STEP 7 as of V14 provides the required PKI for the configuration and operation of secure communication.

Examples:

- The Hypertext Transfer Protokoll (HTTP) turns into Hypertext Transfer Protokoll Secure (HTTPS) with the help of the TLS (Transport Layer Security) protocol. Since HTTPS is a combination of HTTP and TLS, it is called "HTTP over TLS" in the corresponding RFC. You can see in the browser that HTTPS is being used; this is indicated by the URL "https://" instead of "http://" in the address bar of the browser. Most browsers highlight such secure connections.
- Open User Communication turns into secure Open User Communication. The underlying protocol is also TLS.
- E-mail providers also offer access over the "Secure SMTP over TLS" protocol to increase the security of e-mail communication.

The figure below shows the TLS protocol in the context of communication layers.

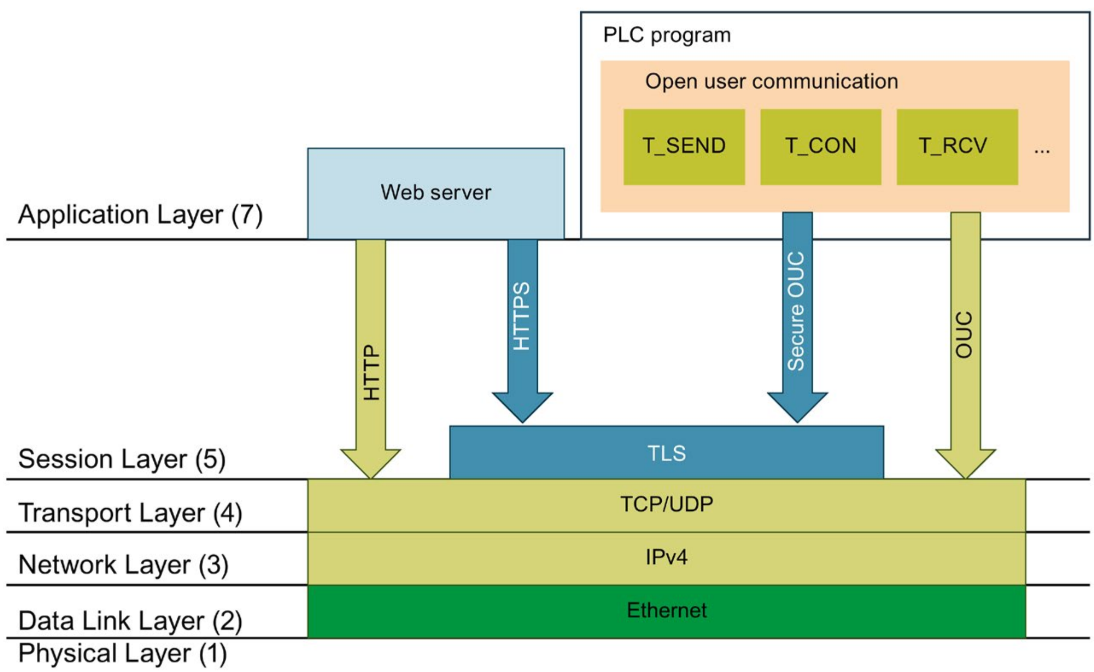

Figure 3-6 TLS protocol in the context of communication layers

Secure communication with OPC UA

An OPC UA server is implemented in S7-1500 CPUs as of firmware V2.0. OPC UA Security also covers authentication, encryption and data integrity with digital X.509 certificates and also uses a Public Key Infrastructure (PKI). Depending on the requirements placed by the application, you can select different security levels for the end point security. You will find the description of the OPC UA server functionality in the section AUTOHOTSPOT.

3.6.2 Confidentiality through encryption

Message encryption is an important element of data security. When encrypted messages are intercepted by third parties during communication, these potential eavesdroppers cannot access the information they contain.

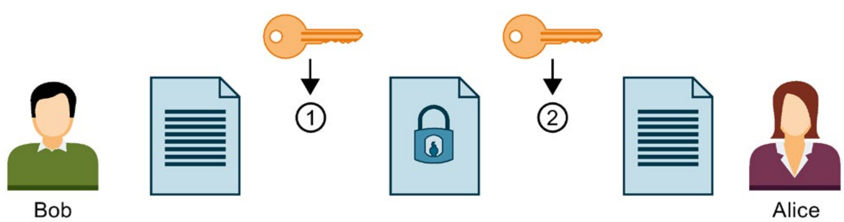
There is a wide range of mathematical processes (algorithms) for encrypting messages.

All algorithms process a "key" parameter to encrypt and decrypt messages.

- Algorithm + key + message => encrypted message
- Encrypted message + key + algorithm => (decrypted) message

Symmetric encryption

The central aspect of symmetric encryption is that both communication partners use the same key for message encryption and decryption, as shown in the figure below. Bob uses the same key for encryption as Alice uses for decryption. In general, we also say that the two sides share the secret key with which they encrypt or decrypt a message as a secret.



① Bob encrypts his message with the symmetric key

② Alice decrypts the encrypted message with the symmetric key

Figure 3-7 Symmetric encryption

The process can be compared to a briefcase to which the sender and recipient have the same key, which both locks and opens the case.

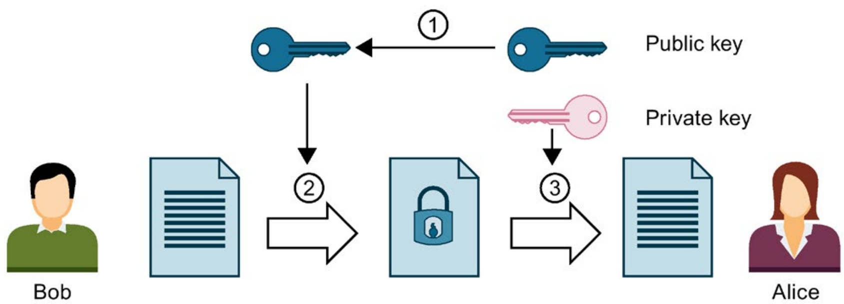
- Advantage: Symmetric encryption algorithms (such as AES, Advanced Encryption Algorithm) are fast.
- Disadvantages: How can the key be sent to a recipient without getting into the wrong hands? This is a key distribution problem. If enough messages are intercepted, the key can also be worked out and must therefore be changed regularly.

If there are a large number of communication partners, there is also a large number of keys to distribute.

Asymmetric encryption

Asymmetric encryption works with a pair of keys consisting of one public key and one private key. Used with a PKI, it is also known as Public Key cryptography or simply PKI cryptography. A communication partner, Alice in the figure below, has a private key and a public key. The public key is provided to the public, in other words any potential communication partner. Anyone with the public key can encrypt messages for Alice. In the figure below, this is Bob.

Alice's private key, which she must not disclose, is used by Alice to decrypt an encrypted message addressed to her.



①	Alice provides Bob with her public key. No precautionary measures are required to this purpose: Anyone can use the public key for messages to Alice if they are sure that it is actually Alice's public key.
②	Bob encrypts his message with Alice's public key.
③	Alice decrypts the encrypted message from Bob with her private key. As only Alice has the private key and never discloses it, only she can decrypt the message. With her private key, she can decrypt any message encrypted with her public key - not only messages from Bob.

Figure 3-8 Asymmetric encryption

The system can be compared to a mailbox into which anyone can put a message, but from which only the person with the key can remove messages.

- Advantages: A message encrypted with a public key can only be decrypted by the owner of the private key. As another (private) key is required for decryption, it is also much harder to work out the decryption key on the basis of large numbers of encrypted messages. This means that the public key does not have to be kept strictly confidential, unlike with symmetric keys.

  Another advantage is easier distribution of public keys. No specially secured channel is required in asymmetric cryptography to transfer the public key from the recipient to the sender encrypting the messages. Less work is thus required in managing the keys than would be the case in symmetric encryption procedures.
- Disadvantages: Complex algorithm (e.g. RSA, named after the three mathematicians Rivest, Shamir and Adleman), and therefore poorer performance than with symmetric encryption.

Encryption processes in practice

In practice, for example with a CPU Web server and Secure Open User Communication, the TLS protocol is used below the relevant application layer. Application layers are HTTP or SMTP, for example, as detailed above.

TLS (Transport Layer Security) uses a combination of asymmetric encryption and symmetric encryption (hybrid encryption) for secure data transfer, for example, over the Internet, and uses the following subprotocols:

- TLS Handshake Protocol, responsible for authentication of communication partners and negotiation of the algorithms and keys to be used for subsequent data transfer on the basis of asymmetric encryption.
- TLS Record Protocol, responsible for encryption of user data with symmetric encryption and data exchange.

Both asymmetric and symmetric encryption are considered secure encryption schemes - there is basically no difference in security between the two procedures. The degree of security depends on parameters such as the selected key length.

Abuse of encryption

You cannot tell what identity is assigned to a public key from the bit string. A fraud could provide their public key and claim to be someone else. If a third party then uses this key thinking that they are addressing their required communication partner, confidential information could end up with the fraud. The fraud then uses their private key to decrypt the message that was not intended for them, and sensitive information falls into the wrong hands.

To prevent this type of abuse, the communication partners must be confident that they are dealing with the right communication partner. This trust is established by using digital certificates in a PKI.

3.6.3 Authenticity and integrity through signatures

Attacks from programs that intercept communication between the server and client and act as if they themselves were client or server, are called man-in-the-middle attacks. If the false identity of these programs is not detected, they can obtain important information about the S7 program, for example, or set values in the CPU and attack a machine or plants. Digital certificates are used to avoid such attacks.

Secure communication uses digital certificates that meet the X.509 standard of the International Telecommunication Union (ITU). This allows the identity of a program, a computer or an organization to be checked (authenticated).

How certificates establish trust

The main role of X.509 certificates is to bind an identity with the data of a certificate subject (for example, e-mail address or computer name) to the public key of the identity. Identities can be people, computers or machines.

Certificates are issued by certificate authorities (Certificate Authority, CA) or by the subject of a certificate itself. PKI systems specify how users can trust the certificate authorities and the certificates that they issue.

The certificate process:

1. Anyone wishing to own a certificate submits a certificate application to a registration authority linked to the certificate authority.
2. The certificate authority assesses the application and applicant on the basis of set criteria.
3. If the identity of the applicant can be clearly established, the certificate authority confirms that identity by issuing a signed certificate. The applicant has now become the certificate subject.

The figure below is a simplified overview of the process. It does not show how Alice can check the digital signature.

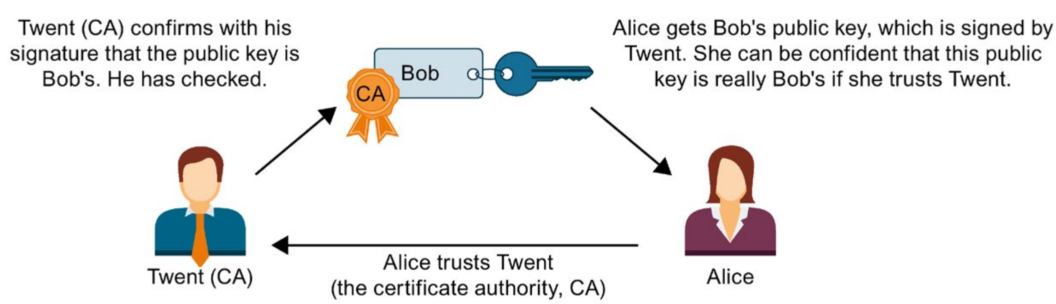


Figure 3-9 Signing of a certificate by a certificate authority

Self-signed certificates

Self-signed certificates are certificates whose signature comes from the certificate subject and not from an independent certificate authority.

Examples:

- You can create and sign a certificate yourself, for example, to encrypt messages to a communication partner. In the example above, Bob (instead of Twent) could himself sign his certificate with his private key. Using Bob's public key, Alice can check that the signature and public key from Bob match. This procedure is sufficient for simple internal plant communication that is to be encrypted.
- A root certificate is, for example, a self-signed certificate, signed by the certificate authority (CA), that contains the public key of the certificate authority.

Features of self-signed certificates

The "CN" (Common Name of Subject) for the certificate subject and "Issuer" attributes of self-signed certificates are identical: You have signed your certificate yourself. The field "CA" (Certificate Autority) must be set to "False"; the self-signed certificate should not be used to sign other certificates.

Self-signed certificates are not embedded in a PKI hierarchy.

Certificate content

A certificate to the X.509 V3 standard, the standard that is also used by STEP 7 and the S7-1500 CPUs, consists primarily of the following elements:

- Public key
- Details of the certificate subject (i.e. the holder of the key), for example, the Common Name (CN) of Subject .
- Attributes such as serial number and validity period
- Digital signature from the certificate authority (CA) confirming that the information is correct.

There are also extensions, for example:

- Specification of what the public key may be used for (Key Usage), for example, signing or key encryption.
  When you create a new certificate with STEP 7, for example in the context of Secure Open User Communication, select the correct entry from the list of possible usages, e.g. "TLS".
- Specification of a Subject Alternative Name (SAN), which is used in secure communication with Web servers (HTTP over TLS), for example, to ensure that the certificate in the address bar of the Web browser also belongs to the Web server specified in the URL.

How signatures are generated and verified

Asymmetric key usage ensures that certificates can be verified: The example of the "MyCert" certificate illustrates the "Sign" and "Verify signature" processes.

Generating a signature:

1. The issuer of the "MyCert" certificate generates a hash value from the certificate data using a specific hash function (for example SHA-1, Secure Hash Algorithm).

   The hash value is a bit string of a constant length. The advantage of the constant length of the hash value is that it always takes the same amount of time to sign.
2. Using the hash value generated in this way and the private key, the issuer of the certificate then generates a digital signature. The RSA signature scheme is often used.
3. The digital signature is saved in the certificate. The certificate is now signed.

Verifying a signature:

1. The authenticator of the "MyCert" certificate obtains the certificate of the issuer and thus the public key.
2. A new hash value is formed from the certificate data with the same hash algorithm that was used for signing (for example SHA-1).
3. This hash value is then compared with the hash value that is determined by means of the public key of the certificate issuer and the signature algorithm for checking the signature.
4. If the signature check produces a positive result, both the identity of the certificate subject as well as the integrity, meaning authenticity and genuineness, of the certificate content are proven. Anyone who has the public key, i.e. the certificate from the certificate authority, can check the signature and thus recognize that the certificate was actually signed by the certificate authority.

The figure below shows how Alice uses the public key in the certificate from Twent (who represents the certificate authority, CA) to verify the signature on Bob's public key. All that is required for verification is therefore the availability of the certificate from the certificate authority at the moment of checking. The validation itself is executed automatically in the TLS session.

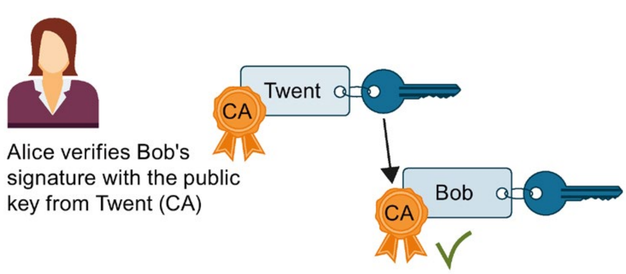

Figure 3-10 Verification of a certificate with the public key of the certificate of a certificate authority

Signing messages

The method described above for signing and verifying also uses the TLS session for signing and verifying messages.

If a hash value is generated by a message and this hash value is signed with the private key of the sender and attached to the original message, the recipient of the message is able to check the integrity of the message. The recipient decrypts the hash value with the public key of the sender, puts together the hash value from the message received and compares the two values. If the values are not the same, the message has been tampered with on the way.

Chain of certificates to root certificate

The certificates of a PKI are often organized hierarchically: The top of the hierarchy is formed by root certificates. Root certificates are certificates that are not signed by a higher-level certificate authority. The certificate subject and certificate issuer of root certificates are identical. Root certificates enjoy absolute trust. They form the "anchor" of trust and must therefore be known to the receiver as trusted certificates. They are stored in an area provided for trusted certificates.

Depending on the PKI, the function of root certificates is, for example, to sign certificates from lower-level certificate authorities, so-called intermediate certificates. This transfers the trust from the root certificate to the intermediate certificate. An intermediate certificate can sign a certificate just like a root certificate; both are therefore referred to as "CA certificates".

This hierarchy can be continued over multiple intermediate certificates until the end-entity certificate. The end-entity certificate is the certificate of the user who is to be identified.

The validation process runs through the hierarchy in the opposite direction: As described above, the certificate issuer is established and the signature checked with the issuer's public key, then the certificate of the higher-level certificate issuer is established along the entire chain of trust to the root certificate.

Conclusion: The chain of intermediate certificates to the root certificate, the certificate path, must be available in every device that is to validate an end-entity certificate of the communication partner, irrespective of the type of secure communication that you configure.

3.6.4 Managing certificates with STEP 7

STEP 7 as of version V14 together with the S7-1500-CPUs as of firmware version 2.0 support the Internet PKI (RFC 5280) in as far as an S7-1500-CPU is able to communicate with devices that also support the Internet PKI.

The usage of X.509 certificates for verifying certificates as described in the preceding sections, for example, is a result of this.

STEP 7 as of V14 uses a PKI similar to Internet PKI. Certificate Revocation Lists (CRLs), for example, are not supported.

Creating or assigning certificates

You create certificates for various applications in STEP 7 for devices with security properties, such as an S7-1500 CPU as of firmware V2.0.

The following areas in the Inspector window of the CPU allow the creation of new certificates or the selection of existing ones:

- "Protection & Security > Certificate manager" - for the generation and assignment of all types of certificates. TLS certificates for Secure Open User Communication are preset for the generation of certificates.
- "Web server > Security" - for the generation and assignment of Web server certificates.
- "OPC UA > Server > Security" - for the generation and assignment OPC UA certificates.

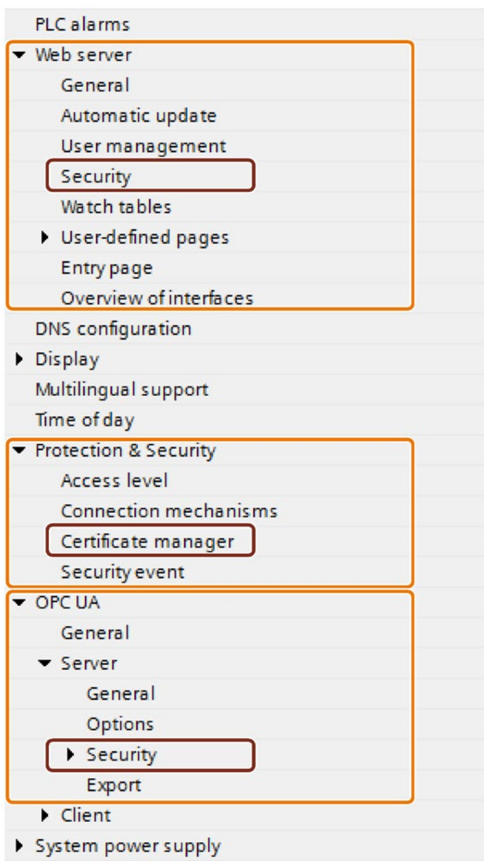

Figure 3-11 Security settings for an S7-1500 CPU in STEP 7

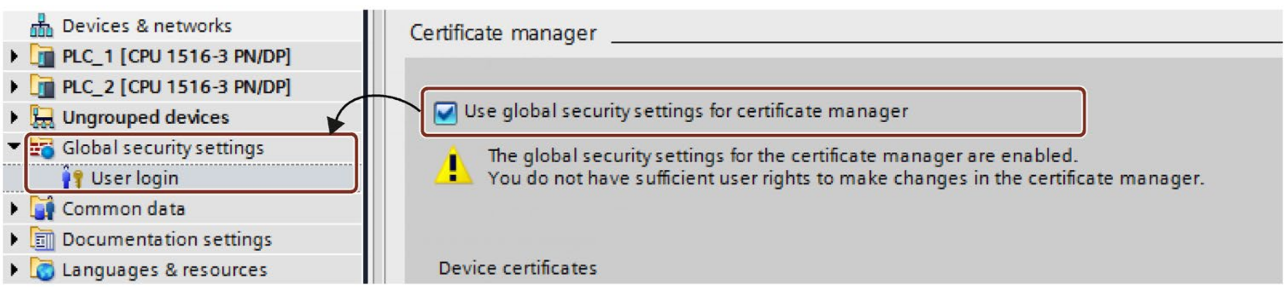
Special features of the section "Protection & Security > Certificate manager"

Only in this section of the Inspector window do you switch between the global, i.e. project-wide, and the local, i.e. device-specific, certificate manager (option "Use global security settings for the certificate manager"). The option decides whether you have access to all the certificates in the project or not.

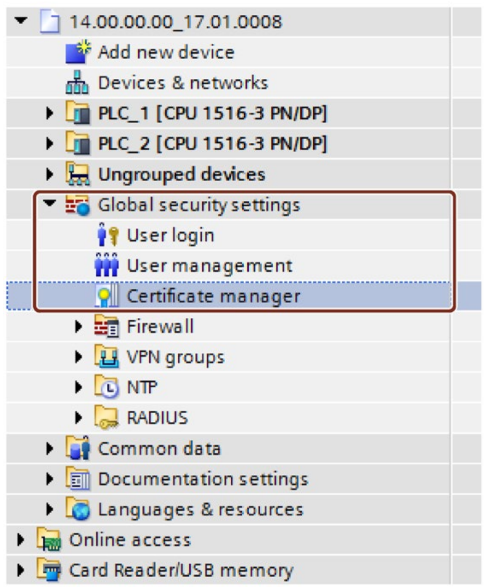
- If you do **not** use the certificate manager in the global security settings, you only have access to the local certificate memory of the CPU. You do not have access, for example, to imported certificates or root certificates. Without these certificates only a restricted functionality is available. You can, for example, only generate self-signed certificates.
- If you use the certificate manager in the global security settings and you are logged on as an administrator, you have access to the global, project-wide certificate memory. You can, for example, assign imported certificates to the CPU, or create certificates that are issued and signed by the project CA (certificate authority of the project).

The figure below shows how the "Global security settings" are shown in the project tree after the "Use global security settings for certificate manager" option has been activated in the Inspector window of the CPU.



When you double-click "User login" in the project tree below the global security settings and log in, a line called "Certificate manager" is displayed, among other data.

When you double-click the "Certificate manager" line, you obtain access to all the certificates in the project, divided into the tabs "CA" (certificate authorities), "Device certificates" and "Trusted certificates and root certificate authorities".



Private keys

STEP 7 generates private keys while generating device certificates and server certificates (end-entity certificates). The location where the private key is stored encrypted depends on the use of the global security settings for the certificate manager:

- If you use global security settings, the private key is stored encrypted in the global (project-wide) certificate memory.
- If you do not use global security settings, the private key is stored encrypted in the local (CPU-specific) certificate memory.

The existence of the private key, which is required to decrypt data, for example, is displayed in the "Private key" column of the "Device certificates" tab of the certificate manager in the global security settings.

When the hardware configuration is loaded, the device certificate, the public key as well as the private key are loaded into the CPU.

NOTICE
The "Use global security settings for certificate manager" option influences the previously used private key: If you have already created certificates without using the certificate manager in the global security settings and then change the option for using the certificate manager, the private keys are lost and the certificate ID can change. A warning draws your attention to this fact. Therefore specify at the beginning of the project configuration which option is required for the certificate manager.

3.6.5 Examples for the management of certificates.

As explained in the preceding sections, certificates are required for every type of secure communication. The following section shows as an example how you handle the certificates with STEP 7 so that the requirements for Secure Open User Communication are fulfilled.

The devices which are involved at the respective communication partners are differentiated below. The respective steps for supplying the required certificates to the communications participants are described. An S7-1500 CPU or an S7-1500 software controller as of firmware version 2.0 is always required.

The general rule is:

While a secure connection is being established (handshake"), the communication partners as a rule only communicate their end-entity certificates (device certificates).

Therefore the CA certificates required to verify the transmitted device certificate must be located in the certificate memory of the respective communication partner.

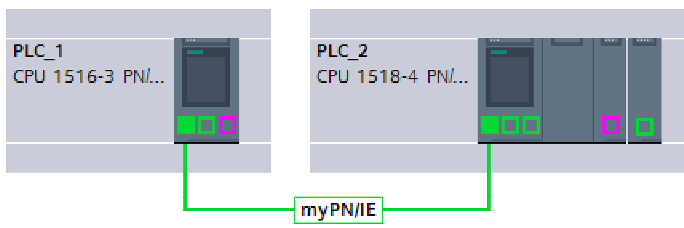
Secure Open User Communication between two S7-1500 CPUs

Two S7-1500-CPUs, PLC_1 and PLC_2, are to exchange data with each other via Secure Open User Communication.

You generate the required device certificates with STEP 7 and assign them to the CPUs as described below.

STEP 7 project certificate authorities (CA of the project) are used to sign the device certificates.

The certificates are to be referenced by their certificate ID in the user program (TCON communication instruction in combination with the associated system data type, for example TCON_IPV4_SEC). STEP 7 assigns the certificate ID automatically during the generation or creation of certificates.



Procedure

STEP 7 automatically loads the required CA certificates together with the hardware configuration to the participating CPUs so that the requirements for certificate verification exist for both CPUs. You therefore only have to generate the device certificates for the respective CPU; STEP 7 does the rest for you.

1. Mark PLC_1 and activate the "Use global security settings for certificate manager" option in the "Protection & Security" section.
2. Log in as a user in the project tree in the "Global security settings" section. For a new project, the "Administrator" role is planned for the first login.
3. Return to the PLC-1 in the "Protection & Security" section. Click in an empty line in the "Certificate subject" column in the "Device certificates" table to add a new certificate.
4. In the drop-down list for selecting a certificate click the "Add" button.

   The "Create Certificate" dialog opens.
5. Leave the default settings in this dialog. They are tailored to the usage of Secure Open User Communication (usage: TLS).

   Tip: Supplement the default name of the certificate subject, in this case the CPU name. In order to differentiate you better leave the default CPU name in case you have to manage a large number of device certificates.

   Example: PLC_1/TLS becomes PLC_1-SecOUC-Chassis17FactoryState.
6. Compile the configuration.

   The device certificate and the CA certificate are part of the configuration.
7. Repeat the steps described above for PLC_2.

In the next step you have to create the user programs for the data exchange and load the configurations together with the program.

Using self-signed certificates instead of CA certificates

When creating device certificates you can select the "Self-signed" option. You can create self-signed certificates without being logged in for the global security settings. This procedure is not recommended because the resulting certificates do not exist in the global certificate memory and can therefore not be assigned directly to a partner CPU.

As described above, you should select the name of the certificate subject with care so that the right certificate can be assigned to a device without any doubt.

Verification with the CA certificates of the STEP 7 project is not possible for self-signed certificates. To ensure that self-signed certificates can be verified you have to include the self-signed certificates of the communication partner into the list of trusted partner devices for each CPU. To this purpose you must have activated the "Use global security settings for certificate manager" option and be logged in as a user in the global security settings.

Proceed as follows to add the self-signed certificate of the communication partner of the CPU:

1. Mark PLC_1 and navigate to the "Certificates of partner devices" table in the "Protection & Security" section.
2. Click in an empty line in the "Certificate subject" column in the "Device certificates" table to add a new certificate.
3. Select the self-signed certificate of the communication partner from the drop-down list and confirm the selection.

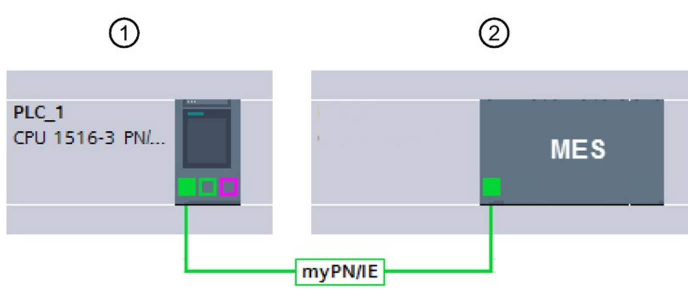
In the next step you have to create the user programs for the data exchange and load the configurations together with the program.

Secure Open User Communication between S7-1500 CPU as a TLS client and an external device as a TLS server

Two devices are to exchange data with each other via TLS connection or TLS session, for example, exchanging recipes, production data or quality data:

- An S7-1500 CPU (PLC_1) as TLS client; the CPU uses Secure Open User Communication
- An external device, for example a Manufacturing Execution System (MES), as TLS server

The S7-1500 CPU establishes the TLS connection / session to the MES system as TLS client.



① TLS client
② TLS server

The S7-1500 CPU requires the CA certificates of the MES system to authenticate the TLS server: The root certificate and, if appropriate, the intermediate certificates for verifying the certificate path.

You have to import these certificates into the global certificate memory of the S7-1500 CPU.

Proceed as follows to import certificates of the communication partner:

1. Open the certificate manager in the global security settings in the project tree.
2. Select the appropriate table (trusted certificates and root certificate authorities) for the certificate to be imported.
3. Right-click in the table to open the shortcut menu. Click "Import" and import the required certificate or the required CA certificates.

   Through the import the certificate has a certificate ID assigned to it and can be assigned to a module in the next step.
4. Mark PLC_1 and navigate to the "Certificates of partner devices" table in the "Protection & Security" section.
5. Click in an empty line in the "Certificate subject" column to add the imported certificates.
6. Select the required CA certificates of the communication partner from the drop-down list and confirm the selection.

Optionally the MES system can also request a device certificate of the CPU to authenticate the CPU (i.e., the TLS client). In this case, the CA certificates of the CPU must be made available to the MES system. The prerequisite for importing the certificates into the MES system is a preceding export of the CA certificates from the STEP 7 project of the CPU. Follow these steps:

1. Open the certificate manager in the global security settings in the project tree.
2. Select the matching table (CA certificate) for the certificate to be exported.
3. Right-click the selected certificate to open the shortcut menu.
4. Click "Export".
5. Select the export format of the certificate.

In the next step you have to create the user programs for the data exchange and load the configurations together with the program.

Secure Open User Communication between an S7-1500 CPU as TLS server and an external device as TLS client

If the S7-1500 CPU acts as TLS server and the external device, for example an ERP system (Enterprise Resource Planning System) establishes the TLS connection / session, you require the following certificates:

- For the S7-1500 CPU, you generate a device certificate (server certificate) with a private key and download it with the hardware configuration into the S7-1500 CPU. You use the "Signed by certificate authority" option when generating the server certificate.

  The private key is required for the key exchange as explained in the figure for the example "HTTP over TLS".
- You have to export the CA certificate of the STEP 7 project for the ERP system and import / load it into the ERP system. With the CA certificate the ERP system verifies the server certificate of the S7-1500 that was transferred from the CPU to the ERP system during the establishment of the TLS connection / session.

① TLS server
② TLS client

Figure 3-12 Secure OUC between an S7-1500 CPU and ERP system

The required steps are described in the preceding sections.

Secure Open User Communication to a mail server (SMTP over TLS)

An S7-1500 CPU can establish a secure connection to an e-mail server with the communication instruction TMAIL-C.

The system data types TMail_V4_SEC and TMail_QDN_SEC allow you to determine the partner port of the e-mail server and thus to reach the e-mail server via "SMTP over TLS".

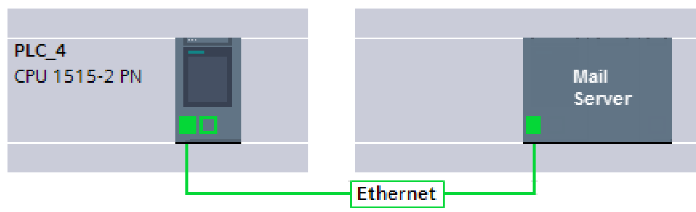


Figure 3-13 Secure OUC between a S7-1500 CPU and a mail server

Requirement for secure e-mail connection is the importing of the root certificate and the intermediate certificates of the mail server (provider) into the global certificate memory of the S7-1500 CPU. By means of these certificates the CPU can check the server certificate that is sent by the mail server during the establishment of the TLS connection / session.

Proceed as follows to import certificates of the mail server:

1. Open the certificate manager in the global security settings in the project tree.
2. Select the appropriate table (trusted certificates and root certificate authorities) for the certificate to be imported.
3. Right-click in the table to open the shortcut menu. Click "Import" and import the required certificate or the required CA certificates.

   As a result of the import, the certificate has a certificate ID assigned to it and can be assigned to a module in the next step.
4. Mark PLC_1 and navigate to the "Certificates of partner devices" table in the "Protection & Security" section.
5. Click in an empty line in the "Certificate subject" column to add the imported certificates.
6. Select the required CA certificates of the communication partner from the drop-down list and confirm the selection.

In the next step you have to create the user programs for the e-mail client function of the CPU and load the configurations together with the program.

3.6.6 Example: HTTP over TLS

The following paragraphs show how the mechanisms described are used to establish a secure communication between a Web browser and the Web server of an S7-1500 CPU.

Initially the changes for the "Permit access only with HTTPS" option in STEP 7 are described. As of STEP 7 V14 you have the possibility to influence the server certificate of the Web server of an S7-1500 CPU as of firmware V2.0: The server certificate is generated as of these versions with STEP 7.

In addition it illustrates the processes that are executed when a website of the CPU Web server is called with a Web browser of a PC through an encrypted HTTPS connection.

Using Web server certificates for S7-1500 CPUs, FW V2.0 or higher

For S7-1500 CPUs with a firmware version before V2.0, you were able to set "Permit access only with HTTPS" when setting the Web server properties, without specific requirements applying.

You did not have to handle certificates for these CPUs; the CPU automatically generates the certificates required for the Web server.

For S7-1500 CPUs as of firmware V2.0, STEP 7 generates the server certificate (end-entity certificate) for the CPU. You assign a server certificate to the Web server in the properties of the CPU (Web server > Security).

Because a server certificate name is always preset, there is no change to the easy configuration of the Web server: You activate the Web server. The "Permit access only with HTTPS" option is enabled by default - STEP 7 generates a server certificate with the default name during compiling.

Irrespective of whether you use the certificate manager in the global security settings or not: STEP 7 has all the information required to generate the server certificate.

In addition, you have the possibility to determine the properties of the server certificate, for example, the name or the validity period.

Loading the Web server certificate

The server certificate generated by STEP 7 is then automatically also loaded to the CPU when the hardware configuration is loaded.

- If you use the certificate manager in the global security settings, the certificate authority of the project (CA certificate) signs the server certificate of the Web server: During loading the CA certificate of the project is loaded as well automatically.
- If you do not use the certificate manager in the global security settings, STEP 7 generates the server certificate as a self-signed certificate.

When you address the Web server of the CPU over the IP address of the CPU, a new server certificate (end-entity certificate) must be generated and loaded with each change in the IP address of an Ethernet interface of the CPU. This is necessary because the identity of the CPU changes with the IP address – and the identity requires a signature in accordance with the PKI rules.

You can avoid this problem by addressing the CPU with a domain name instead of its IP address, for example "myconveyer-cpu.room13.myfactory.com". For this purpose, you have to manage the domain names of the CPU via a DNS server.

Supplying a Web browser with a CA certificate of the Web server

In the Web browser the user who accesses the websites of the CPU through HTTPS should install the CA certificate of the CPU. If no certificate is installed, a warning is output recommending that you do not use the page. To view this page, you must explicitly "Add an exception".

The user receives the valid root certificate for download from the "Intro" Web page of the CPU Web server under "Download certificate".

STEP 7 offers a different possibility: Export the CA certificate of the project with the certificate manager into the global security settings in STEP 7. Subsequently import the CA certificate into the browser.

Course of the secure communication

The figure below shows, in simplified terms, how communication is established ("handshake") focusing on the negotiation of keys used for data exchange (here with HTTP over TLS).

However, the course can be applied to all communication options that are based on the usage of TLS, i.e. also for Secure Open User Communication (see Basics for secure communication).

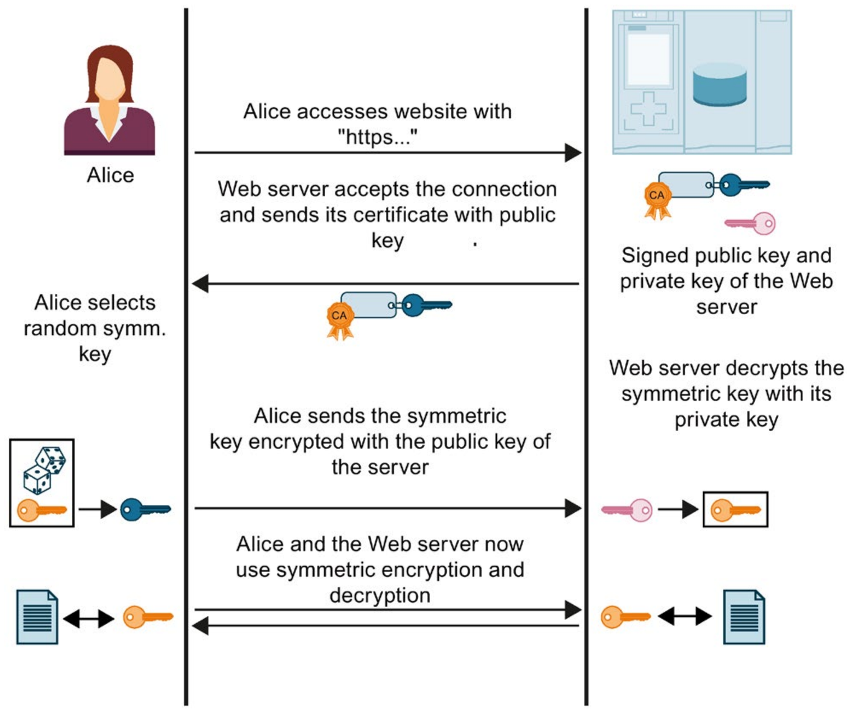

Figure 3-14 Handshake with https

The figure does not show the measures taken at Alice's end (browser) to verify the certificate sent by the Web server. Whether Alice can trust the Web server certificate received and therefore the identity of the Web server, and can accept the exchange of data, depends on positive verification.

The steps for verifying the authenticity of the Web server:

1. Alice must know the public keys of all relevant certificate authorities, which means she requires the complete certificate chain to verify the Web server certificate (i.e. the end-entity certificate of the Web server):

   Alice will generally have the required root certificate in her certificate memory. When a Web browser is installed, a range of trusted root certificates is also installed. If she does not have the root certificate, she has to download it from the certificate authority and install it in the certificate store of the browser. The certificate authority can also be the device on which the Web server is located.

   You have the following options for obtaining the intermediate certificates:

   – The server itself sends the required intermediate certificates to Alice along with its end-entity certificate – in the form of a signed message so that Alice can verify the integrity of the certificate chain.

   – The certificates often contain the URLs of the certificate issuer. Alice can load the required intermediate certificates from these URLs.

   When you work with certificates in STEP 7 it is always assumed that you have imported the intermediate certificates and the root certificate into the project and assigned them to the module.

2. Alice validates the signatures in the certificate chain with the public keys of the certificates.

3. The symmetric key must be generated and transferred to the Web server.

4. If the Web server is addressed by its domain name, Alice also verifies the identity of the Web server in accordance with the Internet PKI rules defined in RFC 2818. She is able to do this because the URL of the Web server, in this case the "Fully Qualified Domain Name" (FQDN), is saved in the end-entity certificate of the Web server. If the certificate entry in the "Subject Alternative Name" field corresponds to the entry in the address bar of the browser, everything is fine.

The process continues with the exchange of data with the symmetric key, as shown in the figure above.

3.7 SNMP

3.7.1 Disabling SNMP

The network management protocol SNMP (Simple Network Management Protocol) is a protocol that uses various services and tools for detection and diagnostics of the network topology.

Which SNMP requests the S7-1500 CPUs and the S7-1200 CPUs can receive, is described in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/79993228).

SNMP uses the transport protocol UDP. SNMP recognizes two network components, the SNMP manager and the SNMP client. The SNMP manager monitors the network nodes: The SNMP clients collect the various network-specific information in the individual network nodes and store it in a structured form in the MIB (Management Information Base). Various services and tools can run detailed network diagnostics with the help of these data.

Under certain conditions, it is useful to disable SNMP. Examples:

- The security guidelines in your network do not allow the use of SNMP.
- You use your own SNMP solution, e.g. with your own communications instructions.

If you disable SNMP for a device, various options for diagnostics of the network topology (e.g. using the PRONETA tool or the Web server of the CPU) are no longer available to you.

Disabling SNMP

To disable SNMP for one of the integrated interfaces of a S7-1500 CPU, follow these steps:

1. In STEP 7, create a data block that contains the structure of data record B071$_H$.
   – The following table shows the structure of the data record B071$_H$.

Byte	Element	Code	Explanation
0-1	BlockID	F003$_H$	Header The data record length is counted starting at byte 4 "Version".
2-3	BlockLength	8	
4	Version	01 $_H$	
5	Subversion	00 $_H$	
6-7	Reserved	-	-
8-11	SNMP controller	Disable/enable SNMP	If you want to disable SNMP, enter the value 0. If you want to enable SNMP, enter the value 1.

2. Transfer the data record B071$_H$ in the startup OB (OB100) with the WRREC instruction (write data record) to the CPU.
   Use the hardware ID of an integrated interface of the CPU here.

3.7.2 Example: Disabling SNMP for a CPU 1516-3 PN/DP

Task

As the security guidelines in your network do not allow SNMP, you want to disable SNMP for a CPU 1516-3 PN/DP.

Requirements

- CPU 1516-3 PN/DP with firmware version V2.0
- STEP 7 as of V14

Solution

First, create a data block that contains the structure of data record $B071_H$. The figure below shows the data block "Deactivate SNMP". The data block "Deactivate SNMP" contains the data record $B071_H$ as well as additional tags that you use to transfer the data record. The tag "snmp_deactivate" is used to trigger the job for WRREC. Place this tag in the retentive memory area so that the value is also available in the startup OB (OB100).

Deactivate SNMP

	Name	Data type	Start value	R...	A...	W...	V...	Comment
1	Static			☐	☐	☐	☐	
2	snmp_deactivate	Bool	TRUE	☑	☑	☐	☑	Tag for deactivation
3	snmp_record	Struct		☑	☑	☐	☑	Data record 16#B071
4	BlockID	UInt	16#F003	☑	☑	☐	☑	
5	BlockLenght	UInt	8	☑	☑	☐	☑	
6	Version	USInt	1	☑	☑	☐	☑	
7	Subversion	USInt	0	☑	☑	☐	☑	
8	Reserved	UInt	0	☑	☑	☐	☑	
9	SNMPControl	UDInt	0	☑	☑	☐	☑	
10	snmp_done	Bool	false	☐	☑	☐	☑	
11	snmp_error	Bool	false	☐	☑	☐	☑	
12	snmp_status	DWord	16#0	☐	☑	☐	☑	

Figure 3-15 Example: Data block for disabling SNMP

Transfer the data record $B071_H$ in the startup OB (OB100) to CPU 1516-3 PN/DP with the WRREC instruction (write data record).

In the following program code, the data record $B071_H$ is transferred with the WRREC instruction in a REPEAT UNTIL loop.

```
ORGANIZATION_BLOCK "Startup"
TITLE = "Complete Restart"
{ S7_Optimized_Access := 'TRUE' }
VERSION : 0.1
BEGIN
 REPEAT
 "WRREC_DB_1"
 (REQ := "Deactivate SNMP".snmp_deactivate,
  //Transfer data record
 INDEX:=16#B071,
  //Data record number for SNMP deactivation
 ID:="Local~PROFINET_interface_1",
  //any integrated PROFINET Interface
 DONE => "Deactivate SNMP".snmp_done,
 ERROR => "Deactivate SNMP".snmp_error,
 STATUS => "Deactivate SNMP".snmp_status,
 RECORD := "Deactivate SNMP".snmp_record)
  //Data record
 UNTIL "Deactivate SNMP".snmp_done OR "Deactivate SNMP".snmp_error
 END_REPEAT;
END_ORGANIZATION_BLOCK
```

Using program code

You will find the full program code here.

Follow these steps to apply the program code to your project:

1. Copy the entire program code to the clipboard with Ctrl+A, Ctrl+C.
2. Open a text editor (e.g. "Editor").
3. Paste the content of the clipboard to the text editor with Ctrl+V.
4. Save the document as an scl file, e.g. SNMP_DEACT.scl.
5. Open your project in STEP 7.
6. Import the scl file as an external source.
   You will find further information on importing external sources in the STEP 7 online help.
7. Generate the startup OB and the data blocks. (right-click on the scl file, shortcut menu: "Generate blocks from source")

Re-enabling SNMP

With small changes, you can use the program code used above to enable SNMP.

In the user program, assign the "Deactivate SNMP".snmp_record.SNMPControl tag the value "1":

```
"Deactivate SNMP".snmp_record.SNMPControl := 1;
```

SNMP will then be enabled again the next time the CPU is started.

4 PG communication

Properties

Using PG communication, the CPU or another module capable of communication exchanges data with an engineering station (for example PG, PC). The data exchange is possible via PROFIBUS and PROFINET subnets. The gateway between S7 subnets is also supported.

PG communication provides functions needed to load programs and configuration data, run tests, and evaluate diagnostic information. These functions are integrated in the operating system of the module capable of communication.

A PG/PC can be connected to a CPU online. The PG/PC can operate a maximum of 4 online connections at one time (for example to 4 CPUs).

Requirements

- The PG/PC is physically connected to the communication-capable module.
- If the communication-capable module is to be reached via S7 routing, the hardware configuration has to be loaded in the participating stations (S7 router and end point).

Procedure for connecting online

You must establish an online connection to the CPU for the programming device communication:

1. Select the CPU in the project tree in STEP 7.
2. Select the "Online > Go online" menu command.
3. In the "Go online" dialog, make the following settings for your online connection:
   - Select interface type (e.g. PN/IE) in the "Type of PG/PC interface" drop-down list.
   - In the "PG/PC interface" drop-down list, select the PG/PC interface (e.g. Ind. Ethernet card) you want to use to establish the online connection.
   - Select the interface or the S7 subnet with which the programming device/PC is physically connected from the "Connection to interface/subnet" drop-down list.

– If the communication-capable module can be reached via an S7 router (gateway), select the S7 router that connects the subnets in question from the "1st gateway" drop-down list.

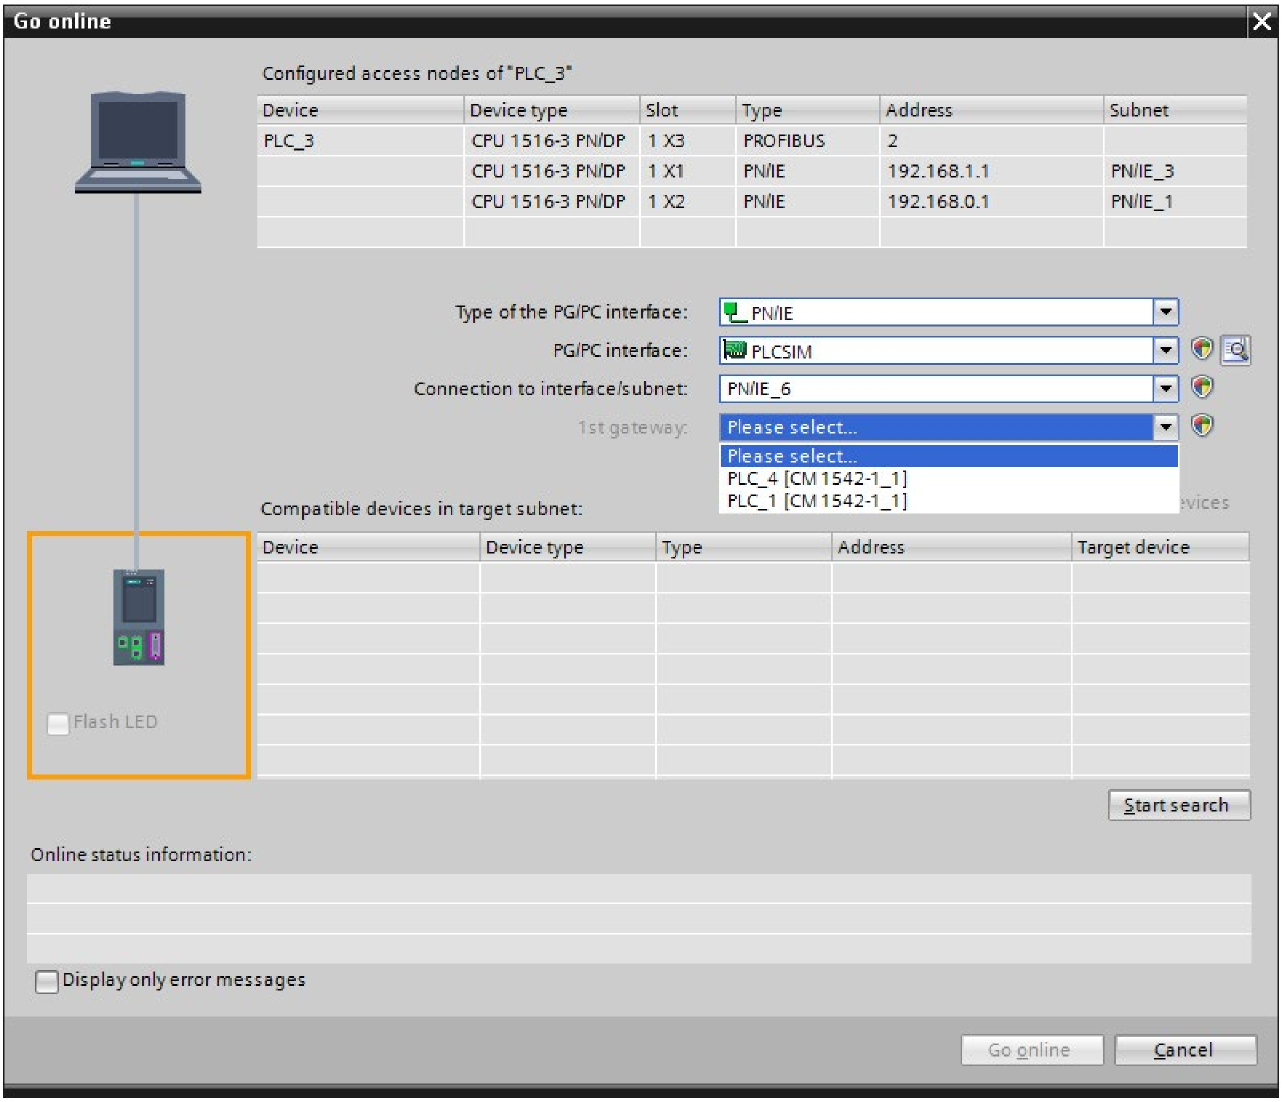

Figure 4-1 Setting up PG communication

4. Click "Start search".
   All devices that you can address with PG communication appear shortly thereafter in the table "Compatible devices in target subnet".
5. In the "Compatible devices in target subnet" table, select the relevant CPU and confirm with "Go online".

Additional information

You can find more information on "Go online" in the STEP 7 online help.

5 HMI communication

Properties

Using HMI communication, one or more HMI devices (for example HMI Basic/Comfort/Mobile Panel) exchanges data with a CPU for operator control and monitoring with via the PROFINET or PROFIBUS DP interface. The data exchange is via HMI connections.

If you want to set up several HMI connections to a CPU, use for example:

- The PROFINET and PROFIBUS DP interfaces of the CPU
- CPs and CMs with the relevant interfaces

Procedure for setting up HMI communication

As soon as you drag-and-drop a tag, for example a tag from a global data block into an HMI screen or into the HMI tag table, STEP 7 automatically sets up an HMI connection. Alternatively, you can also set up the HMI connection yourself.

To set up an HMI connection, follow these steps.

1. Configure the HMI device in an existing configuration with a CPU in the network view of the Devices & networks editor of STEP 7.
2. Select the "Connections" button and then "HMI connection" from the drop-down list.
3. Drag-and-drop a line between the end points of the connection (HMI device and CPU). The end points are highlighted in color. If the required S7 subnet does not yet exist, it is created automatically.

4. In the "Connections" tab, select the row of the HMI connection.

   In the "General" area of the "Properties" tab, you see the properties of the HMI connection, some of which you can change.

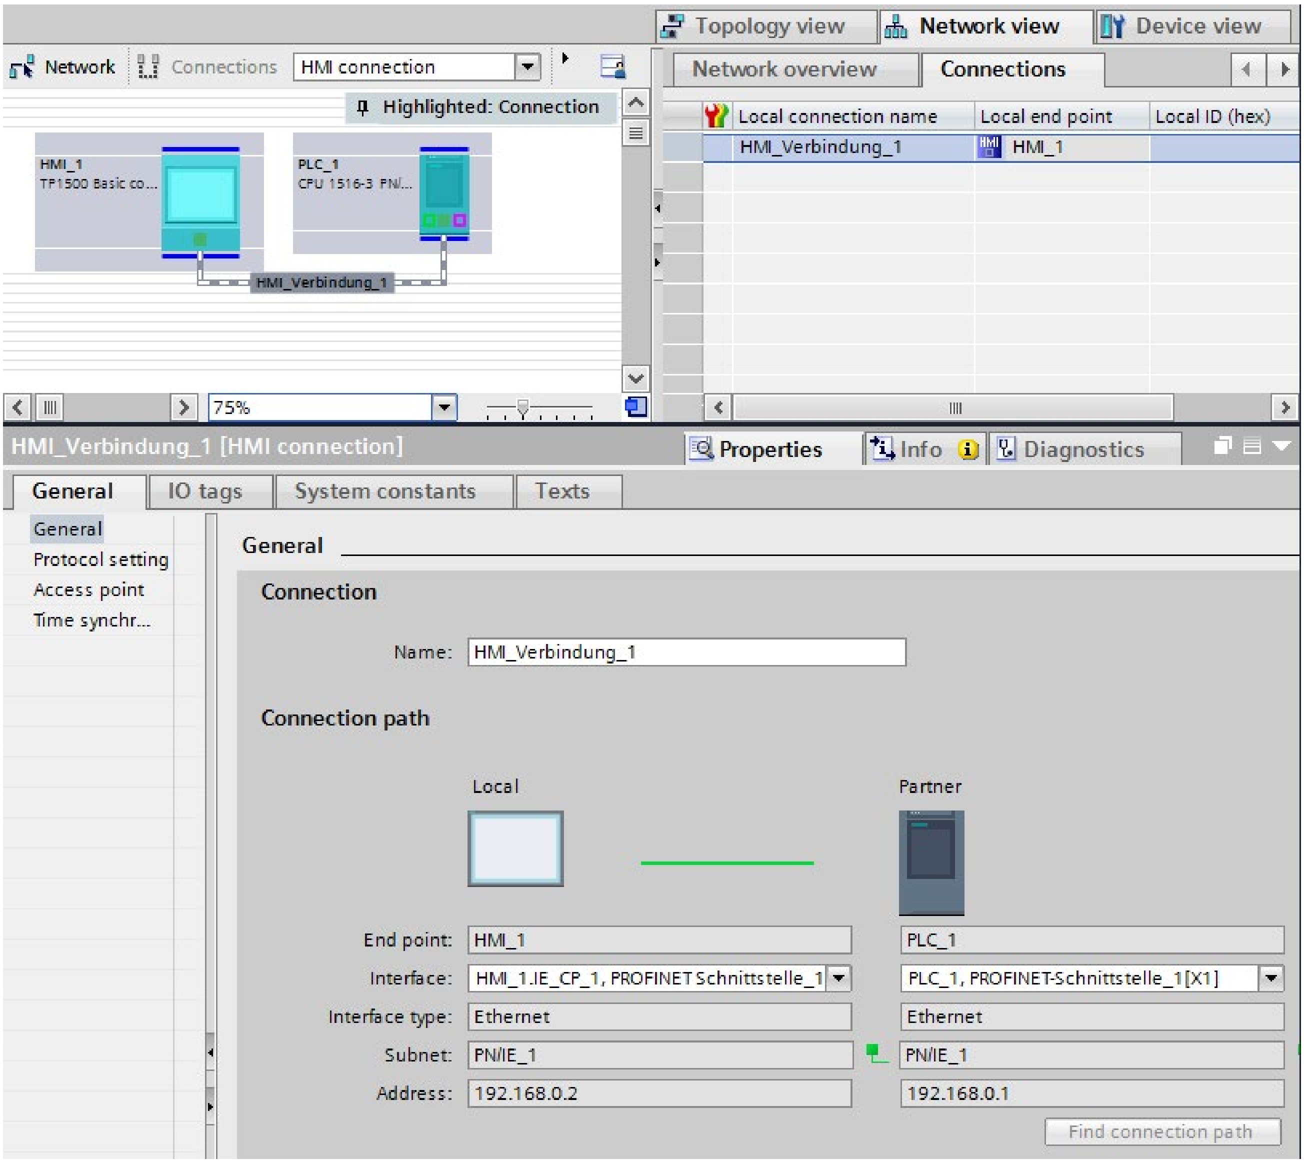

Figure 5-1 Setting up HMI communication

5. Download the hardware configuration to the CPU.
6. Download the hardware configuration to the HMI device.

Additional information

You can find information on S7 routing for HMI connections in the section S7 Routing (Page 260).

You can find more information on setting up HMI connections in the STEP 7 online help.

Open User Communication 6

6.1 Overview of Open User Communication

Features of Open User Communication

Through Open User Communication, also called "open communication", the CPU exchanges data with another device capable of communication. Open User Communication has the following features and characteristics:

- Open standard (communication partners can be two SIMATIC CPUs or a SIMATIC CPU and a suitable third-party device).
- Communication via various protocols (in STEP 7 known as "Connection types")
- High degree of flexibility in terms of the data structures transferred; this allows open data exchange with any communications devices as long as these support the connection types available.
- Secure Communication: To protect your automation system, you can exchange data securely over Open User Communication. With Secure Open User Communication, the data is sent signed and encrypted.
- Open User Communication is possible in various automation systems, see technical specifications of the respective manuals.
  Examples:
  - Integrated PROFINET / Ind. Ethernet interfaces of CPUs (S7-1500, ET 200SP CPU, S7-1500 Software Controller, CPU 1516pro-2 PN)
  - PROFINET / Ind. Ethernet interfaces of communications modules (for example CP 1543-1, CM 1542-1)

Information on Secure Open User Communication is available in the section Secure Communication (Page 37).

Information on S7-1500R/H

You can find information on Open User Communication with the S7-1500R/H redundant system in section Communication with the redundant system S7-1500R/H (Page 283).

6.2 Protocols for Open User Communication

Protocols for Open User Communication

The following protocols are available for open communication:

Table 6- 1 Transport protocols for open communication

Transport protocol	Via interface
TCP according to RFC 793	PROFINET/Industrial Ethernet
ISO-on-TCP according to RFC 1006 (Class 4)	PROFINET/Industrial Ethernet
ISO according to ISO/IEC 8073	Industrial Ethernet (only CP 1543-1)
UDP according to RFC 768	PROFINET/Industrial Ethernet
FDL	PROFIBUS

Table 6- 2 Application protocols for open communication

Application protocol	Used transport protocol
Modbus TCP	**TCP** according to RFC 793
E-mail	**TCP** according to RFC 793
FTP	**TCP** according to RFC 793

TCP, ISO-on-TCP, ISO, UDP

Prior to data transfer, these protocols (except UDP) establish a transport connection to the communications partner. Connection-oriented protocols are used when potential loss of data needs to be avoided.

The following is possible with UDP:

- Unicast to one device or broadcast to all devices on PROFINET via the PROFINET interface of the CPU or the Industrial Ethernet interface of the CP 1543-1
- Multicast to all recipients of a multicast group via the PROFINET interface of the CPU* or the PROFINET / Industrial Ethernet interface of the CP 1543-1

* As of firmware version V2.0, the PROFINET interface of the CPU supports a maximum of 5 multicast groups

Maximum user data lengths UDP: Which maximum user data length is supported for the UPD is described in the technical specifications in the respective manuals.

Protocol for communication via PROFIBUS: FDL

Data transfer via an FDL connection (Fieldbus Data Link) is suitable for the transfer of related blocks of data to a communications partner on PROFIBUS that supports the sending and receiving of data according to the FDL service SDA (Send Data with Acknowledge) according to EN 50170, Vol 2. Both partners have the same rights; in other words, each partner can initiate sending and receiving event-driven.

In keeping with the FDL service SDN (Send Data with No Acknowledge) according to EN 50170, Vol 2, the following is possible with FDL:

- Broadcast to all devices on PROFIBUS via the PROFIBUS interface of the CM 1542-5
- Multicast to all recipients of a multicast group via the PROFIBUS interface of the CM 1542-5

Modbus TCP

The Modbus protocol is a communication protocol with linear topology based on a master/slave architecture. In the Modbus TCP (Transmission Control Protocol), the data is transmitted as TCP/IP packets.

Communication is controlled solely by suitable instructions in the user program.

E-mail and FTP

You can use email to send for example, data block contents (e.g. process data) as an attachment.

You can use the FTP connection (FTP = File Transfer Protocol) to transmit files to and from S7 devices.

The communication is controlled by instructions in the user program at the client end.

Application example: MQTT Publisher for the SIMATIC S7-1500 CPU

The "Message Queue Telemetry Transport" (MQTT) is a simple protocol on the TCP/IP level. It is suitable for the exchange of messages between devices with lower functionality and for the transfer via unreliable networks.

The application example provides a function block with which you can implement the MQTT protocol into the SIMATIC S7-1500.

You can find the application example on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109748872).

Block library for SYSLOG messages

Syslog is a simply structured binary profile on UDP/IP level. It enables applications to send messages, warnings or error states to a Syslog server. Syslog is typically used for computer system management and security monitoring, and has established itself as a standard in the field of protocols.

The "LSyslog" library offers you a solution to implement the Syslog protocol in an S7-1500. In addition to the library, an application example is provided that shows you how to generate Syslog messages in your controller and send them to the Syslog server.

You can find the block library "LSyslog" and the associated application example on the Internet (https://support.industry.siemens.com/cs/ww/en/view/51929235).

6.3 Instructions for Open User Communication

Introduction

You set up Open User Communication via the corresponding connection (for example, TCP connection) as follows:

- By programming in the user programs of the communications partners or
- By configuring the connection in STEP 7 in the hardware and network editor

Regardless of whether you set up the connection by programming or configuring, instructions are always required in the user programs of both communications partners for sending and receiving the data.

Setting up the connection via the user program

If the connection is set up by programming, the connection establishment and termination is implemented using instructions in the user program.

In certain areas of application it is an advantage not to set up the communications connections statically by configuring in the hardware configuration, but to have them set up by the user program. You can set up the connections via a specific application program-controlled and therefore when necessary. Programmed connection setup also allows connection resources to be released following data transfer.

A data structure is necessary for each communications connection that contains the parameters for establishing the connection (for example system data type "TCON_IP_v4" for TCP).

The system data types (SDT) are provided by the system and have a predefined structure that cannot be changed.

The various protocols have their own data structures (see table below). The parameters are stored in a data block ("connection description DB") for example of the system data type TCON_IP_v4.

There are two ways in which you can specify the DB with the data structure:

- Recommendation: Have the data block created automatically in the properties in the program editor during parameter assignment of the connection for the TSEND_C, TRCV_C and TCON instructions.
- Create the data block manually, assign parameters to it and write it directly to the instruction
  Necessary for:
  - Secure OUC
  - Connection over DNS
  - E-mail
  - FTP

You can modify the connection parameters in the "connection description DB".

This FAQ (https://support.industry.siemens.com/cs/ww/en/view/58875807) describes how to program the TCON instruction to set up a connection for Open User Communication between two S7-1500 CPUs.

Protocols, system data types and employable instructions for programmed setup

The following table shows the protocols of the Open User Communication and the matching system data types and instructions.

Table 6- 3 Instructions for programmed setup of the connection

<table>
<tr><th>Protocol</th><th>System data type</th><th>Instructions</th></tr>
<tr><td>TCP</td><td>• TCON_QDN
• TCON_IP_v4</td><td rowspan="3">Establish connection and send/receive data via:
• TSEND_C/TRCV_C or
• TCON, TSEND/TRCV or
• TCON, TUSEND/TURCV (connection can be terminated via TDISCON)</td></tr>
<tr><td>ISO-on-TCP</td><td>• TCON_IP_RFC</td></tr>
<tr><td>ISO according to ISO/IEC 8073 (Class 4)</td><td>• TCON_ISOnative[1]
• TCON_Configured</td></tr>
<tr><td>UDP</td><td>• TCON_IP_v4
• TADDR_Param
• TADDR_SEND_QDN
• TADDR_RCV_IP</td><td>Establish connection and send/receive data via:
• TSEND_C/TRCV_C
• TUSEND/TURCV/TRCV (connection can be terminated via TDISCON)</td></tr>
<tr><td>FDL[1]</td><td>• TCON_FDL</td><td>Establish connection and send/receive data via:
• TSEND_C/TRCV_C or
• TCON, TSEND/TRCV or
• TCON, TUSEND/TURCV (connection can be terminated via TDISCON)</td></tr>
<tr><td>Modbus TCP</td><td>• TCON_IP_v4
• TCON_QDN</td><td>• MB_CLIENT
• MB_SERVER</td></tr>
<tr><td>E-mail</td><td>• TMAIL_v4
• TMAIL_v6
• TMAIL_FQDN</td><td>• TMAIL_C</td></tr>
<tr><td>FTP[2]</td><td>• FTP_CONNECT_IPV4[3]
• FTP_CONNECT_IPV6[3]
• FTP_CONNECT_NAME[3]</td><td>• FTP_CMD</td></tr>
</table>

1 This protocol can only be used with the CM 1542-5

2 This protocol can only be used with the CP 1543-1

3 User-defined data type

The following table shows you the different connections of the Secure Open User Communication and the matching system data types and instructions.

Secure OUC connection	System data type	Instructions
Secure TCP connection from an S7-1500 CPU as TLS client to a third-party PLC (TLS server) Secure TCP connection from an S7-1500 CPU as TLS server to a third-party PLC (TLS client)	• TCON_QDN_SEC	• TSEND_C/TRCV_C • TCON
Secure TCP connection between two S7-1500 stations	• TCON_IP_V4_SEC[1]	
Secure connection to a mail server[2]	• TMAIL_V4_SEC • TMAIL_QDN_SEC	• TMAIL_C (V5.0 or higher)
Secure Modbus TCP connection	• TCON_IP_V4_SEC[1]	• MB_Client • MB_Server
	• TCON_QDN_SEC	

[1] Also possible for CP 1543-1

[2] Secure connection to a mail server also possible with CP1543-1 und TMAIL_C (V4.0)

Setting up the connection with connection configuration

When setting up through the configuration of the connection, the address parameters of the connection are specified in the hardware and network editor of STEP 7.

To send and receive the data, use the same instructions as when the connections are set up by programming:

Table 6- 4 Instructions for sending/receiving with configured connections

Protocol	Send/receive with configured connections
Supported instructions:	
TCP	Send/receive data via: • TSEND_C/TRCV_C or • TSEND/TRCV or • TUSEND/TURCV
ISO-on-TCP	
ISO according to ISO/IEC 8073 (Class 4)	
UDP	Send/receive data via: • TSEND_C/TRCV_C or • TUSEND/TURCV
FDL	Send/receive data via: • TSEND_C/TRCV_C or • TSEND/TRCV or • TUSEND/TURCV
Modbus TCP	Not supported
E-mail	Not supported
FTP	Not supported

Additional instructions for open communication

You can use the following instructions for connections set up in the user program as well as for configured connections:

- T_RESET: Terminating and establishing a connection
- T_DIAG: Check the connection

Basic examples for Open User Communication

The Siemens Online Support offers you function blocks (FBs) that facilitate the handling of the instructions of the Open User Communication. You can find the function block with corresponding examples on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109747710).

Additional information

The STEP 7 online help describes:

- The user and system data types
- The instructions for open communication
- The connection parameters

You will find information about the allocation and release of connection resources in the section Allocation of connection resources (Page 271).

See also

Secure Open User Communication (Page 94)

6.4 Open User Communication with addressing via domain names

As of firmware version V2.0, S7-1500 CPUs, ET 200SP CPUs and the CPU 1516pro-2 PN support Open User Communication with addressing via Domain Name System (DNS). A DNS client is integrated in the CPU. In the case of communication via DNS, you use domain names as an alias for IP addresses to address communication partners. Addressing of the communication partners via domain names is possible for open communication via TCP and UDP.

At least one DNS server must be located in your network as a requirement for communication via DNS.

The S7-1500 software controller supports communication via DNS for all interfaces that are assigned to the software controller.

Setting up communication via DNS

The DNS client of the CPU must know the IPv4 address of at least one DNS server so that a CPU can establish a connection to a communication partner via its domain name. The CPU supports up to 4 different DNS servers.

To set up communication via domain names for an S7-1500 CPU, follow these steps:

1. Select the CPU in the network view of STEP 7.
2. In the Inspector window go to "Properties" > "General" > "DNS configuration".
3. Enter the IPv4 address of a DNS server in the "DNS server addresses" column of the "Server list" table.
   You can enter up to 4 IPv4 addresses of DNS servers.

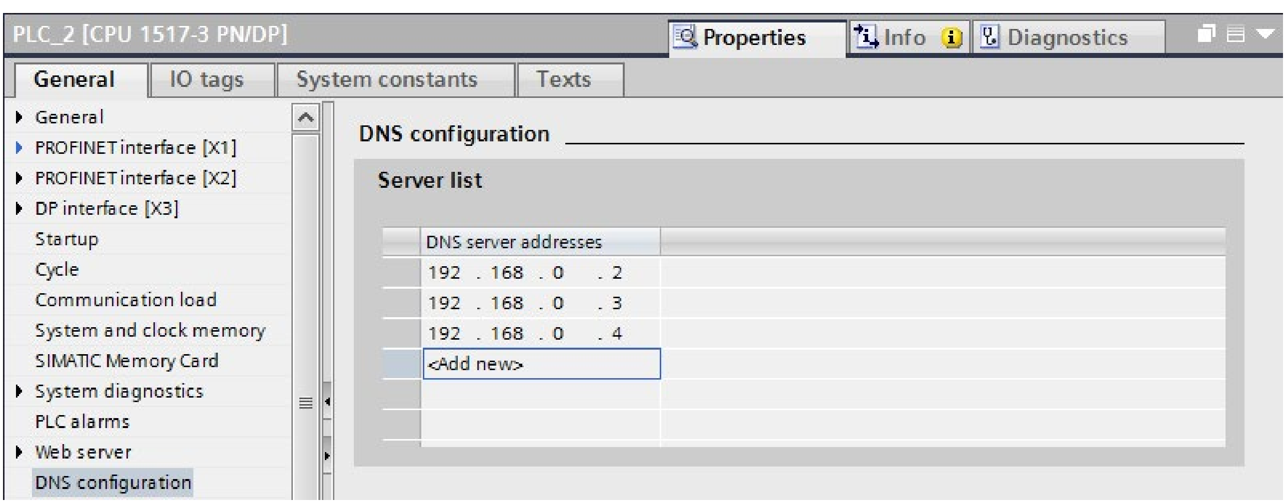

Figure 6-1 Entering DNS server addresses using a CPU 1516-3 PN/DP as an example

Setting up a TCP connection via the domain name of the communication partner

For TCP communication via the domain name you need to create a data block with the TCON_QDN system data type yourself, assign parameters and call it directly at the instruction. The TCON, TSEND_C and TRCV_C instructions support the system data type TCON_QDN:
To set up a TCP connection via the domain name of the communication partner, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_QDN in the global data block.

   The example below shows the global data block "Data_block_1" in which the tag "DNS Connection1" of data type TCON_QDN is defined.

Data_block_1

	Name	Datentyp	Startwert	Kommentar
1	▼ Static			
2	▼ DNS Connection1	TCON_QDN		
3	InterfaceId	HW_ANY	0	not relevant
4	ID	CONN_OUC	16#0	connection reference / identifier
5	ConnectionType	Byte	16#0B	type of connection: 16#0B=11=TCP/IP, 16#13=19=UDP
6	ActiveEstablished	Bool	false	active/passive connection establishment
7	RemoteQDN	String[254]	''	fully or partially qualified domain name of remote partner
8	RemotePort	UInt	0	remote UDP / TCP port number
9	LocalPort	UInt	0	local UDP / TCP port number

Figure 6-2 Data type TCON_QDN

3. Program the parameters of the TCP connection (for example the fully qualified domain name (FQDN)) in the tag of data type TCON_QDN.
4. Create a TCON instruction in the program editor.
5. Interconnect the CONNECT parameter of the TCON instruction with the tag of the data type TCON_QDN.

   In the example below, the CONNECT parameter of the TCON instruction is interconnected with the tag "DNS connection1" (data type TCON_QDN).

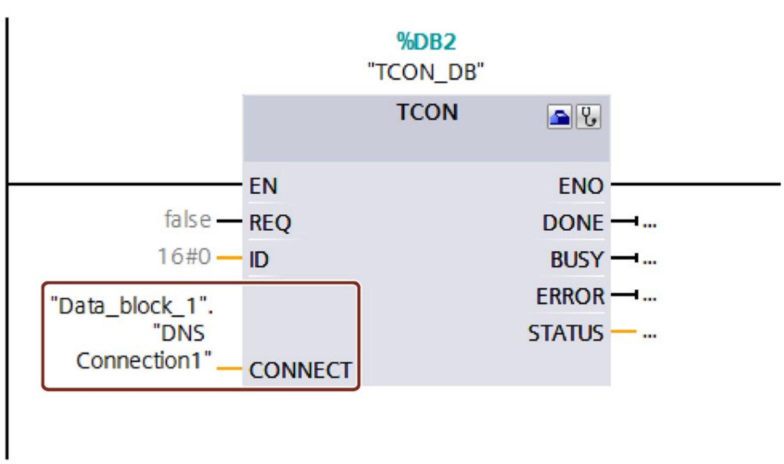

Figure 6-3 TCON instruction

Addressing a UDP connection via the domain name of the communication partner

For S7-1500 CPUs as of firmware version V2.0, you can address the recipient with its fully qualified domain name (FQDN) when sending data via UDP. With the instruction TUSEND at the parameter ADDR, you hereby reference a structure of the type TADDR_SEND_QDN.

The receiver can return an IPv4 or an IPv6 address. With the TURCV instruction at the ADDR parameter, you therefore reference a structure of the TADDR_RCV_IP type. Only this structure can include both IP address types.

Note

Network load

In contrast to the TCP the UDP protocol does not work connection-oriented. For every edge at the block parameter REQ, the TUSEND or TURCV command performs queries of the DNS server. This can lead to high network load or load on the DNS server.

Additional information

You can find more information about the system data types TCON_QDN, TADDR_SEND_QDN and TADDR_RCV_IP in the STEP 7 online help.

How to set up a secure TCP connection via the domain name of the communication partner is described in the section Secure Open User Communication (Page 94).

6.5 Setting up Open User Communication via TCP, ISO-on-TCP, UDP and ISO

Configuring a connection for the TSEND_C, TRCV_C or TCON instructions

Requirement: A TSEND_C, TRCV_C or TCON instruction is created in the programming editor.

1. Select a TCON, TSEND_C or TRCV_C block of Open User Communication in the program editor.
2. Open the "Properties > Configuration" tab in the inspector window.

3. Select the "Connection parameters" group. Until you select a connection partner, only the empty drop-down list for the partner end point is enabled. All other input options are disabled.

   The connection parameters already known are displayed:

   – Name of the local end point
   – Interface of the local end point
   – IPv4 address of the local end point

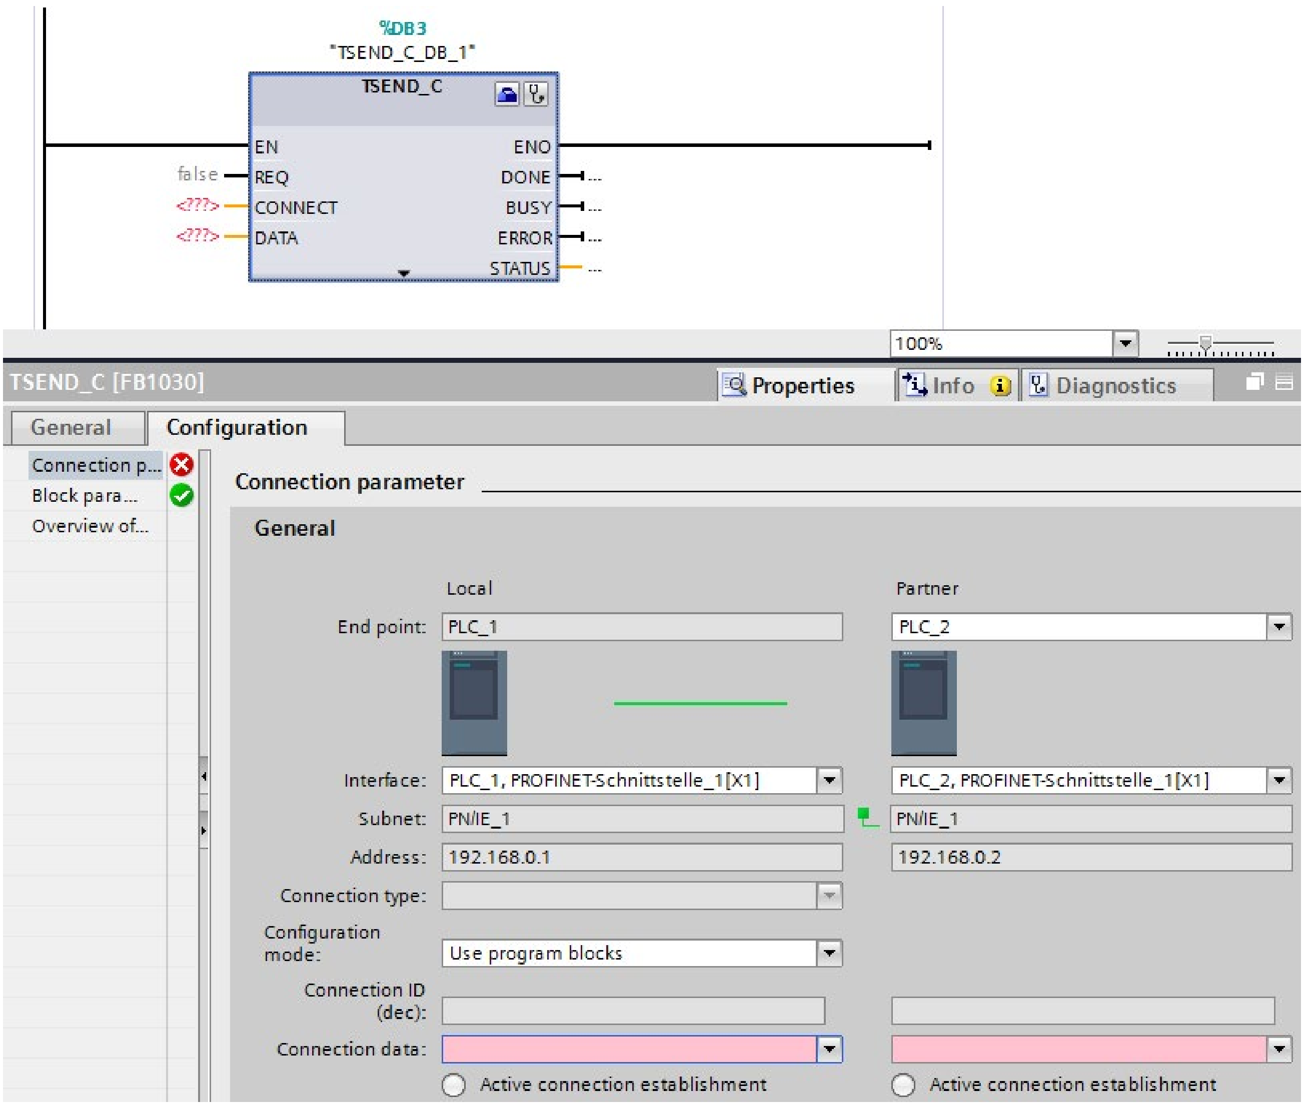

Figure 6-4 Connection parameters for TSEND_C

4. In the drop-down list box of the partner end point, select a connection partner. You can select an unspecified device or a CPU in the project as the communication partner. Certain connection parameters are then entered automatically.

   The following parameters are set:

   – Name of the partner end point
   – Interface of the partner end point

  – IPv4 address of the partner end point

  If the connection partners are networked, the name of the subnet is displayed.

5. In the "Configuration type" drop-down list, select between using program blocks or configured connections.
6. Select an existing connection description DB in the "Connection data" drop-down list or for configured connections select an existing connection under "Connection name". You can also create a new connection description DB or a new configured connection. Later, you can still select other connection description DBs or configured connections or change the names of the connection description DBs in order to create new data blocks:
   – You can also see the selected data block at the interconnection of the CONNECT input parameter of the selected TCON, TSEND_C or TRCV_C instruction.
   – If you have already specified a connection description DB for the connection partner using the CONNECT parameter of the TCON, TSEND_C or TRCV_C instruction, you can either use this DB or create a new DB.
   – If you edit the name of the displayed data block in the drop-down list, a new data block with the changed name but with the same structure and content is generated and used for the connection.
   – Changed names of a data block must be unique in the context of the communication partner.
   – A connection description DB must have the structure TCON_Param, TCON_IP_v4 or TCON_IP_RFC, depending on CPU type and connection.
   – A data block cannot be selected for an unspecified partner.

   Additional values are determined and entered after the selection or creation of the connection description DB or configured connection.

   The following is valid for specified connection partners:
   – ISO-on-TCP connection type
   – Connection ID with default of 1
   – Active connection establishment by local partner
   – TSAP ID
     for S7-1200/1500: E0.01.49.53.4F.6F.6E.54.43.50.2D.31

   The following is valid for unspecified connection partners:
   – TCP connection type
   – Partner port 2000

   The following applies for a configured connection with a specified connection partner:
   – TCP connection type
   – Connection ID with default of 257
   – Active connection establishment by local partner
   – Partner port 2000

   The following applies for a configured connection with an unspecified connection partner:
   – TCP connection type
   – Local port 2000

7. Enter a connection ID as needed for the connection partner. No connection ID can be assigned to an unspecified partner.

   Note

   You must enter a unique value for the connection ID at a known connection partner. The uniqueness of the connection ID is not checked by the connection parameter settings and there is no default value entered for the connection ID when you create a new connection.

8. Select the desired connection type in the relevant drop-down list. Default values are set for the address details depending on the connection type. You can choose between the following:
   – TCP
   – ISO-on-TCP
   – UDP
   – ISO (only with Configuration mode "Use configured connection")

   You can edit the input boxes in the address details. Depending on the selected protocol, you can edit the ports (for TCP and UDP) or the TSAPs (for ISO-on-TCP and ISO).
9. Use the "Active connection establishment" check box to set the connection establishment characteristics for TCP, ISO and ISO-on-TCP. You can decide which communication partner establishes the connection actively.

Changed values are checked immediately for input errors by the connection configuration and entered in the data block for the connection description.

Note

Open User Communication between two communication partners can only work when the program section for the partner end point has been downloaded to the hardware. To achieve fully functional communication, make sure that you load not only the connection description of the local CPU on the device but also that of the partner CPU as well.

Configuring connections, e.g. for TSEND/TRCV

If you want to use the instructions for TSEND/TRCV for open communication, for example, you first need to configure a connection (e.g. TCP connection).

To configure a TCP connection, follow these steps:

1. Configure the communications partners in the network view of the Devices & networks editor of STEP 7.
2. Click the "Connections" button and select the "TCP connection" connection type from the drop-down list.
3. Using drag-and-drop, connect the communication partner with each other (via an interface or local end point). If the required S7 subnet does not yet exist, it is created automatically.

   You can also set up a connection to unspecified partners.
4. Select the created connection in the network view.
5. Set the properties of the connection in the "Properties" tab in the "General" area, for example the name of the connection and the interfaces of the communications partner that will be used.

   For connections to an unspecified partner, set the address of the partner.
   You can find the local ID (reference of the connection in the user program) in the "Local ID" area.
6. In the Project tree, select the "Program blocks" folder for one of the CPUs and open OB1 in the folder by double-clicking on it. The program editor opens.
7. Select the required instruction from the "Instructions" task card, "Communication" area, "Open user communication", for example TSEND and drag it to a network of OB1.
8. At the ID parameter of the instruction, assign the local ID of the configured connection to be used for the transmission of data.
9. Interconnect the "DATA" parameter of the TSEND instruction with the user data, for example in a data block.
10. Download the hardware configuration and user program to the CPU.

Based on the procedure described above, set up the connection on the partner CPU with the instruction for receiving, TRCV, and download it to the CPU.

Point to note with ISO connections with CP 1543-1

If you use the "ISO connection" connection type, you will need to select the "Use ISO protocol" check box in the properties of the CP so that addressing using MAC addresses will work.

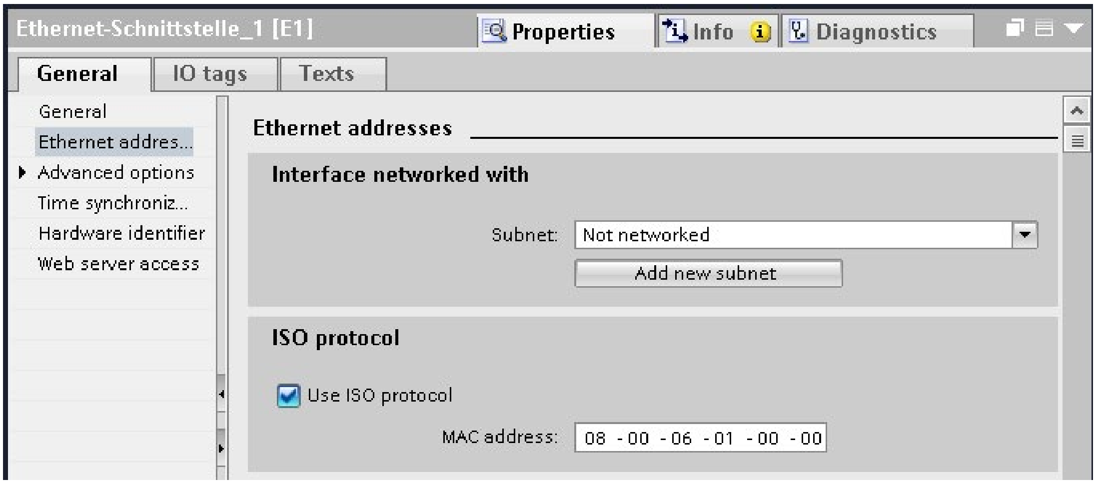

Figure 6-5 Select CP 1543-1 ISO protocol

Additional information

The STEP 7 online help describes:

- The instructions for open communication
- The connection parameters

This FAQ (https://support.industry.siemens.com/cs/ww/en/view/109479564) describes how the instructions TSEND_C and TRCV_C behave in the S7-1500.

6.6 Setting up communication over FDL

Requirements

- Configuration software: STEP 7 Professional V14
- End point of the connection: CPU S7-1500 firmware version V2.0 or higher with communication module CM 1542-5 with firmware version V2.0

Setting up a configured FDL connection

Proceed as follows to set up a configured FDL connection in STEP 7:

1. Create a TSEND_C instruction in the program editor.
2. Select the TSEND_C instruction and go to "Properties" > "General" > "Connection parameters" in the Inspector window.
3. Under End point, select the partner end point. Use one of the two partner end points below:
   – CPU S7-1500 with CM 1542-5
   – Unspecified
4. Under Configuration type, select "Use configured connection".
5. Under Connection type, select "FDL".
6. Under Interface, select the following interfaces:
   – Local: PROFIBUS interface of CM 1542-5
   – Specified partner: PROFIBUS interface of CM 1542-5
7. Under Connection data, select the setting <new>.

The figure below shows a fully configured FDL connection in STEP 7.

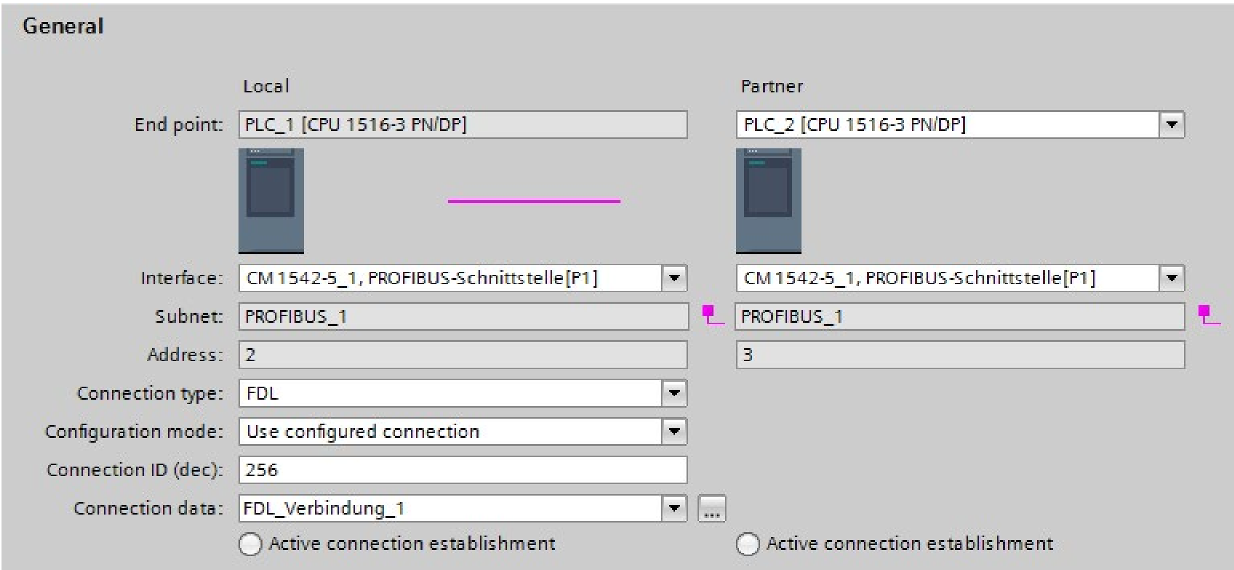

Figure 6-6 Configuring the FDL connection

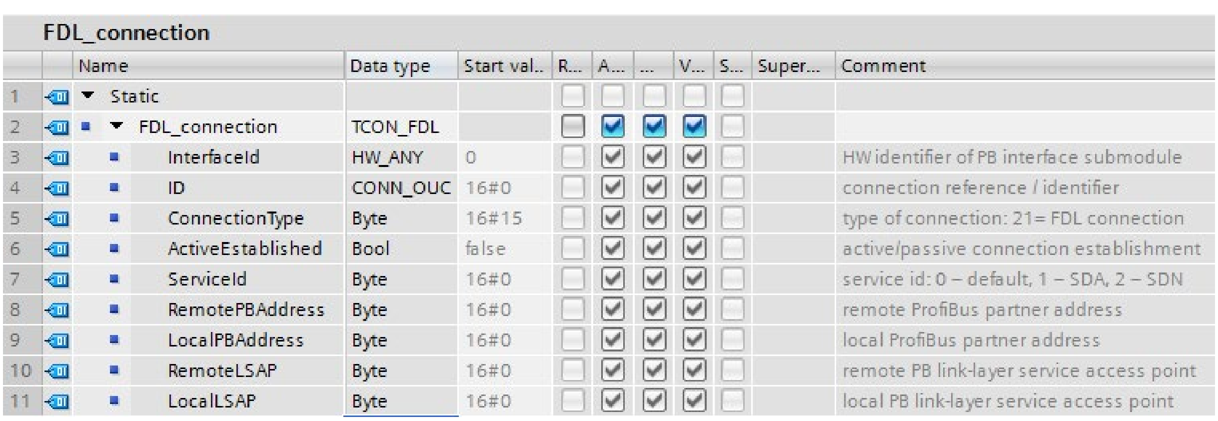
Setting up an FDL connection in the user program

For communication via FDL, you need to create the data block of the TCON_FDL system data type yourself in each case, assign parameters and call it directly at the instruction. Follow these steps:

1. Create a global data block in the project tree.
2. In the global data block, define a tag of the data type TCON_FDL.

   The example below shows the global data block "FDL_connection" in which the tag "FDL_connection" of the data type TCON_FDL is defined.



FDL_connection

	Name	Data type	Start val..	R...	A...	...	V...	S...	Super...	Comment
1	▼ Static			☐	☐	☐	☐	☐		
2	▼ FDL_connection	TCON_FDL		☐	☑	☑	☑	☐		
3	InterfaceId	HW_ANY	0	☐	☑	☑	☑	☐		HW identifier of PB interface submodule
4	ID	CONN_OUC	16#0	☐	☑	☑	☑	☐		connection reference / identifier
5	ConnectionType	Byte	16#15	☐	☑	☑	☑	☐		type of connection: 21= FDL connection
6	ActiveEstablished	Bool	false	☐	☑	☑	☑	☐		active/passive connection establishment
7	ServiceId	Byte	16#0	☐	☑	☑	☑	☐		service id: 0 – default, 1 – SDA, 2 – SDN
8	RemotePBAddress	Byte	16#0	☐	☑	☑	☑	☐		remote ProfiBus partner address
9	LocalPBAddress	Byte	16#0	☐	☑	☑	☑	☐		local ProfiBus partner address
10	RemoteLSAP	Byte	16#0	☐	☑	☑	☑	☐		remote PB link-layer service access point
11	LocalLSAP	Byte	16#0	☐	☑	☑	☑	☐		local PB link-layer service access point

Figure 6-7 Programming an FDL connection

3. Program the parameters of the FDL connection (e.g. the PROFIBUS addresses) in the tag of the data type TCON_FDL.

4. Create a TCON instruction in the program editor.
5. Interconnect the CONNECT parameter of the TCON instruction with the tag of the data type TCON_FDL.

   In the example below, the CONNECT parameter of the TCON instruction is interconnected with the tag "FDL_Connection" (data type TCON_FDL).

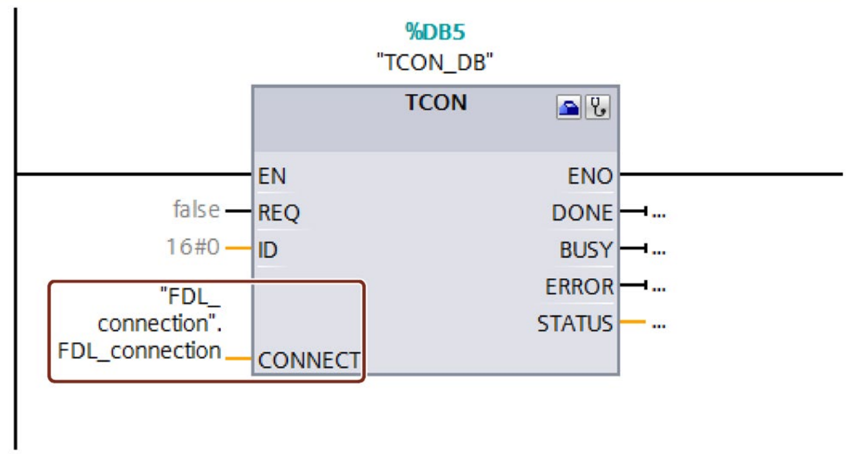


Figure 6-8 Example: TCON Instruction for FDL connection

6.7 Setting up communication with Modbus TCP

Setting up a connection for Modbus TCP via the user program

The parameter assignment takes place in the program editor at the instruction MB_CLIENT or MB_SERVER.

Procedure for setting up communication using Modbus TCP

The MB_CLIENT instruction communicates as a Modbus TCP client via the TCP connection. You establish a connection between the client and the server with the instruction, send Modbus requests to the server and receive the corresponding Modbus responses. You also control the setup of the TCP connection with this instruction.

The MB_SERVER instruction communicates as a Modbus TCP server via the TCP connection. The instruction processes connection requests of a Modbus client, receives and processes Modbus requests and sends responses. You also control the setup of the TCP connection.

Requirement: The client can reach the server via IP communication in the network.

1. Configure an S7-1500 automation system with CPU in the network view of the Devices & networks editor of STEP 7.
2. In the Project tree, select the "Program blocks" folder and open OB1 in the folder by double-clicking on it. The program editor opens.
3. Select the required instruction, for example MB_CLIENT, from the "Instructions" task card, "Communication" area, "Other", "MODBUS TCP" and drag it to a network of OB1.

4. Assign the parameters of the MB_CLIENT or MB_SERVER instruction. Observe the following rules:

   An IPv4 server address must be specified for each MB_CLIENT connection.

   Each MB_CLIENT or MB_SERVER connection must use a unique instance DB with one of the data structures TCON_IP_v4 or TCON_QDN.

   Each connection requires a unique connection ID. The connection ID and instance DB belong together in pairs and must be unique for each connection.

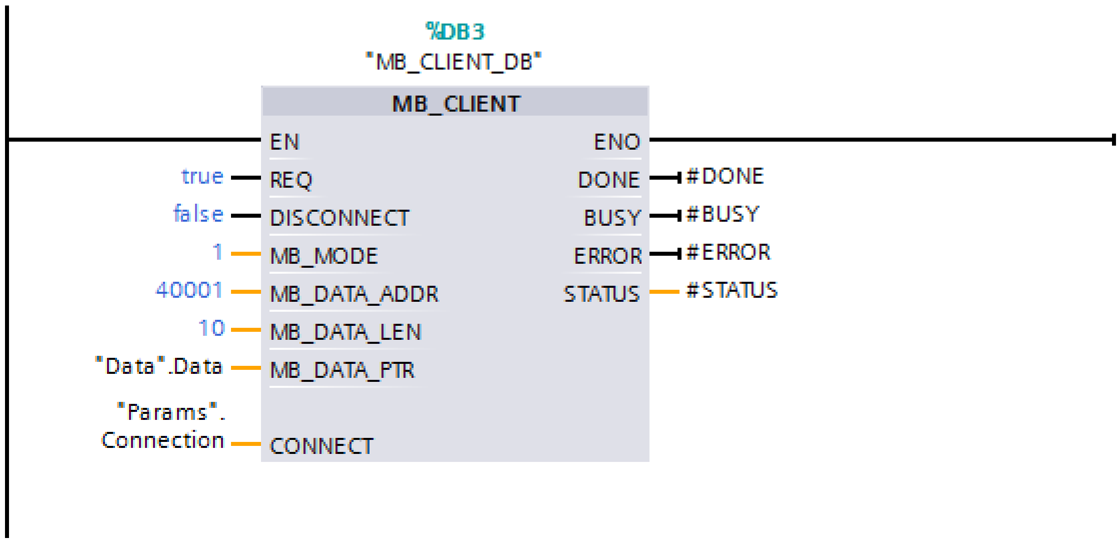

Figure 6-9 MB_CLIENT

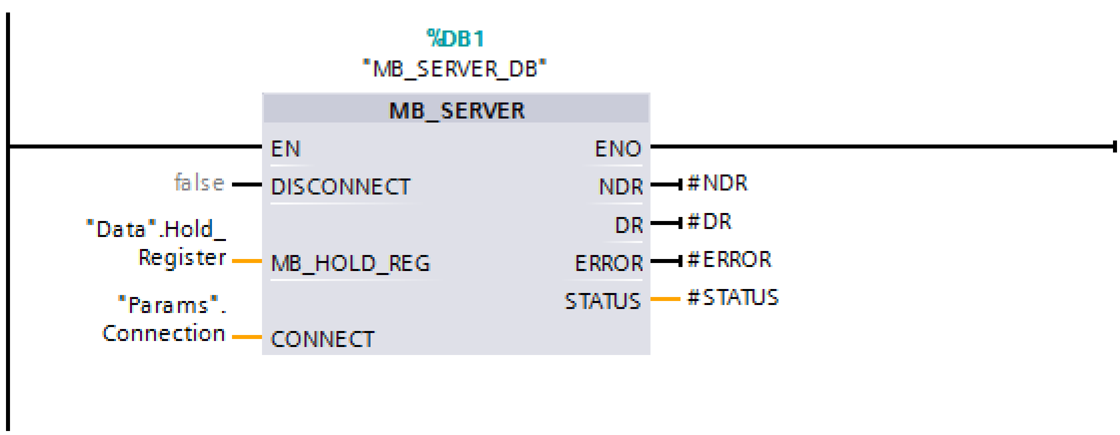

Figure 6-10 MB_SERVER

5. Download the hardware configuration and user program to the CPU.

Modbus TCP server as gateway to Modbus RTU

If you use a Modbus TCP server as a gateway to a Modbus RTU protocol, address the slave device in the serial network using the static parameter, MB_UNIT_ID. The MB_UNIT_ID parameter corresponds to the field of the slave address in the Modbus RTU protocol. The MB_UNIT_ID parameter in this case would forward the request to the correct Modbus RTU slave address.

You do not have to program the gateway function yourself.

You can find the MB_UNIT_ID parameter in the instance data block associated with MB_CLIENT instruction.

You can find more information on the MB_UNIT_ID parameter in the STEP 7 online help.

Reference

- This FAQ (https://support.industry.siemens.com/cs/ww/en/view/94766380) describes how to program and configure the Modbus TCP communication between two S7-1500 CPUs.
- This FAQ (https://support.industry.siemens.com/cs/ww/en/view/102020340) describes how to program and configure Modbus TCP communication between an S7-1500 CPU and an S7-1200 CPU.

6.8 Setting up communication via e-mail

Setting up a connection for e-mail via the user program

For communication using e-mail, you need to create the data block of the relevant system data type yourself, assign parameters and call the instruction directly. This procedure is introduced below.

Procedure for setting up communication using e-mail

A CPU can send e-mails. To send e-mails from the user program of the CPU, use the TMAIL_C instruction.

Requirement: The SMTP server can be reached via the IPv4 network.

1. Configure an S7-1500 automation system with CPU in the network view of the Devices & networks editor of STEP 7.
2. Assign parameters to the instruction TMAIL_C, for example enter the subject of the e-mail in Subject.
3. In a global data block create a variable of the type TMAIL_v4, TMAIL_v6 (only CP 1543-1) or TMAIL_FQDN (only CP 1543-1).
4. Set the connecting parameters of the TCP connection in the variable in the "Start value" column. Enter the IPv4 address of the mail server, for example, for the "MailServerAddress" (for TMAIL_v4)

   Note

   Connection parameters InterfaceId and ID

   Note that you can enter the value "**0**" for the interface ID and the ID with instruction version V5.0 or higher of the instruction TMAIL_C in the data type TMAIL_V4_SEC. In this case the CPU itself searches for a matching local CPU interface or a free connection ID.

   Interconnect the variable to the MAIL_ADDR_PARAM parameter of the TMAIL_C instruction.
5. Download the hardware configuration and user program to the CPU.

Additional information

The STEP 7 online help describes:

- The system data types
- The instructions for open communication
- The connection parameters

6.9 Setting up communication via FTP

Setting up a connection for FTP via the user program

For communication via FTP, you need to create the data block of the relevant system data type yourself, assign parameters and call the instruction directly. This procedure is introduced below.

FTP client and server functionality

Files can be sent by a CPU to an FTP server and can be received from the FTP server. Communication with FTP is only possible for the S7-1500 using the CP 1543-1. The CP can be an FTP server, FTP client or both. FTP clients can also be third-party systems/PCs.

For the FTP server functionality, configure the CP accordingly in STEP 7.

You can use the FTP client functionality to implement, for example, the establishment and termination of an FTP connection, the transfer and deletion of files on the server. For the FTP client functionality, use the FTP_CMD instruction.

Procedure for setting up FTP server functionality

Requirement: The FTP server can be reached via the IPv4 network.

1. Configure an S7-1500 automation system with CPU and CP 1543-1 in the device view of the Devices & networks editor of STEP 7.

   At the same time, you need to select the check box "Permit access with PUT/GET communication from remote partner (PLC, HMI, OPC, ...)" in the HW configuration of the S7-1500 CPU under the "Protection" area navigation in the section "Connection mechanisms".

2. Make the following settings in the properties of the CP under "FTP configuration":

   – Select the "Use FTP server for S7 CPU data" check box.

   – Assign the CPU, a data block and a file name under which the DB for FTP will be stored.

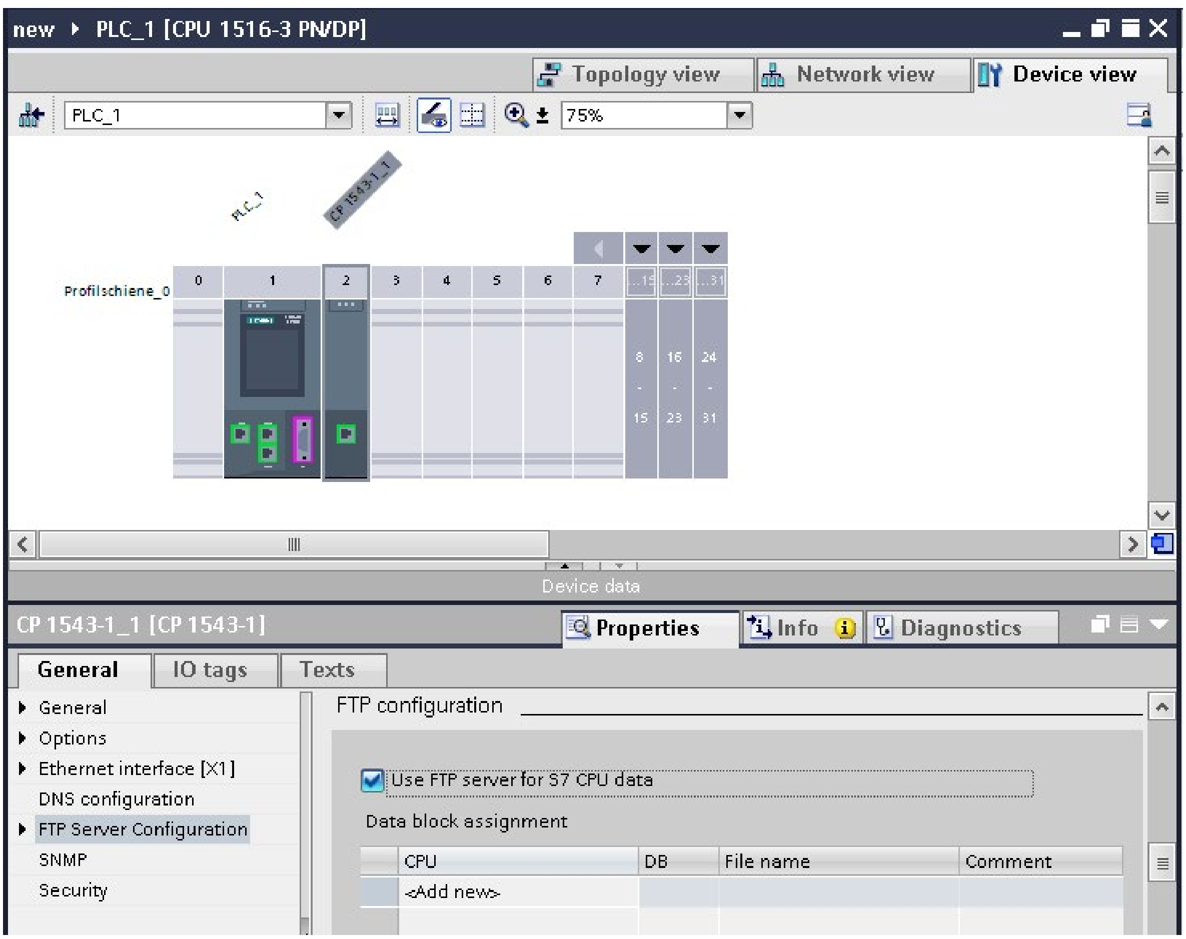

Figure 6-11 Setting up the FTP configuration

3. Download the hardware configuration to the CPU.

Procedure for setting up FTP client functionality

Requirement: The FTP server can be reached via the IPv4 network.

1. Configure an S7-1500 automation system with CPU and CP 1543-1 in the device view of the Devices & networks editor of STEP 7.

   At the same time, you need to select the check box "Permit access with PUT/GET communication from remote partner (PLC, HMI, OPC, ...)" in the HW configuration of the S7-1500 CPU under the "Protection" area navigation in the section "Connection mechanisms".
2. Call the FTP_CMD instruction in the user program of the CPU.
3. Set the connection parameters for the FTP server in the FTP_CMD instruction.
4. Create a global DB and within this DB a tag of the type FTP_CONNECT_IPV4, FTP_CONNECT_IPV6 or FTP_CONNECT_NAME.
5. Interconnect the tag within the data block with the FTP_CMD instruction.
6. For the connection to the FTP server, specify the following in the DB:
   – The user name, the password and the IP address for the FTP access in the relevant data type (FTP_CONNECT_IPV4, FTP_CONNECT_IPV6 or FTP_CONNECT_NAME)
7. Download the hardware configuration and user program to the CPU.

Application examples

- Application example: FTP communication with S7-1500 and CP 1543-1
  You can find the application example on the Internet (https://support.industry.siemens.com/cs/ww/en/view/103550797).
- Application example: FTP client communication with S7-1200/1500
  You can find the application example on the Internet (https://support.industry.siemens.com/cs/ww/en/view/81367009).

Additional information

The STEP 7 online help describes:

- The system data types
- The instructions for open communication
- The connection parameters

6.10 Establishment and termination of communications relations

Establishment and termination of communications

The table below shows the establishment and termination of communications as part of open communication.

Table 6- 5 Establishment and termination of communications

Setting up the connection	Establishing communication	Terminating communication
With the user program	After downloading the user program to the CPUs: The passive communications partner sets up the local connection access by calling TSEND_C/TRCV_C or TCON. Calling TSEND_C/TRCV_C or TCON on the active partner starts connection establishment. If the connection could be established, there is positive feedback to the instructions in the user program. After you have terminated a connection using the instruction T_RESET, the connection is reestablished. If the connection aborts, the active partner attempts to re-establish the connection. This applies only if the connection was successfully established beforehand with TCON.	• Using the TSEND_C/TRCV_C, TDISCON and T_RESET instructions • When the CPU changes from RUN to STOP mode • With POWER OFF/POWER ON on a CPU
By configuring a connection	After downloading the connection configuration and the user program to the CPUs.	By deleting the connection configuration in STEP 7 and downloading the changed configuration to the CPU.

6.11 Secure Open User Communication

6.11.1 Secure OUC of an S7-1500 CPU as TLS client to an external PLC (TLS server)

The following section describes how you can set up Open User Communication via TCP from an S7-1500 CPU as TLS client to a TLS server.

Setting up a secure TCP connection from an S7-1500 CPU as TLS client to a TLS server

S7-1500 CPUs as of firmware version V2.0 support secure communication with addressing via a Domain Name System (DNS).

For secure TCP communication over the domain name you need to create a data block with the TCON_QDN_SEC system data type yourself, assign parameters and call it directly at one of the instructions TSEND_C, TRCV_C or TCON.

Requirements:

- Current date and time are set in the CPU.
- Your network includes at least one DNS server.
- You have configured at least one DNS server for the S7-1500 CPU.
- TLS client and TLS server have all the required certificates.

To set up a secure TCP connection to a TLS server, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_QDN_SEC in the global data block.

   The example below shows the global data block "Data_block_1" in which the tag "DNS ConnectionSEC" of the data type TCON_QDN_SEC is defined.

Data_block_1

	Name	Data type	Start value	Comment
1	Static			
2	DNS Connection SEC	TCON_QDN_SEC		
3	ConnPara	TCON_QDN		parameter of the TCP connection
4	InterfaceId	HW_ANY	0	not relevant
5	ID	CONN_OUC	5	connection reference / identifier
6	ConnectionType	Byte	11	type of connection: 16#0B=11=TCP/IP, 16#13
7	ActiveEstablished	Bool	true	active/passive connection establishment
8	RemoteQDN	String[254]	'plc_1.factory127.'	fully or partially qualified domain name of rem
9	RemotePort	UInt	4000	remote UDP / TCP port number
10	LocalPort	UInt	0	local UDP / TCP port number
11	ActivateSecureConn	Bool	true	activate the security functionality of that conn
12	TLSServerReqClientCert	Bool	false	Just for server side: The TLS server requests a
13	ExtTLSCapabilities	Word	16#0	Bit 0: Just for client side: validate given IPv4 a
14	TLSServerCertRef	UDInt	7	for Server side: Reference to own X.509 V3 se
15	TLSClientCertRef	UDInt	0	for Client side: add id of own X.509 V3 client c

Figure 6-12 Data type TCON_QDN_SEC

3. Set the connection parameters of the TCP connection in the "Start value" column. Enter the fully qualified domain name (FQDN) of the TLS server, for example, for "RemoteQDN".
4. Set the parameters for secure communication in the "Start value" column.
   - "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   - "ExtTLSCapabilities": If you enter the value 1, the client validates the subjectAlternateName in the X.509-V3 certificate of the server to verify the identity of the server. This validation is executed in the context of the instruction.
   - "TLSServerCertRef": ID of the X.509-V3 certificate (usually a CA certificate) that is used by the TLS client to validate the TLS server authentication. If this parameter is 0, the TLS client uses all (CA) certificates currently loaded in the client certificate store to validate the server authentication.

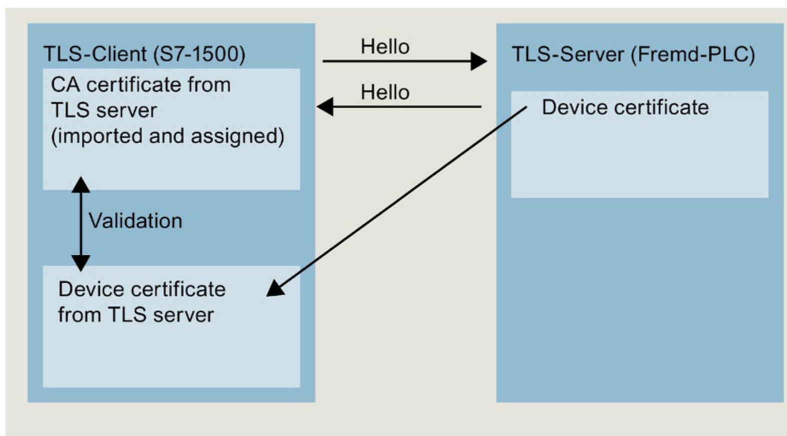

Figure 6-13 Certificate handling from the perspective of the S7-1500 as a TLS client

   - "TLSClientCertRef": ID of the own X.509-V3 certificate.

5. Create one of the instructions TSEND_C, TRCV_C or TCON in the program editor.
6. Interconnect the CONNECT parameter of one of the instructions TSEND_C, TRCV_C or TCON with the tags of the data type TCON_QDN_SEC.

   In the example below, the CONNECT parameter of the TCON instruction is interconnected with the tag "DNS connectionSEC" (data type TCON_QDN_SEC).

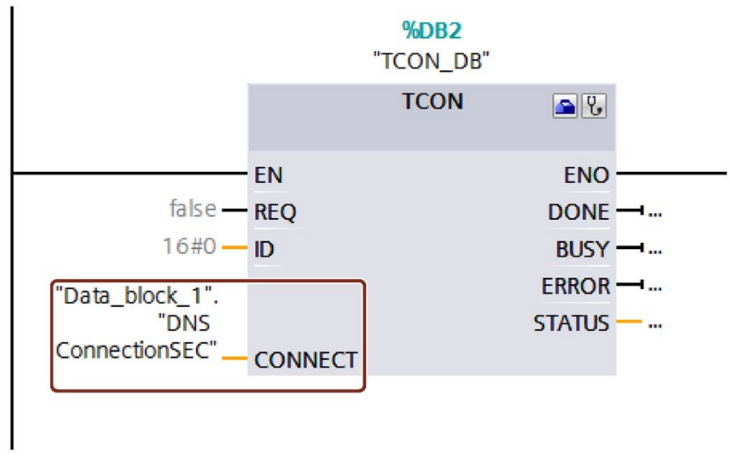

Figure 6-14 TCON instruction

Additional information

You can find more information on the TCON_QDN_SEC system data type in the STEP 7 online help.

For additional information on secure communication, refer to the section Secure Communication (Page 37).

6.11.2 Secure OUC of an S7-1500 CPU as TLS server to an external PLC (TLS client)

The following section describes how you can set up Open User Communication via TCP from an S7-1500 CPU as TLS server to a TLS client.

Setting up a secure TCP connection via the domain name of the communication partner

S7-1500 CPUs as of firmware version V2.0 support secure communication with addressing via a Domain Name System (DNS).

For secure TCP communication over the domain name you need to create a data block with the TCON_QDN_SEC system data type yourself, assign parameters and call it directly at one of the instructions TSEND_C, TRCV_C or TCON.

Requirements:

- Current date and time are set in the CPU.
- Your network includes at least one DNS server.
- You have configured at least one DNS server for the S7-1500 CPU.
- TLS client and TLS server have all the required certificates.

To set up a secure TCP connection to a TLS client, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_QDN_SEC in the global data block.

   The example below shows the global data block "Data_block_1" in which the tag "DNS ConnectionSEC" of the data type TCON_FDL_SEC is defined.

Data_block_1

	Name	Data type	Start value	Comment
1	Static			
2	DNS Connection SEC2	TCON_QDN_SEC		
3	ConnPara	TCON_QDN		parameter of the TCP connection
4	InterfaceId	HW_ANY	0	not relevant
5	ID	CONN_OUC	8	connection reference / identifier
6	ConnectionType	Byte	11	type of connection: 16#0B=11=TCP/IP, 16#13
7	ActiveEstablished	Bool	false	active/passive connection establishment
8	RemoteQDN	String[254]	''	fully or partially qualified domain name of rem
9	RemotePort	UInt	0	remote UDP / TCP port number
10	LocalPort	UInt	2010	local UDP / TCP port number
11	ActivateSecureConn	Bool	true	activate the security functionality of that conn
12	TLSServerReqClientCert	Bool	false	Just for server side: The TLS server requests a
13	ExtTLSCapabilities	Word	16#0	Bit 0: Just for client side: validate given IPv4 ad
14	TLSServerCertRef	UDInt	5	for Server side: Reference to own X.509 V3 se
15	TLSClientCertRef	UDInt	0	for Client side: add id of own X.509 V3 client c

Figure 6-15 TCON_QDN_SEC_Server

3. Set the connection parameters of the TCP connection in the "Start value" column. Enter, for example, the local ID of the TCP connection for "ID".

4. Set the parameters for secure communication in the "Start value" column.
   – "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   – "TLSServerReqClientCert": Request for an X.509-V3 certificate from the TLS client.
   – "TLSServerCertRef": ID of the own X.509-V3 certificate.

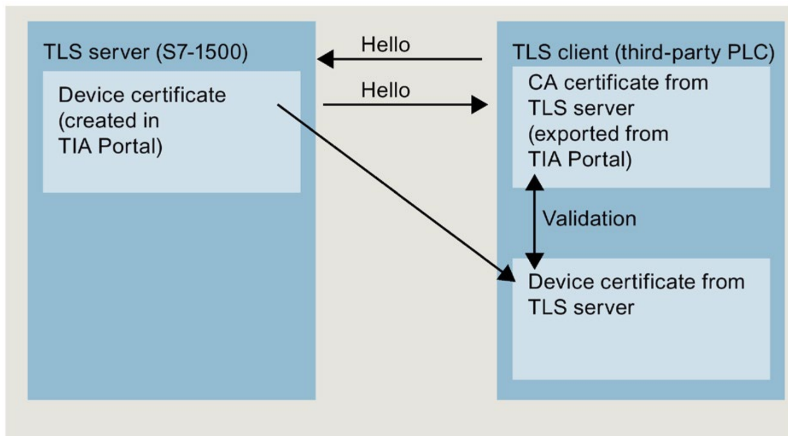

Figure 6-16 Certificate handling from the perspective of the S7-1500 as TLS server

   – "TLSClientCertRef": ID of the X.509-V3 certificate (or a group of X.509-V3 certificates) that is used by the TLS server to validate TLS client authentication. If this parameter is 0, the TLS server uses all (CA) certificates currently loaded in the server certificate store to validate the client authentication.
5. Create one of the instructions TSEND_C, TRCV_C or TCON in the program editor.
6. Interconnect the CONNECT parameter of one of the instructions TSEND_C, TRCV_C or TCON with the tags of the data type TCON_QDN_SEC.

   In the example below, the CONNECT parameter of the TCON instruction is interconnected with the tag "DNS connectionSEC" (data type TCON_QDN_SEC).

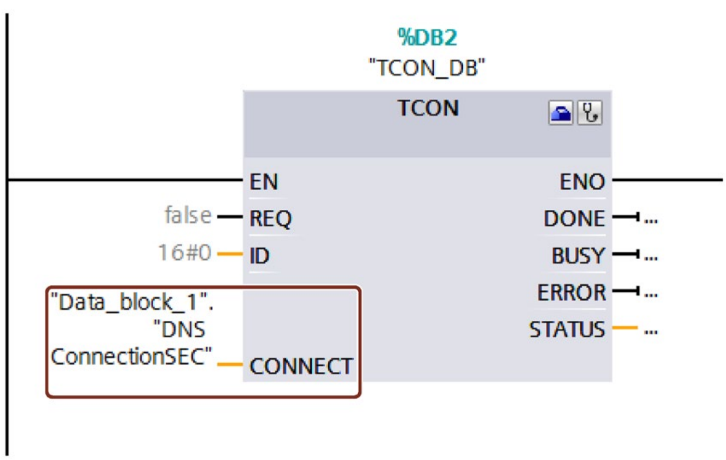

Figure 6-17 TCON instruction

Additional information

You can find more information about the system data types TCON_QDN_SEC in the STEP 7 online help.

For additional information on secure communication, refer to the section Secure Communication (Page 37).

6.11.3 Secure OUC between two S7-1500 CPUs

The following section describes how you can set Secure Open User Communication via TCP between two S7-1500 CPUs. In the process one S7-1500 CPU acts as TLS client (active establishing of the connection) and the other S7-1500 CPU as TLS server (passive establishing of the connection).

Setting up a secure TCP connection between two S7-1500 CPUs

For secure TCP communication between two S7-1500 CPUs you need to create a data block with the TCON_IP_V4_SEC system data type yourself in every CPU, assign parameters and call it directly at one of the instructions TSEND_C, TRCV_C or TCON.

Requirements:

- Current date and time are set in the CPU.
- Both S7-1500 CPUs have at least firmware version V2.0
- TLS client and TLS server have all the required certificates.

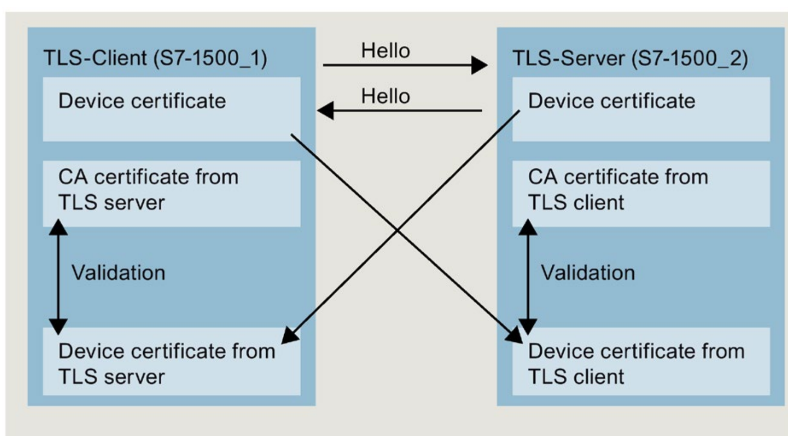

Figure 6-18 Certificate handling for Secure OUC between two S7-1500 CPUs

Settings at the TLS client

To set up a secure TCP connection in the TLS client, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_IP_4_SEC in the global data block.

   The example below shows the global data block "Data_block_1" in which the tag "SEC connection 1 TLS-Client" of the data type TCON_IP_V4_SEC is defined.

Data_block_1

	Name	Data type	Start value	Comment
1	Static			
2	SEC connection 1 TLS-Client	TCON_IP_V4_SEC		
3	ConnPara	TCON_IP_v4		parameter of the TCP connection
4	InterfaceId	HW_ANY	72	HW-identifier of IE-interface submodule
5	ID	CONN_OUC	10	connection reference / identifier
6	ConnectionType	Byte	11	type of connetion: 11=TCP/IP, 19=UDP (17=TCP/IP)
7	ActiveEstablished	Bool	true	active/passive connection establishment
8	RemoteAddress	IP_V4		remote IP address (IPv4)
9	ADDR	Array[1..4] of Byte		IPv4 address
10	ADDR[1]	Byte	192	IPv4 address
11	ADDR[2]	Byte	168	IPv4 address
12	ADDR[3]	Byte	1	IPv4 address
13	ADDR[4]	Byte	100	IPv4 address
14	RemotePort	UInt	4711	remote UDP/TCP port number
15	LocalPort	UInt	4711	local UDP/TCP port number
16	ActivateSecureConn	Bool	true	activate the security functionality of that connection in general
17	TLSServerReqClientCert	Bool	false	Just for server side: The TLS server requests a client certificate
18	ExtTLSCapabilities	Word	16#0	Bit 0: Just for client side: validate given IPv4 address against th
19	TLSServerCertRef	UDInt	1	for Server side: Reference to own X.509 V3 server certificate; fo
20	TLSClientCertRef	UDInt	5	for Client side: add id of own X.509 V3 client certificate; for Serv

Figure 6-19 IP_V4_SEC_Client

3. Set the connection parameters of the TCP connection in the "Start value" column. For example, enter the IPv4 address of the TLS server for "RemoteAddress".

Note

Connection parameters InterfaceId and ID

Note that you can enter the value "**0**" for the interface ID and the ID in the data type TMAIL_V4_SEC. In this case the CPU itself searches for a matching local CPU interface or a free connection ID.

---

4. Set the parameters for secure communication in the "Start value" column.
   – "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   – "TLSServerCertRef": Enter the value 2 (reference to the CA certificate of the TIA Portal project (SHA256) or the value 1 (reference to the CA certificate of the TIA Portal project (SHA1)). If you use a different CA certificate, enter the corresponding ID from the certificate manager of the global security settings.
   – "TLSClientCertRef": ID of the own X.509-V3 certificate.
5. Create one of the instructions TSEND_C, TRCV_C or TCON in the program editor.
6. Interconnect the CONNECT parameter of one of the instructions TSEND_C, TRCV_C or TCON with the tags of the data type TCON_IP_V4_SEC.

Settings at the TLS server

To set up a secure TCP connection in the TLS server, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_IP_4_SEC in the global data block.

   The example below shows the global data block "Data_block_1" in which the tag "SEC connection 1 TLS-Server" of the data type TCON_IP_V4_SEC is defined.

Data_block_1

	Name	Data type	Start value	Comment
1	Static			
2	SEC connection 1 TLS-Server	TCON_IP_V4_SEC		
3	ConnPara	TCON_IP_v4		parameter of the TCP connection
4	InterfaceId	HW_ANY	120	HW-identifier of IE-interface submodule
5	ID	CONN_OUC	10	connection reference / identifier
6	ConnectionType	Byte	11	type of connetion: 11=TCP/IP, 19=UDP (17=TCP/IP)
7	ActiveEstablished	Bool	false	active/passive connection establishment
8	RemoteAddress	IP_V4		remote IP address (IPv4)
9	ADDR	Array[1..4] of Byte		IPv4 address
10	ADDR[1]	Byte	192	IPv4 address
11	ADDR[2]	Byte	168	IPv4 address
12	ADDR[3]	Byte	1	IPv4 address
13	ADDR[4]	Byte	10	IPv4 address
14	RemotePort	UInt	4711	remote UDP/TCP port number
15	LocalPort	UInt	4711	local UDP/TCP port number
16	ActivateSecureConn	Bool	true	activate the security functionality of that connection in general
17	TLSServerReqClientCert	Bool	true	Just for server side: The TLS server requests a client certificate
18	ExtTLSCapabilities	Word	16#0	Bit 0: Just for client side: validate given IPv4 address against the
19	TLSServerCertRef	UDInt	6	for Server side: Reference to own X.509 V3 server certificate; fo
20	TLSClientCertRef	UDInt	1	for Client side: add id of own X.509 V3 client certificate; for Serv

Figure 6-20 IP_V4_SEC_Server

3. Set the connection parameters of the TCP connection in the "Start value" column. For example, enter the IPv4 address of the TLS client for "RemoteAddress".

4. Set the parameters for secure communication in the "Start value" column.
   - "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   - "TLSServerReqClientCert ": Request for an X.509-V3 certificate from the TLS client. Enter the value "true".
   - "TLSServerCertRef": ID of the own X.509-V3 certificate.
   - "TLSClientCertRef": Enter the value 2 (reference to the CA certificate of the TIA Portal project (SHA256) or the value 1 (reference to the CA certificate of the TIA Portal project (SHA1)). If you use a different CA certificate, enter the corresponding ID from the certificate manager of the global security settings.
5. Create one of the instructions TSEND_C, TRCV_C or TCON in the program editor.
6. Interconnect the CONNECT parameter of one of the instructions TSEND_C, TRCV_C or TCON with the tags of the data type TCON_IP_V4_SEC.

   In the example below, the CONNECT parameter of the TSEND_C instruction is interconnected with the "SEC connection 1 TLS client" tags (data type TCON_IP_4_SEC).

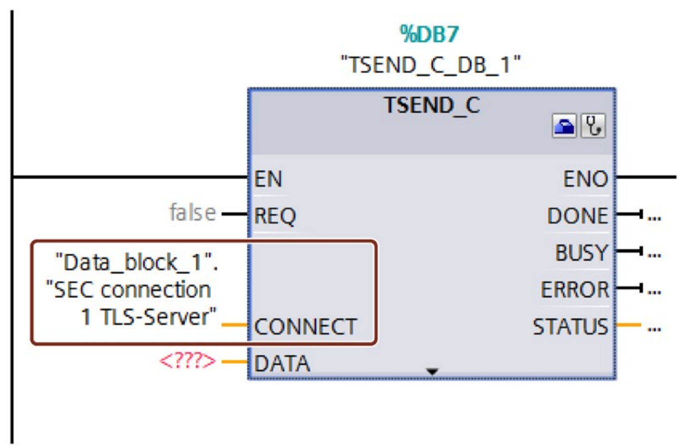

Figure 6-21 TSEND_C

Additional information

You can find more information about the system data types TCON_IP_4_SEC in the STEP 7 online help.

For additional information on secure communication, refer to the section Secure Communication (Page 37).

6.11.4 Secure OUC via CP interface

The following sections describes the particular points to be taken into consideration in the case of Secure Open User Communication via a CP interface. At least one station is an S7-1500 station with the following modules:

- S7-1500 CPU as of firmware version V2.0 (with the exception of S7-1500 Software Controller)
- CP 1543-1 as of firmware version V2.0 or CP 1543SP-1 as firmware version V1.0

The CP acts in an S7-1500 station as a TLS client (active connection establishment) or a TLS server (passive connection establishment).

The fundamental procedure and the concept for using secure communication via a CP interface is similar to that of secure communication via the interfaces of the S7-1500 CPUs. Essentially, you have to assign the certificates to the CPU in the role of a TLS server or TLS client and not to the CPU. Other rules and procedures therefore apply. These are described below.

Handling certificates for CPs

The following applies in general: You have to be logged on at the certificate manager in the global security settings. The generation of self-signed certificates also requires logon for the global security settings. You have to have sufficient rights as a user (administrator or user with the "Standard" role with the right to "Configure security").

The starting point for the generation or assignment of certificates at the CP is the section "Security > Security properties". In this section, you log on for the global security settings.

Procedure:

1. In the network view of STEP 7, mark the CP and select the section "Security > Security properties" in the Inspector window.
2. Click on the "User logon" button.
3. Log on using your user name and password.
4. Enable the "Activate security functions" option.

   The security properties are initialized.
5. Click in the first line of the "Device certificates" table to generate a new certificate or select an existing device certificate.
6. If the communication partner is also an S7-1500 station, you also have to assign a device certificate to the communication partner with STEP 7 as described here or for the S7-1500 CPU.

Example: Setting up a secure TCP connection between two S7-1500 CPUs via CP interfaces

For secure TCP communication between two S7-1500 CPUs you need to create a data block with the TCON_IPv4_SEC system data type yourself in every CPU, assign parameters and call it directly at the one of the instructions TSEND_C, TRCV_C or TCON.

Requirements:

- Both S7 1500 CPUs have at least firmware version V2.0. If you use the CP 1543SP-1: Firmware version as of V1.0.
- Both CPs (for example CP 1543-1) must have at least firmware version V2.0
- TLS client and TLS server have all the required certificates.
  - A device certificate (end-entity certificate) for the CP must be generated and be located in the certificate memory of the CP. If a communication partner is an external device (for example an MES or ERP system), a device certificate also has to exist for this device.
  - The root certificate (CA certificate) with which the device certificate of the communication partner is signed must also be located in the certificate memory of the CP or in the certificate memory of the external device. If you use intermediate certificates, you have to ensure that the complete certificate path exists in the validating device. A device uses these certificates to validate the device certificate of the communication partner.
- The communication partner must always be addressed via its IPv4 address, not via its domain name.

The following figure shows the different certificates in the devices for the case that both communication partners communicate via a CP 1543-1. In addition, the figure shows the transfer of the device certificates during establishment of the connection ("Hello").

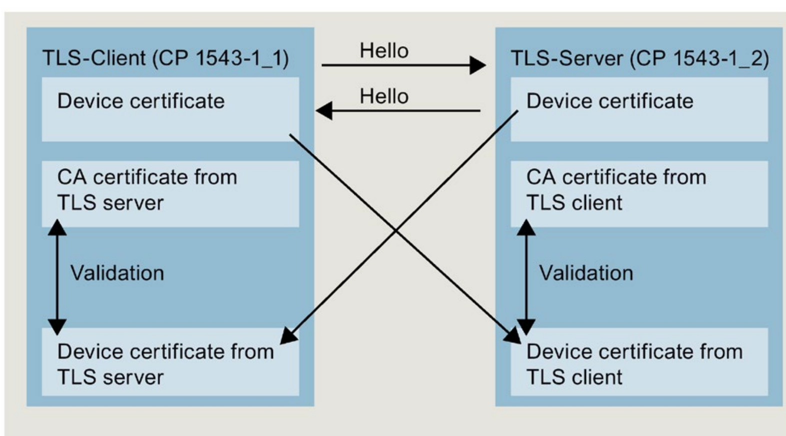

Figure 6-22 Certificate handling in secure OUC between two S7-1500 CPUs via CP interfaces.

Settings at the TLS client

To set up a secure TCP connection in the TLS client, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_IP_4_SEC in the global data block. To do so, enter the string "TCON_IP_V4_SEC" in the "Data type" field.

   The example below shows the global data block "Data_block_1" in which the tag "SEC connection 1 TLS-Client" of the data type TCON_IP_V4_SEC is defined.

   The Interface ID has the value of the HW identifier of the IE interface of the local CP (TLS client).

Data_block_1

	Name	Data type	Start value	Comment
1	Static			
2	SEC connection 1 TLS-Client	TCON_IP_V4_SEC		
3	ConnPara	TCON_IP_v4		parameter of the TCP connection
4	InterfaceId	HW_ANY	258	HW-identifier of IE-interface submodule
5	ID	CONN_OUC	10	connection reference / identifier
6	ConnectionType	Byte	11	type of connetion: 11=TCP/IP, 19=UDP (17=TCP/IP)
7	ActiveEstablished	Bool	true	active/passive connection establishment
8	RemoteAddress	IP_V4		remote IP address (IPv4)
9	ADDR	Array[1..4] of Byte		IPv4 address
10	ADDR[1]	Byte	192	IPv4 address
11	ADDR[2]	Byte	168	IPv4 address
12	ADDR[3]	Byte	1	IPv4 address
13	ADDR[4]	Byte	100	IPv4 address
14	RemotePort	UInt	4711	remote UDP/TCP port number
15	LocalPort	UInt	4711	local UDP/TCP port number
16	ActivateSecureConn	Bool	true	activate the security functionality of that connection in general
17	TLSServerReqClientCert	Bool	false	Just for server side: The TLS server requests a client certificate
18	ExtTLSCapabilities	Word	16#0	Bit 0: Just for client side: validate given IPv4 address against th
19	TLSServerCertRef	UDInt	1	for Server side: Reference to own X.509 V3 server certificate; fc
20	TLSClientCertRef	UDInt	5	for Client side: add id of own X.509 V3 client certificate; for Serv

Figure 6-23 IP_V4_SEC_Client

3. Set the connection parameters of the TCP connection in the "Start value" column. For example, enter the IPv4 address of the TLS server for "RemoteAddress".
4. Set the parameters for secure communication in the "Start value" column.
   - "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   - "TLSServerCertRef": Enter the value 2 (reference to the CA certificate of the TIA Portal project (SHA256) or the value 1 (reference to the CA certificate of the TIA Portal project (SHA1)). If you use a different CA certificate, enter the corresponding ID from the certificate manager of the global security settings.
   - "TLSClientCertRef": ID of the own X.509-V3 certificate.

5. Create one of the instructions TSEND_C, TRCV_C or TCON in the program editor.
6. Interconnect the CONNECT parameter of one of the instructions TSEND_C, TRCV_C or TCON with the tags of the data type TCON_IP_V4_SEC.

Settings at the TLS server

To set up a secure TCP connection in the TLS server, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_IP_4_SEC in the global data block.

   The example below shows the global data block "Data_block_1" in which the tag "SEC connection 1 TLS-Server" of the data type TCON_IP_V4_SEC is defined.

   The interface ID has the value of the HW identifier of the IE interface of the local CP (TLS server).

Data_block_1

	Name	Data type	Start value	Comment
1	Static			
2	SEC connection 1 TLS-Server	TCON_IP_V4_SEC		
3	ConnPara	TCON_IP_v4		parameter of the TCP connection
4	InterfaceId	HW_ANY	260	HW-identifier of IE-interface submodule
5	ID	CONN_OUC	10	connection reference / identifier
6	ConnectionType	Byte	11	type of connetion: 11=TCP/IP, 19=UDP (17=TCP/IP)
7	ActiveEstablished	Bool	false	active/passive connection establishment
8	RemoteAddress	IP_V4		remote IP address (IPv4)
9	ADDR	Array[1..4] of Byte		IPv4 address
10	ADDR[1]	Byte	192	IPv4 address
11	ADDR[2]	Byte	168	IPv4 address
12	ADDR[3]	Byte	1	IPv4 address
13	ADDR[4]	Byte	10	IPv4 address
14	RemotePort	UInt	4711	remote UDP/TCP port number
15	LocalPort	UInt	4711	local UDP/TCP port number
16	ActivateSecureConn	Bool	true	activate the security functionality of that connection in general
17	TLSServerReqClientCert	Bool	true	Just for server side: The TLS server requests a client certificate
18	ExtTLSCapabilities	Word	16#0	Bit 0: Just for client side: validate given IPv4 address against the
19	TLSServerCertRef	UDInt	6	for Server side: Reference to own X.509 V3 server certificate; fo
20	TLSClientCertRef	UDInt	1	for Client side: add id of own X.509 V3 client certificate; for Serv

Figure 6-24 IP_V4_SEC_Server

3. Set the connection parameters of the TCP connection in the "Start value" column. For example, enter the IPv4 address of the TLS client for "RemoteAddress".

4. Set the parameters for secure communication in the "Start value" column.
   – "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   – "TLSServerReqClientCert ": Request for an X.509-V3 certificate from the TLS client. Enter the value "true".
   – "TLSServerCertRef": ID of the own X.509-V3 certificate.
   – "TLSClientCertRef": Enter the value 2 (reference to the CA certificate of the TIA Portal project (SHA256) or the value 1 (reference to the CA certificate of the TIA Portal project (SHA1)). If you use a different CA certificate, enter the corresponding ID from the certificate manager of the global security settings.
5. Create one of the instructions TSEND_C, TRCV_C or TCON in the program editor.
6. Interconnect the CONNECT parameter of the instruction TSEND_C, TRCV_C or TCON with the tags of the data type TCON_IP_V4_SEC.

Upload device as new station

When you upload a configuration with certificates and configured secure Open User Communication as a new station into your STEP 7 project, the certificates of the CP are not uploaded, in contrast to the certificates of the CPU. After the device has been loaded as a new station, no more certificates are contained in the corresponding tables of the CPs for the device certificates.

You have to perform configuration of certificates again after the upload. Otherwise, renewed loading of the configuration results in the certificates that originally exist in the CP being deleted so that secure communication does not function.

Secure OUC connections via CPU and CP interfaces - similarities

- Connection resources:
  No differences between OUC and secure OUC. A programmed secure OUC connection uses a connection resource just like an OUC connection, irrespective of which IE/PROFINET interface communicates with the station.
- Connection diagnostics:
  No differences between OUC and secure OUC connection diagnostics.
- Loading of projects with secure OUC connections into the CPU:
  Only possible in STOP of the CPU, if certificates are loaded as well.
  Recommendation: Load to device > Hardware and software. Reason: Ensuring the consistency between the program with secure OUC, hardware configuration and certificates.
  Certificates are loaded with the hardware configuration - therefore loading requires a stop of the CPU. The reloading of blocks that utilize further secure OUC connections is only possible in RUN if the certificates required for this purpose are already located on the module.

6.11.5 Secure OUC with Modbus TCP

For secure Modbus TCP connection you need to create a data block with one of the system data types TCON_IP_V4_SEC or TCON_QDN_SEC yourself, assign parameters and call it directly at the MB_Server or MB_CLIENT instruction.

Requirements:

- S7-1500 CPU CPU firmware version V2.5 or higher
- The Modbus client (TLS client) can reach the Modbus server (TLS server) over IP communication in the network.
- TLS client and TLS server have all the required certificates.

Example of setting up a secure Modbus TCP connection to a Modbus TCP server

The following section describes how you can set up a Secure Open User Communication over Modbus TCP from a Modbus TCP client to a Modbus TCP server.

To set up a secure connection from a Modus TCP client (TLS client) to a Modbus TCP server (TLS server) and set up the IPv4 address of the mail server, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TCON_IP_V4 SEC in the global data block.

Data_block_1

	Name	Data type	Start value	Comment
1	▼ Static			
2	▼ SEC_ModbusTCP_1	TCON_IP_V4...		
3	▼ ConnPara	TCON_IP_v4		parameter of the TCP connection
4	InterfaceId	HW_ANY	64	HW-identifier of IE-interface submodule
5	ID	CONN_OUC	15	connection reference / identifier
6	ConnectionType	Byte	11	type of connection: 11=TCP/IP, 19=UDP (17=TCP/IP)
7	ActiveEstablished	Bool	true	active/passive connection establishment
8	▼ RemoteAddress	IP_V4		remote IP address (IPv4)
9	▼ ADDR	Array[1..4] of B...		IPv4 address
10	ADDR[1]	Byte	192	IPv4 address
11	ADDR[2]	Byte	168	IPv4 address
12	ADDR[3]	Byte	10	IPv4 address
13	ADDR[4]	Byte	100	IPv4 address
14	RemotePort	UInt	502	remote UDP/TCP port number
15	LocalPort	UInt	502	local UDP/TCP port number
16	ActivateSecureConn	Bool	true	activate the security functionality of that connection in general
17	TLSServerReqClientCert	Bool	false	Just for server side: The TLS server requests a client certificate
18	ExtTLSCapabilities	Word	0	Bit 0: Just for client side: validate given IPv4 address against the subjectAlt
19	TLSServerCertRef	UDInt	2	for Server side: Reference to own X.509 V3 server certificate; for Client side:
20	TLSClientCertRef	UDInt	7	for Client side: add id of own X.509 V3 client certificate; for Server side: add

Figure 6-25 TCON_IP_V4_SEC

3. Set the connection parameters of the TCP connection in the "Start value" column. Enter the IPv4 address of the mail server, for example, for the "MailServerAddress".

4. Set the parameters for secure communication in the "Start value" column. Enter the certificate ID of the CA certificate of the communication partner, for example, for "TLSServerCertRef".
   – "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. In this case you can set up an unsecured Modbus TCP connection.
   – "TLSServerCertRef": Reference to the X.509 V3 (CA) certificate of the Modbus TCP server, which is used by the TLS client to validate the authentication of the Modbus TCP server.
5. Create an MB_CLIENT instruction in the program editor.
6. Interconnect the CONNECT parameter of the MB_Client instruction with the tags of the data type TCON_IP_4_SEC.

6.11.6 Secure OUC via e-mail

Setting up a secure connection to a mail server over the CPU interface

For secure communication to a mail server you need to create a data block with one of the system data types TMAIL_V4_SEC, TMAIL_QDN_SEC yourself, assign parameters and call it directly at the TMAIL_C instruction.

Requirements:

- TMAIL_C instruction version V5.0 or higher
- STEP 7 V15 and higher
- S7-1500 CPU V2.5 and higher
- You have assigned all the CA certificates of the mail server (TLS server) to the CPU (TLS client) and have downloaded the configuration to the CPU.
- Current date and time are set in the CPU.

Process for establishing a secure connection to the mail server

You can choose between two processes for establishing the secure connection to the mail server:

- SMTPS: The client attempts to immediately establish a TLS connection to the mail server ("handshake" process). If the mail server does not support TLS, then no connection is established.
- STARTTLS: Client establishes a TCP connection to the mail server. The client sends a request to "upgrade" the existing connection to a secure TLC connection over the TCP connection. If the mail server supports TLS, the client sends the command to establish a secure connection. The mail server uses the SMTP command "STARTTLS" to do this. The client then establishes a secure connection to the mail server. Advantage: If the mail server does not support TLS, client and mail server can communicate unsecured with each other.

You use the "Remote Port" setting in the data types at the block parameter "MAIL_ADDR_PARAM" to define which process is used for the communication.

Table 6- 6 Port numbers for the SMTPS and STARTTLS processes

Process	Port
SMTPS:	465[1]
STARTTLS	Any (≠465)[2]

[1] The instruction TMAIL_C uses SMTPS only for Port 465. For all other ports STARTTLS is used.

[2] According to RFC, mail servers use Ports 25 and 587 for secure connections with STARTTLS. The use of other port numbers for SMTP is not RFC-compliant, successful communication with such a mail server is not guaranteed.

Example: Setting up a secure connection to a mail server over IPv4

The following section describes how to set up a secure connection to an IPv4 mail server with the TMAIL_C communication instruction.

To set up a secure connection via the IP4 address of the mail server, follow these steps:

1. Create a global data block in the project tree.
2. Define a tag of the data type TMAIL_V4_SEC in the global data block.

   The example below shows the global data block "MailConnDB" in which the tag "MailConnectionSEC" of the data type TMAIL_V4_SEC is defined.

MailConnDB

Name	Datentyp	Startwert	Kommentar
Static			
MailConnectionSEC	TMail_V4_SEC		
InterfaceId	HW_ANY	"Local~CP_1543-1_1~Ethernet-Schnittstelle_1"	Use HW-identifier of the IE-interface to specify th
ID	CONN_OUC	100	connection reference / identifier
ConnectionType	Byte	16#20	type of connection 16#20=32=TMail_V4 or TMai
ActiveEstablished	Bool	true	active / passive connection establishment
WatchDogTime	Time	T#5000ms	watchdog time to monitor SMTP server associat
MailServerAddress	IP_V4		IPv4 address of mail server
ADDR	Array[1..4] of Byte		IPv4 address
ADDR[1]	Byte	144	IPv4 address
ADDR[2]	Byte	145	IPv4 address
ADDR[3]	Byte	2	IPv4 address
ADDR[4]	Byte	20	IPv4 address
UserName	String[254]	'myName'	user name which is necessary to login into the
PassWord	String[254]	'myPW'	user password which is necessary to login into
From	EMAIL_ADDR		source mail address
LocalPartPlusAt...	String[64]	'Mustermann@'	local part of e-mail address plus "@" sign
FullQualifiedD...	String[254]	'siemens.com'	full qualified domain name part of e-mail addre
RemotePort	UInt	587	remote TCP port number
ActivateSecureConn	Bool	TRUE	activate the security functionality of that conne
ExtTLSCapabilities	Byte	16#0	for further capability extensions of the TLS hand
TLSServerCertRef	UDInt	7	Reference to the X.509 V3 (CA-) certificate of the

Figure 6-26 Data type TMAIL_V4_SEC

3. Set the connection parameters of the TCP connection in the "Start value" column. Enter the IPv4 address of the mail server, for example, for the "MailServerAddress".

Note

Connection parameters InterfaceId and ID

Note that you can enter the value "**0**" for the interface ID and the ID with instruction version V5.0 or higher of the instruction TMAIL_C in the data type TMAIL_V4_SEC. In this case the CPU itself searches for a matching local CPU interface or a free connection ID.

---

4. Set the parameters for secure communication in the "Start value" column. Enter the certificate ID of the CA certificate of the communication partner, for example, for "TLSServerCertRef".
   - "ActivateSecureConn": Activation of secure communication for this connection. If this parameter has the value FALSE, the subsequent security parameters are irrelevant. You can set up a non-secure TCP or UDP connection in this case.
   - "TLSServerCertRef": Reference to the X.509 V3 (CA) certificate of the mail server, which is used by the TLS client to validate the authentication of the mail server.
5. Create a TMAIL_C instruction in the program editor.
6. Interconnect the MAIL_ADDR_PARAM parameter of the TMAIL_C instruction with the tag of the data type TMAIL_V4_SEC.

   In the following example the MAIL_ADDR_PARAM parameter of the TMAIL_C instruction is interconnected with the tag "MailConnectionSEC" (data type TMAIL_V4_SEC).

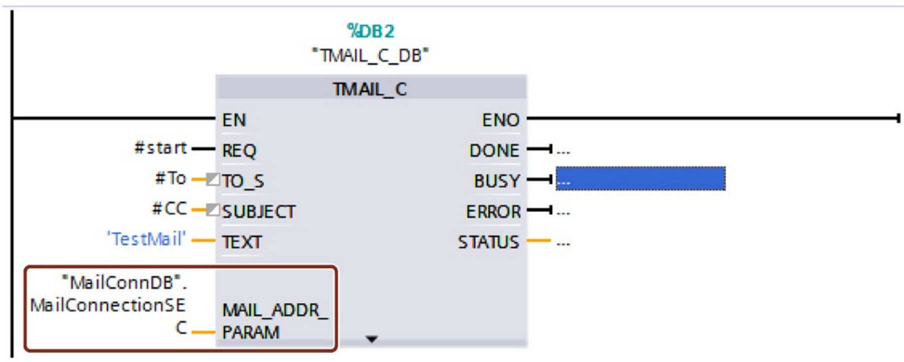

Figure 6-27 TMAIL_C instruction

Setting up a secure connection to a mail server over the interface of a communication module

For secure communication to a mail server over a communication module, you need to create a data block with one of the system data types TMAIL_V4_SEC, TMAIL_QDN_SEC or TMAIL_V6_SEC yourself, assign parameters and call it directly at the TMAIL_C instruction.

Requirements:

- TMAIL_C instruction with version **V4.0**
- S7-1500 CPU as of firmware version V2.0 with communication module CP 1543-1 as of firmware version V2.0
- ET 200SP CPU as of firmware version V2.0 with communication module CP 1542SP-1 (IRC) as of firmware version V1.0
- You have assigned all the CA certificates of the mail server (TLS server) to the CP (TLS client) and have downloaded the configuration to the CPU.
- Current date and time are set in the CPU.

The STEP 7 online help describes how to set up a secure connection to a mail server over the interface of a communication module.

Application example

This application example (https://support.industry.siemens.com/cs/ww/en/view/46817803) show how you can use the CP of an S7-1500 or S7-1200 station to set up a secure connection to an email server and send an email with the default application "TMAIL_C" from the S7 CPU.

Additional information

You can find more information about the system data types TMail_V4_SEC and TMAIL_QDN_SEC in the STEP 7 online help.

For additional information on secure communication, refer to the section Secure Communication (Page 37).

7 S7 communication

Characteristics of S7 communication

S7 communication as homogeneous SIMATIC communication is characterized by vendor-specific communication between SIMATIC CPUs (not an open standard). S7 communication is used for migration and for connecting to existing systems (S7-300, S7-400).

For data transfer between two S7-1500 automation systems, we recommend that you use open communication (see section Open User Communication (Page 67)).

Properties of S7 communication

Using S7 communication, the CPU exchanges data with another CPU. Once the user has received the data at the receiver end, the reception data is automatically acknowledged to the sending CPU.

The data is exchanged via configured S7 connections. S7 connections can be configured at one end or at both ends.

S7 communication is possible via:

- Integrated PROFINET or PROFIBUS DP interface of a CPU
- Interface of a CP/CM

S7 connections configured at one end

For an S7 connection configured at one end, the configuration for this connection takes place in only one communication partner and is only downloaded to it.

A one-sided S7 connection can be configured to a CPU that is only a server of an S7 connection (e.g. CPU 315-2 DP). The CPU is configured and the address parameters and interfaces are thus known.

In addition, a one-sided S7 connection can be configured to a partner who is not in the project and whose address parameters and interface and therefore are not known. You need to enter the address; it is not checked by STEP 7. The partner is initially unspecified (no partner address is registered when you create the S7 connection). Once you enter the address, it is "unknown" (i.e. it is named, but the project is unknown).

This makes it possible to use S7 connections beyond the boundaries of a project. The communication partner is unknown to the local project (unspecified) and is configured in another STEP 7 or third-party project.

S7 connections configured at both ends

When an S7 connection is configured at both ends, the configuration and download of the configured S7 connection parameters takes place in both communication partners.

Instructions for S7 communication

For S7 communication with S7-1500, the following instructions can be used:

- PUT/GET

  You write data to a remote CPU with the PUT instruction. You can use the GET instruction to read data from a remote CPU. The PUT and GET instructions and are one-sided instructions, i.e. you need only an instruction in one communication partner. You can can easily set up the PUT and GET instructions via the connection configuration.

  Note

  Data blocks for PUT/GET instructions

  When using the PUT/GET instructions, you can only use data blocks with absolute addressing. Symbolic addressing of data blocks is not possible.

  You must also enable this service for protection in the CPU configuration in the "Protection" area.

  This FAQ (https://support.industry.siemens.com/cs/ww/en/view/82212115) provides information about how to configure and program an S7 instruction and the GET and PUT communication instructions for data exchange between two S7-1500 CPUs.

- BSEND/BRCV

  The BSEND instruction sends data to a remote partner instruction of the type BRCV. The BRCV instruction receives data from a remote partner instruction of the type BSEND. You use the S7 communication via the BSEND/BRCV instruction pair for secure transmission of data.

- USEND/URCV

  The USEND instruction sends data to a remote partner instruction of the type URCV. The URCV instruction receives data from a remote partner instruction of the type USEND. You use the S7 communication via the USEND/URCV instruction pair for fast, non-secure transmission of data regardless of the timing of the processing by the communications partner; for example for operating and maintenance messages.

S7 communication via PROFIBUS DP interface in slave mode

You can find the "Test, commissioning, routing" check box in STEP 7 in the properties of the PROFIBUS DP interface of communications modules (e.g. CM 1542-5). Using this check box, you decide whether the PROFIBUS DP interface of the DP slave is an active or passive device on PROFIBUS.

- Check box selected: The slave is an active device on PROFIBUS.
- Check box cleared: The DP slave is a passive device on PROFIBUS. You can only set up S7 connections configured at one end for this DP slave.

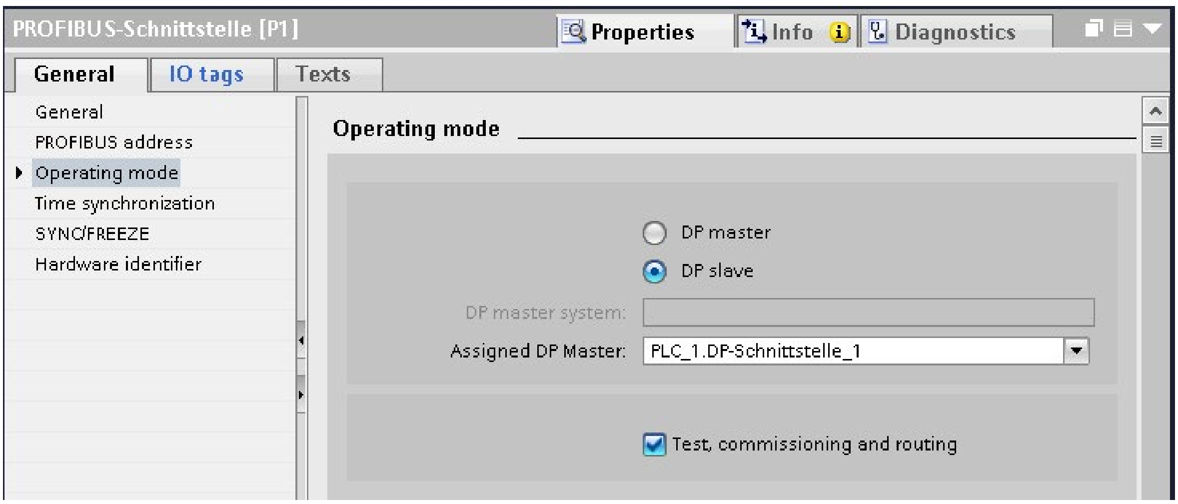

Figure 7-1 "Test, commissioning, routing" check box

Configuring S7 connections for PUT/GET instructions

You can create S7 connections and assign the parameters for these in the connection parameter assignment of the PUT/GET instructions. Changed values are checked immediately by the connection parameter assignment for input errors.

Requirement: A PUT or GET instruction is created in the programming editor.

To configure an S7 connection using PUT/GET instructions, follow these steps:

1. In the program editor, select the call of the PUT or GET instruction.
2. Open the "Properties > Configuration" tab in the inspector window.
3. Select the "Connection parameters" group. Until you select a connection partner, only the empty drop-down list for the partner end point is enabled. All other input options are disabled.

   The connection parameters already known are displayed:

   – Name of the local end point

   – Interface of the local end point

   – IPv4 address of the local end point

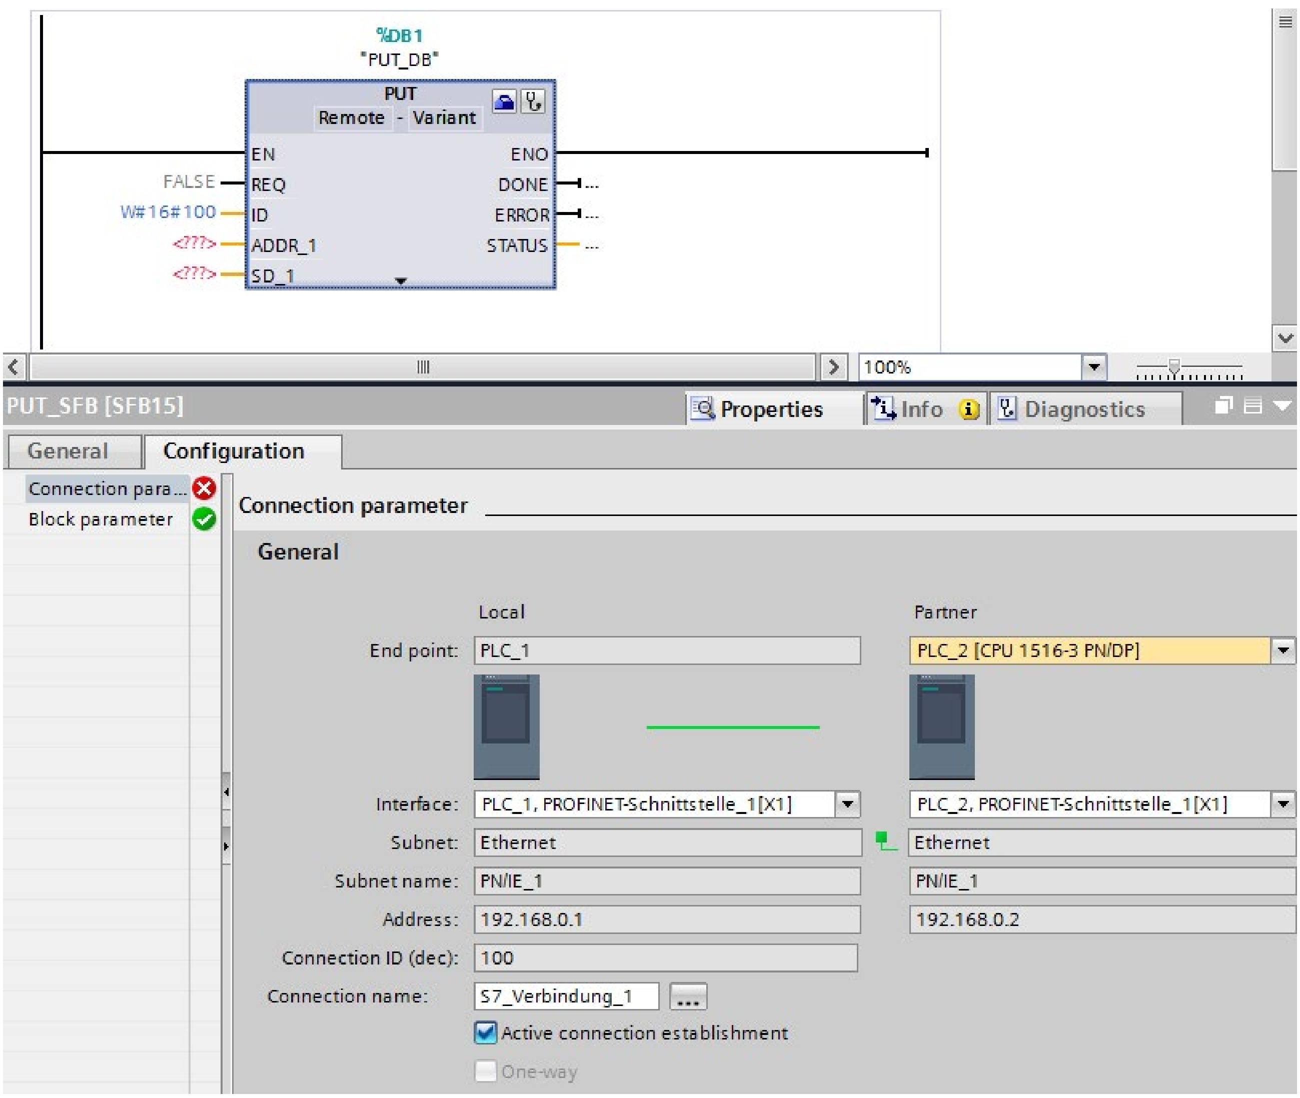

Figure 7-2 Connection configuration for PUT instruction

4. In the drop-down list box of the partner end point, select a connection partner. You can select an unspecified device or a CPU in the project as the communication partner.

   The following parameters are automatically entered as soon as you have selected the connection partner:

   – Name of the partner end point
   – Interface of the partner end point. If several interfaces are available, you can change the interface as required.
   – Interface type of the partner end point
   – Subnet name of both end points
   – IPv4 address of the partner end point
   – Name of the connection which is used for the communication.

5. If required, change the connection name in the "Connection name" input box. If you want to create a new connection or edit an existing connection, click on the "Select connection" button on the right side next to the input box for the connection name.

Note

The PUT and GET instructions between two communication partners can only run if both the hardware configuration and the program part for the partner end point have been loaded into the hardware. To achieve fully functional communication, make sure that you load not only the connection description of the local CPU on the device but also that of the partner CPU as well.

Configuring S7 connections for e.g. BSEND/BRCV

If you want to use the instructions for BSEND/BRCV for S7 communication, for example, you first need to configure an S7 connection.

To configure a S7 connection, follow these steps:

1. Configure the communications partners in the network view of the Devices & networks editor of STEP 7.
2. Select the "Connections" button and the "S7 connection" entry from the drop-down list.
3. Using drag-and-drop, connect the communication partner with each other (via an interface or local end point). If the required S7 subnet does not yet exist, it is created automatically.

   You can also set up a connection to unspecified partners.
4. In the "Connections" tab, select the row of the S7 connection.
5. Set the properties of the S7 connection in the "Properties" tab in the "General" area, for example the name of the connection and the interfaces of the communications partner that will be used.

   For S7 connections to an unspecified partner, set the address of the partner.
   You can find the local ID (reference of the S7 connection in the user program) in the "Local ID" area.
6. In the Project tree, select the "Program blocks" folder for one of the CPUs and open OB1 in the folder by double-clicking on it. The program editor opens.
7. In the program editor, call the relevant instructions for S7 communication in the user program of the communication partner (configured at one end) or in the user programs of the communication partners (configured at both ends). Select the BSEND and BRCV instructions from the "Communication" area of the "Instructions" task card, for example, and drag them to a network of OB1.
8. At the ID parameter of the instruction, assign the local ID of the configured connection to be used for the transmission of data.
9. Assign the parameters for the instructions indicating which data will be written to where and which data will be read from where.
10. Download the hardware configuration and user program to the CPU(s).

S7 communication via CP 1543-1

If you set up S7 communication via the Industrial Ethernet interface of the CP 1543-1, you can select the transport protocol for data transfer in the properties of the S7 connection under "General":

- "TCP/IP" check box selected (default): ISO-on-TCP (RFC 1006): for S7 communication between S7-1500 CPUs
- "TCP/IP" check box cleared: ISO protocol (ISO/IEC 8073): Addressing using MAC addresses

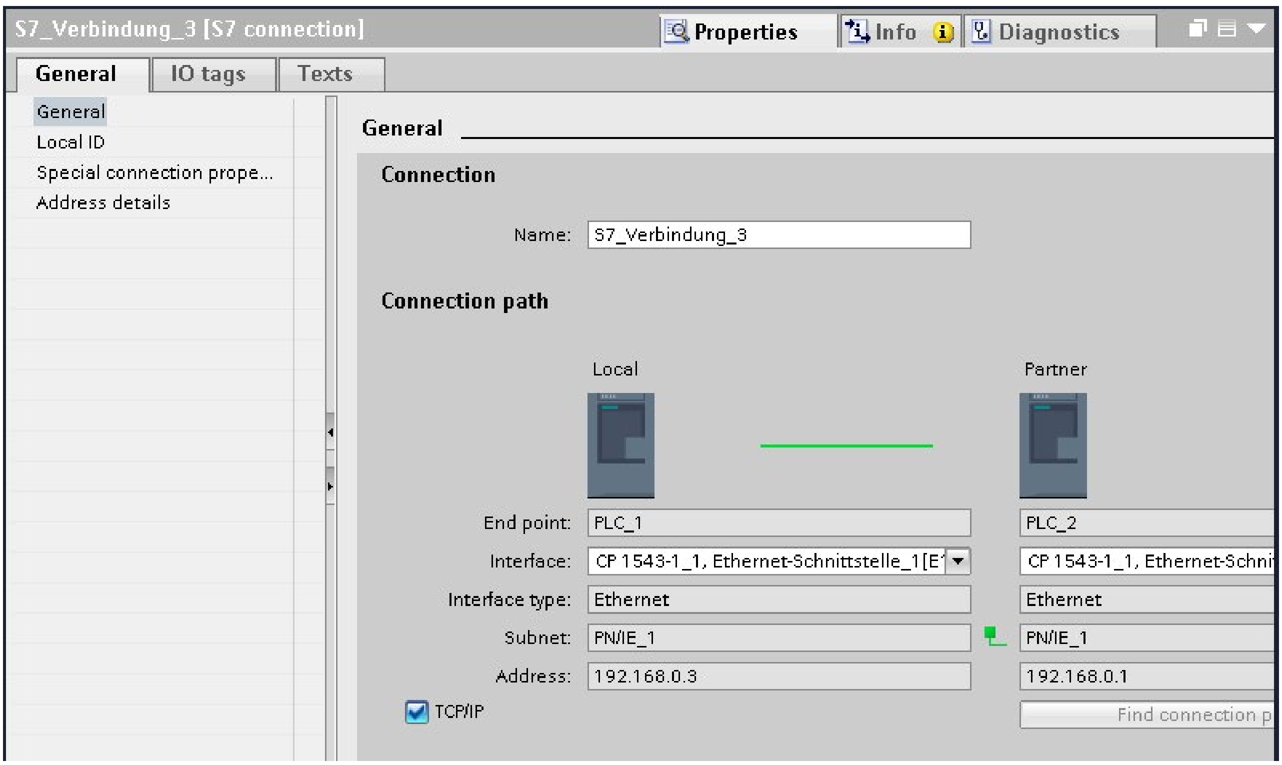

Figure 7-3 Selecting the CP 1543-1 transport protocol

Procedure for setting up an S7 connection via different S7 subnets

You have the option of using an S7 connection over multiple S7 subnets (PROFIBUS, PROFINET/Industrial Ethernet) (S7 routing (Page 260)).

1. Configure the communications partners in the network view of the Devices & networks editor of STEP 7.
2. Select the "Network" button.
3. Connect the relevant interfaces with the S7 subnets (PROFIBUS, PROFINET/Industrial Ethernet) using drag-and-drop.
4. Select the "Connections" button and the "S7 connection" entry from the drop-down list.
5. Using drag-and-drop in our example, connect PLC_1 in the left S7 subnet (PROFIBUS) to PLC_3 in the right S7 subnet (PROFINET).

   The S7 connection between CPU 1 and CPU 3 is configured.

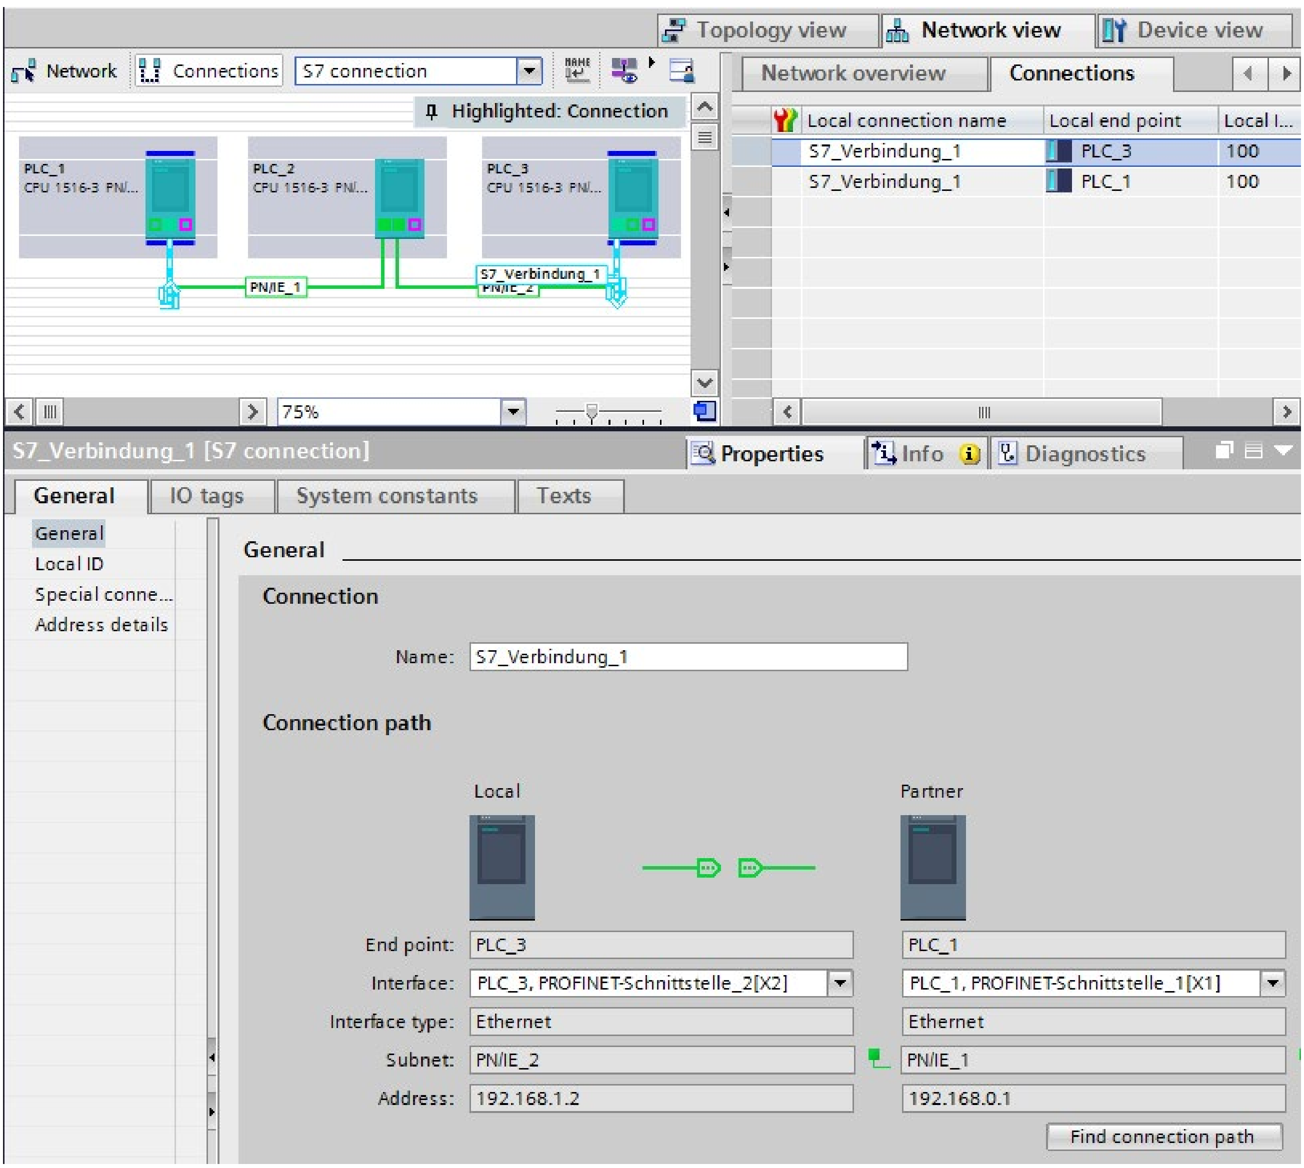

Figure 7-4 S7 connections via different subnets

ET 200SP Open Controller as router for S7 connections

If you assign the "PROFINET onboard [X2]" interface to the CPU 1515SP PC (F) of the SIMATIC PC station, the CPU 1515SP PC (F) can be used as a router for S7 connections. If you use the CP interface for "None, or a different Windows setting", you cannot use the Open Controller as a router for routed S7 connections.

An existing S7 connection routed by the CPU 1515SP PC (F) becomes invalid if the assignment of the interface of the CPU 1515SP PC (F) is changed from "SIMATIC PC station" to "None, or a different Windows setting". Since the PLC now no longer handles routing functions for this connection, when the CPU 1515SP PC (F) is compiled, no message relating to the invalid connection is displayed. The invalid routed S7 connection is displayed only when the end points of the connection are compiled.

The interfaces required for routed S7 connections must remain explicitly assigned on the CPU 1515SP PC (F) . You can edit the assignment of the interface of the CPU 1515SP PC (F) in the properties under "PROFINET onboard [X2] > Interface assignment".

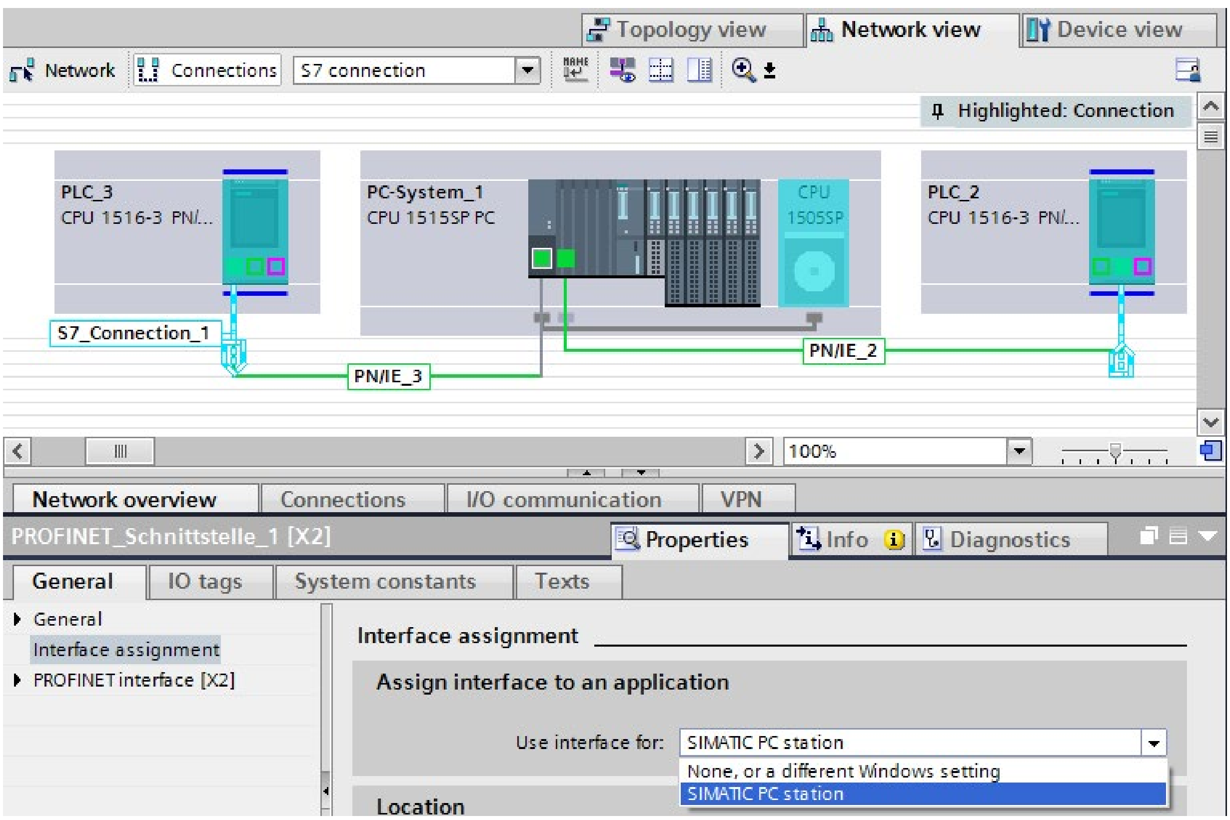

Figure 7-5 S7 routing PC station

Additional information

You can find detailed information on configuring S7 connections and how to use the instructions for S7 communication in the user program in the STEP 7 online help.

Point-to-point link

8

Functionality

A point-to-point connection for S7-1500, ET 200MP and ET 200SP is established via communications modules (CMs) with serial interfaces (RS232, RS422 or RS485):

- S7-1500/ET 200MP:
  - CM PtP RS232 BA
  - CM PtP RS422/485 BA
  - CM PtP RS232 HF
  - CM PtP RS422/485 HF
- ET 200SP:
  - CM PtP

The bidirectional data exchange via a point-to-point connection works between communications modules or third-party systems or devices capable of communication. At least 2 communication partners are required for communication ("point-to-point"). With RS422 and RS485, more than two communications partners are possible.

Protocols for communication via a point-to-point connection

- Freeport protocol (also called ASCII protocol)
- Procedure 3964(R)
- Modbus protocol in RTU format (RTU: Remote Terminal Unit)
- USS protocol (universal serial interface protocol)

The protocols use different layers according to the ISO/OSI reference model:

- Freeport: Uses layer 1 (physical layer)
- 3964 (R), USS and Modbus: Use layer 1 and 2 (physical layer and data link layer; therefore greater transmission reliability than with Freeport). USS and Modbus use additionally layer 4.

Properties of the Freeport protocol

- The recipient recognizes the end of the data transfer by means of a selectable end criterion (e.g. character delay time elapsed, receipt of end character, receipt of a fixed amount of data).
- The sender cannot recognize whether the sent data arrived free of errors at the recipient.

Properties of procedure 3964 (R)

- When the data is sent, control characters are added (start, end and block check characters). Make sure that these control characters are not included as data in the frame.
- Connection establishment and termination makes use of control characters.
- If transfer errors occur, data transfer is automatically repeated.

Data exchange using Freeport or 3964 (R) communication

The data to be sent is stored in the user program of the corresponding CPU in data blocks (send buffer). A receive buffer is available on the communications module for the received data. Check the properties of the receive buffer and adapt them if necessary. You must create a data block for receiving in the CPU.

In the user program of the CPU, the "Send_P2P" and "Receive_P2P" instructions handle the data transfer between the CPU and CM.

Procedure for setting up Freeport or 3964 (R) communication

1. Configure an S7-1500 configuration with CPU and CM in the device view of the hardware and network editor of STEP 7.
2. Select the interface of the CM in the device view of STEP 7.
3. Assign the parameters of the interface (for example connection communication, configuration of message sending) in the Inspector window of STEP 7 under "Properties" > "General".
4. Select the "Send_P2P" or "Receive_P2P" instruction in the "Instructions" task card under "Communication" > "Communications processor" and drag-and-drop the instruction into the user program (for example into a FB).
5. Assign the parameters for the instructions according to your configuration.
6. Download the hardware configuration and user program to the CPU.

Otherwise: Dynamic parameter assignment of the communications module

In certain types of application it is an advantage to set up communication dynamically; in other words, program-controlled by a specific application.

Typical applications for this, could be, for example manufacturers of serial machines. To make the user interfaces as convenient as possible for their customers, these manufacturers adapt the communications services to the particular operator entries.

Instructions for Freeport communication

There are 3 instructions available for the dynamic configuration in the user program for Freeport communication. The following applies to all 3 instructions: the previously valid configuration data is overwritten but not stored permanently in the target system.

- The "Port_Config" instruction is used for the program-controlled configuration of the relevant port of the communications module.
- The "Send_Config" instruction is used for the dynamic configuration, for example of time intervals and breaks in transmission (serial transmission parameters) for the relevant port.
- The "Receive_Config" instruction is used for dynamic configuration, for example of conditions for the start and end of a message to be transferred (serial receive parameters) for the relevant port.

Instructions for 3964 (R) communication

There are 2 instructions available for dynamic configuration in the user program for 3964 (R) communication. The following applies to the instructions: the previously valid configuration data is overwritten but not stored permanently in the target system.

- The "Port_Config" instruction is used for the program-controlled configuration of the relevant port of the communications module.
- The "P3964_Config" instruction is used for the dynamic configuration of protocol parameters.

Properties of the USS protocol

- Simple, serial data transfer protocol with cyclic message frame traffic in half duplex mode that is tailored to the requirements of drive technology.
- Data transfer works according to the master-slave principle.
  - The master has access to the functions of the drive and can, among other things, control the drive, read status values and read and write the drive parameters.

Data exchange using USS communication

The communications module is the master. The master continuously sends frames (job frames) to the up to 16 drives and expects a response frame from each addressed drive.

A drive sends a response frame under the following conditions:

- When a frame is received without errors
- When the drive is addressed in this frame

A drive must not send if these conditions are not met or the drive was addressed in the broadcast.

The connection to the relevant drives exists for the master once it receives a response frame from the drive after a specified processing time (response delay time).

Procedure for setting up USS communication

1. Configure an S7-1500 configuration with CPU and CM in the device view of the hardware and network editor of STEP 7.
2. In the Project tree, select the "Program blocks" folder and open OB1 in the folder by double-clicking on it. The program editor opens.
3. Select the instructions for USS communication according to your task in the "Communication" area, "Communications processor" folder of the "Instructions" task card and drag them to a network of OB1:
   - The "USS_Port_Scan" instruction allows you to communicate via the USS network.
   - The "USS_Drive_Control" instruction prepares send data for the drive and evaluates the response data of the drive.
   - The "USS_Read_Param" instruction is used to read out parameters from the drive.
   - The "USS_Write_Param" instruction is used to change parameters on the drive.
4. Assign the parameters for the instructions according to your configuration.
5. Download the hardware configuration and user program to the CPU.

Properties of the Modbus protocol (RTU)

- Communication takes the form of serial, asynchronous transfer with a transmission speed of up to 115.2 kbps, half duplex.
- Data transfer works according to the master-slave principle.
- The Modbus master can send jobs for reading and writing operands to the Modbus slave:
  - Reading inputs, timers, counters, outputs, memory bits, data blocks
  - Writing outputs, memory bits, data blocks
- Broadcast to all slaves is possible.

Data exchange using Modbus communication (RTU)

The communications module can be a Modbus master or Modbus slave. A Modbus master can communicate with one or more Modbus slaves (the number depends on the physical interface). Only the Modbus slave explicitly addressed by the Modbus master is permitted to return data to the Modbus master. The slave detects the end of the data transfer and acknowledges it. If an error occurs, it provides an error code to the master.

Procedure for setting up Modbus communication (RTU)

1. Configure an S7-1500 configuration with CPU and CM in the device view of the hardware and network editor of STEP 7.
2. In the Project tree, select the "Program blocks" folder and open OB1 in the folder by double-clicking on it. The program editor opens.
3. Select the instructions for Modbus communication according to your task in the "Communication" area, "Communications processor" folder of the "Instructions" task card and drag them to a network of OB1:
   - The "Modbus_Comm_Load" instruction configures the port of the CM for Modbus communication.
   - The "Modbus_Master" instruction is used for Modbus master functionality.
   - The "Modbus_Slave" instruction is used for Modbus slave functionality.
4. Assign the parameters for the instructions according to your configuration.
5. Download the hardware configuration and user program to the CPU.

Additional information

- You can find more detailed information on communication via point-to-point connections and basics of serial data transmission in the function manual CM PtP communication module - Configurations for point-to-point connections (http://support.automation.siemens.com/WW/view/en/59057093).
- You can find a description of how to use the instructions for point-to-point connections in the user program in the STEP 7 online help.
- You can find information about the communications modules with a serial interface in the manual of the particular communications module.

