| Status3 | Status word 3 (Page 2062) | DWORD | 16#00000000 |
| Status4 | Status word 4 (Page 2062) | DWORD | 16#00000000 |

# Counter blocks 11

## 11.1 CountScL - Counter with up and down counting direction

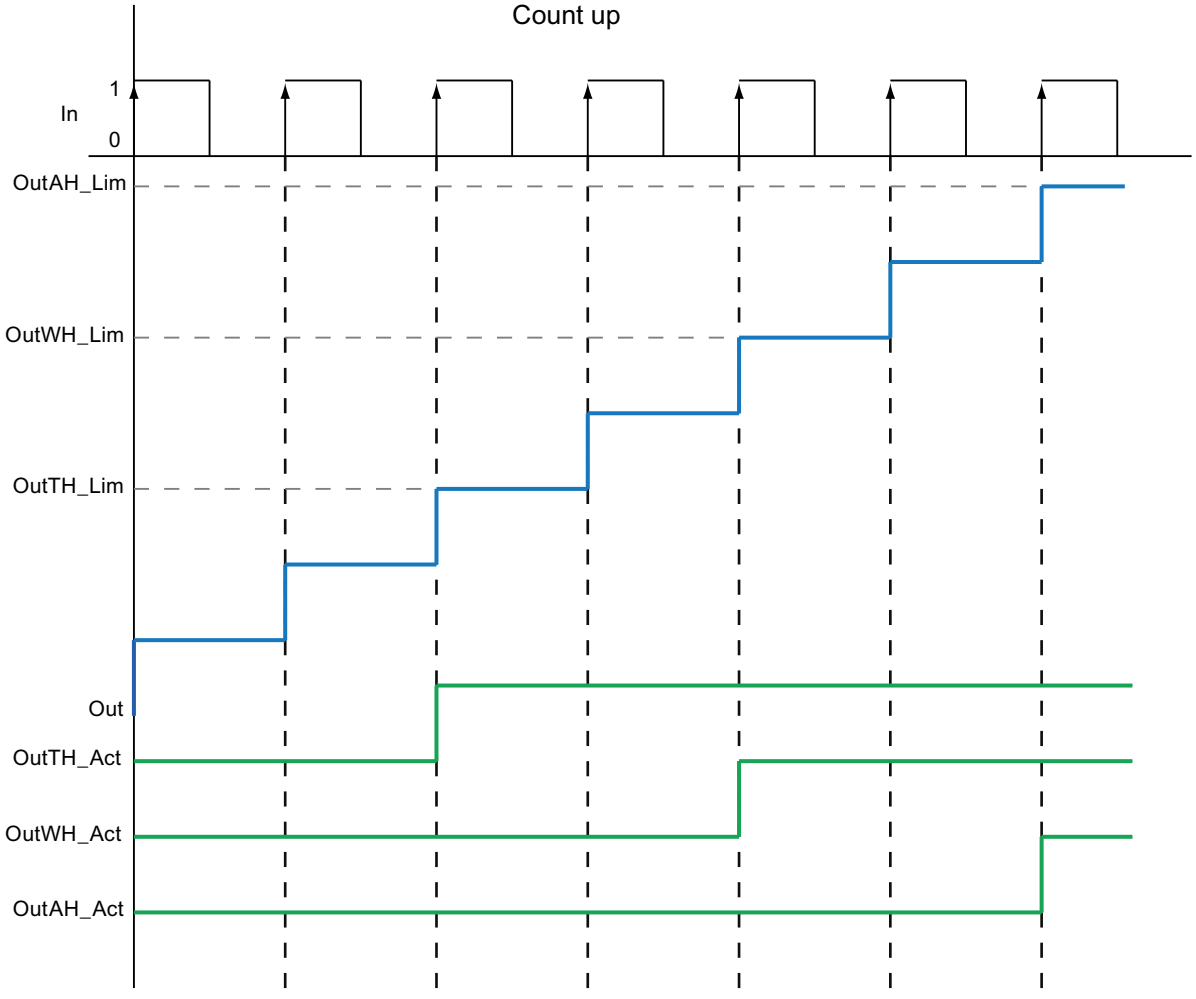
### 11.1.1 Description of CountScL

**Object name (type + number) and family**

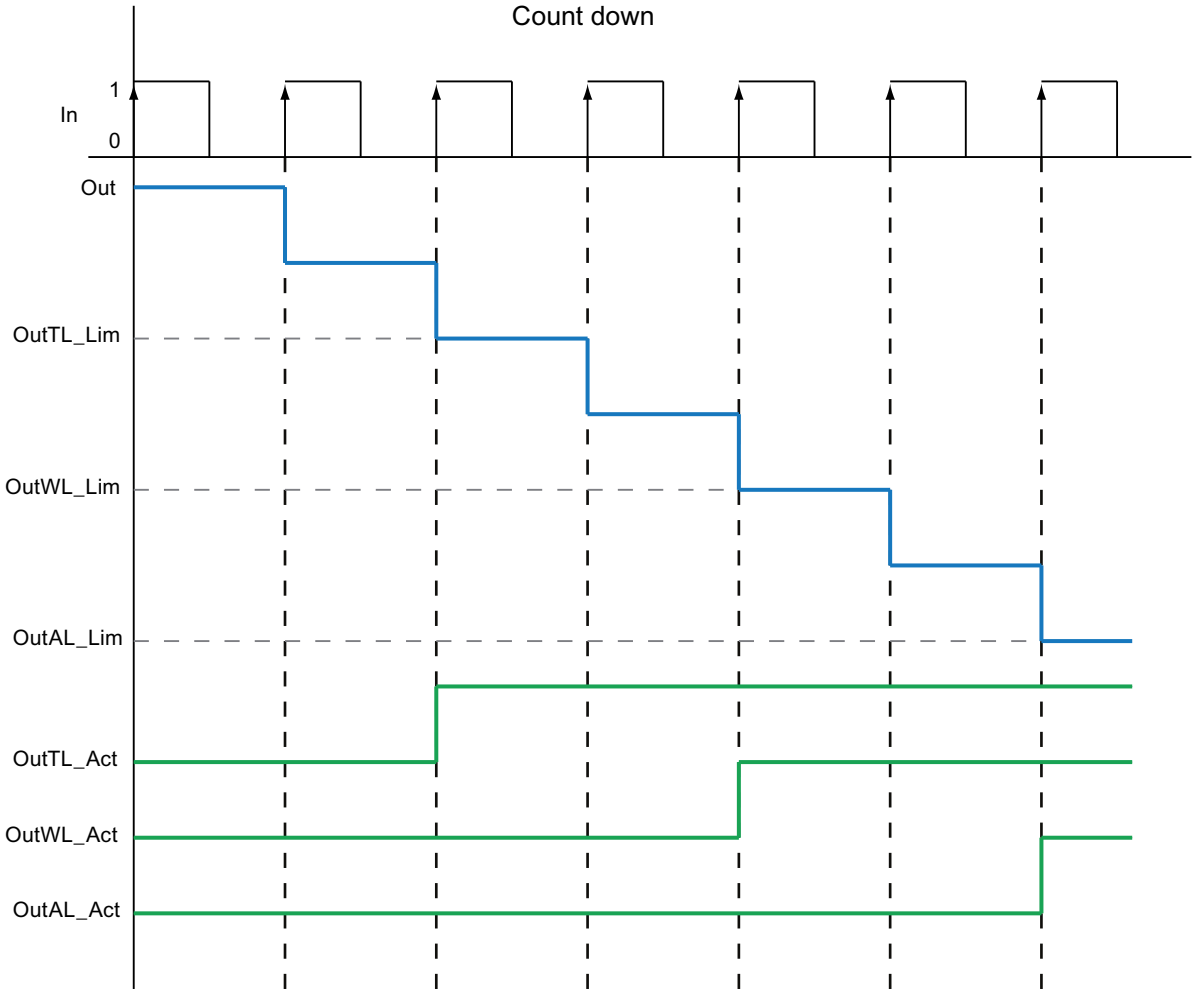
Type + number: FB 1806

Family: Count

**Area of application for CountScL**



The block is used for the following applications:



- Count up or count down with rising edge of the binary input signal.

## How it works

Positive edges at the binary input signal In increment or decrement the count value at Out, depending on settings.

1. Count up (`UpOp` = 1 or `UpLi` =1)
   The block counts up for each rising edge of `In`. (Output parameter `CountMode` = 1)
2. Count down (`DnOp` = 1 or `DnLi` = 1)
   The block counts down for each rising edge of `In`. (Output parameter `CountMode` = 2)
3. Off (`OffOp` = 1 or `OffLi` = 1)
   The block is disabled (output parameter `CountMode` = 0). No counting takes place.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

## Startup characteristics

Define the startup characteristics for this block via two `Feature` Bits:

Bit 0: Set startup characteristics (Page 148)

Bit 5: Use the last value following a complete download as the current value during startup of the block (Page 165)

## Time response

The block does not have any time response.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section CountScL I/Os (Page 2085).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 - 10 | Not used |
| 11 | `LiOp` |
| 12 - 13 | Not used |
| 14 | 1 = Invalid signal status |
| 15 | Not used |
| 16 | Internal error |
| 17-31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock.Value` |
| 1 | `OutAH_Act.Value` |
| 2 | `OutWH_Act.Value` |
| 3 | `OutTH_Act.Value` |
| 4 | `OutTL_Act.Value` |
| 5 | `OutWL_Act.Value` |
| 6 | `OutAL_Act.Value` |
| 7 | `OutAH_En` OR `Feature.Bit23` |
| 8 | `OutWH_En` OR `Feature.Bit23` |
| 9 | `OutTH_En` OR `Feature.Bit23` |
| 10 | `OutTL_En` OR `Feature.Bit23` |
| 11 | `OutWL_En` OR `Feature.Bit23` |
| 12 | `OutAL_En` OR `Feature.Bit23` |
| 13 | `OutAH_MsgEn` |
| 14 | `OutWH_MsgEn` |
| 15 | `OutTH_MsgEn` |
| 16 | `OutTL_MsgEn` |
| 17 | `OutWL_MsgEn` |
| 18 | `OutAL_MsgEn` |
| 19 | Not used |
| 20 | Count up |

| Status bit | Parameter |
|---|---|
| 21 | Counter off |
| 22 | Count down |
| 23 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | Not used |
| 31 | MS_RelOp |

CountScL messaging (Page 2084)

CountScL block diagram (Page 2090)

CountScL error handling (Page 2084)

CountScL modes (Page 2079)

## 11.1.2 CountScL modes

### CountScL operating modes

This block provides the following operating modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit4` =1 and `Feature.Bit4` =0 is as shown below:

| Output Parameters | **Feature.Bit4 =0** | **Feature.Bit4 =1** |
|---|---|---|
| OutAH_Act.ST | 16#XX | 16#60 |
| OutWH_Act.ST | 16#XX | 16#60 |
| OutTH_Act.ST | 16#XX | 16#60 |
| OutTL_Act.ST | 16#XX | 16#60 |
| OutWL_Act.ST | 16#XX | 16#60 |
| OutAL_Act.ST | 16#XX | 16#60 |

CountScL messaging (Page 2084)
CountScL error handling (Page 2084)
Description of CountScL (Page 2075)
CountScL functions (Page 2080)

## 11.1.3 CountScL functions

### Functions of CountScL

The functions for this block are listed below.

### Limit monitoring of the count value

This block provides the standard function Limit monitoring of the count value (Page 96).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Read back the last counted value

When counting (visible at the `Out` output parameter), this count value is passed directly to the `OldOut` input parameter:

`OldOut` = `Out` If a warm restart is performed at this point, the count value (`Out`) is automatically reset to the default value, if the `Feature` Bit Set startup characteristics (Page 148) is set accordingly (= 0) (`OldOut` ≠ `Out`). In this case, the value from `OldOut` is only updated when the (`Out`) count value is changed again by a pulse. `OldOut` = `Out` now applies again.

### Reset counter to zero

The counted value at the `Out` output parameter is reset with the interconnectable `ResetCount` parameter. The reset is made with a 0 - 1 edge.

The count cannot be reset to zero from the faceplate.

You can use `Feature.Bit30` "Set reset depending on operating mode or the `LiOp` parameter" to configure a reset depending on the `LiOp` parameter:

`Feature.Bit30` = 0: The reset does not depend on `LiOp`

`Feature.Bit30` = 1: The reset is only possible when `LiOp =1`.

### Setting the count value to the default setting

You can use the PresetVal input parameter to enter a value at which the count should start, if the command has been given for setting the count to the default via the PresetEn input parameter with 1. This can also be done with the faceplate.

In this case, the Out output parameter is set to the PresetVal value.

You can use Feature.Bit30 "Set reset depending on operating mode or the LiOp parameter" to configure the setting of the count value to a default depending on the LiOp parameter:

Feature.Bit30 = 0: Setting the count value to the default setting does not depend on LiOp

Feature.Bit30 = 1: Setting the count value to the default is only possible if LiOp =0.

### Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status ST_Worst for the block is formed from the following parameter:

- In.ST
- OutST

The following signal status is formed by:

| Signal status | Used status |
|---|---|
| OutST | Count up, count down: Formed from the signal status In.ST and the last signal status OutST.<br>Counter off: Signal status OutST is frozen.<br>Resetting CountScL also resets the signal status: OutST := 16#80 |

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature I/O in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |

| Bit | Function |
|---|---|
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 4 | Changes signal status of outputs in OOS (Page 208) |
| 5 | Use the last value following a complete download as the current value during startup of the block (Page 165) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |

## Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop counting |
| 5 | 1 = Operator can switch to incrementing mode |
| 6 | 1 = Operator can switch to decrementing mode |
| 7 - 11 | Not used |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the limit (`OutAH_Lim`) for high alarm |
| 14 | 1 = Operator can change the limit (`OutWH_Lim`) for high warning |
| 15 | 1 = Operator can change the limit (`OutTH_Lim`) for high tolerance |
| 16 | Not used |
| 17 | 1 = Operator can change the limit (`OutAL_Lim`) for low alarm |
| 18 | 1 = Operator can change the limit (`OutWL_Lim`) for low warning |
| 19 | 1 = Operator can change the limit (`OutTL_Lim`) for low tolerance |
| 20 | Not used |
| 21 | 1 = Operator can set the count to the default value (`PresetEn`) |
| 22 | 1 = Operator can specify the default value (`PresetTime`) |
| 23 | 1 = Operator can activate / deactivate messages via `OutAH_MsgEn` |
| 24 | 1 = Operator can activate / deactivate messages via `OutWH_MsgEn` |
| 25 | 1 = Operator can activate / deactivate messages via `OutTH_MsgEn` |
| 26 | 1 = Operator can activate / deactivate messages via `OutTL_MsgEn` |
| 27 | 1 = Operator can activate / deactivate messages via `OutWL_MsgEn` |
| 28 | 1 = Operator can activate / deactivate messages via `OutAL_MsgEn` |
| 29 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

### Providing limit at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

`OutAH_LimOut` := `OutAH_Lim`

`OutWH_LimOut` := `OutWH_Lim`

`OutTH_LimOut` := `OutTH_Lim`

`OutTL_LimOut` := `OutTL_Lim`

`OutWL_LimOut` := `OutWL_Lim`

`OutAL_LimOut` := `OutAL_Lim`

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 11.1.4 CountScL error handling

### Error handling of CountScL

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 51 | Invalid signal at `LiOp` = 1:<br>• `OffLi` = 1 and `UpLi` = 1 and/or `DnLi` = 1<br>• `OffLi` = 0 and `UpLi` = 1 and `DnLi` = 1 |

## 11.1.5 CountScL messaging

### Messaging

The following messages can be generated for this block:

- Functions for displaying measured limits

Messages generated as a reaction to limit violations, can be suppressed by the settings `MsgEn` and `MsgLock`.

### Associated values for message instance `MsgEvId`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId` | SIG 1 | Alarm - high | $$BlockComment$$<br>High alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>High warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>High tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>Low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>Low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>Low alarm limit violated |
| | SIG 7 | Reserved | $$BlockComment$$ |
| | SIG 8 | Reserved | $$BlockComment$$ |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

| OutTL_En | 1 = Enable count tolerance message (low) | BOOL | 0 |
| OutTL_Lim | Count tolerance message limit (low) | DINT | 0 |
| OutTL_MsgEn | 1 = Enable message for count tolerance message (low) | BOOL | 1 |
| OutUnit | Unit of measure for count Out | INT | 0 |
| OutWH_En | 1 = Enable count warning (high) | BOOL | 1 |
| OutWH_Lim | Count warning limit (high) | DINT | 90 |
| OutWH_MsgEn | 1 = Enable message for count warning (high) | BOOL | 1 |
| OutWL_En | 1 = Enable count warning (low) | BOOL | 1 |
| OutWL_Lim | Count warning limit (low) | DINT | 0 |
| OutWL_MsgEn | 1 = Enable message for count warning (low) | BOOL | 1 |
| PresetEn* | 1 = Set block to default count (PresetVal) | BOOL | 0 |
| PresetVal | Default setting for the count | DINT | 0 |
| ResetCount | 1 = Counter restart | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RunUpCyc | Number of operating cycles for which all messages are suppressed | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelFp2 | Call a block saved in this parameter as an additional face-plate (Page 234) in the preview | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UpLi | 1 = Forward counter, via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UpOp* | 1 = Forward counter, via operator | BOOL | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CountMode | 0 = Counter off<br>1 = Count up<br>2 = Count down | INT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ER_AL_Out | ER alarm high limit Output | DINT | 0 |
| ER_AH_Out | ER alarm low limit Output | DINT | 0 |
| ER_TH_Out | ER Tolerance High Limit Output | DINT | 0 |
| ER_TL_Out | ER Tolerance Low Limit Output | DINT | 0 |
| ER_WH_Out | ER Warning High Limit Output | DINT | 0 |
| ER_WL_Out | ER Warning Low Limit Output | DINT | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see CountScL error handling (Page 2084) | INT | -1 |
| MsgAckn | Message acknowledgement status (output ACK_STATE of first ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Message error (output ERROR of the first ALARM_8P) | BOOL | 0 |
| MsgStat | Message status (output STATUS of the first ALARM_8P) | WORD | 16#0000 |
| MS_Release | Release for maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| O_MS_Ext | Reserved | DWORD | 0 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out | Count | DINT | 0 |
| OutAH_Act | 1 = Count alarm (high) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutAL_Act | 1 = Count alarm (low) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutOpHiScaleOut | OutOpHiScale as output | DINT | 0 |
| OutOpLoScaleOut | OutOpLiScale as output | DINT | 0 |
| OutST | Signal status for Out | BYTE | 16#80 |
| OutTH_Act | 1 = Count tolerance message (high) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutTL_Act | 1 = Count tolerance message (low) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutUnitOut | OutUnit as output | INT | 0 |
| OutWH_Act | 1 = Count warning (high) enabled. You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutWL_Act | 1 = Count warning (low) enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutAH_LimOut | OutAH_Lim as output | DINT | 0 |
| OutWH_LimOut | OutWH_Lim as output | DINT | 0 |
| OutTH_LimOut | OutTH_Lim as output | DINT | 0 |
| OutAL_LimOut | OutAL_Lim as output | DINT | 0 |
| OutWL_LimOut | OutWL_Lim as output | DINT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `OutTL_LimOut` | `OutTL_Lim` as output | DINT | 0 |
| `ST_Worst` | Worst signal status | BYTE | 16#80 |
| `Status1` | Status word 1 (Page 2075) | DWORD | 16#00000000 |
| `Status2` | Status word 2 (Page 2075) | DWORD | 16#00000000 |

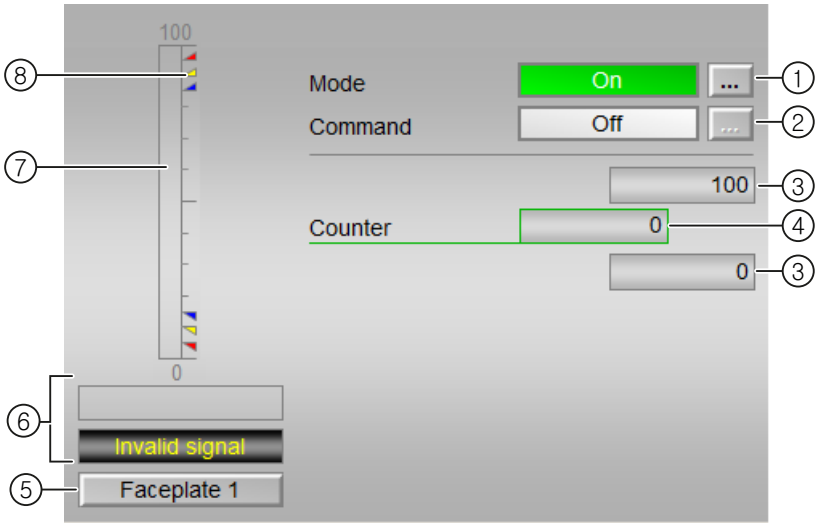
## 11.1.8 Operator control and monitoring

### 11.1.8.1 CountScL views

### Views of the CountScL block

The block CountScL provides the following views:



- CountScL standard view (Page 2091)
- Alarm view (Page 336)
- CountScL limit view (Page 2093)
- Trend view (Page 341)

- CountScL parameter view (Page 2094)
- CountScL preview (Page 2095)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for CountScL (Page 2096)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 11.1.8.2 CountScL standard view

#### CountScL standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

### (2) Enabling and disabling the counter

This area shows you the default operating state for the counter. The following states can be shown and executed here:

- "On ⇑"
- "On ⇓"
- "Off"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (3) High and low scale range for the count value

These values provide information on the display range for the bar graph of the count. The scale range is defined in the engineering system.

### (4) Display of the count value

This area shows the current count value with the signal status `OutST`.

The name for the current count value can be set using the `s7_shortcut` attribute at the corresponding output parameter. The default text is displayed if nothing is specified.

You can find additional information on this in the section Labeling of buttons and text (Page 235) .

### (5) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### (6) Display area for block states

This area provides additional information on the operating state of the block:

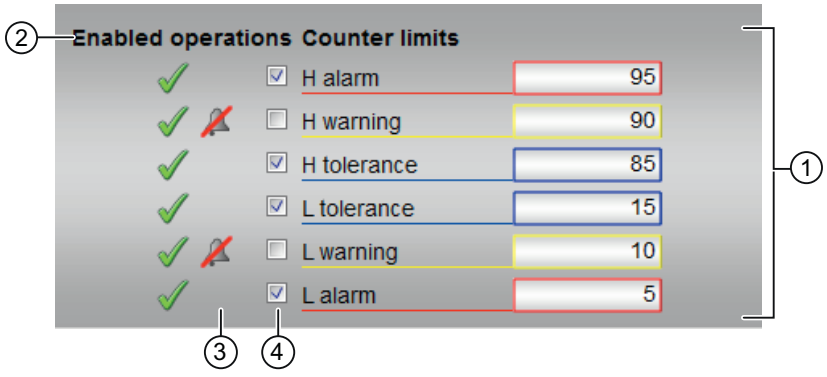
- "Maintenance"
- "Internal error"
- "Invalid Signal"

### (7) Graphic display of the current count value

This area shows you the current count in form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (8) Limit display

These colored triangles indicate the configured limits in the respective bar graph:



- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

In counting mode "count up", only the colored triangles of the upper limits are visible; and in counting mode "count down", only the colored triangles of the lower limits are visible.

For more information, refer: Bar graph (Page 376)

## 11.1.8.3 CountScL limit view

### Limit view of CountScL

### (1) Limits for the counter

In this area, you can enter the limits for the counter. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "H tolerance": Tolerance high
- "L tolerance": Tolerance low
- "L warning": Warning low
- "L alarm": Alarm low

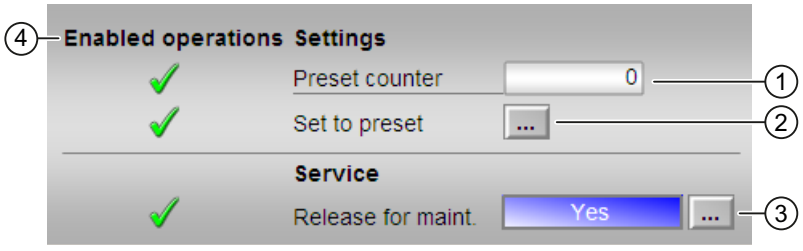
### (2) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (3) "Message suppression"



Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

### (4) Suppress messages

You can enable / disable messages by setting the check mark.

## 11.1.8.4 CountScL parameter view

### Parameter view of CountScL

### (1) Preset counter

Enter the default setting here, where the counter should start. You can find additional information on this in the Changing values (Page 291) section.

### (2) Set to default

Set the counter to the default value here. You can find additional information on this in the Switching operating states and operating modes (Page 289) section.

### (3) Service

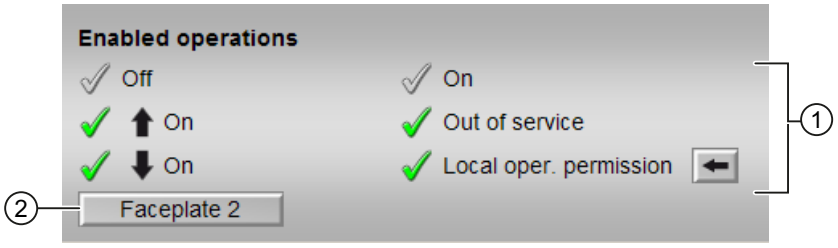
You can select the following function in this area:

- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the Release for maintenance (Page 70) section.

### (4) Enabled operations



This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

## 11.1.8.5 CountScL preview

### Preview of CountScL

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

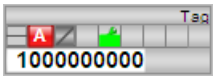
- "Off": You can disable the counter.
- "On ⇑": You can operate the incremental counter.
- "On ⇓": You can operate the decremental counter.

- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

### (2) Navigation button for switching to the standard view of any faceplate

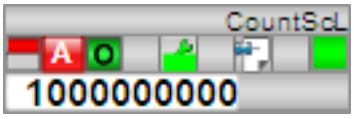
Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

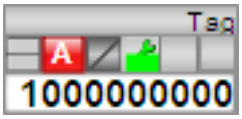
You can find additional information on this in the Opening additional faceplates (Page 234) section.

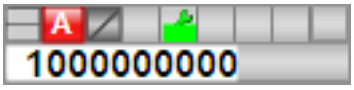


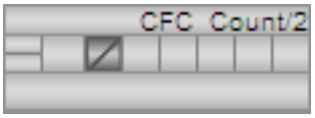
## 11.1.8.6 Block icon for CountScL

### Block icons for CountScL









A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display counter running

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in the CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 11.2 CountOh - Determining runtime

## 11.2.1 Description of CountOh

### Object name (type + number) and family

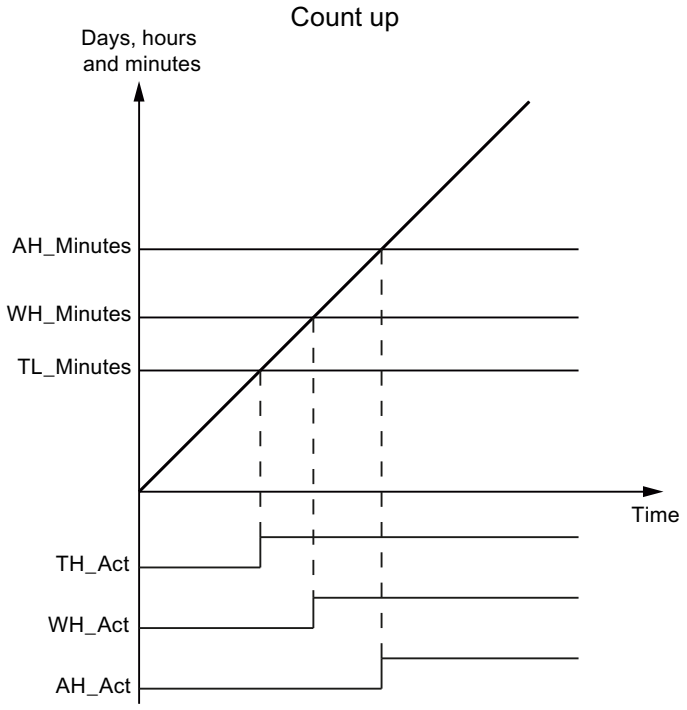
Type + number: FB 1864

Family: Count

### Area of application for CountOh

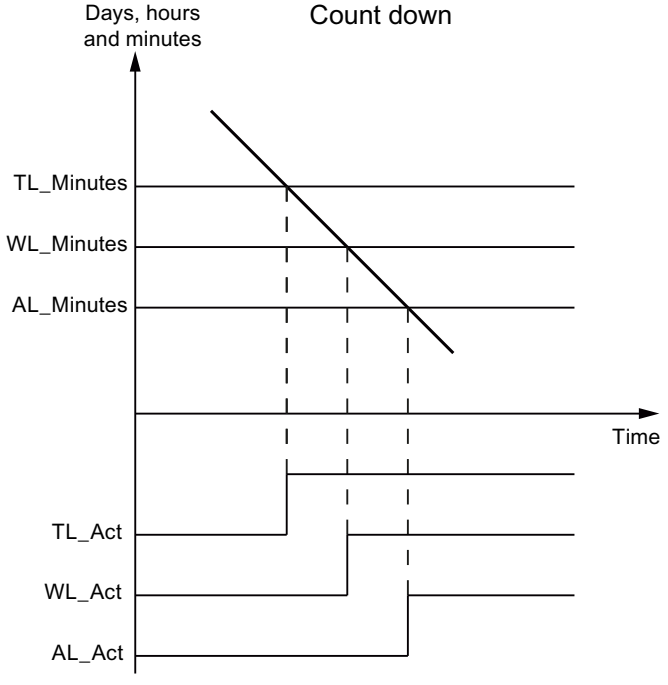
The block is used for the following applications:

- Calculating the runtime of a unit



### How it works

The block calculates the operating time of a unit.



1. Off (`OffOp` = 1 or `OffLi` = 1)
   The block is disabled (output parameter `CountMode` = 0). No counting takes place.
2. Count up (`UpOp` = 1 or `UpLi` = 1)
   The operating time of the connected unit is incremented (output parameter `CountMode` = 1).
3. Count down (`DnOp` = 1 or `DnLi` = 1)
   The operating time of the connected unit is decremented (output parameter `CountMode` = 2).

The operating time is shown depending on the course of days, hours, minutes and seconds.

If the operating time exceeds the configured limits, an alarm is triggered.

When the block counts up and the total operating time `(TimeMin)` of the connected unit is greater than or equal to the limits (`TH_Minutes`, `WH_Minutes` and `AH_Minutes`), the alarms `TH_Act`, `WH_Act` and `AH_Act` are set.

When the block counts up and the total operating time `(TimeMin)` of the connected unit is greater than or equal to the limits (`TL_Minutes`, `WL_Minutes` and `AL_Minutes`), the alarms `TL_Act`, `WL_Act` and `AL_Act` are set.

The operating time can be preset. The value can be specified by the operator. The operator can set values for days, hours and minutes to begin counting, if the required operator control permission has been issues for this.

The maximum configurable value for the operating time is 24855 days, 3 hours and 14 minutes.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is first installed automatically in the startup OB (OB 100).

### Startup characteristics

Define the startup characteristics for this block via two `Feature` bits:

Bit 0: Set startup characteristics (Page 148)

Bit 5: Use the last value following a complete download as the current value during startup of the block (Page 165)

When `Feature.Bit5` is set to 1, then:

- `Days := OldDays`
- `Hours := OldHours`
- `Minutes := OldMinutes`
- `Seconds := OldSeconds`

When you set `Feature.Bit5` and `Feature.Bit0` to 1, then:

- `TotalTime := PresetTime`

The output parameters `Days`, `Hours`, `Minutes` are converted accordingly based on `PresetTime`.

When you set `Feature.Bit5` to 0 and `Feature.Bit0` to 1, no preset is made.

### Time response

The block only functions properly in a cyclic interrupt OB. To ensure correct time acquisition, it should be installed (if configured in CFC) in the same runtime group as the control block of the monitored unit.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section CountOh I/Os (Page 2109).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |

| Status bit | Parameter |
|---|---|
| 5 | Not used |
| 6 | OnAct.Value |
| 7 - 10 | Not used |
| 11 | LiOp |
| 12 - 13 | Not used |
| 14 | 1 = Invalid signal status |
| 15 | Not used |
| 16 | Internal error |
| 17-31 | Not used |

### Status word allocation for Status2 parameter

| Status bit | Parameter |
|---|---|
| 0 | MsgLock.Value |
| 1 | AH Act.Value |
| 2 | WH_Act.Value |
| 3 | TH_Act.Value |
| 4 | TL_Act.Value |
| 5 | WL_Act.Value |
| 6 | AL_Act.Value |
| 7 | AH_En OR Feature.Bit23 |
| 8 | WH_En OR Feature.Bit23 |
| 9 | TH_En OR Feature.Bit23 |
| 10 | TL_En OR Feature.Bit23 |
| 11 | WL_En OR Feature.Bit23 |
| 12 | AL_En OR Feature.Bit23 |
| 13 | AH_MsgEn |
| 14 | WH_MsgEn |
| 15 | TH_MsgEn |
| 16 | TL_MsgEn |
| 17 | WL_MsgEn |
| 18 | AL_MsgEn |
| 19 | Not used |
| 20 | Count up |
| 21 | Counter off |
| 22 | Count down |
| 23 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | Not used |
| 31 | MS_RelOp |

### See also

CountOh functions (Page 2103)

CountOh messaging (Page 2108)

CountOh block diagram (Page 2114)

CountOh error handling (Page 2107)

CountOh modes (Page 2102)

## 11.2.2 CountOh modes

### CountOh operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the On (Page 77) section.

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit4` =1 and `Feature.Bit4` =0 is as shown below:

| Output Parameters | **`Feature.Bit4` =0** | **`Feature.Bit4` =1** |
|---|---|---|
| DeviceOn.ST | 16#XX | 16#60 |
| AH_Act.ST | 16#XX | 16#60 |
| WH_Act.ST | 16#XX | 16#60 |
| TH_Act.ST | 16#XX | 16#60 |
| TL_Act.ST | 16#XX | 16#60 |
| WL_Act.ST | 16#XX | 16#60 |
| AL_Act.ST | 16#XX | 16#60 |

CountOh messaging (Page 2108)

CountOh error handling (Page 2107)

Description of CountOh (Page 2098)
CountOh functions (Page 2103)

## 11.2.3 CountOh functions

### Functions of CountOh

The block provides the following functions:

### Limit monitoring of the operating time

The total time in minutes `(TimeIn)` is displayed for the following limits:

1. Alarm (`AH_Minutes` and `AL_Minutes`)
2. Warning (`WH_Minutes` and `WL_Minutes`)
3. Tolerance (`TH_Minutes` and `TL_Minutes`)

**Note**

**Limit monitoring:**

Limit monitoring depends on the counting direction:

- Operation mode 1 (counting up), limit monitoring top
  - `AH_Minutes`
  - `WH_Minutes`
  - `TH_Minutes`
- Operation mode 2 (counting down), limit monitoring bottom
  - `AL_Minutes`
  - `WL_Minutes`
  - `TL_Minutes`

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the `MsgLock` parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 4 | Changes signal status of outputs in OOS (Page 208) |
| 5 | Use the last value following a complete download as the current value during startup of the block (Page 165) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |

### Read back the last counted value

When counting (`DeviceOn.Value = 1` and `CountMode = 1` or `2`), the inputs of the most recently valid operating time are updated:

- `OldDays := Days`
- `OldHours := Hours`
- `OldMinutes := Minutes`
- `OldSeconds := Seconds`

The inputs `OldDays`, `OldHours`, `OldMinutes`, `OldSeconds` are read back with a complete download.

After a warm restart, the outputs of the operating time are set depending on the configuration of the `Feature` parameter.

When `Feature.Bit5` is set to 1, then:

- `Days := OldDays`
- `Hours := OldHours`
- `Minutes := OldMinutes`
- `Seconds := OldSeconds`

When you set `Feature.Bit5` and `Feature.Bit0` to 1, then:

- `TotalTime := PresetTime`

The output parameters `Days`, `Hours`, `Minutes` are converted accordingly based on `PresetTime`.

When you set `Feature.Bit5` to 0 and `Feature.Bit0` to 1, no preset is made.

### Display and operator input area for process values and setpoints

This block provides the standard function Display and operator input area for process values and setpoints (Page 233).

### Reset counter to zero

The output parameters of the operating time are reset via the interconnectable `Reset` parameter. The reset is made with a 0 - 1 edge.

The count cannot be reset to zero from the faceplate.

You can use `Feature.Bit30` "Set reset depending on operating mode or the LiOp parameter" to configure a reset depending on the LiOp parameter:

`Feature.Bit30` = 0: The reset does not depend on `LiOp`

`Feature.Bit30` = 1: The reset is only possible when `LiOp =1`

### Setting the count value to the default setting

You can enter the operating time at which counting should begin with the input parameters `PresetTime` and `PresetEn`.

When `PresetEn` is set, the following applies:

- `TotalTime := PresetTime`

The outputs `Days`, `Hours`, `Minutes` are converted accordingly based on `PresetTime`. `PresetTime` can also be entered in the faceplate.

The `PresetTime` time value is always indicated in seconds.

You can use the `Feature.Bit30` "Set reset depending on operating mode or the `LiOp` parameter" to configure the setting of the count value to a default depending on the `LiOp` parameter:

`Feature.Bit30` = 0: Setting to the default does not depend on `LiOp`

`Feature.Bit30` = 1: Setting to the default is only possible if `LiOp` =0.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameter:

- `In.ST`
- `TmMinSt`

The following signal status is formed by:

| Signal status | Used status |
|---|---|
| TmMinST | Count up, count down: Formed from the signal status In.ST and the last signal status TmMinST.<br>Counter off: Signal status TmMinST is frozen.<br>Resetting CountOh also resets the signal status: TmMinST := 16#80 |

## Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can start the block |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the block |
| 5 | 1 = Operator can switch to incrementing mode |
| 6 | 1 = Operator can switch to decrementing mode |
| 7 - 11 | Not used |
| 12 | 1 = Operator can enable release for maintenance |
| 13 | 1 = Operator can enter AH_Lim |
| 14 | 1 = Operator can enter WH_Lim |
| 15 | 1 = Operator can enter TH_Lim |
| 16 | Not used |
| 17 | 1 = Operator can enter AL_Lim |
| 18 | 1 = Operator can enter WL_Lim |
| 19 | 1 = Operator can enter TL_Lim |
| 20 | Not used |
| 21 | 1 = Operator can enable default |
| 22 | 1 = Operator can apply configured time |
| 23 | 1 = Operator can activate / deactivate messages via AH_MsgEn |
| 24 | 1 = Operator can activate / deactivate messages via WH_MsgEn |
| 25 | 1 = Operator can activate / deactivate messages via TH_MsgEn |
| 26 | 1 = Operator can activate / deactivate messages via TL_MsgEn |
| 27 | 1 = Operator can activate / deactivate messages via WL_MsgEn |
| 28 | 1 = Operator can activate / deactivate messages via AL_MsgEn |
| 29 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 11.2.4 CountOh error handling

### Error handling of CountOh

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 51 | Invalid signal at `LiOp` = 1<br>• `OffLi` = 1 and `UpLi` = 1 and/or `DnLi` = 1<br>• `OffLi` = 0 and `UpLi` = 1 and `DnLi` = 1 |

## 11.2.5 CountOh messaging

### Messaging

The following messages can be generated for this block:

- Functions for displaying measured limits

Messages generated as a reaction to limit violations, can be suppressed by the settings `xx_MsgEn` and `MsgLock`.

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId 1` | SIG 1 | Alarm - high | $$BlockComment$$<br>High alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>High warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>High tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>Low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>Low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>Low alarm limit violated |
| | SIG 7 | Reserved | $$BlockComment$$<br>For internal use |
| | SIG 8 | Reserved | $$BlockComment$$<br>For internal use |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

### Associated values for message instance `MsgEvId1`

| Associated value | Block parameters |
|---|---|
| 1 | BatchName |
| 2 | StepNo |
| 3 | BatchID |

## 11.2.6 CountOh I/Os

I/Os of CountOh

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AH_En | High alarm enabled | BOOL | 1 |
| AH_MsgEn | Message for high alarm enabled | BOOL | 1 |
| AL_En | Low alarm enabled | BOOL | 1 |
| AL_MsgEn | Message for low alarm enabled | BOOL | 1 |
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch number (Batch ID) | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of block-type<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| DayOpHiScale* | Operating stage - High limit of bar display for OS | INT | 100 |
| DayOpLoScale* | Operating stage - Low limit of bar display for OS | INT | 0 |
| DaysAHLim* | Days - high limit alarm | INT | 95 |
| DaysALLim* | Days - low limit alarm | INT | 0 |
| DaysTHLim* | Days - high limit tolerance | INT | 85 |
| DaysTLLim* | Days - low limit tolerance | INT | 0 |
| DaysWHLim* | Days - limit for high warning | INT | 90 |
| DaysWLLim* | Days - limit for low warning | INT | 0 |
| DnLi | 1 = Decrement via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DnOp* | 1 = Decrement via OS operator | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 2103) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| HrsAHLim* | Hours - high limit alarm | INT | 0 |
| HrsALLim* | Hours - low limit alarm | INT | 0 |
| HrsOpHiScale* | Operating hours - high limit of bar display for OS | INT | 23 |
| HrsOpLoScale* | Operating hours - low limit of bar display for OS | INT | 0 |
| HrsTHLim* | Hours - high limit tolerance | INT | 0 |
| HrsTLLim* | Hours - low limit tolerance | INT | 0 |
| HrsWHLim* | Hours - high limit warning | INT | 0 |
| HrsWLLim* | Hours - low limit warning | INT | 0 |
| In | Device status:<br>1=On<br>0=Off | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LiOp | Switchover of operating mode between:<br>1 = Interconnection<br>0 = Operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MinOpHiScale* | Operating minutes - high limit of bar display for OS | INT | 59 |
| MinOpLoScale* | Operating minutes - low limit of bar display for OS | INT | 0 |
| MinsAHLim* | Minutes - high limit alarm | INT | 0 |
| MinsALLim* | Minutes - low limit alarm | INT | 0 |
| MinsTHLim* | Minutes - high limit tolerance | INT | 0 |
| MinsTLLim* | Minutes - low limit tolerance | INT | 0 |
| MinsWHLim* | Minutes - high limit warning | INT | 0 |
| MinsWLLim* | Minutes - low limit warning | INT | 0 |
| MS_RelOp* | Operator input for release for maintenance, 1: Release for maintenance demand | BOOL | 0 |
| MsgEvId | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1= Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OffLi | Counter disabled via interconnection:<br>1 = Off | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OffOp* | Counter disabled via operator:<br>1 = Off | BOOL | 1 |
| OldDays* | Previous day value | INT | 0 |
| OldHours* | Previous hour value | INT | 0 |
| OldMinutes* | Previous minute value | INT | 0 |
| OldSeconds* | Previous second value | INT | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for CountOh functions (Page 2103) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PresetEn* | 1 = Set block to default time time value (PresetTime) | BOOL | 0 |
| PresetTime* | Default setting for the time value [s] | DWORD | 16#00000000 |
| Reset | 1 = Reset counter | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] | REAL | 0.1 |
| SelFp1 | Open faceplate 1 | ANY | |
| SelFp2 | Open faceplate 2 | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TH_En | High tolerance enabled | BOOL | 0 |
| TH_MsgEn | Alarm for high tolerance enabled | BOOL | 1 |
| TL_En | Low tolerance enabled | BOOL | 0 |
| TL_MsgEn | Alarm for low tolerance enabled | BOOL | 1 |
| UpLi | 1 = Increment (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UpOp* | 1 = Increment (via faceplate) | BOOL | 0 |
| WH_En | High warning enabled | BOOL | 1 |
| WH_MsgEn | Alarm for high warning enabled | BOOL | 1 |
| WL_En | Low warning enabled | BOOL | 1 |
| WL_MsgEn | Alarm for low warning enabled | BOOL | 1 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AH_Act | High alarm enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| AH_Minutes | High alarm time [in min] | DINT | 0 |
| AL_Act | Low alarm enabled<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AL_Minutes | Low alarm time [in min] | DINT | 0 |
| BarOpHiScale | High limit for bar display [min] | DINT | 100 |
| BarOpLoScale | Low limit for bar display [min] | DINT | 0 |
| CountMode | Count mode:<br>0 = Off<br>1 = Increment<br>2 = Count down | INT | 0 |
| Days | Operating stage | INT | 0 |
| DeviceOn | 1 = Unit on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see CountOh error handling (Page 2107) | INT | -1 |
| Hours | Operating hours | INT | 0 |
| Minutes | Operating minutes | INT | 0 |
| MS_Release | Release for maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgAckn | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Message error (output ERROR of ALARM_8P) | BOOL | 0 |
| MsgStat | Message status (output STATUS of ALARM_8P) | WORD | 16#0000 |
| O_MS_Ext | Reserved | DWORD | 16#00000000 |
| OnAct | Block running | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | Block is "out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Operator permission: Output for OS | DWORD | 16#FFFFFFFF |
| OS_PermOut | Operator permission: Output for OS | DWORD | 16#FFFFFFFF |
| Seconds | Operating time [in sec] | INT | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 2098) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 2098) | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| TH_Act | High tolerance enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TH_Minutes | Tolerance high | DINT | 0 |
| TimeMin | Operating period [min] | DINT | 0 |
| TmMinST | Signal Station for TimeMin | BYTE | 16#80 |
| TL_Act | Low tolerance enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TL_Minutes | Low tolerance time [in min] | DINT | 0 |
| TotalTime | Total operating time | DWORD | 16#00000000 |
| WH_Act | High warning enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| WH_Minutes | High warning time [in min] | DINT | 0 |
| WL_Act | Low warning enabled.<br>You can change the reaction for this parameter with Feature.Bit28 (Disabling operating points (Page 156)) and with Feature.Bit29 (Signaling limit violation (Page 181)). | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| WL_Minutes | Low alarm time [in min] | DINT | 0 |

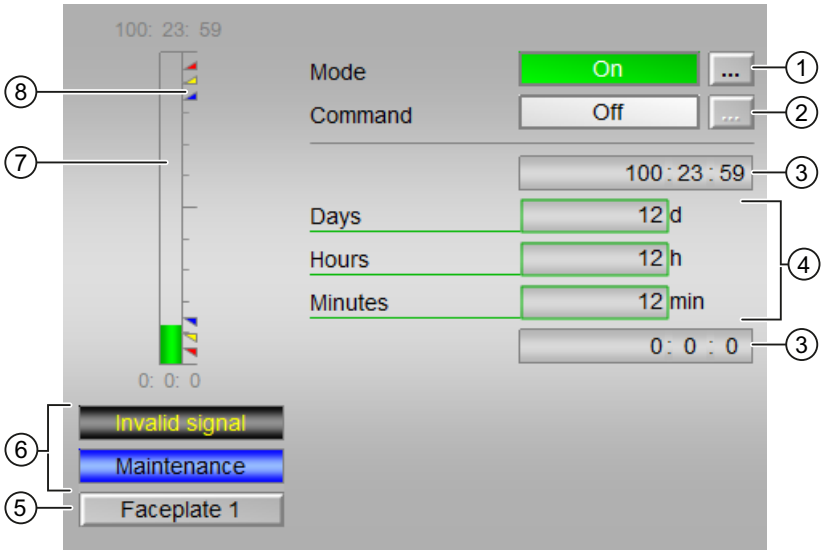
## 11.2.8 Operator control and monitoring

### 11.2.8.1 CountOh views

**Views of the CountOh block**



The block CountOh provides the following views:

- CountOh standard view (Page 2116)
- Alarm view (Page 336)
- CountOh limit view (Page 2118)
- Trend view (Page 341)
- CountOh parameter view (Page 2119)
- CountOh preview (Page 2120)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for CountOh (Page 2121)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 11.2.8.2 CountOh standard view

#### CountOh standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) Enabling and disabling the counter

This area shows you the default operating state for the counter. The following states can be shown and executed here:

- "On ⇑"
- "On ⇓"
- "Off"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

#### (3) High and low scale range for the count value

These values provide information on the display range for the bar graph **(5)** of the count value. The scale range is defined in the engineering system.

### (4) Displaying the counts values

The following counts are shown here:

- "Days" with signal status `TmMinST`
- "Hours" with signal status `TmMinST`
- "Minutes" with signal status `TmMinST`

### (5) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### (6) Display area for block states

This area provides additional information on the operating state of the block:

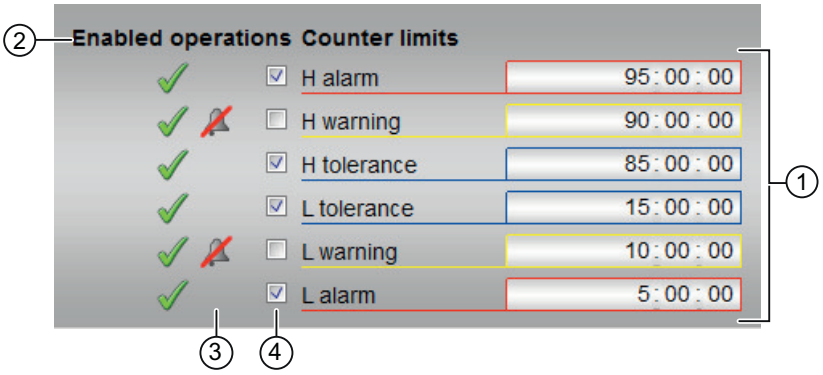
- "Maintenance"
- "Internal error"
- "Invalid Signal"

### (7) Graphic display of the current count value

This area shows you the current count in form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

### (8) Limits

These colored triangles indicate the configured limits in the respective bar graph:



- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

In counting mode "count up", only the colored triangles of the upper limits are visible; and in counting mode "count down", only the colored triangles of the lower limits are visible.

For more information, refer: Bar graph (Page 376)

### 11.2.8.3 CountOh limit view

#### Limit view of CountOh

#### (1) Limits for the counter

In this area, you can enter the limits for the counter. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "H tolerance": Tolerance high
- "L tolerance": Tolerance low
- "L warning": Warning low
- "L alarm": Alarm low

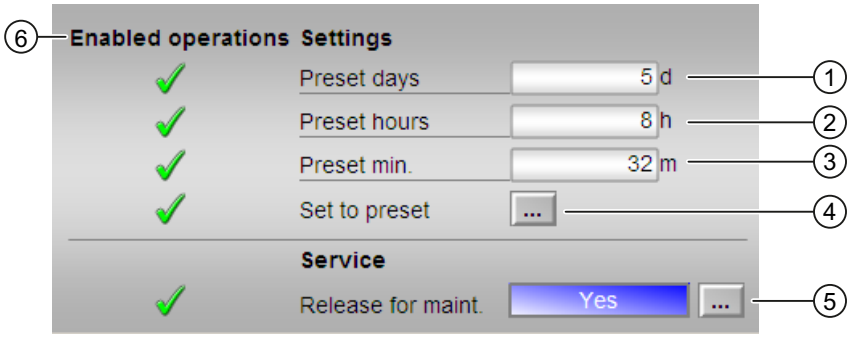
#### (2) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

### (3) "Message suppression"



Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

### (4) Suppress messages

You can enable / disable messages by setting the check mark.

## 11.2.8.4 CountOh parameter view

### Parameter view of CountOh

### (1), (2) and (3) preset counter

Enter the default setting here, where the counter should start.

You can change the following presets:

- "Days"
- "Hours"
- "Minutes"

You can find additional information on this in the Changing values (Page 291) section.

### (4) Set to default

Set the counter to the default value here. You can find additional information on this in the Switching operating states and operating modes (Page 289) section.

### (5)Service

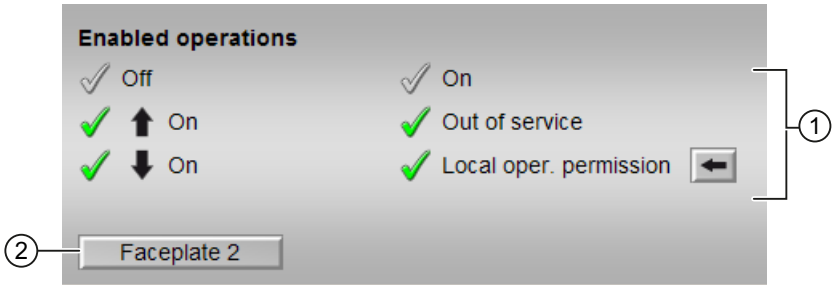
You can select the following function in this area:

- "Release for maintenance"

Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the Release for maintenance (Page 70) section.

### (6) Enabled operations



This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

## 11.2.8.5 CountOh preview

### Preview of CountOh

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

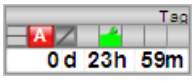
- "Off": You can disable the counter.
- "On ⇑": You can operate the incremental counter.

- "On ⇓": You can operate the decremental counter.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

### (2) Navigation button for switching to the standard view of any faceplate

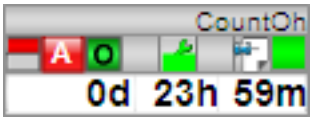
Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

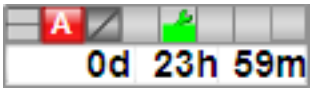
You can find additional information on this in the Opening additional faceplates (Page 234) section.

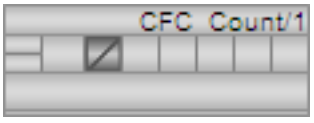


## 11.2.8.6 Block icon for CountOh

### Block icons for CountOh







A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display counter running

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 11.3 TotalL - Additive counter with upward or downward counting direction (totalizer)

## 11.3.1 Description of TotalL

### Object name (type + number) and family

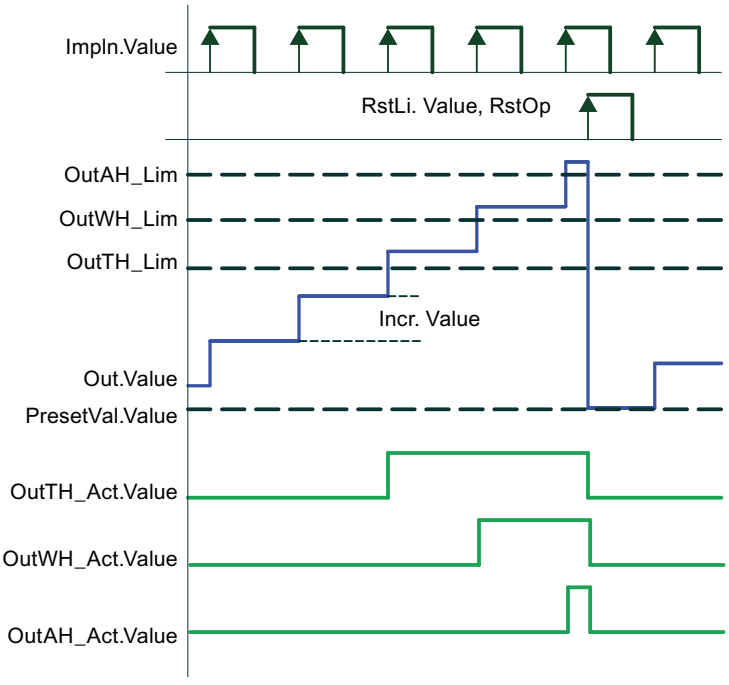
Type + number: FB 1906

Family: Count

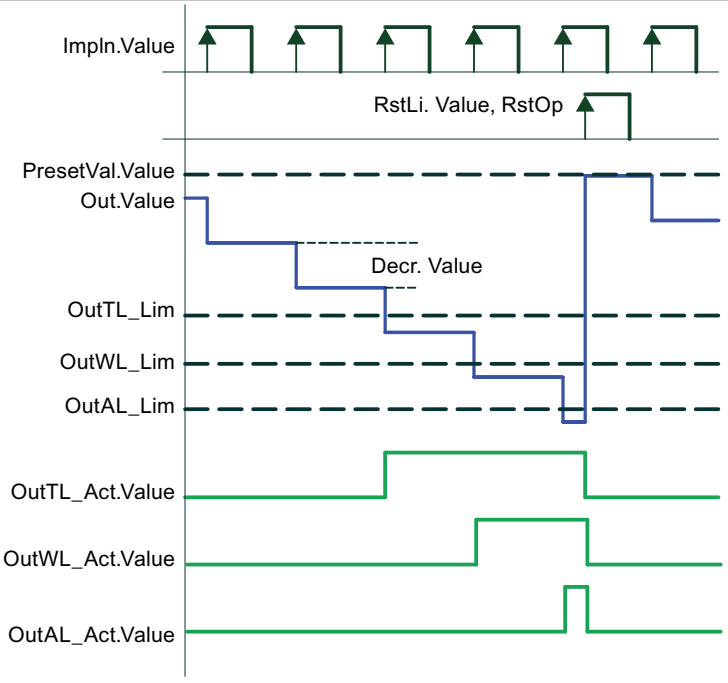
### Area of application for TotalL

The block is used for the following applications:

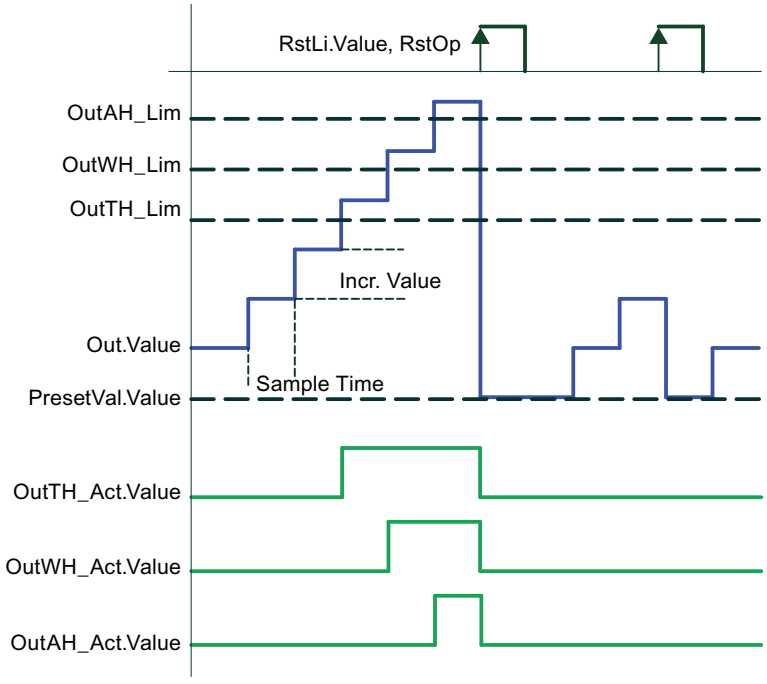
- Triggered upward or downward summing
- Continuous upward or downward summing
- Upward or downward integration of an analog input value



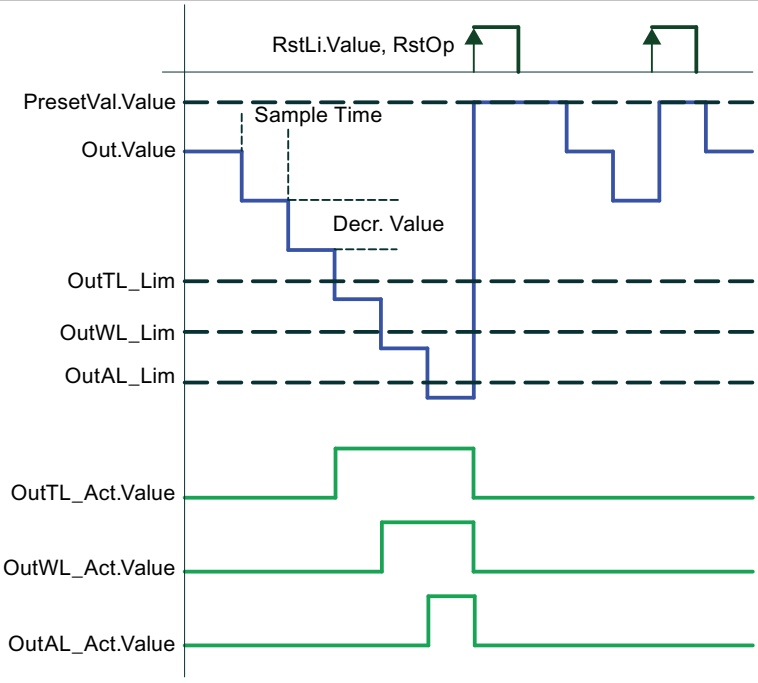
### How it works



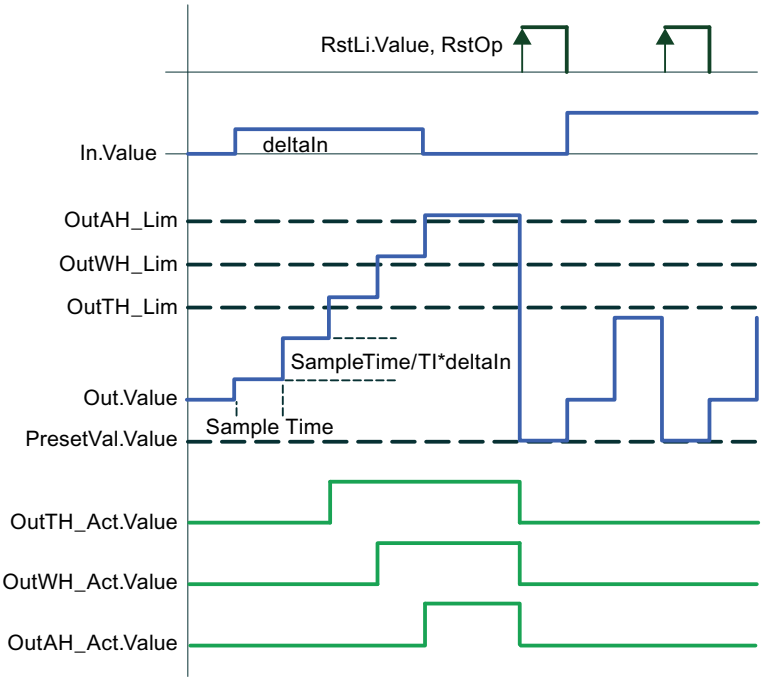
With a positive edge at the input parameter (pulse signal) `P_In` the output parameter `Out` is increased by a variable increment or reduced by a variable decrement.



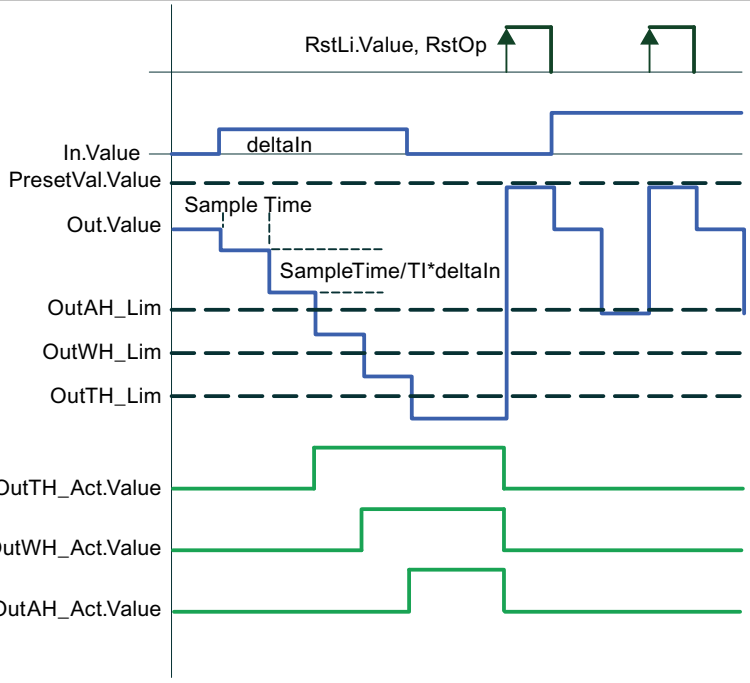
Configure how it works via the following `Feature` Bits:



- `Feature.Bit6`: Block as summing unit or integrator (Page 154)
- `Feature.Bit7`: Summing characteristics continuous or triggered (Page 184)



Using this parameterization, determine whether the block is to operate as an edge-triggered adder or summer, continuous adder or summer or as an integrator:



| Parameterization on the `Feature` Bit | How the block operates |
|---|---|
| `Feature.Bit6` = 0<br>`Feature.Bit7` = 0 | Block operates as an edge-triggered adder or summer.<br>The calculation at the output parameter `Out` is performed with a 0 - 1 edge at input parameter `P_In`.<br>The output parameter `Mode` shows whether the value is incremented or decremented.<br>The pulses counted at the input parameter `P_In` are output to the output parameter `CntOut`. |
| | Triggered sum up<br>$Out.Value = Out.Value_{(n-1)} + Incr.Value$<br> |
| | Triggered sum down<br>$Out.Value = Out.Value_{(n-1)} - Decr.Value$ |

| Parameterization on the `Feature` Bit | How the block operates |
|---|---|
| |  |

| Parameterization on the `Feature` Bit | How the block operates |
|---|---|
| `Feature.Bit6` = 0<br>`Feature.Bit7` = 1 | Block operates as a continuous adder or summer.<br>The calculation at the output parameter `Out` is performed continuously.<br>The output parameter `Mode` shows whether the value is incremented or decremented.<br>The result is output to the output parameter `Out`.<br>The output parameter `CntOut` always includes the value 0. |
| | Continuously sum up<br>$Out.Value = Out.Value_{(n-1)} + Incr.Value$<br> |
| | Continuously sum down<br>$Out.Value = Out.Value_{(n-1)} - Decr.Value$ |

| Parameterization on the `Feature` Bit | How the block operates |
|---|---|
| |  |

| Parameterization on the `Feature` Bit | How the block operates |
|---|---|
| `Feature.Bit6` = 1<br>`Feature.Bit7` = non-operational | Block operates as an continuous integrator.<br>The direction of integration depends on the operation in the faceplate or from the interconnection.<br>The input value `In` is integrated in accordance with the trapezoid rule dependent upon the counting direction according to the formula of the Integral block (Page 2253).<br>The output parameter `Mode` shows whether the value is integrated up or down.<br>The result is output to the output parameter `Out`.<br>The output parameter `CntOut` always includes the value 0. |
| | Continuously integrate up<br>`Mode` = 1: Out.Value = Out.Value n-1 + SampleTime/TI * (In.Value + In.Value n-1)/2<br>Set direction of integration:<br>• Operation in the faceplate using the "On" command (`UpOp` = 1)<br>Requirement: `LiOp.Value` = 0<br>• Interconnection `LiOp.Value` = 1 and `UpLi.Value` = 1<br> |
| | Continuously integrate down<br>`Mode` = 2: Out.Value = Out.Value n-1 - SampleTime/TI * (In.Value + In.Value n-1)/2<br>Set direction of integration:<br>• Operation in the faceplate using the "Off" command (`DnOp` = 1)<br>Requirement: `LiOp.Value` = 0<br>• Interconnection `LiOp.Value` = 1 and `DnLi.Value` = 1 |

| Parameterization on the `Feature` Bit | How the block operates |
|---|---|
| |  |

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

## Startup characteristics

Define the startup characteristics for this block via two `Feature` Bits:

Bit 0: Set startup characteristics (Page 148)

Bit 5: Use the last value following a complete download as the current value during startup of the block (Page 165)

The messages are suppressed after startup for the number of cycles specified in the `RunUpCyc` parameter.

## Time response

The block does not have any time response.

### Status word allocation for `Status1` parameter

You can find a description for each parameter in section TotalL I/Os (Page 2140).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | `SimOn` |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | `BypassAct.Value` |
| 6 | `OnAct.Value` |
| 7 - 8 | Not used |
| 9 | Display of `BypassAct.Value` in faceplate (display and operator controls) and block icon |
| 10 | `SimLiOp.Value` |
| 11 | `LiOp` |
| 12 - 13 | Not used |
| 14 | 1 = Invalid signal status |
| 15 | Triggered summing; `Feature.Bit6` = 0, `Feature.Bit7` = 0 |
| 16 | Continuous summing; `Feature.Bit6` = 0, `Feature.Bit7` = 1 |
| 17 | Integrate; `Feature.Bit6` = 1 |
| 18 - 31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | `MsgLock.Value` |
| 1 | `OutAH_Act.Value` |
| 2 | `OutWH_Act.Value` |
| 3 | `OutTH_Act.Value` |
| 4 | `OutTL_Act.Value` |
| 5 | `OutWL_Act.Value` |
| 6 | `OutAL_Act.Value` |
| 7 | `OutAH_En` OR `Feature.Bit23` |
| 8 | `OutWH_En` OR `Feature.Bit23` |
| 9 | `OutTH_En` OR `Feature.Bit23` |
| 10 | `OutTL_En` OR `Feature.Bit23` |
| 11 | `OutWL_En` OR `Feature.Bit23` |
| 12 | `OutAL_En` OR `Feature.Bit23` |
| 13 | `OutAH_MsgEn` |
| 14 | `OutWH_MsgEn` |
| 15 | `OutTH_MsgEn` |
| 16 | `OutTL_MsgEn` |
| 17 | `OutWL_MsgEn` |

| Status bit | Parameter |
|---|---|
| 18 | `OutAL_MsgEn` |
| 19 | Not used |
| 20 | `Mode` = 1, upward summing or integration |
| 21 | `Mode` = 0, summer/integrator off |
| 22 | `Mode` = 2, downward summing or integration |
| 23 - 28 | Not used |
| 29 | 1= Suppressed messages |
| 30 | Internal error |
| 31 | `MS_RelOp` |

## 11.3.2 TotalL operating modes

### TotalL operating modes

This block provides the following operating modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit4` =1 and `Feature.Bit4` =0 is as shown below:

| Output Parameters | **`Feature.Bit4` =0** | **`Feature.Bit4` =1** |
|---|---|---|
| Out.ST | 16#80 | 16#60 |
| OutAH_Act.ST | 16#XX | 16#60 |
| OutWH_Act.ST | 16#XX | 16#60 |

| Output Parameters | Feature.Bit4 =0 | Feature.Bit4 =1 |
|---|---|---|
| OutTH_Act.ST | 16#XX | 16#60 |
| OutTL_Act.ST | 16#XX | 16#60 |
| OutWL_Act.ST | 16#XX | 16#60 |
| OutAL_Act.ST | 16#XX | 16#60 |

## 11.3.3 TotalL functions

### Functions of TotalL

The functions for this block are listed below.

### Limit monitoring of the count value

This block provides the standard function Limit monitoring of the count value (Page 96).

### Group display SumMsgAct for limit monitoring, CSF and ExtMsgx

The block provides the standard function Group display for limit monitoring, CSF and ExtMsgx (Page 92).

### Suppressing messages using the MsgLock parameter

This block provides the standard function Suppressing messages using the MsgLock parameter (Page 231).

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

For `In` and `Out` different units of measure can be entered.

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

You can simulate the following values:

- Output value (`SimOut, SimOutLi`)

**Note**

**Note on the simulation of the output value `Out`**

For the presetting of the summing or integration value `Out` via the `RstLi` input, a 0 → 1 signal change at the input parameter `RstLi` is necessary during simulation.

### Bypass function

This block provides the standard function Bypassing signals (Page 115).

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is always formed from the following parameters:

- `P_In.ST`
- `Incr.ST`
- `Decr.ST`,
- `PresetVal.ST`
- `In.ST`
- `Out.ST`

The following signal status is formed by:

| Signal status | Used status |
|---|---|
| `Out.ST` | **Block operates as an edge-triggered adder or summer:**<br>Formed from the signal status `Incr.ST, Decr.ST, P_In.ST` and the last signal status `Out.St`.<br>**Block operates as continuous adder or summer:**<br>Formed from the signal status `Incr.ST, Decr.ST` and the last signal status `Out.St`.<br>**Block operates as continuous integrator:**<br>Formed from the signal status `In.ST` and the last signal status `Out.St`.<br>Resetting TotalL also resets the signal status: Out, ST := 16#80 |

With internal simulation, `ST_Worst` and the status of `Out` become `16#60`.

If there is a non-displayable floating-point number at one of the following parameters `In`, `PresetVal`, `TI` or `Out` when integrating `Feature.Bit6` = 1, the result is `ST_Worst` and the status of `Out` is set to `16#28`, provided the internally calculated status of `Out` does not result in `16#0` or the block is in internal simulation.

In addition, the status of `Out` is also written to the status of the output parameter `UpDnAct`.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` I/O in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 3 | Disable limit act output when limit value message is disabled (Page 209) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 4 | Changes signal status of outputs in OOS (Page 208) |
| 5 | Use the last value following a complete download as the current value during startup of the block (Page 165) |
| 6 | Block as summing unit or integrator (Page 154) |
| 7 | Summing characteristics continuous or triggered (Page 184) |
| 9 | Substitution value is active if the block is in bypass (Page 199) |
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 25 | Suppression of all messages (Page 185) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 28 | Disabling operating points (Page 156) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop the summing or integration |
| 5 | 1 = Operator can activate the upward summing or integration |
| 6 | 1 = Operator can activate the downward summing or integration |

| Bit | Function |
|---|---|
| 7 | 1 = Operator can preset the sum value (Out) |
| 8 - 9 | Not used |
| 10 | 1 =Operator can change the simulation value SimOut |
| 11 | 1 = Operator can activate the Simulation function |
| 12 | 1 = Operator can activate the Release for maintenance function |
| 13 | 1 = Operator can change the limit (OutAH_Lim) for high alarm |
| 14 | 1 = Operator can change the limit (OutWH_Lim) for high warning |
| 15 | 1 = Operator can change the limit (OutTH_Lim) for high tolerance |
| 16 | Not used |
| 17 | 1 = Operator can change the limit (OutAL_Lim) for low alarm |
| 18 | 1 = Operator can change the limit (OutWL_Lim) for low warning |
| 19 | 1 = Operator can change the limit (OutTL_Lim) for low tolerance |
| 20 | 1 = Operator can activate bypass functionality |
| 21 | 1 = Operator can deactivate bypass functionality |
| 22 | 1 =Operator can specify the default value (PresetVal.Value) |
| 23 | 1 = Operator can specify the integration time constant (TI) |
| 24 | 1 = Operator can specify the value for the increment (Incr.Value) |
| 25 | 1 = Operator can specify the value for the decrement (Decr.Value) |
| 26 | 1 = Operator can activate / deactivate messages via OutAH_MsgEn |
| 27 | 1 = Operator can activate / deactivate messages via OutAL_MsgEn |
| 28 | 1 = Operator can activate / deactivate messages via OutWH_MsgEn |
| 29 | 1 = Operator can activate / deactivate messages via OutTH_MsgEn |
| 30 | 1 = Operator can activate / deactivate messages via OutTL_MsgEn |
| 31 | 1 = Operator can activate / deactivate messages via OutWL_MsgEn |

The block has the following permissions for the OS1Perm parameter:

| Bit | Function |
|---|---|
| 0 - 15 | reserved |

**Note**

If you interconnect a parameter that is also listed in OS_Perm as a parameter, you have to reset the corresponding OS_Perm bit.

### Readback of the most recently calculated sum

As long as the output parameter Mode ≠ 0, the preceding sum value (OldOut) or the preceding count value (OldCntOut) is corrected to the current value:

- OldOut = Out.Value
- OldCntOut = CntOut.Value

After a warm restart, the sum value (Out) is automatically reset to the default value for the input parameter PresetVal if you have set the Feature Set startup characteristics (Page 148)Bit accordingly.

The count value CntOut in this case is always reset to 0.

The current sum and/or count value is set to the default predecessor values at startup via the Feature bit Use the last value following a complete download as the current value during startup of the block (Page 165).

- Old.Value = OldOut
- CntOut.Value = OldCntOut

### Setting the summing/integrating value to the default

PresetVal is used to specify a summing/integrating value that is used in a warm restart.

