Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent
damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert
symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are
graded according to the degree of danger.

⚠️ DANGER
indicates that death or severe personal injury will result if proper precautions are not taken.

⚠️ WARNING
indicates that death or severe personal injury may result if proper precautions are not taken.

⚠️ CAUTION
with a safety alert symbol, indicates that minor personal injury can result if proper precautions are not taken.

CAUTION
without a safety alert symbol, indicates that property damage can result if proper precautions are not taken.

NOTICE
indicates that an unintended result or situation can occur if the corresponding information is not taken into
account.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will
be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to
property damage.

Qualified Personnel

The device/system may only be set up and used in conjunction with this documentation. Commissioning and
operation of a device/system may only be performed by qualified personnel. Within the context of the safety notes
in this documentation qualified persons are defined as persons who are authorized to commission, ground and
label devices, systems and circuits in accordance with established safety practices and standards.

Proper use of Siemens products

Note the following:

⚠️ WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical
documentation. If products and components from other manufacturers are used, these must be recommended
or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and
maintenance are required to ensure that the products operate safely and without any problems. The permissible
ambient conditions must be adhered to. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of the Siemens AG. The remaining trademarks in this
publication may be trademarks whose use by third parties for their own purposes could violate the rights of the
owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software
described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the
information in this publication is reviewed regularly and any necessary corrections are included in subsequent
editions.
Preface

Scope

This document is part of the SIMOTION Programming documentation package.

This document is valid for product version V4.1, Service Pack 4 of SIMOTION SCOUT (the engineering system of the SIMOTION product family) in conjunction with:

• a SIMOTION device with the following versions of the SIMOTION kernel:
  – V4.1 SP4
  – V4.1 SP2
  – V4.1 SP1
  – V4.0
  – V3.2
  – V3.1
  – V3.0

• The relevant version of the following SIMOTION Technology Packages, depending on the kernel
  – Cam
  – Path (kernel V4.1 and higher)
  – Cam_ext (kernel V3.2 and higher)
  – TControl
  – Gear, Position and Basic MC (only for kernel V3.0).

This document describes the syntax and implementation of the SIMOTION ST Structured Text programming language for this version of SIMOTION SCOUT. It also includes information on the following topics:

• ST Editor and Compiler with program example
• Data storage and data management on SIMOTION devices
• Options for diagnosis and troubleshooting

The scope of the SIMOTION ST programming language may contain new syntax elements compared to earlier versions. These have only been tested using the current version of the SIMOTION kernel and are released only for this kernel version or higher versions.
Conversion of existing projects to the current SIMOTION SCOUT version

It is possible to upgrade existing projects to the current version of SIMOTION SCOUT and the SIMOTION ST programming language. In some cases, recompilation using the current version of the compiler can change the version identifiers in the data storage areas of the programs, thus resulting in deletion and initialization of all retentive and non-retentive data on the SIMOTION device. In exceptional cases, minor changes to the program source files may also be required.

If new syntax elements of the SIMOTION ST programming language are used on a SIMOTION device with an older version of the SIMOTION Kernel, the compiler outputs warning 16700 (version V3.1 and higher of the SIMOTION Kernel). If these syntax elements are used anyway, the project can be stored in the old project format, but can no longer be converted using the compiler of an older version of SIMOTION SCOUT.

Information in this manual

The following is a list of chapters included in this manual along with a description of the information presented in each chapter.

- **Introduction** (Chapter 1)
- **Getting Started with ST** (Chapter 2)
  Requirements for creating programs and a sample program
- **ST Basics** (Chapter 3)
  Elements of the ST programming language, variable and data type declarations, statements
- **Functions, Function Blocks and Programs** (Chapter 4)
  Programming and call of the program organization units (POU)
- **Integration of ST in SIMOTION SCOUT** (Chapter 5)
  Behavior of variables, access to inputs and outputs, libraries, preprocessor
- **Error Sources and Program Test** (Chapter 6)
  Information on error sources, efficient programming, and program testing
- **Appendices**
  - **Formal Language Description** (Appendix A.1)
  - **Compiler Error Messages and Remedies** (Appendix A.2)
  - **Template for Example Unit** (Appendix A.3)
- **Index**

If you want to get started immediately, begin by working through Chapter 2.
SIMOTION Documentation

An overview of the SIMOTION documentation can be found in a separate list of references. This documentation is included as electronic documentation with the supplied SIMOTION SCOUT.

The SIMOTION documentation consists of 9 documentation packages containing approximately 80 SIMOTION documents and documents on related systems (e.g. SINAMICS).

The following documentation packages are available for SIMOTION V4.1 SP4:

- SIMOTION Engineering System
- SIMOTION System and Function Descriptions
- SIMOTION Service and Diagnostics
- SIMOTION Programming
- SIMOTION Programming - References
- SIMOTION C
- SIMOTION P350
- SIMOTION D4xx
- SIMOTION Supplementary Documentation

Hotline and Internet addresses

Siemens Internet address

The latest information about SIMOTION products, product support, and FAQs can be found on the Internet at:

- General information:
  - http://www.siemens.de/simotion (German)
  - http://www.siemens.com/simotion (international)
- Downloading documentation
- Individually compiling documentation on the basis of Siemens contents with the My Documentation Manager (MDM), refer to http://www.siemens.com/mdm
  My Documentation Manager provides you with a range of features for creating your own documentation.
- FAQs
  You can find information on FAQs (frequently asked questions) by clicking http://support.automation.siemens.com/WW/view/en/10805436/133000.
Additional support
We also offer introductory courses to help you familiarize yourself with SIMOTION.
For more information, please contact your regional Training Center or the main Training Center in 90027 Nuremberg, Germany.
Information about training courses on offer can be found at:
www.sitrain.com

Introducti

In addition to conventional open and closed-loop control tasks, today's automation systems are increasingly required to handle data management functions and complex mathematical calculations. ST (Structured Text) is specially designed for these tasks. Standardized to IEC 61131-3 (German standard DIN EN-61131-3), this programming language makes your job as a programmer easier.

1.1 High-level programming language

ST is a high-level, PASCAL-based programming language. This language is based on the IEC 61131-3 standard, which standardizes programming languages for programmable controllers (PLC). ST is based on the Structured Text part of this standard.

Using a high-level language like ST to program control systems offers the user a wide range of possibilities, for example:

- Data management
- Process optimization
- Mathematical/statistical calculations

1.2 Programming language with technology commands

In addition to IEC 61131-3 compliance, the SIMOTION ST programming language also contains commands for SIMOTION devices, motion control and technology.

Technology objects represent a technological functionality, e.g. positioning an axis or assigning parameters for an output cam. Technology commands are language commands provided by the technology objects. Such commands may be used, for example, to activate camming or to control motion sequences, for example, in order to position an axis.

1.3 Execution levels

The SIMOTION execution system provides different execution levels (cyclic, synchronous, time-controlled, alarm-controlled and sequential) for optimal support of the various tasks involved in creating user programs.

SIMOTION SCOUT is the engineering system of the SIMOTION product family. ST is the high-level language for creating user programs; in ST, you can develop user programs for the various execution levels.

The execution of user programs can be time-driven if you want them to run synchronously with the system clock or a defined time cycle. They can be interrupt-driven if they are to start and run once in response to a particular event. Alternatively, they can run sequentially or cyclically at the round robin execution level.
1.4 **ST editor with tools for writing and testing programs**

An easy-to-use text editor is provided for creating programs.

The ST compiler converts the edited program into executable code and indicates any syntax errors, specifying the program line and the cause of the error.

SIMOTION SCOUT provides test functions for testing ST programs. You can test and visualize your programs online.
This chapter uses a simple example to describe how to write a program, compile it into executable code, run it, and test it.

2.1 Integration of ST in SCOUT

The program environment for ST comprises the following components:

- An **editor** for creating programs, consisting of functions (FC), function blocks (FB), and user-defined data types (UDT), etc.
- A **compiler** for compiling the previously edited ST program into executable machine code
- The **program status** for assisting your search for logical program errors in the running program
- A **detail view**, in which, for example, error messages of the compiler are displayed. An important tab of the detail view is the **Symbol browser**, where you can monitor and change variables.

The individual components are easy to use. They are integrated directly in the SIMOTION SCOUT workbench.

For more information about the operation of the workbench and its tools, refer to the SIMOTION SCOUT Configuration Manual.
Getting Started with ST

2.1 Integration of ST in SCOUT

Figure 2-1 Development environment of ST
2.1.1 Getting to know the elements of the workbench

The workbench represents the framework for SIMOTION SCOUT. Its tools allow you to perform all the steps necessary to configure, optimize and program a machine for your application.

The workbench contains the following elements:

- **Menus**
  
  Menus contain menu commands with which you can control the workbench and call tools, etc.

- **Toolbars**
  
  You can execute many of the available menu commands by clicking the corresponding button in one of the toolbars.

- **Project navigator**
  
  The project navigator displays the entire project and its elements (e.g. CPU, axes, programs, cams) in a tree structure.
Getting Started with ST

2.2 Requirements for program creation

- Work Area
  This window allows you to perform specific tasks either independently (by programming) or using wizards (by configuring).
- Detailed view
  The detail view displays additional information about the elements selected in the project navigator, e.g. all global variables for a program or the Compile/Test Output window.

2.2 Requirements for program creation

This section describes the general conditions you will need to meet before writing a program. You will find detailed information in the SIMOTION SCOUT Configuring Manual and the SIMOTION Motion Control function descriptions.

Add or open a project

The project is the highest level in the data management hierarchy. SIMOTION SCOUT saves all data which belongs, for example, to a production machine, in the project directory. This means that the project therefore brackets together all SIMOTION devices, drives, etc. belonging to one machine.

Once you have created a project, you can:
- Configure hardware
- Insert and configure technology objects

Configuring hardware

Within the project, the hardware used must be made known to the system, including:
- SIMOTION device
- Centralized I/O (with I/O addresses)
- Distributed I/O (with I/O addresses)

A SIMOTION device must be configured before you can insert and edit ST source files.

Insert and configure technology objects

The functionality of axes, output cams, etc. is represented in SIMOTION by technology objects (TOs).

You cannot program technology objects using system functions and access their system variables until you have inserted and configured them.
2.3 Working with the ST editor and the compiler

In this section, you will learn how to use the ST editor and the compiler.

2.3.1 Insert ST source file

ST source files are assigned to the SIMOTION device on which they are to run.

Proceed as follows

1. Open the appropriate SIMOTION device in the project navigator.
2. Select the PROGRAMS folder.
3. Select the menu Insert > Program > ST source file.
4. Enter the name of the ST source file.
   Names for program source files must satisfy the rules for identifiers: They are made up of letters (A … Z, a … z), digits (0 … 9) or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters.
   The permissible length of the name depends on the SIMOTION Kernel version:
   – As of Version V4.1 of the SIMOTION Kernel: maximum 128 characters.
   – Up to Version V4.0 of the SIMOTION Kernel: maximum 8 characters.
   Names must be unique within the SIMOTION device.
   Protected or reserved identifiers (Page 82) are not allowed.
   Existing program sources (e.g. ST source files, MCC units) are displayed.
5. If necessary, select further tabs to make local settings (only valid for this ST source file):
   – Compiler tab: Local settings of the compiler (Page 49) for code generation and message display.
   – Additional settings tab: Definitions for preprocessor (Page 54)
6. Select the Open editor automatically checkbox.
7. Confirm with OK.
Notice

With versions of the SIMOTION Kernel up to V4.0, a violation of the permissible length of the program source file name may not be detected until a consistency check or a download of the program source file is performed!
2.3.2 Opening an existing ST source file

Proceed as follows

1. Open the subtree of the appropriate SIMOTION device in the project navigator.
2. Open the PROGRAMS folder.
3. Select the desired ST source file.
4. Select the Edit > Open object menu command.
5. Only for ST source files with know-how protection:
   - If the user with the login assigned to the ST source file has not yet logged on:
     - Enter the corresponding password for the displayed login.
   You can now open additional ST source files to which the same login is assigned without having to re-enter the password.

Note
You can also double-click the required ST source file to open it.

2.3.3 Changing the properties of an ST source file

Proceed as follows

1. Under the SIMOTION device, open the PROGRAMS folder.
2. Select the desired ST source file.
4. If necessary, select further tabs to make local settings (only valid for this ST source file):
   - General tab: General details for the ST source, e.g. timestamp of the last change and the storage location of the project (see figure).
   - Compiler tab: Local settings of the compiler (Page 49) for code generation and message display.
   - Additional settings tab: Definitions for the preprocessor (Page 54) and display the compiler options (Page 52) as specified for the current settings of the compiler.
   - Compilation tab: Display of the compiler options (Page 52) for the last compilation of the ST source.
   - Object address tab: Set the internal object address of the ST source. The object addresses of the other program sources are displayed.
Changing the name of an ST source file

You can also change the names of the ST source file here. To do this, click the [...] button.

Names for program source files must satisfy the rules for identifiers: They are made up of letters (A … Z, a … z), numbers (0 … 9) or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters.

The permissible length of the name depends on the SIMOTION Kernel version:
- As of Version V4.1 of the SIMOTION Kernel: maximum 128 characters.
- Up to Version V4.0 of the SIMOTION Kernel: maximum 8 characters.

Names must be unique within the SIMOTION device.

Protected or reserved identifiers (Page 82) are not allowed.

Existing program sources (e.g. ST source files, MCC units) are displayed.

<table>
<thead>
<tr>

2.3.4 Working with the ST editor

The ST editor makes it easier for you to work with the ST source file, variables and technology objects through the following operator controls:

- Syntax coloring
- Drag&drop
- Menu commands and shortcuts

![ST source file in the ST editor](image)

See also
Shortcuts (Page 27)

2.3.4.1 Syntax coloring

The ST editor represents language elements in different colors:

- Blue: Keywords and compiler built-in functions
- Magenta: Numbers, values
- Green: Comments
- Black: Technology objects, user code, variables
2.3.4.2 Drag&drop

A drag-and-drop operation (dragging while keeping the left mouse button pressed) enables you to:

- Move selected text areas within an ST source file or to another opened ST source file.
- Copy names of variables from the symbol browser to the ST source file.
- Copy names (e.g. of technology objects, functions or function blocks) from the project navigator to the ST source file.
- Copy system functions from the command library to the ST source file.

To copy names of variables from the symbol browser to the ST source file:
1. Select the entire line of the desired variable in the symbol browser. To do this, click the line number at the start of the line.
2. Press the left mouse button and drag the line number to the desired position in the ST source file.
   The name of the selected variable is inserted in the ST source file.

To copy the name of an element (e.g. a technology object, a function or a function block) from the project navigator to the ST source file:
1. Select the Project tab in the project navigator.
2. Select the element in the project navigator.
3. Press the left mouse button and drag the element to the desired position in the ST source file.
   The name of the selected element is inserted in the ST source file.

To copy a system function from the command library to the ST source file:
1. Select the Command Library tab in the project navigator.
2. Select the system function in the command library.
3. Press the left mouse button and drag the system function to the desired position in the ST source file.
   The system function is inserted in the ST source file with its parameters.
2.3.4.3 Shortcuts

The ST editor also provides keyboard shortcuts. Some commands can also be called via the **Edit** or **ST editor** menus:

Table 2-1 ST Editor keyboard shortcuts

2.3.4.4 Settings of the ST editor

Proceed as follows:

1. Select the menu Tools > Settings.
2. Select the ST editor / Scripting tab.
3. Enter the settings.
4. Click OK or Accept to confirm.

Figure 2-6 ST Editor / Scripting

The settings also apply to the script editor.
The table below contains a description of the individual parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Additional Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display line numbering</td>
<td>If active, the line numbers are displayed.</td>
<td>See: Other ST editor tools (Page 44).</td>

</tbody>
</table>
2.3 Working with the ST editor and the compiler

2.3.4.5 Indentations and tabs

Specify tab width
The standard tab width for all ST sources is specified in the settings of the ST editor (Page 30).
This setting is used for all ST source files opened subsequently.

Indent using tabs or spaces
You can select in the settings of the ST editor (Page 30) how the text will be indented (e.g. with the automatic indent and outdent when the Tab key is pressed):
- By adding the appropriate number of space characters ($20).
- By adding the tab character ($09).
This setting is used for all ST source files opened subsequently.

Automatically indent and outdent blocks
The ST editor recognizes blocks introduced with a keyword and terminated with another keyword, e.g.:
- INTERFACE / END_INTERFACE
- IMPLEMENTATION / END_IMPLEMENTATION
- Declaration blocks (e.g. TYPE / END_TYPE, VAR / END_VAR)
- Program organization units (e.g. PROGRAM / END_PROGRAM)
- Control statements (e.g. IF / END_IF, FOR / END_FOR)
During the text input, the ST editor can automatically indent text within blocks by the tab size. The end line of the block will be outdented automatically.
This function is activated in the settings of the ST editor (Page 30).

Note
This setting affects only the behavior during the text input. It does not have any effect on existing text in the ST sources.
Format selection

You can use this function to force the blocks (see above) in an existing text to be indented by the tab size in accordance with their hierarchy. The number of the leading spaces or tabs will be changed:

- As specified by the current tab size of the ST source file.
- As specified by the current setting for the type of the indent (with tabs or spaces).

Follow these steps:

1. Select the text area in the ST editor that you want to format (see Select text (Page 39)).
2. Press the `CTRL+SHIFT+F8` key combination.

 NOTICE

Leading tabs or spaces will be replaced in a line only when the formatting changes their number.

Display indentation level

You can optically highlight the indent and outdent for blocks using vertical help lines (in accordance with the set tab size).

![ST source with visible indent aid](image)

Figure 2-7  ST source with visible indent aid
You can activate or deactivate this function:

- For the active ST source
  - Press the CTRL+ALT+I key combination.
- For all open ST sources:
  - Activate or deactivate the Display indentation level checkbox in the ST editor settings (Page 30).

2.3.4.6 Folds (show and hide blocks)

You can hide blocks in an ST source file so that only the first line of the block remains visible. This increases the legibility during the editing or reading of an ST source file.

A block is introduced with a keyword and terminated with another keyword, e.g.:

- INTERFACE / END_INTERFACE
- IMPLEMENTATION / END_IMPLEMENTATION
- Declaration blocks (e.g. TYPE / END_TYPE, VAR / END_VAR)
- Program organization units (e.g. PROGRAM / END_PROGRAM)
- Control statements (e.g. IF / END_IF, FOR / END_FOR)
- Block comment (* / *)

How to recognize that a block is displayed:

- When the column is shown with the fold information (at the left-hand side next to the editing area), a minus character appears next to the first line of the block.

How to recognize that a block is hidden:

- When the column is shown with the fold information (at the left-hand side next to the editing area), a plus character appears next to the first line of the block.
- A hyphen is displayed below this line.
2.3 Working with the ST editor and the compiler

Figure 2-8  ST source for which all blocks are shown

```
INTERFACE
VAR_GLOBAL
  counterVar : INT := 1; // counter variable
  outputVar : BYTE := 1; // auxiliary tag
END_VAR
PROGRAM Flash;
END_INTERFACE

IMPLEMENTATION
PROGRAM Flash
  IF counterVar := 500 THEN // in every 500th pass
    outputVar := outputVar * 10; // set output byte
  END_IF;
  IF counterVar := 0 THEN // reset counter
    counterVar := counterVar + 1; // increment counter
END_PROGRAM
END_IMPLEMENTATION
```

Figure 2-9  ST source with hidden IF block (including block comment)

```
INTERFACE
VAR_GLOBAL
  counterVar : INT := 1; // counter variable
  outputVar : BYTE := 1; // auxiliary tag
END_VAR
PROGRAM Flash;
END_INTERFACE

IMPLEMENTATION
PROGRAM Flash
  IF counterVar := 500 THEN // in every 500th pass
    outputVar := outputVar * 10; // set output byte
  END_IF;
  IF counterVar := counterVar + 1; // increment counter
END_PROGRAM
END_IMPLEMENTATION
```
Proceed as follows:

How to show or hide the column with the fold information (at the left-hand side of the editing area):

- For the active ST source file:
  - Press the **CTRL+ALT+F** key combination.

- For all open ST sources:
  - Activate or deactivate the **Folding active** checkbox in the settings of the ST editor (Page 30).

How to show or hide blocks (the column containing the folding information must be shown):

- Hide an individual block (options):
  - Click on the **minus** character in the column with the fold information.
  - Position the cursor on the corresponding line of the block and press the **CTRL+ALT+T** shortcut.

  Only the first line of the block remains visible. All subsequent lines of the block (including lines of subordinate blocks) will be hidden.

  The show/hide status of the subordinate blocks is saved. This is reinstated when individual blocks are shown.

- Show an individual block (options):
  - Click on the **plus** character in the column with the fold information.
  - Position the cursor on the visible line of the block and press the **CTRL+ALT+T** shortcut.

  All subsequent lines of the block will be shown. Subordinate blocks are shown as follows:

  If the show/hide status has been saved (when hiding individual blocks, for example), this will be reinstated.

- Hide all blocks:
  - Press the **CTRL+ALT+C** shortcut.

  All the blocks in the ST source file (including all the subordinate blocks) will be hidden. In each case, only the first line of the 1st-level blocks remain visible (usually INTERFACE and IMPLEMENTATION).

- Show all blocks:
  - Press the **CTRL+ALT+D** shortcut.

  All the blocks in the ST source file (including all the subordinate blocks) will be shown. All the lines in the ST source file will be visible.
• Hide subordinate blocks:
  – Position the cursor on the corresponding line of the block and press the **CTRL+ALT+V** shortcut.

All the subordinate blocks for the current block will be hidden and the current block itself will be shown. Only the lines of the current block and the first lines of the blocks on the next level will be visible.

• Show subordinate blocks:
  – Position the cursor on the corresponding line of the block and press the **CTRL+ALT+R** shortcut.

The current block and all subordinate blocks will be shown. All the lines of these blocks will be visible.

---

Note
After opening an ST source in the editor, all lines of the ST source are visible. All blocks are shown.

### 2.3.4.7 Display spaces and tabs

You can display spaces and tabs in the ST source files.

![ST source file with visible spaces and tabs](image)

Figure 2-10  ST source file with visible spaces and tabs
Proceed as follows

How to specify whether spaces and tabs are displayed in the active ST source file:
1. Set the cursor in the opened ST source.
2. Press the CTRL+ALT+W key combination.

This setting is not saved when the ST source is closed.

2.3.4.8 Changing the font size in the ST editor

You can change the font size of the ST source in the editor. The font size of the line numbers and the size of other display elements (e.g. fold marks, bookmarks) will also be changed.

![Figure 2-11 Increased size display of the ST source](image)

Proceed as follows

You can change the font size:
- For the current ST source
- For ST source files to be opened subsequently

How to change the font size for the current ST source (alternative):
- Press the CTRL key while moving the mouse wheel
- Press concurrently the CTRL key and one of the following keys on the numeric block:
  - ADD (+) to increase,
  - MINUS (-) to reduce,
  - DIV for 100%.
How to change the font size for ST sources to be opened subsequently:

1. Open the settings for the ST editor (see Settings of the ST editor (Page 30)).
2. Enter the required font size.

This setting will used for all ST sources that will be opened subsequently. It does not affect the currently opened ST sources.

2.3.4.9 Select text

Selecting lines of text

How to select lines of text:

- With the mouse:
  - With pressed left mouse button, scan the text to be selected.
  or

- With the keyboard or the mouse:
  - Place the cursor with the arrow keys of the keyboard or with the mouse at the start of the text to be selected.
  - Press the Shift key while placing the cursor at the end of the text to be selected.

Please also refer to the keyboard shortcuts (Page 27).

![ST source with selected lines of text](image)
Selecting columns of text

How to select columns of text:

- With the mouse:
  - Press the **Alt** key while keeping the left mouse button pressed, scan the text to be selected.

or

- With the keyboard or the mouse:
  - Place the cursor with the arrow keys of the keyboard or with the mouse at the start of the text to be selected.
  - Press the **ALT+SHIFT** key combination while placing the cursor at the end of the text to be selected. Please also refer to the keyboard shortcuts (Page 27).

![ST source with selected columns of text](image)

Selecting a single line

How to select a single line:

- Click with the left mouse button next to the line number of the appropriate line.

Selecting the complete text

How to select the complete text (alternatives):

- Press the **CTRL** key while clicking with the left mouse button in the column with the line numbers.
- Press the **CTRL+A** key combination.
2.3.4.10 Use bookmarks

You can set bookmarks in the ST editor. This allows you to jump to specific selected lines within the ST source file.

![ST source with bookmarks](image)

Figure 2-14 ST source with bookmarks

Setting and deleting bookmarks

How to set a bookmark for a line of the active ST source file or to delete an existing bookmark:

- With the keyboard and the mouse:
  - Press the Ctrl key.
  - Simultaneously, click with the left mouse button at the right-hand side next to the line number of the appropriate line.

- With the keyboard:
  - Set the cursor in the appropriate line of the ST source.
  - Press the CTRL+F2 key combination.

NOTICE

Bookmarks are not saved when the ST source is closed.
Jump to bookmark
How to jump to the next bookmark within the ST source:
● Press the F2 key.

How to jump to the previous bookmark within the ST source:
● Press the SHIFT+F2 key combination.

Delete all bookmarks
How to delete all bookmarks in an ST source:
● Press the CTRL+SHIFT+F2 key combination.

2.3.4.11 Automatic completion
In the ST editor, you can automatically complete identifiers. A selection list with identifiers that begin with the previously entered characters will be displayed.

![ST editor, automatic completion of an identifier (e.g. END_)](image)
Proceed as follows

How to automatically complete an identifier:

1. Write the first characters of the identifier (e.g. the letters of a word).
2. Press the Ctrl+space key combination.
   The selection possibilities are displayed in a window.
3. Select the required identifier.

Note

If only a single identifier is offered for selection, the selection window will not be opened and the identifier completed immediately.

Functional description

The following identifiers that begin with the specified character will be offered:

- Keywords of the Structured Text language
- Identifiers from the command library
- For technology objects including their system variables and configuration data
- Identifiers of the own ST source:
  - Program organization units (POU)
  - Data types
  - Variables and constants
  - Structure elements
- Identifiers from imported program sources

Note

Identifiers from the own ST source and from imported program sources will be displayed correctly only when the corresponding program source has been compiled.

The display is made context-sensitive, only those types of identifiers that are appropriate at the associated location of the ST source will be offered:

- Within a declaration block, only data types and keywords
- Within a program organization unit (POU), no data types
- For a structure (e.g. var_struct.xx), only structure components
2.3.4.12 Other help for the ST editor

Display bracket pairs

The two brackets of a bracket-pair can be optically highlighted. To do this, place the cursor next to a bracket. The editor attempts to find the associated brackets of the pair and possibly displays both brackets red. This simplifies the recognition of bracket pairs, in particular for nesting.

How to switch this function on or off:

- For the active ST source file:
  - Press the CTRL+SHIFT+B key combination.
- For all open ST sources:
  - Activate or deactivate the Display bracket pairs checkbox in the ST editor settings (Page 30).

This setting is also used for all ST source files opened subsequently.

Show and hide line numbers

Line numbers can be displayed in the ST editor:

How to switch this function on or off:

- For the active ST source file:
  - Press the CTRL+ALT+L key combination.
- For all open ST sources:
  - Activate or deactivate the Display line numbers checkbox in the ST editor settings (Page 30).

This setting is also used for all ST source files opened subsequently.

2.3.4.13 Using the command library

The command library is a tab in the project navigator. It contains the available system functions, system function blocks, and operators.

You can drag these elements from the command library to the ST editor window with drag&drop.
2.3.4.14 ST editor toolbar

This toolbar contains important operating actions for programming:

Table 2-4 ST editor toolbar

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| ![Program status](icon) | Program status  
Click this icon to start the **program status** test mode. During the program execution, you can monitor the values of the variables marked in the ST source.  
The following prerequisites are necessary:  
1. The program must be compiled with the appropriate compiler option.  
2. The project and the program must be loaded into the target system.  
3. An online connection to the target system must have been established.  
Reclick this icon to end the **program status**.  
See: Using the program status (Page 291). |
| ![Stop monitoring](icon) | Stop monitoring of the program variables  
Click this icon in the **program status** test mode to stop the monitoring of the program variables.  
See: Using the program status (Page 291). |
| ![Continue monitoring](icon) | Continue monitoring of the program variables  
Click this icon in the **program status** test mode to continue the monitoring of the program variables.  
See: Using the program status (Page 291). |
| ![Refresh](icon) | Refresh  
Click this symbol in the **program status** test mode to force updating of the values displayed. The monitoring of the program variables must have been activated.  
See: Using the program status (Page 291). |
| ![Insert ST source file](icon) | Insert ST source file  
Click this icon to create a new ST source file. The icon is active only when the PROGRAMS folder where the ST source file is to be saved is selected in the project navigator.  
See: Insert ST source file (Page 21). |
| ![Accept and compile](icon) | Accept and compile  
Click this icon to transfer the current ST source file to the project and compile into executable code.  
See: Starting the compiler (Page 46). |
2.3.5 Starting the compiler

Requirement
The ST source file has been opened with the ST editor.

Proceed as follows
1. Click in the window with the ST editor. The dynamic ST source file menu appears.
2. Select the ST source file > Accept and compile menu command.

Note
The ST source file menu is dynamic. It only appears if the window of the ST editor is active.

The compiler checks the syntax of the ST source file. The "Compile/check output" tab of the detail view displays the successful compilation of the source text or compiler errors. The error details include: The name of the ST source file, the number of the line in which the error occurred, the error number and the error description.

2.3.5.1 Help for the error correction
To obtain help during error correction:

- Double-click the error message in the Compile/check output tab of the detail view.

The cursor is placed at the relevant line in the ST source file.
2.3.6 Making settings for the compiler

You can define the compiler settings (compiler options) as follows:

- Globally for the SIMOTION project, valid for all programming languages, see Global settings of the compiler (Page 47)
- Locally for an individual ST source within the SIMOTION project, see Local settings of the compiler (Page 49)

2.3.6.1 Global compiler settings

The global setting are valid for all programming languages within the SIMOTION project.

Proceed as follows

1. Select the menu **Tools > Settings**.
2. Select the **Compiler** tab.
3. Define the settings according to the following table.
4. Confirm with **OK**.

![Global compiler settings](image)
Parameter

Table 2-5 Parameters for global compiler settings

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning classes¹</td>
<td>In addition to error messages, the compiler can output warnings and information. You can set the scope of the output warning messages:</td>
</tr>
<tr>
<td></td>
<td><strong>Active</strong>: The compiler outputs warnings and information for the selected class.</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong>: The compiler suppresses warnings and information for the respective class.</td>
</tr>
<tr>
<td></td>
<td>See also For meanings of the warning classes (Page 52).</td>
</tr>
<tr>
<td>Selective linking¹</td>
<td><strong>Active</strong> (standard): Unused code is removed from the executable program.</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong>: Unused code is retained in the executable program.</td>
</tr>
<tr>
<td>Use preprocessor¹</td>
<td><strong>Active</strong>: Preprocessor is used (see Control preprocessor (Page 267)).</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong> (standard): Preprocessor is not used.</td>
</tr>
<tr>
<td>Enable program status¹</td>
<td><strong>Active</strong>: Additional program code is generated to enable monitoring of program variables (including local variables).</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong> (standard): Program status not possible.</td>
</tr>
<tr>
<td></td>
<td>See Properties of the program status (Page 289).</td>
</tr>
<tr>
<td>Permit language extensions¹</td>
<td><strong>Active</strong>: Language elements are permitted that do not comply with IEC 61131-3.</td>
</tr>
<tr>
<td></td>
<td>• Direct bit access to variables of a bit data type (Page 128)</td>
</tr>
<tr>
<td></td>
<td>• Accessing the input parameter of a function block while outside the function block (Page 173)</td>
</tr>
<tr>
<td></td>
<td>• Calling a program while in a different program (Page 179)</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong> (standard): Only language elements that comply with IEC 61131-3 are permitted.</td>
</tr>
<tr>
<td>Only create program instance data once¹</td>
<td><strong>Active</strong>: The local variables of a program are only stored once in the user memory of the unit. This setting is required for calling a program while inside a different program (Page 179).</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong> (standard): The local variables of a program are stored according to the task assignment in the user memory of the respective task.</td>
</tr>
<tr>
<td></td>
<td>See Memory ranges of the variable types (Page 212).</td>
</tr>
<tr>
<td>Display all messages with Save and compile all²</td>
<td>Here, you can control the scope of the error log that will be displayed in the workbench's detail view when you call the Save and compile all command in SIMOTION SCOUT.</td>
</tr>
<tr>
<td></td>
<td><strong>Active</strong>: A detailed log is created that is similar to that for single compilation of an ST source file.</td>
</tr>
<tr>
<td></td>
<td><strong>Inactive</strong>: A compressed error log is created.</td>
</tr>
</tbody>
</table>

¹ Local setting also possible, see Local settings of the compiler (Page 49). Please also refer to the description of the effectiveness of global or local compiler settings (Page 51).

² User-specific settings. Valid for all SIMOTION projects that the user processes.

NOTICE

You may have to recompile the project for the settings to take effect.
2.3.6.2 Local compiler settings

Local settings are configured individually for each ST source file; local settings overwrite global settings.

Proceed as follows

1. Open the Properties window for the ST source file, see Changing the properties of an ST source (Page 23):
   Select the ST source file in the project navigator and select the Edit > Object properties menu command.
2. Select the Compiler tab.
3. Define the settings according to the following table.
4. Confirm with OK.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore global settings</td>
<td>see the description under &quot;Effectiveness of global or local compiler settings (Page 51)&quot;.</td>
</tr>
<tr>
<td>Suppress warnings</td>
<td>In addition to error messages, the compiler can output warnings and information. You can set the scope of the warning messages to be output: <strong>Active</strong>: The compiler suppresses all warnings and information concerning this source. The checkboxes for the warning classes can no longer be selected and show as activated against a gray background. <strong>Inactive</strong>: The compiler outputs the warnings and information according to the warning class selection that follows.</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Warning classes**¹              | Only for Suppress warnings = inactive.  
  **Active**: The compiler outputs warnings and information for the selected class.  
  **Inactive**: The compiler suppresses warnings and information for the respective class.  
  **Grey background**: The displayed global setting is adopted (only for Ignore global settings = inactive).  
  See also For meanings of the warning classes (Page 52).  
  **Note**: If "Suppress warnings" is active, the checkboxes can no longer be selected and show as activated against a gray background. |
| **Selective linking**¹            | **Active**: Unused code is removed from the executable program.  
  **Inactive**: Unused code is retained in the executable program.  
  **Grey background**: The displayed global setting is adopted (only for Ignore global settings = inactive). |
| **Use preprocessor**¹            | **Active**: Preprocessor is used.  
  **Inactive**: Preprocessor is not used.  
  **Grey background**: The displayed global setting is adopted (only for Ignore global settings = inactive).  
  See Controlling the preprocessor (Page 267). |
| **Enable program status**¹        | **Active**: Additional program code is generated to enable monitoring of program variables (including local variables).  
  **Inactive**: Program status not possible.  
  **Grey background**: The displayed global setting is adopted (only for Ignore global settings = inactive).  
  See Properties of the program status (Page 289). |
| **Permit language extensions**¹   | **Active**: Language elements are permitted that do not comply with IEC 61131-3.  
  • Direct bit access to variables of a bit data type (Page 128)  
  • Accessing the input parameter of a function block when outside the function block (Page 173)  
  • Calling a program while in a different program (Page 179)  
  **Inactive**: Only language elements are permitted that comply with IEC 61131-3.  
  **Grey background**: The displayed global setting is adopted (only for Ignore global settings = inactive). |
| **Only create program instance data once**¹ | **Active**: The local variables of a program are only stored once in the user memory of the unit. This setting is required for calling a program while inside a different program (Page 179).  
  **Inactive**: The local variables of a program are stored according to the task assignment in the user memory of the respective task.  
  **Grey background**: The displayed global setting is adopted (only for Ignore global settings = inactive).  
  See Memory ranges of the variable types (Page 212). |
| **Enable OPC-XML**                | **Active**: Symbol information for the unit variables of the ST source is available in the SIMOTION device (required for the _exportUnitDataSet and _importUnitDataSet functions, see the SIMOTION Basic Functions Function Manual.  
  **Inactive**: Symbol information is not created. |

¹ Global setting also possible, see Global settings of the compiler (Page 47). Please also refer to the description of the effectiveness of global or local compiler settings (Page 51).
2.3.6.3  Effectiveness of global or local compiler settings

You can control the effectiveness of global and local settings in the "Ignore global settings" parameter of the local compiler settings (Page 49). The selected setting applies to all of the following parameters:

- Warning classes
- Selective linking
- Use preprocessor
- Enable program status
- Permit language extensions
- Only create program instance data once
- Permit single step (only in MCC programming language)

The following setting can be made for "Ignore global settings".

- **Active:**
  
  Only the local settings selected apply to all the parameters referred to above. The global settings are ignored.

  The following statuses can be selected for individual parameters:
  
  - Check mark against a white background: "Active" local setting applies
  - White background only: "Inactive" local setting applies

- **Inactive:**
  
  The global setting can also be adopted for all the parameters referred to above.

  The following statuses can be selected for individual parameters:
  
  - Check mark against a white background: "Active" local setting applies
  - White background only: "Inactive" local setting applies
  - Gray background: The global setting displayed is adopted.

  Check mark against a gray background: "Active" global setting applies
  
  Gray background only: "Inactive" global setting applies

---

**NOTICE**

If you uncheck "Ignore global settings", the global settings of the parameters concerned will not become effective automatically. You can recognize this setting from the fact that the checkboxes still have a white background.

A parameter's global setting will only be adopted and become effective if you have specifically selected the gray background for the respective parameter's checkbox.

---

**Note**

You can check the current compiler options which will be effective the next time the program source is compiled.

- To do this, select the "Additional settings" tab (Page 52) in the Properties window of the program source.
### 2.3.6.4 Meaning of warning classes

The table lists the warning classes and their meanings.

<table>
<thead>
<tr>
<th>Warning class</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Warnings for unreferenced or unused code sections and data</td>
</tr>
<tr>
<td>1</td>
<td>Warnings for hidden identifiers</td>
</tr>
<tr>
<td>2</td>
<td>Warnings for data type conversion, e.g. for data change</td>
</tr>
<tr>
<td>3</td>
<td>Warnings about set compiler options</td>
</tr>
<tr>
<td>4</td>
<td>Warnings about semaphores (potentially faulty functions)</td>
</tr>
<tr>
<td>5</td>
<td>Warnings about alarm functions</td>
</tr>
<tr>
<td>6</td>
<td>Warnings about constructs in libraries (unit variables declared)</td>
</tr>
<tr>
<td>7</td>
<td>Messages of the preprocessor</td>
</tr>
</tbody>
</table>

The detailed description of the compiler error messages specifies which warning classes are assigned to the individual warnings (16001 - 16700) (Page 388) and information (32010 - 32653) (Page 393).

### 2.3.6.5 Display of the compiler options

You can view for a program source the following:

- The current compiler options using the global or local settings of the compiler.
- The compiler options used for the last compilation of the program source.

#### Requirement

The Properties window of the program source (Page 23) is open.

#### Proceed as follows

To display the current compiler options using the global or local settings of the compiler (Page 47):

- Select the **Additional settings** tab.

  The current compiler options for the program source are displayed. They are valid for a future compilation.

To display the compiler options used for the last compilation of the program source:

- Select the **Compiler** tab.

  The following are displayed for the last compilation of the program source:
  - The version of the used compiler.
  - The used compiler options.
### Meaning of the compiler options

<table>
<thead>
<tr>
<th>Compiler option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c²</td>
<td>Do not create debug and symbol information.</td>
</tr>
<tr>
<td>-C lang_ext</td>
<td>&quot;Permit language extensions&quot;¹ active.</td>
</tr>
<tr>
<td>-C lang_iec</td>
<td>&quot;Permit language extensions&quot; inactive.</td>
</tr>

<td>&quot;Enable program status&quot; inactive.</td>
</tr>
<tr>
<td>-w no_warn</td>
<td>&quot;Suppress warnings&quot;¹ active.</td>
</tr>
<tr>
<td>-w all_warn</td>
<td>Display all warnings.</td>
</tr>
<tr>
<td>-w n_off</td>
<td>Warning class n active¹.</td>
</tr>
<tr>
<td>-w n_on</td>
<td>Warning class n inactive¹.</td>
</tr>
</tbody>
</table>

Further options Internal options of the SIMOTION compiler.

¹ Meaning of the compiler option: see "Local compiler settings (Page 49)".

² Only when the compiler is called from the command line, e.g. using scripting.

---

**Note**

The compiler options can also be specified when the compiler is called from the command line, e.g. using scripting.
2.3.7 **Know-how protection for ST source files**

You can protect ST source files from access by unauthorized third parties. Protected ST source files can only be opened or exported as plain text files by entering a password.

The SIMOTION online help provides additional information on know-how protection.

**Note**

If you export in XML format, the ST source files are exported in an encrypted form. When importing the encrypted XML files, the know-how protection, including login and password, remains in place.

See also

Know-how protection for libraries (Page 250)

2.3.8 **Making preprocessor definitions**

You can make definitions for the preprocessor (see Control preprocessor (Page 267)) in the Properties dialog box of the ST source file. This enables you also to control the preprocessor with ST source files with know-how protection (see Know-how protection for ST sources (Page 54)).

**Making preprocessor definitions in the Properties dialog box**

1. Open the Properties window for the ST source file (see Changing the properties of an ST source (Page 23)):

   Select the ST source file in the project navigator and select the **Edit > Object properties** menu command.

2. Select the **Additional settings** tab.

3. Enter the preprocessor definitions (syntax as shown in the following table).

4. Confirm with **OK**.
### Table 2-8 Syntax of the preprocessor definitions

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifier=text</td>
<td>The specified identifier is defined and replaced in the ST source file by the specified text.</td>
</tr>
<tr>
<td>'Identifier=text'</td>
<td>Permissible characters: See table footnote.</td>
</tr>
<tr>
<td>&quot;Identifier=text&quot;</td>
<td>If the expression contains blanks (e.g. in the text), the syntax &quot;Identifier=text&quot; must be used.</td>
</tr>
<tr>
<td>Identifier</td>
<td>The specified identifier is defined and replaced in the ST source file by blank text.</td>
</tr>
<tr>
<td></td>
<td>Permissible characters: See table footnote.</td>
</tr>
</tbody>
</table>

Multiple preprocessor definitions are separated by commas: `Definition_1, Definition_2, ...`

Permissible characters:
- For `identifier`: In accordance with the rules for identifiers: Series of letters (A … Z, a … z), digits (0 … 9) or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters.
- For `text`: Sequence of any characters other than \ (backslash), ' (single quote) and " (double quote). The keywords USES, USELIB and USEPACKAGE are not permitted.

---

**Note**

Preprocessor definitions made within an ST source file with pragmas, overwrite the definitions in the Properties dialog box.

Note the information for preprocessor statement (Page 268)!
2.3.9 Exporting, importing and printing an ST source file

An overview is provided here of the export, import and printing of an ST source file.

2.3.9.1 Exporting an ST source file as a text file (ASCII)

To export an ST source file as an ASCII file:

1. Open the ST source file (Page 23), entering the password if necessary (for ST source files with know-how protection (Page 54)).
2. Make sure that the cursor is in the ST editor.
3. Select the ST source file > Export menu command.
4. Enter the path and file name for the ASCII file and click Save to confirm.

The ST source file is saved as an ASCII file; the file name is given the default extension *.st.

Alternatively, you can also proceed as follows:

1. Select the ST source file in the project navigator.
2. Select Export from the context menu.
3. Only for ST source files with know-how protection (Page 54):
   - Enter the corresponding password for the displayed login.
   - You can now export or open additional ST source files to which the same login is assigned, without having to re-enter the password.
4. Enter the path and file name for the ASCII file and click Save to confirm.

2.3.9.2 Exporting an ST source file in XML format

Follow these steps to export an ST source file in XML format:

1. Select the ST source file in the project navigator.
2. Select the context menu Expert > Save project and export object.
3. Specify the path for the XML export, and confirm with OK.

An XML file with the ST source file name and a folder with additional associated XML files are saved in the specified path.

Note

Know-how-protected ST source files can also be exported in XML format. The ST source files are exported encrypted. When importing the encrypted XML files, the know-how protection, including login and password, remains in place.
2.3.9.3 Importing a text file (ASCII) as an ST source file

To import an ASCII file as an ST source file:

1. Select the PROGRAMS folder under the appropriate SIMOTION device in the project navigator.
2. Select the menu Insert > External source > ST source file.
3. Select the ASCII file to be imported, and click Open to confirm.

The dialog box for inserting an ST source file is displayed.
4. Enter the name of the ST source file and select the additional options (see Insert ST source file (Page 21)).

The ASCII file is incorporated into the current project directory as an ST source file and can be opened.

2.3.9.4 Importing XML data into ST source files

Follow these steps to import XML data into an ST source file:

1. If applicable, insert a new ST source file (see Insert ST source file (Page 21)).
2. Select the ST source file in the project navigator.
3. Select the context menu Expert > Import object.
4. Select the XML data to be imported.

The imported XML data overwrites existing data in the selected ST source file. The entire project is saved and recompiled.

Alternative:

1. In the project navigator, select the PROGRAMS folder.
2. In the context menu, select Import object.
3. Select the XML data to be imported.

A new ST source file is created, and the XML data is imported. This ST source file is assigned the name which is saved in the XML data; if a naming conflict occurs, it is automatically renamed. The entire project is saved and recompiled.

Note

Note that if the XML data to be imported was exported from an ST source file that was know-how protected, the know-how protection, including login and password, remains in place while importing the encrypted XML data.
2.3.9.5 Printing an ST source file

To print an ST source file:
1. Open the ST source file.
2. Make sure that the cursor is in the ST editor.
3. Select the menu Project > Print.

The program is printed with the name and date.

2.3.10 Using an external editor

What external editors can be used?

As an alternative to the default ST editor, you can use any other ASCII editor that supports the following function:

- External programs (for example, compiler) can be called and run on the active window.

In addition, the editor should be capable of highlighting certain text passages of the ST source file in color (syntax coloring).

Note

If you use an external editor, the dynamic ST source file menu and its entries are not available. The corresponding toolbar is also inactive.

It must be possible to start compilation of the ST source file from the external editor.

Status Program continues with the ST editor.
Settings for the use of an external editor

The settings are made in the SCOUT workbench:

1. Select the menu **Tools > Settings**.
2. Select the **ST external editor** tab (see figure).
3. Activate the **Use external ST editor** checkbox.
4. Enter the path of the external editor:
   - Click **Browse...** and select the path and file name of the editor.

![Settings for the use of an external editor](image)

Figure 2-19 Settings for the use of an external editor

Making settings in the external editor

The following notes are of a general nature. Compare the operator instructions of the external editor.

1. Configure the path to the ST compiler in the external editor. The compiler is located in the STEP7 installation directory `s7bin\u7wstcax.exe`.
2. Syntax files are supplied for various editors. These enable the editor to highlight text passages in color (syntax coloring). Copy the syntax file to the relevant directory and configure the editor accordingly.

Note the following when using an external editor:

> **CAUTION**

Close all windows of the external editor before you close a project or exit SIMOTION SCOUT. Failure to do so could result in loss of data!
2.3 Working with the ST editor and the compiler

2.3.11 ST source file menus

2.3.11.1 ST source file menu

Depending on the active application/editor or the mode (ONLINE/OFFLINE), certain commands are not displayed or cannot be selected. The menu is only displayed if the ST editor is active in the working area.