OPC UA communication 9

9.1 What you need to know about OPC UA

9.1.1 OPC UA and Industrie 4.0

Uniform standard for information and data exchange

Industry 4.0 stands for the intensive utilization, evaluation and analysis of the large volumes of data from production in IT systems at the enterprise level. With Industry 4.0, data exchange between the production and enterprise levels is rapidly increasing. However, a prerequisite for success is a uniform standard for the information and data exchange.

The OPC UA (OPC Unified Architecture) standard is particularly suitable for data exchange across different levels thanks to its independence from specific operating systems, its secure transfer procedures and the semantic description of data. OPC UA makes available not only data but also information about the data (data types), at the same time making possible machine-interpretable access to the data.

9.1.2 OPC UA for S7-1500 CPUs

In OPC UA, one system operates as a server and provides data the existing information to other systems (clients).

OPC UA clients, for example, have read and write access to data on an OPC UA server. OPC UA clients call methods on the OPC UA server.

You can access this data online with a client, including e.g. information on performance and diagnostics. In OPC UA terminology, this function is called "Browsen". The "Subscription" function saves the regular reading of a tag - a client only has values sent to it from the server when a change has occurred.

A system can be both a client and a server.

OPC UA server of the S7-1500 CPU

As of firmware version 2.0, an S7-1500 CPU is equipped with an OPC UA server.

The following sections describe how you configure the OPC UA server of the S7-1500 CPU to make data and methods available for OPC UA clients so that clients have read or write access to PLC tags on the CPU and can call server methods.

The following sections also set out how to integrate companion specifications into the address space of the OPC UA server.

OPC UA client of the S7-1500 CPU

As of firmware version V2.6, an S7-1500 CPU is additionally equipped with an OPC UA client.

The following sections show how to use standardized instructions (PLCopen function blocks) to create a user program that, as an OPC UA client, reads data from an OPC UA server or writes data to an OPC UA server or calls methods from an OPC UA server.

STEP 7 (TIA Portal) assists you in creating user programs by providing an editor for client interfaces and a parameter assignment for OPC UA connections:

The OPC UA instructions for an S7-1500 CPU as client are described in detail in the help to the instructions (Instructions > Communication > OPC UA).

OPC UA client for test purposes

The following description uses various different OPC UA clients to illustrate the use of OPC UA clients:

- "UaExpert" of Unified Automation. An extensive client that can be used free of charge:
  Link for downloading UaExpert (https://www.unified-automation.com/downloads/opc-ua-clients.html)
- "UA Sample Client" of the OPC Foundation. This client is available free of charge for users who are registered with the OPC Foundation :
  Link for downloading the example client of the OPC Foundation (https://opcfoundation.org)

Application example in Industry online support

Siemens Industry Online Support provides an application example with a client API free of charge. .NET developers can use the functions of this interface to access the OPC UA server of an S7-1500. The client API is based on the .NET OPC UA stack of the OPC Foundation.

The application example shows how to establish connections between servers and clients, for example. It also demonstrates the reading and writing of PLC tags.

Link to download: OPC UA .NET client for the SIMATIC S7-1500 OPC UA Server (http://support.automation.siemens.com/WW/view/en/109737901)

9.1.3 General features of OPC UA

The key features of OPC UA

- OPC UA does not depend on a specific operating system platform.

  OPC UA can, for example, be used with Windows, Linux, Mac OS X, a real-time operating system or a mobile operating system (such as Android).
- OPC UA is implemented in various different programming languages.

  The OPC Foundation has implemented the OPC UA standard in several programming languages: Stacks for ANSI C, .NET and Java are available.
- The OPC Foundation offers the Java stack and .NET stack as well as example programs as open source software. See Github (https://github.com/opcfoundation).
- A number of companies offer Software Development Kits (SDK) containing the OPC Foundation stacks and other functions to facilitate the development of solutions.

  Advantages of using SDKs:
  - Support from the supplier
  - Tested software
  - Detailed documentation
  - Clear license conditions (important for selling of solutions)
- Scalability

  OPC UA can be used in sensors, embedded systems, controllers, PC systems and smartphones, as well as in servers running MES and ERP applications.

  OPC UA and PROFINET can also be used together. The two protocols use the same network infrastructure.
- Simple client-server principle

  An OPC UA server provides information within a network and an OPC UA client retrieves this information.
- Integrated security mechanisms

  OPC UA uses security mechanisms at various levels:
  - A secure connection can only be established between an OPC UA server and an OPC UA client if the client and server can register with X.509-v3 certificates and accept each other's certificates (security at the application level). Various security policies are possible, including a non-secure connection between server and client (Security Policy: "No security").
  - Before allowing access, a server can request the following information from the user:

    - A certificate (cannot be configured in STEP 7)

    - User name and password

    - No user authorization

The security mechanisms are optional and configurable.

- Independence of a specific transport layer

  The following transport mechanisms are currently supported by OPC UA:

  – The transfer of messages as a binary stream directly via TCP/IP
  – The transfer of messages with XML over TCP/IP and HTTP. This transport mechanism allows only a slow transfer and is therefore almost never used. The S7-1500 CPUs do not support this transport mechanism.

  Binary data exchange is supported by all OPC UA applications (required in OPC UA specification).

- PLC tag mapping

  The information of the OPC UA server (for example the PLC tags) is modeled as nodes connected to one another via references. This makes it possible to browse from node to node with an OPC UA client and find out what content can be read, monitored or written.

- Information

  OPC UA servers provide a lot of information, for example about the CPU, the OPC UA server itself, the data and the data types.

- Instance concept

  OPC UA is based on a type instance concept. Both instances and their type definitions are available in runtime.

- Differentiation of the functionality with profiles: S7-1500 supports the Embedded UA Server Profile, for example

9.1.4 From the Classic OPC interface to OPC UA

Standardized interface

Classic OPC only runs on Windows operating systems.

To get around this restriction, the OPC Foundation developed the OPC UA standard.

The standard is not platform-specific and uses an optimized, TCP-based binary protocol for high-performance applications.

Different systems are therefore able to exchange data, for example:

- Controllers with MES and ERP systems
- Siemens controllers with controllers from other manufacturers
- Smartphones with controllers
- Embedded systems with controllers
- Smart sensors with controllers

9.1.5 Addressing nodes

Nodes in the OPC UA address space are uniquely identified by a NodeId (Node ID or Node Identifier).

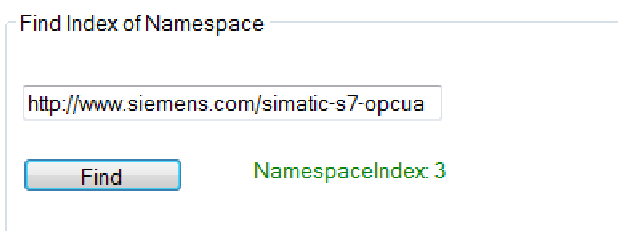
The NodeId consists of an identifier, identifier type and a namespace index. Namespaces are used to avoid naming conflicts. The OPC Foundation has defined a wide range of nodes that provide information about the given OPC UA server. These nodes can be found in the namespace of the OPC Foundation and have the index 0.

The OPC Foundation also defines data types and tag types.

Namespace

All the tags or methods of an S7-1500 are contained in the namespace (Namespace) "http://www.siemens.com/simatic-s7-opcua". By default this namespace has the Index 3. The index may change later if additional namespaces are inserted into the server or if existing ones are deleted. The current index of the namespace therefore needs to be requested from the server before values are read or written.

The figure below shows the result of such a query. The Siemens "UaClient" program is used as an example.

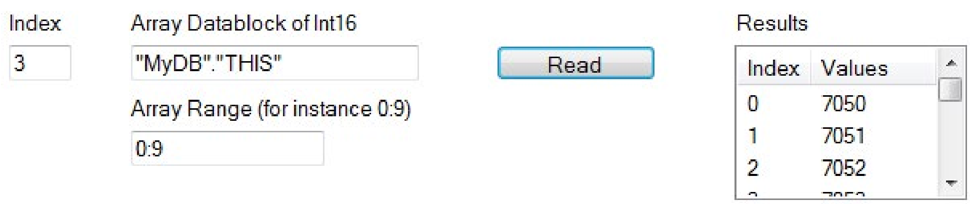


Identifier

The Identifier corresponds to the name of the PLC tag in quotation marks. The quotation mark is the only sign that is not permitted as part of a name in STEP 7. Quotation marks avoid naming conflicts.

The following example reads the value of the "StartTimer" tag:

The Identifier can consist of several components. The individual components are then separated by a dot. The following example reads the "MyDB" array data block completely. This data block contains an array with ten integer values. All ten values should be read in one pass. Therefore, "0:9" is entered at the array range.



PLC tags in the address space of the OPC UA server

The figure below shows where the PLC tags in the example are located in the address space of the OPC UA server (excerpt from UA client):

The "MyDB" data block is a global data block. The data block is therefore located below the node "DataBlocksGlobal". "StartTimer" is a memory tag and is therefore stored below the "Memory" node.

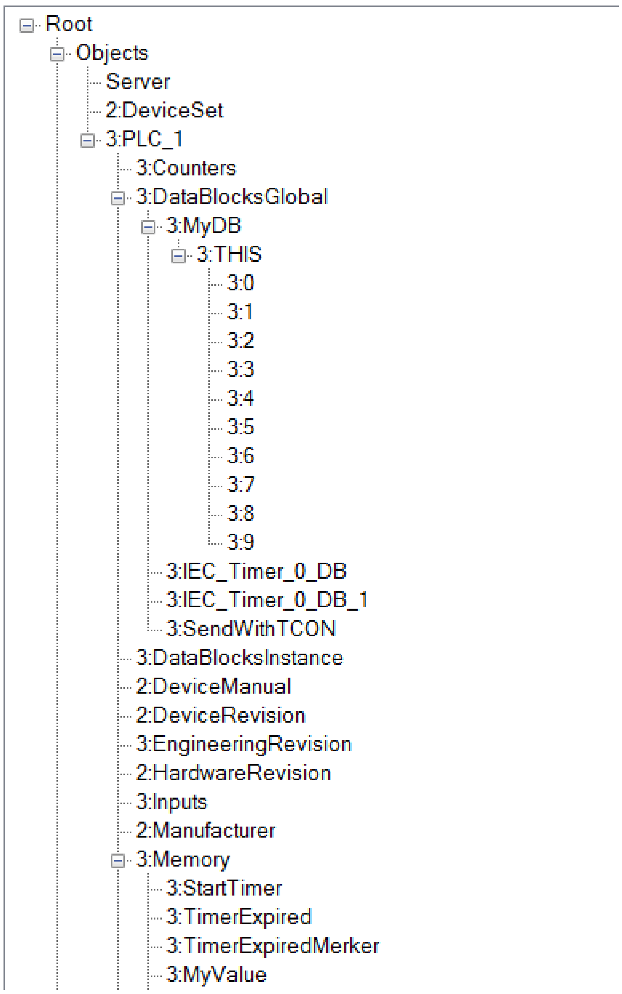


Figure 9-1 PLC tags in the address space of the OPC UA server

Methods in the address space of the OPC UA server

If you implement a method via your user program, this takes the following form in the address space of the OPC UA Server (see AUTOHOTSPOT):

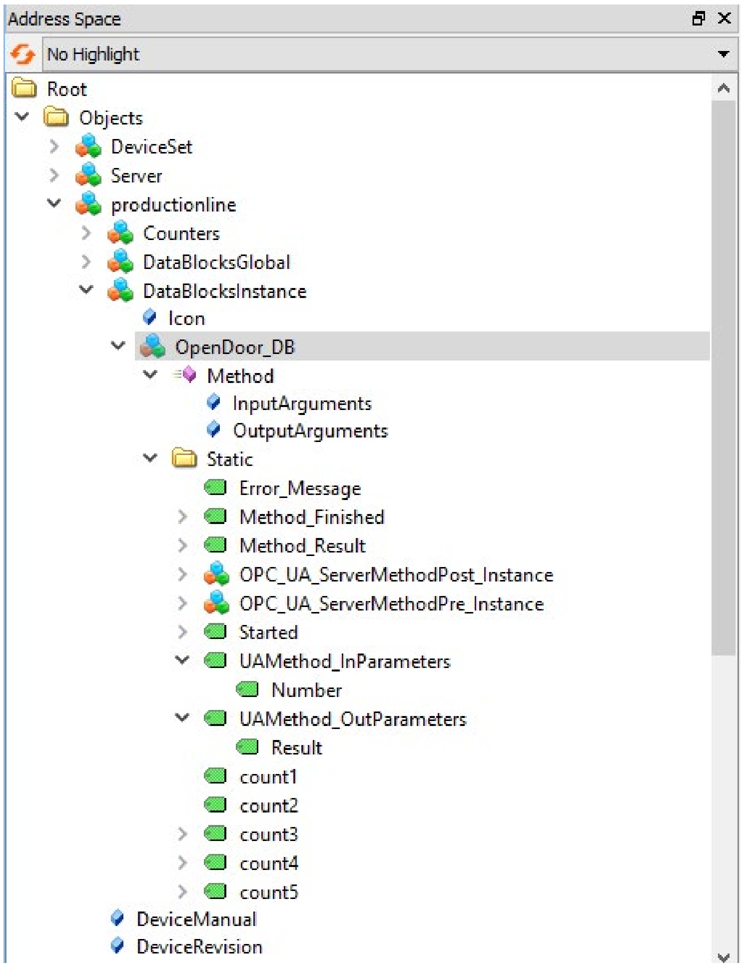

Figure 9-2 Methods in the address space of the OPC UA server

9.1.6 Mapping of data types

SIMATIC and OPC UA data types

SIMATIC data types do not always correspond with OPC UA data types.

S7-1500 CPUs provide SIMATIC tags (with SIMATIC data types) to their own OPC UA server as OPC UA data types so that OPC UA clients can access these tags over the server interface with OPC UA data types.

A client can read the attribute "DataType" from such a tag and reconstruct the original data type in SIMATIC.

Example

A tag has the SIMATIC data type "COUNTER". You read COUNTER → UInt16 in the table. You now know that you do not need to convert; the COUNTER value is sent over the line as a UInt16 data type.

The client detects from the attribute "DataType" that the tag is actually the SIMATIC data type "COUNTER". With this knowledge, the client reconstructs the data type.

Table 9- 1 SIMATIC and OPC UA data types

SIMATIC data type	OPC UA data type
BOOL	Boolean
BYTE	BYTE → Byte
WORD	WORD → UInt16
DWORD	DWORD → UInt32
LWORD	LWORD → UInt64
SINT	SByte
INT	Int16
DINT	Int32
LINT	Int64
USINT	Byte
UINT	UInt16
UDINT	UInt32
ULINT	UInt64
REAL	Float
LREAL	Double
S5TIME	S5TIME → UInt16
TIME	TIME → Int32

SIMATIC data type	OPC UA data type
LTIME	LTIME → Int64
DATE	DATE → UInt16
TIME_OF_DAY (TOD)	TOD → UInt32
LTIME_OF_DAY (LTOD)	LTOD → UInt64
DATE_AND_TIME (DT)	DT → Byte[8]
LDT	DateTime
DTL Special note: You can only describe the structure completely with an OPC UA client. You have read-only access individual elements of this structure (e.g. "YEAR")	mapped as structure
CHAR	CHAR → Byte
WCHAR	WCHAR → UInt16
STRING (Code page 1252 or Windows-1252)	STRING → String
WSTRING (UCS-2; Universal Coded Character Set)	String
TIMER	TIMER → UInt16
COUNTER	COUNTER → UInt16

Arrays

A read or write job with OPC UA is always an array access, which means that it always has an index and length. A single tag is a special case of an array (index 0 and length 1). The data type is simply sent repeatedly on the line. For the tags, the "DataType" attribute indicates the basic data type. The attributes "ValueRank" and "ArrayDimensions" show whether or not you are dealing with an array and how large the array is.

Data types based on arrays

There are SIMATIC data types for which an OPC UA value is mapped to an array of bytes. An array of these data types is then mapped to a two-dimensional array.

Example: The SIMATIC data type DATE_AND_TIME (DT) is mapped to an 8-byte array (Byte[8]), see table above. When you define an array of the SIMATIC data type DATE_AND_TIME (DT), it is considered a two-dimensional array.

This fact affects the use of system data types such as OPC_UA_NodeAdditionalInfo and OPC_UA_NodeAdditionalInfoExt, for example:

For the data types described above, you must use the system data type OPC_UA_NodeAdditionalInfoExt for multidimensional arrays instead of OPC_UA_NodeAdditionalInfo.

Structures

Structures are transferred as ExtensionObject. The S7-1500 server uses binary representation for transmission of the ExtensionObjects over the line; the individual structure elements come one after the other. At the front is the NodeId of the data type; this is used by the client to establish the structure.

For the OPC UA specification <= V1.03, a client must read, decode and interpret the complete DataTypeDictionary for this purpose (unless it has already done so offline with an XML import).

Additional information

More details on mapping of basic data types, arrays and structures can be found in the OPC UA Specification Part 6, "Mappings" (see OPC UA BINARY there).

9.1.7 What you need to know about OPC UA clients

Basics of OPC UA clients

OPC UA clients are programs that do the following:

- Access the information from an OPC UA server (for example an S7-1500 CPU): read, write, subscriptions
- Execute methods through the OPC UA server

However, OPC US clients can access data that is enabled for this purpose (see "Managing write and read rights").

You need the endpoint of the server to establish a connection to an OPC UA server (see "Endpoints of the OPC UA servers (Page 157)").

Reading out information from the OPC UA server

When a connection to an end point of the server exists, you can use the navigation function of the client: You navigate starting from a defined starting point (from the "root" node) through the address space of the server.

The following information is provided in the process:

- Enabled PLC tags, data blocks and data block components
- Namespace index and identifiers of these PLC tags, data blocks and DB components
- Data types of the PLC tags and DB components
- Number of components in arrays (required for reading and writing arrays)

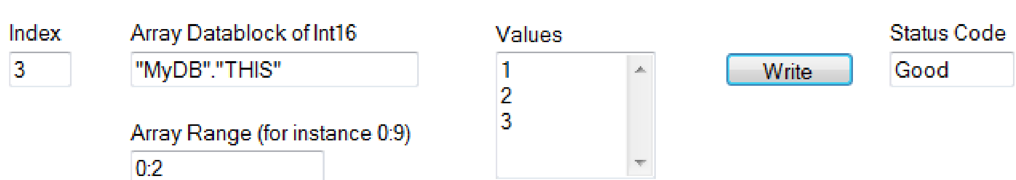
In addition, you receive information about the OPC UA server itself as well as information about the S7-1500 based on the "OPC UA for Devices" standard of the OPC Foundation (for example, serial number, firmware version).

Reading data from the server and writing to the server

You now know the namespace, identifier and data type of PLC tags. This means that you can now specifically read individual PLC tags and DB components as well as complete arrays and structures. Examples for reading Boolean tags and array data blocks are available under Addressing nodes (Page 132).

Rules for access to structures are available here (Page 243).

With the information that you obtain while navigating through the address space of the server (index, identifier and data type), you can also transfer values to the S7-1500 with the OPC UA client. The following example overwrites the first three values in the array data block "MyDB".



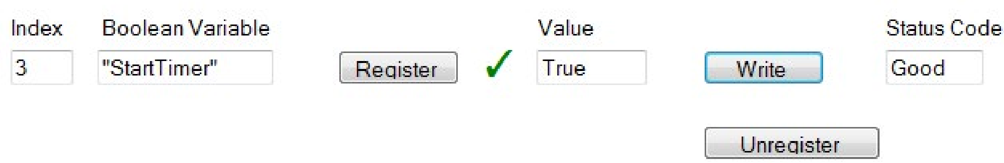
For "Array Range" you specify which components of the array you want to overwrite. The "Good" status code indicates that the values were transferred successfully. However, you can only write the values to the S7-1500 but not the time stamps of these values. The time stamps can only be read.

Faster access through registration

The examples up to now use strings as Identifier, for example, "MyBD2"."THIS". If, however, an Identifier is used as a numeric Node ID instead of a String Node ID, access is much faster. If you access specific tags regularly, you should use the functions "RegisteredRead" and "RegisteredWrite":

In this case, your client first logs in the PLC tag on the server., The server returns an Identifier that the client uses for the actual access. This Identifier applies solely to the current session and has to be queried again when the session connection is terminated/lost.

In the following example, the "StartTimer" tag is first registered on the server. Afterwards, the rapid function "RegisteredWrite" is used for setting the value.



In accordance with the same scheme, the "RegisteredRead" function can also be used, which is particularly useful for recurring data readouts. Take into account, however, that depending on the application it may be advisable to use a Subscription instead.

Recommendation: It is best to place registrations in the startup program of the OPC UA client, since the registration takes up time.

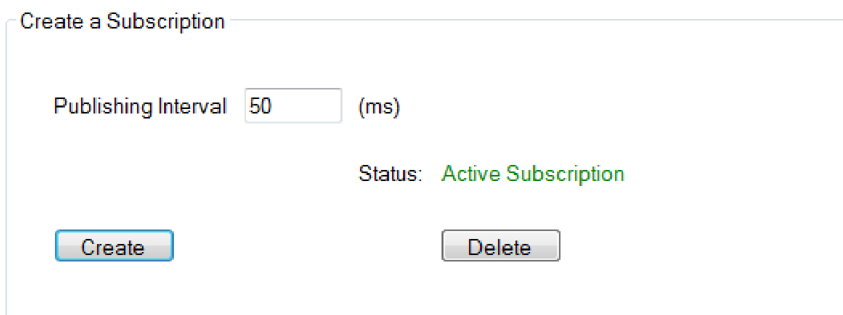
Please note that you can set the maximum number of registered nodes in the properties of the S7-1500 CPU and that the Clients have to respect this number, see AUTOHOTSPOT.

Subscription

The term "Subscription" is used for a function in which only those tags for which an OPC UA client has registered at the OPC UA server are transferred. The OPC UA server only sends a message to the OPC UA client for these registered tags (Subscriptions) when a value has changed. The monitoring of these tags makes constant sampling by the OPC UA client (Polling) superfluous, which reduces the network load.

You have to create a Subscription to use this function. For this purpose, you specify the "Publishing Interval" at the UA client and click the "Create" button. The publishing interval is the time interval in which the server sends new values to the client in a notification (data change notification).

In the following example a subscription has been created: The client receives a message with the new values (publishing interval 50 ms) every 50 milliseconds here.



Preventing server overload

You can set the OPC UA server of the S7-1500 CPU by means of the "Minimum publishing interval" in such a way that it does not serve extremely short send intervals requested by the client; see Settings of the OPC UA server.

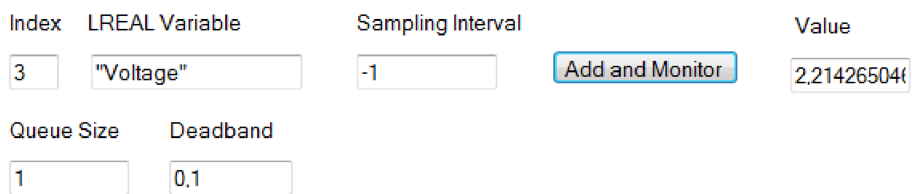
Example: A client wants to be operated at a publishing interval of 50 ms as detailed above. Such a short publishing interval would, however, result in a high network and server load. You should therefore set 1000 ms as the "Minimum publishing interval" for the server. Clients whose subscription requires shorter publishing intervals are "slowed" to 1000 ms and the server is protected from overload.

Sampling and transmission (Sampling & Publishing) within the scope of a subscription are communication processes which, like other communication processes (TCP/UDP/Web server communication...), are processed by the CPU with priority 15. OBs with higher priority interrupt the communication. If you set the sampling and publishing intervals too short, this setting causes a high communication load. Therefore, select intervals as large as possible, which are still sufficient for the application.

For information about the consistency of tags, refer to Consistency of CPU tags (Page 220).

Monitoring of PLC tags

When the Subscription has been created, you inform the server which tags are to be monitored with it. In the following example, the "Voltage" tag was added to the subscription.



The "Voltage" tag contains the value of a voltage that is detected by an S7-1500 CPU.

The sampling interval ("Sampling Interval") contains a negative value (-1). This determines that the default setting of the OPC UA server is used for the sampling interval. The default setting is defined by the "Publishing Interval" of the subscription. If you want to set the smallest possible sampling interval, select the value "0".

In this example, the length of the queue is set to "1": Only one value is read from the CPU at an interval of 50 milliseconds and subsequently sent to the OPC UA client when the value has changed.

The "Deadband" parameter in this example is "0.1": Changes in value have to amount to 0.1 Volt; only then does the sender send the new value to the client. The server does not send smaller changes in value. You can use this parameter, for example, to disable signal noise: Slight changes in a process variable which do not have a real meaning.

9.2 Security at OPC UA

9.2.1 Security settings

Addressing risks

OPC UA allows the exchange of data between different systems, both within the process and production levels and to systems at the control and enterprise level.

This possibility also entails security risks. That is why OPC UA uses a range of security mechanisms:

- Verification of the identity of OPC UA server and clients.
- Checking of the identity of the users.
- Signed/encrypted data exchange between OPC UA server and clients.

These security policies should only be bypassed in cases where it is absolutely necessary:

- During commissioning
- In stand-alone projects without external Ethernet connection

If you have selected the endpoint "None" for "UA Sample Client" of the OPC Foundation, for example, the program issues a clear warning:

Warning: Selected Endpoint has no security.

When STEP 7 compiles your project it also checks whether you have considered the setting options for the protection and warns you of possible risks. This also includes an OPC UA security policy with the setting "no security", which corresponds to the end point "None".

Note

Disabling security policies you do not want

If you have selected all security policies (default setting) in the secure channel settings of the S7-1500 OPC UA server – in other words the end point "None" (no security) – non-secure data traffic (neither signed nor encrypted) between the server and client is also possible. The OPC UA server of the S7-1500 CPU also sends its public certificate to the client at "None" (No security). And some clients check this certificate. However, the client is not forced to send a certificate to the server. The identity of the client may possibly remain unknown. Each OPC UA client can then connect to the server irrespective of any subsequent security settings.

When configuring the OPC UA server, make sure that only security policies that are compatible with the security concept for your machine or plant are selected. All other security policies should be disabled.

Recommendation: Use the setting "Basic256Sha256 - Sign and Encrypt", which means that the server only accepts Sha256 certificates. The security policy "Basic128Rsa15" is disabled by default and should not be used as an end point. Select end points with a higher security policy.

Additional security rules

- Only use the end point "None" in exceptional cases.
- Only use the "guest authentication" of the user in exceptional cases.
- Only allow access to PLC tags and DB components via OPC UA if it is genuinely necessary.
- Use the list of trusted clients in the settings of the S7-1500 OPC UA client to allow access to certain clients only.

9.2.2 Certificates pursuant to ITU X.509

Security mechanisms are integrated in several layers in OPC UA. Digital certificates have an important role here. An OPC UA client can only establish a secure connection to an OPC UA server when the server accepts the digital certificate of the client and classifies it as trusted.

See section "Configuring the OPC UA server of the S7-1500 CPU".

The client must also check and trust the certificate of the server. The server and client must show their identities and prove that they are what they claim to be: They must prove their identity. Mutual authentication of client and server, for example, prevents man-in-the-middle attacks.

Man-in-the-middle attacks

A "man-in-the-middle" could have positioned itself between server and client. A man-in-the-middle is a program that intercepts communication between server and client and claims to be a client or server, and is thus able to obtain information about the S7 program or to set values in the CPU and attack a machine or plant.

OPC UA uses digital certificates that meet standard X.509 of the International Telecommunication Union (ITU).

This allows the identity of a program, a computer or an organization to be proven (authenticated).

X.509 certificates

An X.509 certificate includes the following information:

- Version number of the certificate
- Serial number of the certificate
- Information on the algorithm used by the certificate authority to sign the certificate.
- Name of the certificate authority
- Start and end of the validity period of the certificate
- Name of the program, person or organization for which/whom the certificate has been signed by the certificate authority.
- The public key of the program, person or organization.

An X509 certificate thus links an identity (name of a program, person or an organization) to the public key of the program, person or organization.

Check during connection establishment

When a connection is being established between the client and server, the devices check all information from the certificate that is required to establish integrity, for example signature, validity, application name (URN) and as of firmware V2.5 also the IP addresses of the client in the client certificate.

The validity period stored in the certificate is also checked. The CPU clock must therefore be set and date/time must be within the validity period, otherwise no communication takes place.

Signing and encryption

To allow you to check whether a certificate has been manipulated, certificates are signed.

There are various possible procedures here:

- Within the TIA Portal you have the possibility to generate and sign certificates. If you have protected your project and are logged in as a user with the function right to make security settings, you can use the global security settings. The global security settings allow access to the certificate manager and therefore to the certificate authority (CA) of the TIA Portal.
- Additional options are available for creating and signing certificates. In the TIA Portal, you can import certificates into the global certificate manager.
  - You contact a certificate authority (CA) and have your certificate signed.

    In this case, the certificate authority checks your identity and signs your certificate with the private key of the certificate authority. For this purpose you send a CSR (Certificate Signing Request) to the certificate authority. The process of creating a CSSR with the OpenSSL tool yourself is described here. (Page 148)
  - You yourself create a certificate and sign it.

    To this purpose you use, for example, the "Opc.Ua.CertificateGenerator" program of the OPC Foundation. The procedure is described here (Page 37). Or use OpenSSL: Instructions are available under Generating PKI key pairs and certificates yourself (Page 149).

Useful information: Certificate types

- Self-signed certificate:

  Each device generates and signs its own certificate. Application examples: Static configuration with limited number of communication nodes.

  No new certificates can be derived from a self-signed certificate. However, you need to load all self-signed certificates from partner devices to the CPU (STOP required).

- CA certificate:

  All certificates are generated and signed by a certificate authority. Application examples: Dynamically growing plants.

  You only need to download the certificate from the certificate authority to the CPU. The certificate authority can generate new certificates (partner devices can be added without CPU STOP).

Signing

The signature makes it possible to prove the integrity and source of a message as detailed below.

Signing starts with the sender creating a hash value from the plain text (plain text message). The sender then encrypts the hash value with its private key and subsequently transfers the plain text together with the encrypted hash value to the recipient. To verify the signature, the recipient needs the public key of the sender (this is contained in the X509 certificate of the sender). The recipient uses the sender's public key to decrypt the hash value received. The recipient then forms the hash value themselves from the plain text received (the hash process is contained in the sender's certificate). The recipient compares the two hash values:

- If the two hash values are identical, the plain text message has reached the receiver unchanged and has not been manipulated.
- If the two hash values do not match, the plain text message has not reached the receiver unchanged. The plain text message has been manipulated or has been distorted during transfer.

Encryption

Encrypting data prevents unauthorized parties from reading the content. X509 certificates are not encrypted; they are public and can be viewed by anyone.

Encryption involves the sender encrypting the plain text message with the public key of the recipient. To do so, the sender requires the recipient's X509 certificate, as it contains the public key of the recipient. The recipient decrypts the message with their private key. Only the recipient can decrypt the message: They alone hold the private key. The private key must therefore never be disclosed.

Secure channel

OPC UA uses the private and public key of client and server to establish a secure connection, the secure channel. Once the secure connection has been established, the client and server generate an internal key. The internal key is only known to the client and server. The client and server use this internal key to sign and encrypt messages. This symmetric process (a shared key) is much faster than asymmetric processes (private and public key).

9.2.3 Certificates with OPC UA

Usage of X509 certificates with OPC UA

OPC UA uses three types of X.509 certificates for establishing connections from client to server:

- OPC UA application certificates

  Such X.509 certificates identify the software instance, the installation of client or server software. For the "Organization name" attribute, you enter the name of the company that uses the software.

  Note

  The OPC UA server of the S7-1500 uses application certificates also for the security setting "None" (No security). This ensures compatibility to OPC UA V1.1 and earlier versions.

- OPC UA software certificates

  This X-509 certificate identifies a specific version of the client or server software. These certificates contain attributes that describe which tests this version of the software has passed during certification by the OPC Foundation (or recognized test laboratories). For the "Organization name" attribute, you enter the name of the company that has developed or markets the software.

  Note

  Software certificates are not supported in STEP 7.

- OPC UA user certificates

  This X.509 certificate identifies the specific user who, for example, accesses process data from the OPC UA server of an S7-1500 CPU. This certificate is not required if the user can authenticate themselves with a password, or if anonymous access is configured.

  Note

  User certificates are not supported in STEP 7.

These certificates are end-entity certificates: They identify, for example, a person, an organization, a company or an instance (installation) of a software.

9.2.4 Creating self-signed certificates

Using the client's certificate generator

Many OPC UA client applications or SDKs are integrated in a sample application that allows you to generate certificates for the client from this application.

The description for certificate generation can generally be found in the context for describing the OPC UA client application.

Example client from the online support

The OPC UA .NET client for the SIMATIC S7-1500 OPC UA server (https://support.industry.siemens.com/cs/ww/en/view/109737901) creates a self-signed software certificate of the client application in the Windows Certificate Store during the first program start. The documentation on this example describes the procedure for handling these certificates.

Using the certificate generator of the TIA Portal

If you use an OPC UA client that does not generate a client certificate, self-signed certificates can be created with STEP 7.

To do this, follow these steps:

1. In the properties of the CPU, double-click "<Add new>" under "Protection & Security > Certificate manager > Device certificates".
2. Click "Add".
3. In the "Create a new certificate" dialog, select the "OPC UA client" option for "Usage".
4. Click "OK".

In the field "Subject Alternative Name" STEP 7 automatically enters the URI for the generated certificate. In the program-specific certificate generation by means of the .NET stack of the OPC Foundation, the field is called, for example, "ApplicationUri" - it can have a different name in other tools for certificate generation.

9.2.5 Generating PKI key pairs and certificates yourself

This section is only relevant if you want to use an OPC UA client that cannot itself create a PKI key pair and a client certificate. In this case, you generate a private and a public key using OpenSSL, generate an X.509 certificate, and sign the certificate yourself.

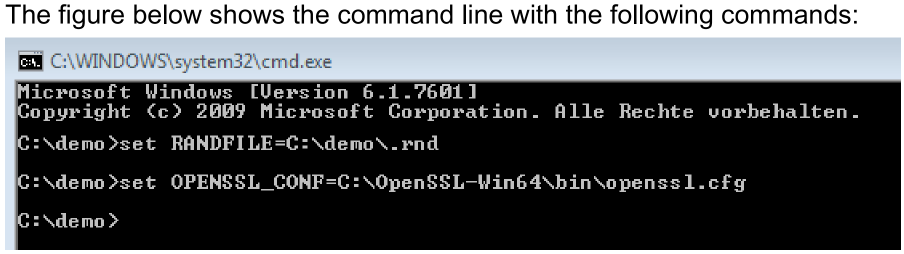
Using OpenSSL

OpenSSL is a tool for Transport Layer Security that you can use to create certificates. You can also use other tools, for example XCA, a type of key management software with a graphical user interface for an improved overview of certificates issued.

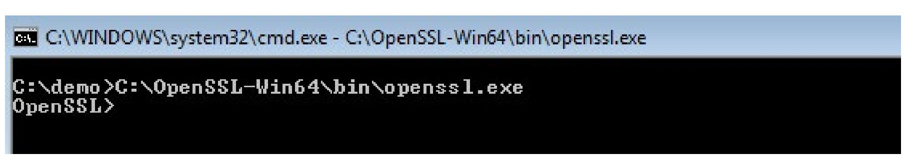
To work with OpenSSL under Windows, follow these steps:

1. Install OpenSSL under Windows. If you are using a 64-bit version of the operating system, install OpenSSL in the "C:\OpenSSL-Win64" directory, for example. You can obtain OpenSSL-Win64 as a download from various providers for open source software.
2. Create a directory, for example "C:\demo".
3. Open the command line (cmd.exe). To do so, click "Start" and enter "cmd" in the search field. Right-click "cmd.exe" in the results list and run the program as an administrator. Windows then opens the command line (DOS prompt)
4. Change to the "C:\demo" directory. To do this, enter the following command: "cd C:\demo".
5. Set the following network variables:
   - set RANDFILE=c:\demo\.rnd
   - set OPENSSL_CONF=C:\OpenSSL-Win64\bin\openssl.cfg

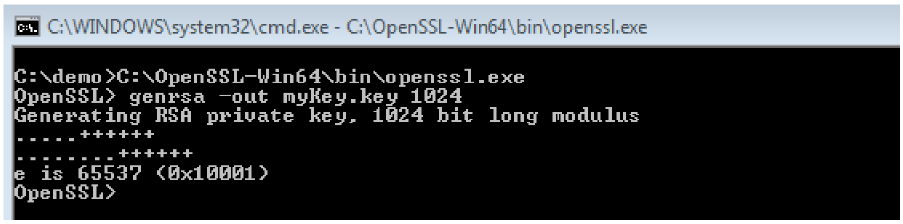
   The figure below shows the command line with the following commands:

6. Now start OpenSSL. If OpenSSL has been installed in the C:\OpenSSL-Win64 directory, enter the following: C:\OpenSSL-Win64\bin\openssl.exe The figure below shows the command line with the following command:

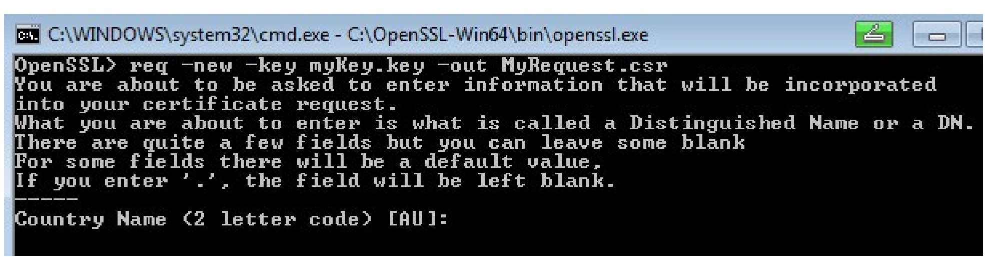
7. Generate a private key. Save the key to the "myKey.key" file. The key in this example is 1024 bits long; for greater RSA security, use 2048 bits in practice. Enter the following command: "genrsa -out myKey.key 2048" ("genrsa -out myKey.key 1024" in the example). The figure below shows the command line with the command and the output of OpenSSL:



8. Generate a CSR (Certificate Signing Request). To do this, enter the following command: "req -new -key myKey.key -out myRequest.csr". During execution of this command, OpenSSL queries information about your certificate:
   - Country name: for example "DE" for Germany, "FR" for France
   - State or province name: for example "Bavaria".
   - Location Name: for example "Augsburg".
   - Organization Name: Enter the name of your company.
   - Organizational Unit Name: for example "IT"
   - Common Name: for example "OPC UA client of machine A"
   - Email Address:

Important: Both the IP address and the URL of the client program (application) have to be stored in the "Subject Alternative Name" field of the created certificate; otherwise, the CPU will not accept the certificate.

The information you enter is added to the certificate. The figure below shows the command line with the command and the output of OpenSSL:



The command creates a file in the C:\demo directory containing the Certificate Signing Request (CSR); in the example, this is "myRequest.csr".

Using the CSR

There are two ways to use a CSR:

- You send the CSR to a certificate authority (CA): Read the information of the respective certification authority. The certificate authority (CA) checks your information and identity (authentication) and signs the certificate with the private key of the certificate authority. You receive the signed X.509 certificate and use this certificate for OPC UA, HTTPS or Secure OUC (secure open user communication), for example. Your communication partners use the public key of the certificate authority to check whether your certificate was really issued and signed by that CA. The certificate authority has confirmed your information in the certificate.
- You sign the CSR yourself: Using your private key. This option is shown in the next step.

Signing the certificate yourself

Enter the following command so that you can generate and sign your certificate (self-signed certificate) yourself: "x509 -req -days 365 -in myRequest.csr -signkey myKey.key -out myCertificate.crt".

The figure below shows the command line with the command and OpenSSL:

The command generates an X.509 certificate with the attributes that you transfer with the CSR (in the example "myRequest.csr"), for example with a validity of one year (-days 365). The command also signs the certificate with your private key ("myKey.key" in the example). Your communication partners can use your public key (contained in your certificate) to check that you are in possession of the private key that belongs to this public key. This also prevents your public key from being misused by an attacker.

With self-signed certificates, you yourself confirm that the information in your certificate is correct. There is no independent body that checks your information.

9.2.6 Secure transfer of messages

Establishing secure connections with OPC UA

OPC UA uses secure connections between client and server. OPC UA checks the identity of the communication partners. OPC UA uses certificates in accordance with X.509-V3 from the ITU (International Telecommunication Union) for client and server authentication. Exception: A secure connection is not established with the "No security" security policy.

Message security mode

OPC UA uses the following security policies to protect messages:

- No security

  All messages are unsecured. In order to use this security policy, establish a connection to a None end point of a server.
- Signing

  All message are signed. This allows the integrity of the messages received to be checked. Manipulations are detected. In order to use this security policy, establish a connection to a Sign end point of a server.
- Sign & Encrypt

  All messages are signed and encrypted. This allows the integrity of the messages received to be checked. Manipulations are detected. What is more, no attacker can read the contents of the message (protection of confidentiality). In order to use this security policy, establish a connection to a "SignAndEncrypt" end point of a server.

The security policies are also named according to the algorithms used. Example: "Basic256Sha256 - Sign & Encrypt" means: Secure endpoint, supports a series of algorithms for 256-bit hashing and 256-bit encryption.

Layers required

The figure below shows the three layers that are always required for establishing a connection: the transport layer, the secure channel and the session.

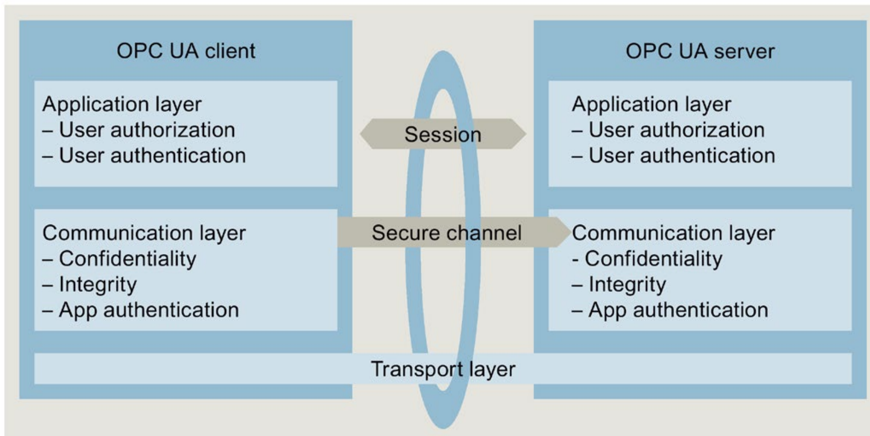


Figure 9-3 Necessary layers: transport layer, secure channel and session

- Transport layer:

  This layer sends and receives messages. OPC UA uses an optimized TCP-based binary protocol here. The transport layer is the basis for the subsequent secure channel.

- Secure channel

  The secure channel receives the data received from the transport layer, and forwards that data to the session. The secure channel forwards data of the session that is to be sent to the transport layer.

  In "Sign" security mode, the secure channel signs the data (messages) that is sent. When a message is received, the secure channel checks the signature to detect any manipulations.

  With a "SignAndEncrypt" security policy, the secure channel signs and encrypts the send data. Data received is decrypted by the secure channel, and the secure channel then checks the signature.

  With the "No security" security policy, the message packages pass the secure channel unchanged (the messages are received and sent in plain text).

- Session

  The session forwards the messages from the secure channel to the application, or receives from the application the messages that are to be sent. The application uses the process values or provides the values.

Establishing the secure channel

The secure channel is established as follows:

1. The server starts establishing the secure channel when it receives a request to this effect from the client. This request is signed or signed and encrypted, or the message is sent in plain text (security mode of the selected server end point). With "Sign" and "Sign & Encrypt", the client sends a "secret" (random number) with the request.
2. The server validates the client certificate (contained in the request, unencrypted) and checks the identity of the client. If the server trusts the client certificate,
   – it decrypts the message and checks the signature ("Sign & Encrypt"),
   – checks the signature only ("Sign"),
   – or leaves the message unchanged ("No security")
3. The server then sends a response to the client (same level of security as the request). The server secret is contained in the response. The client and server calculate a symmetric key from the client and server secret. The secure channel is now established.

The symmetric key (instead of the private and public key of client and server) is now used for signing and encrypting messages.

Establishment of the session

The session is executed as follows:

1. The client starts establishing the session by sending a CreateSessionRequest to the server. This message contains a Nonce, a random number that is only used once. The server must sign this random number (Nonce) to prove that it is the owner of the private key. The private key belongs to the certificate that the server uses to establish the secure channel. This message (and all subsequent messages) is secured in line with the security policies for the selected server endpoint (selected security policies).
2. The server responds with the CreateSession Response. This message contains the public key of the server and the signed Nonce. The client checks the signed Nonce.
3. If the server passes the test, the client sends a SessionActivateRequest to the server. This message contains the information that is required for user authentication:
   – Either the user name and password
   – Or the X.509 certificate of the user (not supported in STEP 7 V15)
   – Or no data (if anonymous access is configured).
4. If the user has the necessary rights, the server returns a message to the client (ActivateSessionResponse). This activates the session.

The secure connection between the OPC UA client and server has been established.

Establishing a connection to PLCopen function block

The PLCopen specification defines a range of IEC 61131 function blocks for OPC UA clients. The instruction UA_Connect initiates both a secure channel and a session following the pattern described above.

9.3 Using the S7-1500 as an OPC UA server

9.3.1 Useful information about the S7-1500 CPU OPC UA server

9.3.1.1 The OPC UA server of the S7-1500 CPUs

The S7-1500 CPUs as of firmware V2.0 are equipped with an OPC UA server. Apart from the Standard-S7-1500 CPUs this applies to the variants S7-1500F, S7-1500T, S7-1500C, S7-1500pro CPUs, ET 200SP CPUs, SIMATIC S7-1500 SW controllers and PLCSIM Advanced.

Convention: "S7-1500 CPUs" also includes the above-mentioned CPU variants.

S7-1500 CPU OPC UA server basics

Access to the OPC UA server of the CPU is possible via all integrated PROFINET interfaces of the S7-1500 CPU.

Direct access to the OPC UA server of the CPU over the backplane bus of the automation system is not possible via a CP or CM.

For access by clients, the server saves the enabled PLC tags and other information in the form of nodes (see Configuring access to PLC tags). These nodes are interconnected and form a network. OPC UA defines access points to this network (well-known nodes) that enable navigation to subordinate nodes.

With an OPC UA client you can read, observe or write values of tags of the PLC program as well as call methods that are available to the server. As of firmware version 2.5 you can implement methods, see AUTOHOTSPOT.

Node classes

OPC UA servers provide information in the form of nodes. A node can be, for example, an object, a tag, a method or a property.

The example below shows the address space of the OPC UA server of an S7-1500 CPU (extract from the OPC UA client "UaExpert" from Unified Automation).

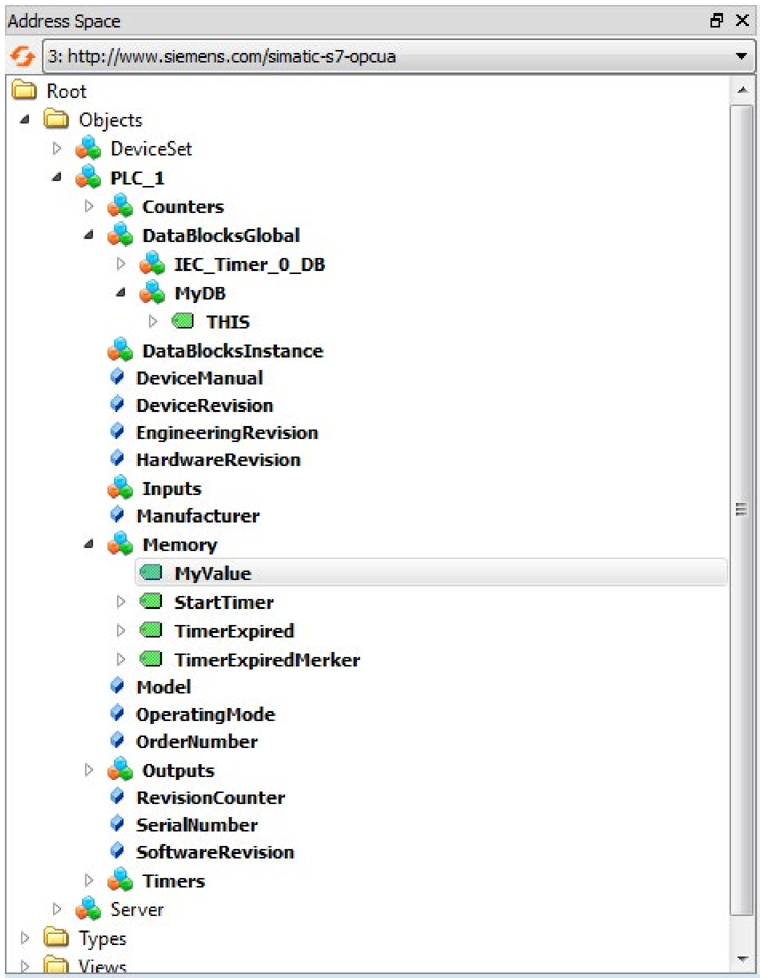

Figure 9-4 Example of the address space of the OPC UA server of an S7-1500 CPU

In the figure above, the "MyValue" tag is selected (highlighted in gray).

This tag is located below the "Memory" node, which has the node class "Object".

"Memory" is below the "PLC_1" node (also an Object).

Address space

The nodes are linked over references, for example, the reference "HasComponent, which represents a hierarchical relationship between a node and its subordinate nodes. With their references, the nodes form a network that can, for example, take the form of a tree.

A network of nodes is also called an address space. Starting from the root, all nodes can be reached in the address space.

9.3.1.2 End points of the OPC UA server

The end points of the OPC UA server define the security level for a connection. Depending on the purpose of use or desired security level, you have to carry out the corresponding settings for the connection at the end point.

Different security settings

Before establishing a secure connection, OPC UA clients ask the server with which security settings connections are possible. The server returns a list with all the security settings (endpoints) that the server offers.

Structure of end points

End points consist of the following components:

- Identifier for OPC: "opc.tcp"
- IP address: 192.168.178.151 (in the example)
- Port number for OPC UA: 4840 (standard port)

  The port number can be configured, see "Settings of the OPC UA server".
- Security setting for messages (Message Security Mode): None, Sign, SignAndEncrypt.
- Encryption and hash procedures (Security Policy): None, Basic128Rsa15, Basic256, Basic256Sha256 (in the example).

The following figure shows the "UA Sample Client" of the OPC Foundation.

The client has established a secure connection to the OPC UA server of an S7-1500 CPU to the end point "opc.tcp://192.168.178.151:4840 - [SignAndEncrypt: Basic128Rsa15:Binary]". The security settings "SignAndEncrypt:Basic128Rsa15" are contained in the end point.

Note

Select an endpoint with as strict as possible a security policy

Select an application-appropriate security policy for the end point and disable the less strict security policy at the OPC UA server.

A Sha256 certificate is required for the most secure end points (Basic256Sha256) of the S7-1500 CPU OPC UA server.

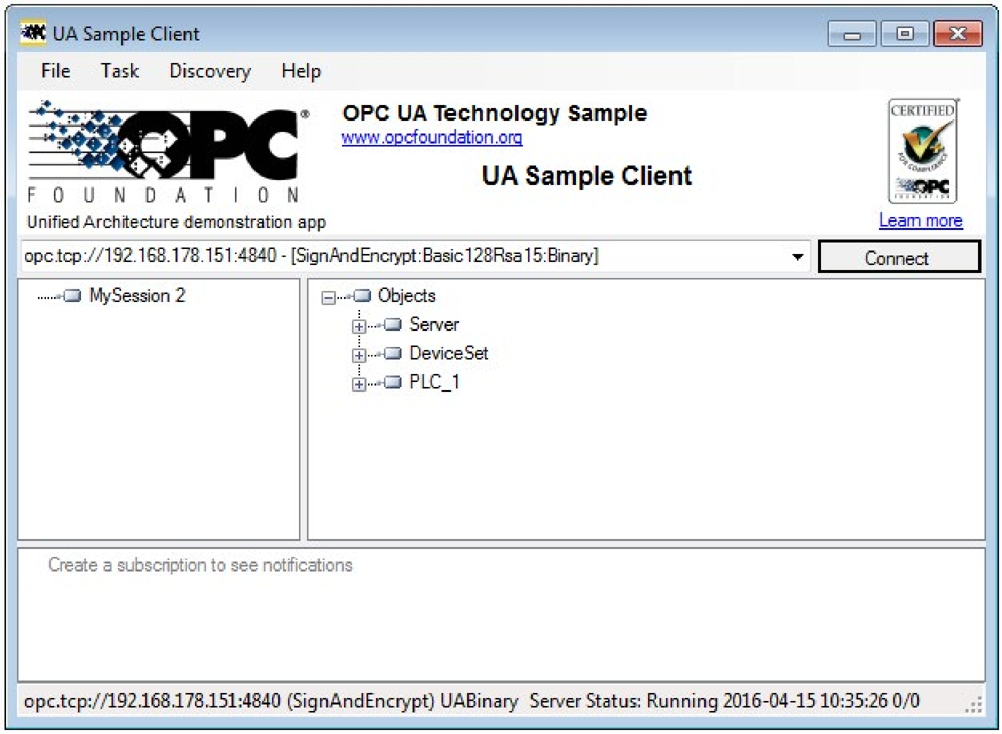

Figure 9-5 "UA Sample Client" program of the OPC Foundation

A connection to a server end point is only established if the OPC UA client complies with the security policies of that end point.

Through the information provided by the OPC UA server

OPC UA servers provide a wide range of information:

- The values of PLC tabs and DB components which clients may access.
- The data types of these PLC tags and DB components.
- Information on the OPC UA server itself and on the CPU.

This gives clients an overview and allows them to read out specific information. Previous knowledge of the PLC program and the CPU data is not required. You do not need to ask the developer of the PLC program when PLC tags are to be read. All necessary information is stored on the server itself (for example, the data types of the PLC tags).

Display of the information of the OPC UA server

You have the following options:

- Online: You have all the available information displayed during the runtime of the OPC UA server. To do so, navigate (browse) the address space of the server.
- Offline: You export an XML file that is based on the XML schemes of the OPC Foundation.

  Server methods created by the user (FB instance that can be called by an OPC UA client) are not exported as of STEP 7 V15.1), see AUTOHOTSPOT.
- Offline with the Openness API: In your program, you use the API (Application Programming Interface) of the TIA Portal to access the function for exporting all PLC tags that can be read by OPC UA. This requires .NET Framework 4.0; see TIA Portal Openness, Automating SIMATIC projects with scripts (https://support.industry.siemens.com/cs/ww/en/view/109477163).
- If you already know the syntax and the PLC program, you can access the OPC UA server without first researching the information.

9.3.1.3 Runtime behavior of the OPC UA server

OPC UA server in operation

The OPC UA server of the S7-1500 CPU starts when you activate the server and download the project to the CPU.

How to activate the OPC UA server is described here.

Response to CPU STOP

An activated OPC UA server remains in operation even if the CPU switches to "STOP". The OPC UA server continues to respond to requests from OPC UA clients.

Server response in detail:

- If you request the values of PLC tags, you will get what were the latest values before the CPU switched to or was set to "STOP".
- If you write values to the OPC UA server, the OPC UA server will accept those values.

  However, the CPU will not process the values because the user program is not executed in "STOP" mode.

  An OPC UA client can nonetheless read the values written at STOP from the OPC UA server of the CPU.

  During restart, the CPU overwrites the values written at STOP with the start of the PLC tags.
- If you call a server method, the error message 16#00AF_0000 (BadInvalidState) is output because the server method (user program) is not running.

Server restart

The OPC UA server is stopped upon each download to the CPU (for example after a configuration or block is downloaded) and then restarts. The duration of the restart depends on the scope of the data structure.

Reading CPU operating mode over OPC UA server

The OPC UA server allows you to read out the CPU mode, see figure below:

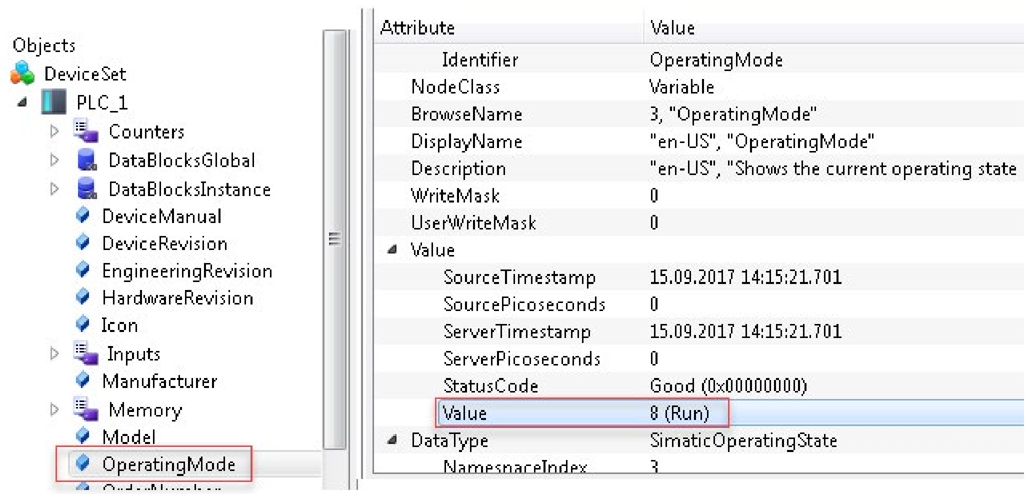

Figure 9-6 Reading CPU operating mode over OPC UA server

In addition to the operating mode of the CPU you can, for example, read out the diagnostics status of the CPU (Good).

9.3.1.4 Diagnostics of the OPC UA server

Online diagnostics of the OPC UA server

The S7-1500 CPU OPC UA server can be diagnosed online with standard OPC UA clients, such as UaExpert.

The diagnostic information is subdivided into the following areas:

- Server Diagnostics
- Sessions Diagnostics
- Subscriptions Diagnostics

In the address space of the server, for example, the following nodes are available with diagnostic information:

- **ServerDiagnosticsSummary**: Server diagnostics summary
  - CurrentSessionCount: Number of active sessions
- **SessionsDiagnosticsSummary**: Session diagnostics summary
  - SessionTimeout: Set time that a session lasts, e.g. in the event of disconnection
  - SecurityRejectedSessionCount: Number of sessions rejected due to mismatching end point security settings between client and server
- **SubscriptionsDiagnosticsArray**: Array with one element per subscription for each session

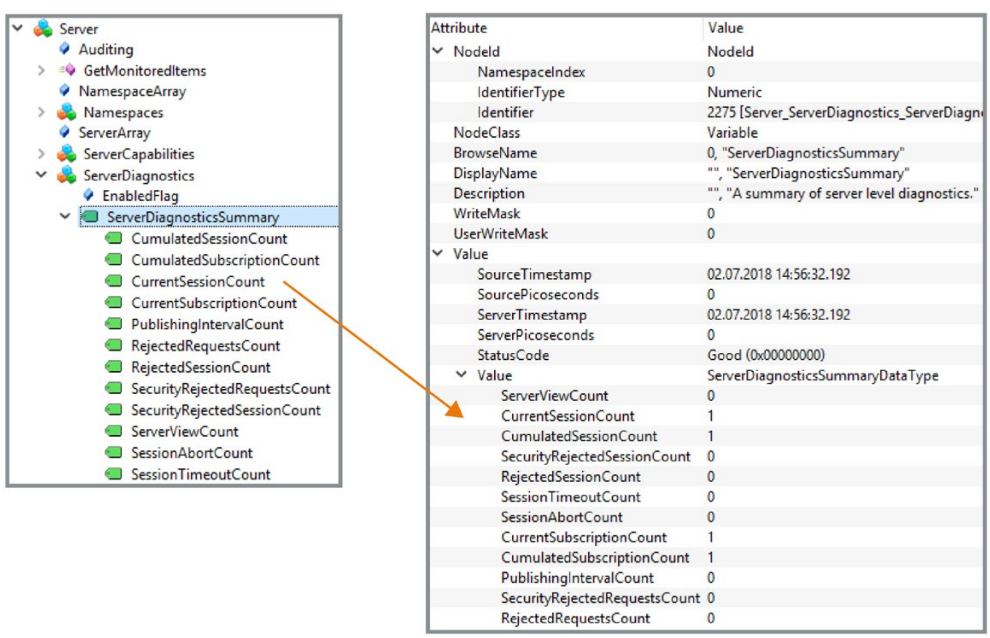

Figure 9-7 Server Diagnostics

The SessionsDiagnosticsSummary node also shows the properties of the client application accessing the server within the session.

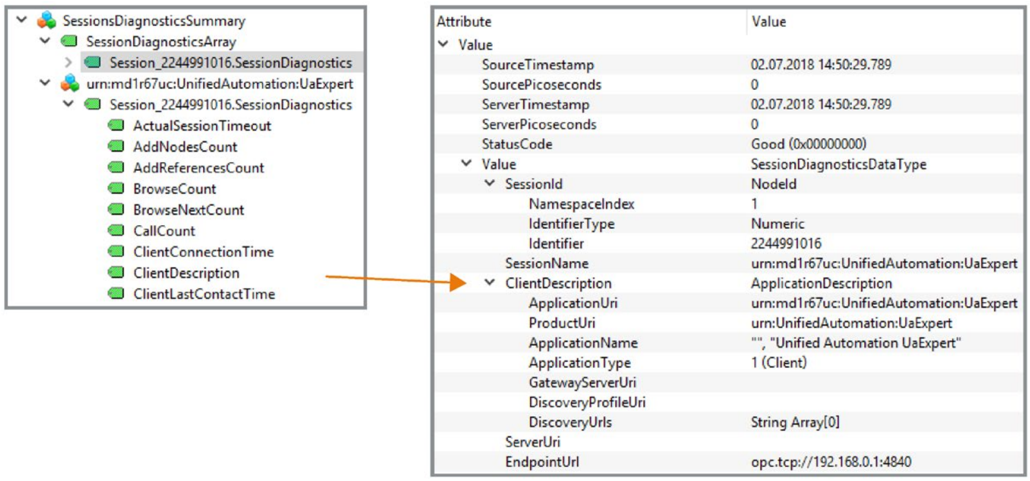

Figure 9-8 Sessions Diagnostics with the properties of the client application

Diagnostics of the connection between client and server

To diagnose the status of the connection during program runtime in the client, use the following instruction:

OPC_UA_ConnectionGetStatus: Read connection status.

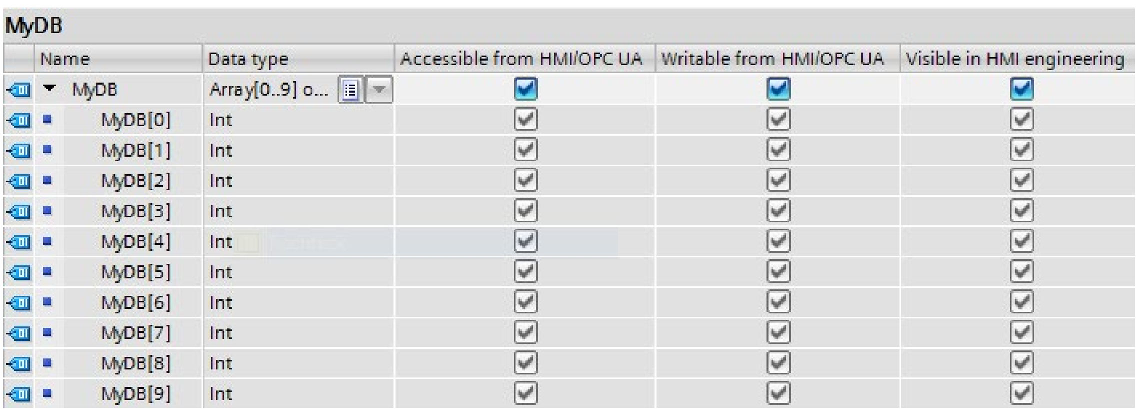
9.3.2 Configuring access to PLC tags

9.3.2.1 Managing write and read rights

Enabling PLC tags and DB tags for OPC UA

OPC UA clients can have read and write access to PLC tags and DB tags if the tags are enabled for OPC UA (default setting). For an enabled tag the check box "Accessible from HMI/OPC UA" is activated.

The following example shows an array data block:



MyDB

Name	Data type	Accessible from HMI/OPC UA	Writable from HMI/OPC UA	Visible in HMI engineering
MyDB	Array[0..9] o...	☑	☑	☑
MyDB[0]	Int	☑	☑	☑
MyDB[1]	Int	☑	☑	☑
MyDB[2]	Int	☑	☑	☑
MyDB[3]	Int	☑	☑	☑
MyDB[4]	Int	☑	☑	☑
MyDB[5]	Int	☑	☑	☑
MyDB[6]	Int	☑	☑	☑
MyDB[7]	Int	☑	☑	☑
MyDB[8]	Int	☑	☑	☑
MyDB[9]	Int	☑	☑	☑

Figure 9-9 Enabling PLC tags and DB tags for OPC UA

This array can be read completely in one pass by OPC UA clients (see Addressing nodes). The check boxes at "Accessible from HMI/OPC UA" and "Writable from HMI/OPC UA" are activated for all the components of the array.

Result: OPC UA clients can both read and write these components.

Removing write rights

If you want to write-protect a tag, deselect the "Writable from HMI/OPC UA" option for that tag. This removes the write right for the OPC UA clients and HMI devices.

Result: Only read access by OPC UA clients and HMI devices is possible. OPC UA clients cannot assign values to this tag and therefore cannot influence execution of the S7 program.

Removing write and read rights

To write-protect and read-protect a tag, disable the "Accessible from HMI/OPC UA" option for that tag (checkbox not selected). This makes the OPC UA server remove the tag from its address space. OPC UA clients can no longer see that CPU tag.

Result: OPC UA clients and HMI devices can neither read nor write the tag.

Write and read rights of structures

If you remove the read or write right for the component of a structure, the structure or the data block cannot be written or read as a whole.

If you remove read and write rights for individual components of a PLC data type (UDT), the rights will also be removed from any data block based on the UDT.

Visible in HMI engineering

The option "Visible in HMI Engineering" applies to Siemens engineering tools. If you disable the option "Visible in HMI Engineering" (check mark not set), you can no longer configure the tag in WinCC (TIA Portal).

The option does not have any effect on OPC UA.

Rules

- Only allow read access to PLC tags and tags of data blocks in STEP 7 if this is necessary for communication with other systems (controllers, embedded systems or MES).

  You should not enable other PLC tags.
- Only allow write access over OPC UA if write rights are genuinely necessary for specific PLC tags and tags of data blocks.
- If you have reset the "Accessible from HMI/OPC UA" option for all elements of a data block, the data block for an OPC UA client is no longer visible in the address space of the OPC UA server of the S7-1500 CPU.
- You can also prevent access to an entire data block centrally (see AUTOHOTSPOT). This setting "overrules" the settings for the components in the DB editor.

9.3.2.2 Managing write and read rights for a complete DB

Hiding DBs or DB contents for OPC UA clients

As of STEP 7 V15, you have the option of easily preventing access to a complete data block by an OPC UA client.

With this option, the data of the corresponding DB, including instance DBs of function blocks, remains hidden for OPC UA clients.

In the default setting, data blocks can be read and written from OPC UA clients.

Procedure

Proceed as follows to completely hide a data block for OPC UA clients or to protect a data block from write access from OPC UA clients:

1. Select the data block to be protected in the project tree.
2. Select the "Properties" shortcut menu.
3. Select the "Attributes" area.
4. Select/clear the "DB accessible from OPC UA" checkbox as required.

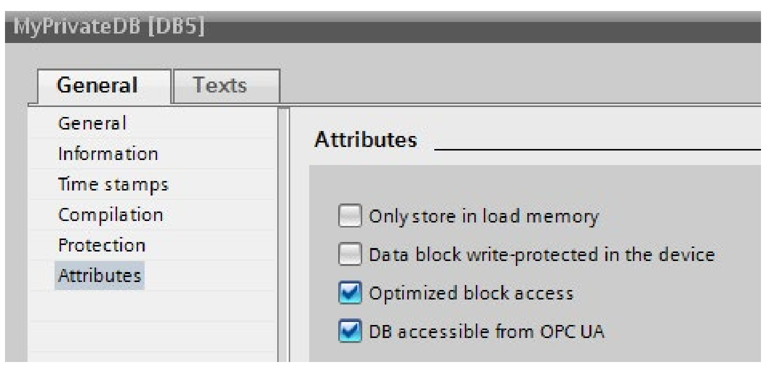


Figure 9-10 Hiding DBs or DB contents for OPC UA clients

Note

Effect on settings in the DB editor

If you hide a DB using the DB attribute described here, the settings for the components in the DB editor are no longer relevant; individual components can no longer be accessed or written.

9.3.2.3 Accessing OPC UA server data

High performance in line with application

OPC UA is designed for the transfer of a high volume of data within a short period of time. You can increase the performance significantly if you do not access individual PLC tags, but rather read and write arrays and structures as a whole.

It is fastest to access arrays. Therefore, you should combine the data for OPC UA clients into arrays.

Recommendations for access to the OPC UA server by the OPC UA client

- For one-off or infrequent data access, use standard read/write access.
- For cyclic access to small amounts of data (up to ca. every 5 seconds), use subscriptions.

  Optimize the settings for the smallest publishing interval and the smallest sampling interval at the OPC UA server.
- If you access specific tags regularly (recurring access), you should use the functions "RegisteredRead" and "RegisteredWrite".

Allow a greater communication load for the PLC by increasing the value for "Cycle load due to communication". Make sure that your application still works properly with the changed settings.

Procedure for creating an array DB

You can create arrays for example in global data blocks, in the instance data block of a function block or as an array DB . The following sections describe how to create an Array-DB.

To create a data block with an array (array data block), follow these steps:

1. Select the CPU with the OPC UA server in the project tree.
2. Double-click "Program blocks".
3. Double-click "Add new block".
4. Click "Data block".
5. Select a unique name for the data block and accept the name that is already entered.
6. Select the "Array DB" entry from the drop-down list for "Type".
7. Select the data type for the individual components of the array from the drop-down list for "Array data type".
8. Enter the high limit of the array for "Array limit".
9. Click "OK".

9.3.2.4 Export OPC UA XML file

Generating an OPC UA export file

OPC UA specifies an information model XML scheme with a standard syntax, with which manufacturers can define their information model of a system component, for example, and make it available in machine-readable form. A file that uses this scheme is also known as a node set file.

With STEP 7 (TIA Portal) you can easily export the standard SIMATIC information model of the S7-1500 CPU as a server to an OPC UA XML file (node set file); including all PLC variables and methods you have enabled for OPC UA.

You use the OPC UA XML file for the offline configuration of an OPC UA client; it is structured according to the OPC UA specification and acts as a standard SIMATIC server interface.

To create and export the OPC UA XML file, follow these steps:

1. Select the CPU. Click on the CPU symbol (for example in the network view).
2. Click "General > OPC UA > Server > Export" in the properties of the CPU.
3. Click "Export OPC UA XML file".
4. Select the directory in which you want to save the export file.
5. Select a new name for the file or keep the name that is already entered.
6. Click "Save".

Note

As of STEP 7 (TIA Portal) V15.1, server methods are contained in the OPC UA export file (node set) together with their input and output parameters.

Exporting all array elements separately

If the "Export all array elements as separate nodes" option is selected in the CPU properties under "OPC UA > Server > Export", the OPC UA XML file contains all elements of arrays as individual XML elements. In addition, the arrays themselves are each described in an XML element in the XML file.

If an array contains many array elements, the XML file can be very large.

Tip

The following FAQ contains a converter with which you can convert the export file into CSV format. You then obtain a list of the tags of the CPU that can be accessed by OPC UA.

You can find the FAQ on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742903).

9.3.3 Configuring the OPC UA server of the S7-1500 CPU

9.3.3.1 Enabling the OPC UA server

Requirement

- You have acquired a Runtime license for the operation of the OPC UA server; see Licenses for the OPC UA server (Page 192).
- When using certificates for secure communication (for example, HTTPS, secure OUC, OPC UA), make sure that the corresponding modules have the current time of day and the current date. Otherwise, the modules will evaluate the certificates used as invalid and secure communication will not work.

Commissioning an OPC UA server

By default, the OPC UA server of the CPU is not enabled for reasons of security: OPC UA clients have neither write nor read access to the S7-1500 CPU.

Follow these steps to activate the OPC UA server of the CPU:

1. Select the CPU. Click on the CPU symbol (for example in the network view).
2. Click "OPC UA > Server" in the properties of the CPU.
3. Activate the OPC UA server of the CPU.
4. Confirm the security notes.
5. Go to the CPU properties, select "Runtime licenses" and set the runtime license acquired for the OPC UA server.
6. Compile the project.
7. Download the project to the CPU.

   The OPC UA server of CPU now starts.

Settings remain stored

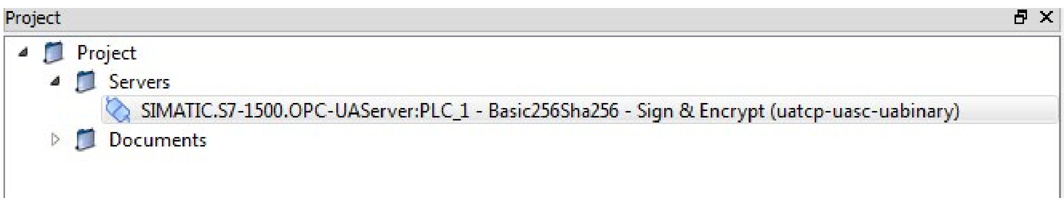
If you have already enabled the server and made settings, those settings are not lost if the server is disabled. The settings are saved as before and are available when you enable the server again.

Application name

The application name is the name of the OPC UA application. The name is displayed under "OPC UA > General":

- The default setting for the server name is: "SIMATIC.S7-1500.OPC-UAServer:PLC1".
- The default consists of "SIMATIC.S7-1500.OPC-UAServer:" and the name of the CPU selected under "General > Product information > Name", in this case "PLC_1".
- Clients identify the server using the application name.

The example below originates from UaExpert:



If you have activated the server, you can also use a different name that is meaningful in your project and which fulfills the requirements of your project, e.g. for worldwide uniqueness.

Changing the application name

To change the name of the OPC UA server, follow these steps:

1. Select the CPU. Click on the CPU symbol (for example in the network view).
2. Click "OPC UA > General" in the properties of the CPU.
3. Enter a meaningful name.

Please note that the application name is also entered on the certificate (Subject Alternative Name) and you may have to generate an existing certificate again after changing the application name.

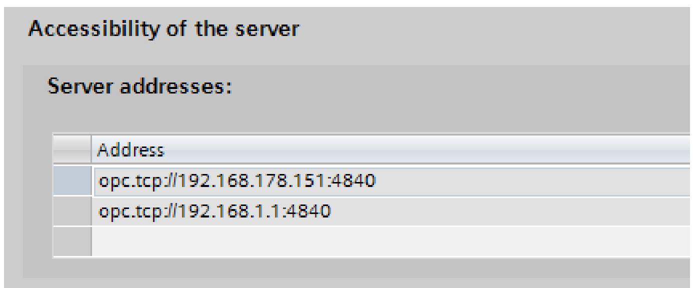
9.3.3.2 Access to the OPC UA server

Server addresses

The OPC UA server of the S7-1500 CPU can be accessed over all internal PROFINET interfaces of the CPU (as of firmware V2.0), but not over the PROFINET interfaces of CP/CM.

With SIMATIC S7-1500 SW controllers, access to the OPC UA server is only possible via PROFINET interfaces that are assigned to the software PLC.

In the example, connections to the OPC UA server of the CPU can be established over the following URLs (Uniform Resource Locator):



The URLs are structured as follows:

- Protocol identifier "opc.tcp://"
- IP address
  - 192.168.178.151

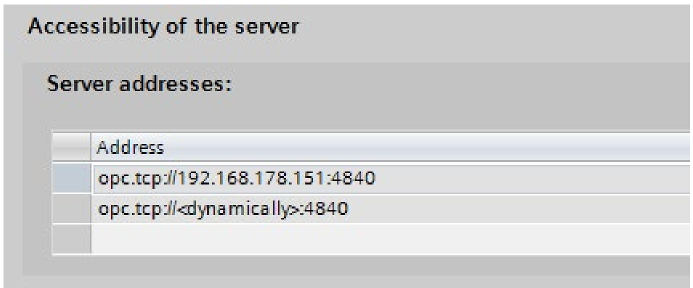
    The IP address at which the OPC UA server can be accessed from the Ethernet subnet 192.168.178.
  - 192.168.1.1

    The IP address at which the OPC UA server can be accessed from the Ethernet subnet 192.168.1.
- TCP Port number
  - Default: 4840 (standard port)

    The port number can be changed under "OPC > UA > Server > Port".

Dynamic IP addresses

In the example below, the IP address for the PROFINET interface [X2] has not yet been specified.



The placeholder "<dynamically>" appears in the table.

The IP address of this PROFINET interface is set later on the device, e.g. via the display of the CPU.

Activating the standard SIMATIC Server interface

If the "Activate Standard SIMATIC server interface" option is selected, the OPC UA server of the CPU provides the enabled PLC tags and server methods to the clients, as is specified in the OPC UA specification.

This option is selected in the default setting.

Leave the option selected so that OPC UA clients can automatically connect to the OPC UA server of the CPU and exchange data.

If you do not select this option, you must add the server interface by entering the "OPC UA communication" entry in the project tree. This interface is then used as OPC UA server interface, see OPC UA server interface configuration (Page 198).

Backward compatible data type definitions according to OPC UA specification ≤ V1.03

The OPC UA specification (<= V1.03) defines mechanisms in order to read out data type definitions, for example for user-defined structures (UDTs), from a server by means of the TypeDictionaries.

In the OPC UA server properties of the CPU, you can set whether the CPU generates these backward compatible data type definitions according to the OPC UA specification ≤ V1.03 for the standard SIMATIC server interface or not.

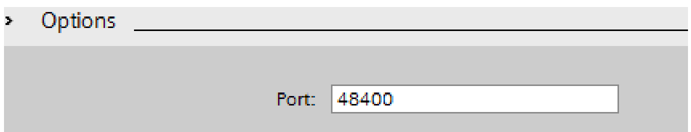
Because TypeDictionaries are complex and result in large OPC UA XML files (server interfaces) which the client has to interpret, a simpler solution was introduced with OPC UA Specification V1.04 (attribute "DataTypeDefinition" at the data type node). If your client supports the OPC UA specification V1.04 or higher, then disable the option.

9.3.3.3 General settings of the OPC UA server

TCP port for OPC UA

By default, OPC UA uses TCP port 4840. You can, however, select a different port. Entries from 1024 to 49151 are possible. You must, however, make sure that there are no conflicts with other applications. OPC UA clients must use the selected port when establishing a connection.

In the example below, port 48400 is selected:



Settings for sessions

- Maximum timeout for sessions

  In this field, you specify the maximum time period before the OPC UA server closes a session without data exchange.

  Possible values between 1 and 600000 seconds.

- Maximum number of OPC UA sessions

  In this field, you specify the maximum number of sessions the OPC UA server starts and simultaneously operates.

  The maximum number of sessions is dependent on the performance capability of the CPU. Each session ties up resources.

Maximum number of registered nodes

In this field, you specify the maximum number of nodes the OPC UA server registers.

The maximum number of registered nodes depends on the capacity of the CPU and is displayed when you configure the field content (place cursor in field). Each registration ties up resources.

Note

No error message following attempt to register more than the configured maximum number of registrable nodes

If a client tries to register more nodes during runtime than the configured maximum number, the server of the S7-1500 CPU only registers the configured maximum number. From the configured maximum number of registrable nodes, the server sends the client the regular string node IDs so the speed advantage gained by registration for these nodes is lost. The client does not receive an error message.

When configuring, make sure you have a sufficient reserve or have the client calculate the maximum number of nodes allowed before registration.

Additional information

Details on which ports are used by the various services for data transfer via TCP and UDP, and what are the points to note when using routers and firewalls can be found in the FAQ (https://support.industry.siemens.com/cs/ww/en/view/8970169).

9.3.3.4 Settings of the server for subscriptions

Subscription instead of cyclic queries

An alternative to cyclic queries for a PLC tag (polling) is to monitor this value. Use a Subscription: The server informs the client if the value of PLC tags changes. See "The OPC UA client".

One server usually monitors a large number of PLC values. At regular intervals, the server therefore sends the client messages (notifications) containing the new values of the PLC tags.

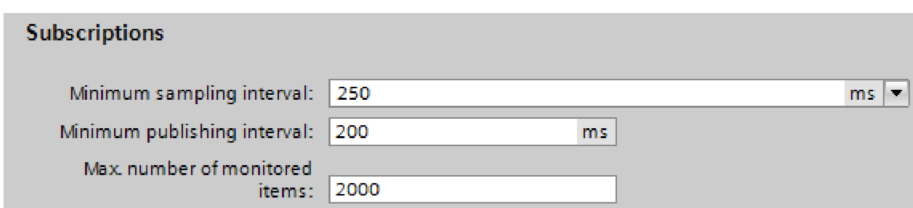
How frequently does the server send notifications?

When a Subscription is set up, the OPC UA client specifies the intervals at which it wants to be sent the new values in the event of changes. To limit the communication load through OPC UA, set a minimum interval for the messages. For this purpose, use the parameters for the minimum publishing interval and the minimum sampling interval.

Minimum publishing interval

With "Minimum publishing interval", you set the time intervals at which the server sends a message to the client with the new values in the event of changes.

250 ms is used as the "Minimum sampling interval" in the figure below. The value 200 ms is entered as the "Minimum publishing interval".



In the example, following a value change the OPC UA server will send a new message every 200 ms if the OPC UA client requests an update.

If the OPC UA client requests an update every 1000 ms, the OPC UA server will only send a message with the new values once every 1000 ms (one second).

If the OPC UA client requests an update every 100 ms, the server will still only send a message every 200 ms (minimum publishing interval).

Minimum sampling interval

With "Minimum sampling interval", you set the time intervals at which the OPC UA server records the value of a CPU tag and compares it with the previous value to detect any changes.

If the sampling interval is selected smaller than the publishing interval and an OPC UA client requests a high sampling rate for certain PLC tags, two or more values may be measured during each publishing interval.

In this case, the OPC UA server writes the value changes into the queue and sends all value changes to the client after the completion of the publishing interval. If more value changes occur in the publishing interval than fit in the queue, the OPC UA server overwrites the oldest values. (depending on the set "Discard Policy", the option "Discard Oldest" has to be activated in this case). The most recent values are sent to the client.

Maximum number of monitored elements (monitored items)

In this field, you specify the maximum number of elements that the OPC UA server of the CPU simultaneously monitors for a value change.

The monitoring ties up resources. The maximum number of monitored elements is dependent on the utilized CPU.

Additional information

Information about the system limits of the OPC UA server of the S7-1500 CPUs (firmware V2.0 and V2.1) regarding subscriptions, sampling intervals and publishing intervals can be found in the following FAQ (https://support.industry.siemens.com/cs/ww/en/view/109755846).

When using subscriptions, certain status codes of errors provide information on the error that occurred. For information on causes and remedies for status codes of OPC UA client that appear, see the list of error codes in the online help of Step 7 (TIA Portal) or in the following FAQ (https://support.industry.siemens.com/cs/ww/en/view/109755860).

9.3.3.5 Handling client and server certificates

A secure connection between the OPC UA server and an OPC UA client is only established when the server can prove its identity to the client. This is done with the server certificate.

Certificate of the OPC UA server

When you have activated the OPC UA server and have confirmed the security prompts, STEP 7 automatically generates the certificate for the server and saves it in the local certificate directory of the CPU. You can view and manage this directory with the local certificate manager of the CPU (exporting or deleting certificates).

The figure below shows the local certificate manager of the CPU with the automatically generated certificate for the OPC UA server:

Figure 9-11 Local certificate manager of the CPU

Alternatively, you can also generate a server certificate yourself.

The certificate of the server is transferred from the server to the client during establishment of a connection. The client checks the certificate.

The client user decides whether the server certificate is to be trusted.

The user at the client side now has to decide whether the server certificate is to be trusted. If the user trusts the server certificate, the client stores the server certificate in its directory containing the trusted server certificates.

The following example shows a dialog of the client "UA Sample Client". When the user clicks the "Yes" button, the client trusts the server certificate:

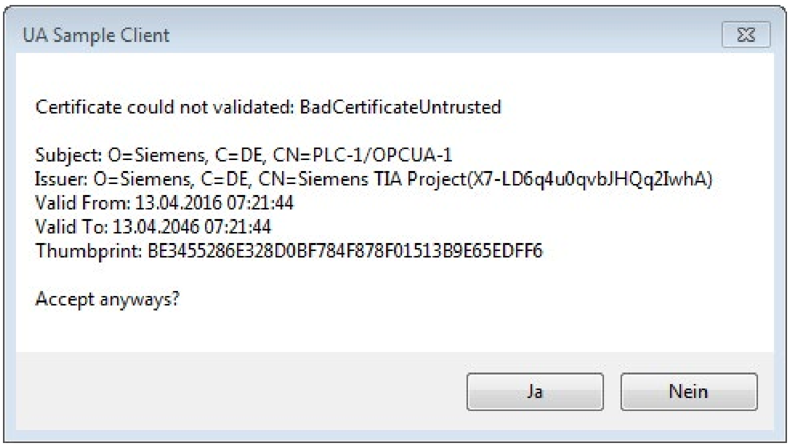


Figure 9-12 Dialog of the client "UA Sample Client"

See also

Generating server certificates with STEP 7 (Page 183)

Secured transferring of messages

Where does a client certificate come from?

When you use UA clients from manufacturers or the OPC Foundation, a client certificate is generated automatically during installation or upon the first program call. You have to import these certificates via the global certificate manager in STEP 7 and use them for the corresponding CPU (as shown above).

When you program an OPC UA client yourself, you can have the certificates generated by the program; see the section "Instance certificate for the client". Alternatively, you can generate certificates with tools, for example with OpenSSL or the certificate generator of the OPC Foundation:

- The procedure for OpenSSL is described here: "Generating PKI key pairs and certificates yourself".
- Working with the certificate generator of the OPC Foundation is described here: "Creating self-signed certificates".

Announcing client certificates to the server

You need to send client certificates to the server to allow a secure connection to be established.

To do this, follow these steps:

1. Select the "Use global security settings for certificate manager" option in the local certificate manager of the server. This makes the global certificate manager available.

   You will find this option under "Protection & Security > Certificate manager" in the properties of the CPU that is acting as server.

   If the project is not yet protected, select "Security settings > Settings" in the STEP 7 project tree, click the "Protect this project" button and log on.

   The "Global security settings" item is now displayed under "Security settings" in the STEP 7 project tree.
2. Double click "Global security settings".
3. Double click "Certificate manager".

   STEP 7 opens the global certificate manager.
4. Click on the "Trusted certificates" tab.
5. Right-click in the tab on a free area (not on a certificate).
6. Select the "Import" command from the shortcut menu.

   The dialog for importing certificates is displayed.
7. Select the client certificate that the server is to trust.
8. Click "Open" to import the certificate.

   The certificate of the client is now contained in the global certificate manager.

   Note the ID of the client certificate just imported.
9. Click the "General" tab in the properties of the CPU that is acting as server.
10. Click "OPC UA > Server > Security > Secure Channel".
11. Scroll down in the "Secure Channel" dialog to the section "Trusted clients".
12. Double-click in the table on the empty row with "<add new>". A browse button is displayed in the row.
13. Click this button.
14. Select the client certificate that you have imported.
15. Click the button with the green check mark.
16. Compile the project.
17. Load the configuration onto the S7-1500 CPU.

Result

The server now trusts the client. If the server certificate is also considered trusted, the server and client can establish a secure connection.

Accepting client certificates automatically

When you select the option "Automatically accept all client certificates during runtime" (below the "Trusted clients" list), the server automatically accepts all client certificates.

NOTICE
Setting after commissioning In order to avoid security risks, deactivate the "Automatically accept client certificates during runtime" option again after commissioning.

Configuring security settings of the server

The figure below shows the available server security settings for signing and encrypting messages.

Figure 9-13 Configuring security settings of the server

By default, a server certificate is created that uses SHA256 signing. The following security policies are released:

- None
  Insecure end point

Note

Disabling security policies you do not want

If you have selected all security policies (default setting) in the secure channel settings of the S7-1500 OPC UA server – in other words the end point "No Security" – non-secure data traffic (neither signed nor encrypted) between the server and client is also possible. The identity of the client remains unknown with "No security". Each OPC UA client can then connect to the server irrespective of any subsequent security settings.

When configuring the OPC UA server, make sure that only security policies that are compatible with the security concept for your machine or plant are selected. All other security policies should be disabled.

Recommendation: If possible, use the setting "Basic256Sha256".

- Basic128Rsa15 -Sign
  Insecure end point, supports a series of algorithms that use the hash algorithm RSA15 and 128-bit encryption.
  This endpoint protects the integrity of the data through signing.
- Basic128Rsa15 -Sign & Encrypt
  Secure endpoint, supports a series of algorithms that use the hash algorithm RSA15 and 128-bit encryption.
  This endpoint protects the integrity and confidentiality of the data through signing and encrypting.
- Basic256Rsa15 -Sign
  Secure endpoint, supports a series of algorithms that use the hash algorithm RSA15 and 256-bit encryption.
  This endpoint protects the integrity of the data through signing.
- Basic256Rsa15 -Sign & Encrypt
  Secure endpoint, supports a series of algorithms that use the hash algorithm RSA15 and 256-bit encryption.
  This end point protects the integrity and confidentiality of the data through signing and encrypting.
- Basic256Sha256 - Sign
  Secure endpoint, supports a series of algorithms for 256-bit hashing and 256-bit encryption.
  This endpoint protects the integrity of the data through signing.
- Basic256Sha256 - Sign & Encrypt
  Secure endpoint, supports a series of algorithms for 256-bit hashing and 256-bit encryption.
  This endpoint protects the integrity and confidentiality of the data through signing and encryption.

To enable the security setting, click the check box in the relevant line.

Note

If you use the settings "Basic256Sha256 -Sign" and "Basic256Sha256 -Sign & Encrypt", the OPC UA server and OPC UA clients must use "SHA256"-signed certificates.

For the settings "Basic256Sha256 -Sign" and "Basic256Sha256 -Sign & Encrypt", the certificate authority of STEP 7 automatically signs the certificates with "SHA256".

"No Security" security policy and authentication via user name and password

You can set the following combination:

Security policy = "No Security" and authentication via user name and password.

- The OPC UA server of the S7-1500 supports this combination. OPC UA clients can connect and encrypt the authentication data or not.
- OPC UA client of the S7-1500 CPU also supports this combination: However, in runtime it only connects if it can send the authentication data encrypted via cable!

9.3.3.6 Handling of the client certificates of the S7-1500 CPU

Where does the client certificate come from?

If you are using the OPC UA client of an S7-1500 CPU (OPC UA client enabled), you can create certificates for these clients with STEP 7 V15 and higher as described in the following sections.

When you use UA clients from manufacturers or the OPC Foundation, a client certificate is generated automatically during installation or upon the first program call. You have to import these certificates with the global certificate manager in STEP 7 and use them for the respective CPU.

When you program an OPC UA client yourself, you can have the certificates generated by the program; see the section "Instance certificate for the client". Alternatively, you can generate certificates with tools, for example with OpenSSL or the certificate generator of the OPC Foundation:

- The procedure for OpenSSL is described here: "Generating PKI key pairs and certificates yourself".
- Working with the certificate generator of the OPC Foundation is described here: "Creating self-signed certificates".

Certificate of the OPC UA client of the S7-1500 CPU

A secure connection between the OPC UA server and an OPC UA client is only established if the server classifies the certificate of the client as trusted.

Therefore you have to make the client certificate known to the server.

The following sections describe how you can initially generate a certificate for the OPC UA Client of the S7-1500 CPU and then make it available to the Server.

1. Generate and export a certificate for the client

For a secure connection you have to generate a client certificate and export the certificate.

To do this, follow these steps:

1. In the "Project tree" area, select the CPU you want to use as a client.
2. Double-click "device configuration".
3. In the properties of the CPU click "Protection & Security > Certificate manager".
4. Double-click "<add>" in the "Device certificates" table.

   STEP 7 opens a dialog.
5. Click "Add".
6. Select the "OPC UA client" entry from the list at the "Usage".

   Attention:

   Under "Alternative name of the certificate holder (SAN)" the IP addresses under which the CPU in your system can be accessed has to be entered.

   You must therefore configure the IP interface of the CPU before you have generate a Client certificate.
7. Click "OK".

   STEP 7 now lists the client certificate in the "Device certificates" table.
8. Right-click this row and select the "Export certificate" entry from the shortcut menu.
9. Select a directory in which you store the Client certificate.

2. Announcing the Client certificate to the server

You have to make the Client certificate available to the server to allow a secure connection to be established.

To do this, follow these steps:

1. Select the "Use global security settings for certificate manager" option in the local certificate manager of the server. This makes the global certificate manager available.

   You will find this option under "Protection & Security > Certificate manager" in the properties of the CPU that is acting as server.

   If the project is not yet protected, select "Security settings > Settings" in the STEP 7 project tree, click the "Protect this project" button and log on.

   The "Global security settings" item is now displayed under "Security settings" in the STEP 7 project tree.
2. Double click "Global security settings".
3. Double click "Certificate manager".

   STEP 7 opens the global certificate manager.
4. Click on the "Trusted certificates" tab.
5. Right-click in the tab on a free area (not on a certificate).
6. Select the "Import" command from the shortcut menu.

   The dialog for importing certificates is displayed.
7. Select the client certificate that the server is to trust.
8. Click "Open" to import the certificate.

   The certificate of the client is now contained in the global certificate manager.

   Note the ID of the client certificate just imported.
9. Click the "General" tab in the properties of the CPU that is acting as server.
10. Click "OPC UA > Server > Security > Secure Channel".
11. Scroll down in the "Secure Channel" dialog to the section "Trusted clients".
12. Double-click in the table on the empty row with "<add new>". A browse button is displayed in the row.
13. Click this button.
14. Select the client certificate that you have imported.
15. Click the button with the green check mark.
16. Compile the project.
17. Load the configuration onto the S7-1500 CPU.

Result

The server now trusts the client. If the server certificate is also considered trusted, the server and client can establish a secure connection.

9.3.3.7 Generating server certificates with STEP 7

The description below shows the procedure for generating new certificates with STEP 7 and applies in principle to various uses of the certificates. STEP 7 sets the appropriate purpose - in this case "OPC UA Client & Server" - depending on which area of the CPU properties is used to start the following dialog.

Recommendation: To use the full functionality for the security of the OPC UA server, use the global security settings.

The global security settings are enabled in the CPU properties under "Protection & Security > Certificate manager".

Customizing server certificates

STEP 7 automatically generates a certificate for the OPC UA server of the S7-1500 when you activate the server (see "Activating the OPC UA server (Page 168)"). In the process STEP 7 uses the default values for the parameters of the certificate. If you want to change the parameters, follow these steps:

1. Click the Browse button under "General > OPC UA > Server > Security > Secure channel > Server certificate" in the properties of the CPU. A dialog is displayed that shows the certificates available locally.
2. Click the "Add" button.

3. The dialog for generating new certificates is displayed (figure below). The values for an example are already entered:

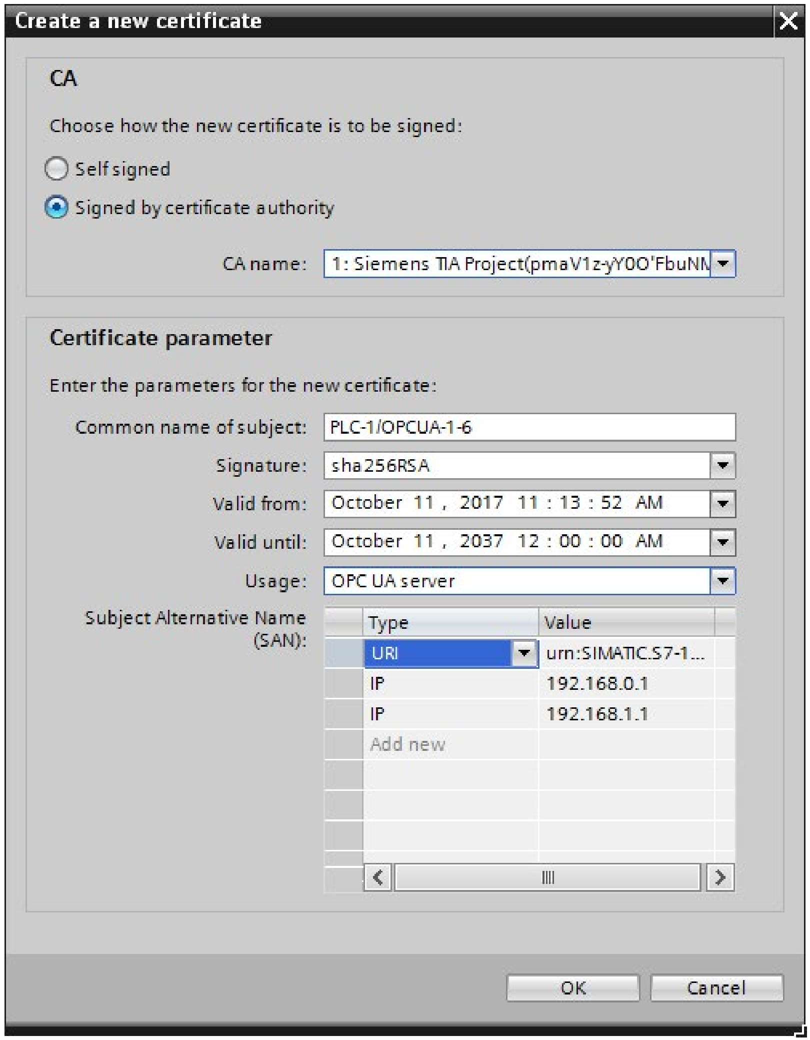

Figure 9-14 Customizing server certificates

4. Use other parameters if this is necessary in accordance with the security specifications in your company or your customer.

Explanation of fields for certificate generation

- CA

  Select whether the certificate is to be self-signed or signed by one of the CA certificates of the TIA Portal. The certificates are described under "Certificates with OPC UA". If you want to generate a certificate that is to be signed by one of the CA certificates of the TIA-Portal, the project must be protected and you must be logged in as a user with all the required function rights. Further information can be found under "Basics of user administration in the TIA Portal".
- Certificate holder

  The default setting always consists of the name of the project and "\OPCUA-1". In the example, the project name is "PLC1". In the properties of the CPU set the project name under "General > Project information" > Name". Keep the default or enter a different name that is more meaningful for the OPC-UA server under "Certificate holder".
- Signature

  Here you select the hash and encryption process that is to be used when signing the server certificate. The following entries are available:
  - "sha1RSA",
  - "sha256RSA".
- Valid from

  Here you enter the date and time for the beginning of the validity of the server certificate.
- Valid until

  Here you enter the date and time for the end of the validity of the server certificate. Ensure that the certificate is valid not only for one year or a few years. In the example the certificate is valid for 30 years. However, for reasons of security you should renew the certificate at much shorter intervals. The long period of validity gives you the opportunity to decide when a suitable moment would be, for example, when the system is being serviced.
- Usage

  The default is "OPC UA client & server". Keep this default for the OPC UA server. The "Generate new certificate" dialog can be called from several points in STEP 7. If, for example, you call this dialog for the Web server of the CPU, "Web server" is entered under "Application". The following entries are available in the Usage drop-down list:
  - "OPC UA client"
  - "OPC UA client & server"
  - "OPC UA server"
  - "TLS"
  - "Web server"
- Alternative name of the certificate holder

  The following is entered in the example above: "URI:urn:SIMATIC.S7-1500.OPC-UAServer:PLC1,IP:192.168.178.151,IP:192.168.1.1". The following entry would also be valid: "IP: 192.168.178.151, IP: 192.168.1.1". It is important that the IP addresses over which the OPC UA server of the CPU can be accessed are entered here (see "Access to the OPC UA server (Page 170)"). This allows OPC UA clients to verify whether a connection to the OPC UA server of the S7-1500 is really to be established or whether in fact an attacker is trying to send manipulated values from another PC to the OPC UA client.

9.3.3.8 Editing the security settings of the OPC UA server.

OPC UA uses secure connections between client and server. OPC UA checks the identity of the communication partners. OPC UA uses certificates in accordance with X.509-V3 from the ITU (International Telecommunication Union) for client and server authentication.

Exception: A secure connection is not established with the "No security" security policy.

Configuring security settings of the server

The figure below shows the available server security settings for signing and encrypting messages.

The security policies are named according to the algorithms used. Example: "Basic256Sha256 - Sign & Encrypt" means: Secure endpoint, supports a series of algorithms for 256-bit hashing and 256-bit encryption.

Figure 9-15 Configuring security settings of the server

By default, a server certificate is created that uses SHA256 signing. The following security policies are released:

- None
  Insecure end point

Note

Disabling security policies you do not want

If you have selected all security policies (default setting) in the secure channel settings of the S7-1500 OPC UA server – in other words the end point "No Security" – non-secure data traffic (neither signed nor encrypted) between the server and client is also possible. The identity of the client remains unknown with "No security". Each OPC UA client can then connect to the server irrespective of any subsequent security settings.

When configuring the OPC UA server, make sure that only security policies that are compatible with the security concept for your machine or plant are selected. All other security policies should be disabled.

Recommendation: If possible, use the setting "Basic256Sha256".

- Basic128Rsa15 -Sign
  Insecure end point, supports a series of algorithms that use the hash algorithm RSA15 and 128-bit encryption.
  This endpoint protects the integrity of the data through signing.
- Basic128Rsa15 -Sign & Encrypt
  Secure endpoint, supports a series of algorithms that use the hash algorithm RSA15 and 128-bit encryption.
  This endpoint protects the integrity and confidentiality of the data through signing and encrypting.
- Basic256Rsa15 -Sign
  Secure endpoint, supports a series of algorithms that use the hash algorithm RSA15 and 256-bit encryption.
  This endpoint protects the integrity of the data through signing.
- Basic256Rsa15 -Sign & Encrypt
  Secure endpoint, supports a series of algorithms that use the hash algorithm RSA15 and 256-bit encryption.
  This end point protects the integrity and confidentiality of the data through signing and encrypting.
- Basic256Sha256 - Sign
  Secure endpoint, supports a series of algorithms for 256-bit hashing and 256-bit encryption.
  This endpoint protects the integrity of the data through signing.
- Basic256Sha256 - Sign & Encrypt
  Secure endpoint, supports a series of algorithms for 256-bit hashing and 256-bit encryption.
  This endpoint protects the integrity and confidentiality of the data through signing and encryption.

To enable the security setting click the check box in the relevant line.

Note

If you use the settings "Basic256Sha256 -Sign" and "Basic256Sha256 -Sign & Encrypt", the OPC UA server and OPC UA clients must use "SHA256"-signed certificates.

For the settings "Basic256Sha256 -Sign" and "Basic256Sha256 -Sign & Encrypt", the certificate authority of STEP 7 automatically signs the certificates with "SHA256".

"No Security" security policy and authentication via user name and password

You can set the following combination:

Security policy = "No Security" and authentication via user name and password.

- The OPC UA server of the S7-1500 supports this combination. OPC UA clients can connect and encrypt the authentication data or not.
- OPC UA client of the S7-1500 CPU also supports this combination: However, in runtime it only connects if it can send the authentication data encrypted via cable!

9.3.3.9 User authentication

Types of user authentication

For the OPC UA server of the S7-1500, you can set what authentication is required for a user of the OPC UA client wishing to access the server.

You have the following options:

- **Guest authentication**

  The user does not have to prove their authorization (anonymous access). The OPC UA server does not check the authorization of the client user

  If you want to use this type of user authentication, select the "Enable guest authentication" option under "OPC UA > Server > Security > User authentication".

  Note

  To increase security, you should only allow access to the OPC UA server with user authentication.

- **User name and password authentication**

  The user has to prove their authorization (no anonymous access). The OPC UA server checks whether the client user is authorized to access the server. Authorization is given by the user name and the correct password.

  If you want to use this type of user authentication, select the "Enable user name and password authentication" option under "OPC UA > Server > Security > User authentication".

  Deactivate the guest authentication.

  Enter the user in the "User management" table.

  To do so, click the "<Add new user>" entry. A new user is created with an automatically assigned name. You can edit the user name and enter the password for the user name. You can add a maximum of 21 users.

- **Additional user administration via the security settings of the project**

  If you select this option, the user management for the open project will also be used for user authentication for the OPC UA server: The same user names and passwords are then valid in OPC UA as in the current project.

  Proceed as follows to activate user management for the project:

  – Click "Security settings > Settings" in the project tree.

  – Click the "Protect this project" button.

  – Enter your user name and your password.

  – Enter additional users under "Security settings > Users and roles".

- If you configure an additional OPC UA server in your project, also select the option "Enable additional user administration via the security settings of the project". Repeated input of user names and passwords is then unnecessary.

9.3.3.10 Users and roles with OPC UA function rights

The following options for user authentication use central project settings for project users:

- For the server:

  For configuration of CPU properties (OPC UA > Server > Security > User authentication). Option: "Enable additional user administration via the security settings of the project"
- For the client:

  For configuration of client interface ("Configuration" tab, "Security"). Option: "User (TIA Portal - security settings)"

Requirement

Before you can edit the security settings, the project must be protected and you must be logged on with sufficient rights, for example as administrator.

Settings in the project tree > "Security settings"

You access the central user settings and roles in the protected project in the project tree under "Security settings". This is where you centrally define users with user name, password and function rights. You can simply use these settings elsewhere.

Reusing central security settings

Examples for reusing elsewhere:

- User selection for user authentication for OPC UA server

  With this setting, you tell the server which client (user) with which user name and which password is allowed to access the server.
- User selection for OPC UA client authentication

  With this setting, you tell the client the user name and password that it is to use for client authentication for the server.

The settings for the client and server must correspond: The user name and password used by the client to log on must have been set up on the server and assigned the required authorizations.

Function rights for server and client

The corresponding function rights for the client or the server must also be enabled for users of the client function and users of the server function on an S7-1500 CPU. It is not enough simply to save the user name and password centrally.

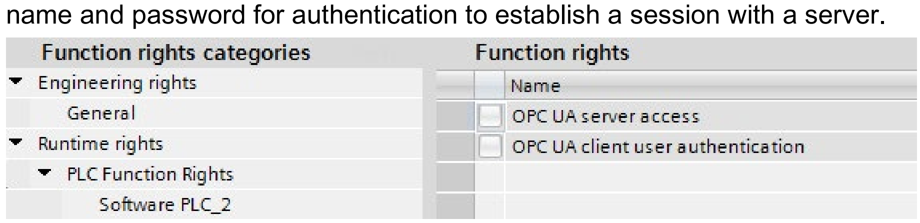
Here is an example to illustrate this type of rights use.

1. Under "Security settings > Users and roles", you define a new role in the "Roles" tab with the name "PLC-opcua-role-all-inclusive", for example.
   Tip: The tab may be covered by an information window ("The current status has not yet been checked..."). In this case, first close the information window.
2. In the "Categories of function rights" section, you navigate to the runtime rights and then to the CPU function rights, and select the CPU whose function rights you want to set, for example PLC_2.
3. You will find the following function rights in the "Function rights" section:
   – OPC UA server access

     This function right apples on the OPC UA server of the S7-1500 CPU. Only when this option is selected does a user of the CPU PLC_2 server who has been assigned the role "PLC-opcua-role-all-inclusive" have the following right: For the establishment of a session with the server, the user requires client authentication with one of the user names and corresponding passwords that have been centrally defined (and loaded to the CPU).

   – User authentication of the OPC UA client

     This function right apples on the OPC UA client of the S7-1500 CPU (with client instructions). Only when this option is selected can the user of the client of CPU PLC_2 who has been assigned the role "PLC-opcua-role-all-inclusive" use the user name and password for authentication to establish a session with a server.



4. The role "PLC-opcua-role-all-inclusive" still needs to be assigned to the relevant users ("Users" tab under "Security settings" in the project tree).

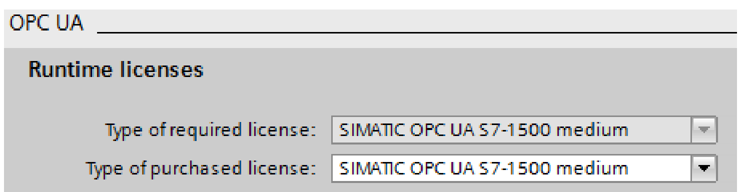
9.3.3.11 Licenses for the OPC UA server

Runtime licenses

A license is required to run the OPC UA server of the S7-1500 CPU. The type of license required depends on the performance of the respective CPU. The following license types are differentiated:

- SIMATIC OPC UA S7-1500 small (required for CPU 1511, CPU 1512, CPU 1513, ET 200SP CPUs, CPU 1515SP PC)
- SIMATIC OPC UA S7-1500 medium (required for CPU 1515, CPU 1516, Software Controller CPU 1507, CPU 1516pro-2PN)
- SIMATIC OPC UA S7-1500 large (required for CPU 1517, CPU 1518)

The required license type is displayed under "Properties > General > Runtime licenses > OPC-UA > Type of required license":



To confirm purchase of the required license, follow these steps:

1. Click "Runtime licenses > OPC UA" in the properties of the CPU.
2. Select the required license from the "Type of purchased license" drop-down list.

9.3.4 Providing methods on the OPC UA server

9.3.4.1 Important facts about server methods

Providing user program for server methods

On the OPC UA server of an S7-1500 CPU (as of firmware V2.5), you have the option of providing methods via your user program. These methods can be used by OPC UA clients, for example to start a manufacturing job using the method call of the S7-1500 CPU.

OPC UA methods, an implementation of "Remote Procedure Calls", provide an efficient mechanism for interactions between different communication nodes. The mechanism provides both job confirmation and feedback values so you no longer have to program handshaking mechanisms.

Using OPC UA methods, you can transfer data consistently without trigger bits/handshaking, for example, or trigger specific actions on the controller.

How does an OPC UA method work?

An OPC UA method in principle operates like a know-how protected function block that is called by an external OPC UA client in runtime.

The OPC UA client only "sees" the defined inputs and outputs. The content of the function block, the method or algorithm, remains hidden to the external OPC UA client. The OPC UA client receives feedback on successful execution and values returned by the function block (method), or an error message if execution has not been successful.

As the programmer, you have full control over and responsibility for the program context in which the OPC UA method runs.

Rules for programming a method and runtime behavior

- Make sure that the values returned by the OPC UA method are consistent with the input values provided by the OPC UA client.
- Follow the rules on assigning name and the structure of parameters, and the permitted data types (see description of the OPC UA server instructions).
- Behavior during runtime: The OPC UA server accepts **one** call per instance. The method instance is not available for other OPC UA clients until the call has been processed by the user program or has timed out.

The basic procedure for implementing a user program as a server method is set out below.

Implementing a server method

A program (function block) for implementing a server method is structured as follows:

1. **Querying the server method call with OPC_UA_ServerMethodPre**

   You first call the "OPC_UA_ServerMethodPre" instruction in your user program (i.e. in your server method).

   This instruction has the following tasks:

   – With this instruction you ask the OPC UA server of the CPU whether your server method was called from an OPC UA client.

   – If the method was called and the server method has input parameters, your server method now receives the input parameters.

     The input parameters of the server method come from the calling OPC UA client.

2. **Editing the server method**

   In this section of the server method, you provide the actual user program.

   You have the same options as in any other user program (for example, access to other function blocks or global data blocks).

   If the server method uses input parameters, these parameters are available to you.

   This section of the server method should only be executed if an OPC UA client has called the server method.

   After successful execution of the method, you set the output parameters of the server method if the method has output parameters.

3. **Responding to server method with OPC_UA_ServerMethodPost**

   To complete the server method, call the "OPC_UA_ServerMethodPost" instruction.

   Use the parameters to notify the "OPC_UA_ServerMethodPost" instruction whether or not the user program has been processed.

   If the user program has been successfully executed, the OPC UA server is notified via the relevant parameters. The OPC UA server then sends the output parameters of the server method to the OPC UA client.

Always call the instructions "OPC_UA_ServerMethodPre" and "OPC_UA_ServerMethodPost" as a pair irrespective of whether the user program is processed by both instructions or continued in the next cycle.

You will find an example of a server method implementation in the STEP 7 online help.

Integrating the server method

The diagram below shows how an OPC UA client (A) calls the server method "Cool":

The CPU executes the instance "Cool1" of the server method "Cool" in the cyclic user program ⑥.

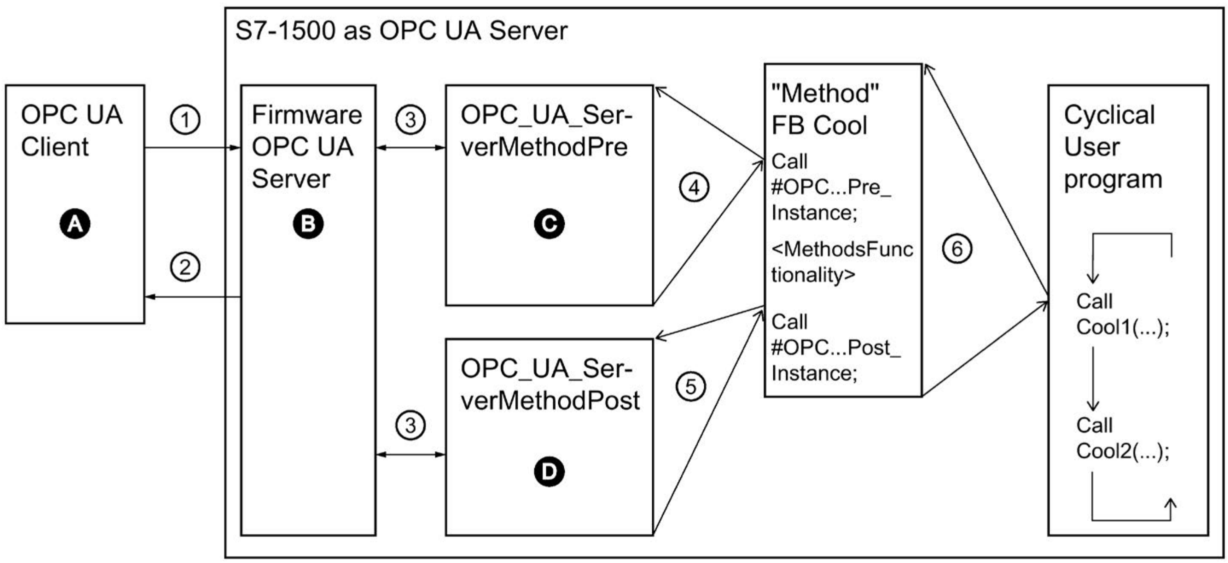
The CPU first uses the instruction "OPC_UA_ServerMethodPre" to query ④ whether an OPC UA client has called the server method "Cool" ①.

- If the server method has not been called, program execution returns directly to the cyclic user program over ④ and ⑥. The CPU resumes the cyclic user program after "Cool1".
- If the server method has been called, this information is returned to the server method "Cool" over ④. The actual functionality is now executed in the Cool server method, see"<Method Functionality>" in the graphic.

The server method then uses the instruction "OPC_UA_ServerMethodPost" ⑤ to notify the firmware (B) that the instruction has been executed ③.

The firmware returns this information over ② to the calling OPC UA client (A).

The CPU resumes the cyclic user program after "Cool1".



A	Call of the server method and management of the "Done" information (method complete)
①	Asynchronous call of the server method
②	Asynchronous "Done" information for the method called (method complete)
B	Wait for OPC UA client calls, management of calls in the queue, forwarding of "Done" information from the cyclic user program to the OPC UA client
③	Data transfer from the OPC UA server to the method instances of the user program and vice versa
C	Check whether method has been called. If it has, forwarding of input data from the OPC UA server to the method instance of the user program and feed-back to the method instance that the method has been called ("called")
④	Synchronous call of the instruction OPC_UA_ServerMethodPre as a multi-instance stating the storage area for the input data from the OPC UA server. The return value indicates whether or not the method has been called by the OPC UA client.
⑤	Check whether the method has been completed or is still active ("busy").
D	Check whether the method has been completed. If it has, the output data of the method instance is forwarded to the OPC UA server and the method instance is notified that the method has been completed. The OPC UA server is notified.
⑥	Call of the method FB (in this case: FB Cool) with the required instance and the process parameters

Information about server instructions

The "OPC_UA_ServerMethodPre" and "OPC_UA_ServerMethodPost" are described in detail in the help to the Instructions > Communication > OPC UA > OPC UA server.

9.3.4.2 Boundary conditions for using server methods

Permitted data types

If you provide server methods, observe the following rule:

- Assign the data types as shown below (SIMATIC data type - OPC UA data type). Other assignments are not permitted.

STEP 7 does not check the observance of this rule and does not prevent an incorrect assignment. You are responsible for the rule-compliant selection and assignment of the data types.

You can also use the listed data types, for example, as elements of structures/UDTs for input and output parameters of self-created server methods (UAMethod_InParameters and UAMethod_OutParameters).

SIMATIC data type	OPC UA data type
BOOL	Boolean
SINT	SByte
INT	Int16
DINT	Int32
LINT	Int64
USINT	Byte
UINT	UInt16
UDINT	UInt32
ULINT	UInt64
REAL	Float
LREAL	Double
LDT	DateTime
WSTRING	String
DINT	Enumeration (Encoding Int32) and all derived data types
User-defined data type required (UDT, user-defined data type) The user-defined data type must be created with the prefix "Union_", for example "Union_MyDatatype". The first element (Selector) in this UDT must have the data type "UDINT".	UNION and all derived data types

Number of implementable server methods and number of arguments

If you implement server methods via your user program, the number of usable methods is limited depending on the CPU type, see the following table.

Technical specification value	CPU 1510SP (F) CPU 1511 (C/F/T/TF) CPU 1512C CPU 1512SP (F) CPU 1513 (F)	CPU 1505 (S/SP/SP F/SP T/SP TF) CPU 1515 (F/T/TF) CPU 1515 SP PC (F/T/TF) CPU 1516 (F/T/TF)	CPU 1507S (F) CPU 1517 (F/T/TF) CPU 1518 (F)
Maximum number of usable server methods or max. number of server method instances (OPC_UA_ServerMethodPre, OPC_UA_ServerMethodPost instructions)	20	50	100
Maximum number of arguments per method (More than the specified number of arguments can be configured and loaded into the CPU, but an OPC UA client cannot call the method).	20	20	20

Error message when exceeded

If the maximum number of server methods is exceeded, the OPC_UA_ServerMethodPre or OPC_UA_ServerMethodPost instructions report the error code 0xB080_B000 (TooManyMethods).

Supply of structured data types with nested arrays

If a structured data type (Struct/UDT) contains an array, the OPC UA server does not provide information about the length of this array.

If you use such a structure as the input or output parameter of a server method, for example, you must ensure that the nested array is supplied with the correct length when the method is called.

If you do not adhere to this rule, the method fails with the error code "BadInvalidArgument".

9.3.5 OPC UA server interface configuration

9.3.5.1 What is a server interface?

Definition

A server interface combines related nodes of an OPC UA address space of a CPU into a unit, so that a specific view of this CPU is provided for OPC UA clients.

1st example:

A CPU controls an injection molding machine.

In this example, a server interface contains all OPC UA nodes of the CPU,

- which you can read with an OPC UA client, to get information about this injection molding machine (from readable PLC tags),
- which you can write with an OPC UA client write, to transfer values to the injection molding machine (in writable PLC tags),
- which you can call with an OPC UA client to start injection molding machine functions (via server methods).

This server interface allows a view of a CPU which can be used to control an injection molding machine.

For injection molding machines, the companion specification "Euromap" defines a whole series of OPC UA nodes that you can combine in a server interface.

Other OPC UA nodes of the CPU are not included in this view.

This provides a better overview.

The section "Create server interface (Page 199)" shows how to create a server interface and add related OPC UA nodes to this server interface.

The "Euromap77" serves as an example for related OPC UA nodes.

2nd example

Plant-specific or customer-specific tasks

You can also define a server interface which, for example, meets the requirements in a customer-specific project.

Specify all required OPC UA nodes in an XML file.

Use a tool for this purpose, for example the free program "SiOME" from Siemens; you can find the explanations and download link here (https://support.industry.siemens.com/cs/ww/en/view/109755133).

9.3.5.2 Create a server interface

Create server interfaces

To create an Server interface, follow these steps:

1. Select the project view in the TIA Portal.
2. Select the CPU that you want to use as an OPC UA server.
3. Click "OPC UA communication > Server interfaces".
4. Double-click "Add new server interface".

   STEP 7 creates a new server interface, names it "Server interface_1" and opens the editor for server interfaces.
5. Change the name of the new server interface so that it is descriptive in your project.
6. Click the "Import companion specification" button in the top right of the Server Interfaces view.

   STEP 7 displays the "Import" dialog.
7. Select an XML file which contains an instance (or multiple instances) of a companion specification.

   The "Using OPC UA companion specification (Page 202)" section describes how to create such an XML file.

   STEP 7 imports the XML file and displays the new server interface in the editor.

   The following figure shows a section of a server interface which uses an instance of the "Euromap" companion specification:

	Name of the node	Node type	Access level	Description		Local data
1	IMM_manufacturer_01234	Object				
2	InjectionUnits	Object				
3	InjectionUnit_1	Object				
4	TemperatureZones	Object				
5	BarrelTemperatureZone_1	Object				
6	ActualTemperature	Double	RD	The ActualTemperat...		"InjectionUnits"."i.
7	EngineeringUnits	EUInformation	RD	Show Placeholde		
8	EURange	Range	RD	Range for this control		
9	NominalTemperature	Double	RD	The nominal Placeh...		"InjectionUnits"."i.
10	EngineeringUnits	EUInformation	RD			
11	EURange	Range	RD			
12	Index	UInt32	RD	The Index Property g...		"InjectionUnits"."i.
13	IsPresent	Boolean	RD	TRUE if present		"InjectionUnits"."i.
14	Name	String	RD	The Name Property r...		"InjectionUnits"."i.
15	TemperatureConfiguration	TemperatureConfig...	RD	The TemperatureCo...		"InjectionUnits"."i.

Information on the server interface

The editor for server interfaces is structured as table and provides a range of information about the imported node set file (OPC UA-XML file).

The tables provides the following information:

- **Name of the node**

  The top node is named "IMM_manufacturer_01234" in the example.

  This name stands for the injection molding machine as a whole. It is the name of the instance of the "Euromap" companion specification that is used here.

  According to the companion specification, the instance name should begin with "IMM", followed by the name of the manufacturer of the injection molding machine; the serial number of the machine is added to the end. This allows a unique identification of the machine.

  The name of this node is assigned by the user.

  The names of all other (lower-level) nodes are defined by the specification (in the example above by the "Euromap" companion specification). These node names must not be changed by the user. This ensures a uniform view of all injection molding machines, which complies with the specification.

- **Node type**

  Type of the node. The type is specified by the companion specification that is used.

  STEP 7 shows a node type in red in the table when the imported XML file contains no type definition.

  In this case, you can find the referenced but missing namespaces in the properties of the server interface under "Namespaces".

  Import the referenced XML files that contain the missing namespaces (and all data types defined in them) into a server interface to be created.

- **Access level**

  Nodes (tags) can only be readable (RD) or readable and writeable (RD/WR).

  The server methods of a specification can always be called. If they were not callable, they would not have been included in the specification.

- **Description**

  The imported XML file may contain descriptions of the nodes in several languages.

  If you have imported such a file, STEP 7 displays the description in the project language.

  If no description is available in the XML file in the project language, then the English description is displayed.

- **Local data**

  STEP 7 displays the data block which is assigned to the node in the CPU (mapping).

  The CPU reads the value of the OPC UA node from this data block.

  The OPC UA server then makes this value available for OPC UA clients.

  If a data block is displayed in red, then the specified data block is not available in the CPU.

  In this case you have to create the missing data block in the CPU (of user program) and supply it with a value.

  Alternative: Change the mapping of the OPC UA node to a local data block (or to a tag of a tag table of your user program) in the XML file.

  The "Using OPC UA companion specification (Page 202)" section describes how to change mapping.

- **Data type**

  This is the data type of the data block in the CPU, from which the value of an OPC UA node is read, or to which a value is written.

Consistency check

You have the option of checking the server interface. STEP 7 hereby checks whether the nodes (e.g. tags) are mapped correctly in the imported node set file (OPC UA XML file).

1. Select the nodes that you want to check.
2. Click "Consistency check".

	Name of the node	Node type	Access level	Description
1	Server	Object		
2	Namespaces	Object		Describes the names.
3	Euromap77_NamespaceMetadata	Object		Provides the metada...
4	IsNamespaceSubset	Boolean	RD	If TRUE then the serv...
5	NamespacePublicationDate	DateTime	RD	The publication date...

The consistency check checks the mapping of the local data against the displayed server interface:

– Do the names of the PLC tags in the CPU program correspond to those of the imported server interface?

– Do the data types of the PLC tags correspond to the corresponding nodes in the server interface? STEP 7 displays corresponding warnings and errors if the above conditions are not met.

9.3.5.3 Using OPC UA companion specifications

Introduction

OPC UA is universally applicable: The standard itself does not, for example, specify how PLC tags are to be named. It is also up to the individual user (application developer) to program and name server methods that can be called over OPC UA.

Information modeling and standardization for devices and sectors

For applications of the same kind, it is worth standardizing your device or machine interface with the "OPC UA toolkit".

Many different bodies and working groups have driven forward standardization and developed a range of companion specifications.

These specifications define:

- The objects, methods and tags with which a typical device or machine is to be described.
- The namespace intended for the specified objects.

Machines are typically structured in functional or technological units, and these units are then standardized.

Companion specifications offer machine and plant operators the benefits of a standardized interface. For example, all RFID readers that comply with the AutoID specifications can be integrated in the same way. This means that all RFID readers that comply with the AutoID specifications can be addressed by OPC UA clients in the same way irrespective of manufacturer.

Another example of companion specifications is the Euromap 77 Companion Specifications from the injection molding machinery sector.

The following section uses the example of Euromap 77 to detail how to apply companion specifications in STEP 7 (TIA Portal) and create the necessary PLC tags.

Example: Euromap 77

Euromap 77 standardizes the exchange of data between injection molding machines and the higher-level MES (manufacturing execution system). This allows the MES to connect all lower-level injection molding machines in the same way.

The standardized data interface facilitates the integration of injection molding machines into a plant.

Using companion specifications: Overview

Euromap 77 is described in the OPC UA XML file "Opc_Ua.EUROMAP77.NodeSet2.xml".

Note

Euromap 77, Euromap 83 and OPC UA for Devices (DI)

With Release Candidate 2, some of the Euromap definitions have been transferred from Euromap 77 to Euromap 83. You will therefore also need to import the OPC UA server interface of Euromap 83.

"OPC UA for Devices" is a generally applicable information model for the configuration of hardware and software components. The information model also serves as the basis for other companion standards and is therefore also imported.

The OPC UA XML files are available here:

Euromap77 (http://www.euromap.org/euromap77)

Euromap83 (http://www.euromap.org/euromap83)

OPC UA for Devices (https://opcfoundation.org/UA/schemas/DI/)

The Euromap OPC UA XML files define the interface of the OPC UA server of an injection molding machine that complies with the Euromap 77 companion standard.

Proceed as follows to model the OPC UA server of the S7-1500 CPU in accordance with the Euromap 77 standard:

1. Generate an XML file by creating an instance of the type "IMM_MES_InterfaceType".

   "IMM_MES_InterfaceType" is the highest-level node in Euromap 77: This data type is directly derived from the OPC UA data type BaseObjectType".

   All Euromap 77 (83) tags and methods are defined under "IMM_MES_InterfaceType".

   "Step 1" sets out the procedure in detail.
2. Assign PLC tags and FB instances (server methods) from your S7-1500 CPU to the tags and methods of Euromap 77 (the Euromap 77 information model).

   "Step 2" sets out the procedure in detail.
3. Import the XML file as "Server interface".

   "Step 3" sets out the procedure in detail.

   Compile the STEP 7 project.

   Download the project to the CPU that acts as the controller for an injection molding machine.
4. In your STEP 7 project, create the PLC tags and server methods to which you have assigned Euromap 77 tags and methods under 2.

   The PLC tags must have compatible data types; see "Mapping data types".

   Enable read and write access to these PLC tags for OPC UA clients in accordance with Euromap 77.

   Save the PLC tags in a data block, for example.

   "Step 4" sets out the procedure in detail.

Result: The Euromap 77 tags and server methods are available for OPC UA clients in the address space of the OPC UA server of your CPU.

Step 1: Creating an instance

The following section describes how to use the free program "SiOME", the "Siemens OPC UA Modelling Editor".

With SiOME, you can create an OPC UA XML file, which describes the server interface (an information model).

To load and publish the new interface into the OPC UA server of an S7-1500 CPU, import the server interface into the STEP 7 project, see section "Create server interface (Page 199)".

When the project is loaded into the CPU, the new server interface is available for OPC UA clients.

Other tools for designing information models

You can also work with other tools to design information models to create a server interface, such as the program "UaModeler" from Unified Automation. You can download the "UaModeler" program from here (https://www.unified-automation.com/downloads/opc-ua-development.html).

The tools for designing information models are constantly being honed and improved. You should therefore always use the documentation provided by the manufacturer.

SiOME

With the help of SiOME (Siemens OPC UA Modeling Editor), a tool for implementing OPC UA companion specifications, you can design information models / address spaces for your OPC UA server and can create new types and instances of OPC UA nodes.

You can also use SiOME to map UA tags to PLC tags and UA methods to PLC function blocks (instances).

Download link and explanations about SIOME are available here (https://support.industry.siemens.com/cs/ww/en/view/109755133).

Proceed as follows to create an XML file with an instance of "IMM_MES_InterfaceType":

1. Download the files "Opc_Ua.EUROMAP77.NodeSet2.xml" and "Opc_Ua_EUROMAP83_NodeSet2.xml" from the Euromap website (see above).
2. Download the file "Opc.Ua.Di.NodeSet2.xml" from the OPC Foundation website.

   Euromap77/83 is an OPC UA Companion specification, this means that it is based on OPC UA and uses data types defined in the file "Opc.Ua.Di.NodeSet2.xml".
3. Start SiOME.

4. First, import the namespace "http://opcfoundation.org/UA/DI/".

   To do so, click the ""Import XML" button in the "Information model" area.

   Select the file "OPCUaDiNodeSet2 "xml" and click "Open" to import the file.

   SiOME imports the XML file and shows the namespace "http://opcfoundation.org/UA/DI/" in the "Namespaces" area.

   The standard namespace "http://opfoundation.org/UA/" is always available in SiOME and does not have to be imported.

5. Now import the namespace "http://www.euromap.org/euromap83/"

   To do so, click the ""Import XML" button in the "Information model" area.

   Select the file "Opc_Ua.EUROMAP83.NodeSet2.xml".

   SiOME imports the XML file and shows the namespace "http://www.euromap.org/euromap83/" in the "Namespaces" area.

6. Now import the namespace "http://www.euromap.org/euromap77/"

   To do so, click the ""Import XML" button again in the "Information model" area.

   Select the file "Opc_Ua.EUROMAP77.NodeSet2.xml".

7. **Defining your own namespace and creating an instance**

   So far, you have imported Euromap77.

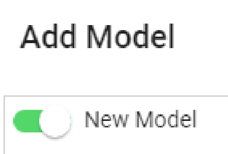
   Now use the companion specification for an injection molding machine, i.e. you create an instance of Euromap77 (a usage).

   In the "Namespaces" area, right-click "Models" and select "Add Model".

   SiOME opens the "Add Model" dialog.

8. Click "New Model", to create a new model.

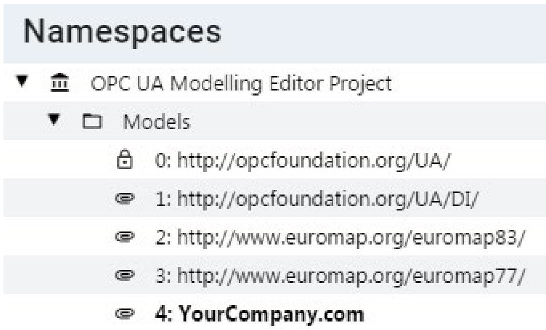
   SiOME now shows in green the switch in front "New Model":

9. Add your own namespace to the XML file.

   Use a unique name for this purpose.

   In the example, enter "YourCompany.com":



10. **Create new sequence**

    Now create now a new instance of Euromap77. This allows you to use the Euromap77 for an injection molding machine.

    Right-click on "Objects" in the "Information model" area.

    SiOME shows a shortcut menu.

11. Click "Add Instance" to add a new instance.

    SiOME displays the "Add Instance" dialog.

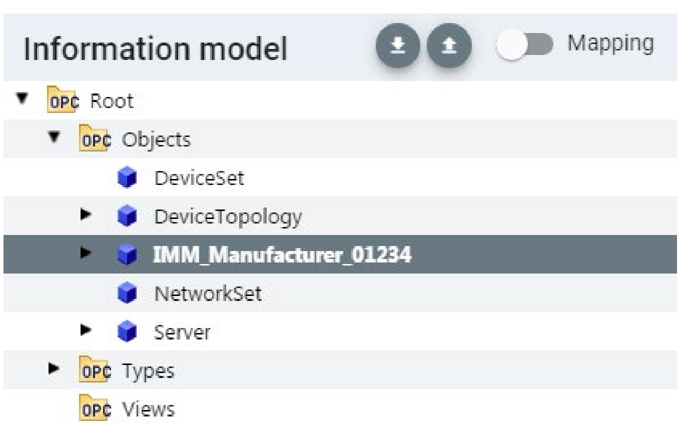
    At "Name" insert a descriptive name for your instance, i.e. for the machine you are using for Euromap77.

    In the example, enter "IMM_Manufacturer_01234".

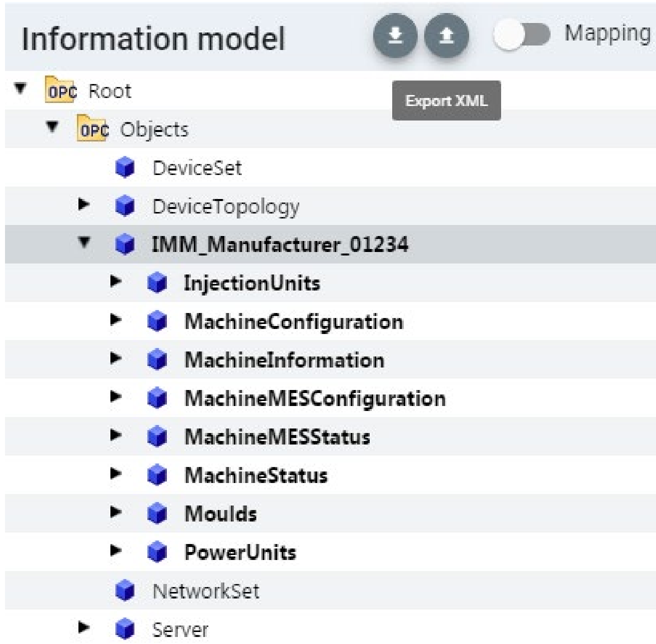
    For "TypeDefinition", select "IMM_MES_InterfaceType".

    Click "OK".

    SiOME shows the new instance in the "Information model" area under "Objects":



12.Click the black arrow in front of "IMM_Manufacturer_01234", to open the instance:



13.Now create a new instance for "InjectionUnits".

Right-click "InjectionUnits".

SiOME displays the "Add Instance" dialog.

At "Name", insert a descriptive name for your instance.

In the example, enter "InjectionUnit_1.

For "TypeDefinition", select "InjectionUnitType".

Click "OK".

14.Now create a new instance each for "Molds" and "PowerUnits", as described above for "InjectionUnits".

15.Now save the XML file.

Export the file for this purpose.

Click the ""Export XML" button in the "Information model" area.

SiOME shows the "Export XML" dialog.

16.Leave the "Include mappings" option unselected, because the file still contains no mappings (UAtags on PLC tags, UAmethods on server methods of the CPU).

The imported namespaces are required for Euromap77. Therefore, SiOME displays these in grey.

Click "OK".

SiOME shows a dialog.

17.Select a descriptive name for the XML file and save the file.

Result:

You have now created an XML file containing the companion specification "Euromap77" and the instances you added. Euromap77 is used for this purpose.

Step 2: Assigning PLC tags

The description below uses the example of a tag to show how you assign specific PLC tags and server methods to the tags and methods of Euromap 77.

The easy way

We recommend using the SiOME tool here as well. You have to enable mapping in SiOME for this purpose:

In the "TIA Portal" area, select the data blocks whose tags you want to assign ("map") to the OPC UA tags of the information model.

The tags from the TIA Portal project can easily be connected to the OPC UA tags using drag-and-drop.

To link methods, you must use drag-and-drop to link the instance data blocks of the corresponding TIA Portal function blocks to the methods of the information model.

When exporting, select the "Include mappings" option, since the information model for an OPC UA server is required here.

This option is not required if you need the information model for an OPC UA client.

A detailed description can be found in the online support application example (OPC UA for Devices (https://opcfoundation.org/UA/schemas/DI/)).

Assigning PLC tags manually

If you do not assign the data with SiOME, proceed as follows:

1. Use an editor to open the file "demo.xml" that you created in "Step 1".

   In the XML file, search for the UA tag with NodeId="ns=1;s=MyIMM_MES_Interface.InjectionUnits.NodeVersion".

   These tags are assigned a PLC tag in the next step.

2. To assign this OPC UA tag a PLC tag, add an extension to the XML element of the OPC UA tag.

   In turn, you then add an element of the type "<si:VariableMapping>" to this extension:

```xml
<UAVariable DataType="String" ParentNodeId="ns=1;s=MyIMM_MES_Interface.InjectionUnits" NodeId=
"ns=1;s=MyIMM_MES_Interface.InjectionUnits.NodeVersion" BrowseName="NodeVersion">
    <DisplayName>NodeVersion</DisplayName>
    <References>
        <Reference ReferenceType="HasProperty" IsForward="false">
        ns=1;s=MyIMM_MES_Interface.InjectionUnits</Reference>
        <Reference ReferenceType="HasTypeDefinition">i=68</Reference>
    </References>
    <Extensions>
        <Extension>
            <si:VariableMapping>"MyIMM_MES_Interface"."InjectionUnits.NodeVersion"
            </si:VariableMapping>
        </Extension>
    </Extensions>
    <Value>
</UAVariable>
```

3. The XML element "<si:VariableMapping>" is defined in the XML namespace "http://www.siemens.com/OPCUA/2017/SimaticNodeSetExtensions".

   You therefore need to assign this namespace to the XML element "<UANodeSet>", for example in a one-off operation with the following code line at the start of the XML file:

   ```xml
   <UANodeSet xmlns:si="http://www.siemens.com/OPCUA/2017/SimaticNodeSetExtensions"
   ```

   If you do not add the namespace, the element "<si:VariableMapping>" will not be known in the file.

4. Save the "demo.xml" file and close the editor.

Useful information: Assigning PLC methods

As well as assigning tags, you can also assign methods to an FB instance (user program or function block as representation of the method).

To assign an OPC UA method to an FB instance, you also need to add an extension to the OPC UA XML file following the procedure outlined below. Please note that the suffix ".Method" without quotation marks must be added to the instance name.

You add an element of the <si:MethodMapping> type to the extension:

The properties of an OPC UA method with the BrowseName "InputArguments" and "OutputArguments" are OPC UA tags and are **not** assigned.

```
<UAMethod ParentNodeId="ns=1;i=5003" NodeId=
"ns=1;s=MyIMM_MES_Interface.MachineConfiguration.SetServerTime" BrowseName="4:SetServerTime"
MethodDeclarationId="ns=2;i=7005">
    <DisplayName>SetServerTime</DisplayName>
    <References>
        <Reference ReferenceType="HasProperty">
        ns=1;s=MyIMM_MES_Interface.MachineConfiguration.SetServerTime.InputArguments</Reference>
        <Reference ReferenceType="HasComponent" IsForward="false">ns=1;i=5003</Reference>
    </References>
    <Extensions>
        <Extension>
            <si:MethodMapping>"MachineConfiguration.SetServerTime_IDB".Method</si:MethodMapping>
        </Extension>
    </Extensions>
</UAMethod>
```

Step 3: Importing server interfaces

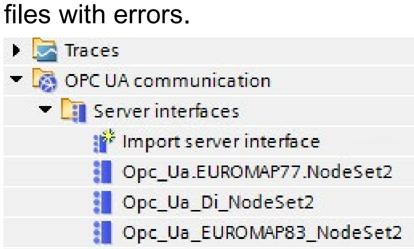
Proceed as follows to import an OPC UA XML file as "Server interface":

1. Open the STEP 7 project.
2. Click "OPC UA communication > Server interfaces".
3. Double-click on "Import server interface".
4. In the "Import" dialog, select the file that you want to import as server interface.

   In the example, this is the file "demo.xml".
5. Click the "Import" button.
6. Also import the files "Opc.Ua.Di.NodeSet2.xml", "Opc_Ua.EUROMAP77.NodeSet2.xml" and "Opc_Ua.EUROMAP83.NodeSet2.xml".

   The "demo.xml" file relates to the files just specified.

   Always use the latest versions of these files as STEP 7 does not compile OPC UA XML files with errors.



The above image of the machine generated in accordance with Euromap 77 specifications is now available in the address space of the OPC UA server.

Step 4: Creating PLC tags and server methods in the STEP 7 project

In the example, you have assigned the PLC tag "MyIMM_MES_Interface"."InjectionUnits.NodeVersion" to the UA tag with NodeId="ns=1;s=MyIMM_MES_Interface.InjectionUnits.NodeVersion"; see "Step 2: Assigning PLC tags".

Proceed as follows to create the required PLC tag with STEP 7 (TIA Portal):

1. Generate a "MyIMM_MES_Interface" data block.
2. Generate the DB element "InjectionUnits.NodeVersion". Use the SIMATIC data type compatible with the OPC UA data type. The UA tag in the example has the OPC UA data type "String" (DataType="String"). The compatible SIMATIC data type is WSTRING.

3. Compile the project.
4. Download the project to the CPU.

Importing exported OPC UA XML files to an S7-1500 CPU

Please note the following information when importing server interfaces that come from the OPC UA XML export of an S7-1500.

Note

Import blocked for namespace "http://www.siemens.com/simatic-s7-opcua"

You cannot import server interfaces with the namespace "http://www.siemens.com/simatic-s7-opcua" to an S7-1500 CPU because this namespace is reserved for S7-1500 CPUs (standard SIMATIC server interface) and is not available for imports.

If you want to import a server interface with the namespace "http://www.siemens.com/simatic-s7-opcua", open the server interface to be imported (OPC UA XML file) and change the namespace in the relevant places. The file thus changed can then be imported.

Integrity of the OPC UA XML files

OPC UA XML files represent the server address space. These files are, for example, imported by you in the context of OPC UA Companion specifications as a server interface after adaptation to the application, loaded with the hardware configuration into the S7-1500 CPU and tested.

WARNING
No checking of imported OPC UA XML files
Protect these OPC UA XML files against unauthorized manipulation since STEP 7 does not check the integrity of these files.

Recommendation

To minimize risks in the case of an extension or adaptation of the server address space, follow these steps:

1. Protect the project (project navigation: Security settings > Settings).
2. Export the corresponding server interface before the extension or adaptation.
3. Revise this OPC UA XML file.
4. Import the file again as a server interface.

Mapping data types

The table below shows the compatible SIMATIC data type for each OPC UA data type.

Assign the data types as shown below (SIMATIC data type – OPC UA data type). Other assignments are not permitted. STEP 7 does not check the observance of this rule and does not prevent an incorrect assignment. You are responsible for the rule-compliant selection and assignment of the data types.

You can also use the listed data types, for example, as elements of structures/UDTs for input and output parameters of self-created server methods (UAMethod_InParameters and UAMethod_OutParameters).

Table 9- 2 Mapping of data types

SIMATIC data type	OPC UA data type
BOOL	Boolean
SINT	SByte
INT	Int16
DINT	Int32
LINT	Int64
USINT	Byte
UINT	UInt16
UDINT	UInt32
ULINT	UInt64

SIMATIC data type	OPC UA data type
REAL	Float
LREAL	Double
LDT	DateTime
WSTRING	String
DINT	Enumeration (Encoding Int32) and all derived data types
User-defined data type required (UDT, user-defined data type) The user-defined data type must be created with the prefix "Union_", for example "Union_MyDatatype"; see example below the table. The first element (Selector) in this UDT must have the data type "UDINT".	UNION and all derived data types

User-defined data type for UNION required

The figure below shows the tag "MyVariable", which has the data type "Union_MyDatatype".

This SIMATIC data type corresponds to an OPC UA tag with the data type UNION.

The figure shows an example of the declaration: When Selector = 1, Union accepts one ByteString; when Selector = 2, Union accepts one WString.

Name	Data type
Static	
Selector	UDInt
ByteArray	Array[0..1] of Byte
WString	WString[42]

Using other OPC UA basic data types

Apart from the OPC UA data types listed in the section "Mapping of data types" and their correspondences on the SIMATIC side, there are the following OPC UA basic data types which you can also use:

- OpcUa_NodeId
- OpcUa_QualifiedName
- OpcUa_Guid
- OpcUa_LocalizedText
- OpcUa_ByteString
- OpcUa_XmlElement

Requirement for the use of the basic data types listed above as variables in the application program: The basic data types have to exist as complex data types that are structured exactly like the corresponding OPC UA basic data types.

- OpcUa_NodeId and OpcUa_QualifiedName exist as system data types; that's why you can use these data types not only for single variables but also as elements of a structure.
- For the remaining basic data types, you have to create a PLC data type in accordance with the OPC UA specification and subsequently use it as an element in a structure so that the data types of the elements can be resolved. What each PLC data type must look like is described below for every single basic data type. "EUInformation" is an example of a data structure in which, for example, the UDT "LocalizedText" is used. EUInformation contains information on EngineeringUnits. You can find an example of the implementation of the EUInformation data structure at the end of the PLC data type descriptions.

System data type "OPC_UA_NodeId"

For the OPC UA basic data type "OpcUa_NodeId", please refer to the following table for the meaning of the parameters. Use OPC_UA_NodeId for the identification of a node in the OPC UA server.

Parameter	S7 data type	Meaning
NamespaceIndex	UINT	Namespace index of the node in the OPC UA server. A node can, for example, be a tag.
Identifier	WSTRING[254]	The designation of the node (object or tag) depends on the identifier type: • Numeric identifier: The node is labeled with a number, for example "12345678". • String identifier: The node is labeled with a name, for example "MyTag". No distinction is made between upper and lower case.
IdentifierType	UDINT	Type of identifier • 0: Numeric identifier • 1: String identifier • 2: GUID • 3: Opaque

System data type "OPC_UA_QualifiedName"

See the following table for the structure of the system data type "OPC_UA_QualifiedName":

Name	S7 data type	Meaning
NamespaceIndex	UINT	The namespace index of the name.
Name	WSTRING[64]	Name of the node or tag.

UDT "Guid"

For the basic data type "Guid", create the following PLC data type. The default values used as examples can also be set differently.

Guid

	Name	Data type	Default value
1	Data1	UDInt	16#11223344
2	Data2	UInt	16#5566
3	Data3	UInt	16#7788
4	Data4	ULInt	16#99AABBCCDDEEFF11

UDT "LocalizedText"

For the basic data type "LocalizedText", create the following PLC data type:

LocalizedText

	Name	Data type	Default value
1	EncodingByte	Byte	16#3
2	Locale	WString[5]	WSTRING#'de-DE'
3	Text	WString[255]	WSTRING#'Text'

The EncodingByte indicates which fields (Locale or Text) are available:

EncodingByte	Meaning
0	The fields Locale and Text are empty
1	The field Locale has content, the field Text is empty
2	The field Locale is empty, the field Text has content
3	The fields Locale and Text have content

UDT "ByteString"

For the basic data type "ByteString", create the following PLC data type; in this case, for example, a ByteString array with 12 elements:

ByteString

	Name	Data type	Default value
1	ByteString	Array[0..11] of Byte	
2	ByteString[0]	Byte	16#0
3	ByteString[1]	Byte	16#0
4	ByteString[2]	Byte	16#0
5	ByteString[3]	Byte	16#0
6	ByteString[4]	Byte	16#0
7	ByteString[5]	Byte	16#0
8	ByteString[6]	Byte	16#0
9	ByteString[7]	Byte	16#0
10	ByteString[8]	Byte	16#0
11	ByteString[9]	Byte	16#0
12	ByteString[10]	Byte	16#0
13	ByteString[11]	Byte	16#0

UDT "XmlElement"

An XmlElement is a serialized XML fragment (UTF-8 string)

For the basic data type "XmlElement", create the following PLC data type:

XmlElement

	Name	Data type	Default value
1	XmlElement	WString	WSTRING#''

Example: Structure of EUInformation with UDT "LocalizedText"

Velocity	"EUInformation"		
NamespaceUri	WString[255]	WSTRING#'http://yourorganization.org'	Identifies the organization (company, standards organization) that defines the EUInformation
UnitId	DInt	1	Identifier for programmatic evaluation. –1 is used if a unitId is not available.
DisplayName	"LocalizedText"		
Encoding...	Byte	16#3	
Locale	WString[5]	WSTRING#'en-EN'	
Text	WString[255]	WSTRING#'m/s'	
Description	"LocalizedText"		
Encoding...	Byte	16#3	
Locale	WString[5]	WSTRING#'en-EN'	
Text	WString[255]	WSTRING#'meter per second'	

MinimumSamplingInterval attribute of tags

In addition to "Value", "DataType" and "AccessLevel", you can also set the "MinimumSamplingInterval" attribute for a tag in the XML file that represents the server address space.

The attribute specifies how fast the server can sample the tag value.

The OPC UA server of the S7-1500 CPU handles the values for MinimumSamplingInterval as follows:

- Negative values and values greater than 4294967 are set to -1 (meaning: Default setting of the server should be used for the sampling interval for sampling. This is defined by the publishing interval of the subscription, see OPC UA specification part 4).
- Decimal numbers are rounded to three decimal places.

9.3.5.4 Missing namespaces

Introduction

A node set file (OPC UA XML file) may contain references to other OPC UA XML files that provide type definitions in other namespaces. You must import all required definitions for the information model in order for the server interface to work properly.

Example for list of namespaces (NamespaceUris) in an OPC UA XML file

```
<NamespaceUris>
    <Uri>http://www.siemens.com/SimaticIdent/RF600R/</Uri>
    <Uri>http://opcfoundation.org/UA/DI/</Uri>
    <Uri>http://opcfoundation.org/UA/AutoID/</Uri>
</NamespaceUris>
```

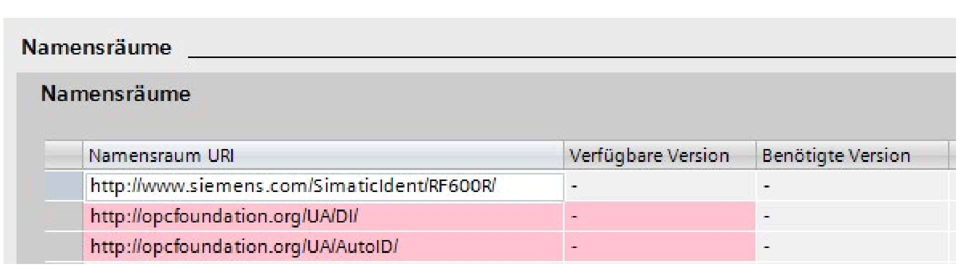
Importing additional namespaces

If namespaces are still missing after the import of an OPC UA XML file, STEP 7 generates an error message.

In this case, import the OPC UA XML files with the missing namespaces into a new server interface. You must create a new server interface, otherwise the additional imported XML file would overwrite the current companion specification (the current information model).

The missing namespaces are displayed in red in the properties of the server interface.

After importing the XML files, you must click the "Refresh interface" button to refresh the view.



Namensräume

Namensräume

Namensraum URI	Verfügbare Version	Benötigte Version
http://www.siemens.com/SimaticIdent/RF600R/	-	-
http://opcfoundation.org/UA/DI/	-	-
http://opcfoundation.org/UA/AutoID/	-	-

9.3.5.5 Coordinating write and read rights for CPU tags

Definition of write and read rights in the information model (OPC UA XML)

In the OPC UA information model, the attribute "AccessLevel" regulates access to tags.

AccessLevel is defined bit by bit:

Bit 0 = CurrentRead and Bit 1 = CurrentWrite. The meaning of the bit combinations is as follows:

- AccessLevel = 0: no access
- AccessLevel = 1: read only
- AccessLevel = 2: write only
- AccessLevel = 3: read+write

Example of the assignment of write and read rights (read+write)

```
<UAVariable NodeId="ns=3;s=&quot;Data_block_2&quot;.&quot;Static_1&quot;"
BrowseName="3:Static_1"
ParentNodeId="ns=3;s=&quot;Data_block_2&quot;"
DataType="INT"
AccessLevel="3">
    <DisplayName>Static_1</DisplayName>
```

Definition of write and read rights in STEP 7

When you define tags, you specify the access rights using the properties "Accessible from HMI/OPC UA" and "Writable from HMI/OPC UA".

Example of the assignment of write and read rights

Name	Data type	Accessible from HMI/OPC UA	Writable from HMI/OPC UA
Static_1	Int	☑	☑
<Add new>		☑	☑

Interaction between write and read rights

If you have imported an OPC UA server interface and AccessLevel attributes are set in this OPC UA XML file, the write and read rights are defined by the following rule: The least extensive access rights for each setting apply.

Example

- AccessLevel = 1 (read only) in the OPC UA server interface
- Both "Accessible from HMI/OPC UA" and "Writable from HMI/OPC UA" are selected in the PLC tag table

Result: The tag is only read.

Rules

If write rights are required:

- AccessLevel = 2 oder 3
- "Writable from HMI/OPC UA" enabled

If read rights are required:

- AccessLevel = 1 (AccessLevel 3 is also possible, but misleading. The settings suggests that an OPC UA client has write and read rights)
- "Accessible from HMI/OPC UA" enabled, "Writable from HMI/OPC UA" disabled

If neither read nor write rights are to be granted (no access):

- AccessLevel = 0
- "Accessible from HMI/OPC UA" disabled

  Only one of the two conditions needs to be met to block all access. In this case, review whether the tag in the OPC UA server interface is actually necessary at all.

Access table

"Accessible from HMI/OPC UA" must be set if access over OPC UA is to be possible at all. "Writable from HMI/OPC UA" must be set to allow an OPC UA client to write a tag / DB element.

Please see the table for the resulting access right.

Table 9- 3 Access table

OPC UA XML	**STEP 7 (TIA Portal), for example tag table**		
AccessLevel	**Accessible from HMI/OPC UA**	**Writable from HMI/OPC UA**	**Resulting access right**
0	x	x	No access
x	0	x	No access
1	Enabled	x	Read only
2	Enabled	Disabled	No access
3	Enabled	Disabled	Read only
2	Enabled	Enabled	Write only
3	Enabled	Enabled	Read+write

(x = don't care)

9.3.5.6 Consistency of CPU tags

"AccessLevelEx" attribute extends access properties

As of firmware version V2.6, the OPC UA server of the S7-1500 CPU supports not only the attribute "AccessLevel" (see Coordinating write and read rights for CPU tags (Page 218)) but also the attribute "AccessLevelEx" which, in addition to the already explained bits for read access and write access, provides information on the consistency of a OPC UA tag. The new attribute was introduced with version V1.04 of the OPC UA specification (Part 3, Address Space Model).

Reading consistency properties

In the OPC UA information model of the OPC UA server, the attribute "AccessLevel" defines the access.

AccessLevelEx is defined bit by bit; in this case, the relevant bits are:

- Bit 0 = CurrentRead
- Bit 1 = CurrentWrite
- Bits 2 to 7 are not relevant for the OPC UA server of an S7-1500 CPU

The meaning of the bit combinations is explained in the section on read and write rights.

The following bits for consistency are also added:

- Bit 8 = NonatomicRead; the bit is set if the tag cannot be read consistently. For read consistency of tags, bit 8=0.
- Bit 9 = NonatomicWrite; is set if the tag cannot be written consistently. For write consistency of tags, or if no write access is granted, bit 9=0.

Examples

An OPC UA tag (structure) is readable and writable; but inconsistent for reading and writing access.

Consequently: Bits 0, 1, 8 and 9 are set: AccessLevelEx = "771" (1+2+256+512).

Another structure is read-only.

Consequently: Bits 0 and 8 are set, bit 1 and bit 9 are not set: AccessLevelEx = "257" (1+0+256+0).

Handling of the attribute in the server

The "AccessLevelEx" attribute is only available in the OPC UA server. The attribute is not present in a node set file (XML export file).

However, the attribute "AccessLevel", which is exported, includes the information from "AccessLevelEx", see next section.

Export

With XML export of the standard Simatic server interface, the server sets the attribute "AccessLevel", which was extended to 32 Bit Advanced in V1.04 compared to V1.03, to the value of attribute "AccessLevelEx".

Import

When importing a node set file (e.g. from an export of a server interface), the S7-1500 CPU sets the attribute "AccessLevelEx" according to its own estimate of the consistency of the imported data type, see next section. The imported value is ignored.

Consistency of data types at the server interface

The consistency of tags ("atomicity" in the language usage of OPC UA) within a program cycle of an S7-1500 CPU is ensured at the nodes of the server interface for the following data types:

- BOOL, BYTE, WORD, DWORD, LWORD
- SINT, INT, LINT, DINT, USINT, UINT, ULINT, UDINT
- REAL, LREAL
- DATE, LDT, TIME, LTIME, TIME_OF_DAY, LTIME_OF_DAY, S5TIME
- CHAR, WCHAR
- System data types and hardware data types that are based on the above-mentioned data types are also consistent.

  Example: HW_ANY, derived from UINT (UInt16).

Tip: If you browse in the address space of the S7-1500 CPU (e.g. with the OPC UA Client UaExpert), you can find the consistent data types under Types > BaseDataType > Enumeration/Number/String.

Tags of the following data types are **not** consistent ("nonatomic" in the language usage of OPC UA):

- SIMATIC structures are generally not consistent. This means that all tags which, for example, have unknown structures or a UDT data type are not consistent.
- System data types such as DTL, IEC_Counter, IEC_TIMER, etc. are data types that are derived from structures.

Tip: If you browse in the address space of the S7-1500 CPU (e.g. with the OPC UA Client UaExpert), you can find data types based on structures under Types > BaseDataType > Structure.

9.3.5.7 Notes on configuration limits when using server interfaces

When you use OPC UA server interfaces, you must comply with limits for the following objects in line with the S7-1500 CPU performance class:

- Number of server interfaces
- Number of OPC UA nodes
- Load object data volume
- If you have implemented methods: Number of server methods or server method instances

Configuration limits for OPC UA server interfaces and methods

The table below sets out the configuration limits for S7-1500 CPUs; these must also be taken into account when you compile and load a configuration.

A violation of configuration limits results in an error message.

Table 9- 4 Configuration limits for OPC UA server interfaces

Technical specification value	CPU 1510SP (F) CPU 1511 (C/F/T/TF) CPU 1512C CPU 1512SP (F) CPU 1513 (F)	CPU 1505 (S/SP/SP F/SP T/SP TF) CPU 1515 (F/T/TF) CPU 1515 SP PC (F/T/TF) CPU 1516 (F/T/TF)	CPU 1507S (F) CPU 1517 (F/T/TF) CPU 1518 (F)
Use of imported companion specifications (information models)			
• Maximum number of OPC UA server interfaces	10	10	10
• Maximum number of OPC UA nodes in user-defined server interfaces	1000	5000	30000
• Maximum size of loadable OPC UA server interfaces	1024 KB	5120 KB	15360 KB
Provision of methods			
Maximum number of usable server methods or max. number of server method instances (instructions OPC_UA_ServerMethodPre, OPC_UA_ServerMethodPost)	20	50	100

9.4 Using the S7-1500 CPU as an OPC UA client

9.4.1 Overview and requirements

With STEP 7 (TIA Portal) Version 15.1 and higher, you can configure and program an OPC UA client that can read PLC tags in an OPC UA server. Furthermore it is possible to transfer new values for PLC tags to an OPC UA server. In addition, you can call methods that an OPC UA server provides in your user program. You use the new instructions for OPC UA clients for this purpose in your user program.

The instructions of the OPC UA client are based on the standard "PLCopen OPC UA Client for IEC61131-3".

PLCopen companion specification

With these standardized instructions, you can use OPC UA client functions in your user program that can be executed in an S7-1500 CPU.

In addition, it is possible with just a few adaptations to run this user program in controllers of other manufacturers if these manufacturers also implemented the OPC UA Companion Specification "PLCopen OPC UA client for IEC61131-3".

Convenient editors in STEP 7

For the parameter assignment of the instructions for OPC UA clients, a convenient editor is available in the TIA Portal – the connection parameter assignment (Page 245).

As of Version 15.1, STEP 7 also features an editor for client interfaces (Page 228).

This section describes how you work with these editors.

First, you will be shown how to create and configure a new interface with the interface editor, because you need this type of interface for the subsequent connection parameter assignment.

The description uses an example for better comprehensibility, see Description of the example (Page 227).

Requirement

To use the client of the S7-1500 CPU, you must enable it:

1. Select the area "OPC UA > Client" in the properties of the CPU.
2. Select the "Enable OPC UA client" option.

If you do not enable the client, the connection is not established. You receive a corresponding error message at the instructions, for example "OPC_UA_Connect".

Overview

To use the editor and the connection parameter assignment, follow these steps:

1. First, specify a client interface. Add to the interface the PLC tags and PLC methods that you want to access ("First step (Page 228)").
2. Next, configure the connection to the OPC UA server (Second step (Page 245)).
3. Finally, use the configured connection for the OPC UA client instructions (Third step (Page 253)).

9.4.2 Useful information about the client instructions

With the standardized OPC UA client instructions you are able to control communication for the following tasks with the S7-1500 CPU as an OPC UA client:

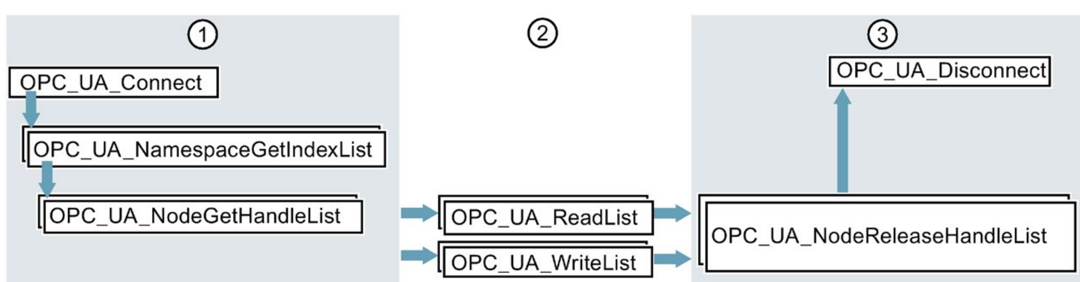
- Read/write tags of the OPC UA server
- Call methods in the OPC UA server

Optional instructions can be used to determine the status of the connection between the OPC UA client and OPC UA server or to determine nodes along a know hierarchy.

Standardized sequence of OPC UA communication

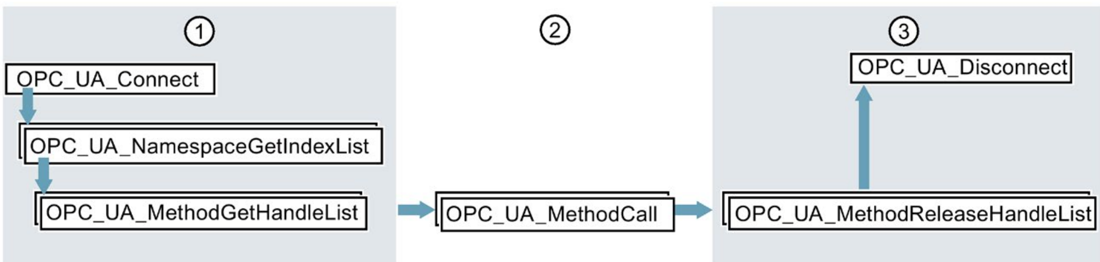
The sequence of the communication, and thus the order of the instructions, follows a pattern that is illustrated in the following.

Run sequence for a read or write operation



① Instructions for preparation of read and write operations
② Read and write instructions
③ Instructions for "clean-up" after a completed read or write operation

Run sequence for a method call in the OPC UA server

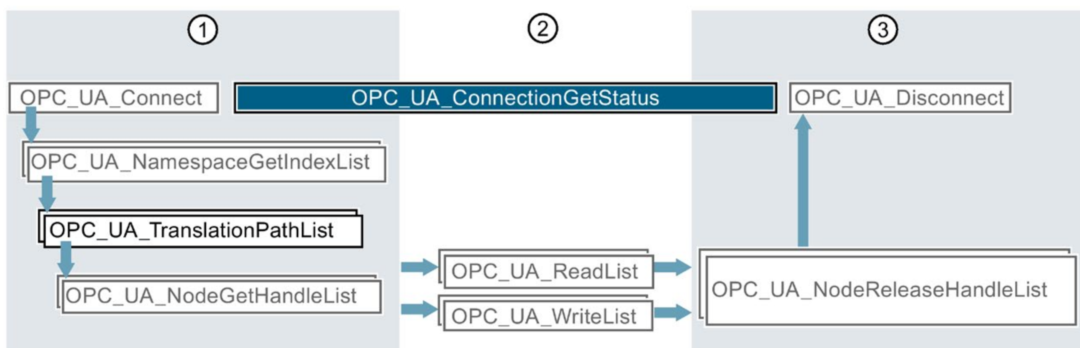


① Instructions for preparation of method calls

② Method calls

③ Instructions for "clean-up" after completed method calls

Optional instructions for reading out the status of a connection between the OPC UA client and OPC UA server and for reading out complete paths from the OPC UA server.



① Instructions for preparation of read and write operations with inserted instruction for requesting, for example, the NodeIDs of nodes of the OPC UA server.

② You can determine the connection status between the establishment and termination of the connection in parallel with other instructions.

③ Instructions for "clean-up"

Convenient editors in STEP 7

The OPC UA client instructions are described in detail in the reference part (STEP 7 information system). For parameter assignment of the instructions, a convenient editor is available in the TIA Portal – the connection parameter assignment (Page 245).

We recommend starting with the connection parameter assignment for the first program draft and using additional instructions and manually optimizing the program as required.

Information about the client instructions

The client instructions are described in detail in the help to the Instructions > Communication > OPC UA > OPC UA client.

9.4.3 Number of client instructions that can be used simultaneously

SIMATIC error codes for OPC UA client instructions

The following limits apply to the simultaneous use of OPC UA client instructions:

Table 9- 5 Quantity structures for OPC UA client instructions

OPC UA instruction	Maximum number for CPU 1510SP (F) CPU 1511 (C/F/T/TF) CPU 1512C CPU 1512SP (F) CPU 1513 (F)	Maximum number for CPU 1505 (S/SP/SP F/SP T/SP TF) CPU 1515 (F/T/TF) CPU 1515 SP PC (F/T/TF) CPU 1516 (F/T/TF)	Maximum number for CPU 1507S (F) CPU 1517 (F/T/TF) CPU 1518 (F)
OPC_UA_Connect	4	10	40
OPC_UA_NamespaceGetIndexList	4	10	40
OPC_UA_NodeGetHandleList	4	10	40
OPC_UA_MethodGetHandleList	4	10	40
OPC_UA_TranslatePathList	4	10	40
OPC_UA_ReadList	20 in total (max. 5 per connection, see OPC_UA_Connect)	50 in total (max. 5 per connection, see OPC_UA_Connect)	200 in total (max. 5 per connection, see OPC_UA_Connect)
OPC_UA_WriteList	20	50	200
OPC_UA_MethodCall	20	50	200
OPC_UA_NodeReleaseHandleList	4	10	40
OPC_UA_MethodReleaseHandleList	4	10	40
OPC_UA_Disconnect	4	10	40
OPC_UA_ConnectionGetStatus	4	10	40

Maximum number of usable OPC UA client interfaces

If you create OPC UA client interfaces using the connection parameter assignment, the number of client interfaces is limited to 40.

Create the OPC UA client interfaces by double-clicking the "Add new client interface" symbol in the project tree of the "OPC UA communication" area.

The maximum number of OPC UA client interfaces is independent of whether you also use the CPU as OPC UA server.

9.4.4 Example configuration for OPC UA

The following sections describe how you can use the client interfaces editor and the connection parameter assignment.

The description is based on a specific example: Two S7-1500 CPUs operate in the system: One CPU serves as the OPC UA client and the other as the OPC UA server.

You can, of course, also use controllers, sensors and IT systems of other manufacturers as OPC UA clients or servers. In particular, the data exchange between different systems (interoperability) is a major advantage of OPC UA.

Connection parameter assignment using an example:

The plant produces blanks in a production line.

The following controllers are used:

1. An S7-1511 CPU serves as the controller of the production line.

   The controller is named "**Productionline**" in the example.

   The OPC UA server of the controller is enabled.

   The CPU has the IP address 192.168.1.1 in the example.

   This CPU publishes the values of following tags via the OPC UA server:

   – **NewProduct**

     The tag has the data type "BOOL".

     When this PLC tag has the value TRUE, the production line has processed a blank.

     The blank is ready for pick-up.

   – **ProductNumber**

     This tag contains the identification number of the blank.

     The tag has the data type "Int".

   – **Temperature**

     This tag contains temperature values recorded during the production of the blank.

     The tag is an array with elements of the "Real" data type.

   In addition, this CPU provides the following writable tag:

   – **ProductionEnabled**

     The tag is set by the OPC UA client.

     The tag has the data type "BOOL".

     If the value is set to TRUE, the production line is released and may produce blanks.

   In addition, this CPU provides the following method via the OPC UA server:

   – **OpenDoor**.

     OPC UA clients can hereby arrange for an access door to be opened to the production line.

2. An S7-1516 CPU controls the interaction with other production lines.

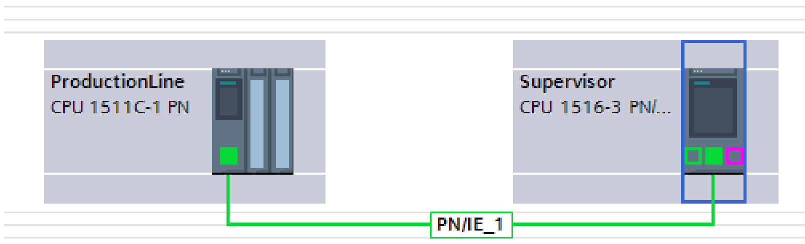
   This CPU is named "**Supervisor**" in the example.

   The OPC UA client of this CPU is enabled.

   Using OPC UA, this CPU can read the NewProduct and ProductNumber tags, set the ProductionEnabled tag and call the OpenDoor method.

   The CPU has the IP address 192.168.1.2 in the example.

The following figure shows the example in the network view of the TIA Portal:



9.4.5 Creating client interfaces

As of Version 15.1, the TIA Portal has an editor for client interfaces.

You group all PLC tags that you want to read or write from an OPC UA server in a client interface.

In addition, the client interface contains all methods that the OPC UA server provides and that you want to call with your user program (that acts as an OPC UA client).

If you create a client interface, STEP 7 also creates data blocks for the parameter assignment of the connection to the OPC UA server from which you want to read data or to which you want to write data.

Maximum number of client interfaces

You can create a maximum of 40 client interfaces.

Editor for client interfaces

To create a client interface, follow these steps:

1. Select the project view in the TIA Portal.
2. In the "Devices" area, select the CPU you want to use as an OPC UA client.
3. Click "OPC UA communication > Client interfaces".
4. Double-click "Add new client interface".

   STEP 7 creates a new client interface and display in the editor.

   STEP 7 names the new interface "Client interface_1". If a "Client interface_1" already exists, the new interface receives the designation "Client interface_2" etc.

   In addition, STEP 7 creates the following data blocks:

   – Client_Interface_1_Configuration

     The data block already contains all system data types that are needed for the instructions of the OPC UA client.

     This data block is filled when you configure the connection to the OPC UA server.

     You configure a connection in the properties of the client interface, see: Example configuration for OPC UA (Page 227).

   – Client_Interface_1_Data

     A data block for the PLC tags that you want to read or write from an OPC UA server.

     You use this data block in your user program.

     This data block is currently still empty.

5. Select a descriptive name for the new client interface.

   Select "Productionline" in the example.

   This also changes the names of the associated data blocks to:

   – Productionline_Data

   – Productionline_Configuration

6. To import an OPC UA server interface, click the "Import interface" button in the top right of the editor.

   This allows you to import an XML file which describes the server interface of an OPC UA server.

   Alternative: To determine online the server interface of a connected OPC UA server, see: Determine server interface online (Page 237).

7. STEP 7 displays a dialog with which you can select an XML file.

   This XML file describes a server interface (address space of an OPC UA server).

   A server interface is the grouping of all PLC tags and server methods which an OPC UA server publishes.

   OPC UA clients can access the server interface:

   - Read PLC tags

   - Write PLC tags

   - Calling Server Methods

   For information on how to create a server interface for an OPC UA server, see Create a server interface (Page 199).

8. Create a read list in this client interface.

   To do this, follow these steps:

   – Click "Add new read list" in the left section of the editor.

     STEP 7 adds a new list named "ReadList_1".

     For the example, change the name to "ReadProduct"

   – Now add the new read list of the PLC tags that you want to read from the OPC UA server.

     In the example the "NewProduct" and "ProductNumber" tags are added to the "ReadProduct" read list.

     Select the "NewProduct" tag in the right-hand field of the editor ("OPC UA Server interface"). Drag the "NewProduct" tag to the "ReadProduct" read list in the middle field of the editor. Follow the same procedure with the "ProductNumber" tag.

The figure below shows the right field of the editor.

OPC UA server interface

Name of the node	Node type	Access level	Node ID
Productionline	Object		http://www.sie...
DataBlocksGlobal	Folder		http://www.sie...
Data_for_OPC_UA_Clients	Object		http://www.sie...
NewProduct	Boolean	RD	http://www.sie...
ProductNumber	Int16	RD	http://www.sie...
Temperature	Array of Float	RD	http://www.sie...
Data_from_OPC_UA_Clients	Object		http://www.sie...
ProductionEnabled	Boolean	RD/WR	http://www.sie...
DataBlocksInstance	Folder		http://www.sie...
OpenDoor_DB	Object		http://www.sie...
InOuts	Folder		http://www.sie...
Static	Folder		http://www.sie...
Method	Method		http://www.sie...

Alternative:

You can also select a new read list by dragging the right field of the editor ("OPC UA Server interface") to a node of the type Object or Folder and then dragging it to "Add new read list" in the left field of the editor. The new read list then contains all PLC tags of the node that has been moved.

In the example, select the object "Data_for_OPC_UA_Clients", which contains the tags "NewProduct" and "ProductNumber". STEP 7 generates the new write list "Data_for_OPC_UA_Clients". In addition, the object contains the tag "Temperature". Delete the "Temperature" tag from the read list. The OPC UA server should not query the "Temperature" tag.

Change the name of the read list in "ReadProduct".

The following figure shows the content of the read list:

ReadProduct

Name of the node	Node type	Access level	Node ID
NewProduct	BOOL	RD	http://www.siemen...
ProductNumber	INT	RD	http://www.siemen...

9. If you want assign new values to PLC tags, create a write list in this client interface.

   To do this, follow these steps:

   – Click "Add new write list" in the left section of the editor.

     STEP 7 adds a new list with the name "ReadList_1".

     For the example, change the name to "WriteStatus".

   – Now add the new write list of all OPC UA server tags to which you want to assign new values.

     In the example, add the "WriteStatus" tag to the write list "ProductionEnabled".

     Select the Tag of right field of the editor ("OPC UA Server interface"). Drag the tag to the write list in the middle field of the editor.

   Alternative:

   You can also create a new write list by selecting a node of the type Object or Folder in the right field of the editor ("OPC UA server interface") and then dragging to "Add new write list" in the left field of the editor.

   The new write list then contains all tags of the relevant node.

   In the example, select the object "Data_from_OPC_UA_Clients", which contains the tag "ProductionEnabled". STEP 7 generates the new write list "Data_from_OPC_UA_Clients". Change the name in "WriteStatus".

   The following figure shows the content of the write list:

WriteStatus

Name of the node	Node type	Access level	Node ID
ProductionEnabled	BOOL	RD/WR	http://www.siemen...

10. If you want to call a method of this OPC UA server, generate a new method list.

    To do this, follow these steps:

    – In the left section of the editor, click "Add new method list".

      STEP 7 adds a new list with the name "Method list_1".

      For the example, change the name to "CallOpenDoor".

    – Now add a method of the OPC UA server to the new method list.

      In this example, add the method "OpenDoor" to the method list "CallOpenDoor".

      Select the method of right field of the editor ("OPC UA Server interface"). Drag the method to the method list in the middle field of the editor.

Alternative:

You can also generate a new method list by selecting a method (node of the type Object) in the right field of the editor (OPC UA Server interface) and then dragging it to "Add new method list" in the left field of the editor. The new method list then contains the method of the relevant node.

The following figure shows the content of the method list:

CallOpenDoor

Name of the node	Node type	Access level	Node ID
Method			http://www.siemen...

If you want to call another method of the OPC UA server, you must create a new method list. Each method list contains only one method.

11. Compile the project.

    To do so, select the project and click the following button in the toolbar:

STEP 7 compiles the project and updates the data blocks that belong to the "ProductionLine" client interface.

Note

During compilation, STEP 7 overwrites all data in the data blocks belonging to the client interface. For this reason, you should neither add to nor correct these data blocks manually.

Note

Renaming nod names (DisplayNames)

In read lists, write lists and method lists you can rename the name of a node by means of the shortcut menu. This is the "DisplayName" in the OPC UA language usage.

If you rename the name of a method list node and the node is already used in a programmed block for the method call "OPC_UA_MethodCall", the compilation of the project leads to consistency errors: During the compilation the UDTs of the method are generated with the changed name. The references to the method used in the program are then no longer correct.

To correct the consistency errors, you can either undo the name change of the method in the client interface or navigate to the method call and assign the relevant parameters again there under "Properties > Block parameters" ("Configuration" tab).

Data blocks of client interface

The following data blocks belong to the "Productionline" client interface:

- **Productionline_Configuration**

  A data block for the configuration.

  In the example, this data block is called "Productionline_Configuration".

  The data block already contains all system data types that are needed for the instructions of the OPC UA client.

  In addition, the data block contains general default values for parameter assignment of the connection to an OPC UA server.

  If you are working with connection parameter assignment, this data block will be filled.

- **ProductionLine_Data**

  A data block for the PLC tags that you have entered in the client interface editor.

  In the example, this data block is called "Productionline_Data".

  The figure below shows the data block.

Static	
ReadProduct	Struct
Variable	"Productionline.ReadProduct"
NewProduct	Bool
ProductNumber	Int
NodeStatusList	Array[0..1] of DWord
NodeStatusList[0]	DWord
NodeStatusList[1]	DWord
TimeStamps	Array[0..1] of LDT
TimeStamps[0]	LDT
TimeStamps[1]	LDT
WriteStatus	Struct
Variable	"Productionline.WriteStatus"
ProductionEnabled	Bool
NodeStatusList	Array[0..0] of DWord
NodeStatusList[0]	DWord
CallOpenDoor	Struct
MethodStatusList	Array[0..0] of DWord
MethodStatusList[0]	DWord
Method	Struct

  Use the "ProductionLine_Data" data block in your user program and access the read values of the "NewProduct" and "ProductNumber" PLC tags. This is explained in the following section using an example.

Reading and writing PLC tags of the client interface

Example: Reading the "ProductNumber" value

For example, you write in an SCL program:

```
#MyLocalVariable :=
"ProductionLine_Data".ReadProduct.Variable.ProductNumber;
```

You use this, for example, to assign the number of the blank that was just produced in the production line to the local tag "#MyLocalVariable".

Requirements:

- A connection exists to the OPC UA server of the CPU, which controls the production line.
- The OPC UA client has read the current values.

For this reason you check whether a read value is valid:

- Check whether the value in "ProductionLine_Data".Product.NodeStatusList[1]" is equal to 0.
- Check when this value was sent from the OPC UA server. This value is in "ProductionLine_Data".Product.TimeStamps[1].

Example: Writing the "ProductEnabled" value

Transfer the new values for PLC tags, in the example for the "ProductionEnabled" tag, to the OPC UA server using the data block.

With the following assignment, you enable the production line in the example plant:

```
"ProductionLine_Data".WriteStatus.Variable.ProductionEnabled :=
TRUE;
```

This is only successful, however, if the following requirements are met:

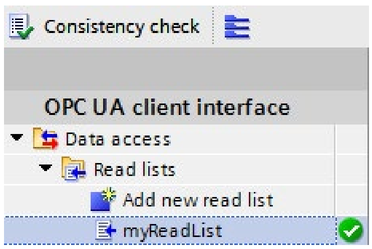
- A connection exists to the OPC UA server of the CPU, which controls the production line.
- Current values are being written via the OPC UA client

Consistency check

Finally, check the consistency of the read/write list or method list.

1. Select the list that you want to check.
2. Click the "Consistency check" button above the "OPC UA client interface" area.

A green check mark indicates an error-free assignment of the tags or methods to the corresponding elements of the server interface.



You can assume that the data exchange between client and server and method calls operate without problem in runtime.

In the event of an error a list appears in the Inspector window. From this list you can jump to the respective error.

During the consistency check, STEP 7 checks

- whether all elements that you use in the respective list are also present in the server.
- Do the data types used match?
- For methods: Do the number, name, order, and data types of method arguments match?

9.4.6 Determine server interface online

With STEP 7 (TIA Portal) you can determine the interface of an OPC UA server online. This provides information on which tags of a connected OPC UA server you can read or set (write) with OPC UA clients. It also provides information on which server methods of the OPC UA server are available for OPC UA clients.

If you are work offline you can create the interface of the OPC UA server by means of an OPC UA XML file. The address space of the server is described in the OPC UA XML file, see: Export OPC UA XML file (Page 167).

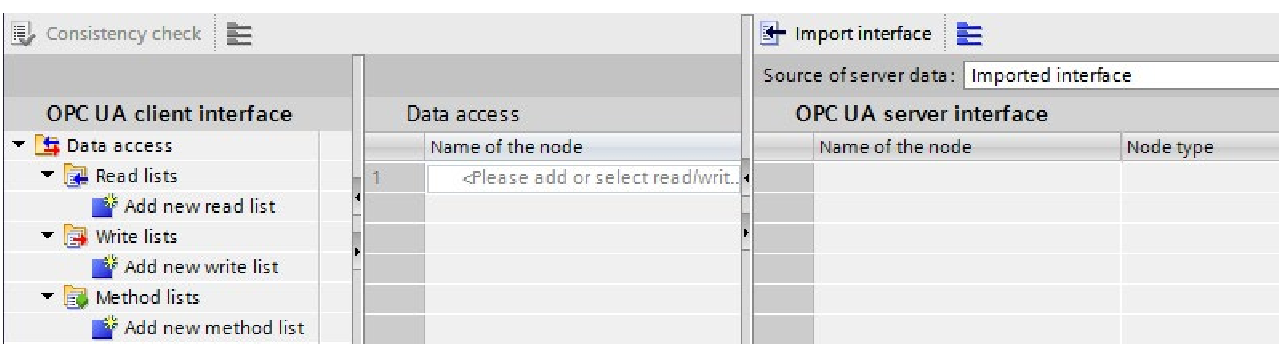
Determine online server interfaces

To determine a server interface online, follow these steps:

1. In the STEP 7 project tree, select the CPU which is configured as OPC UA client (Supervisor in the example).
2. Select the client interface (in the example, OPC UA Communication > Client interfaces > Productionline).

   If no client interface has been created, double-click "Add new client interface".
3. Double-click the selected client interface.

   The editor for client interfaces is displayed.



4. In the left section of the editor, click "Add new read list", "Add new write list", or "Add new method list".
5. In the right field of the editor, select "Online[]" as data source for "Source of server data":

6. Click the "Online access" button.

   STEP 7 displays the "Connect to OPC UA server" dialog:

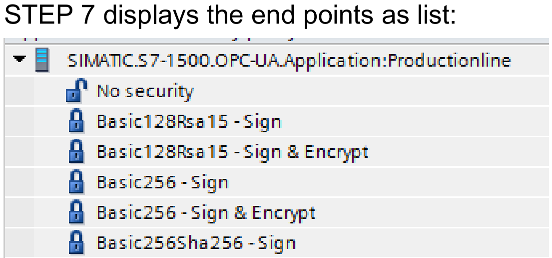
   Tip: When you are establishing an online connection to an OPC UA server for the first time, use the "Online access" button. When reconnecting after a disconnection, select the "Connect to online server" button next to the "Online" selection field.