As long as RstLi or RstOp is set, the following applies:

Out.Value = PresetVal.Value.

When the input PresetVal is not interconnected (PresetVal.ST = FF), the default setting for the count value can also be made from the parameter view of the block.

RstLi or RstOp reset the CntOut output to 0 at the same time.

You can use the Feature.Bit30 "Set reset depending on operating mode or the LiOp parameter" to configure the setting of the count value to a default depending on the LiOp parameter:

Feature.Bit30 = 0: The reset does not depend on LiOp

Feature.Bit30 = 1: Setting to the default depends on LiOp

LiOp =0: Setting to the default PresetVal or resetting of CntOut can only take place via the faceplate or at the RstOp parameter for the faceplate.

LiOp =1: Setting to the default PresetVal or resetting of CntOut can only take place via the interconnectable RstLi input.

### Release for maintenance

This block provides the standard function Release for maintenance (Page 70).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 11.3.4 TotalL error handling

### Error handling of TotalL

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 11 | The integration time constant `TI` is within the range:<br>`-SampleTime` / 2 < `TI` < S`ampleTime` / 2.<br>The integration is stopped. |
| 15 | `PresetVal.Value` > `OutOpScale.High`<br>`PresetVal.Value` < `OutOpScale.Low` |
| 30 | The value of `In.Value` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out.Value` output. |
| 31 | The value of `Out` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 32 | The value of `PresetVal.Value` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out.Value` output. |
| 33 | The value of `TI` can no longer be displayed in the REAL number field. The integration is stopped. |
| 34 | The value `Incr.Value` or `Decr.Value` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out.Value` output. |
| 51 | Invalid signal at `LiOp` = 1:<br>`OffLi` = 1 and `UpLi` = 1 and/or `DnLi` = 1<br>`OffLi` = 0 and `UpLi` = 1 and `DnLi` = 1 |

## 11.3.5 TotalL messaging

### Messaging

The following messages can be generated for this block:

- Functions for displaying measured limits

Messages generated as a reaction to limit violations, can be suppressed by the settings `MsgEn` and `MsgLock`.

### Associated values for message instance `MsgEvId`

| Associated value | Block parameters |
|---|---|
| 1 | `BatchName` |
| 2 | `StepNo` |
| 3 | `BatchID` |
| 4 | `ExtVa104` |
| 5 | `ExtVa105` |

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId` | SIG 1 | Alarm - high | $$BlockComment$$<br>High alarm limit violated |
| | SIG 2 | Warning - high | $$BlockComment$$<br>High warning limit violated |
| | SIG 3 | Tolerance - high | $$BlockComment$$<br>High tolerance limit violated |
| | SIG 4 | Tolerance - low | $$BlockComment$$<br>Low tolerance limit violated |
| | SIG 5 | Warning - low | $$BlockComment$$<br>Low warning limit violated |
| | SIG 6 | Alarm - low | $$BlockComment$$<br>Low alarm limit violated |
| | SIG 7 | AS process control message - fault | $$BlockComment$$<br>External message 1 |
| | SIG 8 | AS process control message - fault | $$BlockComment$$<br>External message 2 |

Explanation:

$$BlockComment$$: Content of the instance-specific comment

## 11.3.6 TotalL I/Os

TotalL I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BatchEn | 1 = Enable allocation | BOOL | 0 |
| BatchID | Batch ID | DWORD | 16#00000000 |
| BatchName | Batch name | S7-String | |
| BlkTypeInfo* | Block Type Version and FB Number of blocktype<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| BypLiOp | 1 = Bypass commands via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypLock | 1 = Bypass activation or deactivation is locked for operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypOut | Substitution value if block is in bypass | REAL | 0.0 |
| BypOutLi | 1 = Select bypass Out (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| BypOutOp | 1 = Select bypass Out (via operator) | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Decr | Decrement for downward summing<br>Decr.ST = FF via operator<br>Decr.ST <> FF via interconnection | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| DnLi* | 1 = Down counter, via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| DnOp* | 1 = Down counter, via operator | BOOL | 0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| ExtMsg1 | Binary input for freely selectable message 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtMsg2 | Binary input for freely selectable message 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ExtVa104 | Associated value 4 for messages (MsgEvId) | ANY | |
| ExtVa105 | Associated value 5 for messages (MsgEvId) | ANY | |
| Feature | I/O for additional functions (Page 2133) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In | Input for integral value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Incr | Increment for upward summing<br>Incr.ST = FF via operator<br>Incr.ST <> FF via interconnection | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| InUnit | Unit of measure for the input parameter In | INT | 1351 |
| LiOp | 1 = Interconnection<br>0 = Operator | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MsgEvId | Message number (assigned automatically) | DWORD | 16#00000000 |
| MsgLock | 1 = Suppress process messages.<br>See also the section Suppressing messages using the MsgLock parameter (Page 231) for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_RelOp* | Operator can switch release for maintenance | BOOL | 0 |
| Occupied | 1 = In use by a batch | BOOL | 0 |
| OffLi* | 1 = Counter disabled via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OffOp* | 1 = Counter disabled via operator | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OldCntOut* | Previous count value | DINT | 0 |
| OldOut* | Previous output value | REAL | 0.0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operating permissions (Page 2133) | STRUCT<br>• Bit 0: BOOL<br>• Bit 10: BOOL<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| OS1Perm | I/O for operator permissions (Page 2133) | STRUCT<br>• Bit 0: BOOL<br>• Bit 15: BOOL | -<br>• 1<br>• 1 |
| OutAH_En | 1 = Enable alarm (high) for count | BOOL | 1 |
| OutAH_Lim | Limit for count alarm (high) | REAL | 95.0 |
| OutAH_MsgEn | 1 = Enable message for count alarm (high) | BOOL | 1 |
| OutAL_En | 1 = Enable alarm (low) for count | BOOL | 1 |
| OutAL_Lim | Limit for count alarm (low) | REAL | 0.0 |
| OutAL_MsgEn | 1 = Enable message for count alarm (low) | BOOL | 1 |
| OutOpScale | Limit for scale in Out bar graph of faceplate | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| OutTH_En | 1 = Enable tolerance message (high) | BOOL | 0 |
| OutTH_Lim | Count tolerance limit message (high) | REAL | 85.0 |
| OutTH_MsgEn | 1 = Enable message for count tolerance message (high) | BOOL | 1 |
| OutTL_En | 1 = Enable count tolerance message (low) | BOOL | 0 |
| OutTL_Lim | Count tolerance message limit (low) | REAL | 0.0 |
| OutTL_MsgEn | 1 = Enable message for count tolerance message (low) | BOOL | 1 |
| OutUnit | Unit of measure for count Out | INT | 1038 |
| OutWH_En | 1 = Enable count warning (high) | BOOL | 1 |
| OutWH_Lim | Count warning limit (high) | REAL | 90.0 |
| OutWH_MsgEn | 1 = Enable message for count warning (high) | BOOL | 1 |
| OutWL_En | 1 = Enable count warning (low) | BOOL | 1 |
| OutWL_Lim | Count warning limit (low) | REAL | 0.0 |
| OutWL_MsgEn | 1 = Enable message for count warning (low) | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| P_In | Input for sum value (pulse input) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PresetVal* | Default setting for the count | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#FF |
| RstBypLi | 1 = Reset bypass Out (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstBypOp | 1 = Reset bypass Out (via operator) | BOOL | 0 |
| RstLi | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RstOp* | 1 = Reset via operator | BOOL | 0 |
| RunUpCyc | Messages can be suppressed for a short time after startup. You can set the number of cycles using the input parameter RunUpCyc | INT | 3 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| SimLiOp | Activation/deactivation of the simulation by:<br>0 = Operator<br>1 = Interconnection or SFC | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOnLi | 1 = Simulation via interconnection or SFC (controlled by SimLiOp = 1) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn* | 1 = Simulation on | BOOL | 0 |
| SimOut* | Output value used for SimOn = 1 | REAL | 0.0 |
| SimOutLi | Output value that is used for SimOnLi.Value = 1 (SimLiOp.Value = 1) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| TI* | Intagral component time | REAL | 1.0 |
| UpLi* | 1 = Forward counter, via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UpOp* | 1 = Forward counter, via operator | BOOL | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| BypassAct | 1 = Bypass is activated in this block | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CntOut | Number of counted pulses | DINT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see TotalL error handling (Page 2138) | INT | -1 |
| Mode | 0 = Totalizer off<br>1 = Totalizer summed/integrated upward<br>2 = Totalizer summed/integrated downward | INT | 0 |
| MsgAckn | Message acknowledgment status (output ACK_STATE of ALARM_8P) | WORD | 16#0000 |
| MsgErr | 1 = Message error (output ERROR of ALARM_8P) | BOOL | 0 |
| MsgStat | Message status (output STATUS of ALARM_8P) | WORD | 16#0000 |

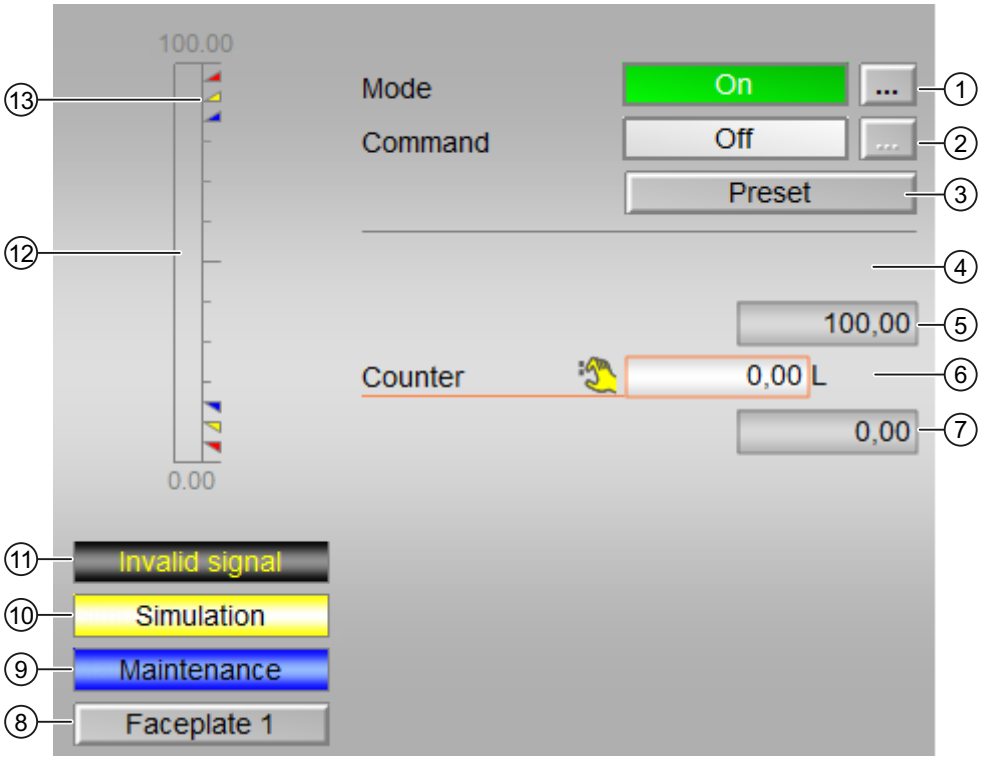
## 11.3.8 Operator control and monitoring

### 11.3.8.1 TotalL views

### Views of the TotalL block



The block TotalL provides the following views:

- TotalL standard view (Page 2147)
- Alarm view (Page 336)
- TotalL limit view (Page 2150)
- Trend view (Page 341)
- TotalL parameter view (Page 2151)
- TotalL preview (Page 2153)
- Memo view (Page 338)
- TotalL block icon (Page 2154)
- Batch view (Page 336)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 11.3.8.2 TotalL standard view

#### TotalL standard view

#### (1) Displaying and switching the operating mode

Operation of inputs `OosOp` and `OnOp`.

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- Bar graph (Page 376): `Status1.Bit3` (`OosAct.Value`)
- Out of service (Page 77): `Status1.Bit6` (`OnAct.Value`)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) Enabling and disabling the counter

Operation of the inputs `UpOp`, `OffOp` and `DnOp`.

This area shows you the default operating state for the counter. The following states can be shown and executed here:

- "On ⇑": `Status2.Bit20` (`Mode` = 1)
- "On ⇓": `Status2.Bit22` (`Mode` = 2)
- "Off": `Status2.Bit21` (`Mode` = 0)

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (3) Default setting

Operation of the input `RstOp`.

This button activates the preset value.

### (4) Display of the count value

The current count values are displayed here:

**Display of input In**

Depending on `Feature.Bit6` and `Feature.Bit7`, either input `In` or an empty frame is displayed:

- "Input": `Feature.Bit6` = 1, otherwise no display

The display is not operational. Format of `In` like display `Out`.

### (5) High scale range for the count value

This value provides information on the display range for the bar graph (above) of the count value. The scale range is defined in the engineering system.

### (6) Display of the count value

The current count values are displayed here:

**Display Out**

Depending on `Feature.Bit6`, the text for the display is switched over:

- "Counter": `Feature.Bit6` = 0
- "Integrator": `Feature.Bit6` = 1

The "Counter" display is not operational, not even in simulation. The format of `In` is like the `Out` display.

The "Integrator" display is only operational in simulation (operation input `SimOut`). The format corresponds to the block icon of `AnalogValueFormat1`.

### (7) Low scale range for the count value

This value provides information on the display range for the bar graph (below) of the count value. The scale range is defined in the engineering system.

### (8) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Maintenance"

You can find more information about this in the section Release for maintenance (Page 70).

### (10) Display area for block states

This area provides additional information on the operating state of the block:

- "Simulation"

You can find additional information on this in the section Simulating signals (Page 64).

### (11) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

You can find additional information on this in the section Error handling (Page 128).

### (12) Graphic display of the current count value

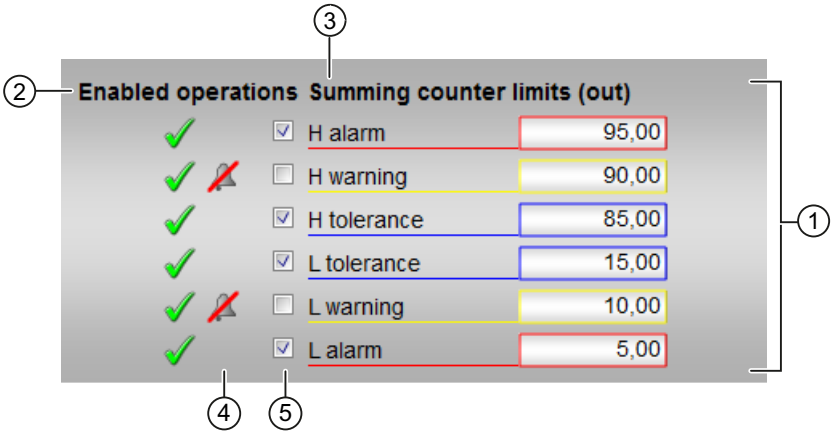
This area shows you the current count in form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES). For more information refer Bar graph (Page 376) section.

### (13) Limit display

These colored triangles indicate the configured limits in the respective bar graph:

- Red: Alarm
- Yellow: Warning
- Blue: Tolerance

In counting mode "count up", only the colored triangles of the upper limits are visible; and in counting mode "count down", only the colored triangles of the lower limits are visible.



For more information, refer: Bar graph (Page 376)

### See also

On (Page 77)

## 11.3.8.3 TotalL limit view

### Limit view of TotalL

### (1) Limits for the counter

In this area, you can enter the limits for the counter. Refer to the Changing values (Page 291) section for more on this.

You can change the following limits:

- "H alarm": Alarm high
- "H warning": Warning high
- "H tolerance": Tolerance high
- "L tolerance": Tolerance low
- "L warning": Warning low
- "L alarm": Alarm low

Format and unit is like the `Out` display in the standard view.

### (2) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

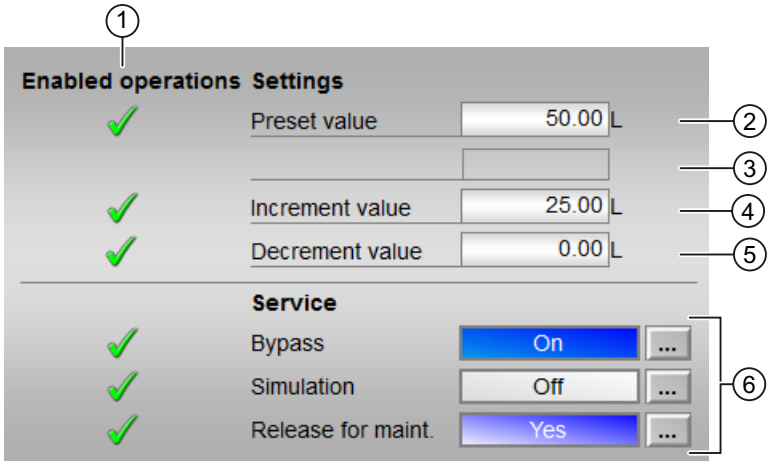
### (3) Dynamic text

Depending on `Feature.Bit6`, the text is switched:

- "Integrator limits (out)": Display for `Feature.Bit6` = 1
- "Summer limits (out)": Display for `Feature.Bit6` = 0

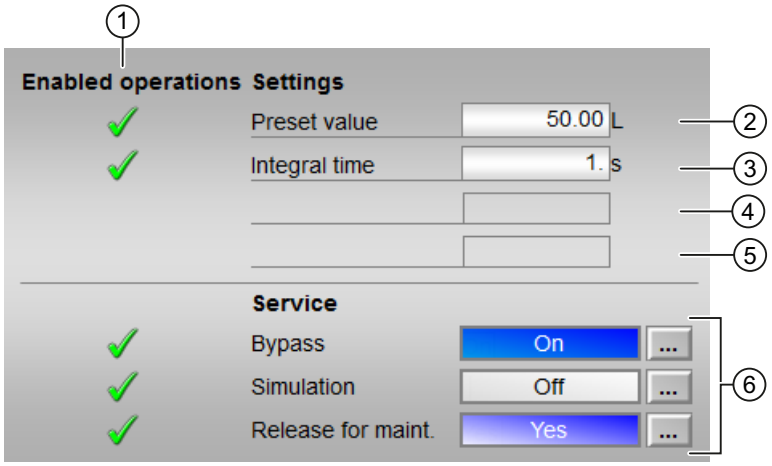
### (4) "Message suppression"

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.



### (5) Suppress messages

You can enable / disable messages by setting the check mark.



## 11.3.8.4 TotalL parameter view

### Parameter view of TotalL

With `Feature.Bit6` = 0:

With `Feature.Bit6` = 1:

### (1) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`).

### (2) Default value

In this section you can enter the value from which the counting should begin. Additional information is available in the section Changing values (Page 291).

### (3) Integral time

The currently integral time in seconds is displayed in this area.

- "Integral time" Display for `Feature.Bit6` = 1, otherwise empty.

### (4) Increment value

The increment value is displayed in this area.

- "Increment value": Display for `Feature.Bit6` = 0, otherwise empty.

### (5) Decrement value

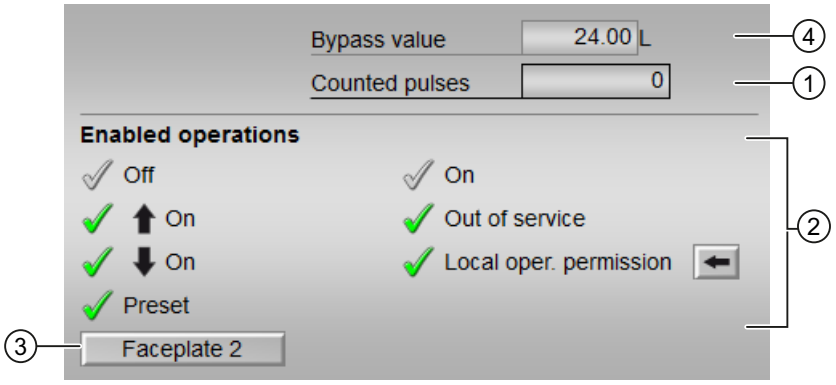
The decrement value is displayed in this area.

- "Decrement value": Display for `Feature.Bit6` = 0, otherwise empty.

### (6) Service

You can select the following function in this area:

- "Bypass"
- "Simulation"
- "Release for maintenance"



Refer to the Switching operating states and operating modes (Page 289) section for more on this.

You can find information on this area in the section:

- Bypassing signals (Page 115)
- Simulating signals (Page 64)
- Release for maintenance (Page 70)

## 11.3.8.5 TotalL preview

### Preview of TotalL

### (1) Counted pulses

The number of pulses already counted is displayed in this area.

- "Counted pulses": `Feature.Bit6` = 0 and `Feature.Bit7` = 0, otherwise empty

### (2) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Off": You can disable the counter.
- "On ⇑": You can operate the incremental counter.
- "On ⇓": You can operate the decremental counter.
- "Default": You can change the default setting.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

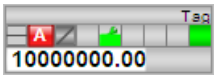
### (3) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

Additional information is available in the section Opening additional faceplates (Page 234).

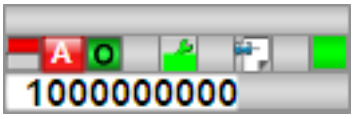
### (4) Bypass value

This area displays the bypass value (`BypOut`).



## 11.3.8.6 TotalL block icon

### Block icons for TotalL



A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of alarm, warning, and tolerance limits
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display counter running

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 11.4 CntOhSc - Runtime determination and counters with counting direction "up"

## 11.4.1 Description of CntOhSc

### Object name (type + number) and family

Type + number: FB 1803

Family: Count

### Area of application of CntOhSc

The block is used for the following applications:

- Incrementing of operating hours
- Incrementing a defined input value

### How it works

The block determines the time in which a unit has been in operation and it counts a defined input value. The block can only count forwards.

1. Off (`OffOp = 1`)
   The block is disabled (output parameter `CountMode = 0`). No counting takes place.
2. Increment (`UpOp = 1`)
   The operating time of the connected unit is incremented (output parameter `CountMode = 1`).

The operating time is shown in days, hours, minutes and seconds. The maximum operating time is 32767 days and 23 hours.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is first installed automatically in the startup OB (OB 100).

### Startup characteristics

Define the startup characteristics for this block via two `Feature` bits:

Bit 0: Set startup characteristics (Page 148)

Bit 5: Use the last value following a complete download as the current value during startup of the block (Page 165)

When you set `Feature.Bit5` to 1, then:

- `Days:= OldDays`
- `Hours:= OldHours`

- `Minutes:= OldMinutes`
- `Seconds:= OldSeconds`

### Status word allocation for `Status1` parameter

Refer to the following section for a description of the individual parameters: CntOhSc I/Os (Page 2161)

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 - 10 | Not used |
| 11 | `LiOp` |
| 12 - 13 | Not used |
| 14 | 1 = Invalid signal status |
| 15 | Not used |
| 16 | Internal error |
| 17 - 31 | Not used |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | Not used |
| 1 | `HrsHiL1Act.Value` |
| 2 | `HrsHiL2Act.Value` |
| 3 | `CntHiL1Act.Value` |
| 4 | `CntHiL2Act.Value` |
| 5 - 6 | Not used |
| 7 | `HrsHiL1En` OR `Feature.Bit23` |
| 8 | `HrsHiL2En` OR `Feature.Bit23` |
| 9 | `CntHiL1En` OR `Feature.Bit23` |
| 10 | `CntHiL2En` OR `Feature.Bit23` |
| 11 - 19 | Not used |
| 20 | Count up |
| 21 | Counter off |
| 22 - 31 | Not used |

## 11.4.2 CntOhSc operating modes

### Operating modes of CntOhSc

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit4` =1 and `Feature.Bit4` =0 is as shown below:

| Output Parameters | **`Feature.Bit4` =0** | **`Feature.Bit4` =1** |
|---|---|---|
| DeviceOn.ST | 16#XX | 16#60 |
| HrsHiL1Act.ST | 16#XX | 16#60 |
| HrsHiL2Act.ST | 16#XX | 16#60 |
| CntHiL1Act.ST | 16#XX | 16#60 |
| CntHiL2Act.ST | 16#XX | 16#60 |

## 11.4.3 CntOhSc functions

### Functions of CntOhSc

The block provides the following functions:

### Reset counter to zero

The output parameters of the operating time `Days`, `Hours`, `Minutes`, `Seconds`, `TimeHours` and `TotalTime` are reset via the interconnect `ResetOh` parameter. The reset is made with a 0 - 1 edge.q

The counted value at the `Cnt` output parameter is reset with the interconnectable `ResetCnt` parameter. The reset is made with a 0 - 1 edge.

The count value and the output parameters of the operating time can also be reset to zero together in the standard view at the `ResetOp` parameter or the interconnectable `ResetLi` parameter via the faceplate.

You can use `Feature.Bit30` "Set reset depending on operating mode or the `LiOp` parameter" to configure a reset depending on the `LiOp` parameter:

`Feature.Bit30` = 0: The reset does not depend on `LiOp`

`Feature.Bit30` = 1: The reset depends on `LiOp`

`LiOp =0`: Separate reset via inputs `ResetOh` and `ResetCnt` is not possible. Simultaneous reset can only be made via the faceplate or at the `ResetOp` parameter.

`LiOp =1`: Separate reset is only possible via interconnectable inputs `ResetOh` and `ResetCnt`. Simultaneous reset can only be made via the interconnectable input `ResetLi`.

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 4 | Changes signal status of outputs in OOS (Page 208) |
| 5 | Use the last value following a complete download as the current value during startup of the block (Page 165) |
| 23 | Limits disabled in faceplate (Page 206) |
| 24 | Enabling local operator authorization (Page 169) |
| 26 | Reaction of the switching points in the "Out of service" operating mode (Page 188) |
| 29 | Signaling limit violation (Page 181) |
| 30 | Set reset depending on the operating mode or the LiOp parameter (Page 174) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can stop counting |
| 5 | 1 = Operator can switch to "Count up" mode |
| 6 | 1 = Operator can reset the count |
| 7 - 12 | Not used |
| 13 | 1 = Operator can change the operating hours high limit 1 (`HrsHi1Lim`) |
| 14 | 1 = Operator can change the operating hours high limit 2 (`HrsHi2Lim`) |
| 15 | 1 = Operator can change the counter high limit 1 (`CntHi1Lim`) |

| Bit | Function |
|---|---|
| 16 | 1 = Operator can change the counter high limit 2 (`CntHi2Lim`) |
| 17 - 31 | Not used |

### Providing limit at the output

For further connections to other blocks the following input parameters will also be displayed on the output:

`CntHi1LimOut` := `CntHi1Lim`;

`CntHi2LimOut` := `CntHi2Lim`;

`HrsHi1LimOut` := `HrsHi1Lim`

`HrsHi2LimOut` := `HrsHi2Lim`;

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `InOh.ST`
- `InCnt.ST`
- `TmHoursST`
- `CntST`

The following signal status is formed by:

| Signal status | Used status |
|---|---|
| `TmHoursST` | Increment: Formed from the worst signal status of `InOh.ST` and the last signal status `TmHoursST`. This means that the worst signal status of `InOh.ST` is stored to `TmHoursST` during increment.<br>Counter off: Signal status `TmHoursST` is frozen.<br>Resetting `CntOhSc` or `ResetOh` also resets the signal status: `TmHoursST` := 16#80 |
| `CntST` | Increment: Formed from the worst signal status of `InCnt.ST` and the last signal status `CntST`. This means that the worst signal status of `InCnt.ST` is stored to `CntST` during increment.<br>Counter off: Signal status `CntST` is frozen.<br>Resetting `CntOhSc` or `ResetCnt` also resets the signal status: `CntST` := 16#80 |

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 11.4.4 CntOhSc error handling

### Error handling of CntOhSc

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | No active fault |
| 51 | Invalid signal at `LiOp = 1`:<br>• `OffLi = 1` and `UpLi = 1` |

## 11.4.5 CntOhSc messaging

### Messaging

This block does not offer messaging.

## 11.4.6 CntOhSc I/Os

I/Os of CntOhSc

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `BatchEn` | 1 = Enable allocation | BOOL | 0 |
| `BatchID` | Batch ID | DWORD | 16#00000000 |
| `BatchName` | Batch name | S7-String | |

| Parameter | Description | Type | Default |
|---|---|---|---|
| BlkTypeInfo* | Block Type Version and FB Number of block-type<br>The block version is coded as a hex value and includes the major, minor, SP and update version of the block type.<br>VersId=16#wxyz<br>w = major version<br>x = minor version<br>y = service pack<br>z = update<br>This input can not be edit or linked and is for internal usage only | STRUCT<br>• TypNr : INT<br>• VersId : WORD | FB-Number<br>16#9100 |
| CntHiL1En | 1 = Counter high limit 1 is enabled | BOOL | 0 |
| CntHiL2En | 1 = Counter high limit 2 is enabled | BOOL | 0 |
| CntHi1Lim | Counter high limit 1 | DINT | 95 |
| CntHi2Lim | Counter high limit 2 | DINT | 90 |
| CntOpHiScale | High limit for scale in count bar graph of face-plate | DINT | 100 |
| CntOpLoScale | Low limit for scale in count bar graph of face-plate | DINT | 0 |
| CntUnit | Unit of measure for count Cnt | INT | 0 |
| Feature | I/O for additional functions (Page 2158) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| HrsHiL1En | 1 = Operating hours high limit 1 is enabled | BOOL | 0 |
| HrsHiL2En | 1 = Operating hours high limit 2 is enabled | BOOL | 0 |
| HrsHi1Lim | Operating hours high limit 1 | DINT | 2280 |
| HrsHi2Lim | Operating hours high limit 2 | DINT | 2160 |
| HrsOpHiScale | Operating hours high limit of bar display for OS | DINT | 2400 |
| HrsOpLoScale | Operating hours low limit of bar display for OS | DINT | 0 |

| OffLi | Counter disabled via interconnection:<br>1 = Off | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OffOp* | Counter disabled via operator:<br>1 = Off | BOOL | 1 |
| OldCnt* | Previous count value | DINT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OldDays | Previous day value | INT | 0 |
| OldHours | Previous hour value | INT | 0 |
| OldMinutes | Previous minute value | INT | 0 |
| OldSeconds* | Previous second value | INT | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via operator | BOOL | 0 |
| OpSt_In | Input parameter for local operator authorization, connected with the Out output parameter of the upstream block, OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for CntOhSc functions (Page 2158) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| ResetCnt | 1 = Input valueCnt reset | BOOL | 0 |
| ResetLi | 1 = Counter reset via interconnection | BOOL | 0 |
| ResetOh | 1 = Operating hours reset | BOOL | 0 |
| ResetOp* | 1 = Counter reset by operator | BOOL | 0 |
| SampleTime | Sampling time [s] | REAL | 0.1 |
| SelFp1 | Open faceplate 1 | ANY | |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UpLi | 1 = Increment (via interconnection) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| UpOp* | 1 = Increment (via faceplate) | BOOL | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CountMode | Count mode:<br>0 = Off<br>1 = Increment | INT | 0 |
| Cnt | Count | DINT | 0 |
| CntHiL1Act | 1 = Counter high limit 1 is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CntHiL2Act | 1 = Counter high limit 2 is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CntHi1LimOut | CntHi1LimOut as output | DINT | 0 |
| CntHi2LimOut | CntHi2LimOut as output | DINT | 0 |
| CntST | Signal status for Cnt | BYTE | 16#80 |
| Days | Operating stage | INT | 0 |
| DeviceOn | 1 = Unit on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see CntOhSc error handling (Page 2161) | INT | -1 |
| Hours | Operating hours | INT | 0 |
| HrsHiL1Act | 1 = Operating hours high limit 1 is active | BOOL | 0 |
| HrsHiL2Act | 1 = Operating hours high limit 2 is active | BOOL | 0 |
| HrsHi1LimOut | HrsHi1Lim as output | DINT | 0 |
| HrsHi2LimOut | HrsHi2Lim as output | DINT | 0 |
| Minutes | Operating minutes | INT | 0 |
| O_MS_Ext | Reserved | DWORD | 16#00000000 |
| OnAct | Block running | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | Block is "out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Operator permission: Output for OS | DWORD | 16#FFFFFFFF |
| OS_PermOut | Operator permission: Output for OS | DWORD | 16#FFFFFFFF |
| Seconds | Operating time [in sec] | INT | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word 1 (Page 457) | DWORD | 16#00000000 |
| Status2 | Status word 2 (Page 457) | DWORD | 16#00000000 |
| TimeHours | Service life [h] | DINT | 0 |
| TmHoursST | Signal status for TimeHours | BYTE | 16#80 |
| TotalTime | Total operating time [in sec] | DWORD | 16#00000000 |

## 11.4.7 CntOhSc block diagram

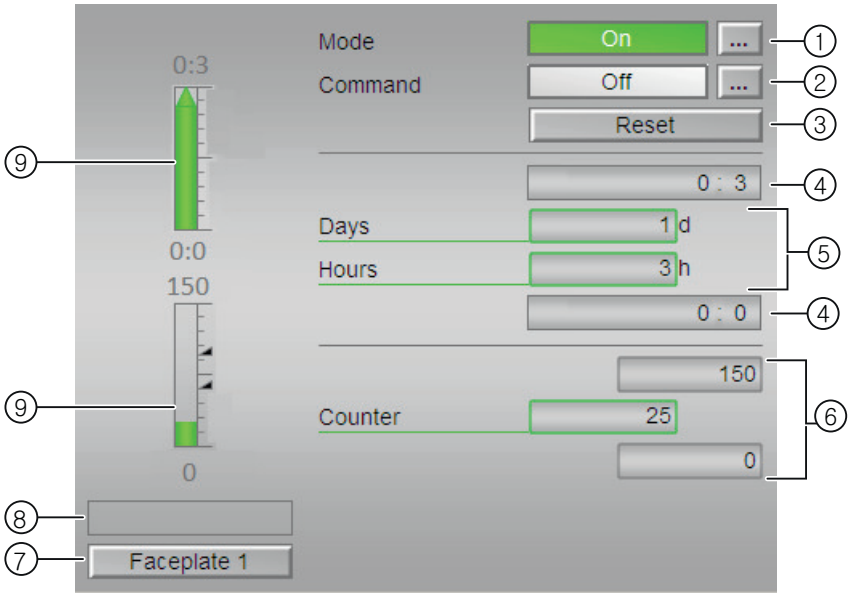
### Block diagram of CntOhSc

A block diagram is not provided for this block.

## 11.4.8 Operator control and monitoring

### 11.4.8.1 CntOhSc views

### Views of the CntOhSc block



The CntOhSc block provides the following views:

- CntOhSc standard view (Page 2166)
- CntOhSc limit view (Page 2168)
- Trend view (Page 341)
- CntOhSc preview (Page 2169)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for CntOhSc (Page 2170)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 11.4.8.2 CntOhSc standard view

#### Standard view of CntOhSc

#### (1) Display and switch the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to section Switching operating states and operating modes (Page 289) for information on switching the operating mode.

#### (2) Enable and disable the counter

This area shows you the default operating state for the counter. The following states can be shown and executed here:

- "On ⇑"
- "Off"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

#### (3) Reset

Operation of the input `RstOp`.

This button activates the preset value.

### (4) High and low scale range for the count value

These values provide information on the display range for the bar graph of the count `HrsOpHiScale` or `HrsOpLoScale`. The scale range is defined in the engineering system.

### (5) Display for counts

The following counts are shown here:

- "Days" with signal status `TmHoursST`
- "Hours" with signal status `TmHoursST`

### (6) Counter

The following values are shown here:

- Current count value with the signal status `CntST`
- High and low scale range for the count

These values provide information on the display range for the bar graph of the count `CntOpHiScale` or `CntOpLoScale`. The scale range is defined in the engineering system.

### (7) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).

### (8) Display area for states of the block

This area provides additional information on the operating state of the block:

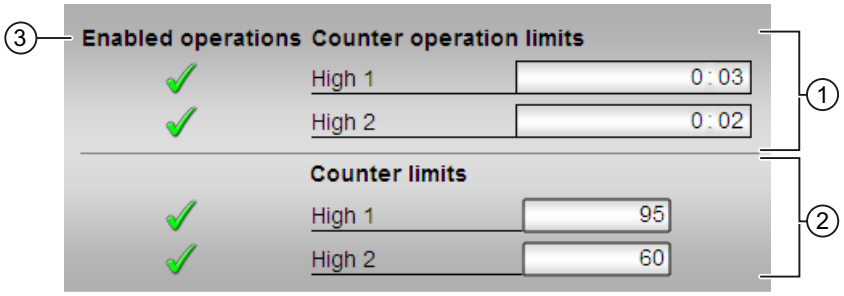
- "Internal error"
- "Invalid Signal"

You can find additional information on this in the section Error handling (Page 128).

### (9) Graphic display for the current count

These areas show the `Cnt` and `TimeHours` counts in the form of a bar graph. The visible area in the bar graph depends on the configuration in the engineering system (ES).

For more information, refer: Bar graph (Page 376)



### Limits

These colored triangles indicate the configured limits in the respective bar graph:

- Red: High limit 1
- Yellow: High limit 2

## 11.4.8.3 CntOhSc limit view

### Limit view of CntOhSc

### (1) Operating hours limits

In this area, you can enter the limits for the operating hours. You can find additional information on this in the section Changing values (Page 291) .

You can change the following limits:

- "High 1": Operating hours high limit 1
- "High 2": Operating hours high limit 2

### (2) Counter limits

In this area, you can enter the limits for the counter. You can find additional information on this in the section Changing values (Page 291) .

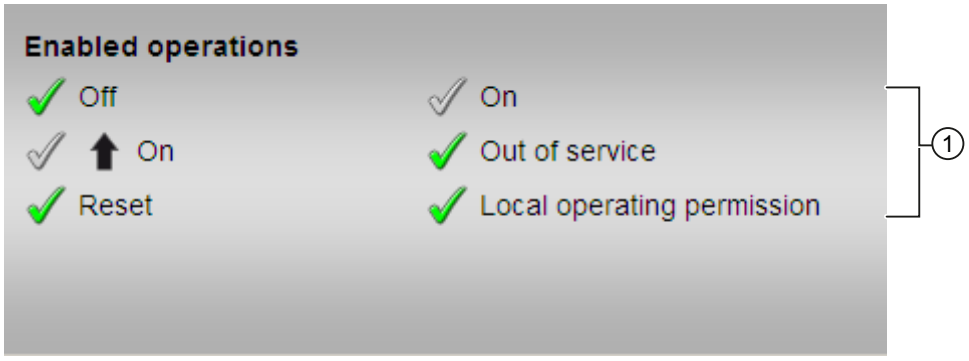
You can change the following limits:

- "High 1": Counter high limit 1
- "High 2": Counter high limit 2

### (3) Enabled operation

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:



- **Green check mark:** The OS operator can control this parameter.
- **Gray check mark:** The OS operator cannot control this parameter at this time due to the process.
- **Red cross:** The OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm`).

### (4) "Message suppression"

Message suppression indicates whether or not the suppression of the associated message in the AS block is activated with the `xx_MsgEn` parameter. The output of messages is not suppressed when the block is installed (all `xx_MsgEn` parameters are preset to 1). Messages can only be output if limit monitoring of the additional analog value has been enabled.

## 11.4.8.4 CntOhSc preview

### Preview of CntOhSc

### (1) Enabled operations

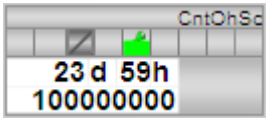
This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

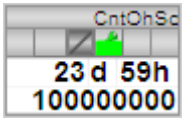
Symbols for enabled operations:

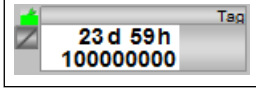
- **Green check mark:** the OS operator can control this parameter
- **Gray check mark:** the OS operator cannot control this parameter at this time due to the process
- **Red cross:** the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm`)

The following enabled operations are shown here:

- "Off": You can disable the counter.
- "On ⇑": You can operate the counter.
- "Reset": You can reset the counter after interlocks or errors.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).

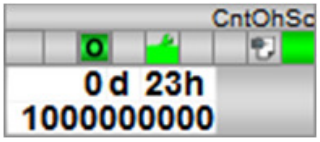


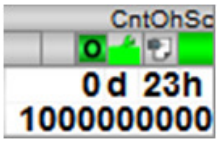




### 11.4.8.5 Block icon for CntOhSc

#### Block icons for CntOhSc





A variety of block icons are available with the following functions:

- Process tag type
- Limits (high/low)
- Violation of the limits
- Operating modes
- Signal status
- Memo display
- Display counter running

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in the CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in the CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | - | Block icon in "Out of service" mode (example with type block icon type 1) |

Additional information on the block icon and the control options in the block icon is available in the following chapters:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# Timers 12

## 12.1 TimerP - Time delays signal forwarding / pulse generator

### 12.1.1 Description of TimerP

#### Object name (type+number) and family

Type + number: FB 1810

Family: TIME

#### Area of application for TimerP

The block is used for the following fields of applications:

- Pulse generator
- Extended pulse
- ON delay
- ON delay with memory
- OFF delay

#### How it works

The TimerP block is used for delayed forwarding of start or stop actions through the `Out` output parameter.

New values at the `Ti` I/O are only applied when a change is made to the `In` I/O.

The inverted signal for `Out` is also provided at the `InvOut` output parameter.

Use the Mode input parameter to define how the block should be used. Refer to the TimerP functions (Page 2174) section for more on this.

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

#### Startup characteristics

The block does not have any startup characteristics.

A startup behavior can be reached with a connection of the input parameter `Init` to the output parameter `InitOut` of the Trigger block. For more information, refer to Startup characteristics over Trigger block (Page 75).

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

TimerP modes (Page 2174)
TimerP error handling (Page 2177)
TimerP messaging (Page 2178)
TimerP I/Os (Page 2178)
TimerP block diagram (Page 2180)

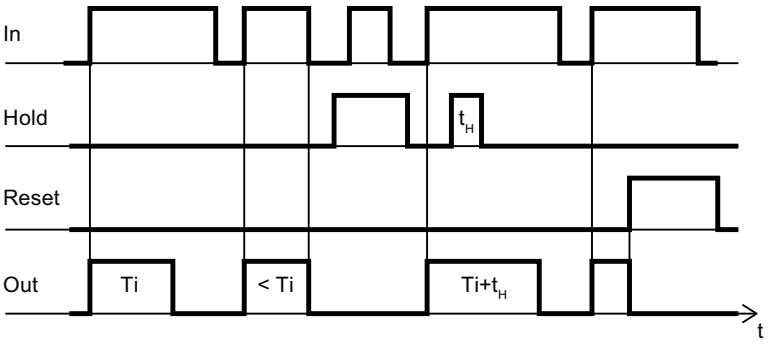
## 12.1.2 TimerP modes

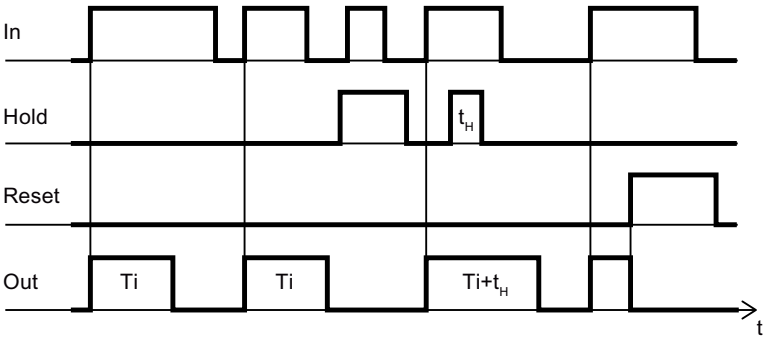
### TimerP operating modes

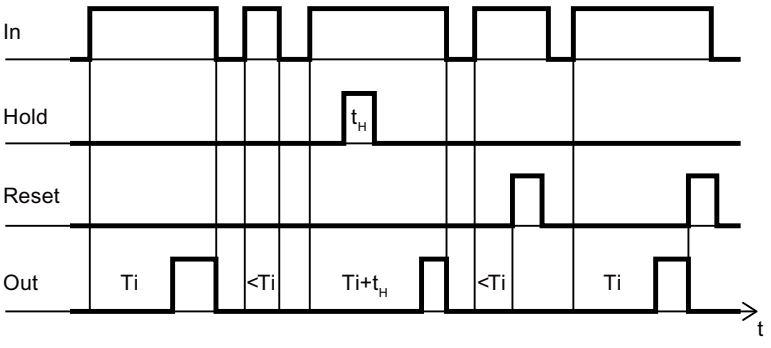
This block does not have any modes.

### See also

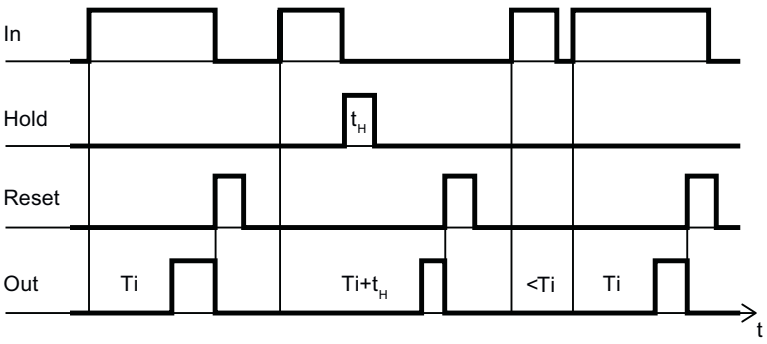
Description of TimerP (Page 2173)
TimerP functions (Page 2174)
TimerP error handling (Page 2177)
TimerP messaging (Page 2178)
TimerP I/Os (Page 2178)
TimerP block diagram (Page 2180)

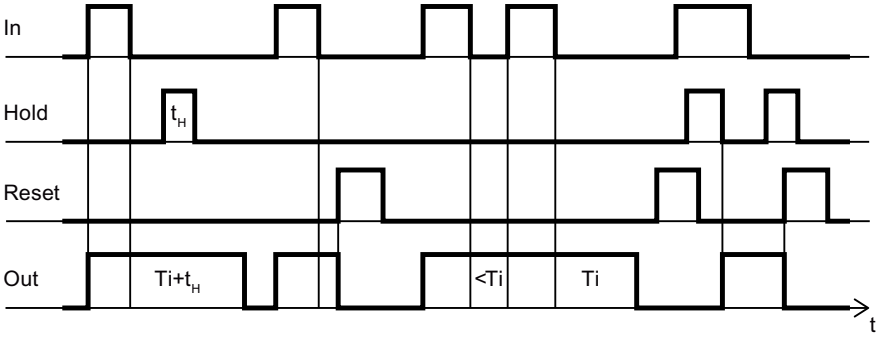






## 12.1.3 TimerP functions





### Functions of TimerP

The functions for this block are listed below.

## Specifying how TimerP works

Use the `Mode` input parameter to specify how the block should work:

| Mode = | How the block works | Graphic representation |
|---|---|---|
| 0 | Start timer as pulse |  |
| 1 | Start extended pulse timer |  |
| 2 | Start ON delay timer |  |

| Mode = | How the block works | Graphic representation |
|---|---|---|
| 3 | Start ON delay timer with memory |  |
| 4 | Start OFF delay timer |  |

## Setting the time

You can use the `Ti` parameter to time for operating the block.

**Note**

Be aware when configuring this, that the time interval between `Ti` and `SampleTime` should not be more than $10^7$.

## Holding the `Out` and `TimeRemaining` output parameters

Use the `Hold.Value` = 1 parameter to freeze the calculation of the outputs `Out` and `TimeRemaining.Value`.

## Resetting the `Out` and `TimeRemaining` output parameters

Use the `Reset.Value` = 1 parameter to reset the output parameters `Out` and `TimeRemaining.Value` to 0.

## Initialization

With the input parameter `Init` = 1, the output parameters `Out` and `TimeRemaining` can be reset to 0 (same behavior as `Reset.Value` = 1). You can use the input parameter `Init` to realize a startup behavior.

To initialize the output parameters `Out` and `TimeRemaining` after a startup, connect the input parameter `Init` with the output parameter `InitOut` of the Trigger block. For more information, refer to Startup characteristics over Trigger block (Page 75).

### Forming the signal status for blocks

The signal status for the block is formed using the following parameters and output at the `Out` and `InvOut` output parameters:

- `In.ST`

TimerP error handling (Page 2177)

TimerP messaging (Page 2178)

TimerP I/Os (Page 2178)

TimerP block diagram (Page 2180)

## 12.1.4 TimerP error handling

### Error handling of TimerP

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 1 | Invalid function type for the block set at the Mode input parameter |
| 11 | `Ti.Value` < `SampleTime`<br>This error causes the `TimeRemaining` and `Out` output parameters to be set to 0. |
| 33 | The value of `Ti` can no longer be displayed in the REAL number field. |

TimerP block diagram (Page 2180)

## 12.1.6 TimerP I/Os

### I/Os of TimerP

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Hold | Hold calculation process | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| In | Input signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Init | Initialize function block | BOOL | 0 |
| Mode | How the block works:<br>0 = Start timer as pulse<br>1 = Start timer as extended pulse<br>2 = Start timer with ON delay<br>3 = Start timer with latching ON delay<br>4 = Start timer with OFF delay | INT | 2 |
| Reset | 1 = Reset output Out | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| Ti* | Time [s] | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see TimerP error handling (Page 2177). | INT | -1 |
| InvOut | Inverted output signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| Out | Output signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| TimeRemaining | Remaining time [s] | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

# 12.2 TimeTrig - Calculations with the date formats DT and TIME

## 12.2.1 Description of TimeTrig

**Object name (type + number) and family**

Type + number: FB 1802

Family: Time

### Area of application of TimeTrig

The block is used for the following applications:

- Minute, Daily, weekly or monthly generation of a pulse (trigger) using a definable time in minutes (0 to 59m), hours (0 to 23h) and day of the week (Sun to Sat) or one day (1 to 31) per month.
- Delayed generation a pulse (trigger) based on the current CPU time and a delay time in seconds (0 to 20 days).

### How it works

When a trigger is enabled, the next trigger time point and the duration until the next trigger time point is determined based on the CPU time. A periodic trigger and additionally a single trigger can be generated:

1. Generate periodic trigger (`PerTrigOn.Value = 1`)
2. Generate single trigger (`(SglTrigOn.Value = 1`)

The single trigger can be delayed by a specified period of time. The maximum delay is 20 days.

The period of time until the next trigger time point is displayed in days, hours, and minutes.

For calculations with the time formats DT and TIME, the block calls the following functions:

| Name | as of APL V8.1 | Family | No. in IEC | Symbol Comment |
|---|---|---|---|---|
| AD_DT_TM_APL | FC455 | IEC | FC1 | DT + add time |
| GE_DT_APL | FC456 | IEC | FC12 | Greater than or equal to DT |
| LE_DT_APL | FC452 | IEC | FC18 | Less than or equal to DT |
| LT_DT_APL | FC453 | IEC | FC23 | Smaller than DT |
| SB_DT_DT_APL | FC454 | IEC | FC34 | DT - DT subtract |

They come from the standard library "IEC function blocks" and are now also applied in the APL.

F1 will open the help from the original IEC function block.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (`OB30` to `OB38`). The block is first installed automatically in the startup OB (`OB100`).

### Startup characteristics

Define the startup characteristics for this block via `Feature.Bit0`:

- Bit 0: Set startup characteristics (Page 148)

### Status word allocation for `Status1` parameter

Refer to the following section for a description of the individual parameters: TimeTrig I/Os (Page 2192).

| Status bit | Parameter |
|---|---|
| 0 | Occupied |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Next trigger is a Minute trigger |
| 6 | `OnAct.Value` |
| 7 | All triggers are switched off:<br>NOT `PerTrigOn.Value OR SglTrigOn.Value OR Trigger.Value` |
| 8 | `PerTrigOn.Value` |
| 9 | NOT `PerTrigOn.Value` |
| 10 | `SglTrigOn.Value` |
| 11 | NOT `SglTrigOn.Value` |
| 12 | `Trigger.Value` |
| 13 | Internal error |
| 14 | Next trigger is a daily trigger |
| 15 | Next trigger is a weekly trigger |
| 16 | Next trigger is a monthly trigger |
| 17 | Next trigger is a single trigger |
| 18 | `PerMode` = 1: Periodic trigger set to daily |
| 19 | `PerMode` = 2: Periodic trigger set to weekly |
| 20 | `PerMode` = 3: Periodic trigger set to monthly |
| 21 | Trigger for weekdays is Sunday |
| 22 | Trigger for weekdays is Monday |
| 23 | Trigger for weekdays is Tuesday |
| 24 | Trigger for weekdays is Wednesday |
| 25 | Trigger for weekdays is Thursday |
| 26 | Trigger for weekdays is Friday |
| 27 | Trigger for weekdays is Saturday |
| 28 | `LiOp.Value` |
| 29 | 1 = Invalid signal status<br>`SetPerLi.Value` and `RstPerLi.Value`,<br>`SetSglLi.Value` and `RstSglLi.Value` |

| Status bit | Parameter |
|---|---|
| 30 | `PerMode` = 4: Periodic trigger set to minute |
| 31 | Not used |

### See also

TimeTrig modes (Page 2183)

TimeTrig functions (Page 2184)

TimeTrig error handling (Page 2191)

TimeTrig messaging (Page 2192)

TimeTrig block diagram (Page 2197)

## 12.2.2 TimeTrig modes

### TimerTrig operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

General information on the "On" mode is available in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit5` =1 and `Feature.Bit5` =0 is as shown below:

| Output Parameters | **`Feature.Bit5` =0** | **`Feature.Bit5` =1** |
|---|---|---|
| PerTrigOn.ST | 16#XX | 16#60 |
| SglTrigOn.ST | 16#XX | 16#60 |
| Trigger.ST | 16#XX | 16#60 |

### See also

Description of TimeTrig (Page 2181)

TimeTrig I/Os (Page 2192)
TimeTrig block diagram (Page 2197)

## 12.2.3 TimeTrig functions

### Functions of TimeTrig

The Time Trig block reads the CPU time for every cycle, if the Local or External time is enabled, based on the enabled signal, local or external time is considered as the input time.

The functions for this block are listed below.

### Periodic output of a trigger

Use the `LiOp` input parameter to define whether the periodic trigger can be enabled (0 - 1, `SetPerOp` or `SetPerLi` parameter) or disabled (1 - 0, `RstPerOp` or `RstPerLi` parameter) via the faceplate or an interconnection.

`LiOp` = 0: Enable/disable via faceplate (`SetPerOp` or `RstPerOp`)

`LiOp` = 1: Enable/disable via interconnection (`SetPerLi` or `RstPerLi`)

You can select the faceplate from four periodic trigger settings:

- Periodic daily minutely output `PerMode` = 4
  You set the time in minutes with the MinuteOfHour parameter.
  For example: Period mode selected is “Minute” and “minute of hour” is set to 10 and current CPU time is 9-hour 11-minute, so next periodic trigger will happen at 10th hour 10th minute.
- Periodic daily output `PerMode` = 1
  You set the time in hours with the `HourOfDay` parameter.
- Periodic weekly output `PerMode` = 2
  You set the day of the week and time of day with the `HourOfDay` and `DayOfWeek` parameters.
- Periodic monthly output `PerMode` = 3
  You set the day of the month and time of day with the `HourOfDay` and `DayOfMonth` parameters. If the day of a month is greater than the last day, the last day is used.

### Delayed output of a single trigger

Use the `LiOp` input parameter to define whether the single trigger can be set (0 - 1, `SetPerOp` or `SetPerLi` parameter) or reset (1 - 0, `RstPerOp` or `RstPerLi` parameter) via the faceplate or an interconnection.

`LiOp` = 0: Set/reset via faceplate (`SetPerOp` or `RstPerOp`)

`LiOp` = 1: Set/reset via interconnection (`SetPerLi` or `RstPerLi`)

The output is delayed by the delay time `DelayTime` starting from the current CPU time. The currently effective delay time is displayed at the `DlyTmEff` output.

### Calculation of the next trigger time point

The next trigger time point is displayed at the `NxTrgDT`, `NxTrgYear`, `NxTrgMon`, `NxTrgDay`, `NxTrgHour`, `NxTrgMin` and `NxTrgSec` outputs . The next trigger time point is calculated from an enabled periodic trigger and an activated single trigger.

If no trigger is activated, the the minimum DT#1990-01-01-0:0:0.0 is output at the `NxTrgDT` output.

### Calculating the time period until the next trigger time point

The period of time until the next trigger time point based on the current CPU time is output at the `DiffTmDay`, `DiffTmHour`, `DiffTmMin` and `DiffTmSec` outputs.

If no trigger is activated, 0 is set at the outputs.

### Reading back the trigger states and the single trigger time point for a complete download

The `PerTrigOn`, `SglTrigOn` trigger states and the single trigger time point are written back to inputs:

- `InPerTrigOn := PerTrigOn`
- `InSglTrigOn := SglTrigOn`
- `InSglTrigDT := SglTrigDT`

If you want to use the reset for a complete download, you must read back the marked parameters in addition to the operated and monitored parameters before a complete download.

The values are written back to the outputs at startup and when `Feature.Bit0` = 1.

Also, in section Set startup characteristics (Page 148), see under "Set startup characteristics for the TimeTrig block".

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 1 | Reaction to the out of service mode (Page 188) |
| 5 | Changes signal status of outputs in OOS (Page 208) |
| 6 | External Input to enable or Disable (Page 211) |
| 7 | Switch over to internal time enable or Disable (Page 211) |
| 8 | AS time enable or Disable (Page 212) |
| 24 | Enabling local operator authorization (Page 169) |

### Operator permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the OS_Perm parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 = Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 = Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can enable the periodic trigger |
| 5 | 1 = Operator can disable the periodic trigger |
| 6 | 1 = Operator can set the single trigger |
| 7 | 1 = Operator can reset the single trigger |
| 8 | Not used |
| 9 | used in OSPermOut, OSPermLog for the display of the Enabled operations symbol of Periodic mode |
| 10 | 1 = Operator can enter HourOfDay |
| 11 | 1 = Operator can enter DayOfWeek |
| 12 | 1 = Operator can enter DayOfMonth |
| 13 | 1 = Operator can enter DelayDay |
| 14 | 1 = Operator can enter DelayHour |
| 15 | 1 = Operator can enter DelayMin |
| 16 | 1 = Operator can enter PulseWidth |
| 17 | 1 = Operator can set LocalTime |
| 18 | 1 = Operator can enter periodic mode Daily |
| 19 | 1 = Operator can enter periodic mode Weekly |
| 20 | 1 = Operator can enter periodic mode Monthly |
| 21 - 27 | used in OSPermLog for the weekdays Sun, Mon ... Sat |
| 28 | 1 = Operator can enter periodic mode Minute |
| 29 | 1 = Operator can enter MinuteOfHour |
| 30 - 31 | Not used |

## Recognizing daylight saving time

The block reads the identifier for daylight saving time from the CPU and writes it to the SummerTime output. The update occurs only when

- The MinuteOfHour, HourOfDay, DayOfWeek, DayOfMonth, DelayTime, PerMode = 1, PerMode = 2, PerMode = 3, PerMode = 4 or LocalTime parameters are changed
- A PerTrigOn or SglTrigOn trigger is enabled
- At startup or leaving Out of Service

If an error occurs when reading the daylight saving time, the status SummerTime.ST := 16#00 is set and the display is not updated. The status is not used in the calculation of ST_Worst.

### Local time

In every cycle, the block reads the CPU time. With `LocalTime` = 1 the block calculates a local time. To this a correction value will be read from CPU and build a difference time, which is added to the CPU time. This correction takes into account the time zone and the time difference in summer time (daylight savings time) and winter time (standard time).

The update of the correction value occurs only when:

- The `MinuteOfHour`, `HourOfDay`, `DayOfWeek`, `DayOfMonth`, `DelayTime`, `PerMode` = 1, `PerMode` = 2, `PerMode` = 3, `PerMode` = 4, or `LocalTime` parameters are changed.
- A `PerTrigOn` or `SglTrigOn` trigger is enabled.
- At startup or leaving "Out of Service" mode.

If an error occurs while reading the correction value, the status `SummerTime.ST` is set to 16#00 and the block does not changes the CPU time.

Local Time:If the LocalTime input is enabled, the block considers the local time as the current time irrespective of Feature Bit status.

If the Current time signal is Local AS time, then the output signal DstCurr is set to one.

When the Local time input is enabled then the output DstLocalAct is set to one.

In addition to feature bits, in order to consider the local time, Local time should be enabled in the CPU properties of the PLC.

The output time is obtained as below:

`Local_DT` = Local Date and Time
`Local_Year` = Local Time year
`Local_Mon` = Local Time Month
`Local_Day` = Local Time Day
`Local_Hou` = Local Time Hour
`Local_Min` = Local Time Minute
`Local_Sec` = Local Time Second

`CPU_DT` = Local Time Date and Time
`CPU_Year` = Local Time year
`CPU_Mon` = Local Time Month
`CPU_Day` = Local Day
`CPU_Hou` = Local Time Hour
`CPU_Min` = Local Time Minute
`CPU_Sec` = Local Time Second

### External Time

When the external time (ExtTime) is given, block uses the external time as the input time and the related outputs (CPU_DT = external time) is set. For the external time setting, for example, the block `BT_LT` (FC 61) can be used.

If the `Feature.Bit6` (=1) is active, and if the `Feature.Bit7` (=0) is not enabled, then external time is considered as the Current time for the generation of trigger pulses.

The output time is obtained as below:

`Ext_DT w` = ExtTime Date and Time
`Ext_Year w` = ExtTime year

Ext_Mon w = ExtTime Month
Ext_Day w = ExtTime Day
Ext_Hou w = ExtTime Hour
Ext_Min w = ExtTime Minute
Ext_Sec w = ExtTime Second

CPU_DT = ExtTime Date and Time
CPU_Year = ExtTime year
CPU_Mon = ExtTime Month
CPU_Day = ExtTime Day
CPU_Hou = ExtTime Hour
CPU_Min = ExtTime Minute
CPU_Sec = ExtTime Second

If the "External day light saving time signal" (DstExtTime) is enabled, then the output DstExtAct is set to one.

If the Current time signal is External time and if the day light saving time (DstExtTime) is enabled for the external time, then the output signal DstCurr is set to one.

### AS Time

When AS time is considered then the output (CPU_DT = AS time) is set.

- If the Feature.Bit8=1, Feature.Bit7=1 and if the external signal is of bad status then AS time is considered as Current time
- If the Feature.Bit6=0 and Feature.Bit8=1 then AS time is considered.

The output time is obtained as below:

AS_DT = AS Date and Time
AS_Year = AS Time year
AS_Mon = AS Time Month
AS_Day = AS Time Day
AS_Hou = AS Time Hour
AS_Min = AS Time Minute
AS_Sec = AS Time Second

CPU_DT = AS Time Date and Time
CPU_Year = AS Time year
CPU_Mon = AS Time Month
CPU_Day = ASTime Day
CPU_Hou = AS Time Hour
CPU_Min = AS Time Minute
CPU_Sec = AS Time Second

If the Current time signal is AS time, then the output signal DstCurr is set to zero.

### Automatic switchover of time signal

Feature.Bit7 acts as the automatic switch over of time signal and this feature is only effective if the 'External time signal(Feature Bit6)' is active, and if the Feature.Bit7 is enabled and the quality code of the external time signal is bad, the block uses the AS time as the basis for Time input.

Example for considering Local time input

- If the input LocalTime is set to one then the Local time is considered as the current time, irrespective of Feature Bits state.
- In the CPU Properties enable the local time.

| Feature Bits | Description | Type | Default |
|---|---|---|---|
| Bit6 | With this function you can activate external time.<br>• If 1 = external time is used for Switching.<br>• If 0 = external time cannot be used for switching | Bool | 0 |
| Bit7 | With this function you can choose internal time or AS Time.<br>• If 1 = switch to internal time(AS time) and if `ExtTime.ST`<>16#80 or 16#60<br>• If 0= internal time not used (AS time). | Bool | 0 |
| Bit8 | With this fuction you can choose AStime.<br>• If 1 = AS internal time<br>• If 0=AS time not used for Current time output | Bool | 0 |

| The probability of Inputs and Outputs for the time trig block | | | | | |
|---|---|---|---|---|---|
| **`FeatureBit6`** | **`FeatureBit7`** | **`FeatureBit8`** | **Local time Connected** | **External time Connected** | **Current Time considered** |
| External (external time used for switching) | Switch to internal time if the signal quality is bad | 1 = AS internal time | - | - | - |
| 0 | 0 | 0 | - | x | CPU TIME OR AS TIME |
| 0 | 0 | 1 | - | x | CPU TIME OR AS TIME |
| 0 | 1 | 0 | - | x | CPU TIME OR AS TIME |

| The probability of Inputs and Outputs for the time trig block | | | | | |
|---|---|---|---|---|---|
| **FeatureBit6** | **FeatureBit7** | **FeatureBit8** | **Local time Connected** | **External time Connected** | **Current Time considered** |
| 0 | 1 | 1 | - | x | CPU TIME OR AS TIME |
| 1 | 0 | 0 | - | 1 | EXTERNAL TIME |
| 1 | 0 | 1 | - | 1 | EXTERNAL TIME |
| 1 | 1 | 0 | - | 1 | BASED ON THE EXTERNAL SIGNAL STATUS, AS OR EXTERNAL TIME IS CONSIDERED |
| 1 | 1 | 1 | - | 1 | BASED ON THE EXTERNAL SIGNAL STATUS, AS OR EXTERNAL TIME IS CONSIDERED |
| x | x | x | 1 | 0 | AS LOCAL TIME=CPU + SUMMERTIME |
| x | x | x | x | 1 | BASED ON FEATURE BITS STATE, THE OUTPUT IS SET |
| NOTE: X represents 0 or 1 state | | | | | |

**Note**

External time is said to be connected if it is not equal to the default value.

Where default value is DT#2011-04-04-00:00:00.000

## Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The worst signal status `ST_Worst` for the block is formed from the following parameter:

- `SetSglLi.ST`
- `RstSglLi.ST`
- `SetPerLi.ST`

- RstPerLi.ST
- ExtTimeQc

The worst signal status ST_Worst is written to the following outputs:

- SglTrigOn.ST
- PerTrigOn.ST
- Trigger.ST

If an error occurs when reading the daylight saving time, the status SummerTime.ST := 16#00 is set and the display is not updated. The status is not used in the calculation of ST_Worst.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

## 12.2.4 TimeTrig error handling

### Error handling for TimeTrig

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 51 | Invalid signal at LiOp =1<br>• SetPerLi = 1 and RstPerLi = 1<br>• SetSglLi = 1 and RstSglLi = 1 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| AS_DT | AS(CPU Time) Date and Time | DT | 1990-01-01-0:0:0.0 |
| AS_Year | AS Time Year | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| AS_Mon | AS Time Month | INT | 0 |
| AS_Day | AS Time Day | INT | 0 |
| AS_Hour | AS Time Hour | INT | 0 |
| AS_Min | AS Time Minute | INT | 0 |
| AS_Sec | AS Time Second | INT | 0 |
| Ext_DTw | External Date and Time | DT | 1990-01-01-0:0:0.0 |
| Ext_Yearw | Ext Time Year | INT | 0 |
| Ext_Monw | Ext Time Month | INT | 0 |
| Ext_Dayw | Ext Time Day | INT | 0 |
| Ext_Hourw | Ext Time Hour | INT | 0 |
| Ext_Minw | Ext Time Minute | INT | 0 |
| Ext_Secw | Ext Time Second | INT | 0 |
| Local_DT | Local(Local CPU Time) Date and Time | DT | 1990-01-01-0:0:0.0 |
| Local_Year | Local Time Year | INT | 0 |
| Local_Mon | Local Time Month | INT | 0 |
| Local_Day | Local Time Day | INT | 0 |
| Local_Hour | Local Time Hour | INT | 0 |
| Local_Min | Local Time Minute | INT | 0 |
| Local_Sec | Local Time Second | INT | 0 |
| DstCurr | Current daylight saving time<br>• DstCurr =0 day light saving not enabled<br>• DstCurr =1 day light saving enabled | BOOL | 0 |
| DstExtact | DstExtact=0 day light saving not enabled for external time<br>DstExtact=1 day light saving enabled for external time | BOOL | 0 |
| DstLocalact | DstLocalact =0 Local time enabled<br>DstLocalact =1 Local time disabled | BOOL | 0 |
| PerTrigOn | 1 = Periodic trigger On | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SglTrigOn | 1 = Single trigger On | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Trigger | Trigger signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CPU_Year | CPU time, year | INT | 0 |
| CPU_Mon | CPU time, month | INT | 0 |
| CPU_Day | CPU time, day | INT | 0 |
| CPU_Hour | CPU time, hour | INT | 0 |
| CPU_Min | CPU time, minute | INT | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CPU_Sec | CPU time, minute | INT | 0 |
| CPU_DayOfWeek | CPU time, weekday | INT | 0 |
| SglTrigDT | Single trigger date and time | DATE_AND_TIME | 1990-01-01-0:00:00 |
| NxTrgDT | Next trigger time point date and time | DATE_AND_TIME | 1990-01-01-0:00:00 |
| NxTrgYear | Next trigger time point year | INT | 0 |
| NxTrgMon | Next trigger time point months | INT | 0 |
| NxTrgDay | Next trigger time point days | INT | 0 |
| NxTrgHour | Next trigger time point hours | INT | 0 |
| NxTrgMin | Next trigger time point minutes | INT | 0 |
| NxTrgSec | Next trigger time point seconds | | |
| DiffTmDay | Day:<br>Period of time starting from the current CPU time until the next trigger time point | INT | 0 |
| DiffTmHour | Hours:<br>Period of time starting from the current CPU time until the next trigger time point | INT | 0 |
| DiffTmMin | Minutes:<br>Period of time starting from the current CPU time until the next trigger time point | INT | 0 |
| DiffTmSec | Seconds:<br>Period of time starting from the current CPU time until the next trigger time point | INT | 0 |
| DlyTmEff | Current effective delay time [sec] | DINT | 0 |
| BarTmSec | Bar graph seconds | DINT | 0 |
| BarOpHiScale | Bar graph minutes | DINT | 60 |
| DayOpHiScale | Scale graph days | INT | 1 |
| HrsOpHiScale | Scale graph hours | INT | 0 |
| MinOpHiScale | Scale graph minutes | INT | 0 |
| SummerTime | Daylight saving time | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OnAct | 1 = Block is in service | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OS_PermOut | Operator permission: Output for OS | DWORD | 16#FFFFFFFF |
| OS_PermLog | Operator permission: Output for OS | DWORD | 16#FFFFFFFF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status1 | Status word (Page 2181) | DWORD | 16#00000000 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see TimeTrig error handling (Page 2191). | INT | -1 |

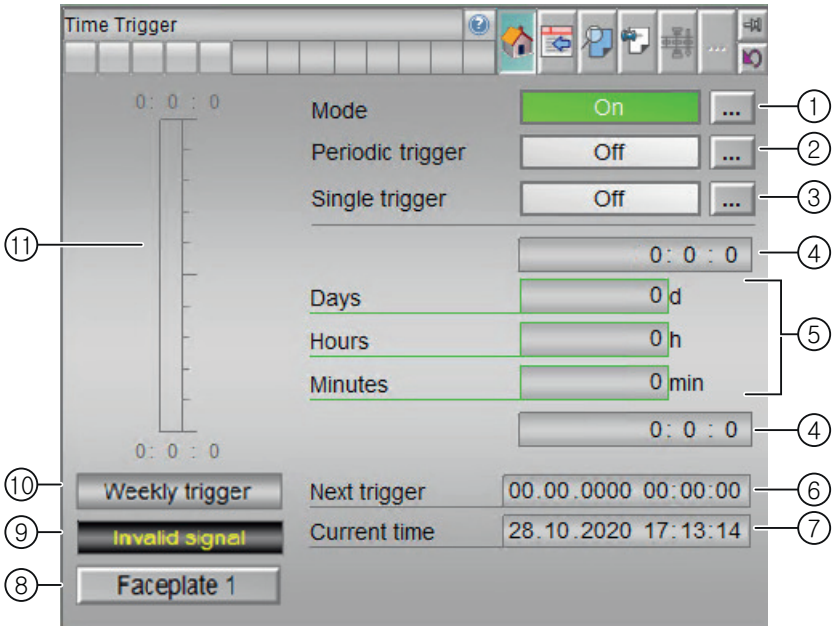
## 12.2.8 Operator control and monitoring

### 12.2.8.1 TimeTrig views

### Views of the TimeTrig block

The block TimeTrig provides the following views:



- TimeTrig standard view (Page 2198)
- TimeTrig parameter view (Page 2201)

- TimeTrig preview (Page 2203)
- Memo view (Page 338)
- Block icon for TimeTrig (Page 2205)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 12.2.8.2 TimeTrig standard view

#### Standard view of TimeTrig

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (2) Enabling and disabling the period trigger

This area shows the default operating mode of the trigger. The following operating modes can be displayed and set here:

- "On"
- "Off"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (3) Enabling and disabling the single trigger

This area shows the default operating mode of the trigger. The following operating modes can be displayed and set here:

- "On"
- "Off"

Refer to the Switching operating states and operating modes (Page 289) section for information on changing the state.

### (4) High and low scale range for the count value

This value provides information on the display range for the bar graph (above) of the count value. The scale range is defined in the engineering system.

### (5) Display of the count value

The following counts are shown here: The amount of time until the next trigger is shown here.

- "Days"
- "Hours"
- "Minutes"

### (6) Display of the time point of the next trigger

This area shows the time of the next trigger.

### (7) Displaying of the actual time of day

This area shows the actual time of day.

### (8) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system (ES). The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234) .

### (9) Display area for block states

This area provides additional information on the operating state of the block:

- "Internal error"
- "Invalid Signal"

### (10) Displaying of the actual trigger operating mode

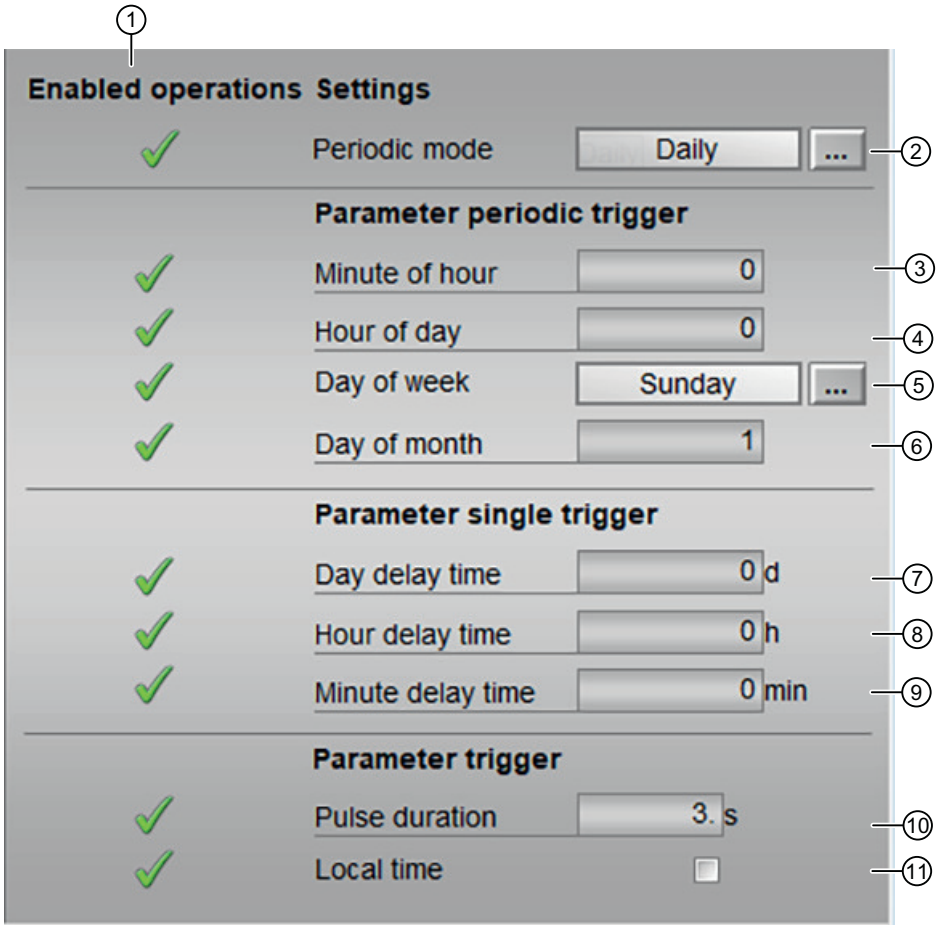
- "Minute trigger"
- "Daily trigger"
- "Weekly trigger"
- "Monthly trigger"
- "Single trigger"

### (11) Graphic display of the current count value

This area shows you the current count in form of a bar graph. You can also see the high and low limits of the bargraph's scale. The visible area in the bar graph depends on the configuration in the engineering system (ES).