You can select the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning/Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close</td>
<td>Select this command to close the active ST source file. In the event of changes, you can decide whether you want to transfer the changed source file to the project.</td>
</tr>
<tr>
<td>Properties</td>
<td>Select this command to display the properties of the active ST source file. Several tabs are provided to make local settings for this source. See: Changing the properties of an ST source file (Page 23).</td>
</tr>
<tr>
<td>Accept and compile</td>
<td>Choose this command to transfer the current ST source file to the project and compile into executable code. See: Starting the compiler (Page 46).</td>
</tr>
<tr>
<td>Use preprocessor</td>
<td>As an option, the preprocessor scans an ST source file before compiling and can, for example, replace character strings in the file, which will then be taken into account during the compilation. You can specifically execute the preprocessor statements with this menu command.</td>
</tr>
<tr>
<td>Export</td>
<td>Select this command to export the active ST source file as text file (ASCII). See: Exporting an ST source file as a text file (ASCII) (Page 56).</td>
</tr>
</tbody>
</table>
| Program status On/Off  | Select this command to start the program status test mode. During the program execution, you can monitor the values of the variables marked in the ST source. The following prerequisites are necessary:  
1. The program must be compiled with the appropriate compiler option.  
2. The project and the program must be loaded into the target system.  
3. An online connection to the target system must have been established. Select the command again to close the program status. See: Using the program status (Page 291). |
| Save variables         | You can save retain, unit and global variables with this menu command. You can save these variables from the RAM/ROM memory of the target device and store them on a data medium as XML file. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device. |
| Restore variables      | You can restore retain, unit and global variables from the previously exported variables with this menu command. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device. |
2.3.11.2 ST source file context menu

Depending on the active application/editor or the mode (ONLINE/OFFLINE), certain commands are not displayed or cannot be selected.

You can select the following functions:

Table 2-10 ST source file context menu

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning/Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open</td>
<td>Select this command to open the selected ST source file. See: Opening an existing ST source file (Page 23).</td>
</tr>
<tr>
<td>Cut</td>
<td>The selected ST source file is deleted and saved on the clipboard.</td>
</tr>
<tr>
<td>Copy</td>
<td>The selected ST source file is copied to the clipboard.</td>
</tr>
<tr>
<td>Inserting</td>
<td>The contents of the clipboard are pasted to the current location of the cursor.</td>
</tr>
<tr>
<td>Delete</td>
<td>The selected ST source file is deleted, including all the data.</td>
</tr>
<tr>
<td>Rename</td>
<td>Select this command in order to change the name of the selected ST source file. Please note that with name changes, it is not possible to change the referencing to this name and that the new name must comply with the Rules for identifiers (Page 80).</td>
</tr>
<tr>
<td>Save variables</td>
<td>You can save retain, unit and global variables with this menu command. You can save these variables from the RAM/ROM memory of the target device and store them on a data medium as XML file. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device.</td>
</tr>
<tr>
<td>Restore variables</td>
<td>You can restore retain, unit and global variables from the previously exported variables with this menu command. When these variables are restored, they can be written from the data medium to the RAM/ROM memory of the target device.</td>
</tr>
<tr>
<td>Import object</td>
<td>Select this command to import XML data to the selected ST source file from an ST source file, which you have previously exported to another project. The existing data in the ST source file being imported is overwritten. See: Importing XML data into an ST source file (Page 57).</td>
</tr>
<tr>
<td>Save project and export object</td>
<td>Select this command to export the selected ST source file in XML format. You can import the exported data into other projects. See: Exporting an ST source file in XML format (Page 56).</td>
</tr>
<tr>
<td>Accept and compile</td>
<td>Choose this command to transfer the current ST source file to the project and compile into executable code. See: Starting the compiler (Page 46).</td>
</tr>
<tr>
<td>Run preprocessor</td>
<td>As an option, the preprocessor scans an ST source file before compiling and can, for example, replace character strings in the file, which will then be taken into account during the compilation. You can specifically execute the preprocessor statements with this menu command.</td>
</tr>
<tr>
<td>Program status On/Off</td>
<td>Select this command to start the program status test mode. During the program execution, you can monitor the values of the variables marked in the ST source file. The following prerequisites are necessary: 1. The program must be compiled with the appropriate compiler option. 2. The project and the program must be loaded into the target system. 3. An online connection to the target system must have been established. Select the command again to close the program status. See: Using the program status (Page 291).</td>
</tr>
</tbody>
</table>
### 2.3 Working with the ST editor and the compiler

#### Getting Started with ST

<table>
<thead>
<tr>
<th>Function</th>
<th>Meaning/Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export</td>
<td>Select this command to export the selected ST source file as a text file (ASCII). See: Exporting an ST source file as a text file (ASCII) (Page 56).</td>
</tr>
</tbody>
</table>
| Know-how protection | Set Select this command to protect the selected ST source file from unauthorized access by third parties. Protected ST source files can only be opened or exported as plain text files by entering a password. See: Know-how protection for ST source files (Page 54).  
Delete Select this command in order to cancel the know-how protection for the selected source file temporarily or permanently. The password needs to be entered in order to do this. See: Know-how protection for ST source files (Page 54). |
| Reference data | Create Select this command in order to create the reference data (cross-reference list, program structure, code attributes) for the selected ST source file. The cross-reference list for the selected ST source file appears after this command is executed. See: Reference data (Page 259), creating a cross-reference list (Page 259). |
| Display  | Cross references The cross-reference list for the selected ST source file is formed from the reference data created previously and is displayed. The cross-reference list contains the declaration and uses all the identifiers for the selected ST source file. See: Content of the cross-reference list (Page 260).  
Program structure The program structure for the selected ST source file is formed from the reference data created previously and is displayed. The program structure contains all the subroutine calls and their nesting within the selected ST source file. See: Content of the program structure (Page 264).  
Code attributes The code attributes for the selected ST source file are formed from the reference data created previously and are displayed. The code attributes contain information about the storage requirements of various data areas of the selected ST source file. See: Code attribute contents (Page 265). |
| Print    | Select this command to print the selected ST source file. You can choose whether you wish to print the text of the ST source file and/or their properties. |
| Print preview | Choose this command to generate a preview of the expected print output. |
| Properties | Select this command to display the properties of the selected ST source file. Several tabs are provided to make local settings for this source file. See: Changing the properties of an ST source file (Page 23). |
2.4 Creating a sample program

In this section, we create a short program to illustrate the steps involved, including starting and testing. Testing is described in Program test (Page 276).

Function

The Flash program sets a bit in an output byte of your target system and rotates it within this byte. This causes each bit of the output byte to be set and reset in succession. After the last bit of the byte, the first bit is to be set again. You can observe the result of the program at the outputs of your target system.

2.4.1 Requirements

To create the sample program, you need

- A SIMOTION project and
- A SIMOTION device (e.g. SIMOTION C240) within the project whose output is configured at address 62.

2.4.2 Opening or creating a project

Projects contain all the information about the hardware and configuration. This includes the programs you use to control the hardware.

Proceed as follows

If a project does not yet exist, proceed as follows:

1. Select Project in the menu bar.
2. Select New or Open.
3. Specify a name for a new project, and click OK to confirm.

For details, see the online help.
Getting Started with ST

2.4 Creating a sample program

Figure 2-20  Creating a new project
2.4.3 Making the hardware known

The steps are as follows:

1. Create and configure a new SIMOTION device (e.g. C240 V4.1).
2. Configure an output in HW Config at Address 62.

For more details on steps 1 and 2, refer to the online help.

Figure 2-21 Change in HW Config
2.4.4 Entering source text with the ST editor

Proceed as follows

1. In the project navigator, open the tree for your SIMOTION device (programs are assigned to the SIMOTION device on which they are to run).

2. Select the PROGRAMS folder and choose Insert > Program > ST source file.

3. Enter a name for the ST source file consisting of up to 128 characters (see figure), e.g. ST_1, and click OK to confirm the entries.

   The ST editor appears in the working area. The ST source file ST_1 is inserted in the navigator.

4. Enter the source text from Source text of the sample program (Page 68), preferably with indented lines. To do this, press the TAB key.

   The features of the ST editor are described in Working with the ST editor (Page 25); the structure of an ST source file is described in detail in Structure of the ST source file (Page 94) and in Source file sections (Page 183).

5. Use comments as often as possible. Enter your comment after the // characters if the comment fits on one line of text. If the comment extends across several lines, insert it between character pairs (* and *).

6. Save the complete project with Project > Save.
2.4.4.1 Functions of the editor

In addition to simple text input, the ST editor provides the following advanced/convenience functions for documenting the functionality of your source text:

- Standard Windows user features (for example, Undo with Ctrl+Z or Redo with Ctrl+Y)
- Syntax coloring (different colors for different language elements)
- Source file printout in an appropriate layout with page number, source file name and printing date
- Export/import of the source file
- Source file archiving (via the project)

A detailed description of the functions is contained in Working with the ST editor (Page 25) and in Making settings for the compiler (Page 47).
2.4.4.2 Source text of the sample program

The table shows the source code of the sample program. You need to enter it in the same way to create executable code.

Table 2-11 Flash sample program

```plaintext
INTERFACE
  VAR_GLOBAL
    counterVar : INT := 1; // counter variable
    outputVar : BYTE := 1; // auxiliary tag
  END_VAR
  PROGRAM Flash;
END_INTERFACE

IMPLEMENTATION
  PROGRAM Flash
    IF counterVar >= 500 THEN // in every 500th pass
      %QB62 := outputVar;  // set output byte
      outputVar := ROL (in := outputVar, n := 1); /* // rotate bit in byte
        one digit to the left*/
      counterVar := 0; // reset counter
    END_IF;
    counterVar := counterVar + 1; // increment counter
  END_PROGRAM
END_IMPLEMENTATION
```
2.4.5 Compiling a sample program

Before you can run or test your program, you must compile it into executable machine code. The compiler performs this task.

2.4.5.1 Starting the compiler

Before you can run or test your program, you must compile it into executable machine code. The ST compiler performs this task.

Start the compiler as follows:

1. Click in the window with the ST editor to display the **ST source file** menu. This menu is a dynamic menu and is only displayed if the window of the ST editor is active.

2. Start the compiler by selecting the **ST source file > Accept and compile** menu command.

2.4.5.2 Correcting errors

The compiler checks the syntax of the ST source file. The **Compile/check output** tab of the detail view displays the successful compilation of the source text or compiler errors. The error details include: Name of the ST source file, the line number where the error occurred, the error number and an error description.

Proceed as follows to correct an error in the sample program:

1. Double-click the error message. The cursor is placed at the relevant line in the ST source file. See Example for error messages (Page 70).

2. Start debugging the first error.

3. Start the compilation operation again.

4. Repeat the entire operation until no more errors are displayed (0 errors).

After a successful compilation, you will have created an application program with the name **flash**. This program is displayed in the project navigator below the **ST_1** program source file.
2.4.5.3 Example of error messages

Figure 2-23 Error messages during ST source file compilation

The figure shows an example of compiling the ST source file ST_1 (see Source text of the sample program (Page 68), in which the following change has been made: The semicolon is missing in the statement "counterVar := counterVar + 1" at the end of line 18.

The compiler does not detect the error until Line19, because it continues with the compilation after the missing semicolon.

Once the missing semicolon is added, the ST source file is compiled without errors.

A detailed list of all compiler error messages can be found in Compiler error messages and their correction (Page 376).

See also

Compiler Error Messages and Remedies (Page 376)
2.4.6 Running the sample program

Before you can run the program, you must assign it to an execution level or task. When you have done this, you can establish the connection to the target system, download the program to the target system and then start it.

2.4.6.1 Assigning a sample program to an execution level

The execution levels specify the order in which the programs run. Each execution level contains one or more tasks to which you can assign programs.

The assignment of a program to a task can only be performed after compilation and before the program is loaded onto the target system.

Assign the sample program to the BackgroundTask. The BackgroundTask is provided for the programming of cyclic sequences without a fixed time frame. It is executed cyclically in the round robin execution level, which means it will be automatically restarted on completion.

How to assign the sample program to the BackgroundTask:

1. When you double-click the Execution system element in the project navigator, the window containing the execution system and the program assignment appears in the working area.
2. Click BackgroundTask to select it for the program assignment.
   The program assignment on the left side of the window shows you all the compiled programs that can be assigned to tasks.
3. In the Programs list, click sample program ST_1.flash. Then, click the >> button to assign the program to the BackgroundTask.
   The result is shown in the following figure. The program ST_1.flash is displayed in the Programs used list box.

For more information on the execution system and assignment of programs to tasks, see SIMOTION Motion Control Basic Functions Function Description.
Figure 2-24 Assigning the sample program to the BackgroundTask
2.4.6.2 Establishing a connection to the target system

Before a connection to the target system can be set up, the PC interface card must be configured and connected to the target system.

Proceed as follows to connect to the target system:

1. Select the Project > Connect to target system menu command.

The Diagnostics overview tab is opened in the detail view. The diagnostics overview shows you the operating state, memory allocation and CPU utilization for the device you are connected to. You can see at the lower right edge of the screen that you are connected to the target system.

Note

For more detailed information, refer to the SIMOTION SCOUT Configuring Manual and SIMOTION SCOUT online help.

![Establishing a connection to the target system](image)

Figure 2-25 Establishing a connection to the target system
2.4.6.3 Downloading the sample program to the target system

Proceed as follows to download the sample program to the target system:

1. Switch the target system to STOP.
2. Select the Target system > Download > Project to target system menu command.
3. Confirm all further queries.

The Target system output window in the detail view opens and displays the result of the download.

![Image of SIMOTION ST interface with code snippet]

Figure 2-26 Downloading the sample program to the target system
2.4.6.4 Starting and testing the sample program

Starting sample program

Proceed as follows to start the sample program:

- Switch your target system to RUN (see hardware description).

The lamps flash in sequence at the outputs of your target system.

Testing a sample program

See Program test (Page 276).
This section describes the language resources available in ST and how to use them. Please note that functions, function blocks and the task control system are described in the following chapters. For a complete formal language description containing all the syntax diagrams, see Appendix Rules (Page 332).

3.1 Language description resources

Syntax diagrams are used as a basis for the language description in the following sections of the manual. They provide you with an invaluable insight into the syntactic (i.e. grammatical) structure of ST.

3.1.1 Syntax diagram

The syntax diagram is a graphical representation of the language structure. The structure is described by a sequence of rules. A rule can build on existing rules.

![Syntax Diagram](image)

Figure 3-1 Syntax diagram

The syntax diagram in the previous figure is read from left to right. The following rule structures must be observed:

- Sequence: Sequence of blocks
- Option: Statement(s) that can be skipped
- Iteration: Repetition of one or more statements
- Alternative: Branch
### 3.1.2 Blocks in syntax diagrams

A block is a basic element or an element that is itself composed of blocks. The figure shows the symbol types used to represent the blocks:

<table>
<thead>
<tr>
<th>Symbol Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Basic element requiring no further explanation.</td>
</tr>
<tr>
<td></td>
<td>Composite element that is described by further syntax diagrams.</td>
</tr>
</tbody>
</table>

These are printable characters and special characters, reserved words and predefined identifiers. The specifications in these blocks should be accepted without modifications.

![Figure 3-2 Blocks](image)

Formatted and unformatted rules must be observed when entering source text, i.e. when converting the blocks or elements of a syntax diagram into source text (see Help for the language description (Page 316)).

**See also**

Formal Language Description (Page 315)

### 3.1.3 Meaning of the rules (semantics)

The rules can only represent the formal structure of the language. The meaning (i.e. semantics) is not always apparent. For this reason, additional information is written beside the rules if the meaning is critical. Examples are:

- Where elements of the same kind have a different meaning, an additional name is appended. For example, an addition is specified in the *date* rule for every *decimal digit string* element - either *year*, *month* or *day* (see Literals (Page 333)). The name indicates the usage.

- Important restrictions are noted next to the rules. For example, in the *integer* rule for *- (minus)*, it is noted that the minus can appear only in front of decimal digit strings of data types SINT, INT, and DINT (see Literals (Page 333)).

**See also**

Formal Language Description (Page 315)
3.2 Basic elements of the language

The basic elements of the ST language include the ST character set, reserved identifiers constructed from the ST character set (e.g. language commands), self-defined identifiers and numbers.

The ST character set and the reserved identifiers are basic elements (terminals) as they are described verbally and not by another rule. Self-defined identifiers and numbers are not terminals as they are described by other rules.

In the syntax diagrams, terminals are represented by circles or oval symbols, while composite elements are represented by rectangles (see Blocks in syntax diagrams (Page 78)). Below is a selection of the main terminals; for a complete overview, refer to Basic elements (terminals) (Page 318).

3.2.1 ST character set

ST uses the following letters and digits from the ASCII character set:

- The lower and upper case letters from A to Z
- The Arabic digits from 0 to 9

Letters and digits are the most commonly used characters. For example, identifiers (see Identifiers in ST (Page 80)) consist of a combination of letters, digits and the underscore. The underscore is one of the special characters.

Special characters have a fixed meaning in ST (see Formal Language Description (Page 315), Basic elements (terminals) (Page 318)).
3.2.2 Identifiers in ST

Identifiers are names in ST. These names can be defined by the system, such as language commands. However, the names can also be user-defined, for example, for a constant, variable or function.

3.2.2.1 Rules for identifiers

Identifiers are made up of letters (A … Z, a … z), numbers (0 … 9) or single underscores (_) in any order, whereby the first character must be a letter or underscore. No distinction is made between upper and lower case letters (e.g. Anna and AnNa are considered to be identical by the compiler).

An identifier can be represented formally by the following syntax diagram:

![Syntax Diagram: Identifier]

Figure 3-3 Syntax: Identifier

When assigning a name, it is best to choose a unique, meaningful name that contributes to the clarity of the program.

The syntax diagram in the figure says that the first character of an identifier must be a letter or underscore. An underscore must be followed by a letter or number, i.e. more than one underscore in succession is not allowed. This can be followed by any number or sequence of underscores, letters or numbers. The only exception here again is that two underscores may not appear together.
### Examples of identifiers

#### Examples of valid identifiers

The following names are valid identifiers:

<table>
<thead>
<tr>
<th>x</th>
<th>y12</th>
<th>_sum</th>
<th>temperature</th>
<th>R_CONTROLLER3</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>area</td>
<td>myFB</td>
<td>table</td>
<td></td>
</tr>
</tbody>
</table>

#### Examples of invalid identifiers

The following names are not valid identifiers:

<table>
<thead>
<tr>
<th>Invalid identifier</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>4ter</td>
<td>The first character must be a letter or underscore.</td>
</tr>
<tr>
<td>*#AB</td>
<td>Special characters (except underscores) are not permitted.</td>
</tr>
<tr>
<td>RR__20</td>
<td>Two underscores in succession are not permitted.</td>
</tr>
<tr>
<td>S_value</td>
<td>Blank spaces are not permitted as they are special characters.</td>
</tr>
<tr>
<td>Array</td>
<td>While ARRAY is formally a valid identifier, it is a reserved identifier, i.e. it may only be used as predefined. This means you cannot use this name for your own purposes, for example, for a variable.</td>
</tr>
</tbody>
</table>

#### Identifiers that may not be used

Never define identifiers that:

- Are identical to a **reserved identifier**
  
  For more information, see Reserved identifiers (Page 82).

- Match a **task name**
  
  For a more detailed explanation, refer to the **SIMOTION Basic Functions Function Manual**.

#### Note

If possible, avoid defining identifiers that begin with _ (underscore), **struct**, enum or **command**.

While these are valid identifiers, their use can cause errors later when you download (additional) technology packages. Command words, parameters or data types in the basic system and in technology packages begin with these characters.
3.2.3  Reserved identifiers

Reserved identifiers may only be used as predefined. You may not declare a variable or data type with the name of a reserved identifier.

There is no distinction between upper and lower case notation.

A list of all identifiers with a predefined meaning can be found in the SIMOTION Basic Functions Function Manual:

- For more information on protected and reserved identifiers in the ST programming language, see also "Protected identifiers (Page 83)" and "Further reserved identifiers (Page 88)"

- For general standard functions and the data types defined in these functions, see also "Error Sources and Program Test (Page 275)"

- General system function blocks

- System functions, system variables and data types of SIMOTION devices
  (see also list manuals of the SIMOTION devices)

- System functions, system variables and data types of technology objects
  (see also parameter manuals for the technology packages)
### 3.2.3.1 Protected identifiers

The protected identifiers of the ST language are listed in the table.

For a brief explanation of all reserved words, please refer to Appendix Reserved Words (Page 323), and Syntax diagrams (Page 77) in Appendix Rules (Page 332).

3.2.4 Numbers and Boolean values

Numbers can be written in various ways in ST. A number can contain a sign, a decimal point or an exponent. The following rules apply to all numbers:

- Commas and blanks may not appear within a number.
- An underscore ( _ ) is allowed as a visual separator.
- The number can be preceded by a plus ( + ) or minus ( – ). If no sign is used, it is assumed that the number is positive.
- Numbers may not violate certain maximum and minimum values.

3.2.4.1 Integers

An integer contains neither a decimal point nor an exponent. An integer is thus a sequence of numeric digits that can be preceded with a sign.

The following are valid integers:

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>+1</th>
<th>-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>743</td>
<td>-5280</td>
<td>60_000</td>
<td>-32_211_321</td>
</tr>
</tbody>
</table>

The following integers are invalid for the reasons indicated:

<table>
<thead>
<tr>
<th>123,456</th>
<th>36.</th>
<th>10 20 30</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Commas are not permitted.</td>
<td>Blanks are not permitted.</td>
</tr>
<tr>
<td></td>
<td>An integer may not contain a decimal point.</td>
<td></td>
</tr>
</tbody>
</table>

In ST, you can represent integers in different number systems. This is achieved by inserting a keyword prefix for the number system.

The following are used:

- 2# for the binary system
- 8# for the octal system
- 16# for the hexadecimal system.

Valid representations of the decimal number 15 are:

2#1111 8#17 16#F
3.2.4.2 Floating-point numbers

A floating-point number can contain a decimal point or an exponent (or both). A decimal point must appear between two digits. A floating-point number therefore cannot start or end with a decimal point.

The following are valid floating-point numbers:

0.0 1.3 -0.2 827.602
0000.0 +0.000743 60_000.15 -315.0066

The following floating-point numbers are invalid:

1. A numeric digit must be present before the decimal point and after the decimal point.
1,000.0 Commas are not permitted.
1.333.333 Two points are not permitted.

3.2.4.3 Exponents

An exponent can be included to define the position of the decimal point. If no decimal point appears, it is assumed that it is on the right side of the digit. The exponent itself must be either a positive or negative integer. Base 10 is expressed by the letter E.

The magnitude $3 \times 10^8$ can be represented in ST by the following correct floating-point numbers:

3.0E+8 3.0E8 3e+8 3E8 0.3E+9
0.3e9 30.0E+7 30e7

The following floating-point numbers are invalid:

3.E+8  A numeric digit must be present before the decimal point and after the decimal point.
8e2.3  The exponent must be an integer.
.333e-3 A numeric digit must be present before the decimal point and after the decimal point.
30  E8  Blanks are not permitted.

3.2.4.4 Boolean values

Boolean values are bit constants. They must be represented by a value of zero (0) or one (1) or by the keywords FALSE or TRUE.

Example:

```plaintext
a := 1;  // is equivalent a := TRUE
b := FALSE;  // is equivalent to b := 0
```
3.2.4.5 Data types of numbers

The compiler automatically selects the elementary data type that is suitable for the number depending on its value and use (in an expression or a value assignment).

You can also specify the data type directly: Place the data type (numeric data type or bit data type) and the character "#" in front of the number.

Examples:

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
<th>Type</th>
<th>Value</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>#255</td>
<td>INT</td>
<td>#16#FF</td>
<td>INT</td>
<td>#8#377</td>
</tr>
<tr>
<td>WORD</td>
<td>#255</td>
<td>WORD</td>
<td>#16#FF</td>
<td>WORD</td>
<td>#8#377</td>
</tr>
<tr>
<td>REAL</td>
<td>#255</td>
<td>REAL</td>
<td>#16#FF</td>
<td>REAL</td>
<td>#8#377</td>
</tr>
<tr>
<td>REAL</td>
<td>#255.0</td>
<td>REAL</td>
<td>#2.55E2</td>
<td>LREAL</td>
<td>#255.0</td>
</tr>
</tbody>
</table>

Note

Floating-point numbers can only be assigned to data types REAL and LREAL.
3.2.5 Character strings

What is a character string?

A character string is a sequence of zero or more characters with an apostrophe at the start and at the end. Each character is encoded with 1 byte (8 bits) in the string.

A character can be entered as follows:

- As printable characters (ASCII code $20$ to $7E$, $80$ to $FF$), except the dollar signs (ASCII code $24$) and apostrophe (ASCII code $27$), as these have a special function within the string
- As the 2-digit hexadecimal ASCII code of the relevant character preceded by the dollar sign ($$)
- As a combination of two characters according to the following table:

<table>
<thead>
<tr>
<th>Character combination</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$$</td>
<td>Dollar sign $ ($24)</td>
</tr>
<tr>
<td>$’</td>
<td>Apostrophe ’ ($27)</td>
</tr>
<tr>
<td>$L or $l</td>
<td>Line Feed LF ($0A)</td>
</tr>
<tr>
<td>$N or $n</td>
<td>Carriage Return + Line Feed CR + LF ($0D$0A)</td>
</tr>
<tr>
<td>$F or $p</td>
<td>Form Feed FF ($0C)</td>
</tr>
<tr>
<td>$R or $r</td>
<td>Carriage Return CR ($0D)</td>
</tr>
<tr>
<td>$T or $t</td>
<td>Horizontal tab (HT) ($09)</td>
</tr>
</tbody>
</table>

Examples:

- ’’ Empty string (length 0).
- ’A’ String of length 1 containing the letter A.
- ’ ‘ String of length 1 containing a blank.
- ’$’ String of length 1 containing an apostrophe.
- ’$R$L’, ’$0D$0A’ Two equivalent representations for a string of length 2 containing the characters CR and LF.
- ’$1.00’ String of length 5 containing $1.00.
- ’Text$R$L’ String of length 6 containing the word Text followed by the characters CR and LF.
- ’ÄÖÜ’ Two equivalent representations for a string of length 3 containing the German umlauts ÄÖü (A, O, u with diaresis).
3.3 Structure of an ST source file

An ST source basically consists of continuous text. This text can be structured by dividing it into logical sections. Detailed rules for this can be found in Source file modules (Page 183).

A brief summary is given below:

- An **ST source file** is a logical unit that you create in your project and that can appear several times. It is often referred to as a unit.
- The logic sections of an ST source file are called **Sections** (see table).
- A **user program** is the sum of all program sources (e.g. ST source files, MCC units).

Each logical section of the ST source file has a beginning and end denoted by specific keywords:

You do not have to program every function yourself. You can also make use of SIMOTION system components. These are preprogrammed sections such as system functions or the functions of the technology objects (TO functions).
Table 3- 4  Major sections of an ST source file

<table>
<thead>
<tr>
<th>Source file section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unit statement (optional)</td>
<td>Contains the name of the ST</td>
</tr>
<tr>
<td>Interface section</td>
<td>Contains statements for importing and exporting variables, types and program organization units (POUs).</td>
</tr>
<tr>
<td>Implementation section</td>
<td>Contains executable sections of the ST source file.</td>
</tr>
<tr>
<td>POU (program organization unit)</td>
<td>Single executable section of the ST source file (program, function, function block)</td>
</tr>
<tr>
<td>Declaration section</td>
<td>Contains declarations (e.g. of variables and types), can be included in the interface section and the implementation section as well as in a POU.</td>
</tr>
<tr>
<td>Statement section</td>
<td>Contains executable statements of a POU.</td>
</tr>
</tbody>
</table>

Note

An extensively annotated template for example unit is also available in the online Help. You can use it as a template for a new ST source file.

Call the ST editor Help and click the relevant link. Copy the text to the open window of the ST editor and modify the template according to your requirements.

Template for example unit contains a copy of this template.
3.3 Structure of an ST source file

3.3.1 Statements

The statement section of a program organization unit (POU – program, function, function block) consists of repeated single statements. It follows the declaration section of a POU and ends with the end of the POU. There are no explicit keywords for the start and end.

There are three basic types of statements in ST:

- **Value assignments**
  Assignment of an expression to a variable; see Variables declaration (Page 116)

- **Control statements**
  Repetition or branching of statements; see Control statements (Page 143)

- **Subroutine execution**
  Functions (FC) and function blocks (FB); see Functions, function blocks, programs (Page 159)

Table 3-5 Examples of statements

```plaintext
// Value assignment
Status := 17;

// Control statement
IF a = b THEN
  FOR c := 1 TO 10 DO
    b := b + c;
  END_FOR;
END_IF;

// Function call
retVal := Test1(10.0);
```

...
3.3.2 Comments

Comments are used for documentation purposes and to help the user understand the source file section. After compilation, they have no meaning for the program execution.

There are two types of comments:

- Line comment
- Block comment

The line comment is preceded by //. The compiler will process the text which follows until the end of the line as a comment.

You can enter a block comment over several lines if it is preceded by (*) and ends with *).

Please note the following when inserting comments:

- You can use the complete extended ASCII character set in comments.
- The character pairs (* and *) are ignored within the line comment.
- Nesting of block comments is not allowed. However, you can nest line comments in block comments.
- Comments can be inserted at any position, but not in rules that have to be maintained, such as in names of identifiers. For more information about these rules, refer to Help for the language description (Page 316).

Table 3-6 Examples of comments

```plaintext
// This is a one-line comment.
a := 5;

// This is an example of a one-line comment
// used several times in succession.
b := 23;

(* The above example is easier to edit as a
  multi-line comment. *)

*)
c := 87;
```
3.4 Data types

A data type is used to determine how the value of a variable or constant is to be used in a program source.

The following data types are available to the user:

- Elementary data types
- User-defined data types (UDT)
  - Simple derivatives
  - Arrays
  - Enumerators
  - Structures (Struct)
- Technology object data types
- System data types

See also

Elementary data types (Page 99)
Description of the technology object data types (Page 112)
System data types (Page 115)
3.4 Data types

3.4.1 Elementary data types

Elementary data types define the structure of data that cannot be broken down into smaller units. An elementary data type describes a memory area with a fixed length and stands for bit data, integers, floating-point numbers, duration, time, date and character strings.

All the elementary data types are listed in the table below:

Table 3-7 Bit widths and value ranges of the elementary data types

<table>

</tbody>
</table>
### 3.4 Data types

#### Time types

These data types are used to represent various date and time values.

<table>
<thead>
<tr>
<th>Type</th>
<th>Reserv. word</th>
<th>Bit width</th>
<th>Range of values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duration in increments of 1 ms</td>
<td>TIME</td>
<td>32</td>
<td>T#0d_0h_0m_0s_0ms to T#49d_17h_2m_47s_295ms</td>
</tr>
<tr>
<td>Date in increments of 1 day</td>
<td>DATE</td>
<td>32</td>
<td>D#1992-01-01 to D#2200-12-31</td>
</tr>
<tr>
<td>Time of day in steps of 1 ms</td>
<td>TIME_OF_DAY</td>
<td>32</td>
<td>TOD#0:0:0:0:0 to TOD#23:59:59.999</td>
</tr>
<tr>
<td>Date and time</td>
<td>DATE_AND_TIME</td>
<td>64</td>
<td>DT#1992-01-01-0:0:0:0.0 to DT#2200-12-31-23:59:59.999</td>
</tr>
</tbody>
</table>

#### String type

Data of this type represents character strings, in which each character is encoded with the specified number of bytes.

The length of the string can be defined at the declaration. Indicate the length in "[" and "]", e.g. STRING[100]. The default setting consists of 80 characters.

The number of assigned (initialized) characters can be less than the declared length.

<table>
<thead>
<tr>
<th>Type</th>
<th>Reserv. word</th>
<th>Bit width</th>
<th>Range of values</th>
</tr>
</thead>
<tbody>
<tr>
<td>String with 1 byte/character</td>
<td>STRING</td>
<td>8</td>
<td>All characters with ASCII code $00 to $FF are permitted. Default ' ' (empty string)</td>
</tr>
</tbody>
</table>

### NOTICE

During variable export to other systems, the value ranges of the corresponding data types in the target system must be taken into account.

---

**Figure 3-5** Syntax: STRING data type

</tbody>
</table>

\(^1\) Internal display only
3.4.1.3 General data types

General data types are often used for the input and output parameters of system functions and system function blocks. The subroutine can be called with variables of each data type that is contained in the general data type.

The following table lists the available general data types:

Table 3-9 General data types

<table>
<thead>
<tr>
<th>General data type</th>
<th>Data types contained</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY_BIT</td>
<td>BOOL, BYTE, WORD, DWORD</td>
</tr>
<tr>
<td>ANY_INT</td>
<td>SINT, INT, DINT, USINT, UINT, UDINT</td>
</tr>
<tr>
<td>ANY_REAL</td>
<td>REAL, LREAL</td>
</tr>
<tr>
<td>ANY_NUM</td>
<td>ANY_INT, ANY_REAL</td>
</tr>
<tr>
<td>ANY_DATE</td>
<td>DATE, TIME_OF_DAY (TOD), DATE_AND_TIME (DT)</td>
</tr>
<tr>
<td>ANY_ELEMENTARY</td>
<td>ANY_BIT, ANY_NUM, ANY_DATE, TIME, STRING</td>
</tr>
<tr>
<td>ANY</td>
<td>ANY_ELEMENTARY, user-defined data types (UDT), system data types, data types of the technology objects</td>
</tr>
</tbody>
</table>

Note

You **cannot** use general data types as type identifiers in variable or type declarations.

The general data type is retained when a user-defined data type (UDT) is derived directly from an elementary data type (only possible with the SIMOTION ST programming language).
3.4.1.4 Elementary system data types

In the SIMOTION system, the data types specified in the table are treated similarly to the elementary data types. They are used with many system functions.

Table 3-10 Elementary system data types and their use

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Bit width</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>StructAlarmId</td>
<td>32</td>
<td>Data type of the alarmId for the project-wide unique identification of the messages. The alarmId is used for the message generation. See Function Manual SIMOTION Basic Functions. Initialization with STRUCTALARMID#NIL</td>
</tr>
<tr>
<td>StructTaskId</td>
<td>32</td>
<td>Data type of the taskId for the project-wide unique identification of the tasks in the execution system. See Function Manual SIMOTION Basic Functions. Initialization with STRUCTTASKID#NIL</td>
</tr>
</tbody>
</table>

<td>StructTaskId</td>
<td>Invalid TaskId</td>
</tr>
</tbody>
</table>

3.4.2 User-defined data types

3.4.2.1 User-defined data types

User-defined data types (UDT) are created with the construct TYPE/END_TYPE in the declaration subsections of subsequent source file modules (see Breakdown of ST source file (Page 94) and Source file modules (Page 183)):

- Interface section
- Implementation section
- Program organization unit (POU)

You can continue to use the data types you created in the declaration section. The source file section determines the range of the type declaration.

See also

- Syntax of user-defined data types (type declaration) (Page 104)
- Derivation of elementary or derived data types (Page 106)
- Derived data type ARRAY (Page 107)
- Derived data type - Enumerator (Page 109)
- Derived data type STRUCT (structure) (Page 110)
3.4.2.2 Syntax of user-defined data types (type declaration)

The declaration of the UDT is introduced with the keyword TYPE.

Figure 3-6 Syntax: User-defined data type
For each data type to be declared, this is followed by (see figure):

1. **Name:**
   The name of the data type must comply with the rules for identifiers.

2. **Data type specification**
   The term *data type* comprises (see Derivation of elementary or derived data types (Page 106)):
   - Elementary data types
   - Previously declared UDTs
   - TO data types
   - System data types
   The following data type specifications are also possible:
   - ARRAY data type specification (see Derived data type ARRAY - field (Page 107))
   - Enumerator data type specification (see Derived data type enumerator (Page 109))
   - STRUCT data type specification (see Derived data type STRUCT – structure (Page 110))
   The references in brackets refer to the following sections, in which the respective data type specification is described in detail.

3. **Optional initialization:**
   You can specify an initialization value for the data type. If you subsequently declare a variable of this data type, the initialization value is assigned to the variable.
   
   Exception: With the STRUCT data type specification, each individual component is initialized within the data type specification.
   
   See also Initialization of variables or data types (Page 119).

The complete UDT declaration is terminated with the keyword END_TYPE. You can create any number of data types within the TYPE/END_TYPE construct. You can use the defined data types to declare variables or parameters.

UDTs can be nested in any way as long as the syntax in the figure is observed. For example, you can use previously defined UDTs or nested structures as a data type specification. Type declarations can only be used sequentially and not in nested structures.

**Note**

You can learn how to declare variables and parameters in Overview of all variable declarations (Page 117), and how to assign values with UDT in Syntax for value assignment (Page 124).

Below is a description of individual data type specifications for UDTs and examples demonstrating their use.
3.4.2.3 Derivation of elementary or derived data types

In the derivation of data types, an elementary or user-defined data type (UDT) is assigned to the data type to be defined in the TYPE/END_TYPE construct:

```
TYPE identifier : Elementary data type { := initialization } ; END_TYPE
TYPE identifier : User-defined data type { := initialization } ; END_TYPE
```

Once you have declared the data type, you can define variables of derived data type identifier. This is equivalent to declaring variables as data type elementary data type.

Table 3-12 Examples of derivation of elementary data types

```
TYPE
    I1: INT;  // Elementary data type
    R1: REAL; // Elementary data type
    R2: R1;   // Derived data type (UDT)
END_TYPE

VAR
    // These variables can be used wherever
    // variables of type INT can be used.
    myI1 : I1;
    myI2 : INT;  // No derived data type!

    // These variables can be used wherever
    // variables of type REAL can be used.
    myR1 : R1;
    myR2 : R2;
END_VAR

myI1 := 1;
myI2 := 2;
myR1 := 2.22;
myR2 := 3.33;
```
3.4.2.4 Derived data type ARRAY

The ARRAY derived data type combines a defined number of components of the same data type in the TYPE/END_TYPE construct. The syntax diagram in the following figure shows this data type, which is specified more precisely after the reserved identifier OF.

\[
\text{TYPE identifier : ARRAY data type specification \{ := initialization \} ; END_TYPE}
\]

![Syntax: ARRAY data type specification](image)

The index specification describes the limits of the array:

- The array limits specify the minimum and maximum value for the index. They can be specified using constants or constant expressions; the data type is DINT (or can be implicitly converted to DINT – see Converting elementary data types (Page 154)).
- The array limits must be separated by two periods.
- The entire index specification is enclosed in square brackets.
- The index itself can be an integer value of data type DINT (or it can be implicitly converted to DINT – see Converting elementary data types (Page 154)).

**Note**

If array limits are violated during runtime, a processing error occurs in the program (see *SIMOTION Basic Functions Function Manual*).

You declare the data type of the array components with the data type specification. All of the options described in this chapter can be used as data types, for example, even user-defined data types (UDT).

There are several different ARRAY types:

- The one-dimensional ARRAY type is a list of data elements arranged in ascending order.
- The two-dimensional ARRAY type is a table of data consisting of lines and columns. The first dimension refers to the line number, the second to the column number.
- The higher-dimensional ARRAY type is an expansion of the two-dimensional ARRAY type that includes additional dimensions.
### 3.4 Data types

#### Table 3-13 Examples of one-dimensional arrays

```plaintext
TYPE
  x : ARRAY[0..9] OF REAL;
  y : ARRAY[1..10] OF C1;
END_TYPE
```

Two-dimensional arrays are comparable to a table with lines and columns. You can create two- or multi-dimensional arrays by means of a multi-level type declaration, see example:

#### Table 3-14 Examples of multi-dimensional arrays

```plaintext
TYPE
  a : ARRAY[1..3] OF INT;    // one-dimensional array (3 columns):
  matrix1: ARRAY[1..4] OF a; // two-dimensional Field
      // (4 rows with 3 columns)
  b: ARRAY[4..8] OF INT;    // one-dimensional array (5 columns):
  matrix2: ARRAY[10..16] OF b; // two-dimensional Field
      // (7 rows with 5 columns)
END_TYPE

VAR
  m: matrix1;       // Variable m of data type two-dim. Field
  n: matrix2;       // Variable m of data type two-dim. Field
END_VAR

m[4][3] := 9;          // Write to Matrix1 at line 4, column 3
n[16][8] := 10;        // Write to Matrix2 at line 7, column 5
```

In the example, you can define:

1. Table columns `a[1]` to `a[3]` as a one-dimensional array that will contain integers.
2. Table lines `matrix1[1]` to `matrix2[4]` also as an array but take as the data type specification the array `a` you just created with the columns of the table.

When you specify an array in the data type specification, you create a second dimension. You can create further dimensions in this way.

Now declare a variable using the data type created for the table. You address each dimension of the table using square brackets, in this case specifying the line and column.
3.4.2.5 Derived data type - Enumerator

In the case of enumerator data types, a restricted set of identifiers or names is assigned to
the data type to be defined in the TYPE/END_TYPE construct:

```plaintext
TYPE identifier : Enumerator data type specification { := initialization } ; END_TYPE
```

Once you have declared the `identifier` data type, you can define variables in the enumerator
data type. In the statement section, you can assign only elements from the list of defined
identifiers (enumerator elements) to these variables.

You can also specify the data type directly: Place the enumerator data type identifier and the
"#" sign in front of the enumerator element (see Table Examples of enumerator data types).

You can obtain the first and last value of an enumeration data type with `enum_type#MIN` and
`enum_type#MAX` respectively, whereby `enum_type` is the enumeration data type identifier.

You can obtain the numeric value of an enumeration element with the ENUM_TO_DINT
conversion function.

<table>
<thead>
<tr>
<th>TYPE</th>
<th>C1: (RED, GREEN, BLUE);</th>
</tr>
</thead>
<tbody>
<tr>
<td>VAR</td>
<td>myC11, myC12, myC13 : C1;</td>
</tr>
<tr>
<td></td>
<td>END_VAR</td>
</tr>
</tbody>
</table>

myC11 := GREEN;
myC11 := C1#GREEN;
myC12 := C1#MIN; // RED
myC13 := C1#MAX; // BLUE

---

**Note**

You will also find enumerator data types as system data types.

Enumerator data types can be components of a structure, meaning that they can be found at
any lower level in the user-defined data structure.
3.4 Data types

3.4.2.6 Derived data type STRUCT (structure)

The derived data type STRUCT, or structure, encompasses an area of a fixed number of components in the TYPE/END_TYPE construct; the data types of these components can vary:

```
TYPE identifier : STRUCT data type specification; END_TYPE
```

![Syntax: STRUCT data type specification](image)

Do not forget to terminate the END_STRUCT keyword with a semicolon!

![Syntax: Component declaration](image)

The following are permitted as data types:

- Elementary data types
- Previously declared UDTs
- System data types
- TO data types
- ARRAY data type specification
You also have the option to assign initialization values to the components. Proceed as when initializing variables or data types (see Initialization of variables or data types (Page 119)).

Note
The following data specifications cannot be used directly within a component declaration:

- STRUCT data type specifications
- Enumerator data type specifications

Solution: Declare a UDT (user-defined data type) beforehand with the above-mentioned specifications and use this in the component declaration.

This allows you to nest STRUCT data types.

You will also find STRUCT data types as system data types.

This example shows how a UDT is defined and how this data type is used within a variable declaration.

Table 3-16 Examples of derived data type STRUCT

```
TYPE  // UDT definition
    S1: STRUCT
        var1 : INT;
        var2 : WORD := 16#AFA1;
        var3 : BYTE := 16#FF;
        var4 : TIME := T#1d_1h_10m_22s_2ms;
    END_STRUCT;
END_TYPE

VAR
    myS1 : S1;
END_VAR

myS1.var1 := -4;
myS1.var4 := T#2d_2h_20m_33s_2ms;
```
3.4 Data types

3.4.3 Technology object data types

3.4.3.1 Description of the technology object data types

You can declare variables with the data type of a technology object (TO). The following table shows the data types for the available technology objects in the individual technology packages.

For example, you can declare a variable with the data type \textit{posaxis} and assign it an appropriate instance of a position axis. Such a variable is often referred to as a reference.

<table>
<thead>
<tr>
<th>Technology object</th>
<th>Data type</th>
<th>Contained in the technology package</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drive axis</td>
<td>driveAxis</td>
<td>CAM\textsuperscript{1,2}, PATH, CAM_EXT</td>
</tr>
<tr>
<td>External encoder</td>
<td>externalEncoderType</td>
<td>CAM\textsuperscript{1,2}, PATH, CAM_EXT</td>
</tr>
<tr>
<td>Measuring input</td>
<td>measuringInputType</td>
<td>CAM\textsuperscript{1,2}, PATH, CAM_EXT</td>
</tr>
<tr>
<td>Output cam</td>
<td>outputCamType</td>
<td>CAM\textsuperscript{1,2}, PATH, CAM_EXT</td>

### See also

Inheritance of the properties for axes (Page 113)
Examples of the use of technology object data types (Page 113)

### 3.4.3.2 Inheritance of the properties for axes

Inheritance for axes means that all of the data types, system variables and functions of the TO driveAxis are fully included in the TO positionAxis. Similarly, the position axis is fully included in the TO followingAxis, the following axis in the TO pathAxis. This has, for example, the following effects:

- If a function or a function block expects an input parameter of the driveAxis data type, you can also use a position axis or a following axis or a path axis when calling.
- If a function or a function block expects an input parameter of the posAxis data type, you can also use a following axis or a path axis when calling.

### 3.4.3.3 Examples of the use of technology object data types

Below, you will see an example of optional use of a variable with a technology object data type (you will find an example of mandatory use of a variable with a TO data type in the SIMOTION Basic Functions Function Manual). A second example shows the alternative without using a variable with TO data type.

A TO function will be used to enable an axis in the main part of a program so that the axis can be positioned. After the positioning operation, the current position of the axis will be recorded using a structure access.
The first example uses a variable with TO data type to demonstrate its use.

Table 3- 19  Example of the use of a data type for technology objects

| VAR              | myAxis : posAxis;   // Declaration variable for axis  
|                  | myPos : LREAL;      // Variable for position of axis  
|                  | retVal: DINT;       // Variable for return value of the  
|                  | // TO function  
| END_VAR          | myAxis := Axis1;    // The name Axis1 was defined when the axis  
|                  | // was configured in the project navigator.  
|                  | // Call of function with variables of TO data type:  
|                  | retVal := _enableAxis(axis := myAxis, commandId := _getCommandId());  
|                  | // Axis is positioned.  
|                  | retVal := _pos(axis := myAxis,  
|                  |    position := 100,  
|                  |    commandId:= _getCommandId() );  
|                  | // Scan the position using structure access  
|                  | myPos := myAxis.positioningState.actualPosition;  

The second example does not use a variable with TO data type.

Table 3- 20  Example of using a technology object

| VAR              | myPos : LREAL;      // Variable for position of axis  
|                  | retVal: DINT;       // Variable for return value of TO function  
| END_VAR          | // Call of function without variable of TO data type  
|                  | // The name Axis1 was defined when the axis  
|                  | // was configured in the project navigator.  
|                  | retVal := _enableAxis(axis := Axis1,  
|                  |    commandId:= _getCommandId() );  
|                  | // Axis is positioned.  
|                  | retVal := _pos(axis := Axis1  
|                  |    position := 100,  
|                  |    commandId:= _getCommandId() );  
|                  | // Scan the position using structure access  
|                  | myPos := Axis1.positioningState.actualPosition;  

You will find details for configuration of technology objects in the SIMOTION Motion Control function descriptions.
3.4.4 System data types

There are a number of system data types available that you can use without a previous declaration. And, each imported technology packages provides a library of system data types.