   In the top right, enter the IP address of the OPC UA server whose server interface you want to determine online (in the example, 192.168.1.1).

7. Click "Find selected server".

   STEP 7 establishes a connection to the OPC UA server and determines all security settings (server endpoints) which the server provides.

   STEP 7 displays the end points as list:



8. Click on the end point you want to use for a connection of step 7 to the OPC UA server.

9. Do you want to use a secure connection?
   – If you have selected a secure end point, then select the entry "TIA Portal" for the "Certificate location".

     And under "Certificate (Client)", select a client certificate for your PC on which STEP 7 (TIA Portal) is currently running.

     If a client certificate does not yet exist for your PC, you can generate a client certificate here in the TIA Portal.

     Proceed as follows to generate a certificate for your PC:

     - Click on the button in the "Certificate (Client)" input field.

     - Click "Add".

     - For "Common name of subject", enter "STEP 7 (TIA Portal)".

     - Select the "OPC UA client" entry at "Usage".

     - For "Subject Alternative Name (SAN)", enter the IP address of your PC on which you are currently running STEP 7 (TIA Portal) under "Value". Overwrite the already entered IP address.

     - If your PC uses a second IP address, enter this address as well. If your PC does not use a second IP address, delete the second IP address already entered.

     - Click "OK".
   – If you have not selected a secure end point, keep the default setting ("None").
10. How do you want log on?
    – If you want to log onto the OPC UA server as guest, then apply the default with "User authentication".
    – If you want to log on with user name and password, select "User name and password".

      Use the user name and password which was stored during the configuration of the OPC UA server in the properties of the CPU under "General > OPC UA > Server > Security > User authentication > User management".
11. Click "Connect".

    When a secure connection is established, a message appears that you must accept the server certificate for the secure connection to be established. In the message window, you can display further details about the server certificate via a link.

    This standard Windows window only provides information about the server certificate. If you click on the button to install the server certificate, the server certificate is not included in the certificate memory of the TIA Portal, i.e. the next time you connect you will be prompted to accept the server certificate again.

    STEP 7 then establishes a connection to the OPC UA server and again displays the editor for client interfaces.

    In the right field of the editor, STEP 7 displays the uppermost level of the address space of the OPC UA server:

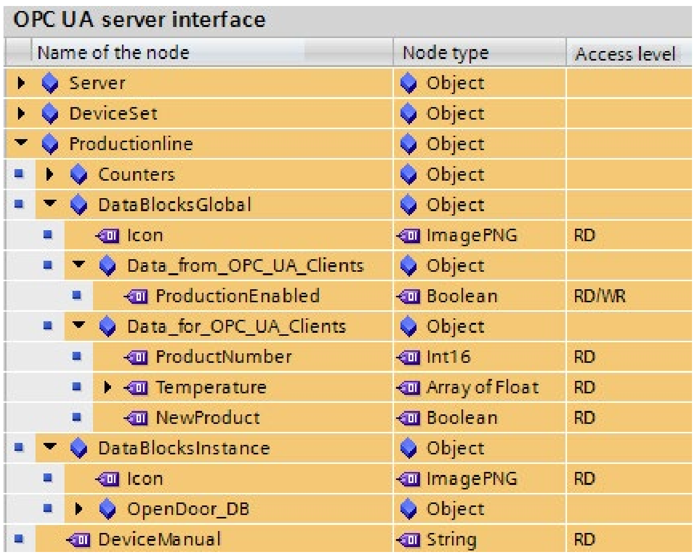
12. Click on the small black triangle next to "Objects".

    STEP 7 now also displays the level below Objects.

13. Click on the small black triangle next to "Productionline".

    STEP 7 now also displays the level below Productionline.

14. Now open additional lower-level folders:



OPC UA server interface

Name of the node	Node type	Access level
Server	Object	
DeviceSet	Object	
Productionline	Object	
Counters	Object	
DataBlocksGlobal	Object	
Icon	ImagePNG	RD
Data_from_OPC_UA_Clients	Object	
ProductionEnabled	Boolean	RD/WR
Data_for_OPC_UA_Clients	Object	
ProductNumber	Int16	RD
Temperature	Array of Float	RD
NewProduct	Boolean	RD
DataBlocksInstance	Object	
Icon	ImagePNG	RD
OpenDoor_DB	Object	
DeviceManual	String	RD

Alternative:

To open the server interface in one stop, click the following symbol:

STEP 7 now displays the fully expanded server interface.

If you click on this symbol again, STEP 7 again displays only the uppermost level of the server address space.

9.4.7 Using multilingual texts

In the client interface editor, you are also importing texts that can be displayed in different languages with the OPC UA XML files (information models). Multilingualism is optional, and each node can be defined differently regarding the languages it offers.

In the XML file, these are the following fields that can be prepared for different languages:

- DisplayName
- Description

Example for multilingual texts in an OPC UA XML file

In the XML file below, the display name and the description, for example, are entered with a "default" text and multiple localizable texts.

- Default text is the first entry without localization information.
- Localized text is the text after "Locale=" followed by a language code, e.g. "it-IT" for Italian

```xml
<UAVariable NodeId="ns=3;i=6070" BrowseName="3:EngineeringRevision" ParentNodeId="ns=3;i=1002"
DataType="String">
    <DisplayName>EngineeringRevision</DisplayName>
    <DisplayName Locale="en-US">EngineeringRevision</DisplayName>
    <DisplayName Locale="de-DE">Revisionsstand</DisplayName>
    <Description>Revision Level of the engineering environment.</Description>
    <Description Locale="en-US">Revision Level of the engineering environment.</Description>
    <Description Locale="de-DE">Revisionsstand der Engineeringumgebung.</Description>
    <Description Locale="fr-FR">Niveau de révision de l'environnement d'ingénierie.</Description>
    <Description Locale="it-IT">Livello di revisione dell'ambiente di ingegneria.</Description>
<References>
    <Reference ReferenceType="HasTypeDefinition">i=68</Reference>
    <Reference ReferenceType="HasModellingRule">i=78</Reference>
</References>
</UAVariable>
```

Display of multilingual texts

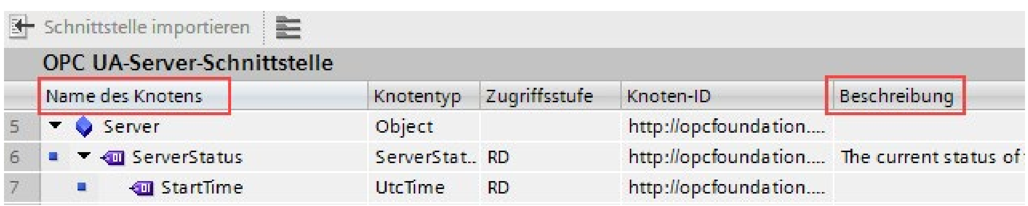
When importing a server interface, the available multilingual texts are saved internally and downloaded to a CPU together with the project.

The client editor displays the text from the OPC UA XML file in the columns "Name of the node" (corresponds to "DisplayName") and "Description" (corresponds to "Description").

The following cascading rules determine which language is shown for a node:

- When the node contains text in the currently used editing language, the text is also displayed in the editing language.

  (Setting the editing language: In the project tree, select the area "Languages & resources > Project languages")
- When the node does not contain text in the editing language but a default text is defined there (without language code), the default text is displayed.
- "Name of the node" column: If no default text is defined either but a text in any other language exists, the DisplayName text is displayed in the first available language. This rule does not apply to description texts (Description).
- If none of the conditions listed above is met, no text is displayed.



When you change the editing language, the multilingual text in the imported interface will also change according to the rules explained above.

You can then apply the nodes in the corresponding lists (read list, write list, method list) with drag and drop.

You cannot change the language in the lists (read list, write list, method list).

Applying the displayed description texts as comment in PLC data types

When you compile the program, STEP 7 automatically creates PLC data types (UDTs) for each read list, for each write list and for inputs or outputs of each method. These UDTs each have one element for each node.

The UDTs apply the description text as comment according to the rules stated above. STEP 7 creates the comment in only one language, just like the texts in the OPC UA server interface can only be displayed in one language.

9.4.8 Rules for the access to structures

The rules for the access to structures are explained below. Note these rules when reading and writing values of complete structures provided by an OPC UA server.

How the client of the S7-1500 CPU accesses structures

The OPC UA client of the S7-1500 CPU uses neither TypeDictionaries nor DataTypeDefinition attributes, which a server offers for the resolution of these structures.

These options of the OPC UA client for checking structural elements in runtime are limited in the client.

Rules for the access to structures

If you use the client interfaces to configure the read and write lists (connection parameterization) and assign the PLC data types to the imported or online determined address model of the server, the read and write accesses to structures operate trouble-free in runtime.

The configuration by means of client interface automatically ensures that the sequence and the data type of the structural elements are coordinated on client and server side.

In runtime the OPC UA client only checks the total length of the transmitted value; more detailed checks are not possible.

Mapping rules apply to the assignment of OPC UA structures to PLC tags or DB tags (see AUTOHOTSPOT). Non-executed data type (such as OPC UA byte strings) are not supported.

Example of an error-free assignment of the structure elements

In the imported node set file (XML export), the structure is defined as follows:

opcUaStruct	Object
allOk	Boolean
myOPCstruct1	myOPCUAstruct
varA	Int64
VarB	Byte
nestedStructZ	"myOPCUAstruct"."nestedStructZ"
varD	Float
varE	Double
varC	Double
DeviceManual	String

The structure mapped in the read list matches, both in the order and in the assigned data types, the corresponding nodes of the node set file.

myOPCstruct1	myOPCUAstruct
varA	LINT
VarB	USINT
nestedStructZ	"myOPCUAstruct"."nestedStructZ"
varD	REAL
varE	LREAL
varC	LREAL

If the structure now changes on the server, for example tagA and tagB are swapped, and the read list remains the same in the client, the assignment is no longer correct:

- The total length of the data remains the same (only the order has changed)
- The configuration of the structure is different for client and server.

> **WARNING**
>
> **No error message in the case of different structure configuration between client and server**
>
> If the structures of client and server do not match, this rule violation will possibly not generate any error during compilation and also not in runtime.
>
> Make sure not to change the configured assignments for structures in runtime. If required, reconfigure the assignment in the read and write lists.

9.4.9 Using connection parameter assignment

9.4.9.1 Creating and configuring connections

With the instructions for OPC UA clients, you create a user program that exchanges data with an OPC UA server. A series of system data types are required for this.

To simplify your work with these system data types, a connection parameter assignment for OPC UA clients is available starting in STEP 7 (TIA Portal) Version 15.1.

Use of the connection parameter assignment is optional and not mandatory. You can also manually create the required system data types.

We use an example to make the description easier to follow, see description of the example (Page 227).

Opening the connection parameter assignment

To configure the connection to an OPC UA server, follow these steps:

1. In the "OPC UA communication" area, double-click the client interface whose parameters you want to assign in the project tree.

   For the example configuration: Double-click the "ProductionLine" client interface.

   
   The section "Create client interface (Page 228)" describes how to create a client interface.
2. Click the "Properties" tab (Inspector window) if the tab is not already displayed.

   STEP 7 now displays the connection parameter assignment for the instructions of the OPC UA client.

   The "General" tab is open.
3. Click the "Configuration" tab.

Setting the connection parameters

You set the connection to the OPC UA server in the "Configuration" tab.

1. Select a descriptive name for the session. For the example, select the name "OPC UA Connection to ProductionLine".
2. In the "Address" field, enter the IP address of the OPC UA server to which your user program (that operates as an OPC UA client) is to establish a connection.

   In the example configuration, the CPU that controls the production line has the IP address "192.168.1.1". A connection to the OPC UA server of this CPU is to be established. For this reason, you enter this IP address in the "Address" field.

3. If the OPC UA server is not using the standard port 4840, you must insert the port number here.

   For example, enter the number 48040 in the field, if the OPC UA server to which you want to establish a connection uses this port number.

   For the example, we accept the default setting "4840" because the OPC UA server of the example is accessible via port 4840.

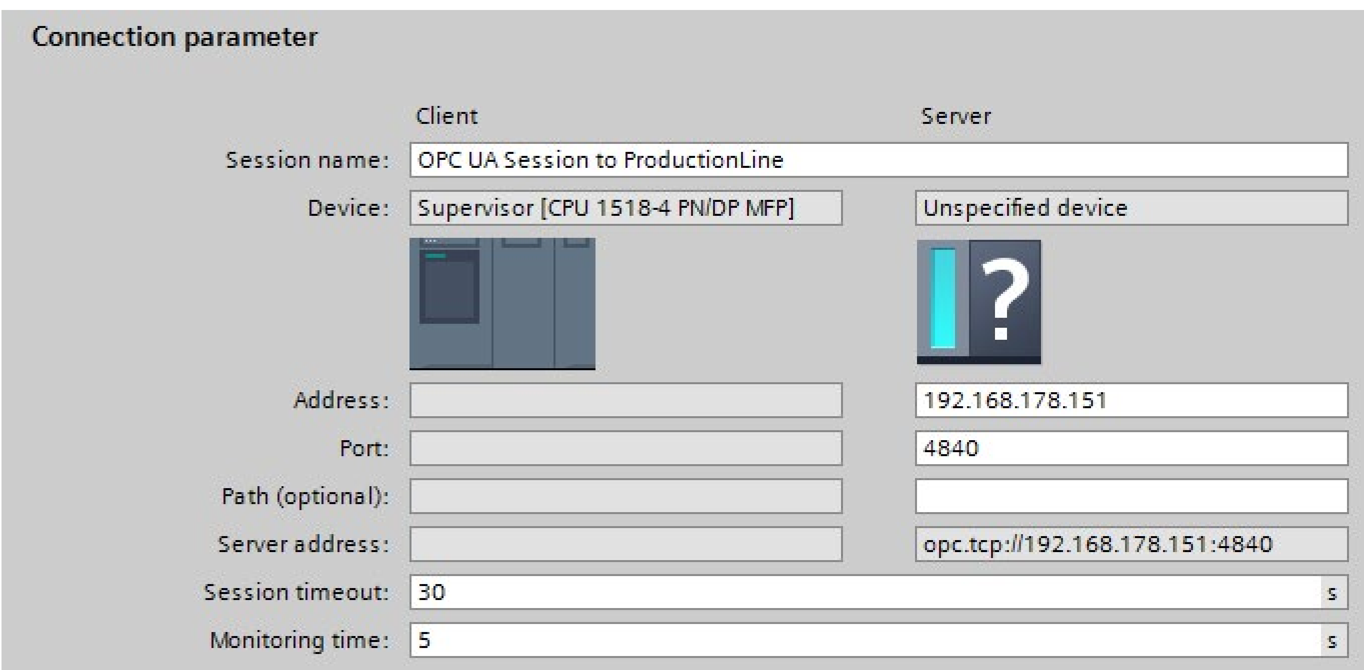
4. Enter a path within the OPC UA server to restrict access to this path.

   When you specify a path, it is automatically entered at the "ServerEndpointUrl" entry in the configuration DB for the client interface. The entry then consists of the components "OPC Schematic Prefix", "IP address", "Port number" and "Server path", for example: "opc.tcp://192.168.0.10:4840/example/path".

   The information is optional. However, some servers only establish a connection if a server path is specified.

5. In addition, you accept the default settings for session timeout (30 seconds) and monitoring time (5 seconds).

   The following figure shows the connection parameters of the example:



Setting the security parameters

1. Click the "Security" area in the "Configuration" tab.

   This area contains all security settings for the connection to the OPC UA server.

The following settings are possible:

"General" area

Security mode:

Select the security mode that the connection to the OPC UA server must meet from the drop-down list.

If the server does not meet the selected mode, a session is not established.

The following settings are available:

- No security: No secure connection.
- Sign: OPC UA server and OPC UA client sign the data transmission (all messages): Manipulations can thus be detected.
- Sign & Encrypt: OPC UA server and OPC UA client sign and encrypt the data transmission (all messages):

Security policy:

Set the encryption techniques for the signing and encryption of messages.

The following settings are possible:

- No security
- Basic128Rsa15
- Basic256
- Basic256Sha256

To configure a secure connection, you must observe the following items:

- A certificate is required for the client for a secure connection.
- You have to make the client certificate known to the server.

To find out how to proceed, see the section "Handling of the server and client certificates" under "Certificate of the OPC UA clients".

"Certificates" area

Client certificate:

The certificate confirms the authenticity of the OPC UA client.

To select a certificate, click the following symbol

STEP 7 displays a list of certificates.

Select the certificate that you have introduced to the server, see the paragraphs under "Certificate of the OPC UA clients" in the section "Handling of the server and client certificates".

Click the symbol with the green check mark:

Or, create a new certificate. To do so, click the "Add" symbol.

When you create a new certificate, you must introduce it to the server, see the paragraphs under "Certificate of the OPC UA clients" in the section "Handling of the server and client certificates".

"User authentication" area

The following settings are possible for user authentication:

- Guest
- User name and password
- Users (TIA Portal - Security Settings)

For more information, see AUTOHOTSPOT.

Setting languages

UA tags of the String type can be localized with OPC UA, that is, texts (values for the UA tag) can be available in different languages for the server. For example, localized texts can be available for DisplayName (Name of the node) and Description (Description).

In the "Languages" area of the "Configuration" tab you can, for example, influence the language of the texts returned by the server as follows:

In the "Languages" area, enter a number of languages that the server transfers to the client during connection setup.

The language or the local ID ("language code") associated with it that you enter in the first line is the language preferred by the client.

- If the server can provide the UA tag in the requested language, it is transferred to the client.
- If the server cannot provide the UA tag in the requested language, it checks whether it can provide the UA tag in the language you have entered in the second line (first substitute language).
- The server works its way down the list, and when it can provide neither the requested language nor a substitute language, it will provide the default language.

9.4.9.2 Handling of the client certificates of the S7-1500 CPU

Where does the client certificate come from?

If you are using the OPC UA client of an S7-1500 CPU (OPC UA client enabled), you can create certificates for these clients with STEP 7 V15.1 and higher as described in the following sections.

When you use UA clients from manufacturers or the OPC Foundation, a client certificate is generated automatically during installation or upon the first program call. You have to import these certificates with the global certificate manager in STEP 7 and use them for the respective CPU.

If you program an OPC UA client yourself, you can generate certificates through the program. Alternatively, you can generate certificates with tools, for example with OpenSSL or the certificate generator of the OPC Foundation:

- The procedure for OpenSSL is described here: "Generating PKI key pairs and certificates yourself (Page 149)".
- Working with the certificate generator of the OPC Foundation is described here: "Creating self-signed certificates (Page 148)".

Certificate of the OPC UA client of the S7-1500 CPU

A secure connection between the OPC UA server and an OPC UA client is only established if the server classifies the certificate of the client as trusted.

Therefore you have to make the client certificate known to the server.

The following sections describe how you can initially generate a certificate for the OPC UA client of the S7-1500 CPU and then make it available to the server.

1. Generate and export a certificate for the client

For a secure connection, you have to generate a client certificate and - if the server and client are located in different projects - export the certificate.

If client and server are in the same project, exporting the client certificate and subsequent import are not necessary.

Requirements

The IP interface of the CPU is configured, an IP address is available.

Background: The IP address under which the CPU can be accessed in your system is entered under "Subject Alternative Name (SAN)".

Generating an OPC UA client certificate

The easiest way to generate a client certificate for an S7-1500 CPU is to configure a client interface.

The configuration of the client interface provides for the selection or generation of a client certificate, see Creating and configuring connections (Page 245).

Alternatively, you can create the client as follows:

1. In the "Project tree" area, select the CPU you want to use as a client.
2. Double-click "Device configuration".
3. In the properties of the CPU click "Protection & Security > Certificate manager".
4. Double-click "<add>" in the "Device certificates" table.

   STEP 7 opens a dialog.
5. Click "Add".
6. Select the "OPC UA client" entry from the list at the "Usage".
7. Click "OK".

   STEP 7 now lists the client certificate in the "Device certificates" table.
8. If the server is in another project: Right-click this line and select "Export certificate" from the shortcut menu.
9. Select a directory in which you store the client certificate.

2. Announcing the client certificate to the server

You have to make the client certificate available to the server to allow a secure connection to be established.

To do so, proceed as follows:

1. If the client was configured in another project and you created and exported the client certificate there:
   – Select the "Use global security settings for certificate manager" option in the local certificate manager of the server. This makes the global certificate manager available.

     You will find this option under "Protection & Security > Certificate manager" in the properties of the CPU that is acting as server.
   – If the project is not yet protected, select "Security settings > Settings" in the STEP 7 project tree, click the "Protect this project" button and log on.

     The "Global security settings" item is now displayed under "Security settings" in the STEP 7 project tree.
   – Double click "Global security settings".
   – Double click "Certificate manager".

     STEP 7 opens the global certificate manager.
   – Click the "Device certificates" tab.
   – Right-click in the tab on a free area (not on a certificate).
   – Select the "Import" shortcut menu.

     The dialog for importing certificates is displayed.
   – Select the client certificate that the server is to trust.
   – Click "Open" to import the certificate.

     The certificate of the client is now contained in the global certificate manager. Note the ID of the client certificate just imported.
2. Click the "General" tab in the properties of the CPU that is acting as server.
3. Click "OPC UA > Server > Security > Secure Channel".
4. Scroll down in the "Secure Channel" dialog to the section "Trusted clients".
5. Double-click in the table on the empty row with "<add new>". A browse button is displayed in the row.
6. Click this button.
7. Select the prepared client certificate.
8. Click the button with the green check mark.
9. Compile the project.
10. Load the configuration into the S7-1500 CPU (server).

Result

The server now trusts the client. If the server certificate is also considered trusted, the server and client can establish a secure connection.

9.4.9.3 User authentication

In the OPC UA client interface of the S7-1500, you can set what authentication is required for a user of the OPC UA client wishing to access the server. To do so, you must select the corresponding client interface in the project tree of the requested S7-1500 CPU under "OPC UA communication > Client interfaces" and select the type of user authentication in the Inspector window under "Properties > Configuration > Security".

Types of user authentication

The following options are available for user authentication:

- **Guest**

  The user does not need to verify authorization (anonymous access). The CPU creates an anonymous session for the user, and the OPC UA server does not check the authorization of the client user.

- **User name and password**

  The user must prove authorization (no anonymous access). The OPC UA server checks whether the client user is authorized to access the server. Authorization is given by the user name and the correct password. These inputs cannot be checked by the client interface, which means all values are accepted as being valid.

  Note

  STEP 7 stores user name and password unencrypted in the data block/instance data block. Recommendation: Use the user authentication "User (TIA Portal - Security Settings)".

- **Users (TIA Portal - Security Settings)**

  You can enter a user name from the list of users entered in the project for authentication. The names of the registered users for the current project are available in the user administration in the project tree under "Security Settings > Users and roles". There you can also enter additional users.

  You can also enter a name that is not listed in the user administration of the project or leave the field blank. This is necessary when the corresponding user name is only provided by a different source during runtime, for example, via HMI or from a different OPC UA client.

"No Security" security policy and authentication via user name and password

You can set the following combination:

Security policy = "No Security" and authentication via user name and password.

- The OPC UA server of the S7-1500 supports this combination. OPC UA clients can connect and encrypt the authentication data or not.
- OPC UA client of the S7-1500 CPU also supports this combination: However, in runtime it only connects if it can send the authentication data encrypted via cable!

Result: With the following configuration, not connection can be established in runtime.

- S7-1500 as OPC UA client
- OPC UA server which supports no encryption of authentication data when "No Security" (="none") is set as security policy.

Additional information

See Users and roles with OPC UA function rights (Page 190)

9.4.9.4 Using a configured connection

Introduction

This section shows you how to use a configured connection for OPC UA instructions (third step).

Requirements

- You have created a client interface and added PLC tags and PLC methods to this interface, see ("First step (Page 228)").
- You have configured a connection to an OPC UA server (Second step (Page 245)).

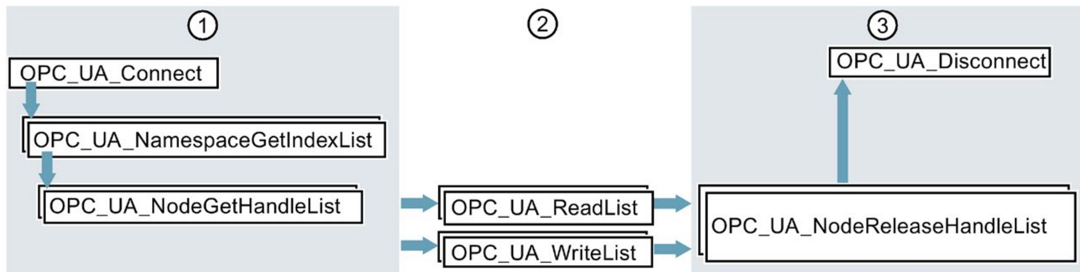
Overview

To read data from an OPC UA server or write data to an OPC UA server, use the following instructions:

- OPC_UA_Connect
- OPC_UA_NamespaceGetIndexList
- OPC_UA_NodeGetHandleList
- OPC_UA_ReadList or OPC_UA_WriteList
- OPC_UA_NodeReleaseHandleList
- OPC_UA_Disconnect

Order of the OPC UA instructions

The following figure shows the order in which the OPC UA instructions are called in a user program in order to use these instructions to read or write PLC tags:



① Instructions for preparation of read and write operations

② Read and write instructions

③ Instructions for "clean-up" after a completed read or write operation

The "OPC_UA_NodeReleaseHandleList" instruction can be omitted if "OPC_UA_Disconnect" is called immediately afterwards.

STEP 7 (TIA Portal) automatically supplies the parameters of these instructions if you are using a client interface and a configured connection to an OPC UA server.

The procedure is shown in the following section.

Using a client interface and configured connection

To use a configured OPC UA connection, follow these steps:

1. Open your user program in the TIA Portal.
2. Using drag-and-drop, move the "**UA_Connect**" instruction into the program editor.

   You will find the instruction under "Instructions > Communication > OPC UA" in the TIA Portal.
3. Select a call option for the instruction

   The example uses a multi-instance.

   STEP 7 displays the instruction in the program editor.

   The editor for the Function Block Diagram (FBD) programming language uses the following display:

   
   The editor for the Ladder Logic (LAD) programming language displays the instruction similarly.
4. Click the toolbox symbol in the editor for FBD or LAD.

   The symbol is located in the heading of the instruction:

   If you are using the editor for STL or SCL: Click the small green rectangle below the first character of the instance name:

   `#OPC_UA_Connect_Instance`

   The example (Page 227) uses "#OPC_UA_Connect_Instance" as the instance name.

   STEP 7 displays the properties of the instruction in a separate dialog.

5. For "Client interface" select the client interface that you want to use for the instruction.

   We select the "ProductionLine" client interface in the example.

   STEP 7 now interconnects the "ProductionLine" client interface with the parameters of the OPC_UA_Connect instruction:

   
   "ProductionLine" is the interface that the OPC UA client of the example (Page 227) uses for data exchange with the OPC UA server "ProductionLine".

6. Using drag-and-drop, move the "UA_NamespaceGetIndexList" instruction into the program editor.

   You will find the instruction under "Instructions > Communication > OPC UA" in the TIA Portal.

   Select the "Multi-instance" call option.

   Click the toolbox symbol (LAD and FBD) or the small green box below the instance name (STL and SCL) if the editor is not already open.

   Select the client interface that you want to use ("ProductionLine" in the example).

   STEP 7 now automatically interconnects all parameters of the "OPC_UA_NamespaceGetIndexList" instruction:

7. Using drag-and-drop, move the "**UA_NodeGetHandleList**" instruction into the program editor.

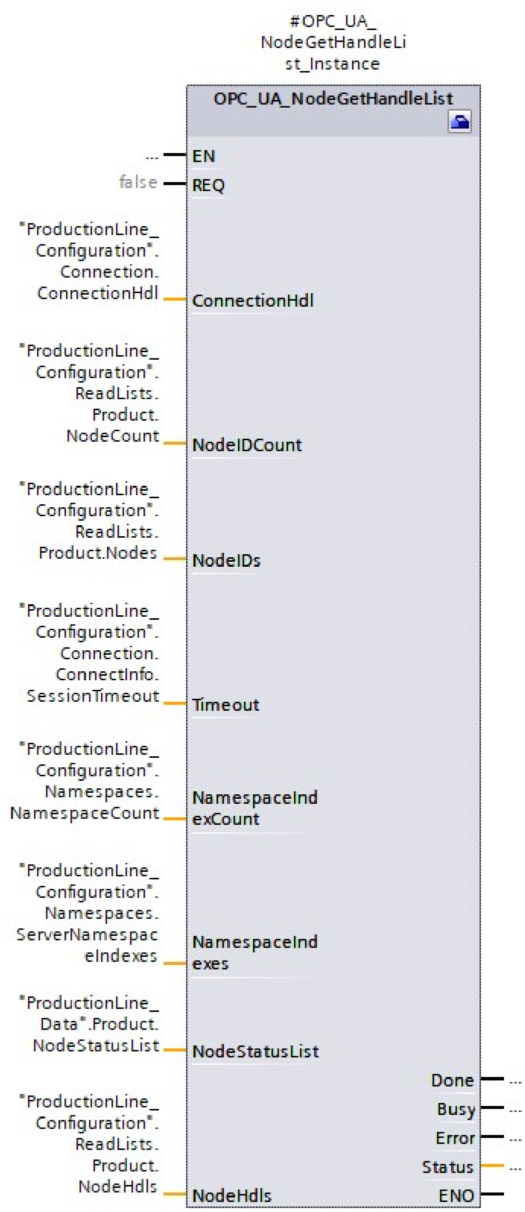
   Select the "Multi-instance" call option.

   Click the toolbox symbol (LAD and FBD) or the small green box below the instance name (STL and SCL) if the editor is not already open.

   Select the client interface that you want to use. The example uses the "ProductionLine" client interface.

   Under "Data access > Read/Writelist" select the read list that you want to use (in the example the read list "Product").

   STEP 7 now automatically interconnects all parameters of the "OPC_UA_NodeGetHandleList" instruction:



If you want to write data to an OPC UA server, select the write list you want to use under "Data access > Read/Writelist" (the "ProductionStatus" write list in the example).

8. Using drag-and-drop, move the "**UA_ReadList**" instruction into the program editor.

   Select the "Multi-instance" call option.

   Click the toolbox symbol (LAD and FBD) or the small green box below the instance name (STL and SCL) if the editor is not already open.

   Select the client interface that you want to use. The example uses the "ProductionLine" client interface.

   Under "Data access > Read/Writelist" select the read list that you want to use (in the example the "Product" read list).

   STEP 7 now automatically interconnects all parameters of the "OPC_UA_ReadList" instruction.

   If you want to write data to an OPC UA server, use the "**OPC_UA_Write**" instruction and select the list of tags you want to send to the server under "Data access > Writelist" ("ProductionStatus" write list in the example).

9. If you use different read lists or write lists as program-controlled lists in your user program, move the "**UA_NodeReleaseHandleList**" instruction to the program editor using drag-and-drop operation.

   Select the client interface that you want to use.

   Now select a read list or write list that you want to release: Only release read or write lists that you rarely use, since re-registering is time-consuming.

   Then, repeat the steps starting with step 7 with the "UA_NodeGetHandleList" instruction.

10. Using drag-and-drop, move the "**UA_Disconnect**" instruction into the program editor.

    Select the "Multi-instance" call option.

    Click the toolbox symbol (LAD and FBD) or the small green box below the instance name (STL and SCL) if the editor is not already open.

    Select the client interface that you want to use. The example uses the "ProductionLine" client interface.

    STEP 7 now automatically interconnects all parameters of the "OPC_UA_Disconnect" instruction.

Supported instructions

For the following instructions, STEP 7 automatically supplies the parameters if you are using a client interface and a configured connection to an OPC UA server:

- OPC_UA_Connect
- OPC_UA_NamespaceGetIndexList
- OPC_UA_NodeGetHandleList
- OPC_UA_MethodGetHandleList
- OPC_UA_MethodReleaseHandleList
- OPC_UA_ReadList
- OPC_UA_WriteList
- OPC_UA_MethodCall
- OPC_UA_NodeReleaseHandleList
- OPC_UA_Disconnect

Routing

10

10.1 S7 routing

Definition of S7 routing

S7 routing is the transfer of data beyond S7 subnet boundaries. You can send information from a transmitter to a receiver across several s7 subnets. The gateway from one S7 subnet to one or more other subnets is provided by the S7 router The S7 router is a device which has interfaces to the respective S7 subnets. S7 routing is possible via various S7 subnets (PROFINET/Industrial Ethernet and/or PROFIBUS).

Requirements for S7 routing

- All devices that can be reached in a network have been configured in a project in STEP 7 and downloaded.
- All devices involved in the S7 routing must receive routing information about the S7 subnets that can be reached through specific S7 routers. The devices obtain the routing information by downloading the hardware configuration to the CPUs, since the CPUs play the role of an S7 router.

  In a topology with several consecutive S7 subnets, the following order must be kept to when downloading: First download the hardware configuration to the CPU(s) directly connected to the same S7 subnet as the PG/PC, then download one by one the CPUs of the S7 subnets beyond this starting with the nearest S7 subnet through to the S7 subnet furthest away.
- The PG/PC you want to use to establish a connection via a S7 router must be assigned to the S7 subnet it is physically connected to. You can assign the PG/PC to a PG/PC in STEP 7 under Online & Diagnostics > Online accesses > Connection to interface/subnet.
- For S7 subnets of the type PROFIBUS: Either the CPU must be configured as DP master or, if it is configured as a DP slave, the "Test, commissioning, routing" check box must be selected in the properties of the DP interface of the DP slave.
- S7 routing for HMI connections is possible as of STEP 7 V13 SP1.

Note

Firewall and S7 routing

A firewall does not recognize the IP address of the sender during S7 routing when the sender is located outside the S7 subnet adjacent to the firewall.

An overview of the devices that support the "S7 routing" function is provided in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/584459).

S7 routing for online connections

With the PG/PC, you can reach devices beyond S7 subnets, for example to do the following:

- Download user programs
- Download a hardware configuration
- Execute test and diagnostics functions

In the following figure, CPU 1 is the S7 router between S7 subnet 1 and S7 subnet 2.

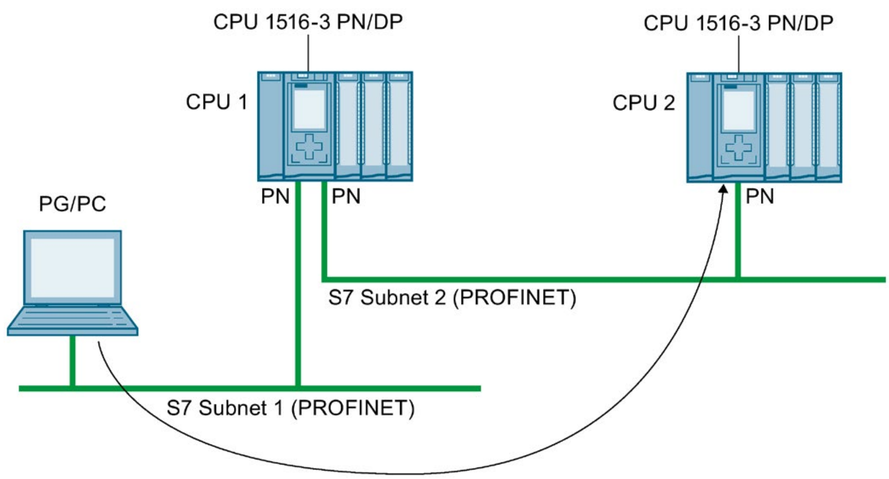


Figure 10-1 S7 routing: PROFINET - PROFINET

The following figure shows the access from a PG via PROFINET to PROFIBUS. CPU 1 is the S7 router between S7 subnet 1 and S7 subnet 2; CPU 2 is the S7 router between S7 subnet 2 and S7 subnet 3.

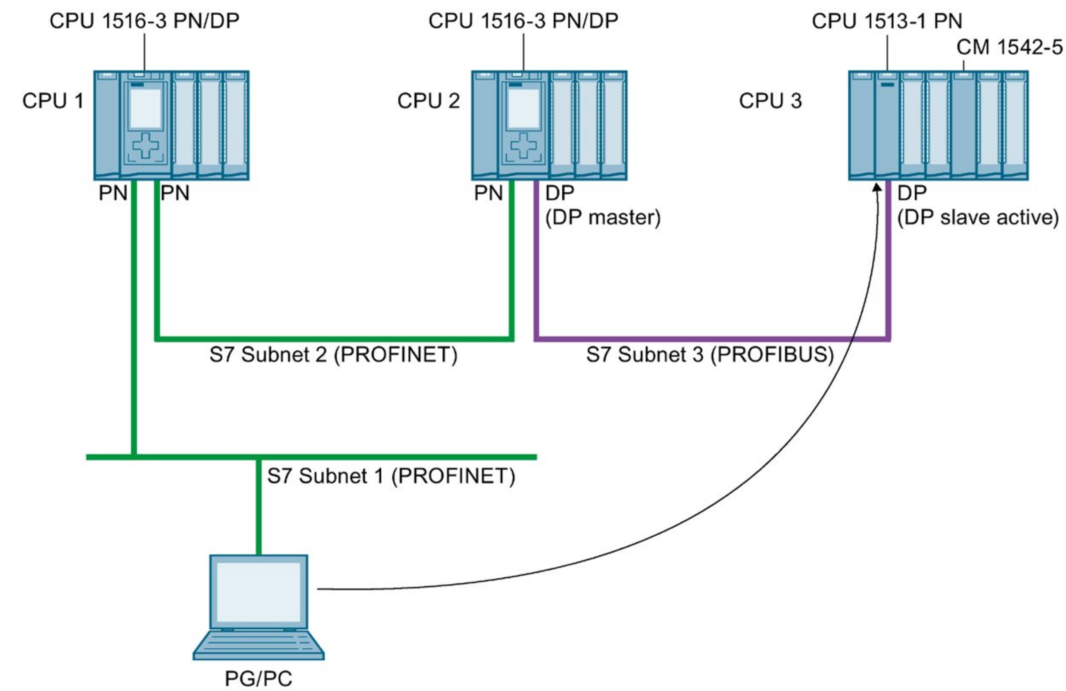

Figure 10-2 S7 routing: PROFINET - PROFIBUS

S7 routing for HMI connections

You have the option of setting up an S7 connection from an HMI to a CPU via different subnets (PROFIBUS and PROFINET or Industrial Ethernet). In the following figure, CPU 1 is the S7 router between S7 subnet 1 and S7 subnet 2.

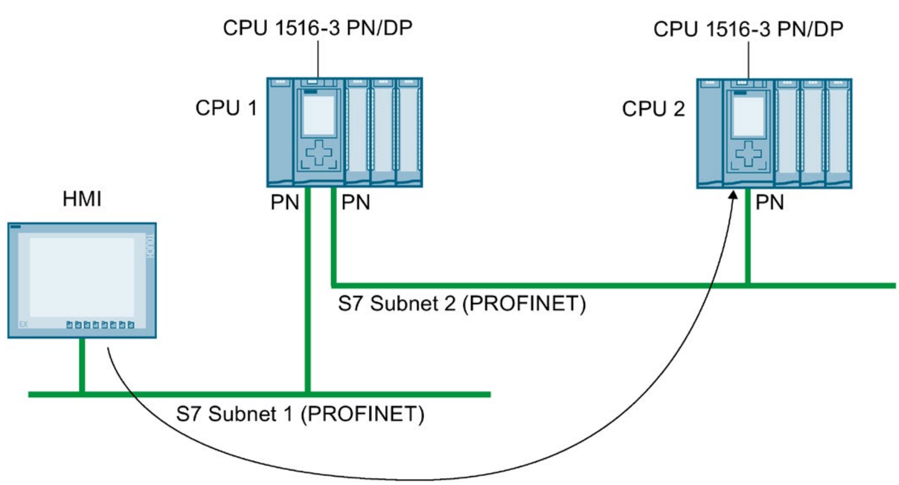

Figure 10-3 S7 routing via HMI connections

S7 routing for CPU-CPU communication

You have the option of setting up an S7 connection from a CPU to another CPU via different subnets (PROFIBUS and PROFINET or Industrial Ethernet). The procedure is described based on examples in the section S7 communication (Page 114).

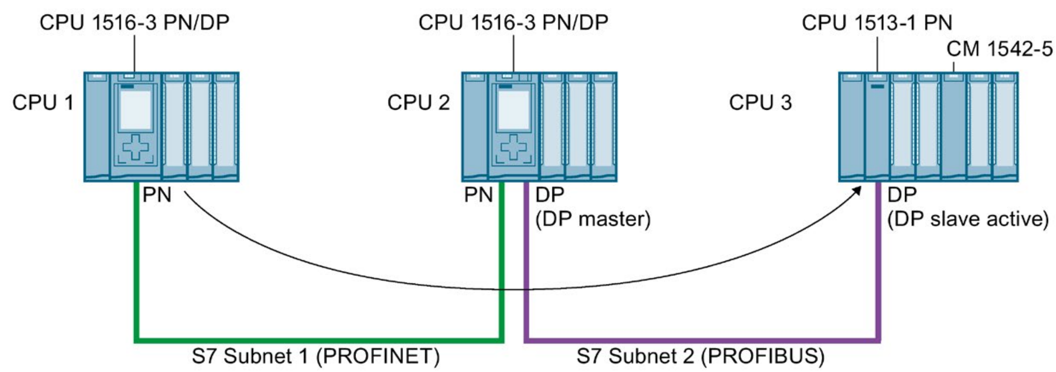

Figure 10-4 S7 routing via CPU-CPU communication

Using S7 routing

For the CPU, select the PG/PC interface and the S7 subnet in the "Go online" dialog of STEP 7. S7 routing is performed automatically.

Number of connections for S7 routing

The number of connections available for S7 routing in the S7 routers (CPUs, CMs or CPs) can be found in the technical specifications in the manuals of the relevant CPU/CM/CP.

S7 routing: Example of an application

The figure below shows the example of an application for remote maintenance of a system using a PG. The connection is made here beyond two S7 subnets via a modem connection.

You configure a remote connection via TeleService in STEP 7 using "Online access" or "Go online".

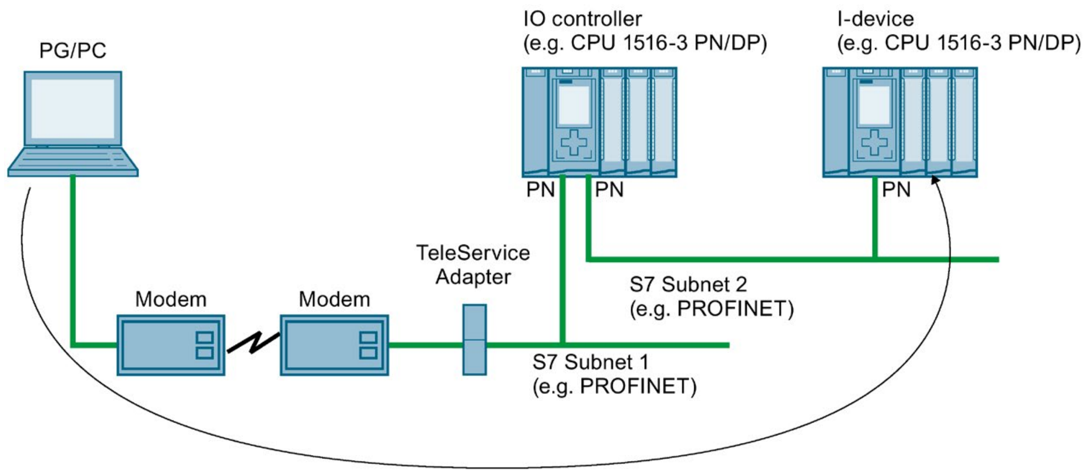

Figure 10-5 Remote maintenance of a plant using TeleService

Additional information

- The allocation of connection resources with S7 routing is described in the section Allocation of connection resources (Page 271).
- You can find more information on setting up TeleService in the STEP 7 online help.
- You can find more information on S7 routing and TeleService adapters when you search the Internet using the following links:
  - Device manual Industrial Software Engineering Tools TS Adapter IE Basic (http://support.automation.siemens.com/WW/view/en/51311100)
  - Downloads for the TS Adapter (http://support.automation.siemens.com/WW/view/en/10805406/133100)

HMI communication (Page 65)

10.2 Data record routing

Definition of data record routing

Data can be sent over PROFINET from an engineering station to field devices via multiple networks. Since the engineering station addresses the field devices using standardized records and these records are routed via S7 devices, the term "data record routing" is used to refer to this type of routing.

The data sent using data record routing include the parameter assignments for the participating field devices (slaves) and device-specific information (e.g. setpoint values, limit values).

Data record routing is used, for example, when field devices of different manufacturers are used. The field devices are addressed using standardized data records (PROFINET) for configuration and diagnostics.

Data record routing with STEP 7

You can perform data routing with STEP 7 by calling a device tool (for example, PCT) via the TCI interface (Tool Calling Interface) and passing call parameters. The device tool uses the communication paths that STEP 7 also uses for communication with the field device.

No configuration is required for this type of routing except the installation of the TCI tools on the STEP 7 computer.

Example: Data record routing with the Port Configuration Tool (PCT)

You can use the Port Configuration Tool (PCT) to configure the IO link master of the ET200 and assign parameters to connected IO link devices. The subnets are connected via data record routers. Data record routers are, for example, CPUs, CPs, IMs, IO link master.

You can learn about the constellations of data record routers supported by the PCT in this FAQ (http://support.automation.siemens.com/WW/view/en/87611392).

The figure below shows an example configuration with the data record routing with PCT.

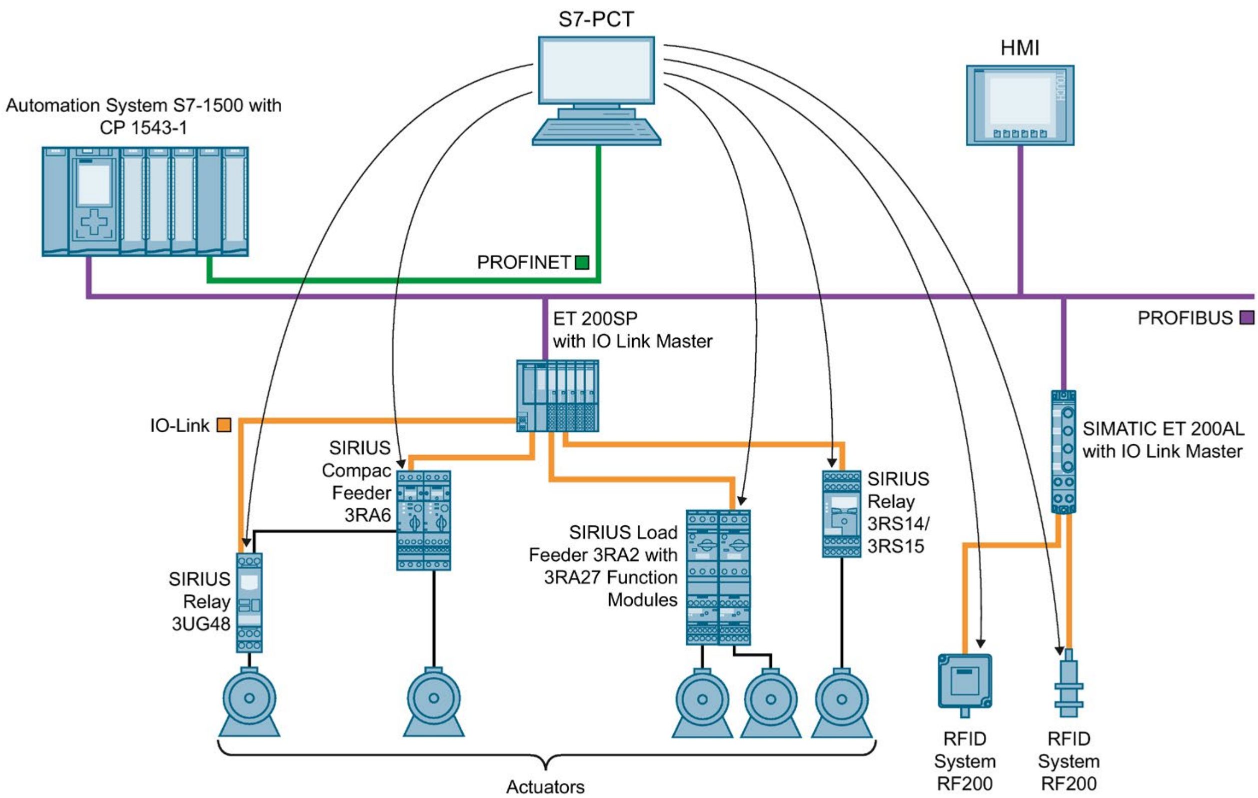

Figure 10-6 Example configuration for data record routing with PCT

Additional information

- The differences that exist between "normal" routing and data record routing are described in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/7000978).
- Whether or not the CPU, CP or CM you are using supports data record routing can be found in the relevant manuals.
- The allocation of connection resources with data record routing is described in the section Allocation of connection resources (Page 271).
- You can find additional information on configuration with STEP 7 in the STEP 7 online help.

Connection resources 11

11.1 Connection resources of a station

Introduction

Some communications services require connections. Connections occupy resources in the automation system (station). The connection resources are made available to the station by the CPUs, communications processors (CPs) and communications modules (CMs).

Connection resources of a station

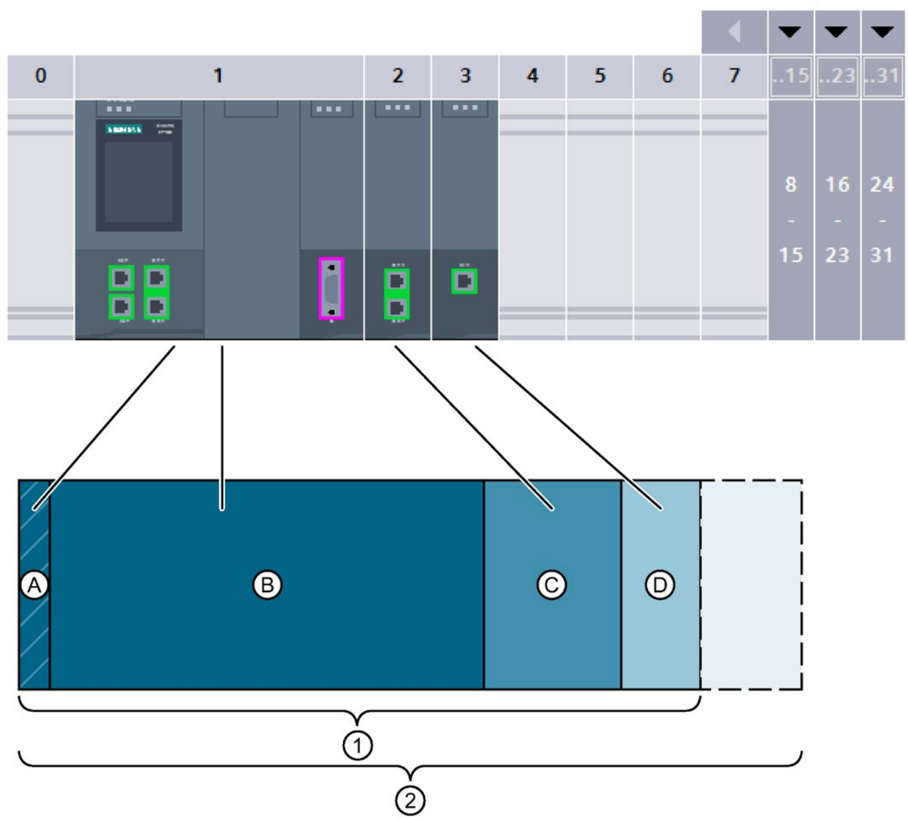
The connection resources available depend on the CPUs, CPs and CMs being used and must not exceed a maximum number per station.

The maximum number of resources of a station is determined by the CPU.

Each CPU has reserved connection resources for PG, HMI and Web server communication. This ensures, for example, that a PG can always establish at least one online connection with the CPU regardless of how many other communications services are already using connection resources.

In addition, dynamic resources exist. The difference between the maximum number of connection resources and the number of reserved connection resources is the maximum number of dynamic connection resources. The communications services PG communication, HMI communication, S7 communication, Open User Communication, Web communication and other communication (for example OPC UA) use the dynamic connection resources from the pool.

The figure below shows an example of how individual components make connection resources available to an S7-1500 station.



①	Available connection resources of the station, of which	
	A	Reserved connection resources of the station
	A + B	Connection resources of CPU 1518
	C	Connection resources of communications module CM 1542-1
	D	Connection resources of communications processor CP 1543-1
②	Maximum communications resources of the station using the example of a configuration from CPU 1518, CM 1542-1 and CP 1543-1	

Figure 11-1 Connection resources of a station

Maximum connection resources of the station		96	128	192	256	320	384
	of which reserved	10					
	of which dynamic	86	118	182	246	310	374
Connection resources of the CPU		64	88	108	128	160	192
Max. additionally usable connection resources by plugging in CMs/CPs		32	40	84	128	160	192
Additional connection resources CM 1542-1		64					
Additional connection resources CP 1543-1		118					
Additional connection resources CM 1542-5		40					
Additional connection resources CP 1542-5		16					

The number of connection resources that a CPU or a communication module supports is specified in the device manuals in the Technical Specifications.

Example

You have configured a CPU 1518-4PN/DP with a communications module CM 1542-1 and a communications processor CP 1542-5.

- Maximum connection resources of the station: **384**
- Available connection resources:
  - CPU 1518-4 PN/DP: 192
  - CM 1542-1: 64
  - CP 1542-5: 16
  - Total: **272**

The setup provides 272 connection resources. By adding additional communications modules, the station can support a maximum of 112 additional connection resources.

Reserved connection resources

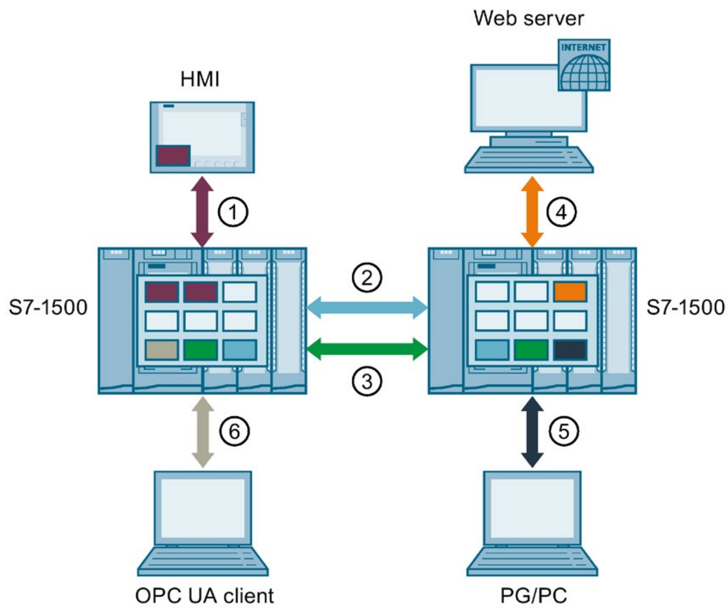
10 connection resources are reserved for stations with S7-1500 CPU, ET 200SP CPU and ET 200pro CPU based on S7-1500:

- 4 for PG communication required by STEP 7, for example, for test and diagnostics functions or downloading to the CPU
- 4 for HMI communication which are occupied by the first HMI connections configured in STEP 7
- 2 for communication with the Web server

11.2 Allocation of connection resources

Overview - occupation of connection resources

The following figure shows how different connections occupy the resources of the S7-1500.



① HMI communication: See below.

② Open User Communication: Connections of Open User Communication occupy a connection resource in every end point.

③ S7 communication: Connections of S7 communication occupy a connection resource in every end point.

④ Web communication: The Web server connection occupies at least one connection resource in the station. The number of occupied connections depends on the browser.

⑤ PG communication: The PG connection occupies one connection resource in the station.

⑥ OPC UA communication: Each session that the OPC UA server of the CPU establishes with an OPC UA client as a rule occupies one connection resource (other communication) in the station.

Connection resource for HMI communication

Connection resource for Open User Communication

Connection resource for S7 communication

Connection resource for Web communication

Connection resource for PG communication

Connection resource for other communication (for example OPC UA)

Figure 11-2 Allocation of connection resources

Connection resources for HMI communication

With HMI communication, the occupation of connection resources in the station depends on the HMI device being used.

Table 11- 2 Maximum occupied connection resources for different HMI devices

HMI device	Maximum occupied connection resources of the station per HMI connection
Basic Panel	1
Comfort Panel	2[1]
RT Advanced	2[1]
RT Professional	3

[1] If you do not use system diagnostics or alarm configuration, the station occupies only one connection resource per HMI connection.

Example: You have configured the following HMI connections for a CPU 1516-3 PN/DP:

- Two HMI connections to an HMI TP700 Comfort. (2 connection resources each)
- One HMI connection to an HMI KTP1000 Basic. (1 connection resource)

In total 5 connection resources are occupied for HMI communication in the CPU.

Connection resources for routing

To transfer data beyond S7 subnets ("S7 routing"), an S7 connection is established between two CPUs. The S7 subnets are connected via gateways known as S7 routers. CPUs, CMs and CPs in S7-1500 are S7 routers.

The following applies for a routed S7 connection:

- A routed connection occupies one connection resource each in both end points. STEP 7 shows these connection resources in the "Connection resources" table.
- On the S7 router, two special connection resources are occupied for S7 routing. STEP 7 does not show the special connection resources for S7 routing in the "Connection resources" table. The number of resources for S7 routing depends on the CPU. You will find the resources for S7 routing in the technical specifications of the CPU in "Number of S7 routing connections".

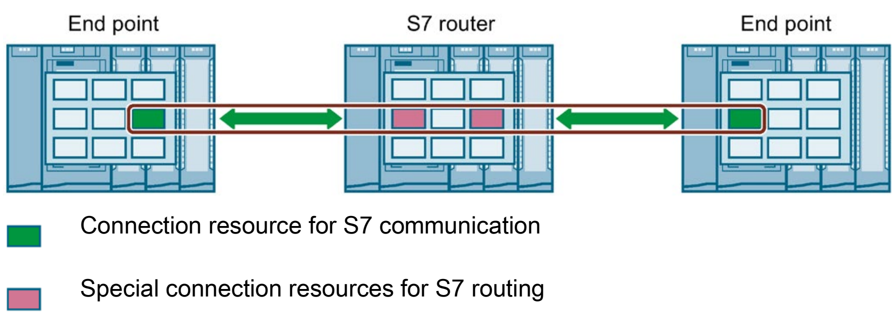


Figure 11-3 Connection resources with S7 routing

Data record routing also enables transfer of data beyond S7 subnets from an engineering station connected to PROFINET to various field devices via PROFIBUS.

With data record routing, as with S7 routing, two of the special connection resources for S7 routing are also occupied on every data record router.

Note

Connection resources with data record routing

With data record routing, on the data record router, two special connection resources for S7 routing are occupied. Neither the data record connection nor the allocated connection resources are displayed in the table of connection resources.

When are connection resources occupied?

The time for the occupation of connection resources depends on how the connection is set up (see section Setting up a connection (Page 30)).

- **Programmed setup of a connection**:
  As soon as an instruction to establish a connection is called in the user program (TSEND_C/TRCV_C or TCON), a connection resource is occupied.

  With suitable parameter assignment of the CONT parameter of the TSEND_C/TRCV_C instructions or by calling the TDISCON instruction, the connection can be terminated following data transfer and the connection resource is available again. When the connection is terminated, the connection resources on the CPU/CP/CM are available again.
- **Configured connections** (e.g. HMI connection):
  If you have configured a connection in STEP 7, the connection resource is occupied as soon as the hardware configuration is downloaded to the CPU.

  After using a configured connection for data transfer, the connection is not terminated. The connection resource is permanently occupied. To release the connection resource again, you need to delete the configured connection in STEP 7 and download the modified configuration to the CPU.
- **PG connection**:
  As soon as you have connected the PG to a CPU online in STEP 7, connection resources are occupied.
- **Web server**:
  As long as you have opened the Web server of the CPU in a browser, connection resources are occupied in the CPU.
- **OPC UA server**:
  A connection resource is occupied in the CPU as long as a session exists between the OPC UA server of the CPU and an OPC UA client.

Monitoring the maximum possible number of connection resources

Offline

During configuration of connections, STEP 7 monitors the occupation of the connection resources. If the maximum possible number of connection resources is exceeded, STEP 7 signals this with a suitable warning.

Online

The CPU monitors the use of connection resources in the automation system. If you establish more connections in the user program than those provided by the automation system, the CPU acknowledges the instruction to establish the connection with an error.

S7-1500 and S7-300 comparison

You will find a comparison of how the communication resources of the S7-1500 and S7-300 are managed in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/109747092).

11.3 Display of the connection resources

Display of the connection resources in STEP 7 (offline view)

You can display the connection resources of an automation system in the hardware configuration. You will find the connection resources in the Inspector window in the properties of the CPU.

Connection resources

	① Station resources			② Module reso...	Module reso...	Module reso...
	Reserved		Dynamic	PLC_1 [CPU ...	CP 1543-1_...	CM 1542-5_...
Maximum number of resources:	10		246	128	118	48
	Maximum	Configured	Configured	Configured	Configured	Configured
PG communication:	4	-	-	-	-	-
HMI communication:	4	4	6	6	4	0
S7 communication:	0	-	23	2	0	21
Open user communication:	0	-	52	39	13	0
Web communication:	2	-	-	-	-	-
Other communication:	-	-	0	0	0	0
Total resources used:		4	81	47	17	21
Available resources:		6	165	81	101	27

Figure 11-4 Example: Reserved and available connection resources (offline view)

① Station-specific connection resources

The columns of the station-specific connection resources provide information about the used and available connection resources of the station.

In the example, a maximum of 256 station-specific connection resources are available for the automation system.

- 10 reserved connection resources, of which 4 are already in use and a further 6 available. The used resources are divided up as follows:
  - 4 Resources for HMI communication
- 246 dynamic connection resources, of which 81 are already in use and a further 165 available.
  The used resources are divided up as follows:
  - 6 resources for HMI communication
  - 23 Resources for S7 communication
  - 52 resources for Open User Communication

The warning triangle in the column of the dynamic station resources is therefore displayed because the sum of the maximum available connection resources of CPU, CP and CM (= 294 connection resources) exceeds the station limit of 256.

Note

Available connection resources exceeded

STEP 7 signals the exceeding of the station-specific connection resources with a warning. To make full use of the connection resources from the CPU, CP and CM, either use a CPU with a higher maximum number of available station-specific connection resources or reduce the number of communications connections.

---

② Module-specific connection resources

The columns of the module-specific connection resources provide information about the use of resources on the CPUs, CPs and CMs of an automation system:

The display is per module and not per interface.

In the example, the CPU makes 128 connection resources available, of which 47 are already in use and a further 81 still available.
The used resources are divided up as follows:

- 6 resources for HMI communication
- 2 resources for S7 communication
- 39 resources for Open User Communication

Display of the connection resources in STEP 7 (online view)

If you are connected to the CPU online, you can also see how many resources are currently being used under "Connection information".

PLC_2 [CPU 1516-3 PN/DP] | Properties | Info | Diagnostics

Device information | Connection information | Alarm display

Connection resources

	Station resources					Module resources	
	Reserved			Dynamic		PLC_2 [CPU 1516-3 PN/DP]	
Maximum number of resources:		10	10	194	194	86	86
	Maximum	Configured	Used	Configured	Used	Configured	Used
PG communication:	4	-	4	-	0	-	0
HMI communication:	4	4	4	4	4	8	8
S7 communication:	0	0	0	72	68	34	34
Open user communication:	0	0	0	118	118	45	45
Web communication:	2	-	2	-	0	-	0
Other communication:	-	-	0	-	0	-	0
Total resources used:		4	10	194	190	82	82
Available resources:		6	0	0	4	4	4

Figure 11-5 Connection resources - online

The online view of the "Connection resources" table in addition to the offline view also contains columns with the connection resources currently being used. Thus, the online view displays **all** used connection resources in the automation system, regardless of how the connection was set up.

The "Other communication" row displays connection resources assigned for communication with external devices. The table is updated automatically.

Note

If a routed S7 connection goes through a CPU, the required connection resources of the CPU do not appear in the table of connection resources.

Display of the connection resources for HMI

For information regarding the availability and assignment of connection resources for HMI connections, refer to the "Connection resources" properties in the Inspector window of the offline view (in the context of the HMI device).

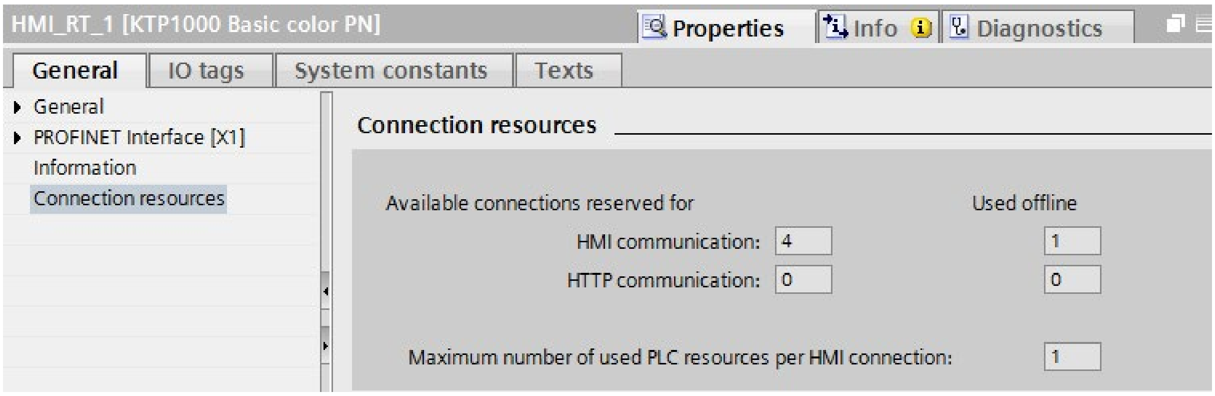

Figure 11-6 Connection resources - HMI communication

The following is displayed in the connection resources area:

- Number of available connections on the HMI reserved for HMI communication and HTTP communication
- Number of connection resources for HMI communication and HTTP communications used offline in the HMI

  If the maximum number of available connection resources for an HMI device is exceeded, a corresponding message is output by STEP 7.
- "Maximum number of used PLC resources per HMI connection". This parameter is a factor that is to be multiplied by the number of HMI connections used offline. The product is the number of HMI resources occupied on the CPU.

Displaying the connection resources in the Web server

You can display the connection resources not only in STEP 7, but also with a browser that displays the relevant page of the Web server.

You will find information on displaying connection resources in the Web server in the Web Server (http://support.automation.siemens.com/WW/view/en/59193560)function manual.

Diagnostics and fault correction 12

12.1 Connection diagnostics

Connections table in the online view

After selecting a CPU in the Devices & networks editor of STEP 7, you will see the status of your connections displayed in the online view of the connections table.

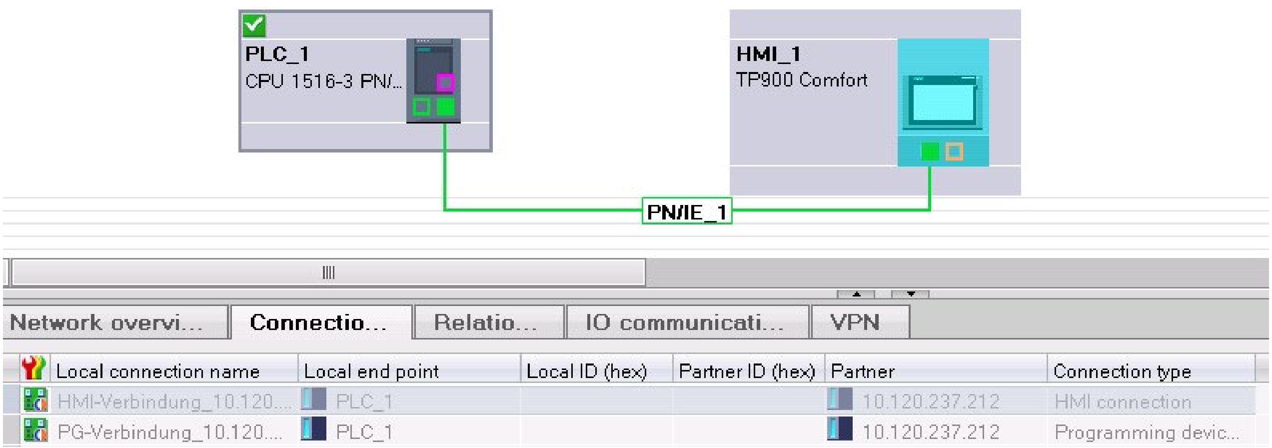

Figure 12-1 Online view of the connections table

After selecting the connection in the connections table, you obtain detailed diagnostic information in the "Connection information" tab.

"Connection information" tab: Connection details

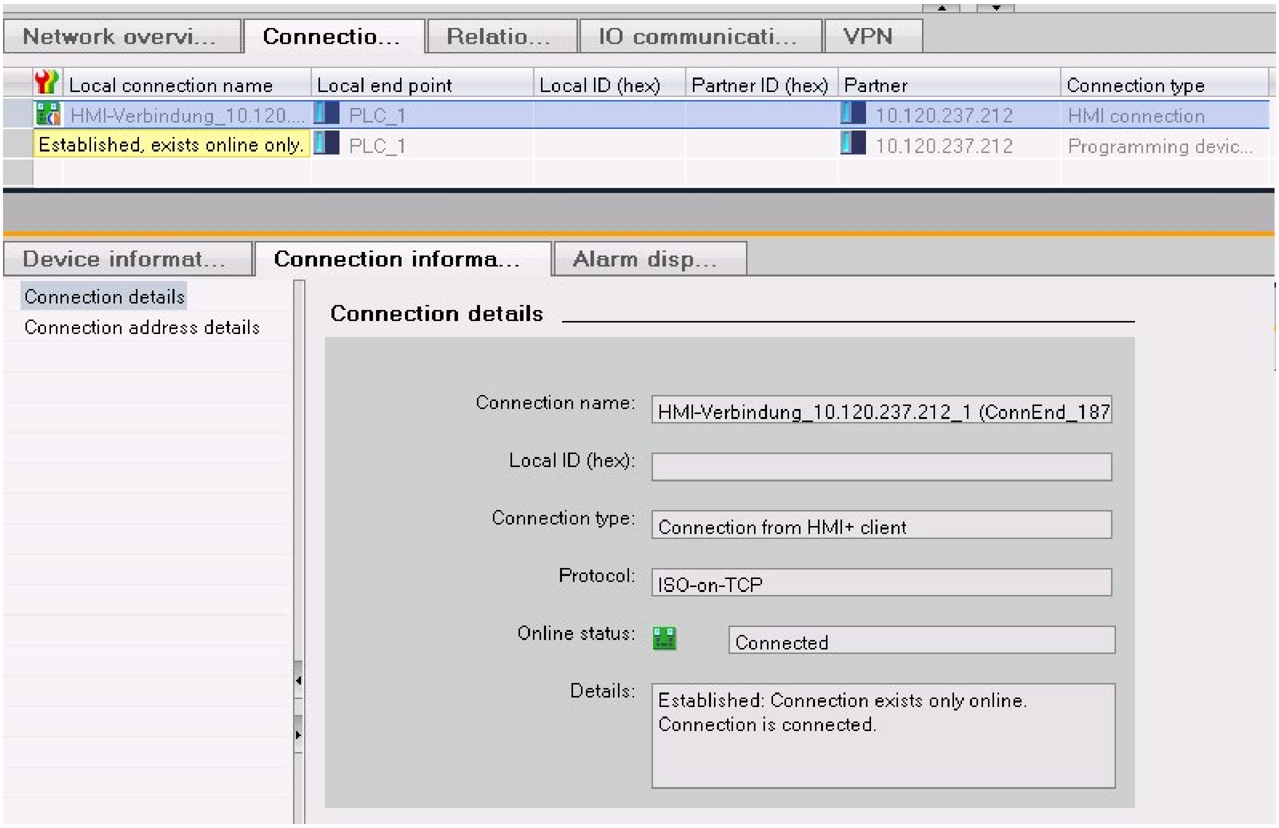

Figure 12-2 Diagnostics of connections - connection details

"Connection information" tab: Address details

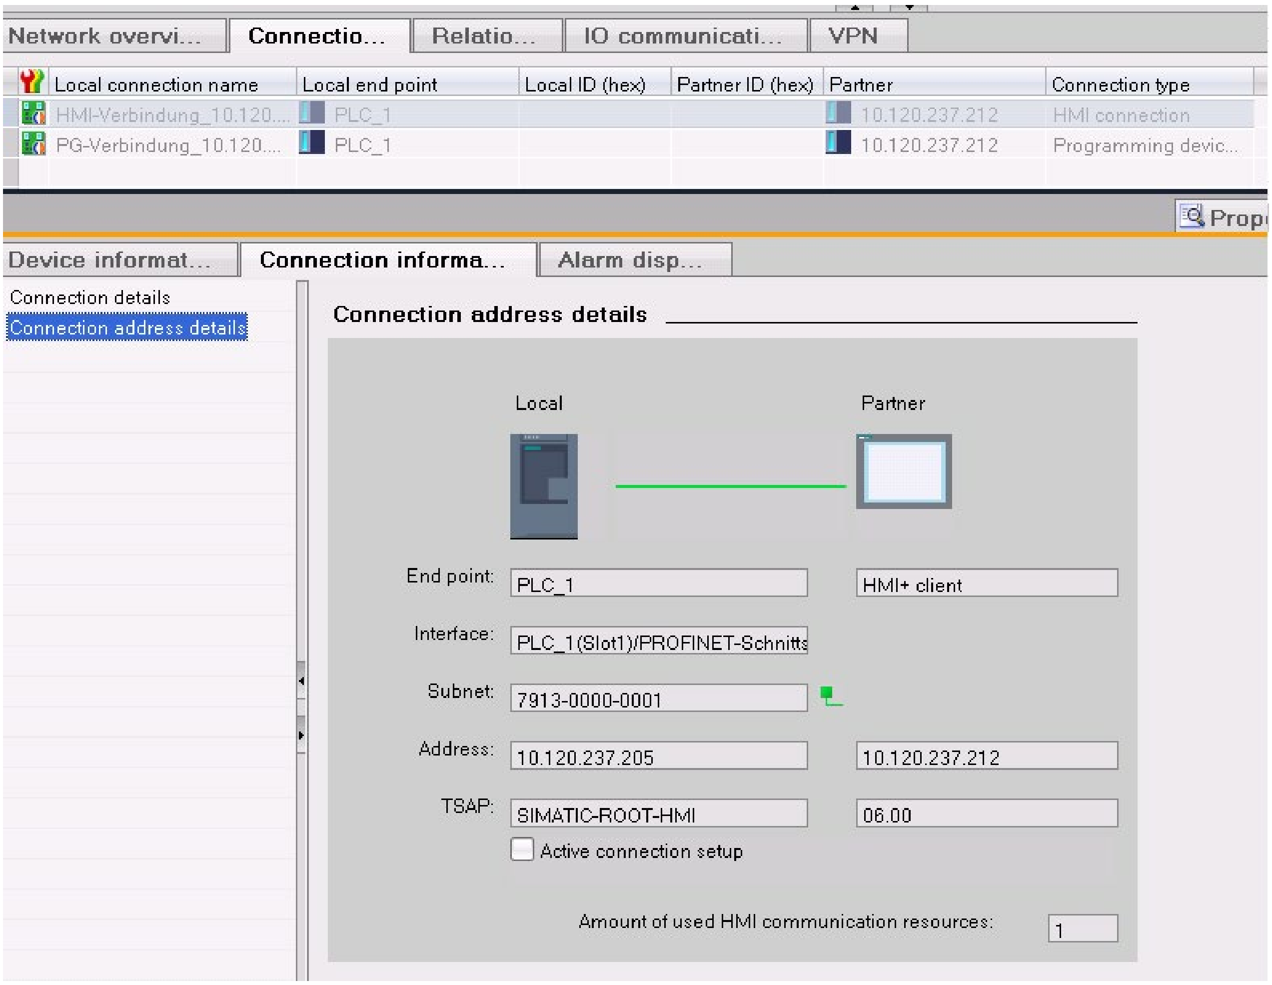

Figure 12-3 Diagnostics of connections - address details

Diagnostics via web server

You can evaluate diagnostic information from the CPU using a web browser via the integrated web server of a CPU.

On the "Communication" Web page, you will find the following information about communication via PROFINET in various tabs:

- Information on the PROFINET interfaces of the CPU (for example addresses, subnets, physical properties).
- Information on the quality of the data transfer (for example number of data packets sent/received error-free).
- Information about the allocation/availability of connection resources.
- The "Connection status" page is similar to the online view in STEP 7 and also provides an overview of all connections with detail view.

Diagnostics with the user program

When you program the T_DIAG instruction, you can evaluate diagnostic information about the configured and programmed connections of the CPU using the user program.

Additional information

You will find the description of the web server functionality in the function manual Web server (http://support.automation.siemens.com/WW/view/en/59193560).

12.2 Emergency address

If you cannot reach the CPU via the IP address, you can set a temporary emergency address (emergency IP) for the CPU. Via this emergency address, you can re-establish the connection with a CPU in order to load a device configuration with a valid IP address.

You can set an emergency address regardless of the protection level of the CPU

When do you need an emergency address?

Your CPU cannot be reached in the following cases:

- The IP address of your PROFINET interface is assigned twice.
- The subnet mask is set incorrectly.

Requirements

- You have selected "Set IP address in the project" for the IP protocol in the device configuration in STEP 7.
- The CPU is in STOP mode.

Restoring a valid device configuration with an emergency address

1. Set the emergency address for the interface of the CPU with a DCP tool. For example, the SIMATIC Automation Tool has a DCP command "Define IP address".
   The maintenance LED of the CPU lights up. The diagnostic buffer also shows that an emergency address was activated for an Ethernet interface.
2. Load a STEP 7 project with a valid IP address into the CPU.
3. Switch the CPU off and on again.
   The emergency address is reset.

Result

The CPU starts up with the valid IP address.

Communication with the redundant system S7-1500R/H 13

Introduction

Communication with the S7-1500R/H redundant system basically functions as with the S7-1500 standard system.

This chapter describes the special features and restrictions for communication with the S7-1500R/H redundant system.

Communication options for the S7-1500R/H redundant system

- Open User Communication via TCP/IP, UDP and ISO-on-TCP
- S7 communication as server
- HMI communication
- PG communication
- SNMP
- Time-of-day synchronization via NTP

Restrictions for communication with the S7-1500R/H redundant system

- Open User Communication:
  - no configured connections
  - Secure Open User Communication: Not supported as certificate management is not possible for the R/H CPUs:

    If you have activated Secure OUC, then although you can compile the user program and load it, you cannot add certificates to the R/H-CPUs.
  - no FDL connections
  - Email: The S7-1500R/H CPUs with firmware version V2.6 do not support versions < V5.0 of the "TMAIL_C" instruction. Version V5.0 is not supported.
  - No support of connection descriptions according to "TCON_Param"
- no OPC UA
- no S7 communication as client
- no web server
- PG communication:
  - It is not possible to access two CPUs online at the same time. You can either access the primary CPU or the backup CPU.
  - Downloading blocks in redundant mode is not possible.
  - No support of the function "Upload device as new station"
- No S7-routing between the PROFINET interface X1 and the PROFINET-interface X2 of the CPUs
- The CPUs of the S7-1500R/H do not support any central communication modules

13.1 System IP addresses

The system IP address of the S7-1500R/H redundant system

In addition to the device IP addresses of the CPUs, the S7-1500R/H redundant system supports system IP addresses:

- System IP address for the PROFINET interfaces X1 of the two CPUs (system IP-address X1)
- System IP address for the PROFINET interfaces X2 of the two CPUs (system IP-address X2)

You use the system IP addresses for communication with other devices (for example, HMI devices, CPUs, PG/PC). The devices always communicate via the system IP address with the primary CPU of the redundant system. This ensures, for example, that the communication partner can communicate with the new primary CPU (previously backup CPU) in the RUN-Solo system state after failure of the original primary CPU in redundant operation.

There is a virtual MAC address for each system IP address.

You enable the system IP addresses in STEP 7.

Advantages of the system IP addresses compared to device IP addresses

- The communication partner communicates specifically with the primary CPU.
- Communication of the S7-1500R/H redundant system via a system IP address still also works in the event of the failure of the primary CPU.

Applications

You use the system IP addresses for the following applications:

- HMI communication with the S7-1500R/H redundant system: With an HMI you manage or monitor the process on the S7-1500R/H redundant system.
- Open User Communication with the S7-1500R/H redundant system:
  - Another CPU or an application on a PC accesses data of the S7-1500R/H redundant system.
  - The S7-1500R/H redundant system accesses a different device.

  TCP, UDP and ISO-on-TCP-connections are possible.

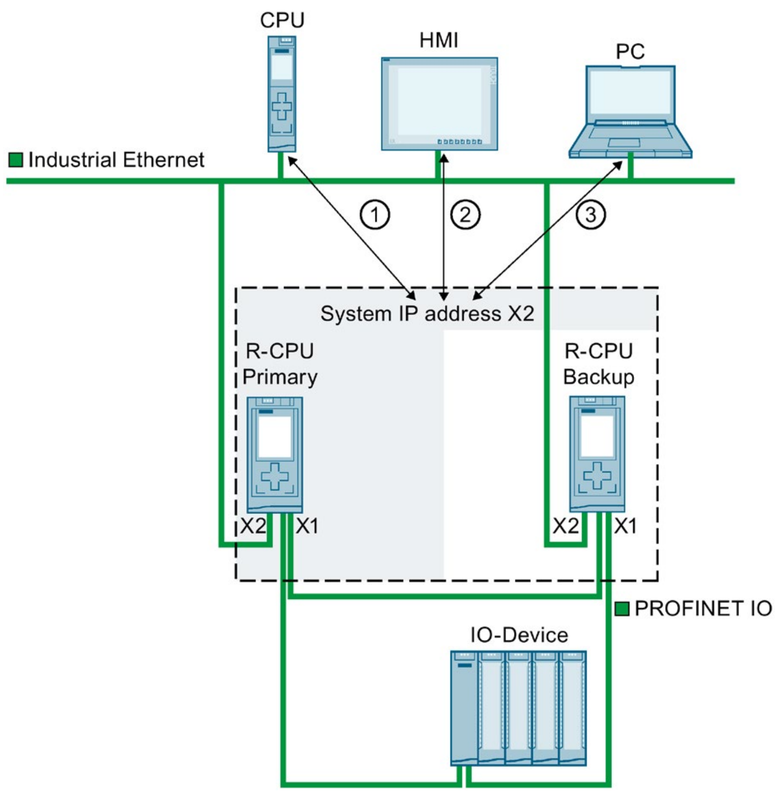
Requirements

- The communication partner and the PROFINET interfaces of the two CPUs are located in the same subnet.
- The communication partner is connected to both CPUs, each via the same interface (e.g. X2).
- The system IP address is enabled.

Communication via the system IP address X2

If the CPUs of the S7-1500R/H redundant system have two PROFINET interfaces, preferably use the PROFINET interface X2 for communication with other devices.

The following figure shows a configuration in which the communication partners are connected via the respective PROFINET interfaces X2 with the CPUs of the redundant system S7-1500R/H.



① Open User Communication between a different CPU and the S7-1500R/H redundant system

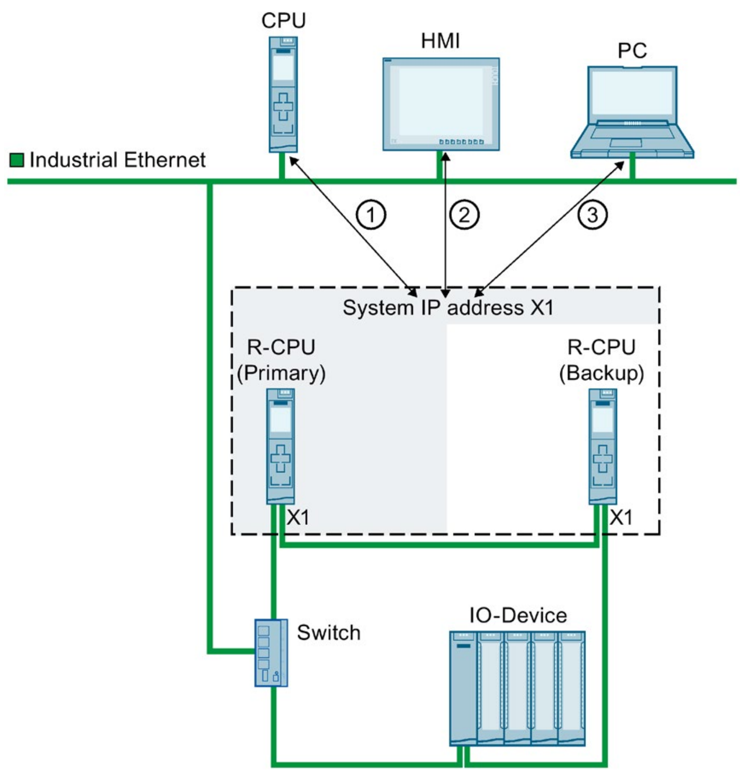
② HMI communication with the S7-1500R/H redundant system

③ Open User Communication between the S7-1500R/H redundant system and a PC

Figure 13-1 Example: Communication of the S7-1515R redundant system via the system IP address X2

Communication via the system IP address X1

The following diagram shows a configuration where the communication partners are connected with a switch to the PROFINET ring of the S7-1500R/H redundant system. The PROFINET ring connects the communication partners with the respective PROFINET interfaces X1 of the two CPUs.
As the CPU 1513R only has one PROFINET interface, connection via the PROFINET ring is the only possibility of communicating via the system IP address X1.

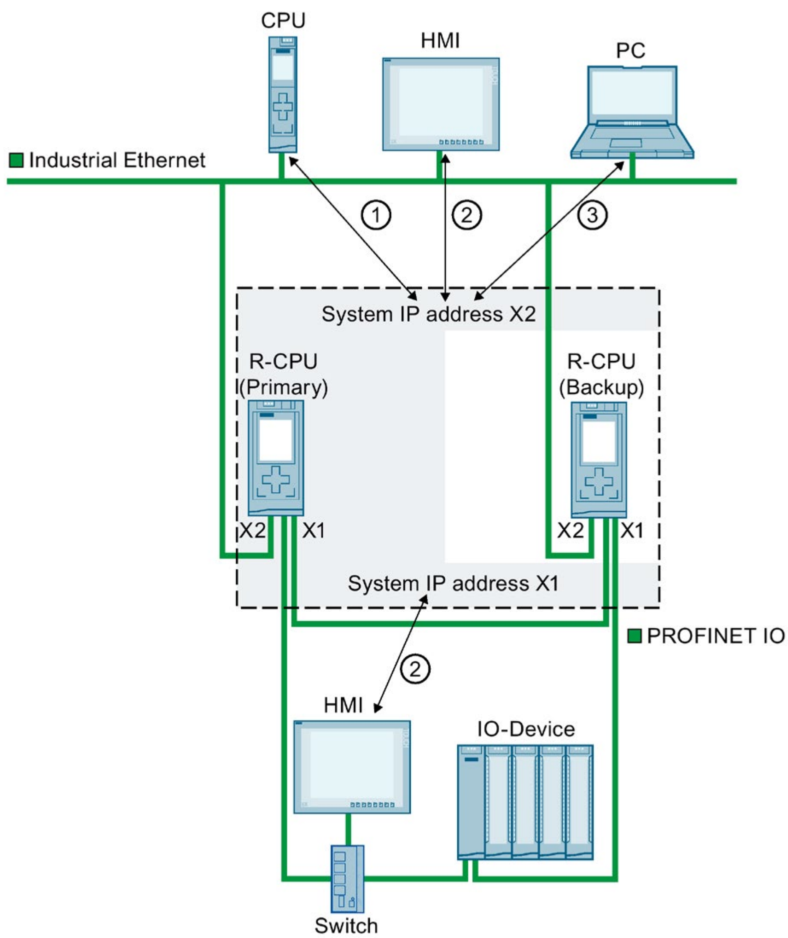


① Open User Communication between the S7-1500R/H redundant system and a different CPU
② HMI communication with the S7-1500R/H redundant system
③ Open User Communication between the S7-1500R/H redundant system and a PC

Figure 13-2 Example: Communication of the S7-1513R redundant system via the system IP address X1

Communication via the system IP addresses X1 and X2

If the CPUs of the redundant system S7-1500R/H have two PROFINET interfaces (X1 and X2), you can use the a system IP address for each PROFINET interface. PROFINET devices which are connected to the interfaces X1 of the CPUs communicate via the system IP address X1. PROFINET devices which are connected to the interfaces X2 of the CPUs communicate via the system IP address X2.



① Open User Communication between the S7-1500R/H redundant system and a different CPU.
② HMI communication with the S7-1500R/H redundant system
③ Open User Communication between the S7-1500R/H redundant system and a PC

Figure 13-3 Example: Communication of the S7-1515R redundant system via the system IP addresses X1 and X2

Enable system IP addresses

Requirements:

- STEP 7 V15.1 or higher
- redundant system S7-1500R/H with two CPUs, e.g. two CPUs 1513R-1PN

If the CPUs of the S7-1500R/H redundant system have two PROFINET interfaces (X1 and X2), then you can use a system IP address for both PROFINET interfaces. The following section describes how to enable the system IP address for the interface X1.

Proceed as follows to enable the system IP address for your S7-1500R/H redundant system:

1. In the network view of STEP 7, select the interface X1 of one of the two CPUs.
2. In the Inspector window go to "Properties" > "General" > "Ethernet addresses" in the area "System IP address for switched communication".
3. Select the check box "Enable the system IP address for switched communication".

   STEP 7 automatically creates a system IP address.

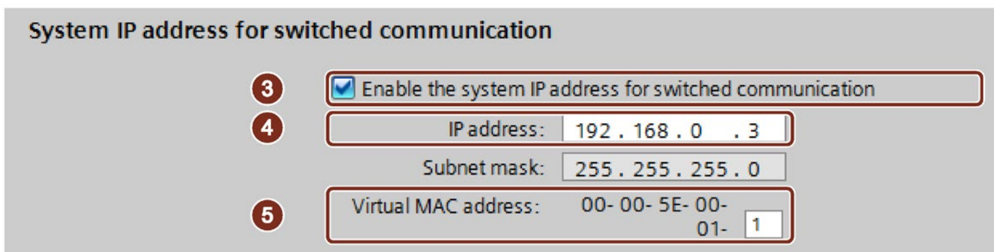


Figure 13-4 Configure IP address

4. Change the system IP address if necessary.
5. If required, change the virtual MAC address. To do this, in "Virtual MAC address", assign a project-wide unique value (value range 01_H to FF_H) for the last byte.

Note

Uniqueness of the virtual MAC address

The redundant system S7-1500R/H uses the Virtual Router Redundancy Protocol (VRRP) for the system IP address and associated virtual MAC address.
If you use further devices with VRRP, e.g. switches, ensure the uniqueness of the Mac addresses within an Ethernet-Broadcast-Domain.

Result: The system IP address X1 for the PROFINET interface X1 of the two CPUs is enabled.

13.2 Response to Snycup

Response of communication connections via the system IP address in the system state SYNCUP

- HMI, PG- and S7-connections are temporarily closed. For a short time during the SYNCUP it is not possible to establish connections to the S7-1500R/H redundant system.
- All existing connections of Open User Communication are interrupted:
  - Connections set up by the CPUs of the redundant system as an active connection partner are set up again after the SYNCUP.
  - The S7-1500R/H redundant system sets up connection endpoints again for the passive connection establishment after the SYNCUP.
- The processing of running instances of the instructions TSEND and TRCV is stopped. The block parameter STATUS returns $80C4_H$ (temporary communication error).

13.3 Response to primary-backup switchover

Response of communication connections via the system IP address during a primary-backup switchover

- Running instances of the instructions TSEND and TRCV are stopped and return the status $80C4_H$ (temporary communication error).
- Connections successfully established by the S7-1500R/H redundant system are established again by the new primary CPU.
- The new primary CPU sets up connection endpoints again for the passive connection establishment.

13.4 Connection resources of the redundant system S7-1500R/H

Maximum number of connection resources of the S7-1500R/H redundant system

The S7-1500R/H redundant system supports a maximum number of connection resources.

The CPU used defines the maximum number of resources for an S7-1500R/H station:

- CPU 1513R: max. 88 connection resources
- CPU 1515R: max. 108 connection resources
- CPU 1517H: max. 160 connection resources

Allocation of connection resources

Communication connections occupy communication resources in the S7-1500R/H redundant system.

Each communication connection to the S7-1500R/H redundant system occupies communication resources in the S7-1500R/H station. Depending on the IP address used, a communication connection also occupies resources in one or both CPUs of the S7-1500R/H redundant system.

The following table shows in which CPU a communication connection occupies connection resources depending on the IP address used.

Connect via...	Connection resources of the station	Connection resources CPU with redundancy ID 1	Connection resources CPU with redundancy ID 2
a system IP address	X	X	X
a device IP address of the CPU with redundancy ID 1	X	X	-
a device IP address of the CPU with redundancy ID 2	X	-	X

Display of the occupied connection resources in STEP 7

Requirements: Online connection to the redundant system S7-1500R/H

You will find the online display of the connection resources in the inspector window under "Diagnostics" > "Connection information". STEP 7 always displays the connection resources of the selected CPU and the S7-1500R/H-station.

Connection resources

	Station resources					Module resources	
	Reserved			Dynamic		CPU 1517H-3 PN (R0/S1)	
Maximum number of resources:		10	10	150	150	160	160
	Maximum	Configured	Used	Configured	Used	Configured	Used
PG communication:	4	-	2	-	0	-	2
HMI communication:	4	0	0	0	0	0	0
S7 communication:	0	-	0	0	0	0	0
Open user communication:	0	-	0	0	0	0	0
Web communication:	2	-	0	-	0	-	0
Other communication:	-	-	0	0	0	0	0
Total resources used:		0	2	0	0	0	2
Available resources:		10	8	150	150	160	158

Figure 13-5 Display of the connection resources of the S7-1500R/H redundant system in STEP 7

13.5 HMI communication with the redundant system S7-1500R/H

13.5.1 HMI connection via the system IP address

Requirements

- redundant system S7-1500R/H, e.g. CPU 1513R-1PN
- System IP address is enabled
- HMI device with PROFINETI-interface

Procedure

To set up a HMI connection to an S7-1500R/H redundant system, follow these steps:

1. In the network view of STEP 7, select a PROFINET interface of the HMI device.
2. Using a drag&drop operation, draw a line between the PROFINET interface of the HMI device and a PROFINET-interface of the S7-1500R/H redundant system.
   The HMI-device and the S7-1500R/H redundant system are networked together.

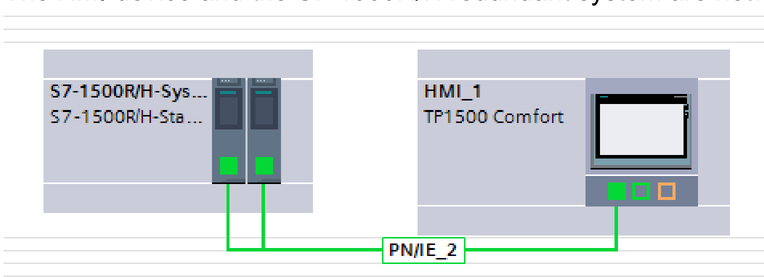

Figure 13-6 Networking an HMI device with the S7-1500R/H redundant system

3. In the list of functions, click the "Connections" icon. This activates connection mode.
4. Using a drag-and-drop operation, draw a line between the HMI device and a CPU of the S7-1500R/H redundant system.
   The list "Connection partners" opens.

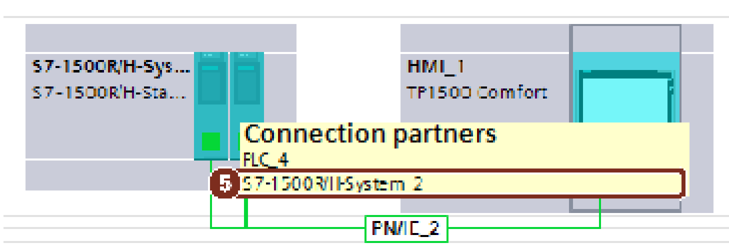

Figure 13-7 Setting up an HMI connection to the S7-1500R/H redundant system

5. Select the S7-1500R/H redundant system in the list "Connection partners".

Result: You have set up a HMI connection between the HMI device and the S7-1500R/H redundant system. The HMI connection uses the system IP address. The HMI device always connects to the primary-CPU.

Changing the HMI connection over to the device IP address

To permanently change the HMI connection over to the selected CPU, clear the check box "Use the system IP address for switched communication" in the properties of the HMI connection. The HMI connection then uses the device IP address of the PROFINET interface. In the event of the failure of this CPU, then the HMI connection to this CPU permanently fails.

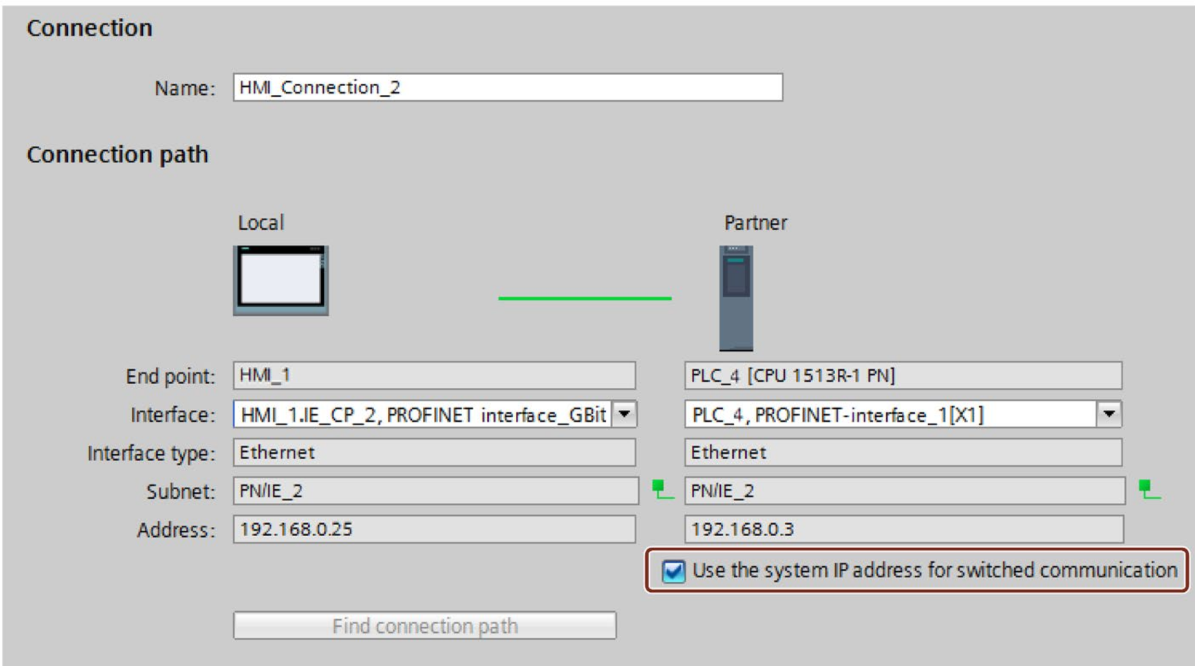

Figure 13-8 Properties of the HMI connection

Note

Automatic setup of HMI connection

When you drag-and-drop a tag from the S7-1500R/H redundant system into an HMI screen or into the HMI tag table, STEP 7 automatically sets up an HMI connection. This HMI connection exists by default between the PROFINET interface of the HMI device and the PROFINET interface X1 of the CPU with redundancy ID 1. The connection uses the device IP address of the PROFINET interface X1.

You can change the HMI connection to a system IP address in the properties of the HMI connection.

13.6 Open User Communication with the redundant system S7-1500R/H

The following table shows which protocols of the Open User Communication you can use for the S7-1500R/H redundant system and the matching system data types and instructions.

Table 13- 1 Protocols, system data types and usable instructions for Open User Communication with the redundant system S7-1500R/H

<table>
<tr><th>Protocol</th><th>System data type</th><th>Instructions</th></tr>
<tr><td>TCP</td><td>• TCON_QDN
• TCON_IP_v4</td><td rowspan="2">Establish connection and send/receive data via:

</table>

13.6.1 Setting up an Open User Communication connection via the system IP address

Introduction

The S7-1500R/H redundant system can communicate with other devices via Open User Communication.

You set up the connections in the user program, e.g. via the "TSEND_C" instruction. The S7-1500R/H redundant system does not support configured connections.

You can either set up the connections either via the device IP addresses or via the system IP addresses of the PROFINET interfaces.

Open User Communication via the system IP addresses of the S7-1500R/H redundant system

If you set up the connection via a system IP address, then communication always takes place via the primary CPU.

Recommendation: Always use a system IP address for Open User Communication.

Open User Communication via the device IP addresses of the S7-1500R/H redundant system

In redundant mode, the redundant system can establish or terminate connections and send or receive data via every device IP address.

If you set up the connection via a device IP address, then communication takes place via the associated CPU. In the event of the failure of the CPU, then the entire communication via the device IP addresses of this CPU fails.

Setting a connection via the system IP address

How to set up a connection from the S7-1500R/H redundant system to a different CPU via the system IP address is described below.

You set up the connection in the user program of the redundant system S7-1500R/H with a TSEND_C instruction. You create a corresponding TRCV_C instruction in the user program of the other CPU.

The procedure is described using the example of a TCP connection between the S7-1500R/H redundant system and a CPU 1516-3PN/DP.

Requirements

- S7-1500R redundant system with two CPUs 1513-1PN
- System IP address of the PROFINET interface X1 is enabled.
- CPU 1516-3PN/DP
- The PROFINET interfaces X1 of the CPUs 1513R and the PROFINET interface X2 of the CPU 1516-3PN/DP are located in the same subnet.

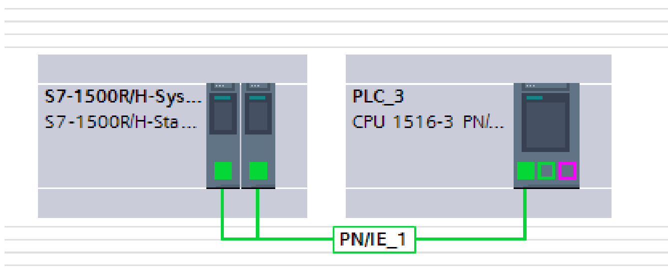

Figure 13-9 Example configuration for TCP-connection

TSEND_C instruction in the user program of the S7-1500R/H redundant system

To set up a TCP-connection to a different CPU, follow these steps:

1. Create a "TSEND_C" instruction in the user program.

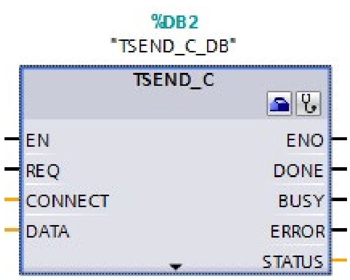

Figure 13-10 S7-1500R/H: "TSEND_C" instruction

2. Select the "TSEND_C" instruction.

3. In the Inspector window, go to "Properties" > "Configuration" > "Connection parameters". On the left-hand side you can see the S7-1500R/H redundant system as a local end point of the connection:
   – "Interface:": X1 is the preset interface.
   – "Subnet:": If the interface X1 is assigned to an S7-subnet, then STEP 7 displays the name of the S7-subnet.
   – The check box "Use address of the H-system" is selected. The system IP address of the S7-1500R/H redundant system is in "Address".

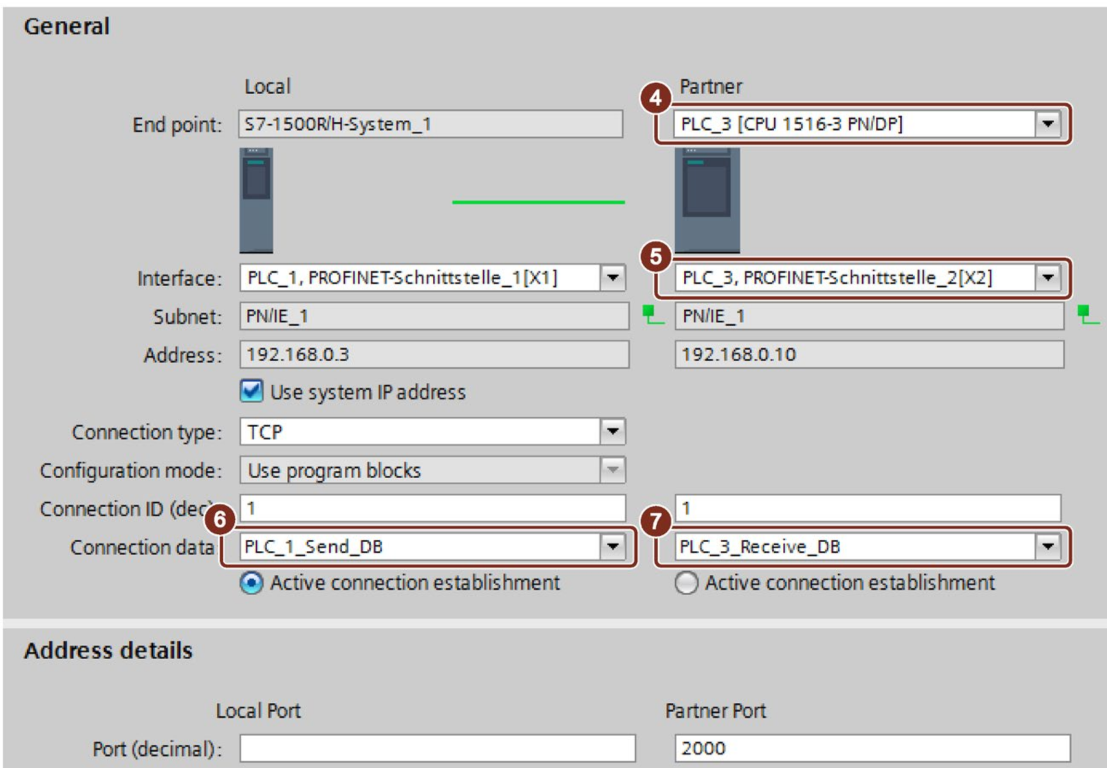

Figure 13-11 S7-1500R/H: Assigning parameters to the TSEND_C instruction in STEP 7

4. In "Partners" under "End point:" select the CPU 1516-3PN/DP as the communication partner.
5. In "Partners" under "Interface:" select the PROFINET interface X2 of the CPU 1516-3PN/DP.
6. In "Local" under "Connection data" select the setting "<new>".
   STEP 7 creates a data block for the connection data in the user program of the S7-1500R/H redundant system.
7. In "Partners" under "Connection type" select the setting "TCP".
   STEP 7 creates a data block for the connection data in the user program of the other CPU.

TRCV_C instruction in the user program of the CPU 1516

Create a TRCV_C instruction in the user program of the CPU 1516-3PN/DP and assign parameters as below:

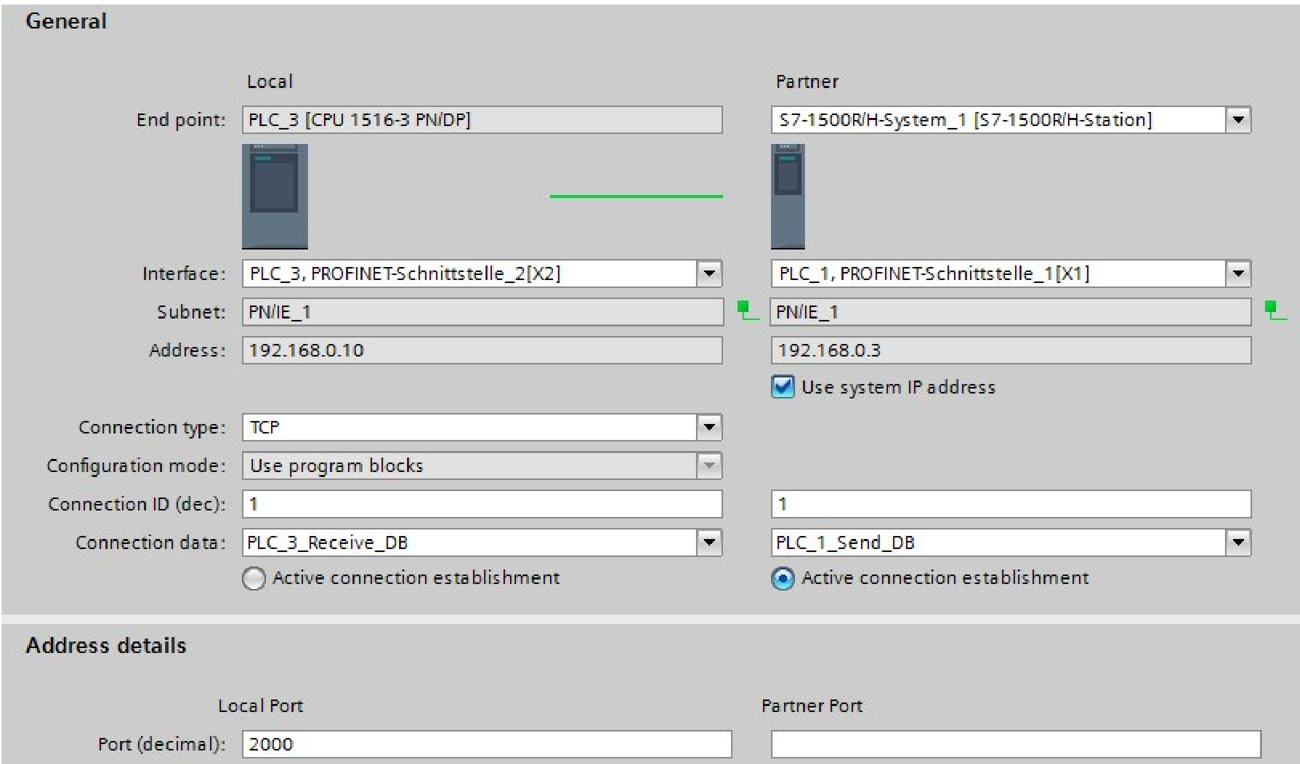

Figure 13-12 S7-1500R/H: Assigning parameters to the TRCV_C instruction in STEP 7

Setting up a connection via a device IP address

To set up an OUC-connection via a device IP address of one of the two CPUs:

- Select a suitable PROFINET interface of the S7-1500R/H redundant system.
- Deselect the "Use address of H-system" check box.

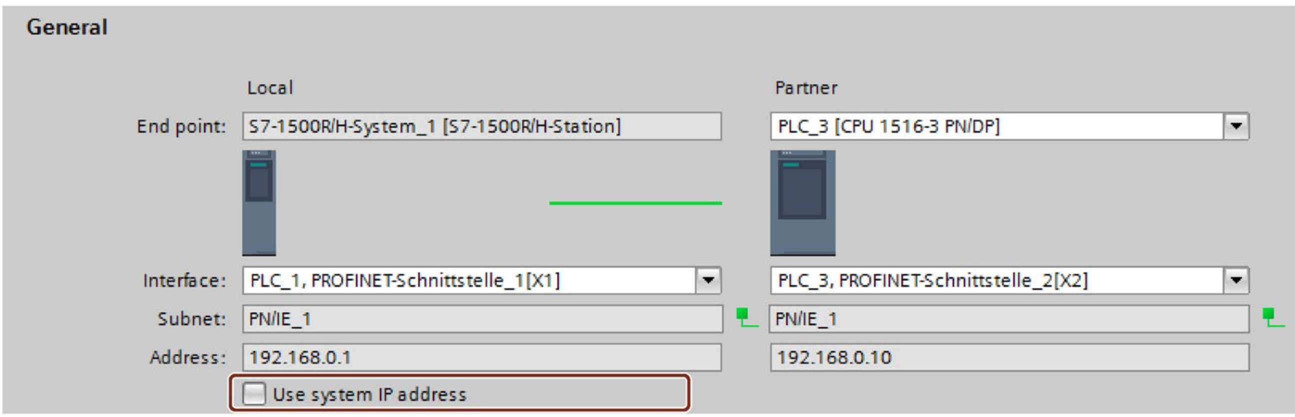

Figure 13-13 OUC-connection via a device IP address

Reference

You can find additional information on system states in the S7-1500R/H (https://support.industry.siemens.com/cs/ww/en/view/109754833) system manual.

Industrial Ethernet Security with CP 1543-1 14

All-round protection - the task of Industrial Ethernet Security

With Industrial Ethernet Security, individual devices, automation cells or network segments of an Ethernet network can be protected. Data transfer can also be protected by a combination of different security measures:

- Data espionage
- Data manipulation
- Unauthorized access

Security measures

- Firewall
  - IP firewall with stateful packet inspection (layer 3 and 4)
  - Firewall also for Ethernet "non-IP" frames according to IEEE 802.3 (layer 2)
  - Bandwidth limitation
  - Global firewall rules

  All network nodes located in the internal network segment of a CP 1543-1 are protected by its firewall.
- Logging

  To allow monitoring, events can be stored in log files that can be read out using the configuration tool or can be sent automatically to a Syslog server.
- HTTPS

  For encrypted transfer of websites, for example during process control.
- FTPS (explicit mode)

  For encrypted transfer of files.
- Secure NTP

  For secure time-of-day synchronization and transmission.
- SNMPv3

  For secure transmission of network analysis information safe from eavesdropping.
- VPN groups
  You can combine the CP 1543-1 with other security modules into VPN groups through configuration. IPsec tunnels are established between all the security modules of a VPN group (VPN). All internal nodes of these security modules can communicate securely with each other through this tunnel.
- Protection for devices and network segments

  The firewall and VPN groups protective functions can be applied to the operation of single devices, multiple devices, or entire network segments.

Additional information

An overview with links to the most important contributions on Industrial Security is available in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/92651441).

14.1 Firewall

Tasks of the firewall

The purpose of the firewall functionality is to protect networks and stations from outside influences and disturbances. This means that only certain previously specified communications relations are permitted.

To filter the data traffic, IPv4 addresses, IPv4 subnets, port numbers or MAC addresses among other things can be used.

The firewall functionality can be configured for the following protocol levels:

- IP firewall with stateful packet inspection (layer 3 and 4)
- Firewall also for Ethernet "non-IP" frames according to IEEE 802.3 (layer 2)

Firewall rules

Firewall rules describe which packets are permitted or forbidden in which direction.

14.2 Logging

Functionality

For test and monitoring purposes, the security module has diagnostics and logging functions.

- Diagnostics functions

  These include various system and status functions that you can use in online mode.

- Logging functions

  This involves the recording of system and security events. Depending on the event type, the recording is made in volatile or non-volatile local buffer areas of the CP 1543-1. As an alternative, it is also possible to record on a network server.

  The parameter assignment and evaluation of these functions is only possible with a network connection.

Recording events with logging functions

You specify which events should be recorded with the log settings. Here you can configure the following recording variants:

- Local logging

  With this variant, you record the events in local buffers of the CP 1543-1. In the online dialog of the Security Configuration Tool, you can then access these recordings, visualize them and archive them on the service station.

- Network Syslog

  With the network Syslog, you use a Syslog server in the network. This records the events according to the configuration in the log settings.

14.3 NTP client

Functionality

To check the time validity of a certificate and the time stamp of log entries, the date and time are maintained on the CP 1543-1 as on the CPU. This time can be synchronized with NTP. The CP 1543-1 forwards the synchronized time to the CPU via the backplane bus of the automation system. This way the CPU also receives a synchronized time for the time events in program execution.

The automatic setting and periodic synchronization of the time takes place either via a secure or non-secure NTP server. You can assign a maximum of 4 NTP servers to the CP 1543-1. A mixed configuration of non-secure and secure NTP servers is not possible.

14.4 SNMP

Functionality

Like the CPU, the CP 1543-1 supports the transfer of management information using the Simple Network Management Protocol (SNMP). To achieve this, an "SNMP agent" is installed on the CP/CPU that receives and responds to the SNMP queries. Information about the properties of devices capable of SNMP is contained in so-called MIB files (Management Information Base) for which the user needs to have the appropriate rights.

With SNMPv1, the "community string" is also sent. The "community string" is like a password that is sent along with the SNMP query. The requested information is sent when the "community string" is correct. The request is discarded when the string is incorrect.

With SNMPv3, data can be transferred encrypted. To do this, select either an authentication method or an authentication and encryption method.

Possible selection:

- Authentication algorithm: none, MD5, SHA-1
- Encryption algorithm: none, AES-128, DES

You can deactivate the use of SNMP for the CP/CPU. Deactivate SNMP if the security guidelines in your network do not permit SNMP or if you use your own SNMP solution.

To find out how to deactivate SNMP for the CPU, refer to section Disabling SNMP (Page 60).

14.5 VPN

Functionality

For security modules that protect the internal network, VPN (Virtual Private Network) tunnels provide a secure data connection through the non-secure external network.

The module uses the IPsec protocol (tunnel mode of IPsec) for tunneling.

In STEP 7 you can assign VPN groups to security modules. VPN tunnels are automatically established between all modules of a VPN group. A module in one project can belong to several different VPN groups at the same time in the process.

Glossary

Automation system

Programmable logic controller for the open-loop and closed-loop control of process chains of the process engineering industry and manufacturing technology. The automation system consists of different components and integrated system functions according to the automation task.

Backup CPU

If the R/H system is in RUN-Redundant system state, the primary CPU controls the process. The backup CPU processes the user program synchronously and can take over process control if the primary CPU fails.

Bus

Transmission medium that connects several devices together. Data transmission can be performed electrically or via optical fibers, either in series or in parallel.

Client

Device in a network that requests a service from another device in the network (server).

CM

→ *Communications module*

Communications module

Module for communications tasks used in an automation system as an interface expansion of the CPU (for example PROFIBUS) and providing additional communications options (PtP).

Communications processor

Module for expanded communications tasks covering special applications, for example in the area of security.

Consistent data

Data that belongs together in terms of content and must not be separated when transferred.

CP

→ *Communications processor*

CPU

Central **P**rocessing **U**nit - Central module of the S7 automation system with a control and arithmetic unit, memory, operating system and interface for programming device.

Device

Generic term for:

- Automation systems (PLC, PC, for example)
- Distributed I/O systems
- Field devices (for example, PLC, PC, hydraulic devices, pneumatic devices) and
- Active network components (for example, switches, routers)
- Gateways to PROFIBUS, AS interface or other fieldbus systems

Device certificates

Such certificates are signed by a certificate authority (CA).

The signature of an end-entity certificate is checked with the public key of the certificate authority certificate.

The "Subject" attribute must not be identical to the "Issuer" attribute.

The "Subject", for example, contains the name of a program as with the OPC UA application certificate.

"Issuer" is the certificate authority that signed the certificate.

The "CA" field must be set to "False".

DP master

Within PROFIBUS DP, a master in the distributed I/O that behaves according to the EN 50170 standard, Part 3.

→ *See also DP slave*

DP slave

Slave in the distributed I/O that is operated on PROFIBUS with the PROFIBUS DP protocol and behaves according to the EN 50170 standard, Part 3.

→ *See also DP master*

Duplex

Data transmission system; a distinction is made between full and half duplex.

Half duplex: One channel is available for alternate data exchange (sending or receiving alternately but not at the same time).

Full duplex: Two channels are available for simultaneous data exchange in both directions (simultaneous sending and receiving in both directions).

End-entity certificate

→ *See also device certificate*

Ethernet

International standard technology for local area networks (LAN) based on frames. It defines types of cables and signaling for the physical layer and packet formats and protocols for media access control.

Ethernet network adapter

Electronic circuitry for connecting a computer to an Ethernet network. It allows the exchange of data / communication within the network.

FETCH/WRITE

Server services using TCP/IP, ISO-on-TCP and ISO for access to system memory areas of S7 CPUs. Access (client function) is possible from a SIMATIC S5 or a third-party device/PC. FETCH: Read data directly; WRITE: Write data directly.

Field device

→ *Device*

Freeport

Freely programmable ASCII protocol; here for data transfer via a point-to-point connection.

FTP

File **T**ransfer **P**rotocol; a network protocol for transferring files via IP networks. FTP is used to download files from the server to the client or to upload files from the client to the server. FTP directories can also be created and read out and directories and files can be renamed or deleted.

HMI

Human **M**achine **I**nterface, device for visualization and control of automation processes.

IE

→ *Industrial Ethernet*

IM

→ *Interface module*

Industrial Ethernet

Guideline for setting up an Ethernet network in an industrial environment. The essential difference compared with standard Ethernet is the mechanical ruggedness and immunity to noise of the individual components.

Instruction

The smallest self-contained unit of a user program characterized by its structure, function or purpose as a separate part of the user program. An instruction represents an operation procedure for the processor.

Interface module

Module in the distributed I/O system. The interface module connects the distributed I/O system via a fieldbus to the CPU (IO controller/DP master) and prepares the data for the I/O modules.

Intermediate CA certificate

This is a certificate authority certificate that is signed with the private key of a root certificate authority.

An intermediate certificate authority signs end-entity certificates with its private key.

The signature of these end-entity certificates is verified with the public key of the intermediate certificate authority.

The "Subject" and "Issuer" attributes of the intermediate CA certificate must not be identical. This certificate authority has after all not signed its certificate itself.

The "CA" field must be set to "True".

IO controller, PROFINET IO controller

Central device in a PROFINET system, usually a classic programmable logic controller or PC. The IO controller sets up connections to the IO devices, exchanges data with them, thus controls and monitors the system.

IO device, PROFINET IO device

Device in the distributed I/O of a PROFINET system that is monitored and controlled by an IO controller (for example distributed inputs/outputs, valve islands, frequency converters, switches).

IP address

Binary number that is used as a unique address in computer networks in conjunction with the Internet Protocol (IP). It makes these devices uniquely addressable and individually accessible. An IPv4 address can be evaluated using a binary subnet mask that results in a network part or a host part as a structure. The textual representation of an IPv4 address consists, for example, of 4 decimal numbers with the value range 0 to 255. The decimal numbers are separated by periods.

IPv4 subnet mask

Binary mask, with which an IPv4 address (as a binary number) is divided into a "network part" and a "host part".

ISO protocol

Communications protocol for message or packet-oriented transfer of data in an Ethernet network. This protocol is hardware-oriented, very fast and allows dynamic data lengths. The ISO protocol is suitable for medium to large volumes of data.

ISO-on-TCP protocol

Communications protocol capable of S7 routing for packet-oriented transfer of data in an Ethernet network; provides network addressing. The ISO-on-TCP protocol is suitable for medium and large volumes of data and allows dynamic data lengths.

Linear bus topology

Network topology characterized by the arrangement of the devices in a line (bus).

MAC address

Worldwide unique device identification for all Ethernet devices. The MAC address is assigned by the manufacturer and has a 3-byte vendor ID and 3-byte device ID as a consecutive number.

Master

Higher-level, active participant in the communication/on a PROFIBUS subnet. The master has rights to access the bus (token) and can request and send data.

→ *See also DP master*

Modbus RTU

Remote **T**erminal **U**nit; Open communications protocol for serial interfaces based on a master/slave architecture.

Modbus TCP

Transmission **C**ontrol **P**rotocol; Open communications protocol for Ethernet based on a master/slave architecture. The data are transmitted as TCP/IP packets.

Network

A network consists of one or more interconnected subnets with any number of devices. Several networks can exist alongside each other.

NTP

The **N**etwork **T**ime **P**rotocol (NTP) is a standard for synchronizing clocks in automation systems via **I**ndustrial Ethernet. NTP uses the connectionless UDP transport protocol for the **I**nternet.

OPC UA

OPC Unified **Automation** is a protocol for communication between machines, developed by the OPC Foundation.

Operating states

Operating states describe the behavior of a single CPU at a specific time.

The CPUs of the SIMATIC standard systems have the STOP, STARTUP and RUN operating states.

The primary CPU of the redundant system S7-1500R/H has the operating states STOP, STARTUP, RUN, RUN-Syncup and RUN-Redundant. The backup CPU has the operating states STOP, SYNCUP and RUN-Redundant.

Operating system

Software that allows the use and operation of a computer. The operating system manages resources such as memory, input and output devices and controls the execution of programs.

PG

→ *Programming device*

PNO

→ *PROFIBUS user organization*

Point-to-point connection

Bidirectional data exchange via communications modules with a serial interface between two communications partners (and two only).

Port

Physical connector to connect devices to PROFINET. PROFINET interfaces have one or more ports.

Primary CPU

If the R/H system is in RUN-Redundant system state, the primary CPU controls the process. The backup CPU processes the user program synchronously and can take over process control if the primary CPU fails.

Process image (I/O)

The CPU transfers the values from the input and output modules to this memory area. At the start of the cyclic program, the CPU transfers the process image output as a signal state to the output modules. The CPU then reads the signal states of the input modules into the process image input. The CPU then executes the user program.

PROFIBUS

Process **Fi**eld **Bus** - European Fieldbus standard.

PROFIBUS address

Unique identifier of a device connected to PROFIBUS. The PROFIBUS address is sent in the frame to address a device.

PROFIBUS device

Device with at least one PROFIBUS interface either electrical (for example RS-485) or optical (for example Polymer Optical Fiber).

PROFIBUS user organization

Technical committee dedicated to the definition and development of the PROFIBUS and PROFINET standard.

PROFIBUS DP

A PROFIBUS with DP protocol that complies with EN 50170. DP stands for distributed I/O = fast, real-time capable, cyclic data exchange. From the perspective of the user program, the distributed I/O is addressed in exactly the same way as the centralized IO.

PROFINET

Open component-based industrial communications system based on Ethernet for distributed automation systems. Communications technology promoted by the PROFIBUS user organization.

PROFINET device

Device that always has a PROFINET interface (electrical, optical, wireless).

PROFINET interface

Interface of a module capable of communication (for example CPU, CP) with one or more ports. A MAC address is assigned to the interface in the factory. Along with the IP address and the device name (from the individual configuration), this interface address ensures that the PROFINET device is identified uniquely in the network. The interface can be electrical, optical or wireless.

PROFINET IO

IO stands for input/output; distributed I/O (fast, cyclic data exchange with real-time capability). From the perspective of the user program, the distributed I/O is addressed in exactly the same way as the centralized IO.

PROFINET IO as the Ethernet-based automation standard of PROFIBUS & PROFINET International defines a cross-vendor communication, automation, and engineering model.

With PROFINET IO, a switching technology is used that allows all devices to access the network at any time. In this way, the network can be used much more efficiently through the simultaneous data transfer of several devices. Simultaneous sending and receiving is enabled via the full-duplex operation of Switched Ethernet.

PROFINET IO is based on switched Ethernet with full-duplex operation and a bandwidth of 100 Mbps.

Programming device

Programming devices are essentially compact and portable PCs which are suitable for industrial applications. They are identified by a special hardware and software configuration for programmable logic controllers.

Protocol

Agreement on the rules by which the communication between two or more communication partners transpires.

PtP

Point-**to**-**P**oint, interface and/or transmission protocol for bidirectional data exchange between two (and only two) communications partners.

Redundant systems

Redundant systems have multiple (redundant) instances of key automation components. Process control is maintained if a redundant component fails.

Ring topology

All devices of a network are connected together in a ring.

Root CA certificates

→ *See also root certificate*

Root certificate

This is the certificate of a certificate authority: It signs end-entity certificates and intermediate CA certificates with its private key.

The "Subject" attribute and the "Issuer" of this certificate must be identical. This certificate authority has signed its certificate itself.

The "CA" field must be set to "True".

TIA Portal V14 has such a root CA certificate:

If you configure the OPC UA server of an S7-1500 in the TIA Portal, the TIA Portal generates an end-entity certificate for the OPC UA server and signs that certificate with its own private key.

The signature of this end-entity certificate can be verified with the public key of the TIA Portal. This key can be found in the root CA certificate of the TIA Portal.

Router

Network node with a unique identifier (name and address) that connects subnets together and allows transportation of data to uniquely identified communications nodes in the network.

RS232, RS422 and RS485

Standard for serial interfaces.

RTU

Modbus RTU (RTU: **R**emote **T**erminal **U**nit, transfers the data in binary form; allows a good data throughput. The data must be converted to a readable format before it can be evaluated.

S7 routing

Communication between S7 automation systems, S7 applications or PC stations in different S7 subnets via one or more network nodes functioning as S7 routers.

SDA service

Send Data with Acknowledge. SDA is an elementary service with which an initiator (for example DP master) can send a message to other devices and then receives acknowledgment of receipt immediately afterwards.

SDN service

Send Data with No Acknowledge. This service is used primarily to send data to multiple stations and the service therefore remains unacknowledged. Suitable for synchronization tasks and status messages.

Security

Generic term for all the measures taken to protect against

- Loss of confidentiality due to unauthorized access to data
- Loss of integrity due to manipulation of data
- Loss of availability due to the destruction of data

Self-signed certificates

These are certificates that you sign with your private key and use as end-entity certificates.

The signature of these end-entity certificates is verified with your public key.

The "Subject" and "Issuer" attributes of self-signed certificates must be identical: You have signed your certificate yourself.

The "CA" field must be set to "False".

You can, for example, use self-signed certificates as application certificates for an OPC UA client.

The procedure required to generate a self-signed certificate with the certificate generator of the OPC Foundation is described here (Page).

Server

A device or more generally an object that can provide certain services; the service is performed at the request of a client.

Slave

Distributed device in a fieldbus system that can only exchange data with a master after the master has requested this.

→ *See also DP slave*

SNMP

Simple Network Management Protocol, uses the wireless UDP transport protocol. SNMP works in much the same way as the client/server model. The SNMP manager monitors the network nodes. The SNMP agents collect the various network-specific information in the individual network nodes and makes this information available in a structured form in the MIB (Management Information Base). This information allows a network management system to run detailed network diagnostics.

Subnet

Part of a network whose parameters must be matched up on the devices (for example in PROFINET). A subnet includes the bus components and all connected stations. Subnets can be linked together, for example using gateways or routers to form one network.

Switch

Network components used to connect several terminal devices or network segments in a local network (LAN).

System states

The system states of the redundant system S7-1500R/H result from the operating states of the primary and backup CPUs. The term system state is used as a simplified expression that refers to the operating states that occur simultaneously on both CPUs. The redundant system S7-1500R/H has the system states STOP, STARTUP, RUN-Solo, SYNCUP and RUN-Redundant.

System IP address

In addition to the device IP addresses of the CPUs, the redundant system S7-1500R/H supports system IP addresses:

- System IP address for the X1 PROFINET interfaces of the two CPUs (system IP address X1)
- System IP address for the X2 PROFINET interfaces of the two CPUs (system IP address X2)

You use the system IP addresses for communication with other devices (for example, HMI devices, CPUs, PG/PC). The devices always communicate over the system IP address with the primary CPU of the redundant system. This ensures that the communication partner can communicate with the new primary CPU (previously backup CPU) in the RUN-Solo system state after failure of the original primary CPU in redundant operation.

TCP/IP

Transmission Control Protocol / Internet Protocol, connection-oriented network protocol, generally recognized standard for data exchange in heterogeneous networks.

Time-of-day synchronization

Capability of transferring a standard system time from a single source to all devices in the system so that their clocks can be set according to the standard time.

Tree topology

Network topology characterized by a branched structure: Two or more bus nodes are connected to each bus node.

Twisted-pair

Fast Ethernet via twisted-pair cables is based on the IEEE 802.3u standard (100 Base-TX). The transmission medium is a shielded 2x2 twisted-pair cable with an impedance of 100 Ohms (22 AWG). The transmission characteristics of this cable must meet the requirements of category 5.

The maximum length of the connection between the terminal and the network component must not exceed 100 m. The connectors are designed according to the 100Base-TX standard with the RJ-45 connector system.

UDP

User **D**atagram **P**rotocol; communications protocol for fast and uncomplicated data transfer, without acknowledgment. There are no error checking mechanisms as found in TCP/IP.

User program

In SIMATIC, a distinction is made between the CPU operating system and user programs. The user program contains all instructions, declarations and data by which a system or process can be controlled. The user program is assigned to a programmable module (for example, CPU, FM) and can be structured in smaller units.

USS

Universal Serial Interface protocol (**U**niverselles **S**erielles **S**chnittstellen-Protokoll); defines an access method according to the master-slave principle for communication via a serial bus.

Web server

Software/communications service for data exchange via the Internet. The web server transfers the documents using standardized transmission protocols (HTTP, HTTPS) to a Web browser. Documents can be static or put together dynamically from different sources by the web server on request from the Web browser.

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

⚠DANGER
indicates that death or severe personal injury **will** result if proper precautions are not taken.

⚠WARNING
indicates that death or severe personal injury **may** result if proper precautions are not taken.

⚠CAUTION
indicates that minor personal injury can result if proper precautions are not taken.

NOTICE
indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

⚠WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This function manual provides an overview of the PROFINET communication system with SIMATIC STEP 7 V15.

STEP 7 V15 is integrated into the high-performance graphical Totally Integrated Automation Portal (TIA Portal), the new integration platform for all automation software tools.

This function manual supports you in planning a PROFINET system. The manual is structured into the following subject areas:

- PROFINET basics
- PROFINET diagnostics
- PROFINET functions

Basic knowledge required

The following knowledge is required in order to understand the manual:

- General knowledge of automation technology
- Knowledge of the industrial automation system SIMATIC
- Knowledge about the use of Windows-based computers
- Knowledge about how to use STEP 7 (TIA Portal)

Scope

This documentation is the basic documentation for all SIMATIC products from the PROFINET environment. The product documentation is based on this documentation.

The examples are based on the functionality of the S7-1500 automation system.

What's new in the PROFINET Function Manual, Edition 10/2018 compared to Edition 12/2017

This manual (version 10/2018) includes the following new functions compared to the previous version (version 12/2017):

Function	Applications	Your benefits
PROFINET IO with the redundant S7-1500R/H system	In a PROFINET IO system with the redundant S7-1500R/H system, the IO communication continues even when one CPU fails.	The redundant S7-1500R/H system offers a high degree of reliability and system availability. A redundant configuration of the most important automation components reduces the probability of production downtimes and the consequences of component failures.

What's new in the PROFINET function manual, version 12/2017 compared to version 09/2016

This manual (version 12/2017) encompasses the following new functions compared to the previous version (version 09/2016):

Function	Applications	Your benefits
Specifying the router for a PROFINET IO device	You can specify the IP address of a router for each IO device. You reach the IO device from outside the IP subnet through the router.	In the past, it was only possible to specify a router for a PROFINET IO interface at the IO controller. The IO devices inherited the setting of the IO controller interface. Now you can set the router address independently of the IO controller setting. This allows, for example, a router address at the IO device although you have not set a router address or have set a different address at the IO controller.
Configuring an IO device through hardware detection	You can detect an existing IO device and enter it in your project.	STEP 7 inserts the IO device with all the modules and submodules into the project. Article numbers and firmware versions between real and configured IO devices match. You reduce the project planning work required.
Asset management	You can centrally manage non-PROFINET components (assets) of a PROFINET device. The PROFINET device makes the identification data of the assets available for evaluation via a standardized data record.	The new standardized PROFINET service makes it possible to manage all the hardware and firmware components of PROFINET devices centrally. The possibilities available for filtering device data, for example, depend on the range of performance of the evaluating application.
Asset management data record for I-devices	Special application of asset management: From the point of view of a higher-level IO controller, the modules plugged into the I-device represent assets. The user program in the I-device compiles the asset management data record. The IO controller can read identification data of the I-device modules through this data record.	See Asset management.

What's new in the PROFINET function manual, Version 09/2016 compared to Version 12/2014

This manual (version 09/2016) encompasses the following new functions compared to the previous version (version 12/2014):

Function	Applications	Your benefits
PROFINET IO on the 2nd PROFINET interface	You can operate another PROFINET IO system on the CPU or connect additional IO devices.	You use a fieldbus type in the plant. The CPU can perform fast and deterministic data exchange as an I-device with a higher-level controller (PROFINET/Ethernet) through the second line.
IRT with very short data cycle times down to 125 µs	You realize high-end applications with IO communication which place very high performance demands on the IO processing.	You make PROFINET IO communication and standard communication possible via one cable even with a send clock of 125 µs.
MRPD: Media Redundancy with Planned Duplication of frames	PROFINET IO IRT enables you to realize applications that place particularly high demands on the reliability and accuracy (isochronous mode).	By sending the cyclic IO data in both directions in the ring, the communication to the IO devices is maintained even when the ring is interrupted and does not result in device failure even with fast update times. You achieve higher reliability than with MRP.
PROFINET performance upgrade	You can implement applications with high speed and send clock requirements. This is of interest to applications with high demands on performance.	Better utilization of the bandwidth results in short reaction times.
Limitation of the data infeed into the network	You limit the network load for standard Ethernet communication to a maximum value.	You flatten peaks in the data feed. You share the remaining bandwidth based on demand.

Conventions

STEP 7: We refer to "STEP 7" in this documentation as a synonym for the configuration and programming software "STEP 7 as of V12 (TIA Portal)" and subsequent versions.

This documentation contains pictures of the devices described. The figures may differ slightly from the device supplied.

You should also pay particular attention to notes such as the one shown below:

Note

A note contains important information on the product, on handling of the product and on the section of the documentation to which you should pay particular attention.

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under (https://www.siemens.com/industrialsecurity).

Siemens Industry Online Support

You can find current information on the following topics quickly and easily here:

- **Product support**

  All the information and extensive know-how on your product, technical specifications, FAQs, certificates, downloads, and manuals.

- **Application examples**

  Tools and examples to solve your automation tasks – as well as function blocks, performance information and videos.

- **Services**

  Information about Industry Services, Field Services, Technical Support, spare parts and training offers.

- **Forums**

  For answers and solutions concerning automation technology.

- **mySupport**

  Your personal working area in Industry Online Support for messages, support queries, and configurable documents.

This information is provided by the Siemens Industry Online Support in the Internet (https://support.industry.siemens.com).

Industry Mall

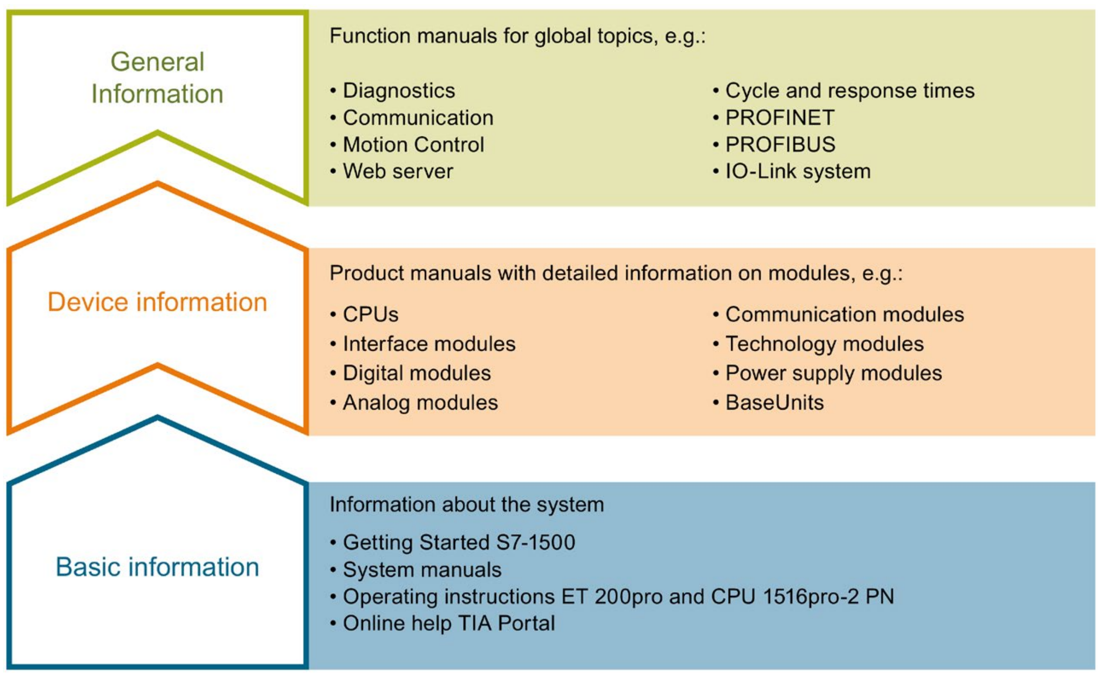
The Industry Mall is the catalog and order system of Siemens AG for automation and drive solutions on the basis of Totally Integrated Automation (TIA) and Totally Integrated Power (TIP).

You can find catalogs for all automation and drive products on the Internet (https://mall.industry.siemens.com).

Table of contents

Documentation guide 1

The documentation for the SIMATIC S7-1500 automation system, for CPU 1516pro-2 PN based on SIMATIC S7-1500, and for the distributed I/O systems SIMATIC ET 200MP, ET 200SP and ET 200AL is divided into three areas.
This division allows you easier access to the specific information you require.



Basic information

System manuals and Getting Started manuals describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, ET 200MP, ET 200SP and ET 200AL systems; use the corresponding operating instructions for CPU 1516pro-2 PN. The STEP 7 online help supports you in configuration and programming.

Device information

Product manuals contain a compact description of the module-specific information, such as properties, terminal diagrams, characteristics and technical specifications.

General information

The function manuals contain detailed descriptions on general topics such as diagnostics, communication, Motion Control, Web server, OPC UA.

You can download the documentation free of charge from the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742705).

Changes and additions to the manuals are documented in product information sheets.

You will find the product information on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/us/en/view/68052815)
- ET 200SP (https://support.industry.siemens.com/cs/us/en/view/73021864)
- ET 200AL (https://support.industry.siemens.com/cs/us/en/view/99494757)

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/ww/en/view/86140384)
- ET 200SP (https://support.industry.siemens.com/cs/ww/en/view/84133942)
- ET 200AL (https://support.industry.siemens.com/cs/ww/en/view/95242965)

"mySupport"

With "mySupport", your personal workspace, you make the best out of your Industry Online Support.

In "mySupport", you can save filters, favorites and tags, request CAx data and compile your personal library in the Documentation area. In addition, your data is already filled out in support requests and you can get an overview of your current requests at any time.

You must register once to use the full functionality of "mySupport".

You can find "mySupport" on the Internet (https://support.industry.siemens.com/My/ww/en).

"mySupport" - Documentation

In the Documentation area in "mySupport" you can combine entire manuals or only parts of these to your own manual.
You can export the manual as PDF file or in a format that can be edited later.

You can find "mySupport" - Documentation on the Internet (https://support.industry.siemens.com/My/ww/en/documentation).

"mySupport" - CAx data

In the CAx data area in "mySupport", you can access the current product data for your CAx or CAe system.

You configure your own download package with a few clicks.

In doing so you can select:

- Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files
- Manuals, characteristics, operating manuals, certificates
- Product master data

You can find "mySupport" - CAx data on the Internet (https://support.industry.siemens.com/my/ww/en/CAxOnline).

Application examples

The application examples support you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus on individual products.

You will find the application examples on the Internet (https://support.industry.siemens.com/sc/ww/en/sc/2054).

TIA Selection Tool

With the TIA Selection Tool, you can select, configure and order devices for Totally Integrated Automation (TIA).
This tool is the successor of the SIMATIC Selection Tool and combines the known configurators for automation technology into one tool.
With the TIA Selection Tool, you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet (https://w3.siemens.com/mcms/topics/en/simatic/tia-selection-tool).

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to run commissioning and maintenance activities simultaneously on different SIMATIC S7 stations as a bulk operation, independently of the TIA Portal.

The SIMATIC automation tool provides a variety of functions:

- Scanning of a PROFINET/Ethernet plant network and identification of all connected CPUs
- Address assignment (IP, subnet, gateway) and station name (PROFINET device) to a CPU
- Transfer of the date and programming device/PC time converted to UTC time to the module
- Program download to CPU
- Operating mode switchover RUN/STOP
- CPU localization by means of LED flashing
- Reading out CPU error information
- Reading of CPU diagnostic buffer
- Reset to factory settings
- Updating the firmware of the CPU and connected modules

You can find the SIMATIC Automation Tool on the Internet (https://support.industry.siemens.com/cs/ww/en/view/98161300).

PRONETA

With SIEMENS PRONETA (PROFINET network analysis), you analyze the plant network during commissioning. PRONETA features two core functions:

- The topology overview independently scans PROFINET and all connected components.
- The IO check is a fast test of the wiring and the module configuration of a plant.

You can find SIEMENS PRONETA on the Internet (https://support.industry.siemens.com/cs/ww/en/view/67460624).

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and optimal exploitation of resources

You can find SINETPLAN on the Internet (https://www.siemens.com/sinetplan).

Description 2

2.1 Introduction to PROFINET

What is PROFINET IO?

Within the framework of Totally Integrated Automation (TIA), PROFINET IO is the logical further development of:

- PROFIBUS DP, the established fieldbus and
- Industrial Ethernet

PROFINET IO is based on 20 years of experience with the successful PROFIBUS DP and combines the normal user operations with the simultaneous use of innovative concepts of Ethernet technology. This ensures the integration of PROFIBUS DP into the PROFINET world.

PROFINET IO as the Ethernet-based automation standard of PROFIBUS/PROFINET International defines a cross-vendor communication, automation, and engineering model.

Objectives of PROFINET

The objectives of PROFINET:

- Industrial networking, based on Industrial Ethernet (open Ethernet standard)
- Compatibility of Industrial Ethernet and standard Ethernet components
- High robustness due to Industrial Ethernet devices. Industrial Ethernet devices are suited to the industrial environment (temperature, noise immunity, etc.).
- Use of IT standards such as TCP/IP, http.
- Real-time capability
- Seamless integration of other fieldbus systems

Implementation of PROFINET in SIMATIC

PROFINET is implemented in SIMATIC as follows:

- We have implemented communication between field devices in SIMATIC with **PROFINET IO**.
- Installation technology and network components are available as SIMATIC NET products.
- Ethernet standard protocol and procedures (e.g., SNMP = Simple Network Management Protocol for network parameter assignment and diagnostics) are used for remote maintenance and network diagnostics.

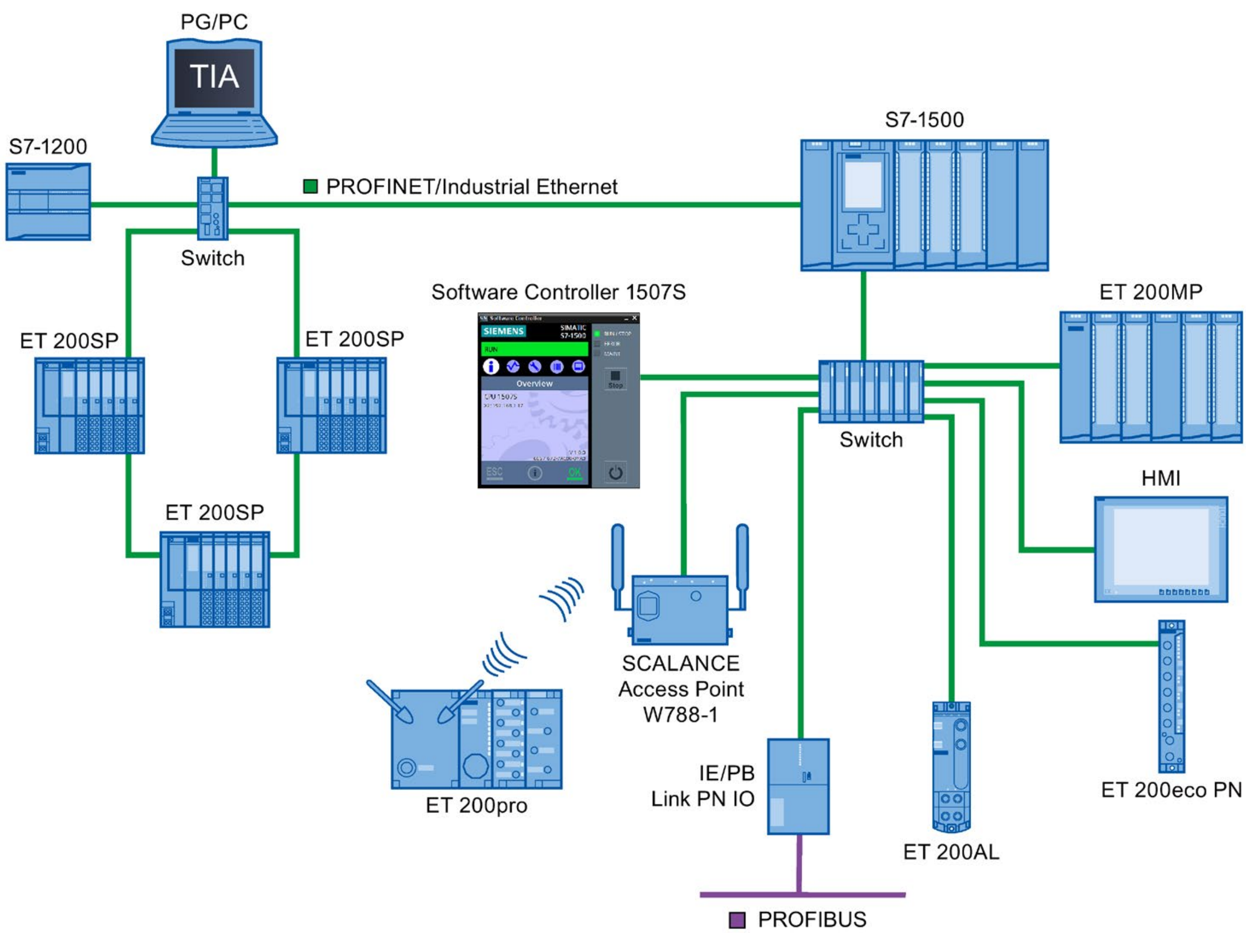


Figure 2-1 PROFINET overview configuration

STEP 7

The STEP 7 engineering tool supports you in setting up and configuring an automation solution. STEP 7 provides a uniform application view over all bus systems.

Documentation from PROFIBUS & PROFINET International on the Internet

You will find numerous documents on the topic of PROFINET at the Internet address (http://www.profibus.com) of the "PROFIBUS & PROFINET International" PROFIBUS user organization, which is also responsible for PROFINET.

Additional information can be found on the Internet (http://www.siemens.com/profinet).

Overview of the most important documents and links

A compilation of the most important PROFINET application examples, FAQs and other contributions in the Industry Online Support is available in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/108165711).

2.1.1 PROFINET terms

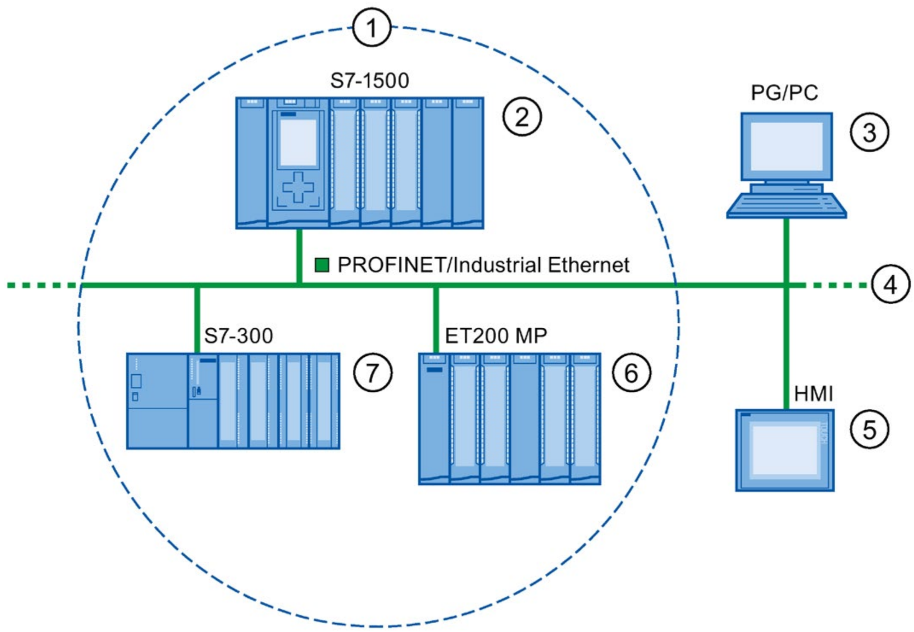
Definition: Devices in the PROFINET environment

In the PROFINET environment, "device" is the generic term for:

- Automation systems (PLC, PC, for example)
- Distributed I/O systems
- Field devices (for example, hydraulic devices, pneumatic devices)
- Active network components (for example, switches, routers)
- Gateways to PROFIBUS, AS interface or other fieldbus systems

PROFINET IO devices

The following graphic shows the general names used for the most important devices in PROFINET. In the table below the graphic you can find the names of the individual components in the PROFINET IO context.

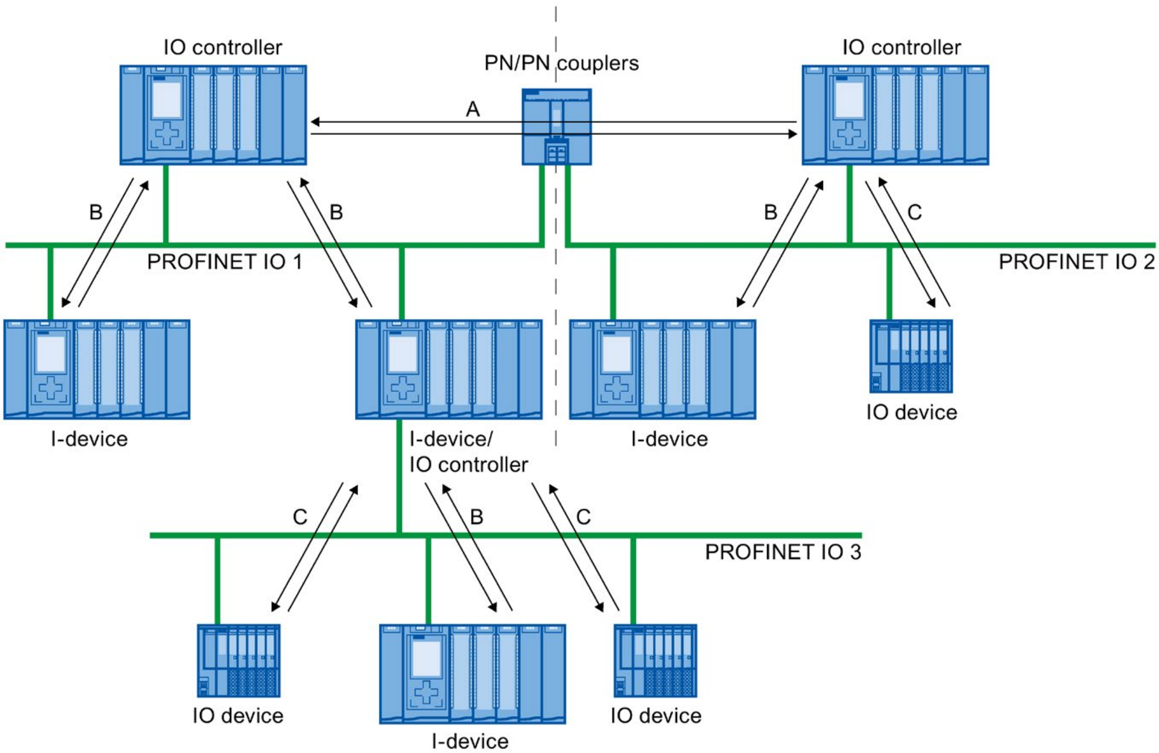


Number	PROFINET	Explanation
①	PROFINET IO System	
②	IO controller	Device used to address the connected IO devices. This means that: The IO controller exchanges input and output signals with field devices.
③	Programming device / PC (PROFINET IO supervisor)	PG/PC/HMI device used for commissioning and for diagnostics
④	PROFINET/Industrial Ethernet	Network infrastructure
⑤	HMI (Human Machine Interface)	Device for operating and monitoring functions.
⑥	IO device	A distributed field device that is assigned to one of the IO controllers (e.g., Distributed IO, valve terminals, frequency converters, switches with integrated PROFINET IO functionality)
⑦	I-device	Intelligent IO device

Figure 2-2 PROFINET devices

IO communication via PROFINET IO

The inputs and outputs of distributed I/O devices are read and written by means of PROFINET IO using what is referred to as IO communication. The following figure provides an overview of IO communication by means of PROFINET IO.



A IO controller - IO controller communication via PN/PN coupler

B IO controller - I-device communication

C IO controller - IO-device communication

Figure 2-3 IO communication via PROFINET IO

IO communication via PROFINET IO

Table 2- 1 IO communication via PROFINET IO

Communication between ...	Explanation
IO controllers and IO devices	The IO controller sends data cyclically to the IO devices of its PROFINET IO system and receives data from these devices.
IO controller and I-device	A fixed quantity of data is transferred cyclically between the user programs in CPUs of IO controllers and I-devices. The IO controller does not access the I/O module of the I-device, but instead accesses configured address ranges, i.e. transfer ranges, which may be located inside our outside the process image of the CPU of the I-device. If parts of the process image are used as transfer ranges, it is not permitted to use these for real I/O modules. Data transfer takes place using load- and transfer operations via the process image or via direct access.
IO controller and IO controller	A fixed quantity of data is cyclically transferred between the user programs in CPUs of IO controllers. A PN/PN coupler is required as additional hardware. The IO controllers mutually access configured address ranges, i.e. transfer ranges, which may be located inside or outside the process image of the CPU. If parts of the process image are used as transfer ranges, it is not permitted to use these for real I/O modules. Data transfer takes place using load- and transfer operations via the process image or via direct access.

Network security (Page 39)

Functions (Page 115)

2.1.2 Basic terminology of communication

PROFINET communication

PROFINET communication takes place via Industrial Ethernet. The following transmission types are supported:

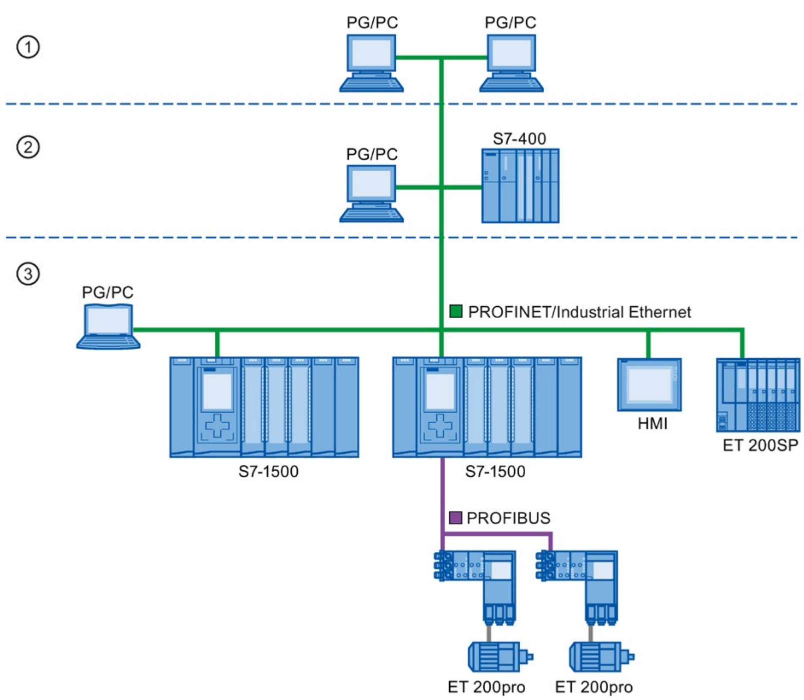
- Acyclic transmission of engineering and diagnostics data and interrupts
- Cyclic transmission of user data

The PROFINET-IO communication takes place in real-time.

For additional information on the real-time communication, refer to chapter Real-time communication (Page 182).

Transparent data access

Access to process data from different levels of the factory is supported by PROFINET communication. By using Industrial Ethernet, standard mechanisms of communication and information technology such as OPC/XML can now be used along with standard protocols such as UDP/TCP/IP and HTTP in automation engineering. This allows transparent access from company management level directly to the data from the automation systems at the control level and production level.



① Management level
② Control level
③ Production level

Figure 2-4 Access to process data

Update time

The update time is a time interval. IO controller and IO device/I-device exchange IO data cyclically in the IO system within this time interval. The update time can be configured separately for each IO device and determines the interval at which output data is sent from the IO controller to the IO device (output module/submodule) as well as input data from the IO device to the IO controller (input module/submodule).

STEP 7 calculates the update time automatically in the default setting for each IO device of the PROFINET IO system, taking into account the volume of data to be exchanged as well as the set send clock.

For additional information on the update time, refer to section Real-time communication (Page 182).

Watchdog time

The watchdog time is the time interval that an IO controller or IO device permits, without receiving IO data. If the IO device is not supplied by the IO controller with data within the watchdog time, the device detects the missing frames and outputs substitute values. This is reported in the IO controller as a station failure.

In STEP 7, the watchdog time is made up from an integral multiple of the update time and can be set by the user.

Send clock

The period of time between two consecutive communication cycles. The send clock is the shortest possible interval in data exchange.

Relationship between the update time and send clock

The calculated update times are reduction ratios (1, 2, 4, 8, ..., 512) of the send clock. The minimum possible update time thus depends on the minimum send clock of the IO controller that can be set and the efficiency of the IO controller and IO device. Depending on the send clock, it can be that only some of the reduction ratios are available (STEP 7 guarantees this through a pre-selection).
The following tables illustrate the dependency of the update time that can be set on the send clock, using an example of the CPU 1516-3 PN/DP. The update times satisfy the requirements of the PROFINET standard IEC 61158.

Table 2- 2 With real-time communication the following applies:

Send clock	Update time	Reduction ratios
250 µs	250 µs to 128 ms	1,2, ..., 512
500 µs	500 µs to 256 ms	1,2, ..., 512
1 ms	1 ms to 512 ms	1,2, ..., 512
2 ms	2 ms to 512 ms	1,2, ..., 256
4 ms	4 ms to 512 ms	1,2, ..., 128

Additional information

For information on real-time communication, refer to the section Real-Time Communication (RT) (Page 183).

2.1.3 PROFINET interface

Overview

PROFINET devices of the SIMATIC product family have one or more PROFINET interfaces (Ethernet controller/interface). The PROFINET interfaces have one or more ports (physical connection options).

In the case of PROFINET interfaces with multiple ports, the devices have an integrated switch.

PROFINET devices with two ports on one interface allow you to configure the system in a line or ring topology. PROFINET devices with three or more ports on one interface are also ideal for setting up tree topologies.

Properties and rules for naming the PROFINET interface and its representation in STEP 7 are explained in the following.

Properties

Every PROFINET device on the network is uniquely identified via its PROFINET interface. For this purpose, each PROFINET interface has:

- A MAC address (factory default)
- An IP address
- A PROFINET device name

Identification and numbering of the interfaces and ports

Interfaces and ports for all modules and devices in the PROFINET system are identified with the following characters:

Table 2- 3 Identification for interfaces and ports of PROFINET devices

Element	Symbol	Interface number
Interface	X	In ascending order starting from number 1
Port	P	In ascending order starting from number 1 (for each interface)
Ring port	R	

Examples of identification

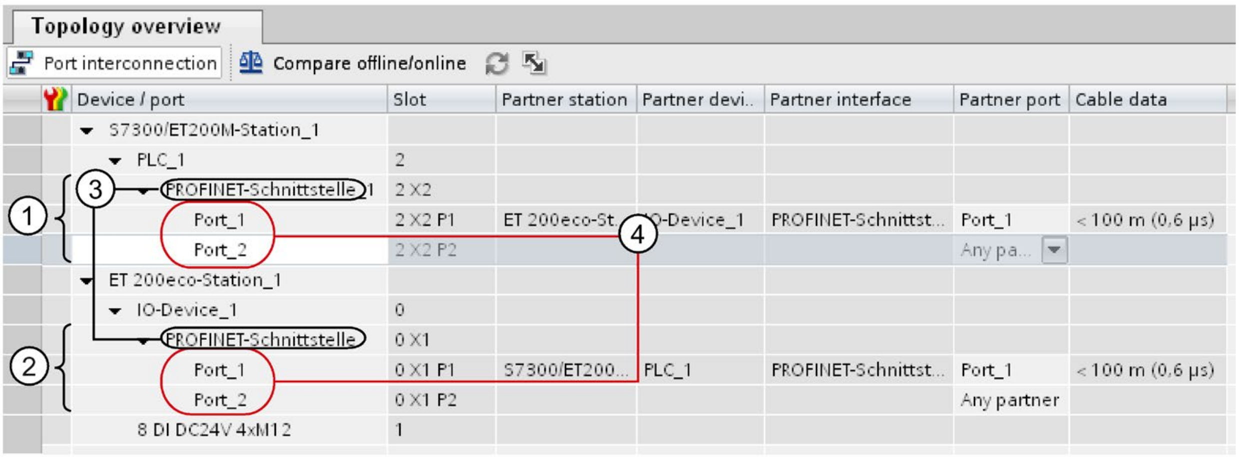
Three examples illustrate the rules for identifying PROFINET interfaces:

Table 2- 4 Examples for identifying PROFINET interfaces

Sample labeling	Interface number	Port number
X2 P1	2	1
X1 P2	1	2
X1 P1 R	1	1 (ring port)

Representation of PROFINET Interfaces in the Topology Overview in STEP 7

You can find the PROFINET interface in the topology overview in STEP 7. The PROFINET interface for an IO controller and an IO device is represented as follows in STEP 7:



Number	Description
①	PROFINET interface of an IO controller in STEP 7
②	PROFINET interface of an IO device in STEP 7
③	These lines represent the PROFINET interface.
④	These lines represent the "ports" of a PROFINET interface.

Figure 2-5 Representation of the PROFINET interfaces in STEP 7

Schematic Representation of a PROFINET Interface with Integrated Switch

The following schematic diagram shows the PROFINET interface with integrated switch and its ports for all PROFINETdevices.

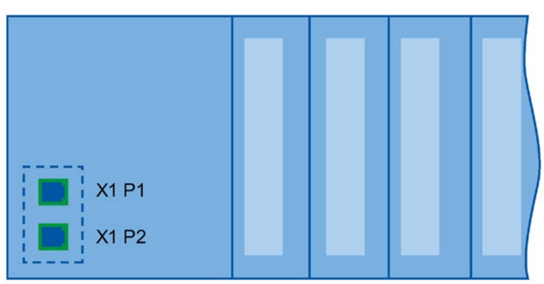


Figure 2-6 PROFINET interface with integrated switch

Functional differences of the PROFINET interfaces

PROFINET interfaces can provide different functions. PROFINET interface functions include identification, configuration, diagnostics and communication services (e.g., open communication). PROFINET interfaces that provide PROFINET IO functions and network security functions are also available.

The following table illustrates the differences using the example of the CPU 1516-3 PN/DP (as of firmware version V2.0), which features two PROFINET interfaces with different functionality.

Table 2- 5 Differences between the PROFINET interfaces of the CPU 1516-3 PN/DP (as of firmware version V2.0)

Additional Information on the Functionality of PROFINET interfaces

You can find information on the number and functionality of the interfaces of a PROFINET device in the documentation for the specificPROFINET device.

PROFINET communication services are described in the Communication function manual.

In the Network security section you can find components that are used to protect networks against hazards.

The Functions section describes the PROFINET IO functions.

2.1.4 Implementation of the PROFINET device model in SIMATIC

Slots and modules

A PROFINET device can have a modular and compact structure. A modular PROFINET device consists of slots into which the modules are inserted. The modules have channels which are used to read and output process signals. A compact device has the same design and can include modules, however, it cannot be physically expanded, which means that no modules can be inserted.

This is illustrated by the following graphic.

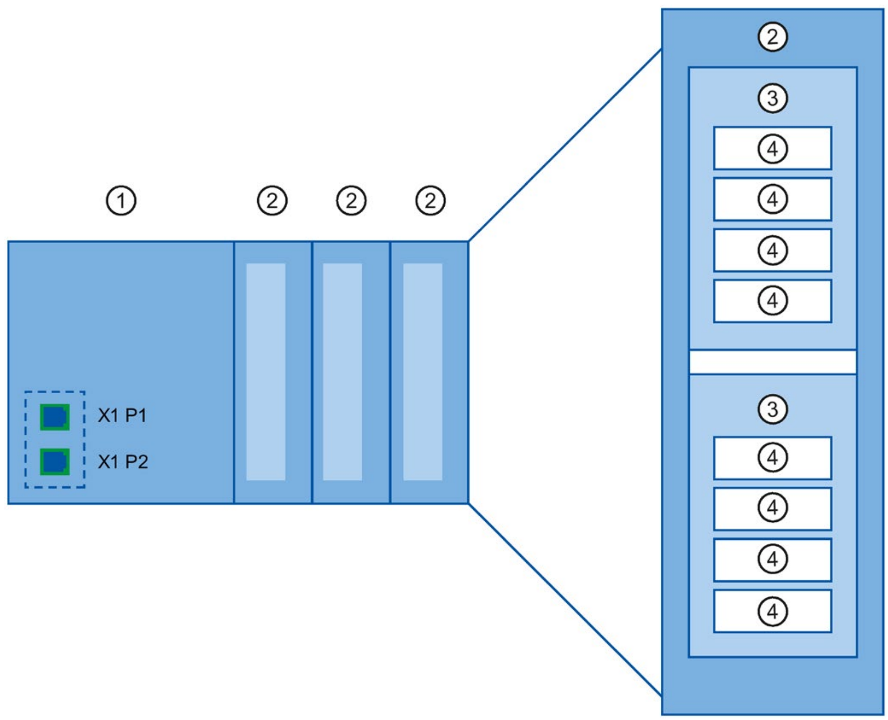

Figure 2-7 Configuration of a PROFINET device

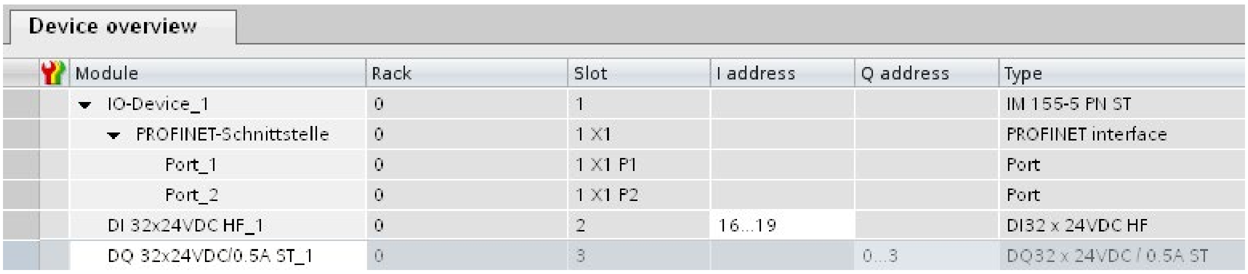
Number	Description
①	Slot with bus interface
②	Slot with module
③	Subslot with submodule
④	Channel

A module can contain multiple submodules.

Representation of PROFINET Device Model in the Device View of STEP 7

The following figure shows the representation of the PROFINET device model in the device view of STEP 7, based on the example of a distributed I/O system ET 200MP:



Device overview

Module	Rack	Slot	I address	Q address	Type
IO-Device_1	0	1			IM 155-5 PN ST
PROFINET-Schnittstelle	0	1 X1			PROFINET interface
Port_1	0	1 X1 P1			Port
Port_2	0	1 X1 P2			Port
DI 32x24VDC HF_1	0	2	16...19		DI32 x 24VDC HF
DQ 32x24VDC/0.5A ST_1	0	3		0...3	DQ32 x 24VDC / 0.5A ST

Figure 2-8 PROFINET device model in the device view of STEP 7

2.2 Setting up PROFINET

Contents of this chapter

The following chapter provides background information on building your communication network.

- Overview of the most important passive network components: These are network components that forward a signal without the possibility of actively influencing it, for example, cables, connectors, etc.
- Overview of the most important active network components: These are network components that actively affect a signal, for example switches, routers, etc.
- Overview of the most common network structures (topologies).

Physical connections of industrial networks

PROFINET devices can be networked in industrial systems in two different physical ways:

- Connected line
  - By means of electrical pulses via copper cables
  - By means of optical pulses via fiber-optic cables
- Wireless via wireless network using electromagnetic waves

PROFINET devices and cabling technology in SIMATIC are suited for industrial use, as they are based on Fast Ethernet and Industrial Ethernet.

- **Fast Ethernet**

  You can use Fast Ethernet to transfer data at a speed of 100 Mbps. This transmission technology uses the 100 Base-T standard for this.
- **Industrial Ethernet**

  Structure of Ethernet in industrial environment.

  The biggest difference from standard Ethernet is the mechanical current carrying capacity and noise immunity of the individual components.

2.2.1 Active Network Components

Introduction

The following active network components are available for PROFINET:

- Switch
- Router

Switched Ethernet

PROFINET IO is based on switched Ethernet with full-duplex operation and a bandwidth of 100 Mbps. In this way, the network can be used much more efficiently through the simultaneous data transfer of several devices. The PROFINET IO frames are processed with high priority.

Switches

Switches are network components used to connect several terminal devices or network segments in a local network (LAN).

For the communication of a device with several other devices on PROFINET, the device is connected to the port of a switch. Other communication devices (including switches) can then be connected to the other ports of the switch. The connection between a communication device and the switch is a point-to-point connection.

A switch has the task of receiving and distributing frames. The switch "learns" the Ethernet address(es) of a connected PROFINET device or additional switches and only forwards those frames that are intended for the connected PROFINET device or the connected switch.

Switch variants

Switches are available in two models:

- Integrated into a PROFINET device

  For PROFINET devices with multiple ports (two or more), we are dealing with devices with an integrated switch (for example, CPU 1516-3 PN/DP).
- As autonomous device (for example, switches of the SCALANCE product family)

Selection Guide for Switches

To use PROFINET with the RT class "RT", you can use any switch of "PROFINET Conformance Class A" or higher. All switches of the SCALANCE product family meet these requirements.

If you want to use PROFINET functions that provide an additional value, such as topology recognition, diagnostics, device exchange without exchangeable medium/programming device, you have to use a switch of the "PROFINET Conformance Class B" or higher.

To use PROFINET with the RT class "IRT", you must use a switch of "PROFINET Conformance Class C". With switches of the SCALANCE product family, watch out for the catalog feature "IRT PROFINET IO switch".

To select appropriate switches, we recommend the SIMATIC NET Selection Tool on the Internet (http://support.automation.siemens.com/WW/view/en/39134641).

Switches of the SCALANCE product family

Use the switches of the SCALANCE product family if you want to use the full scope of PROFINET. They are optimized for use in PROFINET IO.

In the SCALANCE X device family, you will find switches with electrical and optical ports and with a combination of both variants. SCALANCE X202-2IRT, for example, has two electrical ports and two optical ports and supports IRT communication.

Beginning with the SCALANCE X200, you can configure, diagnose and address switches of the SCALANCE X device series as PROFINET IO devices using STEP 7.

Router

A router connects separated network segments with each other (e.g. management level and control level). The volume of data volume must be coordinated with the services of the respective network segment. A router also separates two networks and acts as a mediator between both networks. It thus reduces the network load. Routing functionality is provided in the SCALANCE X device family, with SCALANCE X300 or higher.

Communication devices on different sides of a router can only communicate with one another if you have explicitly enabled communication between them via the router.

If you want to access manufacturing data directly from SAP, for example, use a router to connect your Industrial Ethernet in the factory with the Ethernet in your office.

Note

If devices need to communicate beyond the limits of a network, you must configure the router so that it allows this communication to take place.

Information on routing with STEP 7 is available in the function manual Communication (http://support.automation.siemens.com/WW/view/en/59192925).

2.2.2 Cabling technology

Cables for PROFINET

Electrical and optical cables are available for PROFINET. The type of cable depends on the data transfer requirements and on the ambient conditions.

Simple method for the prefabrication of twisted pair cables

When you set up your PROFINET system, you can cut the twisted-pair cable to the required length on site, strip it with the *stripping tool* (for Industrial Ethernet), and fit the *Industrial Ethernet Fast Connect RJ45 plugs* using the cut-and-clamp method. For more information on installation, refer to the installation instructions in the "SIMATIC NET Industrial Ethernet Network Manual" (http://support.automation.siemens.com/WW/view/en/8763736).

Note

A maximum of four plug-in pairs are allowed between two switches per Ethernet path.

Simple method for the prefabrication of fiber-optic cables

The FastConnect FO cabling system is available for the easy, fast and error-free prefabrication of fiber-optic cables. The glass-fiber optic cable consists of:

- FC FO Termination Kit for SC and BFOC plug (cleave tool, Kevlar scissors, buffer grip, fiber remains container)
- FC BFOC Plug
- FC SC Duplex plug

- PCF cable

  Prefabrication case IE Termination Kit SC RJ PCF plug

Overview of transmission media with PROFINET

The following table summarizes the technical specifications of a PROFINET interface with integrated switch or an external switch, and possible transmission media.

Table 2- 6 Transmission media with PROFINET

Physical properties	**Connection methods**	**Cable type / transmission medium** **standard**	**Transmission rate / mode**	**Max. segment length** (between two devices)	**Advantages**
Electrical	RJ45 connector ISO 60603-7	100Base-TX 2x2 twisted, symmetrical and shielded copper cable, CAT 5 transmission requirement IEEE 802.3	100 Mbps, full duplex	100 m	Simple and cheap cable connection
Optical	SCRJ 45 ISO/IEC 61754-24	100Base-FX POF fiber-optic cable (Polymer Optical Fiber, POF) 980/1000 µm (core diameter / external diameter) ISO/IEC 60793-2	100 Mbps, full duplex	50 m	Use when there are large differences in potential Insensitive towards electromagnetic radiation Low line attenuation Considerably longer segments possible[1]
		Plastic-cladded glass fiber (Polymer Cladded Fiber, PCF) 200/230 µm (core diameter / external diameter) ISO/IEC 60793-2	100 Mbps, full duplex	100 m	
	BFOC (Bayonet Fiber Optic Connector) and SC (Subscriber Connector) ISO/IEC 60874	Monomode glass fiber optic cable 10/125 µm (core diameter / external diameter) ISO/IEC 60793-2	100 Mbps, full duplex	26 km	
		Multimode glass fiber optic cable 50/125 µm and 62.5/125 µm (core diameter / external diameter) ISO/IEC 9314-4	100 Mbps, full duplex	3000 m	
Electromagnetic waves	-	IEEE 802.11 x	Depends on the extension used (a, g, h, etc.)	100 m	Greater mobility Cost-effective networking to remote, difficult to access devices

Assembly Instructions for SIMATIC NET Industrial Ethernet (http://support.automation.siemens.com/WW/view/en/27069465)

PROFINET Installation Guideline (http://www.profibus.com/nc/download/installation-guide/downloads/profinet-installation-guide/display/)

2.2.3 Wireless design

2.2.3.1 Basics

What is Industrial Wireless LAN?

In addition to data communication in accordance with the IEEE 802.11 standard, the SIMATIC NET Industrial Wireless LAN provides a number of enhancements which offer significant benefits for industrial customers. IWLAN is particularly suitable for demanding industrial applications that require reliable wireless communication. This is supported by the following properties:

- Automatic roaming when the connection to Industrial Ethernet is interrupted (Forced Roaming)
- Cost savings generated by using a single wireless network for reliable operation of a process with both process-critical data (alarm message, for example) and non-critical communication (service and diagnostics, for example)
- Cost-effective connection to devices in remote environments that are difficult to access
- Predictable data traffic (deterministic) and defined response times
- Cyclical monitoring of the wireless link (link check)

Objectives and advantages of Industrial Wireless LAN

Wireless data transmission achieves the following objectives:

- Seamless integration of PROFINET devices into the existing bus system via the wireless interface
- Mobile use of PROFINET devices for different production-linked tasks
- Flexible configuration of the system components for fast development in accordance with customer requirements
- Maintenance costs are minimized by savings in cables

Application examples

- Communication with mobile subscribers (mobile controllers and devices, for example), conveyor lines, production belts, translation stages , and rotating machines
- Wireless coupling of communication segments for fast commissioning or cost-effective networking where routing of wires is extremely expensive (e.g. public streets, railroad lines)
- Stacker trucks, automated guided vehicle systems and suspended monorail systems

The following graphic illustrates the many possible applications and configurations for SIMATIC device family wireless networks.

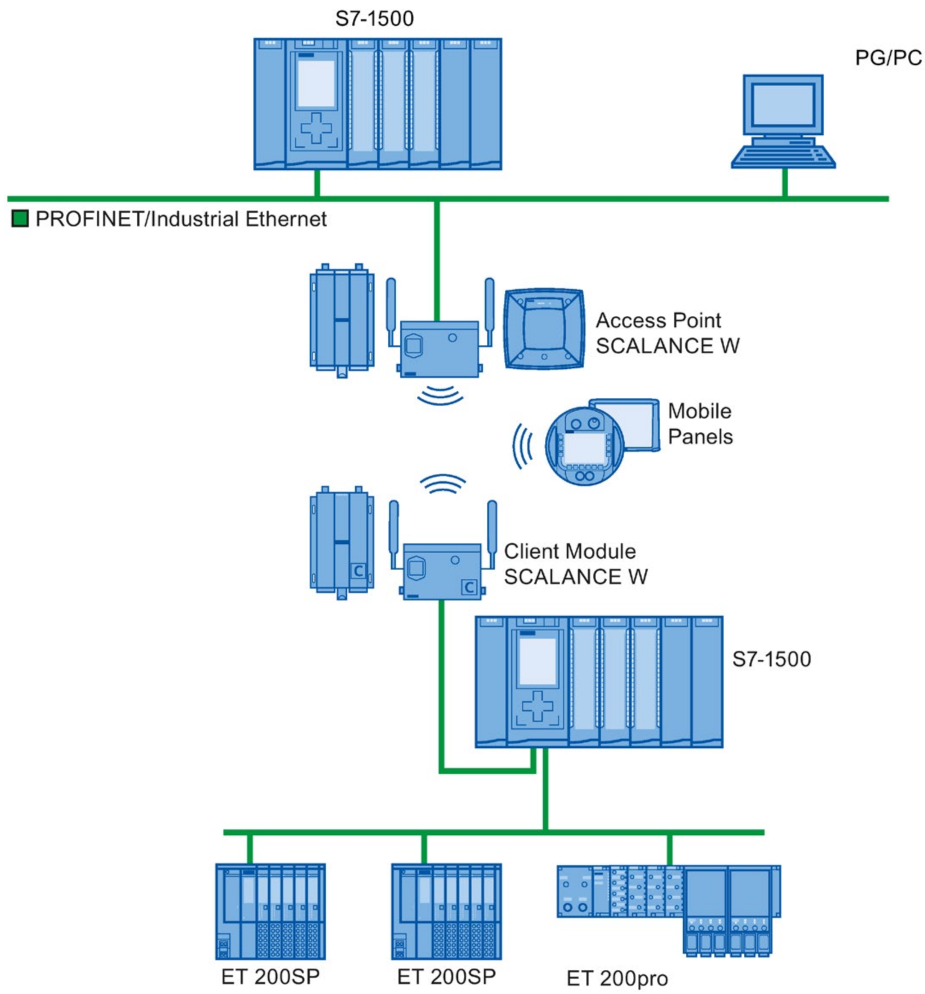

Figure 2-9 Application example for the use of Industrial Wireless LAN

Data transmission rate

In Industrial Wireless LAN, gross data transmission rates of 11 Mbps or 54 Mbps without full duplex are permitted.

Range

With SCALANCE W (access points), wireless networks can be set up indoors and outdoors. Multiple access points can be installed to create large wireless networks in which mobile subscribers are transferred seamlessly from one access point to another (roaming).

As an alternative to a wireless network, point-to-point connections of Industrial Ethernet segments can also be set up over large distances (several hundred meters). In this case, the range and characteristics of the RF field are determined by the antennas used.

Note

Range

The range can be considerably less, depending on spatial factors, the wireless standard used, the data rate, and the antennas on the send and receive sides.

2.2.3.2 Tips on assembly

Wireless networks, SCALANCE device family

With PROFINET, you can also set up wireless networks with Industrial Wireless Local Area Network (IWLAN) technology. We recommend implementing the SCALANCE W device line for this.

Update time in STEP 7

If you set up PROFINET with Industrial Wireless LAN, you may have to increase the update time for the wireless devices. The IWLAN interface provides lower performance than the wired data network: Several communication stations have to share the limited transmission bandwidth. For wired solutions, 100 Mbps is available for each communication device.

The Update time parameter can be found in the "Realtime settings" section in the Inspector window of IO devices in STEP 7.