For more information, refer: Bar graph (Page 376)

### See also



Release for maintenance (Page 70)

Simulating signals (Page 64)

Error handling (Page 128)

### 12.2.8.3 TimeTrig parameter view

**Parameter view of TimeTrig**

**(1) Enabled operation**

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`).

### (2) Periodic operating mode

You can change the operating mode of the periodic trigger:

- "Minute": The trigger is activated once an hour.
- "Daily": The trigger is activated once a day.
- "Weekly": The trigger is activated once a week.
- "Monthly": The trigger is activated once a month.

### (3), (4), (5) and (6) parameters for the periodic trigger

Enter the relevant parameters for the periodic mode:

- "Time": relevant for Minute, daily, weekly and monthly trigger
- "Weekday": relevant for weekly and monthly trigger
- "Day of the month": Relevant for monthly trigger. If the day of a month is greater than the last day, the last day is used.

### (7), (8) and (9) parameters for single triggers

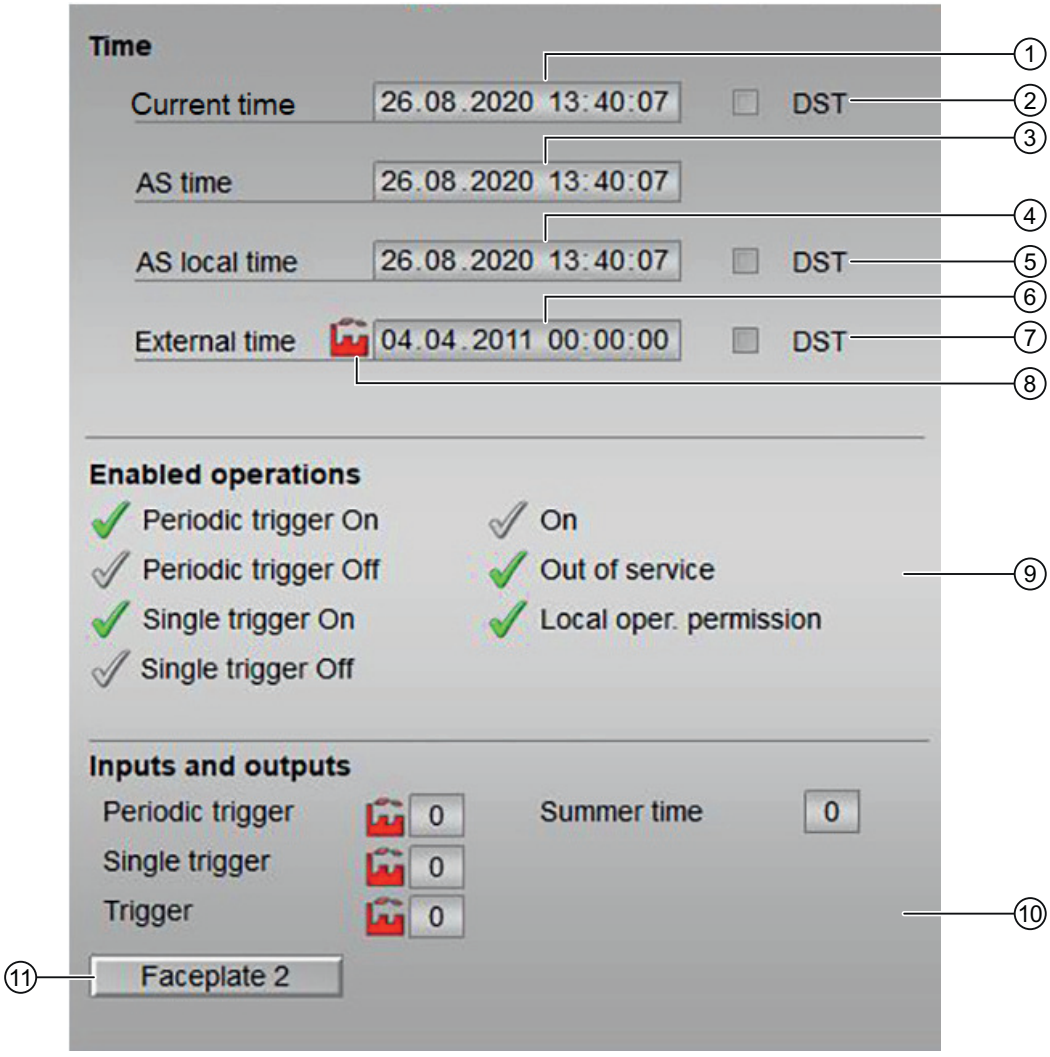
Enter the parameters for the single trigger:

- "Delay time day"
- "Delay time hour"
- "Delay time minute"

### (10) and (11) parameters for the trigger

- "Pulse duration": Enter the duration of the trigger signal.
- "Local time": Activate local time by selecting the check box (☑).

### See also



Changing values (Page 291)

Switching operating states and operating modes (Page 289)

Simulating signals (Page 64)

### 12.2.8.4 TimeTrig preview

**Preview of TimeTrig**

The screen shot also displays the Daylight Saving Time (DST) enabled or disabled status for the Current time, AS local time and for External time

**(1) This shows the current time which is active**

The current time may be AS, Local or External time, based on the parameter set through Feature Bits and Inputs.

**(2) Displays the DST**

Enabled or disabled status for the Current time.

### (3) Displays the CPU Time

### (4) Displays the AS local time

### (5) Displays the DST

Enabled or disabled status for the AS local time.

### (6) Displays the External time

### (7) Displays the DST

Enabled or disabled status for the External time.

### (8) External signal status

### (9) Enable operations

This area shows all operations for which special operator permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Icons for enabled operation:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- "Periodic trigger on": You can enable the periodic trigger.
- "Periodic trigger off": You can disable the periodic trigger.
- "Single trigger on": You can enable the single trigger.
- "Single trigger off": You can disable the single trigger.
- "On": You can operate the trigger.

- "Out of service": You can switch to "Out of service" operating mode.
- "Local operator permission": Use the ← button to switch to the standard view of the "OpStations" block.
  You can find additional information on this in the section Operator control permissions (Page 285).

### (10) Display of current operating signals

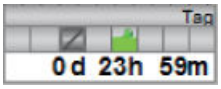
This area shows the most important parameters for this block with the current selection.

- "Periodic trigger":
  - 0 = Periodic trigger is enabled
  - 1 = Periodic trigger is disabled
- "Single trigger":
  - 0 = Single trigger is disabled
  - 1 = Single trigger is enabled
- "Trigger":
  - 0 = Output trigger signal is disabled
  - 1 = Output trigger signal is enabled
- "Daylight saving time":
  - 0 = Daylight saving time is disabled
  - 1 = Daylight saving time is enabled

### (11) Navigation button for switching to the standard view of any faceplate

Use this navigation button to open the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the section Opening additional faceplates (Page 234).



## 12.2.8.5 Block icon for TimeTrig

### Block icons for TimeTrig

A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Memo display
- "Time until the next trigger" display is running

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# Mathematical blocks 13

## 13.1 AbsR - Absolute value of a real value

### 13.1.1 Description of AbsR

#### Object name (type + number) and family

Type + number: FC 395

Family: Math

#### Area of application for AbsR

The block is used for getting the absolute value of a real value.

#### How it works

The AbsR block provides the absolute value of a real value. The following equation is used for the calculation:

`Out` = |`In`|

Where:

`In` = Input value

`Out` = Absolute value

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

#### Startup characteristics

The block does not have any startup characteristics.

#### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 13.1.2 AbsR modes

### AbsR operating modes

This block does not have any modes.

## 13.1.3 AbsR functions

### Functions of AbsR

The functions for this block are listed below.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The worst signal status for the block is formed by the following parameter and output at the `Out` output parameter:

- `In.ST`

## 13.1.4 AbsR error handling

### AbsR error handling

The block does not report any errors.

## 13.1.5 AbsR messaging

### Messaging

This block does not offer messaging.

## 13.1.6 AbsR I/Os

### AbsR I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| In | Analog input value | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#80 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| Out | Analog output value | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#80 |

## 13.1.7 AbsR block diagram

### AbsR block diagram

A block diagram is not provided for this block.

# 13.2 Add04 - Adder with 4 values

## 13.2.1 Description of Add04

### Object name (type + number) and family

Type + number: FC 351

Family: Math

### Area of application for Add04

The block is used for the following applications:

- Adding values
- Output of the total value for further processing

### How it works

The Add04 block calculates the sum of up to 4 values:

`Out` = `In1` +...+ `Inn` (`n` ≤ 4),

Where:

`Out` = sum value

`In1` ... `In4`= values to be added

The sum of all input parameters and the worst input parameter signal status is always output.

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range, the highest or lowest possible REAL value is output.

If the value is not a number `(#NaN)`, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 13.3 Add08 - Adder with 8 values

## 13.3.1 Description of Add08

### Object name (type + number) and family

Type + number: FC 352

Family: Math

### Area of application for Add08

The block is used for the following applications:

- Adding values
- Output of the total value for further processing

### How it works

The Add08 block calculates the sum of up to 8 values:

`Out` = `In1` +...+ `Inn (n` ≤ 8),

Where:

`Out` = sum value

`In1` ... `In8` = values to be added

The sum of all input parameters and the worst input parameter signal status is always output.

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range, the highest or lowest possible REAL value is output.

If the value is not a number `(#NaN)`, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

# 13.4 Average - Mean value calculation

## 13.4.1 Description of Average

### Object name (type + number) and family

Type + number: FB1804

Family: Math

### Area of application for Average

The block is used for the following applications:

- Calculation of a time-based mean value

### How it works

The block calculates the time-based mean value of an analog value `In` based on the time which has expired since its start. The equation below is used:

$$Out = \frac{Out_{(n-1)} \cdot NumCycles + In}{NumCycles + 1}$$

Where:

`In` = input variable

`Out` = present average value

$Out_{(n-1)}$ = calculated average upon successful startup

`NumCycles` = Number of cycles for creating the mean value from the 0 - 1 edge transition of the Run input parameter.

The calculation is started by a 0 - 1 edge at the `Run` input parameter. The `Out` output parameter is overwritten by the `In` input parameter.

The result at output value `Out` is recalculated in the next cycles, and cycle counter `NumCycles` is incremented.

The `NumCycles` cycle counter has the DINT data type and can therefore assume the maximum value of 2147483647. When this value is reached, the `NumCycles` cycle counter is reset to 1. The formation of the mean is then started once again. At a cycle time of 100 ms, this case occurs every 6.8 years.

Calculation is terminated by resetting (1 - 0 edge) the `Run` input parameter. The last results set at `Out` and `NumCycles` are saved.

The parameter `Feature` can be used to specify the startup characteristics of the block.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

## 13.4.3 Average functions

### Functions of Average

The functions for this block are listed below.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Functions |
|---|---|
| 0 | Set startup characteristics (Page 148) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `Out` output parameter:

- `In.ST`

## 13.4.4 Average error handling

### Error handling of Average

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Default value displayed after installation in the block. |
| 0 | There is no error. |
| 30 | The `In` value can no longer be displayed in the REAL number field, the 16#28 status is also output. The last valid value is provided at the `Out` output and calculation is halted. |
| 31 | The `Out` value can no longer be displayed in the REAL number field, the 16#28 status is also output.<br>The last valid value is provided at the `Out` output. |

# 13.5 DeadTime - Delayed signal output

## 13.5.1 Description of DeadTime

### Object name (type + number) and family

Type + number: FB 1807

Family: Math

### Area of application for DeadTime

The block provides the following functions:

- Delay [s] of signal output

### How it works

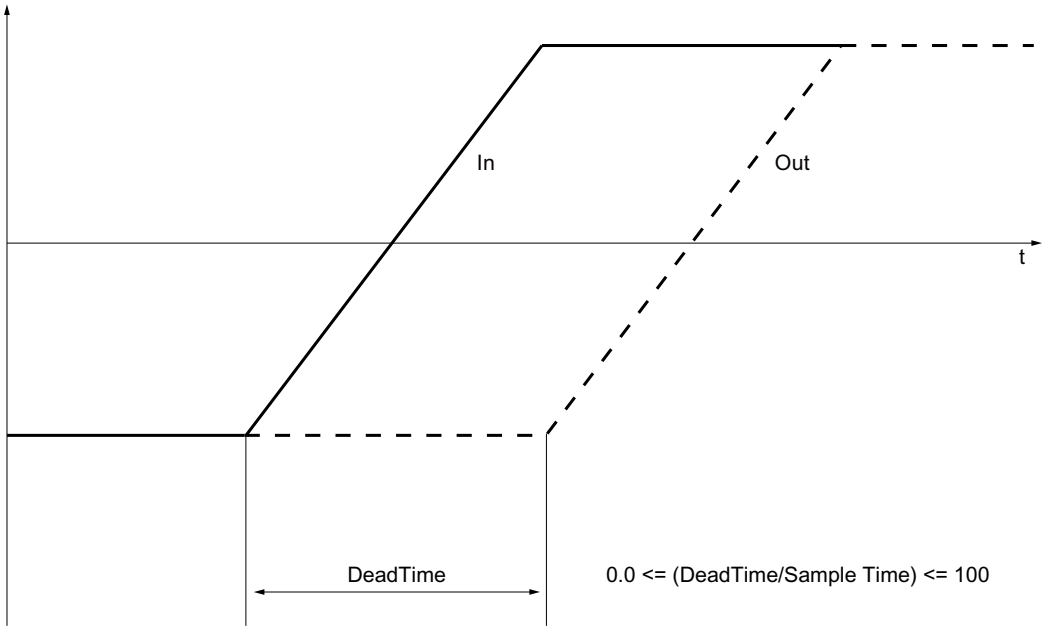
This block delays the output of an input value by a time `DeadTime` [s] selected by the user.

Dead times up to 100 times the `SampleTime` can be realized. If you want to set a longer dead time, you need to connect several dead time blocks in sequence. You can also insert the dead time block in a runtime group with a longer sampling time or scale down the runtime group, but this would lead to loss of input values.

The block operates as follows:

`Out` = `In` (t - `DeadTime`)

Where:



`Out` = output value

t = current time

`DeadTime` = `DeadT_Cyc` · `SampleTime` where:

`DeadT_Cyc` = Number of cycles [0...100], by which the analog input value is delayed

An analog value of input `In` is only output after the variable dead time at `DeadTime` has expired. It is output at `Out`.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

**Note**

If you change the value for the dead time during the runtime of the block, the input value is written to the output. The change to the dead time then takes effect.

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

The resulting sampling time of the block must be long enough for the desired dead time to be specified at the `DeadTime` parameter.

For the DeadTime block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)

## Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

Description of DeadTime (Page 2226)

## 13.5.3 DeadTime functions

### Functions of DeadTime

The functions for this block are listed below.

### Configurable reactions using the `Feature` I/O

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Functions |
|---|---|
| 0 | Set startup characteristics (Page 148) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `Out` output parameter:

- `In.ST`

DeadTime error handling (Page 2229)

## 13.5.4 DeadTime error handling

### Error handling of DeadTime

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed. |
| 0 | There is no error. |

| Error number | Meaning of the error number |
|---|---|
| 30 | The value of `In` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 32 | The value of `DeadTime` can no longer be displayed in the REAL number field.<br>The last valid value is provided at the `Out` output. |
| 45 | The value of `DeadTime` is outside the permitted range<br>`0` ≤ `INT` (`DeadTime` / `SampleTime`) ≤ 100<br>If the value of `DeadTime` is greater than 100 · `SampleTime`, the block works internally with the maximum dead time of 100 · `SampleTime`. |

## 13.5.6 DeadTime I/Os

### I/Os of DeadTime

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DeadTime* | Dead time [s]: Time by which the analog input value is delayed | REAL | 1.0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 2228) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In* | Analog input value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see DeadTime error handling (Page 2229). | INT | -1 |
| DeadT_Cyc | Number of cycles [0 to 100] by which the analog input value is delayed | INT | 0 |
| Out | Analog output value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

# 13.6 Derivative - Obtaining a derivative

## 13.6.1 Description of Derivative

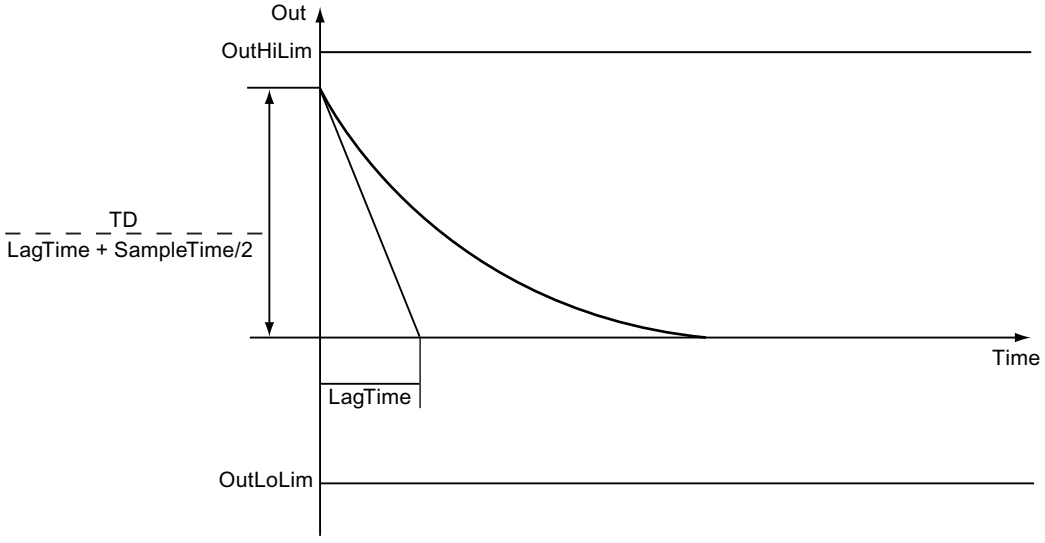
### Object name (type + number) and family

Type + number: FB 1808

Family: Math

### Area of application for Derivative

The block is used for the following applications:



- Forming the D component for the controller design
- Forming a temporal derivative of the input signal

### How it works

The block can be used as part of user-designed closed-loop controller. The block calculates a D component with delay. The derivative of the input signal is formed using the "trapezoid rule".

If only the derivative signal is to be calculated, `TD` = 1 [s] must be set. The speed signal is then formed from the travel signal.

The output signal can be damped using the `LagTime` parameter. Damping is disabled by configuring `LagTime` = 0. The following figure shows the step response from the unit step of the `In` input variable.

The block works according to the following formula:

$$Out_{(n)} = \left( \frac{TD}{LagTime + \frac{SampleTime}{2}} \right) \left( In_{(n)} - PrevIn_{(n)} \right)$$

The $PrevIn_{(n)}$ value is calculated for the next sampling step by means of a first order low pass filter:

$$PrevIn_{(n+1)} = PrevIn_{(n)} + \frac{SampleTime}{TD} Out_{(n)}$$

The following applies for both formulas:

- `Out`$_{(n)}$ = output value
- `TD` = derivative time
- `In`$_{(n)}$ = input value
- `PrevIn`$_{(n)}$ = memory variable of the low pass filter
- `SampleTime` = sampling time [s]
- `LagTime` = delay time [s]

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB3x). The block is then installed automatically in startup OB (OB100).

Further addressing is not required.

For the Derivative block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Description of Derivative (Page 2233)

## 13.6.3 Derivative functions

### Functions of Derivative

The functions for this block are listed below.

### Monitoring the output parameter for limits

The `Out` output parameter can be checked for limit values:

- `OutHiLim`: High limit
- `OutLoLim`: Low limit

If the limits are infringed, this is indicated to you at the corresponding output parameters (output parameter `OutHiAct` or `OutLoAct` = 1).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in section Configurable functions using the Feature I/O (Page 139). The following behavior patterns are available for this block at the relevant bits

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `Out`, `OutHiAct` and `OutLoAct` output parameters:

- `In.ST`

## 13.6.4 Derivative error handling

### Error handling of Derivative

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |
| 30 | The value of `In` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 31 | The value of `Out` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 32 | The value of `LagTime` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 33 | The value of `TD` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |

## 13.6.6 Derivative I/Os

### I/Os of Derivative

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 2236) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In* | Analog input value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| LagTime* | Delay time [s] | REAL | 10.0 |
| OutHiLim | Limit (high) for output value | REAL | 100.0 |
| OutLoLim | Limit (low) for output value | REAL | 0.0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| TD* | Derivative time [s] | REAL | 1.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see Derivative error handling (Page 2237) | INT | -1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Out | Output value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OutHiAct | 1= Limit (high) violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutLoAct | 1= Limit (low) violated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

# 13.7 Div02 - Division of two values

## 13.7.1 Description of Div02

### Object name (type + number) and family

Type + number: FC 358

Family: Math

### Area of application for Div02

The block is used for the following applications:

- Dividing two values
- Output of the division for further processing

### How it works

The block is used to divide two values as follows:

`Out` = `In1` / `In2`

If the input parameter is `In2` = 0, the last valid output value is retained until another division is permitted mathematically.

The worst signal status is also always output at the output parameter.

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range, the highest or lowest possible REAL value is output.

If the value is not a number `(#NaN)` or divided by 0, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 13.8 FlowCorr - Flow correction

## 13.8.1 Description of FlowCorr

### Object name (type + number) and family

Type + number: FB 1916

Family: Math

### Area of application for FlowCorr

The block is used for the following applications:

- Pressure and/or temperature compensation for measurements of the differential pressure method

The block calculates the pressure and/or temperature compensation for measurements with the differential pressure method. This refers to measurements from restrictors, standard flow nozzles, venturi nozzles and pitot tubes. The block can be used for gases and vapors, saturated steam and liquids to calculate the volume flow rate or, for liquids, to calculate the mass flow rate.

### How it works

The block cyclically calculates the volume/mass flow rate.

Mode 1: Gas and steam:

In mode 1, the flow is calculated as shown in the following equation:

$$Q_{cal} = Q_0 * \sqrt{\frac{\Delta P}{\Delta P_0} * \frac{(P + P_B)}{(P_0 + P_B)} * \frac{(T_0 + T_{abs})}{(T + T_{abs})}}$$

Mode 2: Saturated steam, mass flow in liquids:

In mode 2, the flow is calculated as shown in the following equation:

$$Q_{cal} = Q_0 * \sqrt{\frac{\Delta P}{\Delta P_0} * \frac{\rho}{\rho_0}}$$

Mode 3: Volume flow for liquids:

In mode 3, the flow is calculated as shown in the following equation:

$$Q_{cal} = Q_0 * \sqrt{\frac{\Delta P}{\Delta P_0} * \frac{\rho_0}{\rho}}$$

| Block I/O | Icon | Type | Description |
|---|---|---|---|
| Flow | $Q_{cal}$ | Result | Calculated flow |
| Flow0 | $Q_0$ | Parameter | Design flow |
| DiffP | $\Delta P$ | Measurement | Differential pressure [1] |
| DiffP0 | $\Delta P_0$ | Parameter | Design differential pressure |
| P | $P$ | Parameter or measurement | Pressure [bar (abs. or relative)] [2] |
| P0 | $P_0$ | Parameter | Design pressure [bar (abs. or relative)] [3] |
| P_Atmos | $P_B$ | Parameter or measurement | Barometric pressure [mbar (abs.)] [4] |
| Temp0 | $T_0$ | Parameter | Design temperature [0 °C] |
| Temp | $T$ | Parameter or measurement | Temperature [0 °C] |
| TempAbs | $T_{abs}$ | Parameter | [0 °C] in Kelvin (corresponds to 273.15K) |
| Density | $\rho$ | Parameter or measurement | Density [5] |
| Density0 | $\rho_0$ | Parameter | Design density |

1 When the sensor extracts the square root of the differential pressure, the P_SqrtOn parameter must be set to 'true'. In this case, the differential pressure value is squared before the flow has been calculated by the above equation.

2 If a sensor is used for absolute pressure, P_Atmos must be set to '0'. If a sensor is used for differential pressure, P_Atmos must either be set to the local average ambient pressure or linked to the ambient pressure measurement.

3 'P0' must be the same size as 'P' (e.g.: if a sensor for absolute pressure is used for 'P', there must be a matching value for the absolute pressure 'P0').

4 Unit of P_Atmos = unit of P / 1000 (e.g.: P: bar; P_Atmos: mbar)

5 Real density measurement can be connected. An alternative method is often used in practice to determine the density (a process pressure measurement for saturated steam or a temperature measurement for liquids).

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

FlowCorr messaging (Page 2250)
FlowCorr error handling (Page 2249)
FlowCorr functions (Page 2247)
Description of FlowCorr (Page 2245)

## 13.8.3 FlowCorr functions

### Functions of FlowCorr

The functions for this block are listed below.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The worst signal status for the block is formed from the following parameters and output at the `Flow.ST` output parameter:

- `DiffP.ST`
- `DiffP0.ST`
- `P.ST`
- `P0.ST`
- `P_Atmos.ST`
- `Temp.ST`
- `Temp0.ST`
- `Density.ST`
- `Density0.ST`
- `Flow0.ST`
- `TempAbs.ST`

When one of the following conditions applies and depending on `Feature.Bit8` (Switch to substitute value (Page 159)), the last valid value is retained at the `Flow` output or the substitute value `SubsFlow` is applied:

- One of the inputs relevant to the calculation or the `Flow` output is outside the `REAL` counter range
- A division by zero occurs in the calculation
- The Mode parameter is not 1, 2 or 3

`Feature.Bit8` =0: Last valid value is retained and the signal status is set to bad, process-related `16#28` (assuming the signal status is not `16#0`).

`Feature.Bit8` =1: Substitute value `SubsFlow` is applied and the signal status is set to manipulated value (for example, substitute value, simulation, last valid value) `16#60`.

Description of FlowCorr (Page 2245)

## 13.8.4 FlowCorr error handling

### Error handling of FlowCorr

The block does not report any errors.

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

When one of the following conditions applies and depending on `Feature.Bit8` (Switch to substitute value (Page 159)) at the `Flow` output, the last valid value is retained or the substitute value `SubsFlow` is applied:

- One of the inputs relevant to the calculation or the `Flow` output is outside the `REAL` counter range
- A division by zero occurs in the calculation
- The Mode parameter is not 1, 2 or 3

`Feature.Bit8` = 0: Last valid value is retained and the signal status is set to bad, process-related `16#28` (assuming the signal status is not `16#0`).

`Feature.Bit8` = 1: Substitute value `SubsFlow` is applied and the signal status is set to manipulated value (for example, substitute value, simulation, last valid value) `16#60`.

The `Bad.Value` output is set to `true` when the following applies:

- When the signal status is formed, the value is bad, device-related or process-related (`16#00`, `16#28`)
- One of the inputs relevant to the calculation or the `Flow` output is outside the `REAL` counter range
- A division by zero occurs in the calculation
- The Mode parameter is not 1, 2 or 3

### Overview of error numbers

The block has no `ErrorNum` I/O.

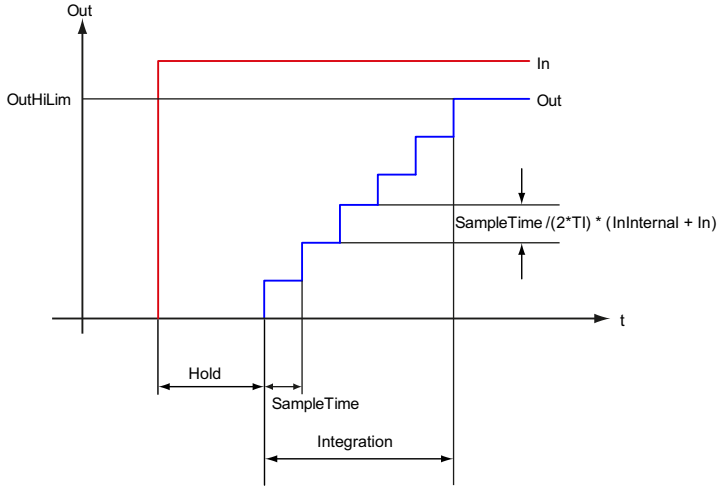
# 13.9 Integral - Generating a time integral

## 13.9.1 Description of Integral

### Object name (type + number) and family

Type + number: FB 1823

Family: Math



### Area of application for Integral

The block is used for the following application:

- Forming the time integral of the connected input signal
- Forming the D component for the controller design

### How it works

The block can be used as part of user-designed closed-loop controller. It integrates the input signal `In` based on the trapezoid rule and outputs the result, the integral action component, at `Out`. If the block should calculate the pure time integral, `TI` = 1 [s] must be set.

The block works according to the following formula:

$$Out_{(n)} = Out_{(n-1)} + \frac{SampleTime}{2 \cdot TI} \cdot \left( In_{(n-1)} + In_{(n)} \right)$$

Where:

- `Out` = Integrated value between high and low limits
- `SampleTime` = Sampling time [s]

- `TI` = Integration time constant [s]
- `In` = Input value
- $\texttt{In}_{(n-1)}$ = Last input value
- $\texttt{Out}_{(n-1)}$ = Last output value

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

There is an example project for the Integral block (APL_Example_xx, xx refers to the language variant) with an application scenario for this block, which explains how the block works.

Application scenario in the example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)

### Startup characteristics

Use the `Feature` bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

Integral I/Os (Page 2258)

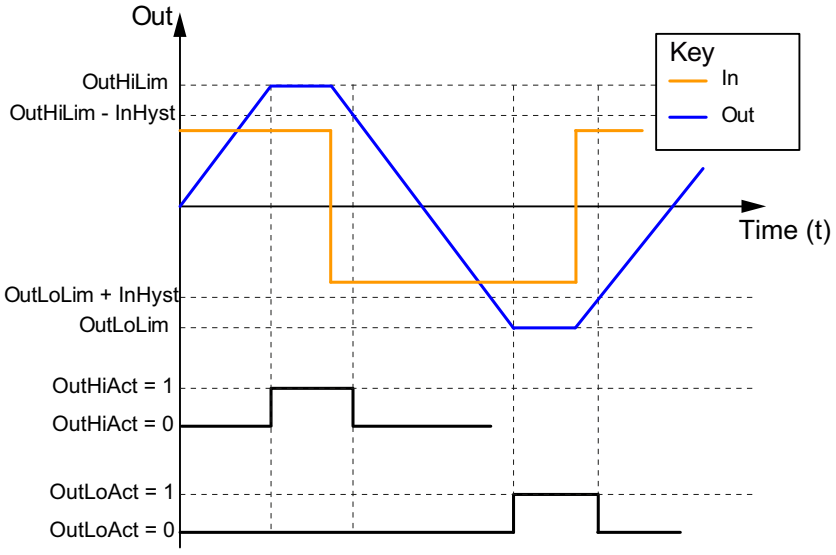
Integral messaging (Page 2258)

Integral error handling (Page 2257)

Integral functions (Page 2255)

Description of Integral (Page 2253)

## 13.9.3 Integral functions



### Functions of Integral

The functions for this block are listed below.

### Monitoring limits

Use the `OutHiLim` and `OutLoLim` I/Os to define the limits of the integrated value `Out`.

If limits are reached or exceeded (`OutHiAct` or `OutLoAct` = 1 I/Os), the output value is set to user-defined limits and output at `Out`.

### Tracking values

You use input parameter `OutTrkOn` = 1 to activate tracking of a value, which is in turn defined at input parameter `OutTrk`.

After tracking mode has been terminated, the block uses the value currently set at `Out` as the value to be integrated.

In tracking mode, the signal status of `Out` is set to the signal status of `OutTrk`.

**Note**

If the integration is stopped, the function (`Hold` = 1) has priority over the tracking.

## Stopping integration

Set input parameter `Hold` = 1 if you want to stop the integration. Limits are no longer monitored and the updating of the `OutHiAct` and `OutLoAct` limit outputs stops. A change to the monitoring limits remains ineffective when integration is stopped. If you start the integration again, the value currently pending at `Out` output parameter is used for the integration process.

## Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 8 | Status output calculation (Page 202) |

## Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for technologic blocks (Page 117).

The signal status for the block is formed using the following parameters and output at the `Out`, `OutHiAct` and `OutLoAct` output parameters:

- `In.ST`
- `Out.ST` Signal status from the last cycle

**Note**

**Special notes for the Integral mathematical block**

Due to its application area (time integral, I-component for the configuration of a controller), the Integral block generates the signal status like the technological blocks.

## 13.9.4 Integral error handling

### Error handling of Integral

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 11 | The integration time constant `TI` is within the range:<br>`-SampleTime` / 2 < `TI` < `SampleTime` / 2.<br>The integration is stopped. |
| 15 | `OutTrk` > `OutHiLim`<br>`OutTrk` < `OutLoLim` |
| 30 | The value of `In` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 32 | The value of `OutTrk` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 33 | The value of `TI` can no longer be displayed in the REAL number field. The integration is stopped. |

# 13.10 Lag - Low-pass filter

## 13.10.1 Description of Lag

### Object name (type + number) and family

Type + number: FB 1828

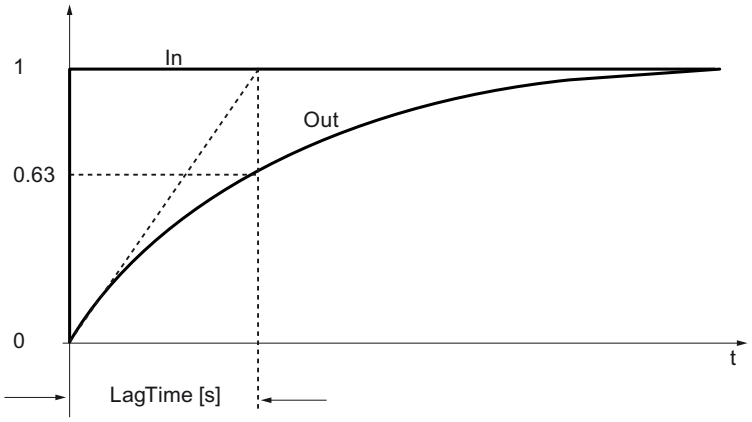
Family: Math

### Area of application for Lag

The block is used for the following application:

- Smoothing the Input value (low-pass filter)

### How it works



The block smoothes the input variable (`In` input) using a 1. order time delay. This delay time can be configured (`LagTime` connection). The block works according to the following formula:

$$Out_{(n)} = In_{(n)} + (Out_{(n-1)} - In_{(n)}) \cdot e^{\left(\frac{-SampleTime}{LagTime}\right)}$$

Where:

- `Out` = Output value
- `LagTime` = Delay time
- `SampleTime` = Sampling time
- `In` = Input value

The formula only applies to `LagTime` > 0. If `LagTime` = 0, the input is passed directly to the output. If the input value is outside the REAL range limits, the calculation is stopped. If the input value is outside the range limits again, the calculation is resumed automatically.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB3x). The block is also installed automatically in the startup OB (OB100).

Further addressing is not required.

For the Lag block, the Advanced Process Library contains templates for process tag types as examples and there is a example project (APL_Example_xx, xx designates the language variant) containing different application cases for this block. Several application cases are simulated in the example project and serve to explain how the block works.

Examples of process tag types:

- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- Model-based predictive control (ModPreCon) (Page 2849)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- Ratio control with PIDConR (RatioR) (Page 2839)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

Application scenario in the example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 13.10.3 Lag functions

### Functions of Lag

The functions for this block are listed below.

### Hold and restart calculation

You can interrupt the calculation by setting `Hold` = 1 . The output value is frozen. Continue calculation by setting `Hold` = 0 . The calculation is continued with the last output value.

### Reset values

You need to set the `Reset` = 1 I/O if you want to reset the output value back to the input value. The output is reset by a rising 0 - 1 edge.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `Out` output parameter:

- `In.ST`

# 13.11 MeanTime - Averaging

## 13.11.1 Description of MeanTime

### Object name (type + number) and family

Type + number: FB 1832

Family: Math

### Area of application for MeanTime

The block is used for the following applications:

- Averaging an analog value over a previous, definable period

### How it works

The MeanTime block is used to calculate the time-based mean value of an analog input signal `In` over a previous, definable period (`TimeWindow` input), according to the formula:

`Out` = (`In1` + ... + `Inn`) / (`TimeWindow` / `SampleTime`)

Where:

- `In1` ... `Inn` the n are the detected values used for averaging.
- The time window for the averaging is set at the `TimeWindow` parameter.
- The block determines the number of values to be saved based on the integer part of the `TimeWindow` / `SampleTime` quotient.
- The block can save up to 32 previous values in its internal memory. By interconnecting the `Mem` input parameter with the `Mem` output parameter of the MemR256 block, the memory size can be expanded to 256 previous values. If the time window is longer than memory spaces are available, an internal message is triggered in addition.

If `SampleTime` or `TimeWindow` is changed, the mean time value is reset.

The signal status is passed from the input parameter directly to the output parameter.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (all OB3x blocks). The block is also installed automatically in the startup OB (OB 100). When using the MemR256 block, the `Mem` output parameter of the MemR256 block must be interconnected with the `Mem` input parameter of the MeanTime block. The MemR256 block can be inserted in any cyclic interrupt level.

**Note**

The MemR256 block always uses one memory cell less than it is necessary for the time window `TimeWindow`, since the input In itself serves as the memory cell.For example: For a time window that requires 256 memory cells, the memory cell Mem.Val255 on the MemR256 block is not updated.

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

MeanTime functions (Page 2270)

MeanTime modes (Page 2269)

## 13.11.2 MeanTime modes

### MeanTime operating modes

This block does not have any operating modes.

### See also

MeanTime block diagram (Page 2274)
MeanTime I/Os (Page 2273)
MeanTime messaging (Page 2272)

MeanTime error handling (Page 2272)
MeanTime functions (Page 2270)
Description of MeanTime (Page 2268)

## 13.11.3 MeanTime functions

### Functions of MeanTime

The functions for this block are listed below.

### Stopping the calculation of mean values

Mean value calculation can be stopped by setting the `Hold` input. To do this, make the following parameter settings:

- `Hold` = 1 and calculation is stopped. The output value is retained for the duration of this period.
- `Hold` = 0 and calculation is resumed

If the hold functionality is active, the output `HoldAct` will be set by the block.

With `Feature.Bit5` Retain last output value in case of bad input signal status (Page 198), you can specify that the calculation of mean value is stopped and the last output value is retained if the signal status of `In` is bad (`In.ST` = 16#00 or 16#28). In this case, the block sets both the outputs `HoldAct` and `Inbad`.

### Setting a mean value constant

You can set the mean value using the `Reset` input. To do this, make the following parameter setting:

- `Reset` = 0 -> 1

The value at the `In` input is now set directly at the `Out` output. All internal values of the block are also adapted to the input value.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 5 | Retain last output value in case of bad input signal status (Page 198) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `Out` output parameter:

- `In.ST`

### Increasing the internal memory to 256 previous values

MeanTime can save up to 32 previous values internally. If the ratio of time window and sampling time gets too large, the number of internal memory slots can be expanded to 256 previous values by using the MemR256 block. To do so insert the MemR256 block into a CFC chart. Interconnect the `Mem` output parameter of the MemR256 block with the `Mem` input parameter of the MeanTime block. Each MeanTime block must be interconnected with its own separate MemR256 block. An internal averaging is automatically activated if the time window is still too large. You detect whether internal averaging is active at the `ExcessCnt` output parameter:

- `ExcessCnt` = 0: no internal averaging active.
- `ExcessCnt > 0`: : internal averaging active.
  Without MemR256: ExcessCnt = TimeWindow / SampleTime Div 32 + 1
  Where MemR256: ExcessCnt = TimeWindow / SampleTime Div 256 + 1

When internal averaging is activated, the `In.Value` input is summed using ExcessCnt values (SumIntern) and after ExcessCnt cycles the internal average is stored as a past value at a memory location (1..UsedBuffer). The current value of the `Out` output is then calculated as follows:

- Out:=( ExcessCnt * Sum + SumIntern) / (UsedBuffer * ExcessCnt + Index )
- UsedBuffer: TimeWindow / SampleTime Div ExcessCnt
- Sum: Sum of all storage locations (UsedBuffer)
- SumIntern: Sum of the internal average value from 1 to index
- Index: Running index from 1 to ExcessCnt

**Note**

The ratio of the time window and sampling time is limited internally to 25600. If the time window is set too large, an error number is output at the `ErrorNum` output parameter.

## 13.11.4 MeanTime error handling

### Error handling of MeanTime

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed. |
| 0 | There is no error. |
| 30 | The value of `In` can no longer be displayed in the REAL number field. The last valid value is provided at the `Out` output. |
| 31 | The value of `Out` can no longer be displayed in the REAL number field. The `In` value is output unmodified at the `Out` output. |
| 50 | The quotient TimeWindow / SampleTime is greater than 25600. The block calculates with a smaller time window, so that the quotient TimeWindow / SampleTime does not exceed the value 25600. |

## 13.11.6 MeanTime I/Os

I/Os of MeanTime

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `Feature` | I/O for additional functions (Page 2270) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| `Hold` | 1 = Hold calculation of mean value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `In*` | Analog input value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `Mem` | Input for Mem Block | ANY | - |
| `Reset` | 1 = Reset output `Out` | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `SampleTime` | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| `TimeWindow` | Size of the time window [s] | REAL | 32.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see MeanTime error handling (Page 2272) | INT | -1 |
| ExcessCnt | Counter for internal averaging;<br>0: no internal averaging. All values of In can be saved as previous values with the current TimeWindow.<br>x: internal averaging of In across x cycles. The internal averaging is saved as previous value. | INT | 0 |
| HoldAct | The block is on hold. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| InBad | 1 = Signal status of the analog input In is bad (16#00 or 16#28) | BOOL | 0 |
| Out | Output for the average time | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

# 13.12 Mul04 - Multiplier with 4 values

## 13.12.1 Description of Mul04

### Object name (type + number) and family

Type + number: FC 360

Family: Math

### Area of application for Mul04

The block is used for the following applications:

- Multiplication of values
- Output of the product for further processing

### How it works

The Mul04 block calculates the product of up to 4 values and returns the result at the `Out` output.

`Out` = `In1` ·...· `Inn` (n ≤ 4),

Where:

`Out` = Product

`In1` ... `In4` = values to be multiplied

The product of all input parameters and the worst input parameter signal status is always output.

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range, the highest or lowest possible REAL value is output.

If the value is not a number `(#NaN)`, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Mul04 block, the Advanced Process Library contains templates for process tag types as examples and there is a example project (APL_Example_xx, xx designates the language variant) containing an application case for this block. An application case is simulated in the example project and serves to explain how the block works.

Examples of process tag types:

- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)

- Model-based predictive control (ModPreCon) (Page 2849)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Ratio control with PIDConR (RatioR) (Page 2839)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

Application scenario in the example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### Functions of Mul04

The functions for this block are listed below.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The worst signal status for the block is formed by the following parameters and output at the `Out` output parameter:

- `In1.ST`
- `In2.ST`
- `In3.ST`
- `In4.ST`

# 13.13 Mul08 - Multiplier with 8 values

## 13.13.1 Description of Mul08

### Object name (type + number) and family

Type + number: FC 361

Family: Math

### Area of application for Mul08

The block is used for the following applications:

- Multiplication of values
- Output of the product for further processing

### How it works

The Mul08 block calculates the product of up to 8 values and returns the result at the `Out` output.

`Out` = `In1` ·...· `Inn` (n ≤ 8),

Where:

`Out` = Product

`In1` ... `In8` = values to be multiplied

The product of all input parameters and the worst input parameter signal status is always output.

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range, the highest or lowest possible REAL value is output.

If the value is not a number `(#NaN)`, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Mul04 (Mul08) block, the Advanced Process Library contains process tag type templates; these serve as examples by providing various application scenarios for this block.

Refer to Description of Mul04 (Page 2275) for more information.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

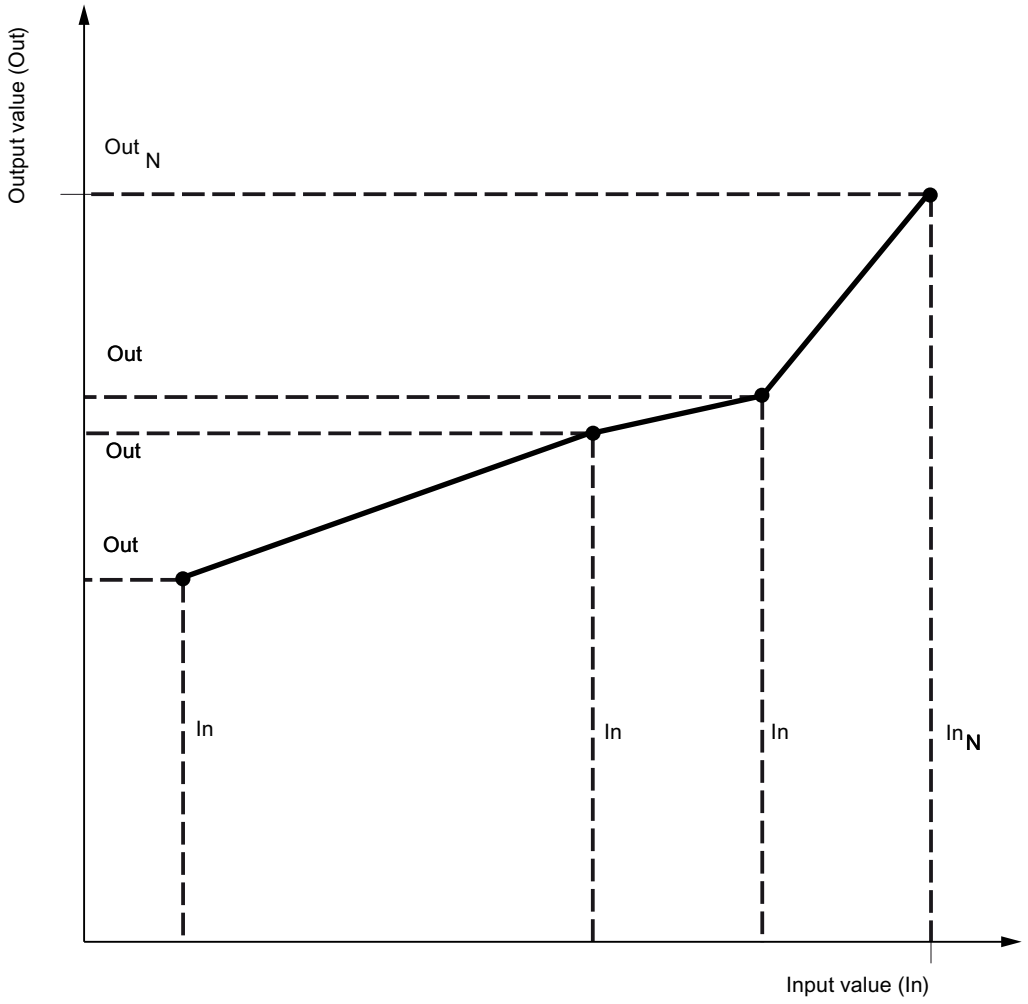
# 13.14 Polygon - Converting the first signal (non-linear)

## 13.14.1 Description of Polygon

### Object name (type + number) and family

Type + number: FB 1881

Family: Math



### Area of application for Polygon

The block is used for the following applications:

- Conversion of the input signal according to a non-linear characteristic

### How it works

An input `In` is converted to output `Out` based on a non-linear characteristic with up to 16 interpolation points per polygon block. The number of interpolation points can be increased by cascading multiple blocks. In cascade mode, the `Cascaded = 1` output is set.

| | |
|---|---|
| Num (N) | - Number of intermediate points in the curve<br>Minimum number of points = 2<br>Maximum number of points = 16 |
| In | - Analog input value |
| Out | - Corresponding output value |

After you have defined the N interpolation points (coordinate pairs $In_i$, $Out_i$ with i = 1 ... N in a sequence with no gaps) and configured the number Num, the block operates as follows:

- Interpolation between the interpolation points is linear
- Beyond the end interpolation points, extrapolation is based on the first two or last two interpolation points.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

## Configuration

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38). The block is installed automatically in OB100.

**Cascade mode**

For the cascading of multiple polygon blocks, the `CasOut` output is interconnected to the `CasIn` input of the following block.

In cascade mode, the interpolation points in all polygon blocks must be configured in ascending order and without gaps. The cascaded polygon blocks must be configured in the same runtime group in ascending run sequence.

The analog input value `In` may only be interconnected at the first polygon block. The `In` input of the next block is tracked to this value.

For the Polygon block, the Advanced Process Library contains templates for process tag types as an example with various application scenarios for this block.

Example of process tag types:

- Source chart for GainSched function block (gain scheduling) (Page 2845)

## Startup characteristics

The block does not have any startup characteristics.

## Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Polygon functions (Page 2290)

Description of Polygon (Page 2287)

## 13.14.3 Polygon functions

### Functions of Polygon

The functions for this block are listed below.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `Out` output parameter:

- `In.ST`

### Configurable reactions using the `Feature` parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in the section Configurable functions with the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 5 | Limit output Out (Page 154) |
| 6 | Substitute value switch in the event of an error (Page 160) |

### Cascading

- Specifying the number of interpolation points
  When n polygon blocks are cascaded, the interpolation points can be increased by the number set for the Num parameter. The configuration of the interpolation points over all cascaded blocks is subject to the same configuration rules as for an individual block, i.e. the interpolation points must be configured in sequence in ascending order and without gaps.
- Data communication
  The data communication 2 interconnected polygon blocks is made using an output -> input interconnection.

Description of Polygon (Page 2287)

Polygon messaging (Page 2292)

Polygon I/Os (Page 2293)

Polygon block diagram (Page 2296)

Polygon error handling (Page 2291)

Polygon modes (Page 2290)

## 13.14.4 Polygon error handling

### Error handling of Polygon

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |
| 30 | The value In or SubV_In can no longer be displayed in the REAL- number field. The last valid value is provided at the Out output. |
| 31 | The calculation of the output Out leads to a result that can no longer be displayed in a REAL- numerical field. The last valid value is provided at the Out output. |
| 48 | No valid interconnection to CasIn. The last valid value is provided at the Out output. |

| Error number | Meaning of the error number |
|---|---|
| 49 | `Num` < 2 or `Num` > 16<br>$In_{(N)} \leq In_{(N-1)}$, in the event of an error, the last valid value is output |
| ≥ 1xx | Error in one of the upstream `xx = ErrorNum` block. The last valid value is provided at the `Out` output. |

**Note**

The substitute value `SubV_In` can be output instead of the last valid value via the `Feature.Bit6` = 1 .

Substitute values that cannot be displayed in the REAL- number format have no effect. The last valid value is provided at the `Out` output in this case.

# 13.15 Smooth - Low pass filter

## 13.15.1 Description of Smooth

### Object name (type + number) and family

Type + number: FB 1890

Family: Math

### Area of application for Smooth

The block is used for the following applications:

- Butterworth low-pass filter, 2nd order with maverick detection

### How it works

The block is used as a low pass filter. This filter allows the signal portions with frequencies below the cutoff frequency to pass practically unattenuated, whereas portions with high frequencies are attenuated. The enables you filter out high frequency interference in the signal (for example, signal noise) and smooth the signal.

In comparison to a first order low pass filter, the Butterworth filter has the advantage that the transition from the passing section to the blocking section is sharper in the Bode diagram. If the frequency area of the interference is known, it can be filtered out with minimal influence on the wanted signal.

The maverick (Page 2885) detection monitors adjacent signals. If signal mavericks are detected, they are not processed any further. The block outputs the last valid signal.

The signal status is passed from the input directly to the output.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

You then set the filter time constant for the low pass filter to achieve the desired effect.

To set the filter time constant, it is helpful to observe the original and filtered signals in the CFC trend plotter. The filtered signal should be smoothed as required but not too delayed. An increase in the filter time constant increases the smoothing effect but also increases the delay. Typical starting values for the time constant are around ten times the sample rate of the signal.

There is a sample project for the Smooth block (APL_Example_xx, xx refers to the language variant) with an application case for this block:

- Filtering of noisy measured values in a control loop (SigSmoothSim) (Page 2877)

### Startup characteristics

When OB100 is called, the state variables of the Butterworth filter are initialized based on the current process values.

### Status word allocation for `Status1` parameter

The block does not have a status word allocation.

Smooth functions (Page 2298)
Description of Smooth (Page 2297)

## 13.15.3 Smooth functions

### Smooth functions

The block provides the following functions:

- Restart low pass filter
- Activate and deactivate maverick detection

### Restart low pass filter

You can recalculated the coefficients of the Butterworth filter. To do this, you must restart filter (`Restart` = 1).

The filter algorithm is then reinitialized, exactly as it is when the CPU is restarted or a change is made to the count value at the input parameter `TimeConstant`. The coefficients of the Butterworth filter are recalculated and the internal state memory of the filter is initialized so that the `CleanPV` output parameter is equal to the `PV` input parameter.

### Activate and deactivate maverick detection

The maverick detection (`OutlDetOn` = 1) monitors the process value `PV` for the difference between two sequential sample values. These have to be within a tolerance range you have specified (`OutlTreshold`).

If the tolerance is violated, the maverick is set to the most recent valid value. The most recent valid measured value is then held constant by the block for a maximum of `OutlCycles` sample steps. If the maverick continues longer than this, it is accepted as a valid measured value.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for mathematical blocks (Page 126).

The signal status for the block is formed using the following parameters and output at the `CleanPV` output parameter:

- `PV.ST`

## 13.15.4 Smooth error handling

### Error handling of Smooth

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 2 | `SampleTime` < 0.001 [s] |
| 30 | The value of `PV` can no longer be displayed in the REAL number field. The last valid value is provided at the `CleanPV` output. |
| 61 | `TimeConstant` < 5 · `SampleTime` |
| 62 | `TimeConstant/SampleTime` > 1000<br>If there is a parametrization error because `ratio = TimeConstant/SampleTime > 1000`, move the function block into another SIMATIC OB with a slower sample time, preferably into the slowest cycle OB30 and recompile the CFC. If this is still not sufficient, you can set the reduction ratio of the CFC runtime group in which the Smooth function block is called. |

### I/Os of Smooth

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | This parameter currently has no use and is reserved for future functions. | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| FilterOn | 1 = Filter active | BOOL | 1 |
| OutlCycles | Number of sampling steps to bridge mavericks | INT | 3 |
| OutlDetOn | 1 = Maverick detection is activated | BOOL | 0 |
| OutlThreshold | Limit (trigger threshold) for maverick detection | REAL | 10.0 |
| PV* | Analog input (process value) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Restart* | Restart the filter algorithm | BOOL | 1 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 1.0 |
| TimeConstant | Butterworth filter time constant [s] | REAL | 10.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| CleanPV | Output of the corrected process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum* | Output of current error number. For error numbers that can be output by this block, see Smooth error handling (Page 2299). | INT | 0 |
| OutlDetected | 1 = Maverick detected | BOOL | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

# 13.16 SqrRoot - Derive the root of a value

## 13.16.1 Description of SqrRoot

### Object name (type + number) and family

Type + number: FC 394

Family: Math

### Area of application for SqrRoot

The block is used to derive the root from a value as follows:

- `Out.Value = SquareRoot(In.Value)`

### How it works

The input value is checked as to whether it is within the REAL value range and is not negative.

- If the input value is not a number (`#NaN`), the last valid output value is displayed at the output. If the input status is not 16#00, the status of the output value is set to 16#28 and `ErrorNum` is set to 30
- If the input value is negative, the last valid output value is displayed at the output. If the input status is not 16#00, the status of the output value is set to 16#28 and `ErrorNum` is set to 30
- If the input value is positive infinity, the the greatest REAL value is displayed at the output. If the input status is not 16#00, the status of the output value is set to 16#28 and `ErrorNum` is set to 30
- 
- The status of the output value is set to 16#28 (if the input status is not below this). ErrorNum is also set to 30.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 13.17 Sub02 - Subtracting two values

## 13.17.1 Description of Sub02

### Object name (type + number) and family

Type + number: FC 381

Family: Math

### Area of application for Sub02

The block is used for the following applications:

- Subtracting two values

### How it works

The block subtracts one value from another and outputs the subtraction at the `Out` output parameter as follows:

- `Out` = `In1` - `In2`

The worst signal status is also always output at the output parameter.

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range, the highest or lowest possible REAL value is output.

If the value is not a number `(#NaN)`, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Sub02 block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Source chart for GainSched function block (gain scheduling) (Page 2845)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- Override control (Page 2846)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 13.18 PowerXY - General power function

## 13.18.1 Description of PowerXY

### Object name (type + number) and family

Type + number: FC 392

Family: Math

### Area of application for PowerXY

The block is used for the following applications:

- Raise one value to the power of another value
- Output of the calculation for further processing

### How it works

This block calculates the output by raising the input variable `In1` to the power of the input variable `In2`.

```
Out = In1^In2
```

The following equation is used for the calculation:

```
If In1 > 0 THEN
Out: = EXP (In2 * LN (In1));
ELSE
Out: = 0;
END_IF;
```

Where:

`In1` = Input value 1

`In1` = Input value 2

`Out` = Output value

`EXP(IN)` = e to the power IN

`LN` = Natural logarithm

The output value is checked to determine if it is within the value range of REAL. If it is outside the value range or If the value is `#NaN`, the last valid output value is output and the status of the output value is set to 16#28 (if none of the input statuses is worse).

If the input parameter is `In1 < =0`, the output value is set to zero until another calculation is permitted mathematically. The worst signal status is also always output at the output parameter.

You can find additional information on forming the signal status under Forming and outputting the signal status for mathematical blocks (Page 126)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# Analog logic blocks

# 14

## 14.1 CompAn02 - Comparison of two analog values

### 14.1.1 Description of CompAn02

#### Object name (type + number) and family

Type + number: FC 387

Family: LogicAn

#### Area of application for CompAn02

The block is used for the following applications:

- Comparison of the analog input values `In1` and `In2`

#### How it works

The block compares the two analog input values `In1` and `In2` to see if they are "less than", "less than or equal to", "greater than", "greater than or equal to" and "equal".

There is an independent result output parameter for every comparison operation.

These outputs are formed as follows.

- `GT.Value = 1`, if `In1` > `In2`
- `GE.Value = 1`, if `In1` ≥ `In2`
- `EQ.Value = 1`, if `In1` = `In2`
- `LT.Value = 1`, if `In1` < `In2`
- `LE.Value = 1`, if `In1` ≤ `In2`

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

Further addressing is not required.

#### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### See also

CompAn02 block diagram (Page 2323)

## 14.1.3 CompAn02 functions

### Functions of CompAn02

The functions for this block are listed below.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status of analog logic blocks (Page 120).

### See also

Description of CompAn02 (Page 2319)

CompAn02 block diagram (Page 2323)

## 14.1.4 CompAn02 error handling

### CompAn02 error handling

The block does not report any errors.

### Behavior of the block leaving the REAL number field

If one of the two input parameters `In1` or `In2` is outside the REAL number field, it is treated like a REAL number.

### Example

- `In1 = #e+INF` and `In2 < #e+INF: GT/GE := 1`, the other output parameters are then 0
- `In1 = #e-INF` and `In2 > #e-INF: LT/LE := 1`, the other output parameters are then 0
- `In1 = #NAN#` or `In2 = #NAN#:` all output parameters are set to 0

## 14.1.6 CompAn02 I/Os

### CompAn02 I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `In1` | Analog input value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `In2` | Analog input value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `ENO` | 1 = Block algorithm completed without errors | BOOL | 0 |
| `EQ` | 1= `In1` = `In2` | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| GE | 1 = In1 ≥ In2 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| GT | 1 = In1 > In2 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| LE | 1 = In1 ≤ In2 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| LT | 1 = In1 < In2 | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |

# 14.2 Limit - Limiting an analog value

## 14.2.1 Description of Limit

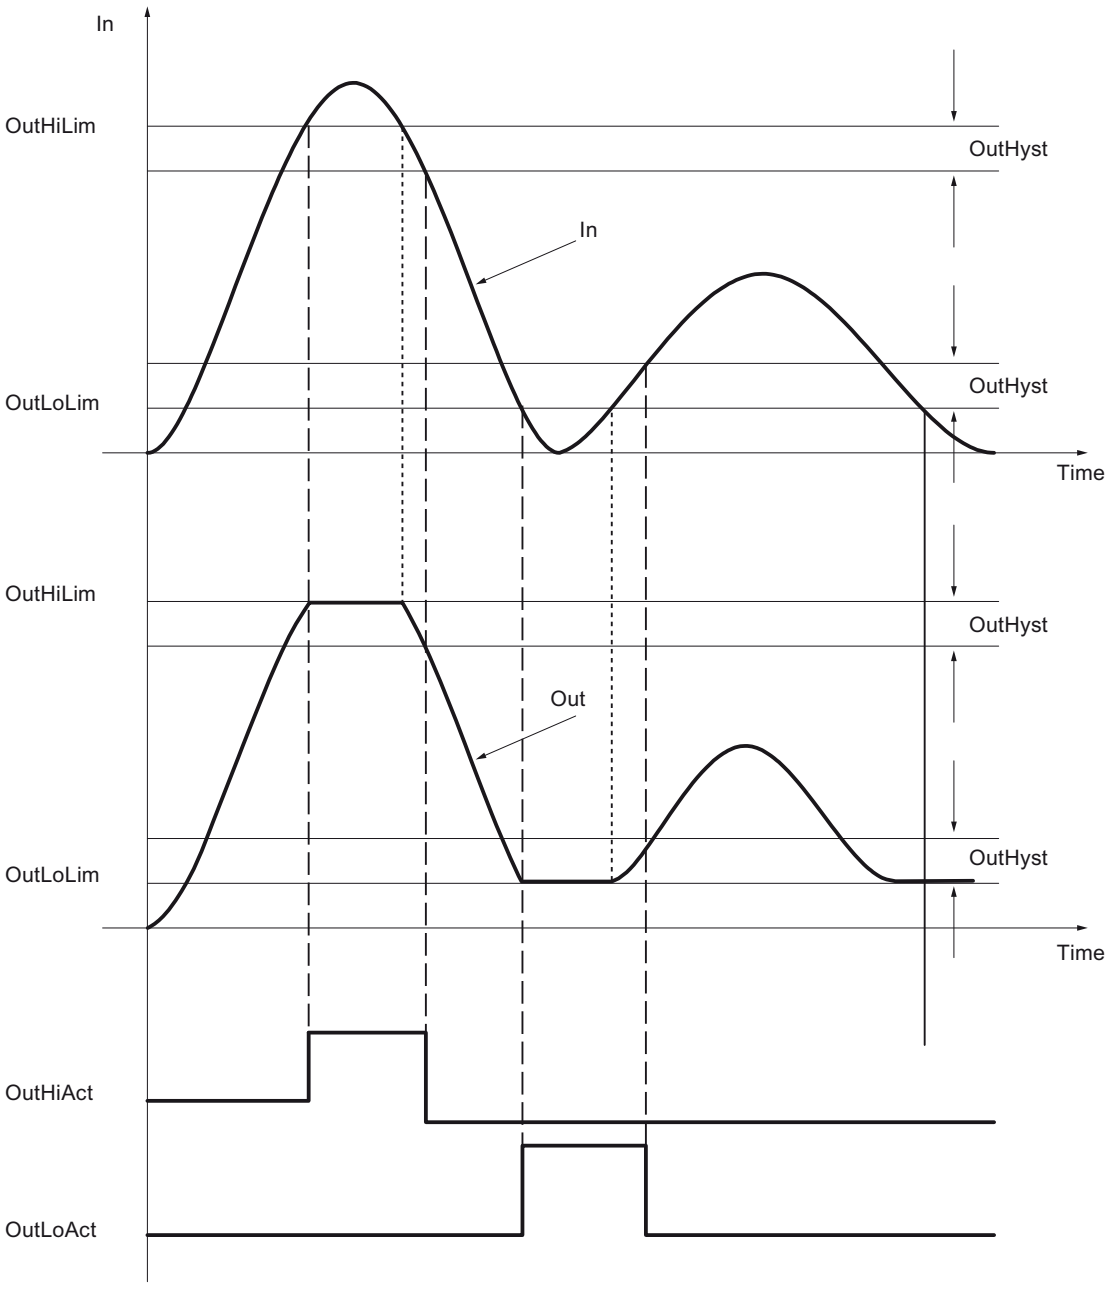
### Object name (type + number) and family

Type + number: FB 1829

Family: LogicAn

### Area of application for Limit

The block is used for the following applications:



- Limiting of values

### How it works

The Limit block is used to limit an analog value to an adjustable range.

The limits are set at the `OutHiLim` (high limit) and `OutLoLim` (low limit) input parameters. If a limit is violated, the limit you entered is output. The limit violation is also shown at the two output parameters `OutHiAct` (high) or `OutLoAct` (low).

You can configure hysteresis (`OutHyst` input parameter) to suppress signal flutters close to the limits.

| Active conditions for setting limit values | Active conditions for resetting limit values |
|---|---|
| High limit active: In >= OutHiLim | High limit active: In < OutHiLim - OutHyst |
| Low limit active: In <= OutLoLim | Low limit active: In > OutLoLim + OutHyst |

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

Further addressing is not required.

### Startup characteristics

The block does not have any startup characteristics.

A startup behavior can be reached with a connection of the input parameter `Init` to the output parameter `InitOut` of the Trigger block. For more information, refer to Startup characteristics over Trigger block (Page 75).

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

Limit functions (Page 2326)

Description of Limit (Page 2324)

## 14.2.3 Limit functions

### Functions of Limit

The function for this block is listed below.

### Initialization

With the input parameter `Init`, the output parameters `OutHiAct` and `OutLoAct` can be initialized:

- `Init` = 0 (default): Normal limitation behavior
  If the input parameter `In` is in the hysteresis range, the output parameters `OutHiAct` and `OutLoAct` will remain unchanged.
- `Init` = 1:
  If the input parameter `In` is in the hysteresis range, the output parameters `OutHiAct` and `OutLoAct` will be reset.

To initialize the output parameters `OutHiAct` and `OutLoAct` after a startup, connect the input parameter `Init` with the output parameter `InitOut` of the Trigger block. For more information, refer to Startup characteristics over Trigger block (Page 75).

## 14.2.6 Limit I/Os

### I/Os of Limit

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 2326) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| In | Analog input value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Init | Initialize function block | BOOL | 0 |
| OutHyst* | Hysteresis in % | REAL | 0.0 |
| OutHiLim | High limit of output value | REAL | 100.0 |
| OutLoLim | Low limit of output value | REAL | 0.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see Limit error handling (Page 2327) | INT | -1 |
| Out | Analog output value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OutHiAct | 1 = High limit overshoot | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OutLoAct | 1 = Low limit undershoot | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

# 14.3 MuxAn03 - Selection of an analog value to increase availability / safety

## 14.3.1 Description of MuxAn03

### Object name (type + number) and family

Type + number: FB 1860

Family: LogicAn

### Area of application for MuxAn03

The block is used for the following applications:

- Selection of an analog value to increase availability or safety in the input of analog values

### How it works

The block uses up to three process values `PV1` ... `PV3` to determine an output value and outputs this with the corresponding signal status at the `PV` output parameter.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any special startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### See also

MuxAn03 error handling (Page 2334)
MuxAn03 functions (Page 2331)
Description of MuxAn03 (Page 2330)

## 14.3.3 MuxAn03 functions

### Functions of MuxAn03

The functions for this block are listed below.

### Selection of output signal

Use the `SelValue` input parameter to select whether the output value is to offer higher availability or higher safety.

### Increasing availability

- **Selection 1 of 2** (SelValue = 0):The block determines the input parameter with the higher priority from the two input parameters PV1 and PV2 based on their signal status. The value determined is written to the PV output parameter.
  If both input parameters have the same signal status, the PV1input parameter is written to the PVoutput parameter.
  **Display of process parameters with bad signal status**
  If the signal status of PV1 is bad (16#00, 16#28), the PV1Bad output is set.
  If the signal status of PV2 is bad (16#00, 16#28), the PV2Bad output is set.
  Regardless of PV3, the PV3Bad output is always set to 0.
  **Mean, median, maximum and minimum**
  They are determined from PV1 and PV2:
  - PV_Mean = (PV1 + PV2) /2
  - PV_Median = PV1
  - PV_Max = Max(PV1, PV2)
  - PV_Min = Min(PV1, PV2)

  The status is formed by PV1.ST and PV2.ST. If the status is the same, it is output at PV_Mean.ST, PV_Median.ST, PV_Max.ST and PV_Min.ST. If the statuses are different, the status with the lower priority is output.
- **Selection 1 of 3** (SelValue = 1): The block determines the input parameter with the highest priority from the three input parameters PV1, PV2 and PV3 based on their signal status. The value determined is written to the PV output parameter.
  If two or more of the input parameters have the same signal status, the one with the lowest index is written to the PV output parameter.
  **Display of process parameters with bad signal status**
  If the signal status of PV1 is bad (16#00, 16#28), the PV1Bad output is set.
  If the signal status of PV2 is bad (16#00, 16#28), the PV2Bad output is set.
  If the signal status of PV3 is bad (16#00, 16#28), the PV3Bad output is set
  **Mean, median, maximum and minimum**
  They are determined from PV1, PV2 and PV3:
  - PV_Mean = (PV1 + PV2 + PV3) /3
  - PV_Median = mean PV value of PV1, PV2 and PV3. If 2 of the 3 PV values are the same, the value of the same PVs is output as the mean PV value
    Examples:
    PV1 =1, PV2 =2, PV3 =3: thus PV_Median =2.
    PV1 =1, PV2 =1, PV3 =3: thus PV_Median =1.
  - PV_Max = Max(PV1, PV2, PV3)
  - PV_Min = Min(PV1, PV2, PV3)
    The status is formed by PV1.ST, PV2.ST and PV3.ST. If the status is the same, it is output at PV_Mean.ST, PV_Max.ST and PV_Min.ST. If the statuses are different, the status with the second highest priority is output.

## Increasing safety

- **Selection 2 of 2** (SelValue = 2): The block determines whether the two input parameters PV1 and PV2 have the same signal status and whether they deviate from one another by no more than the setting at input parameter PlDiff. Only then does the PV output parameter also have this signal status. The analog value of PVis set to a value of PV1. If PV1 and PV2 deviate from one another by more than PlDiff, the PV signal status is set to "Bad, device-related". The analog value of PVis set to a value of PV1.
  If PV1 and PV2 do not deviate from one another by more than PlDiff, but have a different signal state, the PV output parameter is generated from the lower priority signal status of the two input parameters and the associated analog value.
  **Display of non-plausible or bad process parameters**
  If the process value PV1 is non-plausible or bad (16#00, 16#28), the PV1Bad output is set.
  If the process value PV2 is non-plausible or bad (16#00, 16#28), the PV2Bad output is set.
  Regardless of PV3, the PV3Bad output is always set to 0
  **Mean, median, maximum and minimum**
  They are determined from PV1 and PV2. If PV1 and PV2 deviate from one another by more than PlDiff, the signal status of PV_Mean, PV_Median, PV_Max and PV_Min is set to "Bad, device-related" (16#00) and the process values of PV_Mean, PV_Median, PV_Max and PV_Min are frozen. If the absolute deviation is less than or equal to PlDiff, the mean value, maximum and minimum are calculated as follows:
  - PV_Mean = (PV1 + PV2) /2
  - PV_Median = PV1
  - PV_Max = Max(PV1, PV2)
  - PV_Min = Min(PV1, PV2)

  The status is formed by PV1.ST and PV2.ST. If the status is the same, it is output at PV_Mean.ST, PV_Max.ST and PV_Min.ST. If the statuses are different, the status with the lower priority is output.
- **Selection 2 of 3** (SelValue = 3): The block determines whether two of the three input parameters PV1, PV2 and PV3 have the same high priority signal status and whether they deviate from one another by no more than the setting at input parameter PlDiff. Only if this is the case, does the PV output parameter also have this signal status. The analog value of PV is set to the value of the input parameter with the lowest index (PV1 or PV2) of the values determined.
  If all input parameters PV1, PV2 and PV3 deviate from one another by more than PlDiff, the signal status of PV is set to "Bad, device-related". The analog value of PVis set to the value of the PV1 input parameter.
  If at least two input parameters do not deviate from one another by more than PlDiff, but have a different signal state, the value from these input parameters with the signal status of the second highest priority is written to the PV output parameter.
  **Display of non-plausible or bad process parameters**
  If the process value PV1 is non-plausible or bad (16#00, 16#28), the PV1Bad output is set.
  If the process value PV2 is non-plausible or bad (16#00, 16#28), the PV2Bad output is set.
  If the process value PV3 is non-plausible or bad (16#00, 16#28), the PV3Bad output is set.
  **Mean value, maximum and minimum**
  They are determined from PV1, PV2 and PV3. An internal mean value is calculated first from PV1, PV2 and PV3.
  This mean value is used to determine the deviations for each PV value. If all absolute deviations are less than or equal to PlDiff, the mean, median, maximum and minimum are

formed from PV1, PV2 and PV3 and the status with the second highest priority is output (see section Increasing availability, selection 1 to 3).
If at least one of the deviations is outside of PlDiff, the PV with the greatest deviation is excluded from further calculation.
If the two remaining process values (PVx1, PVx2) deviate from one another by more than PlDiff, the signal status of PV_Mean, PV_Median, PV_Max and PV_Min is set to "Bad, device-related" (16#00) and the process values of PV_Mean, PV_Median, PV_Max and PV_Min are frozen. If the absolute deviation is less than or equal to PlDiff, the mean value, maximum and minimum are calculated as follows:

- PV_Mean = (PVx1 + PVx2) /2
- PV_Median = PVx1
- PV_Max = Max(PVx1, PVx2)
- PV_Min = Min(PVx1, PVx2)

The status is formed by PVx1.ST and PVx2.ST. If the status is the same, it is output at PV_Mean.ST, PV_Median, PV_Max.ST and PV_Min.ST. If the statuses are different, the status with the lower priority is output.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for blocks with configurable status prioritization (Page 122).

Description of MuxAn03 (Page 2330)

## 14.3.4 MuxAn03 error handling

### MuxAn03 error handling

Parameter assignment errors are handled as follows:

- If the input parameter is SelValue < 0, the parameter is automatically set to SelValue = 0.
- If the input parameter is SelValue > 3, the parameter is automatically set to SelValue = 3 .
- If the input parameter is SelPrio < 0, the parameter is automatically set to SelPrio = 0 .
- If the input parameter is SelPrio > 7, the parameter is automatically set to SelPrio = 7 .

An error number is not output in any of these cases.

# 14.4 MuxAn08 - Selection of an analog value to increase availability / safety

## 14.4.1 Description of MuxAn08

### Object name (type + number) and family

Type + number: FB 1831

Family: LogicAn

### Area of application of MuxAn08

The block is used for the following applications

- Selection of an analog value to increase availability or safety in the input of analog values

### How it works

The block uses up to eight `PV1 ... PV8` process values to determine an output value and outputs this with the corresponding signal status at the PV output parameter.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any special startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

## 14.4.2 MuxAn08 modes

### MuxAn08 operating modes

This block does not have any operating modes.