Additional system data types (primarily enumerator and STRUCT data types) can be found

- In parameters for the general standard functions (see SIMOTION Basic Functions Function Manual)
- In parameters for the general standard function modules (see SIMOTION Basic Functions Function Manual)
- In system variables of the SIMOTION devices (see relevant parameter manuals)
- In parameters for the system functions of the SIMOTION devices (see relevant parameter manuals)
- In system variables and configuration data of the technology objects (see relevant parameter manuals)
- In parameters for the system functions of the technology objects (see relevant parameter manuals)
3.5 Variable declaration

A variable defines a data item with variable contents that can be used in the ST source file. A variable consists of an identifier (e.g. `myVar1`) that can be freely selected and a data type (e.g. BOOL). Reserved identifiers (see Reserved identifiers (Page 82)) must not be used as identifiers.

3.5.1 Syntax of variable declaration

Variables are always created according to the same pattern in the declaration section of a source file section:

1. Start a declaration block with an appropriate keyword (e.g. VAR, VAR_GLOBAL – see Overview of all variable declarations (Page 117)).
2. This is followed by the actual variable declarations (see figure); you can create as many of these as you wish. The order is arbitrary.
3. End the declaration block with END_VAR.
4. You can create further declaration blocks (also with the same keyword).

![Figure 3-11 Syntax: Variable declaration](image)

Note the following:

- The variable name must be an identifier, i.e. it can only contain letters, numbers or an underscore, but not special characters.
- The following are permissible as data types:
  - Elementary data types
  - UDT (user-defined data types)
  - System data types
  - TO data types
  - ARRAY data type specifications
  - Designation of a function block (instance declaration – see Calling functions and function modules (Page 166)).
- You can assign initial values to the variables in the declaration statement. This is known as initialization (see Initialization of variables or data types (Page 119)).
Deviations from the pattern presented are as follows:

- For constant declarations (a constant must be initialized with a value, see Constants (Page 122)),

- For process image access (see Overview of all variable declarations (Page 117)):
  - A variable declaration is not required for absolute process image access,
  - Initialization is not permitted for symbolic process image access.

Table 3-21  Examples of variable declarations

VAR CONSTANT
PI : REAL := 3.1415;
END_VAR

VAR
// Declaration of a variable ...
var1 : REAL;
// ... or if there are several variables of the same type:
var2, var3, var4 : INT;
// Declaration of a one-dimensional array:
a1 : ARRAY[1..100] OF REAL;
// Declaration of a character string (string):
str1 : STRING[40];
END_VAR

3.5.2  Overview of all variable declarations

You specify the name, data type, and initial values of variables in the variable and parameter declarations. You always execute these declarations in the declaration sections of the following source file sections:

- Interface section
- Implementation section
- POU (program, function, function block, expression)

The source file section also determines which variables you can declare (see table), as well as their range.

For additional information about source file modules, refer to Breakdown of ST source file (Page 94) and Source file modules (Page 183).

</tbody>
</table>
### 3.5.3 Initialization of variables or data types

The assignment of initial values to the variables or data types within a declaration is optional; see Syntax of variables declaration (Page 116) and Syntax of user-defined data types (Page 104).

- If there is no initialization specified in the variable declaration, the compiler automatically assigns the initialization value specified in the data type declaration to the variables.
- If there is no initialization specified in the data type declaration either, the compiler assigns the value of zero to the variables or data types. Exception:
  - For time data types: The initialization value for each data type
  - For enumeration data types: 1st value of the enumeration

You preassign a variable or a user-defined data type with initial values by assigning a value (:=) after the data type specification.

- Assign the elementary data types (or data types derived from elementary data types) a constant expression in accordance with Figure **Syntax: constant expression**.
- Assign an array initialization list to an array (ARRAY) in accordance with the figure titled **Syntax: Array initialization list**.
- Assign a structure initialization list to the individual components of a structure (STRUCT) in accordance with the figure titled **Syntax: Structure initialization list**.
- Assign an enumerator element to an enumerator data type.

---

![Figure 3-12 Syntax: Variable initialization](image)

The initialization value assigned to a variable is calculated from the constant expression at the time of the compilation. For information about the syntax of the constant expression, see the figure titled **Syntax: Constant expression**.
Note that a variable list \((a_1, a_2, a_3, \ldots : \text{INT} := \ldots)\) can be initialized with a common value. In this case, you do not have to initialize the variables individually \((a_1 : \text{INT} := \ldots; a_2 : \text{INT} := \ldots; \text{etc.})\).

**Note**
The constant expressions used for initialization are calculated in the data type of the declared variables or in the declared data type.

```c
VAR

// Declaration of a variable ...
var1 : REAL := 100.0;
// ... or if there are several variables of the same type:
var2, var3, var4 : INT := 1;
var5 : REAL := 3 / 2;
var6 : INT := 5 * SHL(1, 4)
myC1 : C1 := GREEN;
array1 : ARRAY [0..4] OF INT := [1, 3, 8, 4, 0];
array2 : ARRAY [0..5] OF DINT := [6 (7)];
array3 : ARRAY [0..10] OF INT := [2 (2(3),3(1)),0];
    // is equivalent to [2(3),3(1),2(3),3(1)),0]
    // Initialization as follows:
    // Array elements 0, 1 with 3;
    // Array elements 2, 3, 4 with 1;
    // Array elements 5, 6 with 3;
    // Array elements 7, 8, 9 with 1;
    // Array element 10 with 0
myAxis : PosAxis := TO#NIL;
```

END_VAR
3.5 Variable declaration

Table 3-24 Examples of data type initialization

```plaintext
TYPE
  // Initialization of a derived data type
  type1 : REAL := 10.0;
  // Initialization of an enumeration data type
  cmyk_colour : (cyan, magenta, yellow, black) := yellow;
  // Initialization of structures
  var_rgb_colour : STRUCT
    red, green, blue : USINT := 255; // white
  END_STRUCT;
  new_colour : var_rgb_colour := (red := 0, blue := 0); // green
END_TYPE
```

Variables of a technology object (TO) data type are initialized by the compiler with TO#NIL. The effect of tasks on variable initialization is described in the SIMOTION Basic Functions Function Manual.

3.5.4 Constants

Constants are data with a fixed value that you cannot change during program runtime. Constants are declared in the same way as variables:

- In the declaration section of a POU for local constants (see Figure Syntax: Constant block in a POU and syntax: Constant declaration).

- In the interface or implementation section of the ST source file for unit constants (see Figure Syntax: Unit constants in interface or implementation section and syntax: Constant declaration). You can import unit constants declared in the interface section into other ST source files (see Variable model (Page 200)).

The source file section also determines the range of the constant declaration.

```plaintext
Constant block (unformatted)
```

```plaintext
VAR CONSTANT Constant declaration END_VAR
```

Figure 3-16 Syntax: Constant block in a POU

```plaintext
Unit constants / global constant block (unformatted)
```

```plaintext
VAR_GLOBAL_CONSTANT Constant declaration END_VAR
```

Figure 3-17 Syntax: Unit constants in interface or implementation section
The value assigned to a constant is calculated from the constant expression at the time of compilation. For information about the syntax of the constant expression, see the figure titled *Syntax: Constant expression*. 

**Table 3-25 Examples of constants**

```
VAR CONSTANT
    PI : REAL := 3.1415;
    intConst : INT := 10;
    sintConst : SINT := 0;
    dintConst : DINT := 10_000;
    timeConst : TIME := TIME#1h;
    strConst : STRING[40] := 'Example of a string';
    Two_PI : REAL := 2 * PI;
END_VAR
```
3.6 Value assignments and expressions

You have no doubt already created value assignments with the character string :=. This may have been for a statement as part of an example (see table titled Examples of statements in Statements (Page 96)) or when initializing variables in the declaration subsection of a source file module.

However, this is only a small range of the options available for formulating value assignments. This section of the manual now describes this important topic in detail using a large number of examples for illustration purposes.

See also

Notes on avoiding errors and on efficient programming (Page 275)

3.6.1 Value assignments

3.6.1.1 Syntax of the value assignment

A value assignment is used to assign the value of an expression to a variable. The previous value is overwritten. Before a value can be correctly assigned, a variable must be declared in the declaration section (see Syntax of variable declaration (Page 116)).

As shown in the following syntax diagram, the expression is evaluated on the right side of the assignment sign :=. The result is stored in the variable, whose name is on the left side of the assignment sign (target variable). All target variables supported from a formal viewpoint are shown in the figure.
Figure 3-19 Syntax: Value assignments

The following contains explanations and examples for the left side of the value assignment:

- Value assignments with variables of an elementary data type (Page 126)
- Value assignments with variables of the derived enumerator data type (Page 130)
- Value assignments with variables of the derived ARRAY data type (Page 130)
- Value assignments with variables of the derived STRUCT data type (Page 131)
- Value assignments with absolute PI access (to addresses of the process image), see: Absolute access to the fixed process image of the BackgroundTask (absolute PI access) (Page 240).

How the right side of a value assignment, i.e. an expression, is formed, is described in Expressions (Page 132).
3.6 Value assignments and expressions

3.6.1.2 Value assignments with variables of an elementary data type

An expression with an elementary data type (Page 99) can be assigned to a variable when
one of the following conditions is fulfilled:

- Expression and target variable have the same data type.
  Note the following information on the STRING data type (Page 126).
- The data type of the expression can be implicitly converted to the data type of the target
  variable (see Conversion of elementary data types (Page 154) and Functions for the
  conversion of numerical data types and bit data types in the SIMOTION Basic Functions
  Function Manual).

Examples

\[
\begin{align*}
\text{elemVar} & := 3\times 3; \\
\text{elemVar} & := \text{elemVar1}; \\
\end{align*}
\]

See also

Value assignments with variables of a bit data type (Page 128)

3.6.1.3 Value assignments with variables of the STRING elementary data type

Assignments between variables of the STRING data type

There are no restrictions to assignments between variables of the STRING data type
(character strings) that have been declared with different lengths. If the declared length of
the target variable is shorter than the current length of the assigned character string, the
character string is truncated to the length of the target variable.

Exception: The following applies for an in/out assignment (parameter transfer to an in/out
parameter): The declared length of the assigned variable (actual parameter) must be greater
than or equal to the declared length of the target variable (formal in/out parameter). See
Parameter transfer to in/out parameters (Page 167).

Please also refer to Syntax diagram of STRING data type (Page 99):

Examples:

\[
\begin{align*}
\text{string20} & := \text{'ABCDEFG'}; \\
\text{string20} & := \text{string30}; \\
\end{align*}
\]
Access to elements of a string

The individual elements of a string can be addressed in the same way as the elements of an array [1..n]. These elements are converted implicitly to the elementary data type BYTE. In this way assignments between string elements and variables of the BYTE data type are possible.

Examples:

```
byteVar := string20[5];
string20[10] := byteVar;
```

The following special cases have to be taken into account:

1. When assigning a variable of the BYTE data type to a string element (e.g. `stringVar[n:] := byteVar`):
   - The string element to which the value is to be assigned lies outside of the declared length of the string:
     The string remains unchanged, TSI#ERRNO is set to 1.
   - The string element to which the value is to be assigned lies outside of the assigned length of the string (n > LEN(stringVar)), but within the declared length:
     The length of the string is adjusted, the string elements between LEN(stringVar) and n are set to $00.$

2. When assigning a string element to a variable of the BYTE data type (`byteVar := stringVar[n:]`):
   - The string element to which the variable is to be assigned lies outside of the assigned length of the string (n > LEN(stringVar)):
     The variable is set to 16#00, TSI#ERRNO to 2.

Editing strings

Various system functions are available for the editing of strings, such as the joining of strings, replacement and extraction of characters, see SIMOTION Basic Functions Function Manual.

Converting between numbers and strings

Various system functions are available for conversion between variables of numeric data types and strings; see Converting elementary data types (Page 154) and the SIMOTION Basic Functions Function Manual.
3.6 Value assignments and expressions

3.6.1.4 Value assignments with variables of a bit data type

Access to individual bits of a bit data type variable

You can also access the individual bits of a variable of data type BYTE, WORD or DWORD:

- With standard functions (see SIMOTION Basic Functions Function Manual):
  
  You can read, write or invert any bit of a bit string with the functions _getBit, _setBit and _toggleBit.
  
  You can specify the number of the bit via a variable.

- With direct bit access:
  
  You can define the bit of the variable that you want to access as a constant, via a separate point behind the variable.
  
  You can only specify the number of the bit via a constant.

To be able to use this option, you must activate the "Permit language extensions" compiler option (see Global compiler settings (Page 47) and Local compiler settings (Page 49)).

![Diagram of Direct bit access (formatted)](image)

Figure 3-20 Syntax: Direct bit access
### Table 3-26 Example of direct bit access

```simotion
// Only with compiler option "Permit language extensions"
FUNCTION f : VOID
  VAR CONSTANT
    BIT_7 : INT := 7;
  END_VAR
  VAR
    dw : DWORD;
    b : BOOL;
  END_VAR
  b := dw.BIT_7;  // Access to bit 7
  b := dw.3;      // Access to bit 3
  // b := dw.33;   // Compilation error;
  // Bit 33 not permitted.
END_FUNCTION
```

**NOTICE**
The access to bits of an I/O variable or system variable can be interrupted by other tasks. There is therefore no guarantee of consistency.

---

### Editing variables of the bit data types

You can:

1. Combine several variables of the same data type into one variable of a higher-level data type (e.g. two variables of the BYTE data type into one of the WORD data type). Various system functions are available for this, e.g. WORD_FROM_2BYTE.

2. Split one variable into several variables of a lower-level data type (e.g. one variable of the DWORD data type into four of the BYTE data type). Various system functions are available for this, e.g. DWORD_TO_4BYTE.

3. Rotate or shift the bits within a variable. The bit string standard functions ROL, ROR, SHL and SHR are available for this.

These system functions and system function blocks are described in the *SIMOTION Basic Functions Function Manual*.

---

### Logic operators

Variables of the bit data types can be combined with logic operators; see Logic expressions and bit-serial expressions (Page 140).
3.6.1.5 Value assignments with variables of the derived enumerator data type

Each expression and each variable of the derived enumerator data type (see also: Derived enumerator data type (Page 109)) can be assigned to another variable of the same type.

\[
type1 := \text{BLUE};
\]

3.6.1.6 Value assignments with variables of the derived ARRAY data type

An array consists of several dimensions and array elements, all of the same type (see also: Derived ARRAY data type (Page 107)).

There are various ways to assign arrays to variables. You can assign complete arrays, individual elements, or parts of arrays:

- A complete array can be assigned to another array if both the data types of the components and the array limits (the smallest and largest possible array indices) are the same. Valid assignments are:

\[
\text{array}_1 := \text{array}_2;
\]

- An individual array element is addressed by the array name followed by the index value in square brackets. An index must be an arithmetic expression of the data type SINT, USINT, INT, UINT or DINT.

\[
\begin{align*}
\text{elem1} & := \text{array}[i]; \\
\text{array}_1[2] & := \text{array}_2[5]; \\
\text{array}[j] & := 14;
\end{align*}
\]

- A value assignment for a valid subarray can be obtained by omitting a pair of square brackets for each dimension of the array, starting at the right. This addresses a partial area of the array whose number of dimensions is equal to the number of remaining indices (see example below).

Consequently, you can reference rows and individual components within a matrix but not closed columns (closed in the sense of from...to). Valid assignments are:

\[
\begin{align*}
\text{matrix}_1[i] & := \text{matrix}_2[k]; \\
\text{array}_1 & := \text{matrix}_2[k];
\end{align*}
\]
3.6.1.7 Value assignments with variables of the derived STRUCT data type

Variables of a user-defined data type that contain STRUCT data type specifications are called structured variables (see also Derived STRUCT data type (Page 110)). They can either represent a complete structure or a component of this structure.

Valid parameters for a structure variable are:

```plaintext
struct1     // Identifier for a structure
struct1.elem1  // Identifier for a structure component
struct1.array1  // Identifier of a simple array
// within a structure
struct1.array1[5]  // Identifier of an array component
// within a structure
```

There are two ways to assign structures to variables. You can reference complete structures or structure components:

- A complete structure can only be assigned to another structure if the data type and the name of both structure components match.
  
  A valid assignment is:

  ```plaintext
  struct1 := struct2;
  ```

- You can assign a type-compatible variable, a type-compatible expression or another structure component to each structure component.

  Valid assignments are:

  ```plaintext
  struct1.elem1 := Var1;
  struct1.elem1 := 20;
  struct1.elem1 := struct2.elem1;
  struct1.array1 := struct2.array1;
  struct1.array1[10] := 100;
  ```

**Note**

You also use structured variables in the `FBInstanceName.OutputParameter` format, e.g. `myCircle.circumference` to access the output variables of a function block, i.e. the result of the function block. For more detailed information about function blocks, refer to the explanations in Defining functions (Page 160) and Defining function blocks (Page 161).

A further application of structured variables is to access TO variables and the variables of the basic system.
3.6.2 Expressions

An expression represents a value that is calculated when the program is compiled or executed. It consists of operands (e.g. constants, variables or function values) and operators (e.g. *, /, +, -).

The data types of the operands and the operators involved determine the expression type.

ST uses the following types of expression:

- Arithmetic expressions (Page 135)
- Relational expressions (Page 138)
- Logic expressions and bit-serial expressions (Page 140)

3.6.2.1 Result of an expression

The result of an expression can be:

- Assigned to a variable
- Used as a condition for a control statement
- Used as a parameter for a function or function block call.

The data type of the result of an arithmetical or bit-serial expression is determined by the data types of the operands. The data type used is the lowest common data type to which both operands can be implicitly converted.

An expression value can only be assigned to a variable (or a parameter of a function or function block) in the following cases:

- The expression calculated and the variable to be assigned are of the same data type.
- The data type of the calculated expression can be implicitly converted to the data type of the variable to be assigned.

For more information on this error source and its solution, see SIMOTION Basic Functions Function Manual.

---

Note

Expressions containing only the following elements can be used for variable initialization and index specification in ARRAY declarations (for initialization expressions – see Figure Syntax: Constant expression in Initialization of variables or data types (Page 119)):

- Constants
- Basic arithmetic operations
- Logic and relational operations
- Bit string standard functions

The constant expressions used for initialization are calculated in the data type of the declared variables or in the declared data type.
### 3.6.2.2 Interpretation order of an expression

The interpretation order of an expression depends on the following:

- The priority of the operators used,
- The left-to-right rule,
- The use of parentheses (for operators of the same priority).

Expressions are processed according to specific rules:

- Operators are executed according to priority (see table in Operator priority (Page 142)).
- Operators of the same priority are executed from left to right.
- A minus symbol in front of an identifier denotes multiplication by -1.
- An arithmetic operator cannot be followed immediately by another. The expression \( a \times -b \) is therefore invalid, but \( a \times (-b) \) is allowed.
- Parentheses override the operator priority order, i.e. parentheses have the highest priority.
- Expressions in parentheses are treated as individual operands and are always evaluated first.
- The number of opening parentheses must equal the number of closing parentheses.
- Arithmetic operations cannot be used on characters or logic data. For this reason, expressions such as \((n<=0) + (n<0)\) are invalid.

#### Table 3-27 Examples of expressions

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>

<td>Logic expression</td>
</tr>
<tr>
<td><code>A AND (NOT B)</code></td>
<td>Logic expression with negation</td>
</tr>
<tr>
<td><code>(C) &lt; (D)</code></td>
<td>Relational expression</td>
</tr>
<tr>
<td><code>3+3*4/2</code></td>
<td>Arithmetic expression</td>
</tr>
</tbody>
</table>
3.6 Value assignments and expressions

3.6.3 Operands

Definition

Operands are objects which can be used to formulate expressions. Operands can be represented by the syntax diagram:

![Operand Syntax Diagram]

Table 3-28 Examples of operands

- `intVar`
- `5`
- `%I4.0`
- `PI`
- `NOT TRUE`
- `axis1.motionStateData.actualVelocity`

<1> Only for activated "Permit language extensions" compiler option:
3.6.4 Arithmetic expressions

An arithmetic expression is an expression formed with arithmetical operators. These expressions allow numerical data types to be processed.

The following table shows for each arithmetic operation:
- The arithmetic operator
- The permitted data types of the operands
- The data type of the result.

Some of the General data types (Page 102) are used here.

Note

Further operations are possible with standard numeric functions, see Standard numeric functions in the SIMOTION Basic Functions Function Manual.

It is recommended to enclose negative numbers in parentheses, even in cases where it is not absolutely necessary, in order to enhance legibility.

The arithmetic operators are processed in accordance with their rank (Page 142).
### Arithmetic operators

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Operator</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exponential **</td>
<td>ANY_REAL 2)</td>
<td>ANY_REAL 3)</td>
</tr>
<tr>
<td>Unary minus –</td>
<td>ANY_NUM 4)</td>
<td>ANY_NUM</td>
</tr>
<tr>
<td>Multiplication *</td>
<td>ANY_NUM 4)</td>
<td>ANY_NUM</td>
</tr>
<tr>
<td>Division /</td>
<td>ANY_NUM 5)</td>
<td>ANY_NUM 6)</td>
</tr>
<tr>
<td>Modulo division MOD</td>
<td>ANY_INT 5)</td>
<td>ANY_INT</td>
</tr>
<tr>
<td>Addition +</td>
<td>ANY_NUM 4)</td>
<td>ANY_NUM</td>
</tr>
<tr>
<td>Subtraction –</td>
<td>ANY_NUM 5)</td>
<td>ANY_NUM</td>
</tr>
</tbody>
</table>

1) The data type of the result (unless explicitly stated) is the lowest common data type to which both operands can be implicitly converted.

2) The first operand must be greater than zero.

3) Data type of first operand.

4) Other than BOOL data type. The calculation is made using the unsigned integer of the same bit width.

5) The second operand must not be equal to zero.

6) Addition, possibly with overflow.

7) Addition with date correction.

8) Restriction of TIME to TOD before calculation.

9) These operations are based on the modulo of the maximum value of the TIME data type.
Note

If the limits of the value range are exceeded in operations with variables of the general ANY_REAL data type, the result contains the equivalent bit pattern according to IEEE 754.

In order to establish whether the value range was exceeded in the operation, you can verify the result using the function _finite (see SIMOTION Basic Functions Function Manual).

### 3.6.4.1 Examples of arithmetic expressions

#### Examples of arithmetic expressions with numbers

Assuming that \( i \) and \( j \) are integer variables (e.g. of data type INT) with the values of 11 and -3 respectively, some example integer expressions and their corresponding values are presented below:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>( i + j )</td>
<td>8</td>
</tr>
<tr>
<td>( i - j )</td>
<td>14</td>
</tr>
<tr>
<td>( i \times j )</td>
<td>-33</td>
</tr>
<tr>
<td>( i \mod j )</td>
<td>-2</td>
</tr>
<tr>
<td>( i / j )</td>
<td>-3</td>
</tr>
</tbody>
</table>

#### Examples of valid arithmetic expressions with time specifications

Assume the following variables:

- \( t1 \) = T#1D_1H_1M_1S_1MS
- \( t2 \) = T#2D_2H_2M_2S_2MS
- \( d1 \) = D#2004-01-11
- \( d2 \) = D#2004-02-12
- \( tod1 \) = TOD#11:11:11.11
- \( tod2 \) = TOD#12:12:12.12
- \( dt1 \) = DT#2004-01-11-11:11:11.11
- \( dt2 \) = DT#2004-02-12-12:12:12.12

Some expressions with these variables and their values are shown in the example:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t1 + t2 )</td>
<td>T#3D_3H_3M_3S_3MS</td>
</tr>
<tr>
<td>( dt1 + t1 )</td>
<td>DT#2004-01-12-12:12:12.111</td>
</tr>
<tr>
<td>( t1 - t2 )</td>
<td>T#48D_16H_1M_46S_295MS</td>
</tr>
<tr>
<td>( t1 \times 2 )</td>
<td>T#2D_2H_2M_2S_2MS</td>
</tr>
<tr>
<td>( t1 / 2 )</td>
<td>T#12H_30M_30S_500MS</td>
</tr>
<tr>
<td>DATE_AND_TIME_TO_TIME_OF_DAY(dt1)</td>
<td>TOD#11:11:11.110</td>
</tr>
<tr>
<td>DATE_AND_TIME_TO_DATE(dt1)</td>
<td>D#2004-01-11</td>
</tr>
</tbody>
</table>
3.6 Value assignments and expressions

3.6.5 Relational expressions

Definition

A relational expression is an expression of the BOOL data type formed with relational operators (see figure).

![Relational operators](image)

Figure 3-24 Syntax: Relational operators

Relational operators compare the values of two operands (see table) and return a Boolean value as result.

1st Operand Operator 2nd Operand -> Boolean value

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>1. operand is greater than the 2nd operand</td>
</tr>
<tr>
<td>&lt;</td>
<td>1. operand is less than the 2nd operand</td>
</tr>
<tr>
<td>&gt;=</td>
<td>1. operand is greater than or equal to the 2nd operand</td>
</tr>
<tr>
<td>&lt;=</td>
<td>1. operand is less than or equal to the 2nd operand</td>
</tr>
<tr>
<td>=</td>
<td>1. operand is equal to the 2nd operand</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>1. operand is not equal to the 2nd operand</td>
</tr>
</tbody>
</table>

The result of the relational expression is:

- 1 (TRUE), when the comparison is satisfied
- 0 (FALSE), when the comparison is not satisfied.
The following table shows permissible combinations of the data types for the two operands and relational operators.

Table 3-31  Relational expressions: Permissible combinations of the data types and relational operators

<table>
<thead>
<tr>
<th>Data type</th>
<th>1. Operand</th>
<th>2. Operand</th>
<th>Permissible relational operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY_NUM</td>
<td>ANY_NUM(^1)</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td>DATE</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>TIME_OF_DAY (TOD)</td>
<td>TIME_OF_DAY (TOD)</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>DATE_AND_TIME (DT)</td>
<td>DATE_AND_TIME (DT)</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>TIME</td>
<td>TIME</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>STRING</td>
<td>STRING(^2)</td>
<td>(&lt;, &gt;, \leq, \geq, =, \neq)</td>
<td></td>
</tr>
<tr>
<td>Enumerator data type</td>
<td>Enumerator data type(^3)</td>
<td>(=, \neq)</td>
<td></td>
</tr>
<tr>
<td>ARRAY</td>
<td>Field (ARRAY)(^3)</td>
<td>(=, \neq)</td>
<td></td>
</tr>
<tr>
<td>Structure (STRUCT)</td>
<td>Structure (STRUCT)(^3)</td>
<td>(=, \neq)</td>
<td></td>
</tr>
</tbody>
</table>

\(^1\) The comparison is made in the lowest common data type to which both operands can be implicitly converted.

\(^2\) Variables of the STRING data type can be compared irrespective of the declared length of the string.

To compare two variables of the STRING data type with different lengths, the shorter character string is expanded to the length of the longer character string by inserting \$00 on the right-hand side. The comparison starts from left to right and is based on the ASCII code of the respective characters. Example: ‘ABC’ < ‘AZ’ < ‘Z’ < ‘abc’ < ‘az’ < ‘z’.

\(^3\) Data type of the first operand.

Relational expressions and variables or constants of the BOOL data type can be combined with logic operators to form logic expressions (see Logic expressions and bit-serial expressions (Page 140)). This enables the implementation of queries such as if \(a < b \text{ and } b < c\), then ....

**NOTICE**

Relational operators have a higher priority than logic operators in an expression (see Operator priority (Page 142)). Therefore the operands of a relational expression must be placed in brackets if they themselves are logic expressions or bit-serial expressions.

Note that errors can occur when comparing REAL or LREAL variables (also the corresponding system variables, e.g. axis position).
3.6 Value assignments and expressions

3.6.6 Logic expressions and bit-serial expressions

Definition

With the logic operators AND, &, XOR, and OR, it is possible to combine operands and expressions of the general data type ANY_BIT (BOOL, BYTE, WORD, or DWORD).

With the logic operator NOT it is possible to negate operands and expressions of data type ANY_BIT.

The table provides information about the available operators:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Operator</th>
<th>1. Operand</th>
<th>2. Operand</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Negation</td>
<td>NOT</td>
<td>ANY_BIT</td>
<td>-</td>
<td>ANY_BIT</td>
</tr>
<tr>
<td>Conjunction</td>
<td>AND or &amp;</td>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
</tr>
<tr>
<td>Exclusive disjunction</td>
<td>XOR</td>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
</tr>
<tr>
<td>Disjunction</td>
<td>OR</td>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
<td>ANY_BIT</td>
</tr>
</tbody>
</table>

1 The data type of the result is determined by the most powerful data type of the operands.

The expression is designated

- a **logic expression**, if only operands of data type BOOL are used.
  - The operators have the effect on the operands stated in the following truth table.
  - The result of a logic expression is 1 (TRUE) or 0 (FALSE).
- a **bit-serial expression**, if operands of data type BYTE, WORD, or DWORD are used.
The operators have the effect on individual bits of the operands stated in the following truth table.

Table 3-34 Truth table of the logic operators

<table>
<thead>
<tr>
<th>Operands (data type BOOL)</th>
<th>Result (data type BOOL)</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>

<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Examples

Table 3-35 Logic expressions

<table>
<thead>
<tr>
<th>Expression (let n = 10)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>(n&gt;0) AND (n&lt;20)</td>
<td>TRUE</td>
</tr>
<tr>
<td>(n&gt;0) AND (n&lt;5)</td>
<td>FALSE</td>
</tr>
<tr>
<td>(n&gt;0) OR (n&lt;5)</td>
<td>TRUE</td>
</tr>
<tr>
<td>(n&gt;0) XOR (n&lt;20)</td>
<td>FALSE</td>
</tr>
<tr>
<td>NOT ((n&gt;0) AND n&lt;20))</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Table 3-36 Bit-serial expressions

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2#01010101 AND 2#11110000</td>
<td>2#01010000</td>
</tr>
<tr>
<td>2#01010101 OR 2#11110000</td>
<td>2#11110101</td>
</tr>
<tr>
<td>2#01010101 XOR 2#11110000</td>
<td>2#10100101</td>
</tr>
<tr>
<td>NOT 2#01010101</td>
<td>2#10101010</td>
</tr>
</tbody>
</table>

Expression in query (let value1 be 2#01, let value2 be 2#11)

IF (value1 AND value2) = 2#01 THEN...

Condition returns TRUE, because bit-serial expression returns 2#01.
### 3.6.7 Priority of operators

Some general rules for the formulation of expressions were described in Expressions (Page 132). The table shows you the priority of the individual operators within an expression.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Symbol</th>

</tbody>
</table>

Highest

Lowest
3.7 Control statements

Few source file sections can be programmed such that all statements are executed in sequence from start to end. Usually, some statements will be executed only if a condition is true (alternatives) and some will be executed repeatedly (loops). Program control statements within a source file section are the means for accomplishing this.

3.7.1 IF statement

The IF statement is a conditional statement. It specifies one or more options and selects one (or none) of its statement sections for execution.

The specified logic expressions are evaluated when the conditional statement is executed. If the value of an expression is TRUE, the condition is fulfilled, if the value is FALSE, it is not fulfilled.

![IF statement diagram]

The IF statement is processed according to the following rules:

1. If the value of the first expression is TRUE, the statement section after the THEN is executed.
   
   The program is subsequently resumed after the END_IF.

2. If the value of the first expression is FALSE, the expressions in the ELSIF branches are evaluated. If a Boolean expression in one of the ELSIF branches is TRUE, the statement section following THEN is executed.
   
   The program is subsequently resumed after the END_IF.

3. If none of the Boolean expressions in the ELSIF branches is TRUE, the sequence of statements after the ELSE is executed (or, if there is no ELSE branch, no further statements are executed).
   
   The program is subsequently resumed after the END_IF.
Any number of ELSIF statements may be programmed.

Note that there may not be any ELSIF branches and/or ELSE branch. This is interpreted in the same way as if the branches existed with no statements.

**Note**

An advantage of using one or more ELSIF branches rather than a sequence of IF statements is that the logic expressions following a valid expression are no longer evaluated. This helps to reduce the processing time required for the program and to prevent execution of unwanted program routines.

Table 3-37  Examples of the IF statement

```
IF A=B THEN
  n:= 0;
END_IF;

IF temperature < 5.0 THEN
  %Q0.0 := TRUE;
ELSIF temperature > 10.0 THEN
  %Q0.2 := TRUE;
ELSE
  %Q0.1 := TRUE;
END_IF;
```
3.7.2 CASE statement

The CASE statement is used to select 1 of n program sections. This selection determines a selection expression (selector):
- Expression of general data type ANY_INT
- Variable of an enumeration data type (enumerator)

The selection is made from a list of values (value list), whereby a section of the program is assigned to each value or group of values.

The CASE statement is processed according to the following rules:
1. The selection expression (selector) is calculated. It must return a value of general data type ANY_INT (integer) or an enumerator data type.
2. Then a check is performed to determine whether the selector value is contained in the value list. Each value in the list represents one of the allowed values for the selection expression.
3. If a match is found, the program section assigned in the list is executed.
4. The ELSE branch is optional. It is executed if no match is found.
5. If the ELSE branch is missing and no match is found, the program is resumed after END_CASE.

Figure 3-26 Syntax: CASE statement
The value list contains the allowed values for the selection expression.

![Diagram of Value List](image)

**Figure 3-27  Syntax: Value list**

Note the following when formulating the value list:

- Each value list can begin with a constant (*value*), a constant list (*value1, value2, value3, etc.*) or a constant range (*value1 to value2*).
- Values in the value list must be integer values or constants/elements of the enumeration data type of the selector.

**Note**

A value should only occur once in the value lists of a CASE statement.

In the event of multiple occurrence of a value, the compiler will issue an alarm, and only the section of the statement corresponding to the value list in which the value occurred first is executed.

The following example illustrates the use of the CASE statement.

<table>
<thead>
<tr>
<th>Table 3-38</th>
<th>Examples of the CASE statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE intVar OF</td>
<td></td>
</tr>
<tr>
<td>1   : a := 1;</td>
<td></td>
</tr>
<tr>
<td>2,3 : b := 1;</td>
<td></td>
</tr>
<tr>
<td>4..9 : c := 1; d:=2;</td>
<td></td>
</tr>
<tr>
<td>ELSE</td>
<td></td>
</tr>
<tr>
<td>e := 5;</td>
<td></td>
</tr>
<tr>
<td>END_CASE;</td>
<td></td>
</tr>
</tbody>
</table>
3.7.3 FOR statement

A FOR statement or a repeat statement executes a series of statements in a loop, whereby values are assigned to a variable (a count variable) on each pass. The count variable must be a local variable of type SINT, INT or DINT.

The definition of a loop with FOR includes the specification of a start and end value. Both variables must be the same data type as the count variable.

Note
You use the FOR statement when the number of loop passes is known at the programming stage. If the number of passes is not known, the WHILE or REPEAT statement is more suitable (see WHILE statement (Page 149) and REPEAT statement (Page 150)).

![Syntax: FOR statement](image)

Figure 3-28 Syntax: FOR statement
3.7.3.1 Processing of the FOR statement

The FOR statement is processed according to the following rules:

1. At the start of the loop, the count variable is set to the start value and is increased (positive increment) or decreased (negative increment) by the specified increment after each loop pass until the end value is reached. After the first loop pass, the start value is known as the current value.

2. On each pass, the system checks whether the following conditions are true:
   - Start value or current value <= end value (for positive increment) or
   - Start value or current value >= end value (for negative increment)

   If the condition is fulfilled, the sequence of statements is executed.
   If the condition is not fulfilled, the loop and, thus, the sequence of statements is skipped and the program is resumed after END_FOR.

3. If the FOR loop is not executed due to Step 2, the count variable retains the current value.

3.7.3.2 Rules for the FOR statement

The following rules apply to the FOR statement:

- The \textit{BY [increment]} specification can be omitted. If no increment is specified, the default is +1.
- The start value, end value, and increment are expressions (see Expressions (Page 132)). The expression is evaluated once at the beginning of the FOR statement.
- If the start value and end value are of the DINT data type, the value of (end value - start value) must be less than the maximum value range of the double integer, that is, less than $2^{31}-1$.
- Only the first selection statement for which the selector is true is executed.
- The count variable contains the value which triggers the loop exit, i.e. it is incremented before the loop is exited.
- You are not allowed to change the end value and increment value during the execution of the loop.

3.7.3.3 Example of the FOR statement

Table 3- 39 Example of the FOR statement

\begin{verbatim}
FOR k := 1 TO 10 BY 2 DO
  l:=l+1;
  // ...
END_FOR;
\end{verbatim}
3.7.4 WHILE statement

The WHILE statement allows a sequence of statements to be executed repeatedly under the control of an iteration condition. The iteration condition is formulated in accordance with the rules for a logic expression.

Note

You use the WHILE statement when the number of loop passes is not known at the programming stage. If the number of passes is known, the FOR statement is more suitable (see FOR statement (Page 147)).

Figure 3-29 Syntax: WHILE statement

The statement section after DO is repeated until the iteration condition has the value TRUE. The WHILE statement is processed according to the following rules:

1. The iteration condition is evaluated each time before the statement section is executed.
2. If the value is TRUE, the statement section is executed.
3. If the value is FALSE, the WHILE statement is terminated (this can occur the first time the condition is evaluated) and the program is resumed after END_WHILE.

Table 3-40 Example of the WHILE statement

WHILE Index <= 50 DO
  Index:= Index + 2;
END_WHILE;
3.7.5 REPEAT statement

A REPEAT statement causes a sequence of statements programmed between REPEAT and UNTIL to be executed repeatedly until a termination condition is true. The termination condition is formulated in accordance with the rules for a logic expression.

Note

You use the REPEAT statement when the number of loop passes is not known at the programming stage. If the number of passes is known, the FOR statement is more suitable (see FOR statement (Page 147)).

REPEAT statement (unformatted)

The condition is checked after the statement section is executed. That means the statement section is executed at least once, even if the termination condition is true at the start.

The REPEAT statement is processed according to the following rules:
1. The iteration condition is evaluated each time after the statement section is executed.
2. If the value is FALSE, the statement section is executed again.
3. If the value is TRUE, execution of the REPEAT statement is terminated and program execution is resumed after END_REPEAT.

Table 3- 41 Example of the REPEAT statement

Index:= 1;
REPEAT
   Index:= Index + 2;
UNTIL Index > 50
END_REPEAT;
3.7 Control statements

3.7.6 EXIT statement

An EXIT statement is used to exit a loop (FOR, WHILE or REPEAT loop) at any point, irrespective of whether the termination condition is true or false.

This statement has the effect of jumping directly out of the loop immediately surrounding the EXIT statement.

The program resumes after the end of the loop (e.g. after END_FOR).

Table 3-42 Example of the EXIT statement

Index:= 1;
FOR Index := 1 to 51 BY 2 DO
  IF %I0.0 THEN
    EXIT;
  END_IF;
END_FOR;
// The following value assignment is made after the execution of EXIT
// or after the regular end of the FOR loop
// For the execution:
Index_find := Index_2;

3.7.7 RETURN statement

A RETURN statement causes termination of the POU currently being processed (program, function, function block).

When a function or a function block is terminated, program execution continues in the higher-level POU after the position where the function or function block was called.

Table 3-43 Example of the RETURN statement

Index:= 1;
FOR Index := 1 to 51 BY 2 DO
  IF %I0.0 THEN
    RETURN;
  END_IF;
END_FOR;
// The following value assignment is made after the regular end
// of the FOR loop for the execution, however, not after the execution
// of RETURN:
Index_find := Index_2;
3.7 Control statements

3.7.8 WAITFORCONDITION statement

You can use the WAITFORCONDITION statement to wait for a programmable event or condition in a MotionTask. The statement suspends execution of the calling MotionTask until the condition is true. You program this condition in an Expression (Page 180). More information about the WAITFORCONDITION and expressions in this regard is contained in the SIMOTION Motion Control Basic Functions Function Manual.

Expression identifier is a construct declared with EXPRESSION; its value defines (together with WITH edge evaluation, if necessary) whether the condition is considered as been satisfied.

The WITH edge evaluation sequence is optional. Edge evaluation is an expression of data type BOOL; it determines how the value of expression identifier is interpreted:

- Edge evaluation = TRUE: The rising edge of expression identifier is interpreted; i.e. the condition is satisfied when the value of expression identifier changes from FALSE to TRUE.
- Edge evaluation = FALSE: The static value of expression identifier is interpreted; i.e. the condition is satisfied when the value of expression identifier is TRUE.

If WITH edge evaluation is not specified, the default setting is FALSE, i.e. the static value of expression identifier is evaluated.

The statement section must contain at least one statement (empty statements also possible).
### 3.7 Control statements

#### 3.7.9 GOTO statement

The GOTO statement causes a jump to the jump label specified in the command (see Jump statement and labeling (Page 274)).

You program jump statements with the GOTO statement and specify the jump label to which you want to jump. Jumps are only permitted within a POU.

![Syntax: GOTO statement](image)

**Note**

You should only use the GOTO statement in special circumstances (for example, for troubleshooting). It should not be used at all according to the rules for structured programming.

Jumps are only permitted within a POU.

The following jumps are illegal:

- Jumps to subordinate control structures (WHILE, FOR, etc.)
- Jumps from a WAITFORCONDITION structure
- Jumps within CASE statements

Jump labels can only be declared in the POU in which they are used. If jump labels are declared, only the declared jump labels may be used.
3.8 Data type conversions

This section describes how you can implicitly and explicitly convert between elementary data types. It also contains an overview of the additional conversion possibilities.

3.8.1 Elementary data type conversion

The table presents an overview of the conversion options between numerical data types and bit data types. The following are distinct conversion options:

- Implicit conversion: Conversion is automatic when different data types are used in an expression or when values are assigned by the compiler.
- Explicit conversion: Conversion is carried out when the user calls a conversion function (see SIMOTION Basic Functions Function Manual).

Im: Implicit data type conversion possible
Ex: Explicit data type conversion possible using the Quelldatentyp_TO_Zieldatentyp type conversion function
Val: Explicit data type conversion possible using the Quelldatentyp_VALUE_TO_Zieldatentyp type conversion function
Elem: Implicit data type conversion with an element of the STRING data type

For information on conversion functions for date and time data types: Please refer to the SIMOTION Basic Functions Function Manual.
3.8.1.1 Implicit data type conversions

Implicit type conversion is always possible if an enlargement of the value range does not cause any value loss, e.g. from REAL to LREAL or from INT to REAL. The result is always defined.

The following figure provides a graphics-based view of all implicit type conversion chains. Each stage in the type conversion chain - reading from left to right or from top to bottom - always represents an enlargement of the value range.

![Implicit type conversion chains](image)

The following implicit type conversions are supported:

1. Horizontally (from left to right) over one or more levels (e.g. USINT to UDINT)
2. Vertically (from top to bottom) over one level (e.g. UINT to REAL)

The implicit type conversions can be combined in the following order (e.g. INT to LREAL).

All other type conversions cannot be performed implicitly (e.g. UDINT to REAL), that is, you must use an explicit function (see SIMOTION Basic Functions Function Manual).

Note

In arithmetic expressions, the result is always calculated in the largest number format contained in the expression.

A value can only be assigned to the expression if:

- The calculated expression and the variable to be assigned are of the same data type.
- The data type of the calculated expression can be implicitly converted to the data type of the variable to be assigned.

For more information on this error source and its solution: Please refer to the SIMOTION Basic Functions Function Manual.
### 3.8 Data type conversions

#### Table 3-46  Example of data types in expressions and value assignments

```plaintext
VAR
  usint_var  : USINT;
  real_var   : REAL;
  byte_var   : BYTE;
  string_var : STRING[80] := 'example for string';
END_VAR

usint_var := 234 / 10;       // Expression data type: USINT
  // Result = 23

real_var  := 234 / 10;       // Expression data type: USINT
  // Implicit conversion possible
  // Result = 23.0

usint_var := 234 / SINT#10;  // Expression data type: INT
  // Implicit conversion and
  // value assignment not possible

real_var  := 234 / 10.0;     // Expression data type: REAL
  // Result = 23.4

usint_var := 234 / 10.0;     // Expression data type: REAL
  // Implicit conversion and
  // value assignment not possible

byte_var  := string_var[5];  // Implicit conversion possible
  // Result = 16#70 ('p')

string_var[10] := byte_var;  // Implicit conversion possible
  // Result = 'example fpr string'
```

**Note**

If applicable, specify the data type explicitly for numbers (e.g. UINT#127, if the number 127 is to be of data type UINT instead of USINT).
### 3.8.1.2 Explicit data type conversions

Explicit conversion is always required if information could be lost, for example, if the value range is decreased or the accuracy is reduced, as is the case for conversion from LREAL to REAL.

The conversion functions for numeric data types and bit data types are listed in the SIMOTION Basic Functions Function Manual.

The compiler outputs warnings when it detects conversions associated with loss of precision.

---

**NOTICE**

The type conversion may cause errors when the program is running, which will trigger the error response set in the task configuration (see SIMOTION Basic Functions Function Manual).

Special attention is required when converting DWORD to REAL. The bit string from DWORD is taken unchecked as the REAL value. You must make sure that the bit string in DWORD corresponds to the bit pattern of a normalized floating-point number in accordance with IEEE. To do this, you can use the `_finite` and `_isNaN` functions.

Otherwise, an error is triggered (see above) as soon as the REAL value is first used for an arithmetic operation (for example, in the program or when monitoring in the symbol browser).

---

**Note**

The following applies if the value range limits are exceeded during conversion from LREAL to REAL:

- **Underflow** (absolute value of LREAL number is smaller than the smallest positive REAL number):
  
  Result is 0.0.

- **Overflow** (absolute value of LREAL number is larger than the largest positive REAL number):
  
  The error response specified during task configuration is triggered.
3.8.2 Supplementary conversions

The ST system functions and ST system functions also permit the following conversions:

- **Combining bit-string data types**
  These functions combine multiple variables of a bit string data type into one variable of a higher-level data type.

- **Splitting bit-string data types**
  These function blocks split up a variable of a bit string data type into multiple variables of a higher-level data type.

- **Converting between any data types and byte arrays**
  They are commonly used to create defined transmission formats for data exchange between various devices.

  For further information (e.g. on the arrangement of the byte arrays, application example): Please refer to the SIMOTION Basic Functions Function Manual.

- **Conversion of technology object data types**
  It converts variables of a hierarchical TO data type (driveAxis, posAxis, or followingAxis) or of the general ANYOBJECT type to a compatible TO data type.

  For Application Examples and further information: Please refer to the SIMOTION Basic Functions Function Manual.
This chapter describes how to create and call user-defined functions and function blocks. Standard functions are already available in the system for type conversion, trigonometry, and bit string manipulation. The SIMOTION Basic Functions Function Manual describes how to use system functions and functions of technology objects (TO functions).

A function (FC) is a logic block with no static data. All local variables lose their value when you exit the function and are reinitialized the next time you call the function.

A function block (FB) is a code block with static data. Since an FB has memory, its output parameters can be accessed at any time and from any point in the user program. Local variables retain their values between calls.

Programs are similar to FBs, but have no parameters. However, they can be assigned execution levels and tasks (see SIMOTION Basic Functions Function Manual).

FCs and FBs have the advantage that they can be reused, because they are encapsulated source file sections to which parameters can be assigned.

Functions, function blocks, and programs are program organization units (POUs), i.e. they are executable source file sections. You will find an overview of all source file sections in Use of the source file sections (Page 183).

4.1 Creating and calling functions and function blocks

The following description explains how to create and call functions (FCs) and function blocks (FBs). A complete example showing the differences between FC and FB is contained in Comparison of functions and function blocks (Page 175).

The order in which you must define and call the stipulated source file sections is given in Use of the source file sections (Page 183).