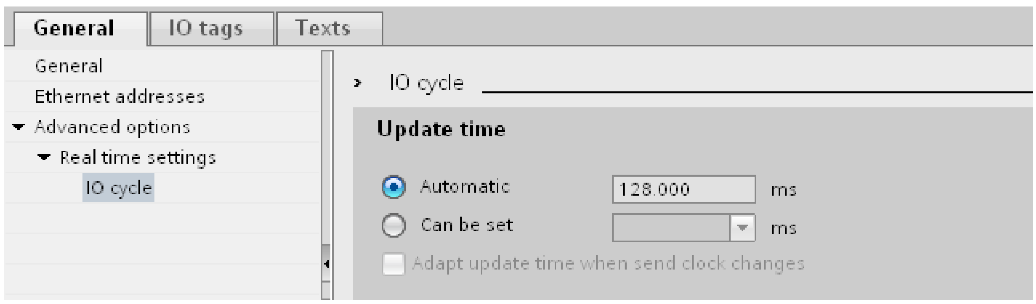

Figure 2-10 Update time in STEP 7

Additional information

More information about SCALANCE W Industrial Wireless LAN components can be found in the manual SIMATIC NET SCALANCE W-700 (http://support.automation.siemens.com/WW/view/en/42784493).

More information about wired data transmission can be found in the manual SIMATIC NET Twisted Pair and Fiber Optic Networks (http://support.automation.siemens.com/WW/view/en/8763736).

More information about wireless data transmission can be found in the manual Basics for configuring an industrial wireless LAN (http://support.automation.siemens.com/WW/view/en/9975764).

You should also read the PROFINET installation guideline of the PROFIBUS User Organization on the Internet (http://www.profibus.com/nc/download/installation-guide/downloads/profinet-installation-guide/display/). Various documents that assist with the setting up of your PROFINET automation solution are available here:

- PROFINET planning guideline
- PROFINET installation guideline
- PROFINET commissioning guideline
- Additional documents for setup of PROFINET

2.2.4 Network security

2.2.4.1 Basics

Introduction

The topic of data security and access protection (Security) has become increasingly important in the industrial environment. The increased networking of entire industrial systems, vertical integration and networking of levels within a company and new techniques such as remote maintenance all result in higher requirements for protecting the industrial plant.

Data security solutions for office environments cannot simply be transferred one-to-one to industrial applications to protect against manipulation in sensitive systems and production networks.

Requirements

Additional security requirements arise from the specific communication requirements in the industrial environment (real-time communication, for example):

- Protection against interaction between automated cells
- Protection of network segments
- Protection against faulty and unauthorized access
- Scalability of network security
- Must not influence the network structure

Definition of security

Generic term for all the measures taken to protect against:

- Loss of confidentiality due to unauthorized access to data
- Loss of integrity due to manipulation of data
- Loss of availability due to destruction of data, for example, through faulty configuration and denial-of-service attacks

Threats

Threats can arise from external and internal manipulation. The loss of data security is not always caused by intentional actions.

Internal threats can arise due to:

- Technical errors
- Operator errors
- Defective programs

Added to these internal threats there are also external ones. The external threats are not really any different to the known threats in the office environment:

- Software viruses and worms
- Trojans
- Man-in-the-middle attacks
- Password Phishing
- Denial of Service

Protective measures

The most important precautions to prevent manipulation and loss of data security in the industrial environment are:

- Filtering and control of data traffic by means of firewall
- A virtual private network (VPN) is used to exchange private data on a public network (Internet, for example).

  The most common VPN technology is IPsec. IPsec (Internet Protocol Security) is a collection of security protocols that are used as the basis for the IP protocol at the mediation level and allow a secured communication via potentially unsecure IP networks.
- Segmenting in protected automation cells

  This concept has the aim of protecting the lower-level network devices by means of security modules. A group of protected devices forms a protected automation cell.
- Authentication (identification) of the devices

  The security modules identify each other over a safe (encrypted) channel using authentication procedures. It is therefore impossible for unauthorized parties to access a protected segment.
- Encrypting the data traffic

  The confidentiality of data is ensured by encrypting the data traffic. Each security module is given a VPN certificate which includes the encryption key.

2.2.4.2 Network components and software

Protection against unauthorized access

The following solutions may be used to connect industrial networks to the intranet and Internet to protect against internal and external threats:

- Communication processors, such as the SIMATIC CP 1543-1
- SCALANCE X-300 and SCALANCE S - the data security components of the SIMATIC NET product family
- SOFTNET security client for use on PCs

Features

Both of these products have a wide variety of features, such as:

- Easy integration of existing networks without configuration, with integrated firewall.
- Segmenting in protected automation cells
- Authentication (identification) of the devices
- Encrypting the data traffic

2.2.4.3 Application example

Data security at the office and production levels

The following graphic contains an application example with protected areas at different levels of the company created using SCALANCE S and the security client. The protected areas are highlighted in light gray.

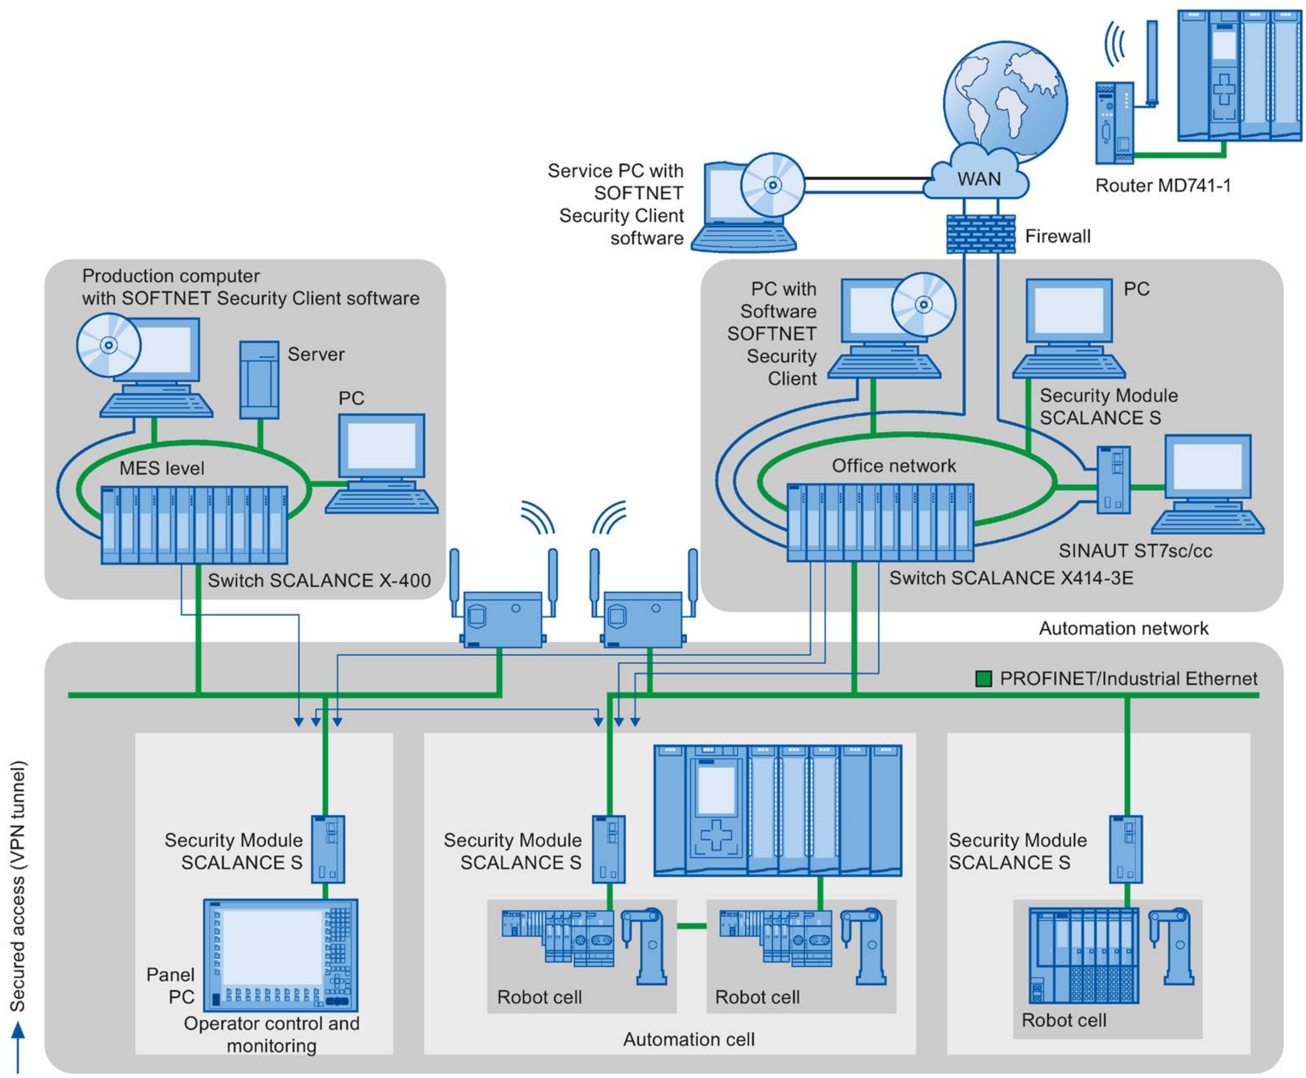

Figure 2-11 Network configuration with the SCALANCE S security module and the SOFTNET security client

Additional information

Additional information on the configuration of a security standard in PROFINET, is available:

- In the PROFINET security guideline. These guidelines can be found on the homepage of the PROFIBUS user organization on the Internet (http://www.profinet.com).
- In the Industrial Ethernet Security (http://support.automation.siemens.com/WW/view/en/56577508) manual
- In the SCALANCE S and SOFTNET Security Client (http://support.automation.siemens.com/WW/view/en/21718449) manual

You can find general information on industrial security concepts, functions and news on the Industrial Security website (http://www.siemens.com/industrialsecurity).

Parameter assignment/addressing 3

To set up an automation system, you will need to configure, assign parameters and interlink the individual hardware components. In STEP 7, the work needed for this is undertaken in the device, topology and network view.

Configuring

"Configuring" is understood to mean arranging, setting and networking devices and modules within the device, topology or network view.

An I/O address is automatically assigned to each module. The I/O addresses can be subsequently modified.

The CPU compares the configuration preset in STEP 7 with the actual current configuration of the system. In this way, potential errors can be detected and reported straight away.

The exact procedure for configuring devices is described in detail in the STEP 7 online help.

Assigning parameters

"Assigning parameters" is understood to mean setting the properties of the components used. The settings for the hardware components and for data communication are configured at the same time.

In STEP 7, you can "assign parameters" for the following settings PROFINET:

- Device names and IP address parameters
- Port interconnection and topology
- Module properties / parameters

The parameters are loaded into the CPU and transferred to the corresponding modules when the CPU starts up. Modules are easy to replace from spare parts, as the parameters assigned for the SIMATIC CPUs are automatically loaded into the new module at each startup.

Adjusting the hardware to the project requirements

You need to configure hardware if you want to set up, expand or change an automation project. To do this, add hardware components to your structure, link these with existing components, and adapt the hardware properties to the tasks.

The properties of the automation systems and modules are preset such that in many cases they do not have to be assigned parameters again.

Parameter assignment is however needed in the following cases:

- You want to change the default parameter settings of a module.
- You want to use special functions.
- You want to configure communication connections.

3.1 Assigning an IO device to an IO controller

PROFINET IO System

A PROFINET IO system is comprised of a PROFINET IO controller and its assigned PROFINET IO devices. After these devices have been placed in the network or topology view, STEP 7 assigns default values for them. Initially, you only have to worry about the assignment of IO devices to an IO controller.

Requirement

- You are in the network view of STEP 7.
- A CPU has been placed (e.g., CPU 1516-3 PN/DP).
- An IO device has been placed (e.g., IM 155-6 PN ST).

Procedure

To assign IO devices to an IO controller, proceed as follows:

1. Place the pointer of the mouse over the interface of the IO device.
2. Press and hold down the left mouse button.
3. Move the pointer.

   The pointer now uses the networking symbol to indicate "Networking" mode. At the same time, you see the lock symbol on the pointer. The lock symbol disappears only when the pointer is over a valid target position.

4. Now move the pointer onto the interface of the IO controller. You can keep the left mouse button pressed or release it when performing this action.
5. Now release the left mouse button or press it again (depending on your previous action).

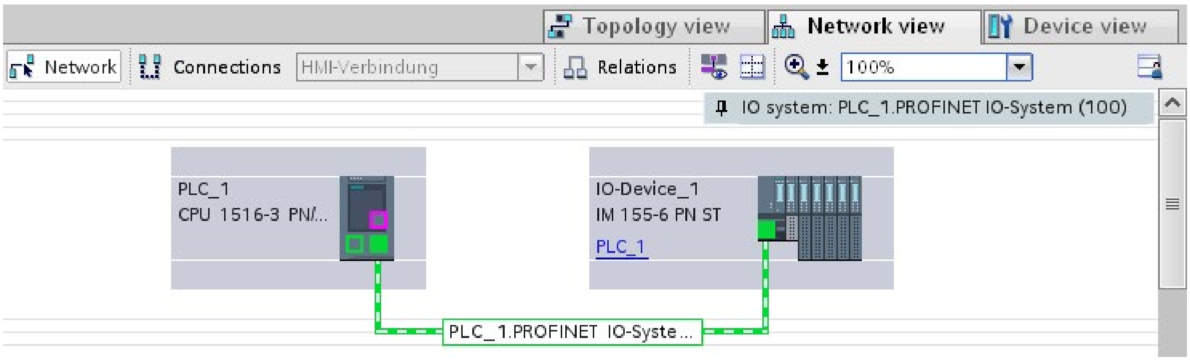

Figure 3-1 Assigning an IO device to an IO controller in the network view of STEP 7

Result

You have assigned an IO device to an IO controller.

Checking the assignment

You can find an overview of the communication relationships in the "IO communication" tab in the tabular area of the network view. This table is context-sensitive for selection in the graphic area:

- Selection of the interface shows the I/O communication of the respective interface.
- Selection of the CPU shows all I/O communication of the CPU (including PROFIBUS).
- Selection of the station (as in the above figure) interface shows the I/O communication of the complete station.

Information on S7-1500R/H

You can find the procedure for assigning an IO device with system redundancy S2 to the redundant S7-1500R/H system in section Configuring an IO device with system redundancy S2 in the redundant S7-1500R/H system (Page 282).

3.2 Device name and IP address

Introduction

In order that the PROFINET device can be addressed as node on PROFINET, the following are required:

- A unique PROFINET device name
- A unique IP address in the relevant IP subnet

STEP 7 assigns a device name during the arrangement of a PROFINET device in the hardware and network editor. The IP addresses are typically assigned automatically by STEP 7 and assigned to the devices based on the device name.

You can change the name and IP address manually.

In STEP 7

You can find the device name and the IP address under "Ethernet addresses" in the properties of the PROFINET interface in the Inspector window.

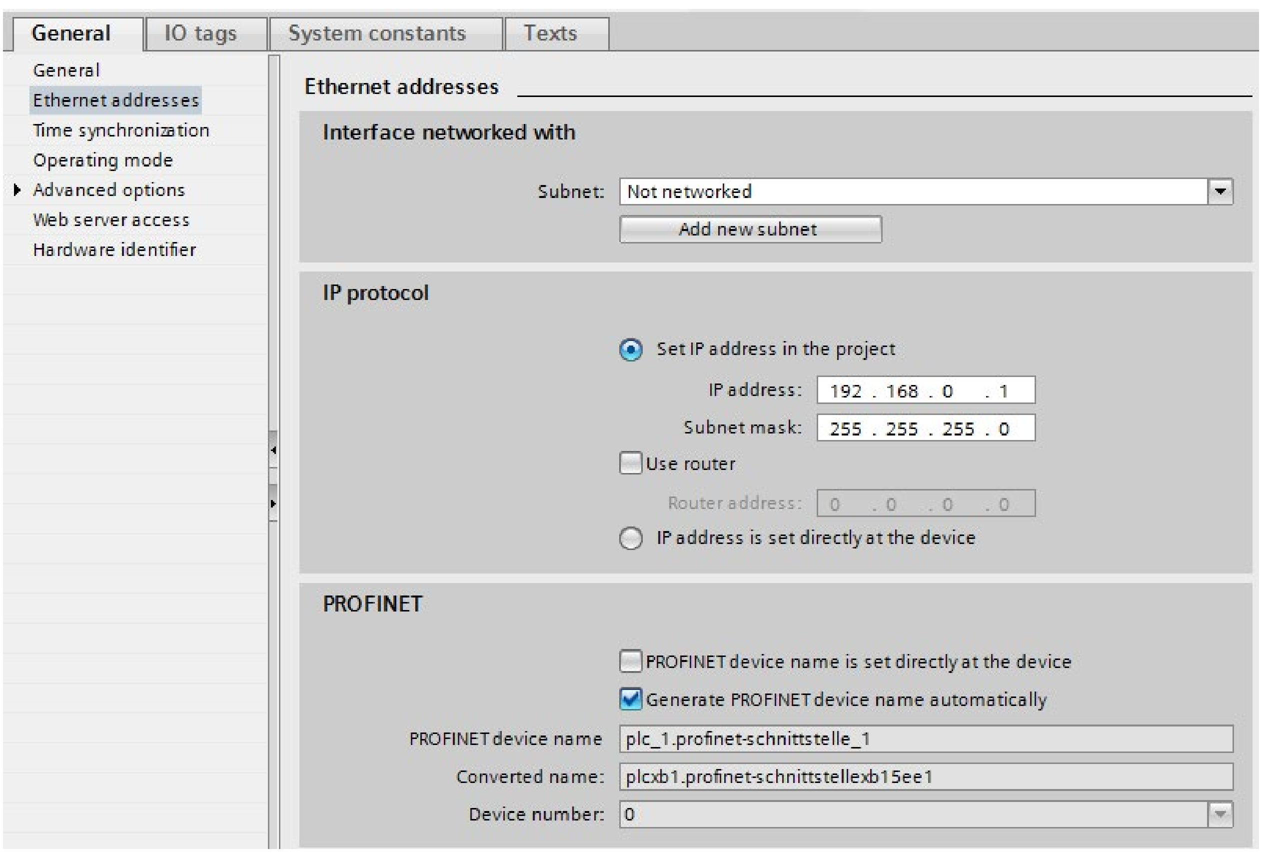

Figure 3-2 Device name and IP address in STEP 7

The function, the assignment and the changing of the device name and the IP address are described in the following sections.

3.2.1 Device name

Device names

Before an IO device can be addressed by an IO controller, it must have a device name. In PROFINET, this method was selected because it is simpler to work with names than with complex IP addresses.

The assignment of a device name for a specific IO device can be compared to setting the PROFIBUS address of a DP slave.

In delivery state, an IO device does not have a device name. A device name must first be assigned before an IO device can be addressed by an IO controller, for example, for transferring configuration data during startup or for exchanging user data in cyclic mode. You assign the device names to the IO device, for example, with the programming device / PC.

IO devices that have a slot for removable storage media provide the option of writing the device name directly to the removable storage medium in the programming device.

When a device is replaced by a device without removable medium, the IO controller assigns the device name based on topological configuration (see section Configuring topology (Page 68)).

Structured device names

The device name is automatically assigned by default for PROFINET devices S7-1200, S7-1500, ET 200MP, ET 200SP and ET 200AL when these are configured in STEP 7. The device names are formed from the name of the CPU or the name of the interface module. For devices with several PROFINET interfaces, the name of the interface is enhanced, for example, "plc_1.profinet-interface_2" or "io-device_1".

You can structure the device names using DNS conventions.

These conventions are defined by "Internationalizing Domain Names in Applications (IDNA). According to this, device names are written in lower case.

The "Domain Name System" (DNS) is a distributed database (http://iana.org), which manages the name space on the Internet. To structure the names, you use the dot ("."). The hierarchy is shown in ascending order from left to right.

...<Subdomain name>.<Domain name>.<Top-level domain name>

If the name is not DNS-compliant, the name will be converted by STEP 7, for example, to "plcxb1.profinet-schnittstellexb2022c" or "io-devicexb15b32".

Device number

In addition to the device name, STEP 7 also assigns a device number beginning with "1" when an IO device is allocated.

The device number is located in the Inspector window in the properties of the PROFINET interface, under "Ethernet addresses" in the area PROFINET.

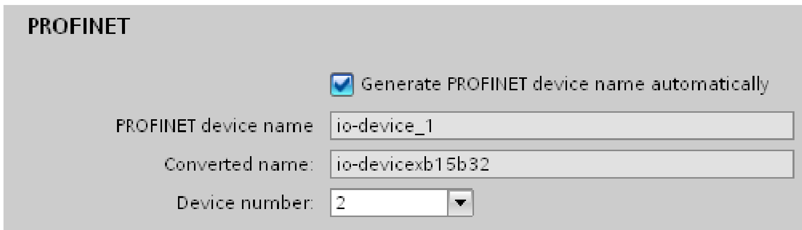

Figure 3-3 Device number

This device number can be used to identify an IO device in the user program (for example, with the instruction "LOG2GEO").

3.2.2 IP address

IP address

To allow a PROFINET device to be addressed as a device on Industrial Ethernet, this device also requires an IP address that is unique within the network. The IP addresses are typically assigned automatically by STEP 7 and assigned to the devices based on the device name. If it is a standalone network, you can apply the IP address and subnet mask suggested by STEP 7. If the network is part of an existing Ethernet company network, obtain the information from your network administrator.

Configuration of the IP address

In accordance with Internet Protocol version 4 (IPv4), the IP address is made up of four decimal numbers with a range of values from 0 through 255. The decimal numbers are separated by periods (for example, 192.162.0.0).

The IP address consists of the following:

- Address of the network
- Address of the device (PROFINET interface of the IO controller/IO device)

Generating IP addresses

The IP addresses of the IO devices are generated by STEP 7 and first assigned to the IO devices when the CPU starts up. In addition, for some IO devices (e.g., SCALANCE X, S7-300 CPs), it is possible not to obtain the IP address during startup of the IO controller, but rather to set it beforehand on the device (see Permitting changes to the device name and IP address directly on the device (Page 60)).

The IP addresses of the IO devices always have the same subnet mask as the IO controller and are assigned from the IP address of the IO controller in ascending order. The IP address can be changed manually, if necessary.

For devices with several PROFINET interfaces (e.g., CPU 1516-3 PN/DP), the IP addresses must be located in different subnets.

Default router

The default router is used when data has to be forwarded via TCP/IP or UDP to a partner located outside the local network.

In STEP 7, the default router is named Router. You can activate the use of a router in the Inspector window of a CPU with the "Use router" check box in the "IP protocol" section. STEP 7 assigns the local IP address to the default router by default.

The router address that is set on the PROFINET interface of the IO controller is automatically transferred for the configured IO devices.

Subnet mask

The bits set in the subnet mask decide the part of the IP address that contains the address of the network.

In general, the following applies:

- The network address is obtained from the AND operation of the IP address and subnet mask.
- The device address is obtained from the AND NOT operation of the IP address and subnet mask.

Example of the subnet mask

Subnet mask: 255.255.0.0 (decimal) = 11111111.11111111.00000000.00000000 (binary)

IP address: 192.168.0.2 (decimal) = 11000000.10101000.00000000.00000010 (binary)

Meaning: The first 2 bytes of the IP address determine the network - i.e., 192.168. The last two bytes address the device, i.e. 0.2.

Relation between IP address and default subnet mask

An agreement exists relating to the assignment of IP address ranges and so-called "Default subnet masks". The first decimal number (from the left) in the IP address determines the structure of the default subnet mask with respect to the number of "1" values (binary) as follows:

IP address (decimal)	IP address (binary)	Address class	Default subnet mask
0 to 126	0xxxxxxx.xxxxxxxx....	A	255.0.0.0
128 to 191	10xxxxxx.xxxxxxxx...	B	255.255.0.0
192 to 223	110xxxxx.xxxxxxxx...	C	255.255.255.0

Note

Range of values for the first decimal point

A value between 224 and 255 is also possible for the first decimal number of the IP address (address class D etc.). However, this is not recommended because there is no address check for these values.

Masking other subnets

You can use the subnet mask to add further structures and form "private" subnets for a subnet that is assigned one of the address classes A, B or C. This is done by setting other, less significant bits of the subnet mask to "1". For each bit set to "1", the number of "private" networks doubles and the number of devices they contain is halved. Externally, the network continues to function as an individual network.

Example:

You have a subnet of address class B (for example, IP address 129.80.xxx.xxx) and change the default subnet mask as follows:

Masks	Decimal	Binary
Default subnet mask	255.255.0.0	11111111.11111111.00000000. 00000000
Subnet mask	255.255.128.0	11111111.11111111.10000000. 00000000

Result:

All devices with addresses from 129.80.001.000 to 129.80.127.254 are located in a subnet, all devices with addresses from 129.80.128.000 to 129.80.255.254 in a different subnet.

Reading out an IP address in the user program

You can read out the IP address of a PROFINET device in the user program of a S7-1500 CPU. You can find information in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/82947835).

3.2.3 Assigning a device name and IP address

Assigning an IP address and subnet mask for an IO controller for the first time

You have the following options:

- **Using a programming device or PC:**

  Connect your programming device/PC to the same network as the relevant PROFINET device. The interface of the programming device/PC must be set to TCP/IP mode. During the download, first of all display all available devices via the "Accessible devices" download dialog box. Select the target device via its MAC address and then assign its IP address before you download the hardware configuration including the configured IP address (IP address is saved retentively).

- **Using the display of a S7-1500 CPU:**

  The S7-1500 CPUs have a front cover with a display and operating keys. You can use this display to assign or change the IP address. To set the IP address, navigate on the display via the menu items "Settings" > "Addresses" > "X1 (IE/PN)" > "Parameters".

- **Using a memory card:**

  If your PROFINET device is equipped for a memory card (Micro Memory Card/SIMATIC memory card), plug this into your programming device/PC and save the hardware configuration together with the configured IP address on this memory card. Then plug the memory card into the PROFINET device. Once inserted, the PROFINET device automatically applies the IP address.

  If you have saved a configuration to the memory card with the "IP address is set directly at the device" option, you must assign the IP address using a different method after inserting the memory card (see section Permitting changes to the device name and IP address directly on the device (Page 60)).

Assigning device names and IP address for "Device replacement without exchangeable medium/programming device"

For devices without exchangeable medium (e.g., ET 200MP, ET 200SP) and devices that support "Device replacement without exchangeable medium/PG" (e.g., ET 200S), the IO controller can identify the device without name from the neighbor relationships specified by the set topology and from actual neighbor relationships determined by the real PROFINET devices. The IO controller then assigns the PROFINET device the configured name and incorporates the PROFINET device in the user data traffic. (See also Device replacement without exchangeable medium (Page 222)).

IP address assignment when replacing IO devices with exchangeable mediumPG

The following is contained on the memory card of the programmable logic controller:

- On the IO controller: Device name and IP address
- On the IO device: Device name

When you remove the memory card from a PROFINET device and insert it in another PROFINET device with exchangeable medium (e.g., ET 200S), device-specific information and the device name are loaded to the device.

If an IO device has to be replaced in its entirety due to a device or module defect, the IO controller automatically assigns parameters and configures the replaced device or module. The cyclic exchange of user data is then restarted. In addition to this, before the power ON of the IO device, the memory card with the valid name must be removed from the faulty IO device and added to the replaced device.

In the event of an error in the PROFINET device, the memory card allows you to replace a module without a programming device/PC. You can also transfer the device data directly from the programming device/PC to the memory card.

Procedure: Changing the device name using properties of the PROFINET interface

You can change the PROFINET name via the properties of the PROFINET interface. This is useful when the PROFINET device has not received its previous name from the automatic generation, for example, in the case of a migration.

1. In the network or device view of the STEP 7 hardware and network editor, select the PROFINET interface of a PROFINET device.
2. In the Inspector window, go to "Ethernet addresses" in the PROFINET area.
3. Clear the "Generate PROFINET device name automatically" check box.
4. Enter the new PROFINET device name in the relevant field.

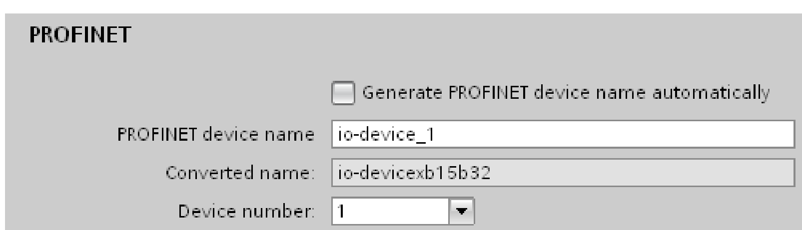

Figure 3-4 Changing the device name of a PROFINET device in the properties

Alternative procedure: Changing the device name of a PROFINET device in the network view

Requirement: The "Generate PROFINET device name automatically" check box is selected.

1. In STEP 7, select the "Network overview" tab in the tabular area of the network view.
2. In the "Device" column, overwrite the name in the row of the relevant PROFINET device.

The name is also changed accordingly in the graphic area of the network view.

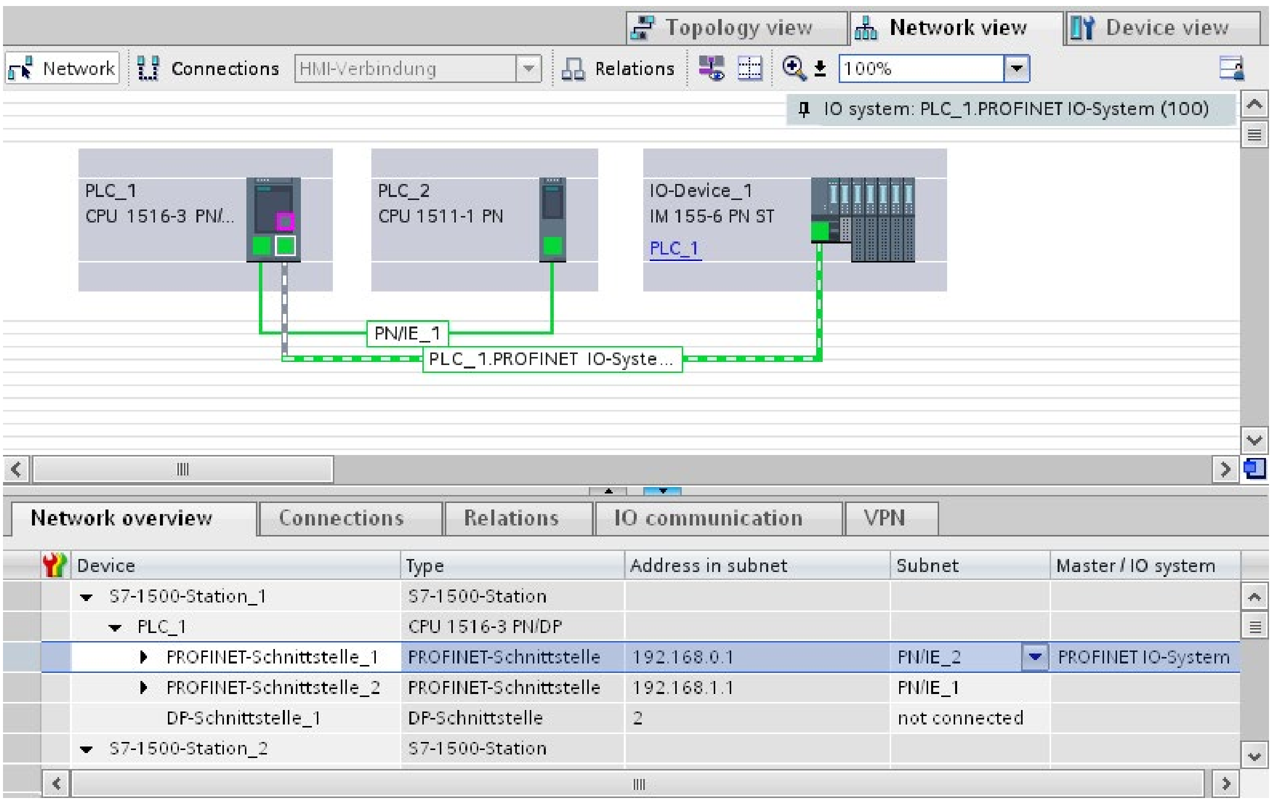

Figure 3-5 Changing the device name of a PROFINET device in STEP 7

Procedure: Changing the IP address

To change the IP address, follow these steps:

1. In the network or device view of the STEP 7 hardware and network editor, select the PROFINET interface of a PROFINET device.
2. In the Inspector window, go to "Ethernet addresses" in the "IP protocol" area.
3. Check that the option "Set IP address in the project" is selected.
4. Enter the new IP address in the relevant field.

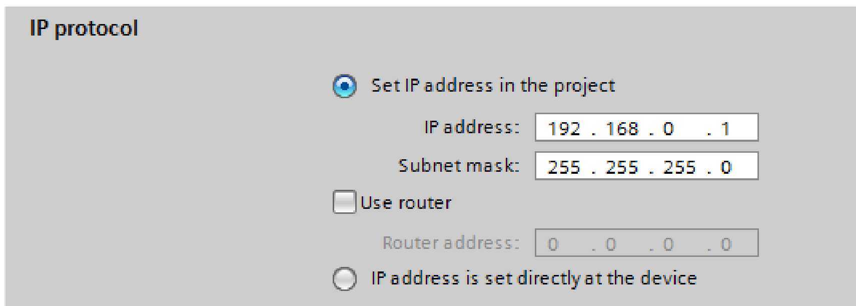

Figure 3-6 Changing the IP address of a PROFINET device in STEP 7

Downloading configured device name to IO device

To load the configured device names to the IO device, follow these steps:

1. Connect your programming device/PC to the same network as the relevant IO device. The interface of the programming device/PC must be set to TCP/IP mode.
2. In STEP 7, select the relevant IO device in the "Accessible devices" dialog based on the MAC address.
3. Click "Assign name" to download the configured device name to the IO device.

   The IO controller recognizes the IO device automatically by its device name and automatically assigns the configured IP address to it.

Identification of the PROFINET device

To clearly identify a device from several identical devices in a control cabinet, for example, you can flash the link LED of the PROFINET device.

To do this, select the menu command **Online > Accessible devices...** in STEP 7. In the "Accessible devices" dialog, set the "PG/PC" interface by means of which you are connected to the devices. STEP 7 now automatically searches for the accessible devices and displays them in the "Accessible devices in target subnet" table. Select the desired PROFINET device and click on the "Flash LED" button. The PROFINET device is identified based on its MAC address.

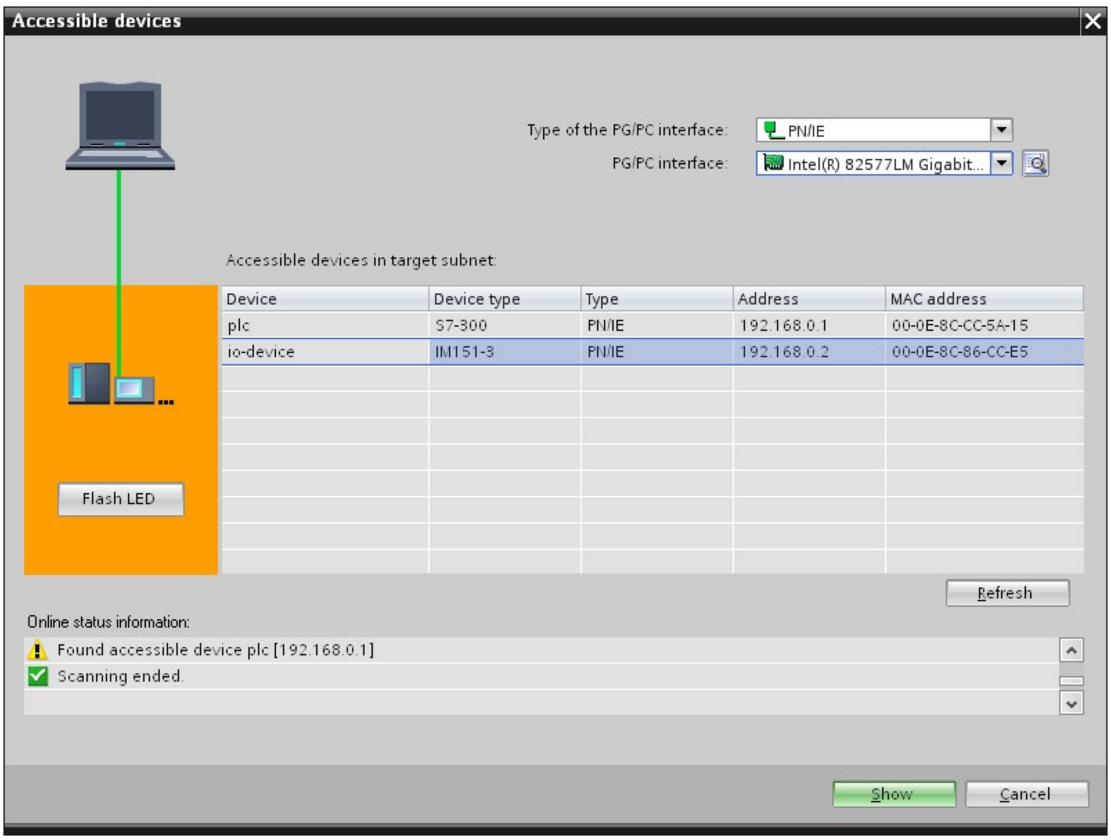

Figure 3-7 "Accessible devices" dialog

Using an different way to assign IP addresses for IO devices

Various IO devices, for example, SCALANCE X,S7-300 CPs, support the option of not having the IP addresses assigned by the IO controller during startup. In this case, the IP address is assigned in a different way. For additional information, refer to the manual of the respective PROFINET device of the SIMATIC device family.

Additional information

You can find a detailed description of the operation and functions of the display of the S7-1500 CPUs in the system manual S7-1500, ET 200MP (http://support.automation.siemens.com/WW/view/en/59191792).

3.2.4 Assign device name via communication table

Introduction

You can assign the device names of PROFINET IO devices configured offline to the devices online. You can do this in the table area of the network view in the table "I/O communication". You can also assign the device names to several devices at the same time.

"Online assignment" tab

In the I/O communication table, you will find the tabs "Offline configuration" and "Online assignment". In the "Online assignment" tab, you can assign the PROFINET device names that were assigned offline to the corresponding IO devices online. To do this, use the buttons "Check devices" and "Assign now".

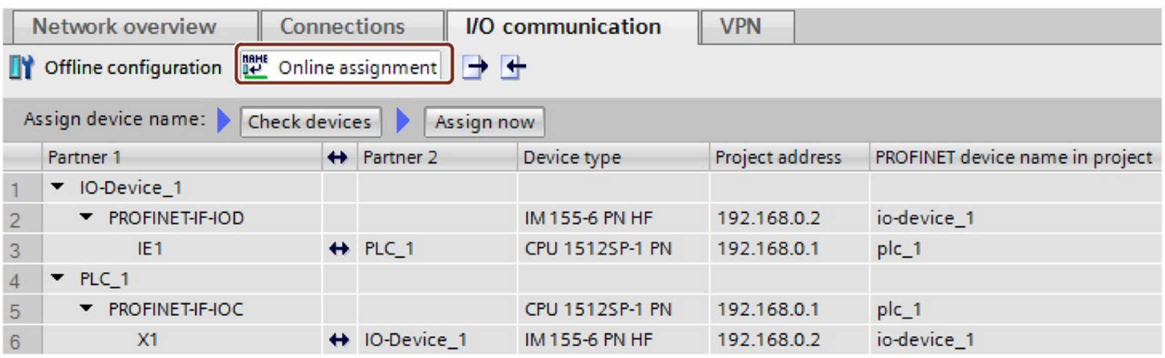

Figure 3-8 Assign device name via communication table

The objects displayed in the table of the "Online assignment" tab depend on the setting of the filter function. If only selected objects should be displayed, only objects of the corresponding context are displayed depending on the selection in the network view.

- PROFINET subnet: All connected devices and their PROFINET interfaces
- IO system All devices involved and their PROFINET interfaces
- Sync domain: All devices involved and their PROFINET interfaces
- Devices: The device and any existing PROFINET interfaces
- Other subnets or interfaces such as MPI or PROFIBUS are not displayed

If the display is set for all devices using the filter function, all devices are displayed that have a PROFINET interface, regardless of whether they are connected via a PROFINET subnet or are part of an IO system. Devices without a PROFINET interface, for example only with a DP or MPI interface, are not displayed.

General procedure

To assign PROFINET device names, you must first detect the IO devices available online. With this procedure, it matters whether the MAC addresses are known or unknown. This results in a general procedure in two steps:

1. Detecting the IO devices available online
2. Assigning configured PROFINET device names to the IO devices available online

Requirements

- You are in the network view.
- There is an online connection to the devices.

Procedure (step 1)

To detect IO devices available online from the I/O communication table, follow these steps:

1. Optional: Entered known MAC addresses in the "MAC address" column. After every valid entry, the check box under "Assign device" is selected for the relevant row.

   Note

   You can enter, insert or import the MAC address in different formats. The correct format is automatically entered in the cell. The following entries are supported and then converted to the required format:

   - "08:00:06:BA:1F:20"
   - "08 00 06 BA 1F 20"
   - "080006BA1F20"

   The formats used in the example are automatically converted to "08-00-06-BA-1F-20".

   ---

2. Click "Check devices" to start the check of the IO devices available online.
3. Set the PG/PC interface in the dialog window and click "Start".

Intermediate result

After the check, the result is displayed for every device in the table. Online data found is automatically entered in the table and the check box "Assign device" is set to "checked" in the rows in which a MAC address was entered or found online. The result of the check is shown as an icon in the "Status" column.

Status	Meaning
	Matching device and compatible type
	Matching device and incompatible type
	Non-matching device
	Device cannot be reached (with a known MAC address)
	Ready for assignment (with known MAC address)

Note

The icon "Ready for assignment" appears when a MAC address exists and matching device data was found, but no PROFINET device name was found online.

You can update the data of the detected devices again via their MAC addresses at any time. To do this, you specify the MAC address and the status of the device is displayed immediately without having to re-detect the device.

Procedure (step 2)

All PROFINET device names configured offline will be assigned to the devices available online in a bulk operation.

1. Click the "Assign now" button.

   Note

   The bulk operation cannot be reversed. A message to this effect appears in a dialog window.

   ---

2. Click "Start" in the dialog window to start the assignment of the PROFINET device names.

Result

The PROFINET device names configured offline will be assigned to the devices available online. This relates to devices in whose row the check box under "Assign device" is selected, that have a MAC address and have the status "Ready for assignment".

Importing and exporting data

Using the import and export button, you can import or export the data of the I/O communication table for the online assignment:

- When you export, the currently displayed data of the table is exported to a CSV file. Using the filter function of the table, you can select which data will be exported.
- When you import, the data of the CSV file is written to the table. If there are conflicts with values already existing in the table, you can decide whether the data should be overwritten or whether the import needs to be stopped.

3.2.5 Permitting changes to the device name and IP address directly on the device

Introduction

Machines are frequently commissioned on site or integrated into the existing infrastructure without STEP 7. You can find typical applications in all areas of the series machine building. Alternative means for assigning the IP address are available for this.

Procedure

1. In the network or device view of the STEP 7 Hardware and Network editor, select the PROFINET interface of an IO controller.
2. Navigate in the Inspector window to "Ethernet addresses".
3. Select the "IP address is set directly at the device" option in the "IP protocol" area.

4. In the "PROFINET" area, select the " PROFINET device name is set directly at the device" check box.

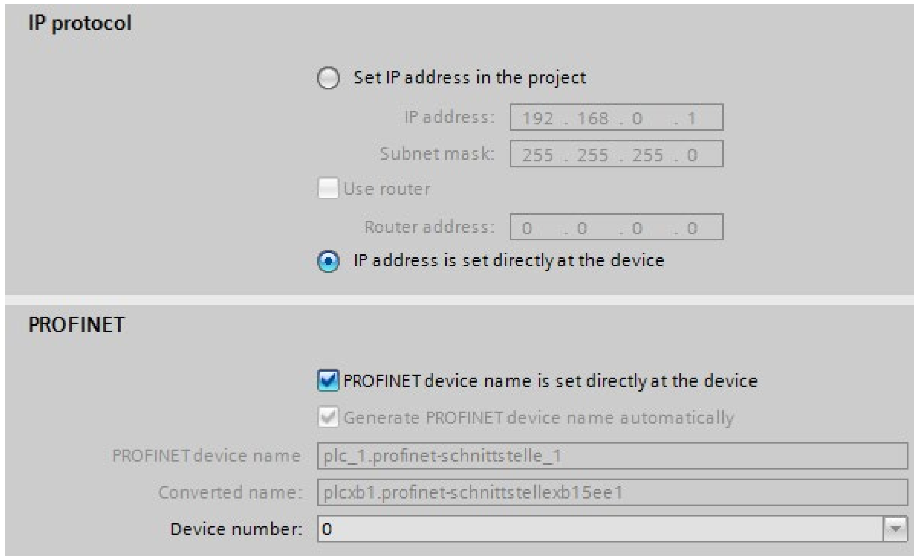

Figure 3-9 Setting the device name and IP address on the device

---

Note

Gateway

When you operate a PROFINET device with the option "Allow adaption of the device name/IP address directly on device", you cannot use this PROFINET device as gateway for S7 routing.

Options for assigning IP addresses and device names

Apart from the known address and device name assignment in the "Ethernet addresses" section of the Inspector window, there are other ways in which the IP address and name can be assigned:

- Assigning by means of the user program with the instruction "T_CONFIG"
- Assignment when downloading the configuration to the target system via the "Extended download to device" dialog box.
- Assignment via the Primary Setup Tool (PST)
- Assignment via the PRONETA ("PROFINET network analysis") commissioning and diagnostics tool
- Assignment via the SIMATIC Automation Tool

Additional information

For information on the "T_CONFIG" instruction and on downloading to the target system, refer to the STEP 7 online help.

A free Download (http://support.automation.siemens.com/WW/view/en/14929629) of the Primary Setup Tool (PST) can be found on the Internet. On this Internet page, you will also find a list of devices for which the PST is approved.

3.3 Configuring an IO device through hardware detection

Introduction

As of STEP 7 V15, you have the possibility to detect a real existing IO device and to import it into your project.

You find the IO device in STEP 7 through the "Hardware detection" function. A detected device can be imported into your project. STEP 7 inserts the IO device with all the modules and submodules.

Requirements

- STEP 7 (TIA Portal) as of V15
- It must be possible to technically access the IO device via IP

Procedure

To detect one or more existing IO devices in STEP 7 and add them to the project, follow these steps:

1. In STEP 7, navigate to "Online" > "Hardware detection".
2. Click "IO devices".
   STEP 7 opens the "Hardware detection of IO devices" window.
3. Select the interface of your programming device at "PG/PC interface:".
4. Click "Start search".
   STEP 7 begins with the hardware detection. When the hardware detection is completed, STEP 7 displays all the detected IO devices.
5. Select the IO devices that you want to add to the project by clicking the corresponding check box before the IO device.
6. Click "Add devices".
   After a brief moment, a window is opens to report about the success or failure of the hardware detection.

Result of the hardware detection

If the hardware detection is successful, STEP 7 inserts the IO device with all the modules and submodules into the project.

An IO device configured via hardware detection responds as follows:

- Modules configured through the "Hardware detection" are configured as if they have been inserted from the catalog.
- MAC address: STEP 7 imports the MAC address of the detected IO device into the project.
- IP settings:
  - If the detected IO device already has an IP address, STEP 7 imports the IP address into the project.
  - If the detected IO device does not have an IP address, STEP 7 automatically assigns an IP address in the project.

  PROFINET device name:
  - If the detected IO device already has a PROFINET device name, STEP 7 imports the PROFINET device name into the project.
  - If the detected IO device does not have a PROFINET device name, STEP 7 automatically assigns a PROFINET device name in the project.
- IO devices configured through "Hardware detection" have neither an IP subnet nor an IO controller assigned.

3.4 Specifying the router for a PROFINET IO device

Introduction

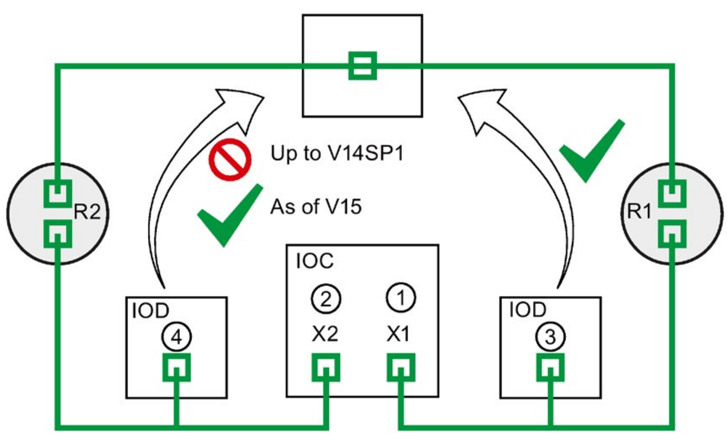
You always require a router (also referred to as a "Standard Gateway") when the PROFINET device has to communicate with a node whose IP addresses lie outside the own IP subnet. If the PROFINET device sends an IP packet to an IP address outside its own IP subnet, the IP packet first goes to the configured router. The router in turn checks the IP address. If this lies outside its own subnet, the router passes the IP packet on to the next router. The IP packet is routed to the next router until it has reached the target address.

Like all S7-1500 CPUs, S7-1500 CPUs with several PROFINET interfaces provide the possibility to configure the IP address of a router. However, there is the restriction that you can only enter the IP address of a router at a PROFINET interface.

You cannot include an IP address of a router on the other PROFINET interfaces of the CPU. IO devices that are connected to this PROFINET interface adopt this setting. Up to and including STEP 7 V14 SP1, these IO devices did not have any possibility to reach devices in a different IP subnet.

As of STEP 7 V15, you have the possibility to assign the address of a router for an IO device independent of the setting of the IO controller. You can now, for example, set a router address at the IO device in the following cases as well:

- You have not set an IP address of a router for the interface of the associated IO controller.
- You have already set a router address for a different interface in the CPU.



① Router R1 configured at PROFINET X1

② If a router is configured at X1, you cannot configure a router at X2.

③ Because a router is configured at X1, the IO device adopts the IP address of the router R1. The IO device can be reached from a different IP subnet.

④ As of STEP 7 V15, you set the IP address of the router R2 at the IO device irrespective of the setting at the interface X2. The IO device can be reached from a different IP subnet.

Figure 3-10 Specifying the router for an IO device

Further information about the "User router" setting

You have the possibility to configure the use of a router including IP address of the router in the "IP protocol" section of the settings for the PROFINET interface (Ethernet addresses).

Rules

Observe the following rules if you want to configure a router for the PROFINET interface of an IO controller:

- A PROFINET IO device supports exactly one router, irrespective of the number of interfaces.
- You can configure a router for exactly one PROFINET interface. All IO devices that are assigned to the PROFINET interface adopt the configured router from the IO controller.
- You cannot configure a router for the further PROFINET interfaces of the CPU. The further PROFINET interfaces take on the IP address "0.0.0.0" as the router and pass it on to their IO devices.

As of STEP 7 V15, you can configure the use of a router for an IO device. This allows the IO device to communicate with a node outside its own IP subnet, irrespective of the setting of the PROFINET interface of the IO controller.

Configuration example: Configuring a router for an IO device

The following example shows a configuration in which you configure a router at the IO device so that the IO device reaches IP addresses in the higher-level network.

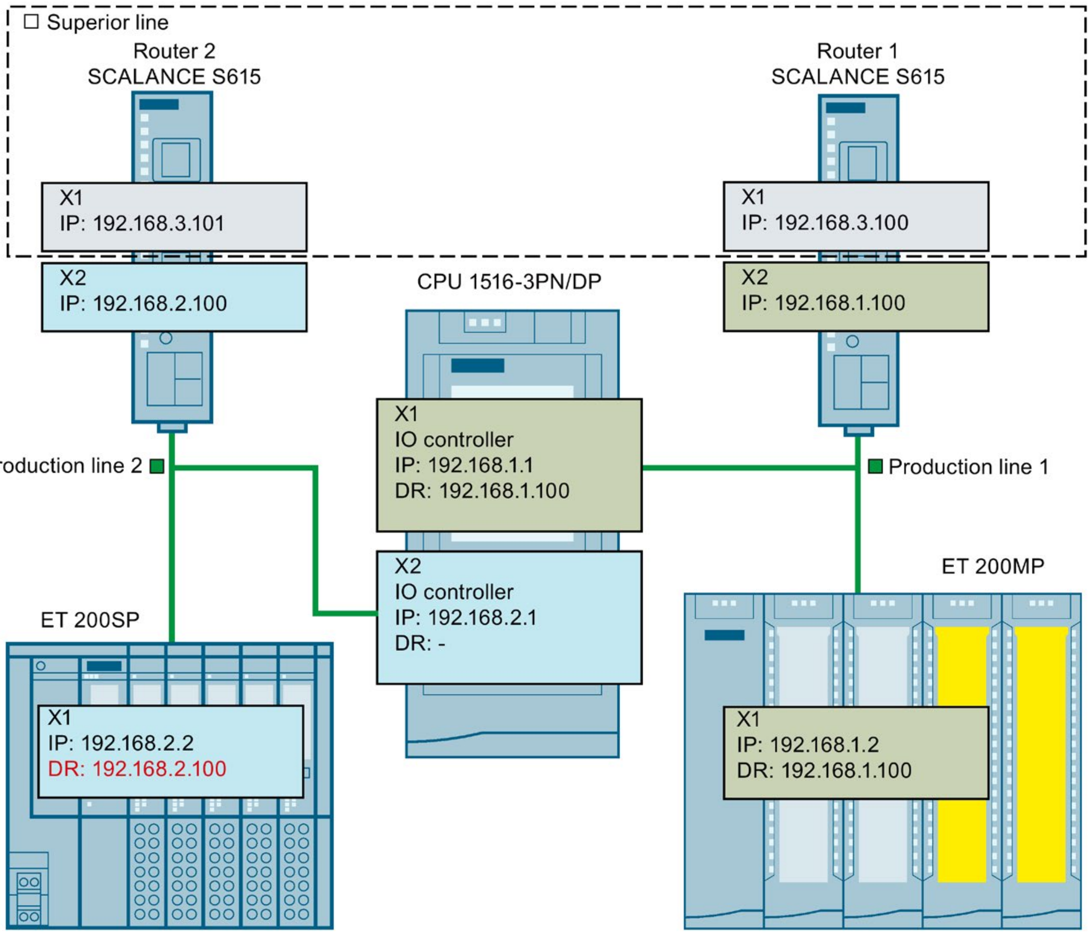


Figure 3-11 Configuration example: Configuring a router for an IO device

You have a CPU 1516-3PN/DP. The two PROFINET interfaces X1 and X2 of the CPU work in the "IO controller" operating mode. The PROFINET interface X1 is connected with the subnet "Production line 1". PROFINET interface X2 is connected with the subnet "Production line 2". The two subnets "Production line 1" and "Production line 2" are each connected via a router with the higher-level network "Superior line".

For PROFINET X1, you configure the router "Router 1" with the IP address 192.168.1.100.

The IO device (ET 200SP) in the "Production line 1" subnet adopts the router from the IO controller.

You cannot configure a router for the PROFINET interface X2 because you have already configured a router for the PROFINET interface X1 of the CPU.

No router is transferred by the PROFINET interface X2 to the IO device in the subnet "Production line 2".

In order for the IO device in the subnet "Production line 2" to reach nodes in the higher-level "Superior line", configure the router "Router 2" with the IP address 192.168.2.100 for the IO device.

Configuring the router for the IO controller

Requirements: You use the "Set IP address in the project" option for the PROFINET interface.

Follow these steps to configure a router for the IO controller in STEP 7:

1. In the network view of STEP 7, select the PROFINET interface of the IO controller.
2. In the Inspector window, navigate to "Properties" > "General" > "Ethernet addresses".
3. Select the "Use router" check box in the "IP protocol" field.
4. Enter the IP address of the router at "Router address".

Configuring a router for an IO device

Requirements:

- STEP 7 as of V15
- CPU 1500 as of firmware version V2.5
- IO device is assigned to the PROFINET interface of an IO controller. The PROFINET interface of the IO controller uses the "Set IP address in the project" option.

Follow these steps to configure a router for the IO device in STEP 7:

1. In the network view of STEP 7, select the PROFINET interface of the IO device.
2. In the Inspector window, navigate to "Properties" > "General" > "Ethernet addresses".
3. Clear the "Synchronize router settings with IO controller" check box.
4. Select the "Use router" check box.
5. Enter the IP address of the router at "Router address".

3.5 Configuring topology

Introduction

If an IO device is assigned to an IO controller, this does not yet specify how the ports are connected to each other.

A port interconnection is not required to use RT, but it provides the following advantages:

- A set topology is assigned with the port interconnection. Based on an online-offline comparison, it is possible to conduct a set-actual comparison with all devices that support this function.
- The "Device replacement without exchangeable medium" function can be used.

A port interconnection is an essential requirement for using IRT.
An overview of various options for setting up a PROFINET network is given below.

Line

All the communication devices are connected in a linear bus topology.

In PROFINET, the linear bus topology is implemented with switches that are already integrated into the PROFINET devices. Therefore, the linear bus topology at PROFINET is merely a special form of tree / star topology.

If a link element (switch, for example) fails, communication across the failed link element is no longer possible. The network is then divided into 2 subsegments.

Linear bus topology structures require the least cabling.

Star

If you connect communication devices to a switch with more than two PROFINET ports, you automatically create a star network topology.

If an individual PROFINET device fails, this does not automatically lead to failure of the entire network, in contrast to other structures. It is only if a switch fails that part of the communication network will fail as well

Tree

If you interconnect several star structures, you obtain a tree network topology.

Ring

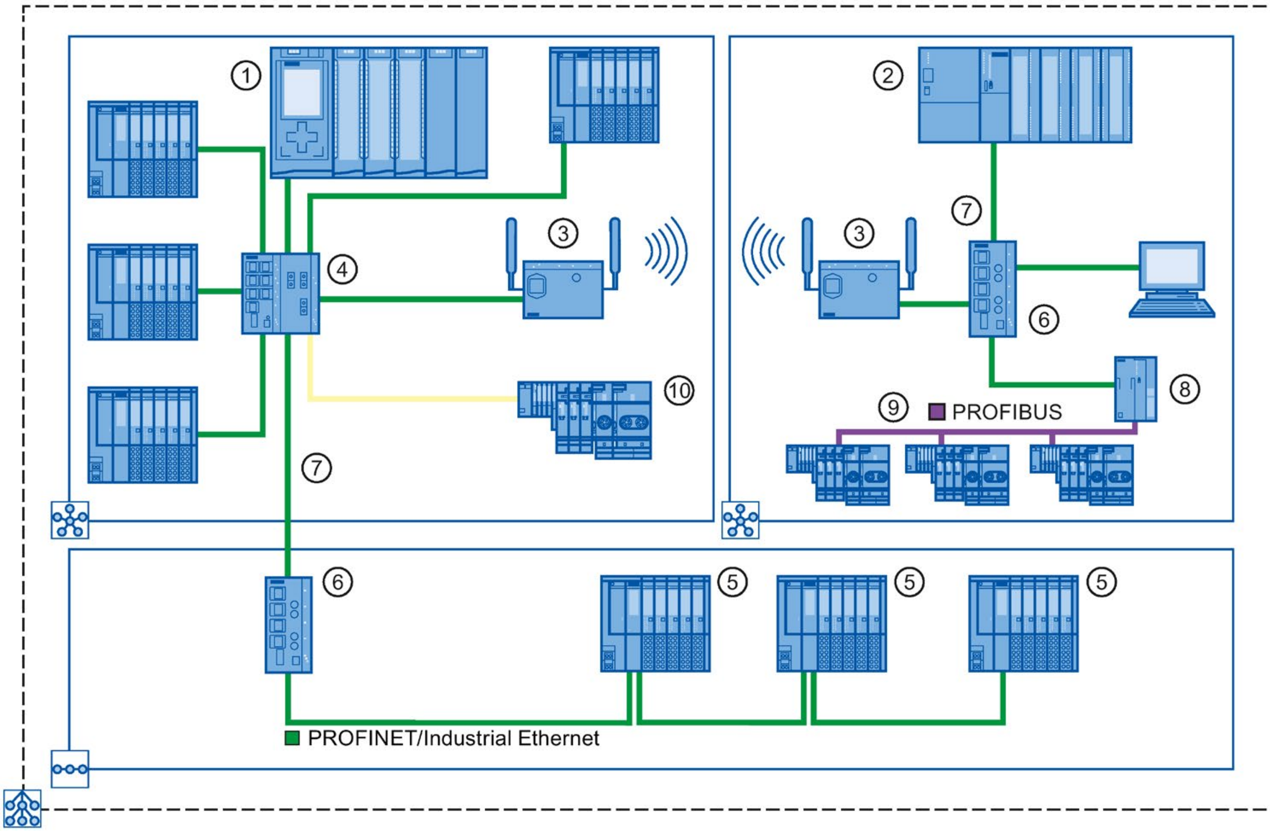
In order to increase the availability of a network, use ring structures. In principle, a linear bus topology is connected to a ring through a so-called redundancy manager.

The task of the redundancy manager is managed by an external switch SCALANCE X, a CPU that supports the Media Redundancy Protocol MRP (e.g., CPU 1516-3 PN/DP) or a CP (e.g., CP 343-1 Lean).

If there is a break in the network, the redundancy manager ensures that the data is redirected over an alternative network connection in the ring.

Example for topology

The following example shows a combination of different topologies.



Number	Meaning
①	S7-1500 as IO controller
②	S7-300 as IO controller
③	Industrial WLAN with SCALANCE W
④	SCALANCE X 307-3 with seven electrical and three optical ports
⑤	ET 200SP with integrated 2-port switch
⑥	SCALANCE X 204 with four electrical ports
⑦	PROFINET/Industrial Ethernet
⑧	IE/PB-Link PN IO
⑨	PROFIBUS DP
⑩	ET 200S with two optical ports
	Star topology
	Linear bus topology
	The combination of topology forms results in a tree topology.

Figure 3-12 Combined topology

Additional information

Observe the PROFINET Installation Guideline (http://www.profibus.com/nc/download/installation-guide/downloads/profinet-installation-guide/display/) of the PROFIBUS User Organization when planning your PROFINET topology.

For more detailed information, see the SIMATIC NET Twisted Pair and Fiber Optic Networks (http://support.automation.siemens.com/WW/view/en/8763736) manual.

You can find basic information in the Communication with SIMATIC (http://support.automation.siemens.com/WW/view/en/1254686) manual.

3.5.1 Topology view in STEP 7

Introduction

The topology view is one of three working areas of the hardware and network editor. You undertake the following tasks here:

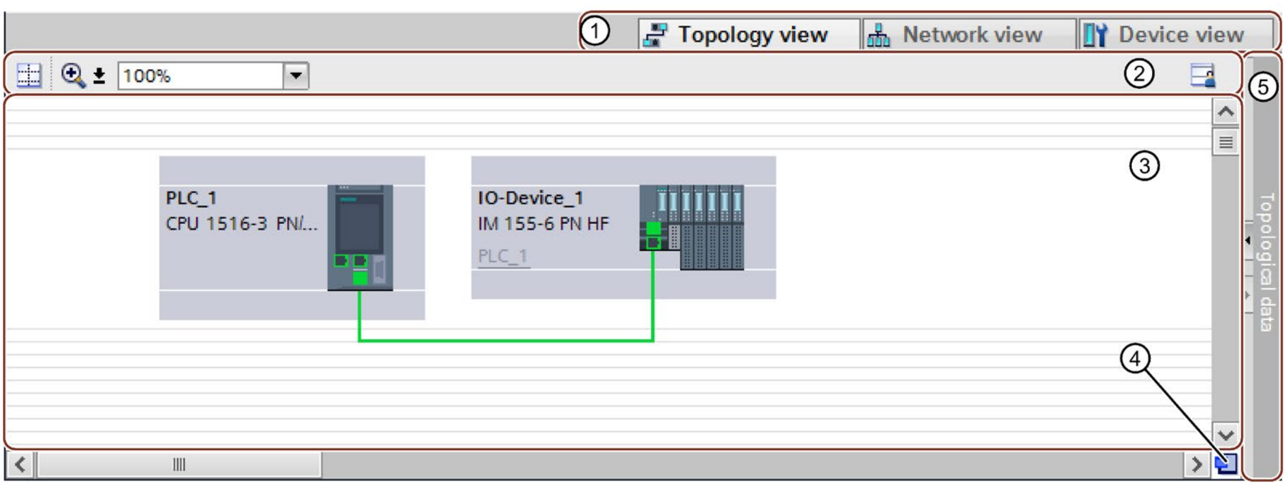
- Displaying the Ethernet topology
- Configuring the Ethernet topology
- Identify and minimize differences between the set and actual topology (online)

The topology view in STEP 7 consists of a graphic area and a table area.

Graphic area

The graphic area of the topology view displays PROFINET devices with their appropriate ports and port connections. Here you can add more PROFINET devices.

The following figure shows the graphic area of the topology view.



① Selector: Device view/Network view/Topology view
② Toolbar
③ Graphic area of the topology view
④ Overview navigation
⑤ Selector for the table area of the topology view

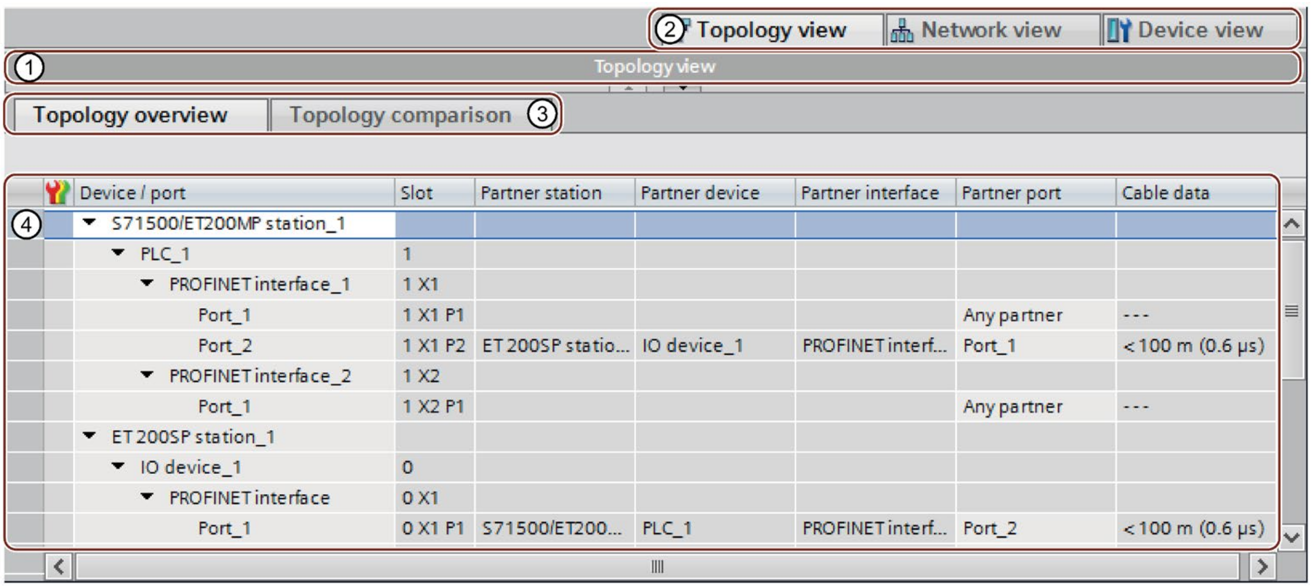
Figure 3-13 Graphic area of the topology view

Overview navigation

Click in the overview navigation to obtain an overview of the created objects in the graphic area. By holding down the mouse button, you can quickly navigate to the desired objects and display them in the graphic area.

Table area

- Topology overview: This displays the Ethernet or PROFINET devices with their appropriate ports and port connections in a table. This table corresponds to the network overview table in the network view.
- Topology comparison: Here you can import devices and port interconnections automatically through offline/online comparison or extended Offline/Online comparison into STEP 7.



① Selector for the graphic area of the topology view
② Selector: Device view/Network view/Topology view
③ Selector: Topology overview/Topology comparison
④ Table area of the topology view

Figure 3-14 Table area of the topology view

3.5.2 Interconnecting ports in the topology view

Requirement

You are in the graphic view of the topology view.

Procedure

To interconnect ports in the topology view, follow these steps:

1. Place the pointer of the mouse on the port you want to interconnect.
2. Press and hold down the left mouse button.
3. Move the pointer.

   The pointer now uses the networking symbol to indicate "Interconnecting" mode. At the same time, you see the lock symbol on the pointer. The lock symbol disappears only when the pointer is over a valid target position.
4. Now drag the pointer to the target port. You can keep the left mouse button pressed or release it when performing this action.
5. Now release the left mouse button or press it again (depending on your previous action).

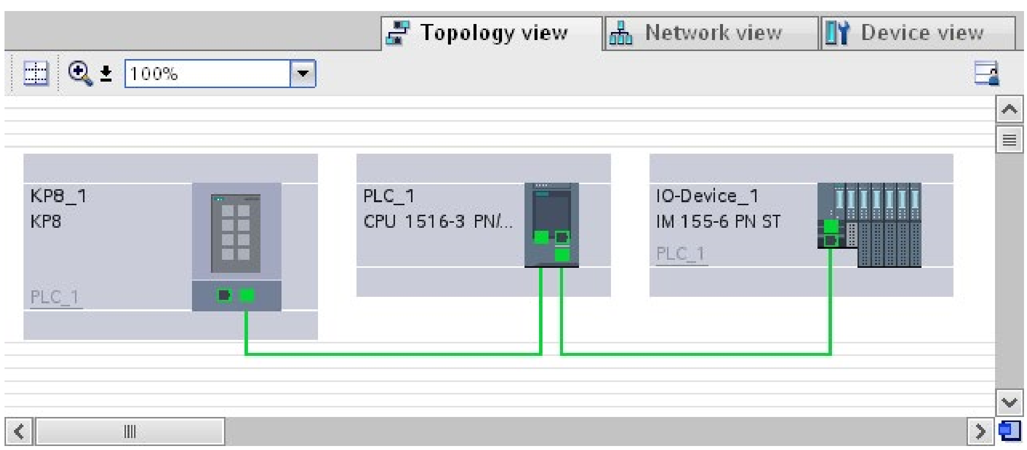


Figure 3-15 Interconnecting ports in the topology view

Result

You have created a port interconnection.

3.5.3 Interconnecting ports - Inspector window

Interconnecting ports in the Inspector window

To interconnect ports, follow these steps:

1. In the device or network view, select the PROFINET device or PROFINET interface.
2. In the Inspector window, navigate to the port property "Port interconnection".

   When the PROFINET interface is selected, you can find this setting in the Inspector window as follows: "Properties > General > Advanced Options > Port [...] > Port Interconnection."
3. In the "Local port" section, you can find the settings at the local port. In the case of fiber-optic cable you can, for example, set the cable names here.

   In the "Partner port" area, select the drop-down list for "Partner port" in order to display the available partner ports and make a selection.

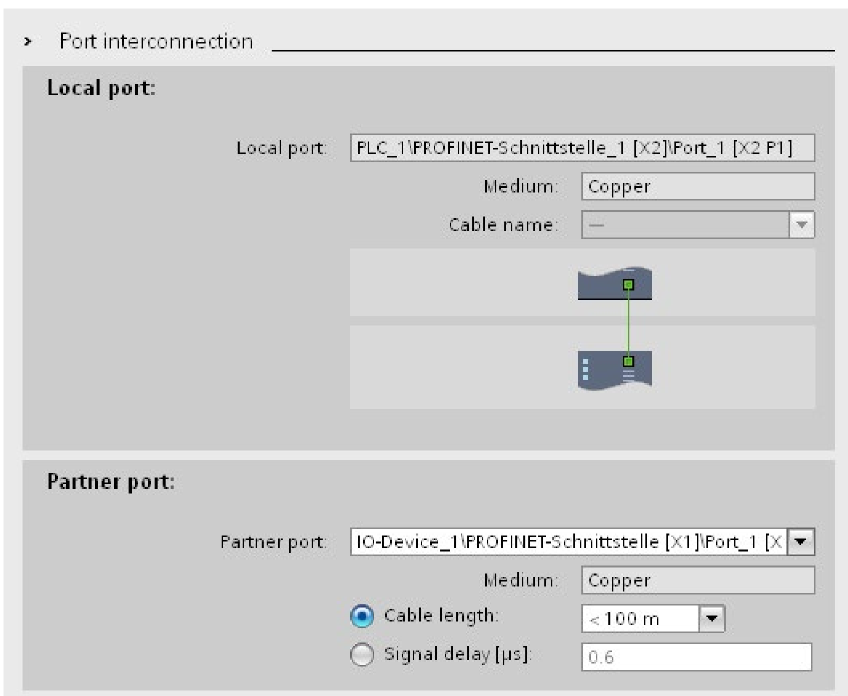

Figure 3-16 Interconnecting ports in the Inspector window in STEP 7

If the PROFINET interface was disconnected, it is automatically connected by this action. In the properties of the subnet you can set whether this subnet should or should not be used for the networking.

3.5.4 Automatic assignment of devices by offline/online comparison

Overview

During the offline/online comparison, the configured topology is compared with the actual existing topology. Devices identified online are automatically assigned to configured devices as far as this is possible.

Start of availability detection

You start the availability detection the first time by clicking the "Compare offline/online" button in the toolbar of the "Topology comparison" tab.

You restart availability detection by clicking the "Update" button.

Note

The availability detection can take several seconds. During this time, no user input is possible.

Automatic assignment of a PNIO device

A PNIO device identified online is automatically assigned to a configured device if the following properties of the two devices match up:

- Article no.
- Type
- PROFINET device name

No automatic assignment

In the following situations, no automatic assignment is possible:

- No device can be identified online to match a configured device. (This means that the corresponding columns in the "Online topology" area of the topology comparison table are empty.)

  In this case, you should add the already configured device to your system or delete the configured device from the configuration.
- A device identified online can be assigned to a configured device, but there are differences in the port interconnections.

  In this case, you can Apply the port interconnections identified online manually to the project (Page 76).
- A device identified online cannot be assigned to a configured device. (In this case, the corresponding columns in the "Offline topology" area of the topology comparison table are empty.)

  In this case, you can Include the devices identified online manually in the project (Page 77).

3.5.5 Apply the port interconnections identified online manually to the project

Requirements

You have run an offline/online comparison in the topology view. The result of this is that at least one device identified online was automatically assigned to a configured device, but that there are differences relating to the interconnection.

Procedure

To adopt one more port interconnections identified online in the project manually, follow these steps:

1. Select the row belonging to the port interconnection.
2. If applicable, select further roles using multi-selection.
3. Select "Apply" > "Use selected" in the shortcut menu.

   The content of the corresponding table cells in the "Action" column changes to "Apply".
4. If you have mistakenly prepared too many port interconnections to be included in the project:

   Select the rows belonging to the port interconnections you have mistakenly prepared for inclusion in the project using multi-selection.

   Select "Reset" > "Reset selected" in the shortcut menu.

   The content of the corresponding table cells in the "Action" column change to "No action".
5. Click the "Synchronize" button.

Result

The port interconnections identified online for the corresponding devices are included in the project. Successful adoption is indicated by the diagnostics icon "Identical topology information" for each port.

Note

If other port interconnections are recognized for a device identified online and these differ from those that exist in the project, adopting these in the project means that the port interconnections that were previously in the project are replaced by those identified online. If no port interconnections are detected for a device identified online, adopting in the project means that all the port interconnections of this device are deleted in the project.

3.5.6 Include the devices identified online manually in the project

Requirements

You have run an offline/online comparison in the topology view. The result of this is that at least one device identified online could not be assigned to any configured device.

Procedure

To adopt one more devices identified online in the project manually, follow these steps:

1. For a configured device without an online partner, move the mouse pointer to the "Device/port" column of the online topology.
2. Select the device you want to assign to the configured device from the drop-down list of this box.
3. Repeat the previous steps if necessary for other configured devices without an online partner.

Result

The selected device that was identified online is moved up from the end of the table. Following this, it is in the row of the configured device to which you have just assigned it.

3.5.7 Automatic assignment of devices by advanced offline/online comparison

Overview

With the advanced offline/online comparison, ICMP is also used alongside DCP to be able to detect devices that do not support DCP.

Automatic assignment of devices detected by ICMP

With devices detected by ICMP, no type is available.

With passive devices, no article number is available. For this reason, passive devices can only be assigned automatically if you have not assigned an article number in the configured data and the offline and online IP addresses match.

With switches, automatic assignment is possible if the offline and online article number, IP address and PROFINET device name match.

Diagnostics and maintenance 4

4.1 Diagnostics mechanisms of PROFINET IO

Totally Integrated Diagnostics Concept

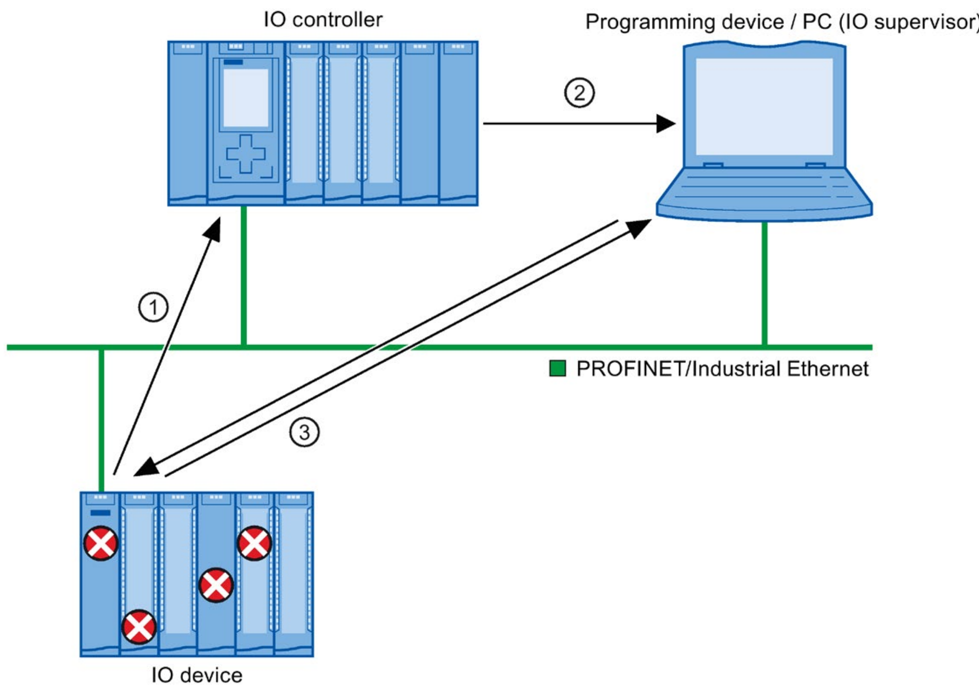
All SIMATIC products have integrated diagnostics functions that they can use to detect and remedy faults. The components automatically flag a potential fault in the operation and provide detailed information.

Each individual error or several errors occurring concurrently are transferred from the IO device to the IO controller. If you require the full status of the IO device including any pending errors, you can also read the status directly from the IO device.

The following sections provide basic information on using diagnostics via PROFINET IO. You can find a detailed description of the system diagnostics for S7-1500, ET 200MP, ET 200SP and ET 200AL in the Diagnostics (http://support.automation.siemens.com/WW/view/en/59192926) function manual.

Accessing the status of an IO device with a PG/PC or an HMI device

If you are connected to the Industrial Ethernet via a PG/PC with STEP 7 or an HMI device, you can also call up diagnostics information online. This is illustrated by the following graphic.



Number	Description
①	The IO device detects an error and sends diagnostics data to the IO controller.
②	The IO controller notifies the programming/HMI device. The display of the system diagnostics is updated.
③	In STEP 7, you can read the station status for "Accessible devices" directly from the IO device regardless of the IO controller. This is only possible if the programming device is connected to Industrial Ethernet. This means that you can access diagnostics information during the commissioning phase or for servicing even if the IO controller is not operational.

Figure 4-1 PROFINET IO diagnostics with PG/PC or HMI device

4.1.1 Diagnostics levels in PROFINET IO

Concept

The IO device sends all error messages that occur to the IO controller. The scope and volume of diagnostics information varies according to the level of diagnostics data evaluation and the PROFINET devices you are using.

Diagnostics levels

You can evaluate diagnostics data at different levels. The number and type of channels is selected, for example, at the diagnostics level 4.

The following figure shows the diagnostics levels with PROFINET IO.

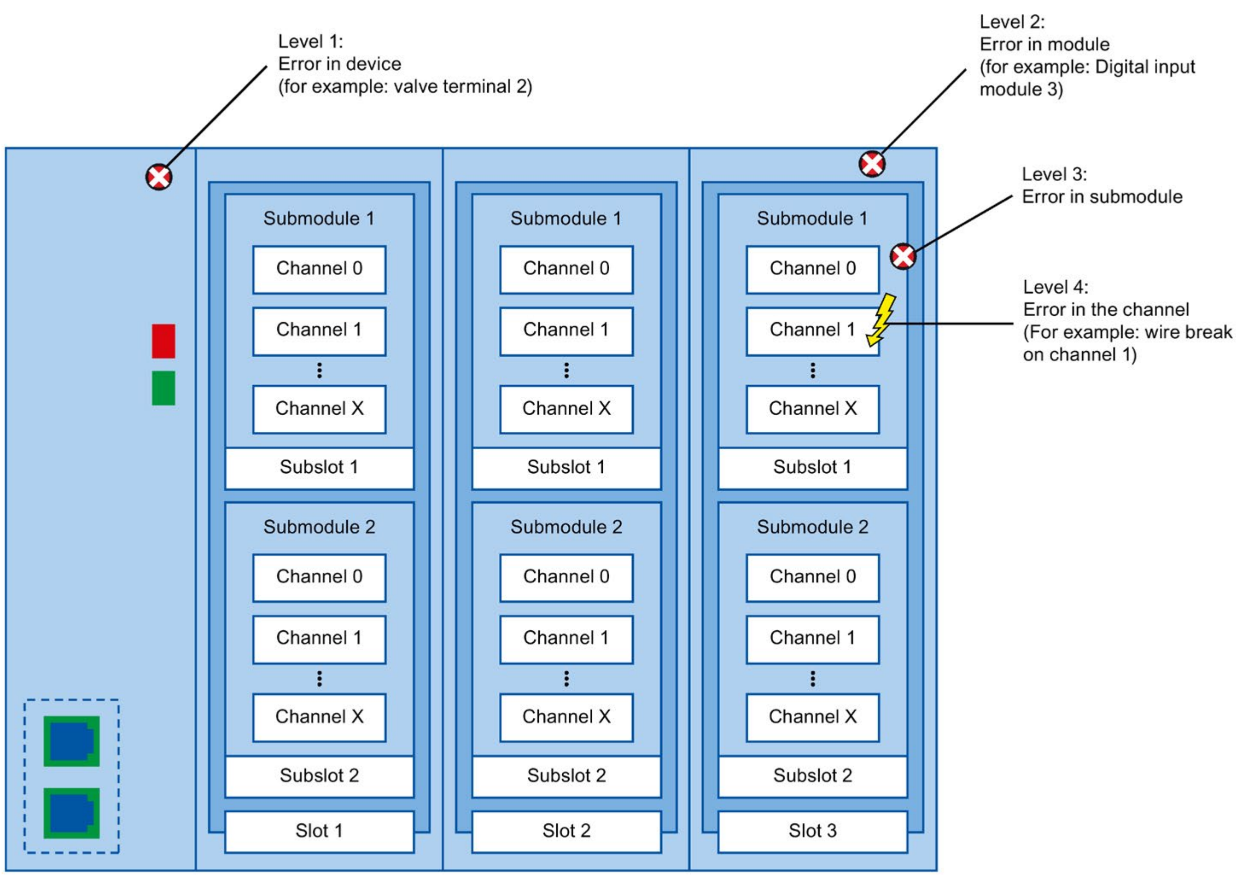


Figure 4-2 Diagnostics levels with PROFINET IO

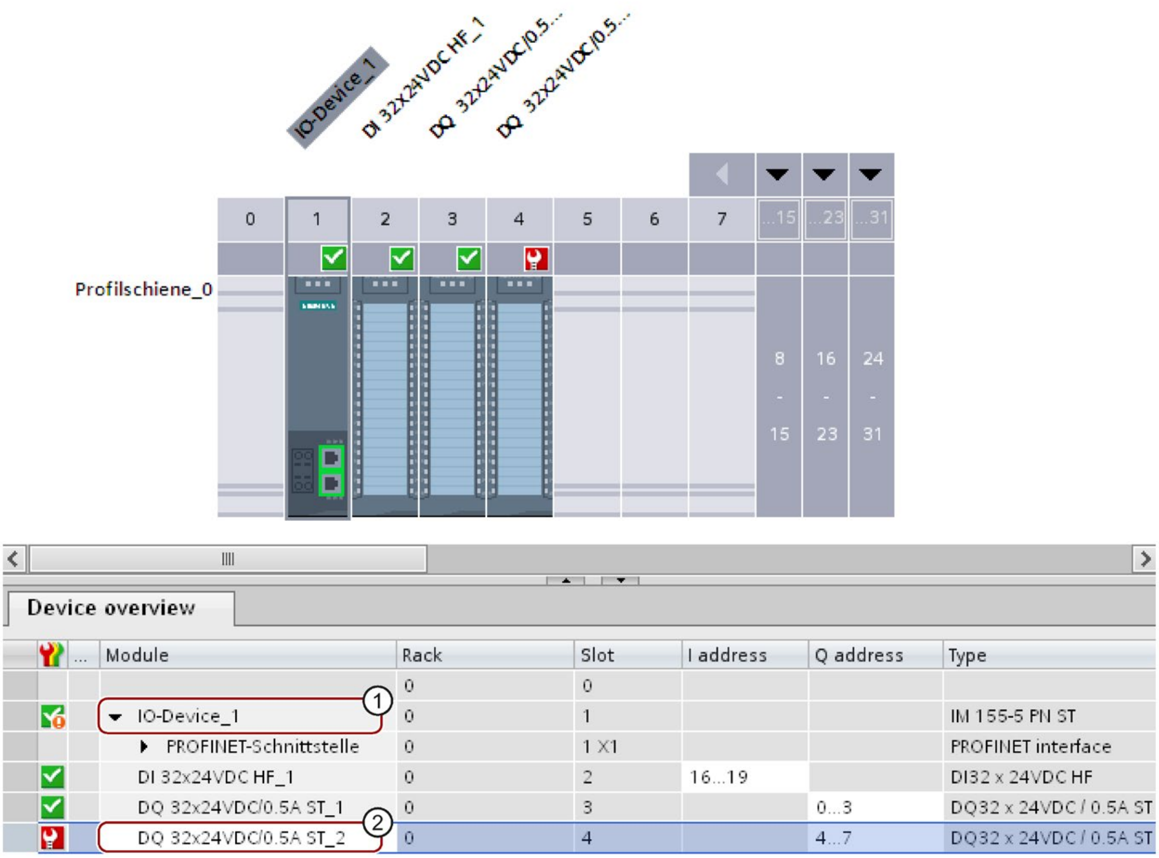
Representation of diagnostics levels in the device view in STEP 7

The following figure shows the representation of the PROFINET device model in the device view of STEP 7, based on the example of a distributed I/O system ET 200MP:



Number	Description	
①	Level 1:	Error(s) in the device
②	Level 2:	Error(s) in the module

Figure 4-3 Diagnostics levels in the device view of STEP 7

Which PROFINET nodes support the extended PROFINET diagnostics?

An overview of the PROFINET nodes that support extended PROFINET diagnostics and of what you have to configure is provided in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/23678970).

4.1.2 Maintenance

4.1.2.1 I&M data (identification and maintenance)

Definition and properties

Identification and maintenance data (I&M) is information saved to module memory in order to provide support when:

- Checking the plant configuration
- Locating hardware changes in a plant

Identification data (I data) is module information (some of which may be printed on the module housing) such as the order and serial number. I data is read-only vendor-specific module data.

Maintenance data (M data) is plant-specific information such as the location identifier and installation date. M data is created during configuration.

The modules can be uniquely identified in online mode by means of the I&M data.

Further information

To find out whether and to what extent a PROFINET device supports I&M data, refer to the documentation of the relevant device.

4.1.2.2 Loading I&M data to PROFINET IO devices and your modules

Which I&M data can be loaded to PROFINET IO devices and your modules?

You can load I&M 1 data (plant designation and location identifier) and/or I&M 2 data (installation date) and/or I&M 3 data (additional information) to the actual hardware.

Requirements

- In the project settings (Options > Settings, Hardware configuration > Compiling and downloading), the option "Download I&M data" must be enabled.
- There is an online connection to the PROFINET IO devices and the modules to which you want to load I&M data.
- You have entered the I&M data you want to download in the properties of the respective PROFINET IO devices and your modules (Inspector window: "Properties" tab > "General" tab, Settings > Identification & Maintenance).

Where do I specify which I&M data is downloaded to which PROFINET IO devices?

You specify which I&M data you want to download to which PROFINET IO devices in the "Load preview" dialog. You will find the following alternatives in the drop-down list of the "Identification and maintenance data (I&M)" row:

- Load nothing

  The check boxes for all PROFINET IO devices as well as the check boxes for the loadable I&M data are cleared.

  No I&M data is transferred to the actual hardware during loading with this setting.
- Load data

  The check boxes for all PROFINET IO devices as well as the check boxes for the loadable I&M data are selected.

  The respective I&M 1, I&M 2 and I&M 3 data is transferred to all PROFINET IO devices during loading with this setting.
- Load selected

  You select the check boxes of those PROFINET IO devices to which you want to load I&M data. You also select the check boxes of the identification data you want to load.

  With this setting, you transfer the selected I&M data to the selected PROFINET IO devices during loading.

Note

Language dependency of the I&M data to be loaded

The I&M data are loaded to the real hardware in the form that you specified in the properties of the relevant PROFINET IO devices and your modules. There is no language dependency.

4.1.2.3 Asset management

Further information about asset management at PROFINET

Operation of machines and plants without a detailed knowledge of devices and assets is difficult to imagine.

Maintenance requires data for this – data that is extensive and up-to-date as far as possible.

The requirement of greater transparency with regard to the data made available by plant components has been fulfilled by PROFIBUS & PROFINET International (PI): The identification and maintenance data familiar since PROFIBUS times have been extended.

The current PROFINET fulfills this requirement through the definition of a special data record: the Asset Management Record (AMR).

The aim of this definition is to enable you to acquire **all** the components to be maintained online - and not only those components that can be addressed and accessed through the PROFINET device model (Device / Module / Submodule). PROFINET now also reaches non-PROFINET components!

Assets general and asset management data records

Assets are components (hardware and software / firmware) of a machine, for example a laser welding machine, or a plant.

A large number of these device components can already be identified through tried-and-tested I&M functions or corresponding data records (I&M0 to I&M5) in the PROFINET context: The device itself as well as its modules and submodules. Meaning all components that can be addressed through the PROFINET device model.

Components that **cannot** be addressed via the PROFINET device model, but whose data it should be possible to acquire online for operation and maintenance, can be identified through **asset management** functions. This asset management data (short: AM data) is stored in a defined structure in a special data record, the **asset management record** (AMR) mentioned above.

The PROFINET Guideline "Identification & Maintenance Functions" differentiates here between I&M functions (I&M data) and asset management functions (AM data): The following sections only deal with the AM data.

The components that can be read additionally online through asset management data records include both hardware components, such as backplane bus modules of a device as well as firmware components such as a drive control unit with own versioning.

Application examples

Importing asset management records enables you to read the following information during installation or operation, for example:

- Are only approved devices being used (whitelist check)?
- A firmware update is due. Obtain a fast overview: Which devices or components are affected and have to be upgraded?

Making asset management data available

The concept for the asset management of PROFINET devices stipulates that the manufacturers of PROFINET devices have to ensure that non-PROFINET automation components are made available through an asset management record. This data record is assigned to the PROFINET device.

In contrast to a "standard" IO device, with an I-device the project engineer has to make the asset management record available. In this case, the central modules of the I-device are assets. From the perspective of PROFINET, these central modules are not visible from the point of view of the higher-level IO controller. The higher-level IO controller only "sees" the transfer areas through which it exchanges IO data with the I-device.

The principle of this provision is explained in the section.

Reading asset management data

The asset management record has the index 0xF880 and is read with standard PROFINET mechanisms by the user of the records, for example a tool or program for evaluating these data.

A user program in the S7-1500 IO controller, for example, can read out the AMR of an IO device with the RDREC instruction (Index 0xF880).

It is not possible to write to this data record.

Further information

Whether and to which extent a PROFINET device supports asset management data, meaning whether it makes an AMR available, is specified in the documentation of the respective device.

Content and structure of an asset management record

Basic structure of the asset management record

You are first provided with an overview of the general structure of the record. The following table describes the framework within which the asset management data blocks are embedded. Each data block represents an asset, a terminal block for example.

Element of the data structure	Designation according to IEC 61158-6-10	Code	Data type / length in bytes
Header AssetManagement-Data	BlockType	0x0035	UINT / 2
	BlockLength	Number of bytes without counting the bytes for BlockType and BlockLength	UINT / 2
	BlockVersion	0x0100	UINT / 2
AssetManagementInfo AssetManagementBlocks (n)	NumbersOfEntries	Number of AssetManage-mentBlocks	UINT / 2
	AssetManagementBlock 1	See the table below	
	AssetManagementBlock 2		
	...		
	AssetManagementBlock n		

Structure of asset management blocks

Each AssetManagementBlock contains identification data and localization information for an asset. An AssetManagementBlock has a substructure with basic characteristics described below.

The header of an AssetManagementBlock contains the coded information about which of the three possible AM data compilations the data record contains. Devices make a suitable BlockType available in accordance with the various device types:

- Complex devices with information about the hardware and firmware (BlockType "AM_FullInformation")
- Complex devices with information about the hardware (BlockType "AM_HardwareOnlyInformation")
- Devices with information about the firmware (BlockType "AM_FirmwareOnlyInformation")

The differentiation provides an efficient data structure below the header. Nevertheless, the data record can have a considerable size (maximum of 64 KB, depending on the number of assets that the IO device supplies).

Table 4- 1 Structure of AssetManagementBlock

Element of the data structure	Designation according to IEC 61158-6-10	Code	Data type / length in bytes
Header AssetManage-mentBlock	BlockType	0x0036 (AM_FullInformation) 0x0037 (AM_HardwareOnlyInformation) 0x0038 (AM_FirmwareOnlyInformation)	UINT / 2
	BlockLength	Number of bytes without counting the bytes for BlockType and BlockLength	UINT / 2
	BlockVersion	0x0100	UINT / 2
	Padding	0x0000 (padding byte)	USINT / 1
	Padding	0x0000 (padding byte)	USINT / 1
AssetManagementBlock (Structure depends on the BlockType. Here it is shown using AM_FullInformation as an example)	IM_UniqueIdentifier	Manufacturer-generated Universal Unique Identifier (UUID) conforming to ISO/IEC 9834-8. Used as a reference key to uniquely identify this asset. Example: 550c5300-d34a-22b4-11d3-5533991111	Array of Byte / 16
	AM_Location	Description of the location of the asset: Either slot-oriented ("Slot and SubslotNum-ber format") or hierarchical ("Twelve level tree format"). See following description	Array of Byte / 16
	IM_Annotation	Manufacturer-specific notation Example: "Terminal block, Type xyz123 ". 64 bytes are always used. Spaces are used for padding if the string is shorter.	Array of Char / 64
	IM_OrderID	Manufacturer-specific article number Example: "6ES7 131-6BF00-0BA0 ". 64 bytes are always used. Spaces are used for padding if the string is shorter.	Array of Char / 64
	AM_SoftwareRevision (not at AM_HardwareOnlyInformation)	Manufacturer-specific SW version Example: "V6.3.8 ". 64 bytes are always used. Spaces are used for padding if the string is shorter. If the asset supports IM_Software_Revision, the AM_SoftwareRevision is padded with spaces.	Array of Char / 64
	AM_HardwareRevision (not at AM_FirmwareOnlyInformation)	Manufacturer-specific hardware version Example: "A4 ". 64 bytes are always used. Spaces are used for padding if the string is shorter. If the asset supports IM_Hardware_Revision, the AM_HardwareRevision is padded with spaces.	Array of Char / 64

Element of the data structure	Designation according to IEC 61158-6-10	Code	Data type / length in bytes
	IM_Serial_Number	Manufacturer-specific unique production-related number. The characters come from the visible range (0x20 ... 0x7E), no control characters. Example: "A78C-1C82 ". 16 bytes are always used. Spaces are used for padding if the string is shorter.	Array of Char / 16
	IM_Software_Revision (not at AM_HardwareOnlyInformation)	Software version, follows a strict structure (SW version prefix, for example "V", digits for functional extension, digits for BugFix, digits for internal change). Example: 'V' 0x01 0x2 0x3 If AM_SoftwareRevision is padded with spaces, you should evaluate IM_Software_Revision. If the asset does not support any hardware, the coding 'V' 0x00 0x00 0x00.	Array of Byte / 4 Prefix (character "V", "R", "P", "U", or "T"), then 3 digits "0" to "9"
	AM_DeviceIdentification	Identification of the device. The structure is as follows: AM_DeviceIdentification.DeviceSubID (for SIEMENS e.g. 0x0000) AM_DeviceIdentification.DeviceID (Device ID from manufacturer, 0x0000 to 0xFFFF) AM_DeviceIdentification.VendorID (Example for Siemens assets: 0x002A) AM_DeviceIdentification.Organization: Example for Siemens assets: 0x0000 (PROFINET)	Array of Byte / 8
	AM_TypeIdentification	Manufacturer-allocated type identification: 0x0000: Unspecified 0x0001: Controller (PLC) 0x0002: PC-based 0x0003: IO module, IO submodule 0x0004: Communications module / submodule 0x0005: Interface module / submodule 0x0006: Active network component 0c0007: Media attached unit (bus adapter) 0x0100 to 0x7FF: Manufacturer-specific	UINT / 2
	IM_Hardware_Revision (not at AM_FirmwareOnlyInformation)	Version of the hardware (0x0000 to 0xFFFF) Example: 0x0003 If AM_HardwareRevision is padded with spaces, you should evaluate IM_Hardware_Revision.	UINT / 2

AM_Location

Asset management at PROFINET supports two formats for coding the location of an asset:

- Slot-oriented format ("Slot and SubslotNumber format")
- Hierarchical format ("Twelve **L**evel **T**ree format" abbreviated **LT** format)

Assets that are part of the PROFINET device use the slot-oriented format. These assets are bound completely to the PROFINET modules and submodules.

Assets that are located outside the PROFINET device use the hierarchical format (LT format) for coding the location of an asset.

These assets are localized by their tree level. The tree level begins with Level 0. The value of Level 0 provides information about the proximity to the PROFINET device:

- If the asset is connected to a module that can be addressed through the PROFINET device model, Level 0 has the value 0. The subsequent levels (Level 1 to Level 3) then have the meaning of slot address, subslot address and channel number. If further assets are connected to this asset, the next Level 4 is used. The limit is reached at Level 11.
- If the asset belongs to a PROFINET device but is not connected to a module that can be addressed through the PROFINET device model, Level 0 has a value between 1 and 0x1FF. An example of such an asset is a power supply unit in the PROFINET device. If a further asset is connected to this power supply unit, for example a sensor, the next tree level is used to localize this sensor (Level 1).
- If the asset is located outside the PROFINET device, but, for example, belongs to a machine into which the PROFINET device is installed, Level 0 has a value between 0x200 and 0x3FE.

The value 0x3FF for a tree level shows that this tree level is not used. This means that no further asset is connected. In this case, all the lower tree levels down to Level 11 must also have this value.

Example AM_Location slot-oriented

A rack and the terminal blocks located on it each supply AM data. The slot assignments are shown in the figure.

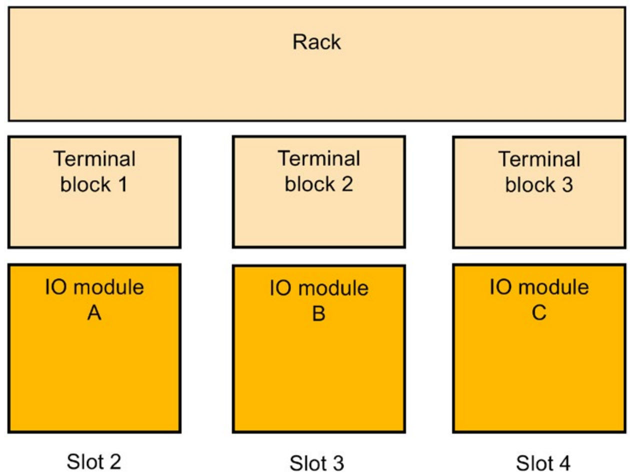


Figure 4-4 Example of assets with slot-oriented AM_Location coding.

Code the AM_Location as an asset for each module as follows:

Bit 0 – 7: AM_Location.Structure = 0x02 (coding "Slot and SubslotNumber format")

Bit 8 – 15: AM_Location.Reserved1 = 0x00 (padding byte)

Bit 16 – 31: AM_Location.BeginSlotNumber = 2 (the "Rack" asset begins from Slot 2 on)

Bit 32 – 47: AM_Location.BeginSubslotNumber = 0xFFFF (the asset encompasses all the subslots of Slot 2. Otherwise you specify the no. of the subslot at which the asset begins)

Bit 48 – 63: AM_Location.EndSlotNumber = 4 (the asset ends at Slot 4)

Bit 64 – 79: AM_Location.EndSubslotNumber = 0xFFFF (the asset encompasses all the subslots of Slot 4. Otherwise you specify the no. of the subslot at which the asset ends)

Bit 80 – 95: AM_Location.Reserved2 = 0x0000 (padding byte)

Bit 96 – 111: AM_Location.Reserved3 = 0x0000

Bit 112 – 127: AM_Location.Reserved4 = 0x0000

Example AM_Location level-oriented

A complex sensor is connected to an IO module (Slot 5, Subslot 1, Channel 1). Two simple sensors, in turn, are connected to the complex sensor. The module can be addressed within the PROFINET device model. Level 0 therefore has the value 0x0000. The next level (Level 1) is specified by the assigned slot. This is followed by the further levels for the subslot and channel and, if appropriate, further subordinate layers.

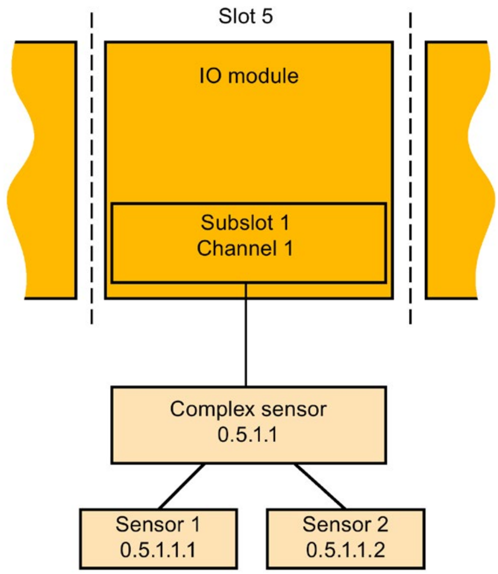

Figure 4-5 Example of assets with hierarchical AM_Location coding.

Detailed coding for the example:

Bit 0 – 7: AM_Location.Structure = 0x01 (LT format)

Bit 8 – 17: AM_Location.Level0 = 0x000 (assets that are assigned to modules always have the Level 0 value 0x000)

Bit 18 – 27: AM_Location.Level1 = 0x005 (Slot 5)

Bit 28 – 37: AM_Location.Level2 = 0x001 (Subslot 1)

Bit 38 – 47: AM_Location.Level3 = 0x001 (Channel 1)

Bit 48 – 57: AM_Location.Level4 = 0x3FF (coding for "Level not used")

Bit 58 – 67: AM_Location.Level5 = 0x3FF (coding for "Level not used")

...

Bit 118 – 127: AM_Location.Level11 = 0x3FF (coding for "Level not used")

Notation used in the screen for the LT coding of complex sensors: 0.5.1.1

The following correspondingly applies for the remaining sensors:

LT coding for simple Sensor 1 at complex sensor: 0.5.1.1.1

LT coding for second simple Sensor 2 at complex sensor: 0.5.1.1.2

Asset management data record for I-devices

With STEP 7 (TIA Portal) as of V15 and with S7-1500 CPUs as of firmware V2.5, you have the option of compiling an asset management data record via a user program. Configured as an I-device, these CPUs then supply the data from centrally plugged modules to a requesting IO controller as assets.

"S7-1500 CPUs" also refers to the CPU variants S7-1500F, S7-1500T, S7-1500C, S7-1500 SW Controller, S7-1500pro CPUs and ET 200SP CPUs.

Asset management records for I-devices

I-devices often represent machines. The PROFINET IO controller to which the I-device is assigned only sees the PROFINET interface (also configured as an IO device) and the transfer areas of the I-device configured by the machine manufacturer. The local modules of the I-device are not visible or cannot be accessed.

The assigned IO controller can read the central modules as assets of the I-device by means of an asset management record that the user program of the I-device compiles.

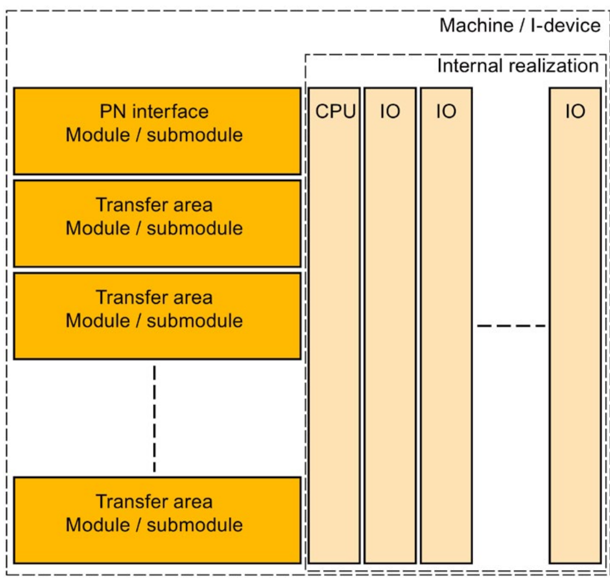

Figure 4-6 Assets of an I-device

Requirement

- S7-1500-CPU as of firmware V2.5, configured as an I-device
- STEP 7 (TIA Portal) as of V15
- If an IO controller is to read the asset management record:

  The PROFINET IO controller is programmed correspondingly to read an asset management record.

  For a SIMATIC IO controller, for example, you call a read instruction (RDREC) with record index 0xF880. The instruction addresses any submodule of the I-device, for example the first configured transfer area submodule.

Basic procedure

The following steps are fundamentally required to create the requirements so that an I-device can make its local modules available as an asset management record to a requesting IO controller:

1. Make the settings in the properties of the PROFINET interface of the CPU.
   – Activate "IO device" operating mode
   – Activate the "Activate asset management using user program" option

     PROFINET interface forwards a request of an IO controller to the user program of the I-device for reading the asset management record only if the option is selected.

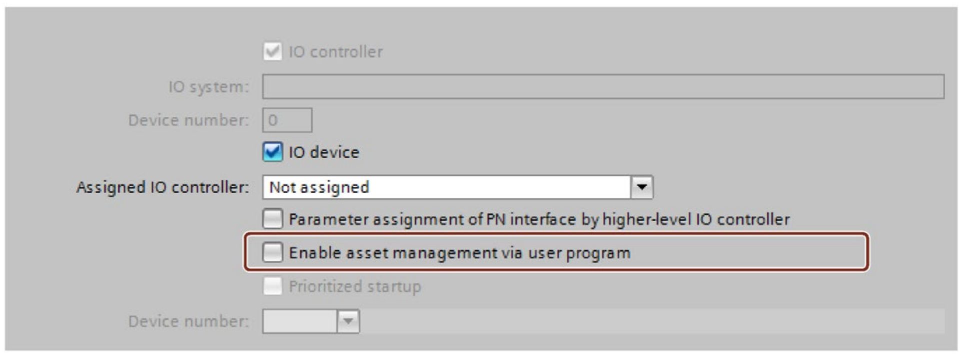

Figure 4-7 Activating asset management using a data record

2. Configure the program routine for compiling the asset management record. The program part collects the required I&M0 data of the plugged central modules and stores them in the corresponding fields of the data record structure of the asset management record.
3. Configure the program part for coordinating the data record provision:
   For this, call the instruction PRVREC (Provide Record) in accordance with the following templates in the corresponding modes:
   – Cyclic calling (for example in the cycle OB) of the PRVREC instruction with Mode 0, in order to recognize the AMR request.
   – When the AM record request is recognized, the PRVREC program has to acknowledge within one second that the request has been recognized. This means that PRVREC must be called with the Mode 2, and with the required AM record. If the I-device does not adhere to the time frame, the I-device acknowledges the record request of the IO controller as negative.

     Particular aspect for configuration of the PRVREC call: PRVREC has to be called with **F_ID = 0**. This codes that this is an IO-device-specific data record. The SLOT and SUBSLOT output parameters therefore also return the value 0.

   – Within 10 seconds the AM record now has to be completed and PRVREC be called with Mode 3 (positive response to the IO controller with provision of the AM record). If the I-device does not adhere to the time frame, the I-device acknowledges the record request of the IO controller as negative.

   A detailed description of the PRVREC instruction and possible error codes for evaluating the function can be found in the online help of STEP 7 (TIA Portal).

Compilation of the asset management record

You have various possibilities for compiling the asset management record for an I-device:

- Recommendation: The Siemens Industry Online Support makes an application available to you that helps you to compile the asset management record.
  The data area of the asset management record is divided in two. The first part consists of an automatically determined area that packages the IM0 data of the slots of the I-device into an asset management block. The second part consists of the user-specific asset management blocks. You configure the user-specific asset management blocks based on pre-configured asset management record structures, fill them with information and make them available to the application.
  The application performs the following:
  - The application determines the required size of all the asset management blocks.
  - The application fills the data block in accordance with the specifications of an asset management record with the automatically determined asset management blocks and your user-specific asset management blocks.
  - The application makes this asset management record available to the higher-level IO controller.

  The application is described in this application example (https://support.industry.siemens.com/cs/ww/en/view/109748894)
- You create the asset management record yourself.
  The following section describes how you can compile an asset management record for an I-device yourself.
  The concept assumes you yourself determine the I&M data for each centrally plugged module and fill the asset management record with this information. The I&M0 data of a module contains basic information about the module such as the manufacturer's code, article number, serial number, hardware and firmware version. These are the data that are also required in the AM record for an asset.

Determine the I&M data of centrally plugged modules

The central structure consists of an optionally plugged power supply unit (Slot 0), followed by the I-device CPU (Slot 1), and then followed by the further modules, such as digital modules, analog modules, etc. (as of Slot 2).

You determine the I&M data with the "Get_IM_Data" instruction for the plugged modules with exception of the CPU:

To assign parameters for the "Get_IM_Data" instruction, you require the hardware identifier (LADDR input parameter). You determine the hardware identifier for each occupied slot with the "GEO2LOG" instruction (Determine hardware identifier from slot).

Summary of the theoretical steps:

1. In a loop, determine the hardware identifiers of the plugged modules with the "GEO2LOG" instruction.
2. For each hardware identifier found, determine the I&M data by using the "Get_IM_Data" instruction and store these data in a data block that you address with the input parameter DATA. Use ARRAY of BYTE for the data storage. This corresponds to the description of the AM record contents in the preceding section.

Forming an AM record with the determined I&M data

The following sections are based on the description of the fundamental structure of the AM record, see the preceding section.

Since each module of an S7-1500 contains hardware and firmware information, select the coding for "AM_FullInformation" for the assigned BlockType.

For the data types used:

- IM_Annotation, IM_OrderID, AM_SoftwareRevision and AM_HardwareRevision: Characters (UTF-8)
- IM_Serial_Number: Characters ("ASCII characters") with the exception of the characters for DEL (0x7F)
- Do not use String data types. They require additional bytes and therefore do not conform to the conventions of the PROFINET standard 61158-6-10 "Application layer protocol specification".

Form the AM_FullInformationBlock for each module as follows:

Table 4- 2 AM_FullInformationBlock for modules

Data record element	Description
IM_UniqueIdentifier	Generate a (pseudo) random UUID (hash value) in accordance with ISO 9834-8 as follows: • Generate an 8-byte hash value across the I&M0 data of the module (as of Slot 2). Use the algorithm Fowler-Noll-Vo (in short: FNV); an algorithm for generating variance coefficients (hash values) across data field, see corresponding example code in the Internet or online support. • Generate an 8-byte hash value across the I&M0 data of the CPU. (Use the algorithm Fowler-Noll-Vo (in short: FNV) as described above) • IM_UniqueIdentifier Byte 0 to 7: Hash value of module I&M0 data Bytes 8 to 15: Hash value for CPU-I&M0 data Required customizations to ISO 9834-8: Byte 8, Bit 7 has to be set to 1, and Byte 8, Bit 6 to 0 (result of the AND operator with 0011 1111, subsequent OR operator with 1000 0000) Byte 6, Bit 4 to 7 have to be set to 0100 (result of the AND operation with 0000 1111, then OR operation with 0001 0000) Since this algorithm is based on the I&M0 data of the CPU as well as of the modules, it generates a constant IM_UniqueIdentifier for an individual module. When the configuration changes the IM_UniqueIdentifier also changes.
AM_Location	Byte 0 = 0x02 (slot-oriented coding), see description in the preceding section.
IM_Annotation	Example: "S7-1500 module" and pad the remaining bytes of IM_Annotation with spaces (0x20).
IM_OrderID	Copy 20 bytes of the I&M0 data of the module (beginning with offset 2 of the I&M0 data). Pad the remaining 44 bytes with spaces (0x20)
AM_SoftwareRevision	Pad the field with 64 spaces (0x20)
AM_HardwareRevision	Pad the field with 64 spaces (0x20)
IM_Serial_Number	Copy 16 bytes of the I&M0 data of the module (beginning with offset 22 of the I&M0 data)
IM_Software_Revision	Copy 4 bytes of the I&M0 data of the module (beginning with offset 40 of the I&M0 data)
AM_DeviceIdentification	Byte 0, 1, 2, 6, 7 = 0x00 Byte 3 = 0x2A (Vendor = Siemens) Byte 4 = 01, Byte 5 = DeviceID (e.g. CPU 15xx = 0x0E)
AM_TypeIdentification	Copy 2 bytes of the I&M0 data of the module (beginning with offset 48 of the I&M0 data)
IM_Hardware_Revision	Copy 2 bytes of the I&M0 data of the module (beginning with offset 38 of the I&M0 data)

4.2 Diagnostics using status LEDs

LEDs for diagnostics on PROFINET

Each port of a PROFINET interface of a SIMATIC device has one LED.

The following table shows a summary of the meaning of these LEDs in the S7-1500, ET 200MP, ET 200SP and ET 200AL systems.

Table 4- 3 S7-1500, ET 200MP, ET 200SP, ET 200AL: LEDs for diagnostics on PROFINET

LED image	Meaning	S7-1500	ET 200MP	ET 200SP	ET 200AL
		LINK/TX/RX LED		LK LED	P1 Link LED P2 Link LED
LED off	There is no Ethernet connection between the PROFINET interface of the PROFINET device and the communication partner. No data is currently being sent/received via the PROFINET interface.	X	X	X	X
LED green	There is an Ethernet connection between the PROFINET interface of your PROFINET device and a communication partner.	X	X	X	X
LED flashes green	The "LED flashing test" is being performed.	X	X	X	X
LED flickers yel-low	Data is currently being received from or sent to a communications partner on Ethernet via the PROFINET interface of the PROFINET device.	X	X	-	-

Additional information

You can find a detailed description of all LEDs of the module with cause of the error and remedies in the relevant documentation for the module.

4.3 Diagnostics via the display of the S7-1500 CPUs

Display

The S7-1500 CPU has a display and operating keys. The display of the CPU shows you the control and status information in different menus. You use operating keys to navigate through the menus and make a variety of settings in the process.

Diagnostics via the display

The following indicators can be evaluated for diagnostics purposes on the display:

- Error and alarm texts (system diagnostics, alarm messages)
- Module status for central and distributed modules

In the following example of a display of the CPU 1516-3 PN/DP, you can see a warning on the diagnostics icon and an exclamation mark on the icon for module.

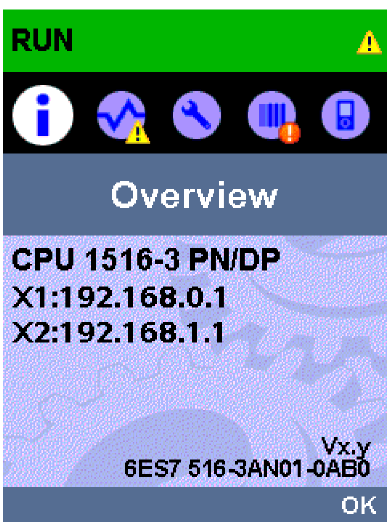

Figure 4-8 Display of overview

Module status

To show the module status, navigate on the display through the menu items "Module" > "PROFINET I/O (X1)" > "Station" > "Slot" > "Status" > "Module status".

The module status indicates that a fault has occurred in the module. The "lower-level status" is the status of the module in the diagnostics level below this. In the example, the status is "good", i.e., the fault is not in the lower diagnostics level submodule or channel, but instead in the module.

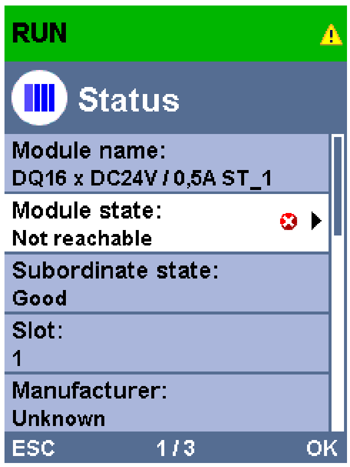

Figure 4-9 Display of module status

Error and alarm texts

You can show diagnostics buffer entries and alarm messages for the relevant automation system on the display.

To show the diagnostics buffer entries of the CPU, navigate on the display via the menu items "Diagnostics" > "Diagnostics buffer".

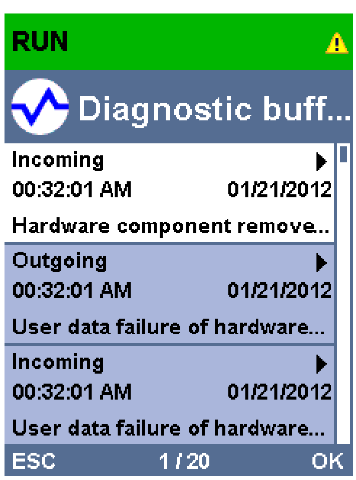

Figure 4-10 Display of diagnostics buffer

To show the alarm messages of the automation system, navigate through the menu items "Diagnostics" > "Alarms" > "Alarm text" on the display.

Note

Updating the alarm display

The display shows the currently read status of the CPU in static form, the display is not automatically updated. The alarm display is updated after it has been exited and opened again.

You set the automatic updating of the diagnostics information under: "Display" > "DiagnosticRefresh".

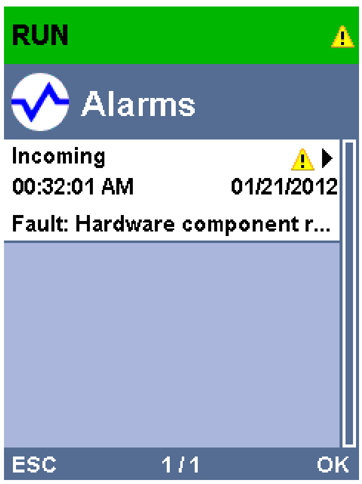

Figure 4-11 Display of alarms

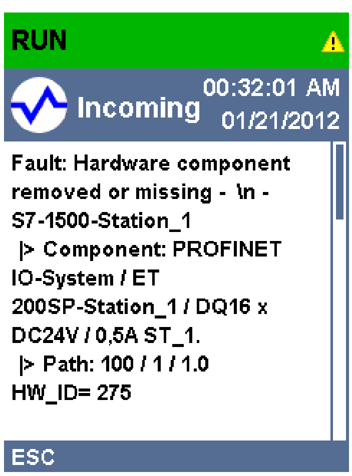

Figure 4-12 Display of alarm message

Additional information

You can find the description of the operation and functions of the display in the SIMATIC S7-1500 Display Simulator (http://www.automation.siemens.com/salesmaterial-as/interactive-manuals/getting-started_simatic-s7-1500/disp_tool/start_de.html).

4.4 Diagnostics via Web server

The CPUs belonging to the S7 family have their own integrated Web server with a wide range of functions.

The following diagnostics options are available to you:

- Start page with general CPU information
- Information on diagnostics
- Contents of the diagnostics buffer
- Module information
- Alarms
- Information about communication
- PROFINET topology
- Motion Control diagnostics
- Trace
- Contents of the diagnostic buffer
- Module status
- Actual topology of the PROFINET system
- Set topology of the PROFINET system (from the configuration)

Set topology and actual topology - graphic view

Requirements for displaying the set and actual topology:

- You have configured the PROFINET ports in the topology editor of the hardware and network editor of STEP 7.
- You have loaded the entire project with STEP 7 in the CPU.

The following shows an example of the graphic view.

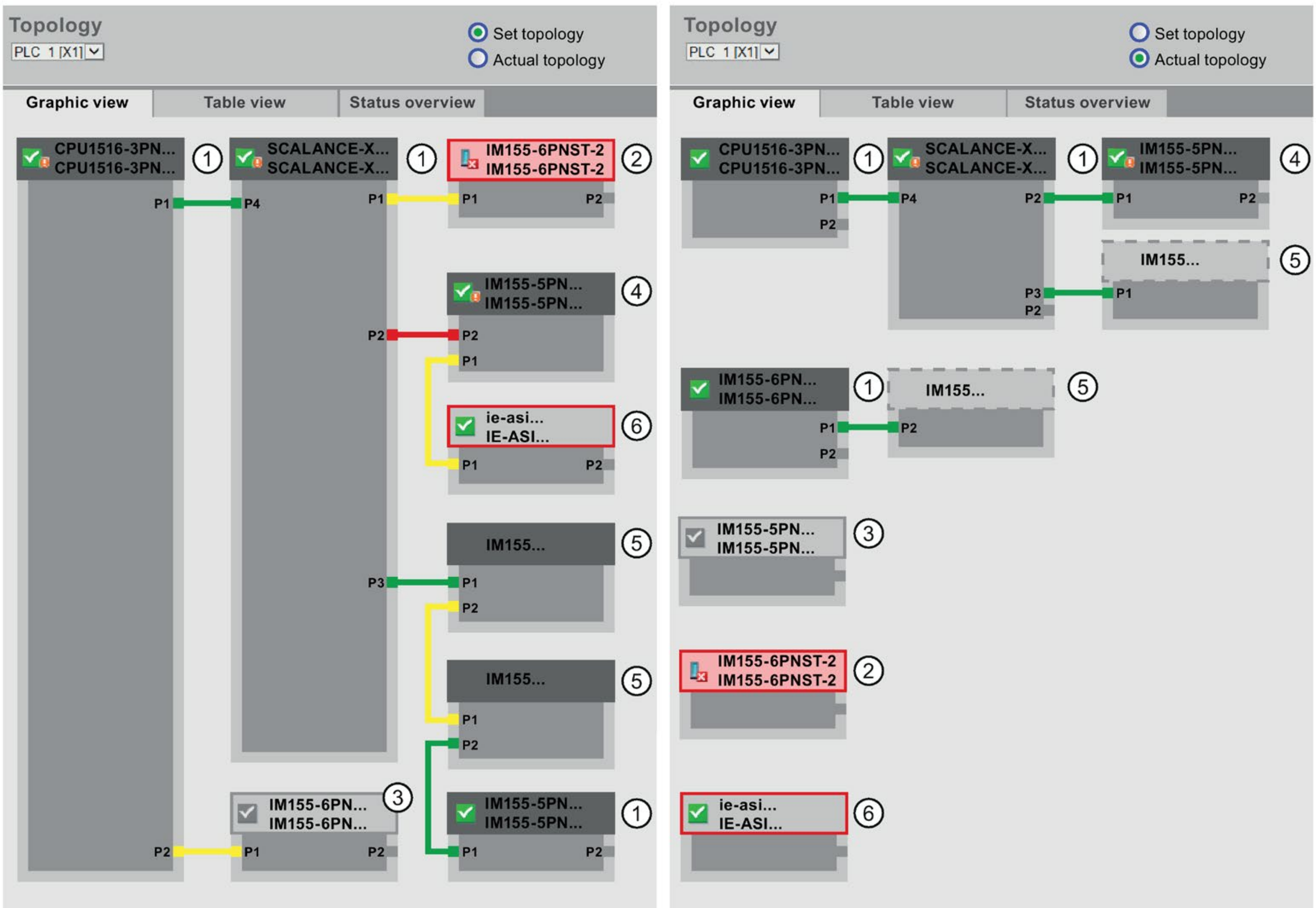

Figure 4-13 Topology - graphic view via the Web server

Meaning of the colored connections in the set/actual topology:

Table 4- 4 Meaning of the colored connections in the set/actual topology:

Connection	Meaning	
	Set topology	**Actual topology**
green	The current actual connection matches the configured set connection.	detected connections
red	The current actual connection does not match the configured set connection (e.g., port interchanged).	-
yellow	The connection cannot be diagnosed. Causes: • The communication to an IO device has been disrupted (e.g., cable removed) • Connection to a passive component • Connection to PROFINET devices of another IO controller or PROFINET system	-

① Configured and accessible PROFINET devices

Configured and accessible PROFINET devices are displayed dark-gray. Connections show the ports through which the PROFINET devices of a station are connected.

① Configured but not accessible PROFINET devices

The configured but not accessible PROFINET devices are displayed in pink with red border (e.g., device has failed, cable disconnected).

③ Disabled devices

All disabled, configured PROFINET devices are displayed light-gray.

④ Interchanged ports

Interchanged ports are marked red in the set topology view. The currently connected ports are displayed in the actual topology, the configured set connection in the set topology.

⑤ PROFINET devices of another PROFINET IO system

- In the set topology:

  A PROFINET device of another PROFINET IO system is displayed with a green connection (or red connected if the ports have been interchanged), when it is directly adjoining a configured and accessible PROFINET device ① and it is also accessible. When the PROFINET device of another PROFINET IO system is not accessible, a yellow connection line is displayed.

  The connection between two PROFINET devices that both belong to a different PROFINET IO system, cannot be determined and is always displayed in yellow.
- In the actual topology:

  A PROFINET device of another PROFINET IO system is only displayed if the PROFINET device is in direct proximity to a configured PROFINET device. The PROFINET device is displayed light-gray and with dashed line.

For PROFINET devices of a different PROFINET IO system, **no** status display is shown on the device head.

⑥ Representation of faulty neighbor relations

The devices whose neighbor relations cannot be read out completely or correctly are displayed light-gray with red border.

Additional information

The tabular view of the actual topology and the status overview of the PROFINET devices in the project are possible.

You can find these views, additional topology examples, and detailed information on the operation and the functions of the Web server in the Web server (http://support.automation.siemens.com/WW/view/en/59193560) manual.

4.5 Diagnostics in STEP 7

For PROFINET, you have the following options to evaluate diagnostics in STEP 7:

- Online & diagnostics - Devices & networks
- Online & diagnostics - diagnostics of PROFINET ports

Online & diagnostics network view

In the hardware and network editor (launched from the "Project tree" by double-clicking "Devices & networks"), you can get an overview of the current state of your system by clicking on the "Go online" button. It also shows the configuration information (for example, non-configured modules). This option is also available in the topology view in similar form.

Schematic drawing of the network view (online):

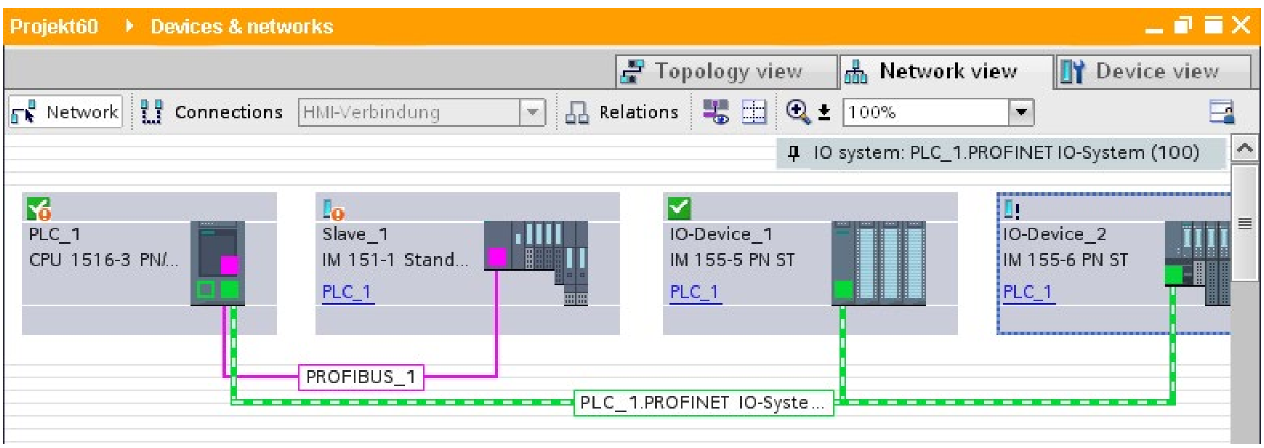

Figure 4-14 Online & diagnostics network view

Online & diagnostics device view

In STEP 7, you can display an overview of the modules in which faults have occurred. To do this, select the menu command "Online > Online & diagnostics". Once you are connected, you can see the status of the accessible devices in the project tree.

Double-click the device which displays an alarm message to access the faulty module directly. The device view is opened in the work area. In the device view of the device that reports the fault you can see directly in which module the fault occurs.

Open the "Diagnostics" tab and the subordinate "Device information" tab in the Inspector window for a more detailed error description.

Schematic drawing of the device view (online):

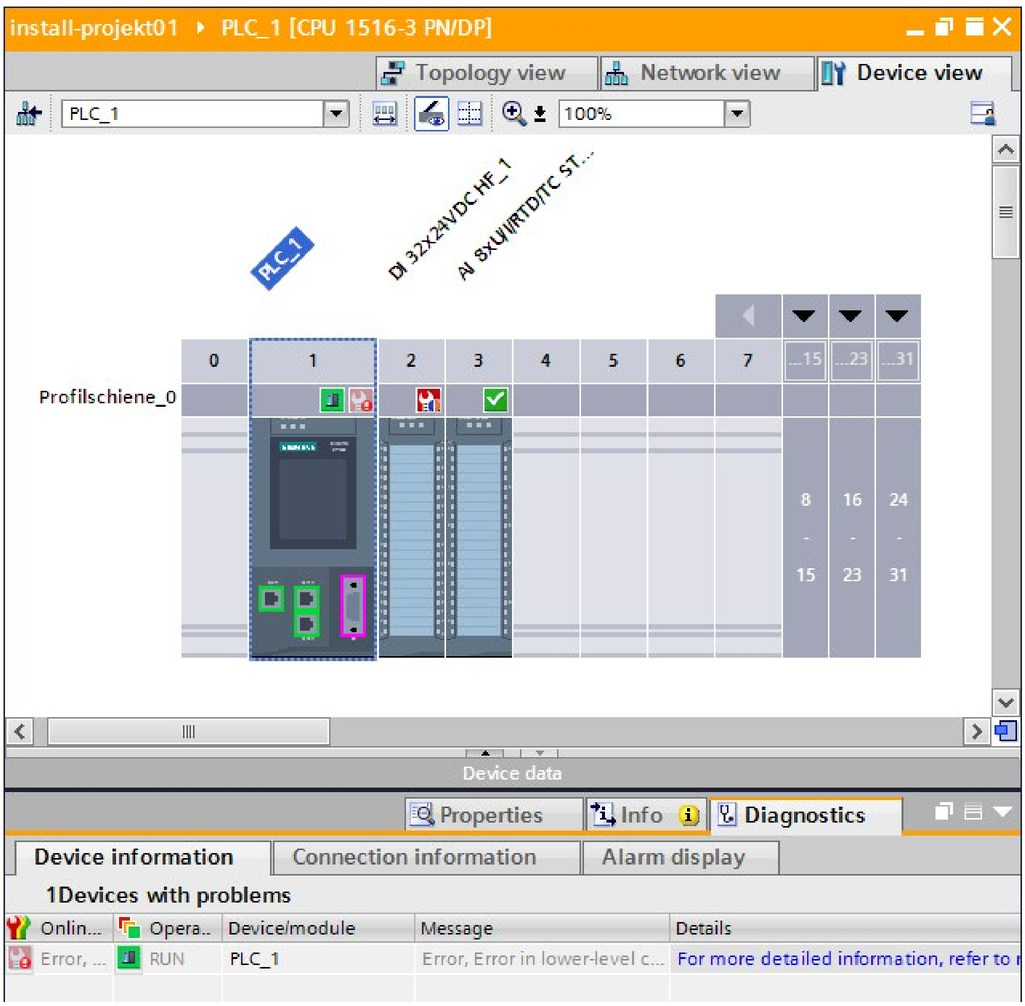

Figure 4-15 Online & diagnostics device view

Diagnostics of PROFINET ports

If you select "PROFINET interface > Ports" in the Diagnostics area in the online & diagnostics device view of a PROFINET device, the ports of the PROFINET interface are listed in a table.

The table provides you with the following information about the ports of the PROFINET interface.

- Name
- Status
- Settings
- Operating mode

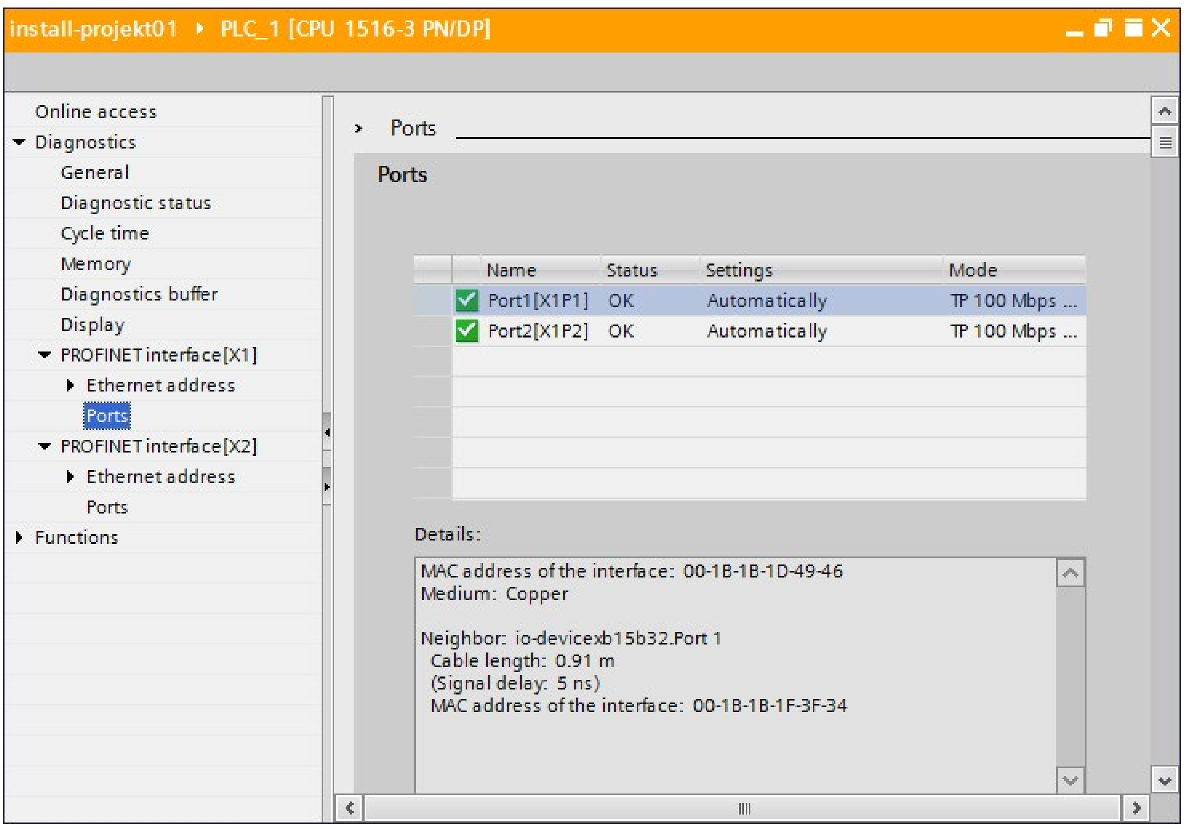

Figure 4-16 Diagnostics of PROFINET ports in STEP 7

Additional information

You can find information on the system diagnostics for S7-1500, ET 200MP, ET 200SP and ET 200AL in the Diagnostics (http://support.automation.siemens.com/WW/view/en/59192926) function manual and online help for STEP 7.

4.6 Extended maintenance concept

Extended maintenance concept

The PROFINET interfaces with integrated switch of the SIMATIC devices support the four-level diagnostics concept in accordance with PROFINET specification Version V2.3 or higher with the following status:

Table 4- 5 Classification of the diagnostic status

Diagnostic status	Symbol		Severity of the error
Good	Green checkmark		Maintenance required	Green wrench		
Maintenance demanded	Yellow wrench		
Bad	Red wrench		

The aim of the diagnostics concept is the early detection and elimination of potential faults - before they cause a production outage.

Other status information is defined in addition to the Good (no fault) and Bad (fault) status information for a PROFINET device.

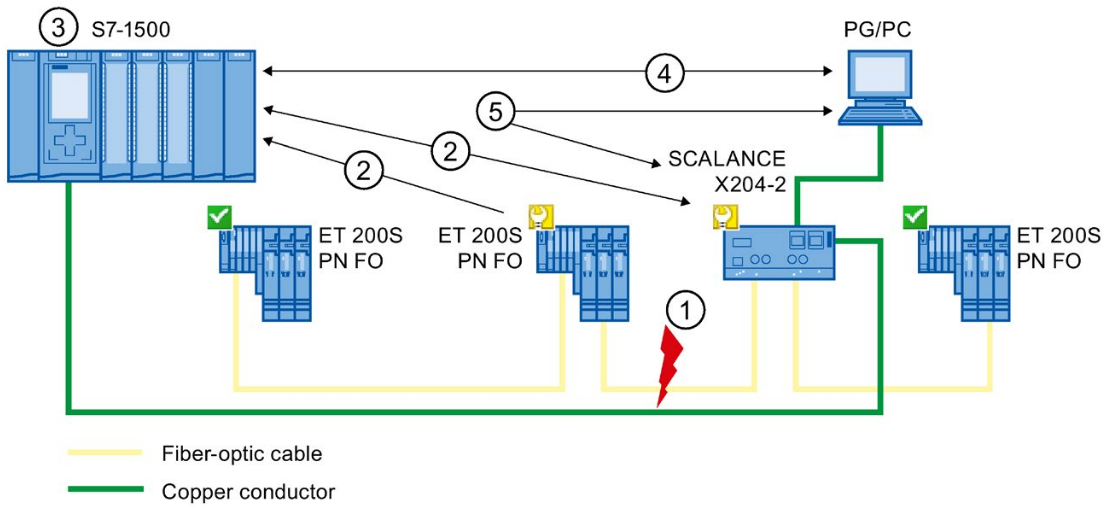
The maintenance information is generated with the following system alarms:

- Maintenance required (symbolized by a green wrench) and
- Maintenance demanded (symbolized by a yellow wrench)

The times at which the two system alarms are generated can be customized for most wear parameters.

Example: Maintenance demanded for a PROFINET cable

The following graphic illustrates how diagnostics information is exchanged when the transmission quality on the optical cable decreases due to ageing, for example. In this example, the scenario is considered after a maintenance required has already been diagnosed.



Num-ber	Description
①	The system reserve of the fiber-optic cable drops below 0 dB.
②	Both the ET 200S PN FO and the switch send the maintenance demanded alarm to the IO controller.
③	Based on the interrupts, the IO controller detects the maintenance demanded from the switch and from the IO device. The module information data is updated in the IO controller and the corresponding error OBs are called. Note: To be able to start the error OBs in the IO controller, the "Call the user program if communication errors occur" property must be selected in STEP 7 for the relevant IO controller.
④	In STEP 7 (on the programming device/PC), the maintenance demanded message is indicated on the IO device and at the switch by a yellow wrench symbol.
⑤	STEP 7 can also read out detailed information directly from the switch.

Figure 4-17 Maintenance demanded for a PROFINET cable

4.7 Diagnostics of the network topology

Availability

As an open standard, you can use any SNMP based systems or software solutions for diagnostics in PROFINET.

Network diagnostics

The network management protocol SNMP (Simple Network Management Protocol) uses the wireless UDP transport protocol. It consists of two network components, similar to the client/server model. The SNMP manager monitors the network nodes and the SNMP clients collect the various network-specific information in the individual network nodes and store it in a structured form in the **MIB** (Management Information Base). This information allows a network management system to run detailed network diagnostics.

MIB

The MIB (Management Information Base) is the database of a device. SNMP clients access this database in the device. The S7 device family supports the following standard MIBs:

- MIB II, standardized in the RFC 1213
- LLDP-MIB, standardized in the international standard IEC 802.1AB
- LLDP-PNIO-MIB, standardized in the international standard IEC 61158-6-10

Detecting the network topology

LLDP (Link Layer Discovery Protocol) is a protocol that is used to detect the closest neighbor. LLDP enables a device to send information about itself and to receive information from its neighbor devices. This information is then saved in the LLDP MIB, for example, and can be queried using SNMP. This information allows a network management system to determine the network topology.

Use of SNMP (Simple Network Management Protocol)

SNMP can be used as follows:

- By users to integrate network diagnostics into a central HMI/SCADA system using the SIMATIC NET OPC server
- By the IT administration of machine and plant operators to monitor their Industrial Ethernet network using standard network management systems.
- By the IT administration, to monitor the automation network, alongside the office network, using standard network management systems.

Use of SNMP in the SIMATIC NET environment

SNMP-compliant devices from the SIMATIC NET family can be monitored and operated via a conventional standard Internet browser. The management system known as web-based management offers a wide range of device-specific information (network statistics, status of redundant supply, for example).

4.8 Diagnostics in the user program

4.8.1 Diagnostics and configuration data records

Diagnostics mechanism

The IO device outputs a diagnostics interrupt to the IO controller when it detects faults such as wire break on an IO module. This interrupt calls a corresponding organization block in the user program (diagnostics interrupt OB82), in order to generate a defined (programmed) response to the fault and passes a diagnostics data record.

Diagnostics data records in PROFINET IO

There are two different types of diagnostics data record:

1. Channel diagnostics data records

   Channel diagnostics data records are generated if a channel is in an error state and / or has triggered an interrupt.

   A diagnostics data record of length 0 is returned if there is no fault.

2. Vendor-specific diagnostics data records

   The structure and size of vendor-specific diagnostics data records depend on the vendor's settings.

   For information about vendor-specific diagnostics data records, refer to the appropriate device manual.

Addressing levels of diagnostics data records

Diagnostics and configuration data is evaluated at the following addressing levels:

- Device level
- AR (Application Relation)
- API (Application Process Identifier)
- Slot
- Subslot

A group of diagnostics and configuration data records are available for each address level (exception: device level always 0xF80c). In HEX representation, the individual groups of data records are distinguished by the first letter of the data record number.

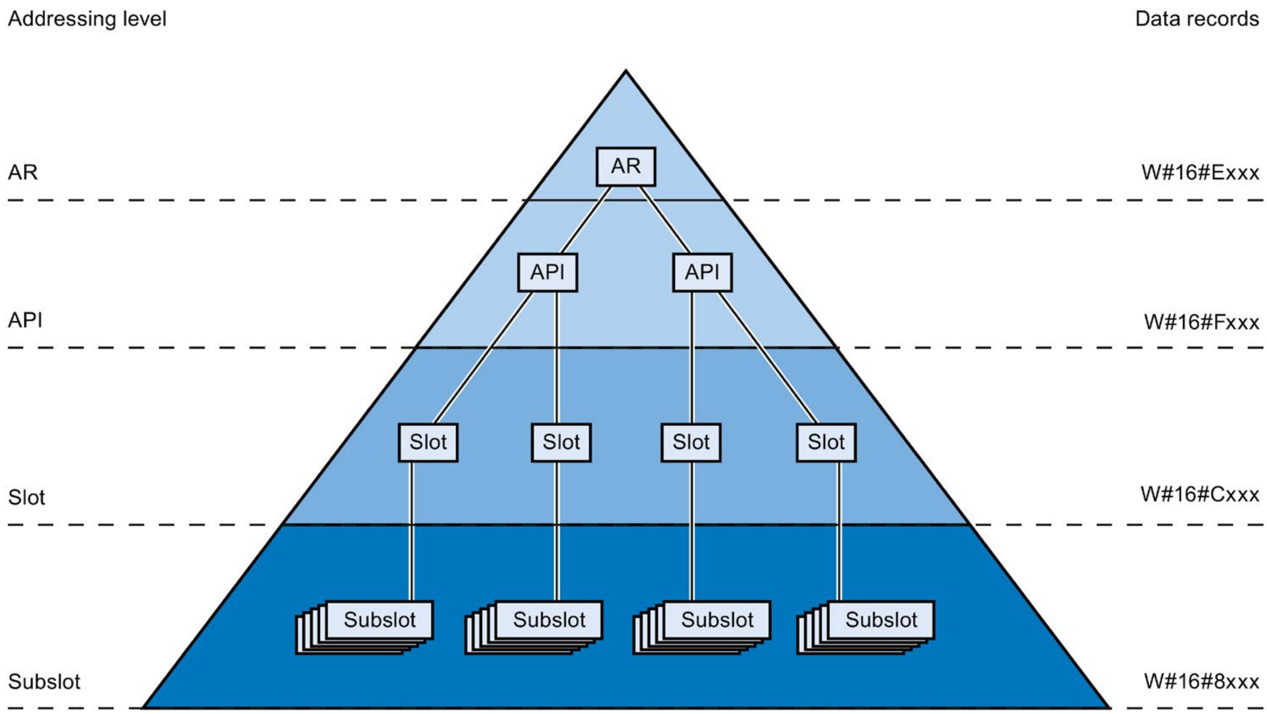


Figure 4-18 Addressing levels of diagnostics data records

The information for each IO device (addressing level AR), module (addressing level slot) or submodule (addressing level subslot) is always transferred in separate diagnostics or configuration data records. The data record returns diagnostics data or configuration data for one or more subslots, slots and APIs, depending on the addressing level.

Note

The diagnostics information is only generated for configured modules / submodules / channels.

Library for PROFINET data records

The "LPNDR" block library contains various function blocks. You can use these blocks to read out various device and status information from a PROFINET device and write parameters.

You can execute the following functions using the library blocks:

- Read device information:
  - Information about the interface, e.g. IP and MAC address
  - Information about the device interface, e.g. status, medium, name
  - Information about the link status of the interfaces, e.g. link down, link up
  - Information about the role of the device for MRP, e.g. client, manager
  - Information about the port statistics, e.g. number of received bytes
- Read the MRP status
- Modification of the parameters of analog input module of the ET 200SP in runtime, e.g. in order to disable/enable the channel diagnostics.

The finished functions are freely adaptable and can therefore be used universally.

The "LPNDR" block library with an example project can be found on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109753067).

4.8.2 Evaluate diagnostics in the user program

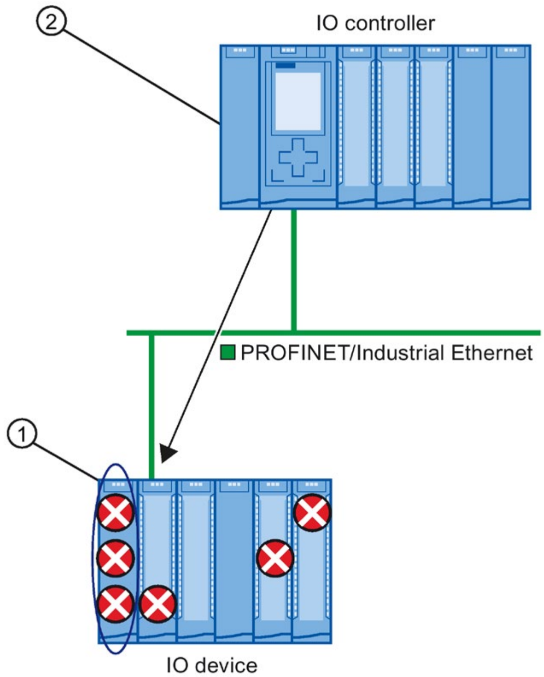
Diagnostics in the user program

For PROFINET IO, a cross-vendor structure of data records with diagnostics information applies. Diagnostics information is created only for channels on which a fault has occurred. With PROFINET, there are two basic ways to obtain diagnostics information.

1. Evaluating the diagnostics status

Read out the diagnostics of your PROFINET IO system using the instructions "DeviceStates" and "ModuleStates", to localize those stations / modules or station / modules with maintenance demanded or maintenance required that have faults within a PROFINET IO system.

The instruction RDREC (read data record) is then used to read various diagnostics data records directly from the module concerned and thus obtain detailed information about the error.

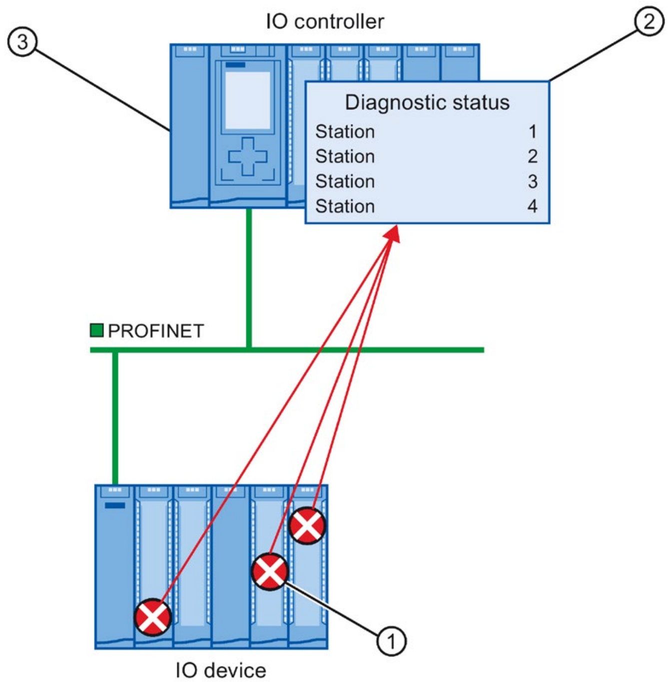


Num-ber	Description
①	All individual errors are collected in a single data record on the interface module.
②	In your user program, the instruction "RDREC" reads the entire station status asynchronously directly from the IO device.

Figure 4-19 Example: Evaluating diagnostics data records with the instruction "RDREC"

2. Evaluation of interrupts

When the error OB (OB 82) is called, the OB's start information provides you with information on the cause and location of the error. Detailed information on the error event can be obtained in the error OB using the instruction "RALRM" (read additional interrupt information).



Number	Description
①	Every error is sent to the IO controller individually as channel diagnostics information in the form of an interrupt.
②	In the IO controller, the module status data is updated automatically and the error OB (OB 82) is started.
③	In your user program in the error OB (OB 82), the instruction "RALRM" reads the error synchronously from the IO controller without addressing the IO device.

Figure 4-20 Diagnostics with OB 82 and the instruction "RALRM"

Instructions and OBs

You will find information on the instructions and OBs in the STEP 7 online help.

Functions

5

Introduction

The following section describes the PROFINET IO functions for field of application, properties and configuration in STEP 7.

Refer to the documentation for the respective device to see to what extent the PROFINET devices support the described functions.

You can find a tabular overview of the PROFINET devices and the functions these support on the Internet (https://support.industry.siemens.com/cs/ww/en/view/102325771).

5.1 Connecting other bus systems

Fieldbus integration

PROFINET allows you to use a proxy-capable PROFINET device to integrate existing fieldbus systems (for example, PROFIBUS, AS interface). The devices of these fieldbus systems are mapped on proxy PROFINET devices. In this way, you can set up any hybrid systems consisting of fieldbus and Ethernet-based subsystems. This allows a continuous exchange of information.

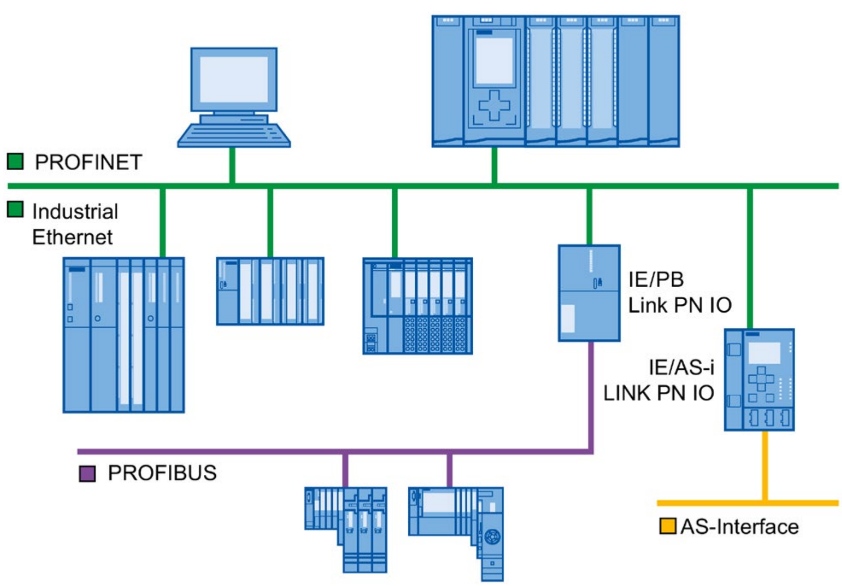


Figure 5-1 Gateways on PROFINET IO

Gateways of an S7-1500 CPU

An overview of the gateways at an S7-1500 CPU is provided in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/88778900).

Connecting to building busses

- BACnet: You can find the procedure for configuring communication between a SIMATIC PLC and a BACnet network with a gateway in this application example (https://support.industry.siemens.com/cs/ww/en/view/109476182).
- M-bus: You can find the procedure for configuring communication between a SIMATIC PLC and an M-bus network with a gateway in this application example (https://support.industry.siemens.com/cs/ww/en/view/109478527).
- DALI: You can find the procedure for configuring communication between a SIMATIC PLC and a DALI network with a gateway in this application example (https://support.industry.siemens.com/cs/ww/en/view/109740160).
- KNX: You can find the procedure for configuring communication between a SIMATIC PLC and a KNX network with a gateway in this application example (https://support.industry.siemens.com/cs/ww/en/view/109739689).

5.1.1 Linking PROFINET and PROFIBUS

Linking PROFINET and PROFIBUS

With a proxy-capable PROFINET device which is equipped with a PROFINET interface in addition to a PROFIBUS interface (for example, IE/PB Link PN IO), you can integrate existing PROFIBUS configurations into the PROFINET configuration.

The following figures shows how a PROFIBUS system is connected via IE/PB Link to a CPU S7-1500 (as of firmware version 1.7).

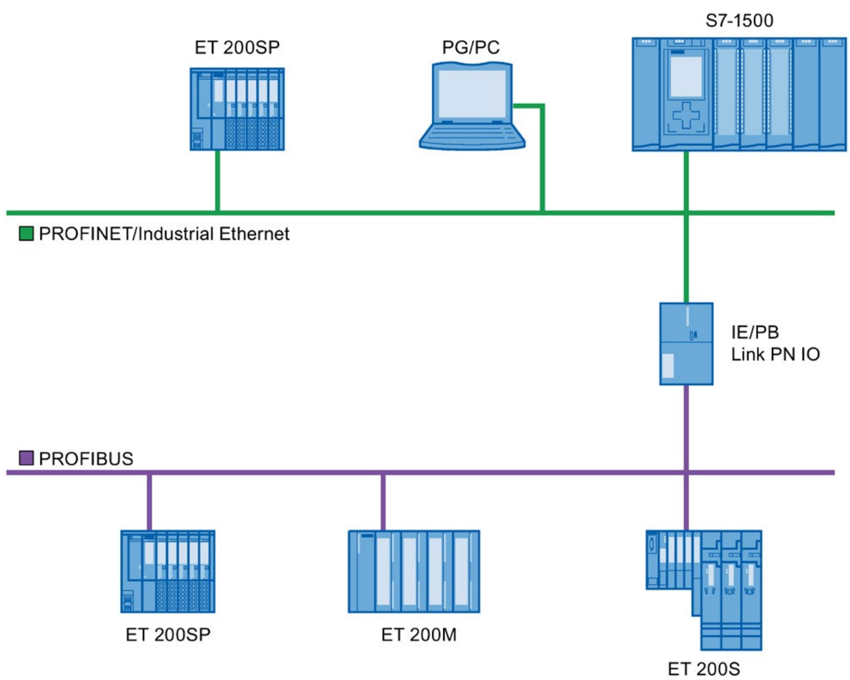

Figure 5-2 Gateway from PROFINET and PROFIBUS via IE/PB link

PROFINET device with proxy functionality

The PROFINET device with proxy functionality is the substitute for a PROFIBUS device on Ethernet. The proxy functionality allows a PROFIBUS device to communicate not only with its master but also with all devices on PROFINET.

With PROFINET you can connect an existing PROFIBUS system to an IO controller, for example with the help of an IE/PB Link PN IO.

From the IO controller perspective, the PROFIBUS DP slaves are connected to the same network as the IE/PB Link PN IO. These slaves have the same device name and IP address as the IE/PB Link PN IO, but different device numbers. Furthermore, each also has a specific PROFIBUS address.

In this way, you can link both DPV0 and DPV1 slaves to PROFINET.

For information on how to connect a DP slave to a PROFINET IO system, refer to section Connect the DP slave via the IE/PB Link to a PROFINET IO system (Page 118).

Diagnostic options with a CPU S7-1500 as IO controller

The CPU S7-1500 (as of firmware version 1.7) as IO controller detects disrupted DP slaves behind the IP/PB link.

5.1.2 Connect the DP slave via the IE/PB Link to a PROFINET IO system

Requirements

- STEP 7 as of V13 SP1
- S7-1500 CPU as of firmware version 1.7
- ET 200SP CPU as of firmware version 1.7
- CPU 1516pro-2 PN as of firmware version 2.0
- S7-1500 Software Controller as of firmware version 1.7
- S7-300/400 CPU

Procedure for connecting a DP slave via an IE/PB Link

To connect a DP slave to a PROFINET IO system via an IE/PB Link in STEP 7, follow these steps:

1. Drag-and-drop a PROFINET CPU, for example CPU 1513-1 PN, from the hardware catalog into the network view of STEP 7.
2. Drag-and-drop an IE/PB Link PN IO from the hardware catalog into the network view of STEP 7. The IE/PB Link PN IO is located under Network components > Gateways > IE/PB Link PN IO.
3. Assign the IE/PB Link PN IO to the CPU.

4. Drag a PROFIBUS interface module e.g. IM155-6 DP HF, from the hardware catalog to the network view.
5. Assign the interface module to the IE/PB Link.

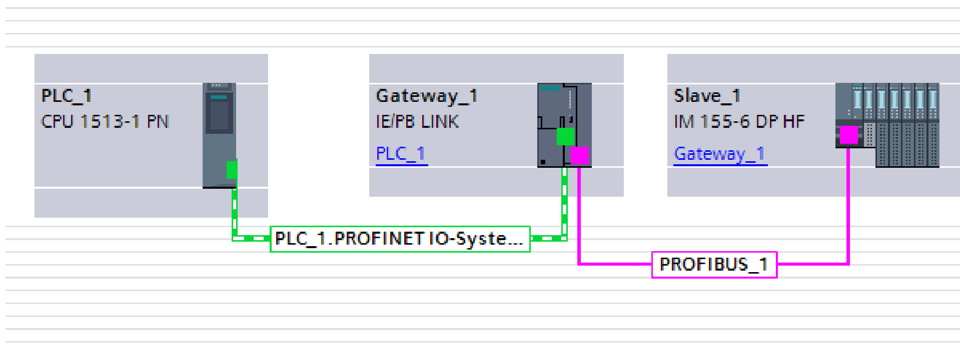

Figure 5-3 Configuring an IE/PB link

6. Select the IE/PB Link PN IO in the network view of STEP 7.
7. In the Inspector window, go to the "Gateway" area and select the "Network gateway as PROFINET IO proxy" option.

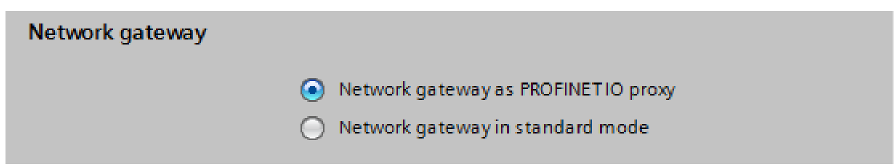

Figure 5-4 Setting a gateway

8. In the PROFINET device number area, you can assign a PROFINET device number for the DP slave.
   If you have selected the "Device number = PB address" check box (default), STEP 7 automatically assigns the device number according to the PROFIBUS address of the slave. In addition, you no longer need to update the device number if the PROFIBUS address changes.

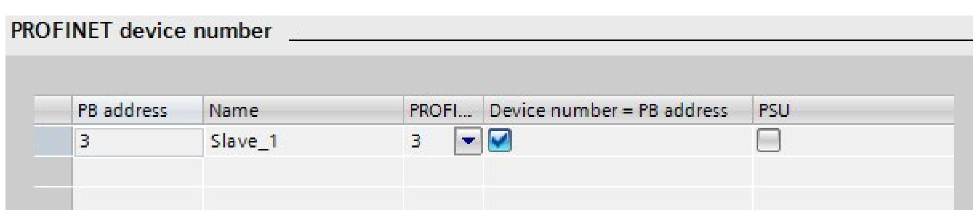

Figure 5-5 Assigning PN device numbers for IE/PB link

Result

You have connected the DP slave to the PROFINET IO system.

Reference

Additional information on the IE/PB link is available in the manual Gateway IE/PB Link PN IO (http://support.automation.siemens.com/WW/view/en/19299692).

5.2 Intelligent IO devices (I-devices)

5.2.1 I-device functionality

I-device functionality

The "I-device" (intelligent IO device) functionality of a CPU facilitates data exchange with an IO controller and operation of the CPU as intelligent preprocessing unit of sub processes, for example. The I-device is linked as an IO device to a "higher-level" IO controller.

The preprocessing is handled by the user program in the I-device. The process values acquired in the centralized or distributed (PROFINET IO or PROFIBUS DP) I/O are preprocessed by the user program and made available to the IO controller.

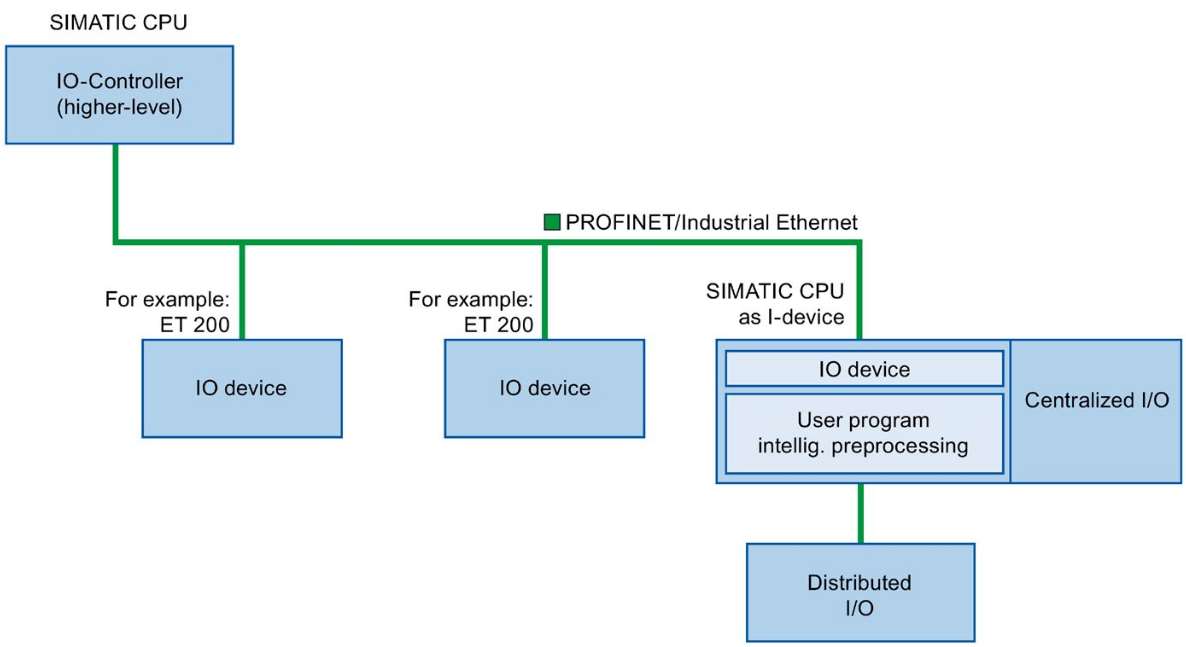

Figure 5-6 I-device

"I-device" naming conventions

In the remainder of this description, a CPU or a CP with I-device functionality is simply called an "I-device".

Application example: Configuration and application of the PROFINET I-device function

A detailed application example is available here (https://support.industry.siemens.com/cs/ww/en/view/109478798).

5.2.2 Properties and Advantages of the I-Device

Fields of application

Fields of application of the I-device:

- Distributed processing

  A complex automation task can be divided into smaller units/subprocesses. This results in manageable processes which lead to simplified subtasks.

- Separating subprocesses

  Complicated, widely distributed and extensive processes can be subdivided into several subprocesses with manageable interfaces by using I-devices. These subprocesses can be stored in individual STEP 7 projects if necessary, which can later be merged to form one master project.

- Know-how protection

  Components can only be delivered with a GSD file for the I-device interface description instead of with a STEP 7 project. The know-how of the user program may no longer be published.

Properties

Properties of the I-device:

- Unlinking STEP 7 projects

  Creators and users of an I-device can have completely separated STEP 7 automation projects. The GSD file forms the interface between the STEP 7 projects. This allows a link to standard IO controllers via a standardized interface.

- Real-time communication

  The I-device is provided with a deterministic PROFINET IO system via a PROFINET IO interface and therefore supports RT (real-time communication) and IRT (isochronous real time).

Advantages

The I-device has the following advantages:

- Simple linking of IO controllers
- Real-time communication between IO controllers
- Relieving the IO controller by distributing the computing capacity to I-devices.
- Lower communication load by processing process data locally.
- Manageable, due to processing of subtasks in separate STEP 7 projects

5.2.3 Characteristics of an I-Device

Principle

An I-device is included in an IO system like a standard IO device.

I-device without lower-level PROFINET IO system

The I-device does not have its own distributed I/O. The configuration and parameter assignment of the I-devices in the role of an IO device is the same as for a distributed I/O system (for example ET 200).

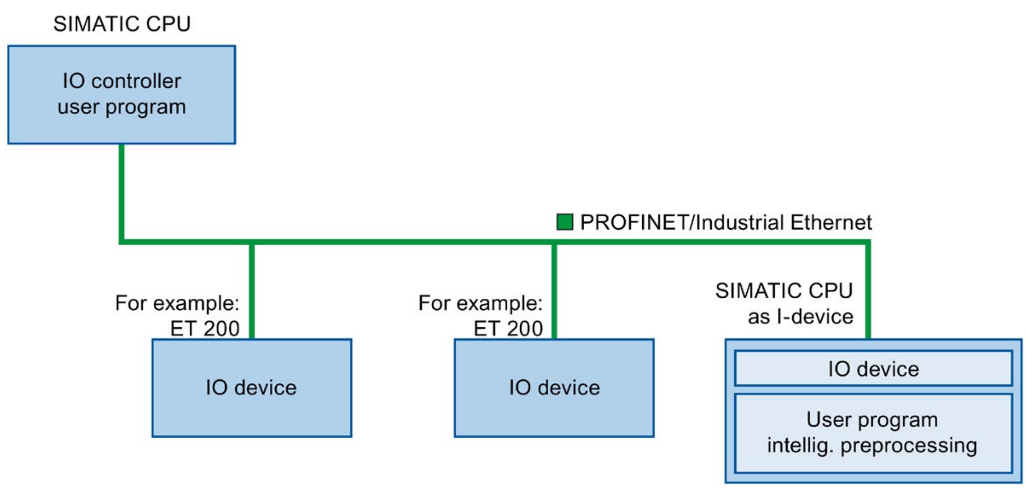

Figure 5-7 I-device without lower-level PROFINET IO system

I-device with lower-level PROFINET IO system

Depending on the configuration, an I-device can also be an IO controller on a PROFINET interface in addition to having the role of an IO device.

This means that the I-device can be part of a higher-level IO system via its PROFINET interface and as an IO controller can support its own lower-level IO system.

The lower-level IO system can, in turn, contain I-devices (see figure below). This makes hierarchically structured IO systems possible.

In addition to its role as IO controller, an I-device can also be used via a PROFIBUS interface as DP master for a lower-level PROFIBUS system.

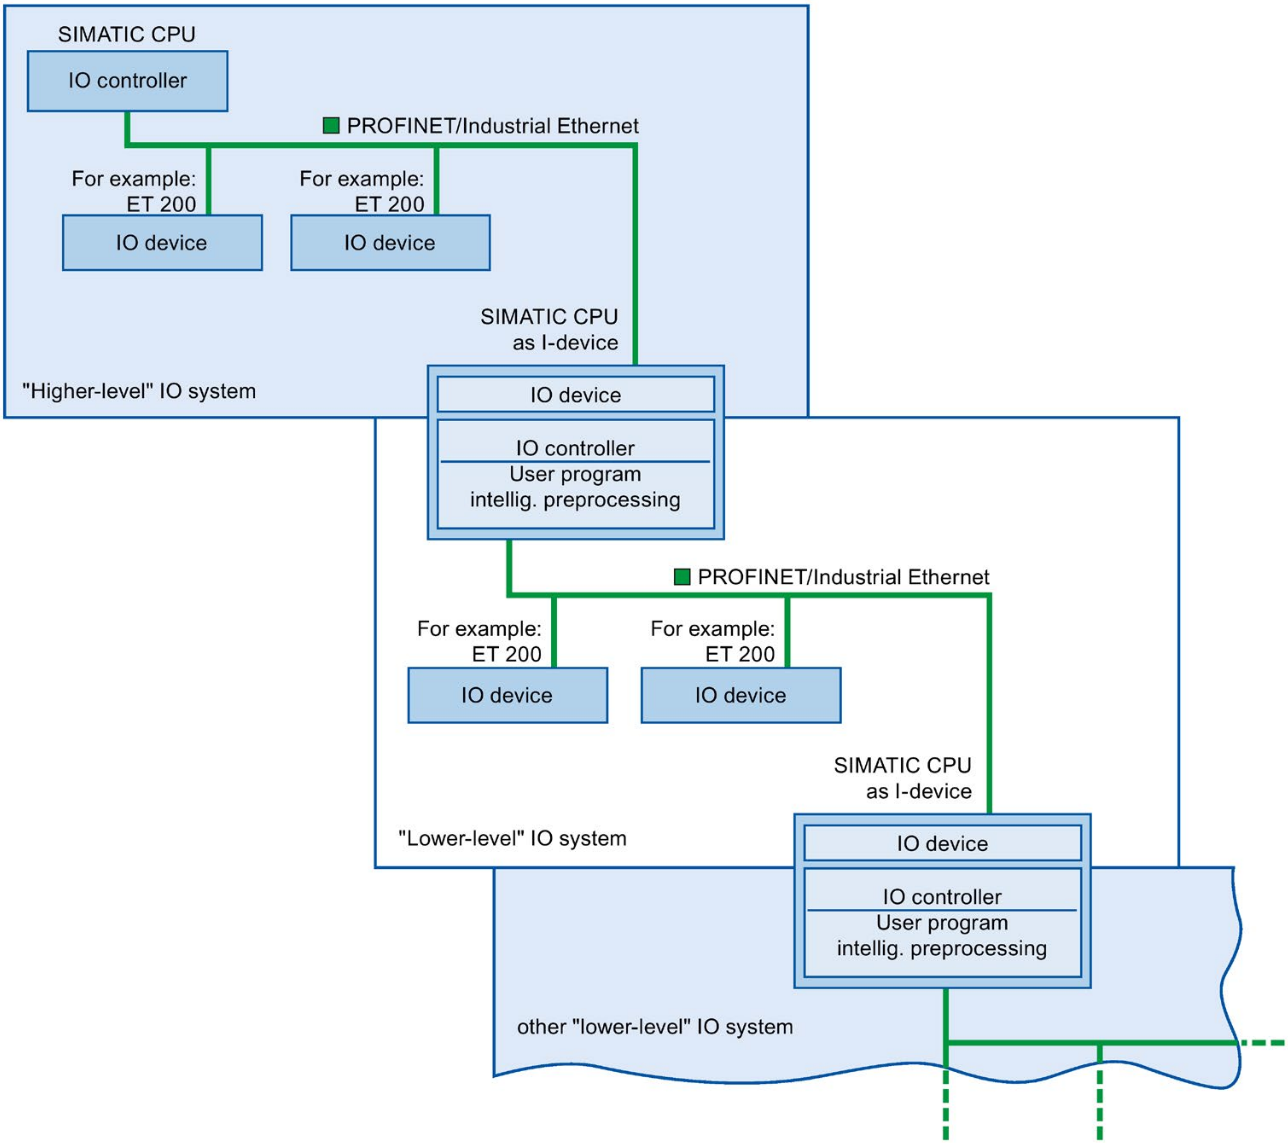

Figure 5-8 I-device with lower-level IO system

Example - the I-device as IO device and IO controller

The I-device as IO device and IO controller is explained based on the example of a print process. The I-device controls a unit (a subprocess). One unit is used, for example, to insert additional sheets such as flyers or brochures in a package of printed material.

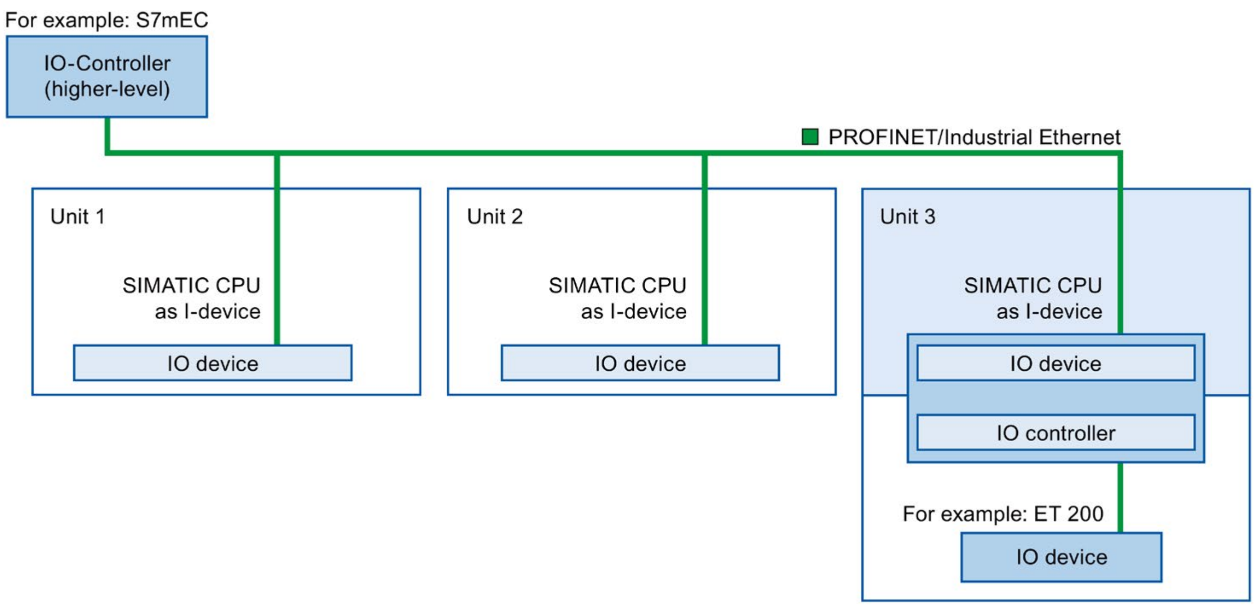

Figure 5-9 Example - the I-device as IO device and IO controller

Unit 1 and unit 2 each consist of an I-device with centralized I/O. The I-device along with the distributed I/O system (for example ET 200) forms unit 3.

The user program on the I-device is responsible for preprocessing the process data. For this task, the user program of the I-device requires default settings (for example control data) from the higher-level IO controller. The I-device provides the higher-level IO controller with the results (for example status of its subtask).

I-device as a shared device

An I-device can also be used simultaneously by multiple IO controllers as a shared device.

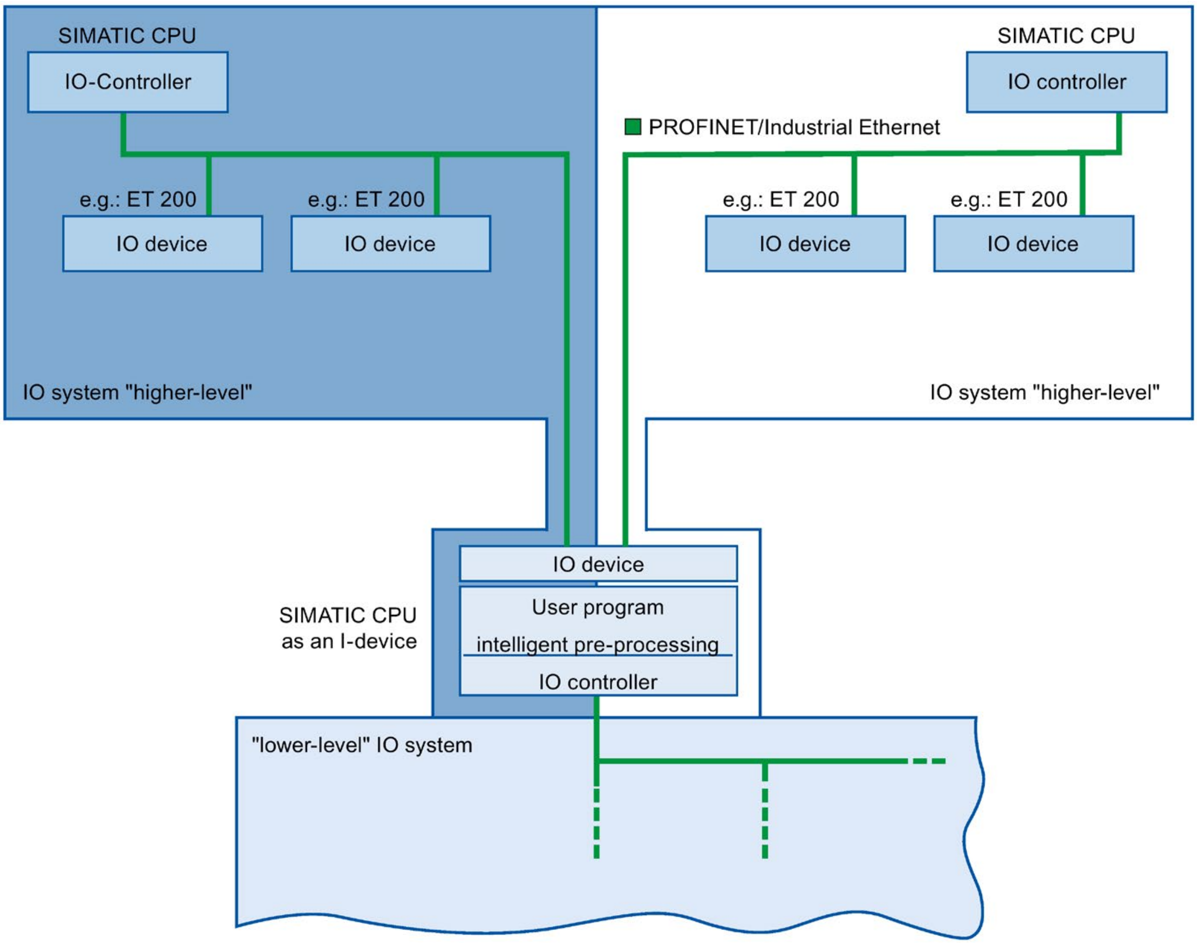

Figure 5-10 I-device as a shared device

Information about configuring an I-device as a shared device is available in the section Configuring an I-device as a shared device (Page 151).

5.2.4 Data Exchange between higher- and lower-level IO system

Introduction

The next chapter shows the data exchange between the higher- and lower-level IO system.

Transfer areas

Transfer areas are an interface to the user program of the I-device CPU. Inputs are processed in the user program and outputs are the result of the processing in the user program.

The data for communication between IO controller and I-device is made available in the transfer areas. A transfer area contains an information unit that is exchanged consistently between IO controller and I-device. You can find more information on configuration and use of transfer areas in the section Configuring the I-device (Page 128).

The next figure shows the data exchange between the higher- and lower-level IO system. The individual communication relations are explained below based on the numbers.

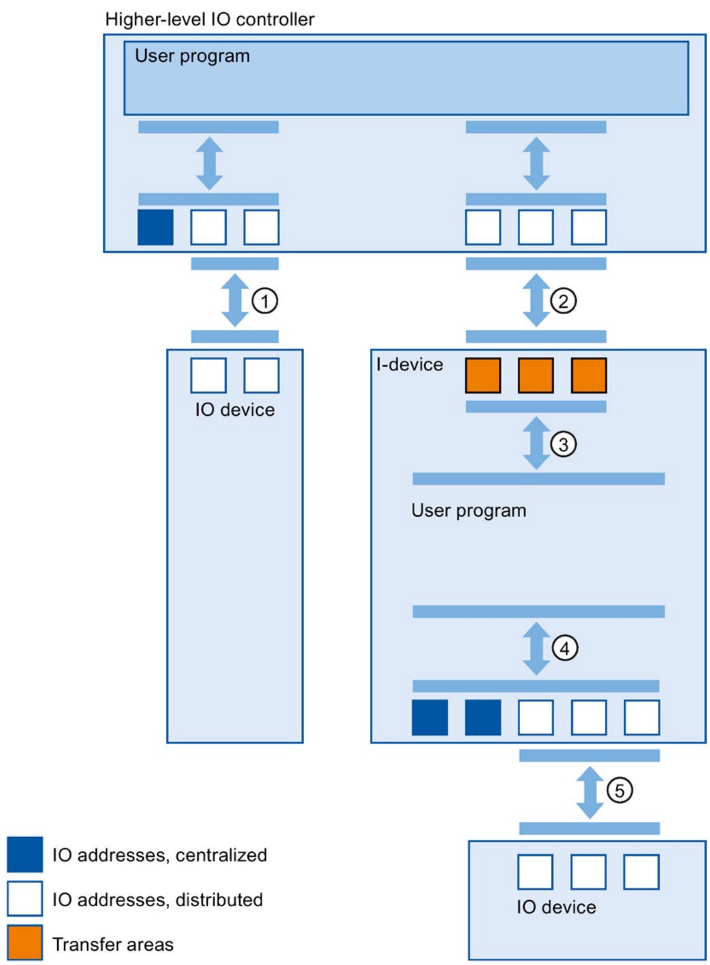

Figure 5-11 Data exchange between higher- and lower-level IO system

① Data exchange between higher-level IO controller and normal IO-device

In this way, the IO controller and IO devices exchange data through PROFINET.

② Data exchange between higher-level IO controller and I-device

In this way, the IO controller and the I-device exchange data through PROFINET.

The data exchange between a higher-level IO controller and an I-device is based on the conventional IO controller / IO device relationship.

For the higher-level IO controller, the transfer areas of the I-devices represent submodules of a preconfigured station.

The output data of the IO controller is the input data of the I-device. Analogously, the input data of the IO controller is the output data of the I-device.

③ Transfer relationship between the user program and the transfer area

In this way, the user program and the transfer area exchange input and output data.

④ Data exchange between the user program and the I/O of the I-device

In this way, the user program and the centralized / distributed I/O exchange input and output data.

⑤ Data exchange between the I-device and a lower-level IO device

In this way, the I-device and its IO devices exchange data. The data transfer is via PROFINET.

5.2.5 Configuring the I-device

Introduction

There are basically two possibilities for configuration:

- Configuration of an I-device within a project
- Configuration of an I-device that is used in another project or in another engineering system.

STEP 7 allows you to configure an I-device for another project or for another engineering system by exporting a configured I-device to a GSD file. You import the GSD file in other projects or engineering systems as with other GSD files. The transfer areas for the data exchange, among other data, are stored in this GSD file.

Configuration of an I-device within a project

1. Drag-and-drop a PROFINET CPU from the hardware catalog into the network view.
2. Drag-and-drop a PROFINET CPU, which can also be configured as an IO device, from the hardware catalog into the network view. This device is configured as I-device (e.g., CPU 1516-3 PN/DP).
3. Select the PROFINET interface for the I-device.
4. In the Inspector window in the area navigation choose "Operating mode" and select the check box "IO device".
5. Now you have the option of choosing the IO controller in the "Assigned IO controller" drop-down list.

   Once you have chosen the IO controller, the networking and the IO system between both devices are displayed in the network view.