## 14.4.3 MuxAn08 functions

### Functions of MuxAn08

The functions for this block are listed below.

### Selection of output signal

Use the `SelValue` input parameter to select whether the output value is to offer higher availability or higher safety.

### Increasing availability

- **Selection 1of 2, 1 of 3, ... 1 of 8** (`SelValue` = 0..6):
  The input parameter `SelValue` defines the relevant input parameters of the process values to be considered for the determination of PV.

| SelValue | Relevant input parameter | Irrelevant input parameter |
|---|---|---|
| 0 | PV1..PV2 | PV3..PV8 |
| 1 | PV1..PV3 | PV4..PV8 |
| 2 | PV1..PV4 | PV5..PV8 |
| 3 | PV1..PV5 | PV6..PV8 |
| 4 | PV1..PV6 | PV7..PV8 |
| 5 | PV1..PV7 | PV8 |
| 6 | PV1..PV8 | - |

The block determines the highest priority of the two input parameters from the relevant input parameters based on their signal status on and writes it to the output parameter PV.
If several input parameters have the same level of signal status priority, the one with the lowest index is written to the output parameter.
**Display of process parameters with "bad" signal status**
When the relevant input parameters (`PV1`, `PV2`, .., `PV8`) have a "bad" signal status (`16#00` or `16#28`), the corresponding output parameters (`PV1Bad`, `PV2Bad`..`PV8Bad`) are set. The output parameters of the irrelevant input parameters are always reset.
**Mean value, maximum and minimum**

- PV_Mean = (PV1 + PV2 + ... +PVn) / n
- PV_Max = Max(PV1, PV2... PVn)
- PV_Min = Min(PV1, PV2... PVn)
  n depends on SelValue
  The status is formed from the `PV1..PV`n input parameters. If the status is the same, it is output at the `PV_Mean`, `PV_Max` and `PV_Min` output parameters. If the states are different, the status with the second highest priority is output at the `PV_Mean`, `PV_Max` and `PV_Min` output parameters.

## Increasing safety

- **Selection 2 of 2..8** (`SelValue` = 7..13):
  The input parameter `SelValue` defines the relevant input parameters of the process values to be considered for the determination of PV.

| SelValue | Relevant input parameter | Irrelevant input parameter |
|---|---|---|
| 7 | PV1..PV2 | PV3..PV8 |
| 8 | PV1..PV3 | PV4..PV8 |
| 9 | PV1..PV4 | PV5..PV8 |
| 10 | PV1..PV5 | PV6..PV8 |
| 11 | PV1..PV6 | PV7..PV8 |
| 12 | PV1..PV7 | PV8 |
| 13 | PV1..PV8 | - |

The block determines whether two of the relevant input parameters have the same level of signal status priority and whether they deviate from one another by no more than the setting at input parameter `PlDiff`. Only then does the `PV` output parameter also have this signal status. The analog value of `PV` is set to the value of the input parameter with the lowest index of the values determined.
If all input parameters deviate from one another by more than `PlDiff`, the signal status of `PV` is set to "Bad, device-related". The analog value of `PV`is set to the value of the `PV1` input parameter.
If the least two input parameters do not deviate from one another by more than `PlDiff`, but have a different signal state, the value with the signal status of the second highest priority from these input parameters is written to the `PV` output parameter.
**Display of process parameters with "bad" signal status**
When the relevant input parameters (`PV1`, `PV2`, .., `PV8`) are not plausible or have a "bad" signal status (`16#00` or `16#28`), the corresponding output parameters (`PV1Bad`, `PV2Bad`..`PV8Bad`) are set. The corresponding output parameters of the irrelevant input parameters are always reset.
**Mean value, maximum and minimum**
The `PV` values are plausible if the absolute values of the deviation are less than or equal to the `PlDiff`.
If the absolute deviation is less than or equal to `PlDiff`, the mean value, maximum and minimum are calculated as follows:

1. Determination of the mean from `PV1.. PV`n
   `n` depends on `SelValue`
2. Determination of the deviations `ABS(PVi` − Mean value)
3. If all `PV` are plausible, then the mean, maximum and minimum are determined, as described in section "Increasing availability `SelValue = 0..6`".

4. If one or more PV are not plausible, repeat the calculation of the mean starting with 1. without PV input with the highest deviation. If there is more than one PV input with equally high deviation, only the first PV input is not used for further calculation.
5. If only 2 PV inputs remain and they are plausible, then the mean, maximum and minimum are determined, as described in section "Increasing availability SelValue = 0". When they are not plausible, the mean value, maximum and minimum are determined as follows:

```
PV_Max.Value: Keep old value
PV_Min.Value: Keep old value
PV_Mean.Value: Keep old value
PV_Max.ST = 16#00;
PV_Min.ST = 16#00;
PV_Mean.ST = 16#00;
```

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for blocks with configurable status prioritization (Page 122).

## 14.4.4 MuxAn08 error handling

### Error handling of MuxAn08

Parameter assignment errors are handled as follows:

- If the input parameter is SelValue < 0, the parameter is automatically set to SelValue = 0.
- If the input parameter is SelValue > 13, the parameter is automatically set to SelValue = 13 .
- If the input parameter is SelPrio < 0, the parameter is automatically set to SelPrio = 0 .
- If the input parameter is SelPrio > 7, the parameter is automatically set to SelPrio = 7 .

An error number is not output in any of these cases.

## 14.4.5 MuxAn08 messaging

### Messaging

This block does not offer messaging.

## 14.4.6 MuxAn08 I/Os

I/Os of MuxAn08

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| PV1 | Process value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV2 | Process value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV3 | Process value 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV4 | Process value 4 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV5 | Process value 5 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV6 | Process value 6 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV7 | Process value 7 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV8 | Process value 8 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PlDiff | Plausibility check value | REAL | 0.0 |
| SelPrio* | Setting of the prioritization for forming the best signal status | INT | 6 |
| SelValue* | Selection criterion for the search | INT | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| PV | Process value determined | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_Mean | Process value mean | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Max | Process value maximum | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV_Min | Process value minimum | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PV1Bad | Process value PV1 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV2Bad | Process value PV2 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV3Bad | Process value PV3 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV4Bad | Process value PV4 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV5Bad | Process value PV5 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV6Bad | Process value PV6 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV7Bad | Process value PV is not plausible or bad (16#00 or 16#28) | BOOL | 0 |
| PV8Bad | Process value PV8 is not plausible or bad (16#00 or 16#28) | BOOL | 0 |

## 14.4.7 MuxAn08 block diagram

### MuxAn08 block diagram

A block diagram is not provided for this block.

# 14.5 RateLim - Signal ramp

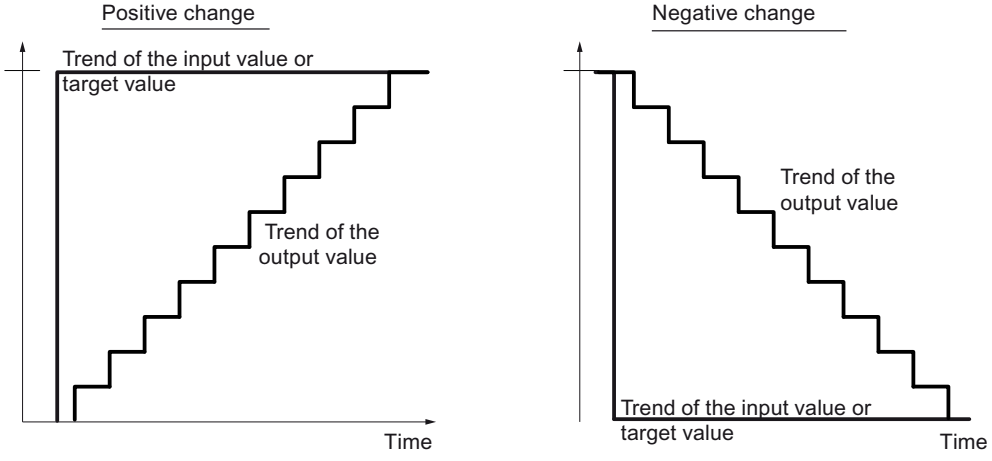
## 14.5.1 Description of RateLim

### Object name (type + number) and family

Type + number: FB 1882

Family: LogicAn

### Area of application for RateLim



The block is used for the following applications:

- Limitation of the slope of an analog signal
- Ramped approach to a target value

### How it works

Slope limit: Starting from the current output value, the new output value is calculated in such a way that it does not exceed a specified positive or negative slope.

Ramp function: The current output value can be ramped up to a target value. The ramp slope can be configured by a time period or by a positive or negative ramp slope.

The input value is forwarded directly when the gradient and ramp function are switched off (`RmpOn.Value = 0`, `RateOn.Value = 0`): `Out.Value = In.Value`.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB3x). The block is then installed automatically in startup OB (OB100).

Further addressing is not required.

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

RateLim functions (Page 2345)

RateLim error handling (Page 2348)

RateLim functions (Page 2345)

Description of RateLim (Page 2344)

## 14.5.3 RateLim functions

### Functions of RateLim

The functions for this block are listed below.

### Limitation of the slope of the analog signal `In.Value`

The block calculates the gradient of the input signal over time and compares it with the `UpRaLim` (positive change) `DnRaLim` (negative change) limits. See the table below.

- If the slope exceeds the amount of the respective limit (`UpRaLim` or `DnRaLim`), the output `Out` is corrected only by the valid limit and the corresponding limit display `UpRaAct` = 1 or `DnRaAct` = 1 is set.
- If the gradient is within the valid range, the input value is transferred (`In` = `Out`) and `UpRaAct` = 1 or `DnRaAct` = 1 are reset.
- If the corresponding limit is 0 (`UpRaLim` with positive gradient or `DnRaLim` with negative gradient), then the input value `In` is written directly to the output `Out`.

| RateOn | ΔIn / Δt | Meaning | Output `Out` | UpRaAct | DnRaAct |
|---|---|---|---|---|---|
| 1 | < \|`DnRaLim`\| | Input value dropping too fast | `Out` - (\|`DnRaLim`\| · `SampleTime`) * Time factor | 0 | 1 |
| 1 | \|`DnRaLim`\| to `UpRaLim` | Change speed `In` is permitted | `In` | 0 | 0 |
| 1 | > \|`UpRaLim`\| | Input value `In` rising too fast | `Out` + (\|`UpRaLim`\| · `SampleTime`) * Time factor | 1 | 0 |
| 0 | - | `RateOn` is deactivated | `In` | 0 | 0 |

In this case, the time factor is formed from the `TimeFactor` parameter.

| `TimeFactor` | Time factor |
|---|---|
| 0 | 1 |
| 1 | 1/60 |
| 2 | 1/(60*60) |

### Ramp function

Starting from the current output value `Out.Value`, the output value can be ramped to the target value `RmpTarget` when the ramp function is switched on or the target value is changed.

You can use the `RmpModTime` input parameter to specify whether the ramp is defined by time or gradients.

- If you select time (`RmpModTime = 1`): The gradient of the ramp is calculated automatically by the block so that after the start (`RmpOn.Value = 0 -> 1`) or a change of the target value (`RmpTarget.Value`), the target value is reached after the configured time (`RmpTime`). The unit of the ramp time (`RmpTime`) depends on `TimeFactor`.
- If you select gradients (`RmpModTime = 0`): The ramp slope corresponds to the configured rates of change `UpRaLim` (positive) or `DnRaLim` (negative).

When the output value has reached the target, the output value remains at the target value as long as the ramp function remains enabled.

### Switching the ramp function and slope limiting function on or off

The ramp function is switched off with the `RmpOn = 0` input; the slope limiting function is switched off with the `RateOn` = 0 input. If both are switched off, the `In` input value is written directly to the `Out` output. Limits are no longer monitored. If both functions are switched on, the ramp function has priority.

### Stopping the caculation of the ramp output value

Set `Hold` = 1 to interrupt the calculation of the ramp output value. The output value `Out` is held and the output parameters `UpRaAct` and `DnRaAct` are set to 0. The status of `Out`, `UpRaAct`, and `DnRaAct` are realized.

Set `Hold` = 0 to continue the calculation of the ramp output value. The calculation is continued with the last output value.

### Time base of the gradient limits

The gradient limits are set at the `UpRaLim` and `DnRaLim` parameters depending on the `TimeFactor`.

`TimeFactor = 0`: Unit of the gradient limiting is Unit/Second

`TimeFactor = 1`: Unit of the gradient limiting is Unit/Minute

`TimeFactor = 2`: Unit of the gradient limiting is Unit/Hour

### Forming the signal status for blocks

The signal status of `Out` is formed from:

```
RmpOn =1: Out.ST := RmpTarget.ST
```

Otherwise: `Out.ST := In.ST`

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) .

The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 8 | Unit for the rate of change (Page 158) |

RateLim error handling (Page 2348)

## 14.5.4 RateLim error handling

### Error handling of RateLim

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 30 | The value of `In` can no longer be displayed in the REAL number field. |
| 43 | Incorrect time unit set at `TimeFactor`. |

I/Os of RateLim

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `DnRaLim` | Maximum negative change in the output value in units/s or %/s | REAL | 3.0 |
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `Feature` | I/O for additional functions (Page 2345) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| `Hold` | Hold calculation | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| `In*` | Analog input value | STRUCT<br>• Value: REAL<br>• ST:BYTE | -<br>• 0.0<br>• 16#80 |
| `InScale` | Scaling of the measuring range as a structure | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| `RateOn` | 1 = Switch on gradient function | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| `RmpModTime` | 1 = Use time (`RmpTime`) for the ramp function<br>0 = Use gradients (`UpRaLim`, `DnRaLim`) for the ramp function | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RmpOn | 1 = Switch on ramp function for target value RmpTarget | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| RmpTarget | Target value for the ramp function | STRUCT<br>• Value: REAL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| RmpTime* | Duration [unit depends on TimeFactor] for ramp function from the current Out to RmpTarget | REAL | 0.0 |
| SampleTime | Sampling time [s] (assigned automatically) | REAL | 0.1 |
| TimeFactor | Time unit:<br>0 = Seconds<br>1 = Minutes<br>2 = Hours | INT | 0 |
| UpRaLim | Maximum positive change in the output value in units/s or %/s | REAL | 3.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DnRaAct | 1 = Negative change in the output value | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see RateLim error handling (Page 2348) | INT | -1 |
| Out | Output value | STRUCT<br>• Value: REAL<br>• ST:BYTE | -<br>• 0.0<br>• 16#80 |
| UpRaAct | 1 = Positive change in the output value | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |

# 14.6 RedAn02 - 1 out of 2 selection for redundant analog values

## 14.6.1 Description of RedAn02

### Object name (type + number) and family

Type + number: FC 385

Family: LogicAn

### Area of application for RedAn02

The block is used for the following applications:

- 1 out of 2 selection for redundant analog values

### How it works

The block selects from two input values the one with the best signal status and outputs it at the output `Out`. In addition, the outputs `SimAct`, `Uncertain` and `LossRed` are set according to the signal status.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

# 14.7 SelA02In - Output of two analog values

## 14.7.1 Description of SelA02In

### Object name (type + number)

Type + number: FB 1886

Family: LogicAn

### Area of application for SelA02In

The block is used for the following applications:

- Selecting one of two analog values and switching it through to the output.

### How it works

Depending on the setting of parameter `SelMode` the block selects one of the two input parameters `In1` or `In2` and writes its value to the output parameter `Out`.

This is displayed at the `In2Selected` output parameter.

### Configuration

Use the CFC editor to install the block in any OB.

For the SelA02In block, the Advanced Process Library contains templates for process tag types as examples and there is a example project (APL_Example_xx, xx designates the language variant) with an application scenario for this block, which describes how the block works.

Examples of process tag types:

- Source chart for GainSched function block (gain scheduling) (Page 2845)
- Override control (Page 2846)
- Override control with PIDConR (OverrideR) (Page 2848)

Application scenario in the example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 14.7.3 SelA02In functions

**Functions of SelA02In**

The functions for this block are listed below.

### Select input parameter

The SelMode parameter can affect the selection as follows:

- SelMode ≤ 0: The selection depends on the parameter Sel_In2
  - Sel_In2 = 0: Input parameter In1 is written with its signal status to output parameter Out.
  - Sel_In2 = 1: Input parameter In2 is written with its signal status to output parameter Out.
- SelMode = 1: The input parameter with the lower value (In1 or In2) is written with its signal status to the output parameter Out.
- SelMode ≥ 2: The input parameter with the higher value (In1 or In2) is written with its signal status to the output parameter Out.

The signal status of Sel_In2 is output at the In2Selected output parameter.

## 14.7.6 SelA02In I/Os

### SelA02In I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `In1` | Analog process value 1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `In2` | Analog process value 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| `SelMode` | Selection of the function:<br>0 = Select with `Sel_In2`<br>1 = Minimum<br>2 = Maximum | INT | 0 |
| `Sel_In2` | Selecting the input parameter:<br>0 = `In1`<br>1 = `In2` | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| In2Selected | Selected input parameter:<br>0 = In1<br>1 = In2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Out | Analog process value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

# 14.8 SelA16In - Output of 16 analog values

## 14.8.1 Description of SelA16In

### Object name (type + number) and family

Type + number: FB 1888

Family: LogicAn

### Area of application for SelA16In

The block is used for the following applications:

- Selecting one of 16 analog values and switching it through to the output.

### How it works

The block writes the value of one of the input parameters `In01` through `In16` to the output parameter `Out`. The selection is performed via the `SelInt` input parameter.

The signal status of the selected input parameter is written to the signal status of the output parameter `Out`. There is no additional signal status evaluation.

The unit `InxUnit` of the selected input parameter `Inx` (x = 01 ...16) is written to the output parameter `OutUnit`.

The analog input 1 (`In01`) is operable only if `OS_Perm.Bit22` is set to 1.

It has an upper limit associated with the parameter `In01HiLim` and a lower limit associated with the parameter `In01LoLim`.

If `Feature.Bit7` is set to 1 and the permission is enabled (`OS_Perm.Bit22` = 1), the analog input 1 (`In01`) can be reserved for the operator. If `Feature.Bit7` is set to 1, the analog input 1 (`In01`) is always visible independent of `Feature.Bit5`.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

You can find a description for each parameter in section SelA16In I/Os (Page 2368).

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 - 11 | Not used |
| 12 – 27 | Used to highlight the green line in the standard view |
| 28 | 1 = With internal/external selection from the operator (`Feature.Bit6`) |
| 29 | 1 = `SelExtAct` |
| 30 | Not used |
| 31 | Internal error |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | 1 = Display input 1 |
| ... | ... |
| 15 | 1 = Display input 16 |
| 16 - 31 | Not used |

### See also

SelA16In error handling (Page 2367)

SelA16In functions (Page 2364)

SelA16In modes (Page 2363)

## 14.8.2 SelA16In modes

### SelA16In operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### "On"

You can find general information about the "On" mode in the section On (Page 77).

### "Out of service"

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

When the mode is changed to "Out of service", the status of the following output parameters with `Feature.Bit3` =1 and `Feature.Bit3` =0 is as shown below:

| Output Parameters | **`Feature.Bit3` =0** | **`Feature.Bit3` =1** |
|---|---|---|
| Out.ST | 16#XX | 16#60 |

SelA16In functions (Page 2364)

Description of SelA16In (Page 2362)

## 14.8.3 SelA16In functions

### Functions of SelA16In

The functions for this block are listed below.

### Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

### Operator control permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 =Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 =Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can set the input 1 |
| 5 | 1 = Operator can set the input 2 |
| 6 | 1 = Operator can set the input 3 |
| 7 | 1 = Operator can set the input 4 |
| 8 | 1 = Operator can set the input 5 |
| 9 | 1 = Operator can set the input 6 |
| 10 | 1 = Operator can set the input 7 |
| 11 | 1 = Operator can set the input 8 |
| 12 | 1 = Operator can set the input 9 |
| 13 | 1 = Operator can set the input 10 |
| 14 | 1 = Operator can set the input 11 |
| 15 | 1 = Operator can set the input 12 |
| 16 | 1 = Operator can set the input 13 |
| 17 | 1 = Operator can set the input 14 |
| 18 | 1 = Operator can set the input 15 |
| 19 | 1 = Operator can set the input 16 |
| 20 | 1 = Operator can switch to external selection |
| 21 | 1 = Operator can switch to internal selection |
| 22 | 1 = Operator can change the value of input 1 |
| 23 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status of analog logic blocks (Page 120).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `In1.ST`

etc. to

- `In16.ST`

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Changes signal status of outputs in OOS (Page 208) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Display only input values that are interconnected in the faceplate (Page 168) |
| 6 | External/internal selection specification (Page 194) |
| 7 | Analog input 1 is reserved for the operator (Page 197) |
| 24 | Enabling local operator authorization (Page 169) |

### Cascading of SelA16In

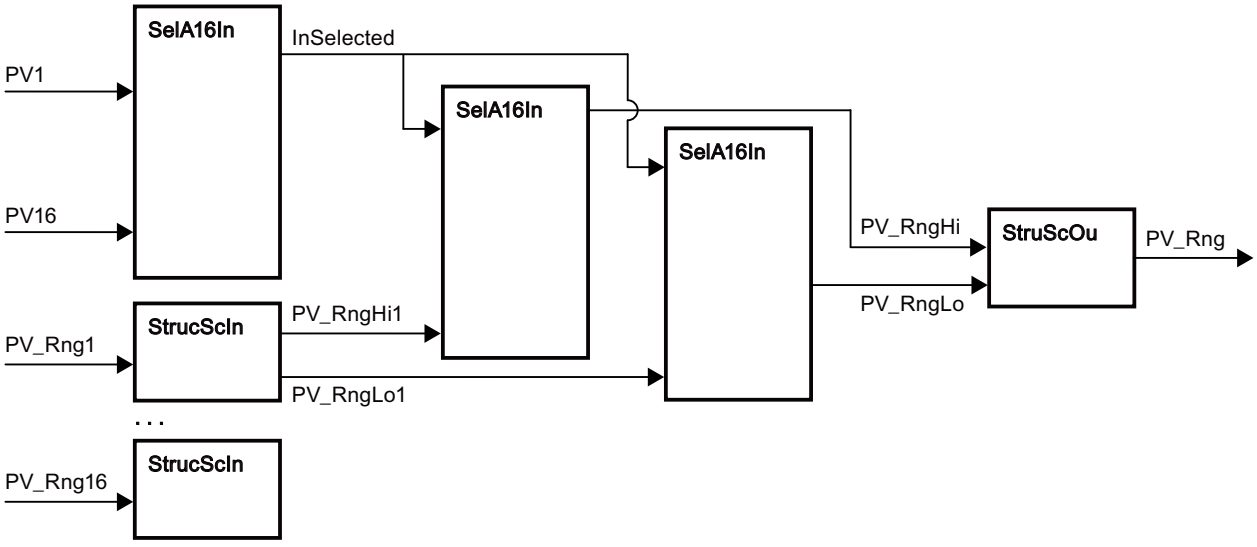

Figure 14-1 Process value area can be realized using conversion blocks and cascaded SelA16In blocks.

### SIMATIC BATCH functionality

This block provides the standard function Auto-Hotspot (Page 73).

## 14.8.4 SelA16In error handling

### Error handling of SelA16In

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 18 | 1 > SelExt > 16 |

| UserStatus2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see SelA16In error handling (Page 2367). | INT | -1 |
| InSelected | Selected input parameter:<br>1 = In01 selected<br>16 = In16 selected | STRUCT<br>• Value: INT<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out | Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OutUnit | Unit for parameter Out | INT | 1001 |
| SelExtAct | 0 = Internal selection is active<br>1 = External selection is active | BOOL | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status | Status word (Page 2362) | DWORD | 16#00000000 |
| Status2 | Status word (Page 2362) | DWORD | 16#00000000 |

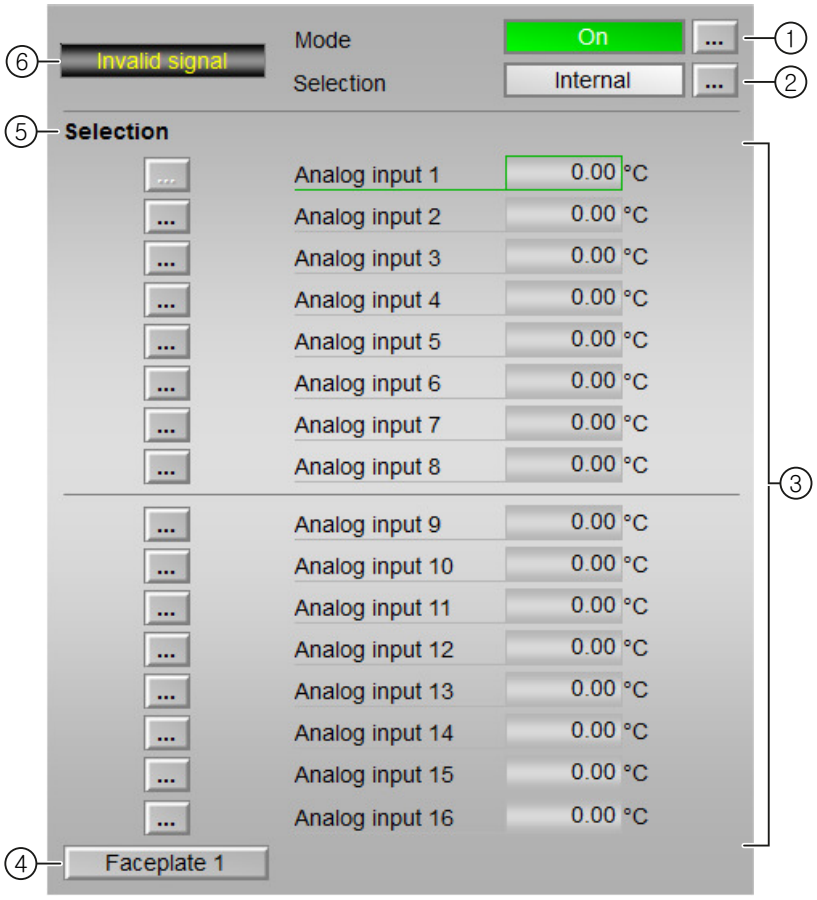
## 14.8.8 Operator control and monitoring

### 14.8.8.1 SelA16In views

**Views of the SelA16In block**



The block SelA16In provides the following views:

- SelA16In standard view (Page 2374)
- SelA16In preview (Page 2376)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for SelA16In (Page 2377)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 14.8.8.2 SelA16In standard view

#### SelA16In standard view

#### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

#### (2) Displaying and switching the selection

This area provides information on the current selection. The following selection can be made:

- External: Selecting values externally (program)
- Internal: Selecting values internally (operator)

### (3) Display of analog inputs

This area shows you the analog values connected in the ES for this block.

You can find additional information on this in Switching operating states and operating modes (Page 289).

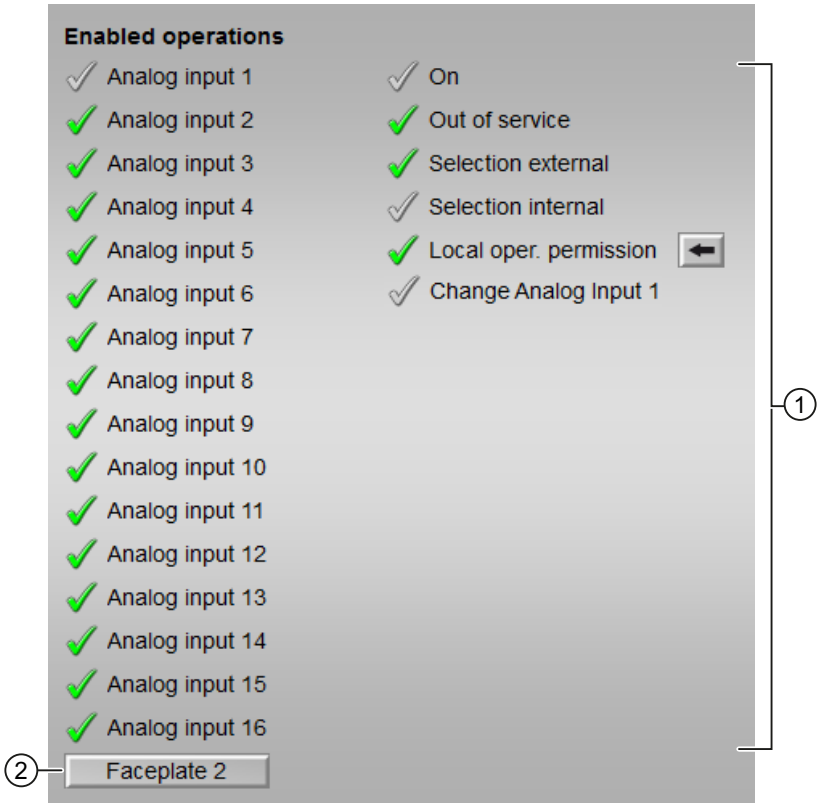
### (4) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### (5) Selection of analog inputs

You can select the required analog input by clicking on the [...] button.



### (6) Display area for block states

This area provides additional information on the operating state of the block:

- Internal error
- Invalid Signal

### 14.8.8.3 SelA16In preview

**Preview of SelA16In**

**(1) Enabled operations**

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

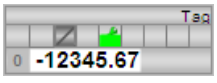
- Analog input 1 to 16: You can switch to this analog input.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Selection external": You can select values externally (program).

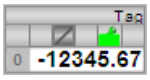
- "Selection internal": You can select values internally (operator).
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions (Page 285).
- "Change analog input 1": You can change the value of analog input 1.

### (2) Navigation button for switching to the standard view of any faceplate

Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

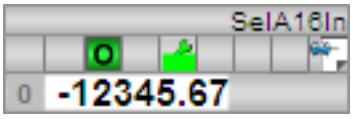
You can find additional information on this in the Opening additional faceplates (Page 234) section.

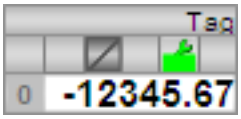


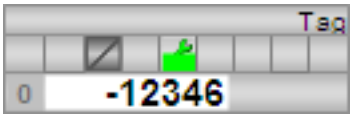


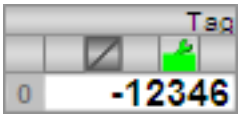
## 14.8.8.4 Block icon for SelA16In

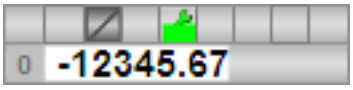
### Block icons for SelA16In

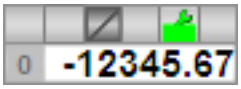


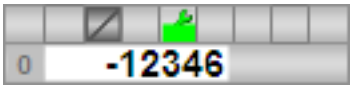


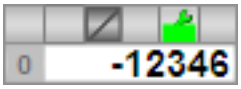


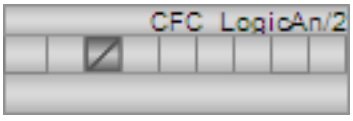












A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display of the selected analog value

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

The block icons from template @TemplateAPLV7.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | Block icon in the full display |
|  | 2 | |
|  | 3 | |
|  | 4 | |
|  | 5 | |
|  | 6 | |
|  | 7 | |
|  | 8 | |
|  | - | Block icon in "Out of service" mode (example with type 1 block icon) |

**Note**

The display of the unit in the types 1/3/5/7 depends on the analog value used, although the unit can only be displayed correctly when the units of the inputs have been configured with a code (see "Selecting a unit of measure (Page 240)"). Units configured with the S7_unit attribute are not supported.

Additional information on the block icon and the control options in the block icon is available in the following sections:

- Configuring the block icons (Page 267)
- Block icon structure (Page 260)
- Operation via the block icon (Page 269).

# 14.9 SelAn16L - Large version of SelAn16In

## 14.9.1 Description of SelAn16L

### Object name (type + number) and family

Type + number: FB 1889

Family: LogicAn

### Area of application for SelAn16L

The block is used for the following applications:

1. Selecting one of 16 analog values and switching it through to the output.
2. Find maximum and minimum value among all connected inputs.

### How it works

The block writes the value of one of the input parameters `In01` through `In16` to the output parameter `Out`. The selection is performed via the `SelInt` input parameter.

The signal status of the selected input parameter is written to the signal status of the output parameter `Out`. There is no additional signal status evaluation.

The unit `InxUnit` of the selected input parameter `Inx` (x = 01 ...16) is written to the output parameter `OutUnit`.

The analog input 1 (`In01`) is operable only if `OS_Perm.Bit22` is set to 1.

It has an upper limit associated with the parameter `In01HiLim` and a lower limit associated with the parameter `In01LoLim`.

If `Feature.Bit7` is set to 1 and the permission is enabled (`OS_Perm.Bit22` = 1), the analog input 1 (`In01`) can be reserved for the operator. If `Feature.Bit7` is set to 1, the analog input 1 (`In01`) is always visible independent of `Feature.Bit5`.

This block also provides the following:

- Maximum and minimum values of connected inputs only along with its units.
- OpScale for the output `Out`.

**Note**

In case no inputs are connected, then the output of Maximum and Minimum value will be 0 and the signal status will be 16#FF.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

You can find a description for each parameter in section SelAn16L I/Os (Page 2386) .

| Status bit | Parameter |
|---|---|
| 0 | `Occupied` |
| 1 | `BatchEn` |
| 2 | Not used |
| 3 | `OosAct.Value` |
| 4 | `OosLi.Value` |
| 5 | Not used |
| 6 | `OnAct.Value` |
| 7 - 11 | Not used |
| 12 – 27 | Used to highlight the green line in the standard view |
| 28 | 1 = With internal/external selection from the operator (`Feature.Bit6`) |
| 29 | 1 = `SelExtAct` |
| 30 | Not used |
| 31 | Internal error |

### Status word allocation for `Status2` parameter

| Status bit | Parameter |
|---|---|
| 0 | 1 = Display input 1 |
| ... | ... |
| 15 | 1 = Display input 16 |
| 16 - 31 | Not used |

### See also

SelAn16L error handling (Page 2385)

SelAn16L functions (Page 2382)

SelAn16L block diagram (Page 2392)

## 14.9.2 SelAn16L modes

### SelAn16L operating modes

The block can be operated using the following modes:

- On (Page 77)
- Out of service (Page 77)

### On

You can find general information about the "On" mode in the section On (Page 77).

### Out of service

You can find general information about the "Out of service" mode in the section Out of service (Page 77).

With `Feature.Bit3` =1 the following output parameter become the status of simulation 16#60, if mode is changed to "Out of service".

With `Feature.Bit3` =0 the following output parameter become the status of 16#80, if mode is changed to "Out of service".

- Out.ST
- In_Min.ST
- In_Max.ST

## 14.9.3 SelAn16L functions

### Functions of SelAn16L

The functions for this block are listed below.

## Opening additional faceplates

This block provides the standard function Opening additional faceplates (Page 234).

## Operator control permissions

This block provides the standard function Operator control permissions (Page 285).

The block has the following permissions for the `OS_Perm` parameter:

| Bit | Function |
|---|---|
| 0 | Not used |
| 1 | 1 =Operator can switch to "On" mode |
| 2 | Not used |
| 3 | 1 =Operator can switch to "Out of service" mode |
| 4 | 1 = Operator can set the input 1 |
| 5 | 1 = Operator can set the input 2 |
| 6 | 1 = Operator can set the input 3 |
| 7 | 1 = Operator can set the input 4 |
| 8 | 1 = Operator can set the input 5 |
| 9 | 1 = Operator can set the input 6 |
| 10 | 1 = Operator can set the input 7 |
| 11 | 1 = Operator can set the input 8 |
| 12 | 1 = Operator can set the input 9 |
| 13 | 1 = Operator can set the input 10 |
| 14 | 1 = Operator can set the input 11 |
| 15 | 1 = Operator can set the input 12 |
| 16 | 1 = Operator can set the input 13 |
| 17 | 1 = Operator can set the input 14 |
| 18 | 1 = Operator can set the input 15 |
| 19 | 1 = Operator can set the input 16 |
| 20 | 1 = Operator can switch to external selection |
| 21 | 1 = Operator can switch to internal selection |
| 22 | 1 = Operator can change the value of input 1 |
| 23 - 31 | Not used |

**Note**

If you interconnect a parameter that is also listed in `OS_Perm` as a parameter, you have to reset the corresponding `OS_Perm` bit.

## Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status of analog logic blocks (Page 120).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `In1.ST`

etc. to

- `In16.ST`

### Selecting a unit of measure

This block provides the standard function Selecting a unit of measure (Page 240).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 1 | Reaction to the out of service mode (Page 188) |
| 2 | Resetting the commands for changing the mode (Page 172) |
| 3 | Changes signal status of outputs in OOS (Page 208) |
| 4 | Setting switch or button mode (Page 177) |
| 5 | Display only input values that are interconnected in the faceplate (Page 168) |
| 6 | External/internal selection specification (Page 194) |
| 7 | Analog input 1 is reserved for the operator (Page 197) |
| 24 | Enabling local operator authorization (Page 169) |

### Cascading of SelA16In

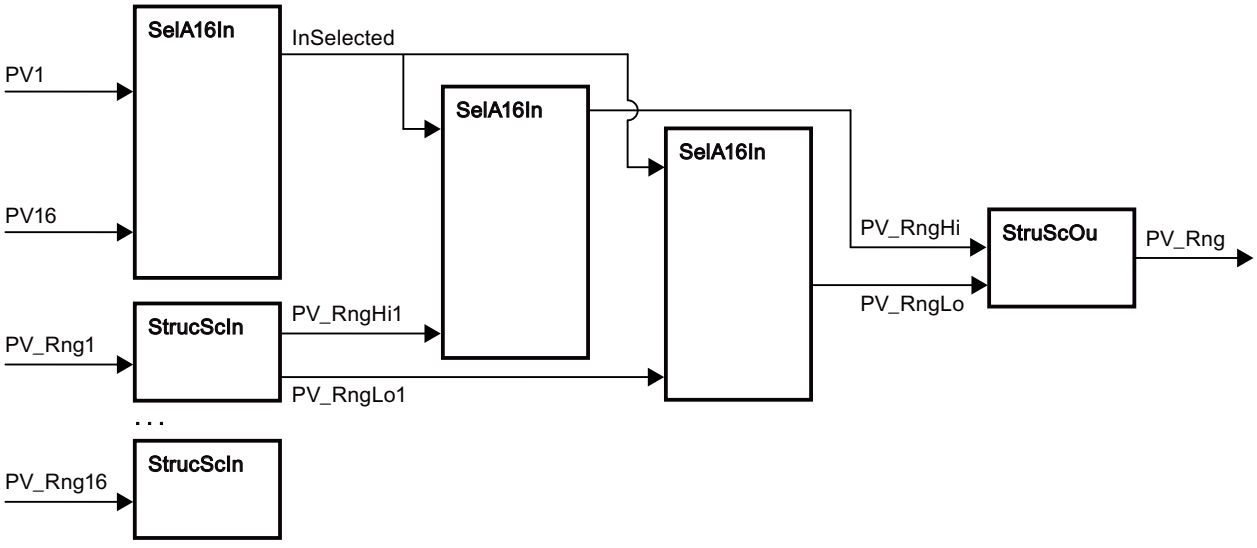

Figure 14-2 Process value area can be realized using conversion blocks and cascaded SelA16In blocks.

### SIMATIC BATCH functionality

This block provides the standard function SIMATIC BATCH functionality (Page 73).

## 14.9.4 SelAn16L error handling

### Error handling of SelAn16L

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 18 | 1 > SelExt > 16 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| LiOp | • With Feature.Bit6 = 0:<br>Selection of the input parameter via:<br>– 0 = Operator (SelInt)<br>– 1 = Interconnection or SFC (SelExt)<br>• With Feature.Bit6 = 1:<br>Internal/external selection via:<br>– 0 = Operator (SelIntOp or SelExtOp)<br>– 1 = Interconnection or SFC (SelIntLi or SelExtLi) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Occupied | 1 = Occupied by batch control | BOOL | 0 |
| OnOp* | 1 = "On" mode via operator | BOOL | 0 |
| OosLi | 1 = "Out of service", via interconnection or SFC (0-1 edge transition) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosOp* | 1 = "Out of service", via OS operator | BOOL | 0 |
| OpSt_In | Input parameter for local operating permission, connected with the Out output parameter of the upstream block, Description of OpStations (Page 457) | DWORD | 16#00000000 |
| OS_Perm | I/O for operator control permissions (Page 460) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 1<br>• 1<br>• 1 |
| SelExt | External selection of the input parameter:<br>1 = In01 selected<br>16 = In16 selected<br>Selection outside the range 1...16 is not possible | INT | 1 |
| SelFp1 | Call a block saved in this parameter as an additional faceplate (Page 234) in the standard view | ANY | |
| SelFp2 | Call a block saved in this parameter as an additional faceplate (Page 234) in the preview | ANY | |
| SelInt* | Selecting the input parameter:<br>1 = In01 selected<br>16 = In16 selected<br>You cannot select anything outside the range of 1 to 16. | INT | 1 |
| SelExtLi | Linkable input for external selection:<br>1 = External selection<br>Active only with Feature.Bit6 = 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SelExtOp | Operator input for external selection:<br>1 = External selection<br>Active only with Feature.Bit6 = 1 | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SelIntLi | Linkable input for internal selection:<br>1 = Internal selection<br>Active only with Feature.Bit6 = 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SelIntOp | Operator Input for Internal Selection:<br>1 = Internal selection<br>Active only with Feature.Bit6 = 1 | BOOL | 0 |
| StepNo | Batch step number | DWORD | 16#00000000 |
| UserStatus | First freely assignable bits for use in OS | BYTE | 16#00 |
| UserStatus 2 | Second freely assignable bits for use in OS | DWORD | 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of current error number. For error numbers that can be output by this block, see SelAn16L error handling (Page 2385). | INT | -1 |
| InSelected | Selected input parameter:<br>1 = In01 selected<br>16 = In16 selected | STRUCT<br>• Value: INT<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| In_Min | Minimum of all connected inputs | STRUCT<br>• Value: INT<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| In_MinUnit | Engineering unit of In_Min | • INT | 1001 |
| In_Max | Maximum of all connected inputs | STRUCT<br>• Value: INT<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| In_MaxUnit | Engineering unit of In_Max | • INT | 1001 |
| OnAct | 1 = "On" mode enabled | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| OosAct | 1 = Block is "Out of service" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpSt_Out | Value of the OpSt_In input parameter, for feedforwarding to other blocks. Bit 31 of this parameter is used by Feature.Bit24 | DWORD | 16#00000000 |
| OS_PermLog | Display of OS_Perm with settings changed by the block algorithm | DWORD | 16#FFFFFFFF |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OS_PermOut | Display of OS_Perm | DWORD | 16#FFFFFFFF |
| Out | Output | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| OutUnit | Unit for parameter Out | INT | 1001 |
| Out_OpScale | OS display range for Out | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100<br>• 0 |
| SelExtAct | 0 = Internal selection is active<br>1 = External selection is active | BOOL | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| Status | Status word (Page 2380) | DWORD | 16#00000000 |
| Status2 | Status word (Page 2380) | DWORD | 16#00000000 |

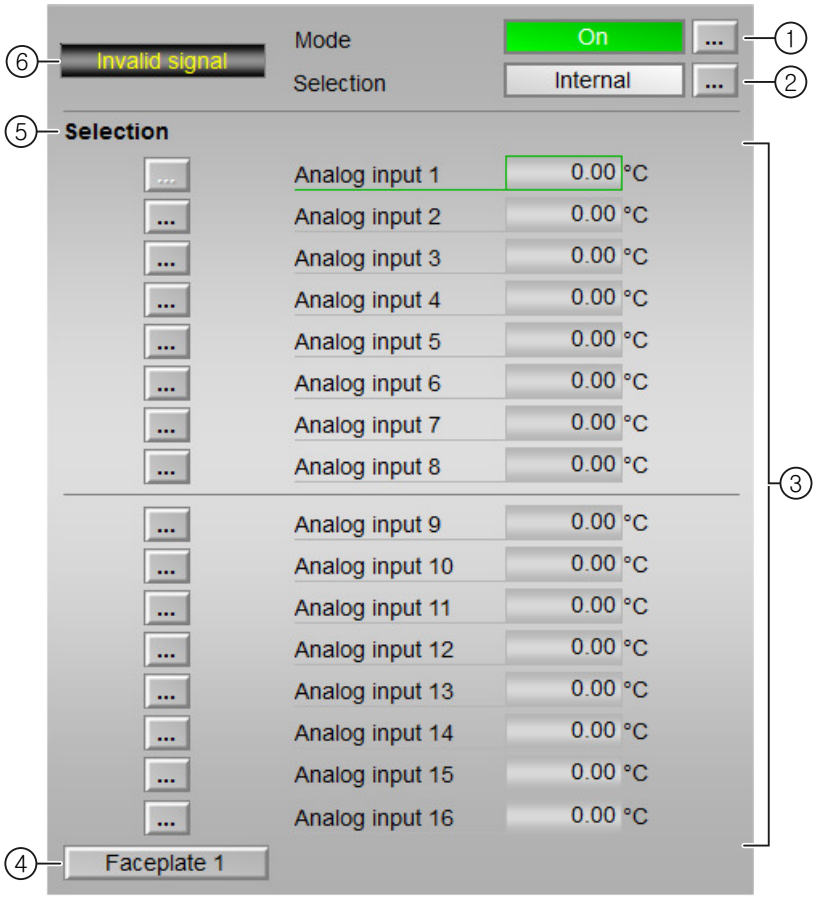
## 14.9.8 Operaror control and monitoring

### 14.9.8.1 SenAn16L views

**Views of the SelAn16L block**



The block SelAn16L provides the following views:

- SelAn16L standard view (Page 2394)
- SelAn16L preview (Page 2395)
- Memo view (Page 338)
- Batch view (Page 336)
- Block icon for SelAn16L (Page 2397)

Refer to the sections Structure of the faceplate (Page 279) and Block icon structure (Page 260) for general information on the faceplate and block icon.

### 14.9.8.2 SelAn16L standard view

### SelAn16L standard view

### (1) Displaying and switching the operating mode

This area provides information on the currently valid operating mode. The following operating modes can be shown here:

- On (Page 77)
- Out of service (Page 77)

Refer to the Switching operating states and operating modes (Page 289) section for information on switching the operating mode.

### (2) Displaying and switching the selection

This area provides information on the current selection. The following selection can be made:

- External: Selecting values externally (program)
- Internal: Selecting values internally (operator)

### (3) Display of analog inputs

This area shows you the analog values connected in the ES for this block.

You can find additional information on this in Switching operating states and operating modes (Page 289).

### (4) Navigation button for switching to the standard view of any faceplate

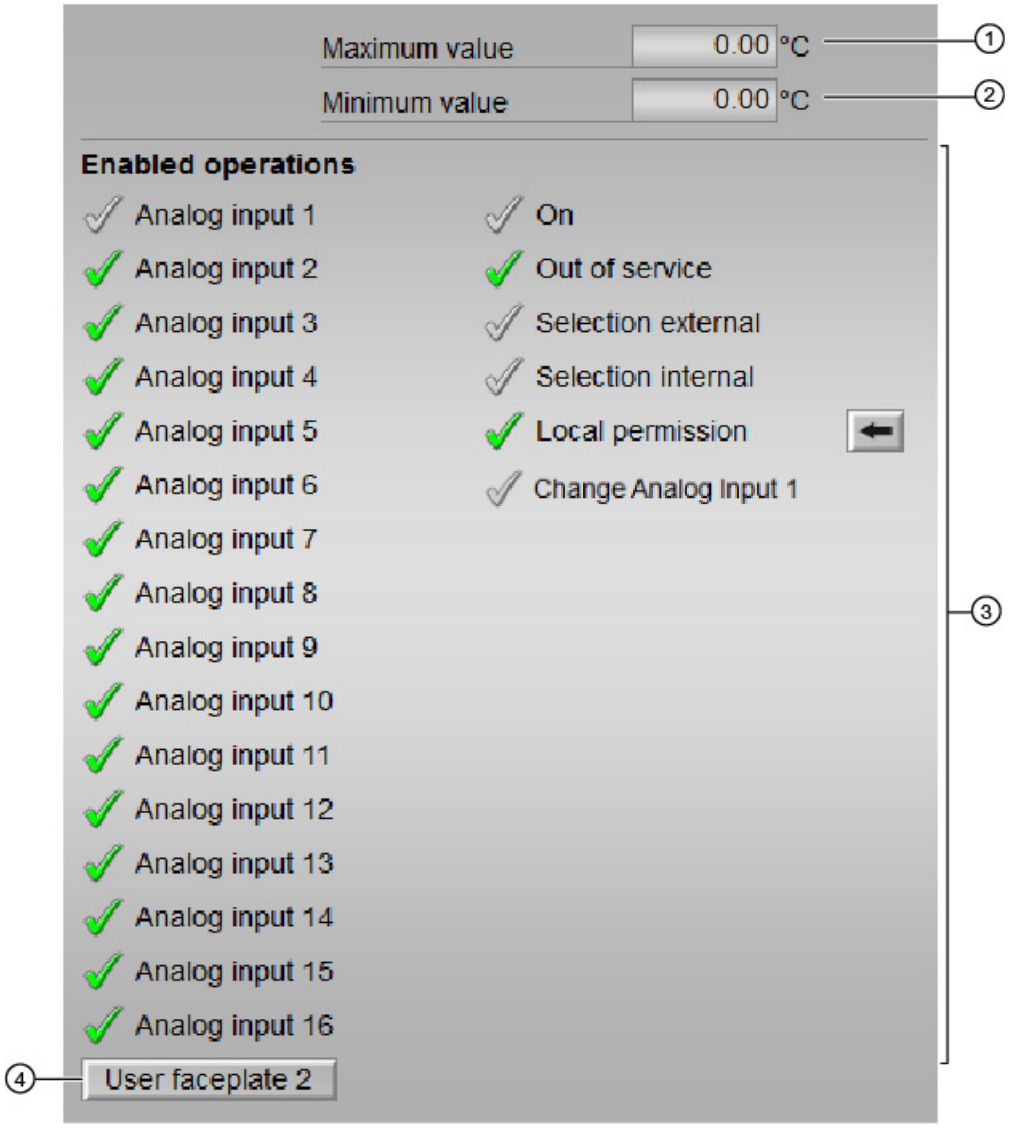
Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates (Page 234) section.

### (5) Selection of Analog inputs

You can select the required analog input by clicking on the [...] button.

### (6) Display area for block states



This area provides additional information on the operating state of the block:

- Internal error
- Invalid Signal

## 14.9.8.3 SelAn16L preview

### Preview of SelAn16L

Preview view of the SelAn16L block is as below:

### (1) Maximum Value

This field shows the maximum value among the 16 analog inputs.

### (2) Minimum Value

This field shows the minimum value among the 16 analog inputs.

### (3) Enabled operations

This area shows all operations for which special operator control permissions are assigned. They depend on the configuration in the engineering system (ES) that applies to this block.

Symbols for enabled operations:

- **Green check mark**: the OS operator can control this parameter
- **Gray check mark**: the OS operator cannot control this parameter at this time due to the process
- **Red cross**: the OS operator cannot control this parameter due to the configured AS operator control permissions (`OS_Perm` or `OS1Perm`)

The following enabled operations are shown here:

- Analog input 1 to 16: You can switch to this analog input.
- "On": You can switch to "On" operating mode.
- "Out of service": You can switch to "Out of service" operating mode.
- "Selection external": You can select values externally (program).
- "Selection internal": You can select values internally (operator).
- "Local operating permission": Use the ← button to switch to the standard view of the OpStations block. Additional information is available in the section Operator control permissions.
- "Change analog input 1": You can change the value of analog input 1.

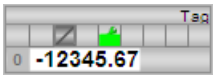
### (4) Navigation button for switching to the standard view of any faceplate

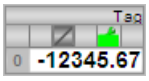
Use this navigation button to reach the standard view of a block configured in the engineering system. The visibility of this navigation button depends on the configuration in the engineering system (ES).

You can find additional information on this in the Opening additional faceplates section.

**Note**

All other views of Faceplate remain same as that of SelA16In.





## 14.9.8.4 Block icon for SelAn16L

### Block icons for SelAn16L

A variety of block icons are available with the following functions:

- Process tag type
- Operating modes
- Signal status, release for maintenance
- Memo display
- Display of the selected analog value

The block icons from template @TemplateAPLV9.PDL:

| Icons | Selection of the block icon in CFC | Special features |
|---|---|---|
|  | 1 | |
|  | 2 | |
|  | 3 | Block icon in the full display |

# Digital logic blocks 15

## 15.1 And04 - Forming an AND signal from 4 binary input signals

### 15.1.1 Description of And04

#### Object name (type + number) and family

Type + number: FC 355

Family: LogicDi

#### Area of application for And04

The block is used for the following applications:

- Forming an AND-output signal from four binary input values

#### How it works

Four input parameters are combined via the AND function ("and-ing") into one output value `Out`.

You can use this block to e.g. start or stop a device if all incoming signals are the same.

You can find additional information on forming the signal status under Forming and outputting the signal status of digital logic blocks (Page 119)

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

#### Startup characteristics

The block does not have any startup characteristics.

#### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 15.2 And08 - Forming an AND signal from 8 binary input signals

## 15.2.1 Description of And08

### Object name (type + number) and family

Type + number: FC 356

Family: LogicDi

### Area of application for And08

The block is used for the following applications:

- Forming an AND- output signal from eight binary input values

### How it works

Eight input parameters are combined via the AND function ("and-ing") into one output value `Out`.

You can use this block to e.g. start or stop a device if all incoming signals are the same.

You can find additional information on forming the signal status under Forming and outputting the signal status of digital logic blocks (Page 119)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 15.3 FlipFlop - Flip Flop with Clock Input

## 15.3.1 Description of FlipFlop

### Object name (type + number) and family

Type + number: FC 389

Family: LogicDi

### Area of application for FlipFlop

The block is used for the following applications:

- SR/RS FlipFlop functionality
- JK-FlipFlop functionality

### How it works

The block provides the function of two types of a flip-flop:

- JK-Flip-Flop (JK_En=1)
- SR/RS-FlipFlop (JK_En=0)

The SR/RS behaviour can be set via the Mode input.

- Mode = 0: SR-Behavior
- Mode = 1: RS-Behavior

If the FlipFlop operates as JK-FlipFlop, the inputs for setting (`SetLi`) and resetting (`RstLi`) are accepted with a positive edge at the input `Clock` and the output `P_Clock` is set for one block cycle.

With a positive edge at the input parameter for setting `SetLi`, the output parameter `Out` is set to 1. Simultaneously, the output parameter `InvOut` is reset.

With a positive edge at the input parameter for resetting `RstLi`, the output parameter `Out` is reset. Simultaneously, the output parameter `InvOut` is set.

If the two input parameters are`SetLi` and `RstLi = 0`, then the block retains its state. In this case, nothing changes at the output parameters.

### How the block operates as SR-FlipFlop (`Mode` = 0) (`JK_En` = 0)

The input parameter for setting `SetLi` has priority over the input parameter for resetting `RstLi`.

Truth table:

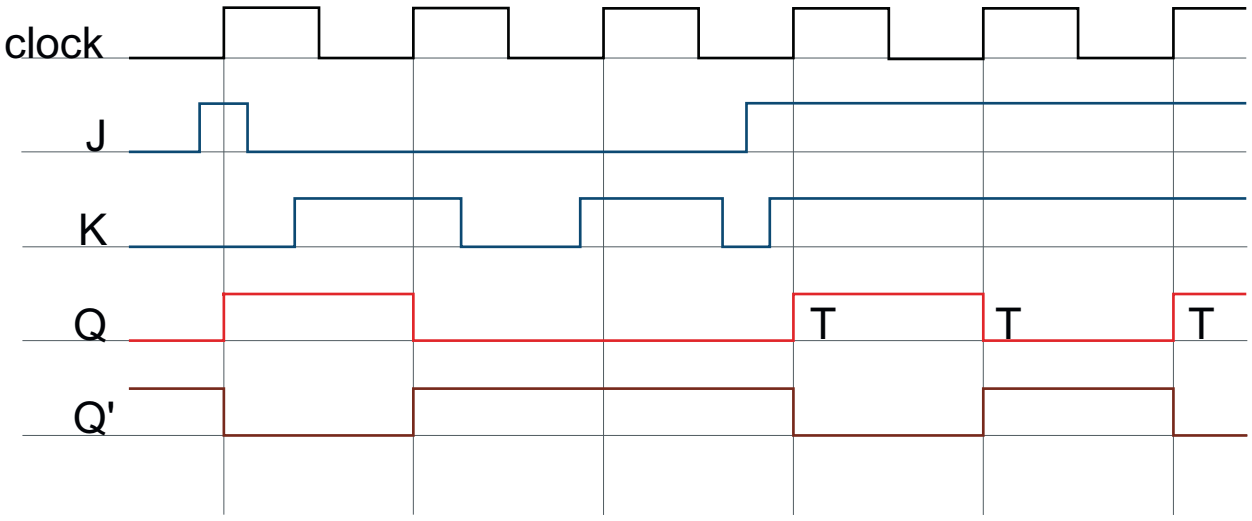
| RstLi | SetLi | Out | InvOut |
|---|---|---|---|
| 0 | 0 | Last value | Last value |
| 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 1 |
| 1 | 1 | 1 | 0 |

### How the block operates as RS-FlipFlop (Mode = 1) (JK_En = 0)

The input parameter for resetting `RstLi` has priority over the input parameter for setting `SetLi`.

Truth table:

| RstLi | SetLi | Out | InvOut |
|---|---|---|---|
| 0 | 0 | Last value | Last value |
| 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 1 |
| 1 | 1 | 0 | 1 |



### How the block operates as JK-FlipFlop (JK_En = 1)

The latch works as a JK-latch, the value of the input `Mode` is not relevant in this case.

Truth table:

| Clock | RstLi | SetLi | Out | P_Clock |
|---|---|---|---|---|
| 0 | x | x | unchanged | 0 |
| 1 | x | x | unchanged | 0 |
| 0→1 | 0 | 1 | 1 (set latch) | 1 (one cycle) |
| 0→1 | 1 | 0 | 0 (reset latch) | 1 (one cycle) |
| 0→1 | 1 | 1 | toggle | 1 (one cycle) |
| x = "0" or "1" | | | | |

This timing diagram of JK-latch is as follows:

Clock → `Clock`
J → `SetLi`
K → `RstLi`.
Q → `Out`
Q' → `InvOut`

T → toggle

## Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

## Startup characteristics

The block does not have any startup characteristics.

A startup behavior can be reached with a connection of the input parameter `Init` to the output parameter `InitOut` of the Trigger block. For more information, refer to Startup characteristics over Trigger block (Page 75).

## Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## See also

FlipFlop I/Os (Page 2414)
FlipFlop block diagram (Page 2416)

## 15.3.3 FlipFlop functions

### Functions of FlipFlop

The block provides the following functions:

### Forming the signal status for blocks – SR-FlipFlop

The signal status is formed as follows:

| RstLi | SetLi | Out.ST | InvOut.ST |
|---|---|---|---|
| 0 | 0 | Last signal status | Last signal status |
| 0 | 1 | = SetLi.ST | = SetLi.ST |
| 1 | 0 | = RstLi.ST | = RstLi.ST |
| 1 | 1 | = SetLi.ST | = SetLi.ST |

### Forming the signal status for blocks - RS-FlipFlop

The signal status is formed as follows:

| RstLi | SetLi | Out.ST | InvOut.ST |
|---|---|---|---|
| 0 | 0 | Last signal status | Last signal status |
| 0 | 1 | = SetLi.ST | = SetLi.ST |
| 1 | 0 | = RstLi.ST | = RstLi.ST |
| 1 | 1 | = RstLi.ST | = RstLi.ST |

### Forming the signal status for blocks - JK-FlipFlop

The signal status is formed as follows:

| RstLi | SetLi | Clock | Out.ST |
|---|---|---|---|
| 0 | 0 | 0 | Last signal status |
| 0 | 1 | 0→1 | = SetLi.ST |
| 1 | 0 | 0→1 | = RstLi.ST |
| 1 | 1 | 0→1 | If Out set to "1"<br>= SetLi.ST |
| | | | If Out set to "0"<br>= RstLi.ST |

### Initialization

With the input parameter `Init`, the output parameters `Out` and `InvOut` can be initialized:

- `Init` = 0 (default): Normal flip-flop behavior
  The `Out` and `InvOut` output parameters are calculated according to the mode parameterization and also using the values of the `SetLi` and `RstLi` inputs. For more information see, "How it works" under Description of FlipFlop (Page 2409)
- `Init` = 1: Outputs will be initialized as follow:

| Mode | Out | InvOut | Out.ST and InvOut.ST |
|---|---|---|---|
| 0 | 0 | 1 | RstLi.ST |
| 1 | 1 | 0 | SetLi.ST |

To initialize the output parameters `Out` and `InvOut` after a startup, connect the input parameter `Init` with the output parameter `InitOut` of the Trigger block. For more information, refer to Startup characteristics over Trigger block (Page 75).

### FlipFlop I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Clock` | Linkable clock Signal | BOOL | 0 |
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `Init` | Initialize function block | BOOL | 0 |
| `JK_En` | 1 = enabeles JK-FlipFlop | BOOL | 0 |
| `Mem` | for internal use | STRUCT | |
| `Mem.mClk` | for internal use | BOOL | 0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Mem.mOut | for internal use | BOOL | 0 |
| Mem.m2 | for internal use | BOOL | 0 |
| Mem.m3 | for internal use | BOOL | 0 |
| Mem.m4 | for internal use | BOOL | 0 |
| Mem.m5 | for internal use | BOOL | 0 |
| Mem.m6 | for internal use | BOOL | 0 |
| Mem.m7 | for internal use | BOOL | 0 |
| Mode | Specifying how the block works:<br>• 0 = SR-FlipFlop<br>• 1 = RS-FlipFlop | BOOL | 0 |
| RstLi | 1 = Reset via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SetLi | 1 = Set via interconnection | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| InvOut | Inverted output signal | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| Out | Output | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| P_Clock | pulse output 0→1 edge deteced at Clock input<br>(always "1" if JK_En=0) | BOOL | 0 |

# 15.4 Or04 - Forming an OR signal from 4 binary input signals

## 15.4.1 Description of Or04

### Object name (type + number) and family

Type + number: FC 364

Family: LogicDi

### Area of application for Or04

The block is used for the following applications:

- Forming an OR-output signal from four binary input values

### How it works

Four input parameters are combined via the OR-function ("or-ing") into one output value `Out`.

You can find additional information on forming the signal status under Forming and outputting the signal status of digital logic blocks (Page 119)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Or04 block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Cascade control with PIDConR (CascadeR) (Page 2843)
- Dosing (Dose_Lean) (Page 2856)
- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- Model-based predictive control (ModPreCon) (Page 2849)
- Override control (Page 2846)
- Override control with PIDConR (OverrideR) (Page 2848)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)

- Ratio control with PIDConR (RatioR) (Page 2839)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Valve (Valve_Lean) (Page 2865)
- Dosing with PA/FF devices (Dose_Lean_Fb) (Page 2857)
- PID controller for PA/FF devices (PIDControl_Lean_Fb) (Page 2821)
- Control valve (VlvAnL) (Page 2868)
- Control valve for PA/FF devices (ValveAnalog_Fb) (Page 2869)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 15.5 Or08 - Forming an OR signal from 8 binary input signals

## 15.5.1 Description of Or08

### Object name (type + number) and family

Type + number: FC 365

Family: LogicDi

### Area of application for Or08

The block is used for the following applications:

- Forming an OR- output signal from eight binary input values

### How it works

Eight input parameters are combined via the OR-function ("or-ing") into one output value `Out`.

You can find additional information on forming the signal status under Forming and outputting the signal status of digital logic blocks (Page 119)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Or08 block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring eight digital process tags (Digital8Monitoring) (Page 2853)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Two-speed motor (Motor2Speed) (Page 2860)
- Reversing motor (MotorReversible) (Page 2861)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Two-way valve (Valve2Way) (Page 2866)
- Motor valve (ValveMotor) (Page 2867)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

# 15.6 Not01 - Inversion of an input signal

## 15.6.1 Description of Not01

### Object name (type + number) and family

Type + number: FC 382

Family: LogicDi

### Area of application for Not01

The block is used for the following applications:

- Inversion of an input signal

### How it works

The block inverts the binary signal available at the `In` input parameter and writes the result to its output parameter `Out`.

The signal status is passed from the input directly to the output.

You can find additional information on forming the signal status under Forming and outputting the signal status of digital logic blocks (Page 119)

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

For the Not01 block, the Advanced Process Library contains a template for process tag types as an example with an application scenario for this block.

Example of process tag types:

- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)

# 15.7 RedDi02 - 1 out of 2 selection for redundant digital values

## 15.7.1 Description of RedDi02

### Object name (type + number) and family

Type + number: FC 386

Family: LogicDi

### Area of application for RedDi02

The block is used for the following applications:

- 1 out of 2 selection for redundant digital values

### How it works

The block selects from two input values the one with the best signal status and outputs it at the output `Out`. In addition, the outputs `SimAct`, `Uncertain` and `LossRed` are set according to the signal status.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### See also

## 15.7.6 RedDi02 I/Os

### I/Os of RedDi02

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| In1 | Digital input value 1 | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| In2 | Digital input value 2 | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| LossRed | 1= Redundancy loss at one of the inputs | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Out | Output of the process value with the better signal status | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = one input value has the Simulation status | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |
| Uncertain | 1 = one input value has the "uncertain" status | STRUCT<br>• Value: BOOL<br>• ST:BYTE | -<br>• 0<br>• 16#80 |

# 15.8 SelD02In - Output of one of two digital signals

## 15.8.1 Description of SelD02In

### Object name (type + number) and family

Type + number: FC 391

Family: LogicDi

### Area of application for SelD02In

The block is used for the following applications:

- Selection from two digital values

### How it works

Depending on the value of the input `Sel_In2`, the block switches the value of the input `In1` or the input `In2` to the output `Out`.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### See also

SelD02In messaging (Page 2438)
SelD02In I/Os (Page 2439)
SelD02In block diagram (Page 2440)

## 15.8.3 SelD02In functions

### Functions of SelD02In

The functions for this block are listed below.

### Select input parameter

You can use the parameter `Sel_In2` to specify whether the input parameter `In1` or `In2` is to be output at the output parameter:

- `Sel_In2` = 0: Input parameter `In1` is written with its signal status to output parameter `Out`.
- `Sel_In2` = 1: Input parameter `In2` is written with its signal status to output parameter `Out`.

### Display of selected value

The output parameter `In2Selected` indicates which of the two input parameters has just been output:

- `In2Selected` = 0: At the output parameter `Out`, the value of the input parameter `In1` is output.
- `In2Selected` = 1: At the output parameter `Out`, the value of the input parameter `In2` is output.

The signal status of `Sel_In2` is output at the `In2Selected` output parameter.

# 15.9 StrctCom - Structure composer for 32-bit structures

## 15.9.1 Description of StrctCom

### Object name (type + number) and family

Type + number: FC 393

Family: LogicDi

### Area of application for StrctCom

The block forms a structure type output with 32 binary structural elements from 32 binary input signals. The structure corresponds, for example, to the `OS_Perm` inputs of the technological blocks and can be interconnected to them.

### How it works

The block is used for create a structure of 32 input bits.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### See also

Description of StrctCom (Page 2441)

## 15.9.3 StrctCom functions

### Functions of StrctCom

The functions for this block are listed below.

Any 32 bits at the input are assigned to the structure in the output.

```
Out.Bit0 = Bit0
Out.Bit1 = Bit1
  .....
Out.Bit31 = Bit31
```

# 15.10 StrctDeC - Structure decomposer for 32-bit structures

## 15.10.1 Description of StrctDeC

### Object name (type + number) and family

Type + number: FC 396

Family: LogicDi

### Area of application for StrctDeC

The block forms a DWORD type output and 32 single binary outputs from a structure type input with 32 binary structural elements. The input structure corresponds, for example, to the `OS_Perm` inputs of the technological blocks. If you use an `OS_Perm` input in a CFC source chart, you can use this block to transform the structured input in separate binary values inside the CFC source chart. For more information, refer to the Source chart for GainSched function block (gain scheduling) (Page 2845).

### How it works

The block is used to create a DWORD or single binary outputs from the structure of 32 input bits.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

StrctDeC block diagram (Page 2449)

## 15.10.3 StrctDeC functions

### Functions of StrctDeC

The functions for this block are listed below.

The input structure `In` is assigned to a DWORD output and to 32 single binary outputs.

```
OutDW = Structure In
Bit0 = In.Bit0
Bit1 = In.Bit1
...
Bit31 = In.Bit31
```

## 15.10.6 StrctDeC I/Os

### I/Os of StrctDeC

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| In | Structure of 0...31 binary signals Bit 0...31 | STRUCT<br>• Bit0: BOOL<br>• ...<br>• Bit31: BOOL | -<br>• 0<br>• 0<br>• 0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| OutDW | DWORD output value | DWORD | 16#00000000 |
| Bit0 | Binary output value | Bit0: BOOL | 0 |
| ... | ... | ... | ... |
| Bit31 | Binary output value | Bit0: BOOL | 0 |

# 15.11 Trigger - Detection of rising and falling edges

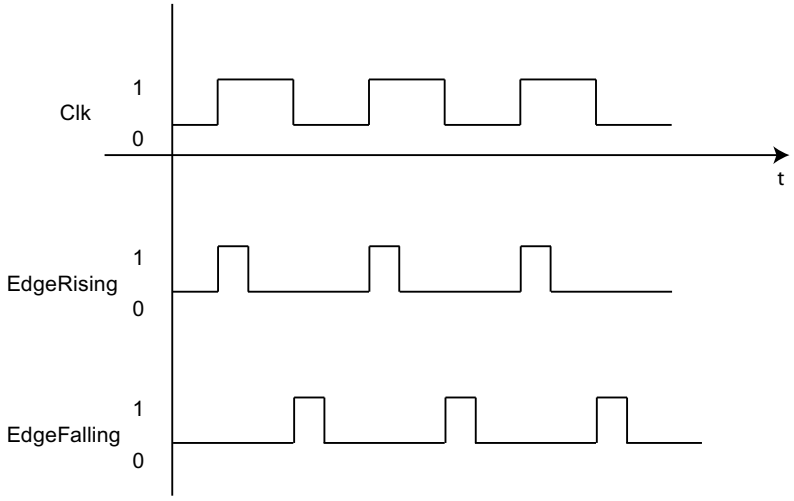
## 15.11.1 Description of Trigger

### Object name (type + number) and family

Type + number: FB 1821

Family: LogicDi

### Area of application for Trigger



The block is used for the following applications:

- Detection of rising and falling edges

### How it works

This block checks the input variable Clk for occurrences of rising and falling edges, and signals them at the outputs `EdgeRising` and `EdgeFalling` .

Output `EdgeRising` is set to 1 for a block cycle at a rising edge. Output `EdgeFalling` is set to 1 for a block cycle at a falling edge.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

Edge detection is suppressed at startup or initial startup.

With the input parameter `InitOnRestart`, you can influence the startup behavior of the output parameters `InitOut`, `EdgeRising`, and `EdgeFalling`:

- `InitOnRestart` = 0 (Default):
  The output parameters `EdgeRising` and `EdgeFalling` remain unchanged and the output parameter `InitOut` will reset to false.
- `InitOnRestart` = 1:
  The output parameters `EdgeRising` and `EdgeFalling` will reset to false and the output parameter `InitOut` will set to true. In the second cycle of OB30 to OB38, the output parameter `InitOut` will be reset. You can connect this output parameter with the input parameter `Init` of the block Limit, TimerP, or FlipFlop to initialize these blocks. For more information, refer to Startup characteristics over Trigger block (Page 75).

After a warm start of CPU with `Clk =1` and `InitOnRestart =1`, the output EdgeRising will set for one cycle.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

Trigger messaging (Page 2454)
Trigger I/Os (Page 2454)
Trigger block diagram (Page 2455)

## 15.11.3 Trigger functions

### Functions of Trigger

This block provides the function:

### Forming the signal status for blocks

The `Clk.ST` status is transmitted with each cycle to `EdgeRising.ST` and `EdgeFalling.ST`.

Trigger forms the signal status as follows:

- `EdgeRising.ST` := `Clk.ST`
- `EdgeFalling.ST` := `Clk.ST`

# 15.12 XOr04 - EXCLUSIVE OR logic operation

## 15.12.1 Description of XOr04

### Object name (type + number) and family

Type + number: FC 388

Family: LogicDi

### Area of application for XOr04

The block is used for the following applications:

- EXCLUSIVE OR logic operation with up to 4 inputs

### How it works

The block performs a logic operation with up to four input parameters `In1` to `In4`. The output parameter `Out` then becomes exactly 1, if there is a 1 at an uneven number of inputs and 0 at the rest of them.

### Truth table

| | In1 | In2 | In3 | In4 | Out |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 0 |
| 1 | 0 | 0 | 0 | 1 | 1 |
| 2 | 0 | 0 | 1 | 0 | 1 |
| 3 | 0 | 0 | 1 | 1 | 0 |
| 4 | 0 | 1 | 0 | 0 | 1 |
| 5 | 0 | 1 | 0 | 1 | 0 |
| 6 | 0 | 1 | 1 | 0 | 0 |
| 7 | 0 | 1 | 1 | 1 | 1 |
| 8 | 1 | 0 | 0 | 0 | 1 |
| 9 | 1 | 0 | 0 | 1 | 0 |
| 10 | 1 | 0 | 1 | 0 | 0 |
| 11 | 1 | 0 | 1 | 1 | 1 |
| 12 | 1 | 1 | 0 | 0 | 0 |
| 13 | 1 | 1 | 0 | 1 | 1 |
| 14 | 1 | 1 | 1 | 0 | 1 |
| 15 | 1 | 1 | 1 | 1 | 0 |

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# Generator blocks 16

## 16.1 NoiseGen - Generating signal noise

### 16.1.1 Description of NoiseGen

#### Object name (type + number) and family

Object name: FB 1863

Family: Genrator

#### Area of application for NoiseGen

The block is used for the following applications:

- Noise generator

The block can only be used for the simulation in the example project.

#### How it works

This block serves to generate signal noise. It is used for demonstration purposes in the example project so that the simulated signals react naturally.

You can employ it for simulation examples, demonstrations, trade fair models etc. It is never needed in real plants because real measuring devices always supply signals with noise.

There is an example project for the NoiseGen block (APL_Example_xx, xx refers to the language variant) with an application scenario for this block, which explains how the block works.

Application scenario in the example project:

- Process simulation including noise generator (ProcSimC; ProcSimS) (Page 2871)

#### See also

NoiseGen I/Os (Page 2461)

### 16.1.2 NoiseGen I/Os

#### NoiseGen I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Enable | 1 = generate noise signals | BOOL | 1 |
| Offset | Mean temporal value of the Noise output signal | REAL | 20.0 |
| Restart* | 1 = block restart | BOOL | 1 |
| StdDev | Standard deviation of the noise signal | REAL | 1.0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| Noise | Generated noise signal | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

### See also

Description of NoiseGen (Page 2461)

# Channel blocks 17

## 17.1 Information on using channel blocks

### Information on using channel blocks

- The descriptions of the channel blocks specify the OBs in which the blocks are installed. Please note that not all OBs listed will be generated for all CPUs. You can find additional information in the online help of the particular OB.
- If the driver generator uses the channel blocks of the PCS 7 libraries, you require firmware version V3.1 or higher on the CPU.
- The CFC function "Generate module drivers" interconnects and configures the required I/Os automatically. The function is called and executed if hardware modifications are detected when compiling the program, for example.
- The channel blocks (except Pcs7HaAI and Pcs7HaAO) evaluate the new first run identifier of the diagnostic function blocks from the PCS 7 Basis Library connected to the `DataXchg1` input.

| **NOTICE** |
| --- |
| **Behavior change in the following cases:**<br>• **when not using the CFC function "Generate module driver"**<br>• **when using 3rd-Party diagnostic blocks**<br>• **when using the function block without `DataXchg1` connection to Basis Library function blocks**<br>Usually, the `DataXchg1` input of the channel blocks is automatically connected when the module drivers are generated. Users who do not use this function must configure the `Feature.Bit27` Do not evaluate first run identifier of the diagnostic blocks (Page 205) with "1" at the respective channel blocks.<br>The `Feature.Bit27` must also be set if 3rd-Party diagnostic blocks are used that do not provide a first run identifier or in the case where the channel block is used without `DataXchg1` connection. |

- The channel blocks support the HART communication protocol. To use the HART protocol, you must ensure that it is activated in the Hardware Configuration of the module.