How to export and import FCs and FBs is explained in Section Import and export between ST source files (Page 194).
4.1.1 Defining functions

You define a function in the declaration part of the implementation section before the section of the source file (program, FB, or FC) in which it is called.

Use the following syntax:

```
FUNCTION Identifier [Data type]

<table>
<thead>
<tr>
<th>Function (unformatted)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUNCTION</td>
</tr>
<tr>
<td>FC declaration section</td>
</tr>
</tbody>
</table>

Note for functions with data type (not VOID): The return value of the function identifier must be assigned in the statement section!
```

Figure 4-1 Syntax: Function (FC)

The FUNCTION keyword is followed by an identifier as the FC name and the data type of the return value. Enter VOID as data type if the FC has no return value.

Then enter (see example in Source file with comments (Page 176)):
- The optional declaration section
- The statement section
- The END_FUNCTION keyword
4.1.2 Defining function blocks

You define a function block in the declaration part of the implementation section before the section of the source file (program, FB or FC) in which the FB is called.

Use the following syntax:

![Diagram of function block syntax]

Figure 4-2 Syntax: Function block (FB)

Enter an identifier as the FB name after the FUNCTION_BLOCK keyword. Then enter (see example in Source file with comments (Page 176)):

- The optional declaration section
- The statement section
- The END_FUNCTION_BLOCK keyword
4.1.3 Declaration section of FB and FC

A declaration section is subdivided into various declaration blocks that are each identified by a separate pair of keywords. Each block contains a declaration list for similar data, such as constants, local variables and parameters. Each type of block may only appear once; the blocks may appear in any order.

The following options are then available for the declaration section of an FC and an FB (see also the example in Source file with comments (Page 176)):

<table>
<thead>
<tr>
<th>Data</th>
<th>Syntax</th>
<th>FB</th>
<th>FC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constant</td>
<td>VAR_CONSTANT Declaration list</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td></td>
<td>END_VAR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Input parameters</td>
<td>VAR_INPUT Declaration list</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td></td>
<td>END_VAR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>In/out parameter</td>
<td>VAR_IN_OUT Declaration list</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td></td>
<td>END_VAR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Output parameters</td>
<td>VAR_OUTPUT Declaration list</td>
<td>X</td>
<td>–</td>
</tr>
<tr>
<td></td>
<td>END_VAR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Local variable (for FC and FB)</td>
<td>VAR Declaration list</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td></td>
<td>END_VAR (static)</td>
<td></td>
<td>(temporary)</td>
</tr>
<tr>
<td>Local variable (for FB)</td>
<td>VAR_TEMP Declaration list</td>
<td>X</td>
<td>–</td>
</tr>
<tr>
<td></td>
<td>END_VAR (temporary)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Declaration list: The list of identifiers of the type to be declared

Parameters are local data and are formal parameters of a function block or function. When the FB or FC is called, the formal parameters are substituted by the actual parameters, thus providing a means of exchanging information between the called and calling source file sections.

- Formal input parameters receive the actual input values (data flow inwards).
- Formal output parameters (only for FB) are used to transfer output values (data flow outwards).
- Formal in/out parameters act as input and output parameters.

The following figures show the syntax for the parameter declaration of an FB or an FC.
You can use the declared parameters the same as other variables within the FB or FC, with the following exception: You cannot assign values to input parameters.
From outside of an FB or an FC, you can access:

- The input and output parameters of an FB by means of structured variables (see User-defined data types (Page 103)).

  The access to the input parameter is possible only when the "Permit language extensions" compiler option has been activated (see Global compiler settings (Page 47) or Local compiler settings (Page 49)).

  Data access to the output parameter is possible as standard.

- The return value of an FC by using the function in an expression and assigning this, for example, to a variable (the specification of the function name calls the function and simultaneously returns a result).
4.1.4 Statement section of FB and FC

The statement section of the FC or FB contains statements that are executed when the FC or FB is called. There is no difference compared to the formal rules for creating a statement section; however, you should note the information in the following table.

Table 4- 2 Use of parameters and variables in FCs and FBs

<table>
<thead>
<tr>
<th>Parameter/variable</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input parameters</td>
<td>With the call of an FC or an FB, assign the current values to the input parameters. These values are used for data processing within the FC or the FB, for example, for calculations, but cannot be modified themselves. Only for activated &quot;Permit language extensions&quot; compiler option (see Global compiler settings (Page 47) or Local compiler settings (Page 49)): The input parameters of an FB can be read and written using structured variables, also outside the FB (e.g. in the calling source file section).</td>
</tr>
<tr>
<td>In/out parameter</td>
<td>You assign a variable to an in/out parameter for the call of the FB or FC. The FC or the FB accesses this variable directly and can change it immediately. Type conversions are not supported. The variable assigned to an in/out parameter must be able to be directly read and written. Therefore, system variables (of the SIMOTION device or a technology object), I/O variables or process image accesses cannot be assigned to an in/out parameter.</td>
</tr>
<tr>
<td>Output parameters</td>
<td>You assign a variable to an in/out parameter for the call of an FB using the ( \Rightarrow ) operator. The value of the output parameter (result) is transferred to the variables when the FB is closed. The output parameters of an FB can also be read using structured variables, also outside the FB (e.g. in the calling source file section). An FC has no formal output parameters, because the function name receives the return value. The function name itself is, in a sense, the output parameter.</td>
</tr>
<tr>
<td>(for FB only)</td>
<td></td>
</tr>
</tbody>
</table>
| Local variables    | Local variables are variables that are declared and used only within the block. All local variables (VAR ... END_VAR) are temporary in an FC, i.e. they lose their value when the FC is terminated. The next time the FC is called, they are reinitialized. A differentiation between static and temporary local variables is made in the FB:  
  - Static variables (VAR ... END_VAR) retain their value when the FB is closed.  
  - Temporary variables (VAR_TEMP ... END_VAR) lose their value when the FB is closed. The next time the FB is called, they are reinitialized. The value of the local variable cannot be queried directly by the calling block. This is only possible using an output parameter. |

Note

For tips on the efficient use of parameters, please refer to Runtime-optimized Programming in the SIMOTION Basic Functions Function Manual.
4.1.5 Call of functions and function block calls

This provides an overview of the call of the functions and function blocks.

4.1.5.1 Principle of parameter transfer

When you call an FC or FB, data exchange takes place between the calling and the called block. The parameters to be transferred must be specified as a parameter list in the call. The parameters are written in parentheses. Several parameters are separated by commas.

```
myCircle (lrRadius := 3, lrCircumf := myCircumf);
```

Figure 4-5 Principle of parameter transfer for the call

Input and in/out parameters are normally specified as a value assignment. In this way, you assign values (actual parameters) to the parameters you have defined in the declaration section of the called block (formal parameters).

The assignment of output parameters is made using the => operator. In this way, you assign a variable (actual parameter) to the output parameters you have defined in the declaration section of the called block (formal parameters).

4.1.5.2 Parameter transfer to input parameters

You transfer the data (actual parameters) to the formal input parameters of an FB or FC by means of input assignments. You can specify the actual parameters in the form of expressions. You can use the formal input parameters in statements within the FB or FC, but you cannot modify their values.

A short form of parameter transfer is supported, but should not be applied in conjunction with user-defined FBs. This short form is required only for some FCs, see SIMOTION Basic Functions Function Manual.
The assignment of actual parameters is optional for an FB. If no input assignment is specified, the values of the last call are retained because an FB is a source file section with memory.

The assignment of an actual parameter is optional for an FC when an initialization expression was specified for the declaration of the formal parameter.

Also refer to the examples in Calling functions (Page 170) and Calling function blocks (instance calls) (Page 171).

You can also gain read and write access to an FB's input parameter at any time outside the FB. For further details, see: Accessing the FB's input parameter outside the FB (Page 173).

### 4.1.5.3 Parameter transfer to in/out parameters

You transfer the data (actual parameters) to the formal in/out parameters of an FB or an FC using in/out assignments. You can only assign a variable of the same type to the formal in/out parameter, data type conversions are not possible.

You can use and change the formal in/out parameters in statements within the FC or the FB. The FC or the FB accesses the variable of the actual parameter directly and can change it immediately.

Also refer to the examples in Calling functions (Page 170) and Calling function blocks (instance calls) (Page 171).
When using the STRING data type in in/out assignments, the declared length of the actual parameter must be greater than or equal to the length of the formal in/out parameter (see following example).

Table 4-3 Example of the use of the STRING data type in in/out assignments

```plaintext
FUNCTION_BLOCK REF_STRING
    VAR_IN_OUT
        io : STRING[80];
    END_VAR
    ; // Statements
END_FUNCTION_BLOCK

FUNCTION_BLOCK test
    VAR
        my_fb : REF_STRING;
        str1 : STRING[100];
        str2 : STRING[50];
    END_VAR
    my_fb(io := str1); // Permitted call
    my_fb(io := str2); // Not permitted call,
                       // compiler error message
END_FUNCTION_BLOCK
```

The variable assigned to an in/out parameter must be able to be directly read and written. Therefore, system variables (of the SIMOTION device or a technology object), I/O variables or process image accesses cannot be assigned to an in/out parameter.

Please note the different parameter access times!
4.1.5.4 Parameter transfer to output parameters (for FB only)

![Diagram showing output assignment (unformatted)](image)

You use an output assignment to assign the formal output parameters of an FB to the variables (actual parameter) that accept the value of the formal output parameter when the FB is closed.

You can use and change the formal output parameters in statements within the FB.

Also refer to the examples in Calling function blocks (instance calls) (Page 171).

Output assignments are optional for the parameter transfer. You can gain read and write access to an FB's output parameter at any time, even outside the FB. For further details, see: Accessing the FB's output parameter outside the FB (Page 173).

4.1.5.5 Parameter access times

The types of access and thus the parameter access times are different:

- In the case of input assignments, the values of the actual parameters are copied into the formal parameters. If large structures, such as arrays, are copied and the FC or FB is called frequently, this can limit performance.

- Values are not copied in in/out assignments. Rather, in this case a link is established between the memory addresses of the formal parameters and those of the actual parameters. Transferring the variables is therefore faster than input assignments (especially where large volumes of data are involved). However, accessing variables from the FB can be slower.

- If you are using unit variables, nothing is copied to the function or function block because these variables are valid in the entire ST source file (see Variable model (Page 200)).

Note

Using in/out parameters instead of input parameters is only faster if a large volume of data is to be passed to the function block.

If unit variables are used predominantly instead of parameters, the resulting program structure will be complex and confusing: object orientation, data encapsulation, multiple use of variable names (encapsulation of validity ranges), etc., are no longer possible.
4.1.5.6 Calling a function

A function is called as follows:

- **Function with return value (data type other than VOID):**
  
  The function is placed on the right-hand side of a value assignment. It can also appear as operand within an expression. After calling the function, its return value is used at the appropriate point to calculate the expression.

  **Examples:**
  
  \[
  y := \sin(x);
  y := \sin(in := x);
  y := \sqrt{1 - \cos(x) \cdot \cos(x)};
  \]

- **Function without return value (VOID data type):**
  
  The assignment consists only of the function call.

  The following example is valid provided a funct1 function with the in1 and in2 input parameters and the inout in/out parameter has already been defined.

  **Example:**
  
  \[
  \text{funct1 (in1 := var11, in2 := var12, inout1 := var13);}
  \]

**Note**

In the function itself, the result (return value) is assigned to the function name (except for data type VOID).
4.1.5.7 Calling function blocks (instance calls)

Before you call a function block (FB), you must declare an instance. You declare a variable and enter the name of the function block as the data type. You declare this instance:

- Locally (within VAR/END_VAR in the declaration section of a program or function block)
- Globally (within VAR_GLOBAL/END_VAR in the interface of implementation section)
- As an in/out parameter (within VAR_IN_OUT / END_VAR in the declaration section of a function block or a function).

![Figure 4-9 Syntax: Instance declaration]

The instance declaration can also be an array, e.g.:

```plaintext
FB_inst : ARRAY [1..2] OF FB_name.
```

**Note**

Pay attention to the different initialization times for different variable types.

You call a function block instance in the statement section of a POU (for information about syntax, see Figure). FB parameters are input and in-out assignments separated by commas.
The example in the following table is applicable, assuming that the supply and motor function blocks have already been defined:

- **FB Supply:**
  - Input parameters in1, in2; in/out parameter inout; output parameter out
- **FB motor:**
  - In/out parameters inout1, inout2; output parameters out1, out2

**Table 4-4 Example of instance declaration, FB call, and access to output parameters**

```plaintext
VAR
  Supply1, Supply2: Supply;
  Motor1 : Motor;
END_VAR

// Parameter transfer (output assignment) when calling the instance of an FB
Supply1 (in1 := var11, in2 := expr12, inout := var13, out => var14) ;
Supply2 (in1 := var21, in2 := expr22, inout := var23, out => var24) ;
Motor1 (inout1 := var31, inout2 := var32, out1 => var33, out2 => var34);
// ...
// Accessing the FB's output parameter outside the FB
var15 := Supply1.out;
var25 := Supply2.out;
var35 := Motor1.out1;
var36 := Motor1.out2;
var41 := Motor1.out1 * Motor1.out2 * (Supply1.out + Supply2.out);
```
4.1.5.8 Accessing the FB's output parameter outside the FB

In addition to the output assignment (Page 169) for the call of an FB, it is always possible to access an FB's output parameter outside the FB.

To do so, use structured variables (Page 110) in the FB instance name.output parameter format, e.g. Supply1.out.

Also refer to the examples in Calling function blocks (instance calls) (Page 171).

The instance name of the FB itself must not be used in a value assignment!

4.1.5.9 Accessing the FB's input parameter outside the FB

In addition to the input assignment (Page 166) for the call of an FB, it is always possible to read and write an FB's input parameter outside the FB.

To do so, use structured variables (Page 110) in the FB instance name.input parameter format, e.g. Supply1.in1.

**NOTICE**

To be able to use this option, the "Permit language extensions" compiler option must be activated (see Global compiler settings (Page 47) and Local compiler settings (Page 49)).

The instance name of the FB itself must not be used in a value assignment!

Table 4- 5 Example of assignment to input parameter

```
// Only with compiler option "Permit language extensions" activated
VAR
  var_fb   : _WORD_TO_2BYTE;
  var_word : WORD;
END_VAR
var_fb.wordin := var_word;
// ..
var_fb();
```
4.1.5.10 Error sources in FB calls

Note the following when calling a function block instance:

- **Only assign in/out parameters with variables that are stored directly in the memory.**
  
  Only the following variables are permissible actual parameters:
  - Global variables (unit variables and global device user variables)
  - Local variables
  - Variables of the data type of the TO (TO instances)
  
  The following are not possible, in particular:
  - System variables (TO variables)
  - Names of technological objects from the Engineering System
  - I/O variables
  - Absolute and symbolic process image access

- **Do not use functions (FCs) as in/out parameters.**
  
  The FC return value, i.e. the FC call, cannot be an actual parameter in an in/out assignment. You must first store the result of the FC in a local variable and then use this variable as an actual parameter in the in/out assignment.

- **Do not use constants as in/out parameters.**
  
  Only variables can be used as actual parameters of an in/out assignment because the value is written back.

- **In/out parameters cannot be initialized.**
4.2 Comparison of functions and function blocks

The differences between user-defined function blocks (FBs) and functions (FCs) are succinctly illustrated below using a complete example.

4.2.1 Description of example

The following example illustrates the differences between FBs and FCs. For simplicity, each type of parameter is used only once, although, in reality, you can define any number of parameters. The terms used are defined both in the detailed descriptions in Define functions (Page 160) and Define function blocks (Page 161).

A block will be created as an FB and an FC in the declaration part of the implementation section for use in calculating the circumference and the area of a circle for a radius input variable.

- An input parameter is defined for the radius.
- An in/out parameter is defined for the circumference of the circle, i.e. the value of the transferred variable is assigned directly during the call of the FB or the FC.
- There are several ways of defining the area of the circle for the FB and the FC:
  - For the FB, an output parameter is defined.
  - For the FC, its return value is used; the data type of the return value is defined appropriately.
- Each FB and FC call will be recorded in a counter (local variable). The explanations for the example state: We will see that this value will continue to be counted only in the FB.
- In the program section, the FB or the FC is called and the actual parameters assigned to the following formal parameters:
  - For the FB: Input, in/out and output parameters
  - For the FC: Input and in/out parameters.

The values for the circumference and the area are available after calling the FB or the FC:

- For the FB: in the actual parameters of the in/out and output parameter.
  - The output parameter can be read even outside the FB.
- For the FC: in the return value of the function and in the actual parameter of the in/out parameter.

<td>• To obtain the return value of the FC:</td>
</tr>
<tr>
<td>• You can read an FB's output parameters, even outside the FB. For this purpose, use structured variables in the following format: FB-instancename.outputparameter.</td>
<td>– Assign the function to a variable.</td>
</tr>
<tr>
<td>The program that executes the call cannot access variables other than the in/out variables and output parameters of the FB. Exception: For activated &quot;Permit language extensions&quot; compiler option (see Global compiler settings (Page 47) or Local compiler settings (Page 49)), the called program can also access the input parameters of an FB. For this purpose, use structured variables in the following format: FB-instancename.inputparameter.</td>
<td>The program that executes the call cannot access any variables other than the return value.</td>
</tr>
</tbody>
</table>
4.3 Programs

Programs are a series of statements placed between the PROGRAM and END_PROGRAM keywords.

Program (unformatted)

Program identifier

PROGRAM Identifier

Program declaration section Statement section

END_PROGRAM

Figure 4-11 Syntax: Program

Programs are declared in the Implementation section (Page 185) of an ST source file and are comparable with the FB. Static local variables (VAR...END_VAR) or temporary local variables (VAR_TEMP...END_VAR) can be created, for example. However, they do not have any formal parameters and so cannot be called with arguments. Examples for programs are contained in the Source file with comments (Page 176) and Source text of the sample program (Page 68) sections.

4.3.1 Assignment of a program in the execution system

By default, programs in the execution system are assigned to a task. The execution behavior of the programs, e.g. the associated task determines the initialization of the variables. For more information about the execution system and the tasks, refer to the SIMOTION Basic Functions Function Manual. This requires the program in the interface section (Page 184) of the ST source file to be specified as the program organization unit to be exported.
4.3.2 Calling a program in the program ("program in program")

Optionally, a program can also be called within a different program or a function block. This requires the following compiler options to be activated (see Global compiler settings (Page 47) and Local compiler settings (Page 49)):

1. "Permit language extensions" for the program source of the calling program or function block and
2. "Create program instance data only once" for the program source of the calling program.

The call is performed as for a function with parameters and return value, see following example.

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>The activated &quot;Create program instance data only once&quot; compiler option causes:</td>
</tr>
<tr>
<td>• The static variables of the programs (program instance data) are stored in a different Memory area (Page 212). This also changes the Initialization behavior (Page 223).</td>
</tr>
<tr>
<td>• All called programs with the same name use the same program instance data.</td>
</tr>
</tbody>
</table>

Table 4-8 Example for calling a program in a program

```simotion
PROGRAM my_prog
  ; // ...
END_PROGRAM

PROGRAM main_prog
  ; // ...
  my_prog();
  ; // ...
END_PROGRAM
```

Note

Most of the programming work involved in assigning programs to tasks can be done if programs are called from within a program. In the execution system, only one calling program needs to be assigned to the associated tasks in each case.
4.4 Expressions

The expression is a special case of a function declaration:

- The data type of the return value is defined as BOOL and is not specified explicitly.

It is used in conjunction with the WAITFORCONDITION statement (Page 152).

An expression can only be declared in the implementation section of the ST source file.

![Diagram of expression syntax]

Note that an expression of the BOOL data type must be assigned to the expression identifier in the statement section!

Optionally, the following can be declared in the declaration section:

- Local (temporary) variables
- Local constants
- User-defined data types (UDT)
- Input and in/out parameters (as of Version V4.1 of the SIMOTION kernel)

The following can be accessed in the statement section:

- To the local variables of the expression
- To the input and in/out parameters (provided their declaration is permitted)
- Unit variables
- Global device variables, I/O variables, and the process image

An expression of data type BOOL must be assigned to the expression name in the statement section of the expression (see figure).

**Note**

The statement section of the expression cannot contain any function calls or loops.
Example

The following example assumes that the feeder program is running in a MotionTask. The option Activation after StartupTask is selected for this MotionTask. The assignment of programs to tasks is performed in SIMOTION SCOUT (see SIMOTION Motion Control Basic Functions function description).

Table 4-9 Example of the use of an EXPRESSION and the WAITFORCONDITION statement

```simotion
INTERFACE
  USEPACKAGE cam;
  PROGRAM feeder; // in MotionTask_1
END_INTERFACE

IMPLEMENTATION
  // Condition for WAITFORCONDITION statement
  EXPRESSION automaticExpr
    automaticExpr := IOfeedCam; // Digital input
END_EXPRESSION

PROGRAM feeder
  VAR
    retVal : DINT;
  END_VAR;
  retVal := _enableAxis (axis := realAxis,
    enableMode := ALL,
    servoCommandToActualMode := INACTIVE,
    nextCommand := WHEN_COMMAND_DONE,
    commandId := _getCommandId());

  // Wait until the start condition is satisfied
  WAITFORCONDITION automaticExpr WITH TRUE DO
    // High-priority execution of all statements
    // to the END_WAITFORCONDITION command
    retVal := _pos (axis := realAxis,
      positioningMode := RELATIVE,
      position := 500,
      velocityType := DIRECT,
      velocity := 300,
      velocityProfile := TRAPEZOIDAL,
      mergeMode := IMMEDIATELY,
      nextCommand := WHEN_MOTION_DONE,
      commandId:= _getCommandId());
  END_WAITFORCONDITION;

  retVal := _disableAxis (axis := realAxis,
    disableMode := ALL,
    servoCommandToActualMode := INACTIVE,
    nextCommand := WHEN_COMMAND_DONE,
    commandId := _getCommandId());
END_PROGRAM
```

SIMOTION ST Structured Text
Programming and Operating Manual, 05/2009 181
Further examples are contained in the SIMOTION Motion Control Basic Functions Function Manual. In particular, the manual describes how, as of Version V4.1 of the SIMOTION kernel, you use an EXPRESSION with parameters and, for example, program a time monitoring in a WAITFORCONDITION statement.
This section describes the interoperability of ST programs and SIMOTION SCOUT.

5.1 Source file sections

An overview of the meaning of the source file sections was provided in Structure of an ST source file (Page 94). This section describes details, such as the syntax of the sections and how to use them to import and export data between several ST source files.

5.1.1 Use of the source file sections

You must follow certain structure and syntax rules in your source file sections (modules), so that the ST source file can be compiled. A few general guidelines are presented here; details on source file sections are presented later in this section:

- When creating the source file, you should always pay attention to the order of the source file sections. A section that is to be called must always precede the calling section; otherwise the section that is to be called will not recognize the calling section.
  
  For example, variables must always be declared before they are used and functions must be defined before they are called.

- The source text for the most common source file sections – program, function or function block – consists of the following:
  - Start of section with reserved word and identifier
  - Declaration section (optional)
  - Statement section
  - End of section with reserved word

- Identifiers for source file sections – hereinafter referred to as name or name_list - follow the general syntax rules for identifiers (Identifiers in ST (Page 80)).

Note

A template with all possible source file sections is available in the online help.
5.1 Source file sections

5.1.1 Interface section

The interface section contains statements for importing and exporting data (data types, variables, function blocks, functions, and programs). Technology packages and libraries can also be downloaded. The interface section has the following syntax:

| Syntax | INTERFACE  
// Interface statements (optional)  
END_INTERFACE  
An individual identifier of the section cannot be specified.  
Optionally, interface statements exist in the following order between reserved words INTERFACE and END_INTERFACE.  
1. Specification of utilized technology package. Syntax:  
USEPACKAGE tp-name [AS namespace];  
For more details, refer to the SIMOTION Basic Functions Function Manual.  
Syntax:  
USELIB library-name-list [AS namespace];  
For more information, see "Using data types, functions and function blocks from libraries (Page 251)".  
3. Reference to other units in order to use their exported components.  
Syntax:  
USES unit_name-list;  
For more information, see "USES statement in an importing unit (Page 197)".  
4. Declarations and specifications for the export  
– Data type definitions (Page 191):  
User-defined data types (UDT) that are valid in the entire ST source file and that are to be exported  
– Variable declarations (Page 192):  
Unit variables and unit constants valid in the entire ST source file and exported.  
Permissible keywords: See table in "Variable declaration (Page 192)".  
– Information regarding program organization units (POU) to be exported.  
Syntax:  
FUNCTION fc_name;  
FUNCTION_BLOCK fb_name;  
PROGRAM program_name;  
All technology packages, libraries, imported units, data type declarations, variable declarations and program organization units listed in the interface section will be exported. For more information on export, see "Interface section of an exporting unit (Page 194)". |

| Sequence | The interface section is the first section of an ST source file\.  
The order of the interface statements 1 to 4 is fixed.  
Within number 4, any order is permitted. The individual declaration blocks for data type definitions and variable definitions can appear more than once.  
Attention: Identifiers must be declared before they are used. |
| Frequency | Once per ST source file |
| Mandatory section | yes |

\ The unit statement can precede the interface section (see "Identifier of the unit (Page 194)".}
5.1.1.2 Implementation section

The implementation section contains the executable sections, comprising the main part of the ST source file.

The implementation section has the following syntax:

Table 5-2 Syntax of the implementation section

<table>
<thead>
<tr>
<th>Syntax</th>
<th>IMPLEMENTATION // Implementation statements (optional) END_IMPLEMENTATION</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>An individual identifier of the section cannot be specified.</td>
</tr>
<tr>
<td></td>
<td>Optionally, implementation statements (main part of the ST source file)</td>
</tr>
<tr>
<td></td>
<td>exist in the following order between the reserved words IMPLEMENTATION and</td>
</tr>
<tr>
<td></td>
<td>END_IMPLEMENTATION:</td>
</tr>
<tr>
<td></td>
<td>1. Reference to other units in order to use their exported components.</td>
</tr>
<tr>
<td></td>
<td>Syntax: USES unit_name-list;</td>
</tr>
<tr>
<td></td>
<td>For more information, see &quot;USES statement in an importing unit (Page 197)&quot;.</td>
</tr>
<tr>
<td></td>
<td>2. Declarations</td>
</tr>
<tr>
<td></td>
<td>- Data type definitions (Page 191):</td>
</tr>
<tr>
<td></td>
<td>User-defined data types (UDT) that are valid in the entire ST source</td>
</tr>
<tr>
<td></td>
<td>file</td>
</tr>
<tr>
<td></td>
<td>- Variable declarations (Page 192):</td>
</tr>
<tr>
<td></td>
<td>Unit variables and constants that are valid in the entire ST source</td>
</tr>
<tr>
<td></td>
<td>file</td>
</tr>
<tr>
<td></td>
<td>Permissible keywords: See table in &quot;Variable declaration (Page 192)&quot;.</td>
</tr>
<tr>
<td></td>
<td>3. Program organization units (POUs) (Page 185)</td>
</tr>
</tbody>
</table>

Sequence
Always follows the interface section.
The order of the implementation statements indicated above is mandatory; within number 2 and 3, any order is permitted:
Attention: Identifiers must be declared before they are used.

Frequency
Once per ST source file

Mandatory section
yes

5.1.1.3 Program organization units (POUs)

POUs are the executable source file sections:

- Functions (FC) (Page 186)
- Expressions (Page 189)
- Function blocks (FB) (Page 187)
- Programs (Page 188)

Note
Called POUs always precede the calling POUs so that they are recognized by the latter.
5.1.4 Functions (FCs)

Functions (FC) are classified as program organization units (POUs). Functions are parameterized source file sections with temporary data that can be called from programs and function blocks. All internal variables lose their values when the function is exited and are reinitialized the next time the function is called.

FCs have the following syntax:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
</table>
| FUNCTION name : function_data_type  
// Declaration section  
// Statement section  
END_FUNCTION |

name stands for the identifier of the function, while function_data_type stands for the data type of the return value.

Permissible keywords for the variable declaration in the declaration section: See table in "Variable declaration (Page 192)".

Note the following for functions with function_data_type <> VOID: In the statement section, an expression of data type function_data_type must be assigned to the function identifier!

Sequence FCs can only be defined in the implementation section.
Pay attention to the order: FCs must come before the POUs from which they are called!
The declaration section (Page 190) must precede the statement section (Page 190).

Frequency Any number of times per ST source file

Mandatory section no

For information on functions (FC), see Creating and calling functions and function blocks (Page 159).
### Function blocks (FBs)

Function blocks (FB) are classified as program organization units (POUs). They are source file sections with static data that can be called from programs and assigned parameters (internal variables retain their value between calls). Since an FB has memory, its output parameters can be accessed at any time and from any point in the user program.

FBs have the following syntax:

#### Table 5- 4 Syntax of the function blocks

| Syntax | `FUNCTION_BLOCK name
// Declaration section
// Statement section
END_FUNCTION_BLOCK`
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>name stands for the identifier of the function block. Permissible keywords for the variable declaration in the declaration section: See table in &quot;Variable declaration (Page 192)&quot;.</td>
<td></td>
</tr>
<tr>
<td>Special features</td>
<td>Before you call a function block (FB), you must declare an instance: You declare a variable and enter the identifier of the function block as the data type. You can declare the instance locally (within VAR / END_VAR in the declaration sections of a program or a function block). You can declare the instance globally (within VAR_GLOBAL / END_VAR in the interface or Implementation section), however, not using function blocks defined in the same ST source file. This is possible only with function blocks made available by imported program source files and libraries. You cannot declare an instance of an FB in FCs.</td>
</tr>
<tr>
<td>Sequence</td>
<td>FBs can only be defined in the implementation section. Pay attention to the order: FBs must precede the POE in which an instance is declared as local variable. The declaration section (Page 190) must precede the statement section (Page 190).</td>
</tr>
<tr>
<td>Frequency</td>
<td>Any number of times per ST source file</td>
</tr>
<tr>
<td>Mandatory section</td>
<td>no</td>
</tr>
</tbody>
</table>

For information on the FB, see Creating and calling functions and function blocks (Page 159).
5.1.6 Programs

Programs are classified as program organization units (POUs). They are called on the target system according to their task assignment (see Configuring the execution system in the SIMOTION Basic Functions Function Manual) and can call FCs and FBs.

Programs have the following syntax:

Table 5-5 Syntax of the programs

<table>
<thead>
<tr>
<th>Syntax</th>
<th>PROGRAM name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>// Declaration section</td>
</tr>
<tr>
<td></td>
<td>// Statement section</td>
</tr>
<tr>
<td></td>
<td>END_PROGRAM</td>
</tr>
<tr>
<td>name stands for the name of the program.</td>
<td></td>
</tr>
<tr>
<td>Permissible keywords for the variable declaration in the declaration section: See table in &quot;Variable declaration (Page 192)&quot;.</td>
<td></td>
</tr>
</tbody>
</table>

Sequence

Programs can only be defined in the implementation section.
It is advantageous to place programs after expressions, FCs, and FBs. This enables the program to recognize and use the source file sections.
The declaration section (Page 190) must precede the statement section (Page 190).

Frequency

Any number of times per ST source file

Mandatory section

no

For more information about programs, see Programs (Page 178).
5.1.7 Expressions

Expressions are a special case of a function declaration with the specified data type BOOL of the return value. The expression within the EXPRESSION <expression identifier> ... END_EXPRESSION reserved words assigned to the function name is evaluated.

You can use the WAITFORCONDITION construct to wait directly for a programmable event or condition in a MotionTask. The statement suspends the task that called it until the condition (expression) is true.

Expressions have the following syntax:

Table 5-6 Syntax of the expressions

| Syntax                        | EXPRESSION name
|-------------------------------|------------------
| // Declaration section       |                  
| // Statement section         |                  
| END_EXPRESSION               |                  
| name stands for the identifier of the expression. |
| Permissible keywords for the variable declaration in the declaration section: See table in "Variable declaration (Page 192)". |
| Attention: In the statement section, an expression of data type BOOL must be assigned to the expression identifier! |

Sequence

An expression can only be declared in the implementation section of an ST source file. Therefore, expressions precede the program in which they are called from a WAITFORCONDITION control structure.

The declaration section (Page 190) must precede the statement section (Page 190).

Frequency

Any number of times per ST source file

Mandatory section

no

For more information on expressions, see Expressions (Page 180). In conjunction with the WAITFORCONDITION statement, see SIMOTION Basic Functions Function Manual.
5.1 Source file sections

5.1.8 Declaration section

The declaration section of a program organization unit (POU) contains the data type
definition and the variable declaration of the POU.

The declaration section has the following structure:

Table 5-7 Structure of the declaration section

<table>
<thead>
<tr>
<th>Structure</th>
<th>// Data type definition</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>// Variable declaration</td>
</tr>
<tr>
<td>Sequence</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The declaration section has no explicit keywords at the start or end. It begins after the keyword of the respective program organization unit (POU) and ends with the first executable statement of the statement section.</td>
</tr>
<tr>
<td></td>
<td>It contains the following in any order:</td>
</tr>
<tr>
<td></td>
<td>• Data type definitions (Page 191):</td>
</tr>
<tr>
<td></td>
<td>User-defined data types (UDT) that are valid locally in the POU</td>
</tr>
<tr>
<td></td>
<td>• Variable declarations (Page 192):</td>
</tr>
<tr>
<td></td>
<td>Variables and constants that are valid locally in the POU</td>
</tr>
<tr>
<td></td>
<td>Permissible keywords according to the respective POU: See table in &quot;Variable declaration (Page 192)&quot;.</td>
</tr>
<tr>
<td></td>
<td>Attention: Identifiers must be declared before they are used.</td>
</tr>
<tr>
<td>Frequency</td>
<td>Once per POU</td>
</tr>
<tr>
<td>Mandatory section</td>
<td>no</td>
</tr>
</tbody>
</table>

5.1.9 Statement section

The statement section of a POU consists of the individual (executable) statements.

The statement section has the following structure:

Table 5-8 Structure of the statement section

<table>
<thead>
<tr>
<th>Structure</th>
<th>// Statements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sequence</td>
<td>The statement section has no explicit keywords at the start or end. It begins after the declaration section and ends with the keyword of the respective POU.</td>
</tr>
<tr>
<td>Frequency</td>
<td>Once per POU</td>
</tr>
<tr>
<td>Mandatory section</td>
<td>no</td>
</tr>
</tbody>
</table>

For more information on statements, see
- Value assignments and expressions (Page 124)
- Control statements (Page 143)
- Calling functions and function blocks (Page 166)
5.1.1.10 Data type definition

For the data type definition, you specify user-defined data types (UDT). You can use them for variable declarations. UDTs can be defined in the interface section, the implementation section, and the declaration section of FCs, FBs, and programs.

The data type definition has the following syntax:

Table 5-9 Syntax of the data type definition

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE name : data_type_specification;</td>
</tr>
<tr>
<td>// ...</td>
</tr>
<tr>
<td>END_TYPE</td>
</tr>
</tbody>
</table>

name represents the name of the individual data type that you use for the Variable declarations. data_type_specification stands for any data type or a structure. Any number of individual data types can appear between TYPE and END_TYPE.

Sequence

You can define UDTs as follows:

- In the Interface section:
  - The UDTs are recognized within the ST source file and will be exported
  - They can be used in the interface and implementation section for declaration of unit variables and in all POUs for declaration of local variables.
  - In addition, they can be used in all units which import this ST source file (in SIMOTION ST with the USES statement).
- In the Implementation section:
  - The UDTs are recognized within the ST source file
  - They can be used in the implementation section for declaration of unit variables and in all POUs for declaration of local variables.
- In the Declaration section of a POU (FC, FB, program, expression)
  - The UDTs are only recognized locally within the POU
  - They can only be used within the POU for declaration of local variables.
UDTs must be defined before they are used in a variable declaration.

Frequency

The TYPE / END_VAR declaration block may appear more than once in a source file section; any number of UDTs are possible within a declaration block.

Mandatory section

no

For more information about the UDT, see User-defined data types (Page 103).
5.1 Source file sections

5.1.1.11 Variable declaration

A declaration section contains variable declarations and can itself be contained in FCs, FBs, and programs (POUs) as well as in the interface section and the implementation section.

The variable declaration has the following syntax:

**Table 5-10 Syntax of variable declaration**

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>variable_type</strong></td>
</tr>
<tr>
<td>name_list : data_type;</td>
</tr>
<tr>
<td>// ...</td>
</tr>
<tr>
<td>END_VAR</td>
</tr>
</tbody>
</table>

variable_type represents the keyword of the variable type being declared. The permitted keywords depend on the source file section.

- In the Interface section or Implementation section of an ST source file:
  - VAR_GLOBAL: Non-retentive unit variable
  - VAR_GLOBAL CONSTANT: Unit constant
  - VAR_GLOBAL RETAIN: Retentive unit variable

- In the Declaration section of a function:
  - VAR: Local variable
  - VAR CONSTANT: Local constant
  - VAR_INPUT: Input parameter
  - VAR_IN_OUT: In/out parameter

- In the Declaration section of a function block:
  - VAR: Local variable
  - VAR CONSTANT: Local constant
  - VAR_TEMP: Temporary variable
  - VAR_INPUT: Input parameter
  - VAR_OUTPUT: Output parameter
  - VAR_IN_OUT: In/out parameter

- In the Declaration section of a program:
  - VAR: Local variable
  - VAR CONSTANT: Local constant
  - VAR_TEMP: Temporary variable

- In the Declaration section of an expression:
  - VAR: Local variable
  - VAR CONSTANT: Local constant
  - VAR_INPUT: Input parameter (as of Version 4.1 of the SIMOTION kernel)
  - VAR_IN_OUT: In/out parameter (as of Version 4.1 of the SIMOTION kernel)

name_list is the list of identifiers of the data_type data type to be declared.
### 5.1 Source file sections

</tr>
</thead>
</table>

For more information about variable declarations, see Variable declaration (Page 116).
5.1 Source file sections

5.1.2 Import and export between ST source files

ST applies the unit concept, where you can access the global variables, data types, functions (FCs), function blocks (FBs), and programs of other source files. Thus, for example, you can compile reusable subroutines and make them available.

5.1.2.1 Unit identifier

Below, unit refers to a program source file (e.g. ST source file, MCC source file). The name of the program source file defined in SIMOTION SCOUT is applied as the identifier.

Optionally, you can set the unit statement as first statement for an ST source file (preceding the interface section). Syntax:

UNIT name;

name corresponds to the name of the ST source file defined in SIMOTION SCOUT, see Add ST source (Page 21) or Change the properties of an ST source file (Page 23).

The unit statement is ignored if the name specified there differs from the name of the ST source file.

5.1.2.2 Interface section of an exporting unit

You can enter the following constructs in the interface section of an exporting unit. The syntax of the constructs is only implied here, for details, see "Interface section (Page 184)".

- The type declarations to be exported
  TYPE
  User-defined data types with their complete declaration.

- The variable declarations to be exported
  VAR_GLOBAL, VAR_GLOBAL RETAIN, or VAR_GLOBAL CONSTANT
  Non-retentive and retentive unit variables and unit constants with their complete declaration.

- POUs (functions, function blocks, and programs) to be exported
  Specify each POU (function, function block, or program) to be exported with the relevant keyword. Close each entry with a semicolon.
  - FUNCTION_BLOCK fb_name ;
  - FUNCTION fc_name ;
  - PROGRAM program_name ;
Specifications can be made in any order; the POU itself is programmed in the implementation section of the ST source file.

Note
The following further specifications are possible in the interface section, they are listed before the exported data types, variables and POU:

1. Specification of utilized technology packages (USEPACKAGE …).
2. Specification of utilized libraries (USELIB …).
3. Reference to other units in order to use their exported units (USES …).

These imported technology packages, libraries and units are also exported. For inheritance, see "USES statement in an importing unit (Page 197)".

You must adhere to the order presented for the specifications in the interface section of a unit (ST source file), see "Interface section (Page 184)". Otherwise, error-free compilation of the ST source file will not be possible.

The programs of an ST source file must be listed in the interface section so that they can be assigned to a task in the execution system (see Configuring the execution system in the SIMOTION Basic Functions Function Manual). The compiler outputs a warning message if programs cannot be exported in the interface section of an ST source file.

Functions and function blocks that are only used in the ST source file should not be listed in the interface section.
5.1.2.3 Example of an exporting unit

Below is an example of an exporting unit (myUnit_A). It is imported by myUnit_B (see Example of an importing unit (Page 199)).

Table 5-11 Example of an exporting unit

UNIT myUnit_A; // Optional, name of the ST source file

INTERFACE

    // ... USES statement also possible here
    TYPE
        color : (RED, GREEN, BLUE);
    END_TYPE
    VAR_GLOBAL
        cycle : INT := 1; // Declaration of the
        // unit variables to be exported
    END_VAR
    FUNCTION myFC; // Export statement of an FC
    FUNCTION_BLOCK myFB; // Export statement of an FB
    PROGRAM myProgram_A; // Export statement of a program
        // (to interface with the execution system)
END_INTERFACE

IMPLEMENTATION

    Function myFC : LREAL // Function written out
        // ... (Statements)
    END_FUNCTION

    Function_BLOCK myFB // Function block written out
        // ... (Statements)
    END_FUNCTION_BLOCK

    PROGRAM myProgram_A // Program written out
        // ... (Statements)
    END_PROGRAM

END_IMPLEMENTATION
5.1.2.4 USES statement in an importing unit

Enter the following statement in the interface or implementation section of an importing unit:

```
USES unit_name-list
```

*unit_name-list* is a list of units separated by commas from which the modules are to be imported.

Example:

```
USES unit_1, unit_2, unit_3;
```

This enables you to access the following elements specified or declared in the interface section of the imported unit (e.g. ST source file, MCC source):

- User-defined data types (UDT)
- Unit variables and unit constants
- Programs, functions and function blocks
- Imported technology packages, libraries and units

You can use the imported elements as if they existed in the current unit.

**Note**

The keyword *USES* can only occur once in the interface section or in the implementation section of a unit. When multiple units are to be imported, enter them as a list separated by commas after the keyword *USES*.

The *USES* statement can appear in either the interface section or the implementation section of a unit. This has far-reaching implications:
Table 5-12  Implications regarding placement of USES statement in interface section or in implementation section

<table>
<thead>
<tr>
<th>Effect</th>
<th>USES statement in the interface section</th>
<th>USES statement in the implementation section</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inheritance</td>
<td>The current unit continues exporting the imported unit; the imported unit is inherited by all other units that access the current unit. Example: 1. Unit B imports Unit A in the interface section. 2. Unit C in turn imports Unit B. 3. Then Unit C also imports Unit A automatically. A → B → C ⇒ A → C Because of inheritance, Unit A must not be imported explicitly into Unit C.</td>
<td>Inheritance is interrupted. Example: 1. Unit B imports Unit A in the implementation section. 2. Unit C in turn imports Unit B. 3. Then Unit C has no automatic access to Unit A. Unit C must explicitly import Unit A if it wants to access Unit A.</td>
</tr>
<tr>
<td>Variable declaration</td>
<td>The declaration of a unit variable of an imported data type is possible in:  • Interface section  • Implementation section</td>
<td>The declaration of a unit variable of an imported data type is only possible in the implementation section.</td>
</tr>
</tbody>
</table>

Note
You will find tips for use of unit variables in the SIMOTION Basic Functions Function Manual.
5.1.2.5 Example of an importing unit

Below is an example of an importing unit (myUnit_B). It imports the unit myUnit_A from Example of an exporting unit (Page 196).

Table 5-13 Example of an importing unit

UNIT myUnit_B; // Optional, name of the ST source file
INTERFACE
// ... if required, USES statement
PROGRAM myProgram_B;
// Specification of programs to be exported, FB, FC
// Data types and unit variables
END_INTERFACE

IMPLEMENTATION
USES myUnit_A; // Specification of unit to be imported

VAR_GLOBAL
myInstance : myFB; // Declaration of an instance
// of the imported FB
mycolor : color; // Declaration of a variable
// of the imported data type
END_VAR

PROGRAM myProgram_B
mycolor := GREEN; // Value assignment to a variable of the
// data type to be imported
cycle := cycle + 1; // Value assignment to
// imported variable
END_PROGRAM
END_IMPLEMENTATION
5.2 Variables in SIMOTION

This summarizes the variables available in ST.

5.2.1 Variable model

The following table shows all the variable types available for programming with ST.

- System variables of the SIMOTION device and the technology objects
- Global user variables (I/O variables, device-global variables, unit variables)
- Local user variables (variables within a program, a function or a function block)

### System variables

<table>
<thead>
<tr>
<th>Variable type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>System variables of the SIMOTION device</td>
<td>Each SIMOTION device and technology object has specific system variables. These can be accessed as follows:</td>
</tr>
<tr>
<td>System variables of technology objects</td>
<td>• Within the SIMOTION device from all programs</td>
</tr>
<tr>
<td></td>
<td>• From HMI devices</td>
</tr>
<tr>
<td></td>
<td>You can monitor system variables in the symbol browser.</td>
</tr>
</tbody>
</table>
### Global user variables

<table>
<thead>
<tr>
<th>Variable type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>I/O variables</td>
<td>You can assign symbolic names to the I/O addresses of the SIMOTION device or the peripherals. This allows you to have the following direct accesses and process image accesses to the I/O: • Within the SIMOTION device from all programs • From HMI devices You create these variables in the symbol browser after you have selected the I/O element in the project navigator. You can monitor I/O variables in the symbol browser.</td>
</tr>
<tr>
<td>Global device variables</td>
<td>User-defined variables which can be accessed by all SIMOTION device programs and HMI devices. You create these variables in the symbol browser after you have selected the GLOBAL DEVICE VARIABLES element in the project navigator. Global device variables can be defined as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor global device variables in the symbol browser.</td>
</tr>
<tr>
<td>Unit variables</td>
<td>User-defined variables that all programs, function blocks, and functions (e.g. ST source, MCC source, LAD/FBD source) can access within a unit. Declare these variables in the unit: • In the interface section: You can import these variables into other units (ST source files, MCC source files, LAD/FBD source files) and they are also available on HMI devices as standard. • In the implementation section: You can only access these variables within the associated unit. You can declare unit variables as retentive. This means that they will remain stored even when the SIMOTION device power supply is disconnected. You can monitor unit variables in the symbol browser.</td>
</tr>
</tbody>
</table>
Local user variables

<table>
<thead>
<tr>
<th>Variable type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>User-defined variables which can be accessed from within the program (or function, function block) in which they were defined.</td>
<td></td>
</tr>
</tbody>
</table>
| Variable of a program (program variable) | Variable is declared in a program. The variable can only be accessed within this program. A differentiation is made between static and temporary variables:  
  • Static variables are initialized according to the memory area in which they are stored. Specify this memory area by means of a compiler option. By default, the static variables are initialized depending on the task to which the program is assigned (see SIMOTION Basic Functions Function Manual).  
  You can monitor static variables in the symbol browser.  
  • Temporary variables are initialized every time the program in a task is called.  
  Temporary variables cannot be monitored in the symbol browser. |
| Variable of a function (FC variable) | Variable is declared in a function (FC). The variable can only be accessed within this function. FC variables are temporary; they are initialized each time the FC is called. They cannot be monitored in the symbol browser. |
| Variable of a function block (FB variable) | Variable is declared in a function block (FB) source. The variable can only be accessed within this function block. A differentiation is made between static and temporary variables:  
  • Static variables retain their value when the FB terminates. They are initialized only when the instance of the FB is initialized; this depends on the variable type with which the instance of the FB was declared.  
  You can monitor static variables in the symbol browser.  
  • Temporary variables lose their value when the FB terminates. The next time the FB is called, they are reinitialized.  
  Temporary variables cannot be monitored in the symbol browser. |

Further information is available from the following sources:

- In the corresponding list manuals, you can find the compressed information on all system variables of the SIMOTION technology packages and SIMOTION devices.
- For more details on the use of system variables of technology objects, please refer to the SIMOTION Motion Control Technology Objects Function Manuals.
In the *SIMOTION Basic Functions* Function Manual you can find information on how to access system variables and configuration data.