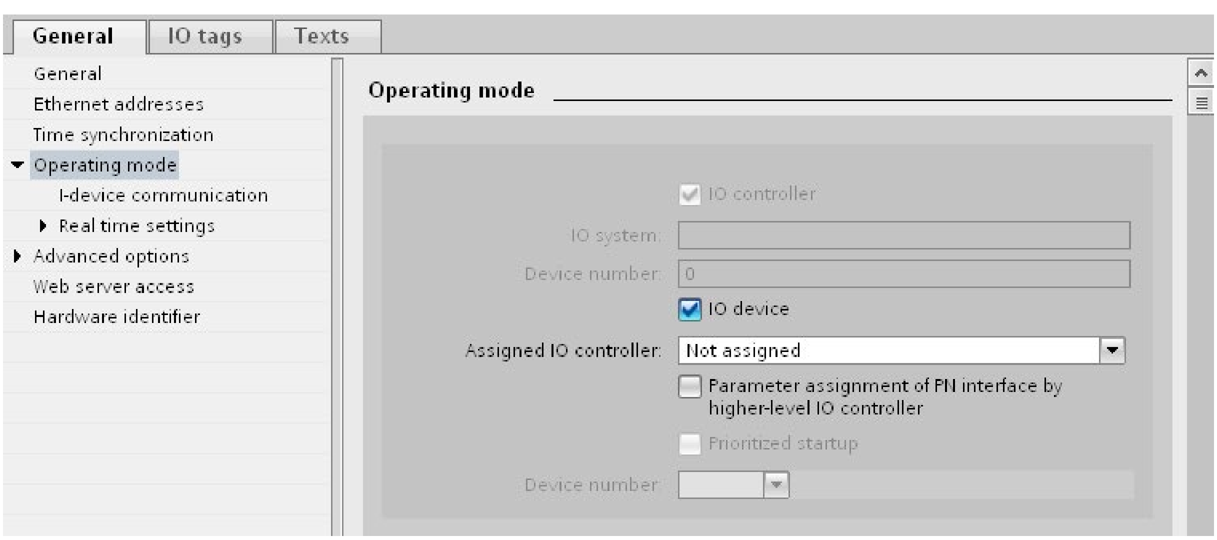

Figure 5-12 Configuring the I-device

6. With the "Parameter assignment of PN interface by higher-level IO controller" check box, you specify whether the interface parameters will be assigned by the I-device itself or by a higher-level IO controller.

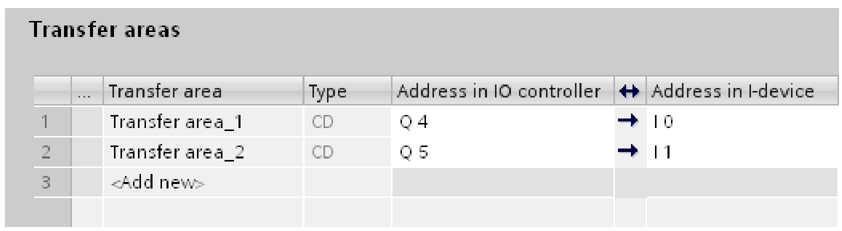
   If you operate the I-device with a lower-level IO system, then the parameters of the I-device PROFINET interface (for example, port parameter) cannot be assigned with the higher-level IO controller.

7. Configure the transfer areas. The transfer areas are found in the area navigation section "I-device communication".

   – Click in the first field of the "Transfer area" column. STEP 7 assigns a default name which you can change.

   – Select the type of communication relation: you can currently only select CD or F-CD for "Controller-device communication relation".

   – Addresses are automatically preset; you can correct addresses if necessary, and determine the length of the transfer area which is to be consistently transferred.



Transfer areas

	...	Transfer area	Type	Address in IO controller	↔	Address in I-device
1		Transfer area_1	CD	Q 4	→	I 0
2		Transfer area_2	CD	Q 5	→	I 1
3		<Add new>				

Figure 5-13 Configuring the transfer areas

8. A separate entry is created in the area navigation for each transfer area. If you select one of these entries, you can adjust the details of the transfer area, or correct them and comment on them.

Configuring an I-device with a GSD file

If you use an I-device in another project, or if the I-device is used in another engineering system, then configure the higher-level IO controller and the I-device as described above.

However, click on the "Export" button after configuring the transfer areas so a new GSD file is created from the I-device. This GSD file represents the configured I-device in other projects.

The "Export" button is found in the "I-device communication" section of the Inspector window.

The hardware configuration is compiled and the export dialog opened.

Assign a name for the I-device proxy as well as a description in the fields provided. Click the "Export" button to complete your process.

Finally, import the GSD file, for example, in another project.

5.2.6 Program examples

Introduction

This simple program example shows how you use the transfer areas of an I-device.

Requirements

You have configured an I-device.

Task

The result of an "AND logic operation" of two inputs (preprocessing) in the I-device is to be provided to the higher-level IO controller. This result is to be assigned to a local output in the IO master (further processing).
Use a transfer area with the following addresses for this purpose:

- Address in the I-device: Q568
- Address in the IO controller: I68

Required steps

The following steps to solve the task:

1. Configuring the transfer area
2. Programming I-device
3. Programming IO controller

Configuring the transfer area

Configure a transfer area with the following properties in the I-device:

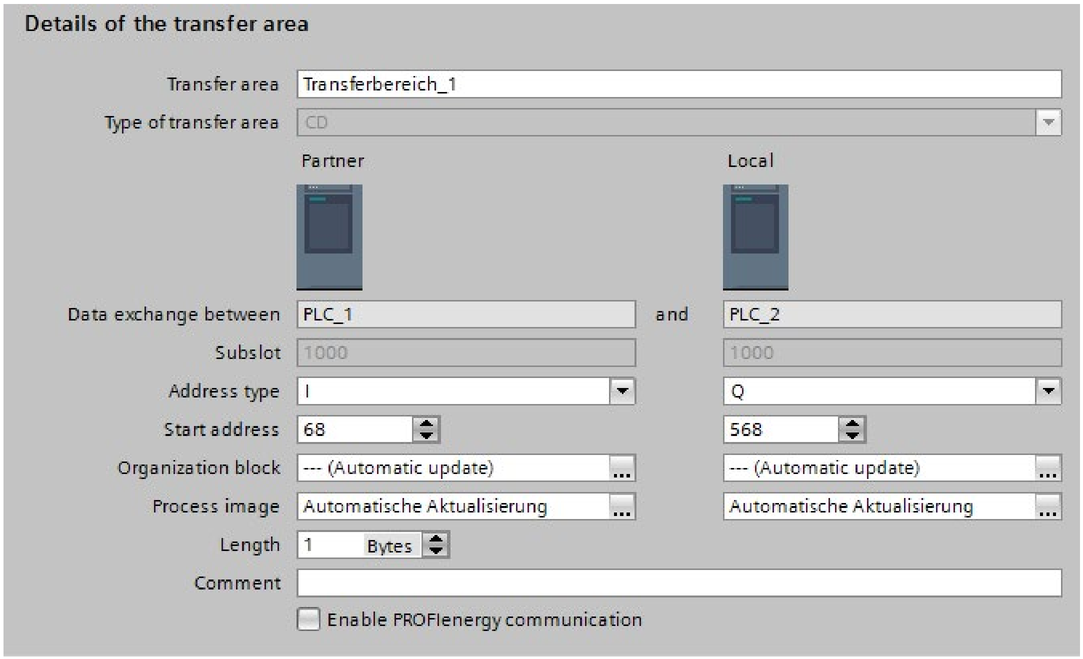


Figure 5-14 I-device transfer area, sample program

Programming I-device

To program the sample program for the I-device, follow these steps:

1. Using the SCL programming language, create a new function with the name "preprocessing" in the project tree in "Program blocks" > "Add new block". Open the function.
2. In the interface of the function "preprocessing", create the following tags:

Name	Data type	Input / output type
input 1	bool	Input
input 2	bool	Input
result	bool	Output

3. In the instruction window of the function "preprocessing", write the following program code:
   #result:=#input 1&#input 2;

4. Call the function "preprocessing" in a program cycle OB, for example, in OB1.
5. Wire the function "preprocessing" in the program cycle OB as follows:

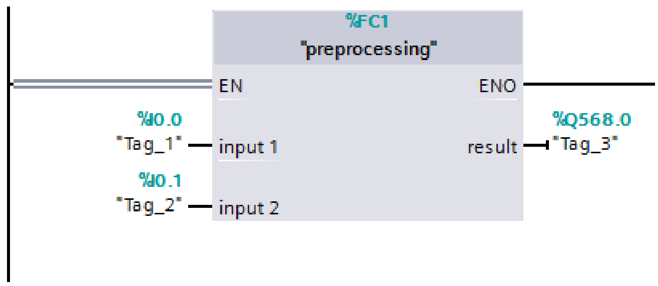

Figure 5-15 I-device sample program

Programming IO controller

To program the sample program for the IO controller, follow these steps:

1. Using the SCL programming language, create a new function with the name "further processing" in the project tree in "Program blocks" > "Add new block". Open the function.
2. In the interface of the function "further processing", create the following tags:

Name	Data type	Input / output type
result	bool	Input
output	bool	Output

3. In the instruction window of the function "further processing", write the following program code:
   #output:=#result;
4. Call the function "further processing" in a program cycle OB, for example, in OB1.
5. Wire the function "further processing" in the program cycle OB as follows:

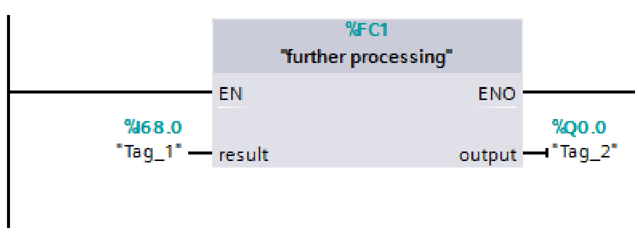

Figure 5-16 IO controller sample program

Result

The IO controller and the I-device can exchange data with each other through the input/output transfer areas.

5.2.7 Diagnostics and interrupt characteristics

Diagnostics and interrupt characteristics

S7 CPUs have numerous diagnostics and interrupt functions that can, for example, report errors or failures of lower-level IO systems. These diagnostics messages reduce down times and simplify localization and elimination of problems.

Diagnostics options in the higher-level IO controller and in the I-device

The following diagnostics functions are available to the higher-level IO controller and the I-device CPU:

- OB 83 (pull/plug)
- OB 86 (rack failure)
- OB 122 (I/O access error)

Note

The diagnostics messages of the I/O can be processed in the user program of the I-device CPU and passed on from there to the higher-level IO controller via transfer areas.

Operating state changes and station failure / station return

In the following table, you can see which consequences an operating state change or the failure of an IO controller / I-device of the SIMATIC family has on the respective other(s):

Table 5- 1 Operating state changes and station failure / station return

Initial status	Event	I-device response	Higher-level IO controller
I-device CPU is in RUN, higher-level IO controller is in RUN	The I-device CPU changes to STOP	-	During the updating of the process image with the instructions "UPDAT_PI" and "UPDAT_PO" an error report is returned at the parameter RET_VAL. With direct IO access to all transfer areas to the I-device: depending on the type of error handling, e.g., call of OB 122 (IO access error).
I-device CPU is in STOP higher-level IO controller is in RUN	The I-device CPU is starting up	Call of OB 100 (startup). Call of OB 83 (pull/plug) for input transfer areas to the higher-level IO controller. Until call of OB 83 in the case of direct access to the input transfer areas to the higher-level IO controller: depending on the type of error handling, e.g., call of OB 122 (IO access error).	Call of OB 83 (pull/plug) for all transfer areas to the I-device. Until call of OB 83 in the case of direct access to the transfer areas to the I-device: depending on the type of error handling, e.g., call of OB 122 (IO access error).
I-device CPU is in RUN, higher-level IO controller is in RUN	The higher-level IO controller changes to STOP	During the updating of the process image with the instructions "UPDAT_PI" and "UPDAT_PO" an error report is returned at the parameter RET_VAL. With direct IO access to the input transfer areas to the higher-level IO controller: depending on the type of error handling, e.g., call of OB 122 (IO access error). Note: Output transfer areas can still be accessed.	-

Initial status	Event	I-device response	Higher-level IO controller
Higher-level IO controller is in STOP, I-device CPU in RUN	The higher-level IO controller starts up	Call of OB 83 (pull/plug) for input transfer areas to the higher-level IO controller. Until call of OB 83 in the case of direct access to the input transfer areas to the higher-level IO controller: depending on the type of error handling, e.g., call of OB 122 (IO access error).	Call of OB 100 (startup).
I-device CPU is in RUN, higher-level IO controller is in RUN	Station failure I-device, for example, through bus interruption	If the I-device continues to run without a bus connection: Call of OB 86 (rack failure). During the updating of the process image with the instructions "UPDAT_PI" and "UPDAT_PO" an error report is returned at the parameter RET_VAL. With direct IO access to all transfer areas to the higher-level IO controller: depending on the type of error handling, e.g., call of OB 122 (IO access error).	Call of OB 86 (rack failure). During the updating of the process image with the instructions "UPDAT_PI" and "UPDAT_PO" an error report is returned at the parameter RET_VAL. With direct IO access to all transfer areas to the I-device: depending on the type of error handling, e.g., call of OB 122 (IO access error).
I-device CPU is in RUN, higher-level IO controller is in RUN, communication connection between IO controller and I-device is interrupted (bus interruption).	The bus connection between the IO controller and I-device has been reestablished and the I-device is again included in the user data traffic.	Call of OB 86 (rack failure). Call of OB 83 (pull/plug) for input transfer areas to the higher-level IO controller. Until call of OB 83 in the case of direct access to the input transfer areas to the higher-level IO controller: depending on the type of error handling, e.g., call of OB 122 (IO access error).	Call of OB 86 (rack failure). Until reporting of station re-integration by OB 86 with direct IO access to all transfer areas to the I-device: depending on the type of error handling, e.g., call of OB 122 (IO access error)

Note

Special characteristic during startup of the higher-level IO controller

In contrast to the station return message from IO devices in the IO controller, which are covered completely by the call of the OB 86, the station return message of a higher-level IO controller in the I-device is separated into 2 parts:

1. Call of the OB 86: The initial values for the outputs of the I-device are set. However, the input values are not yet valid. These values will first be valid with the opening of OB 86 in the higher-level IO controller.
2. Call of OB 83 for each input transfer area; with this call, the validity of an input transfer area is displayed. The starting up of the I device is first complete when the OB 83 has been called for the input transfer areas. This step can be delayed or not occur at all in the following situations:
   - Higher-level IO controller is in STOP: OB 83 is first called at the STOP-RUN transition of the higher-level IO controller.
   - The IRT communication has been disrupted (sync-master failure, topology error, ...). OB 83 is opened only after the IRT communication has taken place.

Reference

For more information on error handling in the case of direct I/O access, refer to "Error handling" in the STEP 7 online help.

5.2.8 Rules for the Topology of a PROFINET IO System with I-Device

Introduction

The following recommendations for the structure and configuration of an IO system when using I-devices will help you to keep the bandwidths required for keeping communication small.

The following communication paths should not overlap:

- Communication paths between the IO controller and the IO device of its IO system.
- Communication paths of the I-device CPU and the IO devices of your IO system.

I-device with one port

Connect an I-device with only one port to a PROFINET switch that is uncoupled from the higher-level IO system. Connect the lower-level IO system to another port of the switch as shown in the following figure.

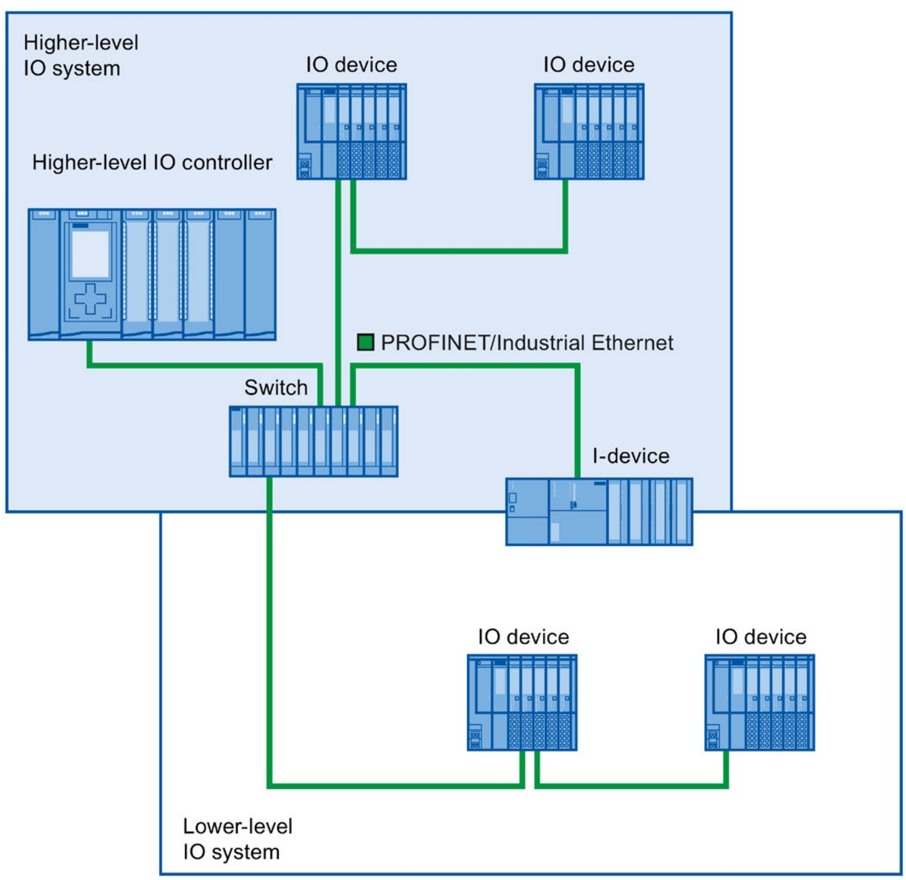

Figure 5-17 I-device with one port

I-device with two ports

With an I-device with two ports, connect one port, uncoupled from the higher-level IO system, to the port of the PROFINET switch. Use the second port for the lower-level IO system as shown in the following figure.

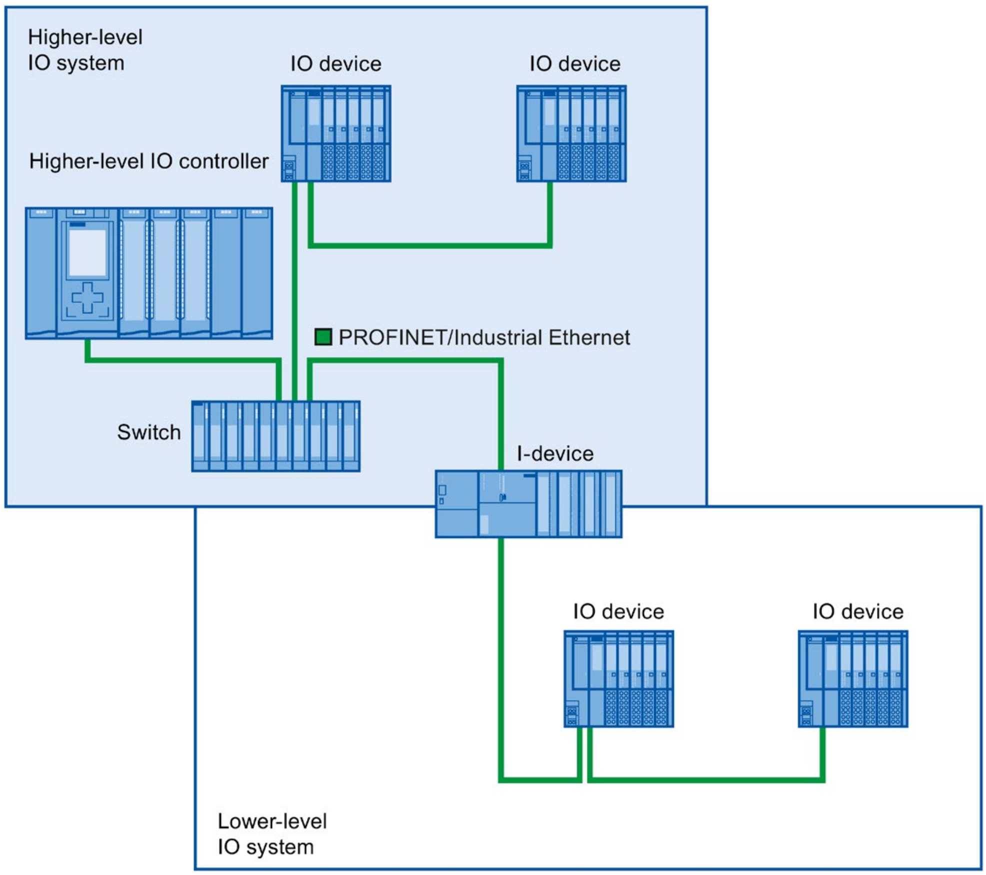

Figure 5-18 I-device with two ports

I-device with three or more ports

If you have an I-device with three or more ports, connect the I-device to one or both ports to the higher-level IO system in a linear bus topology. Connect the third port to the lower-level IO system uncoupled from the linear bus topology as shown in the following figure.

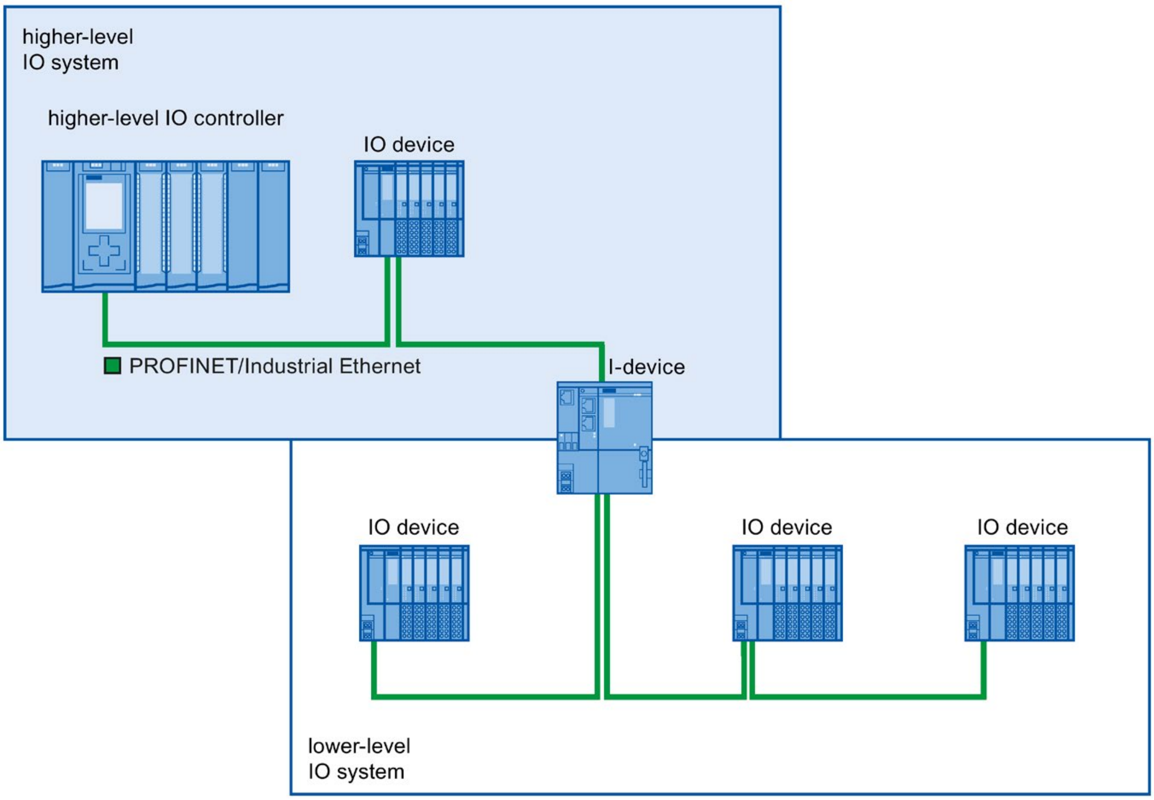

Figure 5-19 I-device with three or more ports

5.2.9 Boundary conditions when using I-devices

Note the following boundary conditions when using I-devices:

Bandwidth

The number of addresses of the configured transfer areas affects the usable bandwidth of the I-device:

- Bandwidth of the transfer areas + bandwidth of the lower-level IO system = total bandwidth used on the I-device

If the address space of the transfer areas is too large, this indicates a larger bandwidth requirement and can thus lead to longer update times.

Tip: Keep the address space of the transfer area as small as possible.

Rules for RT and IRT communication.

IO systems with I-devices are also suitable for setting up real-time applications with RT and IRT communication. The following rules must be followed for this:

- Both the higher-level and the lower-level IO system support RT communication. You can use RT communication for both IO systems at the same time.
- IRT communication can be combined with RT communication. You can use IRT communication in one of the two IO systems. Use IRT either in a higher-level or in a lower-level IO system.

5.2.10 Configuring PROFIenergy with I-devices

The requirement for program-controlled pauses for saving energy with PROFINET devices is that the PROFINET devices support the PROFIenergy protocol.

Only if a PROFINET device (I/O device) supports the PROFIenergy protocol does an I/O controller actually send PE commands to this I/O device, for example to start or stop pauses.

If an I/O device supports the PROFIenergy protocol, this property is saved in its PROFINET GSD file and is available for configuration in an engineering system.

For S7-1500 CPUs as intelligent I/O devices (I-devices), you have the option with STEP 7 V13 service pack 1 or later to set PROFIenergy support for each transfer area.

If you have selected the "Enable PROFIenergy communication" option for a transfer area and import the generated PROFINET GSD file into another project, you can handle an I-device as a PE entity there.

Requirements

- STEP 7 as of V13 service pack 1
- CPU supports PROFIenergy with I-devices, for example CPU 1215C DC/DC/DC as of firmware version 4.2
- You use the PROFINET IO interface as an I-device and have created transfer areas.
- The user program in the I-device handles PROFIenergy commands

  Background: You need to program PROFIenergy functions with I-devices in the user program using the "PE_I_DEV" instruction and corresponding auxiliary blocks; this is different compared with IO devices for which this functionality is made available by the firmware. You may therefore only activate the PROFIenergy support for transfer areas if the user program in the I-device is configured correspondingly as well.

Enabling PROFIenergy for transfer areas of I-devices

Proceed as follows to assign parameters for the support of PROFIenergy:

1. Select the PROFINET interface (X1) of the CPU.
2. Select the required transfer area in the area navigation, for example:

   Operating mode > I-device communication > Transfer_area_1.
3. Select the check box "Enable PROFIenergy communication".

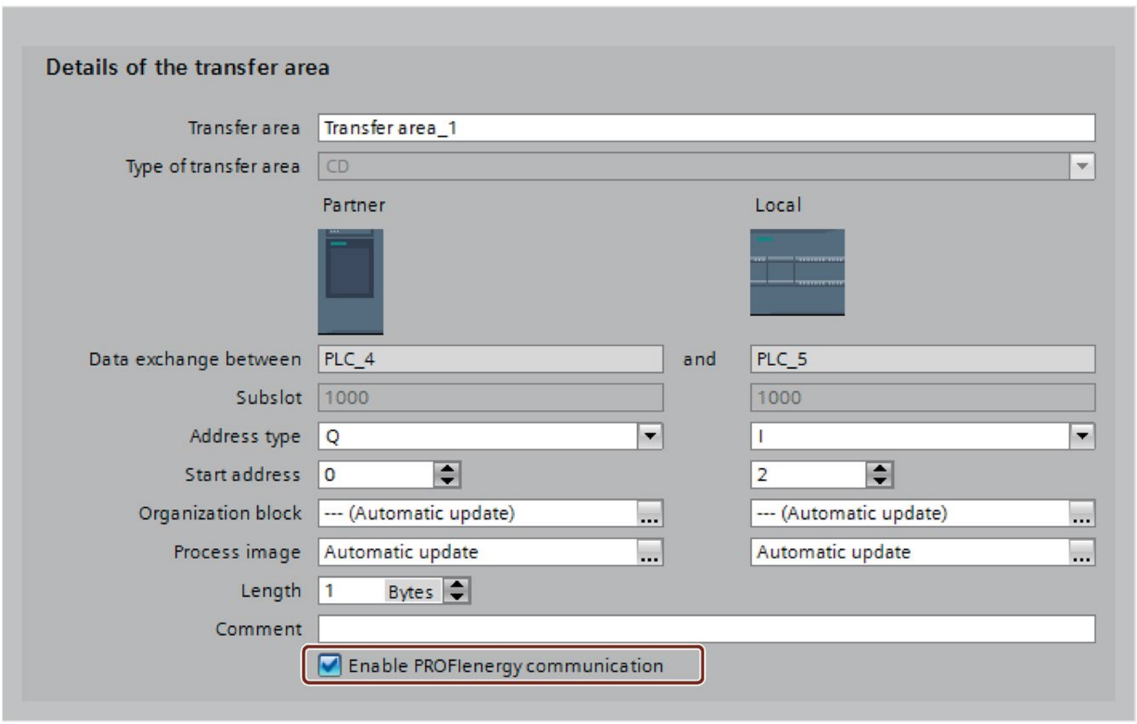

Figure 5-20 Configuring PROFIenergy with I-devices

Once the I-device is fully configured, generate the GSD file for the I-device and import this file in the project for the I/O controller. The GSD file generated contains an entry that specifies that the I-device supports the PROFIenergy profile.

To address the I-device, for example for the PE command "PE_START_END", use the hardware identifier of the "PROFIenergy supporting" transfer area in the I-device.

To address the IO controller for the PE command "PE_I_DEV", use the hardware identifier of the transfer area that is supplied with the data for PROFIenergy on the IO controller.

You can find more information on PROFIenergy in the sectoin Saving energy with PROFIenergy (Page 258).

5.3 Shared device

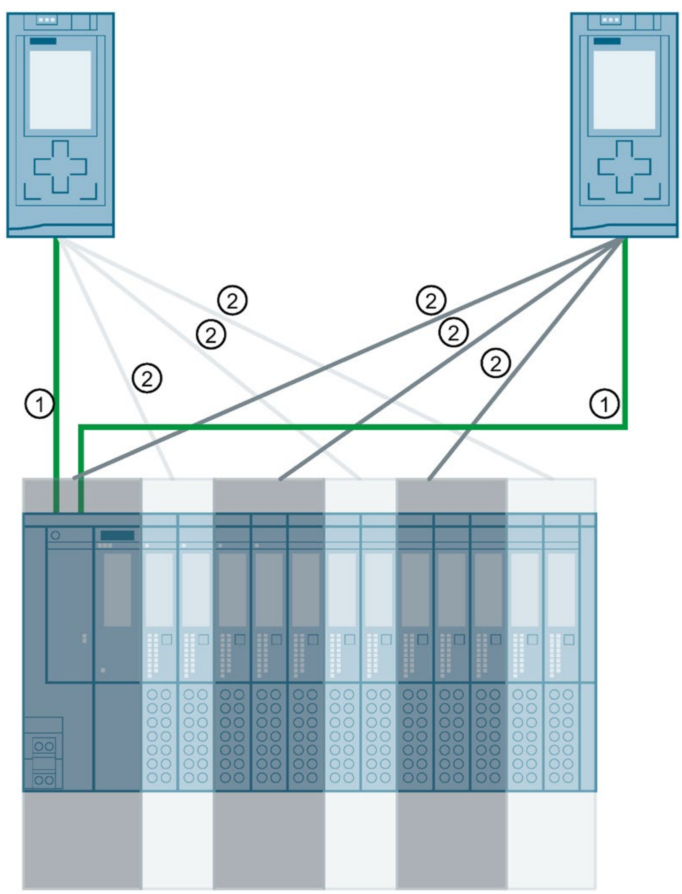
5.3.1 Useful information on shared devices

Shared device functionality

Numerous IO controllers are often used in larger or widely distributed systems.

Without the "Shared Device" function, each I/O module of an IO device is assigned to the same IO controller. If sensors that are physically close to each other must provide data to different IO controllers, several IO devices are required.

The "Shared Device" function allows the modules or submodules of an IO device to be divided up among different IO controllers. Thus allowing flexible automation concepts. You have, for example, the possibility of combining I/O modules lying near other into an IO device.



① PROFINET
② Logical assignment

Figure 5-21 Example: Shared device with 2 IO controllers

Principle

Access to the submodules of the shared device is then divided up among the individual IO controllers. Each submodule of the shared device is assigned exclusively to one IO controller.

Requirement

- STEP 7 V12 Service Pack 1 or higher
- IO device supports the shared device function, e.g. interface module IM 155-5 PN ST
- IO controller supports the shared device function, for example CPU 1516-3 PN/DP as of firmware version 1.1 or CPU 1215 DC/DC/DC as of firmware version 4.1

Explanatory notes:

- A CPU that is configured as an I-device can be used as a shared device. For this purpose, you create a GSD file for the I-device in STEP 7 via "GSD export". You then import the GSD file into a different project and assign the I-device to the IO controller there. The CPU has to support the GSD export, for example CPU 1215C DC/DC/DC as of firmware version 4.1.
  The maximum number of IO controllers that you can assign to a CPU configured as a shared I-device is given in the technical specifications in the CPU manuals.

Configuring the access

The IO device must be present in several projects so that the modules or submodules of an IO device can be assigned to different IO controllers. A separate project is required for each IO controller.

You use the "Shared device" parameter of the interface module to determine the modules or submodules to which the IO controller has access:

- If the local IO controller has access to the configured module, select the name of the IO controller from the list.
- If the IO controller from a different project and not the local IO controller is to have access to the configured module, select the entry "---".

The configuration is consistent regarding access if each module or submodule in exactly one project is assigned to an IO controller.

Module or submodule is assigned to another IO controller

The paragraph below describes the consequences of the "---" setting of the "Shared device" parameter from the point of view of the local IO controller.

In this case, the local IO controller does not have access to the module configured in this way. Specifically, this means:

- No data exchange with the module or submodule
- No reception of alarms or diagnostics, which means no display of the diagnostics status in the online view
- No parameter assignment of the module or submodule

Setting of the real-time properties

STEP 7 calculates the communication load and thus the resulting update times. You must enter the number of project-external IO controllers in the project in which the PROFINET interface of the shared device is assigned to the IO controller so that a calculation is possible with shared device configurations.

The maximum possible number of IO controllers for the shared device depends on the device. This number is stored in the GSD file of the shared device.

You can set a very short send clock with a CPU as IO controller. The send clock can be shorter than the shortest send clock supported by the shared device. In this case, the shared device is operated by the IO controller with a send clock that it supports (send clock adaptation).

Example:

A CPU supports send clocks starting from 0.25 ms. A configured IO device also supports send clocks starting at 0.25 ms; another IO device supports send clocks starting at 1 ms. In this case, you have the option of setting the short send clock of 0.25 ms for the CPU. The CPU operates the "slow" IO device with the send clock of 1 ms, for example.

Rules for the configuration

- IO controllers that use the shared device are created in different projects. In each project, care must be taken that the shared device is configured identically in each station. Only one IO controller may ever have full access to a submodule. Inconsistencies in the configuration result in a failure of the shared device.
- If you have selected the "Use router" option for the IO controllers involved, you must have set the same router address in all these IO controllers.
- I/O addresses of a module or submodule can only be edited if a module or submodule is assigned to the IO controller in the same project.
- The shared device must have the same IP parameters and the same device name in each project.
- The send clock must be identical for all IO controllers that have access to the shared device.
- The S7 subnet ID of the subnet to which the shared device is connected must be identical in all projects.
- The following functions are only available if the PROFINET interface of the shared device is assigned to the local IO controller:
  – IRT operation
  – Prioritized startup
  – Parameter assignment of the port properties

Boundary conditions

The following boundary conditions result because a shared device configuration is distributed across several projects:

- The addresses of modules or submodules that are not assigned to this IO controller are missing in the address overview of each IO controller that has access to a shared device.
- The modules or submodules that are not assigned are not taken into consideration in the configuration limit calculation for the shared device during the consistency check. For this reason, you must verify for yourself that the maximum number of submodules or the maximum amount of cyclic IO data for the shared device will not be exceeded.
  For information on the maximum quantities, refer to the documentation for the devices you are using.
- Configuration errors such as the assignment of a module or submodule to several IO controllers are not detected in STEP 7.
- CPUs that are loaded with a shared device configuration do not have any information on whether the IO device is a shared device. Modules or submodules that are assigned to other IO controllers and therefore other CPUs are missing in the loaded configuration. These modules or submodules are therefore displayed neither in the CPU web server nor in the CPU display.

Response in the event of fault

Information about how PROFINET IO controllers behave in the event of a fault when accessing the data of a shared device is available in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/109572804).

5.3.2 Configuring shared device

Below, you will find a description of how to configure a distributed I/O system as a shared device with STEP 7 V12, Service Pack 1 or higher.

A "distributed" configuration with different engineering tools for different IO controller families is always possible. However, the description of the procedure is based solely on STEP 7 as of V12, service pack 1. The description is limited to two IO controllers of the S7-1500 family that share a shared device.

Two projects are created (Shared-Device-1 and Shared-Device-2), each with one IO controller (PLC1 and PLC2). You must create the shared device in both projects, even though it is physically one and the same IO device.

Requirements

- STEP 7 V12 Service Pack 1 or higher
- The IO controller supports the shared device function, for example CPU 1513-1 PN as of firmware version 1.1.
- IO device supports shared device functionality, for example interface module IM 155-5 PN ST as of firmware version 2.0.

Procedure - Creating project 1

To create the first project with a shared device, follow these steps:

1. Start STEP 7.
2. Create a new project with the name "Shared-Device-1".
3. Insert, for example, a CPU 1513-1 PN from the hardware catalog in the network view. Name it "PLC1".
4. Insert an IO device with the "Shared device" function from the hardware catalog.
5. Assign the IO controller "PLC1" to the IO device.
6. Double-click the IO device and insert all required modules and submodules from the hardware catalog in the device overview table.
7. Assign the module parameters.
8. Save the project.

Procedure - Creating project 2

To create the second project with a shared device, follow these steps:

1. Start STEP 7 once again.

   A new instance of STEP 7 opens.

2. In the new instance, create a new project with the name "Shared-Device-2".
3. Insert, for example, a CPU 1513-1 PN in the network view. Name it "PLC2".
4. Copy the IO device from the project "Shared-Device-1" and insert it in the network view of project "Shared-Device-2".
5. Assign the IO controller "PLC2" to the IO device.
6. Save the project.

Both projects now have an identically structured IO device that must be configured in the next step for the different types of IO controller access.

Procedure - Configuring access to the shared device

The modules and submodules you insert in the shared device are automatically assigned to the local CPU. To change the assignment, follow these steps:

1. Select the interface module in the network view or device view of project "Shared-Device-1".
2. Select the "Shared Device" area in the Inspector window.

   A table shows which CPU has access to the respective module or submodule for all configured modules. The default setting is that the local CPU has access to all modules and submodules.

3. Keep the "PLC1" setting for all modules and submodules that are to remain in the address range of the local CPU.

   Select the setting "---" for all modules and submodules that are to be located in the address range of the CPU from the "Shared-Device-2" project (PLC2). This means that an IO controller outside the project is to have access to the module or submodule.

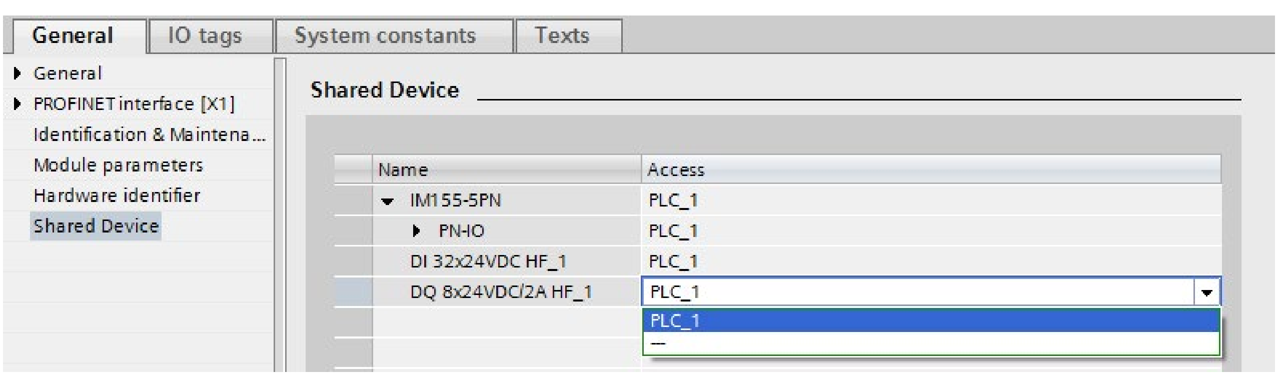


Figure 5-22 Configuring shared device

4. Select the interface module in the network view or device view of project "Shared-Device-2".
5. Select the "Shared Device" area in the Inspector window.

   A table shows which CPU has access to the respective module or submodule for all configured modules.
6. Select the setting "---" for all modules and submodules that are to be located in the address range of the CPU from the "Shared-Device-1" project (PLC1).
7. Finally, check whether the settings for access are "complementary" for each module or submodule in both projects. This means that if the local CPU has access in one project, the option "---" must be set in the other project and vice versa.

   Special consideration: The option "---" for the PROFINET interface and therefore for the ports makes the associated parameters read-only and not changeable. Parameters of the PROFINET interface and port parameters can only be edited in the project in which the PROFINET interface is assigned to the local CPU. The ports can be interconnected in both projects regardless of this.
8. Check whether the same IP address parameters and device name are set for the shared device in all projects.

   Check whether the same S7 subnet ID is set in all projects for the subnet to which the shared device is connected (subnet properties, "General" area in the Inspector window).

Note

If you make changes to the shared device: Make the same changes in each project on the shared device. Make sure that only one IO controller has access to a module or submodule.

Procedure - Adjusting the real-time settings

To ensure that all IO controllers and shared devices are operated with the appropriate send clock and that the update times are calculated correctly based on the communication load, you must adjust and check the following settings:

1. Select the project whose IO controllers have access to the PROFINET interface and the ports of the shared device.
2. Select the interface module of the shared device in the network view.
3. In the Inspector window, navigate to the "PROFINET interface > Advanced options > Real time settings > IO cycle" area.
4. In the "Shared Device" area, set the number of project-external IO controllers. The maximum number depends on the IO device (specification in GSD file).
5. You must set the same send clock for each IO controller that has access to modules and submodules of the shared device:
   - If you configure the IO controller with STEP 7 (TIA Portal):

     Open the corresponding project.

     Select the PROFINET interface of the IO controller.

     Select the "Advanced options > Real time settings > IO communication" area in the Inspector window and set the shared send clock.
   - If you configure the IO controller with a different engineering tool:

     Select the PROFINET interface of the shared device in STEP 7 (TIA Portal) and read out the send clock on the shared device ("Advanced options > Real time settings" area)

     Enter the read send clock in the engineering tool.
   - Special consideration: If you configure **all** IO controllers that have access to the shared device in STEP 7 (TIA Portal or V5.5), you can set shorter send clocks on the IO controller than supported by the shared device (send clock adaptation).

Compiling and loading

You must compile the configurations for the different IO controllers and load them to the CPUs one after the other.

Due to the distributed configuration with separate projects, STEP 7 does not output consistency errors in the case of incorrect access parameter assignment. Example for incorrect access parameter assignment:

- Several IO controllers have access to the same module
- IP address parameters or send clocks are not identical

These errors do not show up until operation and are output as configuration errors, for example.

Note

After a configuration has been loaded in the IO controller, non-assigned modules or submodules retain their current parameterization state to ensure the independence from the parameterizations of other IO controllers.

5.3.3 Configuring an I-device as a shared device

Below, you will find a description of how you configure an S7-1500 as an I-device with STEP 7 Version 13 or higher and then use it in two projects as a shared device.

A "distributed" configuration with different engineering tools for different IO controller families is generally also possible here. The procedure described below is based on STEP 7 V13 and is limited to a configuration with two IO controllers of the S7-1500 family that share the transfer areas of an I-device as a shared device. The I-device itself is also an S7-1500 CPU.

Three projects are created with one IO controller each (PLC-I-Device, PLC_1, and PLC_2).

PLC-I-Device is used to configure the I-device. The PROFINET GSD variant of PLC-I-Device is used in the PLC_1 and PLC_2 projects in order to assign the transfer areas in the respective higher-level IO controller.

Shared I-device concept

For the introduction of the shared I-device concept, two roles are distinguished:

- The role of manufacturer (e.g., machine manufacturer): The manufacturer configures and programs an I-device that performs a particular automation task. Transfer areas are defined as the I/O interface to the operator of the machine. These transfer areas can be assigned to different IO controllers. For the connection to higher-level IO controllers, the manufacturer provides a PROFINET GSD file and discloses the transfer areas via which the I-device can be accessed.
- The role of the operator: The operator uses the I-device as a PROFINET GSD variant during configuration of the PROFINET IO system and, in this process, specifies the I/O addresses under which the IO controllers access the transfer areas.

Manufacturer view

You assign the following parameters for an S7-1500 CPU as an I-device: centralized and distributed I/O, the desired transfer areas, and the number of IO controllers having access to this I-device (always greater than 1 for a shared device!).

Special consideration: The I-device is configured without a higher-level IO controller. As a result, only the local I/O addresses of the transfer area are available (= "Address in the I-device") in order to create the user program for editing the addresses from the transfer area. The I-device that has been completely configured except for the connection to the higher-level IO controller is loaded to the S7-1500 CPU.

You export a PROFINET GSD file from the I-device configuration.

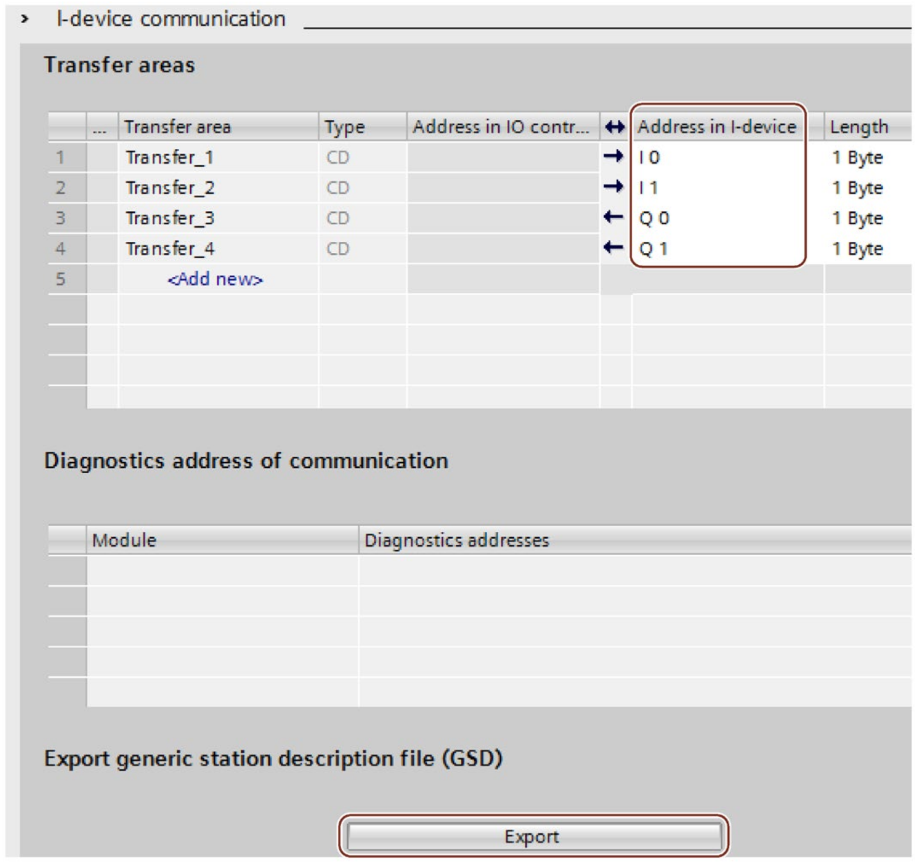

Figure 5-23 Exporting an I-device as a GSD file

Operator view

You must install the PROFINET GSD file created from the I-device configuration in all engineering systems that are involved in configuring a PROFINET IO system with this shared I-device. If all uses of this I-device will be configured with STEP 7 V13, it is sufficient to install the GSD file in STEP 7.

You configure the I-device as a GSD variant on the PROFINET IO system in the projects involved. In STEP 7 V13, this I-device can be found under "Other field devices > PROFINET IO > PLCs & CPs" following installation.

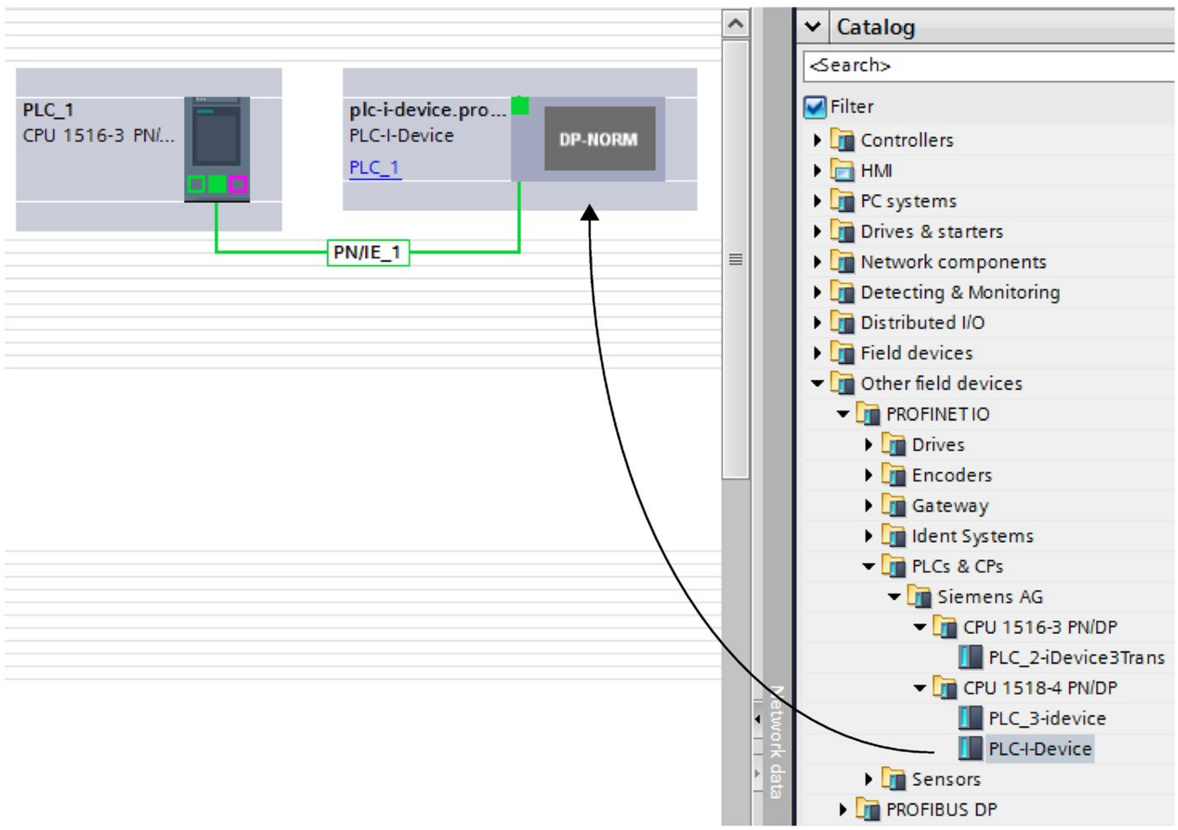

Figure 5-24 Configuring an I-device as a GSD file

In each of the projects involved, you define which transfer areas are assigned exclusively to the higher-level IO controller (default setting: all). You set the other transfer areas to "---" (not assigned). As a result of this setting, the local IO controller has no access to this transfer area and it can therefore be assigned to another IO controller in another project.

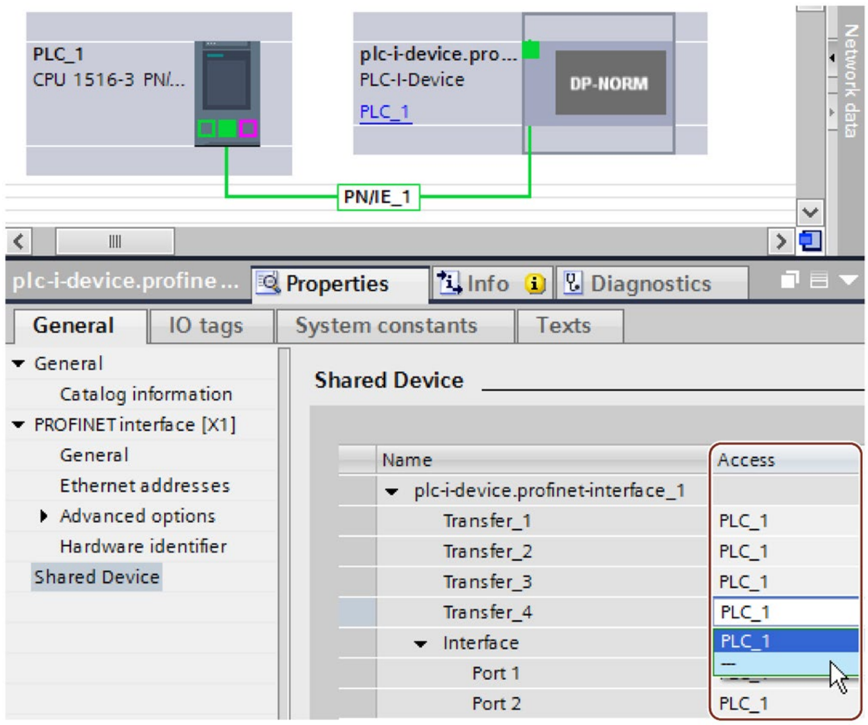

Figure 5-25 Setting the access to the shared I-device.

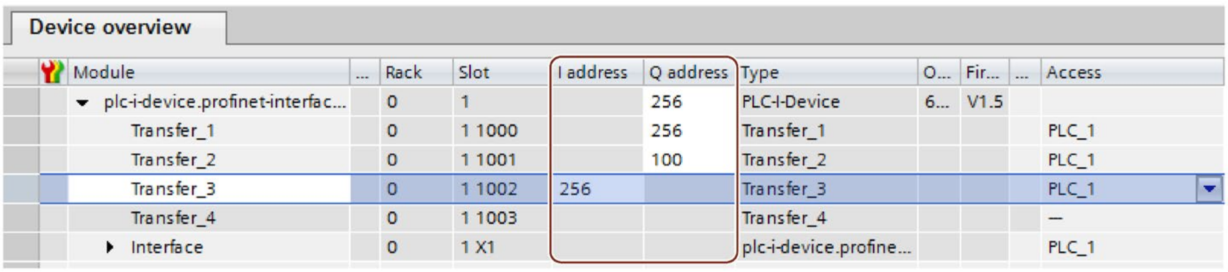
You adapt the addresses from the view of the IO controller in the device overview. To open the device overview, double-click the I-device.



Device overview

Module	...	Rack	Slot	I address	Q address	Type	O...	Fir...	...	Access
plc-i-device.profinet-interfac...		0	1		256	PLC-I-Device	6...	V1.5		
Transfer_1		0	1 1000		256	Transfer_1				PLC_1
Transfer_2		0	1 1001		100	Transfer_2				PLC_1
Transfer_3		0	1 1002	256		Transfer_3				PLC_1
Transfer_4		0	1 1003			Transfer_4				–
Interface		0	1 X1			plc-i-device.profine...				PLC_1

Figure 5-26 I/O addresses of the transfer areas in the device overview

Requirements

- STEP 7 as of V13

Procedure - Creating the PLC-I-device project

To create the project with a shared I-device, follow these steps:

1. Start STEP 7.
2. Create a new project with the name "PLC-I-device".
3. Insert, for example, a CPU 1518-4 PN/DP from the hardware catalog in the network view. Assign the name "PLC-I-device".
4. Double-click the IO device and configure all required modules and submodules.
5. Assign the module parameters.

   In particular, the following settings for the CPU are necessary in the area of the PROFINET interface [X1]:

   – Enable the "IO device" option in the "Operating mode" area.

   – Configure the transfer areas in the "Operating mode" > "I-device configuration" area. The "Address in IO controller" column remains empty because no IO controller is assigned.

Note: To change an input area to an output area, and vice versa, you must navigate to the area of the corresponding transfer area.

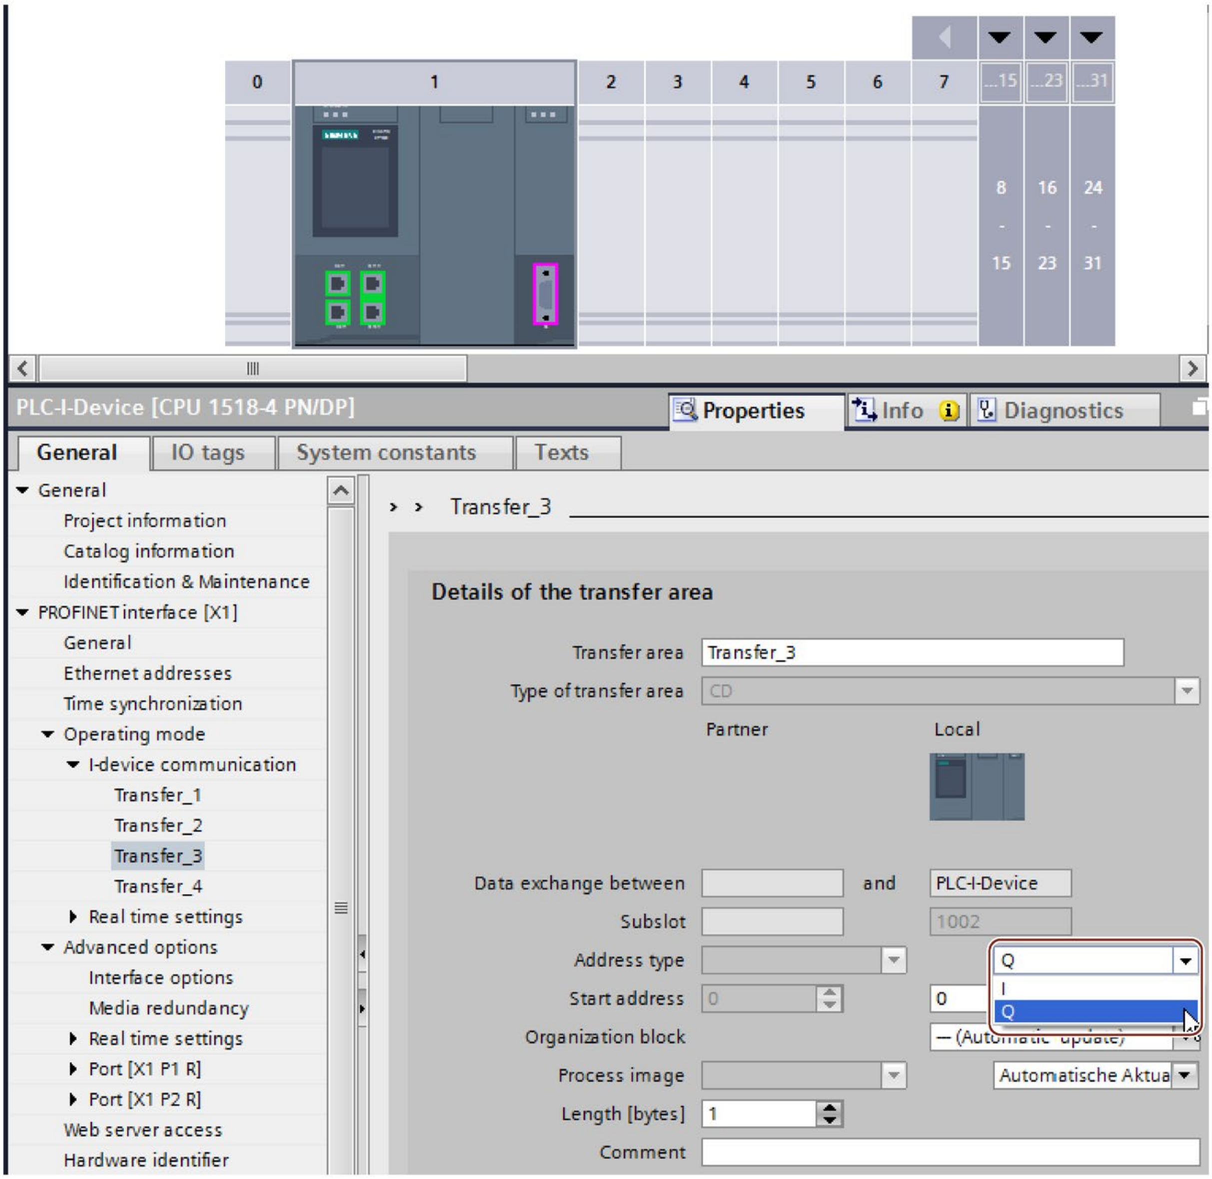


Figure 5-27 Changing the address type for the transfer area

– Select the number of IO controllers (at least two) that will access the shared I-device during operation ("Operating mode" > "Real time settings" area, "Shared Device" area).

6. Save the project.
7. Click the "Export" button ("Mode" > "I-device configuration" area, "Export general station description file (GSD)" section).

   If you do not change the name in the Export dialog, the GSD file has a name in the form "GSDML-V2.31-#Siemens-PreConf_PLC-I-Device-20130925-123456", for example.

Procedure - Creating the PLC_1 project

To create the first project with a shared I-device, follow these steps:

1. Start STEP 7.
2. Install the PROFINET GSD file from the export of the I-device CPU (PLC-I-Device).
3. Create a new project with the name "PLC_1".
4. Insert, for example, a CPU 1516-3 PN/DP in the network view. The name of the CPU should be "PLC_1".
5. Insert the I-device from the hardware catalog (Hardware catalog: Other field devices > PROFINET IO > PLCs & CPs).
6. Assign the IO controller "PLC_1" to the I-device.
7. Select the "Shared Device" area in the properties of the I-device.

   In the table, all transfer areas and the PROFINET interface are assigned to the local IO controller (PLC_1).
8. Define the transfer areas to which the PLC_1 CPU should **not** have access. Select the "---" entry for these areas. These transfer areas are provided for PLC_2.
9. Save the project.

Procedure - Creating the PLC_2 project

To create the second project with a shared I-device, follow these steps:

1. Start STEP 7 once again.

   A new instance of STEP 7 opens.
2. In the new instance, create a new project with the name "PLC_2".
3. Insert, for example, a CPU 1516-3 PN/DP in the network view. Assign the name "PLC_2".
4. Insert the I-device from the hardware catalog (Hardware catalog: Other field devices > PROFINET IO > PLCs & CPs).
5. Assign the IO controller "PLC_2" to the I-device.
6. Adapt the access to the transfer areas as in the PLC_1 project. Ensure that no duplicate assignments result.
7. Adapt the parameters of the subnet and PROFINET interface. Because the shared I-device involves the same device in different projects, these data must match.
8. Save the project.

Both projects now have an identically configured shared I-device. The IO controller access and the parameters of the PROFINET interface should still be checked in the different projects during the next step.

Summary - Assigning parameters for access to the shared device

The transfer areas are automatically assigned to the local IO controller. To change the assignment, follow these steps:

1. Click the "PLC_I-Device" device in the network view of the "PLC_1" project, and select the "Shared Device" area.
2. A table shows which CPU has access to each of the configured transfer areas. The default setting is that the local CPU has access to all modules and submodules.
3. Keep the setting "PLC_1" for all transfer areas that are to remain in the address range of the local CPU

   Select the setting "---" for all transfer areas that are to be located in the address range of the "PLC_2" CPU from the "PLC_2" project. This means that an IO controller outside the project is to have access to the transfer area.
4. Follow the same procedure for the remaining projects.
5. Finally, check whether the settings for access are "complementary" for each module or submodule in both projects. This means that if the local CPU has access in one project, the option "---" must be set in the other project and vice versa.

   Special consideration: The option "---" for the PROFINET interface and therefore for the ports makes the associated parameters read-only and not changeable. Parameters of the PROFINET interface and port parameters can only be edited in the project in which the PROFINET interface is assigned to the local CPU. The ports can be interconnected in both projects regardless of this.
6. Check whether the same IP address parameters and device name are set for the shared device in all projects.

   Check whether the same S7 subnet ID is set in all projects for the subnet to which the shared device is connected (subnet properties, "General" area in the Inspector window).

Note

If you make changes to the I-device (e.g., change the number or length of the transfer areas):

Export the I-device as a GSD file again. Re-install the GSD file in each project that uses the I-device as a shared device. Make sure that only one IO controller has access to a transfer area.

Procedure - Adjusting the real-time settings

To ensure that all IO controllers and shared devices are operated with the appropriate send clock and that the update times are calculated correctly based on the communication load, you must adjust and check the following settings:

1. You must set the same send clock for each IO controller that has access to modules and submodules of the shared device:
   - If you configure the IO controller with STEP 7 (TIA Portal):

     Open the corresponding project.

     Select the PROFINET interface of the IO controller.

     Select the "Advanced options > Real time settings > IO communication" area in the Inspector window and set the shared send clock.
   - If you configure the IO controller with a different engineering tool:

     Select the PROFINET interface of the shared device in STEP 7 (TIA Portal) and read out the send clock on the shared device ("Advanced options > Real time settings" area)

     Enter the read send clock in the engineering tool.
   - Special consideration: If you configure **all** IO controllers that have access to the shared I-device in STEP 7 (TIA Portal or V5.5), you can set shorter send clocks on the IO controller than supported by the shared device (send clock adaptation).

Compiling and loading

You must compile the configurations for the different IO controllers and load them to the CPUs one after the other.

Due to the distributed configuration with separate projects, STEP 7 does not output consistency errors in the case of incorrect access parameter assignment. Example for incorrect access parameter assignment:

- Several IO controllers have access to the same module
- IP address parameters or send clocks are not identical

These errors do not show up until operation and are output as configuration errors, for example.

Note

After a configuration has been loaded in the IO controller, non-assigned modules or submodules retain their current parameterization state to ensure the independence from the parameterizations of other IO controllers.

5.3.4 Module-internal shared input/shared output (MSI/MSO)

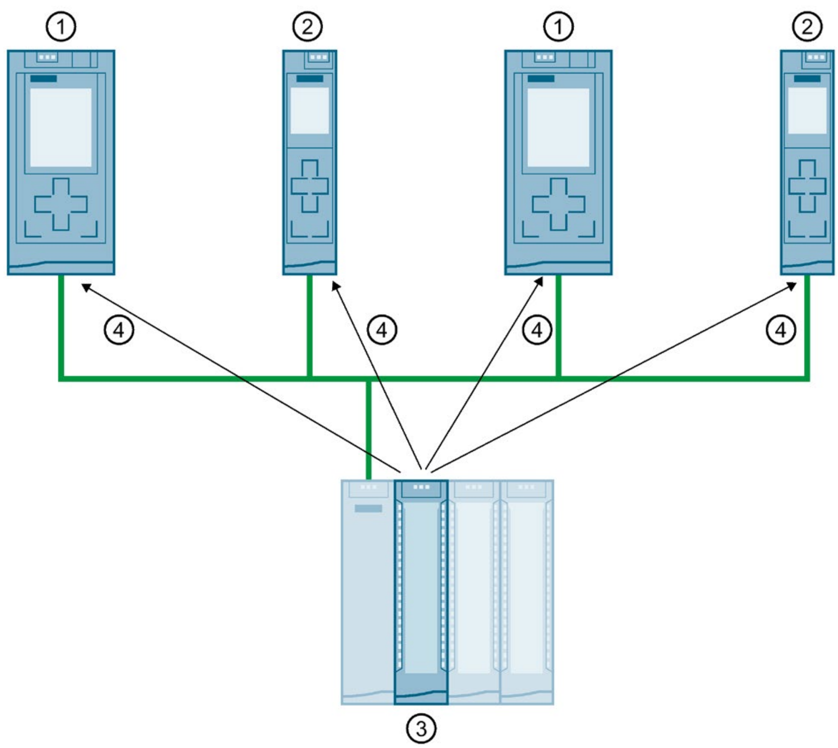
Introduction

This section describes the module-internal shared input/shared output (MSI/MSO) functionality for I/O modules that are operated on PROFINET.

Module-internal shared input/shared output functionality

The module-internal shared input (MSI) function allows an input module to make its input data available to up to four IO controllers. Each controller has read access to the same channels.

The following figure shows the MSI functionality.

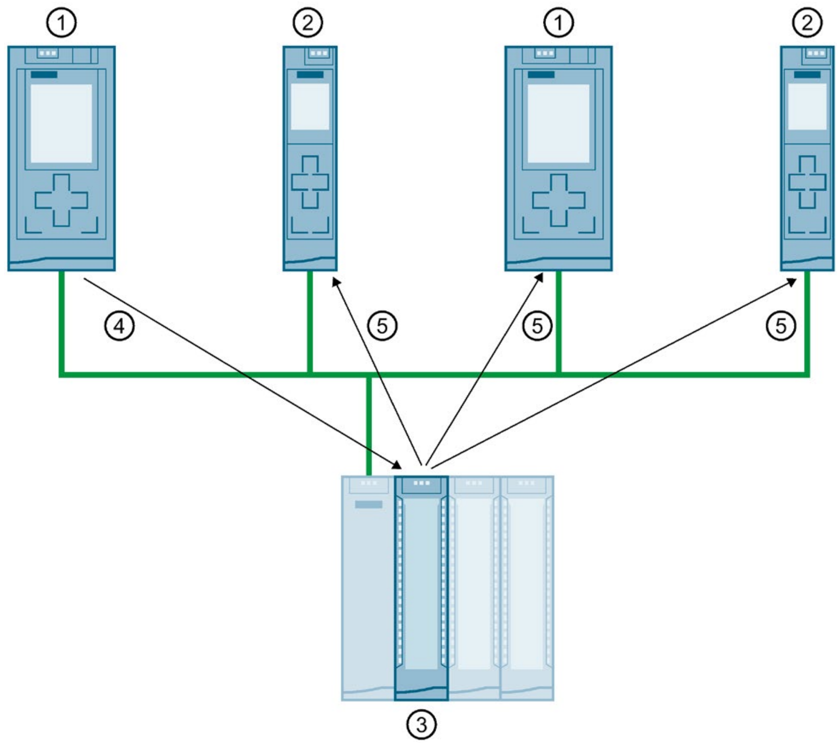


① CPU 1516-3 PN/DP as IO controller
② CPU 1511-1 PN as IO controller
③ Input module with MSI
④ Read access to the input channels of the input module
⑤ Write access to the channels of the I/O module (only with MSO)

Figure 5-28 Example configuration with MSI

The module-internal shared output (MSO) function allows an output module to make its output data available to up to four IO controllers. An IO controller has write access to the channels of the output module. Up to three IO controllers can additionally have read-access to the channels.

The following figure shows the MSO functionality.



① CPU 1516-3 PN/DP as IO controller
② CPU 1511-1 PN as IO controller
③ Output module with MSO
④ Write access to the output channels of the output module
⑤ Read access to the output channels of the output module

Figure 5-29 Example configuration with MSO

Advantages of MSI/MSO

Module-internal shared input/shared output (MSI/MSO) offers the following advantages:

- Real-time acquisition in multiple CPUs
- Lower costs due to saving on additional IO devices and modules
- Lower space requirements due to saving on additional IO devices and modules
- Reduced communication load because no CPU-CPU communication is needed
- No additional programming effort is needed for CPU-CPU communication

Requirements for the use of MSI/MSO

Observe the following requirements:

- MSI/MSO can only be used with PROFINET IO
- Configuration software: STEP 7 (TIA Portal) as of V12 SP1 with GSD file; the modules are integrated in the hardware catalog as of V13.
- The IM 155-5 PN ST interface module and the modules support MSI/MSO as of firmware version V2.0.0.

Boundary conditions for the use of MSI/MSO

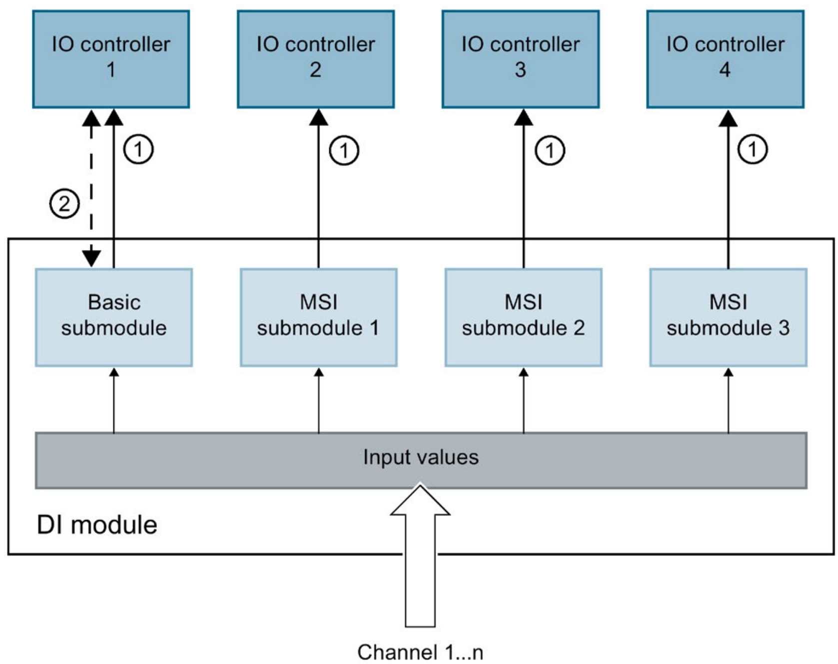
Note the following boundary conditions:

- The use of MSI/MSO is not possible in the case of module grouping.
- Modules with MSI/MSO cannot be operated in isochronous mode.
- The maximum number of IO controllers is dependent on the interface module. To find out how many IO controllers the interface module supports, refer to the manual for the respective interface module.

MSI submodules

The input values of all channels are copied to a basic submodule and up to three other MSI submodules during MSI configuration of an input module. The channels of the module are then available with identical input values in the basic submodule and the MSI submodules. The MSI submodules can be assigned to up to three IO controllers when the module is used in a shared device. Each IO controller has read access to the same channels.

The following figure shows a digital input module with the basic submodule and three MSI submodules. Each submodule is assigned to an IO controller. Diagnostics and parameter assignment of the digital input module can be performed from the IO controller 1 via the basic submodule.



① Read access

② Parameter assignment and system diagnostics

Figure 5-30 DI module with MSI submodules

Value status (Quality Information, QI)

The meaning of the value status depends on the submodule to which it pertains.

With basic submodule (= 1st submodule), the "0" value status indicates that the value is incorrect.

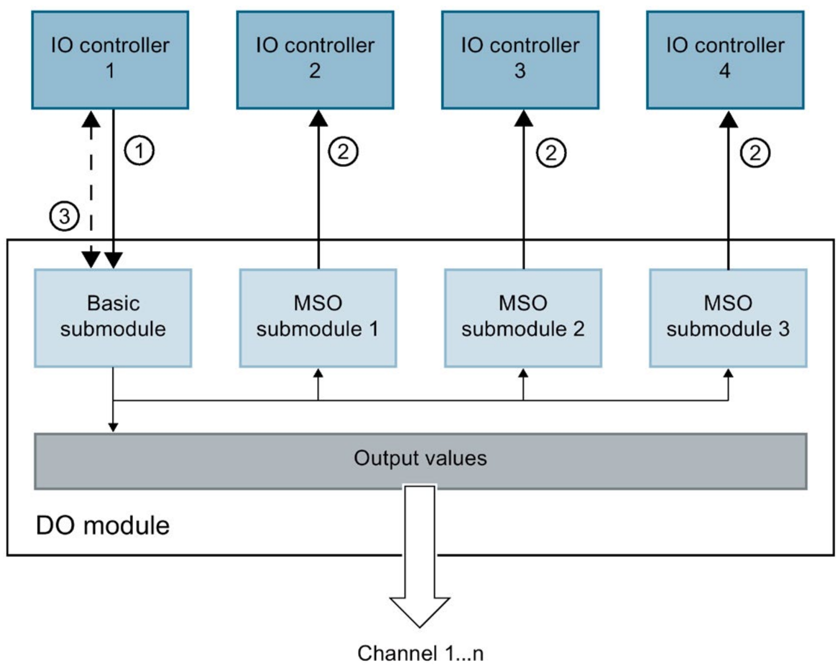
With an MSI submodule (2nd to 4th submodule), the "0" value status indicates that the value is incorrect or the basic submodule has not yet been configured (not ready).

MSO submodules

During MSO configuration of an output module, the output values of all channels of the module are copied from a basic submodule to up to three other MSO submodules. The channels of the module are then available with identical values in the basic submodule and the MSO submodules. The MSO submodules can be assigned to up to three IO controllers when the module is used in a shared device.

- The IO controller to which the basic submodule is assigned has write access to the outputs of the module. The basic submodule therefore occupies output addresses in the process image of the IO controller.
- The IO controllers to which the MSO submodules are assigned have read access to the outputs of the module. MSO submodules therefore occupy input addresses in the process image of the IO controller.

The following figure shows a digital output module with the basic submodule and three MSO submodules. Each submodule is assigned to an IO controller. Diagnostics and parameter assignment of the digital output module can be performed from IO controller 1 via the basic submodule.



① Write access
② Read access
③ Parameter assignment and system diagnostics

Figure 5-31 DQ module with MSO submodule

Value status (Quality Information, QI)

The meaning of the value status depends on the submodule to which it pertains.

With basic submodule (= 1st submodule), the "0" value status indicates that the value is incorrect.

With MSO submodule (= 2nd to 4th submodule) the "0" value status indicates that the value is incorrect or one of the following errors has occurred:

- The basic submodule parameters have not yet been assigned (not ready for operation).
- The connection between the IO controller and the basic submodule has been interrupted.
- The IO controller of the basic submodule is in STOP or POWER OFF state.

Configuring I/O modules with MSI/MSO submodules

Requirements

- Configuration software STEP 7 as of V13
- IO device supports MSI/MSO (for example IM 155-5 PN ST as of firmware version 2.0.0)

Procedure

1. In the network view of STEP 7, insert an IM 155-5 PN ST interface module as of V2.0.
2. Double-click the IO device.

   You are now in the device view.
3. Place the I/O modules from the hardware catalog in a suitable slot.
4. Add MSI/MSO submodules to the I/O modules:
   – Input modules: Select the number of MSI submodules under "Module parameters " > "DI configuration" or "AI configuration" in the area "Copy of module for Shared Device (MSI)".

– Output modules: Select the number of MSO submodules under "Module parameters " > "DQ configuration" or "AW configuration" in the area "Copy of module for shared device (MSO)".

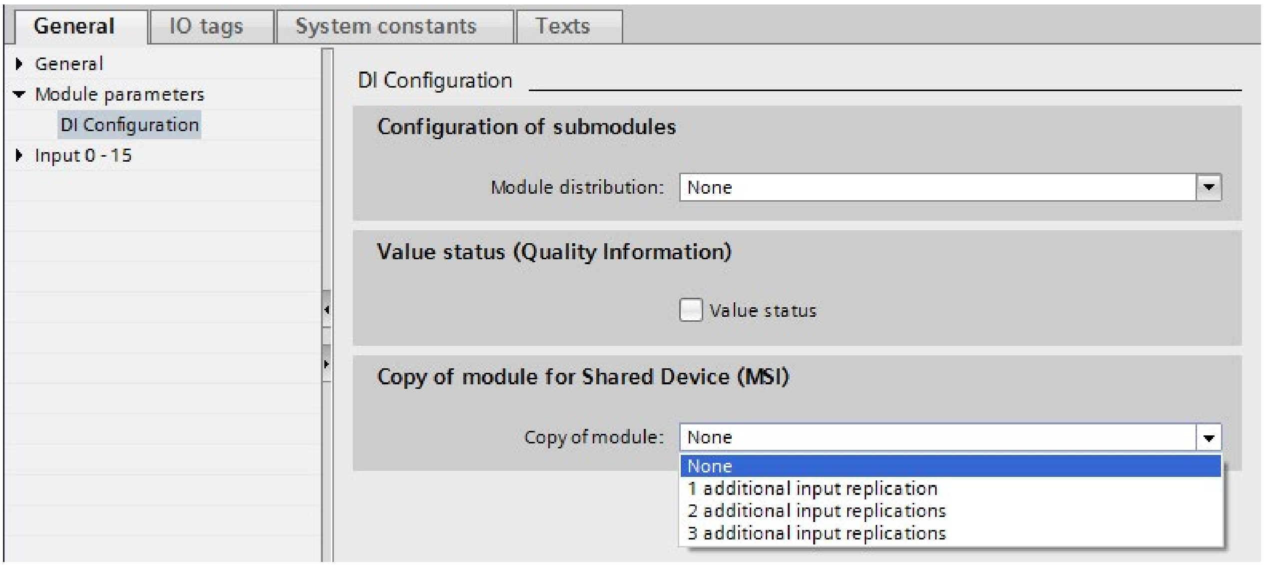


Figure 5-32 Configuring I/O modules with MSI/MSO

Assigning MSI/MSO submodules to an IO controller

You can assign the submodules in a shared device to an IO controller.

For more information, refer to Configuring shared device (Page 147).

Configuring access to a shared device and the module-internal shared input / shared output (MSI /MSO) function

You can learn how to access a shared device and the MSI /MSO function in STEP 7 with this FAQ (https://support.industry.siemens.com/cs/ww/en/view/109736536).

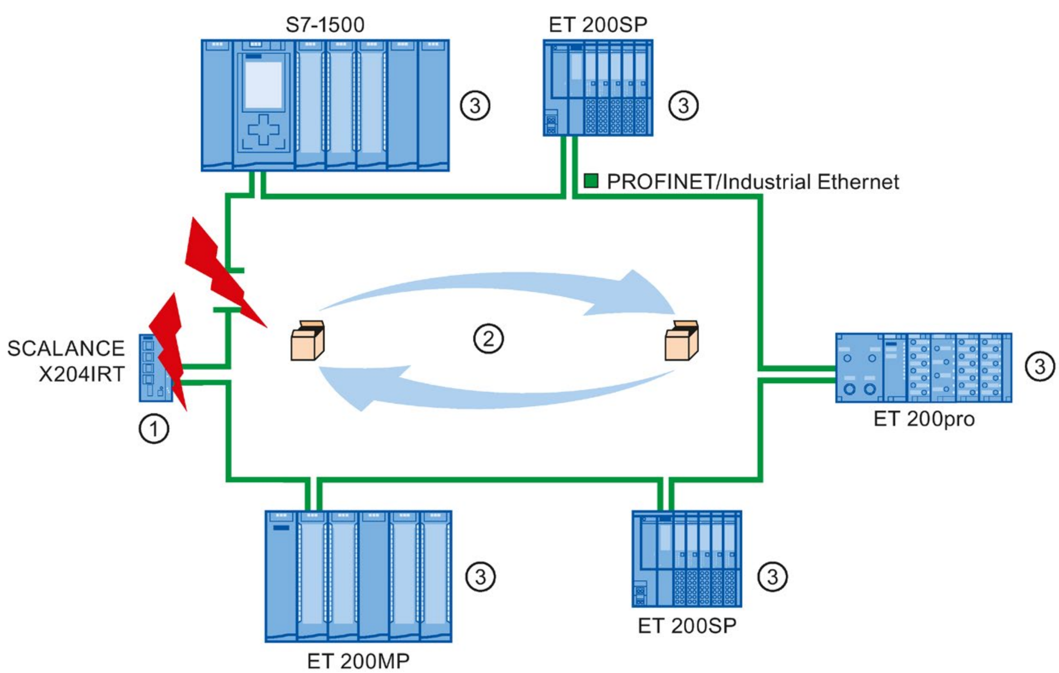
5.4 Media redundancy (ring topologies)

In order to increase the network availability of an Industrial Ethernet network with optical or electrical linear bus topologies, you can convert a linear bus topology to a ring topology by joining the ends together.

Media redundancy in ring topologies

Devices in a ring topology can be IO devices, IO controllers, external switches and/or the integrated switches of communication modules.

To set up a ring topology with media redundancy, you need to bring together the two free ends of a linear bus topology in one device. Closing the linear bus topology to form a ring is achieved with two ports (ring ports) of a device in the ring. One device of the resulting ring then takes over the role of the redundancy manager. All other devices in the ring are redundancy clients.



① Redundancy manager
② Test frames
③ Redundancy clients

Figure 5-33 Media redundancy in ring topology

The ring ports of a device are the ports that establish the connection to the two neighboring devices in the ring topology. The ring ports are selected and set in the configuration of the relevant device (is also preset, if applicable).

How media redundancy works in a ring topology

The data paths between the individual devices are automatically reconfigured if the ring is interrupted at any point. The devices are available again after reconfiguration.

In the redundancy manager, one of the two ring ports is blocked in uninterrupted network operation for normal communication so that no data frames are circulated. In terms of data transmission, the ring topology is a linear bus topology. The redundancy manager monitors the ring for interruptions. For this purpose, it sends test frames not only from ring port 1 but also from ring port 2. The test frames pass through the ring in both directions until they arrive at the other ring port of the redundancy manager.

An interruption of the ring can be caused by loss of the connection between two devices or by failure of a device in the ring.

If the test frames of the redundancy manager no longer arrive at the other ring port during an interruption of the ring, the redundancy manager connects its two ring ports. This substitute path once again restores a functioning connection between all remaining devices in the form of a linear bus topology.

The time between the ring interruption and restoration of a functional linear topology is known as the reconfiguration time.

As soon as the interruption has been eliminated, one of the two ring ports is blocked again in the redundancy manager. The redundancy clients are informed about the change and use the original paths to the other devices again.

Media redundancy method

The standard method of media redundancy in SIMATIC is MRP (Media Redundancy Protocol) with a typical reconfiguration time of 200 ms. Up to 50 devices can participate per ring.

In addition, the real-time capable media redundancy process MRPD (Media Redundancy with Planned Duplication of frames) is also available.

5.4.1 Media Redundancy Protocol (MRP)

Media Redundancy Protocol (MRP)

The "MRP" process works in conformity with the Media Redundancy Protocol (MRP) that is specified in the standard IEC 62439-2.

Requirements

- All devices in the ring support MRP.
- You have complied with the rules for topology set out below. STEP 7 monitors compliance with the rules during compilation and outputs corresponding alarms.

Topology

The following schematic shows a possible topology for devices in a ring with MRP. The devices inside the shaded oval are in the redundancy domain.

Example of a ring topology with the MRP media redundancy protocol:

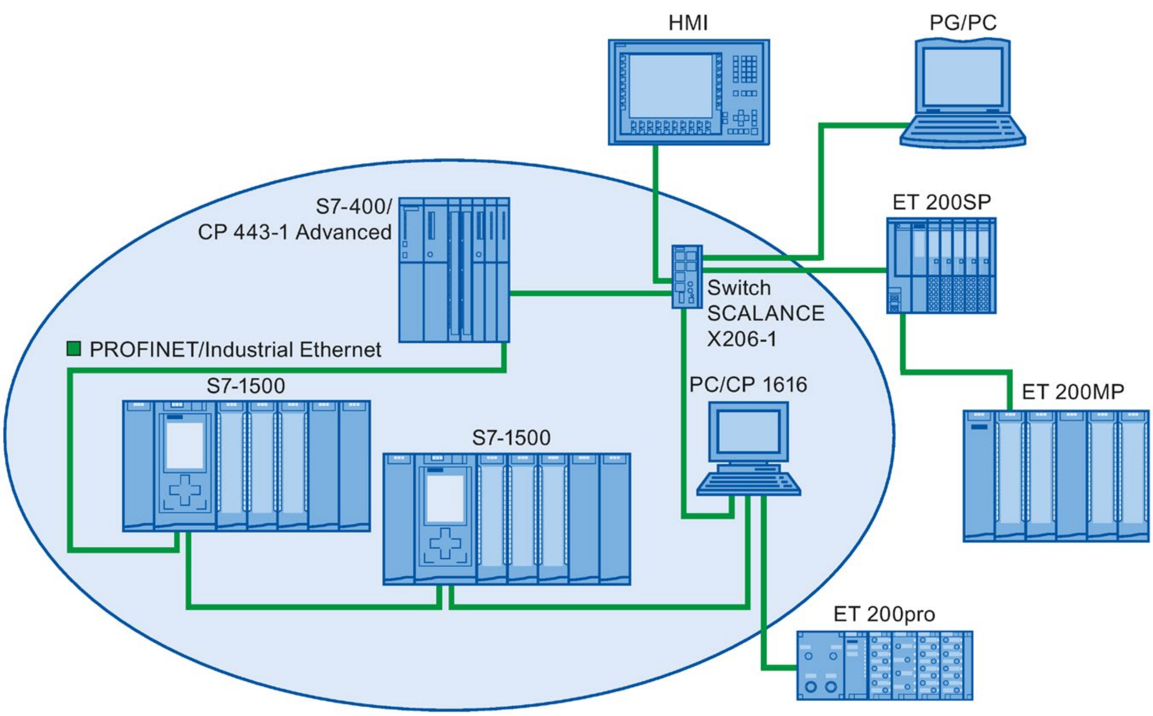


Figure 5-34 Example of a ring topology with the MRP media redundancy protocol:

The following rules apply to a ring topology with media redundancy using MRP:

- All devices must be connected to one other via their ring ports.
- All devices in the ring belong to the same redundancy domain.
- A device in the ring takes on the task of a redundancy manager.
  - One device only has the role of "Manager". No other device may have the role of "Manager". Or
  - Several devices in the ring have the role of "Manager (auto)". The devices with the role of "Manager (auto)" then negotiate between themselves which device is to take on the role of redundancy manager. In this case, no device is permitted to have the role of "Manager".
- All other devices in the ring are redundancy clients.
- You can connect up to 50 devices in a ring.

Non MRP-compliant devices can, for example, be connected to the ring via a SCALANCE X switch or via a PC with a CP 1616.

Rules for loading the devices of an MRP domain

When loading devices of an MRP domain, frame loops can occur and result in network failure if there is an invalid MRP configuration.

Example: You change the MRP roles of several devices and consecutively load the configuration into the devices involved. Configurations can arise that contradict the roles mentioned above, for example, there may be devices that simultaneously have the "Manager" and "Manager (auto)" roles in the ring.

In order to ensure that an invalid MRP configuration does not result in the failure of the network, delete the ring before loading.

Follow these steps:

1. Delete the ring.
2. Load the error-free and consistent MRP configuration from your project onto all the devices involved and ensure that the devices are in data exchange mode (i.e. the application relations (ARs) are set up).
3. Close the ring.

Boundary conditions

MRP and RT

RT operation is possible with the use of MRP.

Note

The RT communication is disrupted (station failure) if the reconfiguration time of the ring is greater than the selected response monitoring time of the IO device. This is why you should select a response monitoring time of the IO devices that is sufficiently large.

MRP and IRT

IRT mode is not possible together with MRP.

If you want to use media redundancy together with IRT in a ring, only use devices that support MRPD.

MRP and TCP/IP (TSEND, HTTP, ...)

The TCP/IP communication with MRP is possible, because lost data packages are resent, if applicable.

MRP and prioritized startup

If you configure MRP in a ring, you cannot use the "prioritized startup" function in PROFINET applications on the devices involved.

If you want to use the "prioritized startup" function, then you must disable MRP in the configuration (the device may also not be part of the ring).

Information on S7-1500R/H

You can find information on the media redundancy method MRP of the redundant S7-1500R/H system in section Configuring PROFINET IO on a redundant S7-1500R/H system (Page 274).

Application example: Reading the MRP status in the user program

The "LPNDR_ReadMRPState" function block from the "LPNDR" block library helps you to determine the status of the MRP ring per program. The block reads the MRP information from the PROFINET device (MRP Manager) and outputs the status.

The "LPNDR" block library and the corresponding documentation can be found in this application example (https://support.industry.siemens.com/cs/ww/de/view/109753067).

5.4.2 Configuring media redundancy

Configuring MRP

Proceed as follows to create a PROFINET IO configuration with MRP in STEP 7:

1. Generate a ring via the port interconnections in the topology view. First interconnect the devices to a line topology. Connect the unassigned port of the last device in the line with the unassigned port of the first device.
   The following example shows one CPU 1516-3 PN/DP and two interface modules IM 155-6 PN HF that are interconnected in a ring in the topology view of STEP 7.

   
   Figure 5-35 Configuring media redundancy

2. Select the PROFINET IO system in the network view.
3. In the Inspector window, navigate to "Properties" > "General" > "PROFINET" > "MRP domains" in the "Ring interconnections" field.
   This field shows you all the topological rings in the IO system with the associated MRP domains.
4. Select the ring generated above in the "Ring interconnections" field.
   The table below it shows all the PROFINET devices in the ring.

5. Set the media redundancy role for the PROFINET devices in the MRP role column.

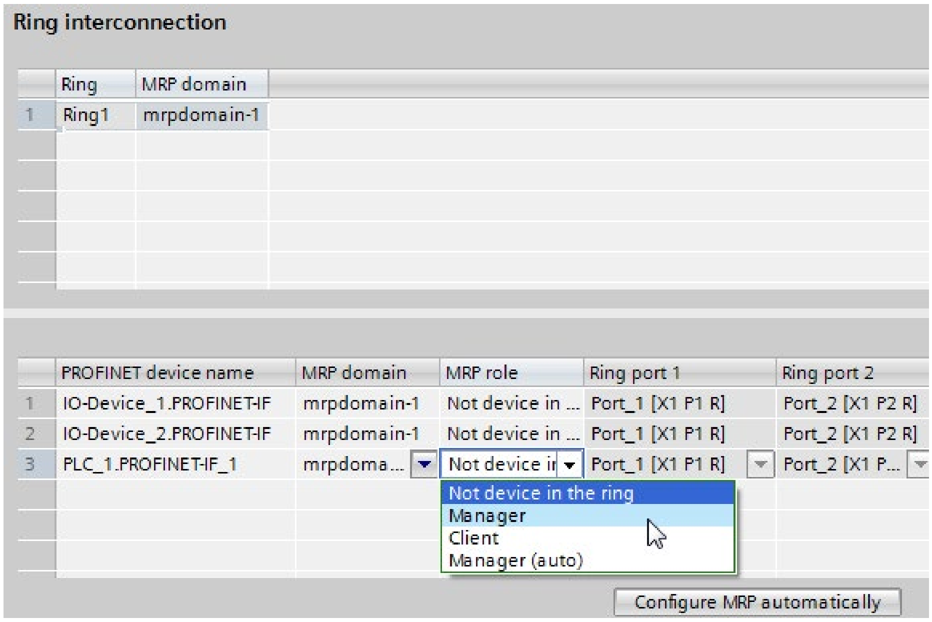

Figure 5-36 MRP domain

Automatic MRP configuration

You can also have the media redundancy roles assigned automatically for your PROFINET devices in the ring.

To have the media redundancy roles assigned automatically, click the "Configure MRP automatically" button. STEP 7 automatically assigns the media redundancy role for each device in the ring. After the automatic MRP configuration, you can make modifications to the media redundancy roles in the "MRP role" column.

"Media redundancy" setting options

Media redundancy role

Depending on the device used, the roles "Manager", "Manager (Auto)", "Client" and "Not device in the ring" are available.

Rules:

- A ring must have precisely one device with the role "Manager". No additional devices with the role "Manager" or "Manager (Auto)" are permissible. All the other devices may only have the "Client" role.
- If a ring has no device with the "Manager" role, the ring must at least have a device with the role "Manager (Auto)". Any number of devices with the "Client" role may exist.
- Managers and clients of an MRP domain can be configured in different projects. In the project without a manager, you need to select the "Redundancy manager outside the project" option so that the configuration can be compiled. For multiple ring configurations, you need to set the option identically for each MRP domain.

Ring port 1 / Ring port 2

Select one at a time those ports you want to configure as ring port 1 or ring port 2. The drop-down list box shows the selection of possible ports for each device type. If the ports are set at the factory, then the fields are unavailable.

If you use single-stage commissioning, use the preset ring ports in STEP 7.

Diagnostic interrupts

If diagnostic interrupts to the MRP state are to be output in the local CPU, select the "Diagnostic interrupts" check box. The following diagnostic interrupts can be configured:

- Wiring or port error

  Diagnostic interrupts will be generated for the following errors in the ring ports:

  – A neighbor of the ring port does not support MRP.

  – A ring port is connected to a non-ring port

  – A ring port is connected to the ring port of another MRP domain.

- Interruption / return (redundancy manager only)

  If the ring is interrupted and the original configuration is returned, diagnostic interrupts will be generated. If both of these interrupts occur within 0.2 seconds, this indicates an interruption of the ring.

You can respond to these events in the user program by programming the appropriate response in the diagnostic error interrupt OB (OB 82).

Reference

You can find the procedure for configuring a common MRP ring and the topology with two projects in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/109741671).

5.4.3 Media redundancy with planned duplication of frames (MRPD; not for S7-1500R/H)

MRP extension "Media Redundancy with Planned Duplication of frames" (MRPD)

The MRP extension "Media Redundancy with Planned Duplication of frames" (MRPD) provides the advantage that, in the case of a failure of a device or a line in the ring, all other devices continue to be supplied with IO data without interruption and with short update times.

MRPD is based on IRT and MRP. To realize media redundancy with short update times, the PROFINET devices participating in the ring send their data in both directions. The devices receive this data at both ring ports so that there is no reconfiguration time.

Requirements for media redundancy with MRPD

- All the devices of the ring must support MRPD, for example interface module IM 155-6 PN HS as of firmware version 4.0.
- You have configured MRP for all the devices of the ring. You have assigned the MRP role "Not device in the ring" to devices that are not located in the ring.
- You have configured IRT for all the involved components.

Configuring MRPD

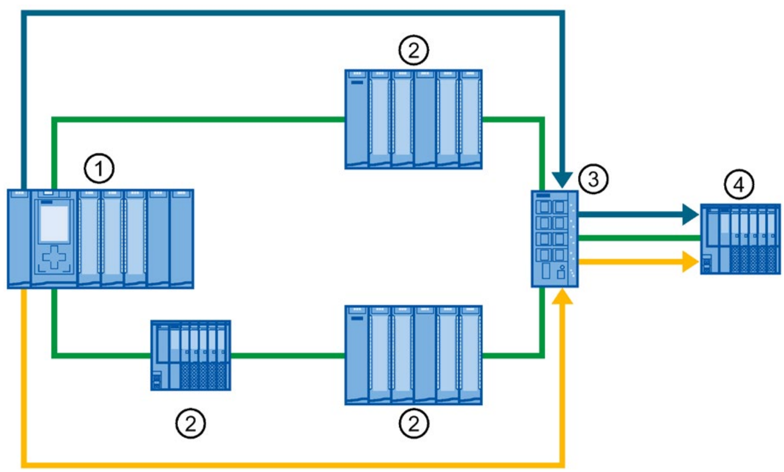
You do not have to explicitly activate MRPD in STEP 7. The function is available automatically as soon as all the requirements for MRPD are fulfilled.

Redundancy levels of IO devices with MRPD

The redundancy level of an IO device specifies how strongly the real-time communication is influenced in the case of a power interruption between an IO device and its IO controller.

- Full redundancy: No influence, because the IO controller and IO device are located in the same ring.
- Partial redundancy:
  - If the interruption takes place on a non-redundant part (line) between the IO device and IO controller, real-time communication is influenced.
  - If the interruption takes place on a redundant part (ring), real-time communication is not influenced.
- No redundancy: No redundant path between the IO device and its IO controller, communication is always influenced.

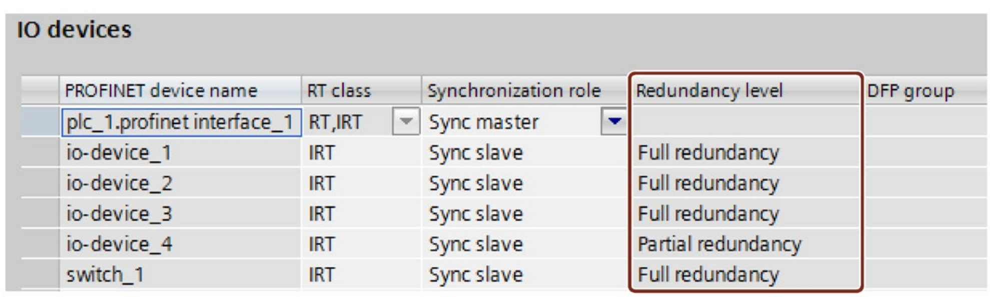
The figure below shows the redundancy levels of the IO devices for an example configuration with MRPD. The three devices in the ring and the switch have the redundancy level "Full redundancy". Device 4 has the redundancy level "Partial redundancy", because the connection between the switch and the device is not redundant.



① IO controller in the ring
② IO device in the ring with redundancy level "Full redundancy"
③ Switch in the ring with redundancy level "Full redundancy"
④ IO device in the spur with the redundancy level "Partial redundancy"

Figure 5-37 Example configuration with MRPD

The figure below shows the display of the redundancy levels in STEP 7 for the example configuration.



IO devices

PROFINET device name	RT class	Synchronization role	Redundancy level	DFP group
plc_1.profinet interface_1	RT,IRT	Sync master		
io-device_1	IRT	Sync slave	Full redundancy	
io-device_2	IRT	Sync slave	Full redundancy	
io-device_3	IRT	Sync slave	Full redundancy	
io-device_4	IRT	Sync slave	Partial redundancy	
switch_1	IRT	Sync slave	Full redundancy	

Figure 5-38 Display of the redundancy levels in STEP 7

5.4.4 Multiple rings

Multiple rings

Use multiple rings to achieve higher availability for PROFINET IO networks with star topology.

In a multiple ring configuration, several PROFINET lines lead from a switch (star topology). The individual PROFINET lines lead from IO device to IO device. Redundant PROFINET cables run back to the switch from the last IO device on each individual line.

The switch operates as a manager. The manager must have two ring ports for each ring. Several rings are possible. For example, the SCALANCE X414 as of firmware version 3.10 supports up to 4 rings.

The manager monitors all the rings individually: It checks for each particular ring (an MRP domain) whether the transmission path is intact. To do this, it uses an MRP instance in each case. An MRP instance is required for each connected ring (set up automatically by STEP 7).

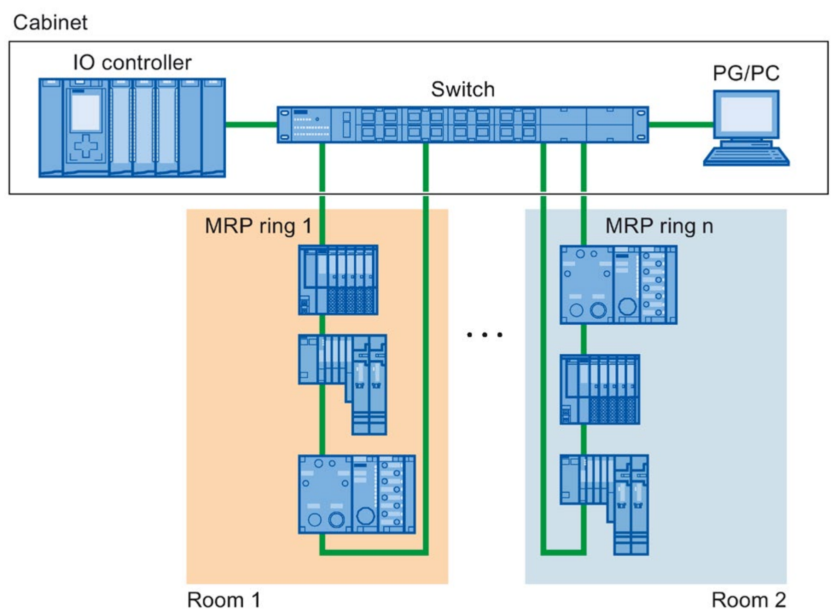


Figure 5-39 Configuration with several rings

Requirements

- SCALANCE X414 as of version 3.10
- SCALANCE X300 as of version 4.0 (configured via GSD file)

Rules for the configuration of multiple rings

- MRP role at multiple rings:
  - The device that belongs to all the rings must have the MRP role in every instance that is entered in the GSD file in the "SupportedMultipleRole" attribute.
  - The switches from the series SCALANCE X300 as of version 4.0 and the switch X414 as of version 4.10 support the MRP role "Manager" for multiple rings.
- If the device that belongs to all rings has the "Manager" role in one ring, no devices with the "Manager (Auto)" role may exist in this ring.

Configuring multiple rings

To configure an MRP configuration with multiple rings, follow these steps:

1. In the topology view, interconnect the ring ports of the devices that are intended to belong to an MRP domain to form a ring.
2. Select the PROFINET IO system in the network view.
3. In the Inspector window, navigate to "Properties" > "General" > "PROFINET" > "MRP domains" in the "Ring interconnections" field.
   This field shows you all the topological rings in the IO system with the associated MRP domains.
4. Select one of the rings generated above in the "Ring interconnections" field.
   The table below it shows all the PROFINET devices in the ring.
5. Set the media redundancy role for the PROFINET devices in the MRP role column.

Example of multiple rings

The following figure shows an example configuration for multiple rings.

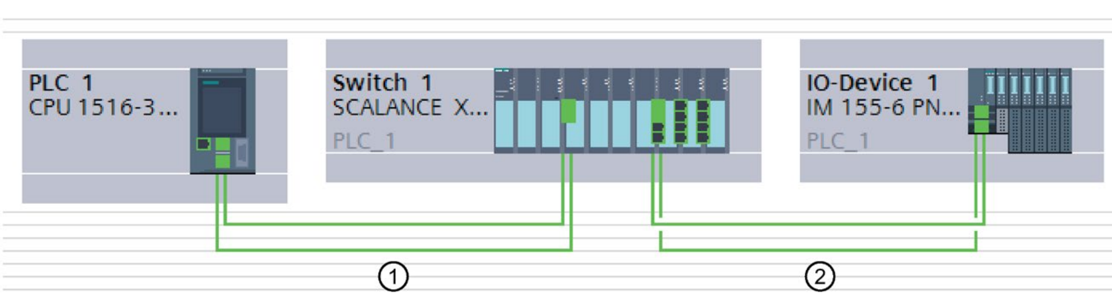

Figure 5-40 Example configuration with two rings ① and ②

In the example, Switch 1 belongs to two MRP rings. Ring 1 is formed by Switch 1 and PLC 1, Ring 2 by Switch 1 and IO device 1.

STEP 7 automatically assigns the "Manager" role to the switch. The other devices receive the "Client" role.

The manager is located at the point of intersection of the two rings 1 and 2. The manager monitors the two rings separately. To do this, it uses two MRP instances.

One MRP instance checks whether all devices in ring 1 are reachable, another instance monitors whether all devices in ring 2 are reachable (only one device in each case in the example).

You can configure each MRP instance separately.

The following figure shows the two MRP instances in the manager (PROFINET interface of the switch). Here in the example, MRP instance 1 checks whether the devices in the MRP domain "mrpdomain-1" can be reached. The MRP instance 2 is responsible for monitoring the devices of the MRP domain "mrpdomain-2".

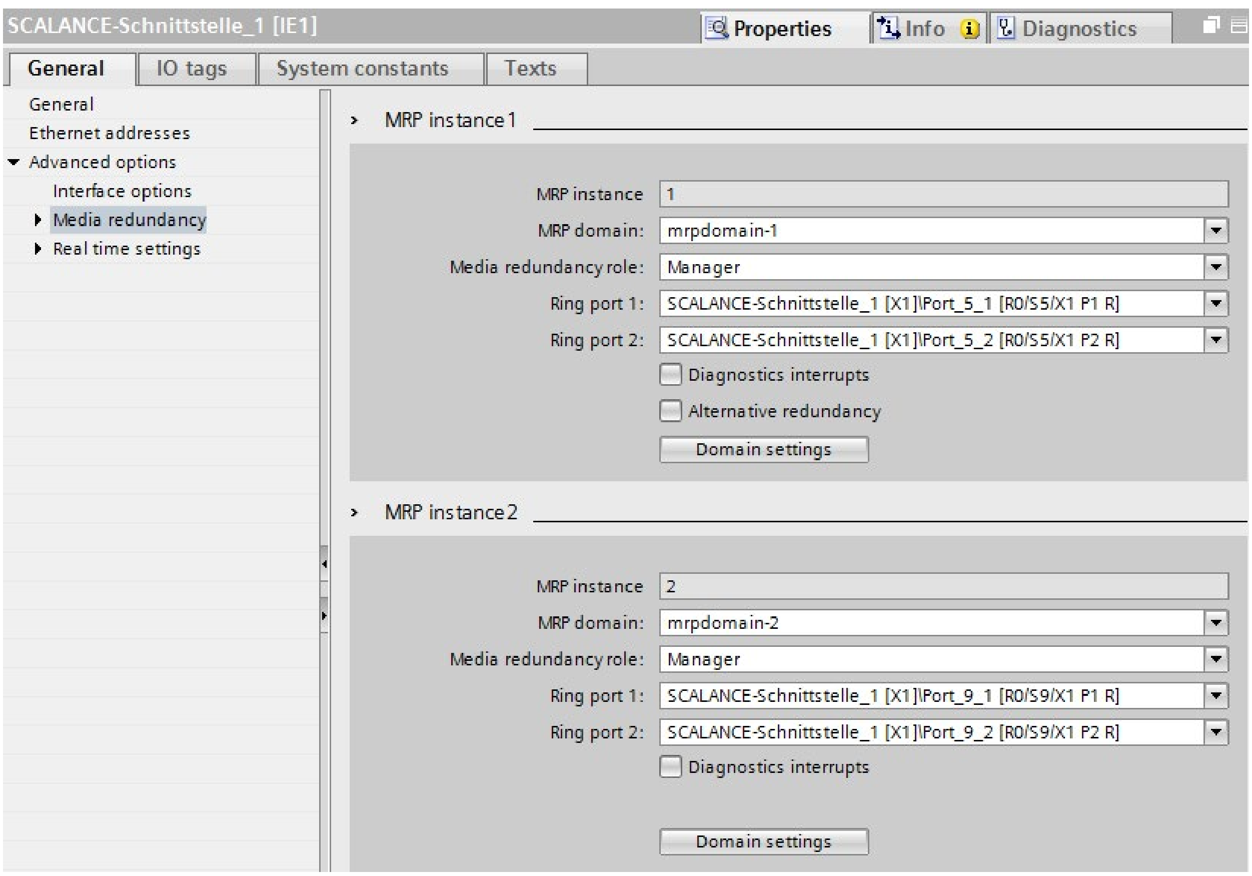

Figure 5-41 Setting media redundancy for multiple rings

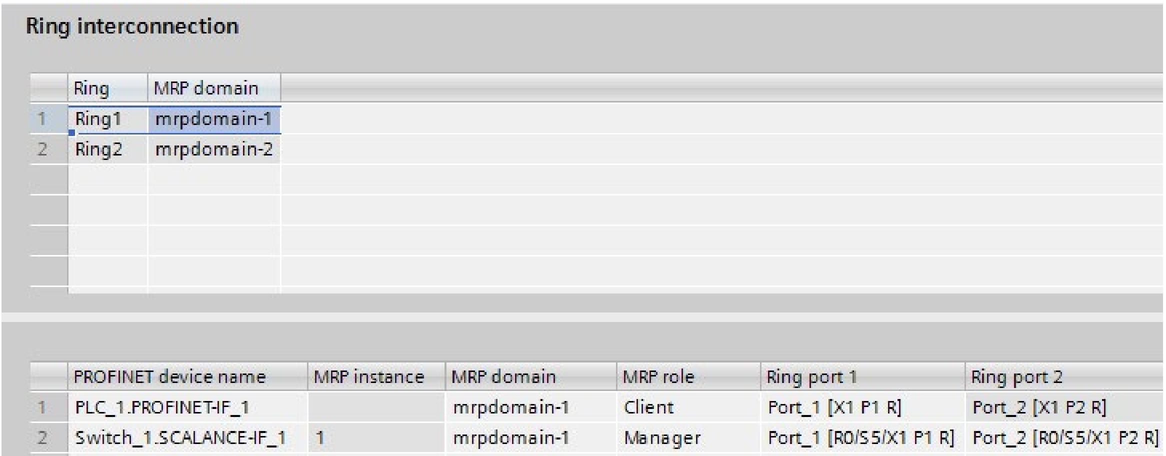
The following figure shows Ring 1 (mrpdomain-1). The participants of the mrpdomain-1 are the PROFINET interface of the CPU as the "Client" and the MRP interface 1 of the PROFINET interface of the switch as the "Manager".



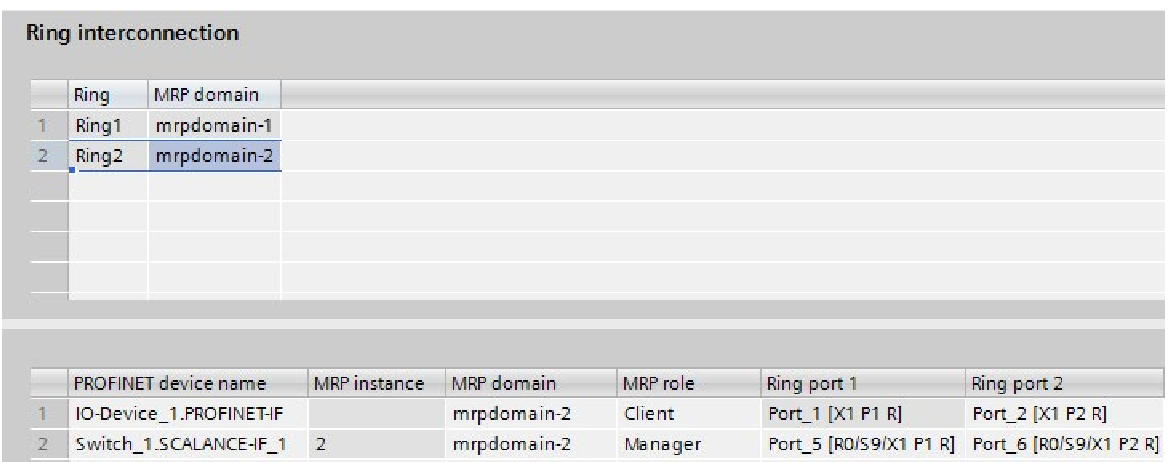
Ring interconnection

	Ring	MRP domain
1	Ring1	mrpdomain-1
2	Ring2	mrpdomain-2

	PROFINET device name	MRP instance	MRP domain	MRP role	Ring port 1	Ring port 2
1	PLC_1.PROFINET-IF_1		mrpdomain-1	Client	Port_1 [X1 P1 R]	Port_2 [X1 P2 R]
2	Switch_1.SCALANCE-IF_1	1	mrpdomain-1	Manager	Port_1 [R0/S5/X1 P1 R]	Port_2 [R0/S5/X1 P2 R]

Figure 5-42 Ring 1

The following figure shows Ring 2 (mrpdomain-2). The participants of the mrpdomain-2 are the PROFINET interface of the IO device as the "Client" and the MRP instance 2 of the PROFINET interface of the switch as the "Manager".



Ring interconnection

	Ring	MRP domain
1	Ring1	mrpdomain-1
2	Ring2	mrpdomain-2

	PROFINET device name	MRP instance	MRP domain	MRP role	Ring port 1	Ring port 2
1	IO-Device_1.PROFINET-IF		mrpdomain-2	Client	Port_1 [X1 P1 R]	Port_2 [X1 P2 R]
2	Switch_1.SCALANCE-IF_1	2	mrpdomain-2	Manager	Port_5 [R0/S9/X1 P1 R]	Port_6 [R0/S9/X1 P2 R]

Figure 5-43 Ring 2

5.5 Real-time communication

5.5.1 Introduction

Properties

PROFINET IO is a scalable real-time communication system based on the Layer 2 protocol for Fast Ethernet. With the RT transmission method, two real-time-support performance levels are available for time-critical process data and IRT for high-accuracy and also isochronous processes .

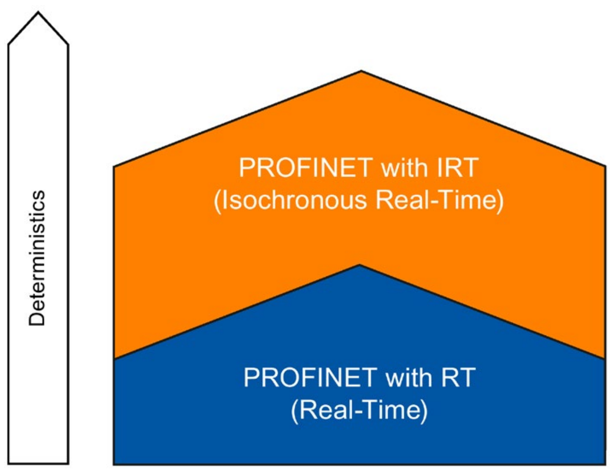


Figure 5-44 Real-time communication performance

Real-time communication and IT communication

Industrial communication, especially in the factory automation and process automation, requires a punctual and deterministic data transmission. This is why, for the cyclic exchange of time-critical IO user data, PROFINET IO does not use TCP/IP, it uses real-time communication (RT) or isochronous real-time communication (IRT) for the synchronized data exchange in reserved time intervals.

Fields of application of PROFINET with RT

PROFINET with RT is suited for:

- Time-critical applications in factory automation
- The implementation of large quantity structures in line process plants

Fields of application of PROFINET with IRT

PROFINET with IRT is particularly suitable for:

- Considerable deterministics with large quantity structures concerning the I/O user data communication (productive data)
- Considerable performance also with many devices concerning the I/O user data communication (productive data)
- Parallel transfer of productive and TCP/IP data via a cable, even with considerable data traffic whilst ensuring the forwarding of productive data by reserving the transmission bandwidth.

International standard IEC 61158

The communication procedures RT and IRT are standardized in the international standard IEC 61158.

5.5.2 RT

PROFINET IO with real-time communication (RT) is the ideal solution for integrating IO systems. This is a solution that also uses standard Ethernet in the devices and commercially available industrial switches as infrastructure components. A special hardware support is not required.

If you want to use PROFINET functions that provide an additional value, such as topology detection, diagnostics, device exchange without exchangeable medium/PG, you have to use switches that support the PROFINET standard according to the IEC 61158 standard. In the integrated switches of PROFINET devices and PROFINET switches (e.g., the SCALANCE product family), PROFINET functions in accordance with the PROFINET standard are implemented and can be used without restriction for integration in the PROFINET IO system (see also section Active network components (Page 31)).

Real-time communication (RT)

PROFINET IO frames have priority over standard frames in accordance with IEEE802.1Q. This ensures the required determinism in the automation technology. The data is transferred via prioritized Ethernet frames. With RT, you can achieve update times ≥ 250 μs with RT.

Switching mechanisms

Switches in SIMATIC meet the real-time requirements with two mechanisms on PROFINET: "Store and forward" and "Cut through".

Store and forward

In the Store and forward method, the switch stores the frames completely and places them in a queue. If the switch supports the international standard IEEE 802.1Q, then the data is sorted according to its priority in the queue. The frames are then forwarded selectively to the specific port that can access the addressed node (Store and forward).

Cut through

In the Cut through process the entire data package is not stored temporarily in a buffer, it is passed directly onto the target port as soon as the target address and the target port have been determined.

The times required by the data package to pass through the switch are then minimal and independent of the frame length. The data are only stored temporarily in accordance with the Store and forward process as per priority when the section between the target segment and the port of the next switch is occupied.

5.5.3 IRT

Isochronous real-time communication (IRT)

IRT is a synchronized communication protocol for cyclic exchange of IRT data between PROFINET devices. A reserved bandwidth is available in the send cycle for IRT data. The reserved bandwidth ensures that the IRT data can be transferred at reserved synchronized intervals, without being influenced also by higher other network loads (such as TCP/IP communication, or additional real-time communication).

Advantages

PROFINET with IRT is synchronized communication in reserved time intervals. With IRT you have the option to be able to control time-critical applications such as motion control via PROFINET. With IRT you use further advantages:

- High-precision deterministics allow highest control quality and thus, for example, exact positioning of axes
- Simple and flexible integration of PROFINET devices for real-time applications in existing company networks
- Shortest response times and highest deterministics by means of bandwidth reservation and thus also for applications that have to satisfy highest performance requirements (e.g., printing control/position control for presses, print-mark recognition with packaging machines)
- Secured standard communication parallel to real-time communication via the same transmission medium
- You can continue to use standard components for your PROFINET IO system outside of the sync domain

Properties of isochronous real-time

Topology configuration is a prerequisite for IRT.

In addition to the reserved bandwidth, the frames from defined transmission paths are exchanged for the further optimization of data transfers. For this, the topological information from the configuration is used for planning the communication. Transmission and reception points of every individual data frame at every communication node are thus guaranteed. This allows you to achieve optimal usage of the bandwidth and reach the best possible performance in the PROFINET IO system.

Use of IRT allows you to achieve update times with very high deterministics ≥ 125 μs and a jitter accuracy of the send clock < 1 μs. Isochronous applications are possible with IRT (see section Isochronous mode (Page 207)).

* The minimum update time depends on the CPU used. The update times supported by a CPU are listed in the technical specifications of the CPU manual.

Note

IWLAN and IRT

PROFINET devices that are connected to PROFINET IO via access points, do not support IRT.

Synchronization

The prerequisite for the IRTcommunication is a synchronization cycle for all PROFINET devices in a sync domain for distributing a mutual time basis. A synchronism of the transmission cycle of the PROFINET devices within a sync domain is achieved with this basic synchronization.

A sync master specifies the clock to which sync slaves are synchronized. An IO controller or an IO device can have the role of sync master. If the sync master fails, all IO devices with IRT will fail.

Sync master and sync slaves are always devices in a sync domain. Bandwidth is reserved within the sync domain for IRT communication. Real-time and non-real-time communication (TCP/IP communication) is possible outside of the reserved bandwidth.

Default sync domain

If you have created a PROFINET subnet, a special sync domain is automatically created, the default sync domain. All PROFINET devices configured for the PROFINET subnet automatically belong to this sync domain.

For additional information on creating sync domains, refer to the STEP 7 online help.

Time ranges of the communication cycle

The communication cycle is divided into three time ranges, which are shown in the following chart:

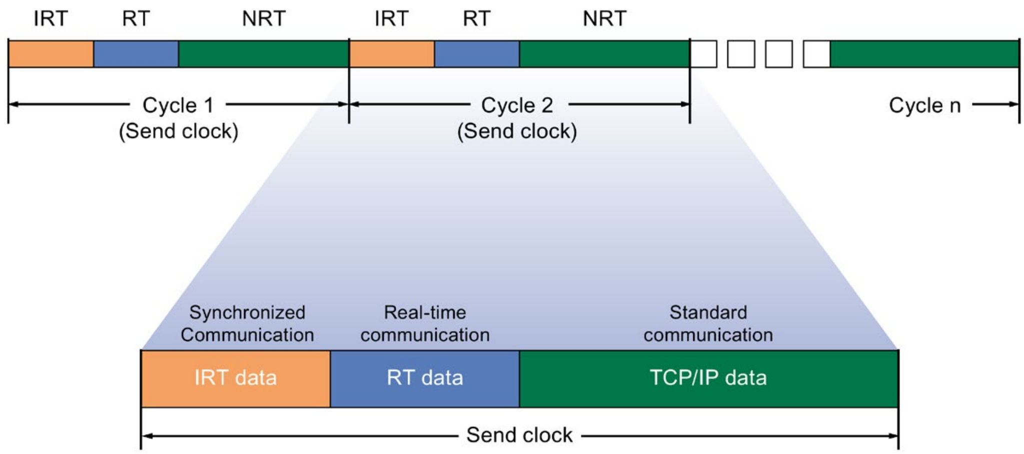

Figure 5-45 Reserving bandwidth

- IRT data (synchronized communication)

  This time range can be reserved in specific steps, depending on the send clock. Only IRT data is transmitted during this time range.

- RT data (real-time communication)

  The cyclic RT data is transferred in this time range. RT data is prioritized over "normal" TCP/IP data. TCP/IP data or Ethernet frames can have a priority of between 1 and 7. RT data have the Priority 6.

- TCP/IP data (standard communication)

  Standard communication (e.g., TCP/IP) is transmitted in the remaining interval of the communication cycle.

In STEP 7, you can set the ratio of the bandwidth usage of cyclic IO data to standard communication. For information on how to set the bandwidth usage, refer to the section Setting the bandwidth usage for the send clock (Page 191)

5.5.4 Comparison of RT and IRT

The most important differences between RT and IRT

Table 5- 2 Comparison between RT and IRT

Property	RT	IRT
Transmission method	Prioritizing the RT frames through Ethernet priority (VLAN tag)	Path-based switching on the basis of a communication path plan; no transmission of TCP/IP frames in the time range with IRT communication.
Determinism	Variance of the duration of transmission by the shared use of the transmission bandwidth with other protocols (e.g., TCP/IP)	Exact, planned transmission, transmission and reception times are guaranteed for all topologies.
Hardware support through special Ethernet controllers is required	Not required	Required
Isochronous application	-	Yes
Starting time of the isochronous application	-	The point in time for the reception of the data is planned exactly. Application can be started synchronized to the cycle.

5.5.5 Configuring PROFINET IO with IRT

Introduction

If you want to configure a PROFINET IO system with IRT, you have to configure the PROFINET IO devices. These PROFINET devices must support IRT. Set which device acts as the sync master and synchronizes the other devices. This is done by configuring a sync domain with a sync master and at least one sync slave.

Requirement

- There is an IO system with an IO controller and at least one IO device.
- You have configured the topology for the IO system.
- The devices support IRT.

Procedure

Proceed as follows to enable an existing IO system for the use of IRT:

1. Select the PROFINET interface of the IO controller.
2. In the Inspector window, navigate to "Advanced options > Real time settings > Synchronization".

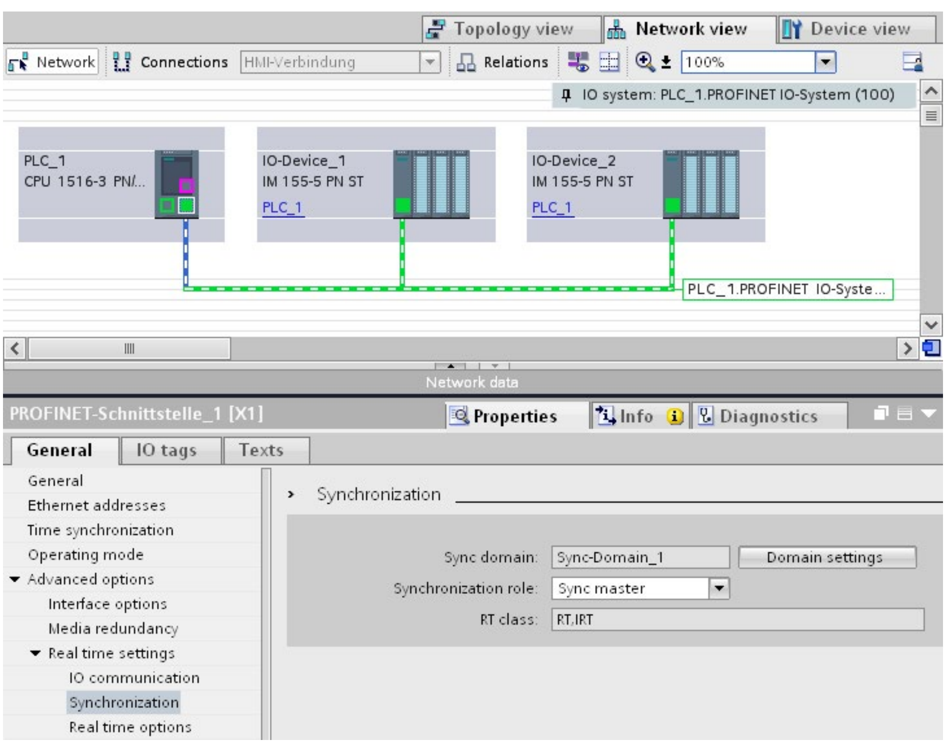

Figure 5-46 IRT configuring sync master

3. Assign the IO controller the role of sync master under "Synchronization role".
4. Select the PROFINET interfaces of an associated IO device.
5. In the Inspector window, navigate to "Advanced options > Real time settings > Synchronization".

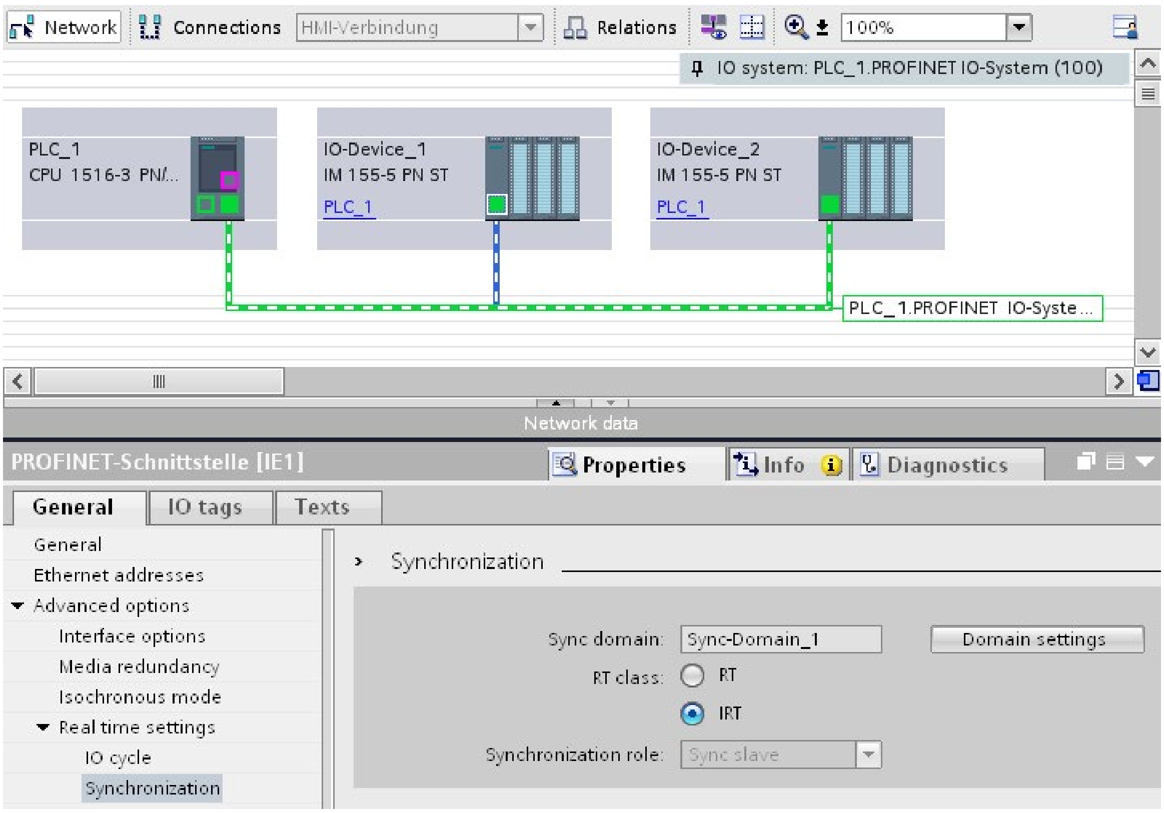

Figure 5-47 IRT configuring sync slave

6. Activate the RT class "IRT". The IO device will then automatically be assigned the synchronization role "sync slave".
7. You can check and correct your settings at any time using the "Domain settings" button.

Or

1. Highlight the PROFINET IO system in the network view.
2. Click on the PROFINET IO system.
3. Navigate to the device of the required sync domain in the Inspector window.

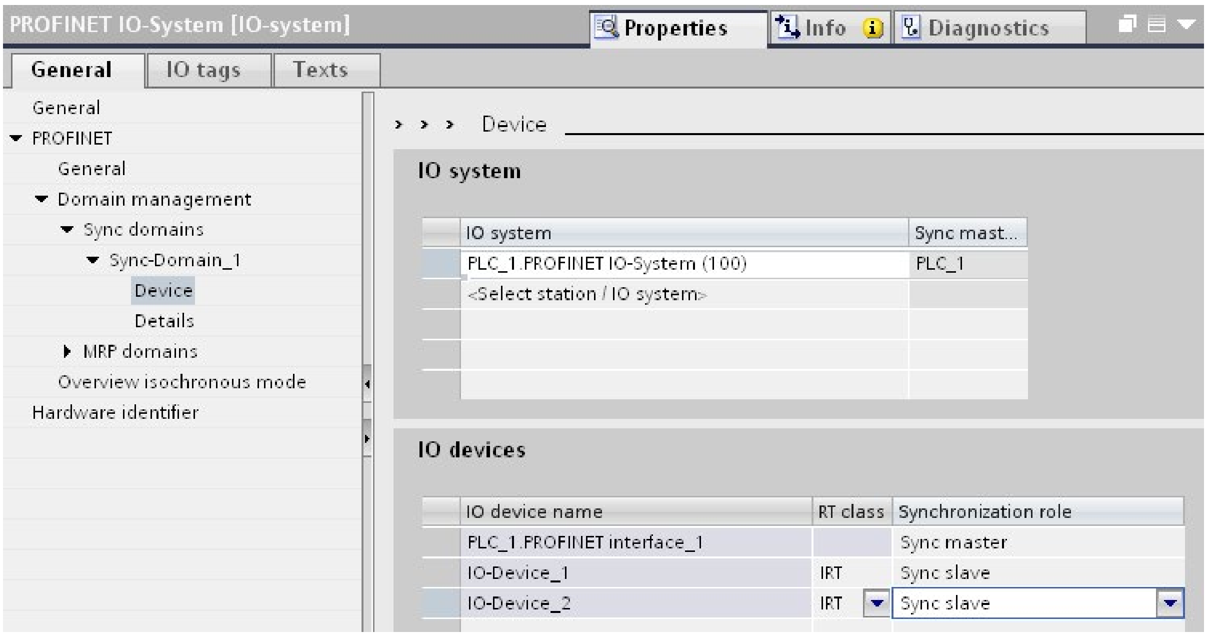

Figure 5-48 IRT configuring sync domain

4. Enter all necessary settings in the tables:
   – Select an IO system.
   – Set the synchronization role "sync master" for the IO controller.
   – Set the RT class for the IO devices to "IRT". The IO devices will then automatically be assigned the synchronization role "sync slave".

You can now load the configuration to the relevant devices with PROFINET IRT.

5.5.6 Setting the bandwidth usage for the send clock

Bandwidth level

For PROFINET IO with IRT, you can specify the maximum portion of the send cycle that you want to use for cyclic IO communication.

You have the following setting options for the bandwidth usage in STEP 7.

- Maximum 25% cyclic IO data. Focus on non-cyclic data.
- Maximum 37.5% cyclic IO data. Focus on non-cyclic data.
- Maximum 50% cyclic IO data. Balanced proportion.
- Maximum 90% cyclic IO data. Focus on cyclic IO data. (Requirement: The "Make 'high performance' possible" option is activated)

Setting the bandwidth usage

To set the bandwidth usage for a PROFINET IO system in STEP 7, follow these steps:

1. Select your IO system in the network view of STEP 7.
2. In the Inspector window, go to "Properties" > "General" > "PROFINET" > "Domain management" > "Sync domains" > "Name of the sync domain" > "Details".
3. Select the desired level of bandwidth usage from the "Bandwidth use" drop-drop down list box.

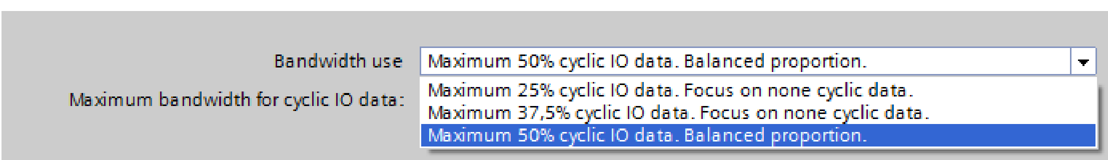

Figure 5-49 Setting the bandwidth usage

For information on how to set the bandwidth usage for IRT with maximum performance, refer to the section Configuration of IRT with high performance (Page 202)

5.5.7 Setup recommendations for optimizing PROFINET

Optimizing PROFINET with RT

PROFINET provides you with high-performance communication on all levels.

The following figures shows an example of an optimized PROFINET topology.

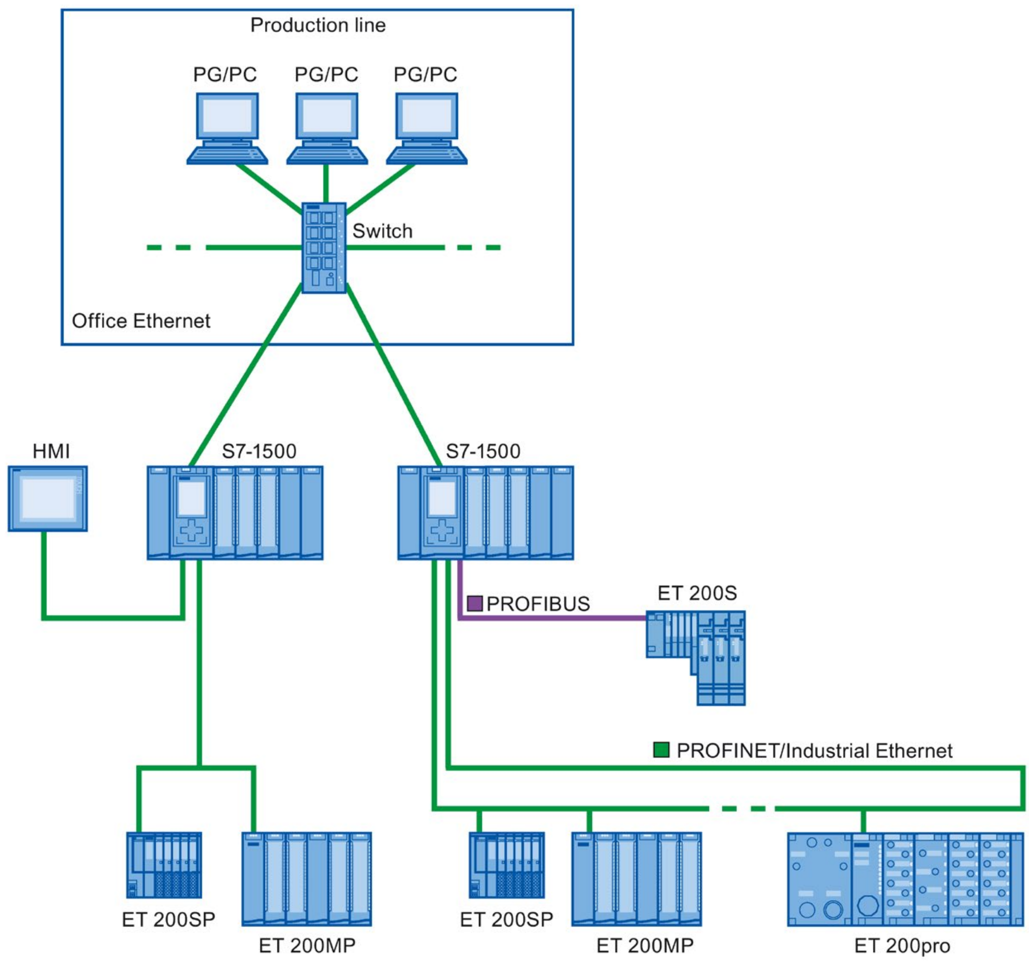

Figure 5-50 Optimized PROFINET topology

When setting up your PN network topology, take care that the various automation applications are distributed among separate network branches so that a sufficient bandwidth reserve will be available for future expansions.

- If you integrate standard Ethernet devices into the network topology or use standard Ethernet communication, take into account the network load caused by standard Ethernet and adapt the network topology as appropriate (max. bandwidth 100 Mbps).
- For communication with higher-level networks with a high data volume, use the most direct paths possible to the higher-level network infrastructure.

Also observe the Installation Guideline (http://www.profibus.com/nc/download/installation-guide/downloads/profinet-installation-guide/display/) of the PROFIBUS User Organization.

Setting up PROFINET with IRT

Keep in mind the following rules for setting up and operating a PROFINET IO system in IRT mode. These rules will ensure best possible operation of your PROFINET IO system.

- When using IRT, you must configure the topology. This will enable exact calculation of the update time, bandwidth, and other parameters.
- If you would like to use multiple sync domains, configure a sync boundary for the port which is currently connected to the PROFINET device of another sync domain.
- In a sync domain, you can only configure one sync master at a time.
- A PROFINET IO system may only be part of a single sync domain.
- If you configure PROFINET devices in a sync domain and want to synchronize with IRT, the PROFINET devices concerned must support IRT communication.
- If possible, use the same PROFINET device as the PROFINET IO controller and sync master.
- If only some of the PROFINET devices in a PROFINET IO system are synchronized, please keep in mind the following: Assign PROFINET devices that are not participating in the IRT communication to the RT class "RT" and the synchronization role "unsynchronized" in the sync domain.

Applications for CPU with multiple PROFINET IO interfaces

- Connecting machines: Your configuration contains machines located on separate IO lines. You can perform real-time communication between the CPUs over PROFINET IO interface X2. Use the I-device or shared I-device function for this purpose.
  The figure below shows an example configuration for two machines connected over the X2 interface with an I-device relationship.

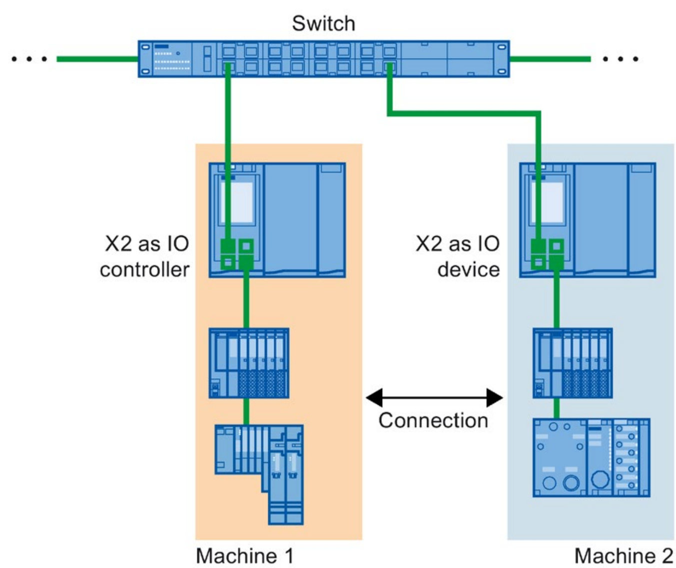

Figure 5-51 I-device connection over 2nd PNIO interface

- Distribution by automation tasks:
  – For automation tasks with high performance and deterministic requirements, use PROFINET with IRT over the X1 interface.
  – For other tasks that you can implement with RT, use the X2 interface.

If you use interface X2 as the PROFINET IO interface for one of the following CPUs, this can affect performance:

- CPU 1515(F)-2 PN
- CPU 1515T(F)-2 PN
- CPU 1516(F)-3 PN/DP
- CPU 1516T(F)-3 PN/DP
- CPU 1516(F)pro-2 PN

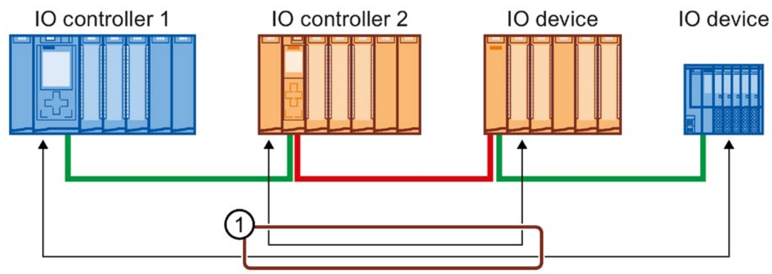
You can find additional information in the section PROFINET interface (Page 25) and in the Cycle and Response Times (https://support.industry.siemens.com/cs/ww/en/view/59193558) function manual.

Topological overlap of IO systems in multi-controller applications

In a configuration with multiple IO controllers, shared paths are subject to the combined network loads of all connected PROFINET IO systems.

To avoid high communication loads in multi-controller applications, observe the following recommendations:

- Avoid paths that are shared by multiple IO systems.
  The figure below shows a configuration with two PROFINET IO systems that use the same paths.



① Shared path

Figure 5-52 Multi-controller application with shared path

In the figure below, the two PROFINET IO systems do not use shared paths.

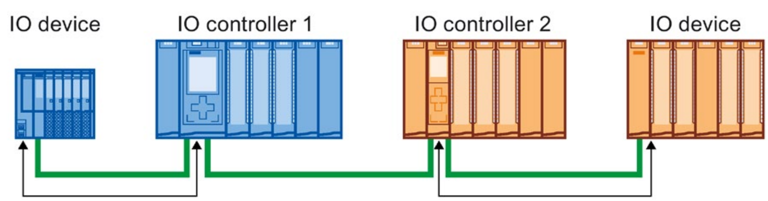


Figure 5-53 Multi-controller application with separate paths

- If separation is not possible: Increase the update time for the affected IO devices.

Installation guidelines of the PROFIBUS user organization

The installation guidelines can be found on the Internet (http://www.profibus.com/nc/download/installation-guide/downloads/profinet-installation-guide/display/).

5.5.8 Limitation of the data infeed into the network

Limiting the data infeed into the network on PROFINET interfaces

The "Limit data infeed into the network" function limits the network load of standard Ethernet communication which is fed into the network by the interface to a maximum value. This does not apply to cyclic real-time communication (RT/IRT).

In a PROFINET IO system, critical network loads can occur quickly with standard Ethernet communication, especially in line topologies. Devices which feed a lot of standard Ethernet communication into the PROFINET IO system, should support the function "Limit data infeed into the network". If necessary, you should optimize your topology by avoiding e.g. standard Ethernet devices in line topologies. You can find additional information on this in section Setup recommendations for optimizing PROFINET (Page 192).

Depending on the interface, you can activate or deactivate the "Limit data infeed into the network" function. If you use the X1 interface of an S7-1500 CPU as the IO controller or I-device, the "Limit data infeed into the network" function is always enabled. Example: If you are not using the X1 interface of an S7-1500 CPU as IO controller or I-device, you can enable or disable the function.

Uses of the limitation of the data infeed to the network

- Division of the bandwidth for standard Ethernet communication between devices:
  In PROFINET networks cyclic real-time communication and standard Ethernet communication share the same network. This means that only a limited bandwidth remains for standard Ethernet communication. The limitation of the data infeed ensures that the remaining bandwidth for standard Ethernet communication is not used just by one device, but is divided between several devices.
- Smoothing peaks in the data infeed:
  The limitation of the data infeed smooths peak loads of standard Ethernet communication (for example, from Open User Communication, access by the Web server).
- Limiting problems in the data infeed:
  If applications in a device generate too much data, this data is not forwarded to the PROFINET network. Negative effects (for example data loss, communication breakdown) remain limited to the device and its communications partner. Other nodes are not disturbed.

Setting limitation of the data infeed into the network for a CPU

To set the limitation of the data infeed into the network, follow these steps:

1. In the network view of STEP 7, select the interface of the CPU.
2. In the Inspector window, go to "Properties" > "General" > "Advanced options" > "Interface options".
3. Select or clear the "Limit data infeed into the network" check box.

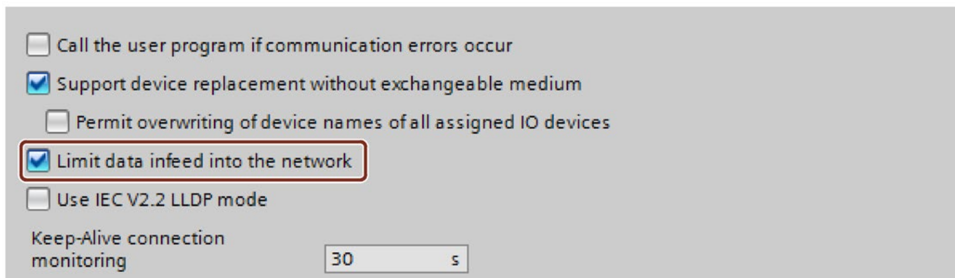

Figure 5-54 Limit data infeed into the network

5.6 PROFINET with performance upgrade

Performance upgrade

The performance upgrade implements the application class "High Performance" of the PROFINET specification V2.3.

The performance upgrade provides a series of measures that lead to the following improvements for PROFINET with IRT:

- Reduction of runtime delays in the IO devices
- Increase in the bandwidth for cyclic IO data
- Reduction of the bandwidth used for PROFINET frames
- Reduction of the send clocks

The improvements achieved with the performance upgrade mean that you can operate your PROFINET IO system with more devices with the same send clock or the same number of devices with a shorter send clock.

With PROFINET, it was previously possible to reach a send clock of 250 µs.

With the performance upgrade, it is now possible to achieve isochronous send clocks of up to 125 µs with the fast forwarding, dynamic frame packing and fragmentation procedures, depending on the performance capability of the CPU (see Technical Specifications in the device manuals). With short send clocks, standard communication remains possible.

The performance upgrade will help you to implement applications with high speed and send clock requirements.

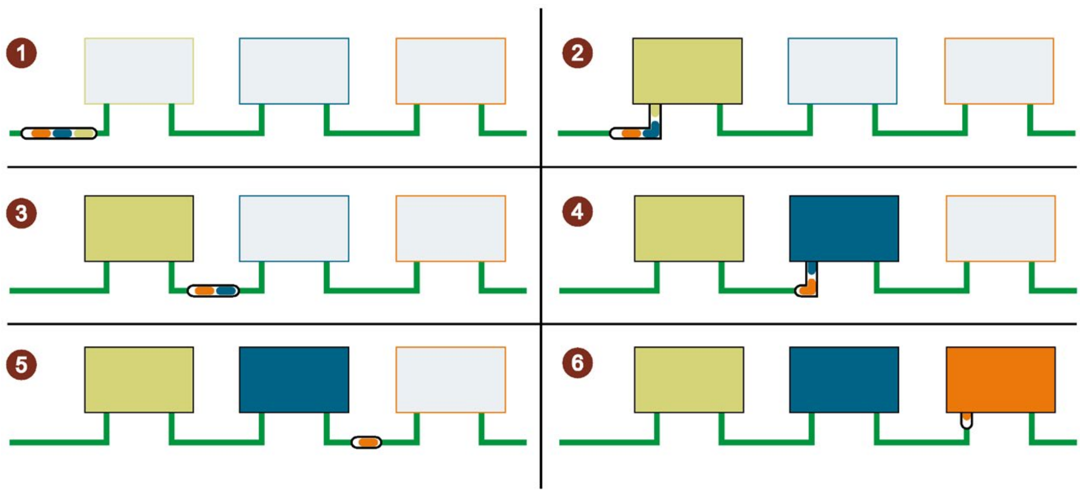
5.6.1 Dynamic frame packing

Dynamic frame packing

Previously, individual PROFINET IO frames were sent for every PROFINET IO device.

The performance upgrade uses the dynamic frame packing procedure that is based on the summation frame method. With the summation frame method, a frame contains the user data for neighboring devices on a line. With Dynamic Frame Packing, every IO device takes its data from the frame and forwards the rest. The frame is shortened from IO device to IO device. Dynamic frame packing improves the use of the bandwidth in a line topology.

The following figure shows how Dynamic Frame Packing works based on the example of a frame containing the user data for 3 IO devices.



① The PROFINET IO frame contains the user data for all 3 IO devices (green, blue and orange).

② The PROFINET IO frame reaches the first IO device. The IO device takes its user data (green) from the frame and forwards the remaining frame.

③ The PROFINET IO frame contains the user data for two IO devices (blue and orange).

④ The PROFINET IO frame reaches the second IO device. The IO device takes its user data (blue) from the frame and forwards the remaining frame.

⑤ The PROFINET IO frame contains the user data for one IO device (orange).

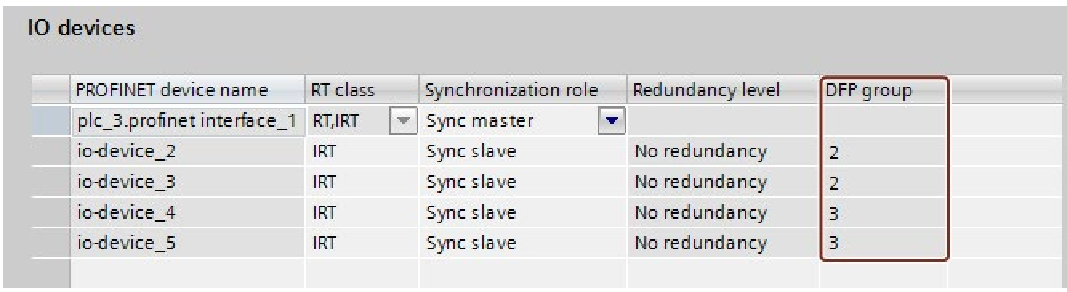
⑥ The PROFINET IO frame reaches the last IO device. The IO device saves the entire frame including user data (orange).

Figure 5-55 Dynamic Frame Packing (DFP)

DFP groups

Dynamic frame packing automatically groups IO devices that support the performance upgrade into DFP groups. To be grouped together in a DFP group. the IO devices must be located one after the other in a line and must have the same update time and watchdog time. As soon as a maximum frame size for the DFP group is exceeded or a maximum number of members for a DFP group is reached, Dynamic Frame Packing automatically opens a new DFP group.

STEP 7 shows the DFP groups in "Domain management" > "Sync domains" > "Name of the sync domain" > "Device" in the "IO devices" box.



IO devices

PROFINET device name	RT class	Synchronization role	Redundancy level	DFP group
plc_3.profinet interface_1	RT,IRT	Sync master		
io-device_2	IRT	Sync slave	No redundancy	2
io-device_3	IRT	Sync slave	No redundancy	2
io-device_4	IRT	Sync slave	No redundancy	3
io-device_5	IRT	Sync slave	No redundancy	3

Figure 5-56 Display of the DFP groups in STEP 7

Note

Dynamic frame packing with high watchdog times

If you set the "Accepted update cycles without IO data" parameter higher than 31 for an IO device, Dynamic Frame Packing does not place this IO device in a DFP group.

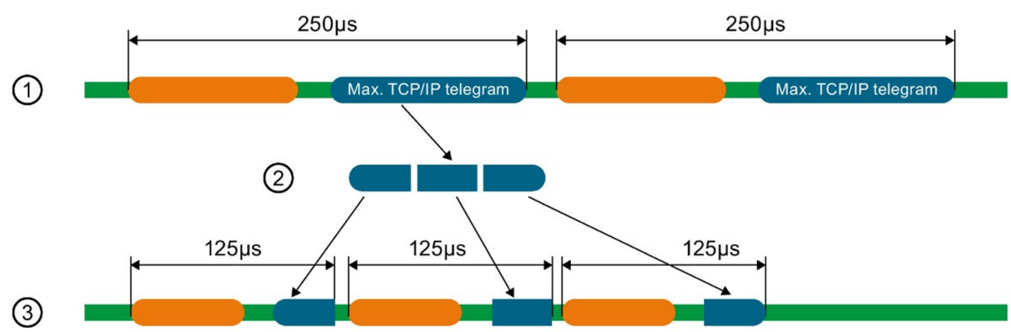
5.6.2 Fragmentation

The transfer of a complete standard Ethernet frame with TCP/IP data takes up to 125 μs. This means that the cycle time for PROFINET IO data cannot be reduced by any desired amount.

The performance upgrade uses the fragmentation procedure, which breaks down TCP/IP frames into sub-frames. These frame segments are transferred to the target device over multiple send clocks; there they are reassembled to the original TCP/IP frame.

Fragmentation is a requirement for cycle times lower than 250 μs. In these short send clocks, you can use more bandwidth for cyclic IO data, since the fragments of the standard Ethernet frames use significantly less bandwidth than a complete standard Ethernet frame.

The following figure shows how fragmentation works.



① A standard Ethernet frame with TCP/IP data is up to 125 μs.
② During fragmentation, the standard Ethernet frame is divided into frame segments.
③ The frame segments are divided into multiple short send clocks.

Figure 5-57 Fragmentation

Note

The PROFINET IO interface of the IO controller supports fragmentation if all the ports except one are deactivated.

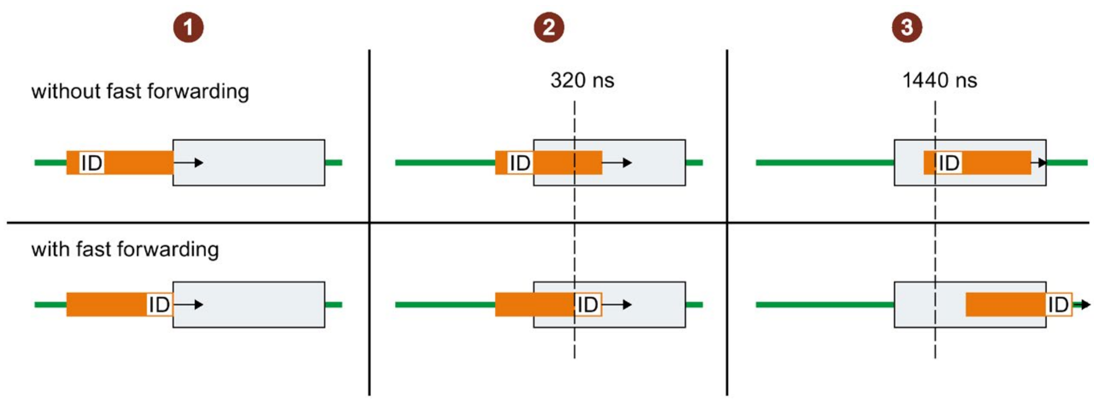
5.6.3 Fast forwarding

To be able to decide whether a frame should be forwarded or used, a PROFINET IO device requires the frame ID. It previously took 1440 ns until the frame ID was present in the IO device.

The performance upgrade uses the fast forwarding procedure in which the frame ID is located nearer the front of the frame. The throughput time in the device is reduced to 320 ns.

With fast forwarding, the throughput time of the frame is reduced in your PROFINET IO system. This results in decisive performance advantages, particularly in line, ring and tree topologies.

The figure below compares the throughput of a PROFINET IO frame in an IO device with and without fast forwarding.



① Start:
- Both PROFINET frames reach the IO device.
  The IO devices start to check the frames for the frame ID

② After 320 ns:
- Without fast forwarding: The IO device is still checking the PROFINET frame for the frame ID.
- With fast forwarding: The IO device receives the frame ID from the PROFINET frame and forwards the frame.

③ After 1440 ns:
- Without fast forwarding: The IO device receives the frame ID from the PROFINET frame and forwards the frame.
- The PROFINET frame with fast forwarding is "ahead" of the PROFINET frame without fast forwarding.

Figure 5-58 Fast forwarding

5.6.4 Configuration of IRT with high performance

High-end applications with IO communication require excellent performance in IO processing, for example in the control of wind turbines (converter control).

To use IRT communication with the highest performance in your PROFINET IO system, enable the option "Make 'high performance' possible".

When you enable the "Make 'high performance' possible" option, this has the following effects:

- You can set send clocks of 187.5 μs and 125 μs (for example CPU 1518-4 PN/DP) or 187.5 μs (for example CPU 1517-3 PN/DP), see Technical specifications in the CPU device manuals.
- You can set more bandwidth use for cyclic IO data.
- You can use the option "Allows the use of 'fast forwarding'".

Requirements

- S7-1500 CPU as of firmware version V2.0

Enable the "Make 'high performance' possible" option.

Follow these steps to activate the "Make 'high performance' possible" option:

1. Select the PROFINET IO system in the network view of STEP 7.
2. In the Inspector window, go to "Properties" > "General" > "PROFINET" > "Domain management" > "Sync domains" > "Name of the sync domain".
3. Enable the "Make 'high performance' possible" option.

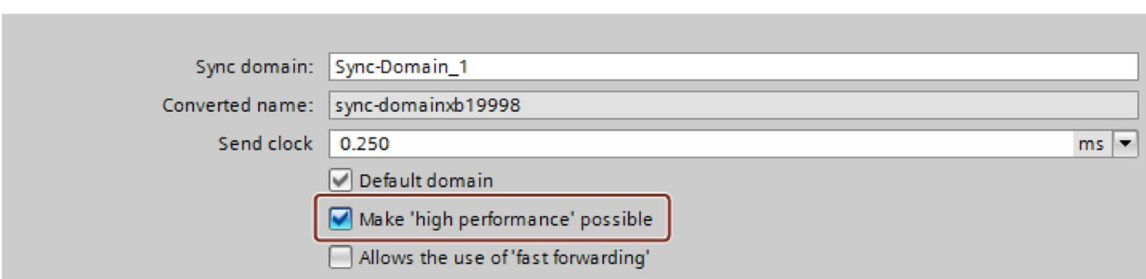


Figure 5-59 Activating high performance

Using more bandwidth for cyclic IO data

Requirement: The "Make 'high performance' possible" option is enabled.

To set more bandwidth for cyclic IO data for your PROFINET IO system, follow these steps:

1. Select your IO system in the network view of STEP 7.
2. In the Inspector window, go to "Properties" > "General" > "PROFINET" > "Domain management" > "Sync domains" > "Name of the sync domain" > "Details".
3. In the drop-down list, select "Maximum 90% cyclic IO data. Focus on cyclic IO data".

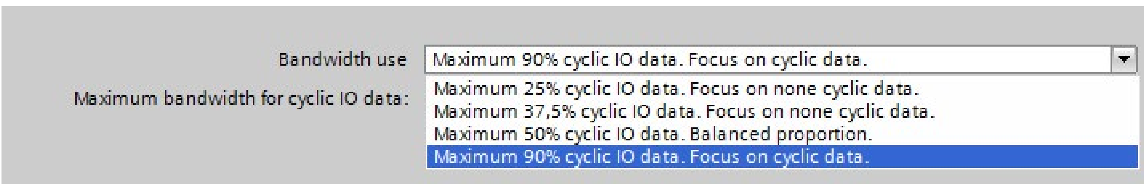

Figure 5-60 Using more bandwidth for cyclic IO data

Note

Bandwidth usage in isochronous mode

If you operate your PROFINET IO system in isochronous mode, avoid using the setting for the bandwidth usage "Maximum 90% cyclic IO data. Focus on cyclic IO data."

Setting low send clocks (example CPU 1518-4 PN/DP)

Requirement: The "Make 'high performance' possible" option is enabled.

1. Select the PROFINET IO system in the network view of STEP 7.
2. In the Inspector window, go to "Properties" > "General" > "PROFINET" > "Domain management" > "Sync domains" > "Name of the sync domain".
3. Select the send clock for "Send clock" in the drop-down list.

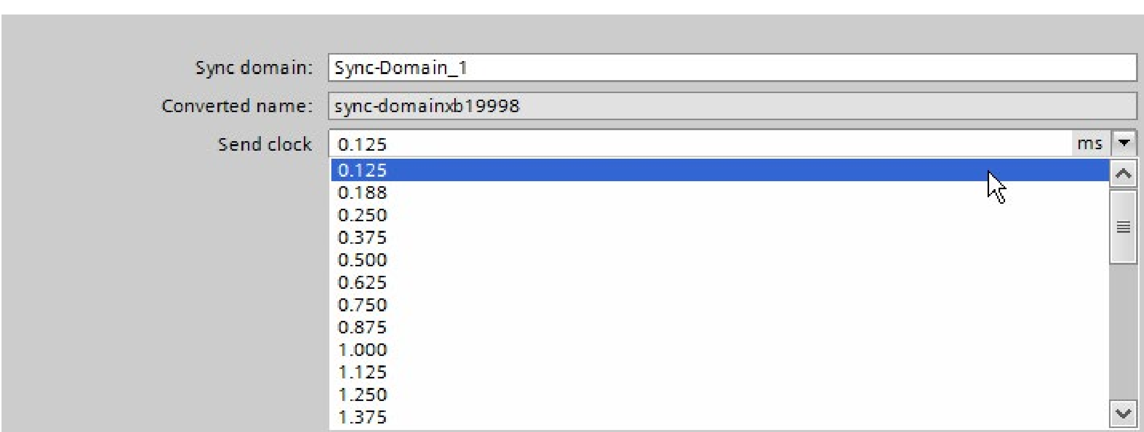

Figure 5-61 Setting low send clocks

Requirements for the fragmentation process (example CPU 1518-4 PN/DP)

If you use the following combinations for send clock and bandwidth settings, the devices in the IO system use the fragmentation process.

- Send clock cycle 125 µs: Always fragmentation irrespective of the bandwidth setting.
- Send clock cycle 187.5 µs: Fragmentation with the bandwidth settings "Maximum 50% cyclic IO data. Balanced proportion." and "Maximum 90% cyclic IO data. Focus on cyclic IO data."

The PROFINET IO interface of the controller supports fragmentation if all the ports except one are deactivated.

Optimizing port settings for low send clocks

You can further optimize the bandwidth use in your PROFINET IO system by using cables with a short cable length (< 20 m) or a short signal delay (max. 0.12 µs) between the devices.

To configure cables with a shorter length or signal delay in STEP 7, follow these steps:

1. Select the port in the topology view of STEP 7.
2. Navigate in the Inspector window to "Port interconnection" in the "Partner port" box.
3. Select the option "Cable length" or "Signal delay:".
4. Select the cable length or enter the signal delay.

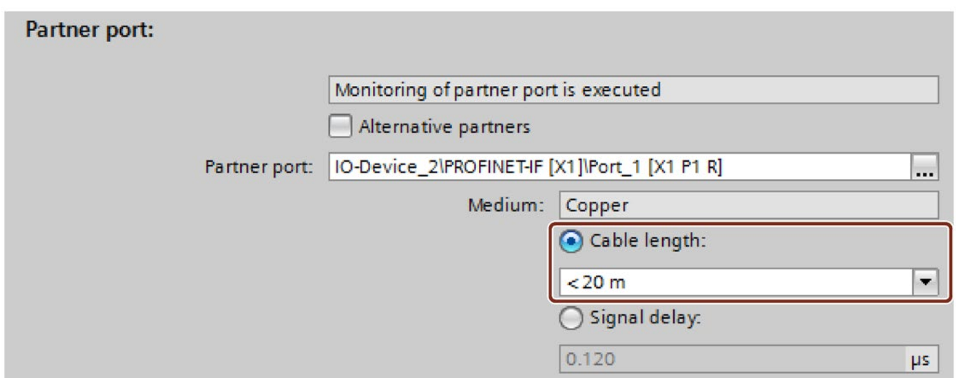

Figure 5-62 Optimizing port settings for low send clocks

Allowing fast forwarding

Requirements:

- The PROFINET IO device has to support the fast forwarding process so that the process can be used by the device.
- The "Make 'high performance' possible" option is enabled.
- The PROFINET IO interface supports fast forwarding if all the ports except one are deactivated.

Follow these steps to allow fast forwarding:

1. Select the PROFINET IO system in the network view of STEP 7.
2. In the Inspector window, go to "Properties" > "General" > "PROFINET" > "Domain management" > "Sync domains" > "Name of the sync domain".
3. Enable the "Allows the use of ‘fast forwarding'" option.

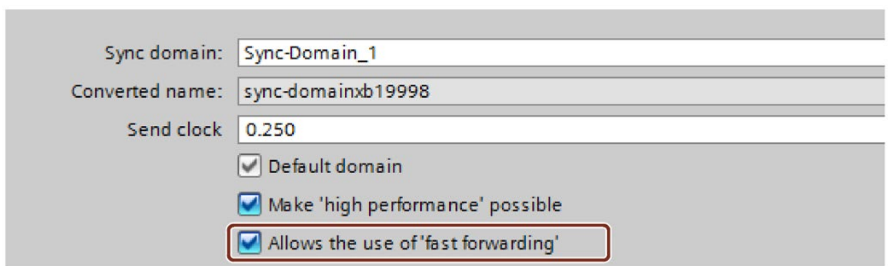

Figure 5-63 Allowing fast forwarding

Note

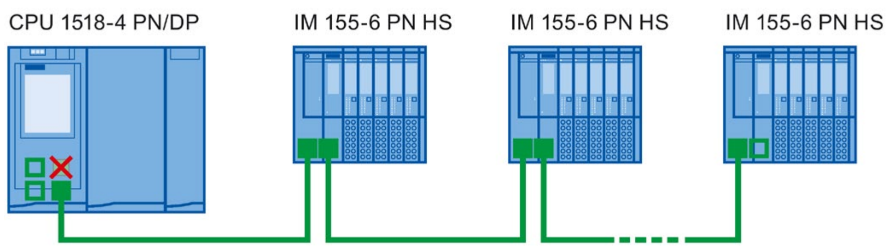
Fast forwarding and IPv6

The operation of fast forwarding in combination with IPv6 is not supported.

As soon as an IO device in the subnet uses an IPv6 address, you must not activate "fast forwarding".

5.6.5 Sample configuration for IRT with high performance

The figure below shows an example configuration with which you can achieve maximum performance.



Port 1 of the X1 interface of the CPU is deactivated.

Port 2 of the X1 interface and the ports of the interface modules on the bus use the following setting: Medium copper, cable length < 20 m or signal delay max. 0.12µs

A programming device connection to the CPU can be established via the interfaces X2 and X3 of the CPU or via the free port at the end of the line.

Figure 5-64 Example configuration for IRT with high performance

Use the following settings for the Sync domain:

- Enable the "Make 'high performance' possible" option.
- Set the send clock to 125 µs.
- Enable the "Allows the use of ‘fast forwarding'" option.

Standard Ethernet communication for IRT with high performance

Standard Ethernet communication is still possible even in a PROFINET IO system with high performance. Keep in mind that you first arrange the IRT nodes, as seen from the IO controller, and arrange the standard Ethernet nodes at the end of the line.

With a large volume of data through standard Ethernet communication, it makes sense to reduce the load on your network by separating standard Ethernet communication and cyclic real-time communication. Example: Use the interface X1 for the PROFINET IO communication and a different interface for the standard Ethernet communication.

5.7 Isochronous mode

5.7.1 What is isochronous mode?

Objectives of isochronous operation

The advantages of the isochronous mode function in automation engineering can be seen in an example from everyday life.

The transmission of data corresponds to the transport of people on public transport. Assuming public transport were to operate at maximum speed while reducing stop times at the passenger terminals to absolute minimum, the last thing many potential passengers would notice of the departing contraption are its red tail lights. The overall travel time is, however, decided by the train, bus or underground-railway clock, because well adjusted timing is essential to a good service. This also applies in automation engineering. Not only fast cycles but also the adaptation and synchronization of the individual cycles result in optimum throughput.

Just-In-Time

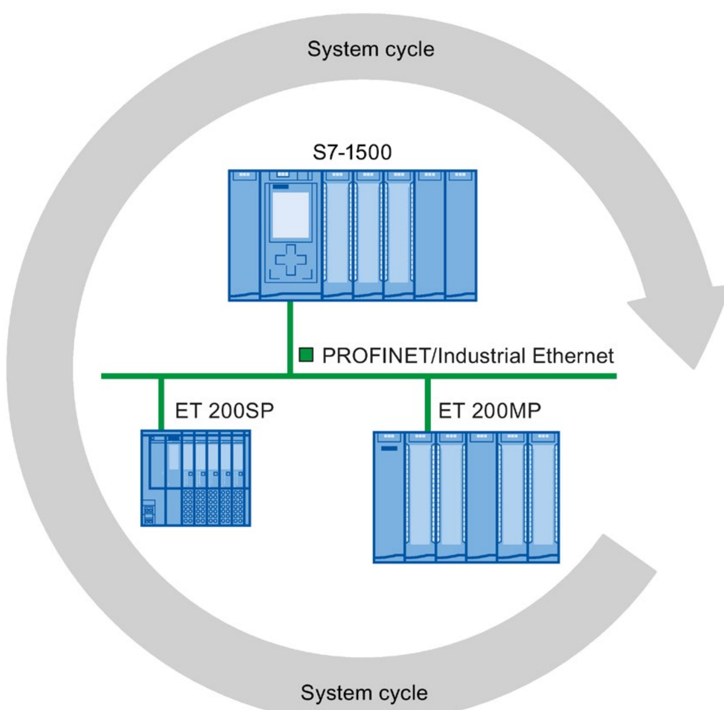


Figure 5-65 System cycle

The fast and reliable response time of a system operating in isochronous mode is due to the fact that all data is provided just-in-time. The basis for this is an equidistant cycle.

The isochronous mode function guarantees synchronization of the following at constant time intervals:

- Signal acquisition and output by the distributed I/O
- Signal transmission via PROFINET IO
- Program execution in the CPU in time with the equidistant PROFINET IO

The result is a system that acquires its input signals, processes them and outputs the output signals at constant time intervals. Isochronous mode guarantees precisely reproducible and defined process response times as well as equidistant and synchronous signal processing for distributed I/O.

Advantages of isochronous mode

The use of isochronous mode allows high-precision control.

- Optimized control loops through constant, calculable dead times
- Determinism, reliable reproducibility of response times
- Consistent (simultaneous) reading in of input data
- Consistent (simultaneous) output of output data

5.7.2 Use of isochronous mode

An isochronous system acquires measured values and process data within a fixed system cycle, processes the signals and outputs them synchronously to the process. Isochronous mode contributes to a high control quality and increased production accuracy. With isochronous mode, the possible fluctuations of process response times are drastically reduced. You make use of the time-assured processing to improve machine cycle times. Even fast processes can be reliably controlled thanks to the precise time reproducibility of all sequences. Shorter cycle times increase the processing speed and help to lower production costs.

In principle, isochronous mode is worthwhile whenever measured values must be acquired synchronously, movements must be coordinated, and process responses must be defined and simultaneously executed, as in the following example. Isochronous mode can thus be used in a wide variety of applications.

Example: Measuring at multiple measurement points with isochronous mode

Automation task

A camshaft production process requires precise measurement of the camshafts for quality assurance purposes.

Feature

For this purpose, a component is needed that can synchronously measure the positions and displacements of the cam during a rotation of the camshaft.

Solution

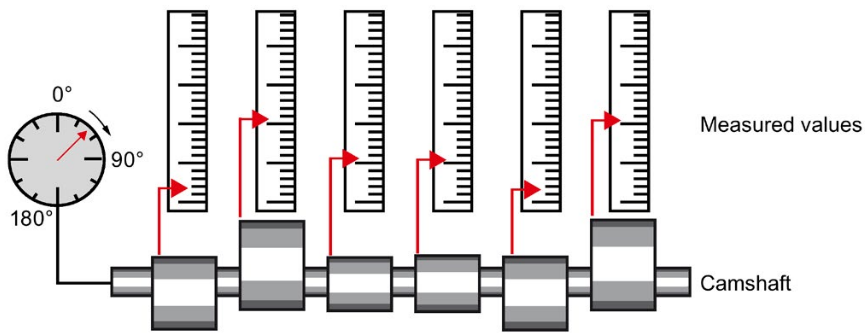

Figure 5-66 Measuring of camshafts

With use of isochronous mode, the measured values are simultaneously acquired at the various measuring points at fixed times. This results in the following workflow:

- Continuously rotate the camshaft
- During continuous rotation, synchronously measure the positions and cam displacements
- Process the next cam shaft

Thus, during a single rotation of the camshaft, all the positions of the camshaft and the associated measured values (red) are measured synchronously. The machine cycle time improves with the same or better measuring accuracy.

Advantage and benefits

The time required for measurement is reduced.

5.7.3 Time sequence of synchronization on PROFINET IO

Introduction

On PROFINET IO, you can isochronously operate I/O modules in distributed I/O systems on a CPU, e.g. in distributed I/O systems ET 200SP, ET 200MP.

Like the I/O modules, the interface modules of the I/O systems must support isochronous mode.

From reading in input data to outputting output data

The basic time sequence of all components involved in synchronization is explained below:

① Measured value acquisition in the process

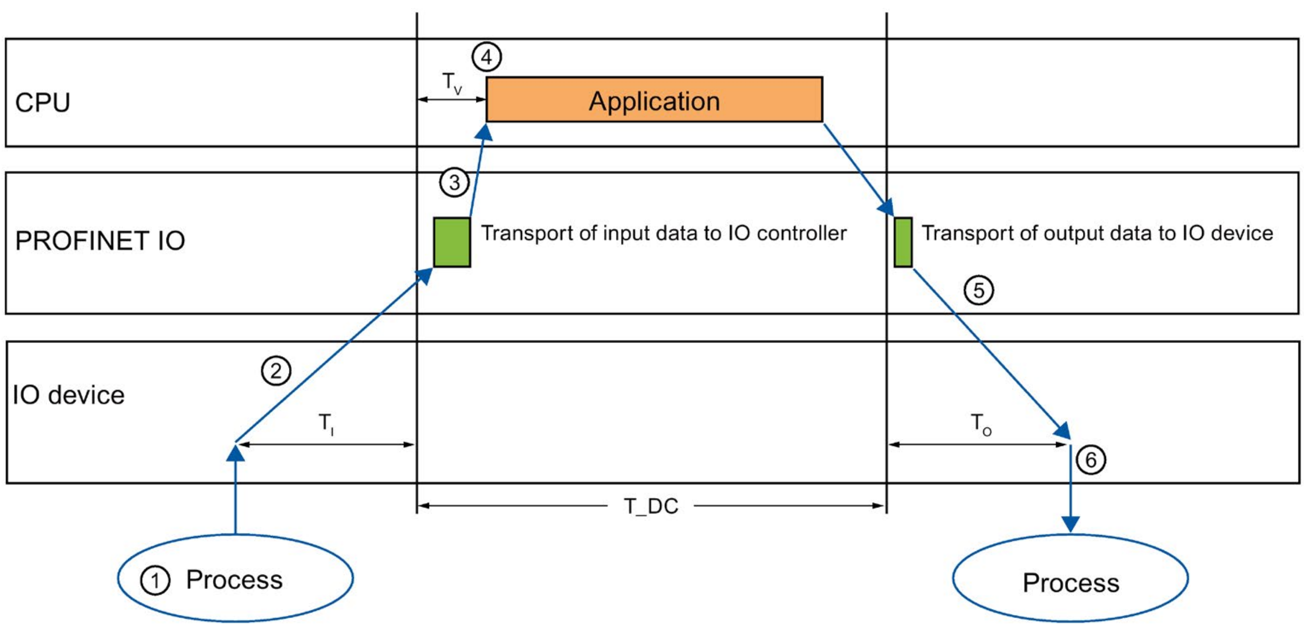
② Isochronous read-in of input data

③ Transport of input data to the IO controller (CPU) via the subnet

④ Further processing in the isochronous application of the CPU

⑤ Transport of output data to the outputting IO device via the subnet

⑥ Isochronous output of output data



T_DC	Data cycle (Time_DataCycle)
T_I	Time for reading in the input data
T_O	Time for outputting the output data
T_V	Configured delay time

Figure 5-67 Time sequence of synchronization on PROFINET IO

To ensure that all input data is ready for transport via the subnet at the next start of the PROFINET IO cycle, the start of the I/O read-in cycle is advanced by the amount of lead time T_I. T_I is the "flashbulb" for the inputs; at this instant, all synchronized inputs are read in. T_I is necessary in order to compensate for analog-to-digital conversion, backplane bus times, and the like. The lead time T_I can be configured by STEP 7 or by you. Let the lead time T_I be assigned automatically by STEP 7. With the default setting, STEP 7 ensures that a common, minimum T_I is set.

The subnet transports the input data to the IO controller/DP master. The application is started synchronized to the cycle. That is, the isochronous mode interrupt OB is called after a configurable delay time T_V. The user program in the isochronous mode interrupt OB defines the process response and provides the output data in time for the start of the next data cycle. The length of the data cycle (send clock/DP cycle time) is always configured by you.

T_O is the time for the compensation arising from the backplane bus and the digital-to-analog conversion within the IO device/DP slave. T_O is the "flashbulb" for the outputs. The synchronized outputs are output at this time. Time T_O can be configured by STEP 7 or by you. Let time T_O be assigned automatically by STEP 7. STEP 7 automatically calculates a common, minimum T_O.

5.7.4 Configuring isochronous mode

5.7.4.1 Introduction

Configuring at a glance

Setting parameters for isochronous operation of the I/O module

You use the properties of the I/O addresses of the corresponding I/O module to:

- Set isochronous mode for the module.
- Assign the inputs and outputs of the module to a process image partition and an isochronous mode interrupt OB.

  The data of the process image partition is updated synchronously to the assigned OB. Isochronous mode interrupts give you the option of starting programs isochronously with the PROFINET send clock. Isochronous mode interrupts are processed with high priority.

Setting the send clock

The send clock is the shortest possible transmission interval for the data exchange. In isochronous mode, the send clock corresponds to data cycle T_DC.

You set the send clock in the properties of the PROFINET interface of the CPU or in the sync domain.

Setting the application cycle

The application cycle is a multiple of data cycle T_DC. If the runtime of the isochronous mode interrupt OB is short, the application cycle can be identical to the data cycle (= send clock).

You can reduce the application cycle of the isochronous mode interrupt OB relative to the send clock of an isochronous PROFINET IO system. Set an integer multiple of the send clock as the reducing factor.

You use the factor to reduce the CPU utilization by executing the isochronous mode interrupt OB less frequently. You set the application cycle in the properties of the isochronous mode interrupt OB.

Setting the delay time

The delay time is the time between the start of the send clock and the start of the isochronous mode interrupt OB. During this time, the IO controller performs cyclic data exchange with the IO devices.

STEP 7 sets the default delay time in such a way that the isochronous update of the process image partition automatically falls within the execution window of the application cycle.

You set the delay time in the properties of the isochronous mode interrupt OB. A shorter delay time enables you to increase the processing time for your user program in the isochronous mode interrupt OB.

Additional configurations for isochronous mode on PROFINET IO:

- **Setting IRT as the RT class for the interconnected PROFINET interfaces**

  A precondition for isochronous operation on PROFINET IO is IRT communication (Isochronous Real Time Communication). IRT means synchronized data exchange at reserved time intervals.

- **Configuring the topology of the configuration**

  A precondition for IRT communication is the topology configuration. In addition to the reserved bandwidth, the exchange of frames on defined transmission paths is used for further optimization of data communication. For this, the topological information of the configuration is used for planning the communication.

- **Using a sync domain**, you assign the IO devices (sync slaves) to an IO controller (sync master) for the isochronous data exchange.

  A precondition for IRT communication is a synchronization cycle for all PROFINET devices in a sync domain, for distribution of a common time base. With this basic synchronization, synchronous operation of the transmission cycle of the PROFINET devices within a sync domain is achieved.

5.7.4.2 Configuring isochronous mode on PROFINET IO

Introduction

The configuring of isochronous mode for a module is described as IO device in the following based on the ET 200MP distributed I/O system. The procedure described also applies to other distributed I/O systems (e.g., ET 200S or ET 200SP).

The IO controller is an S7-1500 CPU.

Requirements

- The STEP 7 network view is open.
- A S7-1500 CPU has been placed (e.g., CPU 1516-3 PN/DP).
- An IM 155-5 PN HF interface module (ET 200MP) has been placed and networked with the CPU via PROFINET IO.
- All requirements for an IRT configuration are met:
  - The ports of the networked PROFINET interfaces of the CPU and interface module are interconnected (topology configuration).
  - The RT class of the PROFINET interface of the interface module is set to "IRT" (area "Advanced options > Real time settings > Synchronization").
  - The "sync master" and "sync slave" roles are assigned for the PROFINET interfaces of the CPU and interface module (in the properties of a PROFINET interface: area "Advanced options" > "Media redundancy" > "Domain settings").

Procedure

To create an isochronous connection between the I/O and user program, follow these steps:

1. Select the IM 155-5 PN HF in the network view of STEP 7. Change to the device view.
2. Insert an I/O module that can be operated isochronously (e.g. DI 16 x 24VDC HF).
3. Go to the "I/O addresses" area in the Inspector window of the selected I/O module.