## Signal-processing blocks

Various types of channel blocks are provided in this PCS 7 library for processing signals from inputs and outputs:

1. **Standard channel blocks**
   This applies to the following blocks:
   - Pcs7AnIn
   - Pcs7AnOu
   - Pcs7Cnt1
   - Pcs7Cnt2
   - Pcs7Cnt3
   - Pcs7DiIn
   - Pcs7DiIT
   - Pcs7DiOu
   - Pcs7HaAI
   - Pcs7HaAO
   - Pcs7AITC
   - Pcs7DiCnt
   - Pcs7Cnt4
   - Pcs7ReIn

   These blocks are used only for processing the signals of S7-300/400 SM modules. Use these standard blocks if you want to optimize memory and runtime utilization and do not need to process any PA devices.

2. **FF/PA channel blocks**
   This applies to the following blocks:
   - FbAnIn
   - FbAnOu
   - FbAnTot
   - FbDiIn
   - FbDiOu
   - FbDrive
   - FbEnMe
   - FbSwtMMS

   These blocks are designed especially for use with PA field devices and the PROFIBUS 3.0 Class A and B or with FF field devices. In particular, you should use these blocks if you want to make use of the special features of these devices. In contrast to standard channel blocks, PA channel blocks not only process the signal itself but also all variables, according to the desired device configuration selected in the hardware configuration.

## MS_Ext (External maintenance status)

The MS_Ext is used to combine an external maintenance like an operation hour counter with the maintenance state of the device. Activate Feature.Bit10 on the channel block and interconnect the MS_Ext input on the channel block with the signals of the external maintenance state. The MSTOu converter block can be used for this.

**Note**

The external maintenance statuses "Maintenance demanded" (corresponding to significance 6) and "Maintenance required" (corresponding to significance 5) only are taken into account in the diagnostics block. These maintenance statuses trigger the messages "Maintenance demanded" (external) and "Maintenance required"(external) in the process control.

MS_Ext supports the following states:

- Maintenance alarm: 16#07
- Function control (Simulation): 16#03

and MS = 7 and MS = 3 must be unblocked in all function blocks

**Text_Ref**
The operator has the possibility to set few external diagnostics information in the maintenance object of the module/device. Therefore, interconnect the Text_Ref input on the channel block with the signals used for displaying the external diagnostic information. The BO_W converter block can be used for this. The individual bits of the Text_Ref input activates the state display in the faceplate and the "External diagnostics" view in process mode. The text must be defined by the operator in the "Advanced Diagnostic" settings.
For more details, refer the *PCS 7 Maintenance Station manual*.

## Channel active information

Channel active information (byte 0, bit 3 in DataXchg1):

0 = channel is deactivated in HW Config.

1 = channel is activated in HW Config.

In case the channel is deactivated, the channel blocks deliver signal state 16#68 (uncertain, maintenance demand) and Bad=false.

# 17.2 FbAnIn - Analog input channel block for field devices

## 17.2.1 Description of FbAnIn

### Object name (type + number) and family

Type + number: FB 1813

Family: Channel

### Area of application for FbAnIn

The block is used for the following applications:

- Signal processing (cyclic service) in accordance with "Transmitter" PROFIBUS PA profile of an analog input value:
  - Of a PA field device in accordance with PROFIBUS 3.0 class A and B
  - Of an auxiliary variable of a HART field device
  - Of an FF field device
- Processing of the redundant input channels.

### How it works

Block FbAnIn cyclically reads the process value and the signal status of the field device from the process image (partition). The process value is available as a physical variable. The signal status contains information about the status of the field device.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PV` input parameter.

In case of redundant I/O configuration, use symbol of the channel of the master module.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected with the corresponding output parameter `OMODE_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.
- The in/out parameter `DataXchg` is interconnected with the corresponding output parameter `DXCHG_xx` of the MOD_PAL0, FF_MOD32 - or MOD_PAX0 block.

- The symbol for the signal status of the analog input channel is interconnected to input PV_ST.
- The MS parameter is interconnected to the O_MS output parameter of the diagnostics block.

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter Mode manually. Refer to the Mode settings for field devices (Page 2698) chapter for more on this.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The in parameter PVSlv is interconnected with the symbol of the slave channel.
- The in parameter PV_ST is interconnected with the symbol of the quality byte of the master channel.
- The in parameter PVSlv_ST is interconnected with the symbol of the quality byte of the slave channel.

For the FbAnIn block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring of an analog process tag for PA/FF devices (AnalogMonitoring_Fb) (Page 2855)
- Dosing with PA/FF devices (Dose_Lean_Fb) (Page 2857)
- PID controller for PA/FF devices (PIDControl_Lean_Fb) (Page 2821)

## Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and:

- the value of the signal with “Good” quality code along with its quality code is transferred to the process when one of the signals delivers “Good” quality code.
- the value of the master signal along with its quality code is transferred to the process when both the signals deliver “Bad” quality code.

## Startup characteristics

The block does not have any startup characteristics.

## Status word allocation for Status parameter

This block does not have the Status parameter.

**See also**

FbAnIn messaging (Page 2472)
FbAnIn error handling (Page 2471)
FbAnIn functions (Page 2468)
Description of FbAnIn (Page 2466)

## 17.2.3 FbAnIn functions

### Functions of FbAnIn

The functions for this block are listed below.

### Obtaining the standard value

The analog value of the process image (partition) is output as a standard value at the `PV_Li` output parameter.

### Holding the last value if raw value is invalid

If the block is to hold its last valid value when the analog value is invalid or in the initialization phase of the device, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

### Output substitute value if raw value is invalid

If the block is to output a substitute value (SubsPV) when the analog value is invalid or in the initialization phase of the device, you must activate this function at the Feature Bit Output substitute value if raw value is invalid (Page 160).

### Outputting an invalid value if analog value is invalid

If the block is to output an invalid value (PV_Li = PV), you must activate this function at the Feature Bit Output invalid raw value (Page 185).

This function is preset.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for Fb channel blocks

The block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

The signal status of process value PV_Li is generated from internal events such as channel errors, higher-level errors, or simulations, as well as from the signal status PV_ST, which comes directly from the device.

The signal status PV_ST can accept values of 16#00 - 16#FF.

The block recognizes a higher-level error, for example, failure of a DP/PA link, via the Mode input parameter.

- If the high byte is Mode = 16#80, then the values in the process image (partition) are valid.
- If the high byte Mode = 16#40 (value status = higher-level error, ModErr = 1), then the analog value is treated as invalid.

The measuring type set in the low word of the Mode input parameter will be ignored.

The bit combinations of signal status PV_ST are output as output parameters (BOOL values). These conform to the bit combinations specified in PROFIBUS 3.0 "General Requirements".

**For FF field devices only:** The values of the signal status PV_ST = 16#84 - 16#87 and 16#90 – 16#93 are evaluated by the link in the same way as signal status 16#80 – 16#83.

If the signal status PV_ST = 16#80 and a process value PV with the value 16#7FFFFFFF (invalid) are transferred from the FF field device, the block will deal with the signal status 16#00 (invalid) from the FF field device.

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 5 | Activate LowCutOff (Page 166) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

If `Feature.Bit5` = 1, the input parameter `LowCutOff` is compared with `PV_Out.Value`.

If `PV_Out.Value` < `LowCutOff`, then `PV_Out.Value` = `Scale.Low` and output parameter `PV_LcoAct.Value` = 1.

If `PV_Out.Value` ≥ `LowCutOff`, then `PV_LcoAct.Value` = 0.

### Sign-of-life monitoring

If an input value whose signal status is `16#80` (good) remains constant for a programmable time (monitoring time), the input value is detected as faulty and the outputs `Bad = 1` and `FrzVal = 1` are set.

The monitoring time is set at the `FrznTmIn` input parameter in seconds. With `FrznTmIn = 0` or `FrznEn = 0` (default setting), the sign-of-life monitoring is deactivated, any pending errors are reset.

The input value is considered as faulty as long as it seen as constant. The monitoring time is restarted each time the input value is changed.

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.2.4 FbAnIn error handling

### Error handling of FbAnIn

Please refer to the section Error handling (Page 128) in the basic instructions.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range
- Frozen input value (sign-of-life monitoring)

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. The channel error is generated from the signal status `PV_ST`.

### Higher-level error / invalid measuring range

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status at `High Word` of the input parameter `Mode` accepts the value 16#40.

A higher-level error is also present when an incorrect measuring type is entered in `Low Word` of the input parameter `Mode`.

In addition, at the output parameter `PV_Li` of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output.

# 17.3 FbAnOu - Analog output channel block for field devices

## 17.3.1 Description of FbAnOu

### Object name (type + number) and family

Type + number: FB 1814

Family: Channel

### Area of application for FbAnOu

The block is used for the following applications:

Signal processing (cyclic service) in accordance with "Actuator" PROFIBUS PA profile of an analog input value:

- Of a PA field device in accordance with PROFIBUS 3.0 class A and B
- Of an FF field device

### How it works

Block FbAnOu cyclically reads the process values and the signal status of the field device from the process image (partition). The process values are available as physical variables. The signal status contains information about the status of the field device.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

You must interconnect each used signal of the block with the symbols configured in HW Config or in the symbol table according to your user data configuration:

| PA device connection | Data type | I/O |
|---|---|---|
| `Rbk` | REAL | Input |
| `RCasOut` | REAL | Input |
| `PosD` | BYTE | Input |
| `SP` | REAL | Output |
| `RCasIn` | REAL | Output |

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected with the corresponding output parameter `OMode_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.
- The in/out parameter `DataXchg` is interconnected with the corresponding output parameter `DataXchg_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.

- The MS parameter is interconnected to the O_MS output parameter of the diagnostics block.
- The corresponding signal status is symbolically interconnected depending on your user data configuration.

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter Mode manually. Refer to the Mode settings for field devices (Page 2698) chapter for more on this.

For the FbAnOu block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- PID controller for PA/FF devices (PIDControl_Lean_Fb) (Page 2821)
- Control valve for PA/FF devices (ValveAnalog_Fb) (Page 2869)

## Startup characteristics

The block is executed once in OB100 at system start. The output and in/out parameters are calculated.

## Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and the value of the signal with "Good" quality code along with its quality code is transferred to the process.

## Status word allocation for Status parameter

This block does not have the Status parameter.

## 17.3.2 FbAnOu modes

### FbAnOu modes

This block does not have any modes.

## 17.3.3 FbAnOu functions

### Functions of FbAnOu

The functions for this block are listed below.

### Obtaining the standard value

The signals of the FF field device are read from the process image (partition) of the inputs and written to the process image (partition) of the outputs. The controlled variable `Rbk` and discrete position feedback`PosD`, are read, as well as the active reference variable `RCasOut`, together with its associated signal status `RbkST`, `PosD_ST` and `RCasOutST` are read and written to the output parameters `SP` and `RCasIn`, with the associated signal status `RbkST` and `RCasInST`.

Additional detailed device information (`Cbk0` - `Cbk2`) can be read as an option. The device information is available per bit at the block output.

The signal status `RbkST` or `RCasOutST` that comes directly from the device can have values from 16#00 – 16#FF.

The values of the signal status `PosD_ST` and `RbkST` of 16#84 - 16#87and 16#90 – 16#93of the FF field device are evaluated like the signal status 16#80 – 16#83.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for Fb channel blocks

The block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

The signal status of the process values (`RCasInLi` or `RbkLi`) is generated from internal events such as channel errors, higher-level errors, or simulations, as well as from the signal status `RbkST` or `RCasInST`, which comes directly from the device.

| Value | Meaning |
|---|---|
| 16#80 | Valid value |
| 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
| 16#28 | Bad, process related |
| 16#68 | Uncertain, device related |
| 16#78 | Uncertain, process related |

| Value | Meaning |
|---|---|
| 16#A4 | Maintenance request present |
| 16#00 | Invalid value |

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Keep last valid raw value

The block provides the standard function Keep last valid raw value if input value is bad (Page 207).

If `Feature.Bit31` is active and the input `SP_Li` has bad quality (16#00 OR 16#28) the outputs `SP`, `SP_ST` keep its value and will not be actualized.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |
| 31 | Keep last valid raw value if input value is bad (Page 207) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.3.4 FbAnOu error handling

### Error handling of FbAnOu

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1.

The channel error is generated from the signal states `RbkST`, `RCasOutST`, and `PosD_ST`. In addition to this, a channel error (`Bad` = 1) also occurs if the signal status has a valid value (`RbkST` or `RCasOutST` is 16#80) and the present position of actuator `Rbk` or `RCasOut` has the value 16#7FFFFFFF (invalid).

### Higher-level error / invalid measuring range

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status at `High Word` of the input parameter `Mode` accepts the value 16#40.

A higher-level error is also present when an incorrect measuring type is entered in `Low Word` of the input parameter `Mode`.

## 17.3.5 FbAnOu messaging

### Messaging

This block does not offer messaging.

### FbAnOu block diagram

A block diagram is not provided for this block.

# 17.4 FbAnTot - Analog totalizer channel block for field devices

## 17.4.1 Description of FbAnTot

### Object name (type + number) and family

Type + number: FB 1817

Family: Channel

### Area of application for FbAnTot

The FbAnTot block processes the cyclic parameters of the "Totalizer" PA profile of a PA field device according to PROFIBUS 3.0 class A and B.

### How it works

The FbAnTot block reads the process value (PV) with the status byte (PV_ST) of the PROFIBUS field device (structure corresponds to the totalizer of the PA profiles) cyclically from the process image (partition). The process value is available as a physical variable. The status byte (PV_ST) contains information about the state of the PROFIBUS field device.

In addition to the status byte and to improve interconnectability, additional important detail information is provided at the output interface as structured variables or in the structures. These conform to the bit combinations specified in PROFIBUS 3.0 "General Requirements".

The PV_Set_Li and PV_Mode_Li input variables can be used to write to the process image (partition) as an option. For this, the values of input variables are transferred to the PV_Set and PV_Mode outputs, which are interconnected to the process image.

The block detects a higher-level error, for example, failure of a DP/PA link, via the Mode input parameter.

- If the high byte is Mode = 16#80, then the values in the process image (partition) are valid.
- If the high byte is Mode = 16#40 (value status = higher-level error, ModErr = TRUE), then the analog value is treated as invalid.

### Configuration

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38). The block is installed automatically in the startup OB (OB100).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The symbol for the quality code of the analog input channel is interconnected with the `PV_ST` input parameter and other selected options.
  The in/out parameter `Mode` is interconnected to the corresponding `OMODE_xx` output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DataXchg` output parameter of the MOD block.

#### tartup characteristics

The block does not have any startup characteristics.

## 17.4.2 FbAnTot modes

#### FbAnTot modes

This block does not have any operating modes.

## 17.4.3 FbAnTot functions

#### FbAnTot functions

The functions for this block are listed below.

#### Obtaining the standard value

The analog value of the process image (partition) is output as a standard value at the `PV_Li` output parameter.

#### Holding the last value if raw value is invalid

If the block is to hold its last valid value when the analog value is invalid or in the initialization phase of the device, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

#### Output substitute value if raw value is invalid

If the block is to output a substitute value (`SubsPV`) when the analog value is invalid or in the initialization phase of the device, you must activate this function at the `Feature` Bit Output substitute value if raw value is invalid (Page 160).

### Outputting an invalid value if analog value is invalid

If the block is to output an invalid value (PV_Li = PV), you must activate this function at the Feature Bit Output invalid raw value (Page 185). This function is preset.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for Fb channel blocks

The block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

The signal status of process value PV_Li is generated from internal events such as channel errors, higher-level errors, or simulations, as well as from the signal status PV_ST, which comes directly from the device.

The signal status PV_ST can accept values of 16#00 - 16#FF.

The block recognizes a higher-level error, for example, failure of a DP/PA link, via the Mode input parameter.

- If the high byte is Mode = 16#80, then the values in the process image (partition) are valid.
- If the high byte Mode = 16#40 (value status = higher-level error, ModErr = 1), then the analog value is treated as invalid.

The measuring type set in the low word of the Mode input parameter will be ignored.

The bit combinations of signal status PV_ST are output as output parameters (BOOL values). These conform to the bit combinations specified in PROFIBUS 3.0 "General Requirements".

**For FF field devices only:** The values of the signal status PV_ST = 16#84 - 16#87 and 16#90 – 16#93 are evaluated by the link in the same way as signal status 16#80 – 16#83.

If the signal status PV_ST = 16#80 and a process value PV with the value 16#7FFFFFFF (invalid) are transferred from the FF field device, the block will deal with the signal status 16#00 (invalid) from the FF field device.

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |

| Bit | Function |
|---|---|
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Sign-of-life monitoring

If an input value whose signal status is `16#80` (good) remains constant for a programmable time (monitoring time), the input value is detected as faulty and the output parameters `Bad = 1` and `FrzVal = 1` are set.

The monitoring time is set at the `FrznTmIn` input parameter in seconds. With `FrznTmIn = 0` or `FrznEn = 0` (default setting), the sign-of-life monitoring is deactivated, any pending errors are reset.

The input value is considered as faulty as long as it seen as constant. The monitoring time is restarted each time the input value is changed.

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.4.4 FbAnTot error handling

### Error handling of FbAnTot

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. Bit is set during startup |

### See also

Error handling (Page 128)

### FbAnTot block diagram

A block diagram is not provided for this block.

# 17.5 FbDiIn - Digital input channel block for field devices

## 17.5.1 Description of FbDiIn

### Object name (type + number) and family

Type + number: FB 1815

Family: Channel

### Area of application for FbDiIn

The block is used for the following applications:

Signal processing of digital input values (discrete input) of a field device (cyclic service in accordance with PROFIBUS PA):

- Of a PA field device in accordance with PROFIBUS 3.0 class A and B
- Of an FF field device

### How it works

Block FbDiIn cyclically reads the process values and the signal status of the field device from the process image (partition). The process values are grouped in one byte. The signal status contains information about the status of the field device.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter Mode is interconnected with the corresponding output parameter `OMode_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.
- The in/out parameter `DataXchg` is interconnected with the corresponding output parameter `DataXchg_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.
- The symbol for the signal status of the analog input channel is interconnected to input `PV_ST`.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually. Refer to the Mode settings for field devices (Page 2698) chapter for more on this.

For the FbDiIn block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring a digital process tag for PA/FF devices (DigitalMonitoring_Fb) (Page 2852)

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Description of FbDiIn (Page 2495)

## 17.5.3 FbDiIn functions

### Functions of FbDiIn

The functions for this block are listed below.

### Obtaining the standard value

The digital values (WORD format) of the process image (partition) are output at the `PV_Li0` - `PV_Li7` output parameters.

The signal status `PV_ST` that comes directly from the device can have values from 16#00 – 16#FF.

The values of the signal status `PV_ST` of 16#84 - 16#87 and 16#90 – 16#93 of the FF field device are evaluated in the same way as 16#80 – 16#83.

### Holding the last value if raw value is invalid

If the block is to hold its last valid value when the digital value is invalid or in the initialization phase of the device, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

### Output substitute value if raw value is invalid

If the block is to output a substitute value (`SubsPV`) when the digital value is invalid or in the initialization phase of the device, you must activate this function at the `Feature` Bit Output substitute value if raw value is invalid (Page 160).

### Output of invalid value if raw value is invalid

If the block is to output an invalid value (`PV_Li` = `PV`), you must activate this function at the `Feature` Bit Output invalid raw value (Page 185).

This function is preset.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for Fb channel blocks

The block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

The signal status of the process value `PV_Li0` - `PV_Li7` is generated from internal events such as channel errors, higher-level errors, or simulations, as well as from the signal status `PV_ST`, which comes directly from the device.

| Value | Meaning |
|---|---|
| 16#80 | Valid value |
| 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
| 16#28 | Bad, process related |
| 16#68 | Uncertain, device related |
| 16#78 | Uncertain, process related |
| 16#A4 | Maintenance request present |
| 16#00 | Invalid value |

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.5.4 FbDiIn error handling

### Error handling of FbDiIn

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. The channel error is generated from the signal status `PV_ST`.

### Higher-level error / invalid measuring range

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status at `High Word` of the input parameter `Mode` accepts the value 16#40.

A higher-level error is also present when an incorrect measuring type is entered in `Low Word` of the input parameter `Mode`.

In addition, at the output parameter `PV_LiX` of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output. (`PV_LiX`: X = 0 ... 7)

| SampleTime | Sample Time [s] | REAL | 0.1 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## In/out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |
| Mode | Value status and measuring type | DWORD | 16#00000000 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Bad | 1 = Process value is not valid | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number. For error numbers that can be output by this block, see FbDiIn error handling (Page 2499) | INT | -1 |
| ModErr | 1 = Device/module is faulty | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Field device is undergoing maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li0 | Process value 0 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li1 | Process value 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li2 | Process value 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li3 | Process value 3 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li4 | Process value 4 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li5 | Process value 5 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Li6 | Process value 6 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| PV_Li7 | Process value 7 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |

# 17.6 FbDiOu - Digital output channel block for field devices

## 17.6.1 Description of FbDiOu

### Object name (type + number) and family

Type + number: FB 1816

Family: Channel

### Area of application for FbDiOu

The block is used for the following applications:

Signal processing of max 8 digital input/output values of a field device (cyclic service in accordance with PROFIBUS PA):

- Of a PA field device in accordance with PROFIBUS 3.0 class A and B
- Of an FF field device

### How it works

Block FbDiOu cyclically reads the process values and the signal status of the field device from the process image (partition). The eight process values are grouped in one byte for each of the input parameters `SP_Li` and `RCasInLi`. The signal status contains information about the status of the field device.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

You must interconnect each used signal of the block with the symbols configured in HW Config or in the symbol table according to your user data configuration:

| I/O field device | Data type | I/O |
|---|---|---|
| `Rbk` | BYTE | Input |
| `RCasOut` | BYTE | Input |
| `SP` | BYTE | Output |
| `RCasIn` | BYTE | Output |

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter Mode is interconnected with the corresponding output parameter `OMode_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.
- The in/out parameter `DataXchg` is interconnected with the corresponding output parameter `DataXchg_xx` of the MOD_PAL0, FF_MOD32- or MOD_PAX0 block.

- The MS parameter is interconnected to the O_MS output parameter of the diagnostics block.
- The corresponding signal status is symbolically interconnected depending on your user data configuration.

**Note**

If you are not using the CFC function "Generate module drivers" you must set the Mode in/out parameter manually. Refer to the Mode settings for field devices (Page 2698) section for more on this.

For the FbDiOu block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Dosing with PA/FF devices (Dose_Lean_Fb) (Page 2857)

### Startup characteristics

The block will run through one time in OB100 at system start. The output and in/out parameters are calculated.

### Status word allocation for Status parameter

This block does not have the Status parameter.

Description of FbDiOu (Page 2505)

## 17.6.3 FbDiOu functions

### Functions of FbDiOu

The functions for this block are listed below.

### Obtaining the standard value

The signals of the FF field device are read from the process image (partition) of the inputs and written to the process image (partition) of the outputs. The input parameter `Rbk` and the active reference variable `RCasOut`, together with its associated signal status `RbkST` and `RCasOutST` are read and written to the output parameters `SP` and `RCasIn` with the associated signal status `RbkST` and `RCasOutSt`. Additional detailed device information (`CbkBy0` - `CbkBy2`) can be read as an option. The device information is available per bit at the block output.

The signal status `RbkST` or `RCasOutST` that comes directly from the device can have values from 16#00 – 16#FF.

The values of the signal status `RbkST` and `RCasOutST` of 16#84 - 16#87and 16#90 – 16#93of the FF field device are evaluated by the link as 16#80 – 16#83.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for Fb channel blocks

The block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

The signal status of the process values (`RCasIn` or `RbkLi`) is generated from internal events such as channel errors, higher-level errors, or simulations, as well as from the signal status `RbkLiST` or `RCasInST`, which comes directly from the device.

| Value | Meaning |
|---|---|
| 16#80 | Valid value |
| 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
| 16#28 | Bad, process related |

| Value | Meaning |
|---|---|
| 16#68 | Uncertain, device related |
| 16#78 | Uncertain, process related |
| 16#A4 | Maintenance request present |
| 16#00 | Invalid value |

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Keep last valid raw value

The block provides the standard function Keep last valid raw value if input value is bad (Page 207).

If `Feature.Bit31` is active and the input `SP_Li` has bad quality (16#00 OR 16#28) the outputs `SP`, `SP_ST` keep its value and will not be actualized.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |
| 31 | Keep last valid raw value if input value is bad (Page 207) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.6.4 FbDiOu error handling

### Error handling of FbDiOu

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. The channel error is generated from the signal states `RbkST` and `RCasOutSt`.

### Higher-level error / invalid measuring range

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status at `High Word` of the input parameter `Mode` accepts the value 16#40.

A higher-level error is also present when an incorrect measuring type is entered in `Low Word` of the input parameter `Mode`.

I/Os of FbDiOu

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `CbkBy0` | Additional information on the actuator status | BYTE | 16#00 |
| `CbkBy1` | Additional information on the actuator status | BYTE | 16#00 |
| `CbkBy2` | Additional information on the actuator status | BYTE | 16#00 |
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `Feature` | I/O for additional functions (Page 2507) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 30: BOOL<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0 |
| `FlutEn` | 1 = Flutter suppression activated | BOOL | 0 |
| `FlutTmIn*` | Flutter time [s] | INT | 0 |
| `MS` | Maintenance status | DWORD | 16#00000000 |
| `MS_Release` | Release for maintenance (interconnected with `MS_Release` of the technology block) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `MS_Ext` | External maintenance status. For more information, refer to the `MS_Ext` (Page 2463)parameter section under information on using channel blocks. | DWORD | 16#00000000 |
| `RCasInLi` | Setpoint for the remote cascade operating mode | BYTE | 16#00 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| RCasInLiST | Signal status for the setpoint value (RCasInLi) | BYTE | 16#80 |
| Rbk | Current position of actuator (actual value) | BYTE | 16#00 |
| RbkST | Signal status of Rbk | BYTE | 16#80 |
| RCasOut | Setpoint from function block in device | BYTE | 16#00 |
| RCasOutST | Signal status of RCasOut | BYTE | 16#80 |
| SP_Li | Setpoint | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimOn | 1 = Simulation on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimRCasInLi | Setpoint for the remote cascade operating mode RCasInLi, used for SimOn = 1 | BYTE | 16#00 |
| SimRbk | 0 = Actuator is closed<br>1 = Actuator is open | BOOL | 0 |
| SimSP_Li | 1 = Setpoint SP_Li, used for SimOn = 1 | BOOL | 0 |
| TextRef | Text reference | WORD | 16#0000 |
| DelTiBad | Delay time for output Bad [s] | REAL | 0.0 |
| SampleTime | Sample Time [s] | REAL | 0.1 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## In/out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |
| Mode | Value status and measuring type | DWORD | 16#00000000 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Bad | 1 = Process value is not valid | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Cbk0 | 1 = Field device in safe position active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Cbk1 | 1 = Request for "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Cbk2 | 1 = Field device in "manual mode" | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Cbk3 | 1 = Emergency override active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

# 17.7 FbDrive - Channel block for compact drives

## 17.7.1 Description of FbDrive

### Object name (type + number) and family

Type + number: FB 1905

Family: Channel

### Area of application of FbDrive

The block is used for the following applications:

- Integration of compact drives in PCS 7

### How it works

The FbDrive block integrates compact drives that meet the following conditions and that can be detected by the system. The detection depends on the modelling that is used by the manufacturer to describe the device.You must check if the following conditions are fulfilled:

- Integration via GSD description.
- Device has to be detected as Normslave.
- Device has to be of slave family = 1 (drive).
- Telegram type "1" with 2 input words and 2 output words or telegram frame type "20" with 6 input words and 2 output words.
- When using GSD / Profibus, the address range of the device with the addresses of the telegram are available either on the module level or the input and the output addresses can be distributed on slots.
- Profinet devices that are integrated via GSDML are not supported at the moment. A few exceptions exist that are based on the OM integration of these devices.
- Addresses of the telegrams have to be defined word wise in the symbol table.

### Configuration

The interconnection is made symbolic to the first input word. All other interconnections are updated automatically using driver wizard.

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PZDIn1` input parameter.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The Mode in/out parameter is interconnected to the corresponding `OMODE_xx` output parameter of the MOD_DRV block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DXCHG_xx` output parameter of the MOD_DRV block.
- With telegram type "1", the inputs `PZDIn1` and `PZDIn2` are interconnected with the corresponding input words and the outputs `PZDOut1` and `PZDOut2` with the corresponding output words of the drive; with telegram type "20", the inputs `PZDIn3` - `PZDIn6` are additionally interconnected with the corresponding input words of the drive.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- The parameterization of Standard Telegram Type 1 and Standard Telegram Type 20 is supported with this block.

**Note**

"Configuration of frequency converters with the APL channel block "FbDrive" in SIMATIC PCS 7 (https://support.industry.siemens.com/cs/document/64181993/configuration-of-frequency-converters-with-the-apl-channel-block-%E2%80%9Efbdrive%E2%80%9D-in-simatic-pcs-7?dti=0&lc=en-WW)"

- The use of different channel block types for the same device type of drive or inverter is not allowed.

### Startup characteristics

The block has startup characteristics.

## 17.7.2 FbDrive modes

### Operating modes of FbDrive

This block does not have any modes.

## 17.7.3 FbDrive functions

### Functions of FbDrive

The functions for this block are listed below.

### Reading messages

You can specify the format of messages using the `Feature` bit Reading messages (Page 158).

### Transmission of messages

If the block is to send messages to the upstream diagnostics block, you must activate this function at the `Feature` bit Transmission of status information of devices (Page 186).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 5 | Setting the scaling for the process values (Page 159) |
| 6 | Failure handling (Page 148) |
| 7 | Behavior in the case of Bus failure (Page 208) |
| 9 | Selection of metadata and diagnostic blocks (Page 205) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Reading messages (Page 158) |
| 29 | Transmission of status information of devices (Page 186) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |

### Forming the control word

When `STW1`(control word) is created and `Stw1ST` is simultaneously at `16#80`, the Boolean control inputs listed below have no effect and the control word `STW1` is set at the process value output `PZDOUT1`.

When the `Stw1ST` signal status has a bad value, the data is taken from the Boolean control inputs.

| | |
|---|---|
| `On` | Control word 1 bit 0 |
| `NoCoastSt` | Control word 1 bit 1 |
| `NoQuickSt` | Control word 1 bit 2 |
| `EnOp` | Control word 1 bit 3 |
| `EnRampGen` | Control word 1 bit 4 |
| `UnfreeRamp` | Control word 1 bit 5 |
| `EnSp` | Control word 1 bit 6 |
| `Ackn` | Control word 1 bit 7 |
| `Jogg1` | Control word 1 bit 8 |
| `Jogg2` | Control word 1 bit 9 |
| `Local` | Control word 1 bit 10 |
| `InvSP` | Control word 1 bit 11 |
| `Ctrl12` | Control word 1 bit 12 |
| `Ctrl13` | Control word 1 bit 13 |
| `Ctrl14` | Control word 1 bit 14 |
| `Ctrl15` | Control word 1 bit 15 |

### Setting the limits for the process value or for the calculation limits

The limits for the process value or the calculation limits are set by the SP_LiScale input.

**Calculation:**

SpeedLi.Value := (PZD2In*((SP_LiScale.HIGH-SP_LiScale.LOW)/16384.0))+SP_LiScale.LOW;

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.7.4 FbDrive error handling

### Error handling of FbDrive

Error handling of all the blocks is described in chapter Error handling (Page 128) in the basic instructions.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 1 | Invalid process value (output parameter Bad = 1) |

## 17.7.5 FbDrive messaging

### Messaging of FbDrive

This block does not offer messaging.

## 17.7.6 FbDrive status word

### Forming the status word

The `ZSW1` (status word), or the Boolean status outputs, are set via the process value input PZDIN1.

| | | |
|---|---|---|
| Status word 1 | Bit 0 | `RdyOn` |
| Status word 1 | Bit 1 | `RdyOp` |
| Status word 1 | Bit 2 | `OpEn` |
| Status word 1 | Bit 3 | `Fault` |
| Status word 1 | Bit 4 | `NoOff2` |
| Status word 1 | Bit 5 | `NoOff3` |
| Status word 1 | Bit 6 | `SwOn` |
| Status word 1 | Bit 7 | `Warning` |
| Status word 1 | Bit 8 | `SpeedErr` |
| Status word 1 | Bit 9 | `CtrlReq` |
| Status word 1 | Bit 10 | `F_N_Reach` |
| Status word 1 | Bit 11 | `Zsw1_11` |
| Status word 1 | Bit 12 | `Zsw1_12` |
| Status word 1 | Bit 13 | `Zsw1_13` |
| Status word 1 | Bit 14 | `Zsw1_14` |
| Status word 1 | Bit 15 | `Zsw1_15` |

## 17.7.7 FbDrive I/Os

**I/Os of FbDrive**

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Ackn` | OR operation with control word 1, bit 7 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `Ctrl12` | Control signal 12 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `Ctrl13` | Control signal 13 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `Ctrl14` | Control signal 14 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Ctrl15 | Control signal 15 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| EnOp | Control word 1 bit 3<br>1= Operator control active<br>0 = Operator control deactivated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| EnRampGen | Control word 1 bit 4<br>1 = Ramp generation active<br>0 = Ramp generation reset | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| EnSp | Control word 1 bit 6<br>1 = Setpoint active<br>0 = Setpoint deactivated | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 29<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |
| FlutEn | 1 = Flutter suppression on | BOOL | 0 |
| FlutTmIn* | Flutter time: If a certain number of status changes occur within this time, the flutter is suppressed | INT | 0 |
| InvSp | Setpoint inverted | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Jogg1 | Control word 1 bit 8 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Jogg2 | Control word 1 bit 9 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Local | Control word 1 bit 10<br>1 = Control via AS<br>0 = No control via AS | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS* | Maintenance status | DWORD | 16#00000000 |
| MS_Release | Release for maintenance (interconnected with MS_Release of the technology block) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| MS_Ext | Maintenance status external. For more information, refer to the MS_Ext (Page 2463) parameter section under information on using channel blocks. | DWORD | 16#00000000 |
| NoCoastSt | Control word 1 bit 1<br>1 = Do not de-energize and coast down drive<br>0 = De-energized and coast down drive | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoQuickSt | Control word 1 bit 2<br>1 = No rapid stop<br>0 = Rapid stop | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PZDIn1 | Input word 1 - ZSW1 | WORD | 16#0000 |
| PZDIn2 | Input word 2 - NIST_A_GLATT/ FIST_GLATT | WORD | 16#0000 |
| PZDIn3 | Input word 3 - IAIST_GLATT | WORD | 16#0000 |
| PZDIn4 | Input word 4 - ITIST_GLATT/ MIST_GLATT | WORD | 16#0000 |
| PZDIn5 | Input word 5 - PIST_GLATT | WORD | 16#0000 |
| PZDIn6 | Input word 6 - MsgNamur | WORD | 16#0000 |
| PZDIn2Unit | Unit of measure for process value | INT | 1342 |

| DelTiBad | Delay time for output Bad [s] | REAL | 0.0 |
| SampleTime | Sample Time [s] | REAL | 0.1 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## In/out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| Mode | Value status and measuring type | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Bad | 1 = Process value is not valid | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| CtrlReq | 1 = Control request | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| CurrentLi | Normal value PZD 3 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| CurrentScale | Scaling PZD 3 | STRUCT<br>• HIGH: REAL<br>• LOW: REAL | -<br>• 100.0<br>• 0.0 |
| CurrentUnit | Unit of measurement PZD 3 | INT | 0 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Output of pending error number | INT | -1 |
| F_N_Reach | 1 = f or n reached or exceeded<br>0 = f or n not reached | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Fault | 1 = Error is present | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| FreeLi | Normal value PZD 6 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| FreeScale | Scaling PZD 6 | STRUCT<br>• HIGH: REAL<br>• LOW: REAL | -<br>• 100.0<br>• 0.0 |
| FreeUnit | Unit of measurement PZD 6 | INT | 0 |
| MsgNamur | PZD 6 in VIK-NAMUR mode | WORD | 16#0000 |
| ModErr | 1 = Device/module is faulty | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoOff2 | 1 = De-energize and coast down not active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| NoOff3 | 1 = Rapid stop not active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Field device is undergoing maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| OpEn | 1 = Enable setpoint operation | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Power1Li | Normal value PZD 4 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Power1Scale | Scaling PZD 4 | STRUCT<br>• HIGH: REAL<br>• LOW: REAL | -<br>• 100.0<br>• 0.0 |
| Power1Unit | Unit of measurement PZD 4 | INT | 0 |
| Power2Li | Normal value PZD 5 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| Power2Scale | Scaling PZD 5 | STRUCT<br>• HIGH: REAL<br>• LOW: REAL | -<br>• 100.0<br>• 0.0 |
| Power2Unit | Unit of measurement PZD 5 | INT | 0 |
| PZDOut1 | Output word 1 - STW1 | WORD | 16#0000 |
| PZDOut2 | Output word 2 - NSOLL_A/ FSOLL | WORD | 16#0000 |
| RdyOn | 1 = Ready to switch on<br>0 = Not ready to switch on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RdyOp | 1 = Ready for operation<br>0 = Not ready for operation | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SpeedErr | 1 = Error speed within the tolerance range<br>0= Error speed outside the tolerance range | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SpeedLi | Normal value PZD 2 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| SpeedScale | Scaling PZD 2 | STRUCT<br>• HIGH: REAL<br>• LOW: REAL | -<br>• 100.0<br>• 0.0 |
| SpeedUnit | Unit of measurement PZD 2 | INT | % |
| SwOn | 1 = Cannot switch on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| Warning | 1 = Warning active<br>0 = No warning active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Zsw1 | Status word | WORD | 0 |
| Zsw1_11 | Device-specific | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Zsw1_12 | Device-specific | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Zsw1_13 | Device-specific | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Zsw1_14 | Device-specific | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Zsw1_15 | Device-specific | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |

## 17.7.8 FbDrive block diagram

### Block diagram of FbDrive

A block diagram is not provided for this block.

# 17.8 FbEnMe - Channel block for ET 200SP Energy Meter

## 17.8.1 Description of FbEnMe

### Object name (type + number) and family

Type + Nubmer: FB 1908

Family: Channel

### Area of application for FbEnMe

The block is used for the following application:

- Integration of energy meter in ET 200SP/ET 200SP HA with firmware V6.0 in PCS 7.

**Note**

ET 200SP HA only supports PN and ET 200SP supports both DP and PN configurations.

### How it works

The block FbEnMe integrates the above mentioned module if the following conditions are fulfilled:

- In the HW Config, user selects the dataset 253 or 252 or 251 or 250 or 159.
- Module version 32 bytes input data/12 bytes output data.
- Module version 32 bytes input data/20 bytes output data.

### Configuration

The interconnection is made symbolic to the first input word. All other interconnections are updated automatically using a wizard.

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PZDIn1` input parameter.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameters `Mode`, `DataXchg`, `DataXchg1`, and `MS_Xchg` of the FbEnMe block are interconnected with the corresponding output parameters `OMODE_00`, `DXCHG_00`, `DXCHG1_00`, and `MS_XCHG_00` of the MOD_ENME block.
- The `PZD1` to `PZD32` input parameters and the `PZDOut1` to `PZDOut12/PZDOut20` (in the case of HF V6.0 Energy Meter) output parameters are interconnected with the corresponding symbols in the process image.

- The output parameters PZDOut13 ... PZDOut20 are connected (via metadata) only in the case of Energy Meters with V6.0 as these type of meters deliver upto 20 bytes output data.
- /*+The MS parameter is interconnected to the O_MS output parameter of the MOD_ENME diagnostic block.

### Startup characteristics

The block has startup characteristics.

### Status word allocation for Status parameter

This block does not have the Status parameter.

FbEnMe block diagram (Page 2539)

## 17.8.3 FbEnMe functions

### Functions of FbEnMe

The functions of this block are listed below.

### Transmission of messages

If the block is to send messages to the upstream diagnostics block, you must activate this function at the `Feature` bit Transmission of status information of devices (Page 186).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139). The following functionalities are available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 29 | Transmission of status information of devices (Page 186) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |

### Forming the control word

When `STW1` (control word) is created and `Stw1ST` is simultaneously set at 16#80, the Boolean control inputs listed below have no effect and the control word `STW1` is set at the process value output `PZDOUT2`.

When the `Stw1ST` signal status has a bad value, the data is taken from the Boolean control inputs.

| | |
|---|---|
| `PZDOut1` | Variant ID from the input word `PZDIn1` |
| `PZDOut2` Bit 6 | `Opn_EnCnt` |
| `PZDOut2` Bit 7 | `Rst_EnCnt` |

**Energy meter gate:**

This function has to be activated in parameter 128 first before you can use the gate. Please refer to hardware manual. If the function is activated, the parameter “Opn_EnCnt” switches the gate to open or close.

**"Reset on request":**

With a positive edge of the parameter `Rst_EnCnt` of this channel block, the values are adopted from energy meter data record 143.

**Note**

The data record 143 of the energy meter will not be written by the channel block FbEnMe to the device. This has to be set by the operator manually.

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.8.4 FbEnMe error handling

### Error handling of FbEnMe

Error handling of all the blocks is described in chapter Error handling (Page 128) in the basic instructions.

The following error can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` parameter can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |

### I/Os of FbEnMe

## Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| PZDIn1 | Input byte 0 | BYTE | 16#00 |
| ... | ... | ... | ... |
| PZDIn32 | Input byte 31 | BYTE | 16#00 |
| MS_Release | Release for maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS | Maintenance state | DWORD | 16#00000000 |
| MS_Ext | External maintenance status. For more information, refer to the MS_Ext (Page 2463) parameter section under information on using channel blocks. | DWORD | 16#00000000 |
| TextRef | Text 1 reference external messages | WORD | 16#0000 |
| FlutEn | 1 = Flutter suppression on | BOOL | 0 |
| FlutTmIn | Flutter suppression time | INT | 0 |
| Stw1 | Control word | BYTE | 16#00 |
| Stw1ST | Control word status | BYTE | 16#00 |
| Rst_EnCnt | Reset energy meter | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Opn_EnCnt | Open energy meter gate | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions (Page 2530) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 29: BOOL<br>• Bit 30: BOOL<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1<br>• 1<br>• 0 |
| DelTiBad | Delay time for output Bad [s] | REAL | 0.0 |
| SampleTime | Sample Time [s] | REAL | 0.1 |

## In/Out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Mode0 | Quality and mode - Phase 1 | DWORD | 16#00000000 |
| Mode1 | Quality and mode - Phase 2 | DWORD | 16#00000000 |
| Mode2 | Quality and mode - Phase 3 | DWORD | 16#00000000 |
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| PZDOut1 | Output byte 0 | BYTE | 16#00 |
| ... | ... | ... | ... |
| PZDOut20 | Output byte 20 | BYTE | 16#00 |
| Bad | 1 = Process value is not valid | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ErrorNum | Error number | INT | -1 |
| ModErr | 1 = Device/module is faulty | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Variant | User data variant | INT | 0 |
| VarError | Configured user data variant is not supported | BOOL | 1 |
| CurL1Li | Current L1 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

# 17.9 FbSwtMMS - Channel block for MM starter

## 17.9.1 Description of FbSwtMMS

### Object name (type + number) and family

Type + number: FB 1907

Family: Channel

### Area of application of FbSwtMMS

The block is used for the following applications:

- Signal processing of motor management starter with profile type 1 with 2 input words and 1 output word. The Input adress of the input words must be configured.

| NOTICE |
| --- |
| **Integration of the block into technological charts**<br>Make sure when installing the block into the technological charts that the device is a switching device of slave family 2 (switching device).<br>Make sure that the device is installed according to profile type 1 for motor managed starters of the LVSG; otherwise, the block will not work correctly. The block is automatically connected with the process image according to the specifications of profile type 1. |

### How it works

The FbSwtMMS block integrates a motor management starter from any switch or starter object.

### Configuration

The interconnection is made symbolic to the first input or output word. All other interconnections are updated automatically using a wizard.

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The `MODE` input is interconnected to the relevant `OMODE` output of the MOD_SWT block.
- The `PZDIn2` input and the `PZDOut1` output are interconnected using the icons of the compact drives.
- The `DataXchg` input is interconnected to the relevant `DXCHG_00` output of the MOD_SWT block.
- The `MS` input is interconnected to the relevant `O_MS` output of the MOD_SWT block.

**Note**

If motor starters which support hardware interrupts are used and if only the APL channel block `FbSwtMMS` is used, the associated hardware interrupts such as OB40 should be deactivated for these devices in order to avoid error messages and unnecessary CPU load.

"Configuration of direct starters with the APL channel block "FbSwtMMS" in SIMATIC PCS 7 (https://support.industry.siemens.com/cs/document/64182525/configuration-of-direct-starters-with-the-apl-channel-block-%E2%80%9Efbswtmms%E2%80%9D-in-simatic-pcs-7?dti=0&lc=en-DE)"

### Startup characteristics

The block has startup characteristics.

## 17.9.2 FbSwtMMS modes

### Operating modes of FbSwtMMS

This block does not have any modes.

## 17.9.3 FbSwtMMS functions

### Functions of FbSwtMMS

The functions for this block are listed below.

### Transmission of messages

If the block is to send messages to the upstream diagnostics block, you must activate this function at the `Feature` bit Transmission of status information of devices (Page 186).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the chapter Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 7 | Behavior in the case of Bus failure (Page 208) |
| 9 | Selection of metadata and diagnostic blocks (Page 205) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |

| Bit | Function |
|---|---|
| 29 | Transmission of status information of devices (Page 186) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |

### Forming the control word

When STW1(control word) is created and Stw1ST is at 16#80, the Boolean control inputs listed below have no effect and the control word STW1 is set at the process value output PZDOUT1.

When the Stw1ST signal status has a bad value, the data is taken from the Boolean control inputs.

| | |
|---|---|
| Rev | Control word 1 bit 0 |
| Off | Control word 1 bit 1 |
| Fwd | Control word 1 bit 2 |
| StartTest | Control word 1 bit 3 |
| StartEmerg | Control word 1 bit 4 |
| Auto | Control word 1 bit 5 |
| ResetTrip | Control word 1 bit 6 |
| Ctrl7 | Control word 1 bit 7 |
| Ctrl8 | Control word 1 bit 8 |
| Ctrl9 | Control word 1 bit 9 |
| Ctrl10 | Control word 1 bit 10 |
| Ctrl11 | Control word 1 bit 11 |
| ManSpec1 | Control word 1 bit 12 |
| ManSpec2 | Control word 1 bit 13 |
| ManSpec3 | Control word 1 bit 14 |
| ManSpec4 | Control word 1 bit 15 |

### Delay the output "Bad"

If input DelTiBad > 0, on receiving an internal bad value, delay timer will start. Timer will abort if DelTiBad is 0. Minimum value of DelTiBad is 0. Only when timer expires i.e., RemDelTiBad = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running Bad.ST will be 16#60. Only after the timer expires the actual ST be updated. Substitute value is updated at PV_Out, only after delay timer expires. When timer is running last valid value will be there at PV_Out. When substitute value is used, ST of PV_Out will be 16#60.

## 17.9.4 FbSwtMMS error handling

### Error handling of FbSwtMMS

Error handling of all the blocks is described in chapter Error handling (Page 128) in the basic instructions.

The following errors can be displayed for this block:

- Error numbers

**Note**

If an error occurs during switching, all outputs are written as before to the field device. The inputs of the field device are displayed and the status with the value 16#00 is formed according to the MS.

**Note**

The outputs are locked during Drive, only the Local and Reset are transmitted to the device. The inputs react as with FbSwtMMS.

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not processed. |
| 0 | There is no error. |
| 1 | Invalid process value (output parameter Bad = 1) |

## 17.9.5 FbSwtMMS messaging

### Messaging

This block does not offer messaging.

## 17.9.6 FbSwtMMS status word

### Forming the status word

The `ZSW1` (status word), or the Boolean status outputs, is set via the process value input `PZDIN1`.

| | | |
|---|---|---|
| Status word 1 | Bit 0 | `FdkRev` |
| Status word 1 | Bit 1 | `FdkOff` |
| Status word 1 | Bit 2 | `FdkFwd` |
| Status word 1 | Bit 3 | `OverlAct` |
| Status word 1 | Bit 4 | `LockTmAct` |
| Status word 1 | Bit 5 | `FdkAuto` |

| | | |
|---|---|---|
| Status word 1 | Bit 6 | ErrAct |
| Status word 1 | Bit 7 | WarnAct |
| Status word 1 | Bit 8 | Status8 |
| Status word 1 | Bit 9 | Status9 |
| Status word 1 | Bit 10 | ManSpcO5 |
| Status word 1 | Bit 11 | ManSpcO6 |
| Status word 1 | Bit 12 | ManSpcO1 |
| Status word 1 | Bit 13 | ManSpcO2 |
| Status word 1 | Bit 14 | ManSpcO3 |
| Status word 1 | Bit 15 | ManSpcO4 |

## 17.9.7 FbSwtMMS I/Os

I/Os of FbSwtMMS

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Auto | Control command for remote control I bit 0.5 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

## 17.9.8 FbSwtMMS block diagram

### Block diagram of FbSwtMMS

A block diagram is not provided for this block.

# 17.10 Pcs7AITC - Analog input driver, dynamic measuring range center

## 17.10.1 Pcs7AITC description

### Object name (type + number) and family

Type + number: FB 1933

Family: Channel

### Area of application for Pcs7AITC

The block is used for the following applications:

- Signal processing of ET 200SP HA AI16 x TC/8xRTD HA (6DL1 134-6JH00-0PH1) with process values in REAL format for Measuring Type Thermocouple and Measuring range Type K [NiCr-NiAl], Type B [PtRh-PtRh], Type N [NiCrSi-NiSi], and Type S [PtRh-Pt]. It is also used in combination with I/O redundancy.
- Signal processing of ET 200SP AI4 x RTD/TC HF (6ES7 134-6JD00-0CA1) module with dynamic scalable measuring range for Measuring Type Thermocouple and Measuring Range Type K [NiCr-NiAl], Type B [PtRh-PtRh], Type N [NiCrSi-NiSi], and Type S [PtRh-Pt].

To use the mentioned modules without process values in REAL format or without scalable measuring range, you can use the channel block Pcs7AnIn.

### How it works

The block cyclically processes all the channel-specific signal functions of an analog input module. It reads the data from the process image (partition) and provides the physical value. The Input parameters that are parameterized by the driver wizard define the channel settings of the module and the corresponding behavior of Pcs7AITC.

The information exchange parameter `MrcXchg` adjusts the current Measuring Range Center (MRC) of ET 200SP analog input module. It is connected to the coordination function block WRDS_CO of the Basis Library by driver wizard.

The block supports the hardware settings for Degrees Celsius (°C) and Degrees Fahrenheit (°F).

### Configuration

You can use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). Additionally, the block is installed automatically in the startup OB (OB100).

Depending on the channel selected, the symbol generated in the HW Config (Symbol table) for the input channel can be manually connected with the input parameter `PV_InR` or `PV_In`.

**Note**

- `PV_InR` is used for AI channels with process values in REAL format for example: ET 200SP HA I/O modules.
- `PV_In` is used for AI channels with scalable measuring range for example: ET 200SP I/O modules.

In case of redundant I/O configuration, use the symbol of the channel in the master module.

When the CFC function "Generate module drivers" is used, the following operations occur automatically:

- The IN_OUT parameter `Mode` is interconnected to the corresponding `OMODE_xx` (xx = channel number) output parameter of the MOD block.
- The IN_OUT parameter `DataXchg` is interconnected to the corresponding `DXCHG_xx` (xx = channel number) output parameter of the MOD block.
- The IN_OUT parameter `DataXchg1` is interconnected to the corresponding `DXCHG1_xx` (xx = channel number) output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- The IN parameter `PV_sel` is set as follows:
  - `PV_sel` = 0 if the input channel uses the data type WORD for process values
  - `PV_sel` = 1 if the input channel uses the data type REAL for process values
- The Input parameter `ChValueAct` is parameterized with the channel number (0...31) from module.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter `ProImQB` is interconnected with the corresponding symbol and the input parameter `SelQB` is set to 1 (otherwise 0).

In case of I/O redundancy (ET 200SP HA):

- the interconnection with the symbols of both the input parameters `ProImQB` and `ProImQBSlv` is done.
- the interconnection with the symbol of the slave channel for input parameter `PV_InRSlv` is done.

If ET 200SP is used (only for scalable measuring range):

- the input parameter `MrcXchg` of type ANY is interconnected with output parameter `MRC_XCHG` of corresponding coordination block WRDS_CO.
- the input parameter `Scale` (`Scale.High` and `Scale.Low`) is parameterized with the start values of scaling, depending on HW Config (HWC) settings (minimum and maximum).
- the input parameter `MrcHWC` is parameterized with the start value for measuring range center from HW Config (HWC).
- `FeatureBit6` is parameterized with the information "Scalable measuring range".

- `FeatureBit7` is parameterized with the information "Scalable measuring range 2 decimal points".
- `FeatureBit8` is parameterized with the information "Scalable measuring range 3 decimal points".

**Note**

If you are not using the CFC function "Generate module drivers" you must set the `IN_OUT` parameter Mode manually. Refer to the Mode Settings for SM Modules (Page 2687) section for more on this.

The handling of channel block Pcs7AITC is similar to Pcs7AnIn thus, the Advanced Process Library does not contain own templates.

Examples of process tag types:

- Monitoring an analog process tag (AnalogMonitoring) (Page 2854)
- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Cascade control with PIDConR (CascadeR) (Page 2843)
- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- Override control with PIDConR (OverrideR) (Page 2848)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- Ratio control with PIDConR (RatioR) (Page 2839)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Model-based predictive control (ModPreCon) (Page 2849)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Dosing (Dose_Lean) (Page 2856)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

## Startup characteristics

The accept value delay is started when `CountLim` ≠ 0.

### Quality code (ET200 SP HA modules)

The quality code is read from the process image and has two states: "Good" (true) or "Bad" (false).

### Redundancy

Depending on the QI, the function block decides which of the two redundant process values is transferred and processed.

- In case the master channel delivers a "good" state in QI, then the master channel process value is used.
- In case the master channel delivers a "bad" state and the slave channel delivers a "good" state, then the slave channel process value is used.
- In case both QI is "bad", it depends on your parameterization if master process value or a substitute value is transferred.

### Status word allocation for Status parameter

This block does not have the `Status` parameter.

### See also

Override control (Page 2846)

## 17.10.2 Pcs7AITC functions

### Functions of Pcs7AITC

The functions for this block are listed below.

### Checking the raw value

The nominal range for converting analog signals into digital values (raw values) on the module, depends on the measuring type and the range of the analog input channel. The nominal range is defined in the hardware configuration and is automatically saved in the in/out parameter when the block driver `Mode` is created.

This includes an overshoot/undershoot range within which an analog signal can still be converted to a digital value. This range is defined in relation to the nominal range (approximately 18.5%). Outside this range, an overflow or underflow occurs and the output parameter `Bad` = 1 is set.

- Output parameter `PV_LoAct` = 1 is set if the value is outside the nominal low range.
- Output parameter `PV_HiAct` = 1 is set if the value is outside the nominal high range.

If dynamic scalable measuring range of ET 200SP AI module is used, the parameters `PV_LoAct` and `PV_HiAct` are only set in case of underflow or overflow.

### Obtaining the standard value

The standard value ( temperature - a physical quantity) is obtained from the scalable measuring range of the ET 200SP AI module. The driver wizard parameterizes the input parameter `Scale` and uses it for managing the functionality of scalable measuring range.

If REAL data format is used with Thermocouple Type K, Type B, Type N, or Type S, then set the values `Scale.Low` = 0 and `Scale.High` = 1. This is because, the raw value from the module is already a physical quantity (temperature).

### Holding the last value if raw value is invalid

If the block is to hold the most recent valid value when the raw value is invalid, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

You can also influence this function via the input parameter `DeltaVal` as follows:

- `DeltaVal` ≤ 0: the last value is retained and is not influenced
- `DeltaVal` > 0: the last or the next to last value is output

If you set the parameter `DeltaVal` > 0, the last `PV_Out`(k - 1) or next to last `PV_Out` (k - 2) is the valid output value and the (`PV_Out`(k) is the current value, where k is the current time).

At parameter `DeltaVal` you can preset a permitted process value change (`PV_Out`) between two calls.

You have the following options:

- For invalid raw values and `DeltaVal` > 0:
  - If |`PV_Out`(k - 1) - `PV_Out`(k - 2)| > `DeltaVal`, then `PV_Out` = `PV_Out`(k - 2) (last but one valid output value is the output)
  - If |`PV_Out`(k) - `PV_Out`(k - 1)| ≤ `DeltaVal`, then `PV_Out` = `PV_Out`(k - 1) (last valid output value is the output)
- For valid raw values and `DeltaVal` > 0:
  - |`PV_Out`(k) - `PV_Out`(k - 1)| > `DeltaVal`, so for one cycle `PV_Out` = `PV_Out`(k - 1) is output, that is, the input parameter. `DeltaVal` is used to limit the change made to the valid raw value. In addition, the signal status at the output parameter `PV_Out` is set to 16#60 and the output parameter is set to `Bad` = 0.
    The value of `DeltaVal` should be selected with due care. If the value is too low, the quality code may flutter between16#80 and 16#60, regardless of the status of the raw value.

### Output substitute value if raw value is invalid

If the block is to output a substitute value (`SubsPV_In`) when the raw value is invalid, you must activate the preset function at the `Feature` Bit Output substitute value if raw value is invalid (Page 160).

### Value application delay

After a restart, or if the output parameter `Bad` changes its value from 1 to 0, the signal status and the value of output parameter `PV_Out` are not updated until the number of cycles for delayed application of the value (input parameter `CountLim`) have elapsed. During the value application delay, the signal status at the output parameter is `PV_Out` = 16#00 and `Bad` = 1. The last value is retained during the value application delay.

If `CountLim` = 0 , the function is deactivated.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for PCS 7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks (Page 127).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable response using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 6 | Scalable measuring range (driver wizard) (Page 203) |
| 7 | 2 decimal points (scalable measuring range) - parameterized by the driver wizard (Page 203) |
| 8 | 3 decimal points (scalable measuring range) - parameterized by the driver wizard (Page 204) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 11 | Reserved |
| 12 | 0 = manual new MRC value,<br>1 = AUTO trigger for new Measuring Range Center |
| 13 | 1 = AUTO value for new Measuring Range Center |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Sign-of-life monitoring

If an analog input value with signal status 16#80 (good) remains constant for a programmable time (monitoring time), the input value is detected as faulty and the output parameters `Bad` and `FrzVal` are set to 1. The signal status is set to `PV_Out.ST` = 16#00.

The monitoring time is defined at the input parameter `FrznTmIn` (in seconds). With `FrznTmIn` = 0 or `FrznEn` = 0 (default setting), the sign-of-life monitoring is deactivated, any pending errors are reset.

The input value is considered as faulty after monitoring time as long as it stays constant. The monitoring time is restarted each time the input value changes.

### Scalable measuring range (only ET 200SP)

Scalable measuring range is a functionality provided by ET 200SP AI modules. It allows an increased resolution in a reduced measuring range . The Measuring Range Center (MRC) and the resolution (2 or 3 decimal places) can be configured.

For more information, refer to the manual "*SIMATIC ET 200SP analog input module AI 4xRTD/TC 2-/3-/4-wire HF*".

Together with coordination block WRDS_CO from the Basis Library, the Pcs7AITC block can request new values for MRC, manually or automatically via WRREC of DS128 to the module. This depends on the setting of `Feature.Bit12` and `Feature.Bit13`. With these two bits the following modes are possible:

- `Feature.Bit12` = 0, `Feature.Bit13` = 0 - "manual mode with trigger input bit"
  With the input parameter `MrcVal`, a new MRC can be defined. With a rising edge on input parameter `MrcReq` the new MRC value is requested.The `MrcReq` is then reset.
- `Feature.Bit12` = 1, `Feature.Bit13` = 0 - "manual mode without trigger input bit"
  With the input parameter `MrcVal`, a new MRC can be defined. With a value change on this parameter, the new value is requested automatically.
- `Feature.Bit12` = 0, `Feature.Bit13` = 1 - "manual update of MRC "
  With a rising at the input parameter `MrcReq`, the current process value (`PV_Out.Value`) is taken for requesting a new MRC.
- `Feature.Bit12` = 1, `Feature.Bit13` = 1 - "automatic update of MRC"
  As soon as the process value approaches current `Scale` values, a new MRC is requested automatically. The corresponding percentage values that define the ranges in which a new MRC is requested, can be defined via the input parameters `MrcPL` and `MrcPH`.

With the input parameter `MrcTime`, a waiting time for a new MRC request can be defined. After having requested a new MRC, this time starts to run and within this time, no new MRC can be requested again.

The input parameter `MrcFrz` defines the time, as long as no new `PV_Out` is calculated after having requested a new MRC. It is suggested to select a bigger value for `MrcTime` than for `MrcFrz`.

The output parameter `MrcCurr` always presents the currently used MRC value. `ScaleOut` is a structured output parameter that contains the currently used `Scale` values. The output parameter `MrcBusy` displays that a new MRC was requested and that the handling is still active. The output parameter `MrcTiLo` = 1 means that the time lock is not yet over (see input parameter `MrcTime`).

If an underflow (PV_In =16#8000) or overflow (PV_In = 16#7FFF) occurs, Pcs7AITC tries to let the underflow/overflow situation disappear. If Feature.Bit12 and Feature.Bit13 are set, Pcs7AITC requests a new MRC value that is identical to the current value of ScaleOut.Low (in case of underflow) or ScaleOut.High (in case of overflow). In case Feature.Bit12 is not set, but Feature.Bit13 is set, MrcReq = 1 is necessary to start each MRC request.

This leads to the fact that in case of wire break, when the module delivers PV_In = 16#7FFF, the described mechanism starts and the output parameter MrcCurr together with Scale.Out reaches highest range. After wire break is reduced, Pcs7AITC finds a suitable MRC for the current process value. During this search that starts at the highest range, a temporary underflow (PV_In = 16#8000) occurs. This can also lead to a corresponding diagnostic from module that leads to the message "Lower limit violated" C/G of the MOD function block.

### Delay the output "Bad"

If input DelTiBad > 0, on receiving an internal bad value, delay timer will start. Timer will abort if DelTiBad is 0. Minimum value of DelTiBad is 0. Only when timer expires i.e., RemDelTiBad = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running Bad.ST will be 16#60. Only after the timer expires the actual ST be updated. Substitute value is updated at PV_Out, only after delay timer expires. When timer is running last valid value will be there at PV_Out. When substitute value is used, ST of PV_Out will be 16#60.

## 17.10.3 Pcs7AITC error handling

### Error handling of Pcs7AITC

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range
- Frozen input value (sign-of-life monitoring)

### Channel error

At the output parameter Bad, channel errors are displayed with the value 1. Channel errors can be detected using the raw value, the Quality Information or the sign-of-life monitoring.

The output parameters PV_LoAct or PV_HiAct remain set to 1, if a channel error occurs due to the module diagnosis "Undershoot or overshoot of the measurement range".

### Higher-level error / invalid measuring range

A higher-level error output is obtained (output parameter `ModErr` = 1 and `Bad` = 1) if either:

- the signal status in the High Word of input parameter mode takes the value 16#40, or
- there is an invalid measuring type in the Low Word of the input parameter mode.

## 17.10.4 Pcs7AITC messaging

### Messaging

This block does not offer messaging.

## 17.10.5 Pcs7AITC I/Os

I/Os of Pcs7AITC

### Input parameters

| Parameter | Data type | Initial value | Description |

# 17.11 Pcs7AnIn - Analog input channel block

## 17.11.1 Description of Pcs7AnIn

### Object name (type + number) and family

Type + number: FB 1869

Family: Channel

### Area of application for Pcs7AnIn

The block is used for the following applications:

- Signal processing of an analog input value of S7-300/400 SM analog input modules including ET 200M Ex-io module in °C.
- Processing of the redundant input channels.

### How it works

The block cyclically processes all channel-specific signal functions of an analog input module.

It reads a raw analog value from the process image (partition) and converts it to its physical value or calculates a percentage value based on this raw value. Use the status at input parameter `Mode` to define the format of the raw value and how it is processed.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected to the corresponding `OMode_xx` output parameter of the MOD block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DataXchg_xx` output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The in parameter `PV_InSlv` is interconnected with the symbol of the slave channel.
- The in parameter `ProImQB` is interconnected with the symbol of the quality bit of the master channel.
- The in parameter `ProImQBSlv` is interconnected with the symbol of the quality bit of the slave channel.

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PV_In` input parameter.

In case of redundant I/O configuration, use symbol of the channel of the master module.

**Note**

If you are not using the CFC function "Generate module drivers" you must set the `Mode` in/out parameter manually. Refer to the Mode Settings for SM Modules (Page 2687) section for more on this.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter `ProImQB` is interconnected with the corresponding symbol and the input parameter `SelQB` is set to 1 (otherwise 0).

For the Pcs7AnIn block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring an analog process tag (AnalogMonitoring) (Page 2854)
- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Cascade control with PIDConR (CascadeR) (Page 2843)
- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- Override control (Page 2846)
- Override control with PIDConR (OverrideR) (Page 2848)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- Ratio control with PIDConR (RatioR) (Page 2839)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Model-based predictive control (ModPreCon) (Page 2849)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Dosing (Dose_Lean) (Page 2856)
- Control valve (VlvAnL) (Page 2868)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

### Startup characteristics

The accept value delay is started when `CountLim` ≠ 0 .

### Quality code (ET200 SP HA modules)

The quality code is read from the process image and has two states: "Good" or "Bad".

### Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and the value of the signal with "Good" quality code along with its quality code is transferred to the process.

In case both the signals deliver "Bad" quality code, the substitute value or the invalid value takes effect depending on the configuration of the Feature parameter.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 17.11.3 Pcs7AnIn functions

### Functions of Pcs7AnIn

The functions for this block are listed below.

### Checking the raw value

The nominal range sets the range for converting analog signals into digital values (raw values), depending on the measuring type and the range of the analog input module. The nominal range is defined in the hardware configuration and is automatically saved in the in/out parameter when the block driver `Mode` is created.

This includes an overshoot/undershoot range within which an analog signal can still be converted to a digital value. This range is defined in relation to the nominal range (roughly 18.5%). Outside this range an overflow or underflow occurs and output parameter `Bad` = 1 is set.

- Output parameter `PV_LoAct` = 1 is set if the value is outside the nominal low range.
- Output parameter `PV_HiAct` = 1 is set if the value is outside the nominal high range.

### NAMUR limit checking (only with modules of 4 to 20 mA)

In "Life Zero" monitoring, the process signal is invalid (`Bad` = 1), if the measured current is less than 3.6 mA or greater than 21 mA (defined by NAMUR).

The NAMUR limits are set as fixed defaults for limit monitoring. You can define other limits by setting input parameter `NamurOff` = 1 and setting corresponding new limits in [mA] at the `HighLimit` and `LowLimit` input parameters. If the active limits are exceeded or undershot (`HighLimit` or `LowLimit` = 1), `Bad` = 1 is set for a "Life Zero" analog signal.

**Note**

The limits that can be selected must be within the overshoot range of the module for `HighLimit` and the undershoot range of the module for `LowLimit`. Values outside the NAMUR range are also possible, if the module does not automatically limit the measured values.

### Obtaining the standard value

The standard value (a physical quantity) is obtained from the raw value using parameters `Scale` and `Mode`. Set two scale values on the structured parameter `Scale`.

- High scale value (`Scale.High`)
- Low scale value (`Scale.Low`)

If you are not using the CFC function "Generate module drivers" you must set the `Mode` in/out parameter manually. Refer to the Mode Settings for SM Modules (Page 2687) section for more on this.

The settings of the parameter `Scale` are copied to the output parameter`ScaleOut`. The output parameter can be interconnected to a corresponding input parameter of a technologic block (e.g. `PV_OpScale`).

The standard value is obtained using a linear characteristic. `Scale.Low` is the lowest physical value that the process variable can take and `Scale.High` is the highest.

If `Scale.Low` = 0 and `Scale.High` = 100 a percentage is obtained.

Special cases when obtaining the standard value using the `Scale` parameter:

- If you set `Scale.High` = `Scale.Low`, you obtain the analog input module's electrical input signal (e.g., mA) according to the `Mode` parameter setting.
- If the raw value is already a physical quantity (for example, RTD or TC), set `Scale.Low` = 0 and `Scale.High` = 1. This will cause the raw value to be output unchanged, as a physical quantity.
- When using measuring type PTC (**P**ositive **T**emperature **C**oefficient binary evaluation of resistance thermometers), the analog value contains an encoded binary signal. The `PV_Out` output provides the following information:
  - If the measured resistance is within the normal range, `PV_Out` = 0.0
  - If the measured resistance is within the prewarning range, `PV_Out` = 4.0
  - If the measured resistance is in the operating range, `PV_Out` = 1.0
    This is only true if the input parameters are `Scale.Low` = 0 and `Scale.High` = 1 . During simulation or if the substitute value is output, you can only set the input parameters `SimPV_In` and `SubsPV_In` to 0.0 or 1.0.
- Measurement type `TC_I` / `TC_E` (linearization is not taken into account) for the modules 6ES7 331-7KF0-x:
  With the measuring type "External or internal comparison of thermocouple values", the raw value is adapted to the physical variable ± 80 mV range for these modules. You have to determine the temperature using the corresponding conversion tables in the module manual. The physical equivalent in [mV] is returned by the module as a raw value. Set `Scale` to ± 80 mV.

### Holding the last value if raw value is invalid

If the block is to hold the most recent valid value when the raw value is invalid, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

You can also influence this function via the input parameter `DeltaVal`.

- `DeltaVal` ≤ 0: the last value is retained and is not influenced
- `DeltaVal` > 0: the last or the next to last value is output

If you set the parameter `DeltaVal` > 0, the last `PV_Out`(k - 1) or next to last `PV_Out`(k - 2) valid output value is output (`PV_Out`(k) is the current value, k is the current time).

At parameter `DeltaVal` you can preset a permitted process value change (`PV_Out`) between two calls.

You have the following options:

- For invalid raw values and DeltaVal > 0:
  - If |PV_Out(k - 1) - PV_Out(k - 2)| > DeltaVal, then PV_Out = PV_Out(k - 2) (last but one valid output value is output)
  - If |PV_Out(k) - PV_Out(k - 1)| ≤ DeltaVal, then PV_Out = PV_Out(k - 1) (last valid output value is output)
- For valid raw values and DeltaVal > 0:
  - |PV_Out(k) - PV_Out(k - 1)| > DeltaVal, so for one cycle PV_Out = PV_Out(k - 1) is output, i.e. DeltaVal is used to limit the change made to the valid raw value. In addition, the signal status at the output parameter PV_Out is set to 16#60 and the output parameter is set to Bad = 0 .
    The value of DeltaVal should be selected with due care. If the value is too low, the quality code may flutter between16#80 and 16#60, regardless whether or not the raw value is OK.

### Output substitute value if raw value is invalid

If the block is to output a substitute value (SubsPV_In) when the raw value is invalid, you must activate this function at the Feature Bit Output substitute value if raw value is invalid (Page 160).

### Output of invalid value if raw value is invalid

If the block is to output an invalid value (PV_Out = PV_In), you must activate this function at the Feature Bit Output invalid raw value (Page 185).

This function is preset.

### Value application delay

After a restart, or if the output parameter Bad changes its value from 1 to 0 the signal status and the value of output parameter PV_Out are not updated until the number of cycles for delayed application of the value (input parameter CountLim) have elapsed. During the value application delay, the signal status at the output parameter is PV_Out = 16#00 and Bad = 1. The last value is retained during the value application delay.

If CountLim = 0 , the function is deactivated.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for PCS 7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks (Page 127).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 5 | Activate LowCutOff (Page 166) |
| 6 | Scalable measuring range (Page 203) |
| 7 | 2 decimal points (scalable measuring range) (Page 203) |
| 8 | 3 decimal points (scalable measuring range) (Page 204) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 11 | Understeering / underflow for measuring range 0...10V (Page 209) |
| 12 | Selecting the Feature Bit when Namur Off = 1 (Page 212) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

If `Feature.Bit5` = 1, the input parameter `LowCutOff` is compared with `PV_Out.Value`.

If `PV_Out.Value` < `LowCutOff`, then `PV_Out.Value` = `Scale.Low` and output parameter `PV_LcoAct.Value` = 1.

If `PV_Out.Value` ≥ `LowCutOff`, then `PV_LcoAct.Value` = 0.

### Sign-of-life monitoring

If an input value whose signal status is `16#80` (good) remains constant for a programmable time (monitoring time), the input value is detected as faulty and the outputs `Bad = 1` and `FrzVal = 1` are set. The signal status is set to `PV_Out.ST = 16#00`.

The monitoring time is set at the `FrznTmIn` input parameter in seconds. With `FrznTmIn = 0` or `FrznEn = 0` (default setting), the sign-of-life monitoring is deactivated, any pending errors are reset.

The input value is considered as faulty as long as it seen as constant. The monitoring time is restarted each time the input value is changed.

### Scalable measuring range

The scalable measuring range is a limited section of a measuring range supported by the module.

It allows you to increase the resolution for a configurable section.

- The "Measuring range resolution" parameter determines the resolution to 2 or 3 decimal places.
- The "Measuring range center" parameter determines the temperature over which the scalable measuring range is symmetrically spanned.

For more infromation, refer to the manual "*SIMATIC ET 200SP analog input module AI 4xRTD/TC 2-/3-/4-wire HF*".

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.11.4 Pcs7AnIn error handling

### Error handling of Pcs7AnIn

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range
- Frozen input value (sign-of-life monitoring)

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. Channel errors can be detected using the raw value, the NAMUR check or the sign-of-life monitoring.

`PV_LoAct` or `PV_HiAct` remain set to = 1 if a channel error occurs due to the module diagnoses "Undershoot or overshoot of the measurement range".

### Higher-level error / invalid measuring range

A higher-level error is output (output parameter `ModErr` = 1 and `Bad` = 1) if either:

- the signal status in the `High Word` of input parameter `Mode` takes the value 16#40, or
- there is an invalid measuring type in the `Low Word` of the input parameter `Mode`.

# 17.12 Pcs7AnOu - Analog output channel block

## 17.12.1 Description of Pcs7AnOu

### Object name (type + number) and family

Type + number: FB 1870

Family: Channel

### Area of application for Pcs7AnOu

The block is used for the following applications:

- Signal processing of an analog output value from S7-300/400 SM analog output groups
- Processing of the redundant output channels

### How it works

The block outputs the process value as analog raw value for a process image (partition). Use the Mode in/out parameter to define how the raw value is to be obtained.

The current raw value is always output to the process image (partition).

Normally, the process value is written to both redundant channels.