This documentation contains information on:
- Accessing I/O addresses with I/O variables (see Direct access and process image of the cyclic tasks (Page 233))
- Accessing the process image (see Access to the fixed process image of the BackgroundTask (Page 239))
- Creating and using global device variables (see Using global device variables (Page 211))
- Use of unit variables and local variables (static and temporary variables).

**Note**
Please note that downloading the ST source file to the target system and tasks that are being executed affect the initialization of variables and (as a result of this) their contents; see Using the same identifiers.

**See also**

Time of the variable initialization (Page 219)
5.2.1.1 Unit variables

Unit variables are valid throughout the entire ST source file, i.e. they can be accessed in any source file section.

Unit variables are declared in the interface and/or implementation section of an ST source file; the location of the declaration determines the validity of the unit variable:

- If you declare the unit variables in the interface section, you create variables that can be used in other program sources (e.g. ST source files, MMC units). For more on importing and exporting between program source files, see Import and export between ST source files (Page 194).

  By default, these unit variables are also available on HMI devices. The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.

- If you declare the unit variables in the implementation section, you create variables that can be used by all program organization units (POUs) of the current source file.

You can change the default setting for the HMI export of the unit variables using a pragma within a declaration block, see Variables and HMI devices (Page 227) and Controlling compiler with attributes (Page 271).

You can define unit variables with different behavior, e.g. in case of power failure:

- Non-retentive unit variables (keyword VAR_GLOBAL): its value is lost in the event of a power failure.

- Retentive unit variables (keyword VAR_GLOBAL RETAIN): its value remains in the event of a power failure.

- Unit constants (keyword VAR_GLOBAL CONSTANT): its value is retained unchanged (see Constants (Page 122)).

You will find tips for the efficient use of unit variables in the SIMOTION Basic Functions Function Manual.

5.2.1.2 Non-retentive unit variables

Non-retentive unit variables lose their value in the event of a power failure.

Figure 5-1 Syntax: Unit variables
This declaration block may appear more than once within an interface or implementation section. You specify the variable name and data type for the variable declaration (see Overview of all variable declarations (Page 117) and Initialization of variables or data types (Page 119)).

For the scope of the declaration and the HMI export, see Unit variables (Page 204).

Note
For initialization of the non-retentive unit variables:

- See Initialization of non-retentive global variables (Page 220).
- The behavior during downloading can be set (Options > Settings menu command, Project Download tab, Initialize all non-retentive device-global variables and program data checkbox)
- The type of version ID and therefore the initialization behavior on downloading depends on the SIMOTION Kernel version. For details, see Version ID of global variables and their initialization during download (Page 225).

Table 5-14 Examples of non-retentive unit variables

```plaintext
INTERFACE
  VAR_GLOBAL //These variables can be exported.
    rotation1 : INT;
    field1 : ARRAY [1..10] OF REAL;
    flag1 : BOOL;
    motor1 : motor; // Instance declaration
  END_VAR
END_INTERFACE

IMPLEMENTATION
  VAR_GLOBAL //These variables cannot be exported
    // MotionTask.
    rotation2 : INT;
    field2 : ARRAY [1..10] OF REAL;
    flag2 : BOOL;
    motor2 : motor; // Instance declaration
  END_VAR
END_IMPLEMENTATION
```
5.2.1.3 Retentive unit variables

Retentive unit variables permit permanent storage of variable values even throughout a power failure.

Retentive variable block (unformatted)

![Diagram of Retentive Variable Block]

This declaration block may appear more than once within an interface or implementation section. You specify the variable name and data type for the variable declaration (see Overview of all variable declarations (Page 117) and Initialization of variables or data types (Page 119)).

For the scope of the declaration and the HMI export, see Unit variables (Page 204).

**Note**

- For initialization of the retentive unit variables:
  - See Initialization of retentive global variables (Page 219).
  - The behavior during downloading can be set (Options > Settings menu command, Project Download tab, Initialize all retentive device-global variables and program data checkbox).
  - The type of version ID and therefore the initialization behavior on downloading depends on the SIMOTION Kernel version. For details, see Version ID of global variables and their initialization during download (Page 225).
- The amount of memory available for retentive variables depends on the device (see quantity framework in the SIMOTION SCOUT Configuration Manual). To make efficient use of limited memory space, use the memory in a single ST source file and sort the variables in descending order!
- Check the capacity utilization of the retentive memory in SIMOTION SCOUT.
  - In online mode, call the **device diagnostics** of the SIMOTION device to be checked (see online help). In the **System utilization** tab under **Retentive data**, you can see how much memory is available.

<table>
<thead>
<tr>
<th>VAR_GLOBAL RETAIN</th>
</tr>
</thead>

</tr>
<tr>
<td>Pass : INT;</td>
</tr>
<tr>
<td>Switch: BOOL;</td>
</tr>
<tr>
<td>END_VAR</td>
</tr>
</tbody>
</table>

**Table 5-15 Examples of retentive variables**
5.2.1.4 Local variables (static and temporary variables)

Local variables are valid only in the source file section (e.g. program, FC or FB) in which they were declared. We distinguish between the following:

- Static variables (Page 209):
  Static variables retain their value over all passes of the source file section (block memory).

- Temporary variables (Page 210):
  Temporary variables are initialized each time the source file section is called again.

See also: Initialization of local variables (Page 222).

Note

Local variables cannot be accessed outside the source file section in which they were declared.

The following table provides an overview of the declaration of static and temporary variables. It shows the source file sections in which these variables can be declared and the keywords that can be used to declare them.

<table>
<thead>
<tr>
<th>Source file section</th>
<th>Keywords for the declaration</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Static variables</td>
</tr>
<tr>
<td>Function</td>
<td>–</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>

<tr>
<td></td>
<td>VAR_INPUT / END_VAR¹</td>
</tr>
<tr>
<td></td>
<td>or</td>
</tr>
<tr>
<td>Program</td>
<td>VAR / END_VAR³</td>
</tr>
</tbody>
</table>

¹ The initialization of the variable depends on initialization of the declared instance. See Initialization of instances of function blocks (FBs) (Page 224).
² The reference (pointer) for the transferred variable is temporary.
³ The initialization of the variables depends on the memory area in which they are stored. See Initialization of static program variables (Page 223).
Note
Please note that downloading the ST source file to the target system and running tasks affect variable initialization and thus the contents of the variables, see Time of the variable initialization (Page 219).

Table 5- 17  Examples of static and temporary variables

```
IMPLEMENTATION

FUNCTION testFkt
  VAR // Declaration of temporary variables
    flag : BOOL;
  END_VAR
END_FUNCTION

FUNCTION_BLOCK testFbst;
  VAR // Declaration of static variables
    rotation1 : INT;
  END_VAR

  VAR_TEMP // Declaration of temporary variables
    help1, help2 : REAL;
  END_VAR
END_FUNCTION_BLOCK

PROGRAM testPrg;
  VAR // Declaration of static variables
    rotation2 : INT;
  END_VAR

  VAR_TEMP // Declaration of temporary variables
    help1, help2 : REAL;
  END_VAR
END_PROGRAM

END_IMPLEMENTATION
```
5.2.1.5 Static variables

Static variables retain their most recent value when the source file section is exited. This value is used again at the next call.

The following source file sections contain static variables:

- Programs
- Function blocks

Static variables are declared in a static variable block.

![Static variable block (unformatted)](image)

You can do the following in the static variable block, according to the syntax in the figure:

- Declare variables (name and data type), optionally with initialization.
- Declare symbolic accesses to the process image of the Background Task.
- Declare instances of the function blocks.

For initialization of the static variables:

- In programs: Depending on the execution behavior to which the program is assigned (see SIMOTION Basic Functions Function Manual).
  
  See also Initialization of static program variables (Page 223).

- In function blocks: Depending on the initialization of the declared instance.
  
  See also Initialization of instances of function blocks (FBs) (Page 224).
5.2.1.6 Temporary variables

Temporary variables are initialized each time the source file section is called. Their value is retained only during execution of the source file section.

The following source file sections contain temporary variables:

- Programs
- Function blocks
- Functions
- Expression

In functions and expressions, you declare temporary variables in the FB temporary variable block (see following figure):

![Figure 5-4 Syntax: Temporary variable block in the FB or program](image)

In functions and expressions, you declare temporary variables in the FC temporary variable block (see following figure):

![Figure 5-5 Syntax: Temporary variable block in an FC](image)
5.2.2 Use of global device variables

Global device variables are user-defined variables that you can access from all program sources (e.g. ST source files, MCC units) of a SIMOTION device.

Global device variables are created in the symbol browser tab of the detail view; to do this, you must be working in offline mode.

Here is a brief overview of the procedure:

1. In the project navigator of SIMOTION SCOUT, select the GLOBAL DEVICE VARIABLES element in the SIMOTION device subtree.
2. In the detail view, select the Symbol browser tab and scroll down to the end of the variable table (empty row).
3. In the last (empty) row of the table, enter or select the following:
   - **Name** of variable
   - **Data type** of variable (only elementary data types are permitted)
4. Optionally, you can make the following entries:
   - **Selection of Retain** checkbox (This declares the variable as retentive, so that its value will be retained after a power failure.)
   - **Array length** (array size)
   - **Initial value** (if array, for each element)
   - **Display format** (if array, for each element)

You can now access this variable using the symbol browser or any program of the SIMOTION device.

In ST source files, you can use a global device variable, just like any other variable.

---

**Note**

If you have declared unit variables or local variables of the same name (e.g. var-name), specify the global device variable with _device.var-name.

An alternative to global device variables is the declaration of unit variables in a separate unit, which is imported into other units. This has the following advantages:

1. Variable structures can be used.
2. The initialization of the variables during the STOP-RUN transition is possible (via Program in StartupTask).
3. For newly created global unit variables, a download in RUN is also possible.

Please refer to the SIMOTION Basic Functions Function Manual.
5.2 Variables in SIMOTION

5.2.3 Memory ranges of the variable types

The different variable types are stored in different memory areas, which are initialized at different times. The table shows:

- The available memory areas for variable types that are declared in ST source files (possibly dependent on the version of the SIMOTION Kernel).
- The initialization time for each memory area.

An explanation using an example is contained in the Example for memory areas, valid as of Kernel V3.1 (Page 214) section.

Table 5- 18 Memory ranges assigned to different variable types and their initialization

5.2.3.1 Example of memory areas, valid as of Kernel V3.1

Table 5-19 Example of memory ranges of the variable types, as of Kernel V3.1 (Part 1)

INTERFACE
// The statements in the interface section specify,
// what source content is exported.
FUNCTION FC1;
FUNCTION_BLOCK FB1;
PROGRAM p1;

// Unit variables of the interface section are also visible
// on HMI devices.
VAR_GLOBAL                // Non-retentive unit variables
                        // are present in the UNIT user memory
     ul_if : INT;
END_VAR
VAR_GLOBAL CONSTANT      // Unit constants are located
                        // in the unit user memory
END_VAR
VAR_GLOBAL RETAIN        // Retentive unit variables are located
                        // in the retentive (power-fail-safe) memory
END_VAR

IMPLEMENTATION
// The implementation section contains the executable code sections
// in different program organization units (POU)
// A POU can be a program, FC, or FB.
// Unit variables of the implementation section can only be used
// within the source file.
VAR_GLOBAL                // Non-retentive unit variables are located
                        // in the unit user memory
     ul_glob : INT;
END_VAR
VAR_GLOBAL CONSTANT      // Unit constants are located
                        // in the unit user memory
END_VAR
VAR_GLOBAL RETAIN        // Retentive unit variables are located
                        // in the retentive (power-fail-safe) memory
END_VAR

LEVEL Variable types:

- **VAR_GLOBAL**: Non-retentive variables, visible in the UNIT user memory.
- **VAR_GLOBAL CONSTANT**: Unit constants, located in the unit user memory.
- **VAR_GLOBAL RETAIN**: Retentive variables, located in the retentive (power-fail-safe) memory.

p_varFB (fb_in_out := p_temp);
ul_glob := 4711;
END_PROGRAM
END_IMPLEMENTATION
5.2.3.2 Memory requirement of the variables on the local data stack (Kernel V3.1 and higher)

The variables stored on the local data stack of a task are listed in Memory ranges of the variable types (Page 212). You set the stack size for each task in the task configuration.

Note the following for memory requirements in the local stack:

- Temporary local variables require their own size on the stack.
- Global variables and static local variables do not require any resources on the stack.
  - If you are using them as input parameters for a function, however, they require their own data size on the stack.
- Even if a function is called more than once in a task, it only uses the stack's resources once.
- Variables of type BOOL require one byte on the stack.

Note
The above details are also true for the use of libraries that have been compiled with reference to the SIMOTION device and the associated version of the SIMOTION kernel (as of Version V3.1).

NOTICE
If the library is not device-dependent (i.e. compiled without reference to a SIMOTION device or SIMOTION Kernel version). These libraries are compiled compatible to the permitted versions of the SIMOTION kernel.

Consequently, the variables of program organization units (POU) called from these libraries occupy the local data stack as for versions of the SIMOTION kernel up to V3.0. See Memory requirement of the variables on the local data stack (valid up to kernel V3.0) (Page 218).

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 263) function.
5.2.3.3 Memory requirement of variables on local data stack (Kernel V3.0 and below)

The variables stored on the local data stack of a task are listed in Memory ranges of the variable types (Page 212). You set the stack size for each task in the task configuration.

Note the following for memory requirements in the local stack:

- Static local variables in programs require double their size on the stack.
- Static local variables in FBs require several times their size on the stack, depending on the calling depth.
- Temporary local variables (in programs, FBs, and FCs) require their own size on the stack.
- Global variables do not occupy any stack memory space.
  If you are using them as input parameters for a function or function block, however, they will occupy their usual space on the stack.
- Even if a function is called more than once in a task, it only uses the stack's resources once.
- Variables of type BOOL require one byte on the stack.

NOTICE

When a function block instance is called, all instance data is copied to the local data stack, even if the instance is declared as a VAR_GLOBAL instance.

If the library is not device-dependent (i.e. compiled without reference to a SIMOTION device or SIMOTION Kernel version): These libraries are compiled compatible to the permitted versions of the SIMOTION kernel. Consequently, the variables of program organization units (POU) called from these libraries occupy the local data stack as described in this section.

The memory requirement on the local data stack is significantly larger than for versions of the SIMOTION kernel as of V3.1, see Memory requirement of the variables on the local data stack (as of Kernel V3.1) (Page 217). Take this into consideration for setting the stack size for the task configuration!

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 263) function.
5.2.4 Time of the variable initialization

The timing of the variable initialization is determined by:

- Memory area to which the variable is assigned
- Operator actions (e.g. source file download to the target system)
- Execution behavior of the task (sequential, cyclic) to which the program was assigned.

All variable types and the timing of their variable initialization are shown in the following tables. You will find basic information about tasks in the SIMOTION Basic Functions Function Manual.

The behavior for variable initialization during download can be set: To do this, as a default setting select the Options > Settings menu and the Download tab or define the setting during the current download.

**Note**

You can upload values of unit variables or global device variables from the SIMOTION device into SIMOTION SCOUT and save them in XML format.

1. Save the required data segments of the unit variables or global device variables as a data set with the function _saveUnitDataSet_.
2. Use the Save variables function in SIMOTION SCOUT.

You can use the Restore variables function to download these data sets and variables back to the SIMOTION device.

For more information, refer to the SIMOTION SCOUT Configuration Manual.

This makes it possible, for example, to obtain this data, even if it is initialized by a project download or if it becomes unusable (e.g. due to a version change of SIMOTION SCOUT).

5.2.4.1 Initialization of retentive global variables

Retentive variables retain their last value after a loss of power. All other data is reinitialized when the device is switched on again.

Retentive global variables are initialized:

- When the backup or buffer for retentive data fails.
- When the firmware is updated.
- When a memory reset (MRES) is performed.
- With the restart function (Del. SRAM) in SIMOTION P350.
- By applying the _resetUnitData_ function (as of kernel V3.2), possible selectively for different data segments of the retentive data.
- When a download is performed according to the following description.
5.2 Variables in SIMOTION

### Table 5-22 Initializing retentive global variables during download

<table>
<thead>
<tr>
<th>Variable type</th>
<th>Time of the variable initialization</th>
</tr>
</thead>
</table>
| Retentive global device variables | The behavior when downloading depends on the *Initialization of all retentive global device variables and program data setting*¹:  
  • Yes²: All retentive global device variables are initialized.  
  • No³:  
    - As of version V3.2 of the SIMOTION Kernel:  
      - *Separate version ID* for retentive global device variables. If the version ID is changed, the retentive global device variables are initialized.  
    - Up to Version V3.1 of the SIMOTION kernel:  
      - *Joint version ID* for all global device variables (retentive and non-retentive). If the version ID is changed, all global device variables are initialized.  
  See: Version ID of global variables and their initialization during download (Page 225). |
| Retentive unit variables    | The behavior when downloading depends on the *Initialization of all retentive global device variables and program data setting*¹:  
  • Yes²: All retentive unit variables (all units) are initialized.  
  • No³:  
    - As of version V3.2 of the SIMOTION Kernel:  
      - *Separate version ID* for each individual data block (= declaration block)⁴ of the retentive unit variables in the interface or implementation section. If the version identification is changed, only the associated data block will be initialized⁵.  
    - Up to Version V3.1 of the SIMOTION kernel:  
      - *Common version ID* for all unit variables (retentive and non-retentive, in the interface and implementation section) of a unit. If the version ID is changed, all unit variables of this unit are initialized.  
  See: Version ID of global variables and their initialization during download (Page 225). |

¹ Default setting in the Options > Settings menu, Download tab, or the current setting for the download.  
² The corresponding checkbox is active.  
³ The corresponding checkbox is inactive.  
⁴ Several data blocks for retentive unit variables in the interface or implementation section can be declared only in the SIMOTION ST programming language. For the SIMOTION MCC and SIMOTION LAD/FBD programming languages, only one data block for retentive unit variables will be created in the interface or implementation section.  
⁵ Also for the download in RUN, provided the associated prerequisites have been satisfied and the following attribute has been specified in the associated declaration block within a pragma (only for the SIMOTION ST programming language):  

{ BlockInit_OnChange := TRUE; }.  

For the download in RUN, see the SIMOTION Basic Functions Function Manual.

5.2.4.2 Initialization of non-retentive global variables

Non-retentive global variables lose their value during power outages. They are initialized:

- For the Initialization of retentive global variables (Page 219), e.g. during a firmware update or general reset (MRES).
- During power up.
- By applying the _resetUnitData_ function (as of kernel V3.2), possible selectively for different data segments of the non-retentive data.
During the download in accordance with the description on the following table.

Only as of Version V4.1 of the SIMOTION Kernel and for non-retentive unit variables:

For transition to the RUN mode when the associated declaration block within a pragma specifies the following attribute (only for SIMOTION ST programming language): { BlockInit_OnDeviceRun := ALWAYS; }

Table 5-23 Initializing non-retentive global variables during download

<table>
<thead>
<tr>
<th>Variable type</th>
<th>Time of the variable initialization</th>
</tr>
</thead>
</table>
| Non-retentive global device variables | The behavior when downloading depends on the Initialization of all non-retentive global device variables and program data setting¹:
  - Yes²: All non-retentive global device variables are initialized.
  - No³:
    - As of version V3.2 of the SIMOTION Kernel:
    - Separate version ID for non-retentive global device variables. If the version ID is changed, the non-retentive global device variables are initialized.
    - Up to Version V3.1 of the SIMOTION kernel:
      - Joint version ID for all global device variables (retentive and non-retentive). If the version ID is changed, all global device variables are initialized.
  See: Version ID of global variables and their initialization during download (Page 225).
| Non-retentive unit variables       | The behavior when downloading depends on the Initialization of all non-retentive global device variables and program data setting¹:
  - Yes²: All non-retentive unit variables (all units) are initialized.
  - No³:
    - As of version V3.2 of the SIMOTION Kernel:
    - Separate version ID for each individual data block (= declaration block)⁴ of the non-retentive unit variables in the interface or implementation section. If the version identification is changed, only the associated data block will be initialized⁵.
    - Up to Version V3.1 of the SIMOTION kernel:
      - Common version ID for all unit variables (retentive and non-retentive, in the interface and implementation section) of a unit. If the version ID is changed, all unit variables of this unit are initialized.
  See: Version ID of global variables and their initialization during download (Page 225).

¹ Default setting in the Options > Settings menu, Download tab, or the current setting for the download.
² The corresponding checkbox is active.
³ The corresponding checkbox is inactive.
⁴ Several data blocks for non-retentive unit variables in the interface or implementation section can be declared only in the SIMOTION ST programming language. For the SIMOTION MCC and SIMOTION LAD/FBD programming languages, only one data block for non-retentive unit variables will be created in the interface or implementation section.
⁵ Also for the download in RUN, provided the associated prerequisites have been satisfied and the following attribute has been specified in the associated declaration block within a pragma (only for the SIMOTION ST programming language): { BlockInit_OnChange := TRUE; }.

For the download in RUN, see the SIMOTION Basic Functions Function Manual.
5.2.4.3 Initialization of local variables

Local variables are initialized:

- For the initialization of retentive unit variables (Page 219).
- For the initialization of non-retentive unit variables (Page 220).
- Also, according to the following description:

Table 5-24 Initialization of local variables

<table>
<thead>
<tr>
<th>Variable type</th>
<th>Time of the variable initialization</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local program variables</td>
<td>Local variables of programs are initialized differently:</td>
</tr>
<tr>
<td></td>
<td>• Static variables (VAR) are initialized according to the memory area in which they are stored.</td>
</tr>
<tr>
<td></td>
<td>• Temporary variables (VAR_TEMP) are initialized every time the program of the task is called.</td>
</tr>
<tr>
<td>Local variables of function blocks (FB)</td>
<td>Local variables of function blocks are initialized differently:</td>
</tr>
<tr>
<td></td>
<td>• Static variables (VAR, VAR_IN, VAR_OUT) are only initialized when the FB instance is initialized.</td>
</tr>
<tr>
<td></td>
<td>• Temporary variables (VAR_TEMP) are initialized every time the FB instance is called.</td>
</tr>
<tr>
<td>Local variables of functions (FC)</td>
<td>Local variables of functions are temporary and are initialized every time the function is called.</td>
</tr>
</tbody>
</table>
5.2.4.4 Initialization of static program variables

The following versions affect the following static variables:

- Local variables of a unit program declared with VAR
- Function block instances declared with VAR within a unit program, including the associated static variables (VAR, VAR_INPUT, VAR_OUTPUT).

The initialization behavior is determined by the memory area in which the static variables are stored. This is determined by the "Create program instance data only once" (Page 47) compiler option.

- For the deactivated "Create program instance data only once" compiler option (default):
  The static variables are stored in the user memory of each task, which is assigned to the program.
  The initialization of the variables thus depends on the execution behavior of the task to which the program is assigned (see SIMOTION Basic Functions Function Manual):
  - Sequential tasks (MotionTasks, UserInterruptTasks, SystemInterruptTasks, StartupTask, ShutdownTask): The static variables are initialized every time the task is started.
  - Cyclic tasks (BackgroundTask, SynchronousTasks, TimerInterruptTasks): The static variables are initialized only during transition to RUN mode.

- For the activated "Create program instance data only once" compiler option:
  This setting is necessary, for example, if a program is to be called within a program.
  The static variables of all programs from the program source (unit) involved are only stored once in the user memory of the unit.
  - They are thus initialized together with the non-retentive unit variables, see Initialization of non-retentive global variables (Page 220).
  - Only as of Version V4.1 of the SIMOTION Kernel:
    In addition, they can be initialized during transition to RUN mode. To do this, the following attribute must be specified in the associated declaration block within a pragma (only SIMOTION ST programming language):
    `{ BlockInit_OnDeviceRun := ALWAYS; }.`
5.2.4.5 **Initialization of instances of function blocks (FBs)**

The initialization of a function block instance (Page 171) is determined by the location of its declaration:

- **Global declaration (within VAR_GLOBAL/END_VAR in the interface of implementation section):**
  
  Initialization as for a non-retentive unit variable, see Initialization of non-retentive global variables (Page 220).

- **Local declaration in a program (within VAR / END_VAR):**
  
  Initialization as for static variables of programs, see Initialization of static variables of programs (Page 223).

- **Local declaration in a function block (within VAR / END_VAR):**
  
  Initialization as for an instance of this function block.

- **Declaration as in/out parameter in a function block or a function (within VAR_IN_OUT / END_VAR):**
  
  For the initialization of the POU, only the reference (pointer) will be initialized with the instance of the function block remaining unchanged.

**Note**

You can obtain information about the memory requirements of a POU in the local data stack using the Program Structure (Page 263) function.

---

5.2.4.6 **Initialization of system variables of technology objects**

The system variables of a technology object are usually not retentive. Depending on the technology object, a few system variables are stored in the retentive memory area (e.g. absolute encoder calibration).

The initialization behavior (except in the case of download) is the same as for retentive and non-retentive global variables. See Initialization of retentive global variables (Page 219) and Initialization of non-retentive global variables (Page 220).

The behavior during the download is shown below for:

- Non-retentive system variables
- Retentive system variables
### Table 5-25 Initializing technology object system variables during download

<table>

</tr>
<tr>
<td></td>
<td>– Change of the identifier or the data type of a variable in the associated declaration block.</td>
<td>– Declaration of global data types in the unit</td>
</tr>
<tr>
<td></td>
<td>– Change of a data type definition (from a separate or imported⁴ unit) used in the associated declaration block.</td>
<td>– Declaration in the interface section of an imported⁴ unit.</td>
</tr>
<tr>
<td></td>
<td>– Add or remove declaration blocks within the same data segment before the associated declaration block.</td>
<td>• During downloading⁵, the rule is: <strong>Initialization of all data segments</strong> if the version ID changes.</td>
</tr>
<tr>
<td></td>
<td>• This version ID does not change on:</td>
<td>• Use of the functions for data backup only possible for: Non-retentive unit variables in the interface section.</td>
</tr>
<tr>
<td></td>
<td>– Add or remove declaration blocks in other data segments.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>– Add or remove declaration blocks within the same data segment after the associated declaration block.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>– Changes in other data blocks.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>– Changes to initialization values¹.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>– Changes to data type definitions that are not used in the associated data block.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>– Changes to functions.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• During downloading⁵, the rule is: <strong>Initialization of a data block</strong> only if its version ID has changed.⁶</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Functions for data backup and initialization take into account the version ID of the data blocks.</td>
<td></td>
</tr>
</tbody>
</table>

¹ Changed initialization values are not effective until the data block or data segment in question is initialized.

² If **Initialization of all retentive global device variables and program data** = No and **Initialization of all non-retentive global device variables and program data** = No.

In the case of other settings: See the sections "Initialization of retentive global variables (Page 219)" and "Initialization of non-retentive global variables (Page 220)".

³ Several declaration blocks per data segment are possible only in the SIMOTION ST programming language. For the SIMOTION MCC and SIMOTION LAD/FBD programming languages, only one declaration block per data segment will be created.

⁴ The import of units depends on the programming language, refer to the associated section (Page 197).

⁵ Also for the download in RUN, provided the associated prerequisites have been satisfied and the following attribute (Page 271) has been specified in the associated declaration block within a pragma (Page 266) (only for the SIMOTION ST programming language): ( **BlockInit_OnChange := TRUE;** ).

For the download in RUN, see the SIMOTION Basic Functions Function Manual.
5.2.5 Variables and HMI devices

The following variables are exported to HMI devices where they are available:

- System variables of the SIMOTION device
- System variables of technology objects
- I/O variables
- Global device variables
- Retentive and non-retentive unit variables of the interface section (default setting).

This default setting can be changed for each declaration block using the following pragma:

{ HMI_Export := FALSE; }

The unit variables of such an identified declaration block are not exported to HMI devices. The HMI consistency check is also omitted for them during the download.

See also Controlling compiler with attributes (Page 271).

The following variables are not exported to HMI devices and are not available there:

- Retentive and non-retentive unit variables of the implementation section (default setting).

This default setting can be changed for each declaration block using the following pragma:

{ HMI_Export := TRUE; }

The unit variables of such an identified declaration block are exported to HMI devices. Consequently, they are subject to the HMI consistency check during the download.

See also Controlling compiler with attributes (Page 271).

- Local variables of a POU
The total size of the unit variables that can be exported to HMI devices is limited to 64 KB per unit.

The effect of the pragma \{ HMI_Export := FALSE; \} and \{ HMI_Export := TRUE; \} depends on the version of the SIMOTION Kernel:

- As of Version V4.1 of the SIMOTION Kernel:
  The pragma affects the export of the corresponding declaration block to HMI devices and the structure of the HMI address space:
  - Only those variables in declaration blocks exported to HMI devices occupy the HMI address space.
  - Within the HMI address space, the variables are arranged according to order of their declaration.

- Up to version V3.2 or V4.0 of the SIMOTION kernel:
  The pragma affects only the export of the corresponding declaration block to HMI devices.
  The HMI address space is also occupied by unit variables of the interface section whose declaration blocks are not assigned to HMI devices.
  Within the HMI address space, the variables are sorted in the following order:
  - Retentive unit variables of the interface section (exported and not exported).
  - Retentive unit variables of the implementation section (only exported).
  - Non-retentive unit variables of the interface section (exported and not exported).
  - Non-retentive unit variables of the implementation section (only exported).
  Within these segments, the variables are arranged according to order of their declaration.

- Up to Version V3.1 of the SIMOTION kernel:
  The pragma has no effect.
Table 5-27  Example for the control of the HMI export with the corresponding pragma

    // ...
    END_IMPLEMENTATION
5.3 Access to inputs and outputs (process image, I/O variables)

5.3.1 Overview of access to inputs and outputs

SIMOTION provides several possibilities to access the device inputs and outputs of the SIMOTION device as well as the central and distributed I/O:

- Via direct access with I/O variables

  Direct access is used to directly access the corresponding I/O address. Define an I/O variable (name and I/O address) without assigning a task to it. The entire address space of the SIMOTION device can be used. It is preferable to use direct access with sequential programming (in MotionTasks); access to current input and output values at a particular point in time is especially important in this case.

  Further information: Direct access and process image of the cyclic tasks (Page 233).

- Via the process image of cyclic tasks using I/O variables

  The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming).

  Define an I/O variable (name and I/O address) and assign a task to it. The entire address area of the SIMOTION device can be used.

  Direct access to this I/O variable is still possible: Specify direct access with \_direct var-name.

  Further information: Direct access and process image of the cyclic tasks (Page 233).

- Using the fixed process image of the BackgroundTask

  The process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device, on which a subset of the I/O address space of the SIMOTION device is mirrored. The mirror image is refreshed with the BackgroundTask and is consistent throughout the entire cycle. This process image is used preferentially when programming the BackgroundTask (cyclic programming).

  The address space 0 .. 63 can be used. I/O addresses that are accessed using the process image of the cyclic task are excluded.

  Further information: Access to the fixed process image of the BackgroundTask (Page 239).

A comparison of the most important properties is contained in "Important properties of direct access and process image (Page 231)".

You can use I/O variables like any other variable, see "Access I/O variables (Page 246)".

Note

An access via the process image is more efficient than direct access.
5.3.2 Important features of direct access and process image access

Table 5-28 Important features of direct access and process image access

<table>
<thead>
<tr>
<th>Permissible address range</th>
<th>Direct access</th>
<th>Access to process image of cyclic tasks</th>
<th>Access to fixed process image of the BackgroundTask</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permissible address range</td>
<td>Entire address range of the SIMOTION device</td>
<td>Cyclic task for selection: - SynchronousTasks, - TimerInterruptTasks, - BackgroundTask.</td>
<td>0..63, except for the addresses used in the process image of the cyclic tasks. Addresses that are not present in the I/O or have not been configured can also be used.</td>
</tr>
</tbody>
</table>

- **Assigned task**
  - None.

- **Updating**
  - Onboard I/O of SIMOTION devices C230-2, C240, C240 PN, and P350:
    - Update occurs in a cycle clock of 125 µs.
  - I/O via PROFIBUS DP, PROFINET, P-Bus, and DRIVE-CLiQ as well as Onboard I/O of the D4xx SIMOTION devices:
    - Update occurs in the position control cycle clock.
    - Inputs are read at the start of the cycle clock.
    - Outputs are written at the end of the cycle clock.

- **Consistency**
  - Consistency is only ensured for elementary data types. When using arrays, the user is responsible for ensuring data consistency.
  - **Exception:** Direct access to output occurs.

- **Use**
  - Preferred in MotionTasks
  - Preferred in the assigned task
  - Preferred in the BackgroundTask

- **Use the absolute address**
  - Not supported.

- **Possible, with the following syntax:** e.g. %IW62, %Q63.3.
## 5.3 Access to inputs and outputs (process image, I/O variables)

<table>
<thead>
<tr>
<th>Direct access</th>
<th>Access to process image of cyclic tasks</th>
<th>Access to fixed process image of the BackgroundTask</th>
</tr>
</thead>
</table>
| Declaration as variable | Necessary, for the entire device as an I/O variable in the symbol browser. Syntax of I/O address: e.g. PIW1022, PQ63.3. | Possible, but not necessary:  
  - for the entire device as an I/O variable in the symbol browser,  
  - As unit variable,  
  - As local variable in a program. |
| Write protection for outputs | Possible; Read only status can be selected. | Not supported. | Not supported. |
| Declaration of arrays | Possible. | | |
| Further information | Direct access and process image of the cyclic tasks (Page 233). | Access to the fixed process image of the BackgroundTask (Page 239). |
| Responses in the event of an error | Error during access from user program, alternative reactions available:  
  - CPU stop\(^1\)  
  - Substitution value  
  - Last value | Error during generation of process image, alternative reactions available:  
  - CPU stop\(^2\)  
  - Substitution value  
  - Last value | Error during generation of process image, reaction: CPU stop\(^2\).  
  **Exception:** If a direct access has been created at the same address, the behavior set there applies. |

Responses in the event of an error: Please refer to the SIMOTION Basic Functions function description.

### Access

- **In RUN mode**  
  - Without any restrictions.  
  - Without any restrictions.  
  - Without any restrictions.

- **During StartupTask**  
  - Possible with restrictions:  
    - Inputs can be read.  
    - Outputs are not written until StartupTask is complete.

- **During ShutdownTask**  
  - Without any restrictions.

Possible with restrictions:  
- Inputs are read at the start of the StartupTask.  
- Outputs are not written until StartupTask is complete.

Possible with restrictions:  
- Inputs retain status of last update  
- Outputs are no longer written.

Possible with restrictions:  
- Inputs retain status of last update  
- Outputs are no longer written.

\(^1\) Call the ExecutionFaultTask.  
\(^2\) Call the PeripheralFaultTask.
5.3.3 Direct access and process image of cyclic tasks

Properties

Direct access to inputs and outputs and access to the process image of the cyclic task always take place via I/O variables. The entire address range of the SIMOTION device (see table below) can be used.

A comparison of the most important properties, also in comparison to the fixed process image of the BackgroundTask (Page 239) is contained in "Important properties of direct access and process image (Page 231)".

Direct access

The direct access is used to directly access the corresponding I/O address. Direct access is used primarily for sequential programming (in MotionTasks). The access to the current value of the inputs and outputs at a specific time is particularly important.

For direct access, you define an I/O variable (Page 236) without assigning it a task.

Note

An access via the process image is more efficient than direct access.

Process image of the cyclic task

The process image of the cyclic tasks is a memory area in the RAM of the SIMOTION device, on which the whole I/O address space of the SIMOTION device is mirrored. The mirror image of each I/O address is assigned to a cyclic task and is updated using this task. The task remains consistent throughout the whole cycle. This process image is used preferentially when programming the assigned task (cyclic programming). The consistency during the complete cycle of the task is particularly important.

For the process image of the cyclical task you define an I/O variable (Page 236) and assign it a task.

Direct access to this I/O variable is still possible: Specify direct access with \_direct.var-name.
Address range of the SIMOTION devices

The address range of the SIMOTION devices depending on the version of the SIMOTION kernel is contained in the following table. The complete address range can be used for direct access and process image of the cyclical tasks.

Table 5-29 Address range of the SIMOTION devices depending on the version of the SIMOTION kernel

<table>
<thead>
<tr>

1 Available with V4.1 SP2 HF4 and higher
2 Available with V4.1 and higher
3 Available with V3.2 and higher
4 For distributed I/O (over PROFIBUS DP), the transmission volume is restricted to 1024 bytes per PROFIBUS DP line.
5 For distributed I/O (over PROFINET), the transmission volume is restricted to 4096 bytes per PROFINET segment.

Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 235).
5.3.3.1 Rules for I/O addresses for direct access and the process image of the cyclical tasks

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>You must observe the following rules for the I/O variable addresses for direct access and the process image of the cyclic task (Page 233). Compliance with the rules is checked during the consistency check of the SIMOTION project (e.g. during the download).</td>
</tr>
</tbody>
</table>

1. Addresses used for I/O variables must be present in the I/O and configured appropriately in the HW Config.
2. I/O variables comprising more than one byte must not contain addresses 63 and 64 contiguously.
   - The following I/O addresses are not permitted:
     - Inputs: PIW63, PID61, PID62, PID63
     - Outputs: PQW63, PQD61, PQD62, PQD63
3. All addresses of an I/O variable comprising more than one byte must be within an address area configured in HW-config.
4. An I/O address (input or output) can only be used by a single I/O variable of data type BYTE, WORD or DWORD or an array of these data types. Access to individual bits with I/O variables of data type BOOL is possible.
5. If several processes (e.g. I/O variable, technology object, PROFIdrive telegram) access an I/O address, the following applies:
   - Only a single process can have write access to an I/O address of an output (BYTE, WORD or DWORD data type).
     Read access to an output with an I/O variable that is used by another process for write access, is possible.
   - All processes must use the same data type (BYTE, WORD, DWORD or ARRAY of these data types) to access this I/O address. Access to individual bits is possible irrespective of this.
     Please be aware of the following, for example, if you wish to use an I/O variable to read the PROFIdrive telegram transferred to or from the drive: The length of the I/O variables must match the length of the telegram.
   - Write access to different bits of an address is possible from several processes; however, write access with the data types BYTE, WORD or DWORD is then not possible.

Note
These rules do not apply to accesses to the fixed process image of the BackgroundTask (Page 239). These accesses are not taken into account during the consistency check of the project (e.g. during download).
5.3.3.2 Creating I/O variables for direct access or process image of cyclic tasks

You create I/O variables for direct access and a process image of the cyclic tasks in the symbol browser in the detail view; you must be in offline mode to do this.

Here is a brief overview of the procedure:

1. In the project navigator of SIMOTION SCOUT, select the I/O element in the subtree of the SIMOTION device.
2. In the detail view, select the "Symbol browser" tab and scroll down to the end of the variable table (empty row).
3. In the last (empty) row of the table, enter or select the following:
   - Name of variable.
   - I/O address according to the "syntax for entering I/O addresses (Page 238)".
   - Optional for outputs:
     - Activate the "Read only" checkbox if you only want to have read access to the output. You can then read an output that is already being written by another process (e.g. output of an output cam, PROFIdrive telegram).
     - A read-only output variable cannot be assigned to the process image of a cyclic task.
   - Data type of the variables in accordance with "Possible data types of the I/O variables (Page 239)".
4. Optionally, you can also enter or select the following (not for data type BOOL):
   - Array length (array size).
   - Process image or direct access:
     - Can only be assigned if the "Read only" checkbox is cleared.
     - For process image, select the cyclic task to which you want to assign the I/O variable. To select a task, it must have been activated in the execution system.
     - For direct access, select the blank entry.
   - Strategy for the behavior in an error situation (see SIMOTION Basic Functions Function Manual).
   - Substitute value (if array, for each element).
   - Display format (if array, for each element), when you monitor the variable in the symbol browser.

You can now access this variable using the symbol browser or any program of the SIMOTION device.
INTEGRATION OF ST IN SIMOTION

5.3 ACCESS TO INPUTS AND OUTPUTS (PROCESS IMAGE, I/O VARIABLES)

NOTICE

Note the following for the process image for cyclic tasks:
- A variable can only be assigned to one task.
- Each byte of an input or output can only be assigned to one I/O variable.

In the case of data type BOOL, please note:
- The process image for cyclic tasks and a strategy for errors cannot be defined. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access or CPU stop).
- The individual bits of an I/O variable can also be accessed using the bit access functions.

Take care when making changes within the I/O variables (e.g. inserting and deleting I/O variables, changing names and addresses):
- In some cases the internal addressing of other I/O variables may change, making all I/O variables inconsistent.
- If this happens, all program sources that contain accesses to I/O variables must be recompiled.

Note

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and then use them in your program sources (e.g. ST sources, MCC sources, LAD/FBD sources).

Outputs can be read and written to, but inputs can only be read.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

You can use I/O variables like any other variable, see "Access I/O variables (Page 246)".
### 5.3.3.3 Syntax for entering I/O addresses

For the input of the I/O address for the definition of an I/O variable for direct access or process image of cyclical tasks (Page 233), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

#### Table 5-30 Syntax for entering I/O addresses for direct access or process image of the cyclical tasks

<table>
<thead>
<tr>
<th>Data type</th>
<th>Syntax for</th>
<th>Permissible address range</th>
<th>Direct access</th>
<th>Process image</th>
<th>e.g. direct access</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>PIn.x</td>
<td>PQn.x</td>

<td>n: 0 .. 16383</td>
<td>D435 V4.1</td>
</tr>
<tr>
<td></td>
<td>x</td>
<td></td>
<td>0 .. 7</td>
<td>0 .. 7</td>
<td></td>
</tr>
<tr>
<td>BYTE</td>
<td>PIBn</td>
<td>PQBn</td>
<td>n: 0 .. MaxAddr</td>
<td>n: 0 .. 16383</td>
<td></td>
</tr>
<tr>
<td></td>
<td>x</td>
<td></td>
<td>0 .. 7</td>
<td>0 .. 7</td>
<td></td>
</tr>
<tr>
<td>WORD</td>
<td>PIWn</td>
<td>PQWn</td>
<td>n: 0 .. 62</td>
<td>n: 0 .. 62</td>
<td></td>
</tr>
<tr>
<td></td>
<td>64 .. MaxAddr - 1</td>
<td></td>
<td>64 .. MaxAddr - 1</td>
<td>64 .. MaxAddr - 1</td>
<td></td>
</tr>
<tr>
<td>DWORD</td>
<td>PIDn</td>
<td>PQDn</td>
<td>n: 0 .. 60</td>
<td>n: 0 .. 60</td>
<td></td>
</tr>
<tr>
<td></td>
<td>64 .. MaxAddr - 3</td>
<td></td>
<td>64 .. MaxAddr - 3</td>
<td>64 .. MaxAddr - 3</td>
<td></td>
</tr>
</tbody>
</table>

n = logical address  
x = bit number  
MaxAddr = Maximum I/O address of the SIMOTION device depending on the version of the SIMOTION kernel, see address range of the SIMOTION devices in "direct access and process image of the cyclical tasks (Page 233)".

1 For data type BOOL, it is not possible to define the process image for cyclic tasks. The behavior defined via an I/O variable for the entire byte is applicable (default: direct access).

#### Examples:

Input at logic address 1022, WORD data type: **PIW1022**.

Output at logical address 63, bit 3, BOOL data type: **PQ63.3**.

#### Note

Observe the rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 235).
5.3.3.4 Possible data types of I/O variables

The following data types can be assigned to the I/O variables for direct access and process image of the cyclical tasks (Page 233). The width of the data type must correspond to the data type width of the I/O address.

If you assign a numeric data type to the I/O variables, you can access these variables as integer.

Table 5-31 Possible data types of the I/O variables for direct access and the process image of the cyclical tasks

<table>
<thead>
<tr>
<th>Data type of I/O address</th>
<th>Possible data types for I/O variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL (Pin.x, PQn.x)</td>
<td>BOOL</td>
</tr>
<tr>
<td>BYTE (PIBn, PQBn)</td>
<td>BYTE, SINT, USINT</td>
</tr>
<tr>
<td>WORD (PIWn, PQWn)</td>
<td>WORD, INT, UINT</td>
</tr>
<tr>
<td>DWORD (PIDn, PQDn)</td>
<td>DWORD, DINT, UDINT</td>
</tr>
</tbody>
</table>

For details of the data type of the I/O address, see also "Syntax for entering I/O addresses (Page 238)".

5.3.4 Access to fixed process image of the BackgroundTask

The process image of the BackgroundTask is a memory area in the RAM of the SIMOTION device, on which a subset of the I/O address space of the SIMOTION device is mirrored. Preferably, it should be used for programming the BackgroundTask (cyclic programming) as it is consistent throughout the entire cycle.

The size of the fixed process image of the BackgroundTask for all SIMOTION devices is 64 bytes (address range 0 ... 63).

A comparison of the most important properties in comparison to the direct access and process image of the cyclical tasks (Page 233) is contained in "Important properties of direct access and process image (Page 231)".

NOTICE

I/O addresses that are accessed with the process image of the cyclic tasks must not be used. These addresses cannot be read or written to with the fixed process image of the BackgroundTask.

Note

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 235) do not apply. The accesses to the fixed process image of the BackgroundTask are not taken into account during the consistency check of the project (e.g. during download).
Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.
You can access the fixed process image of the BackgroundTask by means of:

- Using an absolute PI access (Page 240): The absolute PI access identifier contains the address of the input/output and the data type.
- Using a symbolic PI access (Page 243): You declare a variable that references the relevant absolute PI access.
  - A unit variable
  - A static local variable in a program.
- Using an I/O variable (Page 245): In the symbol browser, you define a valid I/O variable for the entire device that references the corresponding absolute PI access.

**NOTICE**

Please note that if the inputs and outputs work with the little-endian byte order (e.g. the integrated digital inputs of SIMOTION devices C230-2, C240, or C240 PN) and the following conditions are fulfilled:

1. The inputs and outputs are configured to an address 0 .. 62.
2. An I/O variable for direct access (data type WORD, INT or UINT) has been created for these inputs and outputs.
3. You also access these inputs and outputs via the fixed process image of the BackgroundTask.

then the following is valid:

- Access with the data type WORD supplies the same result via the I/O variable and the fixed process image of the BackgroundTask.
- The access to the individual bytes with the `_getInOutByte` function (see SIMOTION Basic Functions Function Manual) supplies these in the Little Endian order.
- Access to the individual bytes or bits with the fixed process image of the BackgroundTask supplies these in the Big Endian order.

For information on the order of the bytes Little Endian and Big Endian: Please refer to the SIMOTION Basic Functions Function Manual.

### 5.3.4.1 Absolute access to the fixed process image of the BackgroundTask (absolute PI access)

You make absolute access to the fixed process image of the BackgroundTask (Page 239) by directly using the identifier for the address (with implicit data type). The syntax of the identifier (Page 241) is described in the following section.

You can use the identifier for the absolute PI access in the same manner as a normal variable (Page 241).

**Note**

Outputs can be read and written to, but inputs can only be read.
5.3.4.2 Syntax for the identifier for an absolute process image access

For the absolute access to the fixed process image of the BackgroundTask (Page 240), use the following syntax. This specifies not only the address, but also the data type of the access and the mode of access (input/output).

You also use these identifiers:

- For the declaration of a symbolic access to the fixed process image of the BackgroundTask (Page 243).
- For the creation of an I/O variables for accessing the fixed process image of the BackgroundTask (Page 245).