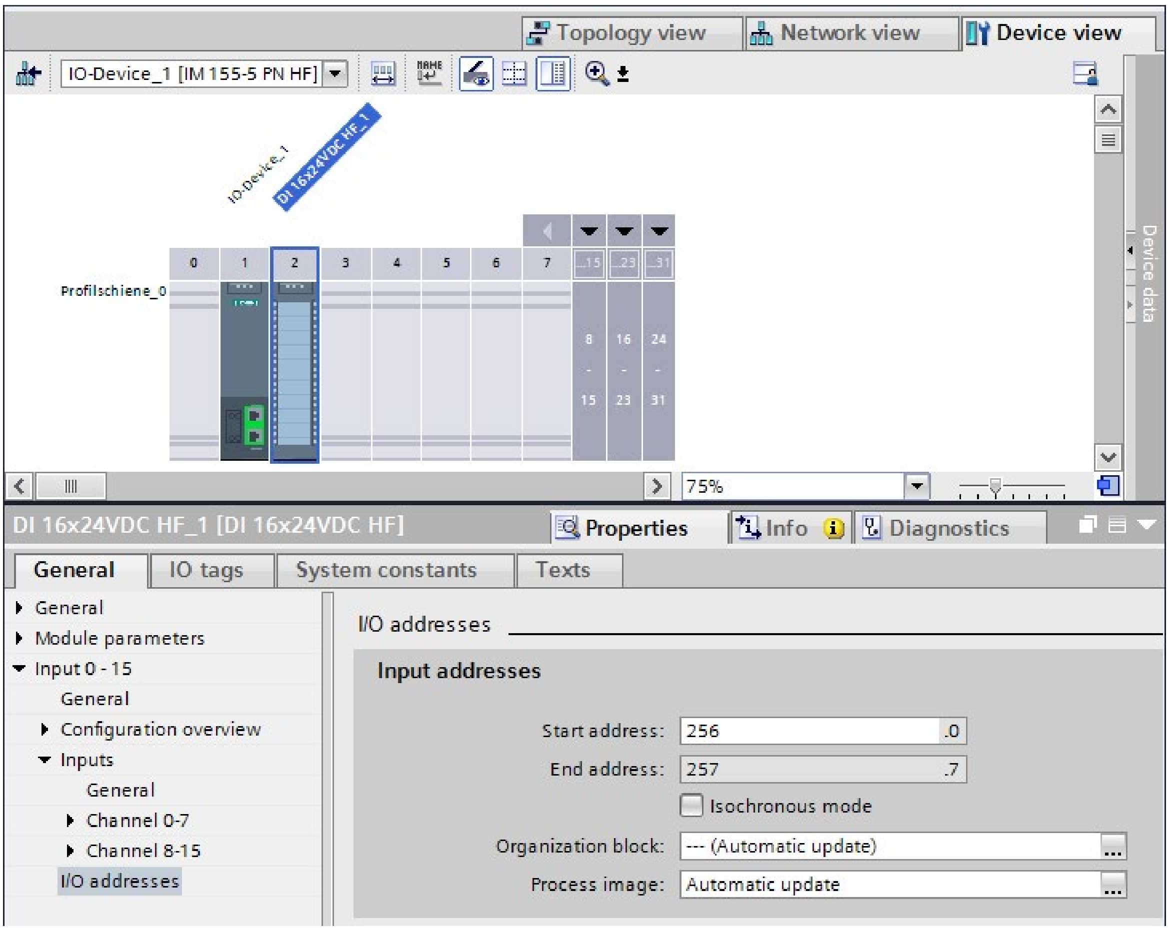


Figure 5-68 Configuring isochronous mode on PROFINET IO

4. Make the following settings in the I/O addresses area:
   – Select the "Isochronous mode" option.
   – Select a process image partition, e.g., process image partition 1.
   – Click the "Organization block" drop-down list. Click the "Add" button or select an existing OB. A dialog box for selecting organization blocks opens.
   – Select the "Synchronous Cycle" OB. Confirm the selection with "OK".

   In the case of automatic number assignment, OB 61 will be generated and opened.

   In the Inspector window, you can continue directly with the setting of the application cycle and delay time (Page 216) in the "Isochronous mode" area and start the programming of the OB in the instruction section.

5. If required, insert additional IO devices in the network view. Adapt the configuration and the settings for the isochronous mode.
6. You want to retrieve information about calculated bandwidths or on adapting the send clock. Select the sync domain in the network view and navigate to the corresponding area of the domain management in the Inspector window.

Reference

You can find examples of parameter assignment and possible settings of isochronous mode for distributed I/O and drives in STEP 7 in this FAQ on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109480489).

5.7.4.3 Setting the application cycle and delay time

Requirements

- You have created an isochronous mode configuration in STEP 7.
- You have created an isochronous mode interrupt OB Synchronous Cycle (OB 6x).
- The isochronous mode interrupt OB is open.

Setting the application cycle

The application cycle is a multiple of data cycle T_DC (send clock). You use the application cycle setting to reduce the CPU utilization caused by execution of the isochronous mode interrupt OB. In the following example, the OB is called only after every 2nd data cycle T_DC in the CPU.

To set the application cycle for your isochronous mode application, follow these steps:

1. Open the "Properties" dialog of the isochronous mode interrupt OB under consideration.
2. In the area navigation, click the "Isochronous mode" group .
3. Set the application cycle in "Application cycle (ms)". Open the drop-down list box and select the application cycle. The drop-down list offers multiples of data cycle T_DC as possible values for the application cycle. Data cycle T_DC is set to 2 ms in the following figure.

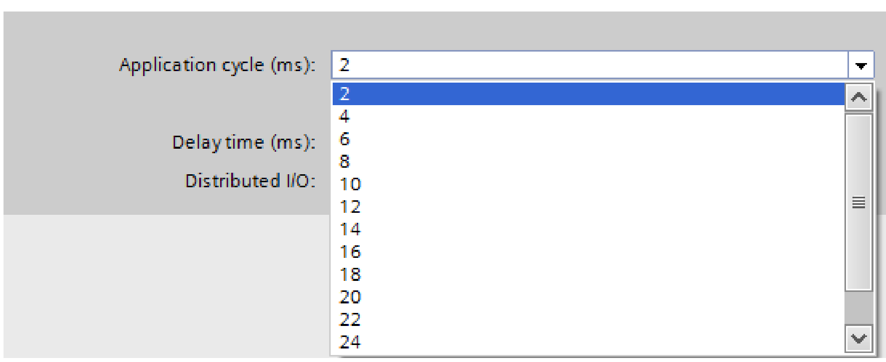

Figure 5-69 Setting the application cycle

Setting the delay time

The delay time is the time between the start of the send clock and the start of the isochronous mode interrupt OB. STEP 7 sets the delay time automatically to the start of the execution window by default. As a result, the isochronous mode update of the process image partition automatically falls within the execution window of the application cycle.

You can also set the delay time manually. A shorter delay time enables you to increase the processing time for your user program in the isochronous mode interrupt OB. If a manual setting is made, note that you must call the "SYNC_PI" and "SYNC_PO" instructions in the execution window of the application cycle.

To set the delay time for your isochronous mode application, follow these steps:

1. Open the "Properties" dialog of the isochronous mode interrupt OB under consideration.
2. In the area navigation, click the "Isochronous mode" group .
3. Clear the "Automatic setting" check box.
4. Enter your desired delay time in "Delay time (ms)".

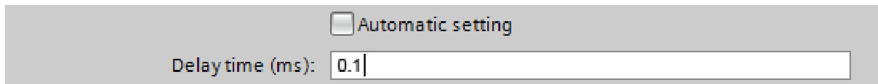

Figure 5-70   Setting the delay time

5.7.5 Programming isochronous mode

5.7.5.1 Basics of Programming

Programming in the isochronous mode interrupt OBs

You program the isochronous section of the program exclusively in the isochronous mode interrupt OBs Synchronous Cycle (OB 6x).

Because the isochronous mode interrupts are processed with high priority, only the time-critical sections of the program should be processed in the isochronous mode interrupt OB. The isochronous mode interrupt OB is called with a configured delay time.

Access to isochronous I/O through call of instructions

You access the isochronous I/O via a process image partition. That is, the addresses of the isochronous modules must be within one process image partition.

You program access to the isochronous IO in isochronous mode interrupt OB Synchronous Cycle (OB 6x) with the SYNC_PI and SYNC_PO instructions.

The isochronous I/O is updated by the call of the "SYNC_PI" and "SYNC_PO" instructions and therefore in the corresponding process image partition.

Note

Recommendation: To prevent inconsistent data from being returned to OB 6x, do not use the "DPRD_DAT" and "DPWR_DAT" instructions (direct data access) in the isochronous mode interrupt OB.

The "SYNC_PI" and "SYNC_PO" instructions update the process image partition only within the permitted execution window. The execution window stretches from the end of the cyclic data exchange to the point in time before the end of T_DC at which the outputs can still be copied in time. The data exchange must be started within this time window. If the execution window is violated by the processing of the "SYNC_PI" and "SYNC_PO" instructions, the instructions indicate a corresponding error message.

Program execution models

Depending on the order of the "SYNC_PI" and "SYNC_PO" instruction calls in OB 6x, there are two basic models for the program execution:

- **IPO** model (read **I**nputs - **P**rocessing - write **O**utputs)
- **OIP** model (write **O**utputs - read **I**nputs - **P**rocessing)

5.7.5.2 Program execution according to the IPO model

If the execution time of the isochronous mode interrupt OB is significantly shorter than one data cycle T_DC, use the IPO model. In the IPO model, you do not reduce the data cycle. That is, the application cycle of the isochronous mode interrupt OB is equal to data cycle T_DC.

The IPO model enables the shortest response times.

Programming according to the IPO model in the isochronous mode interrupt OB

For programming according to the IPO model:

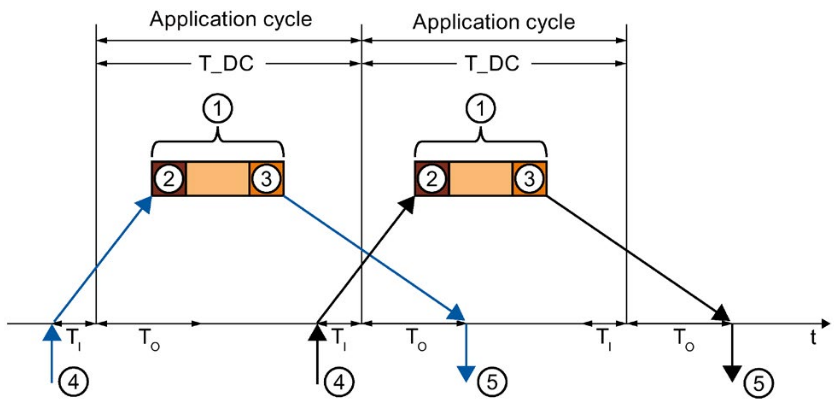
1. Call the SYNC_PI instruction at the start of the isochronous mode interrupt OB.
2. Then call the actual user program.
3. Call the SYNC_PO instruction at the end of the isochronous mode interrupt OB.

Table 5- 3 Programming according to the IPO model

Step	Action	Explanation
1	Read in (I)	The SYNC_PI instruction reads in the inputs of the process image partition and provides them to the isochronous mode interrupt OB.
2	Process (P)	You program the actual user program of the isochronous mode interrupt OB.
3	Output (O)	The SYNC_PO instruction outputs the data changed by the user program via the process image partition.

Signal sequence in the IPO model

The following figure shows the signal sequence in the IPO model from the acquisition and the processing in the CPU to the output of the process values:



① Execution of isochronous mode interrupt OB
② "SYNC_PI" instruction
③ "SYNC_PO" instruction
④ Isochronous read-in of process values on I/O module at time T_I
⑤ Isochronous output of process values on I/O module at time T_O

Figure 5-71 Signal sequence in the IPO model

At time T_I the process values are read in isochronously on the I/O. The processing of the data in the IPO model is completed within one data cycle T_DC. The output data is always available on the I/O in the next data cycle T_DC at time T_O.

With the IPO model, there is a constant execution time from the "input terminal" to the "output terminal" of T_I + T_DC + T_O.

T_I + 2×T_DC + T_O can be guaranteed for the process response time.

5.7.5.3 Program execution according to the OIP model

Use the OIP model in the case of execution cycles of the isochronous mode interrupt OB of different lengths, if the application cycle is greater than data cycle T_DC.

The data exchange with the process is always deterministic in the OIP model, i.e. takes place at a precisely specified time.

Programming according to the OIP model in the isochronous mode interrupt OB

For programming according to the OIP model:

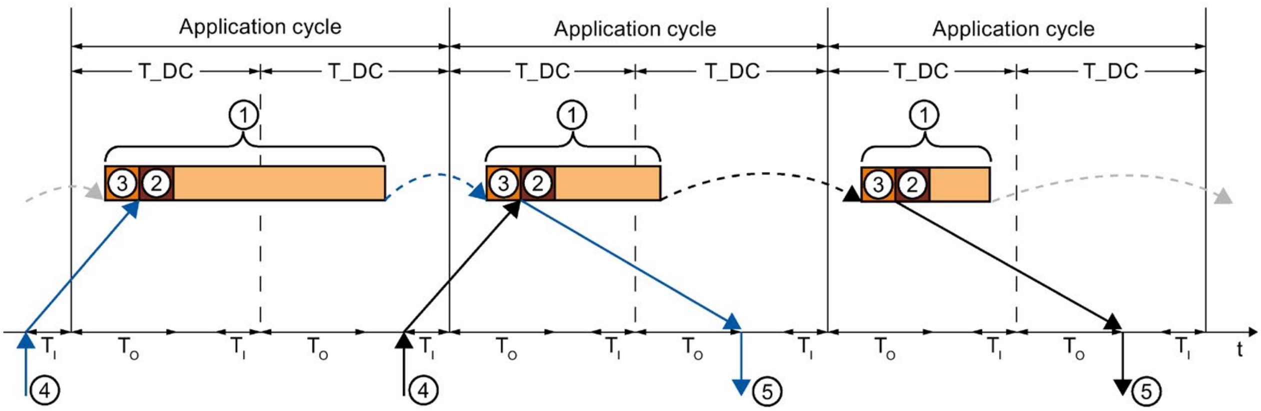
1. Call the SYNC_PO instruction at the start of the isochronous mode interrupt OB.
2. Then call the SYNC_PI instruction.
3. Then call the actual user program.

Table 5- 4 Programming according to the OIP model

Step	Action	Explanation
1	Output (O)	The SYNC_PO instruction outputs the data that was changed by the user program in the previous cycle via the outputs of the process image partition.
2	Read in (I)	The SYNC_PI instruction reads in the inputs of the process image partition of the current cycle and provides the inputs to the isochronous mode interrupt OB.
3	Process (P)	You program the actual user program of the isochronous mode interrupt OB.

Signal sequence in the OIP model

The following figure shows the signal sequence in the OIP model from the acquisition of process values and the processing in the CPU to the output of the process values. The application cycle is twice as long as data cycle T_DC in this example.



① Execution of isochronous mode interrupt OB
② "SYNC_PI" instruction
③ "SYNC_PO" instruction
④ Isochronous read-in of process values on I/O module at time T_I
⑤ Isochronous output of process values on I/O module at time T_O

Figure 5-72 Signal sequence in the OIP model

At time T_I the process values are read in isochronously on the I/O. The data is processed over 2 application cycles in the OIP model. The output data is always available on the I/O in the following application cycle at time T_DC + T_O.

With the IPO model, there is a constant execution time from the "input terminal" to the "output terminal" of T_I + application cycle + T_DC + T_O.

T_I + 2 x application cycle + T_DC + T_O can be ensured as the process response time.

5.8 Device replacement without exchangeable medium

Definition

IO devices which have no slot for exchangeable medium (e.g. ET 200SP, ET 200MP) or IO devices which support the PROFINET functionality "Device replacement without exchangeable medium/PG" can be replaced without having an exchangeable medium with saved device names inserted and without having to assign the device name with the PG. The new IO device is given a device name by the IO controller and not by the exchangeable medium or the PG.

To assign the device name, the IO controller uses the configured topology and the neighborhood relations established from the IO devices.

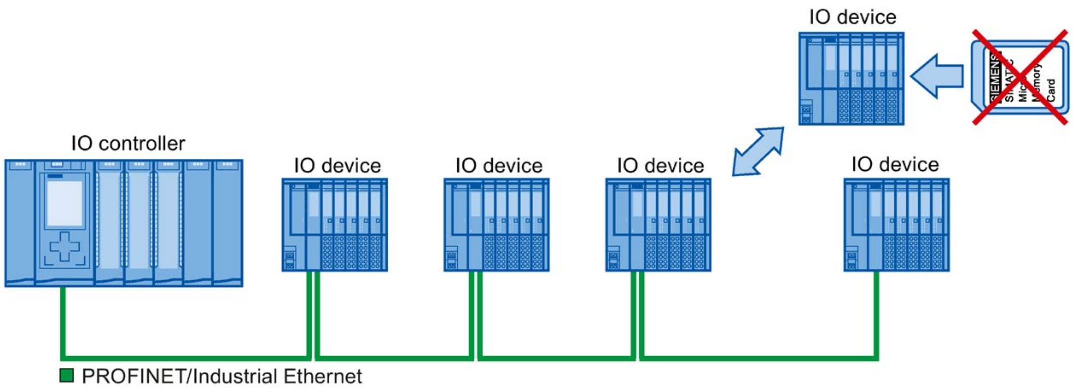


Figure 5-73 Device replacement without exchangeable medium

Note

When you exchange a device, make sure that the PROFINET cable is again inserted into the correct port, as it is configured in STEP 7.

Otherwise, the system will not run.

Advantages

With the Device replacement without exchangeable medium/PG PROFINET functionality, you can profit from the following advantages:

- After the replacement of the IO device, it automatically obtains its device name from the IO controller. You no longer have to assign device names with the PG or exchangeable medium.
- You can save on the storage medium for the IO device that replaces the removed one.
- Simple device name allocation with series machines that have the same configuration and set topology. It is no longer necessary to assign device names via exchangeable medium/PG.

Which devices support device replacement without exchangeable medium?

An overview of the devices that support the "Device replacement without exchangeable medium" function is provided in this FAQ (https://support.industry.siemens.com/cs/ww/en/view/36752540).

5.8.1 Device replacement without exchangeable medium/PG function

Neighborhood

Neighborhood is the physical relationship between two ports of adjacent PROFINET devices. A PROFINET device is connected in this case through one of its ports over a physical Ethernet line to a specific port of the second PROFINET device in close proximity (neighbors).
Both terminal devices, for example, IO controllers and IO devices with a port, and network components, for example, switches, IO controllers and IO devices with multiple ports, are considered PROFINET devices.

Failure and replacement of an IO device

The following example describes device replacement without exchangeable medium in the case of failure of an IO device.

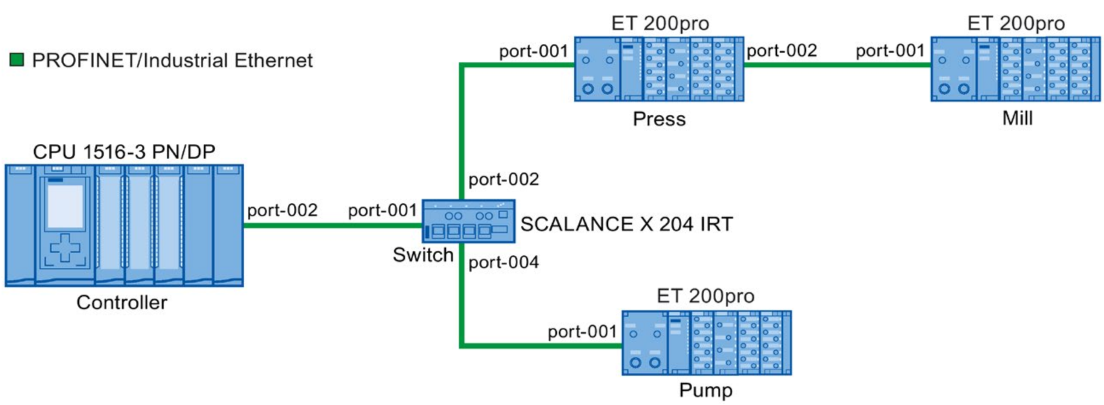

Figure 5-74 Example configuration of device replacement without exchangeable medium

For the device replacement, the following information is available to the IO controller:

PROFINET device	Device alias
Controller	"port-001.Switch"
Switch	"port-002.Controller", "port-001.Press", "port-001.Pump"
Press	"port-002.Switch", "port-001.Mill"
Mill	"port-002.Press"
Pump	"port-004.Switch"

The IO device with the device name "Mill" fails in this example:

Requirement

The PROFINET device replacing the removed one has no device name.

Principles of name assignment

The failure of the "Mill" IO device is considered here.

1. The IO controller queries the device name of the replaced IO device.
2. The IO controller detects that the IO device with the device alias "port-002.Press" does not have a device name.
3. The IO controller assigns the device name "Mill" to the replaced IO device via the device alias "port-002.Press" of the failed IO devices.

Note

If you insert a device with the Device replacement without exchangeable medium/PG PROFINET functionality at a different location than the configuration, a different device name is then assigned to the device.

Reset a wrongly inserted device to delivery state before you use it again.

5.8.2 Replacing an IO device without exchangeable medium

Introduction

Replacement of IO devices is sometimes frequently required in automation systems. The IO devices are generally assigned a device name by either inserting an exchangeable medium or via the programming device. The CPU identifies the IO device by using these device names.

Under certain circumstances, replacing an IO device can be done without inserting an exchangeable medium or without the PG.

Requirements

- The topology of the PROFINET IO system with the respective IO devices must be configured.

  By configuring the topology, the neighbor relationships of all the PROFINET devices located in the PROFINET IO system are announced to the PROFINET IO system or the IO controller. From the neighbor relationships specified by the set topology and the actual neighbor relationships established by the real PROFINET devices, the IO controller can identify the replaced IO device without a name and assign to it the configured name and the IP address and then again list it in the user data traffic.

- The affected IO devices in the automation system must support device replacement without exchangeable medium.

  If the individual IO devices in the automation system do not support device replacement without exchangeable medium, a corresponding alarm is output for the IO device.

  Note

  Use only new IO devices as replacements or restore configured IO devices to their delivery state.

Activating/deactivating device replacement without exchangeable medium

The "Device replacement without exchangeable medium" function is activated in the IO controller by default.

To deactivate device replacement without exchangeable medium, follow these steps:

1. In the device or network view of the STEP 7, select the PROFINET interface in the corresponding IO controller.
2. In the interface properties under "Advanced options > Interface options", clear the "Support device replacement without exchangeable medium" check box.

To reactivate device replacement without exchangeable medium, you must select the "Support device replacement without exchangeable medium" check box again.

5.8.3 Permit overwriting of PROFINET device name

With the option "Permit overwriting of PROFINET device names of all assigned IO devices", you can overwrite PROFINET device names of IO devices during startup of the CPU. This option reduces the effort during automatic commissioning, for example, when replacing a device.

Requirements

- IO controller supports the "Permit overwriting of device names of all assigned IO devices" option, for example CPU 1215C DC/DC/DC as of firmware version 4.0

How the "Permit overwriting of PROFINET device names of all assigned IO devices" option works

The IO controller (CPU) can overwrite the PROFINET device names of IO devices in the IO system when the "Permit overwriting of PROFINET device names of all assigned IO devices" option is enabled.

Multiple use IO systems can only be operated when this option is enabled. The IO controller checks prior to overwriting if the type of the IO device matches the configured type.

If the option is not selected, the IO controller cannot overwrite the device names of the IO devices. In this case, you must manually assign the PROFINET device name on the IO device if the PROFINET device name changes in the configuration or when a device is replaced, or delete the device names of the IO devices prior to an automatic commissioning.

Response during commissioning

Select the option "Permit overwriting of PROFINET device names of all assigned IO devices" only if the following requirements are fulfilled:

- All the configured IO devices are available.
- All IO devices are wired correctly in accordance with the topology configuration.
- No IO device is jumpered.

If configured IO devices are missing or are jumpered (partial commissioning), do not use the option.

⚠ CAUTION
Error at partial commissioning
If device names are assigned incorrectly during partial commissioning or incorrect wiring, these have to be deleted manually after a correction of the wiring in order to attain correct assignment of the device names.

Behavior during operation

After commissioning, you may exchange or jumper IO devices as long as the IO devices do not have a PROFINET device name that is used for a different IO device in the project. Otherwise, incorrect assignment of PROFINET device names in the neighborhood or further vicinity of the IO device can occur.

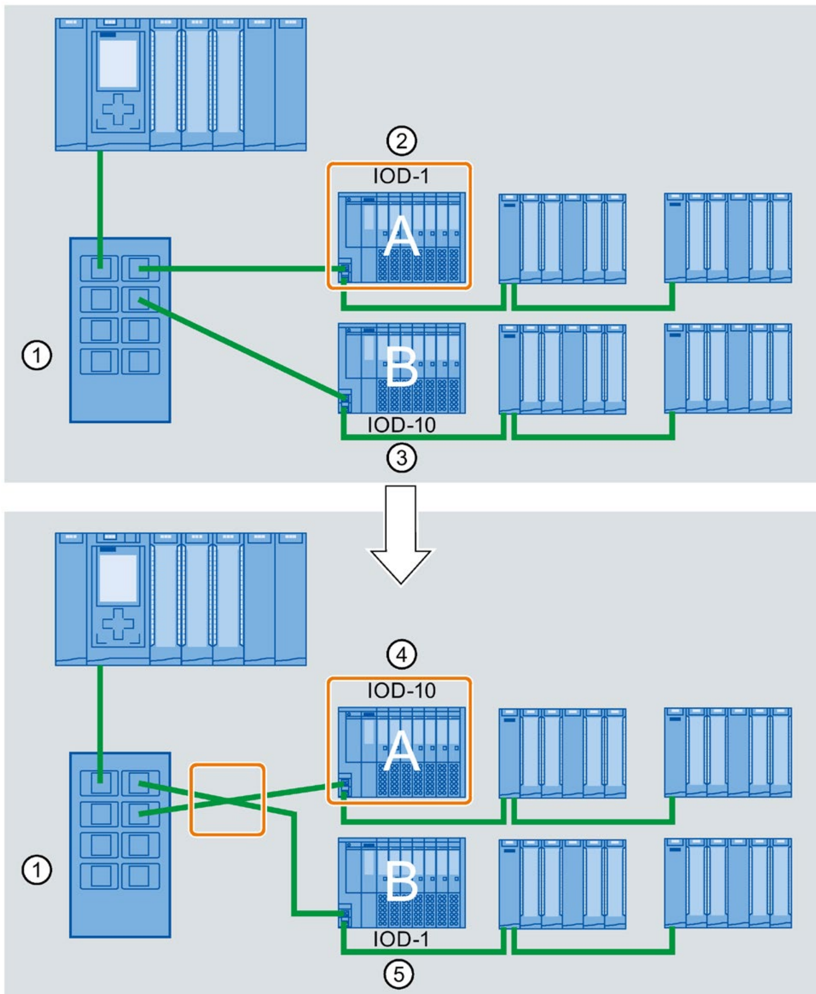
> **WARNING**
>
> **Wrong PROFINET device name**
>
> When the "Permit overwriting of PROFINET device names of all assigned IO devices" option is enabled, incorrectly connected devices can be assigned an incorrect PROFINET device name from the configuration.
>
> Depending on the connected I/O, there is risk of death, severe injuries or damage caused by malfunctions.
>
> To rule out any danger, check whether the suitable replacement device has been connected in case of a device replacement and whether the port interconnection matches the configured preset topology.

Typical source of danger

When replacing an IO device ("standard case"), it is almost guaranteed that the replaced device will be connected according to the configured port interconnection.

The figure below shows a scenario whereby the connections of two identical PROFINET cables are swapped at two switch ports. Because the IO controller assigns the device names according to the preset topology, the incorrect connection of the devices has serious effects on the naming.

Due to the control of different actuators, the plant could become hazardous in this case.



① Switch with connected PROFINET cables
② Device A, device name "IOD-1": controls motor 1
③ Device B, device name "IOD-10": controls motor 10
④ Device A controls motor 10!
⑤ Device B controls motor 1!

Procedure

Proceed as follows to change the "Permit overwriting of PROFINET device names of all assigned IO devices" option:

1. Select the PROFINET interface of the CPU for which you want to change the option in the network view or in the device view.
2. Select the area "Advanced options", section "Interface options".
3. Change the option.

5.9 Standard machine projects

Introduction

Standard machine projects are STEP 7 projects that use a set of innovative functions allowing simple configuration and commissioning of flexible automation solutions for standard machines or for machines with a modular structure.

A hardware configuration consisting of an IO controller and any number of connected IO devices represents a "PROFINET IO system master". This master is configured with a maximum configuration based on a template from which various options can be derived for different standard machines, for example with different configuration variants of the IO system.

Greater flexibility at all levels

Standard machine projects have the following central characteristics:

- Different variants of a standard machine can be loaded from precisely one project with an engineered maximum configuration (IO system options). The standard machine project covers all variants (options) of the IO system.
- An IO system option can be integrated in an existing network locally using simple tools.

Flexibility is provided in more ways than one:

- With suitable configuration, adaptation of the IP address parameters of the IO controller is possible locally using simple tools. This allows a standard machine to be integrated in different plants with little effort or to be included in a network several times.
  IO systems with this property are known as **multiple use IO systems**.
- With suitable configuration and programming, different setups of IO system options can be operated locally that differ in terms of the selection of IO devices used or in terms of the arrangement of the IO devices.
  Since the specific configuration of the IO system is controlled by the user program, this is known as **configuration control for IO systems**.
- Independently of the functions described above, with suitable configuration and programming, you can use different station options of central devices or distributed I/O devices in one project. The devices can be different in terms of the selection and arrangement of the modules.
  Since the concrete configuration of the station is controlled by the user program, this is also known as **configuration control at the device layer**.

Application examples

You can find application examples for configuration control at the device layer, configuration control for IO systems and multiple-use IO systems on the Internet (https://support.industry.siemens.com/cs/ww/en/view/29430270).

Additional information

For more information on multiple use IO systems, refer to section Multiple use IO systems (Page 230).

For more information on the configuration control for IO systems, refer to section Configuration control for IO systems (Page 239).

For more information on configuration control, refer to the system manual S7-1500, ET 200MP (http://support.automation.siemens.com/WW/view/en/59191792).

5.9.1 Multiple use IO systems

5.9.1.1 What you should know about multiple use IO systems

Multiple use automation solutions

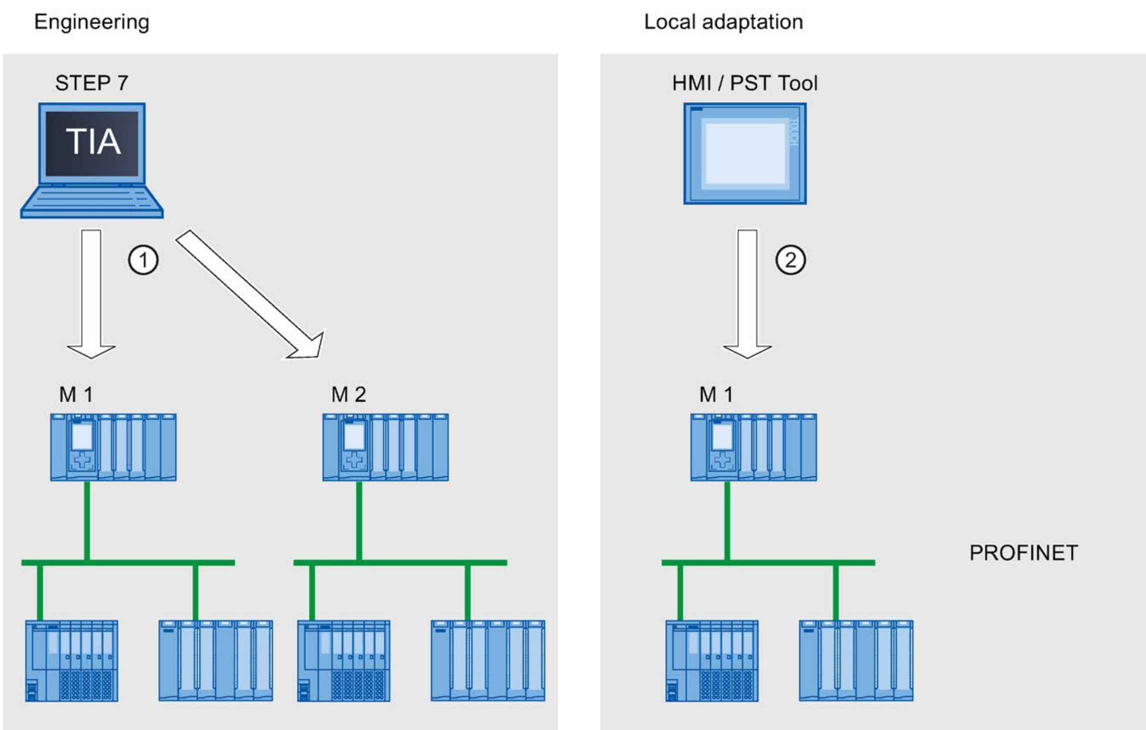
For a flexible reusable automation solution as is the case with series machines, the following use cases are typical:

- The machine (and therefore also the PROFINET IO system) is used more than once by the customers.
- The machine is used in different plants by various customers.

For this to be possible, the automation solution must meet the following requirements:

- A project (configuration and program) can be loaded on various machines of the same type without changes.
- Only a few easy adaptations need to be performed locally to integrate the machine into an existing network infrastructure.

The following figure shows how an automation solution with a multiple use IO system is loaded on different automation systems and then one automation system is adapted to the existing network infrastructure locally.



① Load configuration with multiple use IO system
② Set IP address and device name locally on the IO controller

Figure 5-75 "Multiple use IO system" principle

Principle

The automation components for a machine include a PROFINET IO system, consisting of an IO controller (PROFINET interface of a CPU) and the IO devices assigned to it.

With the "Multiple use IO system" setting for the IO system, you turn a STEP 7 project into a "Standard machine project".

The "Multiple use IO system" setting triggers various settings and checks of the configuration by STEP 7. The settings ensure that the IO system is self-contained and there are no dependencies on components outside the IO system.

Requirements

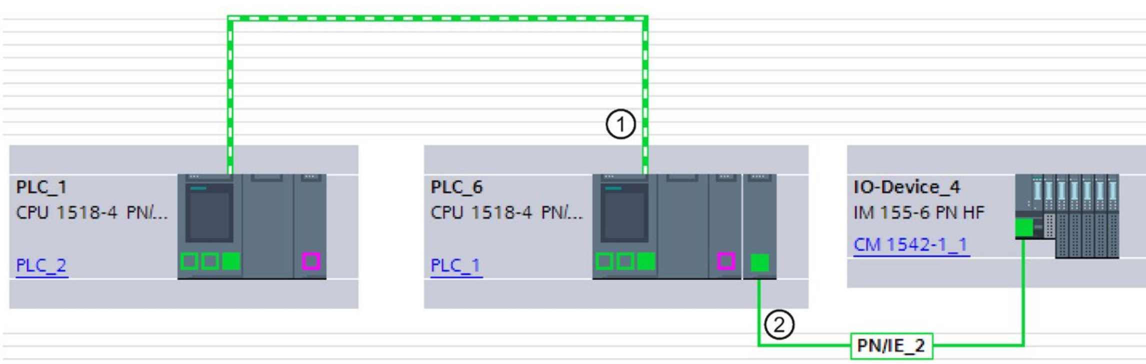
- STEP 7 as of V13
- The IO controller supports the "Multiple use IO system" function, for example a CPU 1512SP-1 PN as of firmware version 1.6.

Rules

The following rules apply to a multiple use IO system:

- No IO device can be configured as shared device.
- The ports of the devices must be interconnected.
  Devices for which no port interconnection is configured, for example, interface module IM 154-6 IWLAN (ET 200pro PN), cannot be operated with STEP 7 V13 as IO devices on a multiple use IO system.
- If an IO device in a multiple use IO system is an I-device (CPU as an "intelligent" IO device):
  – If the I-device has a lower-level IO system, this I-device cannot be connected to the same PROFINET interface as the higher-level IO controller.

    Note: If the I-device is configured using a PROFINET GSD, STEP 7 cannot check for compliance with this rule. In this case, you are responsible for ensuring compliance with the rule.



① I-device in multiple use IO system. The PROFINET interface is operated as IO device. No other IO system is connected here.

② A lower-level IO system on the I-device is connected to another PROFINET interface.

Figure 5-76 Example configuration for "Multiple use IO system" with I-device

  - The PROFINET interface of the I-device must be set to "Parameter assignment of PN interface by higher-level controller".
- If MRP (Media Redundancy Protocol) is configured:
  - All IO devices on the multiple use IO system must belong to the same MRP domain.
- If IRT (Isochronous Real Time) is configured:
  - All IO devices in multiple use IO systems must belong to the same sync domain.
  - The sync domain must not include any other IO devices.
- IE/PB Links cannot be operated as an IO device in a multiple use IO system with STEP 7 V13.

Configuration

You specify whether or not a configuration can be used multiple times in the properties of the IO system.

All other parameter settings for the configured devices are then set automatically by STEP 7 and checked during compilation.

Boundary conditions

To prevent a standard machine project from having dependencies on other devices outside of the machine, observe the following:

- A standard machine project consists of an IO controller and the corresponding IO devices. You should therefore configure only one CPU as IO controller and the corresponding IO devices in the standard machine project.
- Do not use connection configured at both ends for the communication. Instead, use only a connection configured at one end or unspecified connections if necessary.

  Background: To configure the communication in a STEP 7 project, it is always possible to set the IP address parameters in the project. For multiple use IO systems, however, this strategy is not possible since the IP address parameters of the IO controller and the assigned IO devices are assigned locally. At the time of the configuration, the IP address parameters are therefore unknown.

  If you nevertheless want to configure communication with devices on PROFINET, for example with a central coordinator, you can only use communications mechanisms that allow dynamic assignment of the IP address parameters in the user program.

  Example: Open User Communication

  If, for example, the device is configured as an active end point (initiator of the connection), the IP address parameters can be stored, for example, in a data block. You then supply the data block with the currently valid IP address parameters during commissioning. For this dynamic type of IP address parameter assignment, there is no system support; in other words, if you change the configuration of the system, the IP address parameters are not automatically adapted.

  You will find a description of handling instructions for Open User Communication under this keyword in the STEP 7 online help.

5.9.1.2 Configuring multiple use IO systems

Requirements

- STEP 7 as of V13
- The IO controller supports the "Multiple use IO system" function, for example a CPU 1512SP-1 PN as of firmware version 1.6.

Procedure

The configuration of a series machine using an S7-1500-CPU as an example is described below.

To create a standard machine project, follow these steps:

1. Create a project.
2. Configure a CPU as the IO controller, for example a CPU 1518-4 PN/DP as of firmware version 1.5.
3. Configure the required IO devices and assign the IO devices to the IO controller.
4. Configure the port interconnection between the devices.
5. Select the IO system so that you can edit the properties in the inspector window.
6. Select the "Multiple use IO system" check box in the "General" area of the inspector window.

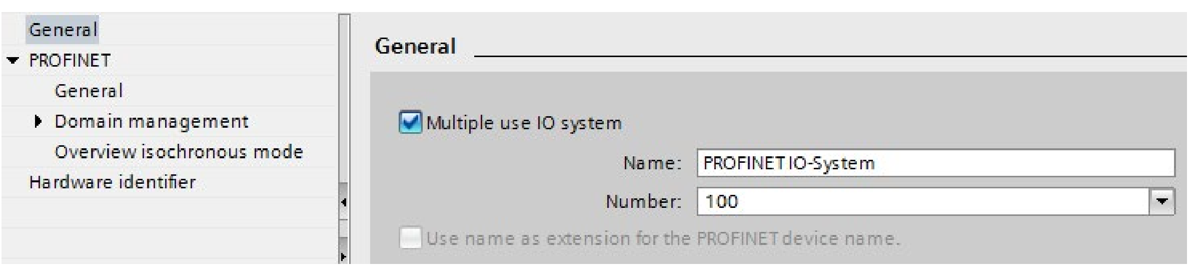


Figure 5-77 Activate "Multiple use IO system"

Result: The following settings are made by STEP 7:

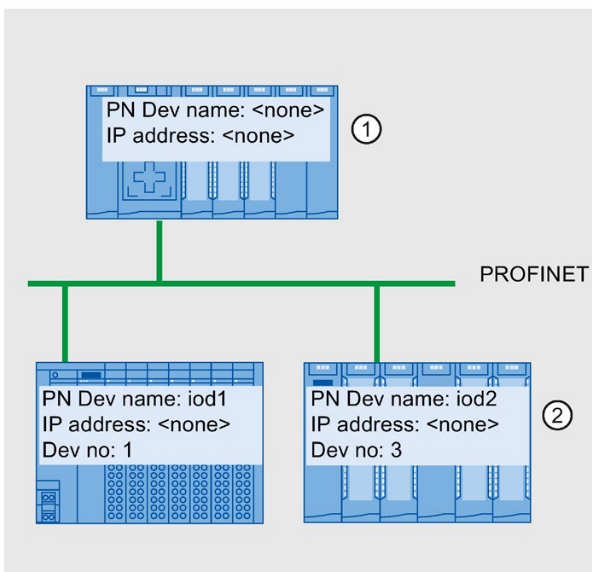
- The device name of the IO controller (CPU) in the standard machine project is set to "PROFINET device name is set directly at the device". The IO controller (CPU) has no PROFINET device name initially.
- The IP protocol of the IO controller (CPU) is set to "IP address is set directly at the device". The CPU has no IP address initially.
- The "Support device replacement without exchangeable medium" option is selected automatically. This option enables automatic commissioning. A commissioning engineer does not have to assign device names to the IO devices locally. The IO controller assigns the device name and IP address to the IO devices based on the preset topology and other settings during startup.
- The device name of the IO devices is set to "Generate PROFINET device name automatically" (from the configured name of the IO device).

- The IP protocol of the IO devices is set to "IP address is set by the IO controller during runtime". The IO devices have no IP address initially. If an IO device is not a typical distributed I/O system (e.g., ET 200 systems), but rather another device such as an HMI device, change the option to "IP address is set directly at the device"; see below.
- The device number for the IO devices is automatically assigned and is used locally for making the IP address unique.

The option "Permit overwriting of PROFINET device name" must be selected (CPU parameters, properties of the PROFINET interface, Ethernet addresses area) so that the IO controller can adapt the device name later at the operator.

This option is disabled by default.

The following figure shows the above-described settings for the IP address and PROFINET device name.



① After the configuration is loaded from the standard machine project, the IO controller has no device name and no IP address.

② Following loading, the IO devices have a device name and a device number but no IP address.

Figure 5-78 Settings for the IP address and the PROFINET device name

How an IO device obtains an IP address locally

Below, you will find an explanation of the "IP address is set by the IO controller during runtime" and "IP address is set directly at the device" options, which can generally be configured for a multiple use IO system.

If you have set the "Multiple use IO system" option for the IO system, STEP 7 automatically sets the "IP address is set by the IO controller during runtime" option for the IO devices.

In this case, the IO controller assigns the IO device an IP address that results from the locally assigned IP address of the IO controller (see next section). This option is appropriate if the IO device is a field device, e.g., ET 200MP, ET 200SP, ET 200AL, or another distributed I/O system.

If the IO device is not a "standard" field device, for example, an HMI device for a Windows operating system, the "IP address is set by the IO controller during runtime" option described above does not work. In this case, choose the "IP address is set directly at the device" option. You must then assign the IP address to the device locally and take steps to ensure that this address is suitable for the IP addresses of the other IO devices and the IP address of the IO controller.

5.9.1.3 Adapt multiple use IO systems locally

A few steps are needed to adapt the machine that was loaded with the standard machine project.

Only the device name and IP address of the IO controller must be adapted locally. The device names and IP addresses of the IO devices result from these adaptations. In this example, the effects of local settings are described for two specific machine modules.

The local settings are possible, for example, with the CPU display and commissioning tools such as Primary Setup Tool (PST) or PRONETA. You do not need a programming device with STEP 7 to make these settings, even though it is possible to do so.

Requirements

- The machine was loaded with a standard machine project (see Configuring multiple use IO systems (Page 234)).
- The display is ready for operation and the desired tool for assigning the IP address and device name is available (e.g., PST Tool, STEP 7).
- The ports of the IO controller and IO devices are interconnected according to the configuration.

Procedure

Observe the boundary conditions and instructions for commissioning an S7-1500. For more information on commissioning an S7-1500 CPU, refer to the system manual S7-1500, ET 200MP (http://support.automation.siemens.com/WW/view/en/59191792).

To adapt a standard machine locally, follow these steps:

1. Integrate the machine into the network.
2. Connect the device for assigning the IP address and device name to the CPU, for example a PG/PC with the appropriate software.
3. Assign the desired device name and IP address to the IO controller.
4. Start up the CPU.

The IO controller then assigns the adapted PROFINET device name and a unique IP address to the IO devices.

The following rules apply to the assignment:

- The device names of the IO devices are formed by chaining together the following name components, separated by a period:

  <configured name of the IO device from the standard machine project>.<name of the associated IO controller set on the device>
- The IP addresses of the IO devices result from the locally configured IP address of the associated IO controller and the device number (sum).

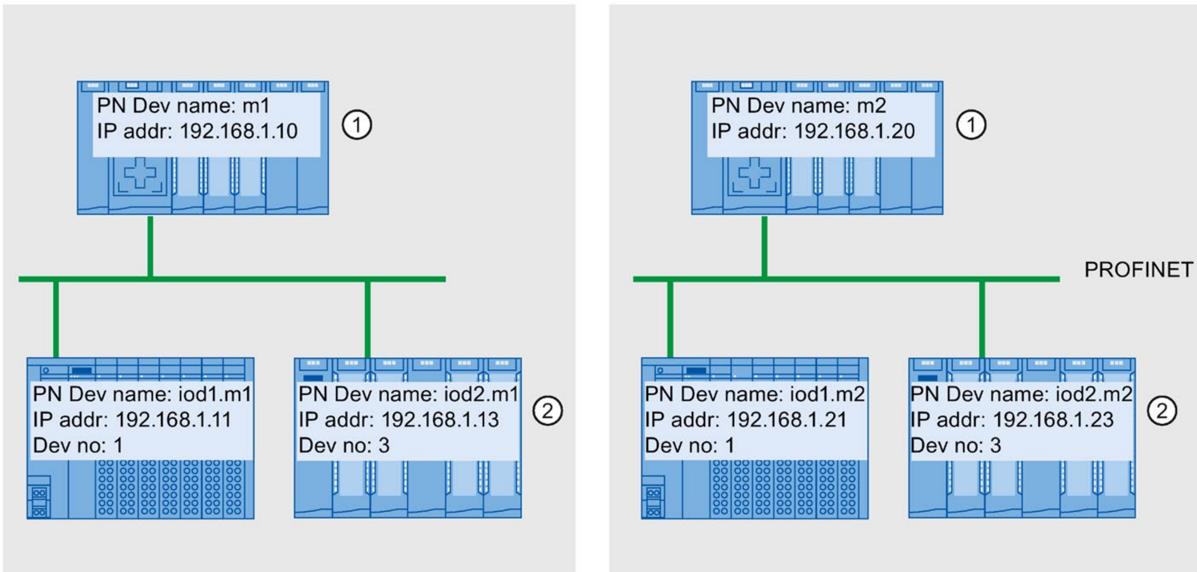
Note

Make sure that duplicate IP addresses cannot be created on the subnet during the assignment. The IO controller does not assign a new IP address in this case.

In the following figure, the device name "m1" and the IP address 192.168.1.10 have been assigned to the IO controller of the first machine.

The device name "m2" and the IP address 192.168.1.20 has been assigned for the second machine.

Refer to the figure for the resulting device names and IP addresses.



① Set device name and IP address on the IO controller

② After startup, the IO devices have an updated device name (<configured device name>.<device name of IO controller>) and an adapted IP address (= <IP address of IO controller> + <device number>)

5.9.2 Configuration control for IO systems

5.9.2.1 Information about configuration control of IO systems

Configuration control of IO systems makes it possible to generate several concrete versions of a standard machine from a standard machine project.

You are given the flexibility to vary the configuration of an IO system for a specific application as long as the real configuration can be derived from the set configuration. The configured configuration therefore represents the superset of all real configurations that can be derived from it.

The following figure shows an example of how two IO systems with a different number of IO devices arise from one standard machine project.

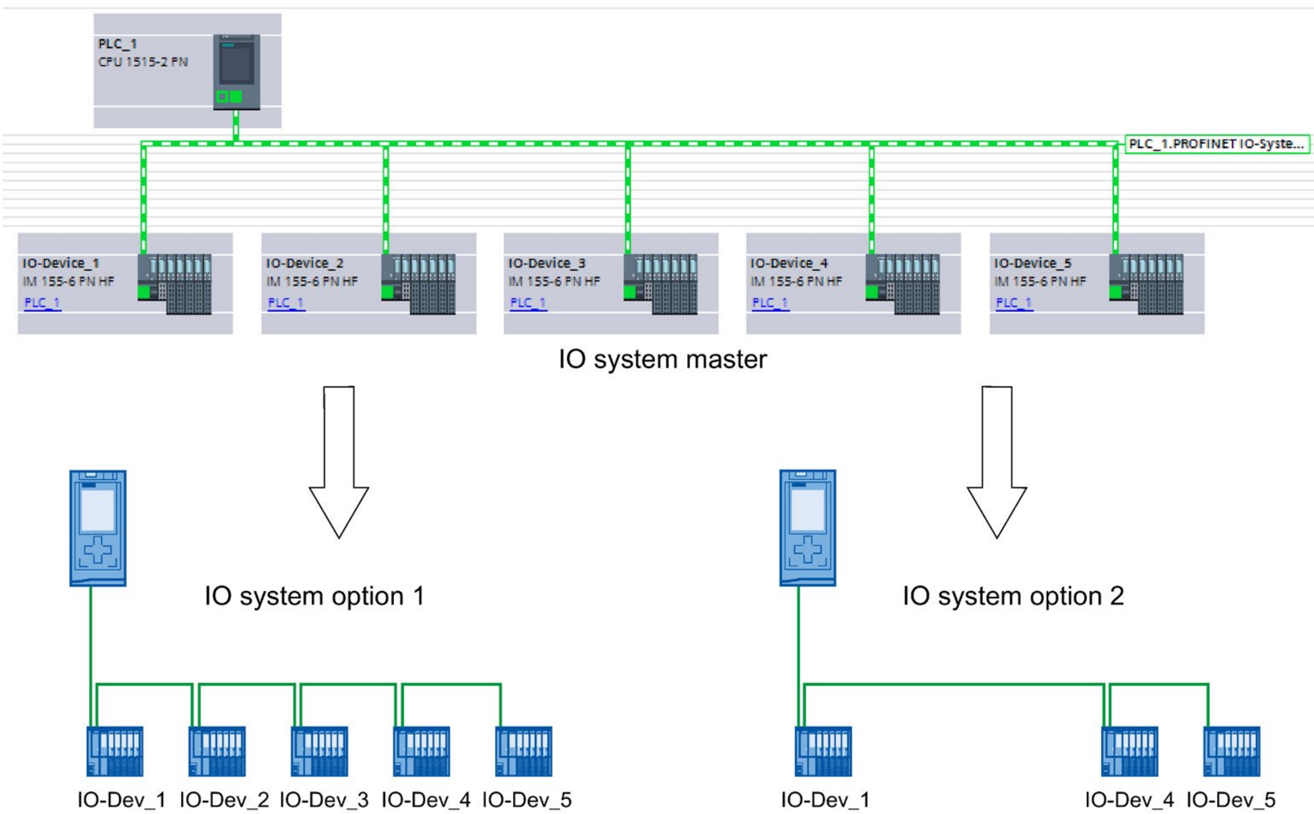

Figure 5-80 Example of configuration control for PROFINET IO systems

In the following sections, you find a description of how to configure and program a PROFINET IO system to commission, for example, a standard machine on-site without using configuration software.

Concept

The principle of configuration control is already known at the device level for the flexible use of submodules/modules ("option handling"). Different configurations can be derived from one engineering project both for central as well as for distributed I/O.

With S7-1500 CPUs as of firmware version V1.7, this principle can also be applied at the IO system level. You have the option of omitting, adding or changing the order of stations (IO devices) of a PROFINET IO system in a specific plant.

Configuration control for devices and configuration control for IO systems can be combined; the functions are independent of each other.

It is possible to operate variants deviating from a maximum configuration of an IO system. In a standard machine project, you can prepare a kit of IO devices which can be flexibly customized for various configurations using configuration control.

The following variations are available:

- Variation of the number of IO devices involved

  You include optional IO devices for the configuration control in the configuration by transferring a suitable data record with the required configuration in the user program.

- Variation of the order of IO devices involved

  You adapt the port interconnection of the IO devices to the topology being used by transferring a suitable data record with the required topology in the user program.

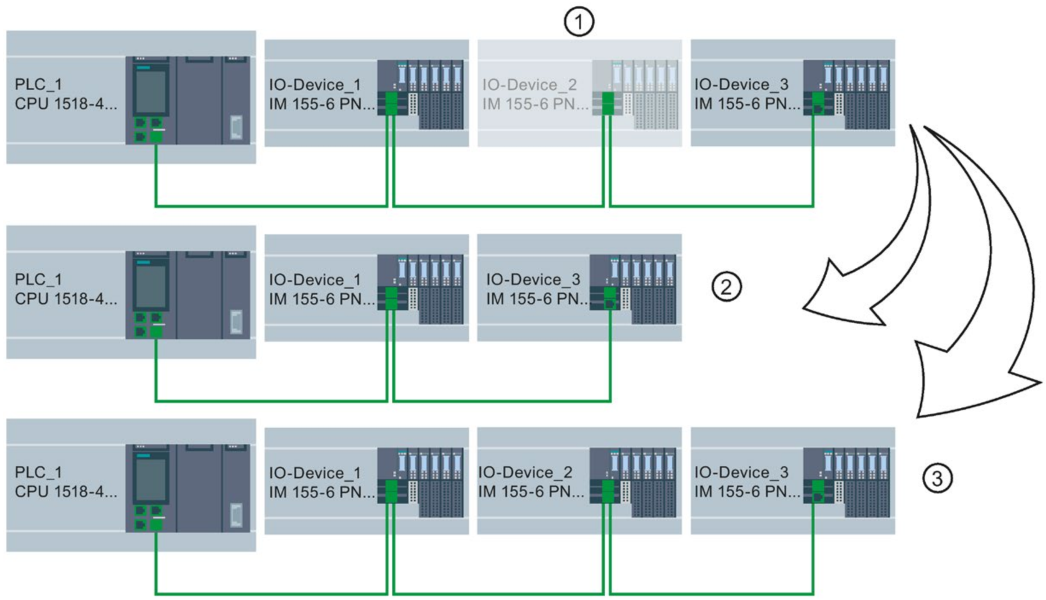
The following figure shows how you serve two different configurations with an IO device marked as optional in the network view of STEP 7.

- Configuration without the optional IO device:

  In this case, you use the instruction "ReconfigIOSystem" to transfer a data record to the PROFINET interface containing the information that no optional IO device is to be included in the configuration.

- Configuration with the optional IO device:

In this case, you use the instruction "ReconfigIOSystem" to transfer a data record to the PROFINET interface adding the optional IO device to the configuration.



① Determined through parameter assignment: IO Device_2 is optional IO device
② Configuration without the optional IO device
③ Configuration with the optional IO device

Figure 5-81 Example configuration with "Optional IO device" and the associated configuration options

Summary: The procedure in principle

The following phases are distinguished when it comes to the implementation of a standard machine concept:

1. Engineering phase: Creating a standard machine project and loading into specific machine or plant:
   – Completely configuring all IO devices (options) ever required in a specific machine or plant
   – Configuring as optional those IO devices that will be omitted in specific machines or plants
   – Preparing user program (see Configuring flexible order of IO devices (Page 250)) with the possibility of selecting on-site the actually existing configuration via switch or HMI device
2. Commissioning phase: Preparing specific machine or plant for operation:
   – Integrating machine or plant in the on-site network (see Adapt multiple use IO systems locally (Page 236))
   – Selecting the currently existing configuration of the IO system via configured option

5.9.2.2 Configuring IO devices as optional

Requirements

- IO controller supports configuration control for IO systems, for example CPU 1516-3 PN/DP as of firmware version 1.7
- STEP 7 V13 SP1 or higher
- The rules (Page 256) for the establishment and operation of a standard machine project have been considered.

Port interconnection

As of STEP 7 V15.1, port interconnection is not necessary for optional IO devices.

A port interconnection between the devices of the IO system that you want to customize with the user program is mandatory in the following cases.

- You have configured IRT.
- You have configured MRP.
- You are using STEP 7 <= V15.

Procedure

To configure an IO device as optional IO device, proceed as follows:

1. Create a project.
2. Configure an S7-1500 CPU firmware version V1.7 or higher as IO controller.
3. Configure the required IO devices and assign the IO devices to the IO controller.
4. Select the IO device you want to mark as optional.
5. Select the area "PROFINET interface [X1]" > Advanced options".
6. Enable the "Optional IO device" option.

Figure 5-82 Configure the IO device as an optional IO device

7. Repeat steps 4 to 6 for all IO devices to be configured as optional.
8. Load the configuration onto the CPU.

Result: Once this configuration is loaded, the system behavior is as follows:

- The CPU is prepared for the configuration control of the IO system.
- All IO devices are disabled.
- Irrespective of whether you customize the configuration with the user program (adding optional IO devices) or make no changes to the loaded configuration: You must call the instruction "ReconfigIOSystem" in the user program and notify the current configuration to the system!

  The system will not be operational without calling the instruction "ReconfigIOSystem".

  For further information on the proceeding see Enabling optional IO devices in the program (Page 244).

Fast parameter assignment in the "IO communication" table

You can also specify whether or not an IO device is optional in the "IO communication" tab.

In an additional "Optional IO device" column, a selectable check box is available for each IO device that indicates whether or not an IO device is optional. Here, you can adjust the setting centrally.

5.9.2.3 Enabling optional IO devices in the program

Requirements

- IO controller supports configuration control for IO systems, for example CPU 1516-3 PN/DP as of firmware version 1.7
- STEP 7 V13 SP1 or higher
- At least one IO device was configured as optional IO device.
- The rules (Page 256) for the establishment and operation of a standard machine project have been considered.

Procedure

Observe the information on and rules for commissioning in the documentation for SIMATIC S7-1500, for the ET 200SP CPUs and for the CPU 1516pro-2 PN.

The following description of the proceeding only includes steps required to understand the program-controlled activation of an optional IO device.

To activate or deactivate IO devices, follow these steps:

1. Create a data record "CTRLREC" for the instruction "ReconfigIOSystem". You can find information on the structure of the data record in the STEP 7 online help.
2. Call the instruction "ReconfigIOSystem" and select MODE 1 to deactivate all IO devices.

   If you set the CPU to STOP or POWER OFF state in order to modify the plant in this status (for example to add an optional IO device), explicit deactivation using "ReconfigIOSystem" with mode 1 is not necessary. In this case, i.e. following a STOP-RUN transition and following a POWER-OFF > POWER-ON transition, all IO devices are deactivated automatically.
3. When you have brought the plant to a safe status that allows restructuring without any danger:

   Put the plant together according to your intended application. Add the required optional IO devices at the points at which you planned this in the configuration (observe the order!) or remove optional IO devices that you no longer require.
4. Network the IO devices.

5. Startup the S7-1500 system and call again the instruction "ReconfigIOSystem". Select MODE 2 to transfer the data record CTRLREC.
6. Following successful transfer of the data record, call again the instruction "ReconfigIOSystem". Select MODE 3 to activate all IO devices forming part of the current configuration.

   Result: The CPU **activates** the following IO devices:

   – All IO devices that you have not set as optional IO devices.

   – All optional IO devices listed in the control data record (CTRLREC).

   The following IO devices remain **disabled**:

   – Docking units (IO devices changing during operation).

   – Optional IO devices that are not listed in the control data record.

Note

Call the instruction "ReconfigIOSystem" for all values of the parameter MODE with the same control data record (CTRLREC)!

If you use different data records for the values of the MODE parameter, this results in an inconsistent customization of the configuration and thus to rather incomprehensible error messages.

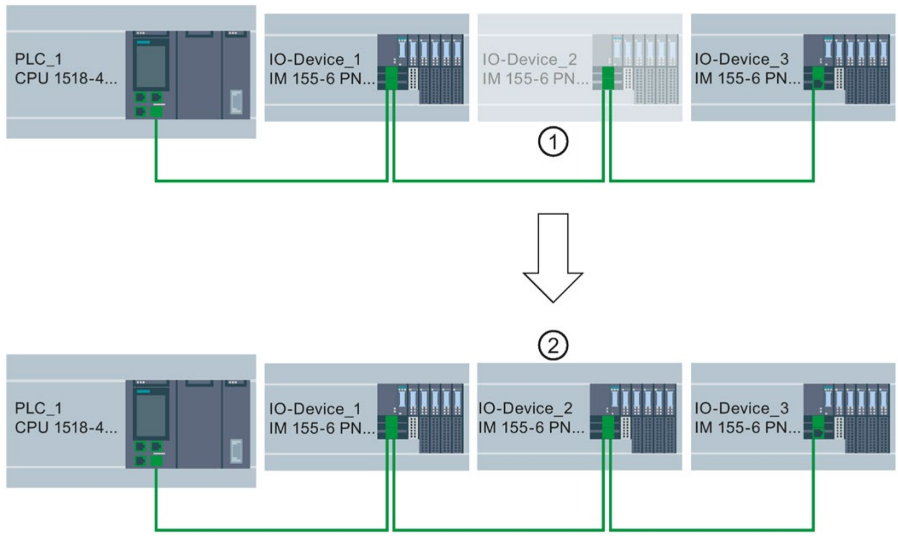
Example: Data record structure for the activation of an IO device

The IO device "IO-Device_2" is to be activated as the only IO device in the user program.

To do this, you only require the hardware identifier of "IO-Device_2".

Recommendation: Use the system constants of the hardware identifiers instead of the absolute values as shown in this example. With this procedure, the content of the DB is not influenced by changes to the hardware identifiers as the result of changes to the configuration.

The data record is to be stored in a data block and to be transmitted to the PROFINET interface of the IO controller in the user program using the instruction "ReconfigIOSystem".



① IO device_2 is configured as optional IO device.

② Once the data record is transmitted and the configuration is activated using the instruction "ReconfigIOSystem" IO device_2 is included in the configuration and participates in the data exchange with the IO controller.

Figure 5-83 Example: Activating an optional IO device

Creating data block

In this example, the control data record is created in a data block. The data block is structured as follows:

Line 2: Array definition: Array of type Word with 4 elements. Array of Word is permitted as the data type.

Line 3: Version of the data record (currently: V1.0).

Line 4: Number of optional IO devices to be activated (here: 1).

Line 5: List of the hardware identifiers of the IO devices, inserted here as system constants.

Line 6: Number of port interconnections that are set in the user program (here: 0).

Line 7: Additional data records (optional)

myCTRLREC

	Name	Data type	Start value	Comment

5	ArrMachineConfig0[2]	Word	"IO-Device_2~IODevice"	
6	ArrMachineConfig0[3]	Word	16#0000	
7	▶ ArrMachineConfig1	Array[0..8] of Word		

Figure 5-84 Data block with control records

Parameter MODE of instruction "ReconfigIOSystem"

You control how the "ReconfigIOSystem" instruction works with the MODE parameter.

The following values are possible for the MODE input parameter:

MODE	Description
1	All IO devices of the IO system can be disabled by calling the instruction with MODE 1. The "ReconfigIOSystem" instruction uses the "D_ACT_DP" instruction internally. "ReconfigIOSystem" returns errors that are detected by D_ACT_DP in the following output parameters: • STATUS (error code) • ERR_INFO (hardware identifier of the IO device causing the error). In STATUS and ERR_INFO, the CPU enters the last determined error/HW identifier and in so doing overwrites an existing error code. For this reason, additional errors can be present besides the entered error.
2	For controlling the actual configuration of the IO system, the instruction transfers the data record to the PROFINET interface, which is addressed with LADDR block parameter (HW identifier of the PROFINET interface).
3	All non-optional IO devices in the IO system and optional IO devices that are listed in the control data record CTRLREC are enabled. The optional IO devices that are **not** listed in the CTRLREC data record remain disabled. If IO devices that are part of docking units (alternating IO devices in operation) are listed in the CTRLREC control data record, the PN IO system reacts as follows: • IO devices of the docking units remain disabled when ReconfigIOSystem is called with MODE 3. This reaction corresponds to the reaction of a configuration without configuration-controlled IO devices. IO devices of docking units are disabled by default and must be enabled in the user program. For more information on docking units, refer to the section Docking systems (Page 260).

Rules for the call sequence of "ReconfigIOSystem"

- Always supply the instruction "ReconfigIOSystem" with the same control data record (CTRLREC input parameter)!
- Call sequence following POWER OFF -> POWER ON transition:
  - ReconfigIOSystem call with MODE 1 (optional).
  - ReconfigIOSystem call with MODE 2 (mandatory, even without previous reconfiguration!).
  - ReconfigIOSystem call with MODE 3 (mandatory).
- Call sequence following STOP > RUN transition:
  - ReconfigIOSystem call with MODE 1 (optional).
  - ReconfigIOSystem call with MODE 2 (mandatory, even when configuration was modified in STOP state). Otherwise not required).
  - ReconfigIOSystem call with MODE 3 (mandatory).
- Call sequence for reconfiguration in RUN state:
  - ReconfigIOSystem call with MODE 1 (mandatory).
  - ReconfigIOSystem call with MODE 2 (mandatory).
  - ReconfigIOSystem call with MODE 3 (mandatory).

Explanations and recommendations concerning the rules

- If you do not list an IO device to be configured as optional IO device in the control data record or data block resp. this IO device does not form part of the configuration and does not take part in data exchange with the CPU.
- If you do not activate any optional IO device at all and work with the loaded configuration without reconfiguration, you still have to follow the proceeding described in the above section and transmit the control data record to the CPU.

  The control data record has the simple structure with the following tags:
  - Version (High Byte =1, Low Byte = 0)
  - Number of optional devices to be activated = 0
  - Number of port interconnections that are set in the user program = 0
- Following a STOP > RUN transition and following a POWER-OFF > POWER-ON transition, all IO devices are deactivated automatically. For this reason, no ReconfigIOSystem call with MODE 1 is required for configuration control to function properly.

If you use your project as a universally valid sample for programming the configuration control, we still recommend to perform the ReconfigIOSystem call with MODE 1 prior to any reconfiguration. This way, the sample can also be used for reconfigurations in RUN mode.

- Commissioning extensive I/O systems (more than 8 optional IO devices) while using IRT at the same time:

  To keep the startup times short when activating the optional IO devices (ReconfigIOSystem, mode 3), note the following tip: Check the device numbers of the IO devices. The device numbers should follow the topological interconnection starting at the IO controller in ascending order. The further an IO device is from the IO controller topologically, in other words the more IO devices there are between the IO controller and the IO device in question, the higher the device number should be.

  You set the device numbers in the "Ethernet addresses - PROFINET" area in the Inspector window with the PROFINET interface selected.

  Example of the assignment of device numbers with a linear topology:

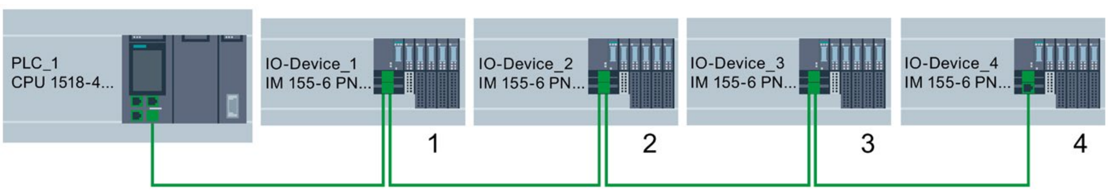

Figure 5-85 Example: Device numbers in a line topology

- The CPU processes the instruction "ReconfigIOSystem" to transfer the control data record asynchronously.

  For this reason, you must call "ReconfigIOSystem" in a loop repeatedly when calling the instruction in the startup program until the output parameter "BUSY" or "DONE" indicate that the data record has been transferred.

  Tip: To program the loop, use the SCL programming language with the instruction REPEAT ... UNTIL.

```
REPEAT
    "ReconfigIOSystem"(REQ := "start_config_ctrl",
               MODE := 1,
               LADDR := 64,
               CTRLREC := "myCTRLREC".ArrMachineConfig0,
               DONE => "conf_DONE",
               BUSY => "conf_BUSY",
               ERROR => "conf_ERROR",
               STATUS => "conf_STATUS");
UNTIL NOT "conf_BUSY"
END_REPEAT;
```

Additional information

For information on the basic structure of the data record and on using the instruction "ReconfigIOSystem" see the STEP 7 online help.

Configuring IO devices as optional (Page 242)

5.9.2.4 Configuring flexible order of IO devices

The following section shows how you can create the conditions required to change the order of IO devices in a PROFINET IO system.

This function is also supported with optional IO devices. For simplicity, a maximum configuration without optional IO devices is shown below.

Concept

A typical application for a standard machine project consists of composing an entire plant from a set of various plant units which only differ with respect to the different arrangement of the units, e.g. in the case of transport systems. Each plant unit consists of a functional unit of mechanics (rails or conveyor belts) and electrics (power supply, IO device with IO modules, sensors, actuators, motors, PROFINET port for data exchange with central control ...).

The following figure shows how, simply by exchanging two rail segments, a new transport system is created that is adapted with an upstream points to the local conditions.

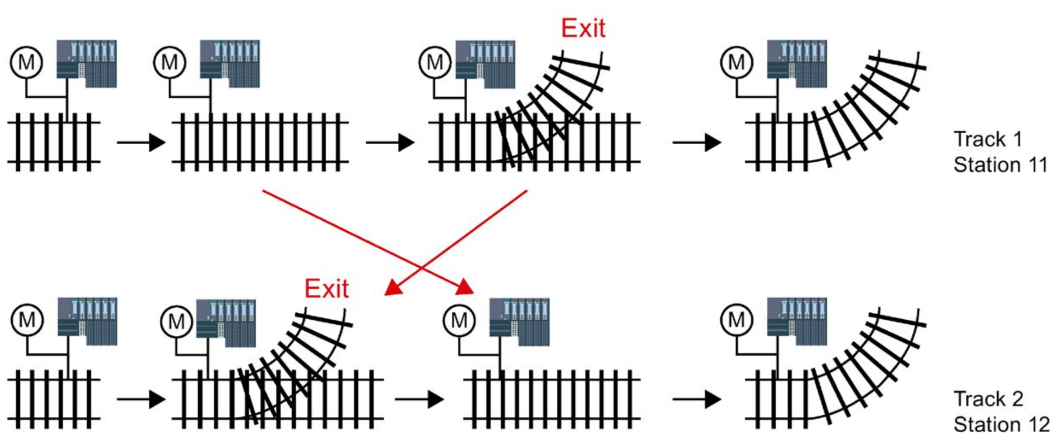

Figure 5-86 Example: Changing the arrangement of IO devices

From the automation viewpoint, no change in the project is required for the flexible adjustment of the PROFINET configuration.

The order of the IO devices is determined by the port interconnection. For each IO device, you define in the port properties the partner port and thus the neighboring device connected at the respective local port. If the partner port is to be defined by the user program, the option "Partner set by user program" is to be selected as partner port.

The figure below shows the initial configuration of the transport system shown above, which is to permit the order of the connected IO devices to be changed via the user program. In the example, the order of IO-Device_2 and IO-Device_3 is to be controlled via the user program.

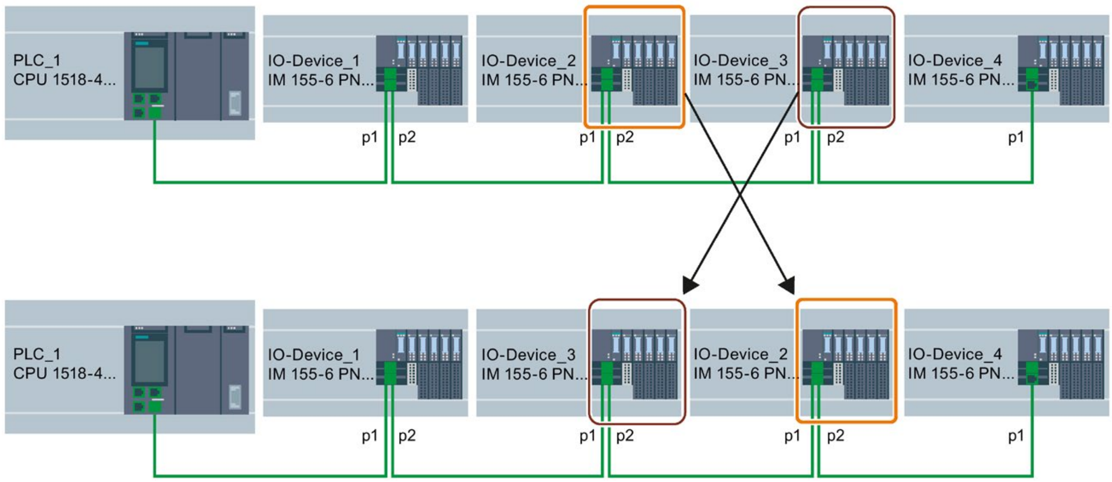

Figure 5-87 Example configuration: Configuring flexible order of IO devices

To determine how the partner port settings are to be selected, you must note for each device and each port of a device which partner can be interconnected.

- If the partner is always the same in the different configurations provided, you select the partner port for this partner.
- If the partners vary in the different configurations, you select "Setting partner by user program".

For the example in the figure above, the following port settings result:

Device	Local port	Partner port setting	Explanation
PLC_1	p1	p1 (IO device_1)	Partner of PLC_1 at port 1 is IO device_1 (always)
IO device_1	p1	p1 (PLC_1)	Partner of IO device_1 at port 1 is PLC_1 (always)
IO device_1	p2	Partner is set by user program	Partner of IO device_1 at port 2 is either IO device_2 or IO device_3 => Setting partner by user program
IO device_2	p1	Partner is set by user program	Partner of IO device_2 at port 1 is either IO device_1 or IO device_3 => Setting partner by user program
IO device_2	p2	Partner is set by user program	Partner of IO device_2 at port 2 is either IO device_3 or IO device_4 => Setting partner by user program

Device	Local port	Partner port setting	Explanation
IO device_3	p1	Partner is set by user program	Partner of IO device_3 at port 1 is either IO device_2 or IO device_1 => Setting partner by user program
IO device_3	p2	Partner is set by user program	Partner of IO device_3 at port 2 is either IO device_4 or IO device_2 => Setting partner by user program
IO device_4	p1	Partner is set by user program	Partner of IO device_4 at port 1 is either IO device_3 or IO device_2 => Setting partner by user program
IO device_4	p2	Any partner	No partner planned at port 2

Requirement

- IO controller supports configuration control for IO systems, for example CPU 1515-2 PN as of firmware version 1.7
- STEP 7 V13 SP1 or higher
- The rules (Page 256) for the establishment and operation of a standard machine project have been considered.

Procedure

To set the partner port for a program controlled interconnection, proceed as follows:

1. Select the PROFINET interface of the device (IO controller or IO device) whose port you want to set.
2. In the properties of the PROFINET interface, select the area "Port interconnection" (Extended options > Port [...] > Port interconnection).
3. From the drop-down list, select "Setting partner by user program" as partner port.
4. Repeat steps 1 to 3 for each port to be interconnected via the user program.

See also

Customizing arrangement of IO devices in the program (Page 253)

5.9.2.5 Customizing arrangement of IO devices in the program

Requirements

- IO controller supports configuration control for IO systems, for example CPU 1516pro-2 PN as of firmware version 1.7 as an IO controller
- STEP 7 V13 SP1
- At least one partner port was configured as "Partner set by user program".
- The rules (Page 256) for the establishment and operation of a standard machine project have been considered.

Procedure

The proceedings corresponds to the proceeding for activating optional IO devices.

Only the structure of the data record must be extended for the program-controlled assignment of the ports. The extension is described in the following sections.

Example: Data record structure for the assignment of partner ports

For the data record structure, you need the HW identifications of the ports.

The data record is to be stored in a data block and to be transmitted to the PROFINET interface of the IO controller in the user program using the instruction "ReconfigIOSystem".

As the input parameter RECORD of the instruction "ReconfigIOSystem" is of the VARIANT data type, you first have to create a data type for the data block.

In the following sections, you find a description of the structure of the PLC data type as well as of the structure of the data block based on this type.

Selecting derived configuration

For the following selected configuration it is shown below what the data record must look like so that the IO devices are interconnected in the planned order by the user program.

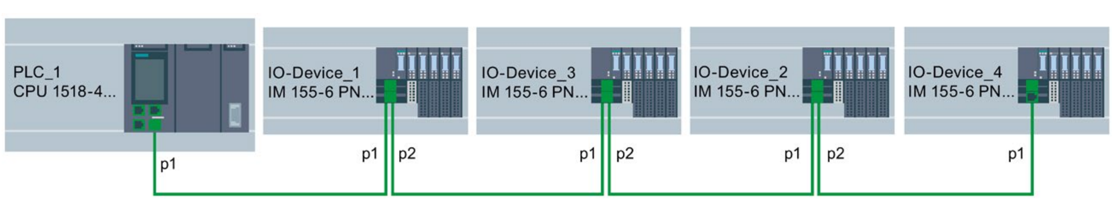

Figure 5-88 Example configuration: Customizing arrangement of IO devices in the user program

This example is based on the flexible configuration from the previous section (Page 250) with the settings for the respective partner ports described there.

The partner ports in the specific derived configuration have been defined so that it is possible to name the HW identifications of the ports involved.

The following table only contains those devices whose ports can be defined by the user program. Only these devices are relevant for the data record structure.

Device	Local port	Partner port setting	Partner port of the selected configuration
IO device_1	p2 = Port 2 HW identifier: 251	Partner is set by user program	Port 1 of IO device_3 HW identifier: 261
IO device_2	p1 = Port 1 HW identifier: 281	Partner is set by user program	Port 2 of IO device_3 HW identifier: 291
IO device_2	p2 = Port 2 HW identifier: 311	Partner is set by user program	Port 1 of IO device_4 HW identifier: 321

Creating data block

For the derived configuration, the structure of the data block "DB-IO-SYSTEM-Port-Interconnections" is explained as an example.

This data block is used when calling the instruction "ReconfigIOSystem" at input parameter "CTRLREC".

Instead of the absolute values for the hardware identifiers of the ports, the system constants of the hardware identifiers are used here.

The data block is structured as follows:

Line 2: Declaration of an Array of Word (only this data type is possible).

Line 3: Version of the control data record: V1.0.

Line 4: Number of optional IO devices: 0.

Line 5: Number of specified port interconnections: 3.

Line 6: Port interconnection 1, local port.

Line 7: Port interconnection 1, partner port.

Line 8: Port interconnection 2, local port.

Line 9: Port interconnection 2, partner port

Line 10: Port interconnection 3, local port.

Line 11: Port interconnection 3, partner port.

IO-SYSTEM-Port-Interconnections					
		Name	Datentyp	Startwert	Kommentar
1		Static			
2		ArrMachineConfig	Array[0..8] of Word		data record for port interconn settings
3		ArrMachineConfig[0]	Word	16#0100	
4		ArrMachineConfig[1]	Word	16#0000	
5		ArrMachineConfig[2]	Word	16#0003	
6		ArrMachineConfig[3]	Word	"IO_device_1~PROFINET_interface~Port_2"	
7		ArrMachineConfig[4]	Word	"IO_device_3~PROFINET_interface~Port_1"	
8		ArrMachineConfig[5]	Word	"IO_device_2~PROFINET_interface~Port_1"	
9		ArrMachineConfig[6]	Word	"IO_device_3~PROFINET_interface~Port_2"	
10		ArrMachineConfig[7]	Word	"IO_device_2~PROFINET_interface~Port_2"	
11		ArrMachineConfig[8]	Word	"IO_device_4~PROFINET_interface~Port_1"	

Figure 5-89 Data block with data record for port interconnections

Interconnection not listed in data block

If the partner port was configured as "Setting partner by user program" in the port properties and this port is not listed in the data record or data block resp., then the CPU sets this port to the setting "any partner". If no data record is transmitted at all, the CPU sets this "any partner" setting for all program-controlled assignments.

Additional information

For information on the basic structure of the data record and on using the instruction "ReconfigIOSystem" see the STEP 7 online help.

5.9.2.6 System behavior and rules

Below, you find a description of how an IO system whose configuration is controlled by the user program behaves in operation.

In addition, rules and restrictions are listed here which must be considered when configuring the maximum structure of the configuration in a standard machine project.

System behavior

- System diagnostics:

  If an optional IO device is deactivated, the IO device is displayed as "deactivated" from the system diagnostics viewpoint (online view or Online & Diagnostics).

- Topology view:

  Offline view: As configured. No interconnection is shown for ports with partner ports configured as "Setting partner by user program".

  Online view: Ports and interconnections with deactivated IO devices are shown in a different shade of green as error-free ports and interconnections of activated IO devices.

- Representation in the Web server:

  The names of devices are shown as configured (Properties > General > Project information).

  The assigned PROFINET device name for the CPU is shown on the "Communication" website, at the "Parameter" tab.

  IP address parameters: Currently assigned IP address parameters are shown on the site "Module state".

  Topology: The current topology resulting from any customizations via user program is shown in the Web server. IO devices configured as optional are shown as "deactivated" IO devices in the Web server.

Rules

The rules for standard machine projects as described here (Page 230) apply.

For configuration-controlled IO systems, the following additional rules apply:

- When configuring MRP (Media Redundancy Protocol):

  The ports configured as ring ports must not be interlinked via user program.

  However, devices with ring ports (devices of an MRP domain) can be optional IO devices.
- When configuring docking stations (= IO devices changing during operation):

  Neither the docking station nor the first IO device of a docking unit may be optional IO devices.

  The ports of the docking units must not be interlinked via user program.
- When configuring IRT:

  The order of synchronized IO devices ("IRT devices") must be defined by the configuration and must not be changed in the different variants of a standard machine. For this reason, the ports of the IRT devices must not be interlinked via user program.

  However, you have the possibility to configure IRT devices primarily as optional IO devices.

  You also have the option to interconnect, by user program, RT devices that are, for example, separated from this line by a switchport (see figure).

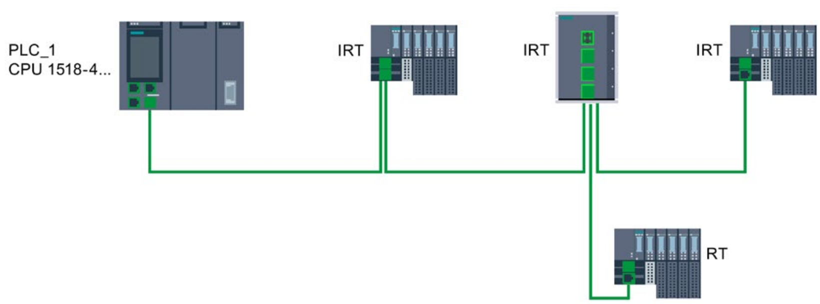

Figure 5-90 Example: Configuration control for IO systems with separated RT device

5.10 Saving energy with PROFIenergy

Saving energy with PROFIenergy

PROFIenergy is a PROFINET-based data interface for switching off consumers centrally and with full coordination during pause times regardless of the manufacturer or device type. Through this, the process should only be provided with the energy that is absolutely required. The majority of the energy is saved by the process; the PROFINET device itself only contributes a few watts of savings potential.

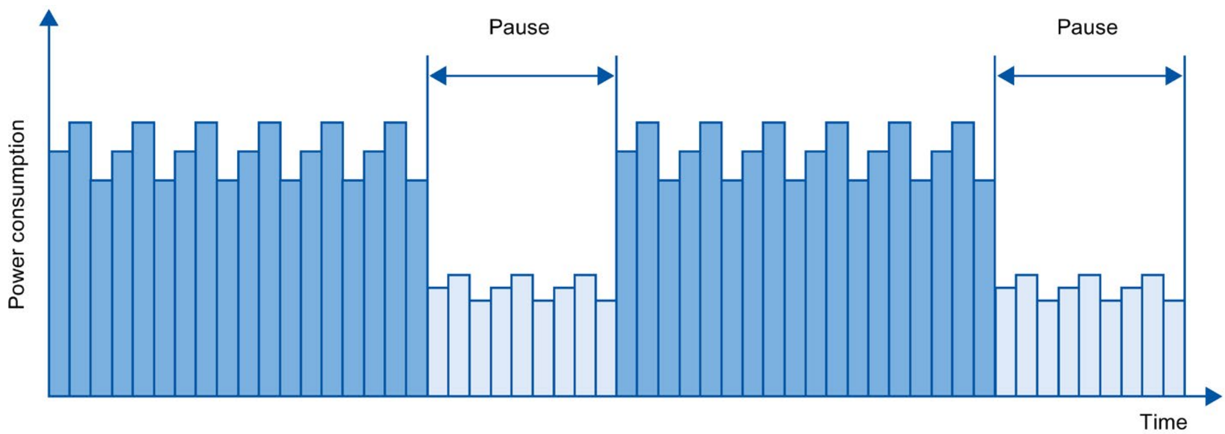

Figure 5-91 Energy savings during pauses with PROFIenergy

Basic information

In order to use the PROFIenergy functionality, the existing IO controller has to be "upgraded" to a so-called "PROFIenergy controller" by means of a function block in the PROFINET IO system and at least one PROFIenergy-capable IO device ("PROFIenergy device") has to exist. The PROFIenergy commands (for example to start or end a pause) are sent by the "PROFIenergy controller" to the individual "PROFIenergy devices". Each "PROFIenergy device" decides individually how it responds to the PROFIenergy command (response is device- and manufacturer-specific).

No additional hardware is needed; the PROFIenergy commands are directly interpreted by the PROFINET devices.

Principle of operation

At the beginning and end of pauses, the system manager enables or disables the pause function of the system; then the IO controller sends the PROFIenergy command "Start_Pause"/"End_Pause" to the PROFINET devices. The device interprets the contents of the PROFIenergy command and switches off or back on.

Through other PROFIenergy functions, device information can be accessed during pauses. The user can use this information in order to optimally time the transfer of the "Start_Pause"/"End_Pause" command.

PROFIenergy instructions for IO controllers

Two instructions are needed for controlling and monitoring the PROFIenergy functions.

The instruction PE_START_END allows you to easily activate and deactivate the idle state of PROFINET devices. This occurs by means of an incoming edge or outgoing edge. The instruction PE_START_END provides a simple interface for implementing the PROFIenergy commands Start_Pause and End_Pause.

The instruction PE_CMD allows you to transmit all PROFIenergy commands, including Start_Pause and End_Pause. The other commands can be used, for example, to query the current status of the PROFINET device or the behavior during the pauses. The instruction PE_CMD is a convenient means for handling all PROFIenergy functions.

PROFIenergy instruction for I-devices

The instruction PE_I_DEV allows you to also implement PROFIenergy on I-devices. The instruction receives PROFIenergy commands on the I-device and forwards these to the user program for execution. After executing the command, the user program calls the PE_I_DEV instruction again in order to send the acknowledgment to the IO controller. For these replies, each command offers you a helper instruction that supplies the reply data to the instruction.

The instructions can be found in the "Instructions" task card of the STEP 7 program editor.

Configuration and programming

The functions can be comfortably integrated into existing systems. No configuration is required for the use of PROFIenergy. However, amendments to the user program are required:

- Before the "Start_Pause" command, you must ensure that your system is brought into a condition that is suitable for a pause.
- A sequential control system for the beginning of the pause of the devices and for the punctual restarting of the device on break must be programmed (depending on the required startup times that the respective PROFINET device demands).
- The error messages of the PE_CMD instruction must be evaluated, and the required reaction must be programmed (for example, cancellation or continuation of further commands on lower-level PROFINET devices).

Note

In the case of the ET 200S distributed I/O system, you have to configure the application of PROFIenergy in STEP 7. You configure PROFIenergy by selecting the "Use energy saving for this potential group" check box in the PM-E DC24V/8A RO power module.

If you want to use PROFIenergy for an I-device, you have to configure this in STEP 7. Information about configuring PROFIenergy for an I-device is available in the section Configuring PROFIenergy with I-devices (Page 141).

Application examples

- SIMATIC S7 library for simple configuration of PROFIenergy.

  The application example is available here
  (https://support.industry.siemens.com/cs/ww/en/view/41986454).

5.11 Docking systems

Using alternating IO devices ("alternating partners") during operation in a docking station

The following figure shows an automation cell with a docking station and several docking units.

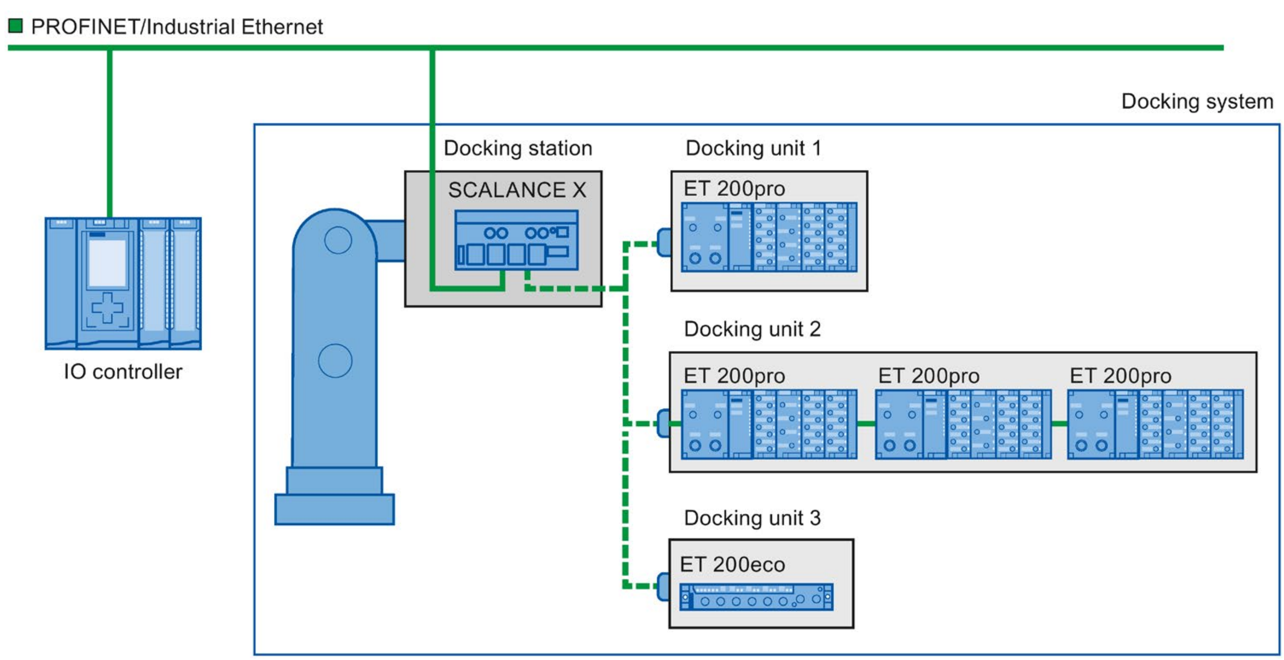

Figure 5-92 Alternating IO devices (partner ports) in a docking system

Area of application for alternating IO devices during operation

You can use the PROFINET function "Alternating IO devices during operation" ("alternating partners"), for the tool changeover for robots, for example. Typical tools include:

- Welding guns
- Positioning tools for manufacturing parts

Requirements for interconnecting alternating partner ports during operation

You can interconnect IO devices with alternating partner ports during operation in the following situations:

- The alternating IO device (docking unit) has no IRT communication configured.
- The PROFINET interface is connected to the Ethernet subnet.
- The PROFINET devices support topology configuration.
- The IO controller, the alternating IO devices (docking unit) and the switch (docking station) on which the alternating IO devices are to be operated support this feature.

Note

Unique IP address

Each docking unit of a docking system must be configured with a unique IP address in a shared project and operated on the same IO controller as all other docking units of the system.

Applicative conditions

The following points should be observed when implementing a docking system with alternating IO devices during operation:

- The IO devices of all docking units must be deactivated by default in the configuration.
- At any time, only one docking unit can be active, i.e., only the IO devices of one docking unit can be activated. All IO devices of other docking units must be deactivated or become deactivated before the IO devices of a docking unit can be activated. You activate an IO device with the "D_ACT_DP" instruction.
- A physical connection to this docking unit and its IO devices must be created in order to activate a docking unit. The IO devices are then switched on (power on). At the same time, all the IO devices of this docking unit must be activated in the user program with the "D_ACT_DP" instruction.

Note

Automatic deactivation in "Startup" mode of the CPU

If the CPU is in "Startup" mode, IO devices of a docking system that alternate during operation are deactivated automatically.

- After the feedback "IO device activated", you can access the IO device by means of direct I/O access.
- Call the "D_ACT_DP" instruction to activate and deactivate the IO device as close as possible to the start of the OB 1 cycle.

Note

Number of alternating IO devices during operation ("alternating partner port") - number of docking units

If you wish to achieve the shortest possible tool changeover times, you must observe the following points that are dependent on the CPU or the CP that is being used:

- Only those IO devices that have been configured with the PROFINET function "Prioritized startup" can start up in an optimized fashion. The number of IO devices with configuration for this PROFINET function is restricted.
- Only a limited number of IO devices can be activated at the same time. This number depends on the available "D_ACT_DP" resources. A docking unit should not contain more than the corresponding number of IO devices. If more IO devices are operated in a docking unit, the IO devices must be activated one after the other, which takes correspondingly longer.

Example: An S7-CPU 1516-3 PN/DP can operate a maximum of 32 IO devices with prioritized startup and can simultaneously activate 8 IO devices by means of "D_ACT_DP".

Therefore, for a scheduled optimum use, a docking unit should include no more than 8 IO devices and no more than 32 IO devices should be used in all the alternating docking units.

5.11.1 Configuring docking systems

Configuring docking systems

The possible connections to the individual IO devices must be configured in STEP 7.

Procedure in STEP 7

1. Configure your system as usual, but do not yet configure the topological interconnections of the individual PROFINET devices.
2. Navigate to the "Topology view" tab.
3. Select the port which you want to operate with alternating partners during operation.
4. Navigate to the "Properties" tab of the inspector window and select "Port interconnection" in the area navigation.
5. Under "Partner port", select the "Alternative partners" option.
6. Select the desired partner ports: To do this, click "<Add alternative partners... and choose a partner port. Repeat this process until all required partner ports are connected.

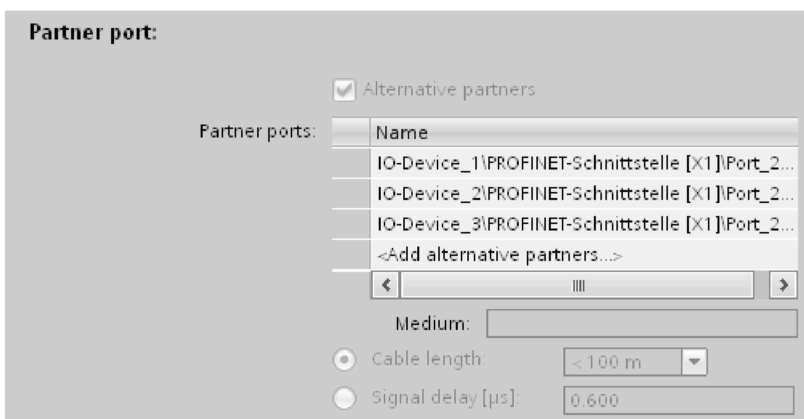

Figure 5-93 Configuring docking systems in STEP 7

Tip: You can also use drag-and-drop operation to connect alternative partner ports in the topology view.

Result

You have interconnected the respective port with one or more alternating IO devices. The connections with the individual alternating partner ports during operation are shown in the topology view by a green, dashed line.

Multiple IO devices as a docking unit ("Alternating partner port")

A docking unit may also consist of several IO devices connected in series. If you use IO devices connected in series as a docking unit, ensure that the topology of the IO devices is configured. A docking unit consisting of two IO devices connected in series (Tool_3_1 and Tool_3_2) is shown at the bottom right in the figure below.

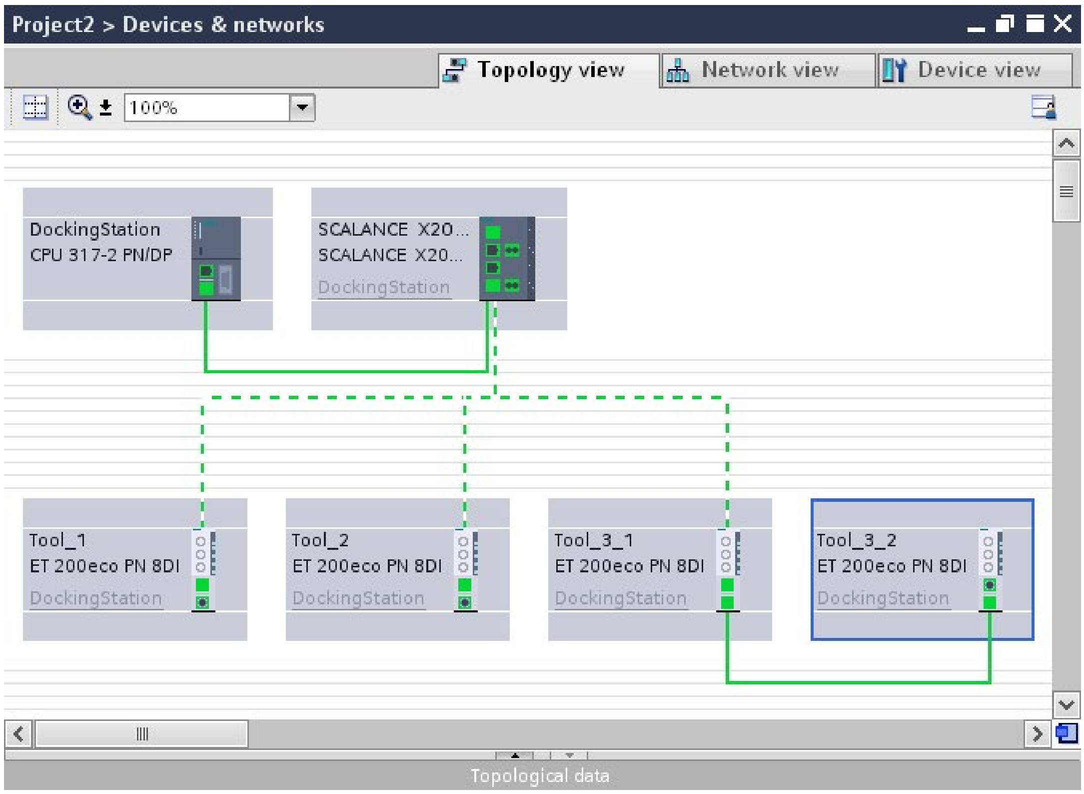

Figure 5-94 Docking system in the topology view of STEP 7

Restriction in the interconnection

The interconnection with a partner port is not possible in the following cases:

- The partner port does not have a suitable type of cable. In this case, a media convertor from the catalog must be inserted.
- The partner port is blocked (deactivated).
- The two ports that are to be interconnected belong to the same interface (it is only possible to interconnect the ports from different interfaces in a station).
- The two ports that are to be interconnected belong to different Ethernet subnets.

Deleting interconnections

Select the port of the alternating partner and remove the interconnection with the "Remove" button.

5.12 Accelerating startup

5.12.1 Options for accelerating the startup of IO devices

Reducing the startup time of IO devices

The time needed for the startup of IO devices depends on various factors and can be reduced in different ways.

You can achieve a significant reduction in the startup time using the "Prioritized startup" PROFINET function.

To further reduce the startup times, use the following measures in addition to the "Prioritized startup":

- Optimize the port settings
- Optimize the cabling of the ports
- Perform measures in the user program (for docking systems only)

These measures will accelerate the startup of IO devices even without "Prioritized startup". However, you can only achieve the fastest startup times of about 500 ms by combining all the measures with "Prioritized startup".

Note

Startup time up to 8 s

In the following situation, despite prioritized startup, a startup time of up to 8 s may occur:

On a docking point, multiple physical IO devices dock as an IO device with identical device names and identical IP configurations (for example, docking point for automatic transport system).

Dependencies

The length of the startup time for an IO device (distributed I/O) with the "Prioritized startup" PROFINET function depends on the following factors:

- IO devices (distributed I/O)
- IO structure of the IO device (distributed I/O)
- Modules of the IO device (distributed I/O)
- IO controller
- Switch
- Port setting
- Cabling
- Configured RT class of the IO device

Note

Startup time and RT class of the IO device

An IO device with IRT communication requires longer than an IO device with RT communication for the accelerated startup.

The longer startup for IRT is due to the necessity of synchronizing the IO device before the communication can be set up.

Note

IWLAN and prioritized startup

PROFINET devices which are connected via access points to PROFINET IO do not support the "Prioritized startup" PROFINET function.

5.12.2 Prioritized startup

Definition

Prioritized startup refers to the PROFINET function for accelerating the startup of IO devices in a PROFINET IO system with RT communication. It shortens the time that the respective configured IO devices require in order to reach the cyclic user data exchange in the following cases:

- After the power supply has returned
- After a station has returned
- After activation of IO devices

> **WARNING**
>
> **Data exchange despite multiple use IP addresses/device names in PROFINET IO system**
>
> To achieve higher ramp-up times, the IO controller checks the uniqueness of device name of IP address parallel to the device ramp-up. In the case of incorrect or double assignment of device name or IP address, a short-time data exchange is possible until the IO controller reacts to the error. In this time the IO controller can exchange IO data with the false device.
>
> During commissioning, ensure that no IP addresses / device names are assigned multiple times in the PROFINET IO system.

Advantages

The PROFINET functionality "prioritized startup" enables PROFINET IO applications in which machine parts or tools and their IO devices have been permanently replaced. Waiting times of several seconds between the scheduled processes of the restart are reduced to a minimum by this optimization. This accelerates the production process with alternating IO devices (PROFINET functionality "docking systems"), e.g. in tool changer applications, and enables a greater throughput in production.

The PROFINET functionality "prioritized startup" also offers a considerable increase in performance for applications where a quick startup time of the IO devices after "power on" or after station failure / station return is required, or when activating IO devices.

Area of application

You can use prioritized startup, for example, for changing tools for robots in the automotive industry. Typical tools are, for example:

- Welding guns
- Positioning tools for the manufacture of car body parts

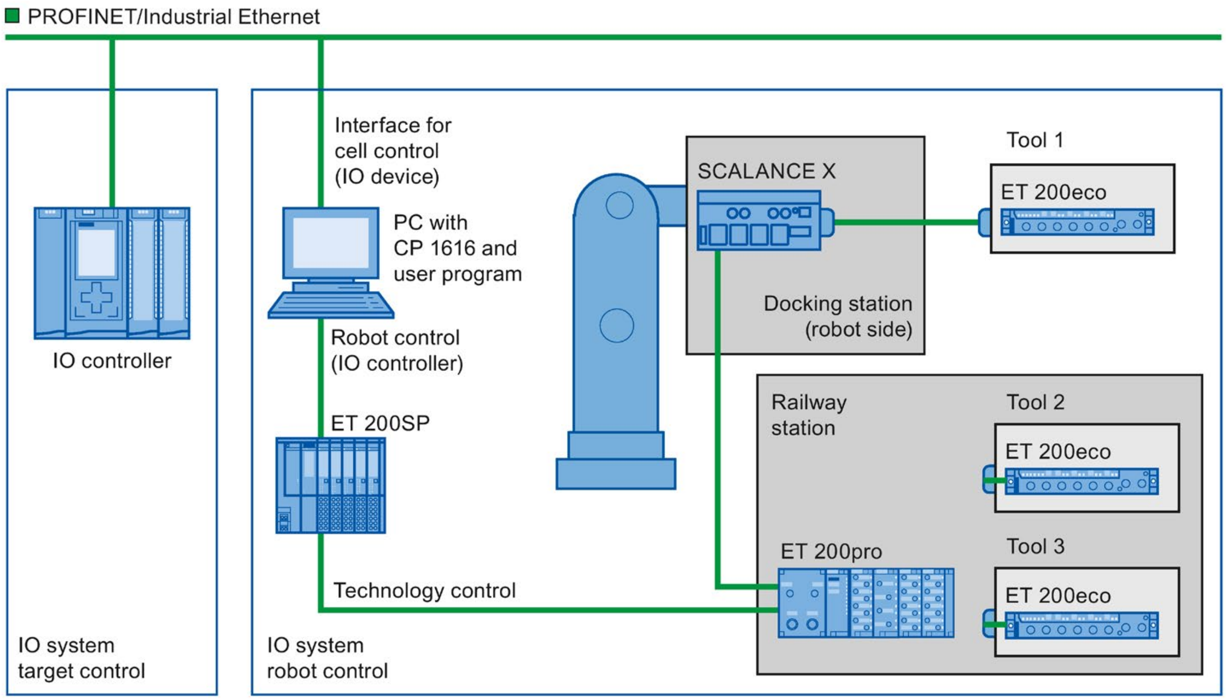

Figure 5-95 Example configuration of a tool changer: Tools 1-3 configured with "Prioritized startup".

5.12.3 Configuring prioritized startup

Requirements

You can enable the "Prioritized startup" PROFINET function for the IO devices (distributed I/O) only in the following cases:

- The IO controller used can prioritize selected IO devices during startup.
- The IO device used supports prioritization.

Procedure

1. Select the IO device in the network view or device view for which you wish to accelerate startup.
2. Open the IO device properties in the Inspector window.
3. Select "PROFINET interface > Advanced options > Interface options".
4. Select the "Prioritized startup" check box.

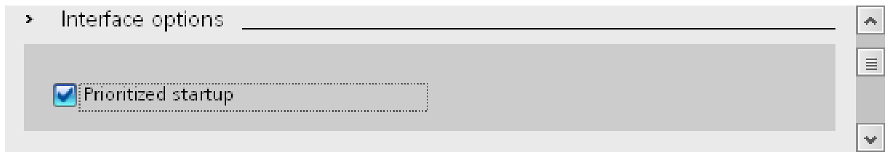

Figure 5-96 Configuring prioritized startup in STEP 7

5. Download the configuration to the IO controller.

Note

Prioritized startup after a startup for the first time

A prioritized startup of the IO device is always available to you after the first configuration of this IO device in the very first startup of the PROFINET IO system. Even in the case of spare parts or a reset to factory settings, the first startup is a standard startup for the respective configured IO devices.

Note

Number of IO devices (distributed I/O) with prioritized startup

You can only start up a maximum number of IO devices with the "Prioritized startup" PROFINET functionality within one PROFINET IO system. This maximum number depends on the IO controller used.

5.12.4 Optimize the port settings

Optimizing port settings on the IO device and IO controller

The transfer medium and the duplex option are checked during startup of the IO device in the case of copper cabling.

These checks require time, but with specific presets of these options you can save the time the check requires. Make certain that the settings made correspond to the actual conditions (using the correct cables).

Optimizing port settings for accelerated startup

To optimize port settings for accelerated startup, follow these steps:

1. Select the ports of the IO controller or the partner port of the corresponding IO device.
2. Navigate to "Port options > Connection" in the Inspector window. Select the setting "TP 100 Mbps full duplex" under "Transmission rate/duplex"
3. Clear the "Enable autonegotiation" check box.

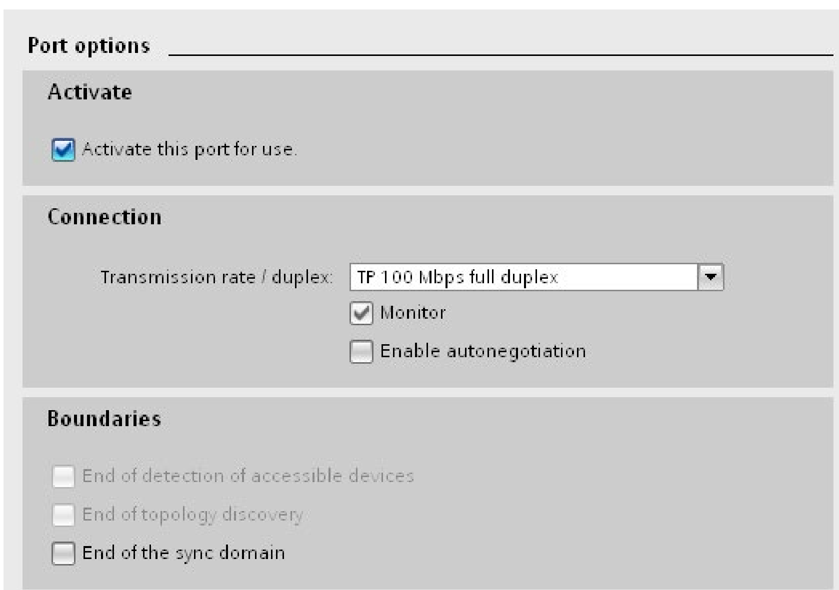

Figure 5-97 Optimizing port settings for accelerated startup in STEP 7

These settings are automatically applied during topology configuration for the partner port.

5.12.5 Optimize the cabling of the ports

Requirements

You have made the following settings for the port in question to reduce the startup time of the IO device:

- Fixed transmission rate
- Autonegotiation deactivated

The time for negotiating the transmission rate during startup is saved.

If you have disabled autonegotiation, you must observe the cabling rules.

Properties of ports

PROFINET devices have the following two types of ports:

Type of port	PROFINET devices
Switch port with crossed pin assignment	For IO devices: Port 2 For S7-CPUs with two ports: Ports 1 and 2
Terminal device port with normal pin assignment	For IO devices: Port 1 For S7-CPUs with one port: Port 1

Crossed pin assignment means that the pin assignment for the ports for sending and receiving between the respective PROFINET devices is inverted internally.

Validity of the cabling rules

The cabling rules described in the following paragraph apply exclusively for the situation in which you have specified a fixed port setting in STEP 7.

Rules for cabling

You can connect several IO devices in series using patch cables. To do this, connect port 2 of the IO device (distributed I/O) with port 1 of the next IO device. The following graphic provides an example with two IO devices.

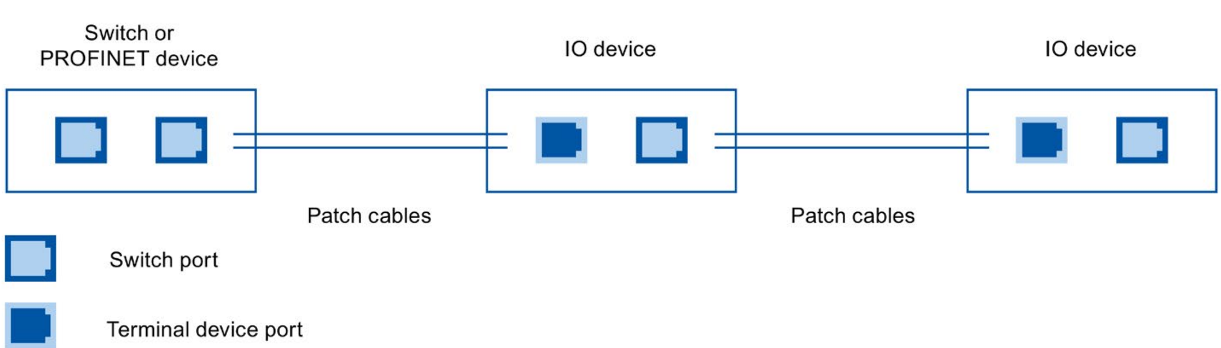

Figure 5-98 Optimized cabling for accelerated startup

5.12.6 Measures in the user program

Introduction

You can make certain changes in the user program to accelerate the startup for IO devices of docking systems that alternate during operation.

Making the required changes to the user program

To accelerate the startup by making changes to the user program, follow these steps:

1. Call the "D_ACT_DP" instruction to activate and deactivate the IO device at the start of the OB 1 cycle.

   If the IO device is replaced, the device that is no longer required must be deactivated and the new device must be activated.
2. If you control the "Power ON" command of the IO devices via the application, then start the activation of the IO devices via the corresponding call of the "D_ACT_DP" instruction as near to the same time as possible. The IO device has to be physically connected for this.
3. You access the IO device using direct access commands after the "D_ACT_DP" instruction has provided the feedback "IO device activated".

PROFINET with the redundant S7-1500R/H system 6

Introduction

The same basic rules apply to PROFINET IO communication with the redundant S7-1500R/H as with the S7-1500 automation system. The redundant S7-1500R/H system exchanges IO data cyclically with the IO devices.

When configuring PROFINET with the redundant S7-1500R/H system, you must observe a few specifics, e.g. special configuration requirements.

The redundant S7-1500R/H system supports a limited scope of PROFINET functions.

Limitations

- Real-time communication:
  - RT with a fixed send clock of 1 ms
  - No IRT
  - No MRPD redundancy method
  - No PROFINET with performance upgrade
- No isochronous mode
- No operation as I-device
- No access to shared devices
- No support of docking systems
- No support of series machine projects
- Port options (only for PROFINET interface X1):
  - No port disabling possible
  - No configuring of boundaries possible
- Functionality as IO controller:
  - No prioritized startup
  - No enabling/disabling of IO devices
  - No support of series machine projects
  - No nested IO systems (e.g. via IE/PB Link)

- PROFINET interface X2 does not support IO functionality.
- No diagnostics using the web server
- No support of the following OBs:
  - OB 55 "Status interrupt OB"
  - OB 56 "Update interrupt OB"
  - OB 57 "OB for vendor or profile-specific interrupt"

6.1 Configuring PROFINET IO on a redundant S7-1500R/H system

Introduction

The redundant S7-1500R/H system uses media redundancy (MRP) in the PROFINET ring. The IO devices must support system redundancy S2 for operation in a redundant S7-1500R/H system.

Media redundancy in the redundant S7-1500R/H system

The two CPUs of the redundant system must be located in a PROFINET ring that uses the media redundancy method MRP. All PROFINET devices in the PROFINET ring are connected to the S7-1500R/H in a media-redundant manner. If the PROFINET ring is interrupted, reconfiguration may occur. After a short reconfiguration time, the PROFINET devices can be accessed again via an alternative path.

H-Sync Forwarding

H-Sync Forwarding enables a PROFINET device with MRP to forward synchronization data (synchronization frames) only within the PROFINET ring.

Through H-Sync Forwarding, the synchronization data is also forwarded during reconfiguration of the PROFINET ring. This reduces the cycle time or makes the CPU switchover time less dependent on the re-configuration time of the PROFINET ring.

H-Sync Forwarding is not relevant for redundant S7-1500H systems.

H-Sync Forwarding is recommended for PROFINET devices that you use in the PROFINET ring of redundant S7-1500R systems.

Note

If you use PROFINET devices that do not support H-Sync Forwarding in S7-1500R, additional cycle time increases may occur in system state RUN-Redundant. If the cyclic program exceeds the cycle monitoring time, the timeout OB (OB 80) may be started.

System redundancy S2

An IO device with system redundancy S2 supports system redundancy ARs. The system redundancy ARs can be present in duplicate (redundantly). Thus, an IO device supports ARs of 2 IO controllers simultaneously (with respect to the same modules).

A system redundancy AR can be either a primary AR or a backup AR. There can be only one primary AR at a time for an IO device. The other AR, if present, must be a backup AR. An IO device activates the data of the primary AR at the outputs. The data of the backup AR is only saved.

- Behavior in system state RUN-Redundant:

  Both CPUs are IO controllers. The PROFINET communication runs simultaneously on both system redundancy ARs, in each case between one of the CPUs (IO controllers) and the IO device. If the primary CPU now fails, the backup CPU becomes the primary CPU and, at the same time, the backup AR changes over to primary AR. The data of this AR becomes active at the outputs.

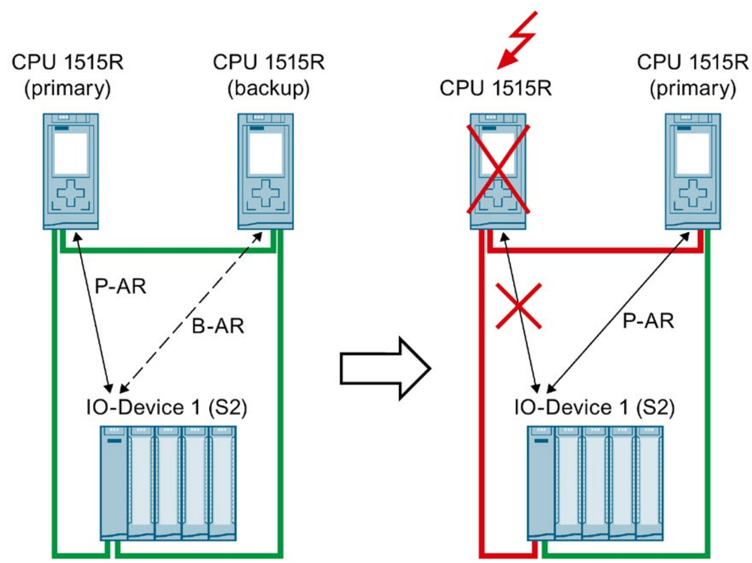

Figure 6-1 Behavior of IO device with system redundancy S2 in system state RUN-Redundant and following failure of the primary CPU

- Behavior in system state RUN-Solo:

  Only the primary CPU is an IO controller. The PROFINET communication runs on the primary AR between the primary CPU (IO controller) and the IO device. There is no AR between the backup CPU and the IO device.

You configure system redundancy S2 for an IO device in STEP 7 by assigning the IO device to both CPUs of the redundant S7-1500R/H system.

Configuration requirements for a ring topology with the redundant S7-1500R system

- The two CPUs have the media redundancy role "Manager (auto)".
- All other devices in the PROFINET ring have the media redundancy role "Client".
- All IO devices that are assigned to the redundant S7-1500R/H system support system redundancy S2.
- No other redundant S7-1500R/H system is present in the PROFINET ring.
- Port interconnection:
  – The two CPUs are directly interconnected via one of the two ports of PROFINET interface X1. No other devices of the ring are located in between.
  – The two CPUs can be indirectly interconnected via the other two ports. The other devices of the ring are located in between. See the examples below.
- Max. number of IO devices: 64
- Number of PROFINET devices (switches, S7-1500R/H CPUs, S7-1500 CPUs (V2.6 or higher) and HMI devices) in the PROFINET ring:
  – max. 50 (recommendation: max. 16)

Note

Recommendation: The number of devices in the PROFINET ring influences the availability of the S7-1500R system. For this reason, operate a maximum of 16 PROFINET devices (including R-CPUs) in the PROFINET ring. If you operate significantly more devices in the PROFINET ring, the availability of the IO devices and R-CPUs is reduced. The technical specifications in the documentation relate to the case in which the maximum recommended number of 16 PROFINET devices are operated in the ring in S7-1500R

Configuration requirements for a ring topology with the redundant S7-1500H system

- The two CPUs have the media redundancy role "Manager (auto)".
- All other devices in the PROFINET ring have the media redundancy role "Client".
- All IO devices that are assigned to the redundant S7-1500R/H system support system redundancy S2.
- No other redundant S7-1500R/H system is present in the PROFINET ring.

PROFINET IO configurations with the redundant S7-1500R/H system

The following figures show you examples of PROFINET IO configurations with the redundant S7-1500R/H system.

All the figures use the following abbreviations for ARs:

- SR-AR: System redundancy AR between an IO device (S2) and one of the CPUs of the redundant S7-1500R/H system
- AR: "normal" AR between an IO device (S1) and the associated IO controller

All configurations use the CPU 1515R as an example. The PROFINET configurations shown also work with the CPU 1513R and CPU 1517H.

IO devices with system redundancy S2 in the PROFINET ring

The redundant S7-1500R system consists of the two CPUs 1515R and two IO devices in the PROFINET ring. The two IO devices are connected in a system-redundant and media-redundant manner.

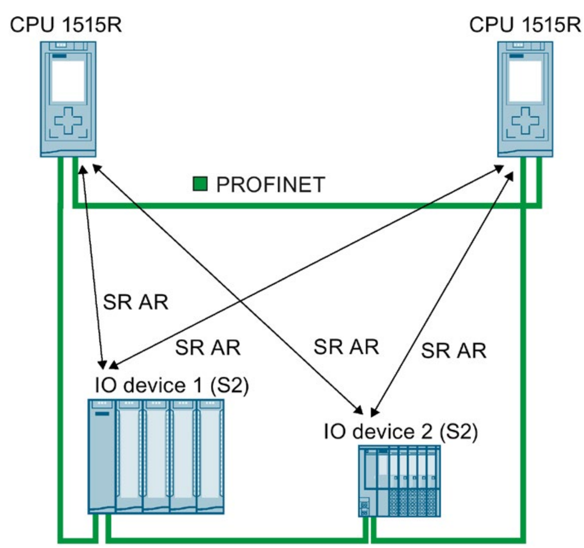

Figure 6-2 Example of a redundant S7-1500R system with two IO devices in the PROFINET ring

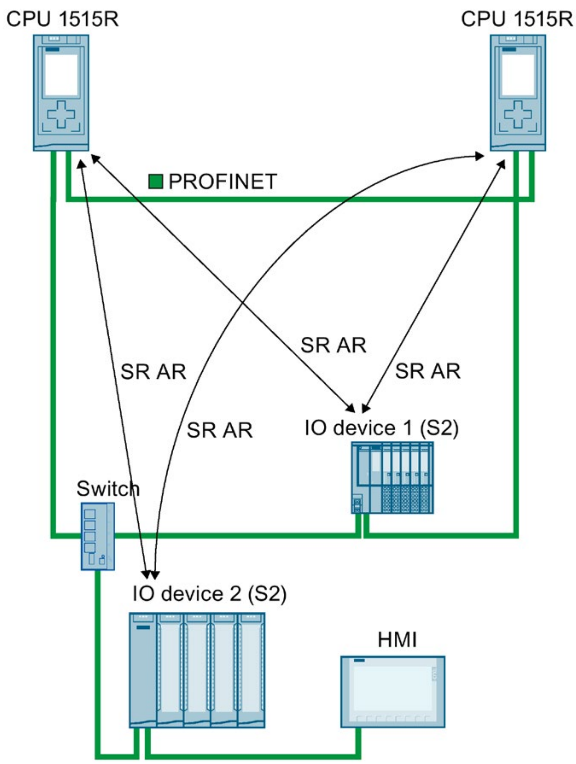
PROFINET devices downstream of a switch

To connect additional PROFINET devices to the PROFINET ring, use a switch. For the redundant S7-1500R system, ensure that a switch in the PROFINET ring supports MRP.

You connect the following devices to the PROFINET ring with a switch.

- IO devices with system redundancy S2
- PROFINET devices without system redundancy S2, e.g. HMI devices

The following figure shows a redundant S7-1500R system with connected PROFINET devices downstream of a switch.



IO device 1 (S2)	IO device 1 is located in the PROFINET ring and is connected to the redundant S7-1500R/H system in a system-redundant and media-redundant manner.
Switch	The switch is located in the PROFINET ring. The switch supports the media redundancy protocol MRP.
IO device 2 (S2)	IO device 2 is connected to the redundant S7-1500R/H system via the switch. IO device 2 is connected to the redundant S7-1500R/H system in a system-redundant manner.
HMI device	The HMI device is connected to the redundant S7-1500R/H system via the switch.

Figure 6-3 PROFINET devices downstream of a switch

Additional PROFINET IO system in the configuration

The configuration can also contain additional IO controllers with their own IO devices. To ensure that enough bandwidth is available in the PROFINET ring for the redundant S7-1500R/H system, place additional IO controllers with their I/O downstream of a switch.

When determining the maximum number of IO devices inside and outside the PROFINET ring, the redundant system does not detect the S7-1500 CPUs and their IO devices. If you use S7-1500 CPUs, you must check the maximum number yourself.

The following figure shows a redundant S7-1515R system. An additional PROFINET IO system with a CPU 1516 as IO controller is located downstream of the switch. The IO controller is assigned its own IO device (S1).

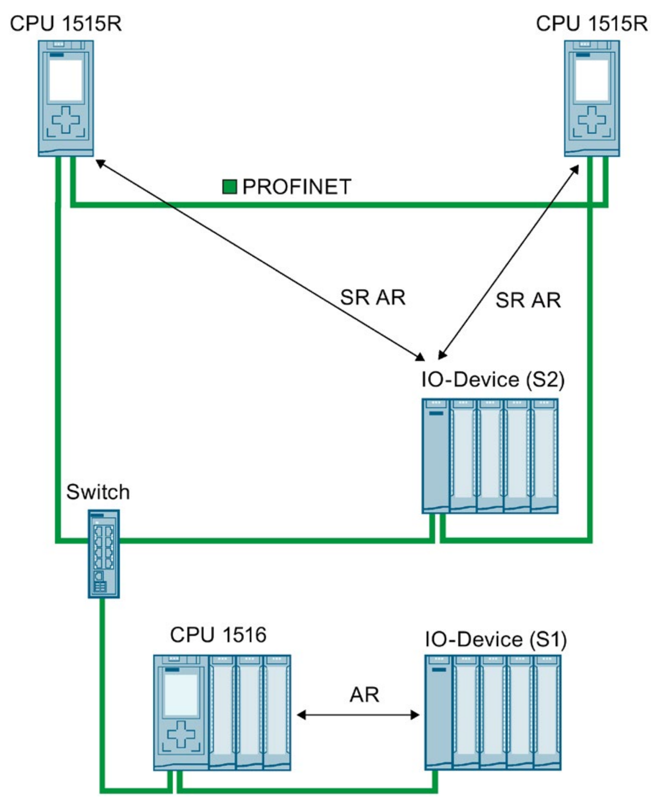


Figure 6-4 Example of a redundant S7-1500R system with an additional PROFINET IO system

Because the redundant S7-1500R/H system does not support I-devices, direct cyclic IO data exchange with the other IO controller is not possible.

Connection to another PROFINET IO system via the PN/PN coupler

The redundant S7-1500R/H system cyclically exchanges IO data with another PROFINET IO system via a PN/PN coupler.

In the following figure, the PN/PN coupler connects a redundant S7-1515R system to another PROFINET IO system. The left side of the PN/PN coupler is assigned to the redundant S7-1515R system. The left side of the PN/PN coupler is system-redundant and media-redundant. The right side of the PN/PN coupler is assigned to the CPU 1516 (IO controller). The PROFINET IO system of the CPU 1516 has no redundancy in this example.

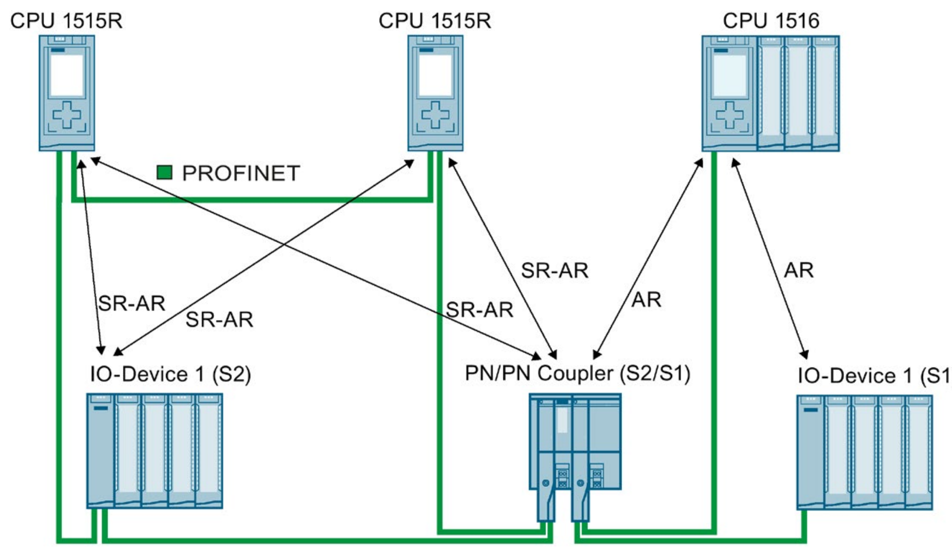

Figure 6-5 Configuration with the PN/PN coupler with one-sided system redundancy (S2/S1)

Connection to an additional redundant S7-1500R/H system via the PN/PN coupler

Two redundant S7-1500R/H systems cyclically exchange IO data via the PN/PN coupler.

In the following figure, the PN/PN coupler connects two redundant S7-1515R systems to each other. Each of the two PN/PN coupler sides are assigned to a redundant S7-1515R system. Each of the two sides of the PN/PN coupler are connected to the respective redundant S7-1515R system in a system-redundant and media-redundant manner.

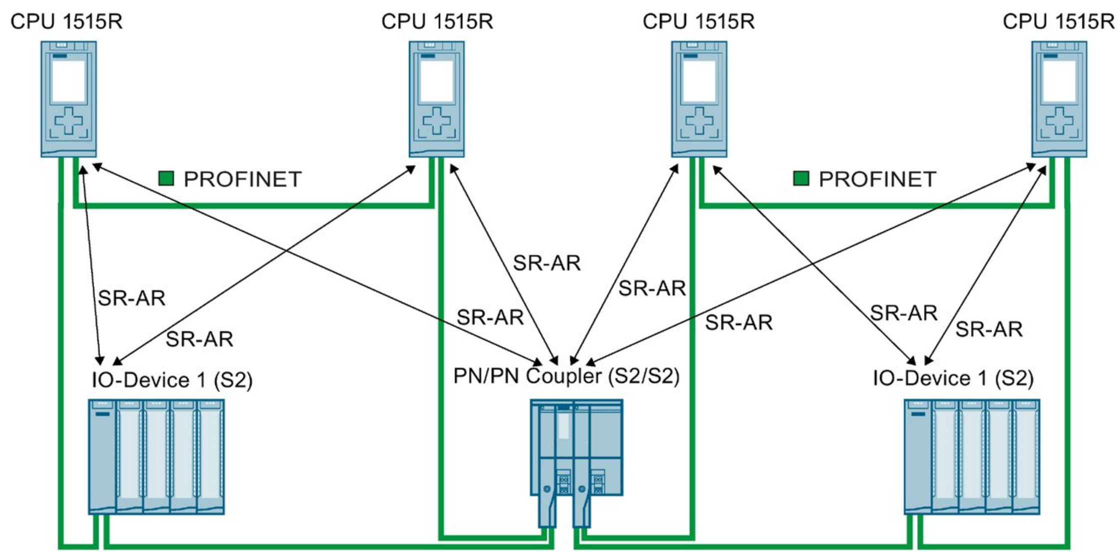

Figure 6-6 Configuration with the PN/PN coupler with two-sided system redundancy (S2/S2)

Reference

You can find more information on the PN/PN coupler in the PN/PN Coupler (https://support.industry.siemens.com/cs/ww/en/view/44319532) manual.

6.2 Configuring an IO device with system redundancy S2 in the redundant S7-1500R/H system

Requirements

- Redundant S7-1500R/H system
- IO device supports system redundancy S2, e.g. IM 155-6 PN HF as of firmware version V4.2

Procedure

To assign an IO device with system redundancy S2 to the redundant S7-1500R/H system, follow these steps:

1. In the network view of STEP 7, select the PROFINET interface of the IO device.
2. Using drag-and-drop, draw a line between the PROFINET interface of the IO device and the PROFINET interface X1 of the left CPU.

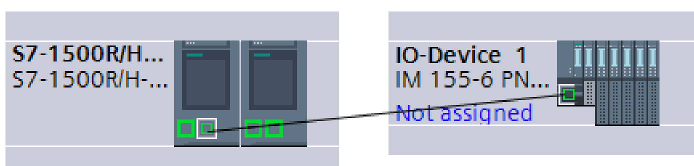

Figure 6-7 Assigning IO device to the left CPU

The IO device is assigned to the left CPU.

3. Using drag-and-drop, draw a line between the PROFINET interface of the IO device and the PROFINET interface X1 of the right CPU.

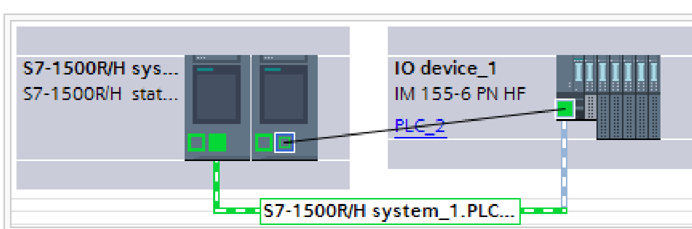

Figure 6-8 Assigning IO device to the right CPU

Result: The IO device is connected to the redundant S7-1500R/H system in a system-redundant manner.

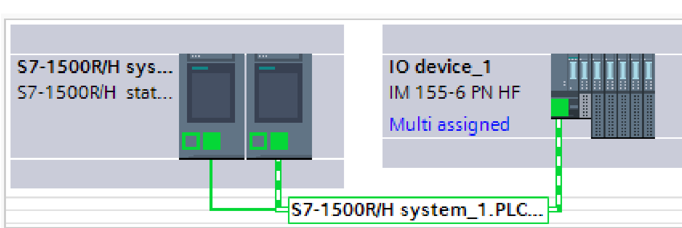

Figure 6-9 IO device assigned in a system-redundant manner

6.3 Configuring media redundancy (MRP) for a configuration with the redundant S7-1500R/H system

Requirements

- Redundant S7-1500R/H system
- All devices in the ring support the media redundancy protocol MRP.
- IO devices are assigned to the redundant S7-1500R/H system.

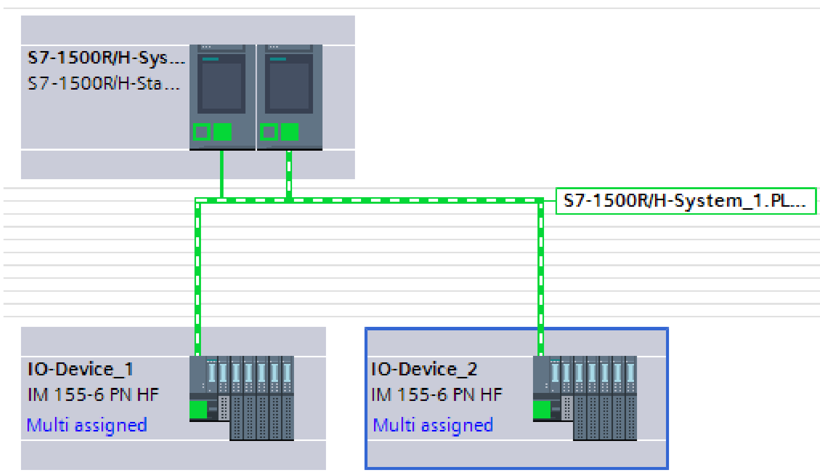

Figure 6-10 Example configuration: Configuring MRP for S7-1500R/H

MRP role of the CPUs of the redundant S7-1500R/H system

As soon as you create a redundant S7-1500R/H system in STEP 7, STEP 7 automatically assigns the MRP role "Manager (auto)" to the PROFINET interfaces X1 of both CPUs.

Defining the MRP role for additional devices of the ring in STEP 7

To specify the media redundancy for additional devices in the ring, follow these steps:

1. In the network view of STEP 7, select the PROFINET interface X1 of one of the two CPUs of the redundant S7-1500R/H system.
2. In the Inspector window navigate to "Properties" > "General" > "Advanced options" > "Media redundancy".
3. Click the "Domain settings" button.

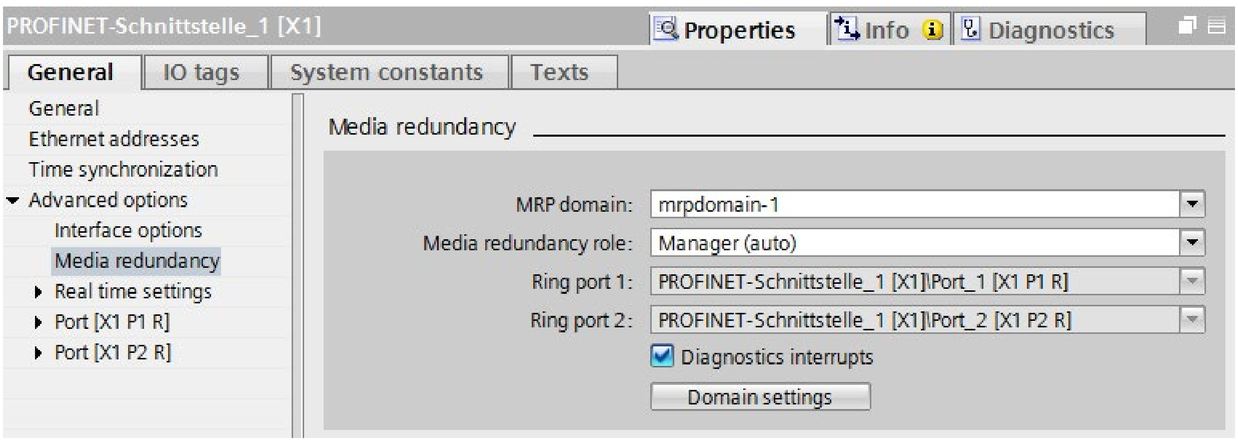

Figure 6-11 S7-1500R/H: MRP role "Manager (auto)"

In the Inspector window, STEP 7 displays the properties of the MRP domain in which the PROFINET interface X1 of the CPU is located.

4. In the "MRP role" column of the "Devices" table, assign the MRP role "Client" to all the other devices of the ring.

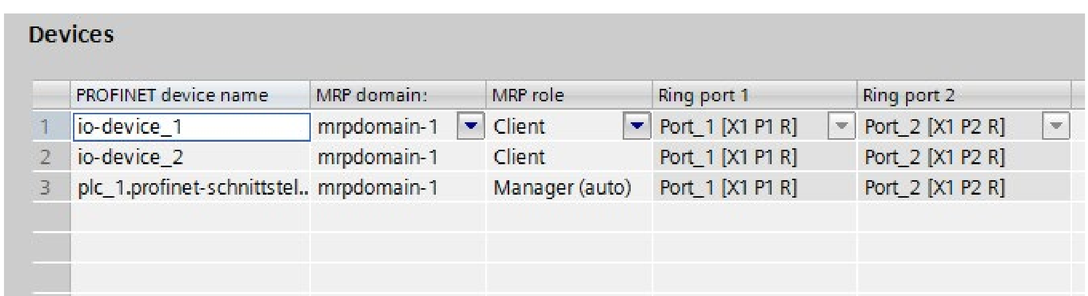

Figure 6-12 S7-1500R/H: Assigning MRP roles for ring devices

Parameter assignment for devices outside the STEP 7 project

Set the MRP role "Client" for the devices of the ring that are not located in STEP 7.
Example: For a switch, set the MRP role "Client" via the web interface of the switch.

Glossary

API

API (**A**pplication **P**rocess **I**dentifier) is a parameter, the value of which specifies the IO data processing process (application).

The PROFINET standard IEC 61158 assigns profiles to specific APIs (PROFIdrive, PROFIsave), which are defined by the PROFINET user organization.

The standard API is 0.

Application

An application is a program that runs directly on the MS-DOS/Windows operating system. An application on the PG is STEP 7, for example.

AR

The AR (**A**pplication **R**elation) comprises all the communication relationships between IO controller and IO device (e.g. IO data, data records, interrupts).

AR is also an addressing level for diagnostic data records.

Asset

An asset is a component of a machine or plant This can be either hardware or software/firmware.

Automation system

Programmable logic controller for the open-loop and closed-loop control of process chains of the process engineering industry and manufacturing technology. The automation system consists of different components and integrated system functions according to the automation task.

Backplane bus

The backplane bus is a serial data bus for module intercommunication and the distribution of the necessary power to the modules. Bus connectors interconnect the modules.

Backup AR

The backup AR is the system redundancy AR between an IO device with system redundancy S2 and the backup CPU of the redundant S7-1500R/H system.

Backup CPU

If the R/H system is in RUN-Redundant system state, the primary CPU controls the process. The backup CPU synchronously executes the user program and can take over the process control on failure of the primary CPU.

Bus

A bus is a transfer medium that interconnects several devices. Data transmission can be performed electrically or via optical fibers, either in series or in parallel.

Communications Cycle and Reservation of Transmission Bandwidth

PROFINET IO is a scalable real-time communication system based on the Layer 2 protocol for Fast Ethernet. With the RT transmission method, two real-time-support performance levels are available for time-critical process data and IRT for high-accuracy and also isochronous processes .

Communications processor

Communication processors are modules used for point-to-point and bus connections.

Configuring

Selecting and putting together individual components of an automation system or installing necessary software and adapting it for a specific application (for example, by configuring the modules).

Consistent data

Data which belongs together in terms of content and must not be separated is known as consistent data.

For example, the values of analog modules must always be handled as a whole, that is, the value of an analog module must not be corrupted as a result of reading out at two different points in time.

CP

→ *Communications processor*

CPU

Central **P**rocessing **U**nit - Central module of the S7 automation system with a control and arithmetic unit, memory, operating system and interface for programming device.

DCP

DCP (**D**iscovery and Basic **C**onfiguration **P**rotocol). Enables the assignment of device parameters (for example, the IP address) using manufacturer-specific configuration/programming tools.

Default router

The default router is used when data has to be forwarded via TCP/IP to a partner located outside the local network.

Determinism

Determinism means that a system responds in a predictable (deterministic) manner.

Device

In the PROFINET environment, "device" is the generic term for:

- Automation systems (for example, PLC, PC)
- Distributed I/O systems
- Field devices (for example, PLC, PC, hydraulic devices, pneumatic devices)
- Active network components (for example, switches, routers)
- Gateways to PROFIBUS, AS interface or other fieldbus systems

Device name (PROFINET device name)

In the PROFINET IO environment, the device name is a unique identifier for the PROFINET IO interface of a device.

Diagnostics

→ *System diagnostics*

Diagnostics buffer

The diagnostics buffer represents a backup memory in the CPU, used to store diagnostics events in their order of occurrence.

Diagnostics error interrupt

Modules capable of diagnostics operations report detected system errors to the CPU by means of diagnostics interrupts.

→ *See also CPU*

DP master

A master which behaves in accordance with EN 50170, Part 3, is known as a DP master.

→ See also Master

DP slave

A slave operated on PROFIBUS with PROFIBUS DP protocol and in accordance with EN 50170, Part 3 is referred to as DP slave.

→ See also Slave

DPV1

The designation DPV1 refers to the functional extension of acyclic services (to include new interrupts, for example) provided by the DP protocol. The DPV1 functionality is integrated in IEC 61158/EN 50170, Volume 2, PROFIBUS.

Duplex

Half duplex: One channel is available for alternating exchange of information.

Full duplex: Two channels are available for simultaneous exchange of information in both directions.

Ethernet

Ethernet is an international standard technology for local area networks (LAN) based on frames. It defines types of cables and signaling for the physical layer and packet formats and protocols for media access control.

GSD file

As a Generic Station Description, this file contains all properties of a PROFINET device that are necessary for its configuration in XML format.

H-Sync Forwarding

H-Sync Forwarding enables a PROFINET device with MRP to forward synchronization data (synchronization frames) only within the PROFINET ring.

Through H-Sync Forwarding, the synchronization data is also forwarded during reconfiguration of the PROFINET ring. This reduces the cycle time utilization.

H-Sync Forwarding is recommended for PROFINET devices that you use in the PROFINET ring of redundant S7-1500R systems.

H-Sync Forwarding is not relevant for redundant S7-1500H systems.

I-device

The "I-device" (intelligent IO device) functionality of a CPU facilitates data exchange with an IO controller, for example, as intelligent preprocessing unit of sub-processes. In its role as an IO device, the I-device is accordingly integrated into a "higher-level" IO controller.

Industrial Ethernet

Industrial Ethernet is a guideline for installing an Ethernet in an industrial environment. The biggest difference from standard Ethernet is the mechanical current carrying capacity and noise immunity of the individual components.

Interrupt

An interrupt is an event that causes the operating system of an S7-CPU to automatically call an assigned organization block (interrupt OB) in which the user can program the desired reaction.

Interrupt, diagnostics

→ *Diagnostics error interrupt*

IP address

To allow a PROFINET device to be addressed as a device on Industrial Ethernet, this device also requires an IP address that is unique within the network. Example: An IPv4 address consists of 4 decimal numbers with the value range 0 to 255. The decimal numbers are separated by periods.

The IP address is made up of the following components:

- Address of the network
- Address of the device (generally called the host or network node).

IRT

IRT is a synchronized communication protocol for cyclic exchange of IRT data between PROFINET devices. A reserved bandwidth is available in the send cycle for IRT data. The reserved bandwidth ensures that the IRT data can be transferred at reserved synchronized intervals, without being influenced also by higher other network loads (such as TCP/IP communication, or additional real-time communication).

LAN

Local **A**rea **N**etwork - a local network to which multiple computers within a company are connected. The LAN therefore has a limited geographical span and is only available to the company or institution.

Line depth

Designates the number of external switches or integrated switches interconnected in series.

MAC address

Worldwide unique device identification for all Ethernet devices. It is assigned by the manufacturer and has a 3-byte vendor ID and 3-byte device ID as a consecutive number.

Every PROFINET device is assigned a worldwide unique device identifier at the factory. This 6-byte long device identifier is the MAC address.

Maintenance Required / Maintenance Demanded

A "Maintenance required" system message can be defined for different wear parameters and an inspection of a component can be recommended, for example, when a certain number of operating hours has elapsed.

The "Maintenance demanded" alarm is sent when the part involved needs to be replaced within a foreseeable period.

(Example printer: The maintenance demanded alarm is sent when the ink/printer cartridges have to be replaced immediately.)

Master

Higher-level, active participant in the communication/on a PROFIBUS subnet. It has rights to access the bus (token), sends data and requests it.

Media redundancy

The so-called **M**edia **R**edundancy **P**rotocol (MRP) enables the configuration of redundant networks. Redundant transmission links (ring topology) ensure that an alternating communication path is made available if a transmission link fails. The PROFINET devices that are a part of this redundant network form an MRP domain.

Micro Memory Card (MMC)

Micro Memory Cards are memory media for CPUs and CPs. Their only difference to the SIMATIC memory card is the smaller size. S7-1500 and ET 200SP-CPUs use SIMATIC memory cards.

MPI

The multipoint interface (**M**ulti **P**oint **I**nterface,MPI) represents the programming device interface of SIMATIC S7. It enables multiple devices (programming devices, text-based displays, OPs) to be operated simultaneously by one or more CPUs. Each device is identified by its unique (MPI) address.

MRPD

MRPD (**M**edia **R**edundancy with **P**lanned **D**uplication of Frames) based on IRT and MRP. To realize media redundancy with short update times, the PROFINET devices participating in the ring send their data in both directions. The devices receive this data at both ring ports so that there is no reconfiguration time.

Network

A network consists of one or more interconnected subnets with any number of devices. Several networks can exist alongside each other.

OB

→ *Organization block*

OPC

OPC (OLE for Process Control) refers to a standard interface for communication in automation technology.

Operating states

Operating states describe the behavior of a single CPU at a specific time.

The CPUs of the SIMATIC standard systems feature the STOP, STARTUP and RUN operating states.

The primary CPU of the S7-1500R/H redundant system has the operating states STOP, STARTUP, RUN, RUN-Syncup and RUN-Redundant. The backup CPU has the operating states STOP, SYNCUP and RUN-Redundant.

Organization block

Organization blocks (OBs) form the interface between the CPU operating system and the user program. The order in which the user program is executed is defined in the organization blocks.

Parameter

1. Tag of a STEP 7 code block:
2. Tag used to set one or several characteristics of a module

In delivery state, every module has practical basic settings, which can be modified by configuration in STEP 7.

There are static and dynamic parameters

PG

→ *Programming device*

PLC

→ *Programmable logic controller*

Primary AR

The primary AR is the system redundancy AR between an IO device with system redundancy S2 and the primary CPU of the redundant S7-1500R/H system.

Primary CPU

If at least one R/H CPU is in RUN state, the primary CPU is the controlling CPU. The primary CPU controls the process (productive data).

The user program is executed identically in the primary CPU and the backup CPU.

Prioritized startup

Prioritized startup denotes the PROFINET functionality for accelerating the startup of IO devices operated on a PROFINET IO system with RT and IRT communication. It reduces the time that the correspondingly configured IO devices require in order to return to cyclic user data exchange in the following cases:

- After the power supply has returned
- After a station has returned
- After activation of IO devices

Process image (I/O)

The CPU transfers the values from the input and output modules to this memory area. At the start of the cyclic program, the CPU transfers the process image output as a signal state to the output modules. The CPU then transfers the signal states of the input modules to the process image of the inputs. Then the CPU executes the user program.

PROFIBUS

Process **Fi**eld **Bus** - European Fieldbus standard.

PROFIBUS device

A PROFIBUS device has at least one PROFIBUS interface with an electrical (RS485) or optical (polymer optical fiber, POF) interface.

PROFIBUS DP

A PROFIBUS with DP protocol that complies with EN 50170. DP stands for distributed I/O (fast, real-time capable, cyclic data exchange). From the perspective of the user program, the distributed I/Os are addressed in exactly the same way as the centralized I/Os.

PROFIBUS Users Organization

Technical committee dedicated to the definition and development of the PROFIBUS and PROFINETstandard. Additional information can be found on the Internet (Page).

PROFIenergy

Function for energy saving in the process, for example, during pause times by briefly switching off the entire system via standardized PROFIenergy commands.

PROFINET

Open component-based industrial communication system based on Ethernet for distributed automation systems. Communication technology promoted by the PROFIBUS Users Organization.

PROFINET device

A PROFINET device always has a PROFINET interface (electrical, optical, wireless). A lot of devices also have a PROFIBUS DP interface to connect PROFIBUS devices.

PROFINET IO

Communication concept for the realization of modular, distributed applications within the scope of PROFINET.

PROFINET IO is based on switched Ethernet with full-duplex operation and a bandwidth of 100 Mbps.

PROFINET IO Controller

Device used to address the connected IO devices. This means that the IO controller exchanges input and output signals with assigned field devices. The IO controller is often the controller on which the automation program runs.

PROFINET IO Device

A distributed field device that is assigned to one of the IO controllers (e.g. remote IO, valve terminals, frequency converters, switches)

PROFINET IO System

PROFINET IO controller with assigned PROFINET IO devices.

Programmable logic controller

Programmable logic controllers (PLCs) are electronic controllers whose function is stored as a program in the control unit. The structure and wiring of the device does not therefore depend on the controller's function. A programmable logic controller is structured like a computer. It consists of a CPU with memory, input/output modules and an internal bus system. The IOs and the programming language are oriented to the requirements of the control technology.

Programming device

Programming devices are essentially compact and portable PCs which are suitable for industrial applications. They are identified by a special hardware and software configuration for programmable logic controllers.

Proxy

The PROFINET device with proxy functionality is the substitute for a PROFIBUS device on Ethernet. The proxy functionality allows a PROFIBUS device to communicate not only with its master but also with all devices on PROFINET.

With PROFINET, existing PROFIBUS systems can be integrated into the PROFINET communication with the aid of an IE/PB link, for example. The IE/PB Link PN IO then handles communication via PROFINET on behalf of the PROFIBUS components.

In this way, you can link both DPV0 and DPV1 slaves to PROFINET.

Real-time

Real-time means that a system processes external events within a defined time.

Real-time communication

Group error for RT and IRT.

PROFINET uses its own real-time channel (RT) rather than TCP/IP for communication of time-critical IO user data.

Redundant systems

Redundant systems are characterized by the fact that important automation components are present multiple times (redundantly). Process control is maintained if a redundant component fails.

Router

A router interconnects two subnets. A router works in a similar way to a switch. With a router, however, you can also specify which communication devices may communicate via the router and which may not. The communication devices on various sides of a router can only communicate with one another if you have explicitly enabled communication between these devices via the router. Real-time data cannot be exchanged beyond subnet boundaries.

RT

PROFINET IO with **R**eal **T**ime communication (RT) is the optimal transmission method for time-critical applications in factory automation. PROFINET IO frames are prioritized over standard frames in accordance with IEEE802.1Q. This ensures the required determinism in the automation technology.

Security

Generic term for all the measures taken to protect against

- Loss of confidentiality due to unauthorized access to data
- Loss of integrity due to manipulation of data
- Loss of availability due to the destruction of data

Send clock

Period between two consecutive intervals for IRT or RT communication. The send clock is the shortest possible transmit interval for exchanging data.

SIMATIC

The term denotes Siemens AG products and systems for industrial automation.

SIMATIC NET

Siemens Industrial Communication division for Networks and Network Components.

SIMATIC PC Station

A "PC station" is a PC with communication modules and software components within a SIMATIC automation solution.

SIMATIC Memory Card (SMC)

→ *Micro Memory Card (MMC)*

Slave

A slave can only exchange data after being requested to do so by the master.

→ *See also DP slave*

SNMP

The network management protocol SNMP (**S**imple **N**etwork **M**anagement **P**rotocol) uses the wireless UDP transport protocol. It consists of two network components, similar to the client/server model. The SNMP manager monitors the network nodes and the SNMP agents collect the various network-specific information in the individual network nodes and stores it in a structured form in the MIB (**M**anagement **I**nformation **B**ase). This information allows a network management system to run detailed network diagnostics.

STEP 7

STEP 7 is an engineering system and contains programming software for the creation of user programs for SIMATIC S7 controllers.

Subnet

All the devices interconnected by switches are nodes of the same network or subnet. All the devices in a subnet can communicate directly with each other.

All devices in the same subnet have the same subnet mask.

A subnet is physically restricted by a router.

Subnet mask

The bits set in the subnet mask decide the part of the IP address that contains the address of the network.

In general, the following applies:

- The network address is obtained from the AND operation of the IP address and subnet mask.
- The device address is obtained from the AND NOT operation of the IP address and subnet mask.

Switch

Network components used to connect several terminal devices or network segments in a local network (LAN).

Sync domain

All PROFINET devices to be synchronized with IRT via PROFINET IO must belong to a sync domain.

The sync domain consists of exactly one sync master and at least one sync slave. An IO controller or switch generally handles the role of the sync master.

Non-synchronized PROFINET devices are not part of a sync domain.

System diagnostics

System diagnostics refers to the detection, evaluation, and signaling of errors that occur within the automation system, for example, programming errors or module failures. System errors can be indicated by LEDs or in STEP 7.

System redundancy AR

In a redundant system, an IO device with system redundancy S2 has a system redundancy AR with each of the two CPUs (IO controllers).

System states

The system states of the redundant S7-1500R/H system result from the operating states of the primary and backup CPUs. The concept of the system state is used to obtain a simplified expression that characterizes the simultaneously occurring operating states of the two CPUs. The following system states are available for the redundant S7-1500R/H system: STOP, STARTUP, RUN-Solo, SYNCUP and RUN-Redundant.

TCP/IP

The Ethernet itself is only a transport system for data - similar to a highway, which is a transport system for people and goods. The actual data transport is performed by so-called protocols - similar to cars and trucks, which transport people and goods on the highway.

The two basic protocols TCP (**T**ransmission **C**ontrol **P**rotocol) and IP (**I**nternet **P**rotocol) - TCP/IP for short - perform the following tasks:

1. The data is broken down into packets at the sender.
2. The packets are transported over the Ethernet to the correct recipient.
3. At the recipient, the packets are reassembled in the correct order.
4. Corrupt packets continue to be sent until they are received correctly.

Most higher-level protocols use TCP/IP to perform their duties. **H**yper **T**ext **T**ransfer **P**rotocol (HTTP), for example transfers documents written in **H**yper **T**ext **M**arkup **L**anguage (HTML) in the **W**orld **W**ide **W**eb (WWW). This technique is what enables you to view web pages in your **I**nternet browser in the first place.

Topology

Structure of a network. Common structures include:

- Linear bus topology
- Ring topology
- Star topology
- Tree topology

Topology configuration

All the interconnected ports of the PROFINET devices in the STEP 7 project and their relationships to each other.

Twisted-pair

Fast Ethernet via twisted-pair cables is based on the IEEE 802.3u standard (100 Base-TX). The transmission medium is a shielded 2x2 twisted-pair cable with an impedance of 100 Ω (AWG 22). The transmission characteristics of this cable must meet the requirements of category 5.

The maximum length of the connection between the terminal and the network component must not exceed 100 m. The connectors are designed according to the 100Base-TX standard with the RJ45 connector system.

Update time

An IO device / IO controller in the PROFINET IO system is supplied cyclically with new data from the IO controller / IO device within this time interval. The update time can be configured separately for each IO device and determines the interval at which data is sent from the IO controller to the IO device (outputs) as well as from the IO device to the IO controller (inputs).

User program

In SIMATIC, we distinguish between the CPU operating system and user programs. The user program contains all instructions, declarations and data by which a plant or process can be controlled. The user program is assigned to a programmable module (for example, CPU, CM) and can be structured in smaller units.

WAN

A network that extends beyond LAN boundaries and enables, for example, intercontinental network communication. Legal rights do not belong to the user but to the provider of the communication network.

XML

XML (E**x**tensible **M**arkup **L**anguage) is a flexible, easy to understand and easy to learn data description language. Information is exchanged using readable XML documents. These include continuous text supplemented by structure information.

Function Manual

12/2014

A5E03775446-AC

Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

DANGER

indicates that death or severe personal injury **will** result if proper precautions are not taken.

WARNING

indicates that death or severe personal injury **may** result if proper precautions are not taken.

CAUTION

indicates that minor personal injury can result if proper precautions are not taken.

NOTICE

indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

WARNING

Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the manual

This function manual provides an overview of the PROFIBUS communication system with SIMATIC STEP 7 V13.

STEP 7 V13 is integrated into the powerful graphic Totally Integrated Automation Portal (TIA Portal), the new integration platform for all automation software tools.

This function manual supports you in planning a PROFIBUS system. The manual is structured into the following subject areas:

- PROFIBUS basics
- PROFIBUS diagnostics
- PROFIBUS functions

Basic knowledge required

The following knowledge is required in order to understand the manual:

- General knowledge of automation technology
- Knowledge of the industrial automation system SIMATIC
- Knowledge about the use of Windows-based computers
- Proficiency with STEP 7

Scope

This function manual is the basic documentation for all SIMATIC products from the PROFIBUS environment. The product documentation is based on this documentation.

The examples are based on the functionality of the S7-1500 automation system.

Changes compared to previous version

As compared to the previous version (version 07/2014), this manual contains the following amendments/changes:

- Extension of the documentation to STEP 7 (TIA Portal) V13 SP1
- Addition of the function Intelligent DP slaves (I-slaves)
- New guide

Conventions

STEP 7: We refer to "STEP 7" in this documentation as a synonym for the configuration and programming software "STEP 7 as of V12 (TIA Portal)" and subsequent versions.

This documentation contains figures of the devices described. The figures may differ slightly from the device supplied.

You should also pay particular attention to notes such as the one shown below:

Note

A note contains important information on the product described in the documentation, on the handling of the product or on the section of the documentation to which particular attention should be paid.

Additional support

You will find information about available technical support in the appendix Service & Support (Page 91).

The technical documentation for the individual SIMATIC products and systems is available on the Internet (http://www.siemens.com/simatic-tech-doku-portal).

The online catalog and the ordering system are available on the Internet (http://mall.industry.siemens.com).

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

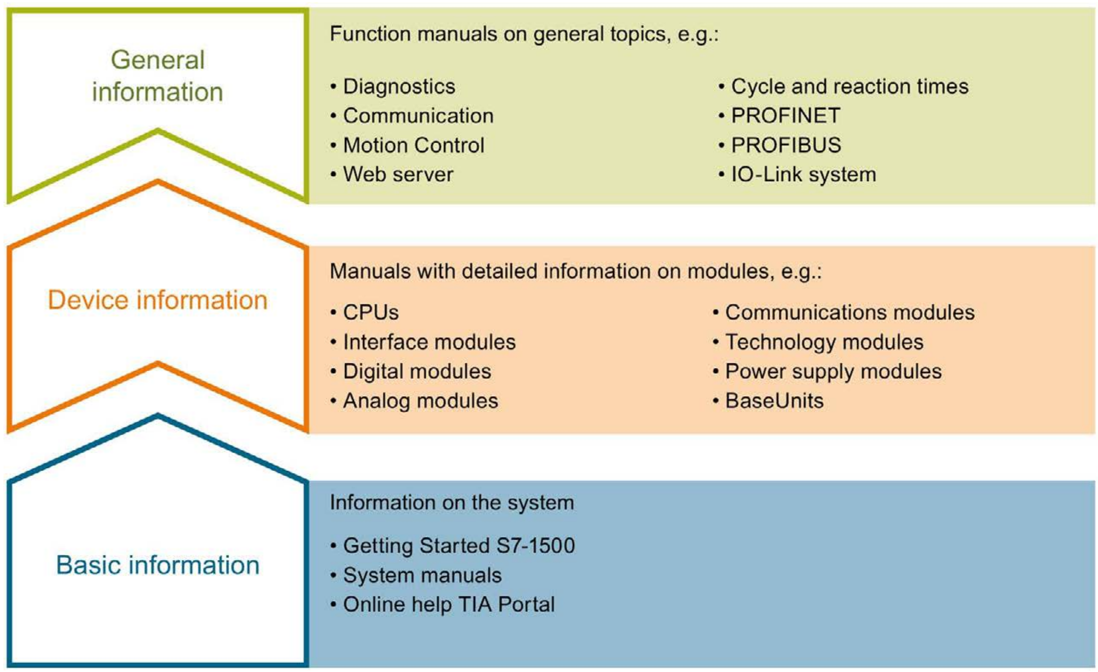
For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. You can find more information about industrial security on the Internet (http://www.siemens.com/industrialsecurity).

To stay informed about product updates as they occur, sign up for a product-specific newsletter. You can find more information on the Internet (http://support.automation.siemens.com).

Table of contents

1 Documentation guide

The documentation for the SIMATIC S7-1500 automation system and the SIMATIC ET 200MP, ET 200SP and ET 200AL distributed I/O systems is divided into three areas. This division allows you easier access to the specific information you require.



Basic information

System manuals and Getting Started describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, ET 200MP, ET 200SP and ET 200AL systems. The STEP 7 online help supports you in the configuration and programming.

Device information

Product manuals contain a compact description of the module-specific information, such as properties, terminal diagrams, characteristics and technical specifications.

General information

The function manuals contain detailed descriptions on general topics such as diagnostics, communication, Motion Control, Web server.

You can download the documentation free of charge from the Internet (http://w3.siemens.com/mcms/industrial-automation-systems-simatic/en/manual-overview/Pages/Default.aspx).

Changes and additions to the manuals are documented in product information sheets.

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP (http://support.automation.siemens.com/WW/view/en/86140384)
- ET 200SP (http://support.automation.siemens.com/WW/view/en/84133942)
- ET 200AL (http://support.automation.siemens.com/WW/view/en/95242965)

My Documentation Manager

The My Documentation Manager is used to combine entire manuals or only parts of these to your own manual.
You can export the manual as PDF file or in a format that can be edited later.

You can find the My Documentation Manager on the Internet (http://support.automation.siemens.com/WW/view/en/38715968).

Applications & Tools

Applications & Tools supports you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus in individual products.

You can find Applications & Tools on the Internet (http://support.automation.siemens.com/WW/view/en/20208582).

CAx Download Manager

The CAx Download Manager is used to access the current product data for your CAx or CAe systems.

You configure your own download package with a few clicks.

In doing so you can select:

- Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files
- Manuals, characteristics, operating manuals, certificates
- Product master data

You can find the CAx Download Manager on the Internet (http://support.automation.siemens.com/WW/view/en/42455541).

TIA Selection Tool

With the TIA Selection Tool, you can select, configure and order devices for Totally Integrated Automation (TIA).
This tool is the successor of the SIMATIC Selection Tool and combines the known configurators for automation technology into one tool.
With the TIA Selection Tool, you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet (http://w3.siemens.com/mcms/topics/en/simatic/tia-selection-tool).

Description 2

2.1 Introduction to PROFIBUS

What is PROFIBUS?

PROFIBUS is a bus system that networks automation systems and field devices that are compatible with PROFIBUS. As communication medium for the field level, PROFIBUS is an important part of Totally Integrated Automation (TIA).

The different communication networks can be used independent of one another or they can be combined with each other.

PROFIBUS protocols

PROFIBUS DP (distributed I/O) is a communication network for the field level according to IEC 61158-2 / EN 61158-2 with the hybrid access protocols token bus and master-slave. The networking takes place by means of two-wire lines or fiber-optic cables. Data transmission rates of 9.6 kbps to 12 Mbps are possible.

PROFIBUS PA is the PROFIBUS for process automation (PA). It connects the PROFIBUS DP communication protocol with the MBP (Manchester Bus Powered) transmission technology to IEC 61158-2.

PROFIBUS PA networks can be designed based on shielded, twisted two-wire lines intrinsically safe and are therefore suitable for hazardous areas (Ex zones 0 and 1). The data transmission rate is 31.25 kbps.

2.1.1 Applications of PROFIBUS DP

Introduction

The efficiency of control systems is not determined by automation devices alone, but depends to a large extent on the overall configuration of an automation solution. This includes a powerful communication system in addition to plant visualization and operator control and monitoring.

The STEP 7 engineering tool supports you during the engineering and configuration of an automation solution.

Applications of PROFIBUS DP

The PROFIBUS network offers wireless connection of several controllers, components and subnets as electrical network, optical network or by using links. Sensors and actuators are controlled centrally by means of PROFIBUS DP.

The following figure shows connection options to PROFIBUS DP:

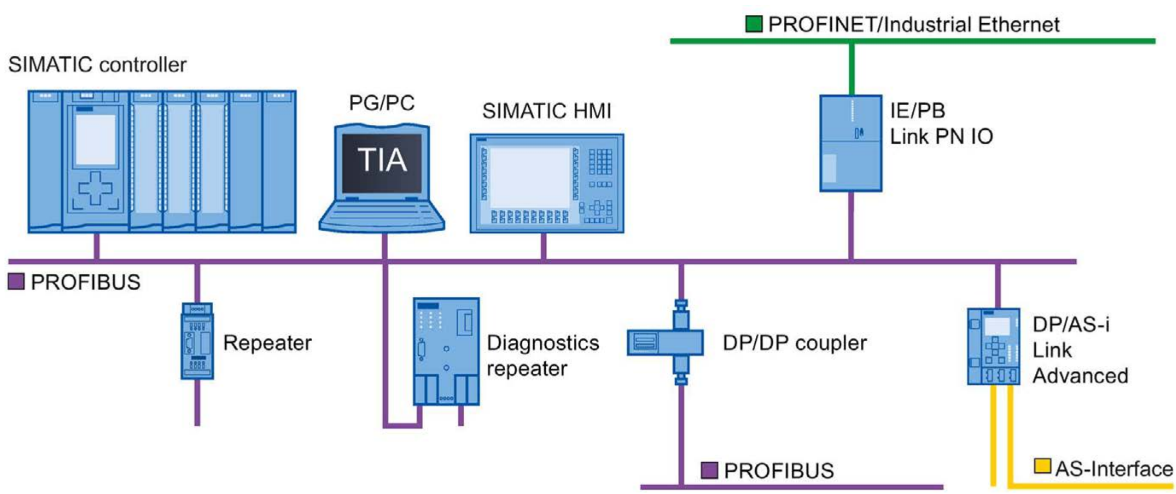


Figure 2-1 Connection options to PROFIBUS DP

Objectives of PROFIBUS DP

Distributed automation systems are increasingly used in production and process automation. This means a complex control task is divided up into smaller, more transparent subtasks with distributed control systems. This creates a high demand for communication between the distributed systems.

Distributed systems offer the following benefits:

- Independent and simultaneous commissioning of individual devices is possible
- Small, manageable programs
- Parallel processing due to distributed automation systems
- Reduced response times
- Higher-level structures can take on additional diagnostics and logging functions.
- Increased plant availability because the rest of the overall system can continue to work when a subordinate station fails.

2.1.2 PROFIBUS terminology

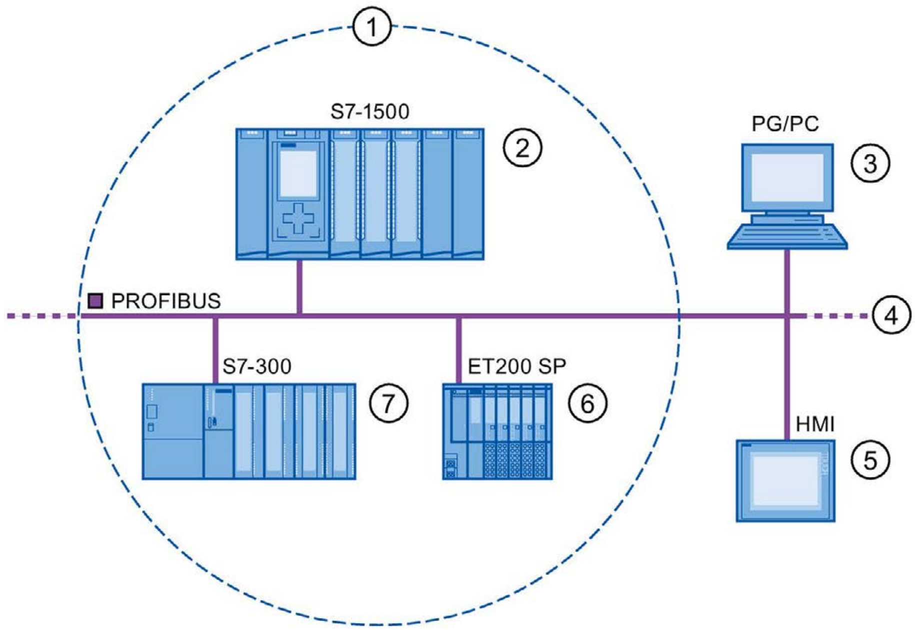
Definition: Devices in the PROFIBUS environment

In the PROFIBUS environment, "device" is the generic term for:

- Automation systems (for example, PLC, PC)
- Distributed I/O systems
- Field devices (for example, hydraulic devices, pneumatic devices)
- Active network components (e.g., diagnostic repeater, optical link module)
- Gateways to AS interface or other fieldbus systems

Devices with PROFIBUS DP

The figure below shows the most important components with PROFIBUS DP. The table below lists the designations of the individual components.



Number	PROFIBUS	Note
①	DP master system	
②	DP master	Device used to address the connected DP slaves. The DP master exchanges input and output signals with field devices. The DP master is often the controller on which the automation program runs.
③	PG/PC	PG/PC/HMI device for commissioning and diagnostics DP master of class 2
④	PROFIBUS	Network infrastructure
⑤	HMI	Device for operating and monitoring functions
⑥	DP slave	Distributed field device assigned to the DP master, e.g., valve terminals, frequency converters.
⑦	I-slave	Intelligent DP slave

Figure 2-2 Devices with PROFIBUS

Overview of I/O communication

I/O communication is the reading or writing of inputs/outputs of the distributed I/O. The figure below gives you an overview of I/O communication using PROFIBUS DP:

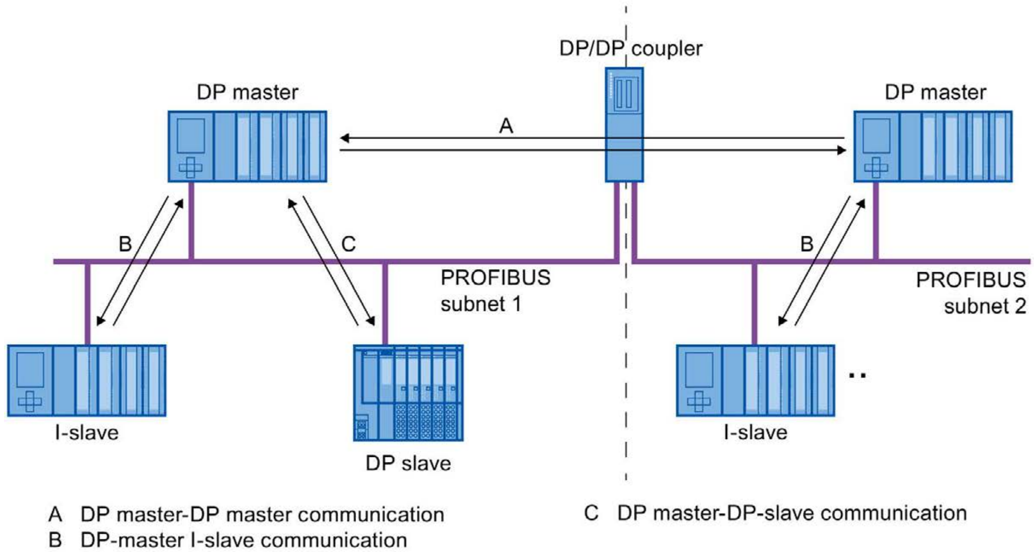


Figure 2-3 I/O communication using PROFIBUS DP

I/O communication is also available with the communication module (CM) or the interface module (IM) with integrated DP interface. These DP interfaces behave like integrated DP interfaces of the CPU.

I/O communication using PROFIBUS DP

Table 2- 1 I/O communication using PROFIBUS DP

Communication between …	Explanation
DP master and DP slave	The data exchange between a DP master and DP slaves with I/O modules takes place as follows: The DP master queries the DP slaves of its master system one after the other, receives input values from the DP slaves, and transmits output data to the DP slaves (master-slave principle).
DP master and I-slave	A fixed amount of data is transmitted cyclically between the user programs in CPUs of DP masters and I-slaves. The DP master does not access the I/O modules of the I-slave, but instead accesses configured address areas, called transfer areas, that can be inside or outside the process image of the I-slave CPU. If parts of the process image are used as transfer areas, these may not be used for actual I/O modules. Data transmission takes place with load and transfer operations using the process image or by direct access.
DP master and DP master	A fixed amount of data is transmitted cyclically between the user programs in CPUs of DP masters. A DP/DP coupler is required as additional hardware. The DP masters mutually access configured address areas, called transfer areas, inside or outside the process image of the CPUs. If parts of the process image are used as transfer areas, these may not be used for actual I/O modules. Data transmission takes place with load and transfer operations using the process image or by direct access.

Additional information

You can find additional information on the hardware configuration in the STEP 7 online help.

2.1.3 PROFIBUS DP interface

Properties

A PROFIBUS device has at least one PROFIBUS interface with an electrical (RS 485) interface or optical (Polymer Optical Fiber, POF) interface.

Table 2- 2 Properties of the PROFIBUS DP interface

Standard	PROFIBUS: IEC 61158/61784
Physical bus/media	PROFIBUS cables (twisted two-wire lines RS 485 or fiber-optic cables)
Transmission rate	9.6 kbps to 12 Mbps

Representation of the PROFIBUS DP interface in STEP 7

In the device view of STEP 7, the PROFIBUS DP interfaces for a DP master and a DP slave are highlighted by a purple rectangle:

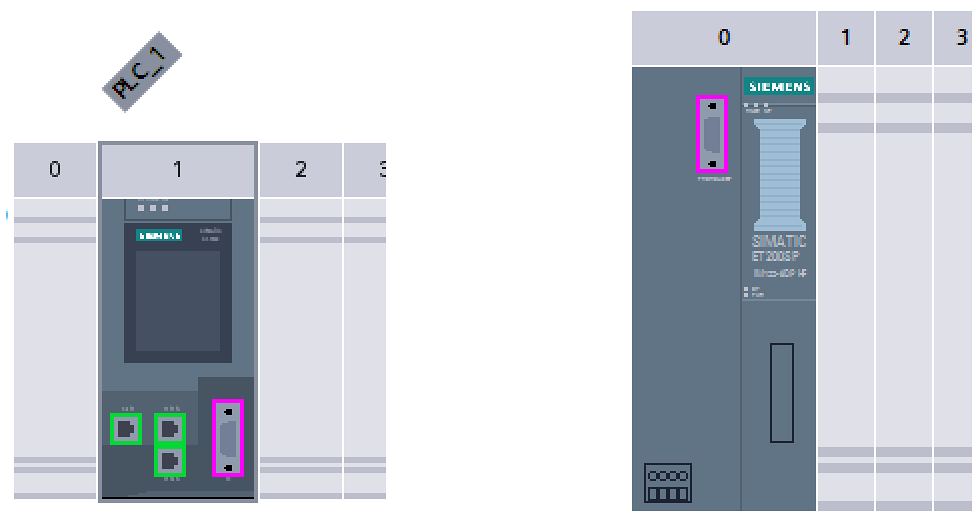

Figure 2-4 PROFIBUS DP interfaces

2.2 Structure of PROFIBUS networks

Contents of this chapter

The following chapter provides background information on building your communication network.

- Overview of the most important passive network components: These are network components that forward a signal without the possibility of actively influencing it, for example, cables, connectors.
- Overview of the most important active network components: These are network components that actively affect a signal, for example, repeaters, diagnostic repeaters.
- Overview of the most common network structures (topologies)

Physical connections of industrial networks

PROFIBUS devices can be networked in industrial plants in two different physical ways:

- By means of electrical signals via copper cables
- By means of optical signals via fiber-optic cables

Selection criteria for networking

The table below includes selection criteria for electrical and optical networking of PROFIBUS devices:

Table 2- 3 Selection criteria for electrical and optical networking

Criteria		Electrical PROFIBUS	Optical network with OLM	Optical network with OBT
Transmission medium	Shielded two-wire line	●	–	–
	POF	–	●	●
	PCF	–	●	●
	Glass	–	●	–
Distances	Max. network span	PROFIBUS DP: 9.6 km PROFIBUS PA: 1.9 km	90 km	9.6 km
	Between two devices	up to 1 km 1)	up to 15 km 2)	up to 300 m 2)
Topology	Bus	●	–	–
	Linear	–	●	●
	Tree	●	●	●
	Ring	–	●	●
Transmission protocols		DP, PA	DP, PA	DP
Connection of devices by means of	OLM	–	●	–
	Integrated interfaces	●	–	●
	Bus terminal	●	–	●
	Bus connector	●	–	–
Electrical network segments can be connected		●	●	–

● Suitable

– Not relevant for this application

1) Depending on data rate and type of service used

2) Depending on cable type used

Installation guideline for PROFIBUS networks

A PROFIBUS segment must be terminated at the start and end; passively with a connector or actively with a bus terminating resistor.

The same principles apply to the installation of a PROFIBUS network as described in the SIMATIC NET PROFIBUS networks (http://support.automation.siemens.com/WW/view/en/35222591) manual.

2.2.1 Passive network components for RS 485 networks

2.2.1.1 RS 485 cables

Introduction

The following applies to all RS 485 cables for PROFIBUS from Siemens:

- Their double shielding makes them especially suited for laying in industrial environments with electromagnetic interference.
- A continuous grounding concept can be implemented by means of the outer shield of the bus cable and the ground terminals of the bus terminals.
- The imprinted meter marking makes it easier to determine the length (accuracy ±5%).

RS 485 cables for PROFIBUS

SIMATIC NET PROFIBUS cables are available in different versions which allow optimum adaptation to different areas of application:

- FC Standard Cable GP (bus cable for fixed laying inside buildings)
- FC Standard Cable IS GP (bus cable for hazardous area)
- FC-FRNC Cable GP (bus cable with halogen-free protective jacket for use inside buildings)
- FC Food Cable (bus cable with PE jacket for use in the food and beverage industry)
- FC Robust Cable (bus cable with PUR jacket for environments subject to chemical and mechanical stress)
- FC Ground Cable (ground cable with PE jacket)
- PROFIBUS FC Trailing Cable (trailing cable for tow chains)
- PROFIBUS Festoon Cable (bus cable for festoon mounting)
- PROFIBUS Torsion Cable (torsion-free bus cable for networking movable plant parts, for example, robots)
- PROFIBUS FC Flexible Cable (bus cable for machine parts that are moved infrequently or cabinet doors)
- SIENOPYR-FR ship cable (for permanent laying on ships and off-shore units in all rooms and on open deck)
- PROFIBUS Hybrid Standard Cable (hybrid cable with 2 power wires (1.5 mm^2) for data and power supply of the ET 200pro)
- PROFIBUS Hybrid Robust Cable (trailable hybrid cable with 2 power wires (1.5 mm^2) for data and power supply of the ET 200pro)

Maximum cable lengths

When using copper cables, the maximum size of a PROFIBUS segment depends on the transmission rate.

If these lengths are not sufficient for your application, you can expand the network by using repeaters. You can achieve a maximum size by cascading up to nine repeaters.

Table 2- 4 Maximum cable lengths

Transmission rate	Maximum cable length of a bus segment	Maximum distance between two stations
9.6 to 187.5 kbps	1000 m	10000 m
500 kbps	400 m	4000 m
1.5 Mbps	200 m	2000 m
3 to 12 Mbps	100 m	1000 m

2.2.1.2 PROFIBUS FastConnect system

PROFIBUS FastConnect (FC)

PROFIBUS FastConnect is a system for fast and easy fabrication of PROFIBUS copper cables.

The system consists of three components:

- FastConnect bus cables for quick mounting
- FastConnect stripping tool
- FastConnect bus connector for PROFIBUS with insulation displacement method

FastConnect bus cables and stripping tool

The special design of the FastConnect bus cables allows for the use of the FastConnect stripping tool to accurately strip away the protective jacket and the braided shield in one step. The connection of the prepared cables takes place in the FastConnect bus connectors using the insulation displacement method.

All PROFIBUS FastConnect bus cables can also be connected to the conventional bus connectors with screw-type terminals.

Area of application

You need FastConnect bus connectors for PROFIBUS for the following applications:

- Connect devices with an electrical 9-pin D-Sub interface to IEC 61158-2 directly with SIMATIC NET PROFIBUS cables.
- Connect electrical segments or individual devices to the Optical Link Module (OLM) and Optical Bus Terminal (OBT).
- Connect devices or programming devices to the repeater.

Versions

The FastConnect bus connector in degree of protection IP20 is available in the following versions:

- with integrated terminating resistor and isolating function
- with or without PG socket
- with a cable outlet of 35°, 90° or 180°
- with device category 3G suitable for zone 2 hazardous area

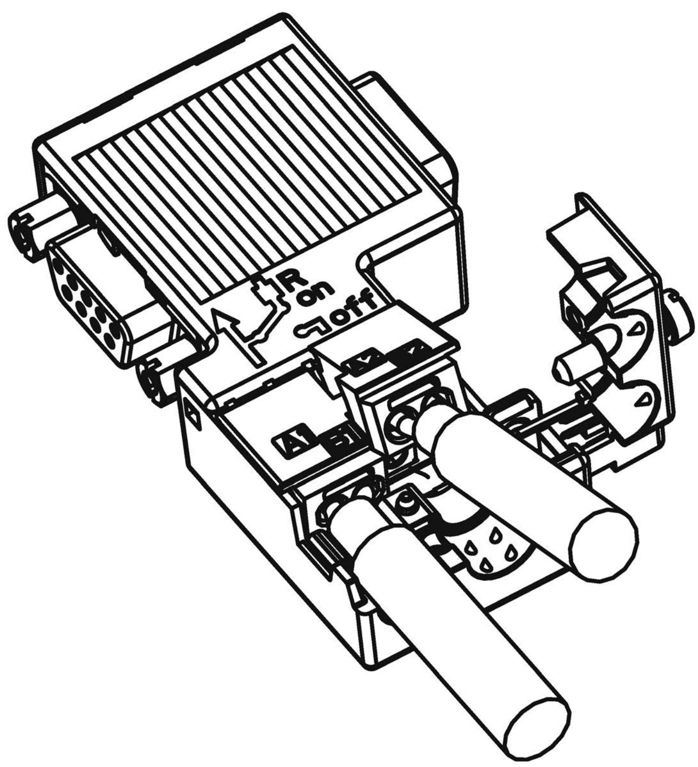

Figure 2-5 Example for PROFIBUS FastConnect bus connector with PG socket, cable outlet 90°

Additional information

For additional information on the available components visit the Siemens Mall (http://mall.industry.siemens.com).

2.2.1.3 PROFIBUS bus connector

Area of application

You need PROFIBUS bus connectors for the following applications:

- Connect devices with a 9-pin D-Sub interface to IEC 61158-2 directly with the SIMATIC NET PROFIBUS cables.
- Connect electrical segments or individual devices to the Optical Link Module (OLM) and Optical Bus Terminal (OBT).
- Connect devices or programming devices to the repeater.

Versions

The PROFIBUS bus connector in degree of protection IP20 is available in the following versions:

- with integrated terminating resistor and isolating function
- with or without PG socket
- with a cable outlet of 35°, 90° or 180°
- with device category 3G suitable for zone 2 hazardous area

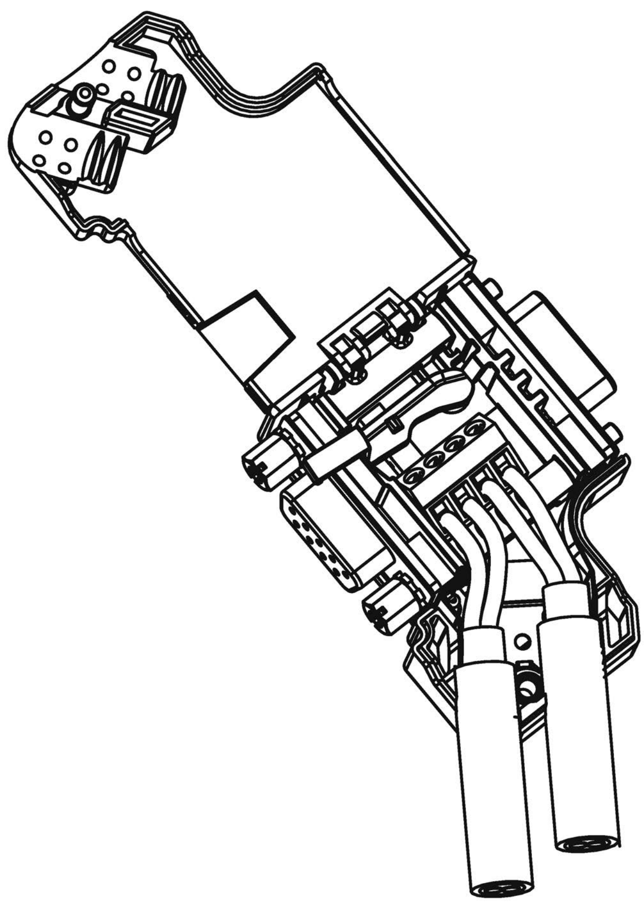

Figure 2-6 Example for PROFIBUS bus connector with PG socket, cable outlet 35°

Additional information

For additional information on the available components visit the Siemens Mall (http://mall.industry.siemens.com).

2.2.1.4 M12 bus connector

Area of application

Devices with an electrical M12 interface can use the M12 bus connector for SIMATIC NET PROFIBUS for direct connection with the SIMATIC NET PROFIBUS cables.