If both redundant modules are working fine but cannot communicate with each other, the channel block Pcs7AnOu reduces the process value to 50%. And therefore, the two redundant channels use double the reduced process value 2 x 50% = 100% and not 2 x 100% = 200% which is incorrect.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected to the corresponding `OMode_xx` output parameter of the MOD block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DataXchg_xx` output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- The `Feature.Bit0` (Set startup characteristics (Page 148)) is set when the module driver is generated in case a substitute value for this channel is parameterized in HW Config.
- Generate module driver changes the value of `StartVal` if a substitute value for this channel was parameterized in HW Config.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The out parameter `PV_OutSlv` is interconnected with the symbol of the slave channel.
- The in parameter `ProImQB` is interconnected with the symbol of the quality bit of the master channel.
- The in parameter `ProImQBSlv` is interconnected with the symbol of the quality bit of the slave channel.

Connect the symbol generated in HW Config (symbol table) for the output channel with the `PV_Out` output parameter.

In case of redundant I/O configuration, use symbol of the channel of the master module.

The templates of the Advanced Process Library contain an example of an Pcs7AnOu application.

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually. Refer to the Mode Settings for SM Modules (Page 2687) chapter for more on this.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter `ProImQB` is interconnected with the corresponding symbol and the input parameter `SelQB` is set to 1 (otherwise 0).

For the Pcs7AnOu block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Cascade control with PIDConR (CascadeR) (Page 2843)
- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- Model-based predictive control (ModPreCon) (Page 2849)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Override control (Page 2846)
- Override control with PIDConR (OverrideR) (Page 2848)
- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- Ratio control with PIDConR (RatioR) (Page 2839)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)

- Control valve (VlvAnL) (Page 2868)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

### Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Quality code (ET200 SP HA modules)

The quality code is read from the process image and has two states: "Good" or "Bad".

### Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and delivers 100% of the application program value to both the signals:

- when one of the signals delivers "Good" quality code, or
- when both signals deliver "Good" quality code and there is no "IO Redundancy Warning" (`Mode` <> 16#x5xxxxxx) reported

In case both the signals deliver "Good" quality code and there is "IO Redundancy Warning" (`Mode` = 16#x5xxxxxx) reported then 50% of the application program value is delivered to the process.

In case both the signals deliver "Bad" quality code, 100 % of the `PV_In` value takes effect at each of the outputs `PV_Out` and `PV_OutSlv`.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Pcs7AnOu functions (Page 2580)

## 17.12.3 Pcs7AnOu functions

### Functions of Pcs7AnOu

The functions for this block are listed below.

### Forming an I/O value

The peripheral value `PV_Out` is formed from:

- the scale value (input parameter `Scale`)
- the process value (input parameter `PV_In`)
- the measuring type (in/out parameter `Mode`)

### Example of measuring type 4 ... 20 mA

If this measuring type is to be used, you must set the Mode parameter with 16#203 accordingly. In the measuring type, the peripheral value for 4mA is output for `PV_In` = `Scale.Low` and the peripheral value for 20 mA is output for `PV_In` = `Scale.High`.

The block writes the input parameter `Scale` directly to the output parameter `ScaleOut` and interconnects it directly to a technologic block. This can be, for example, the input parameter `MV_Opscale` of a control block.

### Limiting the process or peripheral value

The peripheral value can be limited in two different ways:

- Limited to within range limits
- Limited to scale values

**Limited to within range limits (physical limits of the module):** If you want to restrict the peripheral value (`PV_Out`), you must activate this function via the `ScaleOff` = 1 parameter.

The peripheral value is now limited to the following range limits:

- Top: 16#7EFF (32511 dec.)
- Bottom (unipolar): 0 or
- Bottom, unipolar (4 - 20 mA; 1 - 5 V): 16#E500 (-6912 dec.)
- Bottom (bipolar): 16#8100 (-32512 dec.)

If the limits are undershot or overshot `PV_HiAct` = 1 (top) or `PV_LowAct` = 1 (bottom) is displayed at the output parameters. The signal status of the `PV_ChnST` output parameter is set to 16#78 .

**Limited to scale values:** If you want to restrict the peripheral value (`PV_Out`) to the scale values, you must activate this function via the `ScaleOff` = 0 parameter. You define the high and low scale limits in the `Scale` parameter. If one of the limits is violated, the limit you have entered is output at the `PV_Out` output parameter. This is displayed at the `PV_HiAct` or `PV_LoAct` = 1 output parameter. The signal status of the `PV_ChnST` output parameter is set to 16#78.

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Keep last valid raw value

The block provides the standard function Keep last valid raw value if input value is bad (Page 207).

If `Feature.Bit31` is active and the input `PV_In` has bad quality (16#00 OR 16#28) the outputs `PV_Out`, `PV_OutSlv` keep its value and will not be actualized.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Forming the signal status for PCS 7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks (Page 127).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 5 | Reversal of control direction for fail-open valves (Page 211) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |
| 31 | Keep last valid raw value if input value is bad (Page 207) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.12.4 Pcs7AnOu error handling

### Error handling of Pcs7AnOu

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. They can be detected using the raw value or the NAMUR check or a Simatic PDM maintenance state MS=16#7xxx xxxx.

`PV_LoAct` or `PV_HiAct` remain set to = 1 if a channel error occurs due to the module diagnoses "Undershoot or overshoot of the measurement range".

### Higher-level error / invalid measuring range

A higher-level error is output (output parameter `ModErr` = 1 and `Bad` = 1) if either:

- the signal status in the `High Word` of input parameter `Mode` takes the value 16#40, or
- there is an invalid measuring type in the `Low Word` of the input parameter `Mode`.

# 17.13 Pcs7DiCnt - Digital input driver with count functionality

## 17.13.1 Pcs7DiCnt description

### Object name (type + number) and family

Type + number: FB 1935

Family: Channel

### Area of application

The block is used for DI count signal processing of components such as CFU or ET200SP HA.

I/O redundancy is not supported.

### How it works

The block cyclically processes all the channel specific signal functions for the count part of a DI count channel.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is installed automatically in startup OB (OB100). When the CFC function "Generate module drivers" is used after having connected `PV_InMeas` with the corresponding symbol from count address, the following operations occur automatically:

- The IN_OUT parameter `Mode` is interconnected to the corresponding `OMODE_xx` (xx = channel number) output parameter of the MOD function block.
- The IN_OUT parameter `DataXchg` and `DataXchg1` are interconnected to the corresponding `DXCHG_xx` and `DXCHG1_xx` output parameter of the MOD function block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- The input parameter `MS_Xchg` is interconnected with `MS_XCHG_xx` of the diagnostics block.
- The input parameter `PV_InStat` is interconnected with the symbol of the corresponding input address.
- If Quality Information (QI) from ET 200SP HA module is available, the input parameter `ProImQB` is interconnected with the corresponding symbol and `SelQB` = 1 is set.

**Note**

If you are not using the CFC function "Generate module drivers" wizard. you must set the In/Out parameter `Mode` manually. Refer to the Mode Settings for SM Modules (Page 2687) chapter for more on this.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter ProImQB is interconnected with the corresponding symbol and the input parameter SelQB is set to 1 (otherwise 0).

### Startup characteristics

The block has no startup characteristics.

### Status word allocation for Status parameter

This block does not have a Status parameter.

## 17.13.2 Pcs7DiCnt functions

### Functions of Pcs7DiCnt

The functions for this block are listed below.

### Process values in Count and Frequency mode

This channel block provides two main modes called "Count" mode and "Frequency" mode. However, only one of them can be active at a time. This selection depends on the selection of the channel in HWC and is parameterized at input parameter CntMode (1=Count, 2=Frequency) by driver wizard. The provided process value also depends on this selection.

The output parameter PV_Out provides a count or a frequency value (data type REAL). The output parameter PV_OutCnt provides the count value as datatype DINT. Both are obtained by reading a process image partition.

Depending on your configuration, count channel of the module provides count values from 0 up to 4294967295. This corresponds to a data type unsigned DINT. Because STEP 7 does not provide a data type unsigned DINT, a misinterpretation of the highest bit takes place with STEP 7 data type DINT. That means, PV_OutCnt delivers values from 0...2147483647 and then goes on with -2147483648..-1. The count value is provided in parallel by output parameter PV_Out in data type REAL.

If you are not using the CFC function "Generate module drivers", you must set the In/Out parameter mode manually for further settings. Refer to the Mode Settings for SM Modules (Page 2687) section for more on this.

The function block also provides the following status information from the process image:

- PV_LdErr (1= load error of slot mechanism when setting a new count value)
- PV_StDq (status of DQ)
- PV_StGate (status of gate)
- PV_StSGate (status of software gate)

Using the input parameter SwGate, the Software Gate (SW Gate) of this channel can be set or reset.

A new count value in count mode can be predefined using the input parameter `LdVal` and can be requested with `LdReq` = 1. For this, the channel block handles the slot mechanism of the count channel.

### Holding the last value if raw value is invalid

If the block is to hold the most recent valid value when the raw value is invalid, you must activate this function at the Feature Bit Outputting last valid value if raw value is invalid (Page 165).

### Output substitute value if raw value is invalid

If the block is to output a substitute value (SubsPVCnt / SubsPCFreq) when the raw value is invalid, you must activate this function at the Feature Bit Output substitute value if raw value is invalid (Page 160)

### Output of invalid value if raw value is invalid

If the block is to output an invalid value (`PV_Cnt` = `PV_InMeas` or `PV_Freq` = `PV_InMeas`), you must activate this function at the Feature Bit Output invalid raw value (Page 185). This option is preselected.

### Signal status for PCS 7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks.

### Simulating signals

The block provides the standard function Simulating signals. In Count mode the Count value `PV_Out` / `PV_OutCnt` can be simulated, whereas in Frequency mode, the frequency value `PV_Out` can be simulated. In Count mode, the simulation value is specified with the input parameter `SimPV.Value`. If `SimPVCnt.ST` is different from 16#FF, the simulation value is specified with the input parameter `SimPVCnt.Value`.

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable response using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |

| Bit | Function |
|---|---|
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.13.3 Pcs7DiCnt error handling

### Error handling of Pcs7DiCnt

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed as 1.

### Higher-level error / invalid measuring range

A higher-level error is displayed via output parameter `ModErr` = 1, if either- the signal status in the High Word of input parameter `Mode` takes the value 16#40, or there is an invalid measuring type in the Low Word of the input parameter `Mode`.

## 17.13.4 Pcs7DiCnt messaging

### Messaging

This block does not offer messaging.

## 17.13.5 Pcs7DiCnt I/Os

I/Os of Pcs7DiCnt

### Input parameters

| Parameter | Data type | Initial value | Description |
|---|---|---|---|
| **PV_InMeas** | DWORD | 16#00000000 | Counter or frequency value from module |
| PV_InStat | BYTE | 16#00 | Status information counter from module |
| ProImQB | ... | 0 | Quality Information from module |
| **CntMode** | ... | 16#00 | Count or Frequency mode (parameterized by driver wizard) |
| **LdVal** | DINT | 0 | Load value (in count mode) |
| **LdValCnt** | STRUCT<br>Value: DINT<br>ST: BYTE | <br>• L#0<br>• 16#FF | Load value (in count mode) |
| **LdReq** | BOOL | 0 | 1 = Request load value (in count mode) |
| **SwGate** | BOOL | true | Software Gate in Count mode |
| ChValueAct | BYTE | 16#00 | Channel number (parameterized by driver wizard) |
| `Feature` | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | <br>• 0<br>• 0<br>• 0 | I/O for additional functions |
| **SimOn** | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | 1 = Simulation active |
| **SimPV** | STRUCT<br>Value: REAL<br>ST: BYTE | <br>• 0.0<br>• 16#80 | Simulation value for `PV_InMeas` |
| **SimPVCnt** | STRUCT<br>Value: DINT<br>ST: BYTE | <br>• L#0<br>• 16#FF | Simulation value for `PV_InMeas` (Count) |
| **SubsPV** | REAL | 0.0 | Substitution value for Frequency |
| **SubsPVCnt** | DINT | 0 | Substitution value for Count |
| SelQB | BOOL | 0 | 1=Select Qualitybit from Processimage |

| Parameter | Data type | Initial value | Description |
|---|---|---|---|
| **MS_Release** | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | Maintenance release |
| **MS** | DWORD | 16#00000000 | Maintenance state |
| **MS_Ext** | DWORD | 16#00000000 | External Maintenance state |
| DelTiBad | Delay time for output Bad [s] | REAL | 0.0 |
| SampleTime | Sample Time [s] | REAL | 0.1 |
| **TextRef** | WORD | 16#0000 | Text reference external messages |

## Output parameters

| Parameter | Data type | Initial value | Description |
|---|---|---|---|
| **Bad** | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | 1=Bad process value |
| **PV_Out** | STRUCT<br>Value: REAL<br>ST: BYTE | <br>• 0.0<br>• 16#80 | Count / frequency value |
| **PV_OutCnt** | STRUCT<br>Value: DINT<br>ST: BYTE | <br>• 0<br>• 16#80 | Count value |
| PV_OutLoad | DWORD | 16#00000000 | Load value (to process image) |
| PV_OutCmd | BYTE | 16#00 | Command value (to process image) |
| **PV_StDq** | BOOL | 0 | Status DQ (in count mode) |
| **PV_StGate** | BOOL | 0 | Status gate (in count mode) |
| **PV_StSGate** | BOOL | 0 | Status SW gate (in count mode) |
| **PV_LdErr** | BOOL | 0 | Load value error (in count mode) |
| SimAct | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | 1=Simulation active |
| ModErr | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | 1=Higher level failure |
| ErrorNum | INT | -1 | Parameter error |

| Parameter | Data type | Initial value | Description |
|---|---|---|---|
| **OosAct** | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | Field device out of service, maintenance in progress |
| **MS_Req** | STRUCT<br>Value: BOOL<br>ST: BYTE | <br>• 0<br>• 16#80 | Maintenance request |
| `RemDelTiBad` | Remaining delay time for output Bad [s] | REAL | 0.0 |
| **MS_Dev** | DWORD | 16#00000000 | Maintenance State |

## In_Out parameters

| Parameter | Data type | Initial value | Description |
|---|---|---|---|
| **Mode** | DWORD | 16#00000000 | Quality and mode |
| **DataXchg** | DWORD | 16#00000000 | Data exchange |
| **DataXchg1** | DWORD | 16#00000000 | Data exchange |
| **MS_Xchg** | DWORD | 16#00000000 | Maintenance State exchange |

## Automatically interconnected and parameterized inputs

| Parameter name | Type | Driver wizard – Action at the time of compilation | | Parameterization |
|---|---|---|---|---|
| | | Connection with | | |
| | | Diagnostic block | Symbol | |
| `Mode` | IN / OUT | x | | |

# 17.14 Pcs7DiIn - Digital input channel block

## 17.14.1 Description of Pcs7DiIn

### Object name (type + number) and family

Type + number: FB 1871

Family: Channel

### Area of application for Pcs7DiIn

The block is used for the following applications:

- Signal processing of a digital input value from S7-300/400 SM digital input groups
- Processing of the redundant input channels

### How it works

The block cyclically processes all channel-specific signal functions of a digital input module.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected to the corresponding `OMode_xx` output parameter of the MOD block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DataXchg_xx` output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The in parameter `PV_InSlv` is interconnected with the symbol of the slave channel.
- The in parameter `ProImQB` is interconnected with the symbol of the quality bit of the master channel.
- The in parameter `ProImQBSlv` is interconnected with the symbol of the quality bit of the slave channel.

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PV_In` input parameter.

In case of redundant I/O configuration, use symbol of the channel of the master module.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter `ProImQB` is interconnected with the corresponding symbol and the input parameter `SelQB` is set to 1 (otherwise 0).

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually. Refer to the Mode Settings for SM Modules (Page 2687) chapter for more on this.

For the Pcs7DiIn block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Monitoring eight digital process tags (Digital8Monitoring) (Page 2853)
- Monitoring of a digital process tag (DigitalMonitoring) (Page 2851)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Two-speed motor (Motor2Speed) (Page 2860)
- Reversing motor (MotorReversible) (Page 2861)
- Valve (Valve_Lean) (Page 2865)
- Two-way valve (Valve2Way) (Page 2866)
- Motor valve (ValveMotor) (Page 2867)
- Control valve (VlvAnL)  (Page 2868)

### Startup characteristics

The block has startup characteristics.

### Quality code (ET200 SP HA modules)

The quality code is read from the process image and has two states: “Good” or “Bad”.

### Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and:

- When one of the signals delivers “Good” quality code then the value of the signal with “Good” quality code along with its quality code is transferred to the process.
- When both the signals deliver “Good” quality code then the value of the master signal along with its quality code is transferred to the process.

In case both the signals deliver "Bad" quality code then either the substitution value or the last value depending on the selection of the user or neither when both are not selected is delivered to the process.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Description of Pcs7DiIn (Page 2596)

## 17.14.3 Pcs7DiIn functions

### Functions of Pcs7DiIn

The functions for this block are listed below.

### Obtaining the standard value

The digital value of the process image (partition) is output at output parameter `PV_Out` with the signal status 16#80.

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually for further settings. Refer to the Mode Settings for SM Modules (Page 2687) section for more on this.

### Holding the last value if raw value is invalid

If the block is to hold the most recent valid value when the raw value is invalid, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

### Output substitute value if raw value is invalid

If the block is to output a substitute value (`SubsPV_In`) when the raw value is invalid, you must activate this function at the `Feature` Bit Output substitute value if raw value is invalid (Page 160).

### Output of invalid value if raw value is invalid

If the block is to output an invalid value (`PV_Out` = `PV_In`), you must activate this function at the `Feature` Bit Output invalid raw value (Page 185).

This function is pre-selected.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for PCS 7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks (Page 127).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |

| Bit | Function |
|---|---|
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.14.4 Pcs7DiIn error handling

### Error handling of Pcs7DiIn

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. They can be detected using the raw value or the NAMUR check.

### Higher-level error / invalid measuring range

A higher-level error is output (output parameter `ModErr` = 1) if either:

- the signal status in the `High Word` of input parameter `Mode` takes the value 16#40, or
- there is an invalid measuring type in the `Low Word` of the input parameter `Mode`.

# 17.15 Pcs7DiIT - Digital input channel block with time stamp

## 17.15.1 Description of Pcs7DiIT

### Object name (type + number) and family

Type + number: FB 1872

Family: Channel

### Area of application for Pcs7DiIT

The block is used for the following applications:

- Signal processing of a digital input value from S7-300/400 SM digital input modules with time stamp.
- Processing of the redundant input channels.

### How it works

The cyclic block processes all channel-specific signal functions of a digital input module with configured time stamp.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PV_In` input parameter.

In case of redundant I/O configuration, use symbol of the channel of the master module.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected to the corresponding `OMode_xx` output parameter of the MOD block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DataXchg_xx` output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- If the process image (partition) also contains the value status (status bit) of the digital input channel, the corresponding symbol is connected with input `ProImQB` and the input `SelQB` = 1 is set.

- The parameter `TS_In` is interconnected to the output parameter `TS_XX` of the IMDRV_TS block or the parameter `TS_IN_PN` is interconnected to the output parameter `TS_XX` of the IM_TS_PN block.
- The in/out parameter `TS_C` is interconnected to the corresponding `TS_C_xx` output parameter of the IMDRV_TS or IM_TS_PN block.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter `ProImQB` is interconnected with the corresponding symbol and the input parameter `SelQB` is set to 1 (otherwise 0).

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually. Refer to the Mode Settings for SM Modules (Page 2687) chapter for more on this.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The in parameter `PV_InSlv` is interconnected with the symbol of the slave channel.
- The in parameter `ProImQB` is interconnected with the symbol of the quality bit of the master channel.
- The in parameter `ProImQBSlv` is interconnected with the symbol of the quality bit of the slave channel.

If the time stamp for the input channel is deactivated, the aforementioned connections to the block IMDRV_TS or IM_TS_PN are not used. The block can be used as a simple channel block. When the charts are compiled, a warning is issued as the module driver is generated.

Refer to the section on configuring the channel blocks for information on configuration.

### Startup characteristics

The block has startup characteristics.

### Quality code (ET200 SP HA modules)

The quality code is read from the process image and has two states: “Good” or “Bad”.

### Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and:

- When one of the signals delivers “Good” quality code then the value of the signal with “Good” quality code along with its quality code is transferred to the process.
- When both the signals deliver “Good” quality code then the value of the master signal along with its quality code is transferred to the process.

In case both the signals deliver "Bad" quality code then either the substitution value or the last value depending on the selection of the user or neither when both are not selected is delivered to the process.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 17.15.3 Pcs7DiIT functions

### Functions of Pcs7DiIT

The functions for this block are listed below.

### Obtaining the standard value

The digital value of the process image (partition) is output at output parameter `PV_Out` with the signal status 16#80 .

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually for further settings. Refer to the section Mode Settings for SM Modules (Page 2687).

### Holding the last value if raw value is invalid

If the block is to hold the most recent valid value when the raw value is invalid, you must activate this function at the `Feature` Bit Outputting last valid value if raw value is invalid (Page 165).

### Output substitute value if raw value is invalid

If the block is to output a substitute value (`SubsPV_In`) when the raw value is invalid, you must activate this function at the `Feature` Bit Output substitute value if raw value is invalid (Page 160).

### Output of invalid value if raw value is invalid

If the block is to output an invalid value (`PV_Out` = `PV_In`), you must activate this function at the `Feature` Bit Output invalid raw value (Page 185).

This function is pre-selected.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Signal status for PCS 7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks (Page 127).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Time stamp

The block provides the standard function Time stamp (Page 231).

- Connect the symbol generated in HW Config (symbol table) for the input channel with the `PV_In` input parameter. (...)
- The `TS_In` parameter is interconnected to the `TS_XX` output parameter of the `IMDRV_TS` or `IM_TS_PN` block.
- The in/out parameter `TS_C` is interconnected to the corresponding `TS_C_xx` output parameter of the `IMDRV_TS` or `IM_TS_PN` block.

- If the time stamp of the I/O is to be used with `TimeStampOn` = 1(I/O device time) set for an `EventTS` instance, it must be ensured that `Feature.Bit5` = 0 (I/O device time) for all connected `Pcs7DiIT` channel blocks.
- If the CPU-Time is to be used with `TimeStampOn` = 0(CPU-Time) set for an `EventTS` instance, it must be ensured that `Feature.Bit5` = 1 (CPU-Time) for all connected `Pcs7DiIT` channel blocks. In addition the time-stamping for all such channels has to be deactivated in HW Configuration to avoid IM buffer overflow or handshaking problems caused by such unused but activated time-stamped signals.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 5 | Timestamp calculation (Page 210) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.15.4 Pcs7DiIT error handling

### Error handling of Pcs7DiIT

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. The channel error is generated from the signal status `PV_ST`.

### Higher-level error / invalid measuring range

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status at `High Word` of the input parameter `Mode` accepts the value 16#40.

A higher-level error is also present when an incorrect measuring type is entered in `Low Word` of the input parameter `Mode`.

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions (Page 2607) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 28: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |
| FlutEn | 1 = Flutter suppression activated | BOOL | 0 |
| FlutTmIn* | Flutter time [s] | INT | 0 |
| MS | Maintenance status | DWORD | 16#00000000 |
| MS_Ext | External maintenance status. For more information, refer to the MS_Ext (Page 2463) parameter section under information on using channel blocks. | DWORD | 16#00000000 |
| MS_Release | Release for maintenance (interconnected with MS_Release of the technology block) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_In | Process value (raw value) | BOOL | 0 |
| PV_InSlv | Input value of the slave channel | BOOL | 0 |
| ProImQB | Quality bit from the process image | BOOL | 0 |
| ProImQBSlv | Quality bit from the process image of the slave channel | BOOL | 0 |
| SimOn | 1 = Simulation on | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| SimPV_In | Process value used for SimOn = 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SelQB | 1 = Use the quality bit from the process image | BOOL | 0 |
| SubsPV_In | Substitute value | BOOL | 0 |
| TextRef | Text reference | WORD | 16#0000 |
| TS_In | Time stamp of IMDRV_TS;<br>The time is in ISP format | STRUCT<br>• MsgSig: BOOL<br>• TriInf: BOOL<br>• HdSh: BOOL<br>• ST: BYTE<br>• TS0: DWORD<br>• TS1: DWORD | -<br>• 0<br>• 0<br>• 0<br>• 16#80<br>• 16#00000000<br>• 16#00000000 |
| DelTiBad | Delay time for output Bad [s] | REAL | 0.0 |
| SampleTime | Sample Time [s] | REAL | 0.1 |
| TS_In_PN | Time stamp from IM_TS_PN<br>The time is in ISP format | STRUCT<br>• MsgSig: BOOL<br>• TriInf: BOOL<br>• HdSh: BOOL<br>• ST: BYTE<br>• TS0: DWORD<br>• TS1: DWORD<br>• TS2: DWORD | -<br>• 0<br>• 0<br>• 0<br>• 16#80<br>• 16#00000000<br>• 16#00000000<br>• 16#00000000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### In/out parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |
| TS_C | Time-stamp communication | BYTE | 16#00 |

## Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Bad | 1 = Process value is not valid | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ErrorNum | Reserved for future error numbers | INT | -1 |
| ModErr | 1 = Device/module is faulty | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | 1 = Field device is undergoing maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| PV_Out | 1 = Standard value (physical variable) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1 = Simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |
| TS_Out | Time stamp | STRUCT<br>• MsgSig: BOOL<br>• TriInf: BOOL<br>• HdSh: BOOL<br>• ST: BYTE<br>• TS0: DWORD<br>• TS1: DWORD<br>• Link: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 16#80<br>• 16#00000000<br>• 16#00000000<br>• 0 |

# 17.16 Pcs7DiOu - Digital output channel block

## 17.16.1 Description of Pcs7DiOu

### Object name (type + number) and family

Type + number: FB 1873

Family: Channel

### Area of application for Pcs7DiOu

The block is used for the following applications:

- Signal processing of a digital output value from S7-300/400 SM digital output groups.
- Processing of the redundant output channels.

### How it works

The cyclic block processes all channel-specific signal functions of a digital output module.

Normally, the process value is written to both redundant channels.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

The block is also installed automatically in the startup OB (OB100).

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `Mode` is interconnected to the corresponding `OMode_xx` output parameter of the MOD block.
- The in/out parameter `DataXchg` is interconnected to the corresponding `DataXchg_xx` output parameter of the MOD block.
- The `MS` parameter is interconnected to the `O_MS` output parameter of the diagnostics block.
- The `Feature.Bit0` (Set startup characteristics (Page 148)) is set when the module driver is generated in case a substitute value for this channel is parameterized in HW Config.
- Generate module driver changes the value of `StartVal` if a substitute value for this channel was parameterized in HW Config.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The out parameter `PV_OutSlv` is interconnected with the symbol of the slave channel.
- The in parameter `ProImQB` is interconnected with the symbol of the quality bit of the master channel.
- The in parameter `ProImQBSlv` is interconnected with the symbol of the quality bit of the slave channel.

Connect the symbol generated in HW Config (symbol table) for the output channel with the `PV_Out` output parameter.

In case of redundant I/O configuration, use symbol of the channel of the master module.

The templates of the Advanced Process Library contain an example of an Pcs7DiOu application.

If a Quality Information (QI) from the ET 200SP HA module is provided:

- the input parameter `ProImQB` is interconnected with the corresponding symbol and the input parameter `SelQB` is set to 1 (otherwise 0).

**Note**

If you are not using the CFC function "Generate module drivers" you must set the in/out parameter `Mode` manually. Refer to the Mode Settings for SM Modules (Page 2687) chapter for more on this.

For the Pcs7DiOu block, the Advanced Process Library contains templates for process tag types as examples with various application scenarios for this block.

Examples of process tag types:

- Dosing (Dose_Lean) (Page 2856)
- Two-speed motor (Motor2Speed) (Page 2860)
- Reversing motor (MotorReversible) (Page 2861)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Valve (Valve_Lean) (Page 2865)
- Two-way valve (Valve2Way) (Page 2866)
- Motor valve (ValveMotor) (Page 2867)

## Startup characteristics

Use the `Feature` Bit Set startup characteristics (Page 148) to define the startup characteristics of this block.

### Quality code (ET200 SP HA modules)

The quality code is read from the process image and has two states: “Good” or “Bad”.

### Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and the application program value is deliverd to both the signals when one or both of the signals deliver(s) “Good” quality code along with the quality code is transferred to the process.

In case both the signals deliver “Bad” quality code, the application program value is delivered to the process with “Bad” quality code.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Description of Pcs7DiOu (Page 2616)

## 17.16.3 Pcs7DiOu functions

### Functions of Pcs7DiOu

The functions for this block are listed below.

### Forming a peripheral value

The digital value is written to the process image (partition). The signal status of the process value (`PV_ChnST`) is set to "good" (16#80).

### Simulating signals

The block provides the standard function Simulating signals (Page 64).

### Keep last valid raw value

The block provides the standard function Keep last valid raw value if input value is bad (Page 207).

If `Feature.Bit31` is active and the input `PV_In` has bad quality (16#00 OR 16#28) the outputs `PV_Out`, `PV_OutSlv` keep its value and will not be actualized.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73)

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in section Configurable functions using the Feature I/O (Page 139). The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 0 | Set startup characteristics (Page 148) |
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 30 | Outputting a de-energized value for block-external simulation (Page 159) |
| 31 | Keep last valid raw value if input value is bad (Page 207) |

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.16.4 Pcs7DiOu error handling

### Error handling of Pcs7DiOu

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range

### Channel error

At the output parameter `Bad`, channel errors are displayed with 1. The channel error is generated from the signal status `PV_ST`.

### Higher-level error / invalid measuring range

A higher-level error is output (output parameter `ModErr` = 1) if either:

- the signal status in the `High Word` of input parameter `Mode` takes the value 16#40, or
- there is an invalid measuring type in the `Low Word` of the input parameter `Mode`.

# 17.17 Pcs7Cnt1 - Controlling and reading FM 350 modules

## 17.17.1 Description of Pcs7Cnt1

### Object name (type + number)

Type + number: FB 1833

Family: Channel

### Area of application

The Pcs7Cnt1 block is used for controlling and reading count or measured values of an FM 350-1 or FM 350-2 module.

### How it works

"FM 350" refers to the FM 350-1 and FM 350-2 modules in the following.

- The block only communicates through the process image for the FM 350-1. The data are written and read continuously.
- The control and status information and selected count and measured values are contained in the process image for the FM 350-2. The remaining count and measured values can be read via data records.
  In HW Config (User_Type1 and User_Type2) you define how the count or measured values will be saved in the process image. The `LoadPv1` and `CmpVx` parameters are loaded from the FM_CNT block to the FM 350-2 using data records. The writing of the parameters is first triggered in the subsequent cycle of the FM_CNT block.

If an FM 350-2 module is being used, the block writes the `LoadPV1` (load count value immediately) or `CmpVx` (comparison value) parameters to the module (x = channel number) via data records. If the parameter `LoadDir` = 1 is set in the block, it writes `LoadPV1`. If `LoadPre` = 1 is set, it writes in preparation `LoadPV1`. The `CmpVx` parameter is written after every change.

The `Mode` input indicates in what format the count and/or measured value is available in the process image. If the high word of the input parameter `Mode` = 16#40xxxx (value status = higher-level error, `ModErr`= 1), the count or measured value is treated as invalid.

The measured values are written to the corresponding outputs, `PV1`, `PV1_Li` as well as `PV2` and `PV2_Li`; a differential value between the old value and new value is formed for the `PV1` via the last cycle and sent at the `PV1CycLi` output. If the read values are in order, the status of the outputs is set to 16#80.

The units for PV1_UnitLi, ScalePV1_Li, PV2_UnitLi and ScalePV2_Li are set with the extension "_IN" via the inputs of the same name.

**Note**

Status CmpVal0(comparator 1), CmpVal1 (comparator 2), ZeroSt (zero crossing), OFlow (overflow) and UFlow (underflow) are automatically acknowledged. They are active for at least one cycle.

The measured value is output as a numeric value by the FM 350. Additional information on this is available in the manual for the module.

The block also supplies the counted pulses of PV1(PV1_Li) at the PV1CycLi output with each block call.

The LoadPV1 input parameter is the relevant value which is passed to the module. If, however, LoadPV1_Li is interconnected or the status of LoadPV1_Li is 16#80 , the value is written to LoadPV1 and applied.

**Note**

The display in PCS 7 is limited by the data type DINT. However, the settings in the module are permitted unsigned up to 32 bits.

## Configuration

When the CFC function "**Generate module drivers**" is used, the following occurs automatically:

- The Laddr and Channel inputs are configured.
- The Mode input is interconnected with the OMODEx output of the FM_CNT block.
- The FM_DATA structure is interconnected with the structure of the same name of the FM_CNT block.
- The DataXchg input is interconnected to the relevant DXCHG_00 output of the MOD_D1 block.
- The MS input is interconnected to the relevant O_MS output of the MOD_D1 block.

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38) .

## Startup characteristics

The block does not have any startup characteristics.

## Status word allocation

This block does not have the Status parameter.

## 17.17.2 Pcs7Cnt1 modes

### Pcs7Cnt1 operating modes

This block does not have any modes.

## 17.17.3 Pcs7Cnt1 functions

### Functions of Pcs7Cnt1

The functions for this block are listed below.

### Addressing

**1**. Create icons for the required count or measured values in the icon table, in accordance with the base address of the FM 350 module. Please note the following:

- FM 350-1: Count or measured value is always in the process image:
  - Select "ED base address" of the module (e.g. ED512) as the address.
- FM 350-2: Count or measured value of the desired channel is in the process image:
  - In "HW Config FM 350-2 configure counter" you can specify where count or measured values will be stored in the process image. Depending on the configuration of User_Type1 or User_Type2, you must select EW for WORD or ED for DWORD. The address is calculated according to the following table:

| Count or measured value is defined as: | Measured or count value is in User_Type1: | Measured or count value is in User_Type2: |
|---|---|---|
| DWORD or LOW WORD | FM 350-2 base address + 8 bytes | FM 350-2 base address + 12 bytes |
| HIGH WORD | FM 350-2 base address + 10 bytes | FM 350-2 base address + 14 bytes |
| **Example:**<br>The desired count value of channel 2 is in User_Type2 in the high word. The address is calculated for a base address of 512 as: Address = EW 526. | | |

- FM 350-2: Count or measured value of the desired channel is not in the process image:
  - Select as address: Input word "Base address of the module + channel number" interconnected (e.g. base address = 512, channel number = 5; EW517).

**2**. Connect the input `Connect` in the CFC chart with the previously created icon via "Interconnection to address...".

Count and measured values that are not in the process image of the FM 350-2 are read out of the module cyclically as a data record, if the inputs `PV1_EN` or `PV2_EN` = 1. Both inputs should be set to 0 for performance reasons, if count or measured value are not needed for the channel in

the user program. This prevents count or measured values from being read via data records, if they are not in the process image.

**Note**

Even if the PV1_EN or PV2_EN inputs are not set, a read can be performed via data records if the PV1_EN or PV2_EN are set inputs are set at a different instance of Pcs7Cnt1 (other channel) of the associated FM350-2.

## Simulation

The block provides the standard function Simulating signals (Page 64)

With SimOn = 1 , the simulation values SimPV1 and SimPV2 are written to the outputs PV1, PV1_Li as well as PV2 and PV2_Li . The status of the outputs is set to 16#60 and Bad = 1 in the process.

Simulation takes highest priority.

If the block is in simulation state, SimAct = 1 is set.

## Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73).

## Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

## Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

| Value | Meaning |
|---|---|
| 16#80 | Valid value |
| 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
| 16#00 | Invalid value |

The worst signal status ST_Worst for the block is formed from the following parameters:

- LoadDir.ST
- LoadPre.ST
- LoadPV1_Li.ST
- CntRun.ST
- CntDir.ST
- PV1_Li.ST
- PV2_Li.ST

### Delay the output "Bad"

If input DelTiBad > 0, on receiving an internal bad value, delay timer will start. Timer will abort if DelTiBad is 0. Minimum value of DelTiBad is 0. Only when timer expires i.e., RemDelTiBad = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running Bad.ST will be 16#60. Only after the timer expires the actual ST be updated. Substitute value is updated at PV_Out, only after delay timer expires. When timer is running last valid value will be there at PV_Out. When substitute value is used, ST of PV_Out will be 16#60.

## 17.17.4 Pcs7Cnt1 error handling

### Error handling of Pcs7Cnt1

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Higher-level error

### Overview of error numbers

The ErrorNum I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 21 | Pulse counter overflow |

### Higher-level error

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status in the high word of the input parameter `Mode` assumes the value 16#40.

In addition, at the output parameter `PV_Li` of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output.

## 17.17.5 Pcs7Cnt1 messaging

### Messaging

This block does not offer messaging.

## 17.17.6 Pcs7Cnt1 I/Os

I/Os of Pcs7Cnt1

### Input parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| Channel | Channel FM 350 | INT | 0 |
| **CmpV0** | New comparison value 0 | DINT | 0 |
| CmpV1 | New comparison value 1 | DINT | 0 |
| CmpV2 | New comparison value 2 | DINT | 0 |
| CmpV3 | New comparison value 3 | DINT | 0 |
| **Connect** | Connection value (WORD or DWORD) | ANY | |
| **CtrlDO0** | 1 = Enable digital output DO | BOOL | 1 |
| CtrlDO1 | 1 = Enable digital output DO1 (FM 350-1 or FM 350-2 only, dosing mode) | BOOL | 1 |
| CtrlDO2 | 1 = Enable digital output DO2 (FM 350-2 only, dosing mode) | BOOL | 1 |
| CtrlDO3 | 1 = Enable digital output DO3 (FM 350-2 only, dosing mode) | BOOL | 1 |
| EnSetDn | 1 = enable for setting in reverse direction | BOOL | 1 |
| EnSetUp | 1 = Enable for setting in forward direction | BOOL | 1 |
| `Feature` | I/O for additional functions (Page 2627) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 28: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |
| FlutEn | 1 = Flutter suppression active | BOOL | 0 |

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| FlutTmIn* | Flutter suppression time | INT | 0 |
| Laddr | Logical address FM 350 | INT | 0 |

| **StopGate** | 1 = Stop gate | BOOL | 1 |
| **SubsPV1** | Count substitute value | DINT | 0 |
| **SubsPV2** | Measured substitute value | DINT | 0 |
| SubsOn | 1 = substitute value active | BOOL | 0 |
| **SwGateEn** | 1 = Enable SW-TOR | BOOL | 0 |
| `DelTiBad` | Delay time for output Bad [s] | REAL | 0.0 |
| `SampleTime` | Sample Time [s] | REAL | 0.1 |
| **TextRef** | Text reference | WORD | 16#0000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### In/out parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **DataXchg** | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| `DataXchg1` | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| `MS_Xchg` | Exchange of the maintenance status | DWORD | 16#00000000 |
| **Mode** | Operating mode | DWORD | 16#00000000 |

### Output parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **Bad** | 1 = invalid values | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| **CmpVaL0** | 1 = comparison value 1 | BOOL | 0 |
| CmpVal1 | 1 = comparison value 2 | BOOL | 0 |
| CmpVal2 | 1 = comparison value 3 | BOOL | 0 |
| CmpVal3 | 1 = comparison value 4 | BOOL | 0 |

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **CntDir** | Direction counter | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| **CntRun** | 1 = status counter working | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| CntSync | 1 = status counter synchronized | BOOL | 0 |
| ErrorNum | Parameter error | INT | -1 |
| IntGate | 1 = status of internal TOR | BOOL | 0 |
| ModErr | 1 = higher-level error | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| **PV1** | Current load or LATCH value/current count value | DINT | 0 |
| **PV1CycLi** | Pulses per cycle | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#80 |
| **PV1_Li** | Count value as REAL structure | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#80 |
| **PV1_UnitLi** | Unit of the current count value | INT | 0 |
| **PV2** | Measured value | DINT | 0 |
| **PV2_Li** | Measured value as REAL structure | STRUCT | - |
| | | • Value: REAL | • 0.0 |
| | | • ST: BYTE | • 16#80 |
| **PV2_UnitLi** | Unit of the measured value | INT | 0 |
| NewLatch | 1 = new LATCH value (in clock-synchronous mode only) | BOOL | 0 |
| OpErr | 1 = operator error | BOOL | 0 |
| OosAct | Field device out of service, maintenance | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| **OFlow** | 1 = status overflow | BOOL | 0 |
| RstSync | 1 = Reset synchronization | STRUCT | - |
| | | • Value: BOOL | • 0 |
| | | • ST: BYTE | • 16#80 |
| **ScalePV1_Li** | Range of current counter values | STRUCT | - |
| | | • High: REAL | • 100.0 |
| | | • Low: REAL | • 0.0 |

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **ScalePV2_Li** | Range of the measured values | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| **SetDi** | 1 = status digital input DI set | BOOL | 0 |
| SimAct | 1 = simulation values | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| **StartDI** | 1 = digital input DI start | BOOL | 0 |
| **StCmpV0** | 1 = Saved status of comparator 1 | BOOL | 0 |
| StCmpV1 | 1 = Saved status of comparator 2 | BOOL | 0 |
| StCmpV2 | 1 = Saved status of comparator 3; | BOOL | 0 |
| StCmpV3 | 1 = Saved status of comparator 4; | BOOL | 0 |
| **StopDI** | 1 = status digital input DI stop | BOOL | 0 |
| ST_Worst | Worst signal status | BYTE | 16#80 |
| SwGate | 1 = Software gate | BOOL | 0 |
| **UFlow** | 1 = status underflow | BOOL | 0 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |
| **ZeroSt** | 1 = status zero crossing | BOOL | 0 |

## Automatically interconnected and parameterized inputs

| Parameter name | Type | Driver wizard – Action at the time of compilation | | Parameterization |

A block diagram is not provided for this block.

# 17.18 Pcs7Cnt2 - Control and read an 8-DI_NAMUR module of the ET 200iSP

## 17.18.1 Description of Pcs7Cnt2

### Object name (type + number)

Type + number: FB 1834

Family: Channel

### Area of application

The Pcs7Cnt2 block is used to control and read a count or frequency value from an 8-DI NAMUR module of the ET 200iSP. The block supports the following configurations of the module:

- 2 counters or 1 counter cascaded
- 2 frequency measurements

### How it works

Depending on the mode setting of the module in HW Config, the user data of the module are stored in the process image. The Pcs7Cnt2 block differentiates between the following modes:

| MODE (low word) | Operating mode | HW Config setting: "Configuration" | HW Config setting: "Channel (0 to 1) mode" |
|---|---|---|---|
| 1 | Counter (16 bits) without control function by means of digital signals | (Channel 0 to 1): COUNT(Channel 2 to 7): DI | Periodic or normal count functions (up or down counter) |
| 2 | Counter (32 bits) without control function by means of digital signals | (Channel 0 to 1): COUNT (Channel 2 to 7): DI | Cascade function (channel 0 only) (down counter) |
| 3 | Counter (16 bits) with control function by means of digital signals | (Channel 0 to 1): COUNT (Channel 2 to 7): CONTROL | Periodic or normal count functions (up or down counter) |
| 4 | Counter (32 bits) with control function by means of digital signals | (Channel 0 to 1): COUNT (Channel 2 to 7): CONTROL | Cascade function (channel 0 only) (down counter) |
| 5 | Frequency (16 bits) | (Channel 0 to 1): TRACE (Channel 2 to 7): DI | - |

The driver generator sets the module mode configured in HW Config at the `MODE` input of the `MOD_D1` block on the appropriate channel of the module. The `Mode` input indicates in what format the count or frequency value is available in the process image. If the high word of the input parameter `MODE = 16#40xxxx` (value status = higher-level error, `ModErr = 1`), the count or frequency value is treated as invalid.

Depending on the mode, either two independent counters (16 bits) or one counter (32 bits) exist in the process image. The `Channel` input specifies the module counter for which the block is responsible.

The counter functions can be controlled by signals that can be influenced both over the digital inputs of the module or over the user data of the process image.

**Note**

Please note that the signals of the digital inputs are ORed with the equivalent signals from the PIO in the module.

The following signals are available:

| Block input | Module | Meaning |
|---|---|---|
| - | Z1 | Counter pulse counter 1 |
| - | Z2 | Counter pulse counter 2 |
| `StopGate (Channel = 0)` | TOR1 | With the active GATE signal, an active count operation can be interrupted.<br>The GATE = "1" signal stops the count operation despite pending count pulses. At the same time, the assigned output is deactivated if it was active. This state remains until the GATE signal is set to "0". The output is brought to the previous state and the count operation is continued.<br>The GATE signal is subordinate to the RSO and RSC signals, in other words, the RSO and RSC signals have the effect described above regardless of an active GATE signal. |
| `StopGate (Channel = 1)` | TOR2 | See description of "GATE 1" |
| `RstPV1 (Channel = 0)` | RSZ1 | The rising edge of the RSC signal sets the count of the assigned channel as follows:<br>• When counting up (normal counter function), back to zero<br>• When counting down (periodic counter function and cascade function), to the defined setpoint<br>When counting down (periodic counter function and cascade function), any output that is set is also reset. |
| `RstPV1 (Channel = 1)` | RSZ2 | See description of "RSC1" |
| `RstDO (Channel = 0)` | RSA1 | On the rising edge of the RSO signal, the assigned output can be reset.<br>The count is not influenced by setting RSO. |
| `Rst_DO (CHANNEL = 1)` | RSA2 | See description of "RSO2" |

The in/out parameters `RstPV1` and `RstDO` are always reset to zero. After resetting, the earliest point at which a renewed reset will be possible is in the next cycle but one (rising edge).

The count value or frequency value and their states are stored in the process image as shown below and are indicated at the following block outputs:

| Bytes | Bit | Input signal | Block output | Meaning |
|---|---|---|---|---|
| 0, 1 | 0-15 | Proc. value counter 1 | `PV1_Li` | 16-bit counter 1 or 32-bit counter (bytes 0 to 3) or frequency value 1 |
| 2, 3 | 0-15 | Proc. value counter 2 | | 16-bit counter 2 (only with 16-bit counter 1) or frequency value 2 |
| 4 | 0 | A 1 | `ZeroSt` | Zero crossing counter 1 |
| | 1 | A2 | | Zero crossing counter 2 |

| Bytes | Bit | Input signal | Block output | Meaning |
|---|---|---|---|---|
| | 2 | TOR 1 | PV1 | Status gate 1 |
| | 3 | TOR 2 | | Status gate 2 |
| | 4 | RSZ1 | SimAct | Status reset counter 1 |
| | 5 | RSZ2 | | Status reset counter 2 |
| | 6 | RSA1 | RstDO_Out | Status reset outputs counter 1 |
| | 7 | RSA2 | | Status reset outputs counter 2 |

The LoadPV1 parameter is always written to the process image. Depending on the mode set with HW Config, it is either the 16-bit or 32-bit setpoint (down counter) or the count limit (up counter).

Depending on the mode setting, only the following integer values of LoadPV1 or LoadPV1_Li are transferred to the module based on the status at LoadPV1_Li:

- 16-bit counter: 0 to 65 535
- 32-bit counter: 0 to 2 080 374 784

If the value for LoadPV1 or LoadPV1_Li is outside of these limits, the last valid value of LoadPV1 or LoadPV1_Li is retained in the module and OpErr = 1 is set.

The block also supplies the counted pulses of PV1(PV1_Li) at the PV1CycLi output with each block call.

The PV1_UnitLi and ScalePV1_Li outputs are written with the inputs of the same name PV1_Unit and ScalePV1.

The LoadPV1 input parameter is the relevant value which is passed to the module. If, however, LoadPV1_Li is interconnected or the status of LoadPV1_Li is 16#80 , this value is written to LoadPV1 and applied.

**Note**

Make sure that no values with zero are loaded with the "Down counter" counter function.

## Configuration

When the CFC function "**Generate module drivers**" is used, the following occurs automatically:

- The Laddr, Laddr1, Channel inputs are configured.
- The Mode input is interconnected with the OMODEx output of the MOD_D1 block.
- The DataXchg input is interconnected to the relevant DXCHG_00 output of the MOD_D1 block.
- The MS input is interconnected to the relevant O_MS output of the MOD_D1 block.

**Note**

In HW Config, it is possible to use DI2 to DI7 as independent digital input signals with the hardware configuration "(Channel 0 to 1): COUNT (Channel 2 to 7): DI. The addresses of the connections "TOR1 to RSA2 (Byte 4.2 - 4.7)" must be used.

The usage of the digital control signals with the HW Config "Channel 2...7 = CONTROL" is not permitted.

Example:

| Module | Block | Has the effect | |
|---|---|---|---|
| TOR 1 = 1 | StopGate = 0 | | TOR on |
| TOR 1 = 0 | StopGate = 1 | | TOR on |
| TOR 1 = 0 | StopGate = 0 | | TOR off |

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation

This block does not have the Status parameter.

### See also

Pcs7Cnt2 I/Os (Page 2642)

## 17.18.2 Pcs7Cnt2 modes

### Operating modes of Pcs7Cnt2

This block does not have any modes.

## 17.18.3 Pcs7Cnt2 functions

### Functions of Pcs7Cnt2

The functions for this block are listed below.

### Addressing

You must connect the icon (from the icon table) for the count or frequency value with the `Connect` input parameter.

### Simulation

The block provides the standard function Simulating signals (Page 64).

With `SimOn = 1`, the simulation value `SimPV1` is written to the outputs `PV1` and `PV1_Li`. The status of the outputs is set to 16#60 and `Bad = 1` in the process.

Simulation takes highest priority.

If the block is in simulation state, `SimAct = 1` is set.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

You need to assign parameters for three `Feature` bits for the response to an invalid raw value for the channel blocks.

If more than one of these `Feature` bits are set (=1), the following priority applies:

- Output invalid raw value (`Feature.Bit28` = highest priority)
- Output substitute value if raw value is invalid (`Feature.Bit29`)
- Output the last valid value if raw value is invalid (`Feature.Bit30`, lowest priority)

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

| Value | Meaning |
|---|---|
| 16#80 | Valid value |
| 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
| 16#00 | Invalid value |

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `LoadPV1_Li.ST`
- `PV1_Li.ST`
- `RstDO.ST`
- `RstPV1.ST`

### Redundancy

The higher-level MOD_D1 block evaluates the redundancy of DP master systems operating in an H system.

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.18.4 Pcs7Cnt2 error handling

### Error handling of Pcs7Cnt2

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers
- Higher-level error

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 21 | Pulse counter overflow |

### Higher-level error

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status in the high word of the input parameter `Mode` assumes the value 16#40.

In addition, at the output parameter `PV_Li` of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output.

## 17.18.5 Pcs7Cnt2 messaging

### Messaging

This block does not offer messaging.

## 17.18.6 Pcs7Cnt2 I/Os

I/Os of CH_CNT2

### Input parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| Channel | Channel 8 DI NAMUR (outputs) | INT | 0 |
| **Connect** | Connects values | ANY | |
| `Feature` | I/O for additional functions (Page 2639) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 28: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |
| FlutTmIn* | Flutter suppression time | INT | 0 |
| Laddr | Logical input address | INT | 0 |
| Laddr1 | Logical output address | INT | 0 |
| LoadPV1* | Counter load value | DINT | 0 |

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **LoadPV1_Li** | Counter load value structured | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#00 |
| **MS** | Maintenance status | DWORD | 16#00000000 |
| **MS_Release** | Release for maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| **MS_Ext** | External maintenance status. For more information, refer to the `MS_Ext` (Page 2463) parameter section under information on using channel blocks. | DWORD | 16#00000000 |
| **PV1_Unit** | Unit of the current value | INT | 0 |
| **RstDO*** | 1 = Reset digital outputs | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| **RstPV1*** | 1 = Reset counter | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| **ScalePV1** | Range of the current count value | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| **SimOn** | 1 = simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| **SimPV1** | Simulation value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| **StopGate** | 1 = Stop gate | BOOL | 1 |
| **SubsPV1** | Substitute value | DINT | 0 |
| `DelTiBad` | Delay time for output Bad [s] | REAL | 0.0 |
| `SampleTime` | Sample Time [s] | REAL | 0.1 |
| **TextRef** | Text reference | WORD | 16#0000 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

## In/out parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **DataXchg** | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| **Mode** | Operating mode | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |

## Output parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **Bad** | 1 = invalid values | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ErrorNum | Parameter error | INT | -1 |
| Gate | 1 = TOR on | BOOL | 0 |
| ModErr | 1 = higher-level error | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Dev | Maintenance state | DWORD | 16#00000000 |
| MS_Req | 1 = Maintenance request from the diagnostic area | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OosAct | Field device out of service, maintenance is taking place | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| OpErr | 1 = operator error | BOOL | 0 |
| **PV1** | Current count value/frequency value | DINT | 0 |
| **PV1CycLi** | Pulses per cycle | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| **PV1_Li** | Current count value structured | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| **PV1_UnitLi** | Unit of the current count value | INT | |
| RstDO_Out | 1 = Reset digital outputs | BOOL | 0 |
| RstPV1_Out | 1 = Reset counter | BOOL | 0 |
| **ScalePV1_Li** | Range of the current count value | STRUCT<br>• High: REAL<br>• Low: REAL | -<br>• 100.0<br>• 0.0 |
| SimAct | 1 = Simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal value | BYTE | 16#80 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |
| **ZeroSt** | 1 = status zero crossing | BOOL | 0 |

### Automatically interconnected and parameterized inputs

| Parameter name | Type | Driver wizard – Action at the time of compilation | | Parameterization |
|---|---|---|---|---|
| | | Connection with | | |
| | | Diagnostic block | Symbol | |

## 17.18.7 Pcs7Cnt2 block diagram

### Block diagram of Pcs7Cnt2

A block diagram is not provided for this block.

# 17.19 Pcs7Cnt3 - Control and read the 1 COUNT 24V/100kHz module for count mode

## 17.19.1 Description of Pcs7Cnt3

### Object name (type + number)

Type + number: FB 1835

Family: Channel

### Area of application

The block is used to control and read count, measured and latch values of the "1 COUNT 24V/ 100kHz" module (as of 6ES7 138-4DA04-0AB0) for the count and measurement modes.

### How it works

The block communicates via the process image. The data are written and read continuously.

In `Mode` 1- 3, the `LoadVal` parameter is sent to the module when a positive edge is detected either at the `LoadPre` in/out parameter (= load counter in preparation) or `LoadDir` (= load counter immediately). The parameters `CmpV1` (comparison value 1) and `CmpV2` (comparison value 2) are transferred to the module when they are changed and during startup.

In `Mode` 4- 6, the parameters `UFlowLi`(low limit) and `OFlowLi` (high limit) are transferred to the module when they are changed and during startup.

Depending on the mode setting of the module in HW Config, the user data of the module is stored in the process image. The block distinguishes between the following modes:

| MODE (LowWord) | Operating mode | Description |
|---|---|---|
| 1 | Continuous counting | The 1Count24V/100kHz counts continuously from the load value in this mode |
| 2 | One-time counting | In this mode, 1Count24V/100kHz counts once, depending on the configured main counting direction |
| 3 | Periodic counting | In this mode, 1Count24V/100kHz counts periodically, depending on the configured main counting direction |
| 4 | Frequency measurement | 1Count24V/100kHz determines the frequency of the pulse sequence at the input |
| 5 | Speed measurement | 1Count24V/100kHz determines the speed of the device connected to the input |
| 6 | Period duration measurement | 1Count24V/100kHz determines the pulse length of the pulse sequence at the input |

The Mode input indicates the format in which the count and latch value or the count and measured value is available in the process image. If the high byte of input/output parameter is Mode = 16#40 (value status = higher-level error, ModErr = 1), the count, measured and latch values are treated as invalid.

The states PV1_sync (synchronization), CmpVal0 (comparator 0), CmpVal1 (comparator 1), OFlow (overflow), Uflow (underflow) and ZeroSt (zero crossing) are acknowledged automatically by the block. They are active for at least one cycle.

The block also supplies the counted pulses of PV1(PV1_Li) at the PV1CycLi output with each block call.

The units for PV1_UnitLi, ScalePV1_Li, PV2_UnitLi and ScalePV2_Li are set with the PV1_Unit, ScalePV1, PV2_Unit and ScalePV2 inputs of the same name.

The LoadPV1 input parameter is the relevant value which is passed to the module. If, however, LoadPV1_Li is interconnected or the status of LoadPV1_Li is 16#80 , the value is written to LoadPV1 and applied.

## Calling OBs

OB100 and cyclic OB (recommendation 100 ms) in which the data will be received and sent.

## Configuration

Connect the symbol (from the symbol table) for the count value with the Connect input parameter. You need to enter the symbol (Symbol column) in the symbol table and the supplement the row in the Address column with the ED base address of the module (e.g. ED512). When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The Laddr input is configured.
- The Mode input is interconnected to the OMODE_00output of the MOD_D1 block.
- The DataXchg input is interconnected to the relevant DXCHG_00 output of the MOD_D1 block.
- The MS input is interconnected to the relevant O_MS output of the MOD_D1 block.

The block is also installed automatically in the startup OB (OB100).

## Startup characteristics

In Mode 1-3, the parameters CmpV1 (comparison value 1) and CmpV2 (comparison value 2) are transferred to the module during startup.

In Mode 4-6, the parameters UflowLi (low limit) and OFlowLi (high limit) are transferred to the module during startup .

## Status word allocation

This block does not have the Status parameter.

**See also**

Pcs7Cnt3 I/Os (Page 2650)

## 17.19.2 Pcs7Cnt3 modes

### Operating modes of Pcs7Cnt3

This block does not have any modes.

## 17.19.3 Pcs7Cnt3 functions

### Functions of Pcs7Cnt3

The functions for this block are listed below.

### Addressing

Connect the symbol (from the symbol table) for the count value with the `Connect` input parameter.

You need to enter the symbol (Symbol column) in the symbol table and the supplement the row in the Address column with the ED base address of the module (e.g. ED512).

### Simulation

The block provides the standard function Simulating signals (Page 64)

With `SimOn = 1` , the simulation values `SimPV1` and `SimPV2` are written to the outputs `PV1`, `PV1_Li` as well as `PV2` and `PV2_Li` . The status of the outputs is set to 16#60 and `Bad = 1` in the process.

Simulation takes highest priority.

If the block is in simulation state, `SimAct = 1` is set.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks (Page 73).

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks (Page 155) |
| 27 | Do not evaluate the first run of the diagnostic blocks (Page 205) |
| 28 | Output invalid raw value (Page 185) |
| 29 | Output substitute value if raw value is invalid (Page 160) |
| 30 | Outputting last valid value if raw value is invalid (Page 165) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for channel blocks for field devices (Page 127).

| Value | Meaning |
|---|---|
| 16#80 | Valid value |
| 16#60 | Manipulated value (for example, substitute value, simulation, last valid value) |
| 16#00 | Invalid value |

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `LoadPV1_Li.ST`
- `PV1_Li.ST`
- `PV2_Li.ST`

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.19.4 Pcs7Cnt3 error handling

### Error handling of Pcs7Cnt3

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Higher-level error
- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; the block is not executed |
| 0 | There is no error. |
| 21 | Pulse counter overflow |

### Higher-level error

A higher-level error is displayed at the output parameters `ModErr` and `Bad` with 1 if the signal status in the high word of the input parameter `Mode` assumes the value 16#40.

In addition, at the output parameter `PV_Li` of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output.

## 17.19.5 Pcs7Cnt3 messaging

### Messaging

This block does not offer messaging.

## 17.19.6 Pcs7Cnt3 I/Os

I/Os of Pcs7Cnt3

### Input parameters

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| **AckTrip** | 1 = Error detected | BOOL | 0 |
| **CmpV1** | Comparison value 1 | DINT | 0 |
| CmpV2 | Comparison value 2 | DINT | 0 |

# 17.20 Pcs7Cnt4 - Handling counting functionality of TM modules

## 17.20.1 Description of Pcs7Cnt4

### Object name (type + number) and family

Type + number: FB 1836

Family: Channel

### Area of application

The Pcs7Cnt4 block is used for the following applications:

- Control and read a count value from an "Fast input and output and counter functions" module of the ET 200SP HA.

### How it works

Depending on the mode setting of the module in HW Config, the user data of the module is stored in the process image. The Pcs7Cnt4 block differentiates between the following modes:

| MODE (low word) | Operating mode | HW Config setting: "Counting range" |
|---|---|---|
| 1 | Counter range 0 to 4294967295 | 0 to +32 bits |
| 2 | Counter range -2147483648 to 2147483647 | -31 to +31 bits |

The driver generator sets the mode configured in HW Config at the MODE input of the MOD_D32_PN block of the appropriate channel of the module. The Mode input indicates in which format the count value is available in the process image.

If the high word of the input parameter MODE = 16#40xxxx (value status = higher-level error, ModErr = 1), the count or frequency value is treated as invalid.

Depending on the mode, either the range of the counter value is 0 to 4294967295 or -2147483648 to 2147483647.

### Load Value

The value at LoadPV1 is written to the process image as long MODE = xxxx0001 or MODE = xxxx0002 and simulation is not active.

In Mode 1 LoadValue is limited to 0 if LoadValue < 0 and to 4294967295 if LoadValue > 4294967295.

In Mode 2 LoadValue is limited to -2147483648 if LoadValue < -2147483648 and to 2147483647 if LoadValue > 2147483647.

The inputs LoadPrep and LoadDirect can be used to transfer the load value to the module.

If an invalid load value is written to the module the module sets the bit OT_ERR to 1 which is displayed at the block output OpErr. This Bit needs to be reset by the block input RstOpErr before another load value can be written.

## Compare Values

The values at CmpV1 and CmpV2 are written to the process image as long MODE = xxxx0001 or MODE = xxxx0002 and simulation is not active.

In Mode 1 CmpV1/2 is limited to 0 if CmpV1/2 < 0 and to 4294967295 if CmpV1/2 > 4294967295.

In Mode 2 CmpV1/2 is limited to -2147483648 if CmpV1/2 < -2147483648 and to 2147483647 if CmpV1/2 > 2147483647.

The inputs TCmpVal1 and TCmpVal2 can be used to transfer the compare values to the module.

If an invalid compare value is written to the module the module sets the bit OT_ERR to 1 which is displayed at the block output OpErr. This Bit needs to be reset by the block input RstOpErr before another compare value can be written.

**Digital block inputs to control the counter**

The following digital block inputs are available to control the counter:

The functionality of the counter module differs depending on the configuration in HW Config.

| Block Inputs | Description |
|---|---|
| SwGate<br>StopGate | With the active GATE signal, an active count operation can be interrupted despite pending count pulses. The Functionality depends on the configuration in HW Config. Please see the manual for more information (Output Bits “SW_GATE” and “GATE_STP”). |
| LoadDirect<br>LoadPrep<br>EnSetUp<br>EnSetDown | Transfer LoadValue to the module. Please see the manual for more information (Output Bits “L_DIRECT”, “L_PREPAR”, “EN_SET_UP”, “EN_SET_DN”). |
| TCmpVal1<br>TCmpVal2 | Transfer Compare value 1 (CmpVal1) / Compare value 2 (CmpVal2) to the module. Please see the manual for more information (Output Bits “T_CMP_V1”and “T_CMP_V2”). |
| RstSync<br>RstZero<br>RstOpErr | Reset status bits SyncSt, ZeroSt and OpErr. Please see the manual for more information (Output Bits “RES_SYNC”, “RES_ZERO” and “OT_ERR_A”). |
| EnDQ0 E<br>nDQ1 | Enable analog output DQ0 / DQ1. Please see the manual for more information (Output Bits “ENABLE_DQ0” and “ENABLE_DQ1”) |

The Count value (Real) and its status is output at the block output PV1_Li. The Count value is also output as DINT value at the block output PV1. Attention: In Mode 1 the output is only valid for count values in the range of 0 to 2147483647.

The Latch/Load value (Real) and its status is output at the block output PV2_Li. Depending on the modules configuration the latch value or the load value is output. The Latch/Load value is also

output as DINT value at the block output PV2. Attention: In Mode 1 the output is only valid for Latch/Load values in the range of 0 to 2147483647.

The outputs PV1_UnitLi and ScalePV1_Li forward the values of the inputs PV1_Unit and ScalePV1.

## Configuration

Connect the DWord address of input "LATCH_LOAD" of the respective counter channel to the "Connect" input (e.g. ID13). The addressing can also be done via symbols by using the symbol table.

For example the "LATCH_LOAD" input of counter channel 1 has an offset of 13 to the base address of the module. If the input address range of the module starts at 512 the address ID525 needs to be connected to the Connect input to use the first counter channel.

The table below shows the offsets of the respective counter channel

| LATCH_LOAD value of counter channel x | Offset to base address |
|---|---|
| 1 | 13 |
| 2 | 24 |
| 3 | 35 |
| 4 | 46 |

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The Laddr and LaddrOut inputs are configured.
- The Mode input is interconnected to the OMODE_00output of the MOD_D32_PN block.
- The DataXchg input is interconnected to the relevant DXCHG_00 output of the MOD_D32_PN block.
- The DataXchg1 input is interconnected to the relevant DXCHG1_00 output of the MOD_D32_PN block.
- The MS input is interconnected to the relevant O_MS output of the MOD_D32_PN block.
- The ProImQB input is interconnected with the symbol of the counter's quality bit.

## Startup characteristics

The block does not have any startup characteristics.

## Redundancy

The block does not support redundancy.

## Status word allocation

This block does not have the Status parameter.

## 17.20.2 Pcs7Cnt4 modes

### Pcs7Cnt4 modes

This block does not have any modes.

## 17.20.3 Pcs7Cnt4 functions

### Simulation

The block provides the standard function Simulating signals.

With SimOn = 1 , the simulation values SimPV1 and SimPV2 are written to the outputs PV1, PV1_Li as well as PV2 and PV2_Li . The status of the outputs is set to 16#60 and the Bad output is set to 0.

In simulation the block is not reading nor writing from/to the process image.

Simulation takes highest priority.

If the block is in simulation state, SimAct = 1 is set.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks.

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable functions using the Feature I/O. The following functionality is available for this block at the relevant bits:

You need to assign parameters for three Feature bits for the response to an invalid raw value for the channel blocks.

If more than one of these Feature bits are set (=1), the following priority applies:

Output invalid raw value (Feature.Bit28 = highest priority)

Output substitute value if raw value is invalid (Feature.Bit29)

Output the last valid value if raw value is invalid (Feature.Bit30, lowest priority)

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks |
| 27 | Do not evaluate the first run of the diagnostic blocks |
| 28 | Output invalid raw value |
| 29 | Output substitute value if raw value is invalid |
| 30 | Outputting last valid value if raw value is invalid |

### Signal status for PCS7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks.

The worst signal status ST_Worst for the block is formed from the following parameters:

- LoadPV1.ST
- PV1_Li.ST
- PV2_Li.ST
- LoadDirect.ST
- LoadPrep.ST
- TCmpVal1.ST
- TCmpVal2.ST
- PV2_Li.ST
- RstSync.ST
- RstZero.ST
- RstOpErr.ST

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

### Unsigned DINT

Depending on your configuration, count channel of the module provides count values from 0 up to 4294967295. This corresponds to a data type unsigned DINT. Because STEP 7 does not provide a data type unsigned DINT, a misinterpretation of the highest bit takes place with STEP 7 data type DINT. That means, `PV_OutCnt` delivers values from 0...2147483647 and then goes on with -2147483648..-1. The count value is provided in parallel by output parameter `PV_Out` in data type REAL.

## 17.20.4 Pcs7Cnt4 error handling

### PCS7Cnt4 error handling

Refer to the section Error handling in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error

A higher-level error is displayed at the output parameters ModErr and Bad with 1 if the signal status in the high word of the input parameter Mode assumes the value 16#40.

In addition, at the outputs PV1_Li and PV2_Li of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output.

## 17.20.5 Pcs7Cnt4 messaging

### PCS7Cnt4 messaging

This block does not offer messaging.

## 17.20.6 Pcs7Cnt4 I/Os

### Input parameters

| *Parameters* | *Description* | *Type* | *Default* |
|---|---|---|---|
| Connect | Connect to Latch/Load address of counter channel x | DWORD | 16#00000000 |
| CmpV1 | Compare Value 1 | REAL | 0.0 |
| CmpV2 | Compare Value 2 | REAL | 0.0 |
| EnDQ0 | 1 = Enable Digital output DQ0 | BOOL | 0 |
| EnDQ1 | 1 = Enable Digital output DQ1 | BOOL | 0 |
| EnSetDown | 1 = Enable Set Down | BOOL | 0 |
| EnSetUp | 1 = Enable Set Up | BOOL | 0 |
| Feature | I/O for additional functions | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 28: BOOL<br>• ...<br>• Bit 31: BOOL | <br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |
| FlutEn | 1=Fluttersupress active | BOOL | 0 |
| FlutTmIn | Fluttersupress time | INT | 0 |
| Laddr | Logical input address of counter x LatchLoad | INT | 0 |
| LaddrOut | Logical output address of counter x LatchValue | INT | 0 |

| Parameters | Description | Type | Default |
|---|---|---|---|
| LoadDirect | Rising edge: Transfer load value to module and apply load value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| LoadPrep | Rising edge: Transfer load value to module; Falling edge: Apply load value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| LoadPV1 | Load value | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| LoadPV1D | Load value (DINT) | STRUCT<br>• Value: DINT<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| MS | Maintenance state | DWORD | 16#00000000 |
| MS_Ext | External Maintenance state | DWORD | 16#00000000 |
| MS_Release | Maintenance release | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| ProImQB | Qualitybit from Processimage | BOOL | 0 |
| PV1_Unit | Unit of counter value | INT | 0 |
| PV2_Unit | Unit of LatchLoad value | INT | 0 |
| RstOpErr | 1 = Acknowledge OT_ERR | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| RstSync | 1 = Reset Sync Status Bit (STS_SYNC) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| RstZero | 1 = Reset Status Bits STS_ZERO, STS_COMP1 and STS_COMP2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| StopGate | 1 = Close gate | BOOL | 0 |
| SwGate | Software gate; 1 = open; 0 = close | BOOL | 0 |
| TCmpVal1 | Rising edge: Transfer compare value 1 to module; Falling edge: Apply compare value 1 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| TCmpVal2 | Rising edge: Transfer compare value 2 to module; Falling edge: Apply compare value 2 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| ScalePV1 | Range of counter value | STRUCT<br>• High: REAL<br>• Low: REAL | <br>• 100.0<br>• 0.0 |

| *Parameters* | *Description* | *Type* | *Default* |
|---|---|---|---|
| ScalePV2 | Range of LatchLoad value | STRUCT<br>• High: REAL<br>• Low: REAL | <br>• 100.0<br>• 0.0 |
| SelQB | 1 = Select Qualitybit from Processimage | BOOL | 0 |
| SimOn | 1=Simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| SimPV1 | Simulation value Counter | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| SimPV2 | Simulation value LatchLoad | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0.0<br>• 16#80 |
| SubsPV1 | Substitution value Counter | REAL | 0.0 |
| SubsPV2 | Substitution value LatchLoad | REAL | 0.0 |
| DelTiBad | Delay time for output Bad [s] | REAL | 0.0 |
| SampleTime | Sample Time [s] | REAL | 0.1 |
| TextRef | Text reference external messages | WORD | 16#0000 |

## In/out Parameters

| *Parameter* | *Meaning* | *Type* | *Default* |
|---|---|---|---|
| DataXchg | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| DataXchg1 | Internal data exchange channel to the diagnostics block | DWORD | 16#00000000 |
| Mode | Operating mode | DWORD | 16#00000000 |
| MS_Xchg | Exchange of the maintenance status | DWORD | 16#00000000 |

## Output Parameters

| *Parameter* | *Meaning* | *Type* | *Default* |
|---|---|---|---|
| Bad | 1 = bad process values | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| CntDir | Count Direction 0 = up 1 = down | BOOL | 0 |
| Comp1St | Status compare 1 | BOOL | 0 |
| Comp2St | Status compare 2 | BOOL | 0 |

| Parameter | Meaning | Type | Default |
|---|---|---|---|
| DiSetSt | Status of DI-Set | BOOL | 0 |
| DiStartSt | Status Di-Start | BOOL | 0 |
| DiStopSt | Status Di-Stop | BOOL | 0 |
| Dq0St | Status digital output 1 | BOOL | 0 |
| Dq1St | Status digital output 2 | BOOL | 0 |
| ErrorNum | Parameter error | INT | 0 |
| GateSt | Status gate; 1 = Gate open | BOOL | 0 |
| LoadDirectSt | Status of input LoadDirect | BOOL | 0 |
| LoadPrepSt | Status of input LoadPrep | BOOL | 0 |
| ModErr | 1=Higher level failure | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| MS_Dev | Maintenance State | DWORD | 16#00000000 |
| MS_Req | Maintenance request | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| OpErr | 1 = Operator Error | BOOL | 0 |
| OverflowSt | Status overflow: 1 = High counting limit reached | BOOL | 0 |
| PV1 | Counter value - Not valid for Values > 2147483647 (Limit of DInt) | DINT | 0 |
| PV1_Li | Counter value struct | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| PV1_UnitLi | Unit of actual value | INT | 0 |
| PV2 | Latch/Load value - Not valid for Values > 2147483647 (Limit of DInt) | DINT | 0 |
| PV2_Li | Latch/Load value struct | STRUCT<br>• Value: REAL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| PV2_UnitLi | Unit of latch/load value | INT | 0 |
| RstSyncSt | Status of input RstSync | BOOL | 0 |
| RstZeroSt | Status of input RstZero | BOOL | 0 |
| RunSt | 1 = Counter is activated in HW Config | BOOL | 0 |
| ScalePV1_Li | Range of counter value | STRUCT<br>• High: REAL<br>• Low: REAL | <br>• 100.0<br>• 0.0 |
| ScalePV2_Li | Range of LatchLoad value | STRUCT<br>• High: REAL<br>• Low: REAL | <br>• 100.0<br>• 0.0 |

| *Parameter* | *Meaning* | *Type* | *Default* |
|---|---|---|---|
| SimAct | 1= Simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | <br>• 0<br>• 16#80 |
| ST_Worst | Worst Signal Status | BYTE | 0 |
| SwGateSt | Status software gate; 1 = Sw gate open | BOOL | 0 |
| SyncSt | Status synchronisation; 1 = Synchronisation was successful | BOOL | 0 |
| TCmpVal1St | Status of input TCmpVal1 | BOOL | 0 |
| TCmpVal2St | Status of input TCmpVal2 | BOOL | 0 |
| UnderflowSt | Status underflow: 1 = Low counting limit reached | BOOL | 0 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |
| ZeroSt | 1 = Zero crossing detected | BOOL | 0 |

## 17.20.7 Pcs7Cnt4 block diagram

### PCS7Cnt4 block diagram

A block diagram is not provided for this block.

# 17.21 Pcs7HaAI - HART variable channel block for AI-HART modules

## 17.21.1 Description of Pcs7HaAI

### Object name (type + number) and family

Type + number: FC 1931

Family: Channel

### Area of application for Pcs7HaAI

The block is used for providing `MultiHART` variables of an input HART field device. `MultiHART` is a special HART mode supported by ET 200SP HA modules.

The block supports 1 `MultiHART` and 4 `MultiHART`.

### How it works

Pcs7HaAI block provides the following HART variables that can be selected at input and output parameters.

Input parameters:

- `HV_PriEn` = 1 for the primary HART variable
- `HV_SecEn` = 1 for the secondary HART variable
- `HV_TerEn` = 1 for the tertiary HART variable
- `HV_QuaiEn` = 1 for the quaternary HART variable

Output parameters:

- `HV_OutP` primary HART variable including status
- `HV_OutS` secondary HART variable including status
- `HV_OutT` tertiary HART variable including status
- `HV_OutQ` quaternary HART variable including status

The process value is available as a physical variable. The signal status contains information about the status of the field device.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

Connect the symbol generated in HW Config (symbol table) for the input channel with the `PV` input parameter.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `MultiHART` is interconnected with the corresponding output parameter `MULTI_HART_xx` of the MHA_CO or OR_MHA_CO block.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Pcs7HaAI block diagram (Page 2671)

## 17.21.3 Pcs7HaAI functions

### Functions of Pcs7HaAI

The functions for this block are listed below.