Table 5-32 Syntax for the identifier for an absolute process image access

<tr>
<td>WORD</td>
<td>%IWn</td>
<td>%QWn</td>
</tr>
<tr>
<td>DWORD</td>
<td>%IDn</td>
<td>%QDn</td>
</tr>
</tbody>
</table>

\(^1\) The syntax %IXn.x or %QXn.x is not permitted when defining I/O variables.
\(^2\) Except for the addresses used in the process image of the cyclic tasks.

n = logical address
x = bit number
Examples

Input at logic address 62, WORD data type: %IW62.
Output at logical address 63, bit 3, BOOL data type: %Q63.3.

**NOTICE**

Addresses that are accessed with the process image of the cyclic tasks must not be used. These addresses cannot be read or written to with the fixed process image of the BackgroundTask.

**Note**

The rules for I/O addresses for direct access and the process image of the cyclical tasks (Page 235) do not apply. The accesses to the fixed process image of the BackgroundTask are not taken into account during the consistency check of the project (e.g. during download).

Addresses not present in the I/O or not configured in HW Config are treated like normal memory addresses.

Several examples for the assignment of variables of the same type follow:

**Table 5-33 Examples of absolute CPU memory access**

```plaintext
status1 := %I1.1; // BOOL data type
status2 := %IB10; // BYTE data type
status3 := %IW20; // WORD data type
status4 := %ID20; // DWORD data type

%Q1.1 := status1; // BOOL data type
%QB20 := status2; // BYTE data type
%QW20 := status3; // WORD data type
%QD20 := status4; // DWORD data type
```
5.3.4.3 Symbolic access to the fixed process image of the BackgroundTask (symbolic PI access)

You can access the fixed process image of the BackgroundTask (Page 239) symbolically without needing to always specify the absolute process image access.

You can declare symbolic access:

- As a static variable of a program (within the VAR/END_VAR structure in the declaration section)
- As a unit variable (within the VAR_GLOBAL / END_VAR structure in the interface or implementation section of the ST source file)

The syntax for declaring a symbolic name for the PI access is shown in the figure:

![Figure 5-6 Declaration of a symbolic access to the process image](image)

For the absolute PI access, see "Syntax for the identifier for an absolute PI access (Page 241)".

The range of the declared integer or bit data type must correspond to the range of the absolute PI access, see "Possible data types of the symbolic PI access (Page 244)". After declaring a numerical data type, you can address the contents of the process image as an integer.

See also Example for the declaration (Page 244).
### 5.3.4.4 Possible data types for symbolic PI access

In the following cases, a data type that differs from that of the absolute PI access can be assigned to the fixed process image of the BackgroundTask (Page 239). The data type width must correspond to the data type width of the absolute PI access.

- For the declaration of a symbolic PI access (Page 243).
- For the creation of an I/O variable (Page 245).

If you assign a numeric data type to the symbolic PI access or to the I/O variables, you can access these variables as integer.

<table>
<thead>
<tr>
<th>Data type of the absolute PI access</th>
<th>Possible data types of the symbolic PI access</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL (%In.x, %IXn.x, %Qn.x, %QXn.x)</td>
<td>BOOL</td>
</tr>
<tr>
<td>BYTE (%IBn, %QBn)</td>
<td>BYTE, SINT, USINT</td>
</tr>
<tr>
<td>WORD (%IWn, %QWn)</td>
<td>WORD, INT, UINT</td>
</tr>
<tr>
<td>DWORD (%IDn, %PQDn)</td>
<td>DWORD, DINT, UDINT</td>
</tr>
</tbody>
</table>

For the data type of the absolute PI access, see also "Syntax for the identifier for an absolute PI access (Page 241)".

### 5.3.4.5 Example of symbolic PI access

If, for example, you want to access the CPU memory area (absolute PI access (Page 241)) %IB10, but can respond flexibly to changes in your program, then declare a `myInput` variable with this CPU memory area as follows:

```plaintext
VAR
  myInput AT %IB10 : BYTE;
END_VAR
```

If you want to use the integer value of the memory area, declare the `myInput` variable as follows:

```plaintext
VAR
  myInput AT %IB10 : SINT;
END_VAR
```

If you want to use a CPU memory area other than %IB10 in your program at a later time, you only need to change the absolute PI access in the variable declaration.
5.3.4.6 Creating an I/O variable for access to the fixed process image of the BackgroundTask

You create I/O variables for access to the fixed process image for the background task in the symbol browser in the detail view; you must be in offline mode to do this.

Here is a brief overview of the procedure:

1. In the project navigator of SIMOTION SCOUT, select the "I/O" element in the subtree of the SIMOTION device.
2. In the detail view, select the Symbol browser tab and scroll down to the end of the variable table (empty row).
3. In the last (empty) row of the table, enter or select the following:
   - **Name** of variable.
   - **I/O address**, the absolute PI access according to the "syntax for the identifier for an absolute PI access (Page 241)" (exception: The syntax %IXn.x or %QXn.x is not permitted for data type BOOL).
   - **Data type** of the I/O variables according to the "possible data types of the symbolic PI access (Page 244)".
4. Select optionally the display format used to monitor the variable in the symbol browser.

You can now access this variable using the symbol browser or any program of the SIMOTION device.

---

**Note**

I/O variables can only be created in offline mode. You create the I/O variables in SIMOTION SCOUT and use them in your program sources.

Note that you can read and write outputs but you can only read inputs.

Before you can monitor and modify new or updated I/O variables, you must download the project to the target system.

---

You can use I/O variables like any other variable, see "Access I/O variables (Page 246)".
5.3.5 Accessing I/O variables

You have created an I/O variable for:

- Direct access or process image of the cyclic tasks (Page 233).
- Access to the fixed process image of the BackgroundTask (Page 239).

You can use this I/O variable just like any other variable.

**NOTICE**

Consistency is only ensured for elementary data types.

When using arrays, the user is responsible for ensuring data consistency.

---

**Note**

If you have declared unit variables or local variables of the same name (e.g. `var-name`), specify the I/O variable using `_device.var-name` (predefined namespace, see the "Predefined namespaces" table in "Namespaces").

It is possible to directly access an I/O variable that you created as a process image of a cyclic task. Specify direct access with `_direct.var-name` or `_device._direct.var-name`.

---

If you want to deviate from the default behavior when errors occur during variable access, you can use the `_getSafeValue` and `_setSafeValue` functions (see SIMOTION Basic Functions Function Manual).

For errors associated with access to I/O variables, see SIMOTION Basic Functions Function Manual.
5.4 Using libraries

Libraries provide you with user-defined data types, functions and function blocks that can be used from all SIMOTION devices.

Libraries can be written in all programming languages; they can be used in all program sources (e.g. ST source files, MCC units).

You can obtain more details on inserting and managing libraries in the online help.

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
</table>
| The same rules as for the names of program source files apply to the library names, see Insert ST source file (Page 21). In particular, the permissible length of the name depends on the SIMOTION Kernel version:
| • As of Version V4.1 of the SIMOTION Kernel: maximum 128 characters.
| • Up to Version V4.0 of the SIMOTION Kernel: maximum 8 characters.
| With versions of the SIMOTION Kernel up to V4.0, a violation of the permissible length of the library name may not be detected until a consistency check or a download of the project is performed! |

There is also the option of having a library make programs available, which can be called from other programs or function blocks. Please refer to the conditions which apply when calling a “program in a program” (Page 179). In each case, the static data for the program called is stored once in the user memory of the device on which the library program is called. The same program instance data is used every time the program is called on the same device. A library program cannot be assigned to the execution system.
5.4 Using libraries

5.4.1 Compiling a library

In libraries, you can use all ST commands except for the ones listed in the table. In addition, you are not allowed to access some variables; these variables are also listed in this table.

Table 5-35 Illegal ST commands and variable access in libraries

<table>
<thead>
<tr>
<th>Prohibited commands:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• _getTaskId function (see SIMOTION Basic Functions Function Manual).</td>
</tr>
<tr>
<td>• _getAlarmId function (see SIMOTION Basic Functions Function Manual).</td>
</tr>
<tr>

</tr>
<tr>
<td>• If the library is not device-dependent (i.e. compiled without reference to a SIMOTION device or SIMOTION Kernel version):</td>
</tr>
<tr>
<td>– System variables of SIMOTION devices (see the Parameter Manual for SIMOTION devices)</td>
</tr>
<tr>
<td>– Configuration data of technology objects (see Parameter Manual of configuration data for the relevant SIMOTION technology package)</td>
</tr>
</tbody>
</table>

Note

The Program status debug function is not available in libraries.
Compiling an individual library

To compile an individual library, proceed as follows:
1. Select the library in the project navigator.
2. Select the Edit > Object Properties menu command.
3. Select the TPs/TOs tab.
4. Select the SIMOTION devices (with SIMOTION kernel version) and the technology packet that you want to use as a basis for compiling the library; see the SIMOTION Basic Functions Function Manual.
5. Select Accept and compile from the context menu.

The library is compiled with reference to all selected SIMOTION devices, SIMOTION kernel versions and technology packages (and independently of devices).

NOTICE

If the library to be compiled imports another library, note the following:
1. For the imported library, at least the same devices and SIMOTION kernel versions must be selected as for the importing library.
   Alternatively, the imported library can be compiled independently of devices if the prerequisites for this are fulfilled (refer to the SIMOTION Basic Functions Function Manual).
2. The imported library must already be compiled individually with reference to all configured devices, kernel versions and technology packages.
   Compilation of the library as part of a project-wide compilation is generally not sufficient.

Compiling a library as part of a project-wide compilation

When you compile the whole SIMOTION project (e.g. by choosing Project > Save and recompile all or by performing an XML import), the libraries used are also compiled.

NOTICE

When performing project-wide compilation, note the following:
1. The system automatically identifies dependencies between libraries and selects the appropriate compilation sequence.
2. A library is only compiled with reference to the SIMOTION devices (including versions of the SIMOTION kernel) that are configured in the project and which use the library.
3. Other SIMOTION devices and kernel versions set for the library are ignored.
### 5.4.2 Know-how protection for libraries

You can protect libraries and their source files against unauthorized access by third parties. Protected libraries or sources can only be opened or exported as plain text files by entering a password.

You can:

- Provide individual sources of a library with know-how protection:
  
  Only the sources are protected against unauthorized access.

  The setting of the SIMOTION devices including the versions of the SIMOTION Kernel and the technology packages, for which the library is to be compiled, can still be changed and adapted by the user. Please refer to the *SIMOTION Basic Functions* Function Manual.

  The user can thus use the library for other SIMOTION devices and kernel versions.

- Provide the library with know-how protection:
  
  The following is then protected against unauthorized access:
  
  - All sources of the library
  
  - The setting of the SIMOTION device including the versions of the SIMOTION Kernel and the technology packages for which the library is to be compiled.

  You thus prevent that the user can use the library for other SIMOTION devices and kernel versions.

  Only use this setting if this is intended.

The SIMOTION online help provides additional information on know-how protection.

---

**Note**

If you export in XML format, the libraries or sources are exported in an encrypted form. When importing the encrypted XML files, the know-how protection, including login and password, remains in place.
5.4.3 Using data types, functions and function blocks from libraries

Before using data types, functions or function blocks from libraries, you must make them known to the ST source file. To do so, use the following construct in the interface section of the ST source file:

```plaintext
USELIB library-name [AS namespace];
```

In this case, `library-name` is the name of the library as it appears in the project navigator. When multiple libraries are to be specified, enter them as a list separated by commas, e.g.:

```plaintext
USELIB library-name_1 [AS namespace_1],
    library-name_2 [AS namespace_2],
    library-name_3 [AS namespace_1], ...
```

You can use the optional `AS namespace` add-on to define a namespace (see Namespaces (Page 255)).

- You can then access data types, functions, and function blocks in the library that have the same name as such an ST source file of a SIMOTION device (in the PROGRAMS folder).
- You can also use namespaces to change the names of data types, functions and function blocks in the library so that they have different names.

You can also assign the same namespace to different libraries.

---

**Table 5-36 Example of use of namespaces with libraries**

```plaintext
INTERFACE
    USELIB Bib_1 AS NS_1, Bib_2 AS NS_2;
    PROGRAM Main_Program;
END_INTERFACE

IMPLEMENTATION
    FUNCTION Function1 : VOID
        VAR
            ComID : CommandIdType;
        END_VAR
        ComId := _getCommandId();
    END_FUNCTION

    PROGRAM Main_program
        function1(); // Function from this source
        NS_1.Var1:=1;
        NS_2.Var1:=2;
        NS_1.function1(); // Function from the Bib1 library
        NS_2.function1(); // Function from the Bib2 library
    END_PROGRAM
ENDIMPLEMENTATION
```
5.5 Use of the same identifiers and namespaces

5.5.1 Use of the same identifiers

It is possible to use unit variables and local variables (program variables, FB variables, FC variables) with the same name. When compiling a program source, the compiler searches for identifiers beginning with the current POU. The smaller validity range always takes priority over the larger validity range.

You can therefore use the same identifiers in different source file sections, as long as the rules below are adhered to. If a higher-level identifier is hidden by an identifier in a unit or POE, the compiler issues a warning.

**NOTICE**

Under certain circumstances, the compiler may not issue a warning if, for example, the associated technology package is not imported.

Identifiers in a program organization unit (POU)

All following identifiers in a POU must be unique:

- Local variables of the POU.
- Local data types of the POU.

They may not also be identical with the following identifiers:

- Reserved identifiers.
- Identifiers of the POU itself.

The compiler issues a warning when the following identifiers are hidden:

- Unit variables, data types and POU or the same or imported units
- Standard system functions, standard system function blocks and associated data types
- System functions and system data types of the SIMOTION device
- Program organization units (POU) and data types from imported libraries
  - This can be resolved by entering a user-defined namespace.
- System functions and system data types from imported technology packages.
  - This can be resolved by entering a user-defined namespace.
- SIMOTION device variables (system variables, I/O variables, global device variables)
  - This can be resolved by entering the predefined namespace _device.
- Technology objects configured on the SIMOTION device
  - This can be resolved by entering the predefined namespace _to.
Identifiers in a unit

All following identifiers in a unit must be unique:

- Unit variables (declared in the interface or implementation section)
- Data types (declared in the interface or implementation section)
- Program organization units (POUs)

These must not be identical to the following identifiers either:

- Reserved identifiers.
- Unit variables, data types and POU imported units.
- Standard system functions, standard system function blocks and associated data types.
- System functions and system data types of the SIMOTION device.
- Program organization units (POU) and data types from imported libraries.
  - This can be resolved by entering a user-defined namespace.
- System functions and system data types from imported technology packages.
  - This can be resolved by entering a user-defined namespace.

The compiler issues a warning when the following identifiers are hidden:

- SIMOTION device variables (system variables, I/O variables, global device variables).
  - This can be resolved by entering the predefined namespace _device.
- Technology objects configured on the SIMOTION device.
  - This can be resolved by entering the predefined namespace _to.

Identifiers on the SIMOTION device (e.g., I/O variables, global device variables)

All the following identifiers on the SIMOTION device must be unique:

- I/O variables
- Global device variables
- System variables of the SIMOTION device
- System functions and system data types of the SIMOTION device.

These must not also be identical to the following identifiers:

- Reserved identifiers.
- Standard system functions, standard system function blocks and associated data types.
Example

The following example illustrates this situation. It shows that for use of identical names for unit variables (large validity range) and FC variables (small variable scope), only the variables declared in the function are valid within this source file section. The unit variables are only valid in POUs in which no local variables of the same name were declared. See the example.

Table 5-37 Example of identifier validity

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

FUNCTION fc_2: VOID

VAR

| var_b : type_a; // Declaration hides UNIT variable |
| var_c : type_a; // Local variable |
| END_VAR |
| // Permitted statements |
| var_a := -100; // Access to unit variable |
| var_b := enum3; // Access to local variable |
| var_c := enum1; // Access to local variable |
| // Invalid statement |
| // var_b := 200; |
| END_FUNCTION |
5.5.2 Namespaces

You can also access data types, unit variables, functions, and function blocks defined outside of a program source (e.g. in libraries, technology packages, and on the SIMOTION device) using their names.

When compiling a program source, the compiler searches for identifiers beginning with the current POU. The data types, variables, functions, or function blocks declared in a program source therefore hide identifiers with the same name which have been defined outside the source, see Use of the same identifiers (Page 252). In order to still access these hidden identifiers, you can use namespaces in certain cases.

User-defined namespace

In the import instruction for libraries and technology packages, you can define namespaces in order to reach the data types, functions, or function blocks of these libraries and technology packages.

USELIB library-name_1 [AS lib_namespace_1],
library-name_2 [AS lib_namespace_2],
library-name_3 [AS lib_namespace_1], ...

USEPACKAGE tp-name_1 [AS tp_namespace_1],
tp-name_2 [AS tp_namespace_2],
tp-name_3 [AS tp_namespace_1], ...

You can also use namespaces to make names consistent within different libraries.

If you wish to use a data type, a function or a function block from a library or a technology package, place the namespace identifier in front of the name, separated by a period, for example, namespace.fc-name, namespace.fb-name, namespace.type-name
Example

The following example shows how to select the Cam technology package, assign it the namespace Cam1 and use the namespace:

Table 5- 38  Example of selecting a technology package and using a namespace

```plaintext
INTERFACE
  USEPACKAGE Cam AS Cam1;
  USES ST_2;
  FUNCTION function1;
END_INTERFACE

IMPLEMENTATION
  FUNCTION function1 : VOID
    VAR_INPUT
      p_Axis : posAxis;
    END_VAR
    VAR
      retVal : DINT;
    END_VAR
    retVal := Cam1._enableAxis (
      axis := p_Axis,
      nextCommand := Cam1.WHEN_COMMAND_DONE,
      commandId := _getCommandId() );
  END_FUNCTION
END_IMPLEMENTATION
```

NOTICE

If a namespace is defined for an imported library or technology package, this must always be specified if a function, function block, or data type from this library or technology package is being used. See above example: Cam1._enableAxis, Cam1.WHEN_COMMAND_DONE.
Predefined namespace

Namespaces are predefined for device- and project-specific variables as well as TaskID and AlarmID variables. If necessary, write their designation before the variable names, separated by a period, for example, _device.var-name or _task.task-name

Table 5-39 Predefined namespaces

<table>
<thead>
<tr>
<th>Name space</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_alarm</td>
<td>For AlarmId: The _alarm.name variable contains the AlarmId of the message with the name identifier (see SIMOTION Basic Functions Function Manual).</td>
</tr>
<tr>
<td>_device</td>
<td>For device-specific variables (global device variables, I/O variables, and system variables of the SIMOTION device).</td>
</tr>
<tr>
<td>_direct</td>
<td>For direct access to I/O variables – see Direct access and process image of the cyclical tasks (Page 233). Local namespace for _device. Nesting as in _device._direct.name is permitted.</td>
</tr>
<tr>
<td>_project</td>
<td>For names of SIMOTION devices in the project; only used with technology objects on other devices. With unique project-wide names of technology objects, used also for these names and their system variables.</td>
</tr>
<tr>
<td>_task</td>
<td>For TaskID: The _task.name variable contains the TaskId of the task with the name identifier (see SIMOTION Basic Functions Function Manual).</td>
</tr>
<tr>
<td>_to</td>
<td>For technology objects configured on the SIMOTION device, and their system variables and configuration data. Not for system functions and data types of the technology objects. In this case, if necessary, use the user-defined namespace for the imported technology package</td>
</tr>
</tbody>
</table>
5.5 Use of the same identifiers and namespaces

Figure 5-7  Namespaces and identifier hierarchy
5.6 Reference data

The reference data provide you with an overview of:

- on utilized identifiers with information about their declaration and use
  (Cross-reference list (Page 259)).
- on function calls and their nesting
  (Program structure (Page 263))
- on the memory requirement for various data areas of the program sources
  (Code attributes (Page 265))

5.6.1 Cross-reference list

The cross-reference list shows all identifiers in program sources (e.g. ST source files, MCC source files):

- Declared as variables, data types, or program organization units (program, function, function block)
- Used as previously defined types in declarations
- Used as variables in the statement section of a program organization unit.

You can generate the cross-reference list selectively for:

- An individual program source (e.g. ST source file, MCC source file, LAD/FBD source)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library)

5.6.1.1 Creating a cross-reference list

To create the cross-reference list:

1. In the project navigator, select the element for which you want to create a cross-reference list.
2. Select the menu Edit > Reference data > Create.

The cross-reference list is displayed in its own tab in the detail view.

Note

The generated cross-reference list is saved automatically and can be displayed selectively after selecting the appropriate element in the project navigator. To display the cross-reference list, select the Edit > Reference data > Display > Cross-Reference List menu command.

When a cross-reference list is recreated, it is updated selectively (corresponding to the selected element in the project navigator). Other existing cross-reference data are retained and displayed, if applicable.
5.6.1.2 Content of the cross-reference list

The cross-reference list contains all the identifiers assigned to the element selected in the project navigator. The applications for the identifiers are also listed in a table:

Details of how to work with the cross-reference list are described in the section "Working with the cross-reference list (Page 262)".

<td></td>
</tr>
</tbody>
</table>

**Note**

**Activated single-step monitoring in MCC programming**

Each task is assigned two variables TSI#dwuser_1 and TSI#dwuser_2, which can be written and read.

When single step monitoring is activated, the compiler uses these variables to control single step monitoring if at least one MCC chart is assigned to the relevant task. The user then cannot use these variables, because their contents are overwritten by single step monitoring and may cause undesirable side effects.
5.6.1.3 **Working with a cross-reference list**

In the cross-reference list you are able to:

- Sort the column contents alphabetically:
  - To do this, click the header of the appropriate column.

- Search for an identifier or entry:
  - Click the "Search" button and enter the search term.

- Filter (Page 263) the identifiers and entries displayed.

- Copy contents to the clipboard in order, for example, to paste them into a spread-sheet program
  - Select the appropriate lines and columns.
  - Press the CTRL+C shortcut.

- Print the contents ("Project" > "Print" menu).

- Open the referenced program source and position the cursor on the relevant line of the ST source file (or MCC command or LAD/FBD element):
  - Double-click on the corresponding line in the cross-reference list.
  - Place the cursor in the corresponding line of the cross-reference list and click the "Go to application" button.

Further details about working with cross-reference lists can be found in the online help.
5.6.1.4 Filtering the cross-reference list

You can filter the entries in the cross-reference list so that only relevant entries are displayed:

1. Click the "Filter settings" button.
   The "Filter Setting for Cross References" window will appear.
2. Activate the "Filter active" checkbox.
3. If you also want to display system variables and system functions:
   – Deactivate the "Display user-defined variables only" checkbox.
4. Set the desired filter criterion for the relevant columns:
   – Select the relevant entry from the drop-down list box or enter the criterion.
   – If you want to search for a character string within an entry: Deactivate the "Whole words only" checkbox.
5. Confirm with "OK."

The contents of the cross-reference list will reflect the filter settings selected.

---

**Note**

A filter is automatically activated after the cross-reference list has been created.

5.6.2 Program structure

The program structure contains all the function calls and their nesting within a selected element.

When the cross-reference list has been successfully created, you can display the program structure selectively for:

- An individual program source (e.g. ST source file, MCC source file, LAD/FBD source)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Follow these steps:

1. In the project navigator, select the element for which you want to display the program structure.
2. Select the menu **Edit > Reference data > Display > Program structure**.

   The cross-reference tab is replaced by the program structure tab in the detail view.
5.6.2.1 **Content of the program structure**

A tree structure appears, showing:

- as base respectively
  - the program organization units (programs, functions, function blocks) declared in the program source, or
  - the execution system tasks used
- below these, the subroutines referenced in this program organization unit or task.

For structure of the entries, see table:

<p>| Table 5-41 Elements of the display for the program structure |</p>
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base (declared POU or task used))</td>
<td>List separated by a comma</td>
</tr>
<tr>
<td>• Identifier of the program organization unit (POU) or task</td>
<td></td>
</tr>
<tr>
<td>• Identifier of the program source in which the POU or task was declared, with add-on [UNIT]</td>
<td></td>
</tr>
<tr>
<td>• Minimum and maximum stack requirement (memory requirement of the POU or task on the local data stack), in bytes [Min, Max]</td>
<td></td>
</tr>
<tr>
<td>• Minimum and maximum overall stack requirement (memory requirement of the POU or task on the local data stack including all called POUs), in bytes [Min, Max]</td>
<td></td>
</tr>
<tr>
<td>Referenced POU</td>
<td>List separated by a comma:</td>
</tr>
<tr>
<td>• Identifier of called POU</td>
<td></td>
</tr>
<tr>
<td>• Optionally: Identifier of the program source / technology package in which the POU was declared:</td>
<td></td>
</tr>
<tr>
<td>Add-on (UNIT): User-defined program source</td>
<td></td>
</tr>
<tr>
<td>Add-on (LIB): Library</td>
<td></td>
</tr>
<tr>
<td>Add-on (TP): System function from technology package</td>
<td></td>
</tr>
<tr>
<td>• Only for function blocks: Identifier of instance</td>
<td></td>
</tr>
<tr>
<td>• Only for function blocks: Identifier of program source in which the instance was declared:</td>
<td></td>
</tr>
<tr>
<td>Add-on (UNIT): User-defined program source</td>
<td></td>
</tr>
<tr>
<td>Add-on (LIB): Library</td>
<td></td>
</tr>
<tr>
<td>• Line of (compiled) source in which the POU is called; several lines are separated by &quot;</td>
<td>&quot;.</td>
</tr>
</tbody>
</table>
5.6.3 Code attributes

You can find information on or the memory requirement of various data areas of the program sources under code attribute.

When the cross-reference list has been successfully created, you can display the code attributes selectively for:
- An individual program source (e.g. ST source file, MCC source file, LAD/FBD source)
- All program sources of a SIMOTION device
- All program sources and libraries of the project
- Libraries (all libraries, single library, individual program source within a library)

Follow these steps:
1. In the project navigator, select the element for which you want to display the code attributes.
2. Select the Edit > Reference data > Display > Code attributes menu.
   
The Cross-references tab is now replaced by the Code attributes tab in the detail view.

5.6.3.1 Code attribute contents

The following are displayed in a table for all selected program source files:
- Identifier of program source file,
- Memory requirement, in bytes, for the following data areas of the program source file:
  - Dynamic data: All unit variables (retentive and non-retentive, in the interface and implementation sections),
  - Retain data: Retentive unit variables in the interface and implementation section,
  - Interface data: Unit variables (retentive and non-retentive) in the interface section,
- Number of referenced sources.
5.7 Controlling the preprocessor and compiler with pragmas

A pragma is used to insert an ST source file text (e.g. statements), which influences the compilation of the ST source file.

Pragmas are enclosed in {} braces and can contain (see figure):

- Preprocessor statements for controlling the preprocessor, see Controlling the preprocessor (Page 267).
  - The pragmas with preprocessor statements contained in an ST source file are evaluated by the preprocessor and interpreted as control statements.
- Attributes for compiler options to control the compiler, see Controlling compiler with attributes (Page 271).
  - The pragmas with attributes for compiler options contained in an ST source file are evaluated by the compiler and interpreted as control statements.

![Pragma Syntax Diagram](image)

**NOTICE**

Be sure to use the correct pragma syntax (e.g. upper- and lower-case notation of attributes).

Unrecognized pragmas are ignored with no warning message.
5.7.1 Controlling a preprocessor

The preprocessor prepares an ST source file for compilation. For example, character strings can be defined as replacement texts for identifiers, or sections of the source program can be hidden/shown for compilation.

The preprocessor is disabled by default. You can activate it as follows:

- Globally for all program source files and programming languages within the project, see "Global settings of the compiler (Page 47)".
- Local for a program source file, see "Local compiler settings (Page 49)".

During the compilation of a program source file, you will be informed about the preprocessor actions. This requires, however, that the display of warnings class 7 is activated, see Meaning of the warning classes (Page 52). You specify the details for issued warnings and information:

- In the global or local settings of the compiler.
- With the _U7_PoeBld_CompilerOption := warning:n:off or warning:n:on attribute within an ST source file, see "Controlling compiler with attributes (Page 271)".

Like compiler messages, information about the preprocessor is shown in the "Compile/check output" tab of the detail view.

Note

You can also view the text of the ST source file modified by the preprocessor:

1. Open the ST source file.
2. Select the ST source file > Execute preprocessor menu command.

The modified source text is shown in the "Compile/check output" tab of the detail view.
5.7 Controlling the preprocessor and compiler with pragmas

5.7.1.1 Preprocessor statement

You can control the preprocessor by means of statements in pragmas. The statements specified in the following syntax diagram can be used. These statements act on all subsequent lines of the ST source file.

They can be used in ST source files of a SIMOTION device or a library.

You can make definitions for the preprocessor in the property dialog box of the ST source file (see Making preprocessor definitions (Page 54)). This enables you also to control the preprocessor with ST source files with know-how protection (see Know-how protection for ST sources (Page 54)).

Preprocessor statement (unformatted)

```
#define Identifier Text

#undef Identifier

#ifdef Identifier

#else

#endif
```

Each statement must begin with a new line and end with a line break.

The following order must be maintained for the statements below:
#define – #else (optional) – #endif or #ifndef – #else (optional) – #endif.

Text: String of any characters except:
\ (backslash), ‘ (single quote) and “ (double quote).
The keywords USES, USELIB and USEPACKAGE are not permitted.

Figure 5-9 Syntax of a preprocessor statement
### Table 5-42 Preprocessor statements

<table>
<thead>
<tr>
<th>Statement</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#define</code></td>
<td>The specified identifier will be replaced below by the specified text. Permissible characters: See table footnote.</td>
</tr>
<tr>
<td><code>#undef</code></td>
<td>The replacement rule for the identifier is cancelled.</td>
</tr>
<tr>
<td><code>#ifdef</code></td>
<td>For variant formation (conditional compilation) If the specified identifier is defined, the following program lines (until the next pragma that contains #else or #endif) are compiled by the compiler.</td>
</tr>
<tr>
<td><code>#ifndef</code></td>
<td>For variant formation (conditional compilation) If the specified identifier is not defined, the following program lines (until the next pragma that contains #else or #endif) are compiled by the compiler.</td>
</tr>
<tr>
<td><code>#else</code></td>
<td>For variant formation (conditional compilation) Alternative branch to #ifdef or #ifndef. The following program lines (until the next pragma containing #endif) are compiled by the compiler, if the preceding query with #ifdef or #ifndef was not fulfilled.</td>
</tr>
<tr>
<td><code>#endif</code></td>
<td>Concludes variant formation with #ifdef or #ifndef.</td>
</tr>
</tbody>
</table>

Permissible characters:
- For identifiers: In accordance with the rules for identifiers (Page 80). You can also make preprocessor definitions in the property dialog box of the ST source file.
- For text: Sequence of any characters other than \ (backslash), ' (single quote) and " (double quote). The keywords USES, USELIB and USEPACKAGE are not permitted.

### Note

Each preprocessor statement must begin with a new line and end with a line break. Consequently, the curly brackets ({ and }) enclosing the pragma must be placed in separate lines of the ST source file!

In the case of pragmas with `#define` statements, please note:
- Pragmas with `#define` statements in the interface section of an ST source file are exported. The defined identifiers can be imported with the USES statement into other ST source files of the same SIMOTION device or of the same library.
- Identifiers defined in pragmas of libraries cannot be imported into ST source files of a SIMOTION device.
- Redefinition of reserved identifiers is not possible.

You can also make preprocessor definitions in the property dialog box of the ST source file. In the case of different definitions of the same identifiers, `#define` statements within the ST source file have priority.
### 5.7.1.2 Example of preprocessor statements

</tr>
<tr>
<td></td>
<td>warning:\nx.off</td>
<td>Warnings or information specified by the number \nx are not displayed. Permissible values for \nx. \nx = 0 to 7: Warning class, see also Meaning of the warning classes (Page 52). \nx = 16000 and higher: Number for a warning or information:</td>
</tr>
<tr>
<td></td>
<td>warning:\nx.on</td>
<td>Warnings specified by the number \nx are displayed Permissible values for \nx. \nx = 0 to 7: Warning class, see also Meaning of the warning classes (Page 52). \nx = 16000 and higher: Number for a warning or information:</td>
</tr>
<tr>
<td>HMI_Export</td>
<td>FALSE</td>
<td>In the interface section of an ST source file. The unit variables declared in the associated declaration block are not available on HMI devices.</td>
</tr>
<tr>
<td></td>
<td>TRUE</td>
<td>In the implementation section of an ST source file. The unit variables declared in the associated declaration block are available on HMI devices.</td>
</tr>
</tbody>
</table>
### Attribute identifier | Attribute value | Meaning
--- | --- | ---
BlockInit_OnChange | Only as of Version V3.2 of the SIMOTION kernel. The attribute changes the standard definition whether a download in RUN mode is possible when a change is made to the version identification of the associated declaration block. It must be placed directly after the associated keyword of the following declaration blocks:
- VAR_GLOBAL (in the interface and implementation section)
- VAR_GLOBAL RETAIN (in the interface and implementation section)
- VAR (only for programs in a unit when the "Create program instance data only once" compiler option is active).

It affects only the variables declared in the associated declaration block. See also Version ID of global variables and their initialization during download (Page 225).

**FALSE** | Download in RUN mode is not possible when the version identification of the declaration block is changed (default).**

**TRUE** | Download in RUN mode is possible despite the change to the version identification of the declaration block. The variables of the declaration block are initialized in the process.

BlockInit_OnDeviceRun | Only as of Version V4.1 of the SIMOTION kernel. The attribute changes the standard definition whether the variables of the associated declaration block will be initialized for the transition to the RUN mode. It must be placed directly after the associated keyword of the following declaration blocks:
- VAR_GLOBAL (in the interface and implementation section)
- VAR (only for programs in a unit when the "Create program instance data only once" compiler option is active).

It affects only the variables declared in the associated declaration block. See also Memory ranges of the variable types (Page 212).

**DISABLE** | The variables declared in the associated declaration block are not initialized in the transition of the mode from STOP to RUN (default).**

**ALWAYS** | The variables declared in the associated declaration block are initialized in the transition of the mode from STOP to RUN.

---

**NOTICE**

Be sure to use the correct upper- and lower-case notation for attributes!

---

**Note**

The insertion, deletion or changing of the HMI_Export, BlockInit_OnChange or BlockInit_OnDeviceRun attributes in a declaration block does not change its version identification!
Table 5-45  Example of attributes for compiler options

{ _U7_PoeBld_CompilerOption := warning:2:off; }
o_var := REAL_TO_INT(1.0); // No warning 16004
{ _U7_PoeBld_CompilerOption := warning:16004:on; }
o_var := REAL_TO_INT(1.0); // Warning 16004
{ _U7_PoeBld_CompilerOption := warning:16004:off; }
o_var := REAL_TO_INT(1.0); // No warning 16004
{ _U7_PoeBld_CompilerOption := warning:2:off;
  _U7_PoeBld_CompilerOption := warning:16004:on; }
o_var := REAL_TO_INT(1.0); // Warning 16004
END_FUNCTION_BLOCK
END_IMPLEMENTATION
5.8 Jump statement and label

In addition to control statements (see Control statements (Page 143)), a jump statement is also available.

You program jump statements with the GOTO statement and specify the jump label to which you want to jump. Jumps are only permitted within a POU.

Enter the jump label (separated by a colon) in front of the statement at which you want the program to resume.

Alternatively, you can declare the jump labels in the POU (with the structure LABEL/END_LABEL in the POU). Only the declared jump labels can then be used in the statement section.

Syntax of jump statements and labels:

Table 5-46 Example of syntax for jump statements

```
FUNCTION func : VOID
  VAR
    x, y, z BOOL;
  END_VAR
  LABEL
    lab_1, lab_2; // Declaration of the jump labels
  END_LABEL
  x := y;
  lab_1 : y := z; // Jump label with statement
  IF x = y THEN
    GOTO lab_2; // Jump statement
  END_IF;
  GOTO lab_1; // Jump statement
  lab_2 : ; // Jump label with blank statement
END_FUNCTION
```

Note

You should only use the GOTO statement in special circumstances (for example, for troubleshooting). It should not be used at all according to the rules for structured programming.

Jumps are only permitted within a POU.

The following jumps are illegal:

- Jumps to subordinate control structures (WHILE, FOR, etc.)
- Jumps from a WAITFORCONDITION structure
- Jumps within CASE statements

Jump labels can only be declared in the POU in which they are used. If jump labels are declared, only the declared jump labels may be used.
This chapter describes various sources of programming errors and shows you how to program efficiently. You also learn what options are available for program testing. For all possible compilation error messages, i.e. compiler errors, see Compiler error messages and their remedies (Page 376). Possible reactions and remedies are described for each error.

### 6.1 Notes on avoiding errors and on efficient programming

The SIMOTION Basic Functions Function Manual lists some common error sources, which hinder the compilers or prevent the proper execution of a program. There are notes on, e.g.:

- Data types for assigning arithmetic expressions
- Starting functions in cyclic tasks
- Wait times in cyclic tasks
- Errors on download
- CPU does not switch to RUN
- CPU goes to STOP
- Size of the local data stack
- etc.

In addition, you will also find notes on efficient programming there, particularly for

- runtime-oriented programming
- change-optimized programming
6.2 Program debugging

Syntax errors are detected and displayed by the ST compiler during the compilation procedure. Runtime errors in the execution of the program are displayed by system alarms or lead to the operating mode STOP. You can find logical programming errors with the test functions of ST, e.g. with the symbol browser, status program, trace.

To achieve the same results as shown below using the test functions, use of the sample program in Creating a sample program (Page 63) is recommended.

6.2.1 Modes for program testing

6.2.1.1 Modes of the SIMOTION devices

Various SIMOTION device modes are available for program testing.

How to select the mode of a SIMOTION device:

1. Highlight the SIMOTION device in the project navigator.
2. Select the "Test mode" context menu.
3. Select the required mode (see following table).
   - If you have selected "Debug mode":
     - Accept the safety information.
     - Parameterize the sign-of-life monitoring.
   - Observe the following section: Important information about the life-sign monitoring (Page 278).
4. Confirm with "OK".

The SIMOTION device switches to the selected mode.

When the SIMOTION device switches to "Debug mode":

- A connection to the target system will be established automatically (online mode) if SIMOTION SCOUT is currently in offline mode.
- The activated debug mode is indicated in the status bar.
- The breakpoints toolbar is displayed.
Table 6-1  Modes of a SIMOTION device

<table>
<thead>
<tr>
<th>Setting</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| Process mode | Program execution on the SIMOTION device is optimized for maximum system performance. The following diagnostic functions are available, although they may have only restricted functionality because of the optimization for maximum system performance:  
- Monitor variables in the symbol browser or a watch table.  
- Program status (only restricted):  
  - Restricted monitoring of variables (e.g. variables in loops, return values for system functions).  
  - As of version V4.0 of the SIMOTION kernel:  
    No more than one program source (e.g. ST source, MCC source, LAD/FBD source) can be monitored per task.  
  - As of version V3.2 of the SIMOTION kernel:  
    No more than one program source (e.g. ST source, MCC source, LAD/FBD source) can be monitored.  
- Trace tool (only restricted) with measuring functions for drives and function generator, see online help:  
  - No more than one trace on each SIMOTION device. |
| Test mode | The diagnostic functions of the process mode are available to the full extent:  
- Monitor variables in the symbol browser or a watch table.  
- Program status:  
  - Monitoring of all variables possible.  
  - As of version V4.0 of the SIMOTION kernel:  
    Several program sources (e.g. ST sources, MCC sources, LAD/FBD sources) can be monitored per task.  
  - As of version V3.2 of the SIMOTION kernel:  
    No more than one program source (e.g. ST source, MCC source, LAD/FBD source) can be monitored per task.  
- Trace tool with measuring functions for drives and function generator, see online help:  
  - No more than four traces on each SIMOTION device. |
| Note | Runtime and memory utilization increase as the use of diagnostic functions increases. |
| Debug mode | This mode is available in SIMOTION kernel as of V3.2.  
In addition to the diagnostic functions of the test mode, you can use the following functions:  
- Breakpoints  
  Within a program source file, you can set breakpoints (Page 295). When an activated breakpoint is reached, selected tasks will be stopped.  
- Controlling MotionTasks  
  In the "Task Manager" tab of the device diagnostics, you can use task control commands for MotionTasks, see the SIMOTION Basic Functions Function Manual.  
No more than one SIMOTION device of the project can be switched to debug mode.  
SIMOTION SCOUT is in online mode, i.e. connected with the target system.  
Observe the following section: Important information about the life-sign monitoring (Page 278). |
6.2.1.2 Important information about the life-sign monitoring.

<table>
<thead>
<tr>
<th>WARNING</th>
</tr>
</thead>
</table>

You must observe the appropriate safety regulations.

Use the debug mode or a control panel only with the life-sign monitoring function activated with a suitably short monitoring time! Otherwise, if problems occur in the communication link between the PC and the SIMOTION device, the axis may start moving in an uncontrollable manner.

The function is released exclusively for commissioning, diagnostic and service purposes.

The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect.

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.

Accept safety notes

After selecting the debug mode or a control panel, you must accept the safety notes. You can set the parameters for the life-sign monitoring.

Proceed as follows:

1. Click the Settings button.
   
   The "Debug settings" window opens.

2. Read there, as described in the following section, the safety notes and parameterize the life-sign monitoring.

Parameterizing the life-sign monitoring

In the Life-sign monitoring parameterization window, proceed as described below:

1. Read the warning!

2. Click the Safety notes button to open the window with the detailed safety notes.

3. Do not make any changes to the defaults for life-sign monitoring.
   
   Changes should only be made in special circumstances and in observance of all danger warnings.

4. Click Accept to confirm you have read the safety notes and have correctly parameterized the life-sign monitoring.
NOTICE

Pressing the spacebar or switching to a different Windows application causes:

- In debug mode for activated breakpoints:
  - The SIMOTION device switches to STOP mode.
  - The outputs are deactivated (ODIS).
- For controlling an axis or a drive using the control panel (control priority for the PC):
  - The axis or the drive is brought to a standstill.
  - The enables are reset.

WARNING

This function is not guaranteed in all operating modes. Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.
6.2 Program debugging

6.2.1.3 Life-sign monitoring parameters

Table 6-2 Life-sign monitoring parameter description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Life-sign monitoring   | The SIMOTION device and SIMOTION SCOUT regularly exchange life-sign signals to ensure a correctly functioning connection. If the exchange of the life-sign is interrupted longer than the set monitoring time, the following response occurs:  
  • In debug mode for activated breakpoints:  
    – The SIMOTION device switches to STOP mode.  
    – The outputs are deactivated (ODIS).  
  • For controlling an axis or a drive using the control panel (control priority for the PC):  
    – The axis is brought to a standstill.  
    – The enables are reset.  
  The following parameterizations are possible:  
  • **Active** check box:  
    If the check box is selected, life-sign monitoring is active.  
    The deactivation of the life-sign monitoring is not always possible.  
  • Monitoring time:  
    Enter the timeout.  
  **Prudence**  
  Do not make any changes to the defaults for life-sign monitoring, if possible.  
  Changes should only be made in special circumstances and in observance of all danger warnings. |
| Safety information     | **Please observe the warning!**  
  Click the button to obtain further safety information.  
  See: Important information about the life-sign monitoring (Page 278) |
6.2.2 Symbol Browser

6.2.2.1 Properties of the symbol browser

In the symbol browser, you can view and, if necessary, change the name, data type, and variable values. In particular, you can: see the following variables:

- Unit variables and static variables of a program or function block
- System variables of a SIMOTION device or a technology object
- I/O variables or global device variables.

For these variables, you can:

- View a snapshot of the variable values
- Monitor variable values as they change
- Change (modify) variable values

However, the symbol browser can only display/modify the variable values if the project has been loaded in the target system and a connection to the target system has been established.

6.2.2.2 Using the symbol browser

Requirements

- Make sure that a connection to the target system has been established and a project has been downloaded to the target system. To load the project with the sample program, see "Executing the sample program (Page 71)".
- You can run the user program, but you do not have to. If the program is not run, you only see the initial values of the variables.

The procedure depends on the memory area in which the variables to be monitored are stored.

Variables in the user memory of the unit or in the retentive memory

You can use the symbol browser to monitor the variables contained in the user memory of the unit or in the retentive memory, see Memory ranges of the variable types (Page 212):

- Retentive and non-retentive unit variables of the interface section of a program source file (unit)
- Retentive and non-retentive unit variables of the implementation section of a program source file (unit)
- Static variables of the function blocks whose instances are declared as unit variables.
- In addition, if the program source file (unit) has been compiled with the "Create program instance data only once" compiler option (Page 47):
  - Static variables of the programs.
  - Static variables of the function blocks whose instances are declared as static variables of programs.
Follow these steps:

1. Select the program source file in the project navigator (e.g. ST_1).
2. In the detail view, click the **Symbol browser** tab.

You see in the symbol browser all variables of the program source file contained in the user memory of the unit or in the retentive memory.

- All unit variables of the program source file.
- Only if the program source file has been compiled with the "Create program instance data only once" compiler option: The programs of the program source and their static variables (including instances of function blocks).

### Variables in the user memory of the task

You can use the symbol browser to monitor the variables contained in the user memory of the associated task, see Memory ranges of the variable types (Page 212):

If the program source (unit) was compiled **without** the compiler option (Page 47) "Create program instance data only once" (default), the user memory of the task to which the program was assigned contains the following variables:

- Static variables of the programs.
- Static variables of the function blocks whose instances are declared as static variables of programs.

Follow these steps:

1. In the project navigator of SIMOTION SCOUT, select the **EXECUTION SYSTEM** element in the subtree of the SIMOTION device.
2. In the detail view, click the **Symbol browser** tab.

The symbol browser shows all tasks used in the execution system together with the assigned programs. The associated variables contained in the user memory of the task are listed below.

**Note**

You can monitor temporary variables (together with unit variables and static variables) with **Program status** (see Properties of the program status (Page 289)).
System variables and global device variables

You can also monitor the following variables in the symbol browser:

- System variables of SIMOTION devices
- System variables of technology objects
- I/O variables
- Global device variables

Follow these steps:
1. Select the appropriate element in the SIMOTION SCOUT project navigator.
2. In the detail view, click the Symbol browser tab.

The corresponding variables are displayed in the symbol browser.

![Symbol browser screenshot]

Figure 6-1 Viewing variables in the symbol browser
Error Sources and Program Debugging

6.2 Program debugging

Status and controlling variables

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column.
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note when you change the values of several variables:</td>
</tr>
<tr>
<td>The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the symbol browser. There is therefore no guarantee of consistency.</td>
</tr>
</tbody>
</table>

Fix the display of the symbol browser

You can fix the display of the symbol browser for the active object:

- To do so, click the **Retain display** icon in the right upper corner of the symbol browser. The displayed symbol changes to ▪️.
  - The variables of this object are still displayed and updated in the symbol browser even if another object is selected in the project navigator.
- To remove the display, click the ▪️ icon again. The displayed symbol changes back to 🕳️.

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the symbol browser (independently of the SIMOTION device):

<table>
<thead>
<tr>
<th>Table 6-3 Display invalid floating-point numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LED</strong></td>
</tr>
<tr>
<td>1.#QNAN</td>
</tr>
<tr>
<td>-1.#QNAN</td>
</tr>
<tr>
<td>1.#INF</td>
</tr>
<tr>
<td>-1.#INF</td>
</tr>
<tr>
<td>-1.#IND</td>
</tr>
</tbody>
</table>
6.2.3 Monitoring variables in watch table

6.2.3.1 Variables in the watch table

With the symbol browser you see only the variables of an object within the project. With program status you see only the variables of an ST source file within a freely selectable monitoring area.