The M12 bus connector in degree of protection IP65 is available in the following versions:

- with screw-type terminals
- with insulation displacement termination
- with a cable outlet of 180°

2.2.1.5 Bus terminals for RS 485 networks

Bus terminal RS 485 and bus terminal M12

A bus terminal is used for the connection of an individual PROFIBUS station with RS485 interface to the PROFIBUS bus cable.

Bus terminals in degree of protection IP20 are available in the following versions:

- Bus terminal RS 485 with or without PG interface, transmission rate 9.6 kbps to 1.5 Mbps, integrated terminating resistor combination (connectible), with 1.5 m and 3 m connecting cable
- Bus terminal M12, transmission rate 9.6 kbps to 12 Mbps, integrated terminating resistor combination with isolating function, with 1.5 m connecting cable

2.2.1.6 M12 bus terminating resistor

Terminating segment with terminating resistor

If there is a station with M12 connection system at the beginning or end of a PROFIBUS segment, you need an M12 bus terminating resistor.

The M12 PROFIBUS connection of a device consists of an M12 socket for the infeed and an M12 male connector to loop-through the bus signal.

This means you need one bus terminating resistor with male contacts (6GK1905-0EC00) and with female contacts (6GK1905-0ED00) for each M12 bus cable.

2.2.2 Passive components for optical networks

2.2.2.1 Fiber-optic cables

Types of fiber-optic cables

Data transmission with fiber-optic cables takes place through modulation of electromagnetic waves in the range of visible and invisible light. These cables are made of high-quality plastic fibers and glass fibers:

- Plastic and PCF fiber-optic cables (Page 26)
- Glass fiber-optic cables (Page 27)

The different types of fiber-optic cables provide solutions matched to the operating and environmental conditions for the connection of components with each other.

Benefits

Fiber-optic cables offer the following benefits when compared with electrical cables:

- Galvanic isolation of the devices and segments
- No potential equalization currents
- No impact on transmission path through external electromagnetic interference
- No lightning protection elements required
- No noise radiation along the transmission route
- Low weight
- Depending on the type of fiber you can implement cable lengths up to few kilometers at even higher transmission rates.
- No dependency of the maximum permitted distances on the transmission rate

Additional information

Additional information of the properties and technical specifications of the passive components and connectors for fiber-optic cables is available in the PROFIBUS network manual (http://support.automation.siemens.com/WW/view/en/35222591).

2.2.2.2 Plastic and PCF fiber-optic cables

Plastic and PCF fiber-optic cables

Plastic (POF) and PCF fiber-optic cables are used for the connection of Optical Link modules with connections for plastic fiber-optic cables (OLM/P), Optical Bus Terminal (OBT) and devices with integrated optical interfaces. Under certain conditions, they are an inexpensive alternative to conventional glass fiber-optic cables.

Plastic Fiber Optic duplex core

The plastic fiber-optic duplex core is a flat dual core with PVC inner jacket without protective jacket. The cable can be easily assembled on-site.

The cable is intended for indoor applications with low mechanical loads or inside cabinets. For OLM connections and with integrated optical interfaces you cover a length of up to 50 m between two devices with this cable.

Plastic Fiber Optic standard cable

The plastic fiber optic standard cable consists of two plastic fibers with robust polyamide inner jacket surrounded by Kevlar tensile elements and a purple PVC protective jacket. The cable can be easily assembled on-site.

The robust round cable is suited for indoor applications. The maximum distance that can be covered is 80 m for OLM/P connections and 50 m with integrated optical interfaces and OBT.

PCF Standard Cable

The pre-assembled PCF Standard Cable consists of two PCF fibers surrounded by Kevlar tensile elements and a purple PVC protective jacket. It is always supplied with a pulling aid installed on one end to pull in the cable channels.

The robust round cable is suited for indoor applications with cable lengths up to 400 m (OLM) or 300 m (integrated optical interfaces, OBT) between two devices.

PCF Standard Cable GP

The PCF Standard Cable GP consists of two PCF fibers surrounded by Aramid tensile elements and a green PVC protective jacket. The cable is pre-assembled and can be ordered by the meter. It is supplied with a pulling aid installed on one end to pull in the cable channels.

The robust round cable is suited for indoor and outdoor applications with cable lengths up to 400 m (OLM) or 300 m (integrated optical interfaces, OBT) between two devices.

PCF Trailing Cable

The PCF Trailing Cable consists of two PCF fibers surrounded by Aramid tensile elements and a green PUR protective jacket. The cable is pre-assembled and can be ordered by the meter. It is supplied with a pulling aid installed on one end to pull in the cable channels.

The robust round cable is suited for moving indoor and outdoor applications with cable lengths up to 400 m (OLM) or 300 m (integrated optical interfaces, OBT) between two devices.

PCF Trailing Cable GP

The PCF Trailing Cable GP consists of two PCF fibers surrounded by Aramid tensile elements and a green PVC protective jacket. The cable is pre-assembled and can be ordered by the meter. It is supplied with a pulling aid installed on one end to pull in the cable channels.

The robust round cable is suited for moving indoor and outdoor applications with cable lengths up to 400 m (OLM) or 300 m (integrated optical interfaces, OBT) between two devices.

2.2.2.3 Glass fiber-optic cables

Glass fiber-optic cables

Glass fiber-optic cables are suitable for connection of optical interfaces that work in the wavelength range around 850 nm and around 1300 nm. They include two graded-index multimode fibers of the type 62.5/125 µm.

The glass fiber-optic cables are available in different versions which makes for an optimum adaptation to different areas of application:

- Fiber Optic standard cable
- INDOOR Fiber Optic indoor cable
- Flexible Fiber Optic trailing cable

Fiber Optic standard cable

The standard cable is the universal cable for indoor and outdoor use.

INDOOR Fiber Optic indoor cable

The indoor cable is intended for weather-proof indoor use. It is halogen-free, non-crush and flame-retardant.

Flexible Fiber Optic trailing cable

The trailing cable was designed for the special application of forced movement, for example, for constantly moved machine parts such as trailing chains. It is mechanically designed for 100,000 bending cycles by ±90° (with the specified minimum radius). Integrated dummy elements ensure a round cross-section of the cable. The trailing cable can be used indoors and outdoors.

Maximum distances between two optical link modules

The following distances may not be exceeded between two OLMs regardless of the optical power budget:

- OLM/P11, OLM/P12: 400 m
- OLM/G11, OLM/G12, OLM/G12-EEC: 3 km
- OLM/G11-1300, OLM/G12-1300: 15 km

Additional information

All operating instructions (http://support.automation.siemens.com/WW/view/en/10805951/133300) of the SIMATIC NET bus components include information on distances that can be covered with the SIMATIC NET glass fiber-optic cables. You can configure your optical network without any calculations using simple limits.

2.2.3 Active network components

2.2.3.1 Network components in electrical networks

Active network components

The following active network components are available for PROFIBUS in electrical networks:

- Repeater RS485
- Diagnostics repeater
- PROFIBUS Terminator
- DP/DP coupler
- IE/PB Link PN IO
- IWLAN/PB Link PN IO
- Active components for the connection of CAN
- Active components for the gateway between PROFIBUS and AS-Interface
  - DP/AS-i LINK Advanced
  - DP/AS-Interface Link 20E
  - DP/AS-i F-Link

RS485 repeater

The RS485 IP20 repeater connects two PROFIBUS bus segments in RS485 technology with up to 32 devices. It provides transmission rates from 9.6 kbps to 12 Mbps.

The RS485 repeater refreshes a signal regarding amplitude, signal width and edge steepness between two segments. It is used when more than 32 stations are connected to the bus or the maximum cable length of a segment is exceeded.

Bus segments can be operated ungrounded (galvanic isolation of segments) with an RS485 repeater.

Diagnostics repeater

The diagnostic repeater connects three PROFIBUS segments in RS485 technology, two of which are diagnostics-capable segments with 31 devices each. It is designed as DP slave to send diagnostics alarms to the DP master.

The diagnostic function provides the location and the cause of cable faults, such as wire break or missing terminating resistors. The fault location is indicated relative to the existing devices.

The diagnostics repeater refreshes a signal regarding amplitude, signal width and edge steepness between the segments. The cascading depth between any two PROFIBUS devices is limited to nine diagnostics repeaters.

PROFIBUS Terminator

The PROFIBUS Terminator forms an active bus termination. Bus devices can be switched off, removed or replaced without affecting data transmission. This is particularly true for bus devices on both ends of the bus cable at which terminating resistors must be connected or supplied. The PROFIBUS Terminator can be mounted on a standard mounting rail.

IE/PB Link PN for the connection of a PROFIBUS segment to an Industrial Ethernet network

The IE/PB Link PN IO as independent component provides the seamless transition between Industrial Ethernet and PROFIBUS. Through the use of IE/PB Link PN IO as substitute on the Ethernet, the existing PROFIBUS devices can continue to be used and can be integrated into a PROFINET application.

A PROFINET IO controller is required for this configuration. The IE/PB Link PN acts as master on the PROFIBUS end.

IWLAN/PB Link PN IO as gateway between LAN and PROFIBUS

PROFIBUS devices can be coupled to PROFINET IO by means of IWLAN/PB Link PN IO. This means you can integrate existing PROFIBUS configurations into PROFINET.

The IWLAN/PB Link PN IO supports the use of IWLAN and WLAN antennas for wireless data transmission, for example, in suspended monorail systems or conveyor systems. Because of the PROFINET support, the numerous PROFIBUS system services, for example, diagnostics by bus, can continue to be used.

A PROFINET IO controller is required for this configuration. The IWLAN/PB Link PN IO acts as master on the PROFIBUS end.

CANopen module for connection to CAN

You can use the CANopen module to easily connect CANopen applications to PROFIBUS.

Typical areas of application:

- Control of hydraulic valves/hydraulic axes in vehicles
- Control of motors in packaging machines and on conveyor belts
- Use in wind turbines for detection of angular encoders
- Detection of HMI devices on machines, e.g., joysticks
- Detection of measured data from displacement transducers, inclination sensors or angle encoders on tower cranes or gantry cranes

DP/DP coupler for connection of two PROFIBUS networks

The PROFIBUS DP/DP coupler is used to connect two PROFIBUS DP networks. Data (0 to 244 bytes) is transmitted from the DP master of the first network to the DP master of another network and vice versa.

The DP/DP coupler comes equipped with two independent DP interfaces that establish the connection to the two DP networks. There is one slave at each DP network. The data exchange between the two DP networks takes place by internal copying in the coupler.

DP/PA bus link for connection of PROFIBUS PA

The DP/PA bus link is the connection between PROFIBUS DP and PROFIBUS PA. This means it connects the process control systems with the field devices of the process automation.

The following components are available for a DP/PA bus link:

- DP/PA coupler Ex [ia]
- DP/PA coupler FDC 157-0
- Interface module IM 153-2 for establishing a DP/PA link.
- Active field distributor AFDiS for hazardous areas

Active components for the gateway between PROFIBUS and AS-Interface

- **DP/AS-i LINK Advanced**:

  The **DP/AS-i LINK Advanced** is PROFIBUS DPV1 slave (according to IEC 61158-2/EN 61158-2) and AS-Interface master (according to AS-Interface specification V3.0 according to EN 50295) and provides transparent data access to AS-Interface from PROFIBUS DP.

  PROFIBUS DP masters can cyclically exchange I/O data with the AS-Interface; DP masters with acyclic services can also make AS-Interface master calls. The **DP/AS-i LINK Advanced** is particularly suited for distributed configurations and for the connection of a subordinate AS-Interface network.

  The DP/AS-i LINK Advanced in the version as AS-Interface single master is completely sufficient for applications with typical configuration limits.

  For applications with high configuration limits, the DP/AS-i LINK Advanced is used as AS-Interface double master. In this case, the duplicate configuration limits can be used on two independently running AS-Interface strands.

- **DP/AS-Interface Link 20E:**

  The DP/AS-Interface Link 20E is PROFIBUS DP slave (in accordance with EN 61158) and AS-Interface master (in accordance with AS-Interface specification V3.0 according to EN 50295) and supports operation of the AS-Interface on PROFIBUS DP.

  Single PROFIBUS masters can cyclically exchange I/O data with the AS-Interface; masters with acyclic services can exchange I/O data and make master calls.

- **DP/AS-i F-Link:**

  The DP/AS-i F-Link is PROFIBUS DP-V1 slave (according to EN 61158) and AS-i master (according to AS-Interface specification V3.0 to EN 50295) and provides transparent data access to AS-Interface from PROFIBUS DP. The DP/AS-i F-Link is also the only AS-i master that can forward safety-oriented input data of ASIsafe slaves to a fail-safe CPU with PROFIBUS DP master by means of the PROFIsafe protocol. Additional safety cabling or monitoring is not required (in particular, no AS-Interface safety monitor). Depending on the slave type, you can transmit binary values or analog values. All slaves according to AS-Interface specification V2.0, V2.1 or V3.0 can be operated as AS-i slaves.

  As fully-featured AS-i master according to specification V3.0, you can use higher configuration limits on the AS-i network (496 inputs and outputs each, up to 62 digital or analog slaves).

Additional information

Information on the components is available in the Siemens Mall (http://mall.industry.siemens.com).

Additional information is available in these manuals:

WLAN topology (Page 40)

Connecting PROFIBUS to PROFINET (Page 41)

2.2.3.2 Network components in optical networks

Active network components

The following active network components are available for PROFIBUS in optical networks:

- Optical Link Module OLM
- Optical Bus Terminal OBT

Optical Link Module OLM

You can use the PROFIBUS Optical Link Modul OLM to install PROFIBUS networks in line, star structure and redundant ring structure.

The transmission rate of a fiber-optic cable line does not depend on the distance and can be 9.6 kbps to 12 Mbps.

Applications for OLM include, for example, plant buses on PROFIBUS base, networking across buildings using glass fiber-optic cables, mixed networks with electrical and optical segments, large networks (road tunnels, traffic guidance systems) and networks with high demands on availability (redundant ring networks).

Optical Link modules can be combined by means of an RS485 interface and individual devices or entire electrical segments can be integrated into the optical PROFIBUS network.

The following distances may not be exceeded between two OLMs regardless of the optical power budget:

- OLM/P11, OLM/P12: 400 m
- OLM/G11, OLM/G12, OLM/G12-EEC: 3 km
- OLM/G11-1300, OLM/G12-1300: 15 km

Optical Bus Terminal OBT (optical bus terminal)

The Optical Bus Terminal connects an individual PROFIBUS device without integrated optical interface or a PROFIBUS RS 485 segment with up to 31 devices to an optical PROFIBUS.

An individual PROFIBUS DP device is connected with its RS 485 interface by means of a PROFIBUS cable with integrated terminating resistor, for example, connecting cable 830-1T, to the RS 485 interface of the OBT. The OBT is integrated into the optical line by means of two optical interfaces.

The following optical transmission media can be connected to the OBT:

- Plastic fiber-optic cable up to 50 m single distance length. They can be assembled on-site with two 2x2 Simplex connectors.
- PCF fiber-optic cable up to 300 m single distance length. The cables are delivered pre-assembled.

Additional information

Information on the components is available in the Siemens Mall (http://mall.industry.siemens.com).

Additional information is available in these manuals:

- PROFIBUS network manual (http://support.automation.siemens.com/WW/view/en/35222591)
- SIMATIC NET PROFIBUS, Optical Link Module (http://support.automation.siemens.com/WW/view/de/56606534/0/en)

2.2.4 Examples for topology

2.2.4.1 Topology with RS485 repeater

Configuration options with the RS485 repeater

You can operate the RS485 repeater in the following configurations:

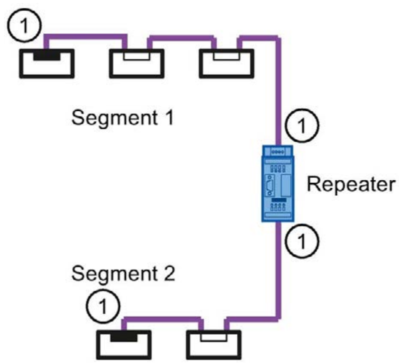

Figure 2-7 Segment 1 and segment 2 connected to RS485 repeater

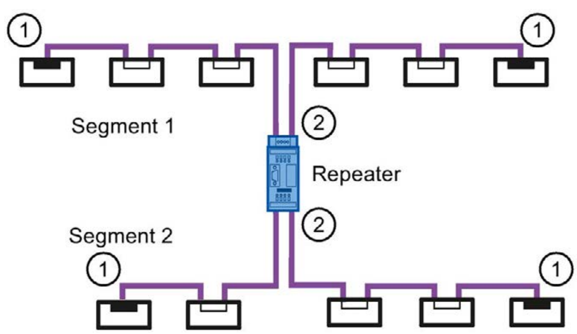

Figure 2-8 Segment 1 and segment 2 looped-through to RS485 repeater

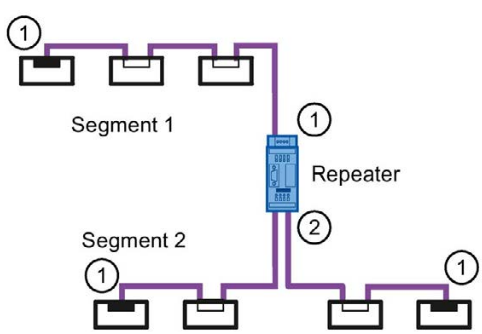

Figure 2-9 Segment 1 connected to RS485 repeater and segment 2 looped-through to RS485 repeater

① Connect terminating resistor

② Do not connect terminating resistor

Configuration example

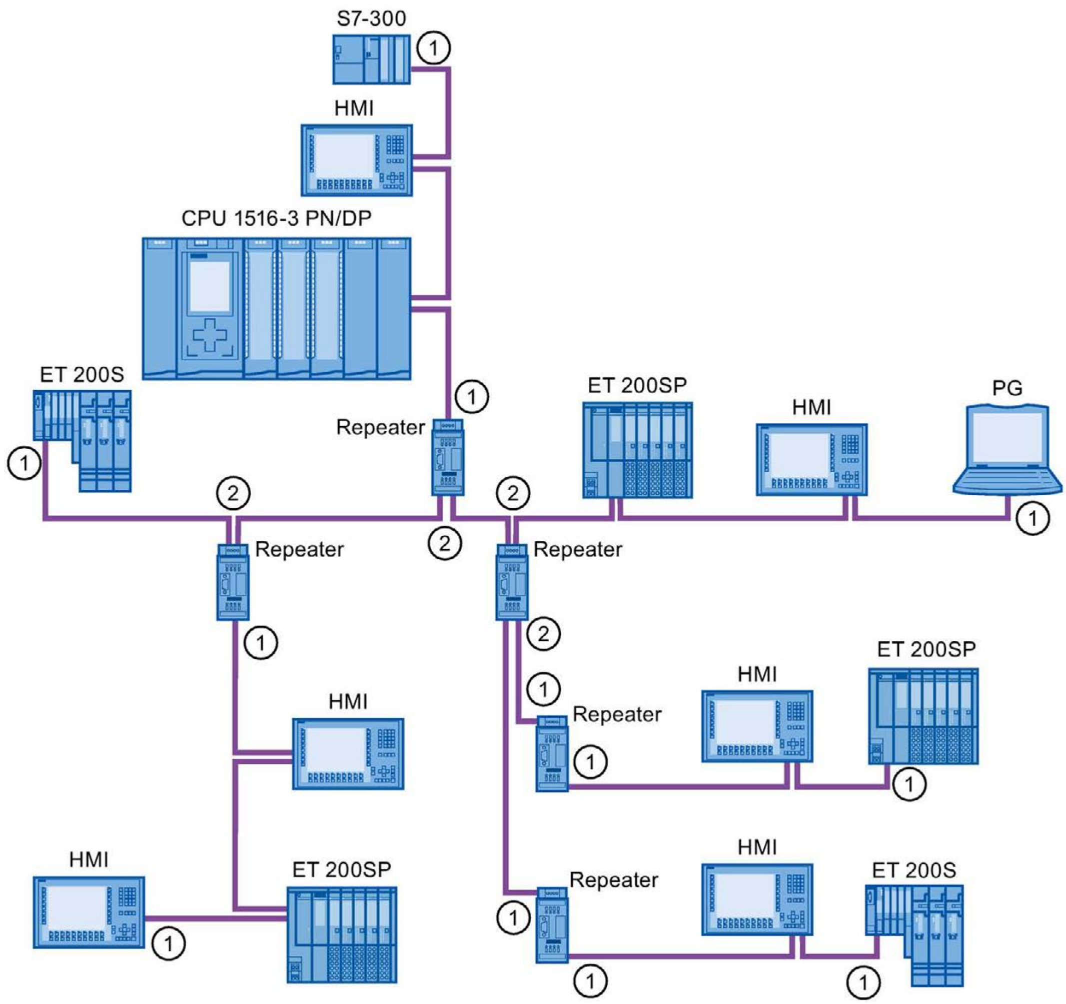

Figure 2-10 Configuration example with five RS485 repeaters

① Connect terminating resistor

② Do not connect terminating resistor

Maximum configuration

If you install a PROFIBUS network with RS485 repeaters, you may not connect more than nine RS485 repeaters in series.

2.2.4.2 Topology with diagnostic repeater

Diagnostic repeater with three segments

You may not exceed the maximum permitted cable length of 100 m per segment that can be monitored for the diagnostic repeater. The segments connected to DP2 and DP3 are diagnostics-capable. The cable length that can be monitored is limited for some cable types.

Maximum cascade depth

You can connect up to nine diagnostic repeaters in series between any two PROFIBUS stations.

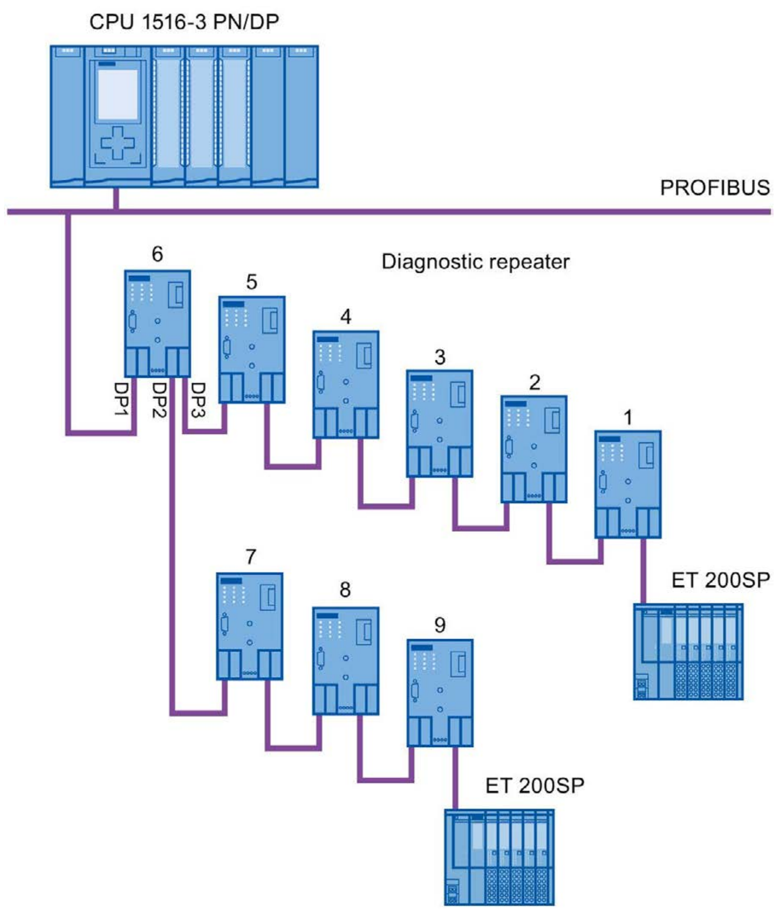

Figure 2-11 Schematic layout of a PROFIBUS network with maximum possible cascade depth at diagnostic repeaters

Example: Maximum cascade depth exceeded

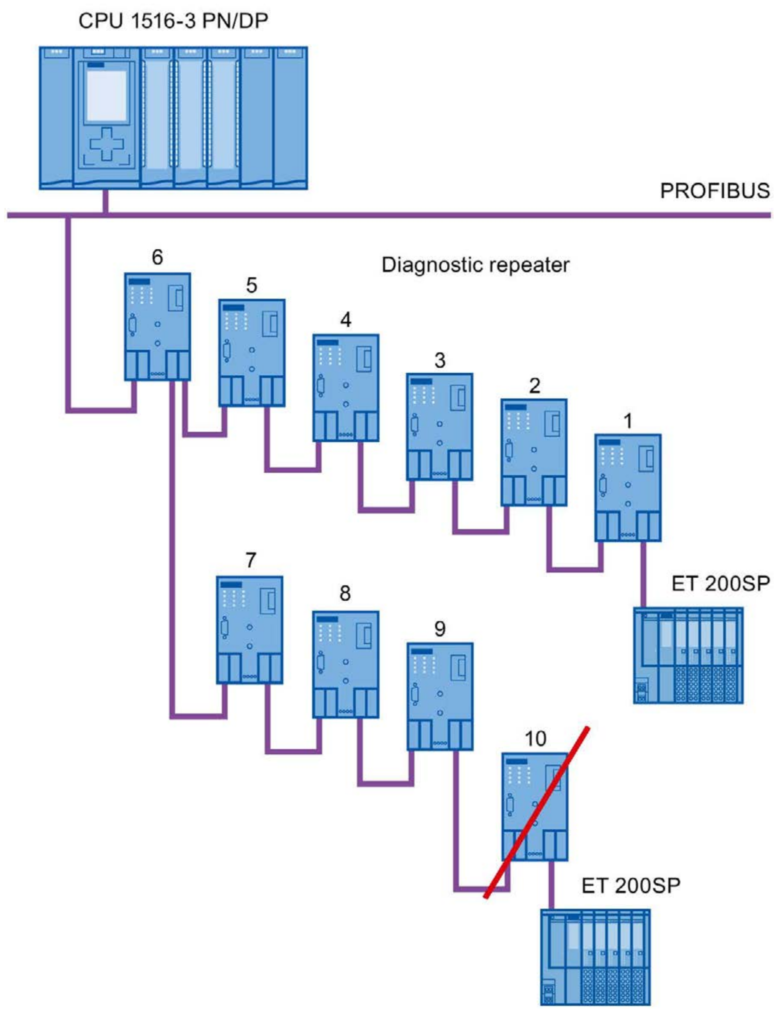

Figure 2-12 Maximum cascade depth exceeded

Layout with several segments

You can increase the number of used diagnostic repeaters by using several segments. The example shows a layout in which the maximum cascade depth is exceeded at two segments.

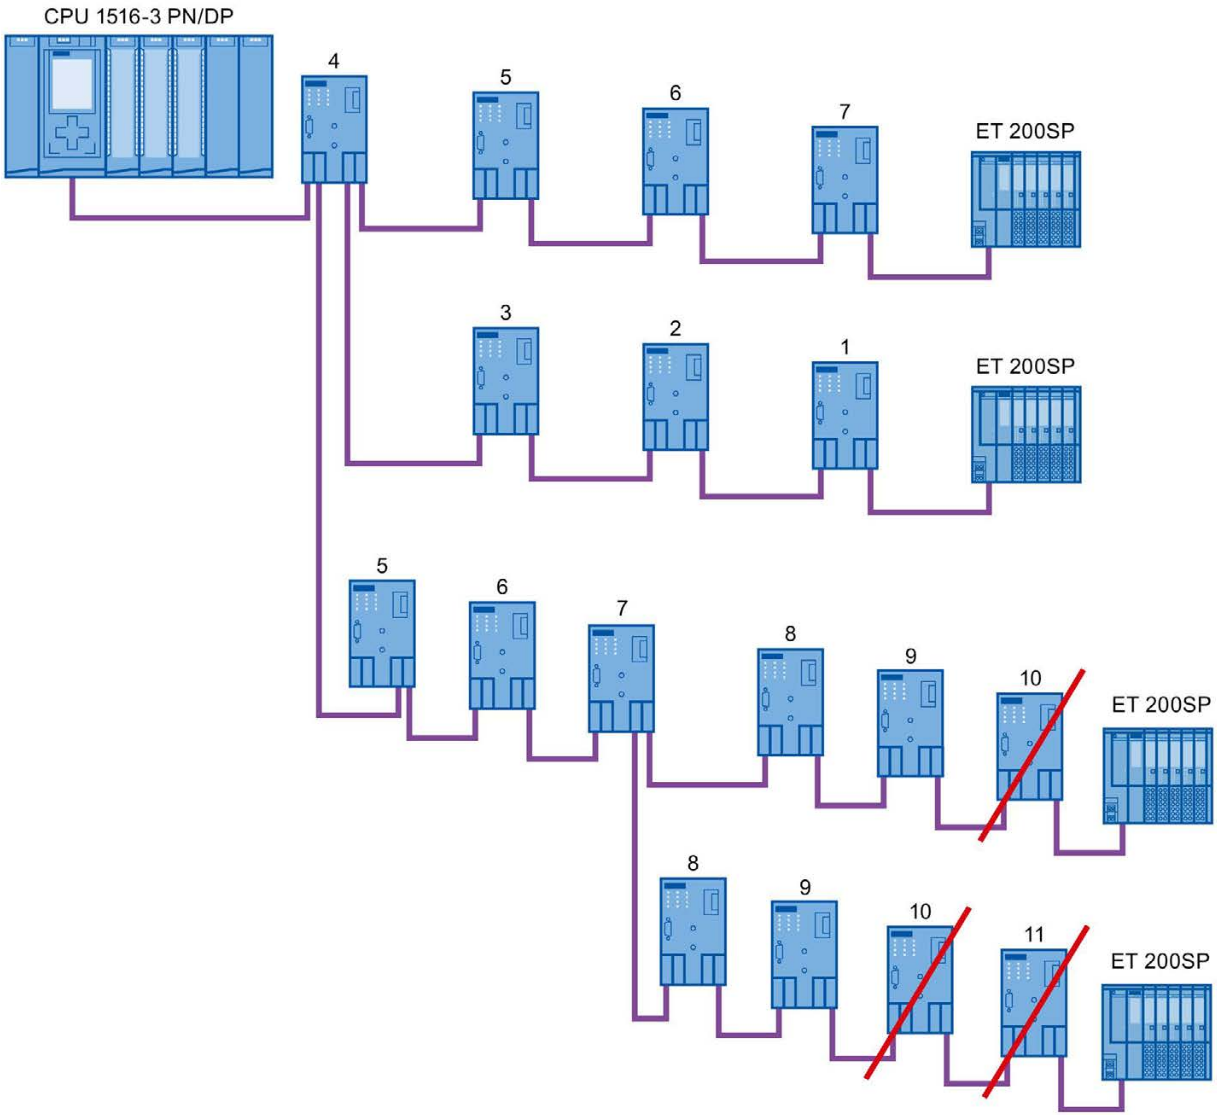

Figure 2-13 Layout with several segments, maximum cascade depth exceeded

Additional information

Additional information is available in the Diagnostic Repeater (http://support.automation.siemens.com/WW/view/en/7915183) manual.

2.2.4.3 OLM topology

Combination of electrical and optical networks with OLM

Additional distances can be covered by means of the Optical Link Module.

Because bus cables across several buildings are particularly vulnerable to damage caused by overvoltage (effect of lightning), the devices in the connected bus segment must be protected against overvoltage.

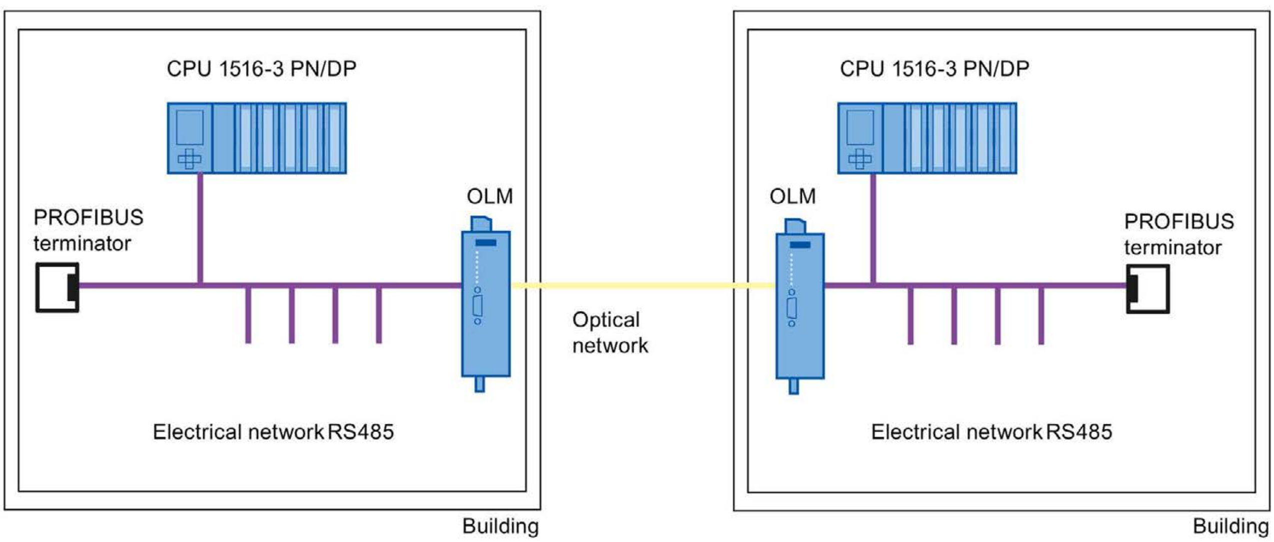

Figure 2-14 Combination of electrical and optical networks

2.2.4.4 WLAN topology

IWLAN/PB Link PN IO as gateway between Industrial Wireless LAN and PROFIBUS

The IWLAN/PB Link PN IO supports the use of IWLAN and WLAN antennas for wireless data transmission. This means the numerous PROFIBUS system services, for example, diagnostic by bus, can be used throughout.

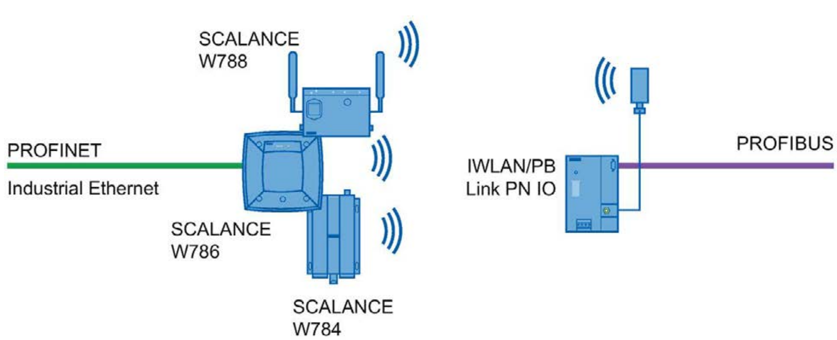

Figure 2-15 PROFIBUS and WLAN

2.2.4.5 Connecting PROFIBUS to PROFINET

PROFIBUS can be integrated in PROFINET. In this way, you can set up any hybrid systems consisting of fieldbus and Ethernet-based subsystems. This provides a continuous data exchange.

Coupling of PROFIBUS and PROFINET

With a proxy-capable PROFINET device that is equipped with a PROFIBUS interface in addition to a PROFINET interface, you can integrate existing PROFIBUS configurations into the PROFINET configuration.

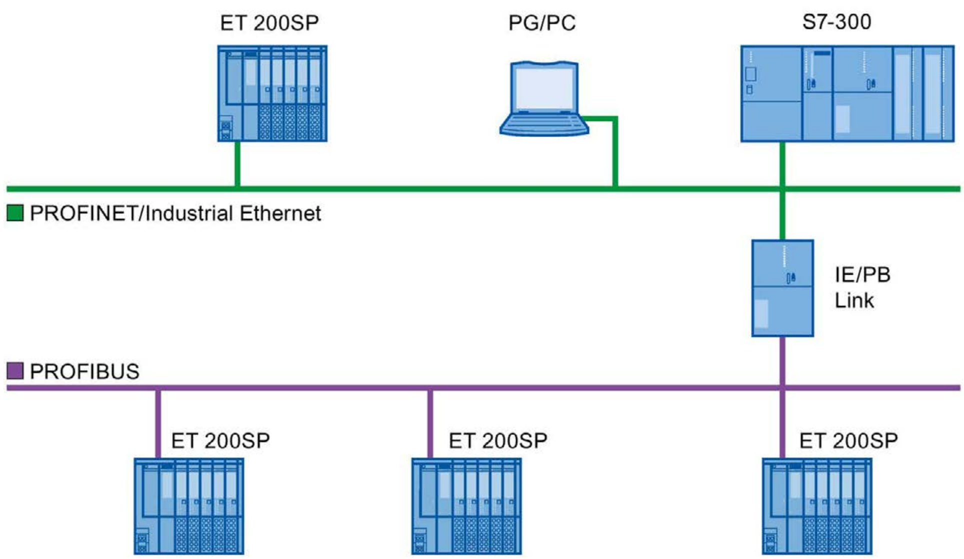

Figure 2-16 Connection of PROFIBUS and PROFINET with IE/PB link

PROFINET device with proxy functionality

The PROFINET device with proxy functionality is the substitute for a PROFIBUS device on Ethernet. The proxy functionality allows a PROFIBUS device to communicate not only with its master but also with all devices on PROFINET.

With PROFINET, existing PROFIBUS systems can be integrated into the PROFINET communication with the aid of an IE/PB link. The IE/PB link PN IO then handles communication via PROFINET on behalf of the PROFIBUS components.

3 Parameter assignment/addressing

To set up an automation system, you will need to configure, assign parameters and link the individual hardware components. The work needed for this is undertaken in the STEP 7 device, topology and network view.

Configuration

"Configuring" is understood to mean arranging, setting and networking devices and modules within the device or network view.

A PROFIBUS address is automatically assigned to each module. The addresses can be subsequently modified.

The CPU compares the preset configuration created in STEP 7 with the actual configuration of the plant. Errors can be detected and signaled immediately this way.

The exact procedure for configuring devices is described in detail in the STEP 7 online help.

Parameter assignment

"Parameter assignment" is understood to mean setting the properties of the components used. The settings for the hardware components and for data exchange are assigned, for example, activating diagnostics, input delay with DI.

The parameters are downloaded into the CPU and transferred to the corresponding modules when the CPU starts up. Modules can be replaced with ease because with SIMATIC CPUs the set parameters are automatically downloaded into the new module during each startup.

Adjusting the hardware to the project requirements

You need to adapt the hardware if you want to set up, expand or change an automation project. To do this, add hardware components to your layout, link them with existing components, and adapt the hardware properties to the tasks.

The properties of the automation systems and modules are preset so that in many cases you do not have to assign parameters again.

But parameter assignment is required in the following cases:

- You want to change the preset parameters of a module.
- You want to use special functions.
- You want to configure communication connections.

Basic procedure for creating a PROFIBUS DP system

- Configuration
  - Creating PROFIBUS devices and modules in STEP 7

3.1 Assigning the DP slave to a DP master

PROFIBUS DP system

A PROFIBUS DP system consists of a PROFIBUS DP master and its assigned PROFIBUS DP slaves. Once the devices have been placed in the network view or device view, STEP 7 assigns default parameter values to them. Initially, you only have to assign the DP slaves to one DP master.

Requirement

- The network view of STEP 7 is open.
- A CPU has been placed (e.g., CPU 1516-3 PN/DP).
- A DP slave has been placed (e.g., IM151-1 HF).

Procedure

To assign DP slaves to a DP master, follow these steps:

1. On the DP slave, use the left mouse button to click on the "Not assigned" link. The "Select DP master" menu opens.
2. Select the DP master in the menu to which you want to assign the DP slave.

   Result: A subnet with a DP system is created on the CPU. The CPU is now the PROFIBUS DP master. The DP slave is assigned to the DP master.
3. Repeat steps 1 and 2 for all other DP slaves that you want to assign to the DP master.

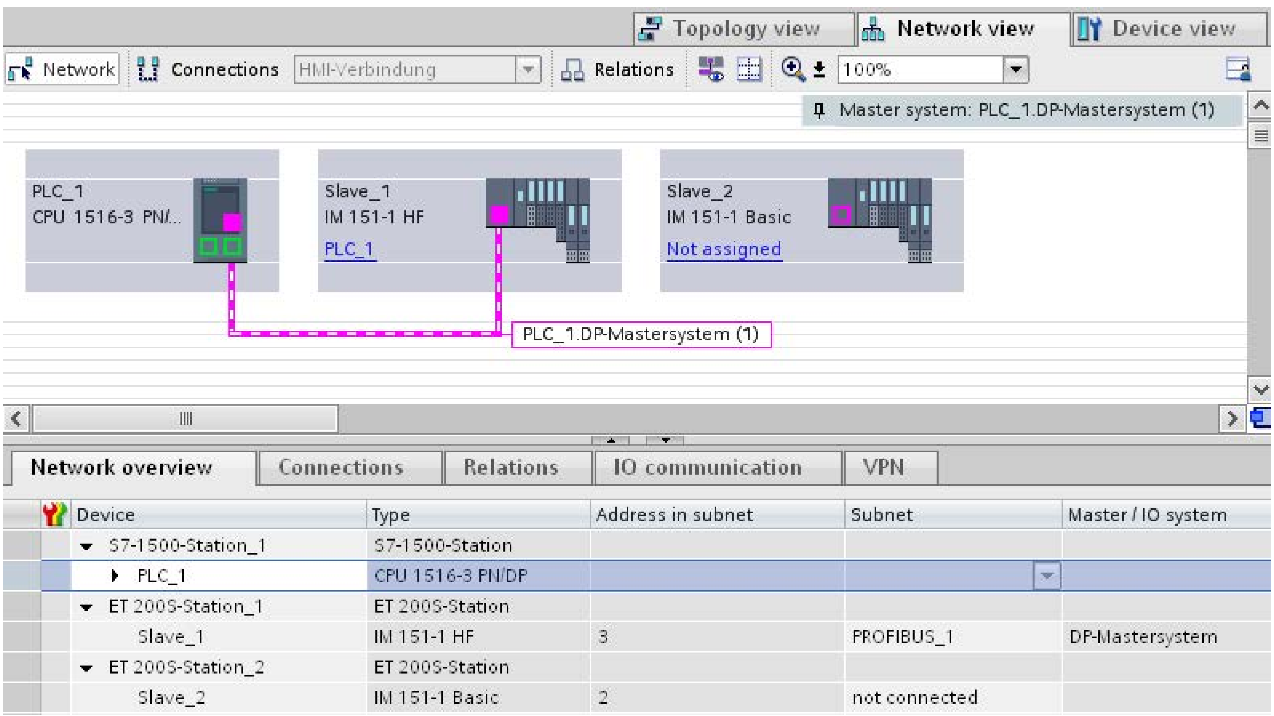

Figure 3-1 Assigning the DP slave to a DP master

Network overview

You can check the communication relationships of the activated interface in the network overview. The network overview is context-sensitive for selection in the network view:

- The selection of the CPU shows the DP communication of the CPU.
- The selection of the station shows the communication of the entire station.
- The selection of the interface shows the DP communication of the interface.

3.2 PROFIBUS address

Devices can be connected to the PROFIBUS subnet that communicate by means of configured connections or that are part of a PROFIBUS DP master system.

If the DP slave has already been assigned to a DP master, the PROFIBUS subnet to which the device is connected is automatically displayed under "Interface linked with".

In the Inspector window under "PROFIBUS", select the subnet to which the interface is linked or add a new subnet.

All devices of a subnet must have different PROFIBUS addresses.

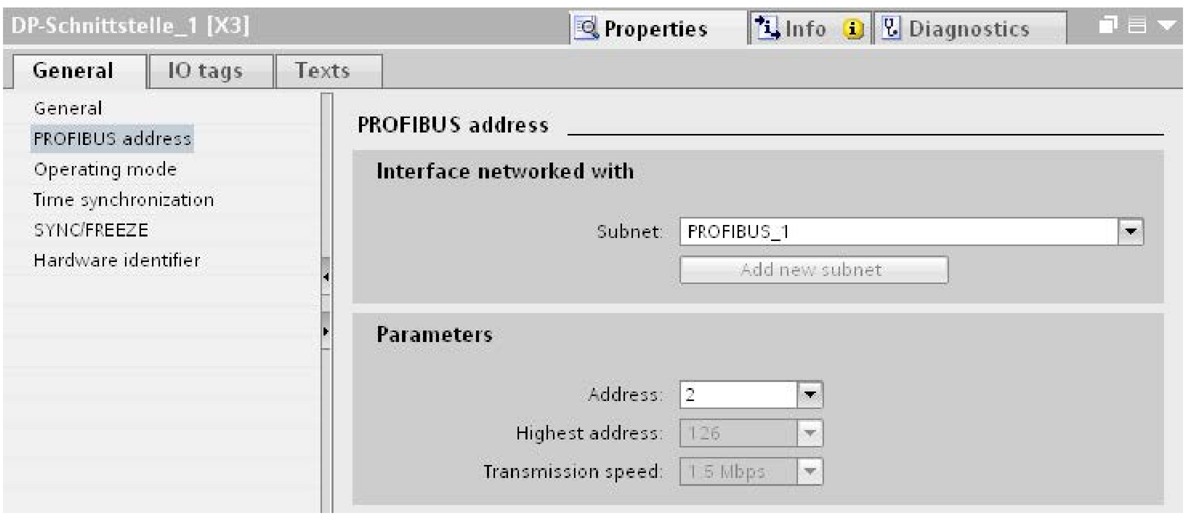

Figure 3-2 PROFIBUS address

Rules for address assignment

STEP 7 automatically assigns device addresses.

You can change the addresses if you observe the following points:

- Assign a unique PROFIBUS address to each device in the PROFIBUS network, each DP master and each DP slave in the PROFIBUS network.
- Depending on the DP slave, not all permitted PROFIBUS addresses are supported. For devices with BCD switches, it is often the case that only the PROFIBUS addresses 1 to 99 are supported.

Changing the PROFIBUS address

You change the PROFIBUS address under "Parameter".

3.3 Network settings

Highest PROFIBUS address (HSA)

Outputs the highest PROFIBUS address of an active device. PROFIBUS addresses greater than HSA are permitted for passive devices, but only up to 126.

Profile

Depending on the connected device types and the protocols used, different profiles are available on the PROFIBUS. The profiles differ with respect to their setting options and calculation of the bus parameters.

The PROFIBUS subnet will only work properly if the bus parameters of all devices have the same values.

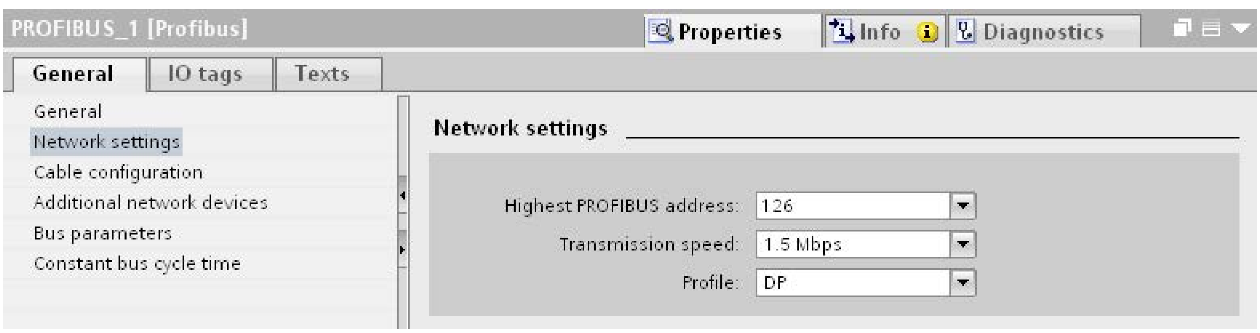

Figure 3-3 Network settings

Profiles and transmission rates

Table 3- 1 Profiles and transmission rates

Profiles	Supported transmission rates
DP	9.6 kbps to 12 Mbps
Standard	9.6 kbps to 12 Mbps
Universal (DP/FMS) (FMS is not supported)	9.6 kbps to 1.5 Mbps
User-defined	9.6 kbps to 12 Mbps

DP (recommended profile)

Select the "DP" profile if only devices meeting the requirements of the standard EN 61158-6-3 are connected to the PROFIBUS subnet. The setting of the bus parameters has been optimized for these devices. These include devices with DP master and DP slave interfaces of SIMATIC S7 as well as distributed I/O devices from third parties.

Note

Profile for constant bus cycle time and isochronous mode

DP is the recommended profile for the configuration of constant bus cycle time and isochronous mode.

Standard

Compared with the "DP" profile, the "Standard" profile gives you the option to take into consideration devices of another project or devices that have not been configured here for calculation of the bus parameters. The bus parameters are then calculated with a simple algorithm that was not optimized.

Universal (DP/FMS) (FMS is not supported)

Select the "Universal (DP/FMS)" profile if individual devices in the PROFIBUS subnet use the FMS service (e.g., CP 343-5, PROFIBUS FMS devices).

As with the "Standard" profile, here, too, you have the option to take additional devices into consideration for calculation of the bus parameters.

User-defined

The PROFIBUS subnet will only work properly if the parameters for the profile have been synchronized. Select the "User-defined" profile if none of the other profiles "match" for operation of a PROFIBUS device and if you have to adapt the bus parameters for your special layout.

You cannot configure all theoretically possible combinations with the user-defined profile either. The PROFIBUS standard prescribes some parameter limits depending on other parameters. It is, for example, not permitted that a responder responds (Min Tsdr) before the initiator is able to receive the frame (Trdy). These standard specifications are also checked in the "User-defined" profile.

Note

User-defined settings

Use user-defined settings only if you are familiar with the PROFIBUS parameters. It is usually better to work with the "DP" profile.

Contact Customer Support (Page 91) if you have any questions.

The bus parameters that were last valid on the PROFIBUS subnet are automatically set as user-defined. If the "DP" bus profile was valid for the subnet, for example, the bus parameters for "DP" are set in the "User-defined" bus profile. You can modify the parameters based on these settings.

The monitoring times are not automatically recalculated in the "User-defined settings" setting so that the uniformity of the set values is not changed without your knowledge, for example, to configure other configuration tools.

You can calculate the monitoring times Ttr and watchdog based on the parameters you have set. To do so, click on the "Recalculate" button.

Additional network stations (Page 51)

3.4 Cable configuration

Considering cable configuration

Information on the cable configuration can be taken into consideration for calculation of the bus parameters. To do so, select the check box "Take into account the following cable configuration" in the properties of the PROFIBUS subnet.

The other information depends on the type of cable used.

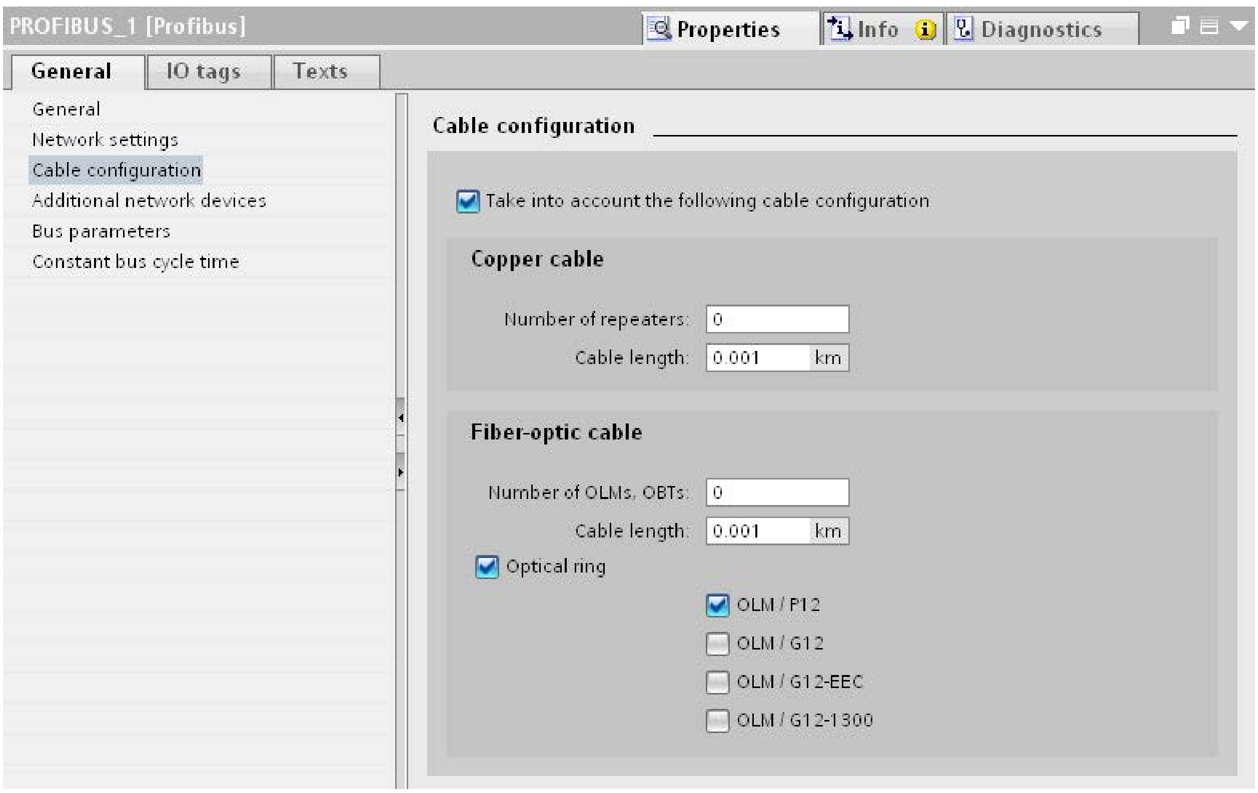

Figure 3-4 Cable configuration

Cable configuration: Fiber-optic cables/optical ring

The calculation depends on the used OLM types. Select the corresponding check box. Multiple selections are possible.

Adapting bus parameters in the optical ring

With the layout as ring, there is a kind of redundancy because you have the option to address all devices using the ring structure even if the connection between two devices is interrupted.

The following configuration conditions must be met in the optical ring:

- A free address below HSA (Highest Station Address)
- Increase of the retry value to at least 3

  (Network settings: user-defined profile)
- Checking and adapting of the slot time

  (Network settings: user-defined profile; bus parameters: Tslot parameter:

  You need short slot time values for OLM / P12, medium slot time values for OLM / G12 and OLM / G12-EEC and high slot time values for OLM / G12-1300. This results in a high performance for small networks and a medium to low performance with medium to large networks.

Additional information

Additional information on adaptation of the retry value and the slot time is available in the PROFIBUS Network Manual (http://support.automation.siemens.com/WW/view/en/35222591).

3.5 Additional network stations

Communication load - considering additional network stations

The bus parameters depend on the communication volume of the active network stations. There are differences between cyclical communication (DP) and connection-oriented, acyclical communication (S7 communication, Send/Receive (FDL)). Contrary to DP, the number and size of the communication jobs (communication load) depends on the user program. This means the communication load cannot always be determined automatically.

If you select the check box "Consider the following network stations", you can consider network stations in the calculation of the bus times that were not configured in the project.

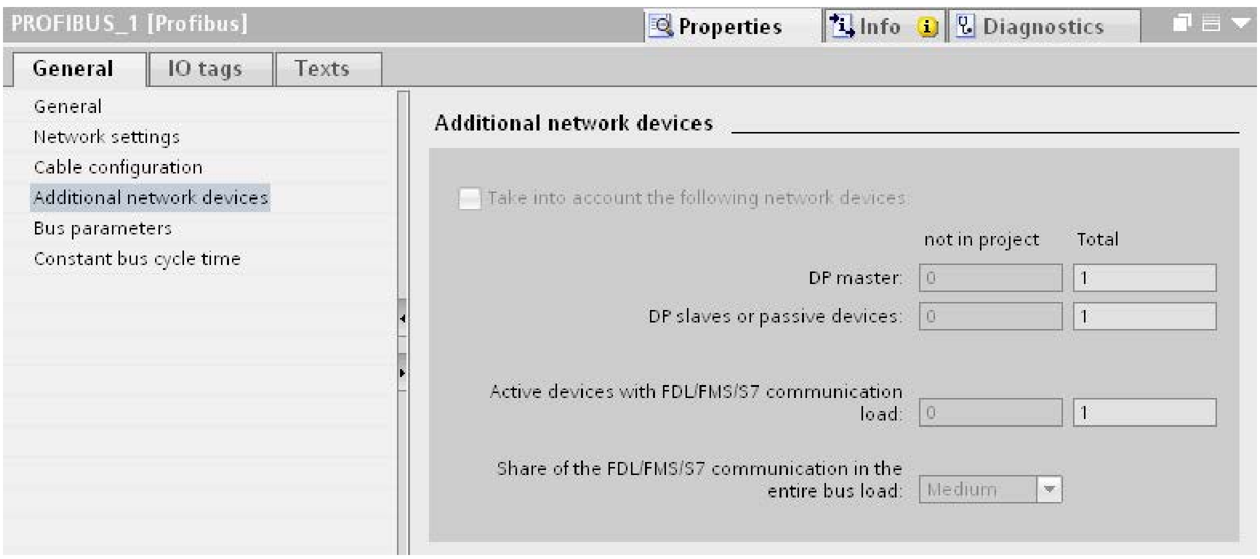

Figure 3-5 Additional network stations

Calculating the bus times

You can specify a network configuration in the parameter group "Additional network stations" for calculation of the bus times that deviates from the configured network configuration.

The network configuration is available for the following profiles:

- Standard
- Universal (DP/FMS)
- User-defined

Quantification of the communication load

The following settings are possible to take the communication load into consideration:

- Number of network stations that are not configured
- Information on the communication load from the user programs for FDL or S7 communication. You can choose from the following levels:
  - Low: Typical for DP, no larger data communication except DP.
  - Medium: Typical for mixed operation of DP and other communication services (e.g., S7 communication), if DP has high time requirements and with medium, acyclical communication volume.
  - High: For mixed operation of DP and other communication services (e.g., S7 communication), if DP has low time requirements and with high, acyclical communication volume.

3.6 Bus parameters

Introduction

Bus parameters control the transmission behavior on the bus. Each device on the bus must correspond with the bus parameters of other devices.

Note

The PROFIBUS subnet will only work properly if the parameters for the bus profile have been synchronized. Change the preset values only if you are familiar with the parameter assignment of the bus profile for PROFIBUS.

Cyclical distribution of the bus parameters

If the check box "Activate cyclical distribution of bus parameters" is selected under "Bus parameters" with the selected PROFIBUS subnet in the Inspector window, the bus parameters are sent cyclically during operation by the modules that support this function. This way you can, for example, connect a programming device to the PROFIBUS during operation.

Disable this function in the following cases:

- In constant bus cycle time mode to minimize the bus cycle.
- If third-party devices are connected in the PROFIBUS subnet whose protocol uses the DSAP 63 (Destination Service Access Point) for multicast.

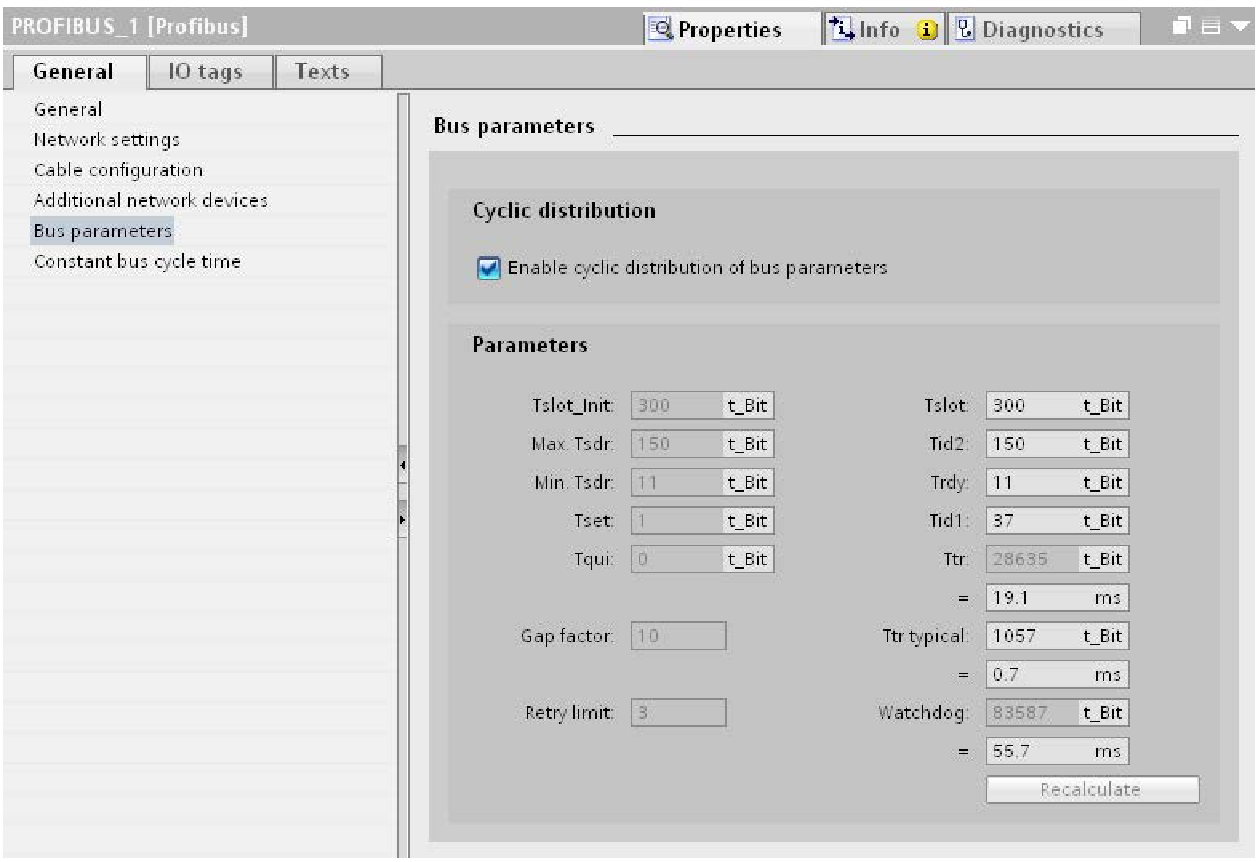

Figure 3-6 Bus parameters

Bus parameters for the bus profile of PROFIBUS subnets

Note

Display of offline values

The offline values of the bus parameters are always displayed even if they are connected online with the target system.

Table 3- 2 Bus parameters - value ranges

Bus parameters	Adjustable [1]	Limit values
Tslot_Init	Yes	Max. Tsdr + 15 <= Tslot_Init <= 16.383 t_Bit
Max. Tsdr	Yes	35 + 2*Tset + Tqui <= Max. Tsdr <= 1,023 t_Bit
Min. Tsdr	Yes	11 t_Bit <= Min. Tsdr <= MIN(255 t_Bit, ... Max. Tsdr - 1, 34 + 2*Tset + Tqui)
Tset	Yes	1 t_bit <= Tset <= 494 t_bit
Tqui	Yes	0 t_bit <= Tqui <= MIN(31 t_bit, Min. Tsdr - 1)
GAP factor	Yes	1 <= GAP factor <= 100
Retry limit	Yes	1 <= Retry limit <= 15
Tslot (slot time)	No	-
Tid2	No	Tid2 = Max. Tsdr
Trdy	No	Trdy = Min. Tsdr
Tid1	No	Tid1 = 35 + 2*Tset + Tqui
Ttr (Target Rotation Time)	Yes	256 t_Bit <= Ttr <= 16,777,960 t_bit
Ttr typical	No	This time is for information only and is not transmitted to the devices.
Watchdog		10 ms <= Watchdog <= 650 s

[1] depending on bus profile

User-defined bus profile

Use the following settings to create a user-defined bus profile:

- minimum Target Rotation Time (Ttr) = 5000x HSA (highest PROFIBUS address of an active device)
- minimum watchdog (Watchdog) = 6250x HSA

Recalculate

Use the button "Recalculate" to recalculate the parameters.

3.7 Constant bus cycle time

Constant bus cycle time

The DP master addresses its assigned DP slaves cyclically. S7 communication may cause the intervals to vary. You can enable a "bus cycle with constant bus cycle time" to achieve identical intervals. This ensures data transmission at the same (constant bus cycle time) intervals.

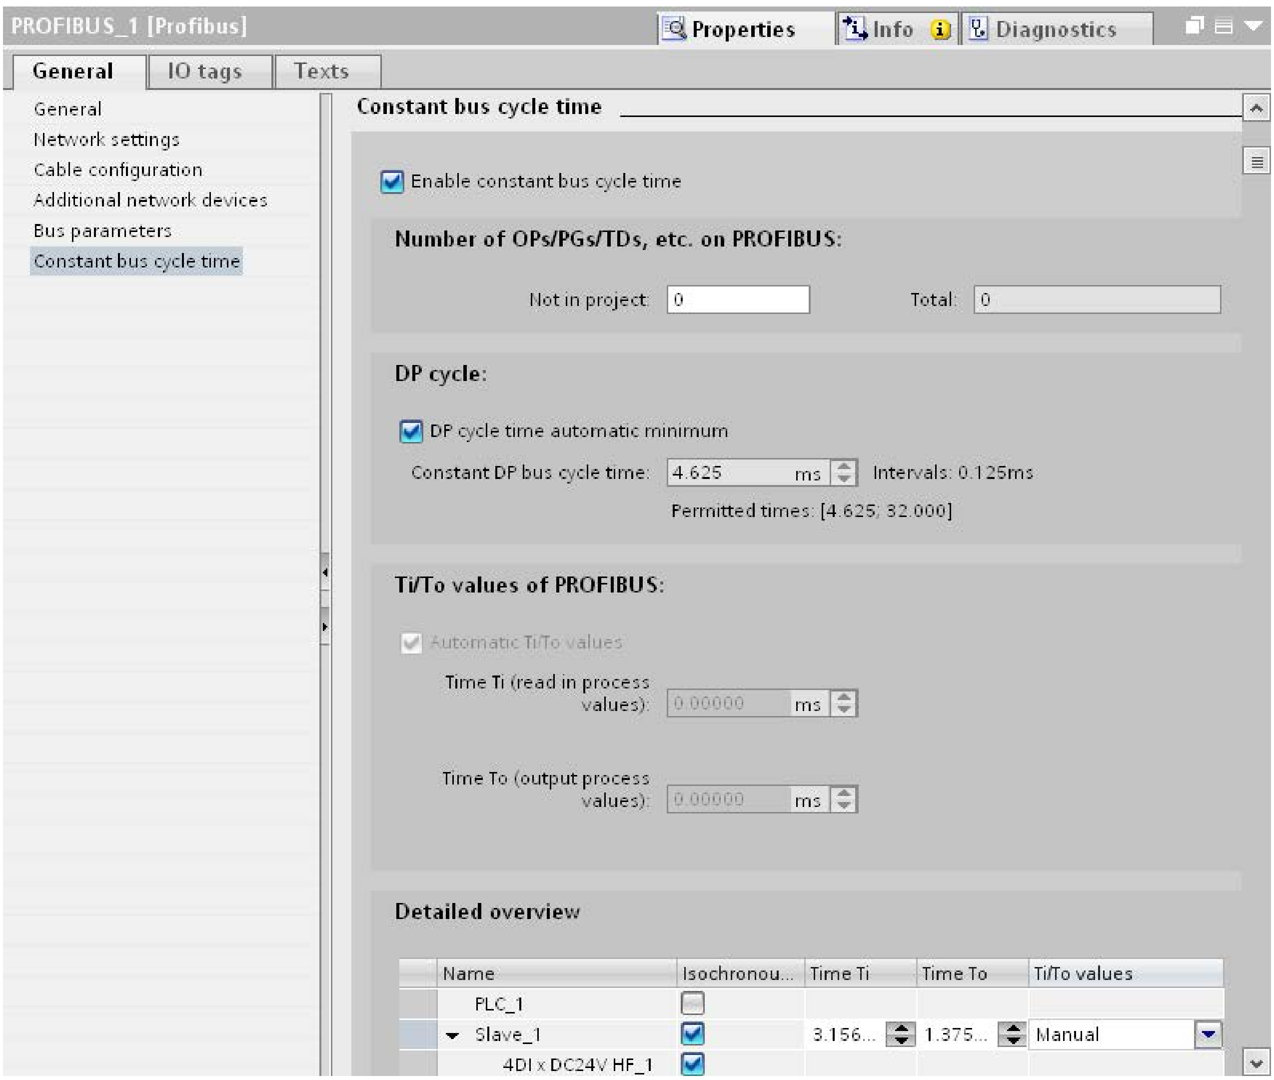

Figure 3-7 Enabling a bus cycle with constant bus cycle time

Number of OPs/PGs/TDs at the PROFIBUS

Here you enter the number of devices that are not configured.

Increasing DP cycle time manually

The following situation can occur especially with very short DP cycle times:
The runtime of the user program is greater than the shortest cycle (see Technical specifications of the CPU, section "Isochronous mode"). You have to manually increase the automatically calculated DP cycle time in this case.

Configuring isochronous mode (Page 67)

4 Diagnostics

4.1 Overview

Diagnostics options

In case of an error you can determine the current status of your automation system and react specifically by using the event-related diagnostics and the evaluation of interrupts.

You can use the following options for diagnostics of the PROFIBUS components:

- Determine the status of the system using the Lifelist in STEP 7.
- Evaluate the module status, error and message texts by using the display of the S7-1500 CPU.
- Run cable diagnostics during operation by means of the diagnostics repeater.
- Evaluate the diagnostics and interrupt behavior in isochronous mode. (Page 70)
- Determine status information for fault localization and fault rectification by using the DP/PA coupler FDC 157-0 configured as PROFIBUS diagnostics slave.

Additional information

Additional information on diagnostics is available in these manuals:

- In the Diagnostics repeater for PROFIBUS-DP (http://support.automation.siemens.com/WW/view/en/7915183) manual for diagnostics with STEP 7, diagnostics in the user program, monitoring function isochronous PROFIBUS, topology display in STEP 7.
- In the Diagnostics (http://support.automation.siemens.com/WW/view/en/59192926) function manual for diagnostics options that are available for the SIMATIC systems S7-1500, ET 200MP, ET 200SP and ET 200AL.
- In the PROFIBUS Network Manual (http://support.automation.siemens.com/WW/view/en/35222591) system manual for diagnostics of fiber-optic cables.
- In the DP/PA Coupler, Active Field Distributors, DP/PA Link and Y Link (http://support.automation.siemens.com/WW/view/en/1142696) operating instructions.
- In the Web Server (http://support.automation.siemens.com/WW/view/en/59193560) function manual for diagnostics options (based on the functionality of the CPU).

4.2 Diagnostics using the display of the S7-1500

Displays

Each CPU in the S7-1500 automation system has a front cover with a display and operating buttons. Control and status information is displayed in different menus on the display. You use the operating buttons to navigate through the menus.

The following states can be evaluated on the display:

- Module status for central and distributed modules
- Error and alarm texts (system diagnostics, user-defined alarms)

Module status

From the station overview you go to the module status for a distributed module via the module overview.

Figure 4-1 Example: Station overview, module overview, module status

Error and alarm texts

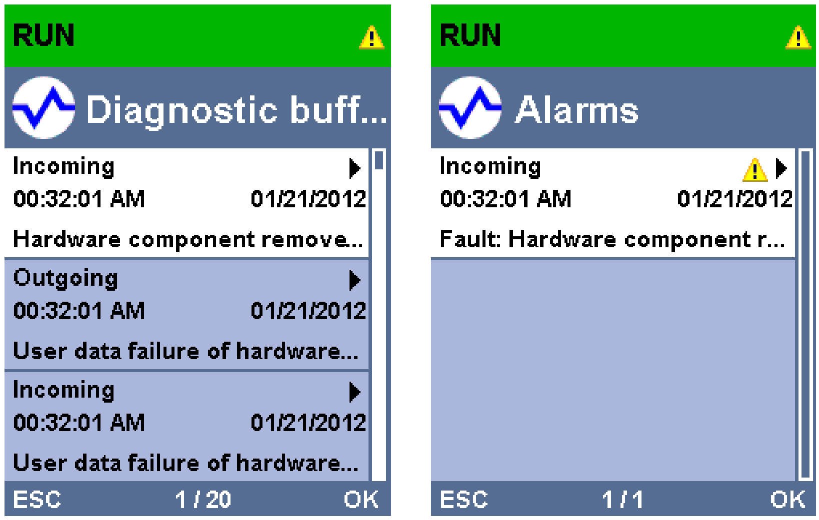

Figure 4-2 Example: Diagnostic buffer, alarms

Additional information

Additional information on the topic "Functions and operation of the display" is available in the documentation for the S7-1500 automation system on the Internet (http://support.automation.siemens.com/WW/view/en/59191792).

4.3 Diagnostics with the diagnostic repeater

Introduction

The diagnostic repeater is a repeater that can monitor two segments of a RS485-PROFIBUS subnet (copper cable) during operation and signal cable faults to the DP master by sending a diagnostic frame. Fault location and the cause of the fault can be displayed in plain text by means of STEP 7 as well as operator control and monitoring devices (SIMATIC HMI).

With its cable diagnostics during operation, the diagnostic repeater allows you to detect and localize cable faults early on. This means plant faults are detected early and plant downtimes can be prevented.

Diagnostic functions

- The diagnostic function provides the location and the cause of cable faults, such as wire break or missing terminating resistors. The fault location is specified relative to the devices present, for example "Break on signal line A and/or B".
- Reading out the saved diagnostic and statistical information.
- Monitoring of the isochronous PROFIBUS, e.g., violation of cycle time.
- Providing identification data.

Additional information

Additional information on diagnostics with STEP 7 and for reading out the diagnostics with the user program is available in the Diagnostic repeater for PROFIBUS DP (http://support.automation.siemens.com/WW/view/en/7915183) manual.

4.4 I&M data (Identification and Maintenance)

Definition and properties

Identification and maintenance data (I&M) is information saved in a module to provide support when:

- Checking the plant configuration
- Locating hardware changes in a plant

Identification data (I data) is module information (some of which may be printed on the module housing) such as the order and serial number. I data is read-only, vendor-specific module information.

Maintenance data (M data) is system-specific information such as the installation location and date. M data is generated in the course of configuration and is written to the module memory.

The modules can be uniquely identified in online mode by means of the I&M data.

Additional information

Information if and to what extent a DP device supports I&M data is available in the respective device manual of the device.

Functions 5

5.1 Isochronous mode

5.1.1 What is isochronous mode?

Why isochronous mode?

Assuming public transport were to operate at maximum speed while reducing stop times at the passenger terminals to absolute minimum, the last thing many potential passengers would notice of the departing contraption are its red tail lights. The overall travel time is, however, decided by the train, bus or underground clock, because well adjusted timing is essential to a good service. This also applies to distributed automation engineering. Not only fast cycles but also the adaptation and synchronization of the individual cycles result in optimum throughput.

Just-In-Time

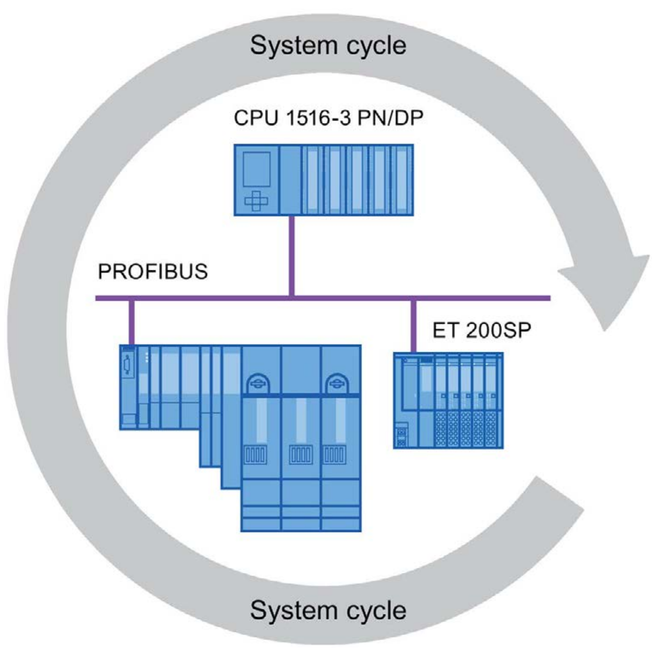

Figure 5-1 System cycle

The high speed and reliable reaction time of a system operating in isochronous mode is based on the fact that all data is provided just-in-time. The constant bus cycle time PROFIBUS DP cycle beats the time here.

Advantages of isochronous mode

The use of isochronous mode provides:

- Optimized controls
- Determinism
- Consistent (simultaneous) reading of input data
- Consistent (simultaneous) output of output data

5.1.2 Use of isochronous mode

The system property "isochronous mode" enables recording of measured values and process data in a defined system cycle. Signal processing takes place in the same system cycle all the way to switching to the "output terminal". This means isochronous mode improves the control quality and provides greater manufacturing precision. Isochronous mode drastically reduces the possible fluctuations of process response times. The time-assured processing can be used for a higher machine cycle.

Isochronous mode is basically always the choice when acquisition of measured values needs to be synchronized, movements need to be coordinated and process reactions need to be defined and take place simultaneously. This means the areas of applications for isochronous mode are manifold.

5.1.3 Isochronous applications

Example: Isochronous measurement at several measuring points

QC requires precise measurement of dimensions within a camshaft production process.

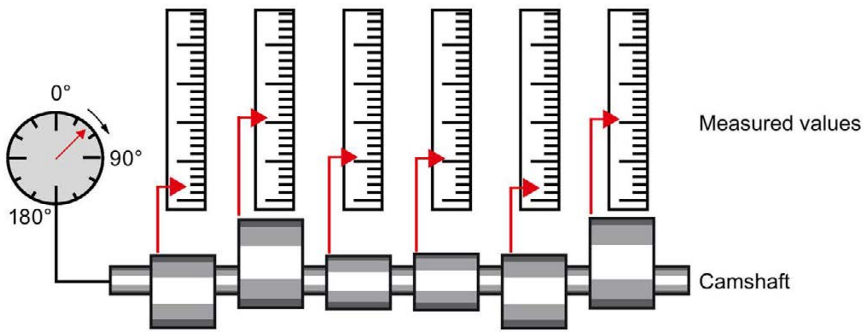

Figure 5-2 Measuring of camshafts

Isochronous workflow

By using the system property "isochronous mode" and the associated simultaneous measured value acquisition, measurement can be performed continuously and the time required for measurement is reduced. Resultant workflow:

- Continuous turning of the camshaft.
- During the continuous turning, measure the positions and cam excursion synchronously.
- Process the next camshaft.

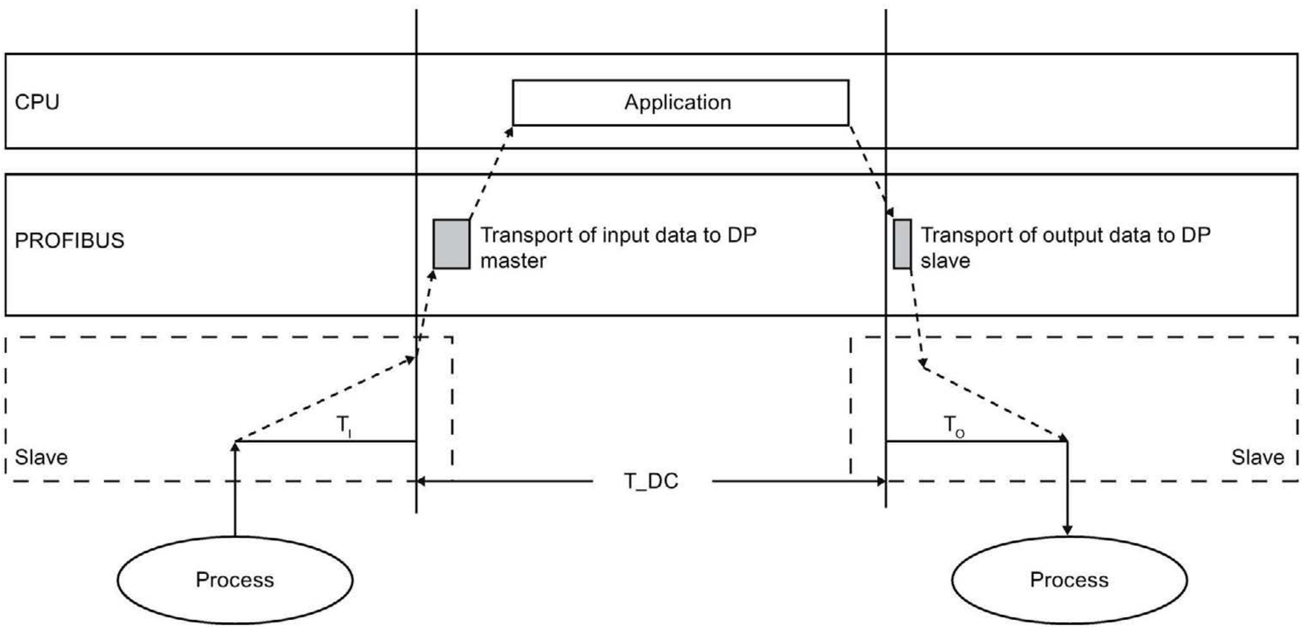
All camshaft positions and the corresponding measured values (red) are measured synchronously within a single rotation of the camshaft. This increases machine output and maintains or enhances precision of the measurement.

5.1.4 Sequence of synchronization

From reading of input data to output of output data

The sequence of all components involved in the synchronization is explained in the paragraphs below:

- Isochronous reading of input data
- Transport of input data by means of the PROFIBUS subnet to the DP master (CPU)
- Further processing in the isochronous application of the CPU
- Transport of output data by means of the PROFIBUS subnet to the output DP slave
- Isochronous output of output data



T_DC Date cycle

T_I Time for reading the input data

T_O Time for output of output data

Figure 5-3 Time sequence of synchronization

To ensure that all input data is ready for transportation via the PROFIBUS DP line when the next PROFIBUS DP cycle begins, the I/O read cycle has a lead time T_I so that it starts earlier. The T_I is the "flash gun" for all inputs. This T_I is necessary to compensate for analog to digital conversion, backplane bus times, etc. The lead time T_I can be configured by STEP 7 or by the user. We recommend that you have T_I assigned automatically by STEP 7 .

The PROFIBUS DP line transports the input data to the DP master. The synchronous cycle interrupt OB SynchronousCycle is called. The user program in the synchronous cycle interrupt OB decides the process reaction and provides the output data in time for the start of the next data cycle. The length of the data cycle is always configured by the user.

T_o is the compensation from the backplane bus and the digital to analog conversion within the slave. The T_o is the "flash gun" for all outputs. The time T_o can be configured by STEP 7 or by the user. We recommend that you have T_o assigned automatically by STEP 7.

Without isochronous mode, application, data transmission and field devices have their own, unsynchronized processing cycles; these result in a higher total cycle time with high jitter. With isochronous mode, application, data transmission and field device are synchronized resulting in a minimum total cycle with minimum jitter.

Isochronous mode and non isochronous mode distributed I/O

It is possible to combine isochronous mode distributed I/O with non isochronous mode distributed I/O on one DP master.

5.1.5 Requirements for configuration

Note the following requirements for configuration of isochronous mode:

- Isochronous mode cannot be used in optical PROFIBUS networks.
- Constant bus cycle time and isochronous mode are only possible with the bus profiles "DP" and "User-defined".
- Isochronous mode is only possible with the DP interfaces integrated in the CPU. Isochronous mode with CPs for PROFIBUS is not possible.
- Only the constant bus cycle time master is permitted as active station on the isochronous PROFIBUS DP. OPs and PGs (for example, PCs with PG functionality) influence the time behavior of the isochronous DP cycle and are therefore not permitted.
- Isochronous mode is not permitted across lines.
- Isochronous I/O can only be processed in process image partitions. Isochronous consistent data transmission is not possible without the use of process image partitions. The adherence to quantity structures is monitored because the number of slaves and bytes on the DP master system is limited for each process image partition.
- The addresses of isochronous modules must be located in a process image partition.
- Full isochronous mode from "terminal" to "terminal" is only possible if all components involved in the chain support the system property "isochronous mode".

  Make sure you look for the entry "Isochronous mode" or "Isochronous processing" in the information box of the module when you select it in the catalog.
- When you configure isochronous mode, you may not assign a SYNC/FREEZE group to the slave.

5.1.6 Configuring isochronous mode

Introduction

A SIMATIC automation solution can be connected to the isochronous PROFIBUS with the isochronous mode function. Isochronous mode guarantees the synchronous reading of input data, the processing and output of output data at the same (isochronous) intervals.

Basic procedure for configuration of isochronous mode

1. Setting the properties for isochronous mode on the DP slave:
   - Isochronous DP cycle
   - Isochronous mode of the modules
2. Setting the properties for isochronous mode on the modules:
   - Synchronous cycle interrupt (SynchronousCycle)
   - Process image partition
   - Input delay
3. Create user program with access to isochronous I/O

Requirement

- The network view in STEP 7 is open.
- A CPU has been placed (e.g., CPU 1516-3 PN/DP).
- An interface module has been placed and networked with the CPU (e.g., IM 151-1 HF).
- I/O modules have been placed (e.g., 2DI x DC24V HF and 2DO x DC24V/0,5A HF).

Configuring isochronous mode on the DP slave

1. Select the DP slave in the network view and navigate to the "isochronous mode" area in the Inspector window.
2. Enable the option for synchronization to the DP cycle for the DP slave.

   Default: The DP slaves get the Ti/To values from the subnet which means the values are automatically the same for all DP slaves of the DP master system.
3. Enable the "Isochronous mode" option the the "Detail view" for all I/O modules you want to operate in isochronous mode.
4. Repeat steps 1 and 3 for all DP slaves that you want to operate in isochronous mode.

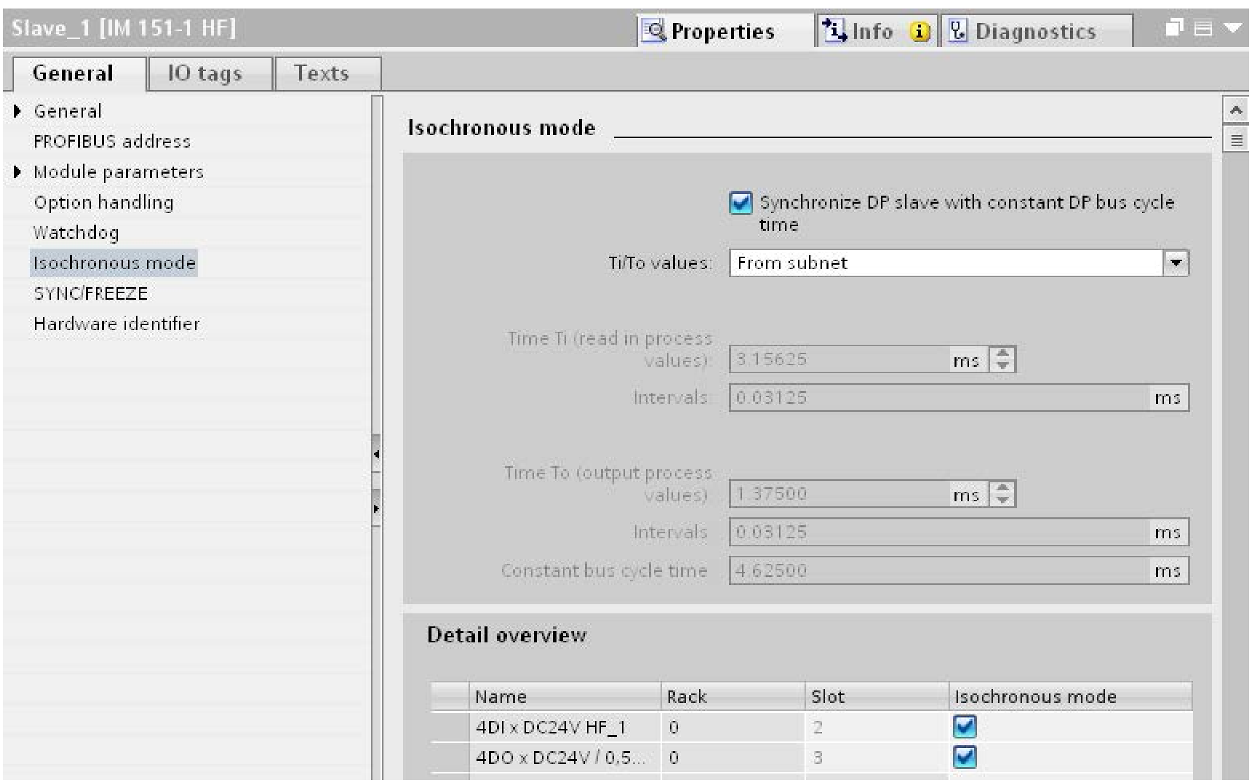


Figure 5-4 Configuring isochronous mode on the DP slave

Configuring synchronous cycle interrupt on the I/O module

1. Select an I/O module in the device view and navigate to the "I/O addresses" area in the Inspector window.
   – The option for isochronous mode is selected.
2. Select the synchronous cycle interrupt in the drop-down list.

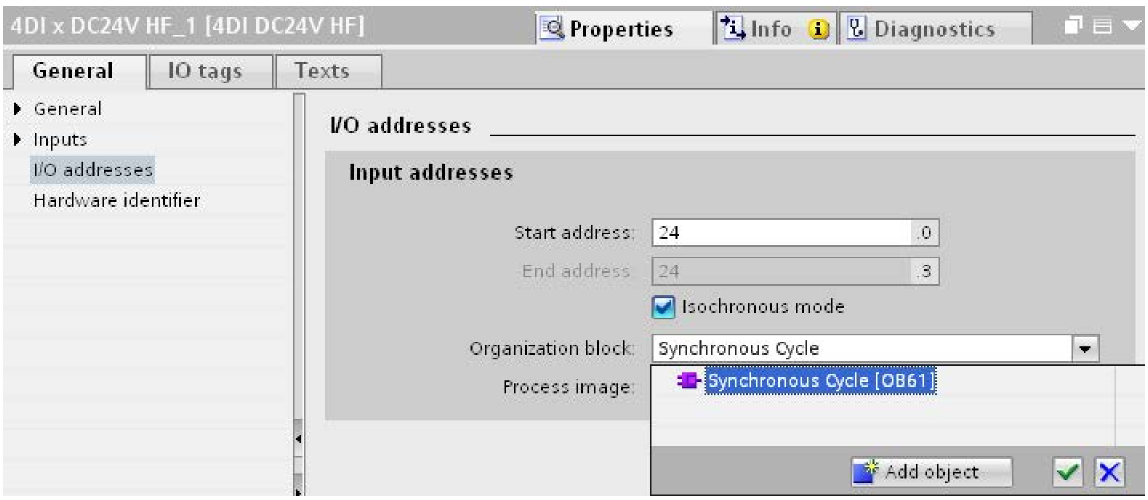

Figure 5-5 I/O addresses - creating the synchronous cycle interrupt OB

3. Assign the process image partition configured in the CPU.

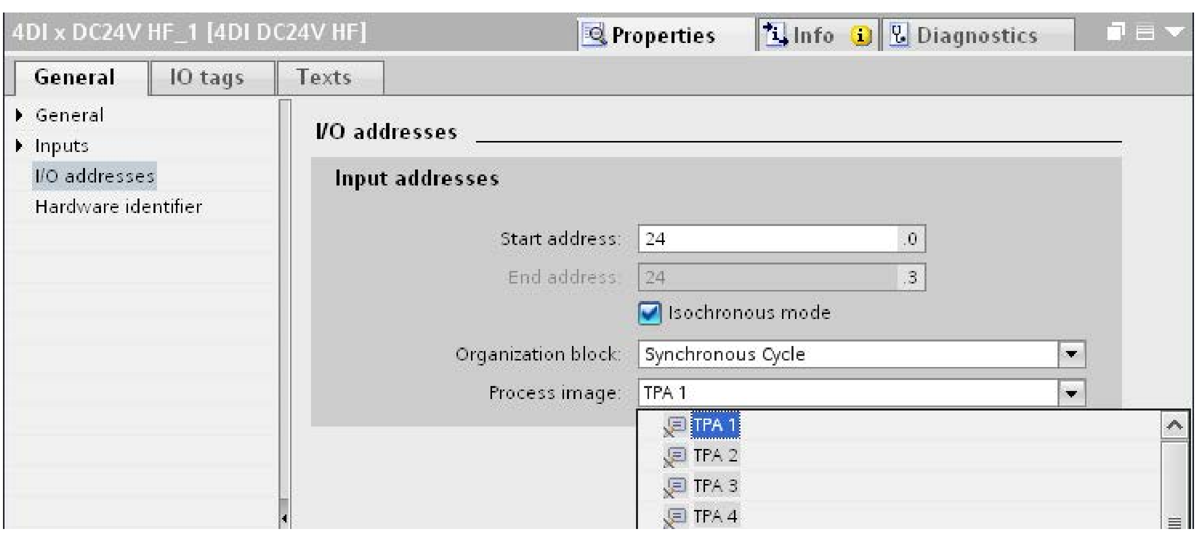

Figure 5-6 I/O addresses - assigning process image partitions

4. Repeat steps 1 and 3 for all I/O modules that you want to operate in isochronous mode.

Programming isochronous mode

To operate your plant in isochronous mode, the user program must be structured accordingly. This means you have to add a synchronous cycle interrupt in the STEP 7 project tree.

You access the isochronous I/O by means of a process image partition, which means the addresses of the isochronous modules must be located in a process image partition. You program access to isochronous I/O with the "SYNC_PI" instructions (updating the process image partitions of the inputs) and "SYNC_PO" (updating the process image partition of the outputs) in the synchronous cycle interrupt OB.

You call the "SYNC_PI" instruction at the start of the synchronous cycle interrupt OB, provided you have selected the automatic setting for the delay time. You call the "SYNC_PO" instruction at the end of the synchronous cycle interrupt OB.

5.1.7 Diagnostics and interrupt functions

The diagnostic and interrupt functions of STEP 7 are available for isochronous mode. These reduce downtimes and simplify localization and elimination of faults.

Events, causes of errors and remedies

Below, you will find the events for diagnostic and interrupt functions and remedies for the problem.

Table 5- 1 Events, causes of errors and remedies

Event	Cause of the error	Remedy
• Synchronous cycle interrupt OB is started with the input parameter EventCount > 0 (number of lost OB calls since last OB call) If configured: • Call of the time error OB • Diagnostic buffer entry "Buffer overflow for OB6x events"	The synchronous cycle interrupt OB takes too long.	• Shorten the synchronous cycle interrupt OB. • Increase the DP cycle. • Reduce the delay time setting (setting with isochronous mode at synchronous cycle interrupt OB).
Error (negative RetVals) when updating the isochronous process image partition with SYNC_PI / SYNC_PO: • Consistency warning • Update time is after / before the permitted access window.	SYNC_PI / SYNC_PO are not called in the permitted access window in the synchronous cycle interrupt OB, which means they are called or processed during the I/O data transfer on PROFIBUS.	• Increase the delay time. • Increase the DP cycle. • Adapt the program.
Error when updating the isochronous process image partition with SYNC_PI / SYNC_PO: • Access error	DP slave / module does not respond / is not available.	

5.1.8 Parameter settings for isochronous mode

Parameter changes as task of the field service technician

The task of a field service technician is to maintain the production process.

In this context the technician has to detect, localize and eliminate errors and performance losses of isochronous mode.

All parameters which influence isochronous mode can be checked and configured using the "Isochronous mode" dialog box.

Parameters should only be changed by experienced users or service technicians.

5.1.8.1 Viewing isochronous mode parameters

"Isochronous mode" dialog box

1. Select "Properties > Isochronous mode" in the Inspector window.

   The "isochronous mode" dialog box opens with an overview of parameters which influence isochronous mode.
   Information on the individual parameters is available under "Detail overview".
2. Compare the values shown with the values in the documentation, or with the value specified by a technician.

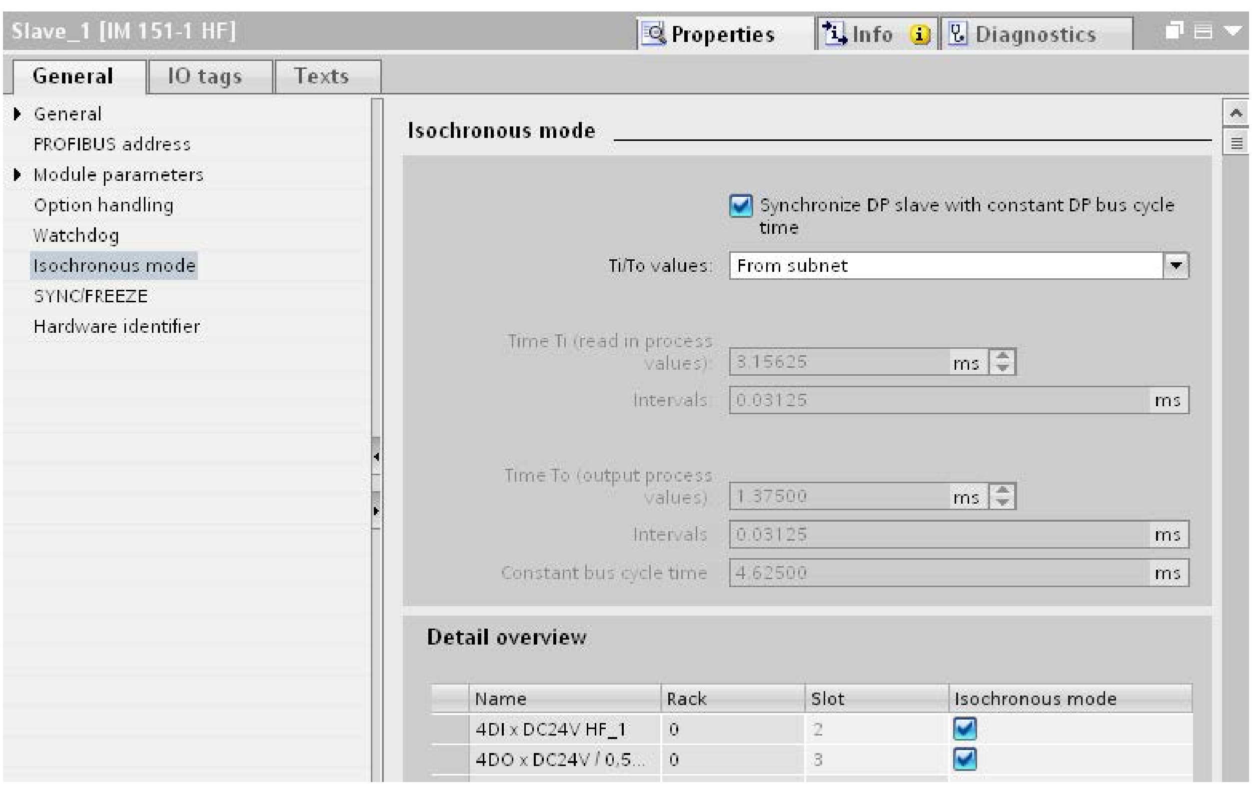

Figure 5-7 Viewing parameters for isochronous mode

5.1.8.2 Change parameters

Changing parameters for the DP master system

You can change the parameters for isochronous mode in the "Constant bus cycle time" dialog box.

1. Select the DP master system in the network view.
2. Select the section "Constant bus cycle time" in the Inspector window.
3. Change the parameters according to the received instructions.

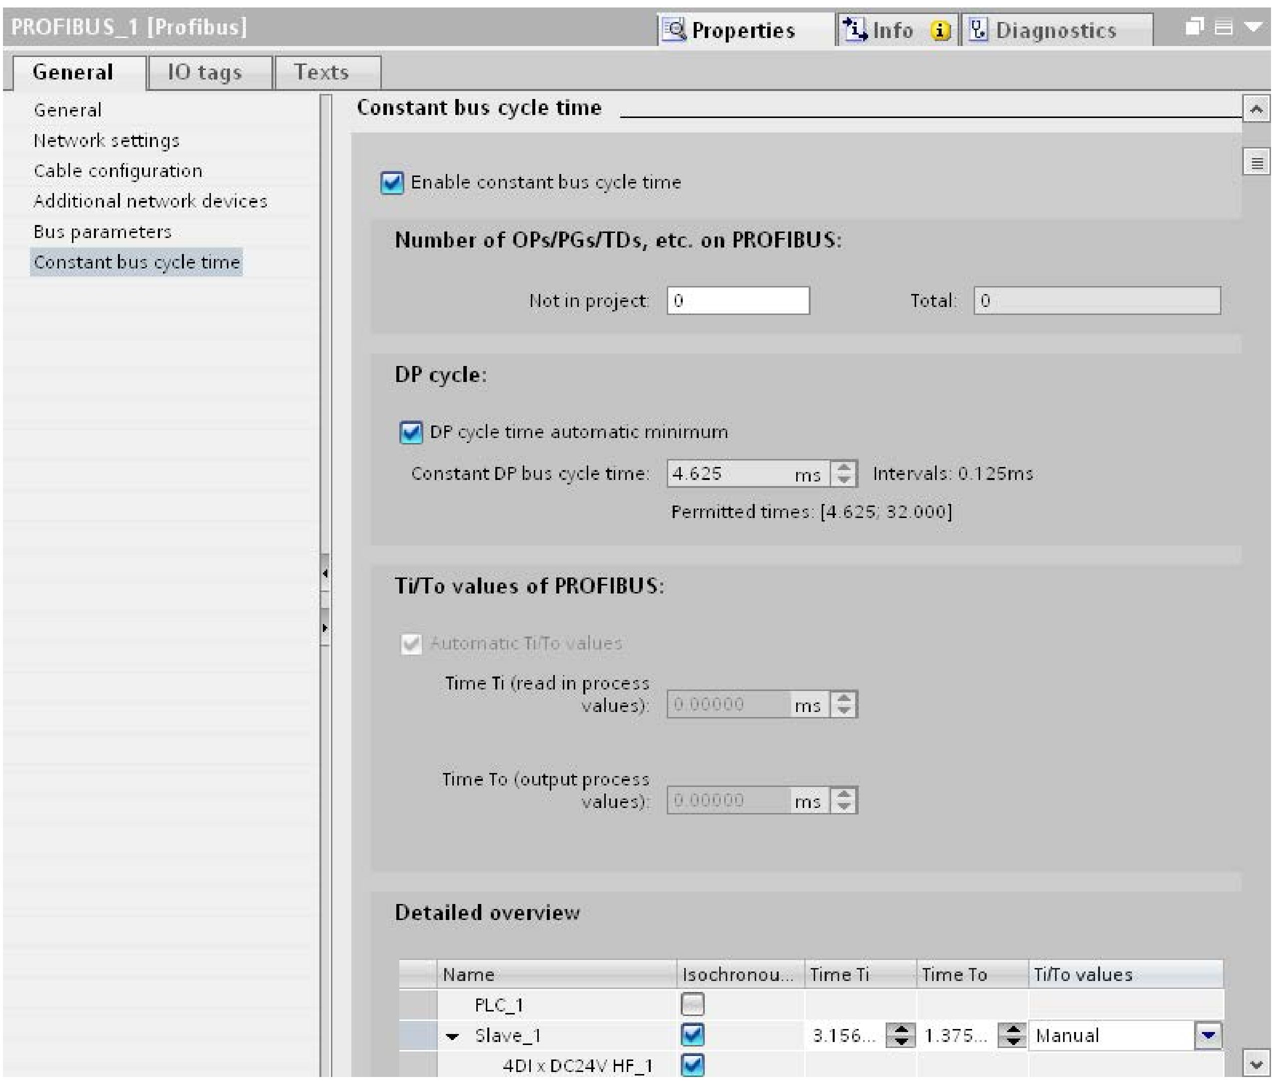

Figure 5-8 Changing parameters for the DP master system

Adapting the input delay

1. Select the input module in the device view.
2. Select the section "Inputs" in the Inspector window.
3. Adapt the input delay.

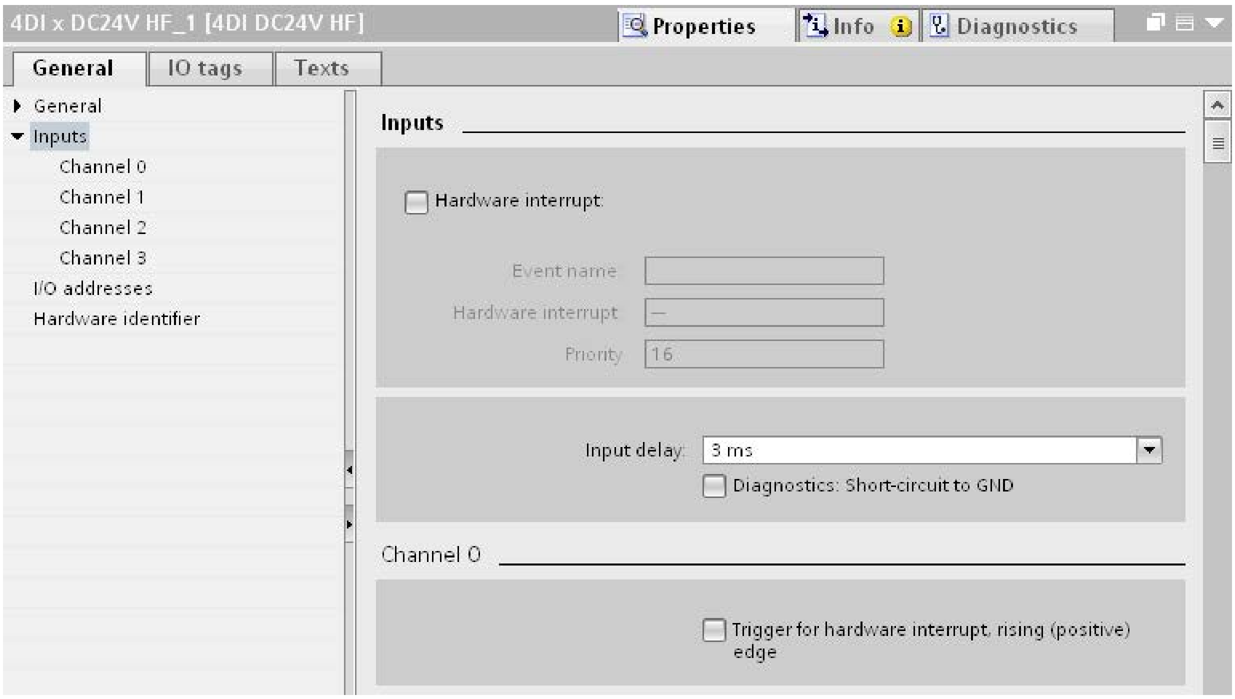

Figure 5-9 Adapting the input delay

Compile, load and save the changed configuration

1. Put the plant out of operation.
2. Select the CPU in the project navigator.
3. Select "Compile > Hardware" in the shortcut menu.
4. Select "Download to device" in the shortcut menu.
5. Save the project.

5.2 Acyclical data exchange

Additional functionality with DPV1 devices (DP master/DP slaves)

DP masters and DP slaves that support DPV1 have the following additional functions compared to the devices that support only DPV0:

- The acyclic data exchange between master and slave is supported.
- Interrupts can be set by a DPV1 slave which ensure handling of the interrupt-triggering event in the master CPU.

Acyclic data exchange

Read/write data record, for example, to change the parameters of a slave during operation. The data records of a module and the structure of these data records is available in the documentation for the respective module.

The table below contains the instructions with their functions for access to DPV1 slaves. Detailed information is available in the STEP 7 online help.

Table 5- 2 Instructions for access to DPV1 slaves

Instructions	Function (DPV1)
RDREC	Read data record
WRREC	Write data record
RALRM	Receive interrupt from a DP slave. (The instruction must be called in the OB that triggers the interrupt.)

5.3 SYNC/FREEZE groups

Assigning the SYNC/FREEZE group to the DP slave

A DP master with the corresponding functionality can send the control commands SYNC and/or FREEZE for synchronization of the DP slaves simultaneously to a group of DP slaves. You must assign SYNC/FREEZE groups to the DP slaves for this purpose.

Requirement: A DP master system has been created in the project.

Procedure

To assign a DP slave to a SYNC/FREEZE group, follow these steps:

1. Select the DP interface of the DP slave you want to assign to a group in the device view or network view.
2. Select the check boxes for the required SYNC/FREEZE groups under the group "SYNC/FREEZE" in the Inspector window.

   You can assign each DP slave to only one SYNC/FREEZE group.

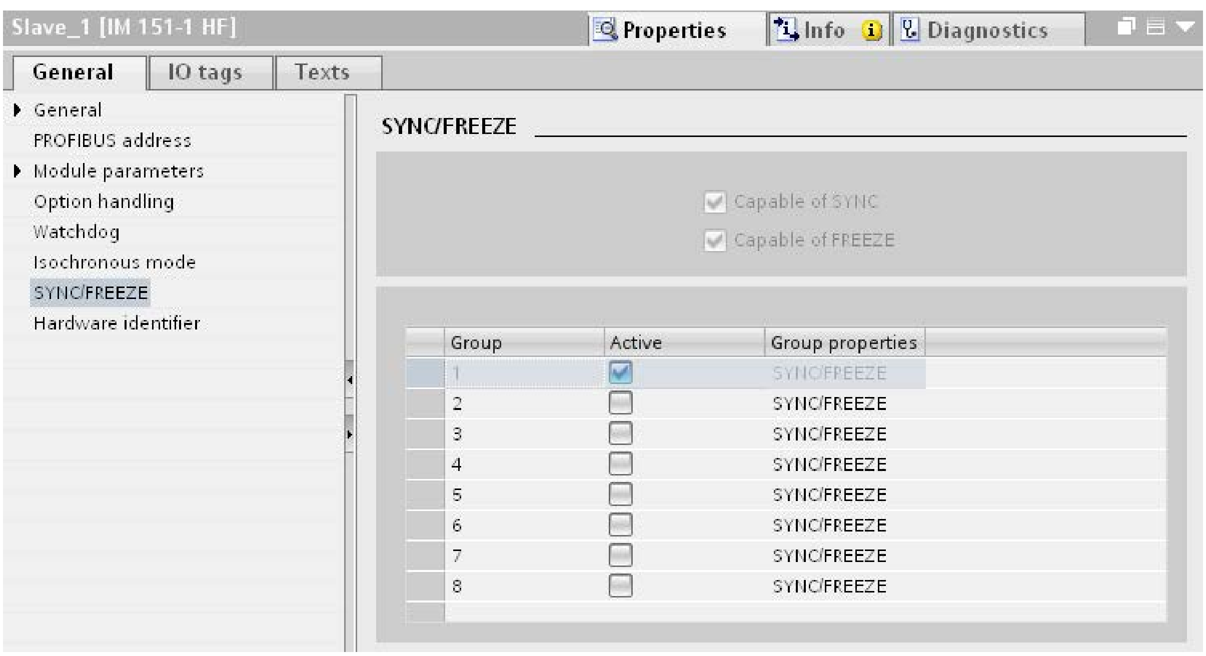

Figure 5-10 Assigning the DP slave to a SYNC/FREEZE group

Important information on the control commands SYNC and FREEZE

You can use the control commands SYNC and FREEZE in the DP master to synchronize the DP slaves event-controlled. The DP master sends the control commands simultaneously to a group of DP slaves in its master system. It does not take into consideration DP slaves that have failed or are currently sending diagnostic information.

Requirement for synchronization using control commands is that you have assigned the DP slaves to SYNC/FREEZE groups.

For a S7 CPU use the instruction DPSYC_FR (SFC 11) to synchronize the DP slaves.

When you select the DP master, you see a list of the eight SYNC/FREEZE groups under "Properties > DP interface > SYNC/FREEZE" in the Inspector window.

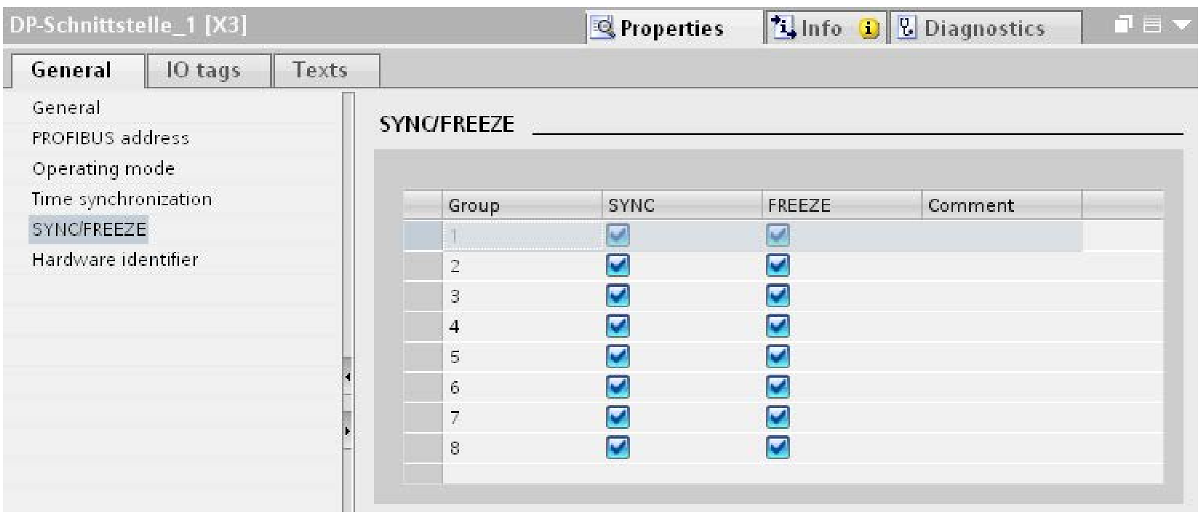

Figure 5-11 SYNC/FREEZE groups on DP master

SYNC control command

The DP master uses the SYNC control command to cause a group of DP slaves to freeze the states of their outputs to the current value.

The DP slaves save the output data of the DP master for the following frames. But the states of the DP slave outputs remain unchanged.

Only after each new SYNC control command does the DP slave set its outputs to the values that it has saved as the output data of the DP master.

The outputs are not updated cyclically again until the DP master has sent a UNSYNC control command.

FREEZE control command

After receiving the FREEZE control command from the DP master, the DP slaves of a group freeze the current status of their inputs. The DP slaves send these frozen input data to the DP master with the following cyclical frames.

The DP slaves freeze the current state of their inputs again after each new FREEZE control command.

The state of the DP slave inputs is only send to the DP master cyclically again when the DP master sends the UNFREEZE control command.

5.4 Interrupts

Interrupts and interrupt OBs for DPV1

Interrupts can be set by a DPV1 slave which ensure handling of the interrupt-triggering event in the master CPU. The interrupt data is evaluated in the CPU and the diagnostics buffer and the module state are updated even in the "STOP" operating mode. The OB is not processed in STOP.

The following DPV1 interrupts are supported:

- Status interrupt
- Update interrupt
- Vendor-specific interrupt

Detailed information is available in the descriptions on the OBs. You can use the corresponding OBs that are provided by the operating system of the S7 CPUs for diagnostic interrupts, hardware interrupts, and pull/plug interrupts.

OB 55 interrupt - Status interrupt

The status interrupt can be triggered when the operating mode of a device or module changes, for example, from RUN to STOP.

OB 56 interrupt - Update interrupt

An update interrupt can be triggered if the parameters of a slot were changed. This may be caused by local access or partner access to the parameters.

OB 57 interrupt - Vendor-specific interrupt

The event that triggers the vendor-specific interrupt can be specified by the manufacturer of a DPV1 slave.

Additional information

A detailed description of the events at which interrupts are triggered is available in the documentation of the respective manufacturer of the DPV1 slave.

5.5 Intelligent DP slaves (I-slaves)

5.5.1 I-slave functionality

I-slave functionality

The "I-slave" (intelligent DP slave) functionality of a CPU supports the exchange of data with a DP master and thus allows the CPU to be used, for example, as intelligent preprocessing unit of subprocesses. The I-slave is connected in its role as DP slave to a "higher-level" DP master.

The preprocessing is handled by the user program in the I-slave. The process values acquired by the I/O modules are preprocessed by the user program and made available to the DP master.

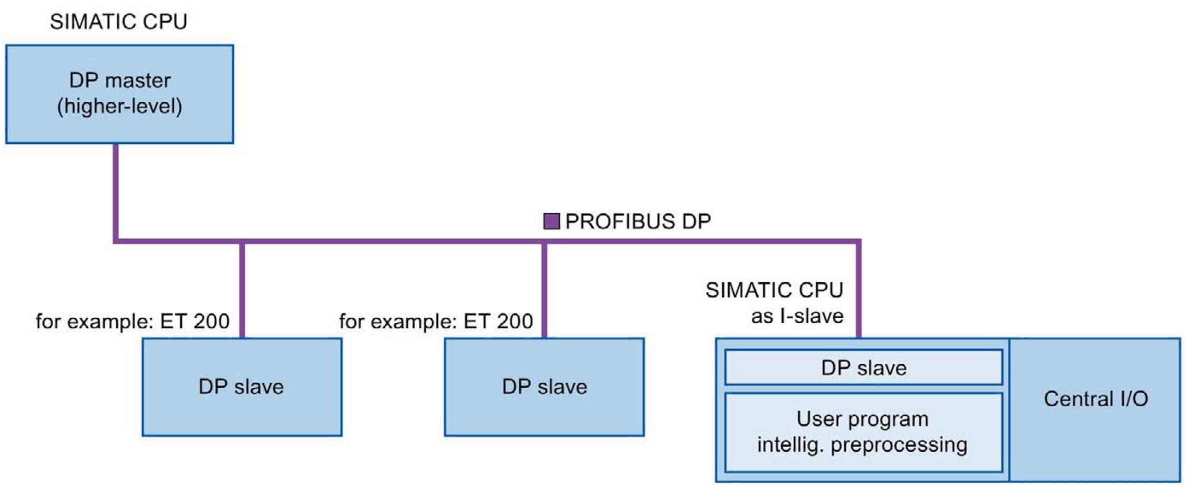

Figure 5-12 I-slave functionality

"I-slave" naming convention

In the remainder of this description, a CPU or a CP with I-slave functionality is simply called an "I-slave".

Advantages of configurations with I-slaves

The I-slave offers the following advantages:

- Simple coupling of CPUs with PROFIBUS interface
- Real-time communication between CPUs and PROFIBUS interface
- Distributed processing

  A complex automation task can be divided into smaller units/subprocesses. This results in manageable processes which lead to simplified subtasks.
- Relieving the DP master by distributing the computing capacity to I-devices
- Lower communication load by processing process data locally
- Separating subprocesses

  Complicated, widely distributed and extensive processes can be subdivided into several subprocesses with manageable interfaces by using I-slaves. These subprocesses can be stored in individual STEP 7 projects if necessary, which can later be merged to form one master project.
- Separating STEP 7 projects

  Creators and users of an I-device can have completely separated STEP 7 projects. The GSD file together with the configuration of the transfer areas of the I-slave form the interface between the STEP 7 projects. This allows coupling to standard DP masters via a standardized interface.
- Know-how protection

  Plant units can now only be delivered with a GSD file and the configuration of the transfer areas instead of with a STEP 7 project for the I-slave interface description. This means that you no longer have to disclose the user program know-how.

Difference: DP slave - I-slave

In the case of a DP slave, the DP master accesses the distributed inputs/outputs directly.

In the case of an I-slave, the DP master accesses a transfer area in the I/O address space of the preprocessing CPU instead of accessing the connected inputs/outputs of the I-slave. The user program running on the preprocessing CPU is responsible for ensuring data exchange between the operand area and inputs/outputs.

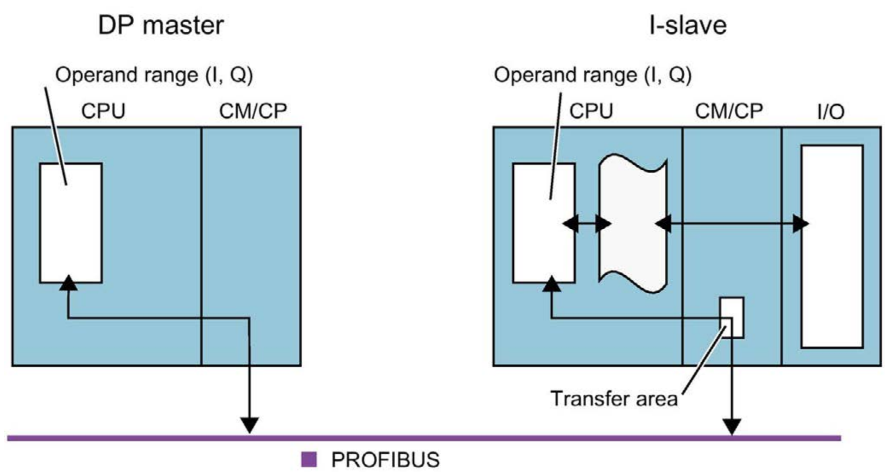

Figure 5-13 Data access to an I-slave

Note

DP master or DP slave

Note: The communication modules of the S7-1500 CPUs/ET 200SP CPUs, for example the CP 1542-5, support the operation as DP master or DP slave only as alternative.

Note

The I/O areas configured for data exchange between the DP master and DP slaves must not be used by I/O modules.

5.5.2 Data exchange with higher-level DP master

Introduction

The following section describes the data exchange between the I-slave and the higher-level DP master.

Transfer areas

Transfer areas are an interface to the user program of the I-slave CPU. Inputs are processed in the user program and outputs are the result of the processing in the user program.

The data for communication between DP master and I-slave is made available in the transfer areas. A transfer area contains an information unit that is exchanged consistently, in terms of bytes, words or overall, between DP master and I-slave. You can find more information on configuration and use of transfer areas in the section Configuring transfer areas (Page 84).

The following figure shows the data exchange between the I-slave and the higher-level DP master. The individual communication relations are explained below based on the numbers.

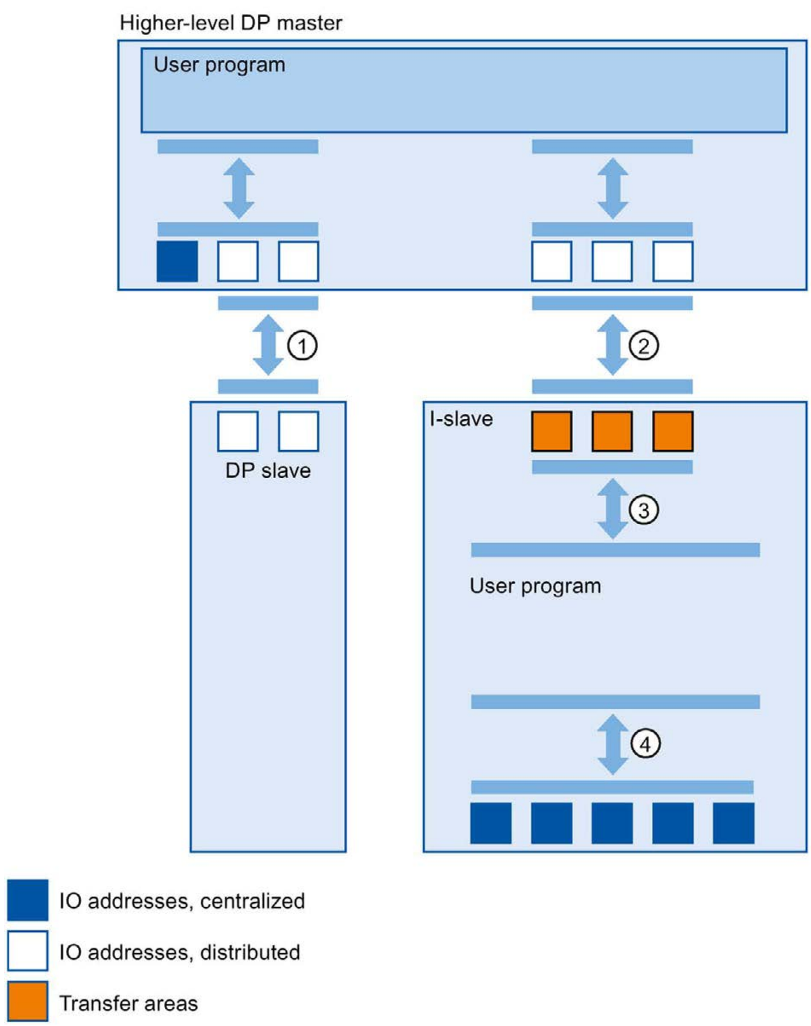

Figure 5-14 Data exchange with the DP master

① Data exchange between higher-level DP master and normal DP slave

In this way, the DP master and the DP slave exchange data through PROFIBUS.

② Data exchange between higher-level DP master and I-slave

In this way, the DP master and the slave exchange data through PROFIBUS.

The data exchange between a higher-level DP master and an I-slave is based on the conventional DP master/DP slave relationship.

For the higher-level DP master, the transfer areas of the I-slave represent submodules of a DP slave.

The output data of the DP master is the input data of the I-slave. Analogously, the input data of the DP master is the output data of the I-slave.

③ Transfer relationship between the user program and the transfer area

In this way, the user program and the transfer area exchange input and output data.

④ Data exchange between the user program and the I/O of the I-slave

In this way, the user program and the centralized I/O of the I-slave exchange input and output data.

5.5.3 Configuring an I-slave

Requirements for configuring an I-slave

The I-slave consists of:

- A CPU from S7-1500 and a communications module CM 1542-5/CP 1542-5
  (STEP 7 as of V12)
- A CPU from ET 200SP and a communications module CM DP (STEP 7 as of V13 SP1)

Procedure for configuring an I-slave

This section shows how to configure an I-slave in STEP 7 based on the example of a CPU 1512SP-1 PN. The procedure for the CPUs from S7-1500 with CM 1542-5/CP 1542-5 and for the CPU 1510SP-1 PN with CM DP is the same.

To configure an I-slave, follow these steps:

1. Drag a CPU 1512SP-1 PN from the hardware catalog to the network view.
2. Open the device view of the CPU.
3. Double-click on the CM DP communications module in the hardware catalog.
   STEP 7 creates the CM DP in the device view.
4. Select the PROFIBUS interface of the CM DP communications module.
5. In the Inspector window in the area navigation, select the "Operating mode" entry and enable the "DP slave" check box.
6. Now you can select the DP master in the "Assigned DP Master" drop-down list.

   Once you have selected the DP master, the networking and the DP master system between both devices are displayed in the network view.

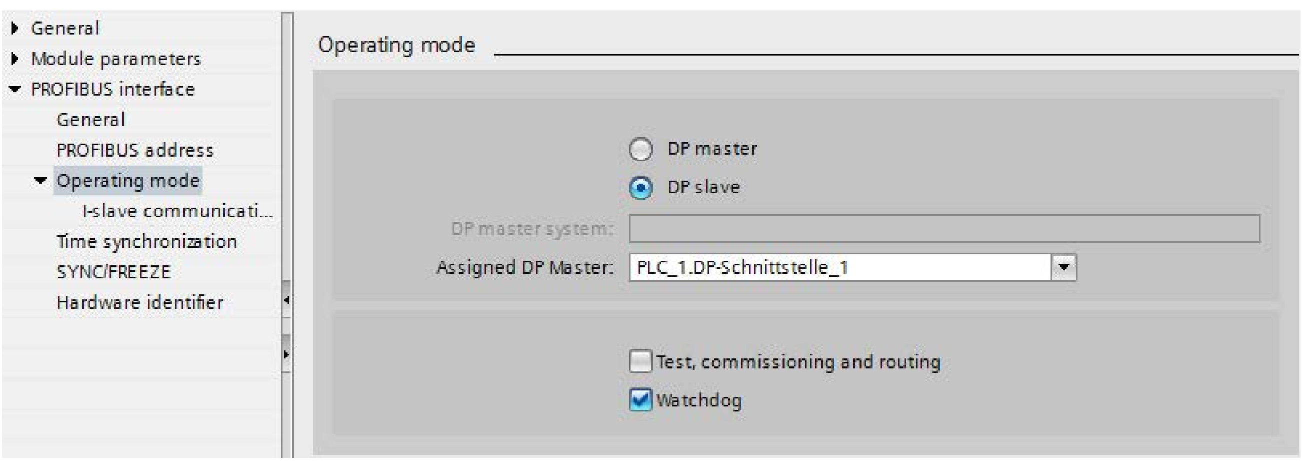

Figure 5-15 Configuring an I-slave

Note

Operation using a GSD file

If you operate an I-slave using a GSD file, you should not select the "Test, commissioning and routing" check box.

Create a DP subnet on the PROFIBUS interface of the I-slave.

Result

You have configured an I-slave.

5.5.4 Configuring transfer areas

Requirements for configuring transfer areas

- You have configured an I-slave in STEP 7.
- You are in the device view of the I-device and have selected the PROFIBUS interface of the communications module.

Procedure for configuring transfer areas

To configure transfer areas for an I-slave in STEP 7, follow these steps:

1. In the area navigation, go to the section "Operating mode" > "I-slave communication" > "Transfer areas".
2. Create transfer areas. Set the properties of the created transfer areas.

① Click in the first cell of the "Transfer area" column. STEP 7 assigns a default name that you can change.

② Select the type of communication relation: Currently, you can only select MS for "master-slave communication relation".

③ STEP 7 assigns the addresses for the transfer area automatically. Correct the addresses if necessary.

④ Set the length of the transfer area. Specify the length of the transfer area in the cell in the following format: [1...64] Byte/Word.
Examples: "32 Byte", "64 Word"

⑤ Specify whether the transfer area is exchanged in units of bytes or words or consistently over the entire length between the DP master and I-slave.

Figure 5-16 Configuring transfer areas

A separate entry is created in the area navigation for each transfer area. If you select one of these entries, you can adjust the details of the transfer area, or correct them and comment on them.

5.5.5 Sample program

Introduction

This simple sample program shows how you use the transfer areas of an I-slave.

Requirement

You have configured an I-slave.

Task

The result of an "AND logic operation" of two inputs (preprocessing) in the I-slave is to be provided to the higher-level DP master. This result is to be assigned to a local output in the DP master (further processing).
Use a transfer area with the following addresses for this purpose:

- Address in the I-slave: Q568
- Address in the DP master: I68

Required steps

The following steps are necessary to solve the task:

1. Configuring the transfer area
2. Programming the I-slave
3. Programming the DP master

Configuring the transfer area

Configure a transfer area with the following properties in the I-slave:

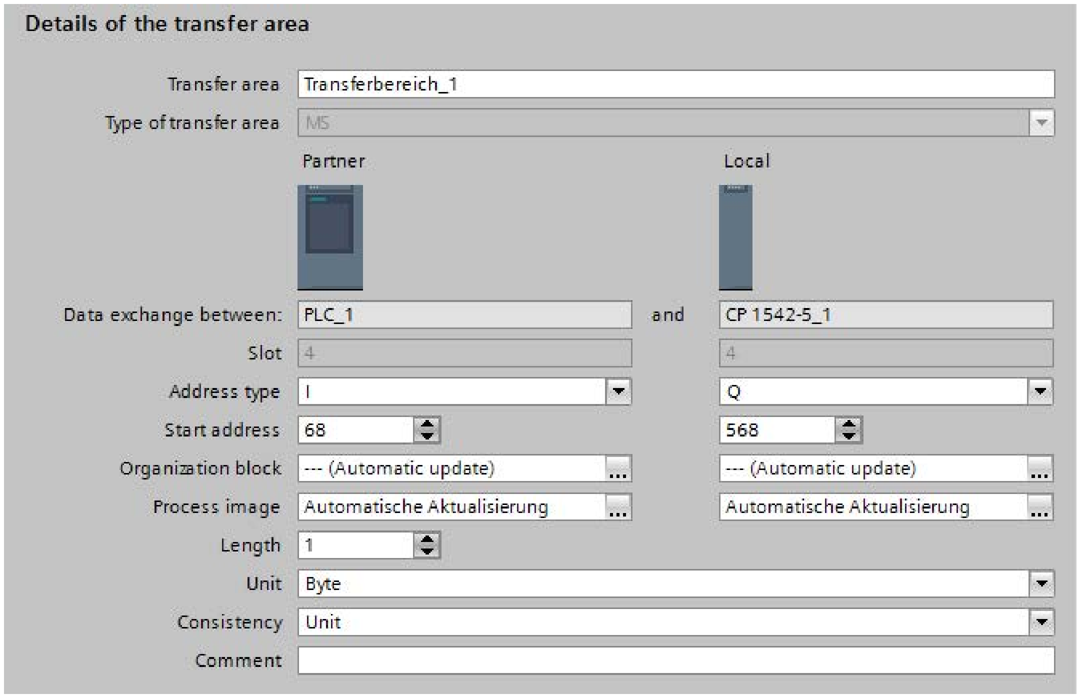

Figure 5-17 Transfer area, I-slave sample program

Programming the I-slave

To program the sample program for the I-slave, follow these steps:

1. Using the SCL programming language, create a new function with the name "preprocessing" in the project tree under "Program blocks" > "Add new block". Open the function.
2. In the interface of the function "preprocessing", create the following tags:

Name	Data type	Input/output type
input 1	bool	Input
input 2	bool	Input
result	bool	Output

3. In the instruction window of the function "preprocessing", write the following program code:
   #result:=#input 1&#input 2;
4. Call the function "preprocessing" in a cycle OB, for example, in OB1.
5. Wire the function "preprocessing" in the cycle OB as follows:

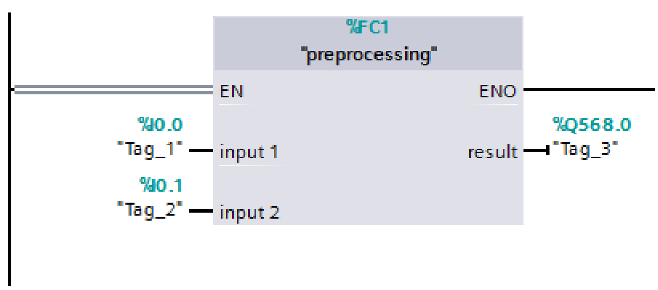

Figure 5-18 I-slave sample program

Programming the DP master

To program the sample program for the DP master, follow these steps:

1. Using the SCL programming language, create a new function with the name "further processing" in the project tree under "Program blocks" > "Add new block". Open the function.
2. In the interface of the function "further processing", create the following tags:

Name	Data type	Input/output type
result	bool	Input
output	bool	Output

3. In the instruction window of the function "further processing", write the following program code:
   #output:=#result;
4. Call the function "further processing" in a cycle OB, for example, in OB1.
5. Wire the function "further processing" in the cycle OB as follows:

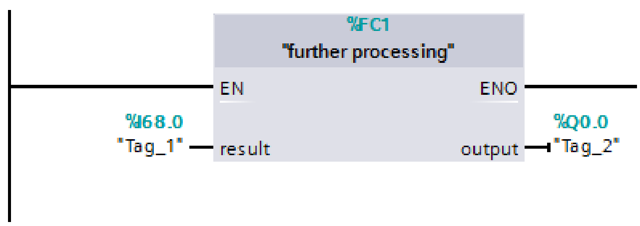

Figure 5-19 DP master sample program

Result

You mastered the task successfully.

5.5.6 Diagnostics and interrupt behavior

Diagnostics and interrupt behavior

S7 CPUs have numerous diagnostics and interrupt functions that can, for example, report errors/faults or failures of underlying DP systems. These diagnostics alarms reduce downtimes and simplify localization and elimination of problems.

Diagnostics options in the higher-level DP master and in the I-slave

The following diagnostics mechanisms are available to the higher-level DP master and the I-slave:

- OB 82 (diagnostic interrupt)

  When the I-slave changes mode, the DP master calls OB 82 (diagnostic interrupt).

  When the DP master changes mode, the I-slave calls OB 82 (diagnostic interrupt).

- OB 86 (rack failure)

  If the bus connection to the I-slave is interrupted, the DP master calls OB 86 (rack failure).

  If the bus connection to the DP master is interrupted, the I-slave calls OB 86 (rack failure).

- OB 122 (I/O access error)

  If you have not set the attribute "Handle errors within block" for OB 122, the following applies:

  – If the bus connection to the I-slave is interrupted, the DP master calls OB 122 (I/O access error) if there is direct access to the relevant transfer areas.

  – If the bus connection to the DP master is interrupted, the I-slave calls OB 122 (I/O access error) if there is direct access to the relevant transfer areas.

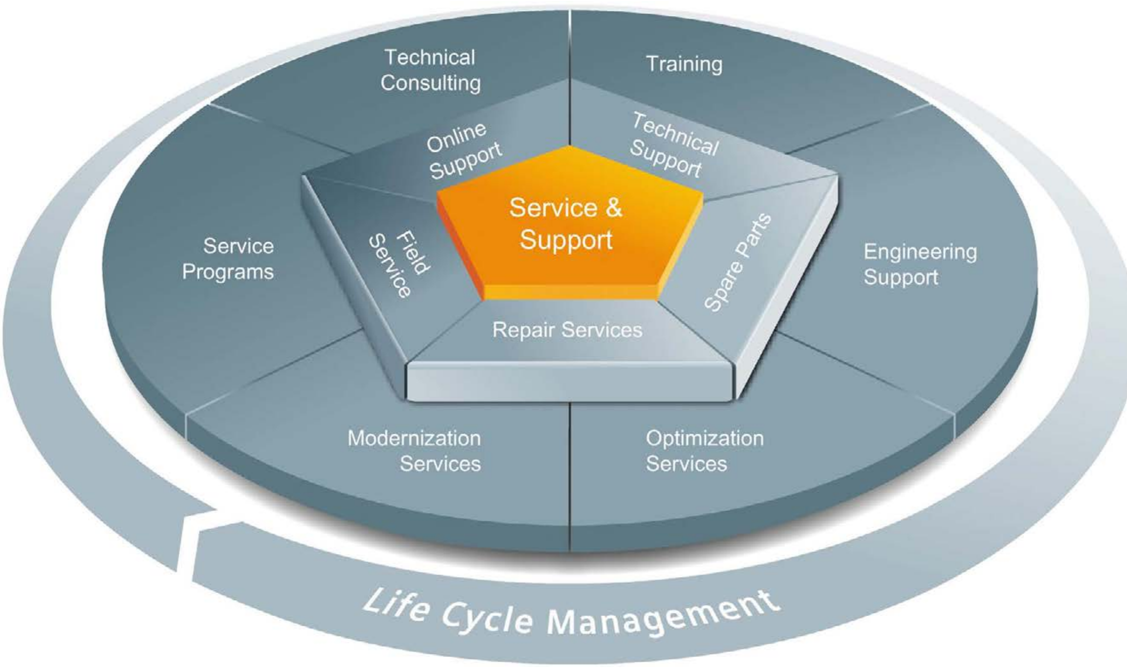
Reaction of the transfer areas to mode changes

Table 5- 3 Reaction of the transfer areas to mode changes

DP master	I-slave	Reaction of DP master input transfer areas	Reaction of I-slave input transfer areas
RUN→STOP	RUN	No updating of the process image	The input transfer areas retain their current values. (no access error)
STOP→RUN	RUN	The input transfer areas are updated by the cyclic user program via the process image.	The input transfer areas are updated via the process image.
RUN	RUN→STOP	The I-slave sets the input transfer areas on the DP master to "0".	No updating of the process image
RUN	STOP→RUN	The I-slave sets the input transfer areas on the DP master to "0". After the startup program of the I-slave, the input transfer areas of the DP master are updated via the process image.	Prior to processing of the startup program, the input transfer areas are updated via the process image.

Service & Support

A



The unmatched complete service for the entire life cycle

For machine constructors, solution providers and plant operators: The service offering from Siemens Industry Automation and Drive Technologies includes comprehensive services for a wide range of different users in all sectors of the manufacturing and process industry.

To accompany our products and systems, we offer integrated and structured services that provide valuable support in every phase of the life cycle of your machine or plant – from planning and implementation through commissioning as far as maintenance and modernization.

Our Service & Support accompanies you worldwide in all matters concerning automation and drive technology from Siemens. We provide direct on-site support in more than 100 countries through all phases of the life cycle of your machines and plants.

You have an experienced team of specialists at your side to provide active support and bundled know-how. Regular training courses and intensive contact among our employees – even across continents – ensure reliable service in the most diverse areas.

Online Support

The comprehensive online information platform supports you in all aspects of our Service & Support at any time and from any location in the world.

You can find Online Support on the Internet at the following address: Internet (http://www.siemens.com/automation/service&support).

Technical Consulting

Support in planning and designing your project: From detailed actual-state analysis, definition of the goal and consultation on product and system questions right through to the creation of the automation solution.

Technical Support

Expert advice on technical questions with a wide range of demand-optimized services for all our products and systems.

You can find Technical Support on the Internet at the following address: Internet (http://www.siemens.com/automation/support-request).

Training

Extend your competitive edge – through practical know-how directly from the manufacturer.

You can find the training courses we offer on the Internet at the following address: Internet (http://www.siemens.com/sitrain).

Engineering Support

Support during project engineering and development with services fine-tuned to your requirements, from configuration through to implementation of an automation project.

Field Service

Our Field Service offers you services for commissioning and maintenance – to ensure that your machines and plants are always available.

Spare parts

In every sector worldwide, plants and systems are required to operate with constantly increasing reliability. We will provide you with the support you need to prevent a standstill from occurring in the first place: with a worldwide network and optimum logistics chains.

Repairs

Downtimes cause problems in the plant as well as unnecessary costs. We can help you to reduce both to a minimum – with our worldwide repair facilities.

Optimization

During the service life of machines and plants, there is often a great potential for increasing productivity or reducing costs.

To help you achieve this potential, we are offering a complete range of optimization services.

Modernization

You can also rely on our support when it comes to modernization – with comprehensive services from the planning phase all the way to commissioning.

Service programs

Our service programs are selected service packages for an automation and drives system or product group. The individual services are coordinated with each other to ensure smooth coverage of the entire life cycle and support optimum use of your products and systems.

The services of a Service Program can be flexibly adapted at any time and used separately.

Examples of service programs:

- Service contracts
- Plant IT Security Services
- Life Cycle Services for Drive Engineering
- SIMATIC PCS 7 Life Cycle Services
- SINUMERIK Manufacturing Excellence
- SIMATIC Remote Support Services

Advantages at a glance:

- Reduced downtimes for increased productivity
- Optimized maintenance costs due to a tailored scope of services
- Costs that can be calculated and therefore planned
- Service reliability due to guaranteed response times and spare part delivery times
- Customer service personnel will be supported and relieved of additional tasks
- Complete service from one source: fewer interfaces and more know-how

Contact

At your service locally, around the globe: your partner for consultation, sales, training, service, support, spare parts... for the entire range of products supplied by Industry Automation and Drive Technologies.

You can find your personal contact in our contacts database at: Internet (http://www.siemens.com/automation/partner).

Glossary

Automation system

Programmable logic controller for the open-loop and closed-loop control of process chains of the process engineering industry and manufacturing technology. The automation system consists of different components and integrated system functions according to the automation task.

Bus

A common transfer route to which all nodes are connected; it has two defined ends.

In the case of PROFIBUS, the bus is a two-wire line or a fiber-optic cable.

Bus connector

Physical connection between the node and bus cable.

Bus system

All stations physically connected to a bus cable form a bus system.

Device

In the PROFIBUS environment, "device" is the generic term for:

- Automation systems (for example, PLC, PC)
- Distributed I/O systems
- Field devices (for example, hydraulic devices, pneumatic devices)
- Active network components
- Gateways to AS interface or other fieldbus systems

Device that can send, receive or amplify data via the bus, for example, a DP slave by means of PROFIBUS DP.

Device

In the PROFIBUS environment, "device" is the generic term for:

- Automation systems (for example, PLC, PC)
- Distributed I/O systems
- Field devices (for example, hydraulic devices, pneumatic devices)
- Active network components
- Gateways to AS interface or other fieldbus systems

Device that can send, receive or amplify data via the bus, for example, a DP slave by means of PROFIBUS DP.

Diagnostics

Monitoring functions for the recognition, localization, classification, display and further evaluation of errors, faults and alarms. They run automatically during plant operation. This increases the availability of systems/plants by reducing commissioning times and downtimes.

DP master

CPU or device that conducts the communication with the DP slaves according to a defined algorithm. To do this, the DP master uses the functions for communication with the DP slaves which are defined by PROFIBUS DP. It acts according to standard EN 50170, Part 3.

→ *Master*

DP slave

Slave in the distributed I/O that is operated on the PROFIBUS with PROFIBUS DP protocol and acts according to standard EN 50170, Part 3. The DP slave is addressed by the DP master and provides it with specified functions (I/O data, diagnostics, etc.).

→ *Slave*

DPV1

The designation DPV1 refers to the functional extension of acyclic services (to include new interrupts, for example) provided by the DP protocol. The DPV1 functionality is integrated in IEC 61158/EN 50170, Volume 2, PROFIBUS.

FDL

Fieldbus Data Link (bus access protocol). Step 2 with PROFIBUS.

HMI device

Human Machine Interface, device for visualization and control of automation processes.

HSA

Highest Station Address. A bus parameter for PROFIBUS. Outputs the highest PROFIBUS address of an active device. PROFIBUS addresses greater than HSA are permitted for passive devices, up to 126.

Industrial Ethernet

Guideline for setting up Ethernet in an industrial environment. The main difference to the standard Ethernet is the mechanical current carrying capacity and interference immunity of the individual components.

I-slave

The "I-slave" functionality of a CPU supports the exchange of data with a DP master and can thus be used, for example, as intelligent preprocessing unit of partial processes. The I-slave is connected in its role as DP slave to a "higher-level" DP master.

Master

A master device that is in possession of the token can send data to other devices and request data from them (= active device).

PCF

Polymer Cladded Fiber (plastic-covered glass fiber)

POF

Polymer Optical Fiber (plastic fiber-optic cable made of light-conducting plastics)

Process image

Address area in the system memory of the DP master. At the start of the cyclic program the signal states of the input modules are transmitted to the process image of the inputs. And the end of cyclic program execution, the process image of the outputs is transmitted to the DP slave as signal state.

PROFIBUS

PROcess FIeld BUS, in IEC 61158-2 as "Type 3" standardized, bit-serial fieldbus system. The standard specifies functional, electrical and mechanical properties.

PROFIBUS is a bus system that networks automation systems and field devices compatible with PROFIBUS at the cell and field level. PROFIBUS is available with the protocols DP (= distributed I/O), FMS (= fieldbus message specification) or PA (process automation).

PROFIBUS address

Unique identification of a device connected to PROFIBUS. The PROFIBUS address is transmitted in the frame for addressing a device. A PC or programming device has the PROFIBUS address "0". DP masters and DP slaves have a PROFIBUS address in the range from 1 to 125.

PROFIBUS device

A PROFIBUS device has at least one PROFIBUS interface with an electrical (RS 485) or optical (Polymer Optical Fiber, POF) interface.

PROFIBUS DP

A PROFIBUS with DP protocol that complies with EN 50170. DP stands for distributed I/O (fast, real-time capable, cyclic data exchange). From the perspective of the user program, the distributed I/Os are addressed in exactly the same way as the centralized I/Os.

PROFINET

Open component-based industrial communication system based on Ethernet for distributed automation systems. Communication technology promoted by the PROFIBUS Users Organization.

RS 485

Asynchronous data transmission process for PROFIBUS DP to ANSI TIA/EIA-RS485-A.

RS 485 repeater

Equipment for amplifying bus signals and for coupling segments over long distances.

Segment

The bus line between two terminating resistors forms a bus segment.

A bus segment can contain up to 32 bus nodes. Segments can be coupled, for example, by means of RS 485 repeaters or diagnostics repeaters.

Slave

Distributed device in a fieldbus system that may exchange data with a master after being requested to do so by the master. Slaves are all DP slaves, for example, such asET 200SP, ET 200MP, ET 200AL.

Standard mounting rail

Standardized metal profile to EN 50022.

The standard mounting rail is used for quick snap-on installation of network components, such as OLM, repeaters, etc.

Subnet

Part of a network whose parameters must be synchronized with the devices (e.g., with PROFIBUS). A subnet includes the bus components and all connected stations.

SynchronousCycle

Name for synchronous cycle interrupt OB in STEP 7.

Target-Rotation-Time (Ttr)

Bus parameter for PROFIBUS. The token is the send permission for a device on PROFIBUS. A device compares a token rotation time it has measured with the Target-Rotation-Time and controls the sending of frames with high priority or low priority based on this comparison.

Terminating resistor

Component that terminates the ends of a data transmission line to prevent reflections in the transmission medium.

Terminator

Terminating resistor of bus segments with transmission rates of 9.6 kbps to 12 Mbps. The power supply is separate from the bus nodes.

TIA Portal

Totally Integrated Automation Portal

Topology

Structure of a network. Common structures are line topology, ring topology, star topology and tree topology.

Transmission rate

Specifies the number of bits transmitted per second.

Watchdog

Mechanism for monitoring the readiness for operation.

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

DANGER

indicates that death or severe personal injury **will** result if proper precautions are not taken.

WARNING

indicates that death or severe personal injury **may** result if proper precautions are not taken.

CAUTION

indicates that minor personal injury can result if proper precautions are not taken.

NOTICE

indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

WARNING

Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This documentation provides important information on configuring and commissioning the point-to-point communication modules for the S7-1500 (ET 200MP) and ET 200SP.

Basic knowledge required

The following knowledge is required in order to understand the documentation:

- General knowledge of automation technology
- Knowledge of the industrial automation system SIMATIC
- Knowledge about the use of Windows-based computers
- Proficiency with STEP 7

Validity of the documentation

This documentation is valid for all point-to-point communication modules of the S7-1500 (ET 200MP) and the ET 200SP when used with STEP 7 (TIA Portal) V12 and higher.

Conventions

The term "CPU" is used in this manual both for the CPUs of the S7-1500 as well as for interface modules of distributed I/O systems, such as the IM 155-5.

Please also observe notes labeled as follows:

Note

The notes contain important information on the product described in the documentation, on the handling of the product or on part of the documentation to which particular attention should be paid.

Recycling and disposal

The products can be recycled due to their low pollutant content. For environmentally compliant recycling and disposal of your old device, please contact a company certified for the disposal of electronic waste.

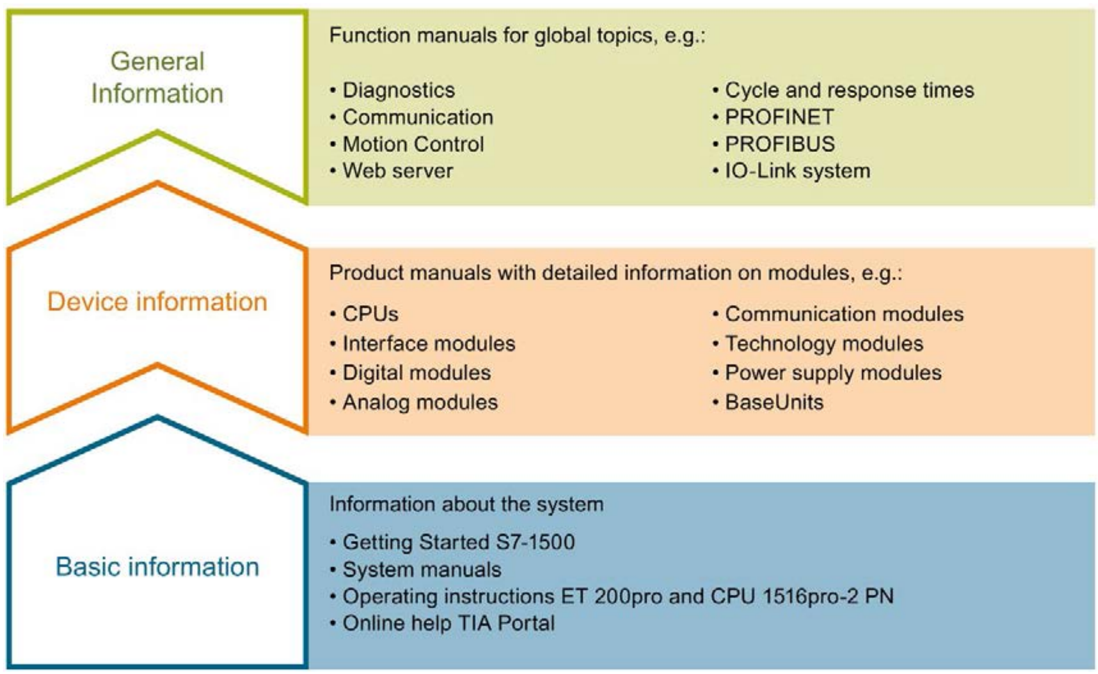
Additional assistance

- Information on the offers of our Technical Support are available in the appendix Service & Support (Page 206).
- The range of technical documentation for the individual SIMATIC products and systems can be found on the Internet (http://www.siemens.com/simatic-tech-doku-portal).
- The online catalog and the ordering system are available on the Internet (http://mall.automation.siemens.com).

Table of contents

1 Guide to documentation

The documentation for the SIMATIC S7-1500 automation system, for CPU 1516pro-2 PN based on SIMATIC S7-1500, and for the distributed I/O systems SIMATIC ET 200MP, ET 200SP and ET 200AL is divided into three areas.
This division allows you easier access to the specific information you require.



Basic information

System manuals and Getting Started manuals describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500, ET 200MP, ET 200SP and ET 200AL systems; use the corresponding operating instructions for CPU 1516pro-2 PN. The STEP 7 online help supports you in configuration and programming.

Device information

Product manuals contain a compact description of the module-specific information, such as properties, terminal diagrams, characteristics and technical specifications.

General information

The function manuals contain detailed descriptions on general topics such as diagnostics, communication, Motion Control, Web server, OPC UA.

You can download the documentation free of charge from the Internet (http://w3.siemens.com/mcms/industrial-automation-systems-simatic/en/manual-overview/Pages/Default.aspx).

Changes and additions to the manuals are documented in product information sheets.

You will find the product information on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/us/en/view/68052815)
- ET 200SP (https://support.industry.siemens.com/cs/us/en/view/73021864)
- ET 200AL (https://support.industry.siemens.com/cs/us/en/view/99494757)

Manual Collections

The Manual Collections contain the complete documentation of the systems put together in one file.

You will find the Manual Collections on the Internet:

- S7-1500/ET 200MP (https://support.industry.siemens.com/cs/ww/en/view/86140384)
- ET 200SP (https://support.industry.siemens.com/cs/ww/en/view/84133942)
- ET 200AL (https://support.industry.siemens.com/cs/ww/en/view/95242965)

"mySupport"

With "mySupport", your personal workspace, you make the best out of your Industry Online Support.

In "mySupport", you can save filters, favorites and tags, request CAx data and compile your personal library in the Documentation area. In addition, your data is already filled out in support requests and you can get an overview of your current requests at any time.

You must register once to use the full functionality of "mySupport".

You can find "mySupport" on the Internet (https://support.industry.siemens.com/My/ww/en).

"mySupport" - Documentation

In the Documentation area in "mySupport" you can combine entire manuals or only parts of these to your own manual.
You can export the manual as PDF file or in a format that can be edited later.

You can find "mySupport" - Documentation on the Internet (http://support.industry.siemens.com/My/ww/en/documentation).

"mySupport" - CAx data

In the CAx data area in "mySupport", you can access the current product data for your CAx or CAe system.

You configure your own download package with a few clicks.

In doing so you can select:

- Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files
- Manuals, characteristics, operating manuals, certificates
- Product master data

You can find "mySupport" - CAx data on the Internet (http://support.industry.siemens.com/my/ww/en/CAxOnline).

Application examples

The application examples support you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus on individual products.

You will find the application examples on the Internet (https://support.industry.siemens.com/sc/ww/en/sc/2054).

TIA Selection Tool

With the TIA Selection Tool, you can select, configure and order devices for Totally Integrated Automation (TIA).
This tool is the successor of the SIMATIC Selection Tool and combines the known configurators for automation technology into one tool.
With the TIA Selection Tool, you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet (http://w3.siemens.com/mcms/topics/en/simatic/tia-selection-tool).

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to run commissioning and maintenance activities simultaneously on different SIMATIC S7 stations as a bulk operation, independently of the TIA Portal.

The SIMATIC automation tool provides a variety of functions:

- Scanning of a PROFINET/Ethernet plant network and identification of all connected CPUs
- Address assignment (IP, subnet, gateway) and station name (PROFINET device) to a CPU
- Transfer of the date and programming device/PC time converted to UTC time to the module
- Program download to CPU
- Operating mode switchover RUN/STOP
- CPU localization by means of LED flashing
- Reading out CPU error information
- Reading of CPU diagnostic buffer
- Reset to factory settings
- Updating the firmware of the CPU and connected modules

You can find the SIMATIC Automation Tool on the Internet (https://support.industry.siemens.com/cs/ww/en/view/98161300).

PRONETA

With SIEMENS PRONETA (PROFINET network analysis), you analyze the plant network during commissioning. PRONETA features two core functions:

- The topology overview independently scans PROFINET and all connected components.
- The IO check is a fast test of the wiring and the module configuration of a plant.

You can find SIEMENS PRONETA on the Internet (https://support.industry.siemens.com/cs/ww/en/view/67460624).

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and optimal exploitation of resources

You can find SINETPLAN on the Internet (https://www.siemens.com/sinetplan).

Introduction 2

2.1 Overview of the communication modules

Automation systems encompass a wide range of components. These also include communication modules. A simple possibility of data exchange is provided by serial communication via point-to-point connections.

Customizing to a wide range of communication partners is possible by setting the communication parameters at a lower layer of the OSI layer model (see section Transmission security (Page 20)).

Communication through point-to-point connection with S7-1500, ET 200MP and ET 200SP takes place exclusively by means of communication modules (CM) with serial interfaces.

SIMATIC S7 offers a number of modules that provide the physical interface and fundamental protocol mechanisms for this purpose.

- RS232: An interface that can coordinate the communication between the partners through additional accompanying signals.
- RS422/RS485: An interface that allows longer lines through the use of differential voltages as transmission technology and also enables structures with more than 2 devices through a bus structure (RS485).

Instructions that carry out the coordination between the CPU and CM (Communication Module) are available to transfer data from the CPU to the respective modules. They inform the user program about a successful transfer or the receipt of new data (in systems without a SIMATIC CPU users have to program the function of these instructions themselves).

The function and use of the PtP communication modules is described in this function manual.

Overview of components and order numbers

Tabular overview of communication modules and their application suitability

Communication module	S7-1500	ET 200MP	ET 200SP	Article number
CM PtP RS232 BA [1)]	X	X	-	6ES7540-1AD00-0AA0
CM PtP RS422/485 BA	X	X	-	6ES7540-1AB00-0AA0
CM PtP RS232 HF [2)]	X	X	-	6ES7541-1AD00-0AB0
CM PtP RS422/485 HF	X	X	-	6ES7541-1AB00-0AB0
CM PtP (ET 200SP)	-	-	X	6ES7137-6AA00-0BA0

1) BA = Basic

2) HF = High Feature

Overview of components and interfaces

Tabular overview of communication modules and their functions.

Communication module	Interface	Protocols					Connection technology	
		Freeport	3964(R)	Modbus Master	Modbus Slave	USS-Master	D-Sub 9-pin	D-Sub 15-pin
CM PtP RS232 BA	RS232	X	X	-	-	X	X	-
CM PtP RS422/485 BA	RS422	X	X	-	-	X	-	X
	RS485	X	-	-	-	X	-	X
CM PtP RS232 HF	RS232	X	X	X	X	X	X	-
CM PtP RS422/485 HF	RS422	X	X	X	X	X	-	X
	RS485	X	-	X	X	X	-	X
CM PtP (ET 200SP)	RS232	X	X	X	X	X	ET 200SP BaseUnit 1)	
	RS422 2)	X	X	X	X	X		
	RS485	X	-	X	X	X		

1) BaseUnit with terminals instead of D-Sub; assignment depending on physical transmission properties

2) The CM PtP communication module can also be used for multipoint connection in RS422 mode

Overview of components and data transmission rates

The communication modules can send and receive data with different data transmission rates. The table below shows the assignment to the individual communication modules.

Communication module	Data transmission rate in bps										
	300	600	1200	2400	4800	9600	19200	38400	57600	76800	115200
CM PtP RS232 BA	X	X	X	X	X	X	X	-	-	-	-
CM PtP RS422/485 BA	X	X	X	X	X	X	X	-	-	-	-
CM PtP RS232 HF	X	X	X	X	X	X	X	X	X	X	X
CM PtP RS422/485 HF	X	X	X	X	X	X	X	X	X	X	X
CM PtP (ET 200SP)	X	X	X	X	X	X	X	X	X	X	X

Overview of components and receive buffer size

Each communication module has a buffer to temporarily store received frames. The table below shows the assignment of the maximum size of an individual frame as well as the size of the memory for the individual communication modules.

Module	Receive buffer size KB	Max. frame length KB	Bufferable frames
CM PtP RS232 BA	2	1	255
CM PtP RS422/485 BA	2	1	255
CM PtP RS232 HF	8	4	255
CM PtP RS422/485 HF	8	4	255
CM PtP (ET 200SP)	4	2	255

Accompanying signals and data flow control

- Software data flow control with XON/XOFF

  The Freeport protocol supports data flow control with XON/XOFF via the RS232 and RS422 interfaces.
- Hardware data flow control with RTS/CTS

  The Freeport protocol supports data flow control with RTS/CTS via the RS232 interface.
- Automatic operation of accompanying signals

  The RS232 accompanying signals can be controlled with the Freeport, Modbus master and Modbus slave protocols by means of the RS232 interface. (Only available if hardware data flow control is not activated.)

Protocols of the communication modules

You may set up a communication connection with different protocols, depending on the communication modules used:

- Freeport: Transmission of ASCII character strings without specified protocol format
- 3964(R): Communication between programmable logic controllers (master/master communication)
- Modbus RTU: Communication between programmable logic controllers (master/slave communication) The communication module can be the master as well as the slave.
- USS: Communication between a programmable logic controller and a drive (master/slave communication) Communication is tailored to the drive technology requirements. The communication module can only be master.

2.2 Overview of the processing steps

Point-to-point connection

The system provides various networking options for the exchange of data between two or more communication partners. The simplest form of data interchange is via a point-to-point connection between two communication partners.

The communication module (CM) forms the interface between a programmable logic controller and a communication partner. Data is sent in serial mode via point-to-point connection with the communication module.

Configuring / parameter assignment

Configuring the communication module includes the arrangement of the communication module in the device configuration of STEP 7 (TIA Portal) as well as the settings of the specific protocol parameters in the properties dialog of the communication module (static configuration).

Programming

Programming includes the program-specific connection of the communication module to the corresponding CPU by means of the user program. You program the communication module with STEP 7 (TIA Portal).

Communication between CPU, communication module and a communication partner takes place through instructions (Page 70). A number of instructions are available for the S7-1500 and S7-1200 automation systems. You can use these instructions to initiate and control communication in the user program as well as influence the configuration for runtime (dynamic configuration).

For more information, please refer to Overview of instructions (Page 17) and the STEP 7 (TIA Portal) online help.

2.3 Overview of instructions

Note

CPU quantity structures

The point-to-point instructions communicate with the communication modules by reading or writing data records.
When using the instructions, you should therefore check the configuration limits of the CPU for reading and writing data records.
If multiple instructions need to read or write data records simultaneously on a CPU, there may need to be a gap between the calls of each instruction by the user program.

Overview of the instructions

The communication protocols are implemented on the communication module. The protocol is used to adapt the interface of the communication module to the interface of the communication partner.

Communication between the CPU, the communication module and a communication partner takes place by means of special instructions and protocols that support the corresponding communication modules.

The instructions form the software interface between the CPU and the communication module. They must be called cyclically from the user program. Data transmission takes place across several cycles.

The instructions are part of STEP 7 (TIA Portal). The instructions are available in the "Instructions" task card under Communication > Communication processor. They apply to all listed communication modules if they support the required function.

Table 2- 1 Instructions for PtP

Instruction	Meaning
Send_P2P (Page 87)	The instruction Send_P2P allows you to send data to a communication partner.
Receive_P2P (Page 91)	The instruction Receive_P2P allows you to receive data from a communication partner.
Receive_Reset (Page 93)	The instruction Receive_Reset allows you to clear the receive buffer of the communication module.
Port_Config (Page 75)	The instruction Port_Config allows you to dynamically assign basic interface parameters.
Send_Config (Page 78)	The instruction Send_Config (send configuration) allows you to dynamically assign serial send parameters of a port.
Receive_Config (Page 80)	The instruction Receive_Config (receive configuration) allows you to dynamically assign serial receive parameters of a port.
P3964_Config (Page 85)	The instruction P3964_Config (protocol configuration) allows you to dynamically configure the parameters of the 3964(R) procedure.
Signal_Get (Page 94)	The instruction Signal_Get allows you to read the RS232 accompanying signals.

Instruction	Meaning
Signal_Set (Page 96)	The instruction Signal_Set allows you to set the RS232 accompanying signals.
Get_Features (Page 98)	The instruction Get_Features allows you to read the extended functions supported by the communication module.
Set_Features (Page 100)	The instruction Set_Features allows you to activate the extended functions supported by the communication module.

Table 2- 2 Instructions for Modbus

Instruction	Meaning
Modbus_Master (Page 125)	The Modbus_Master instruction allows you to communicate as Modbus master by means of the PtP port.
Modbus_Slave (Page 133)	The Modbus_Slave instruction allows you to communicate as Modbus slave by means of the PtP port.
Modbus_Comm_Load (Page 120)	The Modbus_Comm_Load instruction allows you to configure the port of the communication module for Modbus RTU.

Table 2- 3 Instructions for USS

Instruction	Meaning
USS_Port_Scan (Page 172)	The instruction USS_Port_Scan allows you to communicate by means of the USS network.
USS_Drive_Control (Page 176)	The instruction USS_Drive_Control allows you to swap data with the drive.
USS_Read_Param (Page 180)	The instruction USS_Read_Param allows you to read parameters from the drive.
USS_Write_Param (Page 182)	The instruction USS_Write_Param allows you to change parameters in the drive.

Basics of serial communication 3

3.1 Serial data transmission

During serial data transmission, the individual bits of a character of information to be transmitted are sent successively in a defined sequence.

Bidirectional data traffic - operating mode

In the context of bidirectional data traffic, we distinguish between two operating modes for the communication module:

- Half-duplex operation

  The data is exchanged between the communication partners in both directions alternately. In half-duplex operation one communication partner is sending and the other communication partner is receiving at the same time. In the process one line is alternately used for sending or receiving.

- Full-duplex operation

  The data is exchanged between one or more communication partners in both directions simultaneously, which means you can send and receive data at the same time. This process requires one line for sending and one line for receiving.

Asynchronous data transmission

Serial data transmission is performed asynchronously with communication modules. The so-called time base synchronism (a fixed timing code used in the transmission of a fixed character string) is only upheld during transmission of a character. Each character to be sent is preceded by a synchronization impulse, also called start bit. The length of the start-bit transmission determines the clock pulse. The end of character transmission is formed by one or two stop bits.

Declarations

In addition to start and stop bits, additional declarations must be made between the sending and receiving partners before serial transmission can take place. These include:

- Data transmission rate
- Frame start and end criteria (e.g., character delay time)
- Parity
- Number of data bits (7 or 8 bits/characters)
- Number of stop bits (1 or 2)

3.2 Transmission security

Transmission security plays an important role in the transmission of data and in the selection of the transmission procedure. Generally speaking, the more layers of the reference model are applied, the higher the transmission security.

Classification of existing protocols

The figure below illustrates how the protocols of the communication module fit into the reference model.

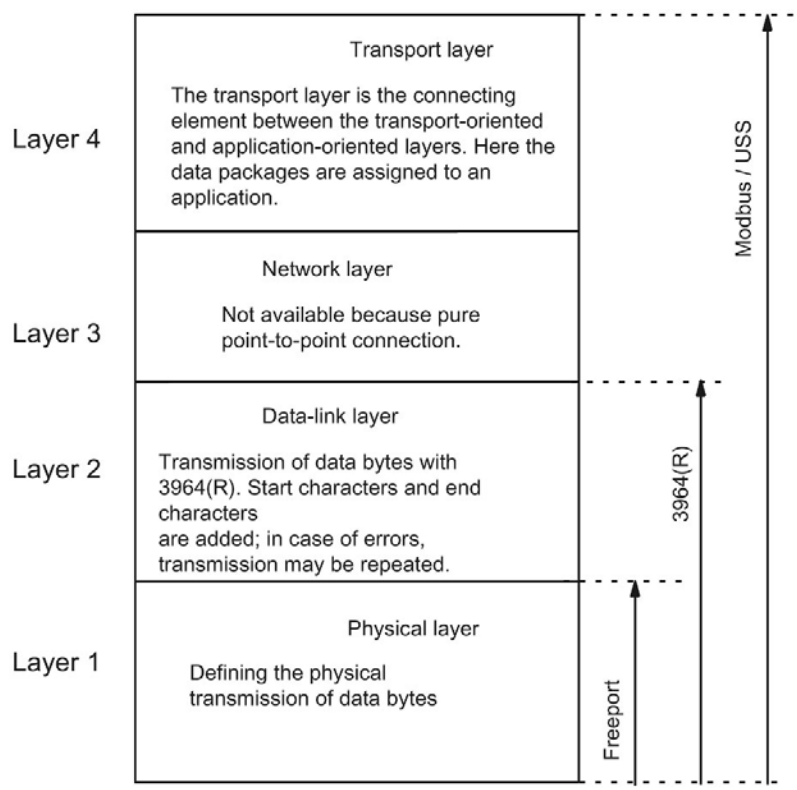


Figure 3-1 Classification of the existing protocols of the communication module in the reference model

Transmission security with Freeport

Transmission security when using Freeport:

- When data is sent with Freeport, there are no data security measures other than the use of a parity bit. This means data transmission with Freeport is very efficient, but data security is not guaranteed. A certain degree of data security can be achieved through parameter assignment of the frame start and frame end conditions.
- Using the parity bit ensures that the inversion of a bit in a character to be sent can be recognized. If two or more bits of a character are inverted, however, there is no guarantee that these errors are still detected.
- To increase transmission security, you can, for example, implement a checksum, a frame length specification, or configurable end conditions. These measures must be implemented by the user.
- A further increase in data security can be achieved by means of acknowledgment frames in response to send or receive frames. This is the case with high-grade protocols for data communication (ISO 7-layer reference model).

Transmission security with 3964(R)

The parity bit is used to increase data security; depending on the configuration, it completes the number of data bits to be transmitted to form an even or odd number.

Using the parity bit ensures that the inversion of a bit in a character to be sent can be recognized. If two or more bits of a character are inverted, however, these errors can no longer be reliably detected.

If parity is set to "none", no parity bit is transmitted. This setup reduces transmission security.

Two different procedures for data transmission can be used, either with or without a block check character:

- Data transmission without block check character: **3964**

  Transmission security is achieved by means of a specified frame structure, frame breakdown, and frame repetitions.
- Data transmission with block check character: **3964R**

  The high degree of transmission security is achieved by means of a specified frame structure and breakdown, frame repetitions, as well as inclusion of a block check character (BCC).

In this manual, the term 3964(R) is used when descriptions and notes refer to both data transmission modes.

Transmission integrity for Modbus and USS

The parity bit is used to increase transmission security; depending on the configuration, it completes the number of data bits to be transmitted to form an even or odd number.

Using the parity bit ensures that the inversion of a bit in a character to be sent can be recognized. If two or more bits of a character are inverted, however, this error can no longer be clearly detected.

If parity is set to "none", no parity bit is transmitted. This setup reduces transmission security.

The CRC (cyclic redundancy check) is additionally used with Modbus. With this method additional redundancy in the form of a so-called CRC value is added for each data block of the user data before data transmission. This is a check value calculated by using a specific procedure that can be used to detect any errors that may occur during transmission.

A BCC (block check character) is additionally used with USS. The block check character is formed during the receipt and is compared with the received BCC after the entire frame has been read in. If these two characters do not match, the frame is not evaluated. (If a character is incorrectly transmitted, an error is reliably detected. If an even number of characters are incorrectly transmitted, an error can no longer be reliably detected.)

3.3 RS232 mode

The following communication modules support RS232 mode:

- CM PtP RS232 BA
- CM PtP RS232 HF
- CM PtP (ET 200SP)

In RS232 mode, data is sent via two lines. A separate line is available for the send direction and the receive direction. Simultaneous sending and receiving is possible (full duplex).

RS232 signals

In addition to the TXD, RXD and GND signals, the communication module provides additional RS232 signals when using RS232 hardware:

TXD	Output	Transmitted data; Interface is transmitting
RXD	Input	Received data; Interface is receiving
GND		Functional ground; isolated
DCD	Input	Data carrier detect; Carrier signal when connecting a modem. The communication partner signals that it recognizes incoming data.
DTR	Output	Data terminal ready; DTR set to "ON": Communication module switched on, ready for operation DTR set to "OFF": Communication module not switched on, not ready for operation
DSR	Input	Data set ready; DSR set to "ON": Communication partner signals readiness for operation DSR set to "OFF": Communication partner not switched on, not ready for operation
RTS	Output	Request to send; RTS set to "ON": Communication module ready to send; signals to the communication partner that there is data ready to send RTS set to "OFF": Communication module not ready to send
CTS	Input	Clear to send; Communication partner can receive data from the communication module (response to RTS = ON of the communication module) CTS set to "ON": Signals readiness to receive to the communication partner CTS set to "OFF": Signals "Not ready to receive" to the communication partner
RI	Input	Incoming call for connecting a modem (ring indicator)

After power on of the communication module, the output signals are in the OFF state (inactive).

You configure the operation of the DTR/DSR and RTS/CTS control signals in the user interface of the communication module.

The RS232 signals cannot be influenced in case of:

- configured data flow control "Hardware RTS always switched"

  (corresponds to automatic operation of the accompanying signals)
- configured data flow control "Hardware RTS always ON"

  (corresponds to hardware flow control with RTS/CTS)
- configured data flow control "Hardware RTS always ON, ignore DTR/DSR"

For more information, refer to chapter Handshake procedure (Page 32).

Connecting cables

The following standard connecting cables of various lengths are available for connecting to a communication partner which also has a 9-pin D-sub male connector:

Article number	6ES7902-1AB00-0AA0	6ES7902-1AC00-0AA0	6ES7902-1AD00-0AA0
Product type designation	S7 connecting cable RS232		
Cable length	5 m	10 m	15 m

The table below shows the pin assignment for the 9-pin D-sub male connector of the respective communication module.

Male connector*	Pin	Designation	Input/ output	Required/optional for self-fabrication
	1	DCD	Input	Optional
	2	RXD	Input	Required
	3	TXD	Output	Required
	4	DTR	Output	Optional
	5	GND	—	Required
	6	DSR	Input	Optional
	7	RTS	Output	Optional
	8	CTS	Input	Optional
	9	RI	Input	Optional

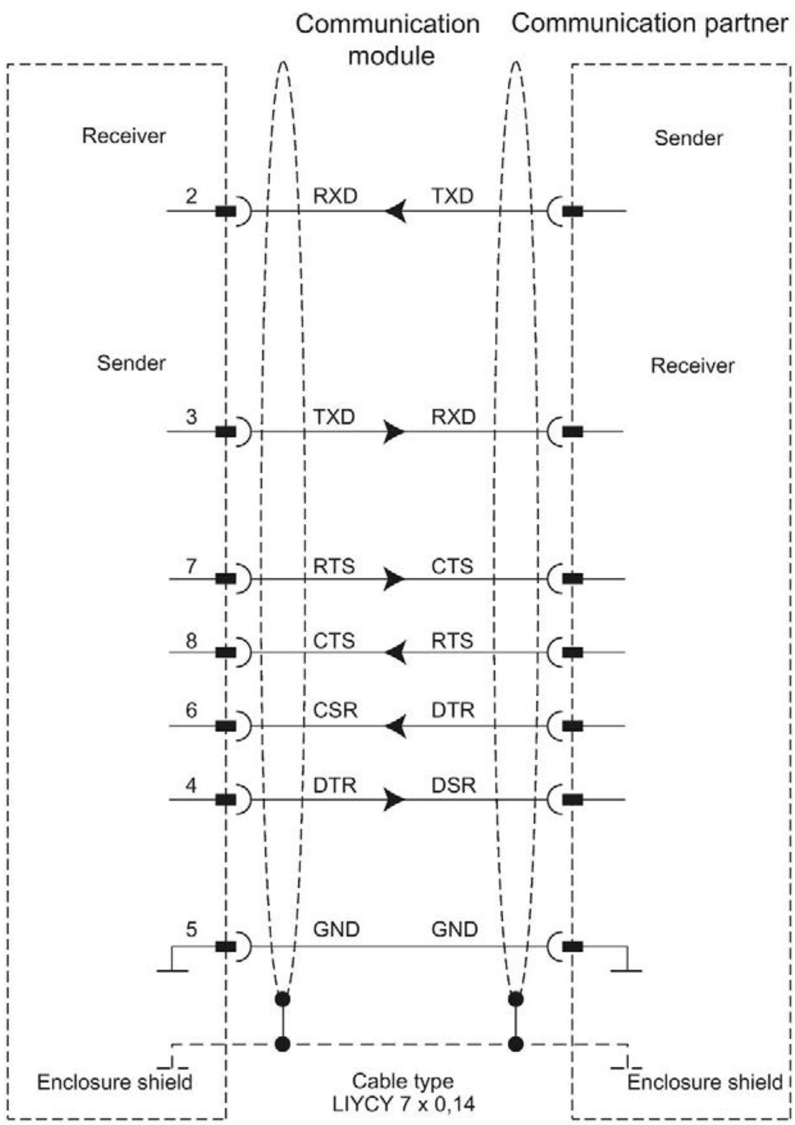
* View from the front

The cable or the connector of the listed connecting cables are not available for order as separate items. If you fabricate your own connecting cables you must remember that unconnected inputs at the communication partner may have to be connected to open-circuit potential.

Note that you may only use shielded connector enclosures. A large surface area of the cable shield must be in contact with the connector enclosure on both ends.

CAUTION
Never connect cable shield with GND
Never connect the cable shield with the GND as this could destroy the interfaces. GND must always be connected on both sides (pin 5), otherwise the interface modules could be destroyed.

The figure below illustrates the cable for a point-to-point connection between a communication module and a communication partner.



3.4 RS422 mode

The following communication modules support RS422 mode:

- CM PtP RS422/485 BA
- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

In RS422 mode, data is transmitted via two line pairs (four-wire operation). A separate line pair is available for the send direction and the receive direction. Simultaneous sending and receiving is possible (full duplex).

All communication partners must be capable of simultaneous operation of a sender and receiver unit.

The data can be exchanged simultaneously between two or more communication partners. In RS422 multipoint mode, only one slave may send data at any given time.

Interface operating modes

The following table is a summary of the interface operating modes for the various communication modules and protocols.

The communication module can be used in the following topologies in RS422 mode:

- Link between two nodes: Point-to-point connection
- Link between several nodes: Multipoint connection
  (only available with CM PtP (ET 200SP))

Operating mode	Description
Full duplex (RS422) four-wire operation (point-to-point connection)	Both devices have the same priority in this operating mode.
Full duplex (RS422) four-wire operation (multipoint master)	The communication module can be used as multipoint master.
Full duplex (RS422) four-wire operation (multipoint slave)	The communication module can be used as multipoint slave.

The following applies for a multipoint master/slave topology in RS422 mode:

- The sender of the master is interconnected with the receivers of all slaves.
- The senders of the slaves are interconnected with the master's receiver.
- Only the receiver of the master and the receiver of one slave have a default setting. All other slaves operate without default settings.

RS422 signals

The following signals are present on the communication module when using the RS422 hardware:

T (A) -	Output	Transmitted data
T (B) +	Output	Transmitted data
R (A) -	Input	Received data
R (B) +	Input	Received data
GND		Functional ground; isolated

Connecting cables

The following standard connecting cables of various lengths are available for connecting to a communication partner which also has a 15-pin D-sub female connector:

Article number	6ES7902-3AB00-0AA0	6ES7902-3AC00-0AA0	6ES7902-3AG00-0AA0
Product type designation	S7 connecting cable RS422		
Cable length	5 m	10 m	50 m

The table below shows the pin assignment of the 15-pin D-sub female connector of the respective communication module.

Socket*	Pin	Designation	Input/output
	1	-	-
	2	T (A) -	Output
	3	-	-
	4	R (A) -	Input
	5	-	-
	6	-	-
	7	-	-
	8	GND	-
	9	T (B) +	Output
	10	-	-
	11	R (B) +	Input
	12	-	-
	13	-	-
	14	-	-
	15	-	-

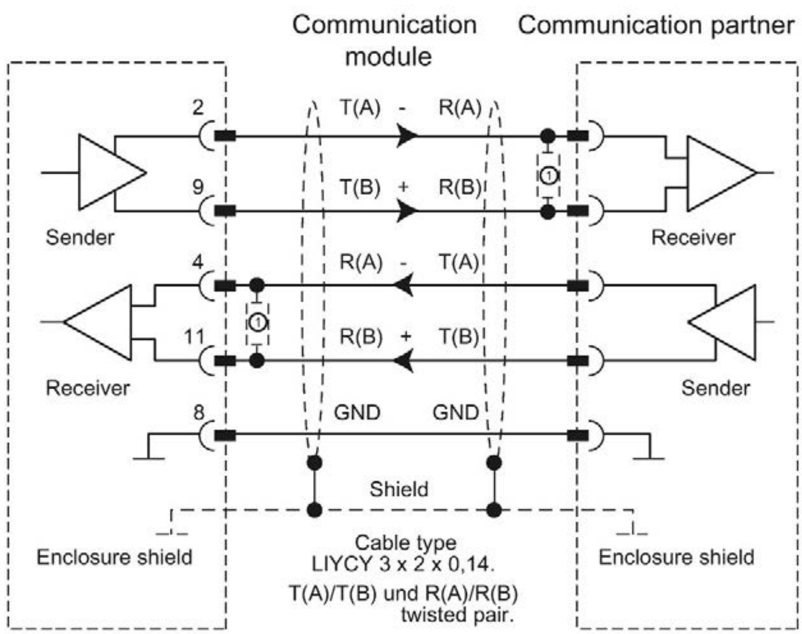
* View from the front

The cable or the connector of the listed connecting cables are not available for order as separate items. If you fabricate your own connecting cables you must remember that unconnected inputs at the communication partner may have to be connected to open-circuit potential.

Note that you may only use shielded connector enclosures. A large surface area of the cable shield must be in contact with the connector enclosure on both ends.

CAUTION
Never connect cable shield with GND
Never connect the cable shield with the GND as this could destroy the interfaces. GND must always be connected on both ends (pin 8), otherwise the interface modules could be destroyed.

The figure below illustrates the cable for a point-to-point connection between a communication module and a communication partner.



① For cable lengths longer than 50 m, you need to solder a terminating resistor of approx. 330 Ω at the receiver end to ensure interference-free data traffic.

Note

This cable type can be used in the following lengths for a communication module as communication partner: max. 1200 m at 19200 baud, max. 500 m at 38400 baud max. 250 m at 115200 Baud.

3.5 RS485 mode

The following communication modules support RS485 mode:

- CM PtP RS422/485 BA
- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

In RS485 mode, data is transmitted via one line pair (two-wire operation). The line pair is available alternately for the send and receive directions. It is possible to either send or receive (half duplex). On completion of a send operation, operation is immediately switched to receive mode (ready to receive). Send mode is reset again as soon as a new send job is received.

Interface operating modes

The following table is a summary of the interface operating modes for the various communication modules and protocols.

Operating mode	Description
Half duplex (RS485) two-wire operation	Operating mode for point-to-point connection or multipoint connection (multipoint) in two-wire operation. The communication module can be the master as well as the slave.

If you operate the Freeport in RS485 mode (half duplex, two-wire operation), you must make provisions in the user program to ensure that only one device sends data at any given time. If more than one device sends data at the same time, the frames are corrupted.

Modbus automatically ensures that only one device is sending.

Changeover times for RS485 communication module in half duplex mode

A maximum time of 0.1 ms is set for the changeover between sending and receiving.

RS485 signals

The following signals are present on the communication module when using the RS485 hardware:

R (A)/T (A) -	Input/output	Received/transmitted data
R (B)/T (B) +	Input/output	Received/transmitted data
GND		Functional ground; isolated

Connecting cables

The table below shows the pin assignment of the 15-pin D-sub female connector of the respective communication module.

Socket*	Pin	Designation	Input/output
	1	-	-
	2	-	-
	3	-	-
	4	R (A)/T (A) -	Input/output
	5	-	-
	6	-	-
	7	-	-
	8	GND	-
	9	-	-
	10	-	-
	11	R (B)/T (B) +	Input/output
	12	-	-
	13	-	-
	14	-	-
	15	-	-

* View from the front

When fabricating the connecting cables, you need to remember that unconnected inputs at the communication partner may have to be connected to open-circuit potential.