### Obtaining the standard value

The HART variable value of the process image (partition) is outputted as a standard value at the HV_OutP/HV_OutS/HV_OutT/HV_OutQ output parameters.

### See also

## 17.21.4 Pcs7HaAI error handling

### Error handling of Pcs7HaAI

The following errors can be displayed for this block:

- Invalid value

### Invalid value

The invalid values are displayed with the value 1 at the output parameters HV_OutPBad/HV_OutSBad/HV_OutTBad/HV_OutQBad. The invalid value error is generated from the signal status HV_PriQC/HV_SecQC/HV_TerQC/HV_QuaQC of the MultiHART in/out parameter when the signal status is 16#00 (initial value from S7- System), 16#37 (initial value from analog module after module start), 16#23 (Communication error or HART-variable in field device not available), or 16#28, 16#29, 16#2A, 16#2B (Bad from HART field device) respectively.

# 17.22 Pcs7HaAO - HART variable channel block for AO-HART modules

## 17.22.1 Description of Pcs7HaAO

### Object name (type + number) and family

Type + number: FC 1932

Family: Channel

### Area of application for Pcs7HaAO

The block is used for providing `MultiHART` variables of an output HART field device. `MultiHART` is a special HART mode supported by ET 200SP HA modules.

The block supports 1 `MultiHART` and 4 `MultiHART`.

### How it works

Pcs7HaAO block provides the following HART variables that can be selected at input and output parameters.

Input parameters:

- `HV_PriEn` = 1 for the primary HART variable
- `HV_SecEn` = 1 for the secondary HART variable
- `HV_TerEn` = 1 for the tertiary HART variable
- `HV_QuaiEn` = 1 for the quaternary HART variable

Output parameters:

- `HV_OutP` primary HART variable including status
- `HV_OutS` secondary HART variable including status
- `HV_OutT` tertiary HART variable including status
- `HV_OutQ` quaternary HART variable including status

The process value is available as a physical variable. The signal status contains information about the status of the field device.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

Connect the symbol generated in HW Config (symbol table) for the output channel with the `PV_Out` output parameter.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in/out parameter `MultiHART` is interconnected with the corresponding output parameter `MULTI_HART_xx` of the MHA_CO or OR_MHA_CO block.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

Pcs7HaAO block diagram (Page 2678)

## 17.22.3 Pcs7HaAO functions

### Functions of Pcs7HaAO

The functions for this block are listed below.

### Obtaining the standard value

The HART variable value of the process image (partition) is outputted as a standard value at the `HV_OutP`/`HV_OutS`/`HV_OutT`/`HV_OutQ` output parameters.

### See also

## 17.22.4 Pcs7HaAO error handling

### Error handling of Pcs7HaAO

The following errors can be displayed for this block:

- Invalid value

### Invalid value

The invalid values are displayed with the value 1 at the output parameters `HV_OutPBad`/ `HV_OutSBad`/`HV_OutTBad`/`HV_OutQBad`. The invalid value error is generated from the signal status HV_PriQC/HV_SecQC/HV_TerQC/HV_QuaQC of the `MultiHART` in/out parameter when the signal status is 16#00 (initial value from S7- System), 16#37 (initial value from analog module after module start), 16#23 (Communication error or HART-variable in field device not available), or 16#28, 16#29, 16#2A, 16#2B (Bad from HART field device) respectively.

# 17.23 Pcs7ReIn - REAL input channel block

## 17.23.1 Description of PCS7ReIn

### Object name (type + number) and family

Type + number: FB 1837

Family: Channel

### Area of application for Pcs7DiIT

The Pcs7ReIn block is used for the following applications:

- Signal processing of an analog input value of floating-point type (IEEE-754) from S7-300/400 SM analog input modules.
- Processing of the redundant input channels.

### How it works

The block cyclically processes all channel-specific signal functions of an analog input module.

It reads an analog value of floating-point type (IEEE-754) from the process image (partition) and outputs this value at PV_Out.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB(OB30 to OB38).

The block is also installed automatically in the startup OB(OB100).

Connect the symbol generated in the HW Config (symbol table) for the input channel with the `PV_In` input parameter. The symbol must be of datatype Real.

In case of redundant I/O configuration, use symbol of the channel of the master module.

When the CFC function "Generate module drivers" is used, the following occurs automatically:

- The in parameter ProImQB is interconnected with the symbol of the quality bit.
- The in/out parameter Mode is interconnected to the corresponding OMode_xx output parameter of the MOD block.
- The in/out parameter DataXchg is interconnected to the corresponding DataXchg_xx output parameter of the MOD block.
- The in/out parameter DataXchg1 is interconnected to the corresponding DataXchg1_xx output parameter of the MOD block.
- The MS parameter is interconnected to the O_MS output parameter of the diagnostics block.

In case of redundancy, connection with both quality bits and connection with the redundant slave channel:

- The in parameter ProImQB is interconnected with the symbol of the quality bit of the master channel.
- The in parameter PV_InSlv is interconnected with the symbol of the slave channel.
- The in parameter ProImQBSlv is interconnected with the symbol of the quality bit of the slave channel.

If you are not using the CFC function "Generate module drivers" you must set the Mode in/out parameter manually. Byte 0 must be set to 16#01 for the block to output valid values. Byte 3 = 16#80 = "valid value". E.g. Mode = 16#80000001. Refer to the Mode Settings for SM Modules section for more on this.

### Startup characteristics

The block does not have any startup characteristics.

### Redundancy

The block monitors the values of the redundant signals (master and slave) with quality code and the value of the signal with “Good” quality code along with its quality code is transferred to the process.

In case both the signals deliver “Bad” quality code, the substitute value with “Bad” quality code is transferred to the process.

### Status word allocation

This block does not have the `Status` parameter.

## 17.23.2 PCS7ReIn modes

### PCS7ReIn modes

This block does not have any modes.

## 17.23.3 PCS7ReIn functions

### Functions of FbAnIn

The functions for this block are listed below.

### Obtaining the standard value

The analog value of the process image (partition) is output as a standard value at the PV_Li output parameter.

### Holding the last value if raw value is invalid

If the block is to hold its last valid value when the analog value is invalid or in the initialization phase of the device, you must activate this function at the Feature Bit Outputting last valid value if raw value is invalid.

### Output substitute value if raw value is invalid

If the block is to output a substitute value (SubsPV) when the analog value is invalid or in the initialization phase of the device, you must activate this function at the Feature Bit Output substitute value if raw value is invalid.

### Outputting an invalid value if analog value is invalid

If the block is to output an invalid value (PV_Li = PV), you must activate this function at the Feature Bit Output invalid raw value.

This function is preset.

### Flutter suppression

This block provides the standard function Flutter suppression for channel blocks

### Signal status for PCS7 channel blocks

The block provides the standard function Forming and outputting the signal status for PCS 7 channel blocks.

### Simulating signals

The block provides the standard function Simulating signals.

### Configurable reactions using the Feature parameter

You can find an overview of all reactions provided by the Feature parameter in the Configurable functions using the Feature I/O . The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 10 | Condition monitoring information at the channel blocks |
| 27 | Do not evaluate the first run of the diagnostic blocks |
| 28 | Output invalid raw value |

| Bit | Function |
|---|---|
| 29 | Output substitute value if raw value is invalid |
| 30 | Outputting last valid value if raw value is invalid |

### Sign-of-life monitoring

If an input value whose signal status is 16#80 (good) remains constant for a programmable time (monitoring time), the input value is detected as faulty and the outputs Bad = 1 and FrzVal = 1 are set.

The monitoring time is set at the FrznTmIn input parameter in seconds. With FrznTmIn = 0 or FrznEn = 0 (default setting), the sign-of-life monitoring is deactivated, any pending errors are reset.

The input value is considered as faulty as long as it seen as constant. The monitoring time is restarted each time the input value is changed.

### Delay the output "Bad"

If input `DelTiBad` > 0, on receiving an internal bad value, delay timer will start. Timer will abort if `DelTiBad` is 0. Minimum value of `DelTiBad` is 0. Only when timer expires i.e., `RemDelTiBad` = 0, the bad value will be updated to the output. If timer is running and internal bad value becomes 0, then whatever time is left will be shown in negative to bring to operators notice that bad value was received. During the time, delay timer is running `Bad.ST` will be 16#60. Only after the timer expires the actual `ST` be updated. Substitute value is updated at `PV_Out`, only after delay timer expires. When timer is running last valid value will be there at `PV_Out`. When substitute value is used, `ST` of `PV_Out` will be 16#60.

## 17.23.4 PCS7ReIn error handling

### Quintessence

Refer to the section Error handling in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Channel error
- Higher-level error
- Invalid measuring range
- Frozen input value (sign-of-life monitoring)

### Channel error

At the output parameter Bad, channel errors are displayed with 1.

### Higher-level error / invalid measuring range

A higher-level error is displayed at the output parameters ModErr and Bad with 1 if the signal status at High Word of the input parameter Mode accepts the value 16#40.

A higher-level error is also present when an incorrect measuring type is entered in Low Word of the input parameter Mode. Only 16#0001 is valid.

In addition, at the outputs PV1_Li and PV2_Li of the signal status, either 16#00 (in the event of an error) or 16#60 (for manipulated value (for example, substitute value, simulation, last valid value) is output.

## 17.23.5 PCS7ReIn messaging

### Messaaging

This block does not offer messaging.

## 17.23.6 PCS7ReIn I/Os

### Input parameters

| Parameters | Description | Type | Default |
|---|---|---|---|
| Deltaval | Delta value (PV_In - Last valid value) | REAL | 0.0 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| Feature | I/O for additional functions | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 28: BOOL<br>• ...<br>• Bit 31: BOOL | <br>• 0<br>• 0<br>• 1<br>• 0<br>• 0 |
| FlutEn | 1=Fluttersupress enable | BOOL | 0 |

| | | Value: BOOL | 0 |
| | | ST: BYTE | 16#80 |
| ModErr | 1=Higher level failure | STRUCT | |
| | | Value: BOOL | 0 |
| | | ST: BYTE | 16#80 |
| MS_Dev | Maintenance State | DWORD | 16#00000000 |
| MS_Req | Maintenance request | STRUCT | |
| | | Value: BOOL | 0 |
| | | ST: BYTE | 16#80 |
| OosAct | 1 = Field device is undergoing maintenance | STRUCT | |
| | | Value: BOOL | 0 |
| | | ST: BYTE | 16#80 |
| PV_Out | Standard value (physical variable) | STRUCT | |
| | | Value: REAL | 0 |
| | | ST: BYTE | 16#80 |
| PV_OutUnit | Unit of the process value | INT | 0 |
| RemTime | Remaining monitoring time [s] | REAL | 0.0 |
| SampleTime | Sampling time [s] | REAL | 0.1 |
| ScaleOut | Range of process value | STRUCT | |
| | | High: REAL | • 100.0 |
| | | Low: REAL | • 0.0 |
| RemDelTiBad | Remaining delay time for output Bad [s] | REAL | 0.0 |
| SimAct | 1= Simulation active | STRUCT | |
| | | Value: BOOL | • 0 |
| | | ST: BYTE | • 16#80 |

## 17.23.7 PCS7ReIn block diagram

### PCS7ReIn block diagram

A block diagram is not provided for this block.

# 17.24 Annex for channel blocks

## 17.24.1 Mode Settings for SM Modules

### Mode Structure

The structure and meaning of the input Mode of data type DWORD are shown below:

| | | |
|---|---|---|
| Byte 3: | 16#80: Value status "valid value"<br>16#85 Value status "valid value"<br>16#00: Value status "invalid value"<br>16#40: Value status "invalid value" | <br>(IO redundancy warning)<br>(Channel error)<br>(Higher-level error) |
| Byte 2: | 16#01: Restart (OB 100) has been carried out<br>16#02: Measuring range high limit violated<br>16#04: Measuring range low limit violated<br>16#xy: Variant identification with multiple mode assignment (see below) | <br>(Channel-error diagnostics)<br>(Channel-error diagnostics) |
| Byte 1, 0 (low word): | Measuring range coding (see below) | |

Example:

16#80010203 = value status "valid value", restart has been carried out, current 4 mA to 20mA

### Mode: Celsius and Fahrenheit

| Variant | x | y | Unit of measurement |
|---|---|---|---|
| 0 | 0, 1<br>(depending on the other variant IDs) | 0,1,2,4 | Celsius |
| 1 | 8, 9<br>(depending on the other variant IDs) | 0,1,2,4 | Fahrenheit |

### Mode: 16#090C and variant

| Variant | x | y | Measuring range |
|---|---|---|---|
| 0 | 0 | 0,1,2,4 | Ni 120 standard range |
| 1 | 1 | 0,1,2,4 | KTY84/110 |

### Mode: 16#090D and variant

| Variant | x | y | Measuring range |
|---|---|---|---|
| 0 | 0 | 0,1,2,4 | Ni 120 climate range |
| 1 | 1 | 0,1,2,4 | KTY84/130 |

### Mode: 16#07 (Coding A) and variant

| Variant | x | y | Measuring range |
|---|---|---|---|
| 0 | 0 | 0,1,2,4 | HART interface |
| 1 | 1 | 0,1,2,4 | Thermocouple, dynamic reference temperature |

### MODE: 16#08, 16#0A, 16#0B, 16#0D, 16#0E (coding A) and variant

Table 17-1 PCS 7 as of V8.1: MODE parameter variant

| Variant | x | y | Measuring range |
|---|---|---|---|
| 0 | 0 | 0,1,2,4 | S7-300 module |
| 1 | 3 | 0,1,2,4 | S7-300, ET 200M Ex I/O module |

Table 17-2 PCS 7 V7.x: MODE parameter variant

| Variant | mode | Measuring range |
|---|---|---|
| 0 | 16#08, 16#0A,<br>16#0B, 16#0D,<br>16#0E | S7-300 module |
| 1 | 16#18, 16#1A,<br>16#1B, 16#1D,<br>16#1E | S7-300, ET 200M Ex I/O module |

### MODE: 1oo1-/1oo2 evaluation for F modules

| Variant | x | y | Measuring range |
|---|---|---|---|
| 0 | 0 | 0,1,2,4 | 1oo1 (1v1) evaluation |
| 1 | 4 | 0,1,2,4 | 1oo2 (2v2) evaluation |

### Measuring range coding of the analog input modules

Depending on the measuring range coding of the analog input modules, the parameter `Mode` (low word = measuring range coding) corresponding to the channel must be specified in accordance with the table. When thermocouples are used there are various options for combining the measurement type (coding A) with the measuring range (coding B). In this case, the low word of parameter `Mode` must be calculated according to the following formula and the result entered at the Mode input parameter as an INTEGER value:

Measuring range coding = 256 · Code A + Code B

Please note: The table shows codes **A** and **B** in binary format, and the measuring range coding as a hexadecimal number as the result.

| Measuring type | Code (A) | Measuring range | Code(B) | Measuring range coding (256*A+B) |
|---|---|---|---|---|
| Disabled | | | | 16#0000 |
| Voltage | 2#0001 | ± 25 mV | 2#1010 | 16#010A |
| | | ± 50mV | 2#1011 | 16#010B |
| | | ± 80 mV | 2#0001 | 16#0101 |
| | | ± 250 mV | 2#0010 | 16#0102 |
| | | ± 500 mV | 2#0011 | 16#0103 |
| | | ± 1 V | 2#0100 | 16#0104 |
| | | ± 2,5 V | 2#0101 | 16#0105 |
| | | ± 5 V | 2#0110 | 16#0106 |
| | | 1 to 5 V | 2#0111 | 16#0107 |
| | | 0 to 10V | 2#1000 | 16#0108 |
| | | ± 10 V | 2#1001 | 16#0109 |
| | | ± 100 mV | 2#1100 | 16#010C |
| 4-wire measuring transducer | 2#0010 | ± 3.2 mA | 2#0000 | 16#0200 |
| | | ± 5 mA | 2#0101 | 16#0205 |
| | | ± 10 mA | 2#0001 | 16#0201 |
| | | 0 to 20 mA | 2#0010 | 16#0202 |

| | | Type E [NiCr-CuNi] (variant 1) | 2#0010 | 16#0702 |
| | | Type R [PtRh-Pt] (variant 1) | 2#0011 | 16#0703 |
| | | Type S [PtRh-Pt] (variant 1) | 2#0100 | 16#0704 |
| | | Type J [Fe-CuNi IEC] (variant 1) | 2#0101 | 16#0705 |
| | | Type L [Fe-CuNi DIN] (variant 1) | 2#0110 | 16#0706 |
| | | Type T [Cu-CuNi IEC] (variant 1) | 2#0111 | 16#0707 |
| | | Type K [NiCr-Ni] (variant 1) | 2#1000 | 16#0708 |

### Effect of the temperature coefficients on the measuring range

- Setting TC = 3850 at GOST Standard Pt 10, Pt 50, Pt 100, Pt 500 sets Bit 7 within the measuring range byte (0 x 40)
- Setting TC = 428 at GOST Standard Cu 10, Cu 50, Cu 100 sets Bit 8 within the measuring range byte (0 x 80)

### Measuring range coding of the analog output modules

Depending on the measuring range coding of the analog output modules, the parameter `Mode` (measuring-range coding) corresponding to the channel must be specified in accordance with the table.

| Measuring type | Measuring range | Mode |
|---|---|---|
| Voltage | ± 5 V | 16#0106 |
| | 1 to 5 V | 16#0107 |
| | 0 to 10V | 16#0108 |
| | ± 10 V | 16#0109 |
| Current | 0 to 10 mA | 16#0206 |
| | 0 to 20 mA | 16#0202 |
| | 4 to 20 mA | 16#0203 |
| | ± 20 mA | 16#0204 |
| HART interface | 4 to 20 mA | 16#070C |

### Measuring-Range Coding of the Digital Input and Output Modules

There is no measuring type and no measuring range for digital input modules and digital output modules:

- `Mode` **= 16#FFFF** (with DI)
- `Mode` **= 16#FFFE** (with DO)

### Measuring range coding of the controller module

There is no measuring type and no measuring range for controller modules:

- `Mode` **= 16#FFFD**

### Measuring range coding of the ET 200SP Analog Input Energy Meter module

There is no measuring type and no measuring range for analoge input energy meter moduls:

- Mode = **16#200C**

## 17.24.2 Mode settings for field devices

### Mode structure

The structure and meaning of the input Mode of data type DWORD are shown below:

| | | |
|---|---|---|
| Byte 3: | 16#80: Value status "valid value"<br>16#00: Value status "invalid value"<br>16#40: Value status "invalid value" | <br>(Channel error)<br>(Higher-level error) |
| Byte 2: | 16#01: Restart (OB 100) has been carried out<br>16#xy: Variant identification with multiple mode assignment (see below) | |
| Byte 1, 0 (low word): | Measuring range coding (see below) | |

Example:

16#80010001 = Value status "valid value", restart has been carried out, PA device with analog input

### PA/FF device variant identifier

| Variant | x | y | Field device |
|---|---|---|---|
| 0 | 0 | 0 | PA device |
| 1 | 1 | 0 | FF device |

### Mode settings for field devices

MODE_xx input parameters are available for a maximum of 32 slots of a PA/FF field device. Their initial value is zero (no read/write access). You must set the combination selected from the options of the PROFIBUS PA 3.0 profile at the MODE_xx input of each slot channel xx:

| Block | Parameter at block ... | ...and at field device | Input/output from block view (PLS view) | Mode 16#xxyy<br>O = xx<br>I = yy | Configuration possible with field device |
|---|---|---|---|---|---|
| Analog input (PA_AI/ FbAnIn) | PV | OUT | I | 16#0001 | PA + FF |
| Totalizer (FbAnTot) | PV | | I | 16#000F | PA + FF |
| Totalizer (FbAnTot) | PV<br>PV_Set | | I<br>O | 16#070F | PA + FF |
| Totalizer (FbAnTot) | PV<br>PV_Set<br>PV_Mode | | I<br>O<br>O | 16#080F | PA + FF |
| Analog output (FbAnOu) | SP | SP | O | 16#0100 | PA + FF |

| Block | Parameter at block ... | ...and at field device | Input/output from block view (PLS view) | Mode 16#xxyy<br>O = xx<br>I = yy | Configuration possible with field device |
|---|---|---|---|---|---|
| Analog output (FbAnOu) | SP<br>Rbk<br>PosD | SP<br>READBACK<br>POS_D | O<br>I<br>I | 16#0103 | PA |

| Binary output (FbDiOu) | RCasIn<br>RCasOut<br>CbkBy0 - CbkBy2 | RCAS_IN_D<br>RCAS_OUT_D<br>CHECK_BACK_D | O<br>I<br>I | 16#050D | PA |
| Binary output (FbDiOu) | SP<br>RCasIn<br>Rbk<br>RCasOut<br>CbkBy0 - CbkBy2 | SP_D<br>RCAS_IN_D<br>READBACK_D<br>RCAS_OUT_D<br>CHECK_BACK_D | O<br>O<br>I<br>I<br>I | 16#060E | PA |

## 17.24.3 Mode settings for Channel blocks

### Mode Structure

Analog input, byte1=16#01 (voltage):

| Measuring type | Measuring range | MODE |
|---|---|---|
| Voltage | 0V to 1V | 16#010D |
| | -20V to 0V | 16#010E |
| | 0V to 20V | 16#0110 |

Analog input, byte1=16#02 (current / 4wire):

| Measuring type | Measuring range | MODE |
|---|---|---|
| Current | -20mA to 0mA | 16#0207 |
| | +/-30mA | 16#0208 |

Analog input, byte1=16#03 (current / 2wire):

| Measuring type | Measuring range | MODE |
|---|---|---|
| Current | -20mA to 0mA | 16#0307 |
| | +/-30mA | 16#0308 |

# Conversion blocks 18

## 18.1 StrgToBy - String in byte structure (Struct of Byte)

### 18.1.1 Description of StrgToBy

#### Object name (type + number) and family

Type + number: FC 384

Family: Convert

#### Area of application for StrgToBy

The block converts a string with a maximum length of 32 into a byte structure (Struct of Byte). This enables strings to be interconnected via the StrgToBy block to the inputs for the associated values (`ExtValxx`) of the technological blocks.

#### How it works

The block uses the input string "`StringIn`", converts it to a byte structure and transfers it to the output parameter `StrctOut`".

#### Configuration

Use the CFC editor to install the block in any OB.

#### Startup characteristics

The block does not have any startup characteristics.

#### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

#### See also

StrgToBy modes (Page 2702)

# 18.2 StruAnIn - Separating an analog structured variable

## 18.2.1 Description of StruAnIn

### Object name (type + number) and family

Type + number: FC 375

Family: Convert

### Area of application for StruAnIn

The block is used for the following applications:

- Separation of an analog value with a structure into a variable of the REAL data type and a signal status

### How it works

The block separates an analog value with a structure interconnected to the `In` input parameter into a variable (`Out`) of the REAL data type and a (`ST`) signal status.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for parameter `Status`

This block does not have the `Status` parameter.

# 18.3 StruAnOu - Creating an analog structured variable

## 18.3.1 Description of StruAnOu

### Object name (type + number) and family

Type + number: FC 376

Family: Convert

### Area of application for StruAnOu

The block is used for the following applications:

- Merging a variable of the REAL data type and a signal status into an analog process value.

### How it works

The block merges an analog value (`Value`) of the REAL data type and a signal status (`ST`) to form an analog value (`Out`) with a structure.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 18.4 StruDiIn - Separating a digital structured variable

## 18.4.1 Description of StruDiIn

### Object name (type + number) and family

Type + number: FC 377

Family: Convert

### Area of application for StruDiIn

The block is used for the following applications:

- Separating a binary process value into a variable of the BOOL data type, a process value and signal status.

### How it works

The block separates a binary process value interconnected to the `In` input parameter into a variable of the BOOL data type and a signal status.

### Configuration

Use the CFC editor to install the block in any OB

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 18.5 StruDiOu - Creating a digital structured variable

## 18.5.1 Description of StruDiOu

### Object name (type + number) and family

Type + number: FC 378

Family: Convert

### Area of application for StruDiOu

The block is used for the following applications:

- Merging a variable of the BOOL data type and a signal status into a binary process value.

### How it works

The block merges a variable of the BOOL data type and a signal status into a binary process value.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 18.6 StruScIn - Separating a display area into two variables

## 18.6.1 Description of StruScIn

### Object name (type + number) and family

Type + number: FC 379

Family: Convert

### Area of application for StruScIn

The block is used for the following applications:

- Separation of a display area into two variables of data type REAL.

### How it works

The block separates a display area interconnected to the `Scale` input parameter into two variables of the REAL. data type

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

# 18.8 STIn - Separating the signal status into individual binary displays

## 18.8.1 Description of STIn

### Object name (type + number) and family

Type + number: FC 373

Family: Convert

### Area of application for STIn

The block is used for the following applications:

- Separation of signal status into individual binary displays

### How it works

The block separates a signal status interconnected to the input parameter into individual binary displays.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 18.9 STOu - Merging individual binary signals into a signal status

## 18.9.1 Description of STOu

### Object name (type + number) and family

Type + number: FC 374

Family: Convert

### Area of application for STOu

The block is used for the following applications:

- Merging individual binary signals into a signal status

### How it works

The block merges individual binary signals into a `Out` signal status.

If several binary signals are set, the one with the highest priority becomes effective, as described in the section Forming and outputting the signal status for technologic blocks (Page 117) for technologic blocks.

If no binary signal is set, the "Bad, process related" signal status is set.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

# 18.10 MSTIn - Separating the maintenance status into individual status displays

## 18.10.1 Description of MSTIn

### Object name (type + number) and family

Type + number: FB 1858

Family: Convert

### Area of application for MSTIn

The block is used for the following applications:

- Separation of the maintenance status into individual status displays

### How it works

The block separates a maintenance status interconnected to the `In` input parameter into individual status displays.

If the input parameter receives information that at least one value is simulated, for example (`In` = 16#00000003), this is indicated at output parameter `MST_03` with the value 1.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### See also

# 18.11 MSTOu - Merging individual status displays into a maintenance status

## 18.11.1 Description of MSTOu

### Object name (type + number) and family

Type + number: FB 1859

Family: Convert

### Area of application for MSTOu

The block is used for the following applications:

- Merging individual status displays into a maintenance status

### How it works

The block merges individual status displays into a maintenance status. If several status displays are set, the status display with the highest number becomes effective.

If status display `MST_03` = 1 is set, for example, this is indicated at output parameter `Out` with the value 16#00000003.

If no status display is set, the `Out` = 16#00 maintenance status is set.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 18.12 RealToDw - Converting REAL to DWORD

## 18.12.1 Description of RealToDw

### Object name (type + number) and family

Type + number: FC 390

Family: Convert

### Area of application for RealToDw

The block is used for the following applications:

- Converting a REAL number to a double word (DWORD)

**Note**

Converts the value of a REAL number into a double word (DWORD). You must use the R_DW block (CFC fundamental blocks) to convert the bit character string.

### How it works

With a REAL number between 0 and 4.294967e09 at input `In`, the value is applied and output as a DWORD at the output `Out`.

**Note**

The floating-point numbers in STEP 7 are accurate to 6 decimal places. You can therefore specify a maximum of 6 decimal places for floating-point constants.

If `In` is outside these limits, the error number 30 is output at the `ErrorNum` output and the `Out` is set to these limits.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for Status parameter

This block does not have the `Status` parameter.

## 18.12.2 RealToDw modes

### Operating modes of RealToDw

This block does not have any modes.

## 18.12.3 ReaLToDw functions

### Functions of RealToDw

There are no other functions for this block.

## 18.12.4 RealToDw error handling

### Error handling of RealToDw

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |
| 30 | `In` cannot be displayed in DWORD format |

## 18.12.5 RealToDw messaging

### Messaging

This block does not offer messaging.

## 18.12.6 RealToDw I/Os

### I/Os of RealToDw

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| In | Analog input value | REAL | 0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ErrorNum | Error number | INT | -1 |
| Out | Converted output value | DWORD | 0 |
| ST | Status | BYTE | 16#80 |

## 18.12.7 RealToDw block diagram

### Block diagram of RealToDw

A block diagram is not provided for this block.

# 18.13 StateMap - Conversion of other signal states into APL signal states

## 18.13.1 Description of StateMap

**Object name (type + number)**

Type + number: FC 383

Family: Convert

### Area of application of StateMap

This block can map other signal states in an APL signal states.

### How it works

This block converts the following signal states into APL signal states.

| State | ST_In | ST_Out |
|---|---|---|
| Valid value | 16#80 | 16#80 |
| Manipulated value (for example, substitute value, simulation, last valid value) | 16#60 | 16#60 |
| **Substitute value** | **16#48** | **16#60** |
| **Last valid value** | **16#44** | **16#60** |
| Uncertain, device related | 16#68 | 16#68 |
| Uncertain, process related | 16#78 | 16#78 |
| **Unknown, device related, range violation** | **16#54** | **16#68** |
| Maintenance request | 16#A4 | 16#A4 |
| Invalid value (-STOP) | 16#00 | 16#00 |
| Uncertain, device related | Otherwise | **16#68** |

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 18.13.2 StateMap modes

**StateMap modes**

This block does not have any operating modes.

## 18.13.3 StateMap functions

**Functions of StateMap**

There are no other functions for this block.

## 18.13.4 StateMap error handling

**StateMap error handling**

This block does not have any error handling.

## 18.13.5 StateMap messaging

**Messaging**

This block does not offer messaging.

## 18.13.6 StateMap I/Os

**I/Os of StateMap**

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Meaning | Data type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| ST_In | Signal status input | BYTE | 16#80 |

### Output parameters

| Parameter | Meaning | Data type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ST_Out | Signal status output | BYTE | 16#80 |

## 18.13.7 StateMap block diagram

### StateMap block diagram

A block diagram is not provided for this block.

# 18.14 StruCmIn - Splitting a structure to outputs

## 18.14.1 Description of StruCmIn

### Object name (type + number) and family

Type + number: FC 446

Family: Convert

### Area of application for StruCmIn

The block is used for the following applications:

- Splitting the structure of process values to separate outputs

The block can be used together with StruCmOu to interconnect a group of process values via only one connection.

### How it works

The block separates a structure interconnected to the `In` input parameter to the separate outputs `AnaVal[x]`, `DigVa[x]`, `CntVal1`, `Scale[n]`, `Int[n]` and `DwVal1`, x=1..6, n=1..2.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for parameter `Status`

This block does not have the `Status` parameter

## 18.14.2 StruCmIn modes

### StruCmIn Modes

This block does not have any modes.

## 18.14.3 StruCmIn functions

### Functions of StruCmIn

There are no other functions for this block.

## 18.14.4 StruCmIn error handling

### StruCmIn Error handling

The block does not report any errors.

## 18.14.5 StruCmIn messaging

### StruCmIn Messaging

This block does not offer messaging.

## 18.14.6 StruCmIn I/Os

I/Os of StruCmIn

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `In.Anaval1 ... In.Anaval6` | Analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>0.0<br>16#00 |
| `In.CntVal1` | Counter value | STRUCT<br>• Value: DINT<br>• ST: BYTE | -<br>0<br>16#80 |
| `In.Digval1 ... In.Digval6` | Digital value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#00 |
| `In.IntVal1 ... In.IntVal2` | Integer value | INT | 0 |
| `In.Scale1H` | Scale high | REAL | 100.0 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| In.Scale1L | Scale low | REAL | 0.0 |
| In.Scale2H | Scale high | REAL | 100.0 |
| In.Scale2L | Scale low | REAL | 0.0 |
| In.DwVal1 | Dword value | DWORD | 16#00000000 |
| EN | 1 = Called block will be processed | BOOL | 1 |
| In | - | STRUCT | - |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| Anaval1 ... Anaval6 | Analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>0.0<br>16#80 |
| Digval1 ... Digval6 | Digital value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>0.0<br>16#80 |
| CntVal1 | Counter value | STRUCT<br>• Value: DINT<br>• ST: BYTE | -<br>0<br>16#80 |
| ENO | - | BOOL | 0 |
| Scale1.High | Scale high | REAL | 100.0 |
| Scale1.Low | Scale low | REAL | 0.0 |
| Scale2.High | Scale high | REAL | 100.0 |
| Scale2.Low | Scale low | REAL | 0.0 |
| IntVal1 ... IntVal2 | Integer value | INT | 0 |
| DwVal1 | Dword value | DWORD | 16#00000000 |

## 18.14.7 StruCmIn block diagram

### StruCmIn block diagram

A block diagram is not provided for this block.

# 18.15 StruCmOu - Merging inputs to a structure

## 18.15.1 Description of StruCmOu

### Object name (type + number) and family

Type + number: FC 447

Family: Convert

### Area of application for StruCmOu

The block is used for the following applications:

- Merging a group of process values to a structure

The block can be used together with StruCmIn to interconnect a group of process values via only one connection.

### How it works

The block merges the inputs `AnaVal[x]`, `DigVa[x]`, `CntVal1`, `Scale[n]`, `Int[n]` and `DwVal1` to a structure (`Out`), x=1..6, n=1..2

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for parameter `Status`

This block does not have the `Status` parameter.

## 18.15.2 StruCmOu modes

### StruCmOu modes

This block does not have any modes.

## 18.15.3 StruCmOu functions

### StruCmOu functions

There are no other functions for this block.

## 18.15.4 StruCmOu error handling

### StruCmOu error handling

This block does not report any errors.

## 18.15.5 StruCmOu messaging

### StruCmOu messaging

This block does not offer messaging.

## 18.15.6 StruCmOu I/Os

**I/Os of StruCmOu**

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `AnaVal1 ... AnaVal6` | Analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>0.0<br>16#80 |
| `DigVal1 ... DigVal6` | Digital value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#80 |
| `DwVal1` | Dword value | DWORD | 16#00000000 |
| `CntVal1` | Counter value | STRUCT<br>• Value: DINT<br>• ST: BYTE | -<br>0<br>16#80 |
| `EN` | 1 = Called block will be processed | BOOL | 1 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| `IntVal1 ... IntVal2` | Integer value | INT | 0 |
| `Scale1.Low` | Scale low | REAL | 0.0 |
| `Scale2.Low` | Scale low | REAL | 0.0 |
| `Scale1.High` | Scale high | REAL | 100.0 |
| `Scale2.High` | Scale high | REAL | 100.0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `Out.AnaVal` | Analog value | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>0.0<br>16#80 |
| `Out.DigVal1 ...Out.DigVal6` | Digital value | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>0<br>16#00 |
| `Out.CntVal1` | Count value | STRUCT<br>• Value: DINT<br>• ST: BYTE | -<br>0<br>16#00 |
| `Out.IntVal1 ... Out.IntVal2` | Integer value | INT | 0 |
| `Out.Scale1H` | Scale high | REAL | 0.0 |
| `Out.Scale1L` | Scale low | REAL | 0.0 |
| `Out.Scale2H` | Scale high | REAL | 0.0 |
| `Out.Scale2L` | Scale low | REAL | 0.0 |
| `Out.DwVal1` | Dword value | DWORD | 16#00000000 |
| `Out` | - | STRUCT | - |
| `ENO` | - | BOOL | 0 |

## 18.15.7 StruCmOu block diagram

### StruCmOu block diagram

A block diagram is not provided for this block.

# 18.16 StruCnIn - Separating a counter structured variable

## 18.16.1 Description of StruCnIn

### Object name (type + number) and family

Type + number: FC 458

Family: Convert

### Area of application for StruCnIn

The block is used for the following applications:

- Separation of an analog value with a structure into a variable of the DINT data type and a signal status

### How it works

The block separates a counter value with a structure interconnected to the `In` input parameter into a variable (`Out`) of the DINT data type and a (ST) signal status.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for parameter `Status`

This block does not have the `Status` parameter.

## 18.16.2 StruCnIn modes

### StruCnIn modes

This block does not have any modes.

## 18.16.3 StruCnIn functions

### StruCnIn functions

There are no other functions for this block.

## 18.16.4 StruCnIn error handling

### StruCnIn error handling

The block does not report any errors.

## 18.16.5 StruCnIn messaging

### Messaging

This block does not offer messaging.

## 18.16.6 StruCnIn I/Os

### StruCnIn I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| In | Counter input value with structure | STRUCT<br>• Value: DINT<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| ST | Signal status | BYTE | 16#80 |
| Value | Counter value without signal state | REAL | 0.0 |

## 18.16.7 StruCnIn block diagram

### StruCnIn block diagram

A block diagram is not provided for this block.

# 18.17 StruCnOu - Creating a structured counter variable

## 18.17.1 Description of StruCnOu

### Object name (type + number) and family

Type + number: FC 459

Family: Convert

### Area of application for StruCnOu

The block is used for the following applications:

- Merging a variable of the DINT data type and a signal status into an analog process value.

### How it works

The block merges a counter value with a structure interconnected to the `In` input parameter into a variable (`Out`) of the DINT data type and a (ST) signal status.

### Configuration

Use the CFC editor to install the block in any OB.

### Startup characteristics

The block does not have any startup characteristics.

# Maintenance blocks 19

## 19.1 MuxMST - Determination of the worst maintenance status

### 19.1.1 Description of MuxMST

#### Object name (type + number) and family

Type + number: FB 1861

Family: Maint

#### Area of application for MuxMST

The block is used for the following applications:

- Determination of the worst maintenance status (from a maximum of 10 statuses)

#### How it works

The block determines the worst of several maintenance states. Each status is made available to the block via interconnection to the `Inx` input parameter (x = 01 ... 10) . The states are compared and the highest value written to the `Out` output parameter.

#### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

#### Startup characteristics

During startup, the `Inx` input parameters (x = 01 ... 10) and output parameter are reset to their defaults.

#### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

# 19.2 MuxST- Determination of the worst signal status

## 19.2.1 Description of MuxST

### Object name (type + number) and family

Type + number: FB 1862

Family: Maint

### Area of application for MuxST

The block is used for the following applications:

- Determination of the worst signal status (from a maximum of 10 statuses)

### How it works

The block determines the worst of several signal states. Each status is made available to the block via interconnection to the `Inx` input parameter (x = 1 ... 10). The states are compared and the value with the highest priority is written to the `Out` output parameter.

Also refer to the section Forming and outputting the signal status for blocks with configurable status prioritization (Page 122) for information on priorities.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

During startup, the `Inx` input parameters (x = 1 ... 10) and output parameter are reset to their defaults.

### Status word allocation for `Status1` parameter

This block does not have the `Status` parameter.

### See also

Description of MuxST (Page 2770)

## 19.2.3 MuxST functions

### Functions of MuxST

The functions for this block are listed below.

### Selecting signals for processing

Using the `SelInput` input parameter, you select the number of interconnectable input parameters to be used for processing in the block. The selected number denotes the input parameters used `In1` ... `Inn`.

If, for example, you set this input parameter to `SelInput` = 3, the input parameters `In1`, `In2` and `In3` will be used for processing.

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for blocks with configurable status prioritization (Page 122).

### See also

## 19.2.6 MuxST I/Os

### MuxST I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| In1 | Input for signal of signal status 0 | BYTE | 16#80 |
| In2 | Input for signal of signal status 1 | BYTE | 16#80 |
| In3 | Input for signal of signal status 2 | BYTE | 16#80 |
| In4 | Input for signal of signal status 3 | BYTE | 16#80 |
| In5 | Input for signal of signal status 4 | BYTE | 16#80 |
| In6 | Input for signal of signal status 5 | BYTE | 16#80 |
| In7 | Input for signal of signal status 6 | BYTE | 16#80 |
| In8 | Input for signal of signal status 7 | BYTE | 16#80 |
| In9 | Input for signal of signal status 8 | BYTE | 16#80 |
| In10 | Input for signal of signal status 9 | BYTE | 16#80 |
| SelInput* | Selection of the input parameter for forming the worst signal status | INT | 2 |
| SelPrio* | Setting of the prioritization for forming the worst signal status | INT | 0 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| Out | Output of the worst signal status | BYTE | 16#80 |

# 19.3 STRep - Status display of block groups

## 19.3.1 Description of STRep

### Object name (type + number) and family

Type + number: FB 1801

Family: MAINT

### Area of application of STRep

The STRep block is used for displaying the status of a group of blocks that is designed for hiding messages automatically.

### How it works

The block has 32 `STRUCT` type inputs that describe defined states. Depending on which `StateX` input is set, it will be output at the INT output `QSTATE`. If several `StateX` inputs are set, the most significant is output and the `MPSA` output is set.

The status of the `StateX` inputs does not influence the result at `QSTATE`.

**Note**

The output `QSTATE` has the attribute S7_enum := 'Operating State'. In your project under the folder 'Shared Declarations' you can use the enumeration 'Operating State' to define the text for the enumeration value. If you want to use your own enumeration, you have to adapt the S7_enum attribute at the output `QSTATE`.

### Configuration

Use the CFC editor to install the block in a cyclic interrupt OB (OB30 to OB38). The block is also installed automatically in the startup OB (OB100).

### Startup characteristics

The block does not have any startup characteristics.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 19.3.2 STRep modes

### Operating modes of STRep

This block does not have any modes.

## 19.3.3 STRep functions

### Functions of STRep

There are no other functions for this block.

## 19.3.4 STRep error handling

### Error handling of STRep

The block does not report any errors.

## 19.3.5 STRep messaging

### Messaging

This block does not offer messaging.

## 19.3.6 STRep I/Os

I/Os of STRep

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `State1 ... State32` | Process status 1 ... 32 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| `QERR` | 1 = Error | BOOL | 1 |
| `QSTATE` | Process status | INT | 0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| MPSA | 1 = More than one process status is active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 1<br>• 16#80 |
| QSTATE | Process status 0...32<br>With attribute:<br>S7_enum := 'Operating State' | INT | 0 |

## 19.3.7 STRep block diagram

### Block diagram of STRep

A block diagram is not provided for this block.

# 19.4 AssetM - Process variable monitoring for violation of limits

## 19.4.1 Description of AssetM

### Object name (type + number) and family

Type and number: FB 1840

Family: Maint

### Area of application of AssetM

The block is used for the following applications:

Monitoring of up to 3 analog process variables for exceeding 3 limits respectively. It reports the maintenance status of the process variables:

- When overshooting a limit
- Via the device-based signal status or
- Via binary message inputs

### How it works

The block monitors up to 3 inputs for high and low violations of three limits respectively. Upon reaching or exceeding a limit, the respective output is set and a corresponding message is generated.

The three process variables are equivalent for limit monitoring as long as the overshoot of a limit (e.g. maintenance request) is reported by one process variable. A new message will only be created again if all process variables have undershot this limit at least for one cycle.

The monitoring of individual limits can be deactivated.

In addition to limit monitoring, the signal status of the individual process variables is also analyzed. The device-specific signal status of a process value triggers the corresponding message that is also used by the limit monitoring.

### Configuration

In the CFC editor, install the block in a cyclic interrupt OB (e.g. OB32). The block is also installed automatically in the startup OB (OB 100).

### Startup characteristics

The messages are suppressed after startup for the number of cycles set at `RunUpCyc`.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

### Binary message inputs

| | | |
|---|---|---|
| Message1 | Bad, maintenance alarm | Message (S) requires acknowledgement |
| Message2 | Uncertain, maintenance request | Message (F) requires acknowledgement |
| Message3 | Good, maintenance required | Message (M) requires acknowledgement |
| Message4 | Bad, local operation/functional check | Message (S) requires acknowledgement |
| Message5 | Uncertain, simulation | Message (SA) does not require acknowledgement |
| Message6 | Bad, device out of service | Message (SA) does not require acknowledgement |
| Message7 | bad, passivated | Message (SA) does not require acknowledgement |

For each PVx, there is an input (PVx_Rst) and an output (P_PVx_Rst) that can be used to reset a technologic block.

The statuses are created with ALARM_8P for messages requiring acknowledgment and with NOTIFY_8P for those not requiring acknowledgment. The message function can be disabled by setting MsgLock = 0. In this case, MS = 8 is set.

The detailed diagnostics is shown in the diagnostic view of the faceplate via the inputs Diag1 to Diag16.

If one of the inputs is set to 1, then the status display is shown in front of the corresponding text.

The texts for the relevant inputs Diag1 to Diag16 are entered in the parameter data of the EDD for the relevant instance (see also section PLT ID).

If one of the inputs Diag1 to Diag16 is set to 1, the explanatory text "Additional status available" is output if an internal interrupt is triggered through PV0, PV1 or PV2.

### PLT-ID

Die PLT-ID is a connection parameter between a PDM object (parameter data EDD) and the faceplate in the maintenance station. The PLT-ID is linked to the PDM object.

The PDM object is generated in the SIMATIC Manager as follows:

1. Select **View > Process Device Plant View** in SIMATIC Manager.
2. In SIMATIC PDM, select a project in which you want to insert the AssetM block.
3. Select **File > New object**.
4. Right-click the inserted tag object and select **Device selection (Reassign)...** from the context menu.
5. In the tree structure **Devices > DATA_OBJECTS > CFC >**, select AssetMon and click **OK**.
6. Right-click the tag object and select **Open object** from the context menu, and then enter all necessary data in the parameter assignment screen form.
7. Select **File > Save** and close the parameter assignment screen form.

You can then assign parameters for the generated PLT-ID at the associated parameter "PLT_ID".

**Note**

The PLT-IDs cannot be changed or deleted individually.

### Creating the maintenance status (MS)

MS depends on:

- From the signal status of the signals `PV0`, `PV1` and `PV2`
- from the binary message inputs (external `MS`)
- from the interconnectable input `MS_In` (external maintenance state)
- The interconnectable input `STATUS`. The process-related errors have no effect; only the device-based errors have an effect.

Of all these events the highest priority event will be displayed in the MS.

The 16 `Diagx` binary inputs do not have any influence on the MS; they are used only for visualization of the detail diagnostics in the diagnostics view of the faceplate.

**Note**

The table is valid exclusively for the MS and not for the signal status displays of the individual process values; these are created exclusively by the `ST` parameters.

The priority is similar to the `MS` coding. Therefore, the following applies: The greater the value of the `MS`, the higher the priority.

| PVx.Value | PVx.ST | MS_In | Event | STATUS | Messa-gex.Value | O_MS |
|---|---|---|---|---|---|---|
| - | - | 9 | Configuration change | 16#84 .. 87 | - | 9 |
| - | - | 8 | Untested/unknown | - | - | 8 |
| PVx.Value >= PVx_AH | 16#00 | 7 | bad, maintenance alarm | 16#00 .. 1B, 16#24 .. 27, 16#44 .. 4B | x = 1 | 7 |
| PVx_AH > PVx.Value >= PVx_DH | 16#68 | 6 | uncertain, maintenance request | 16#40 .. 43, 16#50 .. 5F, 16#64 .. 6B, 16#A8 .. AB | x = 2 | 6 |
| PVx_DH > PVx.Value >= PVx_RH | 16#A4 | 5 | good, maintenance required | 16#A4 .. A7 | x = 3 | 5 |
| - | - | 4 | bad, local operation/functional check | 16#3C .. 3F | x = 4 | 4 |
| - | 16#60 | 3 | Uncertain, manipulated value (for example, substitute value, simulation, last valid value) | 16#60 .. 63, 16#70 .. 73 | x = 5 | 3 |
| - | - | 2 | bad, device out of service | 16#1C .. 1F | x = 6 | 2 |

| PVx.Value | PVx.ST | MS_In | Event | STATUS | Messa-gex.Value | O_MS |
|---|---|---|---|---|---|---|
| - | - | 1 | bad, passivated | 16#23 | x = 7 | 1 |
| PVx_RH > PVx.Value | 16#28, 16#78 | 0 | process-related fault | 16#28 .. 2B, 16#78 .. 7B, 16#A0 .. A3 | - | |

## 19.4.2 AssetM modes

### Operating modes of AssetM

This block does not have any modes.

## 19.4.3 AssetM functions

### Functions of AssetM

The functions for this block are listed below.

### Configurable reactions using the `Feature` parameter

You can find an overview of all reactions provided by the `Feature` parameter in the Configurable functions using the Feature I/O (Page 139) section. The following functionality is available for this block at the relevant bits:

| Bit | Function |
|---|---|
| 22 | Update acknowledgment and error status of the message call (Page 171) |
| 28 | Disabling operating points (Page 156) |

### Forming the signal status for blocks

This block provides the standard function Forming and outputting the signal status for interlock blocks (Page 124).

The worst signal status `ST_Worst` for the block is formed from the following parameters:

- `PV0.ST`
- `PV1.ST`
- `PV2.ST`

## 19.4.4 AssetM error handling

### Error handling of AssetM

Refer to the section Error handling (Page 128) in the basic instructions for the error handling of all blocks.

The following errors can be displayed for this block:

- Error numbers

### Overview of error numbers

The `ErrorNum` I/O can be used to output the following error numbers:

| Error number | Meaning of the error number |
|---|---|
| -1 | Predefined value when inserting the block; block is not processed |
| 0 | There is no error. |

## 19.4.5 AssetM messages

### Messaging

The following messages can be generated for this block:

- Process control fault
- Process messages

### Process control fault

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| `MsgEvId1` | SIG 1 | AS process control message - fault | Maintenance alarm<br>@4W%t#AssetM_TXT@ |
| | SIG 2 | AS process control message - error | Maintenance demanded<br>@4W%t#AssetM_TXT@ |
| | SIG 3 | Preventive maintenance - General | Maintenance required<br>@4W%t#AssetM_TXT@ |
| | SIG 4 | Reserved | |
| | SIG 5 | Reserved | |
| | SIG 6 | Reserved | |
| | SIG 7 | AS process control message - fault | Device out of service |
| | SIG 8 | Reserved | |

### Process messages

| Message instance | Message identifier | Message class | Event |
|---|---|---|---|
| MsgEvId2 | 1 | Status AS | Passivated |
| | 2 | Reserved | |
| | 3 | Status AS | Manipulated value (for example, substitute value, simulation, last valid value) |
| | 4 | Status AS | Manipulated value (for example, substitute value, simulation, last valid value) |
| | 5 | Status AS | Configuration change |
| | 6 | Status AS | Process-related fault |
| | 7 | Reserved | |
| | 8 | Reserved | |

### Associated values

| Message block ALARM 8P | Associated value | Meaning |
|---|---|---|
| MsgEvId1 | 4 | Text number from AssetM_TXT |

### System text library AssetM

| Index | Text |
|---|---|
| 1 | Further status available |
| 2 | No further status available |

## 19.4.6 AssetM I/Os

### I/Os of AssetM

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

## Input parameters

| I/O (parameter) | Meaning | Type | Default |
|---|---|---|---|
| Diagx | Asset detail diagnosis (x = 1 to 16) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Feature | I/O for additional functions (Page 2781) | STRUCT<br>• Bit 0: BOOL<br>• ...<br>• Bit 31: BOOL | -<br>• 0<br>• 0<br>• 0 |
| Message1 | 1 = message: bad, maintenance alarm | BOOL | 0 |
| Message2 | 1 = message: uncertain, maintenance request | BOOL | 0 |
| Message3 | 1 = message: good, maintenance required | BOOL | 0 |
| Message4 | 1 = message: bad, local operation/functional check | BOOL | 0 |
| Message5 | 1 = message: uncertain, simulation | BOOL | 0 |
| Message6 | 1 = message: bad, out of service | BOOL | 0 |
| Message7 | 1 = message: passivated | BOOL | 0 |
| MS* | Maintenance status | DWORD | 16#000000 00 |
| MsgEvId1 | Message event ID 1 | DWORD | 16#000000 24 |
| MsgEvId2 | Message event ID 2 | DWORD | 16#000000 25 |
| MsgLock | 1 = Suppress process messages.<br>Refer also to the Suppressing messages using the MsgLock parameter (Page 231) chapter for more on this. | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| MS_Release | Release for maintenance | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| Ms_In | External interconnectable MS | DWORD | 16#000000 00 |
| PLT_ID | Asset ID of EDD | DWORD | 16#000000 00 |
| PV_Hyst | PV_Hysteresis for messages | REAL | 5.0 |
| PVx_AH | Limit PVx (x=0, 1, 2) maintenance alarm | REAL | 100.0 |
| PVx_AH_EN | 1 = suppress monitoring of the limit PVx (x = 0, 1, 2), maintenance alarm exceeded | BOOL | 0 |
| PVx_DH | Limit PVx (x = 0, 1, 2) maintenance request | REAL | 100.0 |
| PVx_DH_EN | 1 = suppress monitoring of the limit PVx (x = 0, 1, 2), maintenance request exceeded | BOOL | 0 |
| PVx_RH | Limit PVx (x = 0, 1, 2) maintenance required | REAL | 100.0 |
| PVx_RH_EN | 1 = suppress monitoring of the limit PVx (x = 0, 1, 2), maintenance required exceeded | BOOL | 0 |

| I/O (parameter) | Meaning | Type | Default |
|---|---|---|---|
| PVx | Process value PVx (x = 0, 1, 2) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PVx_Rst* | 1 = Reset PVx (x = 0, 1, 2) | BOOL | 0 |
| PVxUnit | Unit of the process value | INT | 0 |
| RunUpCyc | Number of run-up cycles | INT | 3 |
| Status | External status | BYTE | 16#80 |

* Values can be written back to these inputs during processing of the block by the block algorithm.

### Output parameters

| I/O (parameter) | Meaning | Type | Default |
|---|---|---|---|
| ErrorNum | Program error | INT | -1 |
| MsgAckn1 | Message recognized | WORD | 16#0000 |
| MsgErrx | Message errors occurred (x =1, 2) | WORD | 16#0000 |
| MsgStatx | Message error information (x = 1, 2) | WORD | 16#0000 |
| O_MS | Maintenance status | DWORD | 16#00000000 |
| PVx_Diff | Differential value to the next expected alarm (x = 0, 1, 2) | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |
| PVx_AH_AcT | 1 = Limit PVx (x = 0, 1, 2), maintenance alarm exceeded | BOOL | 0 |
| PVx_DH_AcT | 1 = Limit PVx (x = 0, 1, 2), maintenance required exceeded | BOOL | 0 |
| PVx_RH_AcT | 1 = Limit PVx (x = 0, 1, 2), maintenance request exceeded | BOOL | 0 |
| P_PVx_Rst | 1 = Reset PVx (x = 0, 1, 2) | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| ST_Worst | Worst signal status of the inputs PVx (x = 0, 1, 2) | BYTE | 16#80 |

AssetM functions (Page 2781)

## 19.4.7 AssetM block diagram

### Block diagram of ASSETM

A block diagram is not provided for this block.

# System blocks

# 20

## 20.1 AddInt64 - Addition of two 64-bit integer variables

### 20.1.1 Description of AddInt64

#### Object name (type + number) and family

Type + number: FC 353

Family: System

#### Area of application for AddInt64

The block is used for the following applications:

- Addition of two 64-bit integer variables

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.2 AddR64 - Addition of two 64-bit REAL variables

## 20.2.1 Description of AddR64

### Object name (type + number) and family

Type + number: FC 354

Family: System

### Area of application for AddR64

The block is used for the following applications:

- Addition of two 64-bit REAL variables

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.3 DiToInt64 - Converting from DINT to Int64

## 20.3.1 Description of DiToInt64

### Object name (type + number) and family

Type + number: FC 357

Family: System

### Area of application for DiToInt64

The block is used for the following applications:

- Converting from DINT to Int64

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.4 Int64ToDi - Converting from Int64 to DINT

## 20.4.1 Description of Int64ToDi

### Object name (type + number) and family

Type + number: FC 359

Family: System

### Area of application for Int64ToDi

The block is used for the following application:

- Converting from Int64 to DINT

This block will not be described in detail.

# 20.5 MemR256 - Increasing the number of internal previous values

## 20.5.1 Description of MemR256

### Object name (type + number)

Object name (type + number) and family

Type and number: FB 1930

Family: System

### Area of application

The block is used for the following applications:

- Increasing the internal previous values in the MeanTime block.

Therefore this block will not be described in detail.

# 20.6 NegInt64 - Negation of an Int64 variable

## 20.6.1 Description of NegInt64

### Object name (type + number) and family

Type + number: FC 362

Family: System

### Area of application for NegInt64

The block is used for the following applications:

- Negation of an Int64-variable

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.7 NegR64 - Negation of a Real64 variable

## 20.7.1 Description of NegR64

### Object name (type + number) and family

Type + number: FC 363

Family: System

### Area of application for NegR64

The block is used for the following application:

- Negation of an Real64-variable

This block will not be described in detail.

# 20.8 PIDCoefR - Calculation of coefficients

## 20.8.1 Description of PIDCoefR

### Object name (type + number) and family

Type + number: FC 366

Family: System

### Area of application for PIDCoefR

The block is used for the following applications:

- Calculation of coefficients of discrete-time difference equations for PIDConR from the continuous-time input parameters (e.g. `TI`, `TD`)

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.9 R64ToReal - Converting Real64 to REAL

## 20.9.1 Description of R64ToReal

### Object name (type + number) and family

Type + number: FC 367

Family: System

### Area of application for R64ToReal

The block is used for the following applications:

- Converting from Real64 to REAL (32 Bit)

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.10 RealToR64 - Converting REAL to Real64

## 20.10.1 Description of RealToR64

### Object name (type + number) and family

Type + number: FC 368

Family: System

### Area of application for RealToR64

The block is used for the following applications:

- Converting from REAL (32 Bit) to Real64

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.11 SelST16 - Output of the best or worst signal status

## 20.11.1 Description of SelST16

### Object name (type + number) and family

Type and number: FC 369

Family: System

### Area of application for SelST16

The block is used for the following applications:

- Output the best or worst signal status

This block is used by technologic blocks which edit and output a signal status.

Therefore this block will not be described in detail.

# 20.12 ShLeInt64 - Left shift of an Int64 variable

## 20.12.1 Description of ShLeInt64

### Object name (type + number) and family

Type + number: FC 370

Family: System

### Area of application for ShLeInt64

The block is used for the following applications:

- Left shift of a (positive) Int64- variable

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.13 ShRiInt64 - Right shift of an Int64 variable

## 20.13.1 Description of ShRiInt64

### Object name (type + number) and family

Type + number: FC 371

Family: System

### Area of application for ShRiInt64

The block is used for the following applications:

- Right shift of a (positive) Int64- variable

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# 20.14 PIDKernR - Calculation of the manipulated variable

## 20.14.1 Description of PIDKernR

### Object name (type + number) and family

Type and number: FB 1877

Family: System

### Area of application for PIDKernR

The block is used for the following applications:

- Calculation of the manipulated variable in PIDConR

This block is used by the PIDConR block for calculations that are twice as accurate (64-bit number format).

Therefore this block will not be described in detail.

# Communication blocks 21

## 21.1 Snd_DigVal - Send Boolean values including quality code (Snd_DigVal)

### 21.1.1 Description of Snd_DigVal

#### Object name (type + number) and family

Type + number: FB 1891

Family: COMM

#### Area of application for Snd_DigVal

The "Snd_DigVal" block represents a simple user interface to SFB 12 "BSEND". The "Snd_DigVal" block sends 128 DigVal structures via an MPI, PROFIBUS or Industrial Ethernet connection to another CPU. This CPU calls the function block "Rcv_DigVal" (FB 1892) of the PCS 7 Advanced Process Library to receive the data.

#### How it works

Data transfer is initiated by calling the block with the value 1 at the `SendEn` control input. While data is being sent, `SendAct` is set to 1.

If the job is completed without errors, `SendDone` is set to 1. `SendErr` = 1 if an error occurs. A new job is then automatically triggered with the current data until all data have been successfully sent.

If input `SendEn` = 0, incomplete sending is canceled. No further sending takes place afterward (`SendAct` = 0).

The ID parameter is the connection number specified in the connection configuration. and is applied only at the first call after a cold restart.

The parameter R_ID is a random number. The R_ID parameter must be identical at the corresponding send and receive blocks. The R_ID parameter is applied only for the first call after a warm restart.

**Note**

**Error code or message at the data block**

When configuring a block pair for data transmission from an SND_AnaVal block to an RCV_AnaVal block, make sure that the settings for ID/R-ID are unique throughout the project.

Only one Rcv block may be assigned to each Snd block or only one connection via ID/R-ID may be configured.

Make sure that you perform the engineering clean and correctly because the data may otherwise be transferred to several blocks or an incorrect block.

### Configuration

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Time characteristics

The block does not have any time response.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 21.1.2 Snd_DigVal modes

This block has no operating mode.

## 21.1.3 Snd_DigVal functions

Configurable reactions using the `Feature` parameter.

An overview of all the reactions that are provided by the `Feature` parameter is available in the section Configurable functions using the Feature I/O (Page 139).

The following functionality is available for this block at the relevant bits:

- Bit 29: Output substitute values if raw value is invalid

### 21.1.4 Snd_DigVal error handling

Error handling of the block is restricted to the error information of the lower-level SFB 12 "BSEND".

The bits of information are set at the `SendErr(ERR)` and `SendStat(STAT)` parameters.

If an error occurs, a new job is automatically triggered with the current data until all data have been successfully transferred.

### 21.1.5 Snd_DigVal messages

No message behavior is applicable to this block.

### 21.1.6 Snd_DigVal I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

#### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `ID` | ID of physical connection | WORD | 16#0000 |
| `R_ID` | ID of message frame connection | DWORD | 16#00000000 |
| `SndEn` | 1 = Activate continuous sending | BOOL | 1 |
| `PV_In0 ... PV_In127` | Input_0 ... Input_127 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |

#### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `ENO` | 1 = Block algorithm completed without errors | BOOL | 0 |
| `SndAct` | 1 = Command is active | BOOL | 0 |
| `SndDone` | 1 = Command is executed | BOOL | 0 |
| `SndErr` | 1 = Command is executed with error | BOOL | 0 |
| `SndStat` | Type of error | WORD | 16#0000 |

### 21.1.7 Snd_DigVal block diagram

A block diagram is not provided for this block.

# 21.2 Rcv_DigVal - Receive Boolean values including quality code (Rcv_DigVal)

## 21.2.1 Description of Rcv_DigVal

### Object name (type + number) and family

Type + number: FB 1892

Family: COMM

### Area of application for Rcv_DigVal

The "Rcv_DigVal I" block represents a simple user interface to SFB 13 "BRCV". The block receives 128 DigVal structures via MPI, PROFIBUS or Industrial Ethernet connection to another CPU. This CPU must call the function block "Snd_DigVal" (FB 1891) of the PCS 7 Advanced Process Library to send the data.

In STEP 7, a uniform connection must be configured for both communication partners and transferred to the AS.

### How it works

Data are entered in the data block asynchronously to user-program execution. After "`Rcv_DigVal`" has been called, instance DB data may not be processed as long as the job is in progress (`RcvNewData` = 0). If the job is completed without errors, the `RcvNewData` output is set to 1 for one cycle. In the next cycle, the receive enable is automatically sent by the FB to the operating system of the CPU.

The receive enable can take take effect prior to the arrival of the first receive job. In this case, the receive enable is stored by the operating system.

The `ID` parameter is the connection number specified in the connection configuration. and is applied only at the first call after a cold restart.

The parameter `R_ID` is a random number. The `R_ID` parameter must be identical at the corresponding send and receive blocks. The `R_ID` parameter is applied only for the first call after a warm restart.

Call the "Rcv_DigVal" block for the ID/R_ID pair in each program cycle (cyclically or also via timeout alarm). Each message frame requires two calls of "Rcv_DigVal".

**Note**

**Error code or message at the data block**

When configuring a block pair for data transmission from an SND_AnaVal block to an RCV_AnaVal block, make sure that the settings for ID/R-ID are unique throughout the project.

Only one Rcv block may be assigned to each Snd block or only one connection via ID/R-ID may be configured.

Make sure that you perform the engineering clean and correctly because the data may otherwise be transferred to several blocks or an incorrect block.

The outputs `RcvErr` (Error) and `RcvStat` (Status) show the specific error information that correspond to SFB 13 "BRCV".

If an error occurs, use an appropriate substitute strategy with `Feature` (bit 29/30).

If you want to simulate the block, enable simulation via the `SimOn` input. In this case, the values from the inputs `SimPVX` are written to the outputs `PV_Outx`. The data sent are not applied, since data reception is switched off.

### Configuration

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Time characteristics

The block does not have any time response.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 21.2.2 Rcv_DigVal modes

This block has no operating mode.

## 21.2.3 Rcv_DigVal functions

**Configurable reactions using the `Feature` parameter**

An overview of all the reactions that are provided by the `Feature` parameter is available in the section Configurable functions using the Feature I/O (Page 139).

The following functionality is available for this block at the relevant bits:

- Bit 29: Output substitute values in case of communications error (Page 204)
- Bit 30: Output last value in case of communications error (Page 204)

The signal status of all output values with status 16#80 is set to local "Manipulated value" (16#60), all other status values remain unchanged.

## 21.2.4 Rcv_DigVal error handling

Error handling of the "Rcv_DigVal" block is restricted to the error information of the lower-level SFB 13 "BRCV".

You can find additional information in the manual "*System Software for S7-300/400 - System and Standard Functions*".

In the manual "*System Software for S7-300/400 - System and Standard Functions*", you can also find a description of the `RcvErr` and `RcvStat` outputs

The substitute value is output when bit 29 is set in the `Feature` structure and no new data is received after the expiration of "RcvMonCyc" (number of cycles). While the "REC_MON" cycles are running, the last received values are applied to the output.

If Bit29 is not set in the `Feature` structure and an error occurs, the last valid values are always applied to the output.

## 21.2.5 Rcv_DigVal messages

No message behavior is applicable to this block.

## 21.2.6 Rcv_DigVal I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| `EN` | 1 = Called block will be processed | BOOL | 1 |
| `ID` | ID of physical connection | WORD | 16#0000 |

| Parameter | Description | Type | Default |
|---|---|---|---|
| R_ID | ID of message frame connection | DWORD | 16#00000000 |
| RcvMonCyc | Number of cycles for receiving monitoring error | INT | 3 |
| SimOn | 1= simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimPV0 ... SimPV127 | Simulation value | BOOL | 0 |
| SubsPV1 ... SubsPV127 | Substitute value | BOOL | 0 |
| Feature | I/O for additional functions (Page 2807)<br>• Reserved<br>• 1 = Output substitute values in case of communications error<br>• 1 = Output last values in case of communications error<br>• Reserved | STRUCT<br>• Bit0 ... Bit28: BOOL<br>• Bit29: BOOL<br>• Bit30: BOOL<br>• Bit31: BOOL | -<br>• 0<br>• 0<br>• 0<br>• 0 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| PV_Out0 ... PVOut127 | Output_00 ... Output_07 | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| SimAct | 1= simulation active | STRUCT<br>• Value: BOOL<br>• ST: BYTE | -<br>• 0<br>• 16#80 |
| RcvMonErr | 1 = no data received | BOOL | 0 |
| RcvNewData | 1 = no data received | BOOL | 0 |
| RcvErr | 1 = Command is executed with error | BOOl | 0 |
| RcvStat | Type of error | WORD | 16#0000 |

## 21.2.7 Rcv_DigVal block diagram

A block diagram is not provided for this block.

# 21.3 Snd_AnaVal - Send analog values including quality code (SND_AnaVal)

## 21.3.1 Description of Snd_AnaVal

### Object name (type + number) and family

Type + number: FB 1893

Family: COMM

### Area of application for Snd_AnaVal

The "Snd_AnaVal" block represents a simple user interface to SFB 12 "BSEND". The "Snd_AnaVal" block sends 32 analog structures via an MPI, PROFIBUS or Industrial Ethernet connection to another CPU. The other CPU calls the function module "Rcv_AnaVal" (FB 1894) of the PCS 7 Advanced Process Library to receive the data.

### How it works

Data transfer is initiated by calling the block with the value 1 at the `SendEn` control input. The data are sent according to the settings `CylMin`, `CylMax` or `PV_In_HysXX`. While data is being sent, `SendAct` is set to 1. If the job is completed without errors, `SendDone` is set to 1. `SendErr` = 1 if an error occurs. A new job is then automatically sent with the current data until all data have been successfully transferred.

The `ID` parameter is the connection number specified in the connection configuration. and is applied only at the first call after a cold restart.

The parameter `R_ID` is a random number. The `R_ID` parameter must be identical at the corresponding send and receive blocks. The `R_ID` parameter is applied only for the first call after a warm restart.

---

**Note**

**Error code or message at the data block**

When configuring a block pair for data transmission from an SND_AnaVal block to an RCV_AnaVal block, make sure that the settings for ID/R-ID are unique throughout the project.

Only one Rcv block may be assigned to each Snd block or only one connection via ID/R-ID may be configured.

Make sure that you perform the engineering clean and correctly because the data may otherwise be transferred to several blocks or an incorrect block.

---

If input `SendEn` = 0, incomplete sending is canceled. No further sending takes place afterward; `SendAct` = 0.

You can use `CylMin` to set the number of cycles to wait before triggering the transfer of the current input data, regardless of any changes to one or more values.

You can use `CylMax` to specify how many cycles after the last valid data transfer to wait before sending the current input data. Sending is executed even when no value has changed or when the changes of a REAL value are within the hysteresis `PV_In_HysXX`.

The default hysteresis value is `PV_In_HysXX` = 0. If sending is not performed after each change, then configure the `PV_In_HysXX` input accordingly. This involves an absolute value.

When `CylMax` is reached, transfer is forced after the corresponding number of cycles.

### Configuration

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Time characteristics

The block does not have any time response.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 21.3.2 Snd_AnaVal modes

This block has no operating mode.

## 21.3.3 Snd_AnaVal functions

The block has no functions.

## 21.3.4 Snd_AnaVal error handling

Error handling of the block is restricted to the error information of the lower-level SFB 12 "BSEND".

The information is set at the outputs `SendErr`(ERR) and `SendStat`(STAT).

If an error occurs, a new job is automatically triggered with the current data until all data have been successfully transferred.

## 21.3.5 Snd_AnaVal messages

No message behavior is applicable to this block.

## 21.3.6 Snd_AnaVal I/Os

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

### Input parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| EN | 1 = Called block will be processed | BOOL | 1 |
| ID | ID of physical connection | WORD | 16#0000 |
| R_ID | ID of message frame connection | DWORD | 16#00000000 |
| SndEn | 1 = Activate continuous sending | BOOL | 1 |
| CylMin | Minimum waiting cycle | INT | 1 |
| CylMax | Maximum waiting cycle | INT | 10 |
| PV_In_Hys00 ... PV_In_Hys31 | EDC-Hysteresis PV_InR_00 ... EDC-Hysteresis PV_InR_31 | REAL | 0.0 |
| PV_In0 ... PV_In31 | Input_0 ... Input_31 | STRUCT<br>• Value: REAL<br>• ST: BYTE | -<br>• 0.0<br>• 16#80 |

### Output parameters

| Parameter | Description | Type | Default |
|---|---|---|---|
| ENO | 1 = Block algorithm completed without errors | BOOL | 0 |
| SndAct | 1 = Command is active | BOOL | 0 |
| SndDone | 1 = Command is executed | BOOL | 0 |
| SndErr | 1 = Command is executed with error | BOOL | 0 |
| SndStat | Type of error | WORD | 16#00000 |

## 21.3.7 Snd_AnaVal block diagram

A block diagram is not provided for this block.

# 21.4 Rcv_AnaVal - Receive analog values including quality code (Rcv_AnaVal)

## 21.4.1 Description of Rcv_AnaVal

### Object name (type + number) and family

Type + number: FB 1894

Family: COMM

### Area of application for Rcv_AnaVal

The "Rcv_AnaVal" block represents a simple user interface to SFB 12 "BRCV". The block sends 32 analog structures via MPI, PROFIBUS or Industrial Ethernet connection to another CPU. The other CPU calls the function module "Snd_AnaVal" (FB 1893) of the PCS 7 Advanced Process Library to receive the data.

### How it works

Data are entered in the data block asynchronously to user-program execution. After "Rcv_AnaVal" has been called, instance DB data may not be processed as long as the job is in progress (`RcvNewData` = 0). If the job is completed without errors, the `RcvNewData` output is set to 1 for one cycle. In the next cycle, the receive enable is automatically sent by the FB to the operating system of the CPU.

The receive enable can take take effect prior to the arrival of the first receive job. In this case, the receive enable is stored by the operating system.

The `ID` parameter is the connection number specified in the connection configuration. and is applied only at the first call after a cold restart.

The parameter `R_ID` is a random number. The `R_ID` parameter must be identical at the corresponding send and receive blocks. The `R_ID` parameter is applied only for the first call after a warm restart.

Call the "Rcv_AnaVal" block for the `ID/R_ID` pair in each program cycle (cyclically or also via timeout alarm). Each message frame requires two calls of "Rcv_AnaVal".

---

**Note**

**Error code or message at the data block**

When configuring a block pair for data transmission from an SND_AnaVal block to an RCV_AnaVal block, make sure that the settings for ID/R-ID are unique throughout the project.

Only one Rcv block may be assigned to each Snd block or only one connection via ID/R-ID may be configured.

Make sure that you perform the engineering clean and correctly because the data may otherwise be transferred to several blocks or an incorrect block.

---

The outputs `RcvErr` (error) and `RcvStat` (status) show the specific error information that correspond to SFB 13 "BRCV".

If an error occurs, use an appropriate substitute strategy with `Feature.Bit29`.

If you want to simulate the block, enable simulation via the `SimOn` input. In this case, the values from the inputs `SimPVX` are written to the outputs `PV_Outx`. The data sent are not applied, since data reception is switched off.

### Configuration

The block is installed in the CFC editor in a cyclic interrupt OB (OB30 to OB38).

### Startup characteristics

The block does not have any startup characteristics.

### Time characteristics

The block does not have any time response.

### Status word allocation for `Status` parameter

This block does not have the `Status` parameter.

## 21.4.2 Rcv_AnaVal modes

This block has no operating mode.

## 21.4.3 Rcv_AnaVal functions

#### Configurable reactions using the Feature parameter

An overview of all the reactions that are provided by the `Feature` parameter is available in the section Configurable functions using the Feature I/O (Page 139).

The following functionality is available for this block at the relevant bits:

- Bit 29: Output substitute values in case of communications error (Page 204)
- Bit 30: Output last value in case of communications error (Page 204)

The signal status of all output values with status 16#80 is set to local "Manipulated value" (16#60), all other status values remain unchanged.

### 21.4.4 Rcv_AnaVal error handling

Error handling of the "Rcv_AnaVal" block is restricted to the error information of the lower-level SFB 13 "BRCV". You can find additional information in the manual System Software for S7-300/400 - System and Standard Functions. There you can find a description for the `RcvErr` and `RcvStat` outputs.

The substitute value is output when Bit29 is set in the `Feature` structure and no new data is received after the expiration of `RcvMonCyc` (number of cycles). While the `RcvMonCyc` cycles are running, the last received values are applied to the output.

If Bit29 is not set in the `Feature` structure and an error occurs, the last valid values are always applied to the output.

### 21.4.5 Rcv_AnaVal messages

No message behavior is applicable to this block.

### 21.4.6 Rcv_AnaVal I/Os

I/Os of Rcv_AnaVal

For the parameters that are not linkable, refer: Parameters that cannot be connected (Page 75)

#### Input parameters

## 21.4.7 Rcv_AnaVal block diagram

A block diagram is not provided for this block.

# Process tag types (insertible templates) 22

## 22.1 Introduction to process tag types

### Introduction

You can find control engineering information on the standard process tag types of the Advanced Process Library in a separate section in this help:

- PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)
- PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823)
- Step controller with direct access to the actuator and without position feedback (StepControlDirect) (Page 2831)
- Step controller with assigned actuator block and position feedback (StepControlActor) (Page 2832)
- Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)
- Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)
- Ratio control with PIDConR (RatioR) (Page 2839)
- Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)
- Cascade control with PIDConR (CascadeR) (Page 2843)
- Cascade control with PIDStepL (CascadeStepControl) (Page 2844)

If you want to do without control loop monitoring in order to reduce license costs or CPU resources, you can use accordingly simplified process tag types, which are identifiable by the suffix "Lean" in their names (for example, PIDControlLean, CascadeControlLean, RatioControlLean) or you can delete the ConPerMon block from the CFC charts for any of the process tag types.