With watch tables, in contrast, you can monitor selected variables from different sources as a group (e.g. program sources, technology objects, SINAMICS drives - even on different devices).

You can see the data type of the variables in offline mode. You can view and modify the value of the variables in online mode.

6.2.3.2 Using watch tables

You can group variables from various program sources, technology objects, SIMOTION devices, etc. (even on different devices), in a watch table where you can monitor them together and, if necessary, change them.

Creating a watch table

Procedure for creating a watch table and assigning variables:

1. In the Project navigator, select the MONITOR folder.
2. Select Insert > Watch table to create a watch table, and enter the name of the watch table. A watch table with this name appears in the MONITOR folder.
3. In the project navigator, click the object from which you want to move variables to the watch table.
4. In the symbol browser, select the corresponding variable line by clicking its number in the left column.
5. From the context menu, select Add to watch table and the appropriate watch table, e.g. Watch table_1.
6. If you click the watch table, you will see in the detail view of the Watch table tab that the selected variable is now in the watch table.
7. Repeat steps 3 to 6 to monitor the variables of various objects.
Status and controlling variables

If you are connected to the target system, you can monitor the variable contents.

In the **Status value** column, the current variable values are displayed and periodically updated.

You can change the value of one or several variables. Proceed as follows for the variables to be changed:

1. Enter a value in the **Control value** column.
2. Activate the checkbox in this column.
3. Click the **Immediate control** button.

The values you entered are written to the selected variables.

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note when you change the values of several variables:</td>
</tr>
<tr>
<td>The values are written sequentially to the variables. It can take several milliseconds until the next value is written. The variables are changed from top to bottom in the watch table. There is therefore no guarantee of consistency.</td>
</tr>
</tbody>
</table>

Fix the display of the watch table

You can fix the display of the active watch table:

- To do so, click the **Retain display** icon in the right upper corner of the Watch table tab in the detail view. The displayed symbol changes to ![Retain display](image). This watch table is still displayed even if another one is selected in the project navigator.
- To remove the display, click the ![Retain display](image) icon again. The displayed symbol changes back to ![Retain display](image).

Display invalid floating-point numbers

Invalid floating-point numbers are displayed as follows in the watch table (independently of the SIMOTION device):

<table>
<thead>
<tr>
<th>LED</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.#QNAN</td>
<td>Invalid bit pattern in accordance with IEEE 754 (NaN Not a Number). There is no distinction between signaling NaN (NaNs) and quiet NaN (NaNq).</td>
</tr>
<tr>
<td>-1.#QNAN</td>
<td></td>
</tr>
<tr>
<td>1.#INF</td>
<td>Bit pattern for + infinity in accordance with IEEE 754</td>
</tr>
<tr>
<td>-1.#INF</td>
<td>Bit pattern for – infinity in accordance with IEEE 754</td>
</tr>
<tr>
<td>-1.#IND</td>
<td>Bit pattern for indeterminate</td>
</tr>
</tbody>
</table>
6.2.4 Program run

6.2.4.1 Program run: Display code location and call path

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path.

Follow these steps:

1. Click the "Show program run" button on the Program run toolbar.
   The "Program run call stack (Page 288)" window opens.
2. Select the desired MotionTask.
3. Click the "Update" button.

The window shows:

- The position in the code being executed (e.g. line of the ST source file) stating the program source and the POU.
- Recursively positions in the code of other POUs that call the code position being executed.

The following names are displayed for the SIMOTION RT program source files:

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>taskbind.hid</td>
<td>Execution system</td>
</tr>
<tr>
<td>stdfunc.pck</td>
<td>IEC library</td>
</tr>
<tr>
<td>device.pck</td>
<td>Device-specific library</td>
</tr>
<tr>
<td>tp-name.pck</td>
<td>Library of the tp-name technology package, e.g. cam.pck for the library of the CAM technology package</td>
</tr>
</tbody>
</table>
6.2.4.2 Parameter call stack program run

You can display the following for all configured tasks:

- the current code position in the program code (e.g. line of an ST source file)
- the call path of this code position

Table 6-6 Parameter description call stack program run

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected CPU</td>
<td>The selected SIMOTION device is displayed.</td>
</tr>
<tr>
<td>Refresh</td>
<td>Clicking the button reads the current code positions from the SIMOTION device and shows them in the open window.</td>
</tr>
<tr>
<td>Calling task</td>
<td>Select the task for which you want to determine the code position being executed.</td>
</tr>
<tr>
<td></td>
<td>All configured tasks of the execution system.</td>
</tr>
<tr>
<td>Current code position</td>
<td>The position being executed in the program code (e.g. line of an ST source file) is displayed (with the name of the program source file, line number, name of the POU).</td>
</tr>
<tr>
<td>is called by</td>
<td>The code positions that call the code position being executed within the selected task are shown recursively (with the name of the program source file, line number, name of the POU, and name of the function block instance, if applicable).</td>
</tr>
</tbody>
</table>

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 287)".

6.2.4.3 Program run toolbar

You can display the position in the code (e.g. line of an ST source file) that a MotionTask is currently executing along with its call path with this toolbar.

Table 6-7 Program run toolbar

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display program run</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Click this button to open the Program run call stack window. In this window, you can display the currently active code position with its call path.</td>
</tr>
<tr>
<td></td>
<td>See: Program run: Display code position and call path (Page 287)</td>
</tr>
</tbody>
</table>
6.2.5 Program status

6.2.5.1 Properties of the program status

Status program enables monitoring the variable values accurately to the cycle during program execution.

You can select a monitoring area in the ST source file and monitor, in addition to global and static local variables, also temporary local variables (e.g. within a function) there.

The values of the following variables are displayed:

- Simple data type variables (INT, REAL, etc.)
- Individual elements of a structure, provided an assignment is made
- Individual elements of an array, provided an assignment is made
- Enumeration data type variables

While the selected monitoring range is running in the ST source file, the corresponding buffer for the variables to be monitored is filled with the corresponding values on the SIMOTION device. Once the selected monitoring range has been run, the buffer is formatted for display in the SIMOTION SCOUT. SIMOTION SCOUT calls the formatted values at regular intervals and displays them.

As of SIMOTION Kernel V3.2, you can select a location in an ST source file at which a function or instance of a function block is called (call path). This enables you to observe the variable values specifically for this call.

---

Note

Due to the restricted buffer capacity and the requirement for minimum runtime tampering, the following variables cannot be displayed:

- Complete arrays
- Complete structures

Individual array elements or individual structure elements are displayed, however, provided an assignment is made in the ST source file.
### Table 6-8  Differences between process mode and test mode in Program Status

<table>
<thead>
<tr>
<th></th>
<th>Process mode</th>
<th>Test mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optimization of program execution</td>
<td>For maximum system performance, only restricted diagnosis is possible</td>
<td>For full diagnosis options</td>
</tr>
</tbody>
</table>
| Maximum number of monitored program sources (e.g. ST source files, MCC source files, LAD/FBD sources) | • As of version V4.0 of the SIMOTION kernel: Maximum 1 program source per task  
• Up to version V3.2 of the SIMOTION kernel: Maximum 1 program source | • As of version V4.0 of the SIMOTION kernel: Multiple program sources per task  
• Up to version V3.2 of the SIMOTION kernel: Maximum 1 program source per task |
| Loops (e.g. WHILE, REPEAT, FOR) | On repeat loops, the recording is interrupted.  
If the whole loop is selected, the values are displayed on the first run of the loop. | If there are repeats, the recording continues correctly.  
If the whole loop is selected, the values are displayed on the last run of the loop. |
| System functions that contain internal loops (e.g. functions for processing strings) | Values are not displayed in some cases | Values are displayed correctly. |

**NOTICE**

Program status requires additional CPU resources.  
Please note if you want to monitor several programs at the same time with the status program:
• Test mode must be activated (see Operating modes of the SIMOTION devices (Page 276))  
• Up to version V4.0 of the SIMOTION Kernel, the programs must be assigned to various tasks.
6.2.5.2 Using the status program

Before you can work with the Status program, you must instruct the system to run in a special mode:

1. Make sure that the ST source file generates the additional debug code during compilation:
   - Select the ST source file in the project navigator and select the Edit > Object properties menu command.
   - Select the Compiler tab to change the local settings of the compiler (Page 49).
   - Make sure that the Enable Status program checkbox is activated and confirm with OK.
     You can also change this compiler option at global settings of the compiler (Page 47).

2. Open the ST source file and recompile it with ST source file > Accept and compile.

3. Download and start the program in the usual way.

4. Click the button for program status in the ST editor toolbar (Page 45) to start this test mode.

The ST editor window is now divided vertically: You can see the ST source file in the left pane; the right pane displays the selected variables and their values.
Follow the procedure below to test with program status:

1. In the editor, select the section of the ST source file you want to test.

2. As of version V3.2 of the SIMOTION Kernel:
   - If you have selected a section of a POU that is called by several positions in a program source file or several tasks:
     Enter the call path for program status (Page 292).

For the selected section, you can see variables and their values in the right pane of your screen; they are updated cyclically:

- Values that have changed in the current pass are displayed in red.
- Values that have not changed are displayed in black.
- Variables without values, e.g. variables in an unused IF branch are shown in green and marked with a question mark.

If the display of the variable values changes too fast:

- Click the button for Stop monitoring of program variables in the ST editor toolbar (Page 45) to stop the display.
- Click the button for Continue monitoring of program variables in the ST editor toolbar (Page 45) to continue the display.

You can force the update of the displayed values:

- Click the button for Update on the ST editor toolbar (Page 45).

   The buffer of the SIMOTION device is read, even if the selected monitoring range has not yet been completely processed and the values are incomplete. This can be useful, for example, if the program is waiting for a WAITFORCONDITION statement.

   The monitoring of the program variables must have been activated.

6.2.5.3 Call path for program status

With SIMOTION kernel V3.2 and higher, you can specify the call path when monitoring variable values of functions and function blocks. This enables you to observe the variable values specifically for this call.

For this purpose, the Call path window automatically opens in the following cases:

- You have selected a section of a function:
  The function is called at various points in the program source files (e.g. ST source files) of the SIMOTION device.

- You have selected a section of a function block:
  There are several instances of the function block or the instance is called at various points in the program source files (e.g. ST source files) of the SIMOTION device.

- You have selected a section of a program:
  The program is assigned to more than one task.
How to select the call path:

In the Call path status program window, the marked section of the POU (code position) is displayed (with the name of the ST source file, line number, name of the POU).

1. If the code position is called in several tasks:
   – Select the task.

2. Select the code position to be called (in the calling POU).

You can select from the following:

   – The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).

   If the selected calling code position is in turn called by several code positions, further lines are displayed in which you proceed similarly.

   – All:

     All displayed code positions are selected. Moreover, all code positions (up to the top level of the hierarchy) are selected from which the displayed code positions are called.

Program Status for devices with SIMOTION kernel versions up to V3.1

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note the following if you use the &quot;Program status&quot; diagnostic function in devices with SIMOTION Kernels up to V3.1:</td>
</tr>
<tr>
<td>• If the project has been compiled with a SIMOTION SCOUT version up to V3.1, the &quot;Call path/Task selection&quot; window will not always be displayed. This means that &quot;Program status&quot; cannot be used to its full extent.</td>
</tr>
<tr>
<td>• In such cases, you can only specify the call path if you recompile the project with the current version of SIMOTION SCOUT and download it.</td>
</tr>
</tbody>
</table>

When performing a recompilation with the current version of the compiler, note the following:

• Among other effects, this generates new version codes in the data storage areas of the programs.

• When the project is downloaded, all retentive and non-retentive data on the SIMOTION device is deleted and initialized.

• In some cases, minor changes to the program sources may be required.

• Once the project has been saved in an old project format, it must be recompiled with the relevant version of the compiler.
### 6.2.5.4 Parameter call path status program

Table 6-9 Program status call path parameter description

<table>

<td>The selected section of the POU (code position) is shown (with the name of the ST source file, line number, name of the POU)</td>
</tr>
</tbody>
</table>
| is called by        | Select the calling code position. The following are available:  
                        • The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).  
                          If the selected calling code position is in turn called by several code positions, further lines are displayed in which you proceed similarly.  
                        • All:  
                          All displayed code positions are selected. Moreover, all code positions (up to the top level of the hierarchy) are selected from which the displayed code positions are called. |
6.2.6 Breakpoints

6.2.6.1 General procedure for setting breakpoints

You can set breakpoints within a POU of a program source (e.g. ST source, MCC chart, LAD/FBD source). On reaching an activated breakpoint, the task in which the POU with the breakpoint is called is stopped. If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser.

Requirement:

- The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.

Proceed as follows

Follow these steps:

1. Select "Debug mode" for the associated SIMOTION device, see Set debug mode (Page 295).
2. Specify the debug task group, see Specifying the debug task group (Page 297).
3. Set breakpoints, see Setting breakpoints (Page 301).
4. Define the call path, see Defining a call path for a single breakpoint (Page 304).
5. Activate the breakpoints, see Activating breakpoints (Page 310).

6.2.6.2 Setting the debug mode

⚠️ WARNING

You must observe the appropriate safety regulations.

Use the debug mode only with activated life-sign monitoring (Page 278) with a suitably short monitoring time! Otherwise, if problems occur in the communication link between the PC and the SIMOTION device, the axis may start moving in an uncontrollable manner.

The function is released exclusively for commissioning, diagnostic and service purposes. The function should generally only be used by authorized technicians. The safety shutdowns of the higher-level control have no effect!

Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.
To set the debug mode, proceed as follows:

1. Highlight the SIMOTION device in the project navigator.
2. Select **Test mode** from the context menu.
3. Select **Debug mode** (Page 276).
4. Accept the safety information
5. Parameterize the sign-of-life monitoring.
   See also section: Important information about the life-sign monitoring (Page 278).
6. Confirm with **OK**.

   If no connection has been established with the target system (offline mode), the online mode will be established automatically.
   The activated debug mode is indicated in the status bar.
   The breakpoints toolbar (Page 303) is displayed.

---

**Note**

You cannot change the program sources in debug mode!

<table>
<thead>
<tr>
<th>NOTICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pressing the spacebar or switching to a different Windows application causes in debug mode for activated breakpoints:</td>
</tr>
<tr>
<td>- The SIMOTION device switches to STOP mode.</td>
</tr>
<tr>
<td>- The outputs are deactivated (ODIS).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>WARNING</th>
</tr>
</thead>
<tbody>
<tr>
<td>This function is not guaranteed in all operating modes. Therefore, there must be an EMERGENCY STOP circuit in the hardware. The appropriate measures must be taken by the user.</td>
</tr>
</tbody>
</table>
6.2.6.3 Define the debug task group

On reaching an activated breakpoint, all tasks that are assigned to the debug task group are stopped.

Requirement

- The relevant SIMOTION device is in debug mode.

Proceed as follows

How to assign a task to the debug task group:

1. Highlight the relevant SIMOTION device in the project navigator.
2. Select Debug task group from the context menu.
   The Debug Task group window opens.
3. Select the tasks to be stopped on reaching the breakpoint:
   - If you only want to stop individual tasks (in RUN mode): Activate the Debug task group selection option.
     Assign all tasks to be stopped on reaching a breakpoint to the Tasks to be stopped list.
   - If you only want to stop individual tasks (in HALT mode): Activate the All tasks selection option.
     In this case, also select whether the outputs and technology objects are to be released again after resumption of program execution.

NOTICE

Note the different behavior when an activated breakpoint is reached, see the following table.
Table 6-10 Behavior at the breakpoint depending on the tasks to be stopped in the debug task group.

<table>
<thead>
<tr>
<th>Properties</th>
<th>Tasks to be stopped</th>
</tr>
</thead>
<tbody>
<tr>

<td>Active</td>
</tr>
<tr>
<td>Technology</td>
<td>Closed-loop control active</td>
</tr>
</tbody>
</table>

**Note**

You can only make changes to the debug task group if no breakpoints are active.

**Proceed as follows:**

1. Set breakpoints (see Setting breakpoints (Page 301)).
2. Define the call path (see Defining a call path for a single breakpoint (Page 304)).
3. Activate the breakpoints (see Activating breakpoints (Page 310)).
6.2.6.4 Debug task group parameters

Use this window to define the debug task group. On reaching an activated breakpoint, all tasks that are assigned to the debug task group are stopped.

This requires that the relevant SIMOTION device is in debug mode, see Modes of the SIMOTION devices (Page 276).

Table 6-11 Debug settings parameter description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug task group</td>
<td>Select this selection option if you only want to stop individual tasks. The SIMOTION device remains in RUN mode after an activated breakpoint is reached. Outputs and technology objects remain activated. Assign all tasks to be stopped on reaching a breakpoint to the Tasks to be stopped list.</td>
</tr>
<tr>
<td>All tasks</td>
<td>Select this selection option if you only want to stop all user tasks. The SIMOTION device remains in STOP mode after an activated breakpoint is reached, all outputs and technology objects will be deactivated (ODIS activated). In this case, also select whether the outputs and technology objects are to be released again after resumption of program execution.</td>
</tr>
<tr>
<td>'Resume' activates the outputs (ODIS deactivated).</td>
<td>Only if All tasks is selected. Activate the checkbox, to release again the outputs and technology objects after program execution has been resumed. All outputs and technology objects can only be released after a download of the project with deactivated checkbox.</td>
</tr>
</tbody>
</table>

NOTICE

Note the different behavior at the activated breakpoint depending on the tasks to be stopped, see table in Define the debug task group (Page 297).

You can only make changes to the debug task group if no breakpoints are active.
6.2.6.5 Debug table parameter

The debug table shows all debug points (e.g. breakpoints, trace points) in the program sources of a SIMOTION device.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Debug points (table)</strong></td>

</table>
6.2.6.6 Setting breakpoints

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. The relevant SIMOTION device is in debug mode, see Setting debug mode (Page 295).
3. The debug task group is defined, see Defining the debug task group (Page 297).

Proceed as follows

How to set a breakpoint:

1. Select the code location where no breakpoint has been set:
   - SIMOTION ST: Place the cursor on a line in the ST source file that contains a statement.
   - SIMOTION MCC: Select an MCC command in the MCC chart (except module or comment block).
   - SIMOTION LAD/FBD: Set the cursor in a network of the LAD/FBD program.

2. Alternative:
   - Select the Debug > Set/remove breakpoint menu command (shortcut F9).
   - Click the button in the Breakpoints toolbar.

To remove a breakpoint, proceed as follows:

1. Select the code position with the breakpoint.

2. Alternative:
   - Select the Debug > Set/remove breakpoint menu command (shortcut F9).
   - Click the button in the Breakpoints toolbar.

To remove all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Alternative:
  - Select the Debug > Remove all breakpoints menu command (shortcut CTRL+F5).
  - Click the button in the Breakpoints toolbar.
6.2 Program debugging

Note
You cannot set breakpoints:
- For SIMOTION ST: In lines that contain only comment.
- For SIMOTION MCC: On the module or comment block commands.
- For SIMOTION LAD/FBD: Within a network.
- At code locations in which other debug points (e.g. trigger points) have been set.

You can list the debug points in all program sources of the SIMOTION device in the debug table:
- Click the button for "debug table" in the Breakpoints toolbar.

In the debug table, you can also remove all breakpoints (in all program sources) of the SIMOTION device:
- Click the button for "Clear all breakpoints".

Set breakpoints remain saved also after leaving the "debug mode", they are displayed only in debug mode.

You can use the program status (Page 291) diagnosis functions and breakpoints together in a program source file or POU. However, the following restrictions apply depending on the program languages:
- SIMOTION ST: For Version V3.2 of the SIMOTION Kernel, the (marked) ST source file lines to be tested with program status must not contain a breakpoint.
- SIMOTION MCC and LAD/FBD: The commands of the MCC chart (or networks of the LAD/FBD program) to be tested with program status must not contain a breakpoint.

Proceed as follows
1. Define the call path, see Defining a call path for a single breakpoint (Page 304).
2. Activate the breakpoints, see Activating breakpoints (Page 310).
6.2.6.7 Breakpoints toolbar

This toolbar contains important operator actions for setting and activating breakpoints:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| ![set_remove] | Set/remove breakpoint  
Click this icon to set at breakpoint for the selected code position or to remove an existing breakpoint.  
See: Setting breakpoints (Page 301). |
| ![activate_deactivate] | Activate/deactivate breakpoint  
Click this icon to activate or deactivate the breakpoint at the selected code position.  
See: Activating breakpoints (Page 310). |
| ![edit_call_path] | Edit the call path  
Click this icon to define the call path for the breakpoints:  
- If a code position with breakpoint is selected: The call path for this breakpoint.  
- If a code position without breakpoint is selected: The call path for all breakpoints of the POU.  
See: Defining the call path for a single breakpoint (Page 304), Defining the call path for all breakpoints (Page 307). |
| ![activate_all] | Activate all breakpoints  
Click this icon to activate all breakpoints in the current program source or POU (e.g. ST source file, MCC chart, LAD/FBD program).  
See: Activating breakpoints (Page 310). |
| ![deactivate_all] | Deactivate all breakpoints  
Click this icon to deactivate all breakpoints in the current program source or POU (e.g. ST source file, MCC chart, LAD/FBD program).  
See: Activating breakpoints (Page 310). |
| ![remove_all] | Remove all breakpoints  
Click this icon to remove all breakpoints in the current program source or POU (e.g. ST source file, MCC chart, LAD/FBD program).  
See: Setting breakpoints (Page 301). |
| ![debug_table] | Debug table  
Click this icon to display the debug table.  
See: Debug table parameters (Page 300). |
| ![display_call_stack] | Display call stack  
Click this icon after reaching an activated breakpoint to:  
- View the call path at the current breakpoint.  
- View the code positions at which the other tasks of the debug task group have been stopped together with their call path.  
See: Displaying the call stack (Page 312). |
| ![resume] | Resume  
Click this icon to continue the program execution after reaching an activated breakpoint.  
See: Activating breakpoints (Page 310), Displaying the call stack (Page 312). |
6.2.6.8 Defining the call path for a single breakpoint

Requirements:

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. The relevant SIMOTION device is in debug mode, see Setting debug mode (Page 295).
3. The debug task group is defined, see Defining the debug task group (Page 297).
4. Breakpoint is set, see Setting breakpoints (Page 301).

Proceed as follows

To define the call path for a single breakpoint, proceed as follows:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Click the button for "edit call path" in the Breakpoints toolbar.
   In the Call path / task selection breakpoint window, the marked code position is displayed (with the name of the program source file, line number, name of the POU).
3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when the selected breakpoint is reached.
   The following are available:
   - All calling locations starting at this call level
     The user program will always be started when the activated breakpoint in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when the breakpoint in the selected task is reached. The task must be in the debug task group.
   The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).

The following are available:

- **All calling locations starting at this call level**
  
  *No* call path is specified. The user program is always stopped at the activated breakpoint if the POU in the selected tasks is called.

- **Only when a single task is selected:** The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
  
  The call path is specified. The user program will be stopped at the activated breakpoint only when the POU is called from the selected code position.
  
  If the POU of the selected calling code position is also called from other code positions, further lines are displayed successively in which you proceed similarly.

5. If the breakpoint is only to be activated after the code position has been reached several times, select the number of times.

---

**Note**

You can also define the call path to the individual breakpoints in the debug table:

1. Click the button for "debug table" in the Breakpoints toolbar.

2. Click the appropriate button in the "Call path" column.

3. Proceed in the same way as described above:

   - Specify the task.
   - Define the call path (only for functions and function blocks).
   - Specify the number of passes after which the breakpoint is to be activated.

---

**Proceed as follows:**

- Activate the breakpoints, see Activating breakpoints (Page 310).

---

**Note**

You can use the "Display call stack (Page 312)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

---

**See also**

Defining the call path for all breakpoints (Page 307)

| Calling task                  | Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when the selected breakpoint is reached. The following are available:  
  - **All calling locations starting at this call level**  
    The user program will always be started when the activated breakpoint in any task of the debug task group is reached.  
  - **The individual tasks from which the POU with the selected breakpoint can be reached.**  
    The user program will be stopped only when the breakpoint in the selected task is reached. The task must be in the debug task group. The specification of a call path is possible. |
| Current code position         | The code position is shown with the set breakpoint (with the name of the program source file, line number, name of the POU). |
| is called by                  | Only for functions and function blocks:  
  Select the call path, i.e. the code position to be called (in the calling POU).  
  The following are available:  
  - **All calling locations starting at this call level**  
    No call path is specified. The user program will always be stopped at the activated breakpoint when the POU in the tasks is reached.  
    - **Only when a single task is selected:** The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).  
      The call path is specified. The user program will be stopped at the activated breakpoint only when the POU is called from the selected code position.  
    - **If the POU of the selected calling code position is also called from other code positions,** further lines are displayed successively in which you proceed similarly. |
| The breakpoint will be        | If you do not want the breakpoint to be activated until the code position has been reached a certain number of times, set this number. |
| activated at each nth pass.   |             |

**NOTICE**

You can only make changes to the debug task group if no breakpoints are active.
6.2.6.10 Defining the call path for all breakpoints

With this procedure, you can:

- Select a default setting for all future breakpoints in a POU (e.g. MCC chart, LAD/FBD program or POU in an ST source file).
- Accept and compare the call path for all previously set breakpoints in this POU.

Requirements

- The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
- The relevant SIMOTION device is in debug mode, see Setting debug mode (Page 295).
- The debug task group is defined, see Defining the debug task group (Page 297).

Proceed as follows

To define the call path for all future breakpoints of a POU, proceed as follows:

1. Select the code location where no breakpoint has been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.

2. Click the button for "edit call path" in the Breakpoints toolbar.
   In the "Call path / task selection all breakpoints for each POU" window, the marked code position is displayed (with the name of the program source file, line number, name of the POU).

3. Select the task in which the user program (i.e. all tasks in the debug task group) will be stopped when a breakpoint in this POU is reached.
   The following are available:

   - **All calling locations starting at this call level**
     The user program will always be started when an activated breakpoint of the POU in any task of the debug task group is reached.
   - The individual tasks from which the selected breakpoint can be reached.
     The user program will be stopped only when a breakpoint in the selected task is reached. The task must be in the debug task group.

   The specification of a call path is possible.
4. Only for functions and function blocks: Select the call path, i.e. the code position to be called (in the calling POU).

The following are available:

- **All calling locations starting at this call level**
  No call path is specified. The user program is always stopped at an activated breakpoint when the POU in the selected tasks is called.

- Only when a single task is selected: The code positions to be called within the selected task (with the name of the program source, line number, name of the POU).
  The call path is specified. The user program will be stopped at an activated breakpoint only when the POU is called from the selected code position.
  If the selected calling code position is in turn called by other code positions, further lines are displayed successively in which you proceed similarly.

5. If a breakpoint is only to be activated after the code position has been reached several times, select the number of times.

6. If you want to accept and compare this call path for all previously set breakpoints in this POU:
   - Click **Accept**.

**Proceed as follows:**

- Activate the breakpoints, see Activating breakpoints (Page 310).

**Note**
You can use the "Display call stack (Page 312)" function to view the call path at a current breakpoint and the code positions at which the other tasks of the debug task group were stopped.

**See also**
Defining the call path for a single breakpoint (Page 304)
6.2.6.11 Call path / task selection parameters of all breakpoints per POU

Here you can define a presetting for the call path of all future breakpoints to be set in a POU. Moreover, you can also accept this setting for all previously set breakpoints of this POU.

Table 6- 15 Call path / task selection parameter description of all breakpoints per POU

6.2.6.12 Activating breakpoints

Breakpoints must be activated if they are to have an effect on program execution.

Requirements

1. The program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) is open.
2. The relevant SIMOTION device is in debug mode, see Setting debug mode (Page 295).
3. The debug task group is defined, see Defining the debug task group (Page 297).
4. Breakpoints are set, see Setting breakpoints (Page 301).
5. Call paths are defined, see Defining a call path for a single breakpoint (Page 304).

Activating breakpoints

How to activate a single breakpoint:

1. Select the code location where a breakpoint has already been set:
   - SIMOTION ST: Set the cursor in an appropriate line of the ST source.
   - SIMOTION MCC: Select an appropriate command in the MCC chart.
   - SIMOTION LAD/FBD: Set the cursor in an appropriate network of the LAD/FBD program.
2. Alternative:
   - Select the Debug > Activate/deactivate breakpoint menu command (shortcut F12).
   - Click the button in the Breakpoints toolbar.

To activate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:

- Alternative:
  - Select the Debug > Activate all breakpoints menu command.
  - Click the button in the Breakpoints toolbar.

Note

Breakpoints of all program sources of the SIMOTION device can also be activated and deactivated in the debug table:

1. Click the button for "debug table" in the Breakpoints toolbar.
   The "Debug table" window opens.
2. Perform the action below, depending on which breakpoints you want to activate or deactivate:
   - Single breakpoints: Check or clear the corresponding checkboxes.
   - All breakpoints (in all program sources): Click the corresponding button.
Behavior at the activated breakpoint

On reaching an activated breakpoint (possibly using the selected call path (Page 304)), all tasks assigned to the debug task group will be stopped. The behavior depends on the tasks in the debug task group and is described in "Defining a debug task group (Page 297)". The breakpoint is highlighted.

If the breakpoint that initiated the stopping of the tasks is located in a program or function block, the values of the static variables for this POU are displayed in the "Variables status" tab of the detail display. Temporary variables (also in/out parameters for function blocks) are not displayed. You can monitor static variables of other POUs or unit variables in the symbol browser (Page 281).

You can use the "Display call stack (Page 312)" function to:
- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Resuming program execution

How to resume program execution:
- Alternative:
  - Select the Debug > Continue menu command (shortcut CTRL+F8).
  - Click the button on the Breakpoint toolbar to "Continue".

Deactivate breakpoints

To deactivate a single breakpoint, proceed as follows:
1. Select the code position with the activated breakpoint.
2. Alternative:
   - Select the Debug > Activate/deactivate breakpoint menu command (shortcut F12).
   - Click the button in the Breakpoints toolbar.

To deactivate all breakpoints (in all program sources) of the SIMOTION device, proceed as follows:
- Alternative:
  - Select the Debug > Deactivate all breakpoints menu command.
  - Click the button in the Breakpoints toolbar.
6.2.6.13 Display call stack

You can use the "Display call stack" function to:

- View the call path at the current breakpoint.
- View the code positions with the call path at which the other tasks of the debug task group have been stopped.

Requirement

The user program is stopped at an activated breakpoint, i.e. the tasks of the debug task group (Page 297) have been stopped.

Proceed as follows

To call the "Display call stack" function, proceed as follows:

- Click the button for "display call stack" in the Breakpoints toolbar.

  The "Breakpoint call stack" dialog opens. The current call path (including the calling task and the number of the set passes) is displayed.

  The call path cannot be changed.

To use the "Display call stack" function, proceed as follows:

1. Keep the "Breakpoint call stack" dialog open.
2. To display the code position at which the other task was stopped, proceed as follows:
   - Select the appropriate task. All tasks of the debug task group can be selected.

   The code position, including the call path, is displayed. If the code position is contained in a user program, the program source with the POU (e.g. ST source file, MCC chart, LAD/FBD program) will be opened and the code position marked.

3. How to resume program execution:
   - Click the button for "resume" (Ctrl+F8 shortcut) in the Breakpoint toolbar.

   When the next activated breakpoint is reached, the tasks of the debug task group will be stopped again. The current call path, including the calling task, is displayed.

4. Click "OK" to close the "Breakpoint call stack" dialog.

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 287)".

### 6.2.6.14 Breakpoints call stack parameter

When an activated breakpoint (Page 310) is reached, you can display the following for each task in the debug task group (Page 297):

- The position in the program code (e.g. line of an ST source file) at which the task stopped.
- The call path of this code position.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected CPU</td>
<td>The selected SIMOTION device is displayed.</td>
</tr>
<tr>
<td>Calling task</td>
<td>Select the task for which you want to display the code position at which the task was stopped. All tasks of the debug task group can be selected.</td>
</tr>
<tr>
<td>Current code position</td>
<td>The position in the program code (e.g. line of an ST source file) at which the selected task was stopped is displayed (with the name of the program source file, line number, name of the POU).</td>
</tr>
<tr>
<td>is called by</td>
<td>The code positions that call the current code position within the selected task are shown recursively (with the name of the program source file, line number, name of the POU, and name of the function block instance, if applicable).</td>
</tr>
</tbody>
</table>

For names of the SIMOTION RT program sources, refer to the table in "Program run (Page 287)".

### 6.2.7 Trace

Using the **trace tool**, you can record and store the course of variable values over time (e.g. unit variables, local variables, system variables, I/O variables). This allows you to document the optimization, for example, of axes.

You can set the recording time, display up to four channels, select trigger conditions, parameterize timing adjustments, select between different curve displays and scalings, etc.

Aside from isochronous recording, you can also select **Recording at code position**. This lets you record the values of variables whenever the program runs through a specific point in the ST source file.

The trace tool is described in detail in the online help.
Appendix

A.1  Formal Language Description

In this chapter, you will find overviews of the basic elements of ST and a complete compilation of all syntax diagrams with the language elements. This appendix summarizes the basic features of the ST language.
A.1.1 Language description resources

Syntax diagrams are used as a basis for the language description in the individual sections. They provide you with an invaluable insight into the syntactic (i.e. grammatical) structure of ST.

Instructions for using syntax diagrams were presented in Language description resources. Information about the difference between formatted and unformatted rules, of interest to the advanced user, is presented below.

A.1.1.1 Formatted rules (lexical rules)

The lexical rules describe the structure of the elements processed by the compiler during lexical analysis. This means that the notation is formatted and the rules must be followed. In particular, that means:

- Insertion of formatting characters is not allowed.
- Block and line comments cannot be inserted.
- Attributes for identifiers cannot be inserted.

The following figure shows a lexical rule for legal identifiers.

![Figure A-1 Example of a lexical rule](image)

Valid examples according to this rule include:

```
R_CONTROLLER3
_A_ARRAY
_100_3_3_10
```
A.1.1.2 Unformatted rules (syntactic rules)

The syntactic rules build on the lexical rules and describe the structure of ST. You can write your ST program unformatted within the framework of these rules.

The unformatted property means:

- Formatting characters can be inserted anywhere.
- Block and line comments can be inserted.

The following example shows the syntactic rule for assigning a value in a statement.

```
VARIABLE_1 := 100; SWITCH := FALSE;
//'This is a comment
VARIABLE_2:=3.2 +VARIABLE_1;
```

![Figure A-2 Example of a syntactic rule](image)
A.1.2 Basic elements (terminals)

A terminal is a basic element that is declared verbally and not by a further rule. It is represented in the syntax diagrams by an oval or circle.

A.1.2.1 Letters, digits and other characters

Letters and digits are the most commonly used characters. The identifier, for example, consists of a combination of letters, digits, and the underscore. The underscore is one of the special characters.

<table>
<thead>
<tr>
<th>Characters</th>
<th>Subgroup</th>
<th>Character set elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Letter</td>
<td>Upper case</td>
<td>A .. Z</td>
</tr>
<tr>
<td></td>
<td>Lower case</td>
<td>a .. z</td>
</tr>
<tr>
<td>Digit</td>
<td>Decimal digit</td>
<td>0 .. 9</td>
</tr>
<tr>
<td>Octal digit</td>
<td>Octal digit</td>
<td>0 .. 7</td>
</tr>
<tr>
<td>Hexadecimal digit</td>
<td>Hexadecimal digit</td>
<td>0 .. 9, A .. F, a .. f</td>
</tr>
<tr>
<td>Bit</td>
<td>Binary digit</td>
<td>0, 1</td>
</tr>
</tbody>
</table>

You can use the complete extended ASCII character set in comments. You can use all printable ASCII code characters starting from decimal equivalent 32 (blank).

For language commands, identifiers, constants, expressions and operators, you can use special characters, i.e. characters other than letters and digits, only according to certain rules.
### A.1.2.2 Formatting characters and separators in the rules

Formatting characters and separators are used differently in formatted (lexical) and unformatted (syntactic) rules. Language description resources (Page 316) describes the differences between syntactic and lexical rules.

In the tables below, you will find the formatting characters and separators of the lexical and syntactic rules. You are also provided with a description and a list of all rules in which the formatting characters and separators are used as terminals (see Rules (Page 332)).

#### Table A-2 Formatting characters and separators in lexical rules

A.1.2.4 Predefined identifiers for process image access

Below is a list of all predefined variables in ST that you can use to access CPU memory areas (absolute identifiers). Note that you can read and write outputs but you can only read inputs.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
<th>Lexical rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>%In.x</td>
<td>CPU input range with byte and bit address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%IXn.x</td>
<td></td>
<td></td>
</tr>
<tr>
<td>%IBn</td>
<td>CPU input range with byte address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%IWn</td>
<td>CPU input range with word address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%IDn</td>
<td>CPU input range with double word address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%Qn.x</td>
<td>CPU output range with byte and bit address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%QXn.x</td>
<td></td>
<td></td>
</tr>
<tr>
<td>%QBn</td>
<td>CPU output range with byte address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%QWn</td>
<td>CPU output range with word address</td>
<td>Absolute PI access</td>
</tr>
<tr>
<td>%QDn</td>
<td>CPU output range with double word address</td>
<td>Absolute PI access</td>
</tr>
</tbody>
</table>
## Identifiers of the Taskstartinfo

The following identifiers are defined for the Taskstartinfo:

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TSI#alarmNumber</td>
<td>DINT</td>
<td>Scan for alarm number</td>
</tr>
<tr>
<td>TSI#commandId.high</td>
<td>UDINT</td>
<td>Scan for commandId (most significant word)</td>
</tr>
<tr>
<td>TSI#commandId.low</td>
<td>UDINT</td>
<td>Scan for commandId (least significant word)</td>
</tr>
<tr>
<td>TSI#currentTaskId</td>
<td>StructTaskId</td>
<td>Scan for TaskId of current task</td>
</tr>
<tr>
<td>TSI#cycleTime</td>
<td>TIME</td>
<td>Scan for configured cycle time of current task</td>
</tr>
<tr>
<td>TSI#details</td>
<td>DWORD</td>
<td>Scan for detailed information</td>
</tr>
<tr>
<td>TSI#executionFaultType</td>
<td>UDINT</td>
<td>Scan for type of execution error</td>
</tr>
<tr>
<td>TSI#interruptId</td>
<td>UDINT</td>
<td>Scan for triggering event</td>
</tr>
<tr>
<td>TSI#logBaseAdrIn</td>
<td>DINT</td>
<td>Scan for logical base address</td>
</tr>
<tr>
<td>TSI#logBaseAdrOut</td>
<td>DINT</td>
<td>Scan for logical base address</td>
</tr>
<tr>
<td>TSI#logDiagAddr</td>
<td>DINT</td>
<td>Scan for logical diagnostic address</td>
</tr>
<tr>
<td>TSI#shutDownInitiator</td>
<td>UDINT</td>
<td>Scan for cause of transition to STOP</td>
</tr>
<tr>
<td>TSI#startTime</td>
<td>DT</td>
<td>Scan for start time</td>
</tr>
<tr>
<td>TSI#taskId</td>
<td>StructTaskId</td>
<td>Scan for TaskId of triggering task</td>
</tr>
<tr>
<td>TSI#toInst</td>
<td>ANYOBJECT</td>
<td>Scan for TO instance</td>
</tr>
</tbody>
</table>
A.1.2.6 Operators

Below is a list of all ST operators and the syntactic rules in which they are used.

Table A-7 ST operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>:=</td>
<td>Assignment operator (also for initialization values)</td>
<td>Value assignment, input assignment, in/out assignment, variable declaration, constant declaration, user-defined data types, component declaration</td>
</tr>
<tr>
<td>+, –</td>
<td>Arithmetic operators: Unary operators, sign</td>
<td>Expression, exponent</td>
</tr>
<tr>
<td>MOD</td>
<td>Basic arithmetic operators</td>
<td>Expression, basic arithmetic operator</td>
</tr>
<tr>
<td>**</td>
<td>Arithmetic operators: Exponent operator</td>
<td>Expression</td>
</tr>
<tr>
<td>NOT</td>
<td>Logic operators: Negation</td>
<td>Expression, operand</td>
</tr>
<tr>
<td>AND, &amp;; OR, XOR</td>
<td>Basic logic operator</td>
<td>Basic logic operator</td>
</tr>
<tr>
<td>&lt;, &gt;, &lt;<em>, &gt;</em>; =, &lt;&gt;</td>
<td>Relational operator</td>
<td>Relational operator</td>
</tr>
<tr>
<td>=&gt;</td>
<td>Assignment operator</td>
<td>Output assignment</td>
</tr>
</tbody>
</table>

A.1.2.7 Reserved words

Below is an alphabetical list of keywords, predefined identifiers, and standard functions of the basic ST system. You are also provided with a description and the syntactic rule from rules in which they are used as terminals. An exception is standard functions, which are included only implicitly in the syntactic rule for function calls as the standard function name.

Note

Variables must not be assigned the names of keywords or predefined identifiers. For more information about identifiers, see Identifiers in ST. You will find an overview of the identifiers reserved for technology objects and other reserved identifiers in Reserved identifiers.
### Appendix
#### A.1 Formal Language Description

<table>
<thead>
<tr>
<th>Keyword/identifier</th>
<th>Description</th>
<th>Rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS</td>
<td>Standard numeric function</td>
<td>Function call</td>
</tr>
<tr>
<td>ACOS</td>

<tr>
<td>CTUD</td>
<td>Up/down counter</td>
<td>Function block call</td>
</tr>
<tr>
<td>CTUD_DINT</td>
<td>Up/down counter</td>
<td>Function block call</td>
</tr>
<tr>
<td>CTUD_UDINT</td>
<td>Up/down counter</td>
<td>Function block call</td>
</tr>
<tr>
<td>DATE</td>
<td>Elementary data type for date</td>
<td>Time type</td>
</tr>
<tr>
<td>DATE_AND_TIME</td>
<td>Elementary data type for date and time</td>
<td>DATE_AND_TIME</td>
</tr>
<tr>
<td>DATE_AND_TIME_TO_DATE</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DATE_AND_TIME_TO_TIME_OF_DAY</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DELETE</td>
<td>Standard function for string editing</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT</td>
<td>Elementary data type for double precision integer with value range (2^{31}) to (2^{31}-1)</td>
<td>Numeric data type</td>
</tr>
<tr>
<td>DINT_TO_BYTE</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_DWORD</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_INT</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_LREAL</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_REAL</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_SINT</td>
<td>Standard function for type conversion</td>
<td>Function call</td>

<tr>
<td>DINT_TO_STRING</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_UDINT</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_UINT</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_USINT</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_TO_WORD</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DINT_VALUE_TO_BOOL</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DO</td>
<td>Introduces the statement section for FOR statement or WHILE statement</td>
<td>FOR statement, WHILE statement</td>
</tr>
<tr>
<td>DT</td>
<td>Shorthand notation for DATE_AND_TIME</td>
<td>DATE_AND_TIME</td>
</tr>
<tr>
<td>DT_TO_DATE</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DT_TO_TOD</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>
<tr>
<td>DWORD</td>
<td>Elementary data type for double word</td>
<td>Bit data type</td>
</tr>
<tr>
<td>DWORD_TO_BOOL</td>
<td>Standard function for type conversion</td>
<td>Function call</td>
</tr>

A.1.3.3 Comments

Note the following when inserting comments:

- Nesting of line comments is not allowed.
- Nesting of block comments is not allowed, but you can nest line comments in block comments.
- Comments are allowed at any position in the unformatted (syntactic) rules.
- Comments are not allowed in formatted (lexical) rules.

A.2 Compiler Error Messages and Remedies

This section provides an overview of the compiler error messages and their correction.