In addition to the process tag types mentioned above, you will also find the following in the Templates folder of the library:

- PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827)
- PID controller for PA/FF devices (PIDControl_Lean_Fb) (Page 2821)
- PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825)
- Override control (Page 2846)
- Override control with PIDConR (OverrideR) (Page 2848)
- PID controller with Smith predictor (SmithPredictorControl) (Page 2830)
- Model-based predictive control (ModPreCon) (Page 2849)

This list contains prototype process tag types for several of the complex control loop structures shown in the example project (Page 2870). These prototypes are simply examples of how such process tag types might appear. In most process plants, it is assumed that high-level control loop structures must be configured individually some in combination with lower-level control loops. This means that mass production of high-level control loop structures as instances of process tag type represents the exception.

Descriptions for the following process tag types are also available:

- Monitoring eight digital process tags (Digital8Monitoring) (Page 2853)
- Monitoring of a digital process tag (DigitalMonitoring) (Page 2851)
- Monitoring a digital process tag for PA/FF devices (DigitalMonitoring_Fb) (Page 2852)
- Monitoring an analog process tag (AnalogMonitoring) (Page 2854)
- Monitoring of an analog process tag for PA/FF devices (AnalogMonitoring_Fb) (Page 2855)
- Dosing (Dose_Lean) (Page 2856)
- Dosing with PA/FF devices (Dose_Lean_Fb) (Page 2857)
- Two-speed motor (Motor2Speed) (Page 2860)
- Reversing motor (MotorReversible) (Page 2861)
- Reversible motor with controllable speed (MotorSpeedControlled) (Page 2862)
- Motor (Motor_Lean) (Page 2858)
- Motor with an additional analog value and time-stamped signals (Motor_AV_EventTs) (Page 2863)
- Motor valve (ValveMotor) (Page 2867)
- Valve (Valve_Lean) (Page 2865)
- Two-way valve (Valve2Way) (Page 2866)
- Control valve (VlvAnL)  (Page 2868)
- Control valve for PA/FF devices (ValveAnalog_Fb) (Page 2869)

### Using process tag types

When using process tag types in a PCS 7 multiproject, the following procedure is recommended:

- Copy all the required function blocks from the Advanced Process Library to the block folder of the master data library of the multiproject (<Projectname>_Lib).
- Then in the plant view, copy the required process tag types from the Advanced Process Library to the "Process_tag_types" folder of the master data library of the multiproject.
- Make any customizations of the process tag types.

### Generating the process tags

Process tags are the instances of the process tag types.

There are two ways of generating process tags:

1. Copy the process tag type from the master data library and insert it in the target folder in the plant hierarchy. You can then set the parameters for and interconnect the CFC chart in the CFC Editor.
2. Using the Import-Export assistant, you can then generate the required process tags of the process tag type that you then assign parameters to and interconnect based on an import file.

### Notes on the "Measured value failure" application scenario for controller block process tag types

If there is no valid measured value for `PV`, the controller must not remain in automatic mode because a closed control loop no longer exists. The controller is unable to calculate a useful manipulated variable if there is no feedback of the actual process state. The controller must then be changed to manual or tracking mode. OS operators must be made aware of this situation by a corresponding message. Various reactions to the loss of measured values are conceivable depending on the application background:

1. Tracking a fixed, configured neutral position manipulated variable, for example, Valve closed, Heater off, or similar.
2. Holding the last valid manipulated variable `MV` constant to retain a steady process state as far as possible (if the process was already in such a state).
3. Change to manual mode, so that the OS operator can take over responsibility for process control.

A combination of reactions 2 and 3 is implemented in the template. The controller changes to tracking with the last valid manipulated variable as start value. The switchover is made via the input `MV_TrkOn` of the PID block. Since manual mode already has priority over tracking, the OS operator can subsequently use the command.

Caution: It is not advisable to freeze the last valid manipulated value if the signals are subject to heavy noise, or in control loops with frequent setpoint changes. In such situations, it is advisable to change to variant 1.

If a controller intervenes locally in the process via an actuator (for example, a valve with electropneumatic positioner Sipart PS) specific measures similar to those for a cascade controller must be taken:

- If there is local intervention, the controller tracks the current actuator position. In this case, the feedback signal is applied to input `MV_Trk` and an OR element is set before input `MV_TrkOn`.

### Notes on analog position feedback for controller block process tag types

If there is no position feedback, delete the associated analog input channel block at the `MV_Rbk` parameter in the CFC chart. This will also make the corresponding display elements in the standard view of the faceplate invisible.

# 22.2 PID controller (PIDControl_Lean)

## PID controller

This process tag type forms the basis for generating PID control instances for continuous processes. In addition to the actual PID block, it contains functionality that should be implemented consistently in each control loop. This functionality is, however, not implemented within the PID block itself so that users can adapt the functions to a specific project:

- An analog input channel block for the actual value `PV` plus an analog output channel block for the manipulated variable `MV`.
- Certain logic blocks that change the control loop to a safe mode if the measurement of the process value fails. This state is signaled by the signal status of `PV`.

**Note**

Read the information for process tag types with controller blocks in Introduction to process tag types (Page 2817).

# 22.3 PID controller for PA/FF devices (PIDControl_Lean_Fb)

## PID controller

This process tag type forms the basis for generating PID control instances for continuous processes. In addition to the actual PID block, it contains functionality that should be implemented consistently in each control loop. This functionality is, however, not implemented within the PID block itself so that users can adapt the functions to a specific project:

- An analog input channel block for the actual value `PV` plus an analog output channel block for the manipulated variable `MV`.
- Certain logic blocks that change the control loop to a safe mode if the measurement of the process value fails. This state is signaled by the signal status of `PV`.

**Note**

Read the information for process tag types with controller blocks in Introduction to process tag types (Page 2817).

# 22.4 PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon)

### PID controller with safety logic and control loop monitoring

This process tag type forms the basis for generating PID control instances for continuous processes. In addition to the actual PID block, it contains functionality that should be implemented consistently in each control loop. This functionality is, however, not implemented within the PID block itself so that users can adapt the functions to a specific project:

- An analog input channel block for the actual value `PV` and (if available) the position feedback (`Rbk`), plus an analog output channel block for the manipulated variable `MV`.
- A simple process simulation of the first order, controlled by the manipulated variable `MV` which provides simulation values to analog input `PV`. This functionality allows at least elementary function tests control loop before a real process is connected.
- Certain logic blocks that change the control loop to a safe mode if the measurement of the process value fails. This state is signaled by the signal status of `PV`.
- An additional function block for control loop monitoring that should be installed in all PID control loop.

**Note**

Read also the information on controller block process tag types in Introduction to process tag types (Page 2817).
You can find information on the use of control loop monitoring in ConPerMon functions (Page 845).

# 22.5 PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon)

## PIDConR with safety logic and control loop monitoring

This process tag type corresponds to the process tag type PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822) and control loop monitoring when PIDConR is used rather than PIDConL.

# 22.6 PID controller with safety logic and manipulated variable ramp (PIDConR_MV_Ramp)

### PID controller with safety logic and manipulated variable ramp

This process tag type is derived from the process tag type PIDConR with safety logic and control loop monitoring (PIDConR_ConPerMon) (Page 2823). But in this case, a manipulated variable ramp is realized instead of a control loop monitoring.

The degree of manipulated variable is limited outside of PIDConR with the block RateLim. The limited `MV` value is fed back to the input parameter `ExtReset` of the block PIDConR.

# 22.7 PID - control with operating-point-oriented parameter control (GainScheduling)

## PID - control with operating-point-oriented parameter control

Many technical processes have a non-linear response due to non-linear physical, chemical or thermodynamic effects. When such a process needs to be kept in the close vicinity of a fixed operating point, the transfer response can be linearized around this operating point. A linear PID controller can be designed for this linearized transfer function. If, however, the process has a strongly non-linear response and/or operates at different operating points, no constantly good control response can be expected throughout the entire operating range. Due to the non-linearity, various gain factors or process time constants are in effect at different operating points. In keeping with this, different controller parameters will be considered to be optimum.

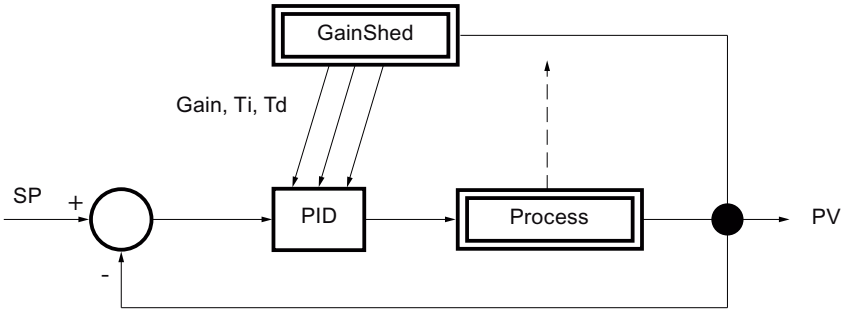

Figure 22-1 Operating-point-oriented parameter adaptation

One possible (the simplest) solution to this problem is known as gain scheduling or parameter scheduling. Using a tool such as the PCS 7 PID Tuner, various experiments are performed at different operating points, in each case with low signal amplitudes. This results in different PID parameter sets for each operating point. Up to three such parameter sets can be stored in the GainSched Function block. The suitable parameter set is selected depending on a continuously measurable variable that describes the state of the process, typically the control variable PV itself. Between the operating points for which there are exact parameter values, the values are calculated by linear interpolation of the neighboring interpolation points so that soft and bumpless transitions are possible between the operating points. The term "parameter scheduling" makes it clear that the "timetable" for adjusting the parameters is specified in advance. In contrast, an adaptive controller adapts itself automatically to the differing process response during operation.

The function block GainSched is produced from the CFC chart "fbGainSched" by compiling it as a block type. This CFC chart is supplied with the library so that the user has the option of

expanding the existing basic functionality as necessary, for example to more than three operating points.

**Note**

The combination of several locally optimized controllers by gain scheduling to form a non-linear controller does not necessarily represent an optimum non-linear controller for the non-linear process when considered from a mathematical point of view. This becomes clear even with benign non-linearities (that are continuous and can be differentiated) when setpoint step changes are made between different operating points. Great caution is needed with non-linearities that are discontinuous or cannot be differentiated or with non-monotonic non-linearities.

## Examples of applications

- Control (especially temperature control) of batch processes, for example, batch reactors and batch columns
- pH value control
- Temperature control with phase transitions (for example, fluid/vapor form)
- Control of semi-batch plants (continuous plants with operating point changes, for example, polymerization reactors)
- Control in power plants with load changes

# 22.8 PID controller with dynamic feedforward control (FfwdDisturbCompensat)

## PID controller with dynamic feedforward control

Feedforward can be used when a known, strong disturbance affects the process and its cause can be measured. In these cases, the following general strategy applies: "Control as much as possible (if known in advance and described by a model), control as much as necessary (the rest including the model error and immeasurable disturbances)".

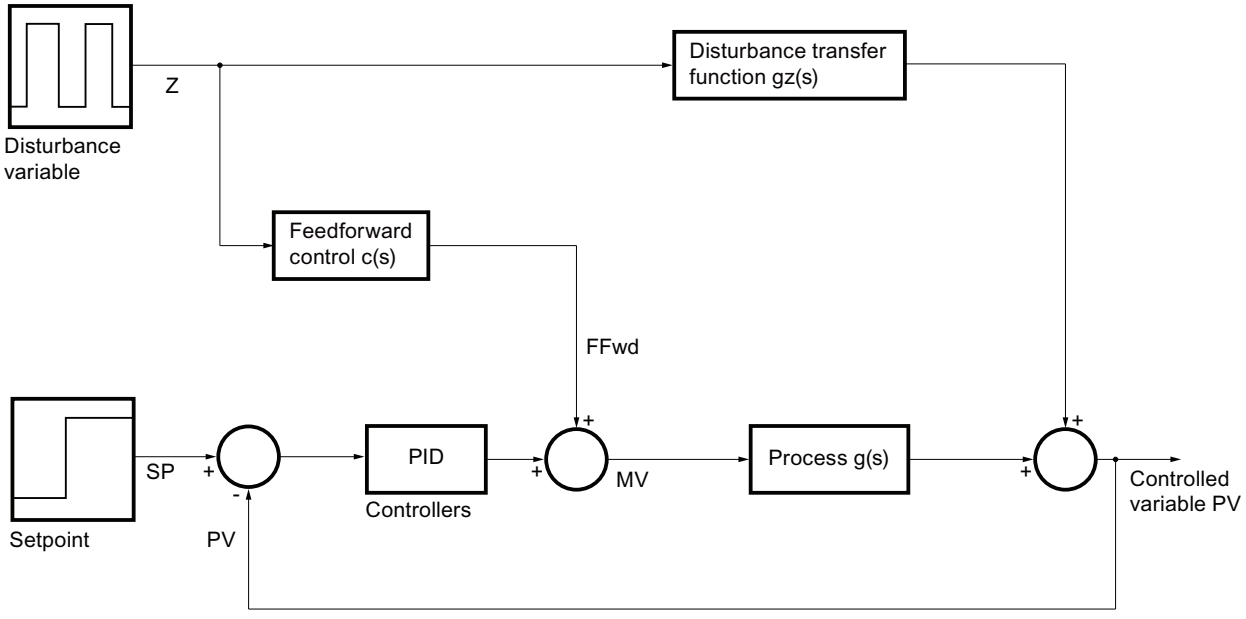

Figure 22-2 Dynamic feedforward control

The effect of a measurable disturbance can be estimated in the form of a transfer function $g_z(s) = y(s) / z(s)$ when the controller is running in manual mode so that no changes whatsoever to the controlled variable y = PV are caused by the manipulated variable and all changes can be attributed to the disturbance z(s).

The transfer function of an ideal feedforward control c(s) can be derived from the requirement that the effect of z on y should be zero for any disturbance signal z(s):

$g_z(s) \cdot z + c(s) \cdot g(s) \cdot z = (g_z(s) \cdot g(s)) \cdot z = 0$

To meet this equation, the compensation block must approximate the equation

$$c(s) = -\frac{g_z(s)}{g(s)}$$

as well as possible. For this to happen, the disturbance transfer function $g_z(s) = y(s) / z(s)$ must be known and the transfer function of the main controlled system $g(s) = y(s) / u(s)$, u = MV must be inverted. If both transfer functions can be modeled as first order with dead time

$$g(s) = \frac{k_s}{1 + t_1 s} \cdot e^{-s\theta}$$

and

$$g(s) = \frac{k_{sz}}{1 + t_{1z} s} \cdot e^{-s\theta_z}$$

and $\theta < \theta_z$ applies, the resulting compensation element must represent the transfer

$$c(s) = -\frac{k_{SZ}}{k_S} \cdot \frac{1 + t_1 s}{1 + t_{1Z} s} \cdot e^{-s(\theta_Z - \theta)}$$

function.

In general, the following dynamic transfer function is required for additive feedforward control:

$$FFwd(s) = -k_c \cdot \frac{t_{cd} s + 1}{t_{cl} + 1} \cdot e^{-\theta_c s} \cdot z(s)$$

where:

$MV = MV_{PID} + FFwd$

In the example above, this function includes the following parameters:

$$k_c = \frac{k_{sz}}{k_s}, \quad t_{cd} = t_1, \quad t_{cl} = t_{1z}, \quad \theta_c = \theta_z - \theta'$$

This transfer function can be created outside the controller with a combination of elementary CFC blocks: one DT1 (Diff),, one PT1 (TimeLag) and one DeadTime block. As shown in the process tag type, the Diff block and TimeLag block are connected in parallel, and the DeadTime block as well as a multiplier are connected in series in front as a gain factor.

The input parameters $k_c$, $t_{cd}$, $t_{c1}$ need to be configured by the user. For a static feedforward control, both time constants are set to zero.

## Examples of applications

- Controlling the outlet temperature of a heat exchanger via steam pressure or heating/cooling medium flow. Flow and inlet temperature of the medium are measurable disturbance variables.
- Fill level control in a drum steam generator using the inlet volume. The outflow is the measurable disturbance variable that is determined by the variable steam consumption in the plant.

- Temperature control in a distillation column using the reflux ration or or heating steam volume. The measurable disturbance variable is the mixture inlet.
- Temperature and concentration control in an agitated tank reactor using cooling medium flow and discharge volume. The temperature and possibly also the concentration of the inflow are measurable disturbance variables.

# 22.9 PID controller with Smith predictor (SmithPredictorControl)

### PID control with Smith predictor

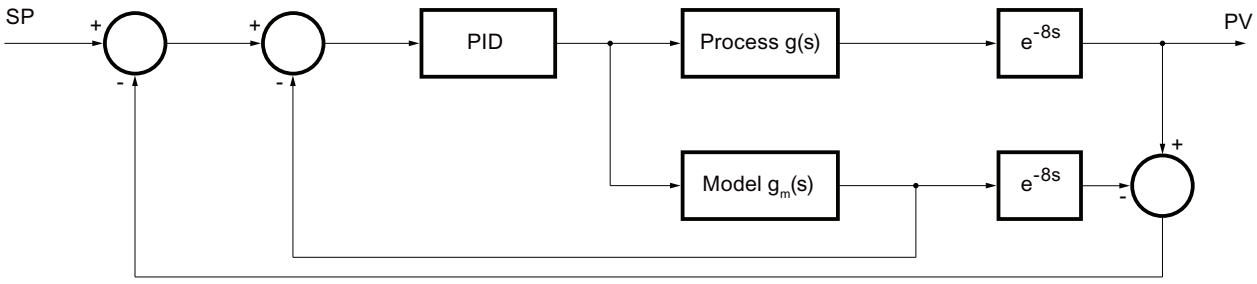

Figure 22-3 PID control with Smith predictor

In processes with large dead times (relative to the dominating time lag constant), a standard PI controller must be set very slowly and compromises must therefore be accepted in the control quality. The control quality can be significantly improved with a Smith predictor that can be derived from the IMC principle (**I**nternal **M**odel **C**ontrol) of model-based control. To achieve this, the transfer function $g_s(s) = g(s) \cdot e^{-s\theta}$ of the controlled system is split up into a part without dead time g(s) and a purely dead time slice $e^{-s\theta}$ with dead time θ. Only the controlled variable y affected by dead time can be measured in the real process. However, a virtual estimate of the controlled variable free of dead time can be taken from the process model (that will become part of the controller) and fed to the controller. This means that the controller itself can be designed for the process without a dead time slice and can therefore be set much more tightly. To compensate unknown disturbances, an estimate of the controlled variable affected by dead time is made in the model and compared with the genuine measured controlled variable. This difference is also fed back to the controller.

In terms of practical application, it must be pointed out that the performance of the Smith predictor depends largely on the model fit, in other words, the dead time must be known. The dead time must be constant or its value must be permanently adapted.

**Note**

To control processes with large dead times, a model predictive controller (see Description of ModPreCon (Page 970)) is also suitable in a single variable situation. It provides greater flexibility in the system modeling and is more convenient thanks to the integrated design procedures, it does however require more CPU resources.

# 22.10 Step controller with direct access to the actuator and without position feedback (StepControlDirect)

### Step controller with direct access to the actuator and without position feedback

The output of the PIDStepL block is directly connected to the process via two digital output channel blocks. This is the simplest form of a step control. The operator can control the actuator (push-button open/close) in the faceplate of the controller. This push-button operation is preferable when operating simple actuators without position feedback since it allows bumpless switchover to auto mode. This switchover is not possible if actuators without position feedback are operated manually from any location outside the control block. For this reason, the template is designed with a PIDStepL block without position feedback.

# 22.11 Step controller with assigned actuator block and position feedback (StepControlActor)

### Step controller with assigned actuator block and position feedback

The output of the PIDStepL block is directly interconnected with the process by way of an actuator block (for example, a motor or a valve). This additional effort is justified when special automation functions of the actuator block, for example motor current monitoring, motor protection and operation in local mode are required. The option of such combinations allows users to do without special functions for operation in local mode or actuator monitoring functions within the controller block.

If the actuator block is not in external default setpoint, or there is an interlock, motor protection or monitoring error, the actuator is incapable of accepting and executing controller commands.

In this context, the resulting structure must be interpreted as a "cascade circuit" consisting of the (primary) controller and actuator block (secondary controller) and measures similar to those for cascade control must be taken. For this purpose, the `CascaCut` output of the actuator block must be interconnected to the `TrkOn` input of the primary controller.

To ensure the bumpless switchover from local or manual mode back to cascade mode, the current actuator position must be fed back to the tracking input of the primary controller. This is, however, only possible when using actuators with position feedback. For this reason, the template is designed for operation with a PIDStepL block with position feedback.

**Note**

The Valve motor valve is configured for operation without motor feedback: `Feature.Bit12` = 1

# 22.12 Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl)

## Split-range controller with control loop monitoring (ConPerMon)

A PID closed-loop controller can use a Split-Range block downstream of the controller output to distribute its manipulated variable to several actuators that influence the same control variable based on different physical principles and in different directions. A typical example of such an application is a temperature control, with heating via a live steam valve and cooling via a cooling water valve. The controller can request heating or cooling energy, depending on the sign of the control deviation (or more precisely of the manipulated variable). In other words, it can work with a bidirectional `MV` output (for example: -100% < `MV` < 100%), although each actuator only supports unipolar operation (for example: 0% < valve position < 100%).

The Split-Range function block contains two separate (static) characteristics for both actuators. Any significant difference between the two actuators in terms of performance (can be interpreted as different steady state gains for heating and cooling), can be compensated by setting different gradients for the characteristics, so that as far as possible, the controller is presented with a linear process response (independent of the sign).

## Example: The cooling effect is not as strong as the heating effect.

If cooling is half as effective as heating, the split-range characteristic for cooling should have twice the gradient.

**Note**

The effective maximum values of the manipulated variables are obtained from the manipulated variable limits of the controller multiplied by the gradients of the split-range characteristics.

The cooling valve cannot go beyond fully open, in other words, the effective limitation for opening the valve is 100%. If a split range characteristic with gradient 2 is used for cooling, the low limit for the manipulated variable must be set to MV_LoLim = -50% on the controller.

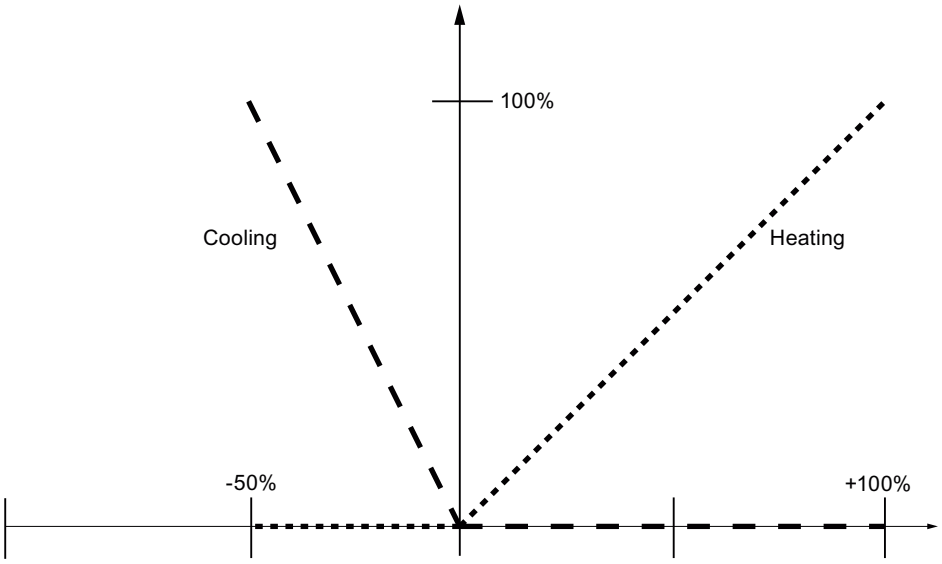

Figure 22-4 Split-range function of the example

The actual split-range function is supplied as separate SplitRange function block that is described in detail in the online help of the block.

**Examples of applications:**

- Control of the temperature of chemical reactors by means of steam heating valves and water cooling valves.
- Temperature control of glass furnaces or sprue channels by means of gas burners and cooling fans
- Temperature control of extruders by means of electrical heating and cooling fans
- Pressure control in a gas phase reactor by means of inlet and outlet valves
- Pressure control at a steam collecting track that supplies steam to several units by means of inlet valves from several steam generators, or the heating power of several steam generators.

# 22.13 Split-Range control (SplitRangeControl_Lean)

### Split-range control

This process tag type is identical to the following process tag type:

Split-range controller with control loop monitoring through ConPerMon (SplitrangeControl) (Page 2833)

The ConPerMon block is not included, however.

# 22.14 Ratio control with control loop monitoring through ConPerMon (RatioControl)

## Ratio control

Specific mixtures of several liquids or gases can be produced by means of a ratio control system consisting of several flow controllers and a Ratio block. The flow setpoint of an additive is obtained from one of these values:

1. From the current `PV` value of the main flow.
   This is the preferred alternative if the primary flow controller operates with steady-state deviation.
   or
2. From the setpoint `SP` of the main flow.
   This alternative provides a smooth, noise-free setpoint signal to the second controller, and allows for a more precise control of specified ratios in transition states where both flow control loops have approximately the same dynamic response.

It is generally advisable to use the second "setpoint-oriented" alternative for main flow controllers with I action.

Interconnect the selected reference value (actual value or setpoint of the main flow) to the In input parameter of the Ratio block.

The ratio control can be expanded by adding further components, in other words, setpoints 3 to n can be derived from `SP1` (or `PV1`) with the help of additional Ratio blocks.

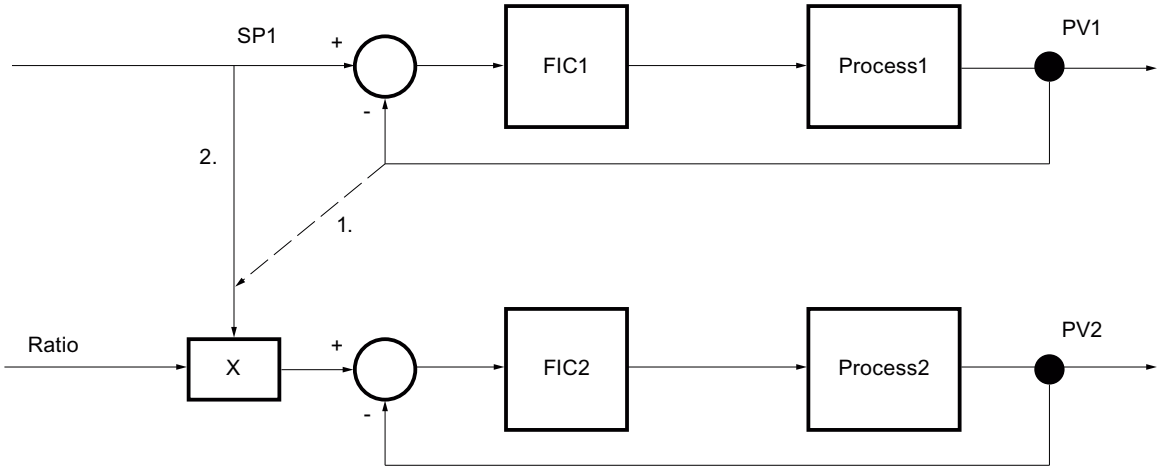

Figure 22-5 Ratio control, process value-oriented (1.) and setpoint-oriented (2.)

The main task of the Ratio block is to define the external setpoint of the secondary (added) component in accordance with

$$Out = In \cdot Ratio + Offset$$

. The actual ratio of the two flow actual values is also calculated in accordance with

$$RatioPV = \frac{SecComPV - Offset}{InPV}$$

and displayed on the control panel for checking purposes. In addition, interconnect the actual value of the main flow to the input parameter `InPV` of the Ratio block and the actual value of the flow of the secondary component to the input parameter `SecComPV`.

In both cases 1 and 2, the current value of the ratio is not controlled directly in the closed loop (no feedback-control) but rather uses feedforward-control.

**Note**

If the PID_Componet1 secondary controller is switched from automatic to another operating mode, the `CascaCut` output parameter is set and the Ratio block is switched to external. In this case, the external setpoint is corrected to the actual value ratio for the ratio of the control actual value to the component actual value: RatioExt = RatioPV. This results in a soft transition to automatic mode.

An additional function block for control loop monitoring must be installed, because it should always be installed in every PID control loop.

## 22.15 Ratio control (RatioControl_Lean)

### Ratio control

This process tag type is identical to the following process tag type:

Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836)

The ConPerMon block is not included, however.

# 22.16 Ratio control with PIDConR (RatioR)

### Ratio control with PIDConR

This process tag type corresponds to the process tag type Ratio control with control loop monitoring through ConPerMon (RatioControl) (Page 2836) when PIDConR is used rather than PIDConL.

You need to set `Feature.Bit21` Switching operator controls for external setpoint to visible (Page 154) to 1 with a flow controller for the secondary component.

# 22.17 Cascade control with control loop monitoring through ConPerMon (CascadeControl)

## General information on cascade control

A cascade control involves two or more PID controllers connected in series. The manipulated variable of the primary controller is interconnected to the external setpoint of the secondary controller so that both control loops are nested. The advantage of cascade control is that disturbances affecting the inner loop can be compensated much more quickly in the secondary loop than in the slower primary loop. In some situations, non-linear effects of the actuator can be compensated in the secondary loop so that a linear process response can be created for the primary loop. Cascade control is possible only when there are further measurable variables in the process in addition to the main control variable and when the internal control loop is significantly faster than the external loop.

## Aspects to be clarified for the cascade control

With any cascade control, the following aspects must be carefully considered and clarified:

- The actuation range of the primary controller must match the setpoint range of the secondary controller to ensure proper operation of the anti-Windup functions of the primary controller.
- If the secondary controller is not operated in "cascade" mode (automatic mode with external setpoint) but in any other mode (for example manual or automatic mode with local setpoint) and therefore does not respond to commands of the primary controller, the primary controller must be put into "tracking" mode to prevent integration of the I action in the primary controller. The manipulated value of the primary controller tracks the process value or setpoint of the secondary controller to allow a bumpless return to cascade mode. The difference between tracking the setpoint and tracking the process value becomes apparent when the secondary controller is put into manual mode. If the process value is tracked, the response is similar to the "Track setpoint to process value in manual mode" of a simple controller.
- If the secondary controller reaches a (high/low) manipulated variable limit, the integrator of the primary controller should be blocked to prevent it going any further in this direction (up / down). The secondary controller cannot go any further in this direction anyway. This prevents any windup of the primary controller when the real actuator has already reached its physical limits while the primary controller has not yet reached its manipulated variable limits.
  Caution:
  - Swap the two bits of this interconnection if the secondary controller has a negative gain.
  - If the secondary controller then reaches a high or low limit, the integrator of the primary controller must be prevented from further integration in this direction.

### Procedure

When you set up and commission the controller, you work from the "inside to the outside", in other words, you start by making the settings for the secondary controller and putting it into auto mode. You then set the primary controller parameters and change the secondary controller to cascade mode. When you set the parameters for the primary controller, remember that from its perspective the entire, inner closed control loop is the "controlled system". The parameters you set for the primary controller depend to a greater or lesser extent on the settings you made for the secondary controller. This becomes less important the greater the difference in dynamic response between the primary and secondary control loop.

### Priorities

The tracking by the primary controller that is initiated by the secondary controller has lower priority than the manual mode on the primary controller. In turn, manual mode has lower priority than forced mode on the master controller as can, for example, be requested by external logic during an emergency shutdown of the plant (controller input `MV_Forced`, unlimited, activated by `MV_ForOn` with highest priority). For this reason, the PIDConL block for cascade control has an additional tracking input `MV_Trk` that is activated by `MV_TrkOn` and is subject to the normal manipulated variable limiting and has lower priority than manual mode.

### Additional application examples

- Temperature control of a distillation column (primary controller) based on the reflux ratio (secondary controller at the top of the column), and heating steam flow rate (secondary controller at the column sump),
- Temperature control of a furnace using a secondary controller to control the fuel flow rate,
- Fill level control for a container using a secondary controller for the inlet and/or outlet flow.
- Position control (in drive engineering) with a secondary controller for the speed and torque.

### Using secondary flow controllers

Secondary controllers are usually used for flow control to prevent detrimental effects on the primary controller resulting from changes in flow rate. The non-linearities frequently often found in a flow control element (for example a valve) are "hidden" in the secondary loop because the secondary closed loop has a linear response and non-linearities have no effect on the primary controller or its tuning.

**Note**

Control loop monitoring is only practical for primary controllers, as explained in the description of the ConPerMon block in the section, Functions/Cascade Control.

# 22.18 Cascade control (CascadeControl_Lean)

## Cascade control

This process tag type is identical to the following process tag type:

Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840)

The ConPerMon block is not included, however.

# 22.19 Cascade control with PIDConR (CascadeR)

### Cascade control with PIDConR

This process tag type corresponds to a large extent to the process tag type Cascade control with control loop monitoring through ConPerMon (CascadeControl) (Page 2840) when PIDConR is used rather than PIDConL.

Special note: The current `PV_Out` output of the PID_Slave secondary controller is used as an external Reset `ExtReset` on the primary controller. Unlike cascade control, the PID_Master primary controller does not therefore have to be changed to tracking when the cascade is disconnected with all other PID controllers. There is also no need for the direction-dependent blocking of the integrator for the primary controller.

Since the primary controller is reliant on the external Reset, any control deviations in the secondary closed loop interfere with the primary controller; secondary controllers without I action are not therefore recommended for PIDConR.

You need to set the `Feature` bit Switching operator controls for external setpoint to visible (Page 154) to 1 with a secondary controller of the cascade.

# 22.20 Cascade control with PIDStepL (CascadeStepControl)

### Cascade control with a step controller as a valve positioner and a downstream actuator block

The step controller is used in this template as a positioner, which regulates the position of a valve that does not have an internal positioner and is only controlled via binary inputs (open, stop, close). The motorized control valve can thus include delay behavior, i.e. that does not stop immediately at a stop command. The output of the PIDStepL block is directly connected to the process via the actuator block VlvMotL (see StepControlActor template). The PIDStepL runs as a slave controller in a cascade structure and gets his external setpoint from a master controller (flow or pressure regulator).

The PIDStepL is configured as a step controller without position feedback (WithRbk =0). The position feedback signal is applied in this example to the `PV` input and controlled to the external setpoint, which is also set by higher-level master controller (PIDConL). Master and slave controllers are connected in such a way that the following conditions are met (see CascadeControl template):

- The calculated valve position of the master controller is forwarded to the external setpoint of the slave controller.
- The master controller is switched to tracking if there is a bad process value on the master controller or with an open loop by the PIDStepL slave controller or by the VlvMotL valve block. The tracking value corresponds to the valve position at the `PV` input of the PIDStepL step controller. In case of an open loop by the VlvMotL valve block, the open and close control signals of the PIDStepL slave controller are also tracked.
- If the valve position is fully open or fully closed, the I-component of the master controller is stopped (Windup measure).

The same rules as those set in the CascadeControl template and described in the Procedure section apply for the controller setting and commissioning.

# 22.21 Source chart for GainSched function block (gain scheduling)

## Source chart for GainSched function block

In contrast to all other function blocks, the `GainSched` block is implemented as a CFC chart and is generated with the "Compile chart as block type" function. Several application options are available in this case:

- You can use the precompiled function block `GainSched` from the library if the standard functionality is adequate for your needs.
- If you require special additional functions for gain scheduling in your application (for example more than three operating points, additional logic functions for selecting the parameters), you will need to modify the CFC source chart and compile it as a block type with a different FB number.

Internally, the `GainSched` block consists essentially of three instances of the Polygon block, one for each of the three controller parameters, Gain, TI and TD.

The polygon block itself would extrapolate linearly outside of the boundary points and thereby exceed the value range of its interpolation points. However, as this presents too high a risk for controller parameters, the controller parameters which are output are effectively limited to the table values at the boundary operating points by the automatic introduction of additional interpolation points with a horizontal end tangent outside of the specified range.

# 22.22 Override control

## Override control

In an override control, two or more controllers share a common actuator. Depending on the current process state, a decision is made as to which controller actually has access to the actuator, in other words, the various controllers can override each other.

A typical use case is a gas pipeline with pressure and flow control using a single valve. The main aim of the control is to achieve a certain flow rate, however due to safety considerations, the pressure must be kept within certain limits. The pressure controller is therefore known as the "limiting controller" or "secondary controller".

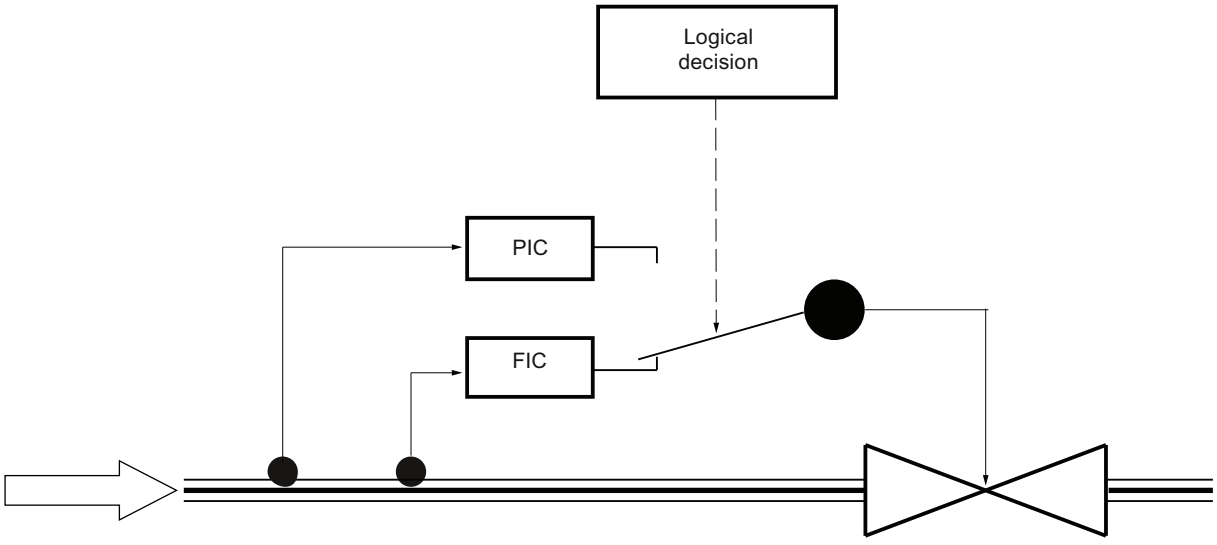

Figure 22-6 Override control with main controller FIC and limiting controller PIC

### Criteria for the type of override control

The logical decision as to which controller should be active can be made based on two different criteria resulting in two different types of override controls:

1. The decision is based on a measurable process output variable, for example one of the two controlled variables. In the example above, the warning limits of the pressure controller can be used to decide whether the pressure controller should be active. The passive controller is in tracking mode to avoid Windup problems and to ensure bumpless transfer. The setpoint of the secondary controller must be somewhat lower than the switchover threshold so that the transfer can be reversed again. This type of override control is easy to understand and to implement. Its advantage is that the high and low limit of the secondary controlled variable (for example pressure) can be monitored; its disadvantage is that a limit cycle oscillation results as soon as the limiting controller needs to intervene. The secondary controller will always attempt to return its controlled variable to the safe range and to return command to the main controller (for example flow rate) so that the active and passive controllers swap over continuously. This variant is therefore only recommended when the secondary controller is seldom required and functions mainly as a safety or backup system.
2. The decision is based on a comparison of the manipulated variables of both controllers, for example the controller that demands the higher (or lower) controlled variable takes control of the actuator. In the example above, the controller that wants to open the valve further takes over control. The setpoint of the secondary controller defines the switching threshold. Both controllers run the entire time in automatic mode. To avoid Windup problems, the manipulated variable limits must be tracked in a crossover structure: When the higher (lower) manipulated variable wins, the low (high) limits of all controllers of the currently highest (lowest) manipulated variable must be corrected slightly up or down by, for example, 2% of the manipulated variable range. This means that this scheme can also be used in applications with more than two controlled variables. There is no Windup problem at the high limit because the highest manipulated variable takes over control anyway. This approach avoids the limit cycle oscillation of alternative 1 but is, in principle asymmetrical, in other words either a high or a low limit of the secondary controlled variable can be monitored but not both.
   This type of override control is described in most control textbooks, particularly in the USA. It can, however, only be used with PID algorithms that allow online manipulation of the manipulated variable limits (in PCS 7 as of V6.0).

### Additional application examples

- **Steam generator:** The primary controlled variable is the steam pressure but the water level in the steam tank must be monitored so that the heating coils remain completely covered by water and the tank does not overflow. The only manipulated variable is the outlet valve.
- **Compressor:** The primary controlled variable is the throughput but the pressure must be monitored to make sure it does not exceed a safety limit. The only manipulated variable is the motor speed.
- **Steam distribution system:** Every plant involving industrial processes has a network of pipes to distribute steam at various pressures throughout the plant. The high pressure of the steam is reduced to lower levels via a valve. The primary controlled variable is the pressure at the lower-level stage, however the pressure in the high pressure piping must also be monitored to make sure that it does not exceed a safety limit.

# 22.23 Override control with PIDConR (OverrideR)

### Override control with PIDConR

This process tag type corresponds for the most part to the process tag type Override control (Page 2846) when PIDConR is used rather than PIDConL.

Special note: The current manipulated variable output at the final controlling element (e.g. the maximum `MaxMV.Out` manipulated variable proposed by the main controller and limiting controller) is used as the external Reset`ExtReset` for both controllers. Unlike override control, the manipulated variable limits (e.g. `MV_LoLim`) of both controllers do not have to be tracked within a defined space (e.g. `MaxMV_Minus2.Out`) by the manipulated value output at the final controlling element with all other PID controllers.

# 22.24 Model-based predictive control (ModPreCon)

## Model-based predictive control

The process tag type shows how users can expand the ModPreCon block by adding extra functions:

- External alarming with the MonAnL block
- Control quality monitoring with the ConPerMon block
- Safety logic for measure value loss.

You can find details about the ModPreCon block in Description of ModPreCon (Page 970).

## Note on using the ConPerMon block in a system with multi-variable

The mathematical concept of the ConPerMon block is designed for single variable applications. If any increase of variance is detected in the channel of a multi-variable control, the ConPerMon algorithm is unable to determine whether this problem is caused by its own internal control channel or by interaction of neighboring channels. It may be helpful, however, to include a ConPerMon block for each control channel of a multi-variable system to monitor whether the control performance during operation remains within the range determined during commissioning. To achieve this, several logic operations must be performed before the `ManSuprCPI` input bit of each ConPerMon block:

- If one or several of the other channels of the multi-variable system are are not in a steady state ("root caused in this channel") due to local causes (for example a setpoint step change) that is indicated by output bit `CPI_SuRoot = 1`, the increase of variance in its own channel cannot be avoided and should not trigger a CPI warning in its own channel.
- If one or several other channels of the multi-variable system exhibit strong variations as indicated by output bit `CPI_WrnAct = 1`, the increase in variance in its own channel cannot be avoided and should not trigger a CPI warning in its own channel. This may be helpful to localize the actual cause of the problem. The channel in which excessive variations are first detected outputs the first alarm; the other channels which may only be affected by errors resulting from the first error do not generate their own alarms.

## Examples of applications

- Quality control in distillation columns, for example control of the column top and sump temperature based on the reflux ratio and heating steam volume
- Temperature control of several adjacent zones of furnaces with several burners, for example, tunnel furnaces, glass smelting plants, glass sprue channels etc.
- Quality control in chemical reactors by adjusting of reaction conditions such as pressure, temperature, feed/drain etc.

- Vaporizers, for example, drum steam generators
- Mills, for example, cement mills, sieve mills: quality control (grain size) in combination with flow rate maximized, manipulated variables: sieve speed and mill feed

**Note**

The statistical evaluation of the service factor (time slice in automatic mode) and the time slices in the manipulated variable limits can be performed in a WinCC trend control, as in the customary case of a single variable. The binary variables from ModPreCon required for this are archived automatically. However, an appropriate trend control must be manually configured on the operator station, since the view archive in the ConPerMon block is not designed for such quantities.

# 22.25 Monitoring of a digital process tag (DigitalMonitoring)

### Monitoring a digital process tag

This process tag type serves as a basis for monitoring a digital process tag using the MonDiL block.

The digital measurement signal is read from the I/O through the PCS7DiIn block.

The process tag type contains the required interconnections between Pcs7DiIn and MonDiL.

# 22.26 Monitoring a digital process tag for PA/FF devices (DigitalMonitoring_Fb)

## Monitoring a digital process tag

This process tag type serves as a basis for monitoring a digital process tag using the MonDiL block.

The digital measurement signal is read from the I/O through the FbDiIn block.

The process tag type contains the required interconnections between FbDiIn and MonDiL.

# 22.27 Monitoring eight digital process tags (Digital8Monitoring)

## Monitoring eight digital process tags

The process tag type serves as a basis for monitoring up to eight digital process tags using the MonDi08 block.

The digital measurement signals are read from the I/O through the PCS7DiIn block.

The process tag type contains the required interconnections between the eight Pcs7DiIn and MonDi08 blocks.

# 22.28 Monitoring an analog process tag (AnalogMonitoring)

## Monitoring an analog process tag

This process tag type serves as a basis for monitoring an analog process tag using the MonAnL block.

The analog value is read from the I/O through the PCS7AnIn block.

The process tag type contains the required interconnections between Pcs7AnIn and MonAnL.

If you wish to monitor and forward the slope of the process value, you usually need to smooth the process value. You can insert a filter block such as Smooth between Pcs7AnIn and MonAnL for this purpose. The gradient of the process value can also be smoothed using the TimeLag parameter at MonAnL.

Procedure for smoothing the process value and its gradient:

1. Check the process value PV in the trend recorder and smooth it using a filter block such as Smooth only as much as is needed.

2. Check the gradient PV_Grad of the process value in the trend recorder and smooth the trend at the TimeLag parameter of MonAnL.

The sum of the time constants of Timelag from MonAnL and TimeConstant from Smooth approximately result in the length of a varying time window in which the gradient is averaged.

# 22.29 Monitoring of an analog process tag for PA/FF devices (AnalogMonitoring_Fb)

## Monitoring an analog process tag

This process tag type serves as a basis for monitoring an analog process tag using the MonAnL block.

The analog value is read from the I/O through the FbAnIn block.

The process tag type contains the required interconnections between FbAnIn and MonAnL.

If you wish to monitor and forward the slope of the process value, you usually need to smooth the process value. You can insert a filter block such as Smooth between FbAnIn and MonAnL for this purpose. The gradient of the process value can also be smoothed using the TimeLag parameter at MonAnL.

Procedure for smoothing the process value and its gradient:

1. Check the process value PV in the trend recorder and smooth it using a filter block such as Smooth only as much as is needed.

2. Check the gradient PV_Grad of the process value in the trend recorder and smooth the trend at the TimeLag parameter of MonAnL.

The sum of the time constants of Timelag from MonAnL and TimeConstant from Smooth approximately result in the length of a varying time window in which the gradient is averaged.

# 22.30 Dosing (Dose_Lean)

## Dosing

This process tag type serves as a basis for dosing either as "Single component dosing via flow measurement" or as "Fill/extraction weighing via dosing scale" using the DoseL block.

The analog measurement signal is read from the I/O through the PCS7AnIn block.

The interlock signals of DoseL are interconnected to the Intlk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.31 Dosing with PA/FF devices (Dose_Lean_Fb)

## Dosing

This process tag type serves as a basis for dosing either as "Single component dosing via flow measurement" or as "Fill/extraction weighing via dosing scale" using the DoseL block.

The analog measurement signal is read from the I/O through the FbAnIn block.

The interlock signals of DoseL are interconnected to the Intlk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via FbDiIn.

The digital output signals are sent to the I/O through the FbDiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.32 Motor (Motor_Lean)

## Motor with current monitoring

This process tag type serves as a basis for controlling motors with one control signal using the MotL block.

The feedback signal of the motor is read from the I/O through the PCS7DiIn block.

The interlock signals of MotL are interconnected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.33 Motor with PROFIdrive Drive Profile telegram 1 and 20 (Namur)

### Motor with adjustable speed and two directions of rotations according to the speed control mode with standard telegram 1 and 20

The process tag type serves as a basis for control of motors according to the profile "Speed control mode with standard telegram 1 and 20 with and without Namur" with the help of blocks FbDrive and MotSpdCL.

The interlock signals of MotSpdCL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The input/output signals of MotSpdCL are sent to the I/O through the FbDrive block.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.34 Two-speed motor (Motor2Speed)

### Two-speed motor

This process tag type serves as a basis for controlling motors with two speeds using the MotSpdL block.

The speed feedback signals of the motor are read from the I/O through the PCS7DiIn blocks.

The interlock signals of MotSpdL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.35 Reversing motor (MotorReversible)

### Reversing motor

This process tag type serves as a basis for controlling reversing motors using the MotRevL block.

The feedback signals of the motor are read from the I/O through the PCS7DiIn blocks.

The interlock signals of MotRevL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.36 Reversible motor with controllable speed (MotorSpeedControlled)

### Reversible motor with controllable speed

This process tag type serves as a basis for controlling reversible motors with controllable speed using the MotSpdCL block.

The digital feedback signals of the motor are read from the I/O through the PCS7DiIn blocks.

The speed feedback of the motor is read from the I/O through the PCS7AnIn block.

The interlock signals of MotSpdCL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The speed control signal is output to the I/O through the PCS7AnOu block.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.37 Motor with an additional analog value and time-stamped signals (Motor_AV_EventTs)

## Motor with an additional analog value and time-stamped signals

This process tag type shows the monitoring of an additional analog value, for example, for motor current monitoring (AV block) and additional binary signals (EventTs block) at a technologic block with MotL as an example.

By interconnecting the AV or EventTs block, messages of this block are displayed in the message view of the technologic block connected to it and can be acknowledged there.

## Use of the AV block

The analog signal to be monitored can be read via the Pcs7AnIn block, for example. This has to be interconnected to the AV block. The `AV_Tech` output parameter of the AV block has to be interconnected to the `AV` input parameter of the technologic block.

## Use of the EventTs block

A non-time-stamped binary signal from the I/O can be read via the Pcs7DiIn block, for example. The `PV_Out` output parameter of Pcs7DiIn has to be interconnected to the `Inx` input parameter of the EventTs block. The time stamp of this signal is generated by the EventTs block at signal change.

A time-stamped binary signal from the I/O must be read via the Pcs7DiIT block. The `TS_Out` output parameter of Pcs7DiIT has to be interconnected to the `InTSx` input parameter of the EventTs block.

The `EventTsOut` output parameter of the EventTs block has to be interconnected to the EventTsIn input parameter of the technologic block.

## Additional interconnections

The interlock signals of MotL are interconnected to the IntLk02 interlock blocks. In turn, these interlock blocks are interconnected to other blocks, for example, to digital process tags via the Pcs7DiIn block.

The digital output signal is output to the I/O through the PCS7DiOu block.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.38 Motor according to the profile for low voltage switchgear devices with profile 1 of the MM_Starter

### Reversible motor according to the manage motor starter with profile type 1

The process tag type serves as a basis for control of motors according to the profile "Manage motor starter - profile type 1" with the help of blocks FbSwtMMS and MotRevL.

The interlock signals of MotRevL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The input/output signals of MotRevL are sent to the I/O through the FbSwrtMMS block.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.39 Valve (Valve_Lean)

## Valve

This process tag type serves as a basis for controlling a valve with two positions (open/close) using the VlvL block.

The feedback signals of the valve are read from the I/O through the PCS7DiIn blocks.

The interlock signals of VlvL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.40 Two-way valve (Valve2Way)

### Two-way valve

This serves as a basis for controlling a

- multi-way valves with up to three switching positions or
- three individual valves (valve network) to implement a 2-way valve circuit with neutral position

using the Vlv2WayL block.

The feedback signals of the valve or valves are read from the I/O through the PCS7DiIn blocks.

The interlock signals of Vlv2WayL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.41 Motor valve (ValveMotor)

## Motor valve

This process tag type serves as a basis for controlling a motor valve using the VlvMotL block.

The feedback signals of the valve are read from the I/O through the PCS7DiIn blocks.

The interlock signals of VlvMotL are connected to the IntLk02 interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via Pcs7DiIn.

The digital output signals are sent to the I/O through the PCS7DiOu blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.42 Control valve (VlvAnL)

### Analog control valve

This process tag type serves as a basis for controlling an analog control valve (0 to 100%) using the `VlvAnL` block.

The feedback signals of the valve's total travelled positions (open/closed) are read by the I/Os through the `Pcs7DiIn` blocks.

The feedback signal of the current analog position is read through the `Pcs7AnIn` block.

The interlock signals of `VlvAnL` are interconnected to the `IntLk02` interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via `Pcs7DiIn`.

The analog actuating signal is output to the peripherals via the `Pcs7AnOu` blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

# 22.43 Control valve for PA/FF devices (ValveAnalog_Fb)

### Analog control valve

This process tag type serves as a basis for controlling an analog control valve (0 to 100%) using the `VlvAnL` block.

The feedback signals of the valve's total travelled positions (open/closed) and the current analog position of the value are read by the I/Os through the `FbAnOu` blocks.

The analog actuating signal is output to the peripherals via the `FbAnOu` blocks.

The process tag type contains the required interconnections between the blocks mentioned above.

The interlock signals of `VlvAnL` are interconnected to the `Intlk02` interlock blocks. These interlock blocks in turn are connected to other blocks, for example, to digital process tags via `FbDiIn`.

# 22.44 Example project APL_Example_xx

## 22.44.1 Introduction to the PCS 7 example project for Advanced Process Control

### Introduction

This document relates to the PCS 7 example project, Process Control (APL_Example_xx, xx indicates the language variant) for the PCS 7 Advanced Process Library.

In contrast to the process tag types (insertable templates), the example project is primarily intended for training purposes:

The main aim was to familiarize users with with the new advanced process control structures by allowing them to experiment without having to intervene in the real process. The examples provide realistic process simulation. Working with these examples helps you to understand the concept and specific structural requirements, and to assess the uses of these functions before you implement them in a real system. For this reason, the examples contain a third-order simulation model with gain, equivalence value, and measurement noise but no analog channel blocks. The process model is supplied as the "ProcSimC" CFC chart and incorporated in the examples using the chart-in-chart technique.

The following examples are provided:

- Cascade control of temperature by using the heat flow (CascadeSim) (Page 2873)
- Control loop monitoring for simulation with colored noise (ConPerMonSim) (Page 2875)
- Feedforward control to compensate a measurable disturbance variable (DisturbCompSim) (Page 2875)
- Operating point-oriented adaptation of parameters (gain scheduling) for non-linear processes (GainSchedSim) (Page 2876)
- Override control on a pipeline (OverrideSim) (Page 2877)
- Smith predictor for a dead time system (SmithPredictorSim) (Page 2877)
- Filtering of noisy measured values in a control loop (SigSmoothSim) (Page 2877)
- Predictive control of a 2x2 multi-variable controlled system (ModPreConSim) (Page 2879)
- Predictive control of a non-linear process (ModPreConNonLinSim) (Page 2879)

A template for Fuzzy Control using the *PCS 7 add-on product FuzzyControl++* can be downloaded from the Internet pages of *Siemens I&S* and is therefore not included in the demo project.

A separate tree folder ("Unit") is provided for each example in the PCS 7 example project. Each folder contains a CFC chart with an interconnection example, a brief explanatory text, and an assigned OS picture with self-explanatory visualization of the process example based on a pre-configured trend recorder. A short text in the OS picture describes commissioning and presentation.

## 22.44.2 Process simulation including noise generator (ProcSimC; ProcSimS)

### Process simulation including noise generator

Users require only a few standard blocks to create a dynamic process model that reflects the response pattern of many technological processes with adequate precision. This model is used in all example projects (APL_Example_xx). However, you can also use this model for sales presentations or to test closed-loop control functions, in other words in a project phase in which the real plant is not yet available ("virtual process", "shadow plant"). Process simulation is supplied as an open source CFC chart "ProcSimC" that users can install in other CFC charts as a nested chart (chart-in-chart ). It contains three first order delay elements, a gain factor, an equivalence value `PV` (for `MV = 0`), and a noise generator for white measurement noise. An additive input is provided for (artificial) interference of the input. The Laplace transformation function described below is implemented by means of this model.

$$PV(s) = \frac{Gain}{(TimeLag1 \cdot s + 1)(TimeLag2 \cdot s + 1)(TimeLag3 \cdot s + 1)}(MV(s) + DisV(s)) + PV_0 + Noise$$

### Use cases

Users can adapt this flexible model to suit the requirements of various use cases, for example:

- **Simulation of temperature control systems:** `PV0` represents the temperature without heating, for example, the ambient temperature. The value of `TimeLag1` is typically significantly higher than `TimeLag2` and `TimeLag3`. The value of the latter can also be zero. The sensor develops a typical quantization noise of 0.1° C. The gain is positive can be interpreted as the theoretical maximum temperature that can be reached at full heating power. However, in most situations this cannot be measured experimentally because many actuators are dimensioned so that the only require approximately one third of the heating power for constant operation at the operating point. The power reserve is only intended to cover operating point changes and heating up phases.
- **Simulation of pressure control systems:** If you define the valve position so that it is closed at 0% and open at 100%, the process Gain of a container pressure control system is normally a negative value because the pressure reduces (>0) when the outlet valve of the container is opened. In contrast to this, the gain of an overpressure value is positive. `PV0 > 0` is the pressure when the value is completely closed. The situation is, of course, the opposite when pressures below ambient pressure are involved, for example, in vacuum systems. Note that most valves do not return a reproducible characteristic in the region of their closed position (actuation ratio 1:20 or 1:50). The time constants for pressure control of liquids are typically fast, whereas with pressure control in gas tanks, particularly in large tanks, they are slower. The magnitude of the process gain depends largely on the physical units of pressure, for example, Bar or Pa. Pressure sensors typically develop higher measurement noise than temperature sensors.
- **Simulation of flow control systems:** If you define the valve position so that it is closed at 0% and open at 100%, the process `Gain` is usually positive, since the flow rate increases when the valve opens. `PV0 = 0` if the flow stops completely when the valve is closed, in other words, the valve closes tight. The time constants are significantly faster than in temperature controls and are usually all of the same order. The magnitude of the process gain depends largely on the physical units of flow, for example, m3/s or l/min. The measurement noise affecting flow sensors is normally higher than with temperature sensors.

To implement a dead time for process simulation, you can insert a DeadTime block before the ProcSimC input and call it in a different cyclic interrupt OB (OB3x).

### Model variants

Two different model variants are supplied:

1. Continuous process simulation ProcSimC in which the MV input is an analog value, for example, heating power or valve position.
2. Process simulation ProcSimS for step controllers, with control of the actuator by two binary inputs "up"/"down" or "open"/"close". Internally, the actuator is modeled as an integrator, whereby:
   - MotorHiLim = 100%,
   - MotorLoLim = 0%
   - TI = MotorTime.
   The integrator input is derived from the binary inputs according to the following formula:

$$\overline{Integ.Input} = \begin{Bmatrix} 100 & if\ Up = True \\ -100 & if\ Down = True \\ 0 & otherwise \end{Bmatrix}$$

### See also

NoiseGen I/Os (Page 2461)

## 22.44.3 Cascade control of temperature by using the heat flow (CascadeSim)

### Cascade control of a temperature by using the heat flow

This template contains simulation models for a flow and temperature controlled system and the parameters of the noise generator block (see the I/O table). You can use this model to test the mode transitions described in the Cascade control (Page 2840) section. You can also try out the properties of different parameter sets for the primary and secondary controllers. The following features are typical for this type of application:

- The controlled temperature system is slower than the controlled flow system.
- There are two time constants that are far apart.
- There is an offset corresponding to ambient temperature.
- It has less noise than the controlled flow system.

**Process parameters of the example project for cascade control**

| ProcSimC | Gain | TimeLag1 | TimeLag2 | PV0 | NoiceVariance |
|---|---|---|---|---|---|
| Flow control loop | 8 | 1 | 1 | 0 | 0.22 |
| Temperature control loop | 0.3 | 8 | 1 | 20 | 0.1 |

**Parameters for PID controllers --> PI cascade with fast control response**

The parameters listed in the table below apply to a fast control response with low control error but with strong actuator intervention.

| PID | Gain | TI | TD |
|---|---|---|---|
| TIC101 | 10 | 8.8 | 2.6 |
| FIC101 | 0.1 | 1.8 | 0 |

**Controller parameters for PI --> P cascade with soft controller intervention**

The advantage of the parameters listed in the table below is that the controller "goes easy" on final control element (for example a valve).

| PID | Gain | TI | TD |
|---|---|---|---|
| TIC101 | 10 | 6.8 | 0 |
| FIC101 | 0.1 | 0 | 0 |

It is generally advisable to make the secondary controller "simpler" than the primary controller, in other words to reduce the number of different dynamic channels so that it is genuinely secondary to the primary controller.

The steady state control error in the secondary loop is not normally relevant for the application. On the other hand, the reaction time of the secondary loop is important because the time constants of the secondary closed control loop are part of the controlled system for the primary controller. If you do without I action in the secondary controller for these reasons, it is not advisable limit the setpoint ranges of the secondary controller precisely to the achievable physical range of the process value in the secondary loop, as you would not be able to use the full actuating range of the secondary controller due to the steady state deviation. You should instead set more generous setpoint limits for the secondary controller and manipulated variable limits for the primary controller. The anti-Windup measures of the primary controller are oriented on the interconnection of `IntHoldNeg` and `IntHoldPos`. If the secondary controller does not have any I action, if will not be capable of a bumpless manual-automatic changeover. You should therefore set an `MV_Offset` that approximates the typical `MV` value for the operating point of the process.

A cascade temperature control system with a secondary controller for heating and/or cooling medium flow is commonly used for

- Heat exchangers
- Reactors without a cooling jacket

## 22.44.4 Control loop monitoring for simulation with colored noise (ConPerMonSim)

### Control loop monitoring with simulation of colored noise

The interconnection of the ConPerMon block with a PID controller can be found in the process tag type PID_Control (see PID controller with safety logic and control loop monitoring (PIDConL_ConPerMon) (Page 2822)). The example project supports you and helps to familiarize you with the concept and the potential of closed control loop monitoring. To do this, the template includes a process simulation with disturbance model. The colored noise is generated with the aid of a shape filter from a white noise signal. This produces a spectrum of disturbance signals that also contains energy components in the lower frequency ranges of the bandwidth of the closed control loop. Part of the disturbances can therefore be compensated by the PID controller while the high-frequency measurement noise cannot be corrected by any controller.

### Application

After commissioning the controller and ConPerMon block, you should be able to watch the effects of the following actions that demonstrate the potential of control loop monitoring:

- Switch the controller to manual mode:
  The variance of the controlled variable will rise but the `CPI` becomes invalid because no statements can be made about the control fit unless the control loop is closed.
- Change the parameters of the process simulation, for example, change `TimeLag2` from 2s to 8s:
  This deterioration of the dynamic characteristics of the process (for example due to wear and tear) brings about a deterioration of the control quality that becomes visible in the `CPI` value long before it can be seen with the naked eye in the standard `PV` trends. If the control quality drops below a defined level, a `CPI` warning or even an alarm is generated.
- Request a setpoint step change from the controller:
  The `CPI` will become temporarily invalid because all stochastic characteristics of the control quality, such as the variance, are based on the assumption of a steady state with a constant mean value. Select the "Setpoint" view from the drop-down list box in the ConPerMon faceplate to be able to watch the deterministic characteristics such as overshoot and settling ratio. Once a steady state is achieved again at the new setpoint and the entire time window is filled with data from the steady state, the monitoring of the stochastic characteristics is reactivated automatically.

You can find detailed information on the ConPerMon block and notes on interpreting its displays in the online help on the block (Page 841).

## 22.44.5 Feedforward control to compensate a measurable disturbance variable (DisturbCompSim)

### Feedforward control to compensate a measurable disturbance variable

The example is based on the process tag type PID controller with dynamic feedforward control (FfwdDisturbCompensat) (Page 2827) and uses the following parameter sets:

Main controlled system:

$$g(s) = \frac{2}{2s+1} e^{-1.2s}$$

Disturbance transfer function:

$$g_z(s) = \frac{1}{3s+1} e^{-1.6s}$$

- PID: Gain = 0.197
- TI= 1.9
- TD= 0

Feedforward control:

$$c(s) = -\frac{g_z(s)}{g(s)} = -\frac{1}{2} \cdot \frac{2s+1}{3s+1} e^{-0.4s}$$

The same process simulation is set up twice, one instance with disturbance feedforward and the other without (all other process and controller parameters identical). The advantages of the feedforward control can be tested in a direct comparison ("benchmark simulation", "parallel slalom ").

## 22.44.6 Operating point-oriented adaptation of parameters (gain scheduling) for non-linear processes (GainSchedSim)

### Operating point-oriented adaptation of parameters (gain scheduling) for non-linear processes

The example is based on the process tag type PID - control with operating-point-oriented parameter control (GainScheduling) (Page 2825).

In the simulation template, the settings of the two most important process parameters are changed based on polylines depending on the operating point. The process and controller parameters for the example are shown in the following table.

| Operating point | X=PV | ProcSim.Gain | ProcSim.TmLag1 | ProcSim.TmLag2 | Gain | TI | TD |
|---|---|---|---|---|---|---|---|
| 1 | 20 | 4 | 5 | 10 | 0.6 | 14.7 | 3.7 |
| 2 | 100 | 3 | 3 | 10 | 1 | 8.8 | 2.2 |
| 3 | 200 | 2 | 1 | 10 | 10 | 4.1 | 1.1 |

The same process simulation is set up twice, one instance with gain scheduling and the other without (all other process and controller parameters are identical). The advantages of the gain scheduling can be tested in a direct comparison ("benchmark simulation", "parallel slalom").

## 22.44.7 Override control on a pipeline (OverrideSim)

### Override control on a pipeline

The example is based on the process tag type Override control (Page 2846) and uses the following parameter sets:

**Primary process (flow control):**

$$g(s) = \frac{3}{(2s+1)^2}$$

Flow increases when the valve is opened and it disappears when the valve is closed.

**PI flow controller**: Gain= 0.33 , TI= 2.7

**Secondary process (pressure control):**

$$g_p(s) = \frac{-0.8}{(7s+1)(1s+1)}$$

The pressure rises when the valve is opened and is 80 bar when it is fully open.

**PI pressure controller:** Gain= 2.8 , TI= 4

Switching limits 15 bar < pressure < 70 bar.

## 22.44.8 Smith predictor for a dead time system (SmithPredictorSim)

### Smith predicator for a dead time system

The example is based on the process tag type PID controller with Smith predictor (SmithPredictorControl) (Page 2830).

In the example, the same process simulation is set up twice, one instance with Smith predictor and the other without (all other process parameters are identical). The advantages of the Smith predictor can be tested in a direct comparison ("benchmark simulation", "parallel slalom").

## 22.44.9 Filtering of noisy measured values in a control loop (SigSmoothSim)

### Filtering of noisy measured values in a control loop

The example illustrates the use of the Smooth block in a closed control loop. The block can be connected to any signal source without specialist knowledge so there is no need for a special process tag type. The simulation template is useful in testing the effects of a low-pass filter on a closed control loop by simulation. Increasing the filter time constant improves the smoothing effect but also causes a phase lag in the control loop that can have detrimental effects on the control quality and even the stability.

## Parameters used

The following parameters are used in the simulation example:

**Process transfer function:**

$$g(s) = \frac{3}{(15s+1)(2s+1)}$$

with white noise on the output signal.

**PI controller:**

- Gain = 0,5
- TI = 7 s
- Sample time = 0.1s

**Butterworth filter:**

- TimeConstant = 3 s.

At 0.3 seconds, hardly any smoothing effect can be recognized, at 15 seconds significant deterioration of the control quality is already noticeable.

Processes with signals strongly affected by noise are a typical area of application (for example pressure sensors) and sensitive actuators (for example valves).

You can find detailed information on the Smooth block in the online help on the block (Page 2297).

## 22.44.10 Predictive control of a 2x2 multi-variable controlled system (ModPreConSim)

### Predictive control of a 2x2 multi-variable controlled system

The example is based on the process tag type Model-based predictive control (ModPreCon) (Page 2849).

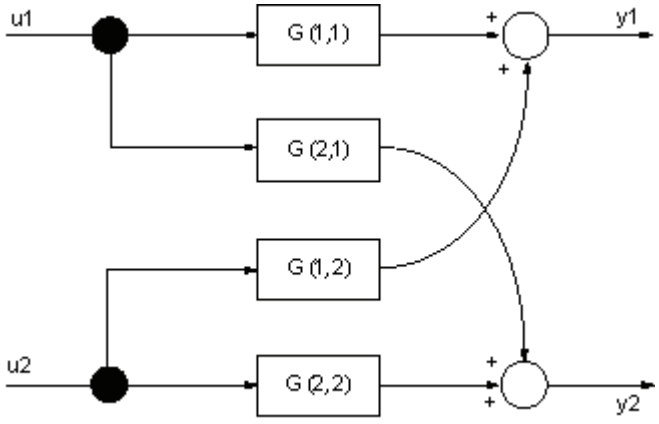

Figure 22-7 MIMO 2x2 process with a p-canonical structure

The example shows the application of the ModPreCon block for simulating a 2x2 multi-variable process consisting of the following four transfer functions:

$$\underline{G}(s) = \begin{bmatrix} G(1,1) & G(1,2) & \cdots & G(1,n_u) \\ G(2,1) & G(2,2) & \cdots & G(2,n_u) \\ \vdots & \vdots & \ddots & \vdots \\ G(n_y,1) & G(n_y,2) & \cdots & G(n_y,n_u) \end{bmatrix} = \begin{bmatrix} \dfrac{3}{(30s+1)(4s+1)} & \dfrac{1.2}{(34s+1)(14s+1)(6s+1)} \\ \dfrac{1.3}{(28s+1)(12s+1)(6s+1)} & \dfrac{4}{(26s+1)(6s+1)} \end{bmatrix}$$

where $n_y$ = 2 = number of controlled variables, $n_u$ = 2 = number of manipulated variables, and $G(i_y, i_u)$ the transfer function from input $i_u$ to output $i_y$. This simplest of multi-variable control systems helps familiarize newcomers with the concept and application of model-based multi-variable controllers.

## 22.44.11 Predictive control of a non-linear process (ModPreConNonLinSim)

### Predictive control of a non-linear process

The example is based on the approach used by multi-model controlling as described in the section ModPreCon functions (Page 976), Controlling linear and non-linear processes.

A multi-variable process is observed with two input variables and two output variables. The non-linear reaction of four partial transfer functions Proc511, Proc512, Proc521 and Proc522 depends on a measurable process value, in this case the controlled variable PV511.

The assumption that all non-linearities of the multi-variable process depend on the current operating point, which is defined by a single measurable variable, restricts the range of application but is reasonable in many practical applications. The approach of the presented multi-model controlling only makes sense with this assumption.

In the example it is assumed that the operating point is defined by a temperature, and the process reaction is different at high temperatures (200° C) than it is at low temperatures (20° C).

Some parameters of the third order partial transfer function

$$Proc(i, j) = \frac{CV(i)}{MV(j)} = \frac{Gain}{(TmLag1 \cdot s + 1) \cdot (TmLag2 \cdot s + 1)(TmLag3 \cdot s + 1)}$$

are set using polylines continually depending on the operating point.

The extreme values of the operating-point-oriented parameters for the example are shown in the following table:

| Operating point | PV511 | Proc511.Gain | Proc511.TmLag2 | Proc521.Gain | Proc512.TmLag2 | Proc522.Gain |
|---|---|---|---|---|---|---|
| 1 | 20 | 4 | 12 | 0,9 | 19 | 3 |
| 2 | 200 | 2 | 2 | 1,7 | 9 | 5 |

The changes of the process parameters are so substantial that a single linear controller cannot achieve enough control performance over the entire operating range. The changes, however, are continual and reproducible, which is an important requirement for the multi-model approach.

All other process parameters are constant:

| | Gain | TmLag1 | TmLag2 | TmLag3 |
|---|---|---|---|---|
| **Proc511** | variable | 30 | variable | 0 |
| **Proc512** | 1,2 | 34 | variable | 6 |
| **Proc521** | variable | 28 | 12 | 6 |
| **Proc522** | variable | 26 | 6 | 0 |

The primary controller TIC511522Low was designed using the MPC Configurator for the low operating point at 20° C, the secondary controller TIC511522High is made for the high operating point at 200° C.

The matching functions for relevance of the two controllers are polylines with four interpolation points at 0, 30, 190 and 300° C. In the range between 0 and 30° C, only the controller designed for 20° C is active; only the controller designed for 200° C is active between 190 and 300° C. The manipulated variables of both controllers overlap between 30 and 190°.

# Definitions

# 23

## 23.1 Batch process

**Batch process**

A batch process is a process control process, which is executed according to a recipe control batch by batch, i.e. intermittently, in a continually repeating sequence, for example, dosing raw material, tempering, performing chemical reactions, cooling, discharging reactors.

## 23.2 Approximation

### Approximation

An approximation method in the mathematical sense.

# 23.3 Prediction horizon

**Prediction horizon**

For predictive controller: Time period running from the present to the future with a defined length. A process reaction is predicted within the prediction horizon.

## 23.4 Trajectory

### Trajectory

In physics: refers to a flight path or track.

In control engineering: course of a variable over time, described by a sequence of values in a specified time scale.

## 23.5 Maverick

### Maverick

A maverick in a continuous physical measurement is a numerical value that changes from one sampling point to another more than would be physically plausible. In other words, the difference between two neighboring values is greater than a specified tolerance range.

# 23.6 Ergodic process

## Ergodic process

An ergodic process in mathematical statistics is a stationary process, in which the expected value can be estimated by generating the mean value over a time period of infinite length.

# 23.7 Conti process

## Conti process

A Conti process is a process control process, whereby raw material is fed in a continual flow, and the products are continually output.

# 23.8 Multivariable controller

## Multivariable controller

With a multivariable controller, one manipulated variable can influence several controlled variables and one controlled variable can be influenced by several manipulated variables, as is shown in the following diagram.

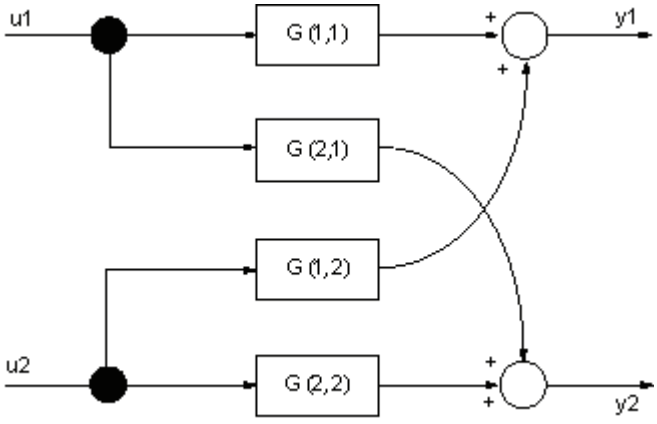

Figure 23-1 Example of a multivariable controller

When a multivariable section is automated using several individual PID controllers, the individual controllers do not take account of the interactions or links in the process. The stronger the links between the sub-sections, the harder it is to set individual controllers and the worse the control performance.

In such cases a multivariable controller offers higher control performance and simpler controller settings.

# 23.9 non-phase minimum

### Non-phase minimum behavior mean

A phase minimum system is described by a linear, time-invariant transfer function, the frequency of which displays the smallest possible clockwise phase rotation for the given number of poles and zeros if the frequency interval is run through from negative to positive in full an infinite number of times. This means that both the transfer function and its inverse are stable.

Non-phase minimum behavior means for example that the process initially deflects downwards when the manipulated variable jumps positively before moving in a positive direction. Dead time systems are also non-phase minimal.