A.2.1 File access errors (1000 – 1100)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
<td>A read/write error has occurred on file access.</td>
</tr>
<tr>
<td>1001</td>
<td>Unable to load the file with the plain text error messages; cannot output error message texts. Please refer to the online help using the error number!</td>
</tr>
<tr>
<td>1002</td>
<td>The created code could not be stored. Please close some windows and recompile!</td>
</tr>
<tr>
<td>1003</td>
<td>A read/write error has occurred on opening the file. Please close the application and try again!</td>
</tr>
</tbody>
</table>
| 1100  | The option for stating a preprocessor definition contains an invalid identifier as the defined token. The correct syntax of the call option is: -D identifier[=][text]  
Examples:  
- -D myident // Definition of myident; this can be queried using #ifdef.  
- -D myident= // myident is defined as empty character string  
- -D "myident=This is a text" // myident is defined as character string 'This is a text'. The quotation marks only have to be used if the replacement text contains a blank. |

A.2.2 Scanner errors (2001, 2002)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001</td>
<td>The specified character is illegal.</td>
</tr>
<tr>
<td>2002</td>
<td>The specified identifier contains illegal characters or combinations of characters. According to IEC 61131, an identifier must start with a letter or an underscore. Any number of letters, digits, or underscores may follow, but no more than one underscore in a row.</td>
</tr>
</tbody>
</table>
A.2.3 Declaration errors in POU (3002 – 3027)

Table A-11 Declaration errors in POU (3002 – 3027)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3002</td>
<td>Keyword &quot;IMPLEMENTATION&quot; to identify the code section of the load unit is expected.</td>
</tr>
<tr>
<td>3003</td>
<td>The specified declaration block is not permitted in this context.</td>
</tr>
<tr>
<td>3004</td>
<td>The VAR, VAR_INPUT, VAR_OUTPUT, VAR_IN_OUT, VAR_CONSTANT variable declaration blocks are permitted just once for each POU. Up to Version V3.1 of the SIMOTION kernel, the VAR_GLOBAL, VAR_GLOBAL CONSTANT, VAR_GLOBAL RETAIN declaration blocks are permitted just once in the interface or implementation section.</td>
</tr>
<tr>
<td>3005</td>
<td>TASK statement: The task link has already been made in the source file for the specified task. Further task linking not possible.</td>
</tr>
<tr>
<td>3006</td>
<td>Incorrect stack size for task specified. Only positive integers are permitted.</td>
</tr>
<tr>
<td>3007</td>
<td>The specified identifier must be a task identifier; see task configuration.</td>
</tr>
<tr>
<td>3008</td>
<td>The specified identifier must be a program identifier. The declaration is made in the statement PROGRAM xx ... END_PROGRAM.</td>
</tr>
<tr>
<td>3009</td>
<td>The EXPRESSION keyword must be followed by an identifier. The declaration is made in the statement EXPRESSION xx ... END_EXPRESSION.</td>
</tr>
<tr>
<td>3010</td>
<td>The specified identifier is not an EXPRESSION identifier. Check whether the declaration was made using the statement EXPRESSION xx ... END_EXPRESSION.</td>
</tr>
<tr>
<td>3011</td>
<td>The TASK statement is not permitted in the unit. Use the task configuration in the Workbench.</td>
</tr>
<tr>
<td>3012</td>
<td>The specified identifier has already been declared at another position. It cannot be used again as a function identifier.</td>
</tr>
<tr>
<td>3013</td>
<td>The specified identifier has already been declared at another position. It cannot be used again as a function block identifier.</td>
</tr>
<tr>
<td>3014</td>
<td>The UNIT statement is expected. The following forms are permissible: • UNIT myunit; • UNIT myunit : dvtype; The UNIT statement is only required when compiling at the ASCII file level. It is optional when the compiler is called from the Workbench.</td>
</tr>
<tr>
<td>3015</td>
<td>The source file is not ended with END_IMPLEMENTATION. Observe the structure for a source file!</td>
</tr>
<tr>
<td>3016</td>
<td>No further statements may be specified after keyword END_IMPLEMENTATION.</td>
</tr>
<tr>
<td>3017</td>
<td>The task declaration is not ended with END_TASK. Observe the structure for a source file!</td>
</tr>
<tr>
<td>3018</td>
<td>The POU declaration is not ended with END_FUNCTION, END_FUNCTION_BLOCK, or END_PROGRAM. Observe the structure for a source file!</td>
</tr>
<tr>
<td>3019</td>
<td>A POU starting with keywords FUNCTION, FUNCTION_BLOCK, or PROGRAM is expected.</td>
</tr>
<tr>
<td>3020</td>
<td>The task linking statement is expected. Configuration: TASK tname ... END_TASK;</td>
</tr>
<tr>
<td>3022</td>
<td>The keyword INTERFACE is expected. See the structure for a source file.</td>
</tr>
<tr>
<td>3023</td>
<td>Keyword INTERFACE or IMPLEMENTATION is expected. See the structure for a source file.</td>
</tr>
<tr>
<td>3024</td>
<td>Syntax error in TASK statement. Correct structure: TASK tname ... END_TASK;</td>
</tr>
<tr>
<td>3025</td>
<td>The specified identifier has already been declared at another position. It cannot be used again as a program identifier.</td>
</tr>
</tbody>
</table>
A.2 Compiler Error Messages and Remedies

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3026</td>
<td>The WAITFORCONDITION statement cannot be used recursively. An attempt was made to use a WAITFORCONDITION statement a second time within a WAITFORCONDITION statement. This is not possible.</td>
</tr>
<tr>
<td>3027</td>
<td>An attempt was made to insert a WAITFORCONDITION statement within an EXPRESSION ... END_EXPRESSION block. This is not possible. The WAITFORCONDITION statement cannot be used within an expression.</td>
</tr>
</tbody>
</table>

A.2.4 Declaration errors in data type declarations (4001 – 4051)

Table A-12 Declaration errors in data type declarations (4001 – 4051)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4001</td>
<td>The specified identifier is a standard function identifier that cannot be overwritten. Choose a different identifier.</td>
</tr>
<tr>
<td>4002</td>
<td>The specified identifier has already been used. Use as a type identifier is not possible. Choose a different identifier.</td>
</tr>
<tr>
<td>4003</td>
<td>The specified identifier has already been used. Use as a constant identifier is not possible. Choose a different identifier.</td>
</tr>
<tr>
<td>4004</td>
<td>The specified initialization value has an incorrect format. Choose the initialization value that corresponds to the data type declaration.</td>
</tr>
<tr>
<td>4005</td>
<td>Syntax error in type declaration.</td>
</tr>
<tr>
<td>4006</td>
<td>Syntax error in the structure element specification in the structure declaration.</td>
</tr>
<tr>
<td>4007</td>
<td>Syntax error in declaration of an ARRAY data type.</td>
</tr>
<tr>
<td>4008</td>
<td>Syntax error in the identifier list specification. The identifiers must be separated by commas.</td>
</tr>
<tr>
<td>4009</td>
<td>The specified constant identifier has been assigned different values. This occurs when enumeration data types are declared. Identical enumeration elements in different enumeration data types must be located in the same position in the type declaration.</td>
</tr>
<tr>
<td>4010</td>
<td>The specified type identifier is not exported from the source file, although the POU in which it is used, is exported. Use a different data type or declare the data type in the implementation section.</td>
</tr>
<tr>
<td>4011</td>
<td>A constant declaration requires the specification of an initialization value. Example: x : DINT := 5;</td>
</tr>
<tr>
<td>4012</td>
<td>The specified data type must be declared outside the POU. For VAR_INPUT, VAR_OUTPUT, and VAR_IN_OUT, the type identifiers must not be declared locally in the POU, as they must also be known outside the POU for parameter transfer purposes.</td>
</tr>
<tr>
<td>4013</td>
<td>The specified value is used several times in the enumeration data type. The values in the enumeration data type must differ, however.</td>
</tr>
<tr>
<td>4050</td>
<td>The data type or variable declaration creates a data type that is larger than the specified maximum permissible data size.</td>
</tr>
<tr>
<td>4051</td>
<td>The variable declaration requires a memory area that is larger than the specified maximum permissible memory size.</td>
</tr>
</tbody>
</table>
### A.2.5 Declaration errors in variables declarations (5001 – 5509)

Table A-13 Declaration errors, variables declarations (5001 – 5509)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5001</td>
<td>The specified constant value causes the value range to be exceeded and cannot be converted to the requested type.</td>
</tr>
<tr>
<td>5002</td>
<td>The specified identifier has already been used. Use as a variable identifier is not possible. Choose a different identifier.</td>
</tr>
<tr>
<td>5003</td>
<td>Syntax error in variable declaration.</td>
</tr>
<tr>
<td>5004</td>
<td>The specification of a data type is expected (simple or derived data type).</td>
</tr>
<tr>
<td>5005</td>
<td>The specified constant value has the wrong data type or causes the value range to be exceeded.</td>
</tr>
<tr>
<td>5006</td>
<td>Check the number of initialization values for array initialization.</td>
</tr>
<tr>
<td>5007</td>
<td>Syntax error in the specification of the time and date literals.</td>
</tr>
<tr>
<td>5008</td>
<td>A function block instance cannot be created at the specified position. For example, FB instances cannot be created in functions. In addition, output parameters (VAR_OUTPUT) of function blocks cannot be FB instances.</td>
</tr>
<tr>
<td>5009</td>
<td>The data type specified in the declaration cannot be applied to the variable with absolute address. An integer or bit data type with matching bit width must be used.</td>
</tr>
<tr>
<td>5010</td>
<td>An attempt was made to assign a memory address to a variable. This is not possible at the specified position. Use this assignment only within the VAR_GLOBAL declaration of a unit or within the VAR declaration of a PROGRAM.</td>
</tr>
<tr>
<td>5012</td>
<td>The specified variables cannot be preassigned an initialization value.</td>
</tr>
<tr>
<td>5014</td>
<td>Incorrect initialization of a data structure. The initialization value for a component was specified more than once.</td>
</tr>
<tr>
<td>5016</td>
<td>The initialization of variables and data types with technology objects defined in the project is not possible. Technology objects are themselves variables and so cannot be used for the initialization.</td>
</tr>
<tr>
<td>5100</td>
<td>The specified variables cannot be preassigned an initialization value.</td>
</tr>
<tr>
<td>5110</td>
<td>Special characters can be specified via $... in the following way: $S, $T, $L, $N, $P, $R, $T. Moreover, the numeric value of a character can be specified via $xx, whereby xx stands for the two-digit hexadecimal specification of the character code.</td>
</tr>
<tr>
<td>5111</td>
<td>The special character can only be specified via $... This affects $L, $N, $P, $R, $T.</td>
</tr>
<tr>
<td>5112</td>
<td>Multi-line character string constants are not permitted. To produce a new line in the output, use the appropriate special character in the character string, e.g. $N, $R$L.</td>
</tr>
<tr>
<td>5500</td>
<td>The specified jump label identifier was already defined. Choose a different name.</td>
</tr>
<tr>
<td>5501</td>
<td>The specified jump label identifier has not been defined. Include this identifier in the LABEL declaration.</td>
</tr>
<tr>
<td>5502</td>
<td>The jump label identifier has been assigned more than once. However, each jump label can only be used once as a label.</td>
</tr>
<tr>
<td>5503</td>
<td>The jump label is specified as a jump destination, but the associated label is missing.</td>
</tr>
<tr>
<td>5504</td>
<td>No jumps are possible in subordinate control structures (e.g. WHILE loops). The specified jump label cannot be used at this position.</td>
</tr>
<tr>
<td>5505</td>
<td>No jumps are possible in subordinate control structures (e.g. WHILE loops). The specified jump destination cannot be reached.</td>
</tr>
</tbody>
</table>
### Error Description

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5506</td>
<td>No jumps are possible in <code>WAITFORCONDITION</code> blocks. The specified jump label cannot be used at this position.</td>
</tr>
<tr>
<td>5507</td>
<td>No jumps are possible in <code>WAITFORCONDITION</code> blocks. The specified jump destination cannot be reached.</td>
</tr>
<tr>
<td>5509</td>
<td>Jump labels cannot be used within a <code>CASE</code> statement. The syntax does not allow any differentiation between a jump label and the value list of the <code>CASE</code> statement.</td>
</tr>
</tbody>
</table>

#### A.2.6 Errors in the expression (6001 - 6201)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6001</td>
<td>Syntax error: A statement terminated with a semicolon is expected, e.g. <code>a := b*c;</code></td>
</tr>
<tr>
<td>6002</td>
<td>Syntax error: An expression is expected, e.g. <code>x &lt; y</code>.</td>
</tr>
<tr>
<td>6003</td>
<td>The specified identifier is no variable identifier. You must specify a variable identifier. Check whether the indicated identifier is covered. Up to and including V4.0, access to global device identifiers was possible within a program or function block of the same name despite warning 16021.</td>
</tr>
<tr>
<td>6004</td>
<td>The index for array access must be the DINT data type. Perform a suitable type conversion or use another expression.</td>
</tr>
<tr>
<td>6005</td>
<td>Type conflict in the expression. One of the operands cannot be converted to the data type of the calculation, or the result assignment produces a type conflict.</td>
</tr>
</tbody>
</table>
| 6006   | The specified variable cannot be accessed. Therefore it cannot be used in the expression. Possible causes:  
<p>|        | • Variable cannot be read.                                                               |
|        | • Attempt to access a local variable of a function or function block from outside.                                                 |
| 6007   | Cannot write specified variable. A value assignment is not possible.                                                                   |
| 6008   | The specified function does not supply a return value. An application in the expression is therefore not possible (function declared with a return value of VOID). |
| 6009   | The specified identifier does not refer to a function or a function block instance. Therefore it cannot be used as function identifier. |
| 6010   | The specified identifier is not included as an input parameter (VAR_INPUT) or in/out parameter (VAR_IN_OUT) in the declaration of the POU (function or function block). It cannot be used in the POU call.|
| 6011   | The number of function arguments in the call differs from the declaration, or the call parameters required are missing in the call.   |
| 6012   | RETURN is not permitted syntactically at this position. RETURN may only be used in functions.                                             |
| 6013   | EXIT is not permitted syntactically at this position. EXIT can only be used within FOR, WHILE, and REPEAT.                               |
| 6014   | The specified index value is outside the array limits. Only index values that match the array declaration are permissible.            |
| 6015   | The specified task control command cannot be applied to the task. It is not allowed for this type of task.                            |</p>
<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6016</td>
<td>The specified task is deactivated in the execution system. It must be enabled before it can be used.</td>
</tr>
<tr>
<td>6017</td>
<td>Syntax error on specifying programs within a task. The programs must be listed by name and separated by commas.</td>
</tr>
<tr>
<td>6018</td>
<td>The specified identifier does not refer to a PROGRAM. Therefore it cannot be used as a program identifier.</td>
</tr>
<tr>
<td>6019</td>
<td>Multiple assignment of program to task. Only one assignment is possible.</td>
</tr>
<tr>
<td>6020</td>
<td>Syntax error on specifying directly displayed variables. Inputs must have the syntax %Ix.y and outputs the syntax %Qx.y.</td>
</tr>
<tr>
<td>6021</td>
<td>The specified byte offset of the directly displayed variables lies outside the permissible address space.</td>
</tr>
<tr>
<td>6022</td>
<td>The specified byte offset of the directly displayed variables lies outside the permissible address space. Values 0 to 7 are permissible.</td>
</tr>
<tr>
<td>6023</td>
<td>The return value of the function was not assigned. An assignment is however imperative.</td>
</tr>
<tr>
<td>6024</td>
<td>A variable with the specified identifier is not included in the task start information.</td>
</tr>
<tr>
<td>6025</td>
<td>The condition variable and condition values of a CASE statement must be of the data type SINT, INT, DINT, USINT, UINT or UDINT. It must be possible to implicitly convert the condition values to the data type of the condition variables.</td>
</tr>
<tr>
<td>6026</td>
<td>The specified message identifier is not contained in the message configuration. Switch to the message configuration and add the identifier.</td>
</tr>
<tr>
<td>6027</td>
<td>System variable access is only possible directly by means of a technology object reference. Access by means of a structure or array is not possible. Create a local variable of type TO and assign the TO reference to this variable. You can then access the required system variable by means of this local TO variable.</td>
</tr>
<tr>
<td>6028</td>
<td>Type conflict in expression at specified operation. One of the operands cannot be converted to the data type of the calculation, or the result assignment produces a type conflict. The specified data type in the expression is expected.</td>
</tr>
<tr>
<td>6029</td>
<td>The specified function parameter does not have a default value, so it is imperative to specify a value when the function is called.</td>
</tr>
<tr>
<td>6030</td>
<td>An attempt was made to transfer an expression to an in/out parameter (VAR_IN_OUT). This is not possible. User variables must be specified as in/out parameters.</td>
</tr>
<tr>
<td>6031</td>
<td>An attempt was made to transfer a system variable (TO, I/O direct access) to an in/out parameter (VAR_IN_OUT). This is not possible. User variables must be specified as in/out parameters.</td>
</tr>
<tr>
<td>6032</td>
<td>An attempt was made to transfer a variable in the process image to an in/out parameter (VAR_IN_OUT). This is not possible. User variables must be specified as in/out parameters.</td>
</tr>
<tr>
<td>6033</td>
<td>An attempt was made to transfer a variable with a non-matching data type to an in/out parameter (VAR_IN_OUT). However, an Implicit type conversion is not possible. User variables with the correct data type must be specified as in/out parameters.</td>
</tr>
<tr>
<td>6034</td>
<td>An attempt was made to transfer a read only variable to an in/out parameter (VAR_IN_OUT). This is not possible. In/out parameters must be read/write.</td>
</tr>
<tr>
<td>6035</td>
<td>An attempt was made to transfer a constant to an in/out parameter (VAR_IN_OUT). This is not possible. In/out parameters must be user variables.</td>
</tr>
</tbody>
</table>
| 6036  | An operation is applied to a constant. The value of the constant is outside the definition range for the function. Examples are:  
- Application of SQRT to a negative number.  
- Use of logarithmic functions on a number <= 0.  
- Use of ASIN or ACOS on a number outside the interval [0..1] |
## Appendix
### A.2 Compiler Error Messages and Remedies

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6037</td>
<td>An attempt was made to divide a constant by zero. This operation is not permitted.</td>
</tr>
<tr>
<td>6038</td>
<td>The specified function parameter occurs more than once in the argument list.</td>
</tr>
</tbody>
</table>
| 6039  | The specified POU (function or function block) cannot be used. Possible causes:  
  - The definition of the POU in the implementation section is missing. Only the prototype was  
    specified in the interface section.  
  - The POU is fully defined only after its use (e.g. call, instance declaration). If necessary, move  
    this POU in the program source before the POU in which it is used.  
  - An instance of the function block cannot be declared as unit variable in the same program  
    source in which this function block is defined. |
| 6040  | Only simple variables may be used as semaphores; indexing is not possible. |
| 6041  | The message function requires an auxiliary value of the specified data type. Type conversion is  
    not possible. |
| 6042  | The message function requires that you specify a message number. The specified message  
    number is invalid. |
| 6050  | Type conflict in expression at specified operation/variable. One of the operands cannot be  
    converted to the type of the calculation, or the result assignment produces a type conflict. A  
    conversion between source file type and target type is not possible. |
| 6051  | The expression contains a type conflict for the specified operation. One of the operands cannot  
    be converted to the data type of the other operand to perform the calculation, or the operand data  
    types are not permitted for this operation. |
| 6052  | Type conflict in the expression. The specified data type cannot be used for the operation (see  
    marshalling functions). |
| 6053  | The expression contains a type conflict for the specified operation. This operation is not  
    permissible on the specified data type. |
| 6054  | Type conflict in the expression. The specified variable cannot be used as indexed array variable. |
| 6060  | At the function call, there is a mixture of assignments of function arguments and setting  
    parameters. Use one form of the function call. Example:  
    - \( f(x, y); \) or  
    - \( f(in1 := x, in2 := y); \) |
| 6061  | The specified parameter of the function or the function block is an in/out parameter.  
    Consequently, a variable must be assigned when the POU is called. |
| 6062  | The specified identifier cannot be used as a function argument. Only variables from the  
    declaration blocks VAR_INPUT and VAR_IN_OUT are permitted. |
| 6070  | Access to configuration data is only possible for variables that have been specified completely.  
    Append the name according to the configuration data for the selected technology object. |
| 6080  | The specified variable is no input or output variable that can be directly accessed. Such a variable  
    must be declared in the I/O container of the respective device; it must have the syntax PI* or PQ*. |
| 6100  | The specified construct can only be compiled if the device type is set. Add the device type to the  
    unit statement or set the device type in the program container. |
| 6110  | The specified construct cannot be used in libraries. |
| 6111  | The specified construct cannot be used in libraries. |
| 6112  | The specified construct cannot be used in libraries. |
| 6113  | Access to technology objects and devices is not allowed in libraries. |
| 6130  | The specification of an interval is not permissible for the data type indicated in the CASE  
    statement. |
### A.2 Compiler Error Messages and Remedies

### A.2 Compiler Error Messages and Remedies

#### A.2.7 Syntax errors, errors in the expression (7000 - 7014)

Table A-15 Syntax errors, errors in the expression (7000 - 7014)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
</table>
| 7000  | A syntax error has occurred. Possible causes:  
- Incorrectly ended control structures (e.g. END_IF missing)  
- Statements not terminated with ;  
- Missing parentheses |
| 7001  | The specified identifier does not refer to a constant. Please enter one constant per value or identifier. |
| 7002  | A signed integer is expected. The integer can be of data type SINT, INT, or DINT. |
| 7003  | When specifying the interval, the initial value must be less than or equal to the end value. This applies to the declaration of arrays and the specification of the interval in CASE selection conditions. |
| 7004  | An initialization value is expected. The value must be a constant. Constants can be assigned as follows:  
- Directly per value  
- Symbolically via a preceding constant declaration  
- As an expression containing constants only |
| 7009  | An expression that supplies data type BOOL is expected as condition for WHILE, REPEAT, and IF. This can be specified as a variable of data type BOOL or via a comparison expression. You can also specify a function with a return value of data type BOOL. |
| 7010  | A syntax error has occurred. Possible causes:  
- Incorrectly terminated control structures (e.g. END_IF missing)  
- Statements not terminated with ;  
- Missing parentheses |
| 7011  | A syntax error has occurred. Possible causes:  
- Incorrectly terminated control structures (e.g. END_IF missing)  
- Statements not terminated with ;  
- Missing parentheses |
| 7012  | A syntax error in the statement, that starts at the specified line, has occurred. Possible causes:  
- Incorrectly terminated control structures (e.g. END_IF missing)  
- Statements not terminated with ;  
- Missing parentheses |
| 7013  | A syntax error has occurred. An illegal construct is being used. |
| 7014  | A syntax error has occurred. Possible causes:  
- Incorrectly terminated control structures (e.g. END_IF missing)  
- Statements not terminated with ;  
- Missing parentheses |
A.2.8 Error when linking a source file (8001, 8100)

Table A-16 Error when linking a source file (8001, 8100)

<table>

A.2.9 Errors while loading the interface of another UNIT or a technology package (10000 - 10037, 10100 - 10101)

Table A-17 Errors while loading the interface of another UNIT or a technology package (10000 - 10037, 10100 - 10101)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10000</td>
<td>The specified unit has an invalid file format. Probably, the unit was created using an older version of the compiler or compiled using incompatible options. If a unit is involved, it should compiled first. Then repeat the current compilation. If a package is involved, a newer version should be installed.</td>
</tr>
</tbody>
</table>
| 10001 | The unit name has an invalid format. The rules for identifiers in ST are also true for unit names; the following restrictions apply to their length:  
  - Up to Version V4.0 of the SIMOTION Kernel: 8 characters.  
| 10002 | Error while loading the interface of another UNIT, a library or technology package. The specified identifier is contained in two different imported units, libraries or technology packages.  
  - Remove a unit, library or technology package from the import list or  
  - Establish uniqueness between the identifiers in imported units, libraries or technology packages. Change the exporting units in the interface section or specify a namespace for a library or a technology package (USELIB ... AS namespace; USEPACKAGE ... AS namespace; ). |
| 10003 | The specified data type has an invalid memory layout. Probably, the unit was created using an older version of the compiler or compiled using incompatible options. If a unit is involved, it should compiled first. Then repeat the current compilation. You can also perform "Save and recompile everything".  
  - If a package is involved, a newer version should be installed.  
  - If the error persists, inform the support department. |
| 10004 | The exported identifiers of the specified unit could not be loaded. Close some applications and try again. |
| 10005 | A recursion was detected on loading packages. The specified package has already been loaded with USEPACKAGE and cannot be specified a second time. |
| 10006 | A recursion was detected on loading the unit. The specified unit has already been loaded with USES and cannot be specified a second time. |
## A.2 Compiler Error Messages and Remedies

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10007</td>
<td>The maximum number of imported units which can be referenced in a unit was exceeded. A maximum of 223 imported units per load unit are permissible. Both units imported directly with USES and indirectly imported units are counted.</td>
</tr>
<tr>
<td>10008</td>
<td>The number of imported packages that can be referenced in a unit has been exceeded. A maximum of 127 imported packages per load unit are permissible.</td>
</tr>
<tr>
<td>10009</td>
<td>The specified package is used in the unit, but it is not available on the device. This error message occurs when you compile with the &quot;implicit package utilization&quot; option and have programmed a USEPACKAGE statement that has a different content than the packages specified on the device.</td>
</tr>
<tr>
<td>10010</td>
<td>The specified package is used in Unit a but not in Unit b. This error message occurs when different packages have been specified with USEPACKAGE in units that reference each other with USES. Correct the USEPACKAGE statements.</td>

<td>The specified definition is not considered during code generation. It is not possible to define keywords differently.</td>
</tr>
<tr>
<td>15200</td>
<td>The specification of a bit offset for a bitstring variable requires the &quot;Permit language extensions&quot; compiler option (-C lang_ext).</td>
</tr>
</tbody>
</table>

A.2.11 Warnings (16001 - 16700)

You can control the output of warnings and information:

- In the global compiler settings (Page 47)
- In the local compiler settings (Page 49)
- In an ST source file by specifying the following attribute (Page 271) within a pragma (Page 266): \{ _U7_PoeBld_CompilerOption := warning:n:on \} or \{ _U7_PoeBld_CompilerOption := warning:n:off \}, where \( n \) is the warning class or the number for the warning or information.

You can also redefine individual warnings and information as errors:

- In an ST source file by specifying the following attribute (Page 271) within a pragma (Page 266): \{ _U7_PoeBld_CompilerOption := warning:n:err \}, where \( n \) is the number for the warning or information.
Table A-19  Warnings (16001 - 16700)

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>16001</td>
<td>(Warning class: 0) Only in conjunction with the &quot;Selective Linking&quot; compiler option. The specified function, the function block, or the program are neither exported nor called in the current unit. No code is generated.</td>
</tr>
<tr>
<td>16002</td>
<td>(Warning class: 0) Only in conjunction with the &quot;Selective Linking&quot; compiler option. The specified unit does not contain any exported PROGRAM nor any task link. No code is generated for the unit.</td>
</tr>
<tr>
<td>16003</td>
<td>(Warning class: 2) The operands of the comparison operation do not contain any explicit type definition. The data type listed in the comparison can be seen in the warning message issued. Specify the data type of the used constants explicitly with &lt;type&gt;#&lt;value&gt;.</td>
</tr>
<tr>
<td>16004</td>
<td>(Warning class: 2) The specified type conversion may cause the variable value to change due to the reduced display width or inadequate accuracy of the target data type.</td>
</tr>
<tr>
<td>16005</td>
<td>(Warning class: 2) During type conversion, the dependency of the variable value can cause the sign to change.</td>
</tr>
<tr>
<td>16006</td>
<td>(Warning class: 2) The specified value will be rounded to the next displayable value due to insufficient display width.</td>
</tr>
<tr>
<td>16007</td>
<td>(Warning class: 2) A loss of accuracy occurred during type conversion. Not all decimal places are considered.</td>
</tr>
<tr>
<td>16008</td>
<td>(Warning class: 2) A loss of accuracy occurred during initialization of the specified variables. The constant will be converted to the specified data type. Not all decimal places are considered.</td>
</tr>
<tr>
<td>16009</td>
<td>(Warning class: 0) Only in connection with compiler option Selective Linking. The specified unit does not contain any exported PROGRAMs or any task linking. Unable to access unit code. Unable to call relevant POU.</td>
</tr>
<tr>
<td>16010</td>
<td>(Warning class: 0) Specified program not exported to unit; therefore unable to use it in configuration of the execution level.</td>
</tr>
<tr>
<td>16011</td>
<td>(Warning class: 0) The source file does not contain any exported global variables. No data are loaded to the target system.</td>
</tr>
<tr>
<td>16012</td>
<td>(Warning class: 0) The specified source file name was taken over from the PROGRAMS container of the selected device. The identifier of the source file in the UNIT statement was ignored.</td>
</tr>
<tr>
<td>16013</td>
<td>(Warning class: 2) Because of the marshalling function, the specified data type is not portably convertible. Only use SIMOTION devices in connection with this data type, or perform an explicit conversion of the data type.</td>
</tr>
<tr>
<td>16014</td>
<td>(Warning class: 2) With the specified operation, a data type conversion is performed between signed and unsigned. Because the bit string is adopted in this case, the resulting numerical value can differ from the specified value.</td>
</tr>
</tbody>
</table>
## A.2 Compiler Error Messages and Remedies

### Error Description

16015  
**Warning class: 2**
For the assignment of the character string constants to the variables, only part of the character string constants is transferred, because the length of the variable is insufficient to accept all characters.

16016  
**Warning class: 2**
The operands in the expression do not contain any explicit type definition. The data type of the operation is determined by specifying the values. The resulting data type in which the expression is calculated can be seen in the issued warning message. To define the data type:
- Specify the data type of the used constants explicitly with `<type>`#`<value>`.
- Use an explicit data type conversion.

16017  
**Warning class: 2**
The operands in the expression contain only constants. The data type of the operation can be determined by specifying the data type (in the form `<type>`#`<value>`) or explicit data type conversion.
This output is used for finding problems, in particular, for the use of symbolic constants, because the data type of the operation cannot normally be determined easily.

16018  
**Warning class: 2**
The data type of the comparison operation is defined using the value of a constant that has a larger value range than the contained variable. The comparison is performed with the data type of the constant.

16020  
**Warning class: 1**
The declaration hides the specified identifier, which has been globally defined in its own source file or an imported source file. Access to the global identifier is no longer possible from the POU where this identifier is declared locally.

16021  
**Warning class: 1**
The declaration hides the specified identifier, which is defined on the device. You can access the global device identifier with `_device.<name>`.

16022  
**Warning class: 1**
The declaration hides the specified identifier, which is defined in the project (e.g. technology object or device). You can access the global project identifier with `_project.<name>`.

16023  
**Warning class: 1**
The declaration hides the specified identifier for the data type of a technology object. Access to the data type identifier is no longer possible.

16024  
**Warning class: 1**
The declaration hides the access to the technology object on the device. You can access this TO with `_to.<name>`.

16025  
**Warning class: 1**
The declaration hides the IEC standard function with the identical name. Access to this function is no longer possible in the current context.

16026  
**Warning class: 1**
The specified identifier is reserved by SIEMENS for potential extensions. The use of this identifier can cause compiler errors in later versions. If you want to avoid this, change this identifier.

16030  
**Warning class: 1**
A label has been specified several times in a CASE statement. Only the first label is ever evaluated. Other specifications have no effect.

<td>16230 (Warning class: 4)</td>
<td>The expression with the specified values does not cause any change to the result; optimized code will be created.</td>
</tr>
<tr>
<td>16240 (Warning class: 4)</td>
<td>The expression with the specified values exceeds the definition range of the operation. The result may be incorrect.</td>
</tr>
</tbody>
</table>
## A.2 Compiler Error Messages and Remedies

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>16300</td>
<td>(Warning class: 5) The auxiliary value has a data type that cannot be converted to the data type configured for the message.</td>
</tr>
<tr>
<td>16301</td>
<td>(Warning class: 5) The specified auxiliary value is not evaluated during output of the message.</td>
</tr>
<tr>
<td>16302</td>
<td>(Warning class: 5) The data type of the auxiliary value cannot be determined from the message configuration. The specified data type is used.</td>
</tr>
<tr>
<td>16303</td>
<td>(Warning class: 5) No auxiliary value has been specified for the function although the message configuration requires such a value. A default value of the corresponding data type was added.</td>
</tr>
</tbody>
</table>
| 16304   | (Warning class: 5) An alarm accompanying value is specified using a constant or a constant expression. The resulting data type of the alarm accompanying value can be seen in the issued warning message. To define the data type:  
  • Specify the data type of the used constants explicitly with `<type>`#`<value>`.  
  • Use an explicit data type conversion. |
| 16400   | (Warning class: 6) A global variable has been declared in a library. This may mean that the library cannot be used more than once.         |
| 16420   | (Warning class: 6) The return value has not been assigned within the function. If such a function is called, it returns a random value. |
| 16421   | (Warning class: 6) A variable that has neither been assigned nor read in the code has been declared.                                    |
| 16450   | (Warning class: –) A global variable has been created in the retentive memory range. This declaration is not permissible at the specified position. |
| 16451   | (Warning class: –) The initialization of large arrays with values other than 0 causes a high data volume in the controller. This results in long load times as well as high memory utilization. |
| 16452   | (Warning class: –) The specified program has a large quantity of instance data to be initialized. This can lead to a runtime violation when the task is started because both the initialization code and the user code are being executed. In particular, caution is advised in the case of SynchronousTasks. |
| 16470   | (Warning class: -) The specified construct does not conform to the language standard, however, for compatibility reasons, is not supported for old platforms. Convert the usage to the specified alternative. |
| 16600   | (Warning class: 6) The specified variable is not contained in the initialization list. The default initialization value is used.          |
| 16601   | (Warning class: 6) The specified variable is not contained in the initialization list. The default initialization value is used.          |

A.3  Template for Example Unit

A.3.1  Preliminary information

This appendix presents a comprehensive annotated template that you can call in the online Help. You can use it as a template for a new ST source file.

//-------------------------------------------------------------------------------
// Notes for the INITIALIZATION of the user data are available
// at the end of the template
//-------------------------------------------------------------------------------

INTERFACE
// All statements added between INTERFACE and END_INTERFACE/
// Keywords are used to define which source contents
// (variables, functions, function blocks, etc.) also in other
// sources (units) are available or exported.

USEPACKAGE cam;
// The technology packages to be used are known here and thus
// made usable in the source. Technology object (TO)-specific
// Commands can be used in this UNIT only when the
// appropriate package has been included.
// If a source file that uses USEPACKAGE cam is integrated via USES,
// it will be "inherited". USEPACKAGE can then be omitted.
// The package used in this example is "cam". However, other
// technology packages can also be used (see documentation).

USELIB testlib;

// If library functions are to be used in the source file, they must be made
// known in the source, too. If the library
// with the name "testlib" does not exist in the project,
// the error message
// "Error 10035, "testlib.lib" library could not be loaded"
// "Error 10032, "testlib" library could not be loaded"
// will be output.
// If libraries are not being used, this line can be
// deleted..

USES header;

// USES is used to import contents exported from a different source
// (NAME here "header") and made usable in "Template".
// If the source with the name "header" does not exist in the project,
// the error message
// "Error 10018, "header" source could not be loaded"
// will be output. In this case, the NAME of an existing source file must be
// used in place of "header".
A.3.2 Type definition in the interface

// ********************************************************
// * Type definition in the INTERFACE                        *
// ********************************************************
VAR_GLOBAL CONSTANT
   PI : REAL := 3.1415;
   ARRAY_MAX : INT := 3;
END_VAR
// Declaration of a global constant. In the source file
// no other value can be assigned to the identifier.
// User defined variable types (UDT) are
// defined between TYPE and END_TYPE.
TYPE
   array1dim : ARRAY [0..ARRAY_MAX] OF INT;
   // Definition of a one-dimensional array with four array elements from
   // type INT under the name "array1dim". With "array1dim" as the data type
   // in all source file segments, one-dimensional arrays can now
   // be declared by type INT.

   array2dim : ARRAY [0..3] OF array1dim;
   // A two-dimensional array is an array of one-dimensional arrays.
   // Here a two-dimensional field with 16 elements occurs
   // of the type INT under the name "array2dim"

   enumTrafficLight : (RED, YELLOW, GREEN);
   // Definition of enumerator "enumTrafficLight" as a
   // user-defined variable type. Variables of this type can
   // only accept the values "RED", "YELLOW", and "GREEN".

   structCollection : STRUCT
      toAxisX : posaxis;
      aInStruct1dim : array1dim;
      eTrafficInStruct : enumTrafficLight;
      iCounter : INT;
      bStatus : WORD;
   END_STRUCT;
   // A user-defined structure is created here. It is possible to
   // combine elementary data types (here INT and WORD) or already defined
   // user data types (here "array1dim" and "enumTrafficLight") into
   // one structure. In addition, types
   // of technology objects can also be used.
   // In the example, the structure contains an element of
   // a positioning axis (posAxis) TYPE.
   // In the definition, make certain to sort the variables
   // by size in increasing sequence
   // (ARRAY, STRUCT, LREAL, DWORD, INT, BOOL ...)

   arrayOfStruct : ARRAY [0..5] OF structCollection;
   // Nesting is also possible. The type "arrayOfStruct"
   // contains a field comprising six elements of type "structCollection"
END_TYPE
A.3.3 Variable declaration in the interface

```simotion
// ********************************************************
// * Variable declaration in the INTERFACE               *
// ********************************************************
VAR_GLOBAL        // In the user memory of the UNIT.
                 // Also visible using HMI services.

  g_aMyArray : ARRAY [0..11] OF REAL := [3 (2(4), 2(18))];
  // Example of a declaration of a one-dimensional array without
  // previous type declaration. The initialization performed here is
  // read as follows:
  // Two elements each are initialized with the value 4,
  // two elements with the value 18. This pattern is used in the field
  // "g_aMyArray" three times in succession.
  // The field elements are thus assigned as follows:
  // 4, 4, 18, 18, 4, 4, 18, 18, 4, 4, 18, 18.

  g_aMy2dim : array2dim;
  // Example of a declaration of a two-dimensional array

  g_aMy1dim : array1dim;
  // Example of a declaration of a one-dimensional array with
  // use of a type declaration.

  g_sMyStruct : structCollection;
  // Variable of the type or with the structure of
  // user_struct.

  g_aMyArrayOfStruct : arrayOfStruct;
  // The variable generated here contains a field from
  // structural elements as declared in section TYPE/END_TYPE

  g_tMyTime : TIME := T#0d_1h_5m_17s_4ms;
  // ...as elementary time types and derived data types (see below).

  g_eMyTraffic : enumTrafficLight := RED;
  // An enumerator of type "enumTrafficLight" is created here and
  // assigned the value "RED".

  g_iMyInt : INT := -17;
  // Variables of an elementary numerical data type can
  // also be declared in variable declarations...

END_VAR```

Appendix

A.3 Template for Example Unit

VAR_GLOBAL RETAIN

END_VAR

// The variables declared with the add-on RETAIN are
// stored in the RETAIN data area of the hardware platform used and
// are therefore safe from network failure.
// The declaration of VAR, VAR_CONSTANT, VAR_TEMP, VAR_INPUT, VAR_OUTPUT
// and VAR_IN_OUT is not permissible here.
// Variables that are defined in this section and thus exported
// can be reimported by means of the USES "template" into another source file (UNIT).

FUNCTION FC_myFirst;
FUNCTION_BLOCK FB_myFirst;
PROGRAM myPRG;

// The function blocks (FBs),
// functions (FCs) and programs defined in the implementation part are exported here
in the interface part,
// so that they can be used in other units.
// Non-exported FBs and FCs can only be used in this source file
// ("information hiding", placing in the interface only
// what other units absolutely need).
// A program that has not been exported cannot be assigned to any TASK!

END_INTERFACE
A.3.4 Implementation

// ***********************************************************************
// * IMPLEMENTATION section *
// ***********************************************************************
IMPLEMENTATION
// In the IMPLEMENTATION section of a unit, the executable code sections
// are stored in various program organization units (POUs).
// A POU can be a program, FC, or FB.

VAR_GLOBAL CONSTANT
END_VAR

TYPE
END_TYPE
// The type definition can also be made in the IMPLEMENTATION section.
// However, this definition cannot be imported in another source file.
// The type definition can, however, be used for variables
// in all POUs of the source file "Template". The definition of types must
// be performed before the declaration of a variable.
VAR_GLOBAL        // In the user memory of the UNIT
  g_boDigInput1 : BOOL;
  // Boolean variable for "EXPRESSION" example (see below).
END_VAR

VAR_GLOBAL RETAIN
END_VAR
// The variables declared with the add-on RETAIN are
// stored in the RETAIN data area of the hardware platform used and
// are therefore safe from network failure.
// Variable declaration in the IMPLEMENTATION section.
// The declaration of VAR, VAR CONSTANT, VAR_TEMP, VAR_INPUT, VAR_OUTPUT
// and VAR_IN_OUT is not permissible here.

EXPRESSION xCond
  xCond := g_boDigInput1;
END_EXPRESSION
// Definition of an EXPRESSION.
// An EXPRESSION is a special function case, which recognizes only the
// return values TRUE and FALSE. It is used in conjunction with the
// statement WAITFORCONDITION (see myPRG) and should only be used
// if the program is executed as part of
// a MotionTask. If "dig_input_1" (usual in a digital input or a
// condition in the program) takes on the value 1, the return value of the
// EXPRESSION is TRUE.
A.3.5 Function

// ********************************************************
// * FUNCTION                                          *
// ********************************************************
// The declaration of an FB or FC must be placed in the source file
// before the actual use (the call), so that the code of the
// block is already known to the calling point.

FUNCTION FC_myFirst : INT
    // The statement section of the POU FUNCTION begins here. The return value
    // of the function has the type integer in this case.
    // The stack of the calling TASK is initialized on each call.
    // The return value is located on the stack and is written by the FUNCTION.
    VAR CONSTANT
END_VAR

TYPE
END_TYPE
// The type declaration can also be made in POUs. The basic difference is
// the validity of the type declaration. A type declared in a POU can only
// be used for variables within associated POU.

VAR_INPUT // In the stack of the calling TASK, will be placed on
    // stack on call, assignment optional.
END_VAR

VAR // In the Stack of the calling TASK, used in FUNCTION.
END_VAR
// Variable declaration in an FC.
// The declaration of VAR_TEMP, VAR_GLOBAL, VAR_GLOBAL CONSTANT,
// VAR_GLOBAL RETAIN, VAR_OUTPUT and VAR_IN_OUT is not
// permissible here.

// The use of unit-global variables for data acceptance in FCs
// and FBs is the fastest option for the runtime. The use
// of the input parameters VAR_INPUT and the return via the
// return value is slower, since the values are copied respectively.

// Comment: Variables declared with VAR and VAR CONSTANT are
// temporary. On the next call, the contents from the latest
// call are no longer available, in contrast to the FB.
// **********************************************************
// * Area for FC code or statements *
// **********************************************************
// Code is in the user memory.
g_eMyTraffic := YELLOW; // e.g. change the traffic light.

FC_myFirst := 17;
// In this example, the function returns the value "17" to the
// calling program.

END_FUNCTION
FUNCTION_BLOCK FB_myFirst

// The declaration of an FB or FC must be placed in the source file
// before the actual use (the call), so that the code of the
// block is already known to the calling point.

VAR CONSTANT
END_VAR

// Variables declared with VAR and VAR CONSTANT are
// static, i.e., on the next block call, their contents remain
// available and valid.

TYPE
END_TYPE

// The type definition can also be made in POUs. The
// basic difference is the validity of the
// Type definition. A type defined in a POU can only
// be used for variables within associated POU.

VAR_INPUT // In the user memory of the UNIT or TASK,
   // assignment optional on call.
END_VAR

VAR_IN_OUT // In the user memory of the UNIT or TASK,
   // reference must be assigned on call.
END_VAR

VAR_OUTPUT // In the user memory of the UNIT or TASK.
END_VAR

VAR // In the user memory of the UNIT or TASK,
   // can be used in the FB.
END_VAR

VAR_TEMP // In the stack of the calling task,
   // is initialized on each call.
END_VAR
// Variable declaration in an FB.
// The declaration of VAR_GLOBAL, VAR_GLOBAL CONSTANT and
// VAR_GLOBAL RETAIN is not permissible here.

// *********************************************
// * Area for FB code or statements *
// *********************************************

g_eMyTraffic := GREEN;    // e.g. change the traffic light.
END_FUNCTION_BLOCK
A.3.7 Program

// ******************************************************
// * PROGRAM
// ******************************************************
PROGRAM myPRG
// The statement section of the POU PROGRAM begins here.

VAR CONSTANT
END_VAR

TYPE
END_TYPE
// The type definition can also be made in POU's. The
// basic difference is the validity of the
// Type definition. A type defined in a POU can only
// be used for variables within associated POU.
VAR     // In the user memory of the TASK.
instFBMyFirst : FB_myFirst;
// In order to be able to call an FB, an area for static
// variables (forming an instance) must be generated. This has to do with
// the "memory" of the FB.

retFCMyFirst : INT;
// Variable for the return value of the function.
END_VAR

VAR_TEMP    // In the stack of the task, initialized in each pass.
END_VAR
// Variable declaration in a PROGRAM.
// The declaration of VAR_GLOBAL, VAR_GLOBAL CONSTANT,
// VAR_GLOBAL RETAIN, VAR_INPUT, VAR_OUTPUT and VAR_IN_OUT
// is not permissible here.

// Comment: Whether the local variables declared via VAR
// are temporary variables depends on the task context in which the
// PROGRAM is used.
//
// In non-cyclic tasks (StartupTask, ShutdownTask, MotionTasks,
// SystemInterruptTasks and UserInterruptTasks) the previous
// contents of VAR and VAR_TEMP are no longer available.
// The variables are thus temporary.
//
// With other cyclic tasks (BackgroundTask, IPOsynchronousTask,
// IPOsynchronousTask_2 and TimerInterruptTasks), the contents
// of variables declared in the VAR section remain the same
// for the following run. The variables are thus static.
// Variables from VAR_TEMP are always temporary.
instFBMyFirst ();  // FB call with a valid instance.
retFCMyFirst := FC_myFirst ();  // FC call and assignment of return value.

WAITFORCONDITION xCond WITH TRUE DO
  // The statements programmed here come immediately for
  // execution if the condition "xcond" defined in the associated
  // EXPRESSION is logically true.
  
END_WAITFORCONDITION;
// WAITFORCONDITION is generally used only in MotionTasks.
  // These remain in the location and the
  // condition defined in the EXPRESSION is checked with high priority.

END_PROGRAM

END_IMPLEMENTATION
//-------------------------------
A.3.8 Notes on initialization

//  INSTRUCTION FOR INITIALIZATION OF USER DATA
//  * User data (variables from elementary data types, structures, and arrays)
//  * are initialized as different times. The time
//  * depends on the location (i.e., memory area) of the data.
//  * A distinction is always made between the main memory of a task (stack) and
//  * in the user memory of the TASK. There is a user memory
//  * for a TASK and for a UNIT.

// Data in the main memory of a task (stack):
//=-------------------------------------------------------------------------------------=
// Each task has a reserved memory for stack data (parameters for
// function calls, temporary variables). The stack size of a TASK is
// calculated by the compiler and can be influenced by the user in the
// execution system under task configuration (Reserve for Download in the RUN).
// * The main memory of a TASK (stack) contains the following data:
//  - VAR of FUNCTIONs
//  - VAR_TEMP of FUNCTION_BLOCKS and PROGRAMs
//  - VAR_INPUT and return value of FUNCTIONs
// * These are initialized at each call (delete / set to zero and
//   from the program, if necessary).

// The user memory (heap) is managed separately for each UNIT and for each
// TASK:
//=-------------------------------------------------------------------------------------=
// The user memory of a UNIT contains the following data:
// - VAR_GLOBAL from INTERFACE and IMPLEMENTATION
// * These are initialized (delete / set to zero and write initial values
//   from the program, if necessary):
//   - During startup
//   - during loading (if initialization of all non-retentive data is selected)
// *
// * The user memory of a TASK contains the following data:
//  - VAR of PROGRAMs
// * These are initialized (delete / set to zero and write initial values
//   from the program, if necessary):
//   - For cyclic tasks, once when STOP->RUN
//   - For non-cyclic tasks, at start of task
// *
// * The instance data of FUNCTION_BLOCKS (VAR_INPUT, VAR_OUTPUT,
// VAR_IN_OUT (reference), VAR) are dependent on where the instance of the FB
// is formed, in the user memory of a UNIT or TASK.
// Instantiation of the FB in
// - VAR_GLOBAL: Instance is located in the user memory of the UNIT
// - VAR in the PROGRAM: Instance is located in the user memory of the TASK
// - VAR in the FB: Instance is located in the user memory according to
//   higher-level FB
// * The instance data are initialized as described above.
// Which variable type is located in which data area can be obtained in
// comments in the template.
//=-------------------------------------------------------------------------------------=

   Data types for numbers, 98
   Description, 90
   Notation, 90
   Numeric data types, 99
Operands
   Syntax, 364
Operating mode
   Process mode, 277
   Test mode, 290
Operators, 323
   Priority, 142
   Relational operators, 138
   Syntax, 367
Output parameters
   Access in the function block, 173
   Function block, 165
   Transfer, 169
   outputCamType, 112
Index

Parameter
  Access times, 169
  Block (syntax), 162
  Declaration, 162
  Declaration, general, 117
  Function and function block, 162
  Transfer (in/out parameter), 167
  Transfer (input parameter), 166
  Transfer (output parameter), 169
  Transfer (principle), 166

Parameter fields
  Syntax, 351
  posAxis, 112

Pragma
  Attribute, 271
  Preprocessor statement, 268

Preprocessor
  Activating, 48, 50
  Controlling, 267
  Preprocessor statement, 268
  Using, 48, 50
  Warning class, 52

Printing
  ST source file, 58

Process image
  Cyclic tasks, 233
  Features, 231
    principle and use, 230, 239
  Symbolic access, 243

Process image of the BackgroundTask, 230

Process image of the cyclic tasks, 230

Process mode, 277

Program
  Assigning tasks, 71
  Call path, 292
  Compiling, 69
  Connecting to target system, 73
  Creating (example), 66
  Download, 74
  Executing, 71, 75
  Locating errors, 276
  Source file section, 188
  starting, 71, 75
  Status (test tool), 289
  Testing, 276

Program organization units
  Source file section, 185
  Syntax, 345

Program run, 287
  Toolbar, 288

Program structure, 263

Program structuring, 143
  program variables
    Definition, 207
    In the data model, 206
    Variable model, 200

Programming environment, 17

Project
  Opening, 63
  Prototypes, 194

REAL, 99

Real number
  See Floating-point number, 91

Reference, 112

References, 5

Relational expressions, 138

REPEAT statement
  Description, 150

Repetition statements and jump statements
  Syntax, 372

Reserved identifiers, 82, 323

RETAIN, 118, 206

Retentive variables
  Definition, 206
  Variable model, 200

RETURN statement
  Description, 151

Rules
  Formatted, 316, 332
  Semantics, 78
  Unformatted, 317, 332

RUN
  Effect on variable initialization, 219

SCOUT Workbench > See Workbench, 17

sections
  Syntax, 342
  Separators, 319

Sequential program execution
  Effect on I/O access, 230, 233
  Effect on variable initialization, 219

Setting
  Compiler, 47

Shortcuts, 27

Simple data types
Derivation, 106
Single-element variables, 126