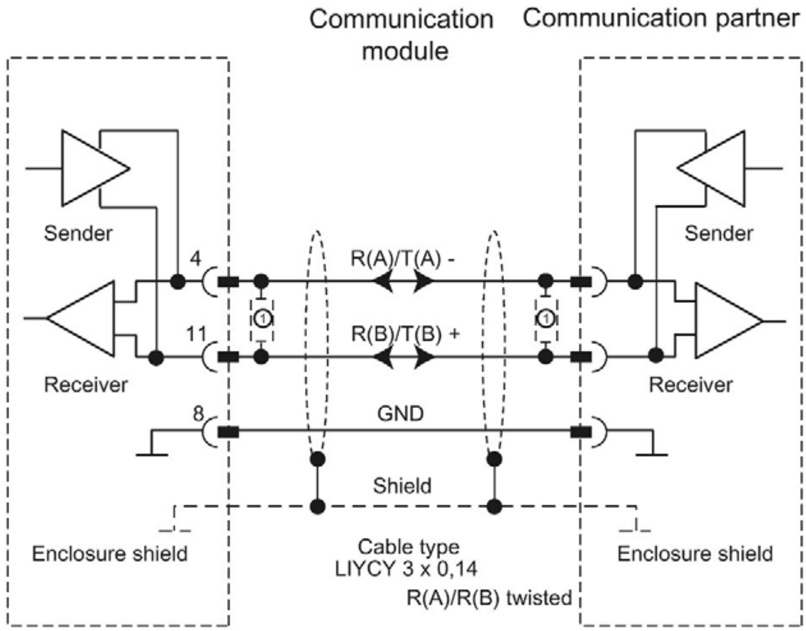
Note that you may only use shielded connector enclosures. A large surface area of the cable shield must be in contact with the connector enclosure on both ends.

CAUTION

Never connect cable shield with GND

Never connect the cable shield with the GND as this could destroy the interfaces. GND must always be connected on both ends (pin 8), otherwise the interface modules could be destroyed.

The figure below illustrates the cable for a point-to-point connection between a communication module and a communication partner.



① For cable lengths longer than 50 m, you need to solder a terminating resistor of approx. 330 Ω at the receiver end to ensure interference-free data traffic.

3.6 Handshake procedure

Introduction

Handshaking controls the data flow between two communication partners. The use of the handshaking method prevents data loss during transmission if the devices are operating at different speeds.

We can basically distinguish between the following methods:

Table 3- 1 Overview of methods and interfaces

Method	RS232	RS422	RS485
Software data flow control XON/XOFF	X	X	-
Hardware data flow control (RTS/CTS)	X	-	-
Automatic operation of accompanying signals	X	-	-

Software data flow control

Software data flow control is implemented as follows on the communication module:

- **XON/XOFF**
  - As soon as the communication module has been set to the "XON/XOFF" operating mode by means of parameter assignment, it sends the XON character, thereby allowing the communication partner to send data.
  - On reaching the configured maximum number of frames, or 16 characters ahead of receive buffer overflow, the communication module sends the XOFF character, thereby requesting that the communication partners stop sending. If the communication partner nonetheless continues to send data, an error message is generated if the receive buffer overflows. Data received in the last frame is discarded.
  - As soon as a frame has been fetched by the CPU and the receive buffer is ready to receive data again, the communication module sends the XON character.
  - If the communication module receives the XOFF character during sending, it cancels the current send operation until it receives a XON again from its communication partner. If no XON is received within a specific configurable time, send operation is canceled and a corresponding error message is output.

Note

You can configure the characters for XON and XOFF (any ASCII character).

During parameter assignment of the XON/XOFF software data flow control, user data may not contain any of the configured XON or XOFF characters.

Hardware data flow control

Note

The DTR/DSR signals do not have to be wired for "Hardware RTS always ON, ignore DTR/DSR" parameter assignment.

If "Hardware RTS always ON" is configured, it is imperative that you fully wire the interface signals used. Make sure that the local RTS (out) is connected with the CTS (in) of the communication partner and the local CTS is connected with the RTS of the communication partner. Accordingly, the local DTR must be connected with the DSR of the communication partner and the local DSR with the DTR of the communication partner.

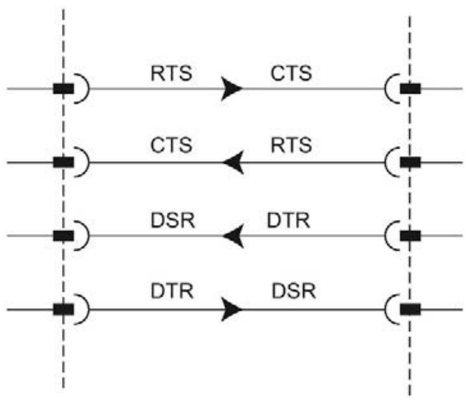


Figure 3-2 Wiring of the interface signals

- **Hardware RTS always ON, ignore DTR/DSR**
  - As soon as the communication module has been set to an operating mode with "Hardware RTS always ON" through parameter assignment, it outputs the RTS = ON signal to the communication partner to indicate its ready state.
  - RTS is set to OFF as soon as the configured maximum number of frames or 16 characters before buffer overflow is reached.
    If the communication partner nonetheless continues to send data, an error message is generated on overflow of the receive buffer. Data received in the last frame is discarded.
  - RTS is reset to ON as soon as the frame has been fetched by the CPU and the receive buffer is ready to receive data again.
  - If CTS switches to OFF during the send operation, the communication module interrupts the send operation until CTS is reset to ON. If CTS is not reset to ON within a specific configurable time, the send operation is canceled and a corresponding error message is output.
- **Hardware RTS always ON**

  The "Hardware RTS always ON" mode corresponds to the "Hardware RTS always ON, ignore DTR/DSR" mode. However, you also need to wire DTR and DSR.
  - As soon as the communication module has been set set to an operating mode with "Hardware RTS always ON" through parameter assignment, it sets DTR = ON and RTS = ON to signal its general ready state to the communication partner.
  - RTS is set to OFF as soon as the configured maximum number of frames or 16 characters before buffer overflow is reached.
    If the communication partner nonetheless continues to send data, an error message is generated on overflow of the receive buffer. Data received in the last frame is discarded.
  - RTS is reset to ON as soon as the frame has been fetched by the CPU and the receive buffer is ready to receive data again.
  - If CTS switches to OFF during the send operation, the communication module interrupts the send operation until CTS is reset to ON. If CTS is not reset to ON within a specific configurable time, the send operation is canceled and a corresponding error message is output.
  - A switch from DSR = ON to DSR = OFF cancels an active send job and triggers an error message.

Automatic operation of accompanying signals

- **Hardware RTS always switched**

  "Hardware RTS always switched" is implemented as follows on the communication module:

  – As soon as the communication module is set to the operating mode with "Hardware RTS always switched" through parameter assignment, it sets the line RTS to OFF and DTR to ON (communication module ready for operation).

    It is not possible to send frames until the DSR line is set to ON. No data is sent via the RS232C interface as long as DSR is set to OFF. A send job is canceled and a corresponding error message is generated.

  – When a send job is pending, RTS is set to ON and the configured RTS ON delay starts. On expiration of the data output time, the system checks whether the communication partner has set CTS to ON. If so, the data is sent via the RS232 interface.

  – If the CTS line is not set to ON within the RTS ON delay, or if CTS changes to OFF during transmission, the send job is aborted and an error message is generated.

  – Once the data has been sent and the configured clear RTS OFF delay has elapsed, the RTS line is set to OFF. The system does not wait for CTS to change to OFF.

  – It is always possible to receive data via the RS232 interface. There will be no reaction if there is a danger of the receive buffer of the communication module overflowing.

  – A switch from DSR = ON to DSR = OFF cancels an active send job and triggers an error message.

Note

Set the "RTS ON delay" in such a way that the communication partner is able to enter the ready to receive state before the time elapses.

Set the "RTS OFF delay" in such a way that the communication partner is able to receive the last characters of the frame completely before RTS is set to OFF and the send request is canceled.

Note

When automatic operation of the RS232 signals is configured, RTS and DTR cannot be controlled by means of the corresponding instruction!

Time diagram

The figure below shows the chronological sequence of a send job with configured data flow control "Hardware RTS always switched":

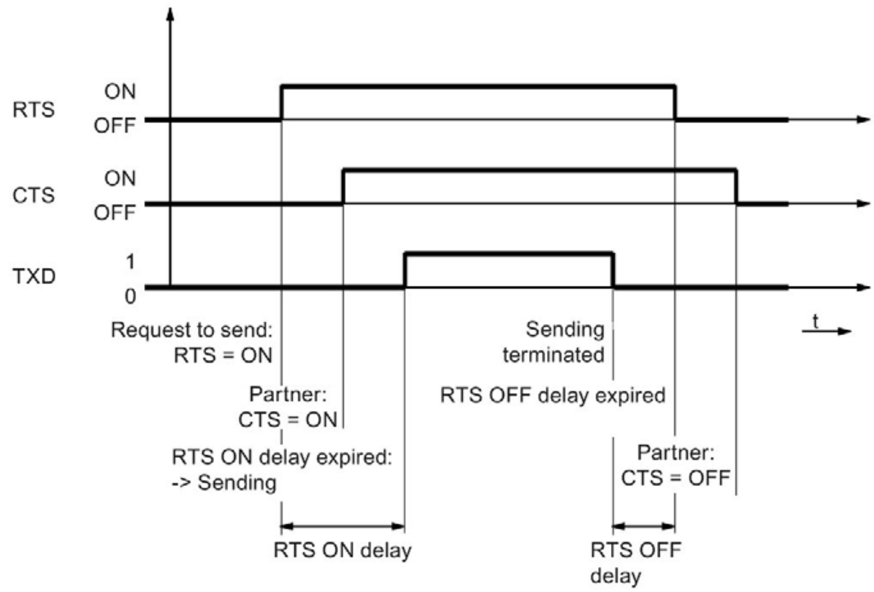

Figure 3-3 Time diagram for Hardware RTS always switched

Additional information

Note

Operation of DTR/DSR or RTS/CTS is accepted by the communication module with the following settings:

- Hardware RTS always ON, ignore DTR/DSR
- Hardware RTS always ON
- Hardware RTS always switched

4 Configuring / parameter assignment

4.1 Configuring / parameter assignment of a communication module

The following sections contain explanations on the following protocols and their parameters:

- Communication using Freeport (Page 38)
- Communication using 3964(R) (Page 47)
- Communication through Modbus RTU (Page 52)
- Communication using USS (Page 59)

This information is required to carry out the parameter assignment and subsequently programming of the communication in accordance with the used protocol.

Configuration and parameter assignment are carried out in the device view of STEP 7 (TIA Portal) and in the properties dialog of the communication module. Some configurations can also be changed during runtime by means of the corresponding "Config" instructions (Port_Config, Send_Config, Receive_Config, P3964_Config).

Procedure for setting up point-to-point communication

The procedure does not depend on the communication module used.

1. Configure an S7-1500 design with CPU and communication module in the device view of the STEP 7 (TIA Portal) hardware editor.
2. You assign the parameters of the communication module interface (protocol, protocol parameters, addresses) in the "General" area of the "Properties" tab.

4.2 Communication using Freeport

4.2.1 Procedure for establishing a serial connection with Freeport

Requirements

- The hardware is set up and there is an electrical connection to the link partner.
- The project has been created in STEP 7 (TIA Portal) and the CPU has been inserted into the hardware configuration.

Procedure - Hardware configuration

1. Insert the CM PtP communication module into the hardware configuration.
2. Set the communication parameters according to the link partner:

   For example, transmission speed, character frame, frame start and frame end

   These parameters are transferred to the CM PtP communication module every time the CPU is started.

Procedure - Programming

1. Create the data structure that is to include the data to be transferred.

Sending data

1. Insert the instructions from the PtP Communication library: Send_P2P for sending data
2. Interconnect the input and output parameters of the instruction, e.g.:
   – HWID from the system tags at the PORT input
   – Data structure with the data to be sent at the BUFFER input

   Note: During operation, each positive edge at the REQ input will send the specified data area once. The block must be called until DONE indicates that the data was transferred to the module.

   In case of an error, setting ERROR once and displaying the corresponding information in STATUS indicates that the data was not transferred.

Receiving data:

1. Insert the instructions from the PtP Communication library: Receive_P2P for sending data
2. Interconnect the input and output parameters of the instruction, e.g.:
   - HWID from the system tags at the PORT input
   - Data structure for storage of received data at the BUFFER input

   Note: A high level at the NDR output during operation indicates that new data was received and stored in the specified data area. The block must be called until NDR=TRUE. The received data can then be analyzed and the RECEIVE_P2P can be called again.

Optional additions

- Instructions that end in _Config can be used optionally to change the parameters of the hardware configuration during operation of the user program. The changes are not saved in the hardware configuration. They are overwritten at the next restart.
- The instructions Signal_Set and Signal_Get can be used to control the RS232 accompanying signals individually if automatic operation is not a suitable option.

4.2.2 Data transmission with Freeport

Introduction

Freeport is a freely programmable frame-based protocol that is also known as ASCII protocol.

The Freeport protocol controls data transmission by means of a point-to-point connection between the communication module and a communication partner. The Freeport protocol contains the physical layer (Layer 1).

The Freeport protocol supports sending and receiving of messages with any structure (all characters from 00H through FFH (for character frames with 8 data bits) or from 00H through 7FH (for character frames with 7 data bits)).

The frame start and end criteria must be configured both for the send and the receive direction. The start and end criteria can be configured differently.

Instructions are available for communication with a communication partner (see Overview of point-to-point programming (Page 63)).

4.2.3 Sending data with Freeport

Specifying settings for sending

To send a message, the partner must be informed of the start and end of the message. These settings can be set fixed in the hardware configuration or be adjusted during runtime by using the instruction Send_CFG. You can select one of the following options or also combine them:

- Send break before frame start

  You can specify that an additional Break is sent at the beginning of each message transmission on expiration of the RTS ON delay time.
  The duration of the "Break" is specified in bit times.

  Compliance with the send break can be deactivated if other mechanisms are used for synchronization.

- Send idle line

  You can specify that an additional "Idle Line" signal is output at the start of each message transmission.
  The duration of the "Idle Line" is specified in bit times.

  Compliance with the send break can be deactivated if other mechanisms are used for synchronization.

- RTS ON delay

  You can configure the time that has to expire after the RTS (Request to send) before the actual data transmission starts (RS232 only).

- RTS OFF delay

  You can configure the time that has to expire after transmission has been completed before the RTS signal is deactivated (RS232 only).

- Send up to and including the end delimiter

  You can configure the number of end delimiters (1 or 2) and their value.

  All data up to the end delimiter(s) is sent, independent of the selected frame length. The end delimiter must be included in the data to be sent. Data is sent only up to and including the delimiter, even if the specified data length is longer.

- Number of appended characters

  Input of the number of appended characters. Sending takes place up to the configured length. The end delimiter(s) is/are appended automatically. Depending on the number of end delimiters, one to five characters more than the number specified at the instruction are sent to the partner.

Note

If you combine "Send break before frame start", "Send idle line" and "RTS ON delay", these are processed in the order "RTS ON delay", "Send break before frame start" and "Send idle line".

4.2.4 Receiving data with Freeport

Specifying the message start

For data transmission with Freeport, you can choose between several different start criteria. The start criterion defines when a frame starts. Once a criterion that indicates the start of the message is met, the data stream is scanned for message end criteria. Here you select the settings that correspond to the properties of the sending communication partner.

Two different methods are available for detecting the message start:

- **Start on any character**

  Any character can be used to define the start of the message (default).

  This means that the first character sent at the start of communication, or after the frame end has been detected, will be identified as the first character of a message.

- **Start on special condition**

  The start of the message is detected based on the following specified conditions.

  – **After detection of a line break**

    The frame start is not accepted unless a break has been received beforehand, in other words, it is compulsory for the partner to send a break before sending a frame.

  – **After detection of an idle line**

    The frame start is not accepted until the configured idle line duration has expired. This procedure requires a minimum interval between two frames.

  – **After receipt of a start character**

    The frame start is detected when the configured start character is identified.

  – **After detection of one or several start sequences**

    The frame start is detected when the configured string with a length of up to five characters is identified. You can configure up to 4 start sequences. The start sequences that are up to 5 characters long can also contain "don't care characters".

Example:

Table 4- 1 Configured start conditions

Start condition	1. character	2. character	3. character	4. character	5. character
1	0x68	xx	xx	0x68	xx
2	0x10	0xaa	xx	xx	xx
3	0xdc	0xaa	xx	xx	xx
4	0xe5	xx	xx	xx	xx
:					

The following message has been received: 68 10 aa 68 bb 10 aa 16

The evaluation of the start criteria begins with the receipt of the first character 0x68.
The 2nd and 3rd characters are free.
When the 4th character (second 0x68) is received, the first start condition is met and further evaluation of the message begins.

Specifying the message end

You can choose from several different end criteria for data transmission using the Freeport protocol. The end criterion defines the point at which a frame has been received completely.

Configurable end criteria are:

- **Recognize message end by message timeout**
- **Recognize message end by response timeout**
- **After character delay time elapses (default)**
- **After receipt of a fixed frame length**
- **After receipt of a maximum number of characters**
- **Read message length from message**
- **After receipt of an end sequence**

Message timeout

When data is received, the end of frame is detected on expiration of the configured time for transferring a frame. Time measurement starts after the start criterion has been met.

Response timeout

The response time is used to monitor the response behavior of the communication partner. If a valid frame start is not recognized after the completion of a send job, the send job is acknowledged with a corresponding message.

The actual end criterion has to be configured additionally.

Expiration of character delay time

When data is received, the frame end is detected when the configured maximum time between successive characters is exceeded (character delay time). The value is specified in bit times.

In this case, the character delay time must be set in such a way as to ensure that it expires between two consecutive frames. However, it should be of sufficient length to exclude incorrect identification of the end of the frame whenever the communication partner performs a transmission pause within a frame.

Fixed frame length

When data is received, the end of the frame is identified after the configured frame length has been reached.

An error message is output and the frame is discarded if the character delay time expires (if activated) before the fixed frame length has been reached.

Please note the following if the frame length of the received characters does not match the fixed configured frame length:

- All characters received after the fixed configured frame length has been reached will be discarded until a new start criterion is detected.
- An error message is output and the frame is discarded if another (activated) end criterion is met before the fixed frame length has been reached.

Maximum number of characters

When receiving data, the end of the frame is recognized after the declared number of characters have arrived.

This setting can be combined with the "Character delay time" settings. The frame received is also assessed as free of error if another end condition occurs, regardless of whether the maximum number of characters has been reached.

Please note the following if the frame length of the received characters does not match the configured maximum frame length:

- All characters received after the configured maximum number of characters has been reached will be discarded until a new start criterion (e.g. "Idle Line") is detected.
- If a different (activated) end criterion is met before the configured maximum number of characters has been reached, this "frame part" is assessed as a valid frame and the partner waits for a new start criterion. All characters received prior to fulfillment of a new start criterion are discarded.

Note

If no further end criterion is activated, the fixed frame length and maximum number of characters will respond in the same way.

Message length in the message

When data is received, the frame end is detected when the frame length sent with the received frame has been reached.

The following parameters define the characters to be used for evaluation of the message length:

- **Offset of length field in message**

  In the message, the value defines the position of the character that is to be used to determine the message length.

  You can set values from 0 to 4095 characters, depending on the buffer size.

- **Size of length field**

  This value specifies the number of characters as of the first evaluation position to be used to determine the message length.

  You can set values of 1, 2 and 4 characters.

- **Number of characters not counted in length specification**

  Number of characters appended to the frame without counting towards the frame length. This value defines the number of bytes at the end of the frame which should not be included in the evaluation of the message length.

  You can set values from 0 to 255 characters.

Example:

Parameter assignments for "Message length in the message"

Offset of length field in message:	3. byte ("2" has to be configured as offset)
Size of length field:	1 byte
Number of characters not counted in length specification:	3 bytes

Message					**Number of characters not counted in length specification**		
Start character	**Address**	**Length field**			**Checksum**	**End delimiter**	
Byte 1	Byte 2	Byte 3	Byte ...	Byte X	Byte X+1	Byte X+2	Byte X+3

End sequence

When data is received, the end of the frame is identified when the configured end sequence (max. 5 characters) is received. The end sequence which is up to 5 characters long can also contain "don't care characters". The received data is applied by the CPU, including the end sequence.

If you are working with the end sequence, transmission is not code-transparent and you must exclude the presence of end code in the user data.

Note

Frame end sequence

If there is only one end delimiter, the entry **must** take place in the 5th line.

If there are two end delimiters, the entries **must** take place in the 4th and 5th line (no gaps).

The same applies to the use of additional characters.

4.2.5 Code transparency

Code transparency

Code-transparent means that any character combinations can occur in the user data without the end criterion being recognized.

The code transparency of the procedure depends on the selection of the configured end criterion and flow control:

- With specified end sequence or using XON/XOFF flow control
  - Not code-transparent
- End criterion character delay time, fixed frame length, maximum frame length, message timeout, or response timeout and message length in the message
  - Code-transparent

4.2.6 Receive buffer

Receive buffer of the module

The communication modules have a receive buffer that stores the received frames temporarily until they are transmitted to the CPU. The receive buffer is implemented as a ring buffer, which means the frames are transmitted to the CPU in the order in which they were received until the receive buffer is full. If additional frames are received once the buffer is full, the oldest frame is overwritten. If "Prevent overwriting" was configured, a corresponding message is generated when the receive buffer is full. All further frames are rejected until the receive buffer is ready to receive new ones.

During the parameter assignment, you can specify whether the receive buffer should be deleted during startup. You can also specify the range of values (1 to 255) for the number of buffered receive frames.

The receive buffer of the module may have a size of up to 8 KB, depending on the communication module used (see chapter Introduction (Page 13)). The frame has a maximum length of 4 KB. This means that each communication module is capable of buffering at least two frames.

If you always want to transfer the last frame received to the CPU, you must set the value "1" for the number of buffered frames and deactivate overwrite protection.

Note

If continuous reading of the received data in the user program is interrupted for a certain time, you may find when the receive data is requested again, that the communication module first sends older frames before the CPU receives the most recent one. At the time of interruption, the old frame had already been transmitted from the receive buffer of the communication module and prepared for transmission to the CPU.

4.3 Communication using 3964(R)

4.3.1 Procedure for establishing a serial connection with 3964(R)

Requirements

- The hardware is set up and there is an electrical connection to the link partner.
- The project has been created in STEP 7 (TIA Portal) and the CPU has been inserted into the hardware configuration.

Procedure - Hardware configuration

1. Insert the CM PtP communication module into the hardware configuration.
2. Set the communication parameters according to the link partner:

   For example, transmission speed, character frame, frame start and frame end

   These parameters are transferred to the CM PtP communication module every time the CPU is started.

Procedure - Programming

1. Create the data structure that is to include the data to be transferred.

Sending data:

1. Insert the instructions from the PtP Communication library: Send_P2P for sending data
2. Interconnect the input and output parameters of the instruction, e.g.:
   - HWID from the system tags at the PORT input
   - Data structure with the data to be sent at the BUFFER input

   Note: During operation, each positive edge at the REQ input will send the specified data area once. The block must be called until DONE indicates that the data was transferred to the module.

   In case of an error, setting ERROR once and displaying the corresponding information in STATUS indicates that the data was not transferred.

Receiving data:

1. Insert the instructions from the PtP Communication library: Receive_P2P for sending data
2. Interconnect the input and output parameters of the instruction, e.g.:
   - HWID from the system tags at the PORT input
   - Data structure for storage of received data at the BUFFER input

   Note: A high level at the NDR output during operation indicates that new data was received and stored in the specified data area. The block must be called until NDR=TRUE. The received data can then be analyzed and the RECEIVE_P2P can be called again.

Optional additions

- Instructions that end in _Config can be used optionally to change the parameters of the hardware configuration during operation of the user program. The changes are not saved in the hardware configuration. They are overwritten at the next restart.
- The instructions Signal_Set and Signal_Get can be used to control the RS232 accompanying signals individually if automatic operation is not a suitable option.

4.3.2 Data transmission with 3964(R) procedure

Introduction

The 3964(R) procedure controls point-to-point data exchange between the communication module and a communication partner. and contains both the physical layer (layer 1) and the link layer (layer 2).

Instructions are available for communication with a communication partner (see Overview of point-to-point programming (Page 63)).

4.3.3 Control characters

Introduction

During data transmission, the 3964(R) procedure adds control characters to the information data (link layer). The communication partner can use these control characters to check whether it has received all data completely and without errors.

Control characters of the 3964(R) procedure

The 3964(R) procedure evaluates the following control characters:

STX	Start of Text	Beginning of the character string to be transmitted	02H
DLE	Data Link Escape	Data transmission changeover	10H
ETX	End of Text	End of the character string to be transmitted	03H
NAK	Negative Acknowledge	Negative acknowledgment	15H
BCC	Block Check Character (only with 3964R)	Block check character	

BCC is formed and monitored automatically in the communication module. The block check character is not transmitted as frame content to the CPU.

Note

If the DLE character is transmitted as an information character within a frame, it is sent twice (DLE duplication) to distinguish it from the DLE control character during connection establishment and termination. The receiver reverses the DLE duplication.

Priority

With the 3964(R) procedure, one communication partner must be assigned a higher and the other a lower priority. If both partners start to establish a connection at the same time, the partner having lower priority will cancel its send job.

4.3.4 Block check character

Block check character

With the 3964R transfer protocol, data security is enhanced by sending an additional block check character (BCC = Block Check Character).

The block check character is the even longitudinal parity (EXOR logic operation of all data bytes) of a sent or received block. Its calculation begins with the first byte of user data (first byte of the frame) after the connection establishment, and ends after the DLE ETX character at connection termination.

Note

With DLE duplication, the DLE character is included twice in the BCC calculation.

4.3.5 Sending data with 3964(R)

Connection establishment for sending

The 3964(R) procedure sends the STX control character to set up the connection. If the communication partner responds with the DLE character before the acknowledgment delay time expires, the procedure switches to send mode.

If the communication partner answers with NAK or any other character (except for DLE or STX), or the acknowledgment delay time expires without a response, the procedure tries to set up the connection again. After the configured number of unsuccessful setup attempts, the procedure cancels the connection setup and sends the NAK character to the communication partner. The communication module outputs a corresponding error message.

Sending data

If the connection is successfully established, the user data contained in the output buffer of the communication module is sent to the communication partner with the selected transmission parameters (a DLE recognized in the user data is doubled during the send job). The communication partner monitors the time intervals between the incoming characters. The interval between two characters must not exceed the character delay time. Monitoring of the character delay time starts immediately after the connection has been established.

If the communication partner sends the NAK character during an active send operation, the procedure cancels the block and repeats it as described above, beginning with connection establishment. If a different character is sent, the procedure first waits for the character delay time to expire and then sends the NAK character to set the communication partner to idle state. Then, the procedure restarts sending with the connection setup STX.

Connection termination during sending

Once the contents of the buffer have been sent, the procedure appends the DLE and ETX characters and (only with 3964R) the block checksum BCC as the end identifier, and then waits for an acknowledgment character. If the communication partner sends the DLE characters within the acknowledgment delay time, the data block has been received without errors. If the communication partner responds with NAK, any other character (except DLE), or with a corrupted character, or if the acknowledgment delay time expires without a response, the procedure restarts sending with the connection setup STX.

After the configured number of attempts to send, the procedure stops the process and sends an NAK to the communication partner. The communication module outputs a corresponding error message.

4.3.6 Receiving data with 3964(R)

Connection setup for receiving

In idle state, when there is no send job to be processed, the procedure waits for the communication partner to set up the connection.

A wait time is started (wait time = acknowledgment delay time - 10 ms, however, maximum of 400 ms) if no free receive buffer is available during the connection setup with STX. An error message is generated if no free receive buffer is available on expiration of this time. The procedure sends the NAK character and returns to the idle state. Otherwise, the procedure sends a DLE and receives the data as described above.

The acknowledgment delay time should be set to the same value at both communication partners.

If the procedure receives any character (except for STX or NAK) while in idle state, it waits for the character delay time (CDT) to expire and then sends the NAK character. The communication module outputs a corresponding error message.

Receiving data

After a successful connection establishment, the incoming receive characters are saved to the receive buffer. If two consecutive DLE characters are received, only one of these is saved to the receive buffer.

After connection has been established and after each receive character, the procedure waits for the next character during the character delay time. If this period expires before another character is received, an NAK is sent to the communication partner. The communication module outputs a corresponding error message. A retry is then expected.

If transmission errors occur during receiving (frame errors, parity errors, etc.), the procedure continues to receive data until the connection is terminated and then sends an NAK to the communication partner. A retry is then expected. If the block still cannot be received without errors after the specified number of transfer attempts, or if the communication partner does not start the retry within a block wait time of 4 seconds, the procedure cancels the receive operation. The communication module reports the first corrupted transfer and the final cancelation.

Connection setup for receiving

If the 3964 procedure detects a DLE ETX string, it terminates the receive operation and confirms a successfully received block by sending a DLE to the communication partner. In the case of a receive error, an NAK is sent to the communication partner. A retry is then expected.

The 3964R procedure terminates the receive operation after having detected the DLE ETX BCC string. It compares the received block check character BCC with the internally calculated longitudinal parity. If the BCC is correct and no other receive errors have occurred, the 3964R procedure sends a DLE and returns to the idle state. The communication module informs the control system that new receive data is available.

If the BCC is faulty or a different receive error occurs, an NAK is sent to the communication partner. A retry is then expected.

4.4 Communication through Modbus RTU

4.4.1 Procedure for establishing a serial connection with Modbus RTU

Requirements

- The hardware is set up and there is an electrical connection to the link partner.
- The project has been created in STEP 7 (TIA Portal) and the CPU has been inserted into the hardware configuration.

Procedure - Hardware configuration

1. Insert the CM PtP communication module into the hardware configuration.
2. Select the Modbus RTU protocol.

   Note: With Modbus RTU, most communication parameters are set using the Modbus_Comm_Load instruction during CPU start.

Procedure - Programming

1. Create the data structure that is to include the data to be transferred.
2. Integrate the Modbus_Comm_Load instruction into the cyclic sequence for parameter assignment of the communication module.
3. Interconnect the HWID from the system tags at the PORT input.
4. Call the instruction until successful execution is displayed at the DONE output. Do not call the instruction again thereafter unless you want to change the communication parameters.

Operation as Modbus master:

1. Insert the Modbus_Master instruction from the MODBUS (RTU) library:
2. Interconnect the data structure with the data to be sent at the BUFFER input.
3. Interconnect the instance DB of the Modbus_Master instruction at the MB_DB input of the Modbus_Comm_Load.

   Note: During operation, each positive edge at the REQ input will process the specified job once. The block must be called until DONE indicates that the data was transferred to the module.

   In case of an error, setting ERROR once and displaying the corresponding information in STATUS indicates that the data was not transferred.

Operation as Modbus slave:

1. Insert the Modbus_Slave instruction from the MODBUS (RTU) library.
2. Interconnect the data structure with the Modbus hold registers.
3. Enter the Modbus slave address at the MB_ADDR input.
4. Interconnect the instance DB of the Modbus_Master instruction at the MB_DB input of the Modbus_Comm_Load.

   Note: A high level at the NDR output during operation indicates that new data was received and stored in the specified data area.

4.4.2 Overview of modbus communication

Modbus RTU communication

Modbus RTU (Remote Terminal Unit) is a standard protocol for communication in the network and uses the electrical RS232 or RS422/485 connection for serial data transmission between Modbus devices in the network.

Modbus RTU uses a master/slave network in which the entire communication is triggered by only one master device while the slaves can only respond to the request of the master. The master sends a request to a slave address and only this slave address responds to the command (exception: broadcast frames to slave address 0 which are not acknowledged by the slaves).

The procedure used is a code-transparent, asynchronous half-duplex procedure. Data transmission is carried out without handshake.

Position in the system environment

The following Modbus description refers to the use of the corresponding communication modules.

- CM PtP RS232 HF
- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

Function of the coupling

With the corresponding communication modules and the related instructions, you can establish a communication connection between a remote Modbus control system and a SIMATIC S7.

The GOULD-MODBUS protocol in RTU format is used for transmission.

Function codes 01, 02, 03, 04, 05, 06, 08, 15 and 16 are used for communication between a communication module operated as a Modbus slave and a master system (see Function Codes (Page 57)).

If a SIMATIC S7 communication module is operated as a Modbus master, function codes 11 and 12 are also available.

SIMATIC S7 as a Modbus slave

The master has the initiative for transmission, the communication module works as a slave.

frame traffic from slave to slave is not possible.

The instruction Modbus_Slave makes the data available on a SIMATIC data area in accordance with the mapping specification or stores them.

SIMATIC S7 as a Modbus master

As master, the communication module initiates transmission and, after outputting a request frame, it waits for the configured response monitoring time for a response frame from the slave. If the slave does not respond, the master repeats the request in accordance with the configuration before it outputs an error message.

frame structure

The data exchange "Master-Slave" and/or "Slave-Master" begins with the **slave address**, followed by the **function code**. Then the data are transferred. The structure of the data field depends on the function code used. The CRC check is transmitted at the end of the frame.

ADDRESS	FUNCTION	DATA	CRC-CHECK
Byte/Word	Byte	n byte	2 byte

ADDRESS	Modbus slave address • Standard address: 1 to 247 (bytes) • Extended station address: 1 to 65535 (word)
FUNCTION	Modbus Function Codes (Page 57)
DATA	frame data: Management and net data depending on the function code
CRC-CHECK	frame checksum

Slave address

The slave address can be range from 1 to 247 (byte) or 1 to 65535 (word). The address is used to address a defined slave on the bus.

Broadcast Message

The master uses slave address 0 to address all slaves on the bus.

Broadcast messages are only permitted in conjunction with writing Function codes 05, 06, 15 and 16.

A broadcast message is not followed by a response frame from the slave.

Data Field DATA

The data field DATA is used to transfer the function code-specific data such as:

- Bytecount, Coil_Startaddress, Register_Startaddress; Number_of_Coils, Number_of_Registers, ...

  For details, see "Function Codes (Page 57)".

CRC-Check

The end of the frame is identified by means of the CRC 16 checksum consisting of 2 bytes. It is calculated by the following polynominal: $x^{16} + x^{15} + x^2 + 1$.

The low byte is transmitted first, followed by the high byte.

End of frame

The end of frame is recognized when no transmission takes place during the time period required for the transmission of three and a half characters (3.5 times character delay time) (see Modbus Protocol Reference Guide).

This end of frame TIME_OUT therefore depends on the data transmission rate and is indicated in bit times (35 bit times are fix coded internally; further bit times can be configured in addition at the instruction).

The Modbus frame received from the connection partner is evaluated and formally checked after the end of frame TIME_OUT is received.

Exception responses

On recognition of an error in the request frame from the master, for example, register address illegal, the slave sets the highest value bit in the function code of the response frame.

This step is followed by transmission of a byte exception code that describes the cause of the error.

A detailed description of the meaning of the above-mentioned parameters is available in the "GOULD MODICON Modbus Protocol" (not part of this documentation).

Exception code frame

The exception code frame from the slave has the following structure:

- for example, slave address 5, function code 5, exception code 2

Response frame from the slave EXCEPTION_CODE_xx:

05H	Slave address
85H	Function code
02H	Exception code (1...7)
xxH	CRC checksum "Low"
xxH	CRC checksum "High"

On receipt of an exception code frame by the driver, the current job is completed with error.

The following error codes are defined in accordance with the Modbus specification:

Error code	Meaning in accordance with Modbus specification	Cause - Short Description *
1	Illegal function	Illegal function code
2	Illegal data address	Slave has illegal data address
3	Illegal data value	Slave has illegal data value
4	Failure in Associated Device	Slave has internal error
5	Acknowledge	Function is carried out
6	Busy, Rejected message	Slave is not ready to receive
7	Negative acknowledgement	The function cannot be carried out.
* Check slave for further details.		

RS232 mode

The following communication modules support RS232 mode:

- CM PtP RS232 HF
- CM PtP (ET 200SP)

For more information on RS232 mode, see the chapter RS232 mode (Page 23).

For information on hardware data flow control and on automatic operation of the accompanying signals, refer to the Handshake procedure (Page 32) chapter.

RS422/485 mode

The following communication modules support RS422/485 mode:

- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

For more information on RS422/485 mode, see the chapters RS422 mode (Page 26) and RS485 mode (Page 29).

FAQ

For more information, see the following FAQs in the Siemens Industry Online Support:

- Entry ID 68202723 (https://support.industry.siemens.com/cs/ww/en/view/68202723)
- Entry ID 58386780 (https://support.industry.siemens.com/cs/ww/en/view/58386780)

4.4.3 Function Codes

Used function codes

The function code defines the meaning of the frame. It also defines the structure of a frame.

The following function codes are supported by the communication module:

Function code	Function in accordance with MODBUS specification	Range
01	Read Coil Status	1 to 2000 bit/request
02	Read Input Status	1 to 2000 bit/request
03	Read Holding Registers	1 to 124/125 bit/request (124 at extended station address)
04	Read Input Registers	1 to 124/125 bit/request (124 at extended station address)
05	Force Single Coil	1 bit/request
06	Preset Single Register	1 word/request
08 *	Loop Back Test	Read slave status or reset event counter in the slave
11 *	Fetch Communications Event Counter (only master)	-
15	Force Multiple Coils	1 to 1968 bits/request
16	Preset Multiple Registers	1 to 123 bit/request

* Diagnostic information for slave communication

Modbus function code 00 sends a broadcast message to all slaves (without slave response).

Assignment of the Modbus addresses to the SIMATIC addresses

The table below shows the assignment of the Modbus addresses to the SIMATIC addresses.

Modbus				S7-1500	
FC [1]	**Function**	**Declaration**	**Address area**	**Declaration**	**CPU address**
01	Read bits	Output	1 - 9999	Process image of outputs	Q0.0 - Q1249.6
02	Read bits	Input	10001 - 19999	Process image of inputs	I0.0 - I1249.6
03 [2]	Read words	Holding Register	40001 - 49999 or 400001 - 465535	DW0 - DW19998 or DW0 - DW131068	The M address area depends on the CPU
04	Read words	Input	30001 - 39999	Process image of inputs	IW0 to IW19996
05 [2]	Write bits	Output	1 - 9999	Process image of outputs	Q0.0 to Q1248.7
06	Write words	Holding Register	40001 - 49999 or 400001 - 465535	DW0 - DW19998 or DW0 - DW131068	The M address area depends on the CPU
15	Write bits	Output	1 - 9999	Process image of outputs	Q0.0 - Q1249.6
16 [2]	Write words	Holding Register	40001 - 49999 or 400001 - 465535	DW0 - DW19998 or DW0 - DW131068	The M address area depends on the CPU

1) FC = function code

2) The value of the HR_Start_Offset determines whether data areas or bit memory address areas can be addressed with the FCs 03, 05 and 16 in the SIMATIC CPU.

4.5 Communication using USS

4.5.1 Procedure for establishing a serial connection with Modbus USS

Requirements

- The hardware is set up and there is an electrical connection to the link partner.
- The project has been created in STEP 7 (TIA Portal) and the CPU has been inserted into the hardware configuration.

Procedure - Hardware configuration

1. Insert the CM PtP communication module into the hardware configuration.
2. Select the Freeport protocol and set the communication parameters.

   Note: The USS functionality is implemented by the instructions.

Procedure - Programming

1. Insert the USS_Port_Scan instruction from the USS Communication library.
2. Interconnect the HWID from the system tags at the PORT input.
3. Insert the USS_Drive_Control instruction from the USS Communication library.
4. Interconnect the USS_DB data structure in the instance DB of the USS_Drive_Control instruction to the USS_DB input of the USS_Port_Scan instruction. The data structure contains the data to be transferred for all drives.
5. Insert an additional call of the USS_Drive_Control instruction for each additional axis that is to be connected via the USS interface.

   Use the same instance DB each time. The distinction takes place with the help of the USS address that you specify at the DRIVE input of the USS_Drive_Control instruction. This means you have access to the control and feedback data at the parameters of the respective call for each drive.

4.5.2 Overview of USS communication

Position in the system environment

The following USS description refers to the use of the corresponding communication modules.

- CM PtP RS232 BA
- CM PtP RS422/485 BA
- CM PtP RS232 HF
- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

Introduction

The USS® protocol (Universal Serial Interface Protocol) is a basic serial data transmission protocol designed to meet the requirements of drive technology.

The USS protocol defines an access method based on the master-slave principle for communication via a serial bus. One master and up to 16 drives (slaves) can be connected to the bus. The individual drives are selected by the master using an address character in the frame. A drive can never send anything without first being initiated by the master. Therefore, direct data transmission between individual drives is not possible. Communication functions in half-duplex mode. The master function cannot be transferred.

Drive technology requires specific response times for the control tasks and therefore strict cyclical frame traffic:

The master continuously sends frames (job frames) to the drives and expects a response frame from each addressed drive.

A drive must send a response frame if

- it has a received a frame without errors and
- it was addressed in this frame.

A drive may not send if these conditions are not met or the drive was addressed in the broadcast.

The connection with the respective drives exists for the master once it receives a response frame from the drive after a specified processing time (response delay time).

frame structure

Each frame begins with a start character (STX), followed by the length specification (LGE) and the address byte (ADR). The data field comes after that. The frame ends with the block check character (BCC). The frame length includes the user data (quantity n), the address byte (ADR) and the data verification character (BCC).

STX	LGE	ADR	1	2	...	N	BCC

For single-word (16-bit) data, the high byte is sent first followed by the low byte. Correspondingly, with double-word data the high word is sent first, followed by the low word. The length of a frame is specified in bytes.

Data encryption

The data is encrypted as follows:

- STX: 1 byte, start of text, 02H
- LGE: 1 byte, contains the frame length as a binary number
- ADR: 1 byte, contains the slave address and frame type in binary code
- Data fields: One byte each, content depending on job
- BCC: 1 byte, block check character

Data transmission procedure

The master ensures cyclic data transmission in frames. The master addresses all slave devices one after another with a job frame. The nodes addressed respond with a response frame. In accordance with the master-slave procedure, the slave must send the response frame to the master after it has received the job frame. Only then can the master address the next slave.

Data field in the frame

The data field is divided into two areas: the parameter area (PKW) and the process data area (PZD).

STX	LGE	ADR	Parameter (PKW)	Process data (PZD)	BCC

- **Parameter area** (PKW)

  The PKW area handles parameter transmission between two communication partners (e.g., controller and drive). This involves, for example, reading and writing parameter values and reading parameter descriptions and the associated text. The PKW interface generally contains jobs for operation and display, maintenance and diagnostics.
- **Process data area** (PZD)

  The PZD area consists of signals that are required for automation:
  - Control words and setpoints from the master to the slave
  - Status words and actual values from the slave to the master

  The contents of the parameter area and process data area are defined by the slave drives.

  For additional information on this, refer to the drive documentation.

4.5.3 Overview of functions

Transmission sequence

The instructions process the data transmission cyclically with up to 16 drive slaves. Only one job is active for each drive at any one time.

Performance features:

- Creation of data storage areas for communication, depending on the bus configuration
- Execution and monitoring of PKW jobs
- Monitoring of the complete system and troubleshooting
- Communication with the CPU
- Access to the drive functions
- Reading the drive parameters
- Writing the drive parameters

Programming - communication using instructions 5

5.1 Overview of point-to-point programming

Data exchange using Freeport or 3964(R) communication

You must make the send data available in data blocks or in the bit memory address area in the user program of the corresponding CPU. A receive buffer is available in the communication module for the receive data. A corresponding data block is set up in the data block.

In the user program of the CPU, the following instructions carry out the data transfer between the CPU and the communication module.

- Send_P2P
- Receive_P2P

The receive buffer can be deleted with the instruction Receive_Reset.

Dynamic configuration by means of the user program

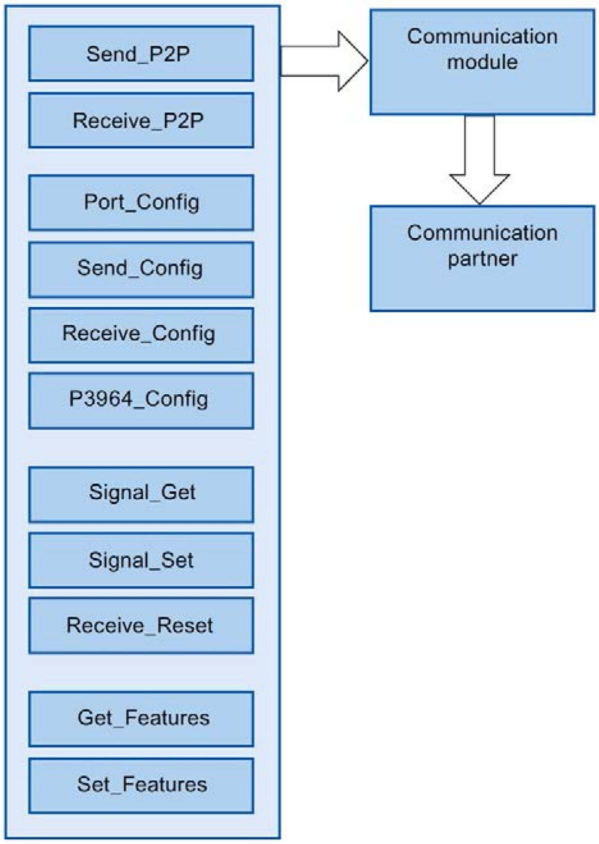
As an alternative to or in addition to the parameter assignment of the communication module interface described in section Configuring / parameter assignment of a communication module (Page 37), it may be advisable in certain application areas to set up the communication dynamically, i.e., program-controlled by a specific application.

All parameters assigned in the properties dialog of the communication module can also be changed during runtime by means of one of the following "Config" instructions:

Port_Config, Send_Config, Receive_Config, P3964_Config

Program calls for point-to-point communication - sequence

The figure below shows the function of the point-to-point instructions for communication between the user program and communication partner.



PtP instructions

Application	Instruction	Description
Data exchange between CPU, communication module and communication partner (communication)	Send_P2P (Page 87)	The instruction Send_P2P (send point-to-point data) can be used to send data to the communication partner. Call up the instruction Send_P2P to send data using the Freeport protocol. You have to call the instruction cyclically until you receive a corresponding acknowledgement at the output parameters of the instruction. Note: During parameter assignment of the XON/XOFF data flow control, user data may not contain any of the configured XON or XOFF characters. Default settings are DC1 = 11H for XON and DC3 = 13H for XOFF.
	Receive_P2P (Page 91)	The instruction Receive_P2P (receive point-to-point data) can be used to pick up the messages received in the communication module from a communication partner. Call the Receive_P2P instruction cyclically to receive data using the Freeport protocol. The instruction indicates at the NDR parameter if new received data is available. To signal the start and end of a message transmission, you need to define criteria in the Freeport protocol which identify the start and end of the message.

Application	Instruction	Description
Deletion of the receive buffer	Receive_Reset (Page 93)	The instruction Receive_Reset (delete receive buffer) allows you to clear the receive buffer of the communication module.
Dynamic parameter assignment of the inter-face or the protocol (optional)	Port_Config (Page 75)	You can use the Port_Config instruction (port configuration) to configure basic interface parameters, such as the data transmission rate, parity and data flow control dynamically through your user program.
	Send_Config (Page 78)	With the instruction Send_Config(send configuration) you can configure serial send parameters, such as RTS ON delay / RTS OFF delay, dynamically for a point-to-point communication interface.
	Receive_Config (Page 80)	The instruction Receive_Config (receive parameter assignment) allows you to dynamically assign serial receive parameters to a communication module. This instruction configures the conditions that specify the start and the end of a received message.
	P3964_Config (Page 85)	The instruction P3964_Config(configure protocol) can be used to dynamically configure protocol parameters of the procedure 3964(R), such as character delay time, priority and block check using your program.
Operation of RS232 accompanying signals	Signal_Get (Page 94)	With the Signal_Get instruction (get RS232 signals) you can read the current states of the RS232 signals.
	Signal_Set (Page 96)	With the Signal_Set instruction (get RS232 signals), you can set the states of the RS232 signals DTR and RTS.
Enable Modbus CRC support and diagnostic interrupt	Get_Features (Page 98)	You can use the instruction Get_Features(get extended functions) to get information on the Modbus support and on generating diagnostic alarms.
	Set_Features (Page 100)	If supported by the module, you can use the instruction Set_Features(set extended functions) to activate the generation of diagnostic alarms.

Procedure for setting up Freeport or 3964(R) communication

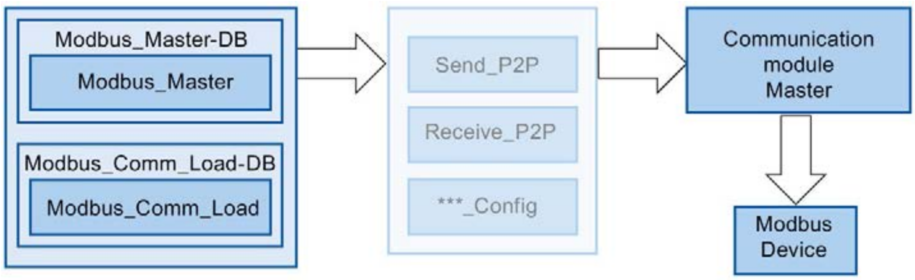
Requirement: The configuration and parameter assignment of a CPU and a communication module in the device view and in the properties dialog of the communication module are complete.

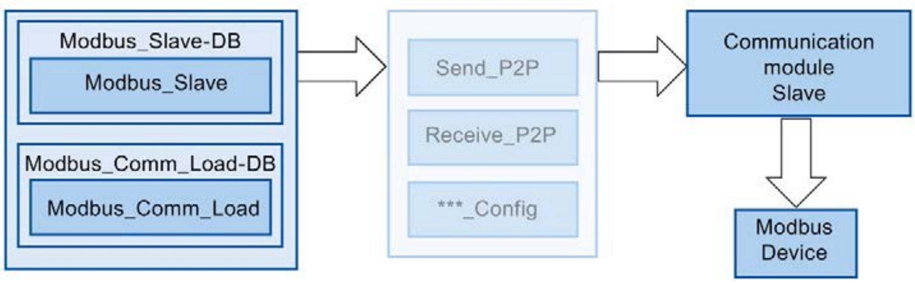
1. In the project navigation for the CPU select the folder "Program blocks" and open the Main (OB1) in the folder by double-clicking it. The program editor opens.
2. From the "Instructions" task card, "Communication" area select the instructions Send_P2P and Receive_P2P and drag-and-drop them into a network of the Main (OB1).
3. Configure the instructions in accordance with your specifications.
4. Download the hardware configuration and the user program to the CPU.

5.2 Overview of Modbus programming

Program calls for Modbus communication - sequence

The figure below shows the function of the Modbus instructions for communication between user program and Modbus device. (The instructions Send_P2P, Receive_P2P and the Config instruction are required downstream).





Modbus instructions

Application	Instruction	Description
Data exchange between user program and Modbus device (communication)	Modbus_Master (Page 125)	The Modbus_Master instruction allows you to communicate as Modbus master by means of the PtP port. The CPU can be used as Modbus RTU master device with the Modbus_Master instruction for communication with one or several Modbus slave devices.
	Modbus_Slave (Page 133)	The Modbus_Slave instruction allows you to communicate as Modbus slave by means of the PtP port. The CPU can be used as Modbus RTU slave device with the Modbus_Slave instruction for communication with one Modbus master device.
Parameter assignment of the interface and the protocol (mandatory)	Modbus _Comm_Load (Page 120)	The instruction Modbus_Comm_Load allows you to configure the port of the communication module for Modbus RTU. You have to run Modbus_Comm_Load to set up PtP port parameters, such as data transmission rate, parity and flow control. Once you have configured the interface for the Modbus RTU protocol, it can only be used by the instruction Modbus_Master or the instruction Modbus_Slave .

Note

Alternative use of Modbus_Slave and Modbus_Master

A communication module can be operated either as master or as slave.

Procedure for setting up Modbus communication

Requirement: The configuration and parameter assignment of a CPU and a communication module in the device view and in the properties dialog of the communication module are complete.

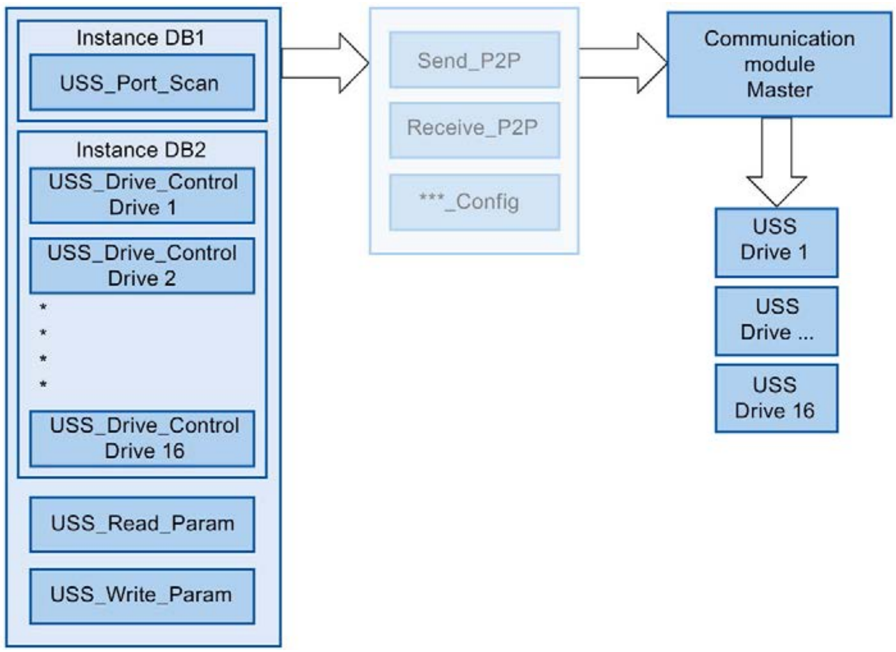
1. In the project navigation for the CPU select the folder "Program blocks" and open the Main (OB1) in the folder by double-clicking it. The program editor opens.
2. From the "Instructions" task card, "Communication" area select the instructions for Modbus communication in accordance with your task and drag-and-drop them into a network of the Main (OB1):
   – The instruction Modbus_Comm_Load configures the port of the communication module for Modbus communication.

     The Modbus_Comm_Load must be called in Main (OB1) until DONE (or ERROR) is reported.
   – The instruction Modbus_Master is used for the Modbus master functionality.
   – The instruction Modbus_Slave is used for the Modbus slave functionality.
3. Configure the instructions in accordance with your specifications.
4. Download the hardware configuration and the user program to the CPU.

5.3 Overview of USS programming

Program calls for USS communication - sequence

The figure below shows the function of the USS instructions for communication between user program and USS drive. (The instructions Send_P2P, Receive_P2P and the Config instruction are required downstream).



USS instructions

Application	Instruction	Description
Data communication between CPU, commu-nication module and USS drive	USS_Port_Scan (Page 172)	The USS_Port_Scan instruction allows you to communicate via a com-munication module with up to 16 drives using a USS network (must be called cyclically). The instruction USS_Port_Scan controls the communication between CPU and the drives by means of the PtP communication port. A commu-nication with the drive is processed every time you call this function. The instruction USS_Port_Scan is required once: Since most drives features a configurable internal function that monitors the integrity of the communication based on a timeout, the instruction USS_Port_Scan should be called from a time-controlled OB.

Application	Instruction	Description
Exchange data with USS drive	USS_Drive_Control (Page 176)	The USS_Drive_Control instruction allows you to prepare the send data for a drive and to display the received data. The inputs and outputs of the instruction correspond to the states and operating functions of the drive. The USS_Drive_Control instruction must be called once for each drive. Only one common instance DB is required for all calls of the instruction USS_Drive_Control for a USS network. Interconnect all calls of the instructions USS_Drive_Control for a USS network with the same instance DB. The USS_Drive_Control instruction should be called from the cyclic Main (OB1) of the main program.
Read or modify parameters in USS drive	USS_Read_Param (Page 180)	The USS_Read_Param instruction allows you to read parameters from the drive. You use the USS_Read_Param instruction to read the operating parameters of the drive that controls the internal drive functions. The USS_Read_Param instruction should be called from the cyclic Main (OB1) of the main program.
	USS_Write_Param (Page 182)	The USS_Write_Param instruction allows you to change parameters in the drive. The USS_Write_Param instruction should be called from the cyclic Main (OB1) of the main program.

Procedure for setting up USS communication

Requirement: The configuration and parameter assignment of a CPU and a communication module in the device view and in the properties dialog of the communication module are complete.

1. In the project tree for the CPU, select the "Program blocks" folder and open the desired time-controlled OB by double-clicking it. The program editor opens.
2. From the "Instructions" task card, "Communication" area select the instruction USS_Port_Scan and drag-and-drop it into a network of a time-controlled OB.

   The instruction USS_Port_Scan allows you to communicate by means of the USS network.
3. In the project navigation for the CPU select the folder "Program blocks" and open the Main (OB1) in the folder by double-clicking it. The program editor opens.
4. From the "Instructions" task card, "Communication" area select the instructions for USS communication in accordance with your task and drag-and-drop them into a network of the Main (OB1):
   - The instruction USS_Drive_Control is used for data exchange with the drive.
   - The instruction USS_Read_Param is used for reading parameters from the drive.
   - The instruction USS_Write_Param is used for changing parameters in the drive.
5. Configure the instructions in accordance with your specifications.
6. Download the hardware configuration and the user program to the CPU.

5.4 Instructions

5.4.1 Point-to-point

5.4.1.1 Overview of Freeport communication

STEP 7 offers extended instructions that can be used for Freeport communication with a protocol specified in the user program. These instructions can be divided into two categories:

- Configuration instructions
- Communication instructions

Note

CPU capacity

The Freeport instructions communicate with the communication modules by reading or writing data records.
When using the instructions, you should therefore check the capacity of the CPU for reading and writing data records.
If several instructions need to read or write data records simultaneously on a CPU, the user program may need to create a time offset between the calls of each instruction.

Configuration instructions

Before the user program can start the Freeport communication, the communication interface and the parameters for sending and receiving of data must be configured.

The interface configuration and the data configuration can be set for each CM in the device configuration or with the following instructions of your user program:

- Port_Config (Page 75)
- Send_Config (Page 78)
- Receive_Config (Page 80)
- P3964_Config (Page 85)

NOTICE

Device configuration <-> Configuration instructions

The device configuration parameters are transferred to the CM upon each Power On of the CPU (return of voltage).

The parameters of the configuration instructions are transferred to the CM as defined in your user program.

The parameters of the device configuration are not synchronized with the parameters of the configuration instructions, which means the parameters of the configuration instructions are not applied to the CPU device configuration.
With your user program, you determine the parameters that apply in the CM and when they apply.

Communication instructions

The user program uses the instructions for Freeport communication to send data to and receive data from the communication interfaces. The CMs send data to and receive data from the communication stations.

- Send_P2P (Page 87)
- Receive_P2P (Page 91)

Note

Data consistency

- If the data to be sent is transmitted consistently, it cannot be changed after the positive edge at the REQ parameter until DONE has been set by the Send_P2P instruction.
- If the receive data is to be read consistently, it may only be evaluated in the cycle in which NDR = TRUE.

The receive buffer can be reset with additional instructions and special RS232 signals can be queried and set.

- Receive_Reset (Page 93)
- Signal_Get (Page 94)
- Signal_Set (Page 96)

The following instructions let you read or write extended functions, as long as these are supported by the module.

- Get_Features (Page 98)
- Set_Features (Page 100)

All Freeport instructions work asynchronously. The instructions must therefore be called until the DONE output parameter indicates that execution is complete.

The user program can determine the send and receive status with the help of the query architecture. Send_P2P and Receive_P2P can be run at the same time. The communication modules buffer the send and receive data as required until a module-specific maximum buffer size has been reached.

Note

Resolution of bit times

The number of bit times is specified with the configured data transmission rate for different parameters. Specifying the parameter in bit times makes it independent of the data transmission rate. All parameters with unit of bit times can be specified with a maximum number of 65535.

5.4.1.2 Using the instructions

The Freeport instructions must be called cyclically to query received data or the end of transmission for a send process.

Depending on the data volume, data transmission may take place over several calls (program cycles).
If a command is completed with DONE = TRUE or NDR = TRUE, it has been executed without errors.

Note

Backing up STATUS

The DONE, NDR, ERROR and STATUS parameters are only available for one block cycle. To display the STATUS, you should therefore copy it to a free data area.

Master

Typical sequence for a master:

1. The Send_P2P instruction triggers transmission to the CM.
   Data transmission is initiated by a positive edge at the REQ input.
2. The Send_P2P instruction is executed in subsequent cycles to query the status of the transmission process.
3. When the Send_P2P instruction signals that transmission is complete at the DONE output, the user code can prepare the receipt of the answer.
4. The Receive_P2P instruction is run repeatedly to query an answer. If the CM has acquired response data, the Receive_P2P instruction copies the response to the CPU and signals that new data has been received at the NDR output.
5. The user program can process the response.
6. Back to step 1 and repetition of the sequence.

Slave

Typical sequence for a slave:

1. The user program runs the Receive_P2P instruction in each cycle.
2. If the CM has received a request, the Receive_P2P signals that new data is available at the NDR output and the request is copied to the CPU.
3. The user program processes the request and creates a response.
4. The response is returned to the master with the Send_P2P instruction.
5. The Send_P2P instruction must be run repeatedly to ensure that the send process is actually taking place.
6. Back to step 1 and repetition of the sequence.

The slave must ensure that Receive_P2P is called up often enough so that a transmission can be received by the master before it cancels the process due to a timeout while waiting for the response. To do so, the user program Receive_P2P can be called from within a cycle OB whose cycle time is sufficiently short so that the master can receive a transmission before the timeout setting expires. If the OB cycle time is set so that two runs can take place during the timeout setting of the master, the user program can receive all transmissions without any losses.

5.4.1.3 General parameters for Freeport operations

Table 5- 1 General input parameters of the Freeport instructions

Parameter	Description
REQ	Data transmission is initiated by a positive edge at the REQ input. Another edge at REQ may only be generated after the command has been completed (DONE or ERROR). Data transmission can take several calls (program cycles), depending on the data volume. When you add a Freeport instruction to your program, STEP 7 prompts you to specify the instance DB (or to have STEP 7 create a corresponding instance DB). Use a unique DB for each PtP instruction call.
PORT	A port address is assigned during configuration of the communication module. The PORT parameter communicates assignment to a specific communication module to the instruction. You can select a symbolic name for the standard port after the configuration. The assigned CM port value is the "Hardware ID" property of the device configuration with S7-1200/1500 and the "Input address" with S7-300/400. The symbolic port name is assigned in the symbol table.

The output parameters DONE, NDR, ERROR and STATUS of the Freeport instructions indicate the execution status of the Freeport functions.

Table 5- 2 Output parameters DONE, NDR, ERROR and STATUS

Parameter	Data type	Standard	Description
DONE	Bool	FALSE	Set to TRUE for one cycle to indicate that the last request was completed with errors; otherwise FALSE.
NDR	Bool	FALSE	Set to TRUE for one cycle to indicate that new data has been received; otherwise FALSE.
ERROR	Bool	FALSE	Set to TRUE for one cycle to indicate that the last request was completed with errors; the corresponding error code can be found in STATUS; otherwise FALSE.
STATUS	Word	16#0000 or 16#7000	Result status: • If the DONE or NDR bit is set, STATUS is set to 0/16#7000 or to a specific error code. • If the ERROR bit is set, STATUS displays an error code. • If none of the bits listed above is set, the instruction can return status results that describe the current status of the function. The value in STATUS is valid until you call this instruction again (with one and the same port address).

Table 5- 3 In/out parameter COM_RST

Parameter	Data type	Standard	Description
COM_RST	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. COM_RST is then set back to FALSE. Note: You must set COM_RST to TRUE during startup and should not subsequently change the parameter (that is, do not assign a value when you call the instruction). COM_RST is reset by the instruction following initialization of the instance DB.

Note

Please note that the parameters DONE, NDR, ERROR and STATUS are only set for one cycle.

Table 5- 4 Shared error codes

Error code	Description
16#0000	No error
16#7000	Function not active
16#7001	Initial call after request started.
16#7002	Subsequent call after request started.
16#8x3A	Invalid pointer in parameter x

Table 5- 5 Shared error classes of the STATUS parameter

Description of the class	Error classes	Description
Port configuration	16#81Ax	For the description of frequent errors in the interface configuration
Send configuration	16#81Bx	For the description of errors in the send configuration
Receive configuration	16#81Cx	For the description of errors in the receive configuration
Sending	16#81Dx	For the description of runtime errors during sending
Receiving	16#81Ex	For the description of runtime errors during receiving
RS232 accompanying signals	16#81Fx	For the description of errors in connection with signal processing

5.4.1.4 Port_Config: Configure PtP communication port

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Port_Config instruction (port configuration) allows you to change parameters such as the data transmission rate in runtime using your program. The data pending in the CM is deleted with the execution of Port_Config.

Configuration changes of Port_Config are saved on the CM and not in the CPU. When the voltage returns, the CM is configured with the data saved in the device configuration.

Parameters

<table>
<tr><th rowspan="2">Parameter</th><th rowspan="2">Declaration</th><th colspan="2">Data type</th><th rowspan="2">Default</th><th rowspan="2">Description</th></tr>
<tr><th>S7-1200/1500</th><th>S7-300/400/WinAC</th></tr>
<tr><td>REQ</td><td>IN</td><td colspan="2">Bool</td><td>FALSE</td><td>Starts the transmission of data to the CM upon a positive edge at this input.</td></tr>
<tr><td>PORT</td><td>IN</td><td>PORT (UInt)</td><td>Word</td><td>0</td><td>Specifies the communication module which is used for the communication:
For S7-1500/S7-1200: "HW identifier" from the device configuration.
The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there.
For S7-300/S7-400: "Input address" from the device configuration.
In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.</td></tr>
<tr><td>PROTOCOL</td><td>IN</td><td>UInt</td><td>Word</td><td>0</td><td>Protocol
0 = Freeport protocol
1 = Protocol 3964(R)</td></tr>
</table>

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/ WinAC		
BAUD	IN	UInt	Word	6	Data transmission rate of the port: • 1 = 300 bps • 2 = 600 bps • 3 = 1200 bps • 4 = 2400 bps • 5 = 4800 bps • 6 = 9600 bps • 7 = 19200 bps • 8 = 38400 bps • 9 = 57600 bps • 10 = 76800 bps • 11 = 115200 bps
PARITY	IN	UInt	Word	1	Parity of the port: • 1 = no parity • 2 = even parity • 3 = odd parity • 4 = mark parity • 5 = space parity • 6 = any
DATABITS	IN	UInt	Word	1	Bits per character: • 1 = 8 data bits • 2 = 7 data bits
STOPBITS	IN	UInt	Word	1	Stop bits: • 1 = 1 stop bit • 2 = 2 stop bits
FLOWCTRL	IN	UInt	Word	1	Flow control: • 1 = no flow control • 2 = XON/XOFF • 3 = Hardware RTS always ON • 4 = Hardware RTS switched • 5 = Hardware RTS always ON, ignore DTR/DSR
XONCHAR	IN	Char		16#0011	Specifies the character that serves as XON character. It is typically a DC1 character (11H). This parameter is only evaluated when software flow control is active.
XOFFCHAR	IN	Char		16#0013	Specifies the character that serves as XOFF character. It is typically a DC3 character (13H). This parameter is only evaluated when software flow control is active.
WAITIME	IN	UInt	Word	2000	Specifies how long to wait for an XOFF character after receipt of an XON character or how long to wait for a CTS = ON signal after CTS = OFF (0 to 65535 ms). This parameter is only evaluated when flow control is active.

Parameter	Declara-tion	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
MODE	IN	USInt	Byte	0	Operating mode Valid operating modes are: • 0 = Full duplex (RS232) • 1 = Full duplex (RS422) four-wire mode (point-to-point) • 2 = Full duplex (RS 422) four-wire mode (multipoint master; CM PtP (ET 200SP)) • 3 = Full duplex (RS 422) four-wire mode (multipoint slave; CM PtP (ET 200SP)) • 4 = Half duplex (RS485) two-wire mode 1)
LINE_PRE	IN	USInt	Byte	0	Receive line initial state Valid initial states are: • 0 = "No" initial state 1) • 1 = signal R(A)=5 V, signal R(B)=0 V (break detection): Break detection is possible with this initial state. Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • 2 = signal R(A)=0 V, signal R(B)=5 V: This default setting corresponds to the idle state (no active send operation). No break detection is possible with this initial state.
BRK_DET	IN	USInt	Byte	0	Break detection The following settings are permitted: • 0 = break detection deactivated • 1 = break detection activated
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
DONE	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed without errors
ERROR	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed with errors
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

1) Required setting for the use of PROFIBUS cables with CM 1241 for RS485

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.5 Send_Config: Configure PtP sender

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Send_Config instruction (send configuration) allows you to change send parameters in runtime using your program (conditions that identify the start and the end of the data to be sent). Any data pending in a CM is deleted when Send_Config is executed.

Configuration changes of Send_Config are saved on the CM and not in the CPU. The parameters saved in the device configuration are restored once the voltage returns to the CPU or the communication module.

Parameters

Parameter	Declaration	Data type		Default	Description%%
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Activates the configuration change upon a positive edge at this input.
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
RTSONDLY	IN	UInt	Word	0	Number of milliseconds to wait after activation of RTS before a transmission of send data is started. This parameter is only valid if the hardware flow control is active. The valid range is 0 to 65535 ms. The value 0 deactivates the function.
RTSOFFDLY	IN	UInt	Word	0	Number of milliseconds to wait after transmission of send data before RTS is deactivated: This parameter is only valid if the hardware flow control is active. The valid range is 0 to 65535 ms. The value 0 deactivates the function.

Parameter	Declaration	Data type		Default	Description%%
		S7-1200/1500	S7-300/400/WinAC		
BREAK	IN	UInt	Word	0	This parameter specifies that a BREAK is to be sent at the start of each frame for the specified number of bit times. The maximum is 65535 bit times. The value 0 deactivates the function.
IDLELINE	IN	UInt	Word	0	This parameter specifies that the line is to remain in idle for the specified number of bit times prior to the start of each frame. The maximum is 65535 bit times. The value 0 deactivates the function.
USR_END	IN	STRING[2]		0	Input of end delimiters. No more than 2 end delimiters can be configured. All data including the end delimiter(s) is sent, independent of the configured frame length.
APP_END	IN	STRING[5]		0	Input of characters to be appended. You can append up to 5 characters.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
DONE	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed without errors
ERROR	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed with errors
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.6 Receive_Config: Configure PtP recipient

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Receive_Config instruction (receive configuration) allows you to change receive parameters in runtime using your program. This instruction configures the conditions that mark the start and the end of received data. Any data pending in a CM is deleted when Receive_Config is executed.

Configuration changes of Receive_Config are saved **non-retentive** on the CM. The parameters saved in the device configuration are restored once the voltage returns to the CPU or the communication module. The Receive_Config instruction therefore must be called again from the user program when the voltage returns to the CPU or to the communication module in order to overwrite the parameters stored in the device configuration.

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Activates the configuration change upon a positive edge at this input.
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
RECEIVE _CONDITIONS	IN	Variant	Any	-	The data structure of Receive_Conditions specifies the start and end conditions used to identify the start and end of a frame.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
DONE	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed without errors
ERROR	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed with errors
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

Start conditions for the Receive_P2P instruction

The Receive_P2P instruction uses the configuration specified in the device configuration or by the Receive_Config instruction to determine the start and end of Freeport communication frames. The start of the frame is defined by the start conditions. The start of the frame can be determined with one or several start conditions.
If Break as well as Idle Line is activated, Break must be met first and then Idle Line as well. After that, one of the other conditions (start character or start sequence) is sufficient to start data transmission.
The start condition "Any character" cannot be combined with other start conditions.

Data type structure of the Receive_Conditions parameter, part 1 (start conditions)

Table 5- 6 Structure of Receive_Conditions for start conditions

Parameter	Declaration	Data type	Default	Description
START .STARTCOND	IN	Word	16#0002	Specifying the start condition • 01H - detection of the start character • 02H - Any character • 04H - detection of a line break • 08H - detection of an idle line • 10H - detection of start sequence 1 • 20H - detection of start sequence 2 • 40H - detection of start sequence 3 • 80H - detection of start sequence 4 The start conditions can be combined by adding the values together.
START .IDLETIME	IN	Word	16#0028	The number of bit times required in the idle state for a new frame start to be detected (default value: W#16#28). Only in connection with the condition "Detection of an idle line". 0 to FFFF
START .STARTCHAR	IN	Byte	16#0002	The start character for the condition "Start character". (default value: B#16#2)

Parameter	Declaration	Data type	Default	Description
START SEQ[1].CTL	IN	Byte	0	Start sequence 1, deactivate/activate comparison for each character: (default value: B#16#0) These are the activation bits for each character of the start character string. • 01H - character 1 • 02H - character 2 • 04H - character 3 • 08H - character 4 • 10H - character 5 When a bit is deactivated for a specific character, this means that each character in this position in the character string represents a valid start character string (e.g. 1FH = all 5 characters interpreted).
START.SEQ[1] .STR[1] .. START.SEQ[1] .STR.[5]	IN	Char[5]	0	Start sequence 1, start character (5 characters).
START.SEQ[2] .CTL	IN	Byte	0	Start sequence 2, deactivate/activate comparison for each character. Default value: B#16#0)
START.SEQ[2] .STR[1] .. START.SEQ[2] .STR.[5]	IN	Char[5]	0	Start sequence 2, start character (5 characters).
START.SEQ[3] .CTL	IN	Byte	0	Start sequence 3, deactivate/activate comparison for each character. Default value: B#16#0
START.SEQ[3] .STR[1] .. START.SEQ[3] .STR.[5]	IN	Char[5]	0	Start sequence 3, start character (5 characters).
START.SEQ[4] .CTL	IN	Byte	0	Start sequence 4, deactivate/activate comparison for each character. Default value: B#16#0
START.SEQ[4] .STR[1] .. START.SEQ[4] .STR.[5]	IN	Char[5]	0	Start sequence 4, start character (5 characters),

Example

Have a look at the following received data in hexadecimal coding: "**68** 10 aa **68** bb 10 aa 16". The configured start character strings are available in the following table. Start character strings are evaluated once the first character 68H has been successfully received. After the fourth character has been successfully received (the second 68H), start condition 1 has been met. Once the start conditions have been met, the evaluation of the end conditions starts.

Processing of the start character string can be canceled due to different errors in parity, framing or time intervals between characters. These errors prevent receipt of the data because the start condition has not been met (an error message is output).

Table 5- 7 Start conditions

Start condition	First character	First character +1	First character +2	First character +3	First character +4
1	**68**H	xx	xx	**68**H	xx
2	10H	aaH	xx	xx	xx
3	dcH	aaH	xx	xx	xx
4	e5H	xx	xx	xx	xx

End conditions for the Receive_P2P instruction

The end of a frame is defined by the first occurrence of one or more configured end conditions.

You can configure the end conditions either in the properties of the communication interface in the device configuration, or with the Receive_Config instruction. The receive parameters (start and end conditions) are reset to the settings in the device configuration each time the voltage returns to the CPU or the communication module. When the STEP 7 user program executes Receive_Config, the settings are set to the parameters of Receive_Config .

Data type structure of the Receive_Conditions parameter, part 2 (end conditions)

Table 5- 8 Structure of Receive_Conditions for end conditions

Parameter	Declaration	Data type	Default	Description
END.ENDCOND	IN	Word	0	This parameter specifies the condition for the frame end: • 01H - response timeout • 02H - message timeout • 04H - character delay time • 08H - maximum frame length • 10H - read message length from message (N+LEN+M) • 20H - end sequence • 40H - fixed frame length
END.FIXLEN	IN	Word	1	Fixed frame length: Only used if the end condition "Fixed frame length" has been selected. 1 to 4000 bytes (up to 4 KB depending on the module)
END.MAXLEN	IN	Word	1	Maximum frame length: Only used if the end condition "Maximum frame length" has been selected. 1 to 4000 bytes (up to 4 KB depending on the module)
END.N	IN	Word	0	Byte position of the length field in the frame. Only used with end condition N+LEN+M. 1 to 4000 bytes (up to 4 KB depending on the module)
END.LENGTHSIZE	IN	Word	0	Size of the length field (1, 2, or 4 bytes). Only used with end condition N+LEN+M.
END.LENGTHM	IN	Word	0	Number of characters after the length field that are not included in the value of the length field. This entry is only used with end condition N+LEN+M. 0 to 255 bytes
END.RCVTIME	IN	Word	200	Specify the wait time for the first received character after a frame has been sent. The receive instruction is terminated with an error message if a character is not received within the specified time. This information is used only with the condition "Response timeout". (0 to 65535 ms). Note: This parameter cannot be used as sole end criterion but only in connection with at least one other end condition.
END.MSGTIME	IN	Word	200	Specify how long to wait for receipt of the complete frame after receipt of the first character. This parameter is used only if the condition "Message timeout" is selected. (0 to 65535 ms)
END.CHARGAP	IN	Word	12	Enter the maximum number of bit times between characters. If the number of bit times between characters exceeds the specified value, the end condition has been met. This information is used only with the condition "Character delay time". (0 to 65535 bit times)

Parameter	Declaration	Data type	Default	Description
END.SEQ.CTL	IN	Byte	0	Character sequence 1, deactivate/activate comparison for each character: These are the activation bits for each character of the end character string. Character 1 is bit 0, character 2 is bit 1, ..., character 5 is bit 4. If a bit is deactivated for a specific character, this means that each character represents a congruence at this position of the character string.
END.SEQ.STR[1] .. END.SEQ.STR[5]	IN	Char[5]	0	Character string 1, start character (5 characters)

Table 5- 9 General parameters of the Receive_P2P instruction

Parameter	Declaration	Data type	Default	Description
GENERAL .MBUF_SIZE	IN	Byte	255	Input number of frames that are to be buffered in the receive buffer of the CM. If no other conditions are active that influence the reaction of the receive buffer (prevent timeout, data flow control), additional frames are discarded once the limit has been reached. (1 to 255 frames)
GENERAL .OW_PROT	IN	Byte	0	Activates the no overwriting function of the buffered frame if the CM receives a new frame and the receive buffer of the CM was not yet read. This step prevents already buffered received frames from being lost. • 0 - not activated • 1 - activated
GENERAL .CLR_MBUF	IN	Byte	0	Activates deletion of the receive buffer during CPU startup. The receive buffer is automatically deleted when the CPU switches from STOP to RUN. The receive buffer only contains frames received after CPU startup. • 0 - not activated • 1 - activated

5.4.1.7 P3964_Config: Configuring the 3964(R) protocol

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The P3964_Config instruction (protocol configuration) allows you to change protocol parameters for 3964(R), such as character delay time, priority and block check, in runtime using your program.

Configuration changes of P3964_Config are saved on the CM and not in the CPU. The parameters saved in the device configuration are restored once the voltage returns to the CPU or the communication module.

Parameters

<table>
<tr><th rowspan="2">Parameter</th><th rowspan="2">Declara-tion</th><th colspan="2">Data type</th><th rowspan="2">Default</th><th rowspan="2">Description</th></tr>

<tr><td>Priority</td><td>IN</td><td>USInt</td><td>Byte</td><td>1</td><td>Selection of the priority
0 = low priority
1 = high priority</td></tr>
</table>

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
CharacterDelayTime	IN	UInt	Word	16#00DC	Setting the character delay time (depending on the set data transmission rate) (default value: 220 ms) 1 ms to 65535 ms
AcknDelayTime	IN	UInt	Word	16#07D0	Setting the acknowledgment delay time (depending on the set data transmission rate) (default value: 2000 ms) 1 ms to 65535 ms
BuildupAttempts	IN	USInt	Byte	16#0006	Setting the number of connection attempts (default value: 6 connection attempts) 1 to 255
RepetitionAttempts	IN	USInt	Byte	16#0006	Setting the number of transmission attempts (default value: 6 connection attempts) 1 to 255
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
DONE	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed without errors
ERROR	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed with errors
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.8 Send_P2P: Sending data

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Send_P2P instruction (send point-to-point data) starts the transmission of data and transmits the contents of the assigned buffer to the communication module. The CPU program is still being executed while the CM sends the data with the data transmission rate. Only one send instruction per communication module may be pending at any time. The CM signals an error if a second Send_P2P instruction is executed while the CM is already sending a frame.

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Starts the transmission of data to the CM upon a positive edge at this input.
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
BUFFER	IN	Variant	Any	0	This parameter points to the memory area of the send buffer. **Notes:** • Boolean data and Boolean fields are not supported. • If the send buffer is in the optimized memory area, the maximum permitted length of the sent data is 1024 bytes. Exception: Arrays of Byte, Word or DWord are supported up to a length of 4096 bytes. • If the send buffer is a String or WString, the content of the string is transferred without the current and maximum length. Additional information under "Using the BUFFER and LENGTH parameters for communication operations (Page 90)"
LENGTH	IN	UInt	Word	0	Length in bytes of the data to be transferred. The memory area addressed in the BUFFER parameter is completely transmitted with LENGTH = 0. Additional information under "Using the BUFFER and LENGTH parameters for communication operations (Page 90)"
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the Send_P2P instruction The instruction is initialized with 1. The instruction then resets COM_RST to 0. Note: The parameter is only available for S7-300/400 instructions.
DONE	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed without errors
ERROR	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed with errors
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

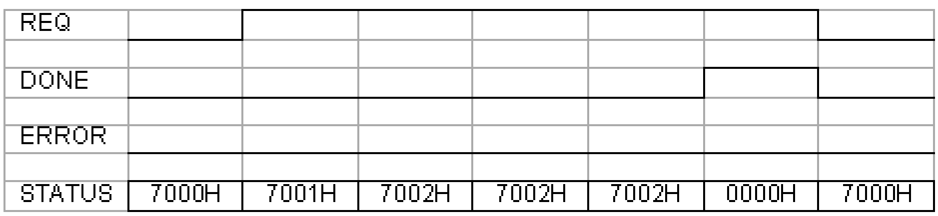
Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

Parameters

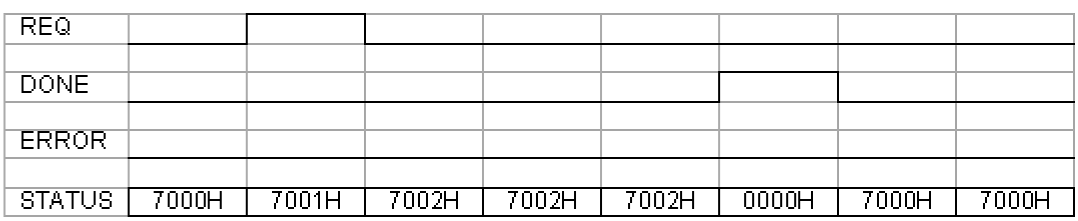
The DONE and ERROR outputs are in FALSE status when a send instruction is being processed. At the end of the send instruction, one of the DONE or ERROR outputs is set to TRUE for one cycle to signal the status of the send instruction. The error code at the STATUS output can be evaluated when the status of ERROR is TRUE.

The instruction outputs the status 16#7001 when the communication interface accepts the send data. Subsequent executions of Send_P2P output the value 16#7002 if the CM is still sending. At the end of the send instruction, the CM outputs the status 16#0000 for the send instruction (if no error has occurred). Subsequent executions of Send_P2P with REQ = 0 output the status 16#7000 (free).

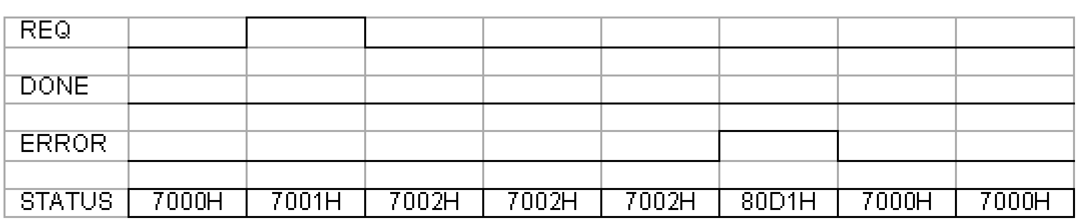
The diagram below shows the relationship between the output values and REQ. It is based on the assumption that the instruction is called cyclically to check the status of the send process (indicated by the STATUS values).



The figure below shows how the DONE and STATUS parameters are only valid for one cycle if a pulse is pending at the REQ line (for one cycle) to trigger the send instruction.



The figure below shows the relationship of the DONE, ERROR and STATUS parameters in case of an error.



The DONE, ERROR and STATUS values are only valid until Send_P2P is executed again with the same instance DB.

5.4.1.9 Using the BUFFER and LENGTH parameters for communication operations

Interaction of BUFFER and LENGTH parameters for Send_P2P

The minimum data size sent by the Send_P2P instruction is one byte.

The BUFFER parameter specifies the size of the data to be sent if a "0" is passed at the LENGTH parameter during call. The specification of a tag is sufficient for this.

You cannot use the data type Bool or arrays of the Bool type for the BUFFER parameter. If large amounts of data are being transferred we recommend the mapping to the array or structure data types.

Table 5- 10 BUFFER parameter

BUFFER	Description
Elementary data type	When sending: The LENGTH value must include the byte size of this data type. Example: For a Word value, the LENGTH must be two. For a DWord value or Real value, the LENGTH must be four.
Structure	For optimized memory: The maximum permitted length of the BUFFER is 1024 Byte; otherwise 4 KB are permitted depending on the module. For sending: The LENGTH value can include a byte size smaller than the complete byte length of the structure; in this case, only the first LENGTH bytes of the structure from BUFFER are sent.
Array	For optimized memory: If the array data type is not equal to Byte, Word or DWord, the maximum permitted buffer length is 1024 Byte. Depending on the module, up to 4 KB can be transmitted if the memory is not optimized, independent of the data structure. For sending: The LENGTH value can include a byte size smaller than the complete byte length of the array, whereby, this byte size is a multiple of the byte size of the data element. Example: The LENGTH parameter of an array of the Word type must be a multiple of two and a multiple of four for an array of the Real type. If LENGTH is specified, the number of array elements is transmitted. If BUFFER includes an array with 15 DWord elements (a total of 60 Bytes), for example, and you specify LENGTH = 20, the first five DWord elements from the array are transmitted.
String	The LENGTH parameter includes the number or characters to be sent. Only the characters of the String are transmitted. The bytes with the maximum and actual length of the String are not sent.

Table 5- 11 LENGTH parameter

LENGTH	Description
= 0	The complete content of the memory area specified by BUFFER is transferred. If BUFFER points to a string, the entire content of the string is transferred, without the bytes with the maximum and actual length.
> 0	The content up to the configured length of the memory area specified by BUFFER is transferred.

5.4.1.10 Receive_P2P: Receiving data

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Receive_P2P instruction (receive data using point-to-point communication) checks the frames received in the CM. If a frame is available, it is transmitted from the CM to the CPU. A receive error is indicated at the STATUS parameter.

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
BUFFER	IN	Variant	Any	0	This parameter points to the start address of the receive buffer. This buffer must be large enough to receive the maximum frame length. **Note:** • Boolean data or Boolean fields are not supported. • If the receive buffer is in the optimized memory area, the maximum permitted length of the received data is 1024 bytes. Exception: Arrays of Byte, Word or DWord are supported up to a length of 4096 bytes. • If the receive buffer is a String or WString, the received data is written to the content of the string and the current length of the string is set accordingly. Additional information under "Using the BUFFER and LENGTH parameters for communication operations (Page 90)"

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/ WinAC		
LENGTH	OUT	UInt	Word	0	Length of the frame received in bytes Additional information under "Using the BUFFER and LENGTH parameters for communication operations (Page 90)"
NDR	OUT	Bool		FALSE	TRUE for one cycle if new data is available and the instruction has been completed without errors.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
ERROR	OUT	Bool		FALSE	TRUE for one cycle once the instruction has been completed with an error.
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

The error code at the STATUS output can be evaluated if the status of ERROR is TRUE.
The STATUS value provides the reason for terminating the receive operation in the CM. This is usually a positive value which indicates that the receive operation has been successful and the frame criterion that has been detected.
If the STATUS value is negative (the most significant bit of the hexadecimal value is set), the receive operation was terminated due to an error condition, such as a parity, framing or overflow error.

Each communication module can buffer a module-specific number for frames. If several frames are available in the CM, the Receive_P2P instruction outputs the oldest available frame (FIFO).

5.4.1.11 Receive_Reset: Clear receive buffer

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Receive_Reset instruction (reset receiver) clears the receive buffer in the CM.

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Starts the transmission of data to the CM upon a positive edge at this input.
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
DONE	OUT	Bool		FALSE	TRUE for one cycle means that the last request was completed without errors.
ERROR	OUT	Bool		FALSE	TRUE means that the last request was completed with errors. If this output is TRUE, the STATUS output contains the corresponding error codes.
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.12 Signal_Get: Read status

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Signal_Get instruction (get RS232 signals) reads the current states of the RS232 accompanying signals and displays them at the corresponding instruction outputs.

Note

Restriction

- This instruction can only be used with CMs RS232 BA and RS232 HF.
- If RS232C is set for the operating mode, this instruction can also be used with CM PtP (ET200SP).

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Starts the transmission of data to the CM upon a positive edge at this input.
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
NDR	OUT	Bool		FALSE	TRUE for one cycle if the RS232 accompanying signals have been read and the instruction has been completed without errors.
ERROR	OUT	Bool		FALSE	TRUE for one cycle once the instruction has been completed with an error
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
DTR	OUT	Bool		FALSE	Data device ready, module ready (output)
DSR	OUT	Bool		FALSE	Data device ready, communication station ready (input)
RTS	OUT	Bool		FALSE	Send request, module ready to send (output)
CTS	OUT	Bool		FALSE	Ready to send, communication station can receive data (input)
DCD	OUT	Bool		FALSE	Data carrier signal detected, signal level received
RING	OUT	Bool		FALSE	Call display, signaling incoming call

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.13 Signal_Set: Set accompanying signals

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Signal_Set instruction (set RS232 signals) allows you to set the RS232 communication signals.

Note

Restrictions

- This instruction can only be used with CMs RS232 BA and RS232 HF.
- If RS232C is set for the operating mode, this instruction can also be used with CM PtP (ET200SP).

Parameters

<table>
<tr><th rowspan="2">Parameter</th><th rowspan="2">Declara-tion</th><th colspan="2">Data type</th><th rowspan="2">Default</th><th rowspan="2">Description</th></tr>
<tr><th>S7-1200/1500</th><th>S7-300/400/WinAC</th></tr>
<tr><td>REQ</td><td>IN</td><td colspan="2">Bool</td><td>FALSE</td><td>Starts the instruction upon a positive edge of this input.</td></tr>
<tr><td>PORT</td><td>IN</td><td>PORT (UInt)</td><td>Word</td><td>0</td><td>Specifies the communication module which is used for the communication:
For S7-1500/S7-1200: "HW identifier" from the device configuration.
The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there.
For S7-300/S7-400: "Input address" from the device configuration.
In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.</td></tr>
<tr><td>SIGNAL</td><td>IN</td><td colspan="2">Byte</td><td>0</td><td>Selection of the signal to be set (more than one possible):
01H = RTS
02H = DTR
04H = DSR (for interface type DCE only)</td></tr>
</table>

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
RTS	IN	Bool		FALSE	Send request, module ready to send Set this value at the output (TRUE or FALSE), default value: FALSE
DTR	IN	Bool		FALSE	Data terminal ready, module ready Set this value at the output (TRUE or FALSE), default value: FALSE
DSR	IN	Bool		FALSE	Data terminal ready (for DCE interface type only), not used.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
DONE	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed without errors
ERROR	OUT	Bool		FALSE	TRUE for one cycle after the last request has been completed with errors
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.14 Get_Features: Get extended functions

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

If supported by the module, you can use the Get_Features instruction (get extended functions) to get information on the ability of the module to support CRC and to generate diagnostic messages.

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Starts the instruction upon a positive edge of this input.
PORT	IN	PORT	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
NDR	OUT	Bool		FALSE	TRUE for one cycle if new data is available and the instruction has been completed without errors
MODBUS_CRC	OUT	Bool		FALSE	Modbus CRC support
DIAG_ALARM	OUT	Bool		FALSE	Generation of diagnostic messages
SUPPLY_VOLT	OUT	Bool		FALSE	Diagnostics for missing supply voltage L+ is available
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
ERROR	OUT	Bool		FALSE	TRUE for one cycle once the instruction has been completed with an error
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.15 Set_Features: Set extended functions

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

If supported by the module, you can use the Set_Features instruction (select extended functions) to activate CRC support and the generation of diagnostic messages.

Parameters

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	The instruction to set extended functions is started upon a positive edge at this input.
PORT	IN	PORT (UInt)	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
EN_MODBUS_CRC	IN	Bool		FALSE	Activate Modbus CRC support
EN_DIAG_ALARM	IN	Bool		FALSE	Activate generation of diagnostic messages
EN_SUPPLY_VOLT	IN	Bool		FALSE	Enable diagnostics for missing supply voltage L+
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE.
DONE	OUT	Bool		FALSE	TRUE for one execution once the last request is completed without errors

Parameter	Declaration	Data type		Default	Description
		S7-1200/1500	S7-300/400/WinAC		
ERROR	OUT	Bool		FALSE	TRUE for one cycle once the instruction has been completed with an error
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 102))

Additional information about the general parameters is available at "General parameters for Freeport operations (Page 73)".

5.4.1.16 Error messages

Overview of error messages - PtP

The error messages are provided at the STATUS output of an instruction and can be evaluated there or processed in the user program.

Error code	Description	Remedy
16#0000	No error	-
RECEIVE status and error codes		
16#0094	frame end identified based on the "Receipt of fixed/maximum frame length"	-
16#0095	frame end identified based on "Message timeout"	-
16#0096	frame end identified based on expiration of the "Character delay time"	-
16#0097	The frame was aborted because the maximum response time was reached.	-
16#0098	frame end identified based on the fulfillment of the "Read message length from message" conditions	-
16#0099	frame end identified based on the receipt of the "End sequence"	-
SEND status and error codes		
16#7000	Block idle	-
16#7001	Initial call for a new frame: Data transmission initiated	-
16#7002	Interim call: Data transmission running	-
16#8085	Invalid length	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (Byte)
16#8088	The specified length exceeds the range set in the receive buffer. Note: If the data type STRING has been specified at the BUFFER parameter, this error code also appears if the current string is shorter than the length specified at the LENGTH parameter.	Change the range in the receive buffer or select a frame length which corresponds to the range set in the receive buffer. The following are valid (depending on the module): 1-1024/2048/4096 (bytes)
16#8090	Configuration error: Odd number of bytes for WString	Select an even number of bytes.
RECEIVE status and error codes		
16#7002	Interim call: Data transmission running	-
16#8088	The number of characters received exceeds the number specified at the BUFFER parameter.	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (bytes)
16#8090	Configuration error: Odd number of bytes for WString	Select an even number of bytes.

Error code	Description	Remedy
Error message codes of the special functions		
16#818F	Incorrect parameter number setting (with USS only)	Select a suitable parameter number (PARAM). The following numbers are valid: 0-2047
16#8190	Incorrect setting of the CRC calculation	Select a suitable value for the CRC calculation. The following are valid: deactivated or activated. Check whether the module addressed supports CRC calculation.
16#8191	Incorrect setting of the diagnostic error interrupt	Select a suitable value for "Diagnostic error interrupt". The following are valid: Diagnostic error interrupt deactivated or diagnostic error interrupt activated. Check whether the module addressed supports the generation of diagnostic interrupts.
16#8193	The module does not support supply voltage diagnostics L+.	Select a suitable value for "Diagnostic interrupt". The following are permitted: Diagnostic interrupt deactivated or diagnostic interrupt activated. Check whether the module addressed supports the generation of diagnostic interrupts.
Error message codes of the "Port configuration"		
16#81A0	The module does not support this protocol.	Select a valid protocol for the module (PROTOCOL).
16#81A1	The module does not support this data transmission rate.	Select a valid data transmission rate for the module (BAUD).
16#81A2	The module does not support this parity setting.	Select a suitable value for "Parity" (PARITY). The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
16#81A3	The module does not support this number of data bits.	Select a suitable value for "Number of data bits" (DATABITS). The following are valid: • 7 (2) • 8 (1)
16#81A4	The module does not support this number of stop bits.	Select a suitable value for "Number of stop bits" (STOPBITS). The following are valid: • 1 (1) • 2 (2)
16#81A5	The module does not support this type of data flow control.	Select a valid data flow control for the module (FLOWCTRL).

Error code	Description	Remedy
16#81A7	Invalid value for XON or XOFF	Select suitable values for XON (XONCHAR) and XOFF (XOFFCHAR). Valid range of values: 0...255
16#81AA	Invalid operating mode	Valid operating modes are: • Full duplex (RS232) (0) • Full duplex (RS422) four-wire mode (point-to-point) (1) / (CM PtP (ET 200SP)) • Full duplex (RS422) four-wire mode (multipoint master) (2)/ (CM PtP (ET 200SP)) • Full duplex (RS 422) four-wire mode (multipoint slave) (3) • Half duplex (RS485) two-wire mode. (4)
16#81AB	Invalid receive line initial state	Valid initial states are: • "No" default setting (0) • Signal R(A)=5 V, signal R(B)=0 V (break detection) (1): Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • Signal R(A)=0 V, signal R(B)=5 V (2): This default setting corresponds to the idle state (no active send operation).
16#81AC	Invalid value for "Break detection"	Select a suitable value for "Break detection". The following are valid: • Break detection deactivated (0) • Break detection activated (1).
16#81AF	The module does not support this protocol.	Select a valid protocol for the module.
Error codes of the "Send configuration"		
16#81B5	More than two end delimiters or end sequence > 5 characters	Select suitable values for "End delimiter" and "End sequence". The following are valid: • deactivated (0), • 1 (1) or 2 (2) end delimiters or • deactivated (0), • 1 (1) up to 5 (5) characters for the end sequence.
16#81B6	Send configuration rejected because the 3964(R) protocol was selected	Make sure that no send configuration is transmitted if the 3964(R) protocol is set.

Error code	Description	Remedy
Error codes of the "Receive configuration"		
16#81C0	Invalid start condition	Select a suitable start condition. The following are valid: • Send break before frame start • Send Idle Line.
16#81C1	Invalid end condition or no end condition selected	Select a suitable end condition (see Sending data with Freeport (Page 40)).
16#81C3	Invalid value for "Maximum message length"	Select a suitable value for "Maximum message length" (MAXLEN). Valid range of values (depending on the module): 1-1024/2048/4096 (Byte)
16#81C4	Invalid value for "Offset of the length specification in the message"	Select a suitable value for "Offset of the length specification in the message". Valid range of values (depending on the module): 1-1024/2048/4096 (Byte)
16#81C5	Invalid value for "Size of length field"	Select a suitable value for "Size of length field" (LENGTHSIZE). Valid range of values in bytes: • 1 (1) • 2 (2) • 4 (4)
16#81C6	Invalid value for "Number of characters not counted in length specification"	Select a suitable value for "Number of characters not counted in length specification" (LENGTHM). Valid range of values: 0 to 255 (bytes)
16#81C7	The total of "Offset in the message + size of length field + number of characters not counted" is greater than the maximum frame length	Select a suitable value for "Offset in message", "Size of length field" and "Number of characters not counted". Valid range of values: • Offset in the message (depending on the module): 0-1024/2048/4096 (bytes) • Size of length field: 1, 2, or 4 (bytes) • Number of characters not counted: 0 to 255 (bytes)
16#81C8	Invalid value for "Response timeout"	Select a suitable value for "Response timeout". Valid range of values: 1-65535 (ms)
16#81C9	Invalid value for "Character delay time"	Select a suitable value for "Character delay time". Valid range of values: 1 to 65535 (bit times)
16#81CB	frame end sequence is activated, but no character is activated for the check	Activate one or several characters for the check.
16#81CC	frame start sequence is activated, but no character is activated for the check	Activate one or several characters for the check.

Error code	Description	Remedy
16#81CD	Invalid value for "Prevent overwriting"	Select a suitable value for "Prevent overwriting". The following are valid: • Prevent overwriting is deactivated (0) or • Prevent overwriting is activated (1)
16#81CE	Invalid value for "Clear receive buffer on startup"	Select a suitable value for "Clear receive buffer on startup". The following are valid: • Clear receive buffer at startup is deactivated (0) • Clear receive buffer at startup is activated (1)
SEND status and error codes		
16#81D0	Receiving send request during runtime of a send command	Make sure that you do not receive an additional send request during runtime of a send command.
16#81D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or change the parameters, if necessary.
16#81D2	"Hardware RTS always ON": Send job canceled due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ON for the entire duration of transmission.
16#81D3	Send buffer overflow / send frame too long	Select a shorter frame length. The following are valid (depending on the module): 1 to 1024/2048/4096 (bytes)
16#81D5	Transmission canceled due to parameter changes, detected wire break, or CPU in STOP	Check the parameter assignment, wire break, and CPU status.
16#81D6	Transmission canceled because end identifier was not received	Check the parameter assignment of the end characters and the frame of the communication partner.
16#81D7	Communication error between the user program and module	Check the communication (e.g., matching the sequence number).
16#81D8	Transmission attempt rejected because module is not configured	Configure the module.
16#81DF	The module has reset the interface to the FB for one of the following reasons: • Module was restarted • Module parameters were reassigned • CPU STOP	—

Error code	Description	Remedy
Error codes of the receive configuration		
16#81E0	Frame aborted: Send buffer overflow / send frame too long	Increase the call rate for the receive function in the user program or configure communication with data flow control.
16#81E1	Frame aborted: Parity error	Check the connection line of the communication partners, or verify that the same data transmission rate, parity and stop bit number are configured for both devices.
16#81E2	Frame aborted: Character frame error	Check the settings for start bit, data bits, parity bit, data transmission rate, and stop bit(s).
16#81E3	Frame aborted: Character overflow error	Firmware error: Please contact Customer Support.
16#81E4	Frame aborted: The total length of "Offset in the message + size of the length field + number of characters not counted" is greater than the receive buffer	Select a suitable value for offset in message, size of the length field, and number of characters not counted.
16#81E5	Frame aborted: Break	Receive line to partner is interrupted. Reconnect or switch on partner.
16#81E6	Maximum number of "Buffered received frames" exceeded	In the user program call the instruction more often or configure a communication with data flow control or increase the number of buffered frames.
16#81E7	Synchronization error module and Receive_P2P	Make sure that different instances of the Receive_P2P do not access the same module.
16#81E8	Frame aborted: The character delay time has expired before the message end criterion was detected	Partner device faulty or too slow. Check this, if required, using an interface tester that is interconnected in the transmission line.
16#81E9	Modbus CRC error (only communication modules which support Modbus)	Checksum error of the Modbus frame. Check the communication partner.
16#81EA	Modbus frame too short (only communication modules which support Modbus)	Minimum length of Modbus frame not met. Check the communication partner.
16#81EB	Frame aborted: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1-1024/2048/4096 (bytes) Check the parameters for end of frame detection.

Error code	Description	Remedy
Error codes V24 accompanying signals		
16#81F0	The module does not support V24 accompanying signals	You have tried to set accompanying signals for a module that does not support V24 accompanying signals. Make sure that this is an RS232 module or that RS232 mode (ET 200SP) is set.
16#81F1	No operation of the V24 accompanying signals	The V24 accompanying signals cannot be operated manually if hardware data flow control is active.
16#81F2	The DSR signal cannot be set because the module has the type DTE.	Check the configured type of the module. The module type must be DCE (data communication equipment).
16#81F3	The DTR signal cannot be set because the module has the type DCE.	Check the configured type of the module. The module type must be DTE (data terminal equipment).
16#81F4	Block header error (e.g. incorrect block type or incorrect block length)	Check the instance DB and the block header.
Error codes of the receive configuration		
16#8201 1)	Receive_Conditions is a pointer to an invalid data type	Enter a pointer to one of the following data types: DB, BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL, DATE, TIME_OF_DAY, TIME, S5TIME, DATE_AND_TIME, STRING
16#8225	Receive_Conditionspoints to an optimized memory area greater than 1 kB or Receive_Conditions points to an optimized memory area and the receive length is greater than the area addressed by Receive_Conditions.	Enter a pointer to an area with a maximum length of: • Optimized memory area: 1 KB • Non-optimized memory area: 4 KB Note: If the pointer points to an optimized memory area, do not send more than 1 KB.
16#8229 1)	Receive_Conditions is a pointer to BOOL with a number of bits not equal to n * 8	If you are using a pointer to BOOL, the number of bits must be a multiple of 8.
Error codes, general		
16#8280	Negative acknowledgment when reading module	You can find more detailed information on error causes in theRDREC.STATUS static parameters and in the description of the SFB RDREC. • Check the input at the PORT parameter • Set the COM_RST parameter before the 1st call.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter You can find more detailed information on error causes in the WRREC.STATUS static parameters and in the description of the SFB WRREC.
16#8282	Module not available	Check the input at the PORT parameter and ensure that the module can be reached.

Error code	Description	Remedy
Error codes of the receive configuration		
16#82C1	Invalid value for "Buffered received frames".	Select a suitable value for "Buffered received frames". Valid range of values: 1-255
16#82C2	Receive configuration rejected because the 3964(R) protocol was selected	Make sure that no receive configuration is sent if the 3964(R) protocol is set.
16#8301 [1)]	Receive_Conditions is a pointer to an invalid data type	Select a valid data type. The following are valid: DB, BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL, DATE, TIME_OF_DAY, TIME, S5TIME, DATE_AND_TIME, STRING
16#8322	Range length error when reading a parameter	Check the input at the Receive_Conditions parameter
16#8324	Range error when reading a parameter	Check the input at the Receive_Conditions parameter
16#8328	Setting error when reading a parameter	Check the input at the Receive_Conditions parameter
SEND status and error codes		
16#8328 [1)]	BUFFER is a pointer to BOOL with a number of bits not equal to n * 8	If you are using a pointer to BOOL, the number of bits must be a multiple of 8.
Error codes of the receive configuration		
16#8332	Invalid data block at the Receive_Conditions parameter	Check the input at the Receive_Conditions parameter
16#833A	The designation of the data block at the Receive_Conditions parameter refers to a data block which is not loaded.	Check the input at the Receive_Conditions parameter
16#8351	Invalid data type	Check the input at the Receive_Conditions parameter
16#8352 [1)]	Receive_Conditions does not point to a data block	Check the pointer to Receive_Conditions
16#8353 [1)]	Receive_Conditions does not point to a structure of the typeReceive_Conditions	Check the pointer to Receive_Conditions
Error codes 3964(R) protocol		
16#8380	Parameter assignment error: Invalid value for "Character delay time".	Select a suitable value for "Character delay time" (CharacterDelayTime). Valid range of values: 1 to 65535 (ms)
16#8381	Parameter assignment error: Invalid value for "Response timeout".	Select a suitable value for "Response timeout" (AcknDelayTime). Valid range of values: 1 to 65535 (ms)
16#8382	Parameter assignment error: Invalid value for "Priority".	Select a suitable value for "Priority" (Priority). The following are valid: • High (1) • Low (0)
16#8383	Parameter assignment error: Invalid value for "Block check"	Select a suitable value for "Block check" (BCC). The following are valid: • With block check (1) • Without block check (0)

Error code	Description	Remedy
16#8384	Parameter assignment error: Invalid value for "Connection attempts".	Select a suitable value for "Connection attempts" (BuildupAttempts). Valid range of values: 1-255
16#8385	Parameter assignment error: Invalid value for "Transmission attempts".	Select a suitable value for "Transmission attempts" (RepetitionAttempts). Valid range of values: 1-255
16#8386	Runtime error: Number of connection attempts exceeded	Check the interface cable and the transmission parameters. Also check whether the receive function is configured correctly at the partner device.
16#8387	Runtime error: Number of transmission attempts exceeded	Check the interface cable, the transmission parameters and the configuration of the communication partner.
16#8388	Runtime error: Error at the "Block check character" The internally calculated value of the block check character does not correspond to the block check character received by the partner at the connection end.	Check whether the connection is seriously disrupted; in this case you may also occasionally see error codes. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#8389	Runtime error: Invalid character received while waiting for free receive buffer	The send request of the communication partner (STX, 02H) is only answered with DLE when the receive buffer is empty. No additional character may be received before (except STX again). Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#838A	Runtime error: Logical error during receiving. After DLE was received, a further random character (other than DLE or ETX) was received.	Check if partner DLE in frame header and in data string is always in duplicate or the connection is released with DLE ETX. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#838B	Runtime error: Character delay time exceeded	Partner device too slow or faulty. Verify by using an interface test device that is switched into the transmission line, if necessary.
16#838C	Runtime error: Wait time for free receive buffer has started	In the user program call the instruction more often or configure a communication with data flow control.
16#838D	Runtime error: frame repetition does not start within 4 s after NAK	Check the communication partner. A received frame that is possibly corrupted must be repeated by the partner within 4 seconds.
16#838E	Runtime error: In idle mode, one or several characters (other than NAK or STX) were received.	Check for proper function of the partner device, possibly using an interface test device that is switched into the transmission line.
16#838F	Runtime error: Initialization conflict - Both partners have set high priority	Set the "Low" priority at one of the partners
16#8391	Parameter assignment error: 3964 configuration data rejected because Freeport is set	If the Freeport protocol is set, make sure that no 3964 parameter assignment data is sent.

1) Only with instructions for S7-300/400 CPUs

Overview of error messages - Modbus

Error code	Description	Remedy
16#0000	No error	-
Configuration error of the interface - Modbus_Comm_Load		
16#8181	The module does not support this data transmission rate.	Select a valid data transmission rate for the module at the BAUD parameter.
16#8182	The module does not support this parity setting.	Select a suitable value for "Parity" at the PARITY parameter. The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
16#8183	The module does not support this type of data flow control.	Select a valid data flow control for the module at the FLOW_CTRL parameter.
16#8184	Invalid value for "Response timeout".	Select a suitable value for "Response timeout" at the RESP_TO parameter. Valid range of values: 1 to 65535 (ms)
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the Send_Config.RDREC.STATUS or Receive_Config.RDREC.STATUS static parameters or RDREC.STATUS and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the Send_Config.WRREC.STATUS or Receive_Config.WRREC.STATUS static parameters or WRREC.STATUS and in the description of the SFB WRREC.
16#8282	Module not available	Check the input at the PORT parameter and ensure that the module can be reached.

Error code	Description	Remedy
Configuration error - Modbus_Slave		
16#8186	Invalid slave address	Select a suitable slave address at the MB_ADDR parameter. The following are valid: 1-247 at standard address area; 1-65535 at extended address area (0 is reserved for Broadcast)
16#8187	Invalid value at MB_HOLD_REG parameter	Select a suitable value for the hold register at the MB_HOLD_REG parameter.
16#8188	Invalid operating mode or broadcast (MB_ADDR = 0) and MODE parameter ≠ 1	Select the value 1 for MODE in Broadcast mode or select a different operating mode.
16#818C	The pointer to a MB_HOLD_REG area must be a data block or a bit memory address area.	Select a suitable value for the pointer to the MB_HOLD_REG area.
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.WRREC.STATUS or Receive_P2P.WRREC.STATUS, and in the description of the SFB WRREC.
16#8452 1)	MB_HOLD_REG is not a pointer to a DB or a bit memory area	Check the MB_HOLD_REG pointer
16#8453 1)	MB_HOLD_REG is not a pointer of type BOOL or WORD	Check the MB_HOLD_REG pointer
16#8454 1)	The area addressed by MB_HOLD_REG is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the MB_HOLD_REG pointer
16#8455 1)	MB_HOLD_REG points to a write-protected DB	Check the MB_HOLD_REG pointer
16#8456 1)	Error during instruction execution. The cause of the error is shown in the STATUS parameter.	Determine the value of the SFCSTATUS parameter. Check what this means in the description for SFC51, STATUS parameter.

Error code	Description	Remedy
Configuration error - Modbus_Master		
16#8180	Invalid value for MB_DB parameter	The value configured for MB_DB (instance data DB) at the Modbus_Comm_Load instruction is not valid. Check the interconnection of the Mod-bus_Comm_Load instruction and its error messages.
16#8186	Invalid station address	Select a suitable station address at the MB_ADDR parameter. The following are valid: 1-247 at standard address area; 1-65535 at extended address area (0 is reserved for Broadcast)
16#8188	Invalid operating mode or broadcast (MB_ADDR = 0) and MODE parameter ≠ 1	Select the value 1 for MODE in Broadcast mode or select a different operating mode.
16#8189	Invalid data address	Select a suitable value for the data address at the DATA_ADDR parameter. See description Modbus_Master (Page 125) in the Info system
16#818A	Invalid length	Select a suitable data length at the DATA_LEN pa-rameter. See description Modbus_Master (Page 125) in the Info system
16#818B	Invalid value for DATA_PTR	Select a suitable value for the data pointer at the DATA_PTR parameter (M or DB address). See description Modbus_Master (Page 125) in the Info system
16#818C	Interconnection error of the DATA_PTR parameter	Check the interconnection of the instruction.
16#818D	The area addressed by DATA_PTR is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the DATA_PTR pointer
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.RDREC.STATUS or Re-ceive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.WRREC.STATUS or Re-ceive_P2P.WRREC.STATUS or Receive_Reset and in the description of the SFB WRREC.

Error code	Description	Remedy
Communication errors - Modbus_Master and Modbus_Slave		
16#80D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or change the parameters, if necessary.
16#80D2	"Hardware RTS always ON": Send job canceled due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ON for the entire duration of transmission.
16#80E0	Frame aborted: Send buffer overflow / send frame too long	In the user program call the instruction more often or configure a communication with data flow control.
16#80E1	Frame aborted: Parity error	Check the connection line of the communication partners, or verify that the same data transmission rate, parity and stop bit number are configured for both devices.
16#80E2	Frame aborted: Character frame error	Check the settings for start bit, data bits, parity bit, data transmission rate, and stop bit(s).
16#80E3	Frame aborted: Character overflow error	Check the number of data in the frame of the communication partner.
16#80E4	Frame aborted: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1 to 1024/2048/4096 (bytes)
Communication error - Modbus_Master		
16#80C8	The slave does not respond within the set time	Check the data transmission rate, parity and wiring of the slave.
16#80C9	The slave does not respond within the time set by Blocked_Proc_Timeout.	Check the setting for Blocked_Proc_Timeout. Check if the module has been configured with the Modbus_Comm_Load instruction. The module may possibly need to be reconfigured using Modbus_Comm_Load after a pull/plug or after voltage recovery.
16#8200	The interface is busy with an ongoing request.	Repeat the command later. Make sure that there are no commands still running before you start a new one.
Protocol error - Modbus_Slave (only communication modules that support Modbus)		
16#8380	CRC error	Checksum error of the Modbus frame. Check the communication partner.
16#8381	The function code is not supported or is not supported for broadcast.	Check the communication partner and make sure that a valid function code is sent.
16#8382	Invalid length information in the request frame	Select a suitable data length at the DATA_LEN parameter.
16#8383	Invalid data address in the request frame	Select a suitable value for the data address at the DATA_ADDR parameter.
16#8384	Invalid data value error in the request frame	Check the data value in the request frame of the Modbus master
16#8385	The diagnostic value is not supported by the Modbus slave (function code 08)	The Modbus slave only supports the diagnostic values 16#0000 and 16#000A.

Error code	Description	Remedy
Protocol error - Modbus_Master (only communication modules that support Modbus)		
16#8380	CRC error	Checksum error of the Modbus frame. Check the communication partner.
16#8381	Response frame from Modbus Slave with the following error message: The function code is not supported.	Check the communication partner and make sure that a valid function code is sent.
16#8382	Response frame from Modbus Slave with the following error message: Invalid length	Select a suitable data length.
16#8383	Response frame from Modbus Slave with the following error message: Invalid data address in the request frame	Select a suitable value for the data address at the DATA_ADDR parameter.
16#8384	Response frame from Modbus Slave with the following error message: Data value error	Check the request frame to the Modbus slave.
16#8385	Response frame from Modbus Slave with the following error message: The diagnostic value is not supported by the Modbus slave	The Modbus slave only supports the diagnostic values 16#0000 and 16#000A.
16#8386	The returned function code does not match the requested function code.	Check the response frame and the addressing of the slave.
16#8387	A slave that was not requested answers	Check the response frame of the slave. Check the address settings of the slave.
16#8388	Error in the response of the slave to a write request.	Check the response frame of the slave.
16#8828 1)	DATA_PTR points to a bit address that is not equal to n * 8	Check the DATA_PTR pointer
16#8852 1)	DATA_PTR is not a pointer to a DB or a bit memory area	Check the DATA_PTR pointer
16#8853 1)	DATA_PTR is not a pointer of type BOOL or WORD	Check the DATA_PTR pointer
16#8855 1)	DATA_PTR points to a write-protected DB	Check the DATA_PTR pointer
16#8856 1)	Error during call of SFC51	Call the Modbus_Master instruction again
Error - Modbus_Slave (only communication modules that support Modbus)		
16#8428 1)	MB_HOLD_REG points to a bit address that is not equal to n * 8	Check the MB_HOLD_REG pointer
16#8452 1)	MB_HOLD_REG is not a pointer to a DB or a bit memory area	Check the MB_HOLD_REG pointer
16#8453 1)	MB_HOLD_REG is not a pointer of type BOOL or WORD	Check the MB_HOLD_REG pointer
16#8454 1)	The area addressed by MB_HOLD_REG is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the MB_HOLD_REG pointer
16#8455 1)	MB_HOLD_REG points to a write-protected DB	Check the MB_HOLD_REG pointer
16#8456 1)	Error during call of SFC51	Call the Modbus_Slave instruction again

1) Only with instructions for S7-300/400 CPUs

Overview of error messages - USS

Error code	Description	Remedy
16#0000	No error	-
16#8180	Length error in response of drive	Check the response frame of the drive.
16#8181	Data type error	Select a suitable data type. The following are valid: • Real • Word • Double word
16#8182	Data type error: "Double word" or "Real" may not be returned for the "Word" request.	Check the response frame of the drive.
16#8183	Data type error: "Word" may not be returned for the "Double word" or "Real" request.	Check the response frame of the drive.
16#8184	Checksum error in response of drive	Check the drive and the communication connection.
16#8185	Addressing error	Valid drive address range: 1 to 16
16#8186	Setpoint error	Valid setpoint range: -200% to +200%
16#8187	Incorrect drive number returned	Check the response frame of the drive.
16#8188	Invalid PZD length	Permitted PZD lengths: 2, 4, 6, 8 words
16#8189	The module does not support this data transmission rate.	Select a valid data transmission rate for the module.
16#818A	A different request for this drive is currently active.	Repeat the parameter read or write command later.
16#818B	The drive does not respond.	Check the drive.
16#818C	The drive responds with an error message to a parameter request.	Check the response frame of the drive. Check the parameter request. Check if the instructions USS_Read_Param, USS_Write_Param or USS_Port_Scan have reported an error. If they have, check the value of the static tag USS_DB. w_USSExtendedError of the USS_Drive_Control instruction.
16#818D	The drive responds with an access error message to a parameter request.	Check the response frame of the drive. Check the parameter request.
16#818E	The drive was not initialized.	Check the user program and make sure that the USS_Drive_Control instruction is called for this drive.

Error code	Description	Remedy
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Port_Config.RDREC.STATUS, Send_Config.RDREC.STATUS , Re-ceive_Config.RDREC.STATUS , Send_P2P.RDREC.STATUS or Re-ceive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Port_Config.WRREC.STATUS, Send_Config.WRREC.STATUS , Re-ceive_Config.WRREC.STATUS , Send_P2P.RDREC.STATUS or Re-ceive_P2P.RDREC.STATUS, and in the description of the SFB WRREC.

1) Only with instructions for S7-300/400 CPUs

5.4.2 MODBUS (RTU)

5.4.2.1 Overview of the Modbus RTU communication

Modbus RTU communication

Modbus RTU (Remote Terminal Unit) is a standard protocol for communication in the network and uses the RS232 or RS422/485 connection for serial data transmission between Modbus devices in the network.

Modbus RTU uses a master/slave network in which all communication is triggered by a single master device while the slaves can only respond to the request of the master. The master sends a request to a slave address and only the slave with this slave address responds to the command.

Exception: Modbus slave address 0 sends a broadcast frame to all slaves (without slave response).

Modbus function codes

- A CPU that is operated as a Modbus RTU master can read and write data and I/O states in a Modbus RTU slave connected by means of a communication connection.
- A CPU operated as a Modbus RTU slave allows a Modbus RTU master connected over a communication connection to read and write data and I/O states in its own CPU.

Table 5- 12 Functions for reading data: Reading distributed I/O and program data

Modbus function code	Functions for reading data from the slave (server) - standard addressing
01	Read output bits: 1 to 2000/1992[1)] bits per request
02	Read input bits: 1 to 2000/1992[1)] bits per request
03	Read hold register: 1 to 125/124[1)] words per request
04	Read input words: 1 to 125/124[1)] words per request

1) for extended addressing

Table 5- 13 Functions for writing data: Changing distributed I/O and program data

Modbus function code	Functions for writing of data in the slave (server) - standard addressing
05	Write one output bit: 1 bit per request
06	Write one hold register: 1 word per request
15	Write one or several output bits: 1 to 1960 bits per request
16	Write one or several hold registers: 1 to 122 words per request

- The Modbus function codes 08 and 11 offer diagnostic options for communication with the slave device.
- Modbus slave address 0 sends a broadcast frame to all slaves (without slave response; for function codes 5, 6, 15, 16).

Table 5- 14 Station addresses in the Modbus network

Station		Address
RTU station	Standard station address	1 to 247 and 0 for broadcast
	Extended station address	1 to 65535 and 0 for broadcast

Modbus memory addresses

The number of Modbus memory addresses (input/output addresses) that is actually available depends on the CPU version and the available work memory.

Modbus RTU instructions in your program

- Modbus_Comm_Load: You need to run Modbus_Comm_Load to set up PtP parameters such as data transmission rate, parity and data flow control. Once you have configured the communication module for the Modbus RTU protocol, it can only be used by the Modbus_Master instruction or the Modbus_Slave instruction.
- Modbus_Master: The CPU can be used as Modbus RTU master device with the Modbus master instruction for communication with one or more Modbus slave devices.
- Modbus_Slave: The CPU can be used as Modbus RTU slave device with the Modbus slave instruction for communication with one Modbus master device.

5.4.2.2 Modbus_Comm_Load: Configure communication module for Modbus

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Modbus_Comm_Load instruction configures a communication module for communication by means of the Modbus RTU protocol. An instance data block is automatically assigned when you add the Modbus_Comm_Load instruction in your program.

Configuration changes of Modbus_Comm_Load are saved on the CM and not in the CPU. With voltage recovery and pulling/plugging, the CM is configured with the data saved in the device configuration. The Modbus_Comm_Load instruction must be called in these scenarios.

Parameters

Parameter	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	Starts the instruction upon a positive edge of this input.
PORT	IN	Port	Laddr	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.
BAUD	IN	UDInt	DWord	9600	Selection of the data transmission rate Valid values are: 300, 600, 1200, 2400, 4800, 9600, 19200, 38400, 57600, 76800, 115200 bit/s.
PARITY	IN	UInt	Word	0	Selection of parity: • 0 – None • 1 – Odd • 2 – Even

Parameter	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
FLOW_CTRL	IN	UInt	Word	0	Selection of flow control: • 0 – (default) no flow control • 1 – Hardware flow control with RTS always ON (not with RS422/485 CMs) • 2 – Hardware flow control with RTS switched (not with RS422/485 CMs)
RTS_ON_DLY	IN	UInt	Word	0	Selection RTS ON delay: • 0 – No delay from "RTS active" until the first character of the frame is sent. • 1 to 65535 – Delay in milliseconds from "RTS active" until the first character of the frame is sent (not with RS422/485 CMs). RTS delays must be used independent of the selection FLOW_CTRL.
RTS_OFF_DLY	IN	UInt	Word	0	Selection RTS OFF delay: • 0 – No delay after transmission of last character until "RTS inactive" • 1 to 65535 – Delay in milliseconds after transmission of last character until "RTS inactive" (not with RS422/485 ports). RTS delays must be used independent of the selection FLOW_CTRL.
RESP_TO	IN	UInt	Word	1000	Response timeout: 5 ms to 65535 ms - Time in milliseconds that Modbus_Master waits for a response from the slave. If the slave does not respond within this period, Modbus_Master repeats the request or terminates the request with an error if the specified number of repetitions (see below, RETRIES parameter) has been sent.
MB_DB	IN/OUT	MB_BASE		-	A reference to the instance data block of the Modbus_Master or Modbus_Slave instructions. The MB_DB parameter must be connected with the (static and therefore not visible in the instruction) MB_DB parameter of the Modbus_Master or Modbus_Slave instruction.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the Modbus_Comm_Load instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE. Note: The parameter is only available for S7-300/400 instructions.
DONE	OUT	Bool		FALSE	The DONE bit is TRUE for one cycle after the last request has been completed without errors.

Parameter	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
ERROR	OUT	Bool		FALSE	The ERROR bit is TRUE for one cycle after the last request has been completed with errors. The error code in the STATUS parameter is only valid in the cycle in which ERROR = TRUE.
STATUS	OUT	Word		16#7000	Error code (see Error messages (Page 151))

Modbus_Comm_Load is executed to configure a port for the Modbus RTU protocol. Once you have configured the port for the Modbus RTU protocol, it can only be used by the Modbus_Master or Modbus_Slave instructions.

You have to run Modbus_Comm_Load for the configuration of each communication port that is to be used for Modbus communication. You must assign a unique Modbus_Comm_Load instance DB to each port that you use. Only run Modbus_Comm_Load again if you need to change communication parameters, such as data transmission rate or parity, or in case the network has returned.

For example, an instance data block is assigned to the instruction if you add Modbus_Master or Modbus_Slave to your program. You need to connect the MB_DB parameter of the Modbus_Comm_Load instruction to the MB_DB parameter of the Modbus_Master or Modbus_Slave instruction.

Modbus_Comm_Load data block tags

The table below shows the public static tags in the instance DB of Modbus_Comm_Load that you can use in your program.

Table 5- 15 Static tags in the instance DB

Tag	Data type		Standard	Description
	S7-1200/1500	S7-300/400/WinAC		
ICHAR_GAP	Word		0	Maximum character delay time between characters. This parameter is specified in milliseconds and increases the anticipated period between the received characters. The corresponding number of bit times for this parameter is added to the Modbus default value of 35 bit times (3.5 character times).
RETRIES	Word		2	Number of retries that the master executes before the error code 0x80C8 for "No response" is returned.
EN_SUPPLY_VOLT	Bool		0	Enable diagnostics for missing supply voltage L+
MODE	USInt	Byte	0	Operating mode Valid operating modes are: • 0 = Full duplex (RS232) • 1 = Full duplex (RS422) four-wire mode (point-to-point) • 2 = Full duplex (RS 422) four-wire mode (multipoint master, CM PtP (ET 200SP)) • 3 = Full duplex (RS 422) four-wire mode (multipoint slave, CM PtP (ET 200SP)) • 4 = Half duplex (RS485) two-wire mode 1)
LINE_PRE	USInt	Byte	0	Receive line initial state Valid initial states are: • 0 = "No" initial state 1) • 1 = signal R(A)=5 V, signal R(B)=0 V (break detection): Break detection is possible with this initial state. Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • 2 = signal R(A)=0 V, signal R(B)=5 V: This default setting corresponds to the idle state (no active send operation). No break detection is possible with this initial state.
BRK_DET	USInt	Byte	0	Break detection The following are valid: • 0 = break detection deactivated • 1 = break detection activated

Tag	Data type		Standard	Description
	S7-1200/1500	S7-300/400/WinAC		
EN_DIAG_ALARM	Bool		0	Activate diagnostics interrupt: • 0 - not activated • 1 - activated
STOP_BITS	USINT	Byte	1	Number of stop bits; • 1 = 1 stop bit, • 2 = 2 stop bits, • 0, 3 to 255 = reserved

1) Required setting for the use of PROFIBUS cables with CM 1241 for RS485

Instruction versions

Version 3.1 is functionally identical to version 3.0 and its version number was only incremented due to internal measures.

5.4.2.3 Modbus_Master: Communicate as Modbus master

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

The Modbus_Master instruction communicates as Modbus master via a port configured by the Modbus_Comm_Load instruction. An instance data block is automatically assigned when you add the Modbus_Master instruction in your program. The MB_DB parameter of the Modbus_Comm_Load instruction must be connected to the (static) MB_DB parameter of the Modbus_Master instruction.

Parameters

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		FALSE	FALSE = no request TRUE = request to send data to the Modbus slave
MB_ADDR	IN	UInt	Word	-	Modbus RTU station address: Standard addressing range (1 to 247 as well as 0 for Broadcast) Extended addressing range (1 to 65535 as well as 0 for Broadcast) The value 0 is reserved for the broadcast of a frame to all Modbus slaves. Only the Modbus function codes 05, 06, 15 and 16 are supported for the broadcast.
MODE	IN	USInt	Byte	0	Mode selection: Specifies the type of request (read, write or diagnostics). Additional information is available in the table of Modbus functions below.
DATA_ADDR	IN	UDInt	DWord	0	Start address in the slave: Specifies the start address of the data that is accessed in the Modbus slave. The valid addresses are listed in the table of Modbus functions below.
DATA_LEN	IN	UInt	Word	0	Data length: Specifies the number of bits or words this instruction is to access. The valid lengths are listed in the table of Modbus functions below.
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the Modbus_Master instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE. Note: The parameter is only available for S7-300/400 instructions.

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
DATA_PTR	IN/OUT	Variant	Any	-	Data pointer: Points to the flag or DB address for the data to be written or read. As of instruction version V3.0: The parameter may point to an optimized memory area. In the optimized memory area, a single element or an array is permitted with the following data types: Bool, Byte, Char, Word, Int, DWord, DInt, Real, USInt, UInt, UDInt, SInt, WChar. Every other data type results in error message 16#818C.
DONE	OUT	Bool		FALSE	The DONE bit is TRUE for one cycle after the last request has been completed without errors.
BUSY	OUT	Bool		-	• FALSE – no command active for Modbus_Master • TRUE – command for Modbus_Master in progress
ERROR	OUT	Bool		FALSE	The ERROR bit is TRUE for one cycle after the last request has been completed with errors. The error code in the STATUS parameter is only valid in the cycle in which ERROR = TRUE.
STATUS	OUT	Word		0	Error code (see Error messages (Page 151))

Tags in the data block of the Modbus master

The table below shows the public static tags in the instance DB of Modbus_Master that you can use in your program.

Table 5- 16 Static tags in the instance DB

Tag	Data type	Standard	Description
Blocked_Proc_Timeout	Real	3.0	Duration (in seconds) for which to wait for a blocked Modbus master instance before this instance is removed as ACTIVE. This may happen, for example, if a master request was output and the program then stops to call the master function before it has completely finished the request. The time value must be greater than 0 and less than 55 seconds to avoid an error to occur. See also "Rules for communication by the Modbus-Master" and "Calling theModbus_Master instruction with different parameter settings".
Extended_Addressing	Bool	FALSE	Configures the slave station address as single or double byte. • FALSE = One-byte address; 0 to 247 • TRUE = Two-byte address (corresponds to extended addressing); 0 to 65535
Compatibility_Mode [1)]	Bool	FALSE	Compatibility mode with CP 341 and CP 441-2 and ET 200SP 1SI with driver for Modbus RTU and with ET 200SP 1SI for Modbus. The default value is 0. • FALSE = as per Modbus specification, not compatible • TRUE = compatible – For FC1 and FC2: The data read from the received frame is written word for word to the addressed CPU memory and exchanged byte by byte. If the number of bits to be transmitted is not a multiple of 16, the bits which are not relevant are set to null in the last word. – For FC15: The words to be transmitted are read word by word from the addressed memory and written byte by byte to the send frame. If the number of bits to be transmitted is not a multiple of 8, the bits in the last byte which are not relevant are read unchanged from the addressed memory and entered in the send frame.
MB_DB	MB _BASE	-	The MB_DB parameter of the Modbus_Comm_Load instruction must be connected to this MB_DB parameter of the Modbus_Master instruction.

[1)] The PtP communication modules respond as defined in the Modbus specification. To retain a response as with CP 341, CP 441-2 and ET 200SP 1SI for Modbus, use the "Compatibility_Mode" parameter.

You program can write values to the Blocked_Proc_Timeout and Extended_Addressing tags to control the Modbus master operations.

Rules for communication by the Modbus-Master

- Modbus_Comm_Load must be run to configure a port so that the Modbus_Master instruction can communicate with this port.
- A port which is to be used as Modbus master must not be used by Modbus_Slave . You can use one or several instances of Modbus_Master [1)] with this port. But all versions of the Modbus_Master must use the same instance DB for the port.
- The Modbus instructions do not use communication alarm events to control the communication process. Your program must query the Modbus_Master instruction for completed commands (DONE, ERROR).
- We recommend to call all executions of Modbus_Master for a specific port from a program cycle OB. Modbus master instructions can only be executed in one program cycle or in one cyclical/time-controlled processing level. They may not be processed in different processing levels. The priority interruption of a Modbus master instruction by another Modbus master instruction in a processing level with higher priority results in improper operation. Modbus master instructions may mot be processed in startup, diagnostic or time error levels.

[1)] "Instance of Modbus master" here means a call of the Modbus_Master instruction with the same interconnection to a Modbus_Comm_Load instruction and the same setting for the MB_ADDR, MODE, DATA_ADDR and DATA_LEN parameters.

Example

Modbus_Master is called with MODE=0 and DATA_ADDR=10

This job is now active until it is completed with DONE=1 or ERROR=1 or until the time monitoring configured at the Blocked_Proc_Timeout parameter has expired. If a new command is started after the watchdog time expires and before the previous command has been completed, the previous command is aborted without an error message.

If, while this command is running, the instruction is now called a second time with the same instance data but different MODE and DATA_ADDR parameter settings, this second call is terminated with ERROR=1 and STATUS=8200.

Calling the Modbus_Master instruction with different parameter settings

If multiple calls of the Modbus_Master instruction with different settings for MB_ADDR, MODE, DATA_ADDR or DATA_LEN are placed in your program, you must ensure that only one of these calls is active at any given time. Otherwise, the error message 16#8200 is output (interface is busy with an ongoing request).

If a call cannot be processed in full, the watchdog is activated by the Blocked_Proc_Timeout parameter and terminates the ongoing command.

REQ parameter

FALSE = no request; TRUE = request to send data to the Modbus slave

Enable the requested transmission. This transmits the contents of the buffer to the point-to-point communication interface.

You use the DATA_ADDR and MODE parameters to select the Modbus function code.

DATA_ADDR (Modbus start address in the slave): Specifies the start address of the data that is accessed in the Modbus slave.

The Modbus_Master instruction uses the MODE input instead of a function code input. The combination of MODE and DATA_ADDR specifies the function code that is used in the actual Modbus frame. The table below shows how the MODE parameter, the Modbus function code and the Modbus address range in DATA_ADDR are related.

Table 5- 17 Modbus functions

MODE	DATA_ADDR (Modbus address)			DATA_LEN (data length)			Modbus function code	Operation and data		
0				Bits per request			01	Read output bits:		
	1	to	9999	1	to	2000/1992 [1]		0	to	9998
0				Bits per request			02	Read input bits:		
	10001	to	19999	1	to	2000/1992 [1]		0	to	9998
0				Words per request			03	Read hold register:		
	40001	to	49999	1	to	125/124 [1]		0	to	9998
	400001	to	465535	1	to	125/124 [1]		0	to	65534
0				Words per request			04	Read input words:		
	30001	to	39999	1	to	125/124 [1]		0	to	9998
1				Bits per request			05	Write one output bit:		
	1	to	9999	1				0	to	9998
1				1 word per request			06	Write one hold register:		
	40001	to	49999	1				0	to	9998
	400001	to	465535	1				0	to	65524
1				Bits per request			15	Write multiple output bits:		
	1	to	9999	2	to	1968/1960 [1]		0	to	9998
1				Words per request			16	Write multiple hold registers:		
	40001	to	49999	2	to	123/122		0	to	9998
	400001	to	465534	2	to	123/122 [1]		0	to	65534
2 [2]				Bits per request			15	Write one or several output bits:		
	1	to	9999	1	to	1968/1960 [1]		0	to	9998
2 [2]				Words per request			16	Write one or several hold registers:		
	40001	to	49999	1	to	123		0	to	9998
	400001	to	465535	1	to	122 [1]		0	to	65534
11	Both DATA_ADDR and DATA_LEN operands of the Modbus_Master are ignored with this function.						11	Read status word and event counter of the slave communication. The status word indicates busy (0 – not busy, 0xFFFF - busy). The event counter is incremented for each successful processing of a frame.		

MODE	DATA_ADDR (Modbus address)			DATA_LEN (data length)			Modbus function code	Operation and data		
80				1 word per request			08	Check slave status with data diagnostic code 0x0000 (loopback test – slave returns an echo of the request)		
	-			1				-		
81				1 word per request			08	Reset slave event counter using data diagnostic code 0x000A		
	-			1				-		
104				Words per request			04	Read input words		
	0	to	65535	1	to	125/124 [1]		0	to	65535
3 to 10, 12 to 79, 82 to 103, 105 to 255	-			-				Reserved		

[1] In extended addressing, see the Extended_Adressing parameter, the maximum data length is shorter by 1 byte or 1 word depending on the data type of the function.

[2] MODE 2 allows you to write one or more output bits and one or more holding registers using the Modbus functions 15 and 16.
MODE 1 uses the Modbus functions 5 and 6 to write 1 output bit and 1 holding register, and Modbus functions 15 and 16 to write multiple output bits and multiple holding registers.

DATA_PTR parameter

The DATA_PTR parameter points to the DB or bit memory address in which reading or writing is performed. If you use a data block, you must create a global data block that provides the data memory for read and write processes on Modbus slaves.

Note

S7-1200/1500 - The data block addressed using DATA_PTR must support direct addressing

The data block must permit direct (absolute) and symbolic addressing.

Note

Using function code 5

Function code 5 is used to set or delete individual bits.

When a bit is set, the value "16#FF00" must be specified in the first word of the addressed DB or bit memory area via DATA_PTR.

- With S7-1200, the value "16#0100" can also be specified to set a bit.
- To reset a bit, the value "16#0000" must be specified in the first word of the DB or bit memory area addressed via DATA_PTR.

All other values are rejected with ERROR = TRUE and STATUS = 16#8384.

Data block structures for the DATA_PTR parameter

- These data types are valid for reading words of the Modbus address range (DATA_PTR) 30001 to 39999, 40001 to 49999 and 400001 to 465535 as well as for writing words to the Modbus address range (DATA_PTR parameter) 40001 to 49999 and 400001 to 465535.
  - Standard array of data types WORD, UINT or INT
  - Named structure of the WORD, UINT or INT type in which each element has a unique name and a 16-bit data type.
  - Named complex structure in which each element has a unique name and a 16-bit or 32-bit data type.
- For reading and writing bits for the Modbus address range (DATA_PTR parameter) 00001 to 09999 and for reading bits from 10001 to 19999.
  - Standard field from Boolean data types.
  - Named Boolean structure from clearly named Boolean tags.
- It is not essential, but nevertheless advisable, to allocate each Modbus_Master instruction its own separate memory area. The reason for this is that data destruction is far more likely if multiple Modbus_Master instructions are reading and writing in the same memory area.
- It is not necessary for the data areas for DATA_PTR to be located in the same global data block. You can create a data block with several areas for Modbus read processes, a data block for Modbus write processes or a data block for each slave station.

Instruction versions

Version 3.0 is functionally identical to version 2.4 and its version number was only incremented due to internal measures.

See also

Modbus_Slave: Communicate as Modbus slave (Page 133)

5.4.2.4 Modbus_Slave

Modbus_Slave: Communicate as Modbus slave

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Description

Your program can use the Modbus_Slave instruction to communicate as a Modbus slave by using a CM (RS422/485 or RS232). STEP 7 automatically creates an instance DB when you add the instruction. The MB_DB parameter of the Modbus_Comm_Load instruction must be connected to the (static) MB_DB parameter of the Modbus_Slave instruction.

Parameters

Parameters	Declara-tion	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
MB_ADDR	IN	UInt	Word	-	Standard address of the Modbus slave: Standard addressing range (1 to 247) Extended addressing range (0 to 65535) Note: 0 is the broadcast address
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the Modbus_Slave instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE. Note: The parameter is only available for S7-300/400 instructions.

Parameters	Declara-tion	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
MB_HOLD_REG	IN/OUT	Variant	Any	-	Pointer to the Modbus hold register DB: The Modbus hold register may be the memory area of the flags or a data block. As of instruction version V4.0: The parameter must point to a memory area that has a length of at least 16 bits. A shorter length results in error message 16#8187. This applies to single elements, arrays, STRUCTs and UDTs. For example, a Single Bool or an array consisting of less than 16 Boolean elements results in the error message. If the length is not a multiple of 16 bits, the remaining bits at the end of the memory area cannot be read or written by the Modbus_Slave instruction. The parameter may point to an optimized memory area. In the optimized memory area, a single element or an array is permitted with the following data types: Bool, Byte, Char, Word, Int, DWord, DInt, Real, USInt, UInt, UDInt, SInt, WChar. Every other data type results in error message 16#818C.
NDR	OUT	Bool		FALSE	New data available: • FALSE – No new data • TRUE – Indicates that new data was written by the Modbus master The NDR bit is TRUE for one cycle after the last request has been completed without errors.
DR	OUT	Bool		FALSE	Read data: • FALSE – No data read • TRUE – Indicates that the instruction has stored the data received by the Modbus master in the target area. The DR bit is TRUE for one cycle after the last request has been completed without errors.
ERROR	OUT	Bool		FALSE	The ERROR bit is TRUE for one cycle after the last request has been completed with errors. If the execution was terminated with an error, the error code in the STATUS parameter is only valid in the cycle in which ERROR = TRUE.
STATUS	OUT	Word		0	Error code (see Error messages (Page 151))

The function codes of the Modbus communication (1, 2, 4, 5 and 15) can read and write bits and words directly in the process image input and in the process image output of the CPU. The MB_HOLD_REG parameter must be defined as data type greater than one byte for these function codes. The table below shows the sample assignment of Modbus addresses to the process image in the CPU.

Table 5- 18 Assignment of Modbus addresses to the process image

Modbus functions						**S7-1200**			
Code	**Function**	**Data area**	**Address area**			**Data area**	**CPU address**		
01	Read bits	Output	0	to	8191	Process image output	O0.0	to	O1023.7
02	Read bits	Input	0	to	8191	Process image input	I0.0	to	I1023.7
04	Read words	Input	0	to	511	Process image input	IW0	to	IW1022
05	Write bit	Output	0	to	8191	Process image output	O0.0	to	O1023.7
15	Write bits	Output	0	to	8191	Process image output	O0.0	to	O1023.7

Table 5- 19 Assignment of Modbus addresses to the process image

Modbus functions						**S7-1500 / S7-300 / S7-400**			
Function code	**Function**	**Data area**	**Address area**			**Data area**	**CPU address**		
01	Read bits	Output	0	to	9998	Process image output	O0.0	to	A1249.6
02	Read bits	Input	0	to	9998	Process image input	I0.0	to	I1249.6
04	Read words	Input	0	to	9998	Process image input	IW0	to	IW19996
05	Write bit	Output	0	to	9998	Process image output	O0.0	to	A1249.6
15	Write bits	Output	0	to	9998	Process image output	O0.0	to	A1249.6

Note

The available address area may be smaller, depending on the memory configuration of the CPU.

The function codes of the Modbus communication (3, 6, 16) use a Modbus hold register which is an address area in the memory area of the flags or a data block. The type of holding register is specified by the MB_HOLD_REG parameter of the Modbus_Slave instruction.

Note

S7-1200/1500 - type of the MB_HOLD_REG data block

The data block with Modbus hold register must permit direct (absolute) and symbolic addressing.

Table 5- 20 Diagnostics functions

Modbus diagnostic functions of the S7-1200 Modbus_Slave		
Function codes	**Subfunction**	**Description**
08	0000H	Output request data of echo test: The Modbus_Slave instruction returns the echo of a received data word to the Modbus master.
08	000AH	Clear communication event counter: The Modbus_Slave instruction clears the communication event counter used for Modbus function 11.
11		Call communication event counter: The Modbus_Slave instruction uses an internal communication event counter to detect the number of successful Modbus read and Modbus write requests that are sent to the Modbus slave. The counter is not incremented for function 8, function 11 and broadcast requests. It is also not incremented for requests that result in communication errors (for example, parity or CRC errors).

The Modbus_Slave instruction supports broadcast write requests from Modbus masters as long as the requests include access to valid addresses. Modbus_Slave generates error code 16#8188 for function codes that are not supported by the broadcast function.

Variables of the Modbus slave in instruction version V3.0

This table below shows the public static tags in the instance data block of Modbus_Slave that you can use in your program.

Table 5- 21 Variables of the Modbus slave

Tag	Data type	Standard	Description
HR_Start_Offset	Word	0	Specifies the start address of the Modbus hold register (default = 0)
QB_Start	Word	0	Start address of the valid writable addressing range of the outputs (byte 0 to 65535) Note: The variable is not available for S7-300, S7-400 and WinAC.
QB_Count	Word	0xFFFF	Number of output bytes that can be written by the Modbus master. Note: The variable is not available for S7-300, S7-400 and WinAC.
Extended_Addressing	Bool	FALSE	Extended addressing, configures slave addressing as single or double byte (FALSE = single byte address, TRUE = double byte address)
Request_Count	Word	0	The number of all requests received by this slave
Slave_Message_Count	Word	0	The number of requests received for this specific slave
Bad_CRC_Count	Word	0	The number of received requests that have a CRC error
Broadcast_Count	Word	0	The number of received broadcast requests
Exception_Count	Word	0	Modbus-specific errors that are acknowledged with an exception to the master
Success_Count	Word	0	The number of received requests without protocol errors for this specific slave
MB_DB	MB _BASE	-	The MB_DB parameter of the Modbus_Comm_Load instruction must be connected to this MB_DB parameter of the Modbus_Master instruction.

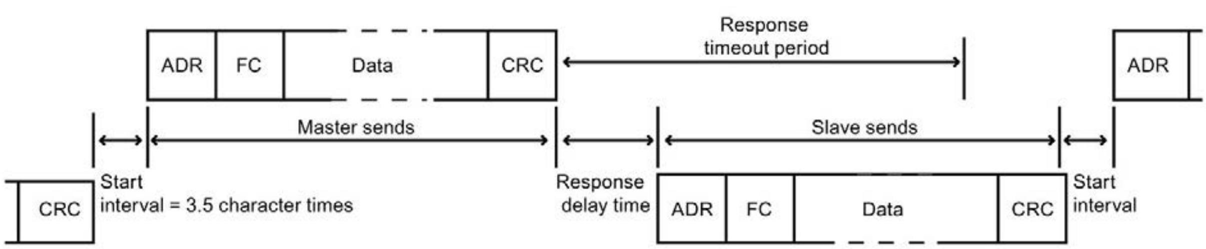
You program can write values to the HR_Start_Offset and Extended_Addressing tags and control the Modbus slave operations. The other tags can be read to monitor the Modbus status.

Rules for Modbus slave communication

- Modbus_Comm_Load must be run to configure a port so that the Modbus_Slave instruction can communicate by means of this port.
- If a port is to respond as slave to a Modbus master, this port may not be programmed with the Modbus_Master instruction.
- Only one instance of Modbus_Slave can be used with a specific port; otherwise you may encounter unexpected behavior.
- The Modbus instructions do not use communication alarm events to control the communication process. Your program must control the communication process by querying the Modbus_Slave instruction for completed send and receive processes.
- The Modbus_Slave instruction must be executed regularly with a frequency that allows a timely response to incoming requests of a Modbus master. We recommend executing Modbus_Slave in each cycle from a program cycle OB. Modbus_Slave can be executed from a cyclic interrupt OB but we do not recommend it, because excessive time delays in the interrupt program can temporarily block the execution of other interrupt programs.

Time control of the Modbus signal

Modbus_Slave must be executed regularly to receive each request of the Modbus master and respond accordingly. The frequency with which Modbus_Slave is executed depends on the timeout value specified for the response by the Modbus master. This can be seen in the figure below.



The timeout period of the (RESP_TO) response is the duration that a Modbus master waits for the beginning of an answer from a Modbus slave. This period is not defined by the Modbus protocol, but by a parameter of the Modbus_Comm_Load instruction. As both receiving and sending a frame requires multiple calls of the Modbus_Slave instruction (at least three), you should execute Modbus_Slave at least twelve times during the timeout period for the response of the Modbus master so that the Modbus slave receives and sends data twice as many times as specified by the timeout period.

HR_Start_Offset

The Modbus holding register addresses start at 40001 or 400001. These addresses correspond to the start address of the holding register in the target system memory. But you can configure the HR_Start_Offset tag to configure a start address different than 40001 or 400001 for the Modbus hold register.

The address 0 in the received frame correspond to the start address of the hold register in the target system memory. Use the tag HR_Start_Offset to configure a start address other than 0 for the Modbus hold register.

You can, for example, configure a hold register with start at MW100 and a length of 100 words. With HR_Start_Offset = 20, the address 20 in the received frame corresponds to the start address of the holding register in the target memory (MW100). Each address in the received frame below 20 and above 119 results in an addressing error.

Table 5- 22 Example for addressing the Modbus hold register when DATA_PTR is a pointer to MW100 with a length of 100 words

HR_Start_Offset	Address	Minimum	Maximum
0	Modbus address (word)	0	99
	S7-1500 address	MW100	MW298
20	Modbus address (word)	20	119
	S7-1500 address	MW100	MW298

HR_Start_Offset is a word value which specifies the start address of the Modbus hold register and is saved in the Modbus_Slave instance data block. You select this public static tag by means of the parameter drop-down list once you have added Modbus_Slave in your program.

If you have added Modbus_Slave to an LAD network, for example, you can go to a previous network and assign the value HR_Start_Offset using the move command. The value must be assigned prior to execution of Modbus_Slave.

Enter Modbus slave tag using the standard DB name:

1. Position the cursor in the OUT1 parameter field and enter the character m.
2. Select the required instance DB of the Modbus_Slave instruction from the drop-down list.
3. Position the cursor to the right of the DB name (after the quotation mark) and enter a point.
4. Select "Modbus_Slave_DB.HR_Start_Offset" in the drop-down list.

Instruction versions

Version 4.0 is functionally identical to version 3.0 and its version number was only incremented due to internal measures.

Access to data areas in DBs instead of direct access to MODBUS addresses as of version V5.0

Access to data areas in DBs instead of direct access to MODBUS addresses as of version V4.0

As of instruction version V4.0 of Modbus_Slave and as of firmware versions V2.5 (S7-1500 CPUs) or V4.2 (S7-1200 CPUs), you can access data areas in DBs instead of directly accessing process images and holding registers. In doing so, the attribute "Optimized block access" must be disabled for the DB and it must not be located solely in the load memory.

If a MODBUS request arrives and you have not defined a data area for the MODBUS data type of the corresponding function code, the request is treated as in the previous instruction versions, i.e. process images and holding registers are accessed directly.

If you have defined a data area for the MODBUS data type of the function code, however, the Modbus_Slave instruction reads from this data area or writes to it. Whether it reads or writes depends on the job type.

One individual MODBUS request can only ever be read from or written to one data area. If, for example, you want to read holding registers that extend over multiple data areas, you therefore require multiple MODBUS requests.

Rules for defining data areas

You can define up to eight data areas in different DBs; each DB must only contain one data area. An individual MODBUS request can only ever read from precisely one data area or write to precisely one data area. Each data area corresponds to one MODBUS address area. The data areas are defined in the static tag Data_Area_Array of the instance DB; Data_Area_Array is a field consisting of eight elements.

If you want to use less than eight data areas, the required data areas must be located one behind the other without any gaps. The first blank entry in the data areas ends the data area search during processing. If, for example, you have defined the field elements 1, 2, 4 and 5, only field elements 1 and 2 will be recognized as field element 3 is empty.

The Data_Area_Array field consists of 8 elements: Data_Area_Array[1] to Data_Area_Array[8]

Each field element Data_Area_Array[x], 1 <= x <= 8, is a UDT of the type MB_DataArea and is structured as follows:

Parameter	Data type	Meaning
Data _type	UInt	Identifier for the MODBUS data type that is mapped to this data area: • 0: Identifier for an empty field element or an unused data area. In this case, the values of db, start and length are irrelevant. • 1: Process image output (used with function codes 1, 5 and 15) • 2: Process image input (used with function code 2) • 3: Holding register (used with function codes 3, 6 and 16) • 4: Input register (used with function code 4) Note: If you have defined a data area for a MODBUS data type, the instruction MB_SERVER can no longer access this MODBUS data type directly. If the address of a MODBUS request for such a data type does not correspond to a defined data area, a value of W#16#8383 is returned in STATUS.

Parameter	Data type	Meaning
db	UInt	Number of the data block to which the MODBUS register or bits subsequently defined are mapped. The DB number must be unique in the data areas. The same DB number must not be defined in multiple data areas. The DB must have standard access and must not be located solely in the load memory. Data areas also start with the byte address 0 of the DB. Permitted values: 1 to 60999
start	UInt	First MODBUS address that is mapped to the data block starting from address 0.0. Permitted values: 0 to 65535
length	UInt	Number of bits (for the values 1 and 2 of data_type) or number of registers (for the values 3 and 4 of data_type). The MODBUS address areas of one and the same MODBUS data type must not overlap. Permitted values: 1 to 65535

Examples of the definition of data areas

- First example: data_type = 3, db = 1, start = 10, length = 6

  The holding registers (data_type = 3) are mapped in data block 1 (db = 1). The Modbus address 10 (start = 10) is located at data word 0. The last valid Modbus address 15 (length = 6) is located at data word 5.

- Second example: data_type = 2, db = 15, start = 1700, length = 112

  The inputs (data_type = 2) are mapped in data block 15 (db = 15). The Modbus address 1700 (start = 1700) is located at data word 0. The last valid Modbus address 1811 (length = 112) is located at data word 111.

Restriction of read access to process images as of version V5.0

Restriction of read access to process images

As of instruction version V4.0 of Modbus_Slave, you can define one area each in the process image of the inputs and in the process image of the outputs to which remote MODBUS devices have read access. Read access by remote MODBUS devices to addresses outside these process image areas is then no longer possible.

Note

Restriction of write access to process images

The option for restricting write access to the process image of the outputs to a specific area is available as of instruction version V3.0.

Definition of read areas in the process images

Read areas in the process images are defined in the following static tags of the instance DB:

- QB_Read_Start: Address of the first byte in the process image output that can be read by a remote MODBUS device (applies to function code 1)
- QB_Read_Count: Number of bytes in the process image output that can be read by a remote MODBUS device (applies to function code 1)
- IB_Read_Start: Address of the first byte in the process image input that can be read by a remote MODBUS device (applies to function codes 2 and 4)
- IB_Read_Count: Number of bytes in the process image input that can be read by a remote MODBUS device (applies to function codes 2 and 4)

Static tags in the instance DB for defining write and read areas in the process images

The following table describes the static variables listed above in the instance DB of the Modbus_Slave instruction that you use to define the read areas in the process images.

For the sake of completeness, the static variables with which you define the write areas in the process images (QB_Start and QB_Count) as of version V3.0 are also specified.

Tag	Data type	Start value
QB_Start	UInt	0
QB_Count	UInt	65535
QB_Read_Start	UInt	0
QB_Read_Count	UInt	65535
IB_Read_Start	UInt	0
IB_Read_Count	UInt	65535

5.4.2.5 Frame structure

Extended_Addressing

You access the Extended_Addressing tag as described for the HR_Start_Offset reference, except that the Extended_Addressing tag is a Boolean value.

You can configure a single byte (Modbus standard) or two bytes (Extended_Adressing = TRUE) with Extended_Adressing = FALSE for addressing the Modbus slave. Extended addressing is used to address more than 247 devices in a single network. With Extended_Adressing = TRUE you can address up to 65535 addresses. The following example shows a Modbus frame.

Table 5- 23 Slave address with one byte (Byte 0)

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	
Request	Slave address	Function code	Start address		Data		
Valid response	Slave address	Function code	Length	Data...			
Error message	Slave address	0xxx	Exception code				

Table 5- 24 Slave address with two bytes (Byte 0 and Byte 1)

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Request	Slave address		Function code	Start address		Data	
Valid response	Slave address		Function code	Length	Data...		
Error message	Slave address		0xxx	Exception code			

Frame description

Data traffic between master and slave / slave and master starts with the slave address, following by the function code. The data is then transferred. The structure of the data field depends on the function code used. The checksum (CRC) is transmitted at the end of the frame.

Function code 1 - This function allows individual output bits to be read

Table 5- 25 FC 1 - Read output bits

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 1	Start address		Number of outputs	
Valid response	Slave address	Function code 1	Length [1]	Output data [3)]		
Error message	Slave address	0x81	Exception code [2]	---		

[1] Length: If there is a remainder when the number of outputs is divided by 8, the number of bytes must be increased by 1.

[2] E code: 01 or 02 or 03 or 04

[3] The output data can comprise multiple bytes

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 1	Start address		Number of outputs	
Valid response	Slave address		Function code 1	Length [1]	Output data		
Error message	Slave address		0x81	Exception code [2]	---		

[1] Length: If there is a remainder when the number of outputs is divided by 8, the number of bytes must be increased by 1.

[2] E code: 01 or 02 or 03 or 04

[3] The output data can comprise multiple bytes

Function code 2 - This function allows individual input bits to be read

Table 5- 26 FC 2 - Read input bits

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 2	Start address		Number of inputs	
Valid response	Slave address	Function code 2	Length [1]	Input data		
Error message	Slave address	0x82	Exception code [2]	---		

[1] Length: If there is a remainder when the number of inputs is divided by 8, the number of bytes must be increased by 1.

[2] E code: 01 or 02 or 03 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 2	Start address		Number of inputs	
Valid response	Slave address		Function code 2	Length [1]	Input data		
Error message	Slave address		0x82	Exception code [2]	---		

[1] Length: If there is a remainder when the number of inputs is divided by 8, the number of bytes must be increased by 1.

[2] E code: 01 or 02 or 03 or 04

Function code 3 - This function allows individual registers to be read

Table 5- 27 FC 3 - Read hold register

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 3	Start address		Number of registers	
Valid response	Slave address	Function code 3	Length [1]	Register data		
Error message	Slave address	0x83	Exception code [2]	---		

[1] Length: Number of bytes

[2] E code: 01 or 02 or 03 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 3	Start address		Number of registers	
Valid response	Slave address		Function code 3	Length [1]	Register data		
Error message	Slave address		0x83	Exception code [2]	---		

[1] Length: Number of bytes

[2] E code: 01 or 02 or 03 or 04

Function code 4 - This function allows individual registers to be read

Table 5- 28 FC 4 - Read input words

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 4	Start address		Number of input words	
Valid response	Slave address	Function code 4	Length [1]	Input data		
Error message	Slave address	0x84	Exception code [2]	---		

[1] Length: 2 * number of input words

[2] E code: 01 or 02 or 03 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 4	Start address		Number of input words	
Valid response	Slave address		Function code 4	Length [1]	Input data		
Error message	Slave address		0x84	Exception code [2]	---		

[1] Length: 2 * number of input words

[2] E code: 01 or 02 or 03 or 04

Function code 5 - This function can set or delete individual bits

Table 5- 29 FC 5 - Write an output bit

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 5	Start address		Value	
Valid response	Slave address	Function code 5	Length	Value		
Error message	Slave address	0x85	Exception code [1]	---		

[1] E code: 01 or 02 or 03 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 5	Start address		Value	
Valid response	Slave address		Function code 5	Length	Value		
Error message	Slave address		0x85	Exception code [1]	---		

[1] E code: 01 or 02 or 03 or 04

Function code 6 - This function allows individual registers to be written

Table 5- 30 FC 6 - Write hold register

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 6	Address		Register	
Valid response	Slave address	Function code 6	Address		Register	
Error message	Slave address	0x86	Exception code [1]	---		

[1] E code: 01 or 02 or 03 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 6	Address		Register	
Valid response	Slave address		Function code 6	Address		Register	
Error message	Slave address		0x86	Exception code [1]	---		

[1] E code: 01 or 02 or 03 or 04

Function code 8 - This function is used to check the communication connection

Table 5- 31 FC 8 - Slave status

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 8	Diagnostic code		Test value	
Valid response	Slave address	Function code 8	Diagnostic code		Test value	
Error message	Slave address	0x88	Exception code [1]	---		

[1] E code: 01 or 03 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 8	Diagnostic code		Test value	
Valid response	Slave address		Function code 8	Diagnostic code		Test value	
Error message	Slave address		0x88	Exception code [1]	---		

[1] E code: 01 or 03 or 04

Function code 11 - This function can read 2 bytes of "Status word" and 2 bytes of "Event counter"

Table 5- 32 FC 11 - Event counter for slave communication

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5
Query	Slave address	Function code 11	---			
Valid response	Slave address	Function code 11	Status		Event counter	
Error message	Slave address	0x8B	Exception code [1]	---		

[1] E code: 01 or 04

	Byte 0	Byte 1	Byte 2	Byte 3	Byte 4	Byte 5	Byte 6
Query	Slave address		Function code 11	---			
Valid response	Slave address		Function code 11	Status		Event counter	
Error message	Slave address		0x8B	Exception code [1]	---		

[1] E code: 01 or 04

Function code 15 - This function allows multiple bits to be written

Table 5- 33 FC 15 - Write one/multiple output bits

<table>
<tr><th></th><th>Byte 0</th><th>Byte 1</th><th>Byte 2</th><th>Byte 3</th><th>Byte 4</th><th>Byte 5</th><th>Byte 6</th><th>Byte 7</th><th>Byte n</th></tr>

5.4.2.6 Error messages

Overview of error messages - PtP

The error messages are provided at the STATUS output of an instruction and can be evaluated there or processed in the user program.

Error code	Description	Remedy
16#0000	No error	-
RECEIVE status and error codes		
16#0094	frame end identified based on the "Receipt of fixed/maximum frame length"	-
16#0095	frame end identified based on "Message timeout"	-
16#0096	frame end identified based on expiration of the "Character delay time"	-
16#0097	The frame was aborted because the maximum response time was reached.	-
16#0098	frame end identified based on the fulfillment of the "Read message length from message" conditions	-
16#0099	frame end identified based on the receipt of the "End sequence"	-
SEND status and error codes		
16#7000	Block idle	-
16#7001	Initial call for a new frame: Data transmission initiated	-
16#7002	Interim call: Data transmission running	-
16#8085	Invalid length	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (Byte)
16#8088	The specified length exceeds the range set in the receive buffer. Note: If the data type STRING has been specified at the BUFFER parameter, this error code also appears if the current string is shorter than the length specified at the LENGTH parameter.	Change the range in the receive buffer or select a frame length which corresponds to the range set in the receive buffer. The following are valid (depending on the module): 1-1024/2048/4096 (bytes)
16#8090	Configuration error: Odd number of bytes for WString	Select an even number of bytes.
RECEIVE status and error codes		
16#7002	Interim call: Data transmission running	-
16#8088	The number of characters received exceeds the number specified at the BUFFER parameter.	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (bytes)
16#8090	Configuration error: Odd number of bytes for WString	Select an even number of bytes.

Error code	Description	Remedy
Error message codes of the special functions		
16#818F	Incorrect parameter number setting (with USS only)	Select a suitable parameter number (PARAM). The following numbers are valid: 0-2047
16#8190	Incorrect setting of the CRC calculation	Select a suitable value for the CRC calculation. The following are valid: deactivated or activated. Check whether the module addressed supports CRC calculation.
16#8191	Incorrect setting of the diagnostic error interrupt	Select a suitable value for "Diagnostic error interrupt". The following are valid: Diagnostic error interrupt deactivated or diagnostic error interrupt activated. Check whether the module addressed supports the generation of diagnostic interrupts.
16#8193	The module does not support supply voltage diagnostics L+.	Select a suitable value for "Diagnostic interrupt". The following are permitted: Diagnostic interrupt deactivated or diagnostic interrupt activated. Check whether the module addressed supports the generation of diagnostic interrupts.
Error message codes of the "Port configuration"		
16#81A0	The module does not support this protocol.	Select a valid protocol for the module (PROTOCOL).
16#81A1	The module does not support this data transmission rate.	Select a valid data transmission rate for the module (BAUD).
16#81A2	The module does not support this parity setting.	Select a suitable value for "Parity" (PARITY). The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
16#81A3	The module does not support this number of data bits.	Select a suitable value for "Number of data bits" (DATABITS). The following are valid: • 7 (2) • 8 (1)
16#81A4	The module does not support this number of stop bits.	Select a suitable value for "Number of stop bits" (STOPBITS). The following are valid: • 1 (1) • 2 (2)
16#81A5	The module does not support this type of data flow control.	Select a valid data flow control for the module (FLOWCTRL).

Error code	Description	Remedy
16#81A7	Invalid value for XON or XOFF	Select suitable values for XON (XONCHAR) and XOFF (XOFFCHAR). Valid range of values: 0...255
16#81AA	Invalid operating mode	Valid operating modes are: • Full duplex (RS232) (0) • Full duplex (RS422) four-wire mode (point-to-point) (1) / (CM PtP (ET 200SP)) • Full duplex (RS422) four-wire mode (multipoint master) (2)/ (CM PtP (ET 200SP)) • Full duplex (RS 422) four-wire mode (multipoint slave) (3) • Half duplex (RS485) two-wire mode. (4)
16#81AB	Invalid receive line initial state	Valid initial states are: • "No" default setting (0) • Signal R(A)=5 V, signal R(B)=0 V (break detection) (1): Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • Signal R(A)=0 V, signal R(B)=5 V (2): This default setting corresponds to the idle state (no active send operation).
16#81AC	Invalid value for "Break detection"	Select a suitable value for "Break detection". The following are valid: • Break detection deactivated (0) • Break detection activated (1).
16#81AF	The module does not support this protocol.	Select a valid protocol for the module.
Error codes of the "Send configuration"		
16#81B5	More than two end delimiters or end sequence > 5 characters	Select suitable values for "End delimiter" and "End sequence". The following are valid: • deactivated (0), • 1 (1) or 2 (2) end delimiters or • deactivated (0), • 1 (1) up to 5 (5) characters for the end sequence.
16#81B6	Send configuration rejected because the 3964(R) protocol was selected	Make sure that no send configuration is transmitted if the 3964(R) protocol is set.

Error code	Description	Remedy
Error codes of the "Receive configuration"		
16#81C0	Invalid start condition	Select a suitable start condition. The following are valid: • Send break before frame start • Send Idle Line.
16#81C1	Invalid end condition or no end condition selected	Select a suitable end condition (see Receiving data with Freeport (Page 41)).
16#81C3	Invalid value for "Maximum message length"	Select a suitable value for "Maximum message length" (MAXLEN). Valid range of values (depending on the module): 1-1024/2048/4096 (Byte)
16#81C4	Invalid value for "Offset of the length specification in the message"	Select a suitable value for "Offset of the length specification in the message". Valid range of values (depending on the module): 1-1024/2048/4096 (Byte)
16#81C5	Invalid value for "Size of length field"	Select a suitable value for "Size of length field" (LENGTHSIZE). Valid range of values in bytes: • 1 (1) • 2 (2) • 4 (4)
16#81C6	Invalid value for "Number of characters not counted in length specification"	Select a suitable value for "Number of characters not counted in length specification" (LENGTHM). Valid range of values: 0 to 255 (bytes)
16#81C7	The total of "Offset in the message + size of length field + number of characters not counted" is greater than the maximum frame length	Select a suitable value for "Offset in message", "Size of length field" and "Number of characters not counted". Valid range of values: • Offset in the message (depending on the module): 0-1024/2048/4096 (bytes) • Size of length field: 1, 2, or 4 (bytes) • Number of characters not counted: 0 to 255 (bytes)
16#81C8	Invalid value for "Response timeout"	Select a suitable value for "Response timeout". Valid range of values: 1-65535 (ms)
16#81C9	Invalid value for "Character delay time"	Select a suitable value for "Character delay time". Valid range of values: 1 to 65535 (bit times)
16#81CB	frame end sequence is activated, but no character is activated for the check	Activate one or several characters for the check.
16#81CC	frame start sequence is activated, but no character is activated for the check	Activate one or several characters for the check.

Error code	Description	Remedy
16#81CD	Invalid value for "Prevent overwriting"	Select a suitable value for "Prevent overwriting". The following are valid: • Prevent overwriting is deactivated (0) or • Prevent overwriting is activated (1)
16#81CE	Invalid value for "Clear receive buffer on startup"	Select a suitable value for "Clear receive buffer on startup". The following are valid: • Clear receive buffer at startup is deactivated (0) • Clear receive buffer at startup is activated (1)
SEND status and error codes		
16#81D0	Receiving send request during runtime of a send command	Make sure that you do not receive an additional send request during runtime of a send command.
16#81D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or change the parameters, if necessary.
16#81D2	"Hardware RTS always ON": Send job canceled due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ON for the entire duration of transmission.
16#81D3	Send buffer overflow / send frame too long	Select a shorter frame length. The following are valid (depending on the module): 1 to 1024/2048/4096 (bytes)
16#81D5	Transmission canceled due to parameter changes, detected wire break, or CPU in STOP	Check the parameter assignment, wire break, and CPU status.
16#81D6	Transmission canceled because end identifier was not received	Check the parameter assignment of the end charac-ters and the frame of the communication partner.
16#81D7	Communication error between the user program and module	Check the communication (e.g., matching the se-quence number).
16#81D8	Transmission attempt rejected because module is not configured	Configure the module.
16#81DF	The module has reset the interface to the FB for one of the following reasons: • Module was restarted • Module parameters were reassigned • CPU STOP	—
Error codes of the receive configuration		
16#81E0	Frame aborted: Send buffer overflow / send frame too long	Increase the call rate for the receive function in the user program or configure communication with data flow control.
16#81E1	Frame aborted: Parity error	Check the connection line of the communication partners, or verify that the same data transmission rate, parity and stop bit number are configured for both devices.
16#81E2	Frame aborted: Character frame error	Check the settings for start bit, data bits, parity bit, data transmission rate, and stop bit(s).
16#81E3	Frame aborted: Character overflow error	Firmware error: Please contact Customer Support.

Error code	Description	Remedy
16#81E4	Frame aborted: The total length of "Offset in the message + size of the length field + number of characters not counted" is greater than the receive buffer	Select a suitable value for offset in message, size of the length field, and number of characters not counted.
16#81E5	Frame aborted: Break	Receive line to partner is interrupted. Reconnect or switch on partner.
16#81E6	Maximum number of "Buffered received frames" exceeded	In the user program call the instruction more often or configure a communication with data flow control or increase the number of buffered frames.
16#81E7	Synchronization error module and Receive_P2P	Make sure that different instances of the Receive_P2P do not access the same module.
16#81E8	Frame aborted: The character delay time has expired before the message end criterion was detected	Partner device faulty or too slow. Check this, if required, using an interface tester that is interconnected in the transmission line.
16#81E9	Modbus CRC error (only communication modules which support Modbus)	Checksum error of the Modbus frame. Check the communication partner.
16#81EA	Modbus frame too short (only communication modules which support Modbus)	Minimum length of Modbus frame not met. Check the communication partner.
16#81EB	Frame aborted: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1-1024/2048/4096 (bytes) Check the parameters for end of frame detection.
Error codes V24 accompanying signals		
16#81F0	The module does not support V24 accompanying signals	You have tried to set accompanying signals for a module that does not support V24 accompanying signals. Make sure that this is an RS232 module or that RS232 mode (ET 200SP) is set.
16#81F1	No operation of the V24 accompanying signals	The V24 accompanying signals cannot be operated manually if hardware data flow control is active.
16#81F2	The DSR signal cannot be set because the module has the type DTE.	Check the configured type of the module. The module type must be DCE (data communication equipment).
16#81F3	The DTR signal cannot be set because the module has the type DCE.	Check the configured type of the module. The module type must be DTE (data terminal equipment).
16#81F4	Block header error (e.g. incorrect block type or incorrect block length)	Check the instance DB and the block header.

Error code	Description	Remedy
Error codes of the receive configuration		
16#8201 [1)]	Receive_Conditions is a pointer to an invalid data type	Enter a pointer to one of the following data types: DB, BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL, DATE, TIME_OF_DAY, TIME, S5TIME, DATE_AND_TIME, STRING
16#8225	Receive_Conditionspoints to an optimized memory area greater than 1 kB or Receive_Conditions points to an optimized memory area and the receive length is greater than the area addressed by Receive_Conditions.	Enter a pointer to an area with a maximum length of: • Optimized memory area: 1 KB • Non-optimized memory area: 4 KB Note: If the pointer points to an optimized memory area, do not send more than 1 KB.
16#8229 [1)]	Receive_Conditions is a pointer to BOOL with a number of bits not equal to n * 8	If you are using a pointer to BOOL, the number of bits must be a multiple of 8.
Error codes, general		
16#8280	Negative acknowledgment when reading module	You can find more detailed information on error causes in theRDREC.STATUS static parameters and in the description of the SFB RDREC. • Check the input at the PORT parameter • Set the COM_RST parameter before the 1st call.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter You can find more detailed information on error causes in the WRREC.STATUS static parameters and in the description of the SFB WRREC.
16#8282	Module not available	Check the input at the PORT parameter and ensure that the module can be reached.
Error codes of the receive configuration		
16#82C1	Invalid value for "Buffered received frames".	Select a suitable value for "Buffered received frames". Valid range of values: 1-255
16#82C2	Receive configuration rejected because the 3964(R) protocol was selected	Make sure that no receive configuration is sent if the 3964(R) protocol is set.
16#8301 [1)]	Receive_Conditions is a pointer to an invalid data type	Select a valid data type. The following are valid: DB, BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL, DATE, TIME_OF_DAY, TIME, S5TIME, DATE_AND_TIME, STRING
16#8322	Range length error when reading a parameter	Check the input at the Receive_Conditions parameter
16#8324	Range error when reading a parameter	Check the input at the Receive_Conditions parameter
16#8328	Setting error when reading a parameter	Check the input at the Receive_Conditions parameter

Error code	Description	Remedy
SEND status and error codes		
16#8328 1)	BUFFER is a pointer to BOOL with a number of bits not equal to n * 8	If you are using a pointer to BOOL, the number of bits must be a multiple of 8.
Error codes of the receive configuration		
16#8332	Invalid data block at the Receive_Conditions parameter	Check the input at the Receive_Conditions parameter
16#833A	The designation of the data block at the Receive_Conditions parameter refers to a data block which is not loaded.	Check the input at the Receive_Conditions parameter
16#8351	Invalid data type	Check the input at the Receive_Conditions parameter
16#8352 1)	Receive_Conditions does not point to a data block	Check the pointer to Receive_Conditions
16#8353 1)	Receive_Conditions does not point to a structure of the typeReceive_Conditions	Check the pointer to Receive_Conditions
Error codes 3964(R) protocol		
16#8380	Parameter assignment error: Invalid value for "Character delay time".	Select a suitable value for "Character delay time" (CharacterDelayTime). Valid range of values: 1 to 65535 (ms)
16#8381	Parameter assignment error: Invalid value for "Response timeout".	Select a suitable value for "Response timeout" (AcknDelayTime). Valid range of values: 1 to 65535 (ms)
16#8382	Parameter assignment error: Invalid value for "Priority".	Select a suitable value for "Priority" (Priority). The following are valid: • High (1) • Low (0)
16#8383	Parameter assignment error: Invalid value for "Block check"	Select a suitable value for "Block check" (BCC). The following are valid: • With block check (1) • Without block check (0)
16#8384	Parameter assignment error: Invalid value for "Connection attempts".	Select a suitable value for "Connection attempts" (BuildupAttempts). Valid range of values: 1-255
16#8385	Parameter assignment error: Invalid value for "Transmission attempts".	Select a suitable value for "Transmission attempts" (RepetitionAttempts). Valid range of values: 1-255
16#8386	Runtime error: Number of connection attempts exceeded	Check the interface cable and the transmission parameters. Also check whether the receive function is configured correctly at the partner device.
16#8387	Runtime error: Number of transmission attempts exceeded	Check the interface cable, the transmission parameters and the configuration of the communication partner.

Error code	Description	Remedy
16#8388	Runtime error: Error at the "Block check character" The internally calculated value of the block check character does not correspond to the block check character received by the partner at the connection end.	Check whether the connection is seriously disrupted; in this case you may also occasionally see error codes. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#8389	Runtime error: Invalid character received while waiting for free receive buffer	The send request of the communication partner (STX, 02H) is only answered with DLE when the receive buffer is empty. No additional character may be received before (except STX again). Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#838A	Runtime error: Logical error during receiving. After DLE was received, a further random character (other than DLE or ETX) was received.	Check if partner DLE in frame header and in data string is always in duplicate or the connection is released with DLE ETX. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#838B	Runtime error: Character delay time exceeded	Partner device too slow or faulty. Verify by using an interface test device that is switched into the transmission line, if necessary.
16#838C	Runtime error: Wait time for free receive buffer has started	In the user program call the instruction more often or configure a communication with data flow control.
16#838D	Runtime error: frame repetition does not start within 4 s after NAK	Check the communication partner. A received frame that is possibly corrupted must be repeated by the partner within 4 seconds.
16#838E	Runtime error: In idle mode, one or several characters (other than NAK or STX) were received.	Check for proper function of the partner device, possibly using an interface test device that is switched into the transmission line.
16#838F	Runtime error: Initialization conflict - Both partners have set high priority	Set the "Low" priority at one of the partners
16#8391	Parameter assignment error: 3964 configuration data rejected because Freeport is set	If the Freeport protocol is set, make sure that no 3964 parameter assignment data is sent.

Overview of error messages - Modbus

Error code	Description	Remedy
16#0000	No error	-
Configuration error of the interface - Modbus_Comm_Load		
16#8181	The module does not support this data transmission rate.	Select a valid data transmission rate for the module at the BAUD parameter.
16#8182	The module does not support this parity setting.	Select a suitable value for "Parity" at the PARITY parameter. The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
16#8183	The module does not support this type of data flow control.	Select a valid data flow control for the module at the FLOW_CTRL parameter.
16#8184	Invalid value for "Response timeout".	Select a suitable value for "Response timeout" at the RESP_TO parameter. Valid range of values: 1 to 65535 (ms)
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the Send_Config.RDREC.STATUS or Receive_Config.RDREC.STATUS static parameters or RDREC.STATUS and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the Send_Config.WRREC.STATUS or Receive_Config.WRREC.STATUS static parameters or WRREC.STATUS and in the description of the SFB WRREC.
16#8282	Module not available	Check the input at the PORT parameter and ensure that the module can be reached.

Error code	Description	Remedy
Configuration error - Modbus_Slave		
16#8186	Invalid slave address	Select a suitable slave address at the MB_ADDR parameter. The following are valid: 1-247 at standard address area; 1-65535 at extended address area (0 is reserved for Broadcast)
16#8187	Invalid value at MB_HOLD_REG parameter	Select a suitable value for the hold register at the MB_HOLD_REG parameter.
16#8188	Invalid operating mode or broadcast (MB_ADDR = 0) and MODE parameter ≠ 1	Select the value 1 for MODE in Broadcast mode or select a different operating mode.
16#818C	The pointer to a MB_HOLD_REG area must be a data block or a bit memory address area.	Select a suitable value for the pointer to the MB_HOLD_REG area.
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.WRREC.STATUS or Receive_P2P.WRREC.STATUS, and in the description of the SFB WRREC.
16#8452 [1)]	MB_HOLD_REG is not a pointer to a DB or a bit memory area	Check the MB_HOLD_REG pointer
16#8453 [1)]	MB_HOLD_REG is not a pointer of type BOOL or WORD	Check the MB_HOLD_REG pointer
16#8454 [1)]	The area addressed by MB_HOLD_REG is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the MB_HOLD_REG pointer
16#8455 [1)]	MB_HOLD_REG points to a write-protected DB	Check the MB_HOLD_REG pointer
16#8456 [1)]	Error during instruction execution. The cause of the error is shown in the STATUS parameter.	Determine the value of the SFCSTATUS parameter. Check what this means in the description for SFC51, STATUS parameter.

Error code	Description	Remedy
Configuration error - Modbus_Master		
16#8180	Invalid value for MB_DB parameter	The value configured for MB_DB (instance data DB) at the Modbus_Comm_Load instruction is not valid. Check the interconnection of the Modbus_Comm_Load instruction and its error messages.
16#8186	Invalid station address	Select a suitable station address at the MB_ADDR parameter. The following are valid: 1-247 at standard address area; 1-65535 at extended address area (0 is reserved for Broadcast)
16#8188	Invalid operating mode or broadcast (MB_ADDR = 0) and MODE parameter ≠ 1	Select the value 1 for MODE in Broadcast mode or select a different operating mode.
16#8189	Invalid data address	Select a suitable value for the data address at the DATA_ADDR parameter. See description Modbus_Master (Page 125) in the Info system
16#818A	Invalid length	Select a suitable data length at the DATA_LEN parameter. See description Modbus_Master (Page 125) in the Info system
16#818B	Invalid value for DATA_PTR	Select a suitable value for the data pointer at the DATA_PTR parameter (M or DB address). See description Modbus_Master (Page 125) in the Info system
16#818C	Interconnection error of the DATA_PTR parameter	Check the interconnection of the instruction.
16#818D	The area addressed by DATA_PTR is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the DATA_PTR pointer
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.WRREC.STATUS or Receive_P2P.WRREC.STATUS or Receive_Reset and in the description of the SFB WRREC.

Error code	Description	Remedy
Communication errors - Modbus_Master and Modbus_Slave		
16#80D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or change the parameters, if necessary.
16#80D2	"Hardware RTS always ON": Send job canceled due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ON for the entire duration of transmission.
16#80E0	Frame aborted: Send buffer overflow / send frame too long	In the user program call the instruction more often or configure a communication with data flow control.
16#80E1	Frame aborted: Parity error	Check the connection line of the communication partners, or verify that the same data transmission rate, parity and stop bit number are configured for both devices.
16#80E2	Frame aborted: Character frame error	Check the settings for start bit, data bits, parity bit, data transmission rate, and stop bit(s).
16#80E3	Frame aborted: Character overflow error	Check the number of data in the frame of the communication partner.
16#80E4	Frame aborted: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1 to 1024/2048/4096 (bytes)
Communication error - Modbus_Master		
16#80C8	The slave does not respond within the set time	Check the data transmission rate, parity and wiring of the slave.
16#80C9	The slave does not respond within the time set by Blocked_Proc_Timeout.	Check the setting for Blocked_Proc_Timeout. Check if the module has been configured with the Modbus_Comm_Load instruction. The module may possibly need to be reconfigured using Modbus_Comm_Load after a pull/plug or after voltage recovery.
16#8200	The interface is busy with an ongoing request.	Repeat the command later. Make sure that there are no commands still running before you start a new one.
Protocol error - Modbus_Slave (only communication modules that support Modbus)		
16#8380	CRC error	Checksum error of the Modbus frame. Check the communication partner.
16#8381	The function code is not supported or is not supported for broadcast.	Check the communication partner and make sure that a valid function code is sent.
16#8382	Invalid length information in the request frame	Select a suitable data length at the DATA_LEN parameter.
16#8383	Invalid data address in the request frame	Select a suitable value for the data address at the DATA_ADDR parameter.
16#8384	Invalid data value error in the request frame	Check the data value in the request frame of the Modbus master
16#8385	The diagnostic value is not supported by the Modbus slave (function code 08)	The Modbus slave only supports the diagnostic values 16#0000 and 16#000A.

Error code	Description	Remedy
Protocol error - Modbus_Master (only communication modules that support Modbus)		
16#8380	CRC error	Checksum error of the Modbus frame. Check the communication partner.
16#8381	Response frame from Modbus Slave with the following error message: The function code is not supported.	Check the communication partner and make sure that a valid function code is sent.
16#8382	Response frame from Modbus Slave with the following error message: Invalid length	Select a suitable data length.
16#8383	Response frame from Modbus Slave with the following error message: Invalid data address in the request frame	Select a suitable value for the data address at the DATA_ADDR parameter.
16#8384	Response frame from Modbus Slave with the following error message: Data value error	Check the request frame to the Modbus slave.
16#8385	Response frame from Modbus Slave with the following error message: The diagnostic value is not supported by the Modbus slave	The Modbus slave only supports the diagnostic values 16#0000 and 16#000A.
16#8386	The returned function code does not match the requested function code.	Check the response frame and the addressing of the slave.
16#8387	A slave that was not requested answers	Check the response frame of the slave. Check the address settings of the slave.
16#8388	Error in the response of the slave to a write request.	Check the response frame of the slave.
16#8828 [1)]	DATA_PTR points to a bit address that is not equal to n * 8	Check the DATA_PTR pointer
16#8852 [1)]	DATA_PTR is not a pointer to a DB or a bit memory area	Check the DATA_PTR pointer
16#8853 [1)]	DATA_PTR is not a pointer of type BOOL or WORD	Check the DATA_PTR pointer
16#8855 [1)]	DATA_PTR points to a write-protected DB	Check the DATA_PTR pointer
16#8856 [1)]	Error during call of SFC51	Call the Modbus_Master instruction again
Error - Modbus_Slave (only communication modules that support Modbus)		
16#8428 [1)]	MB_HOLD_REG points to a bit address that is not equal to n * 8	Check the MB_HOLD_REG pointer
16#8452 [1)]	MB_HOLD_REG is not a pointer to a DB or a bit memory area	Check the MB_HOLD_REG pointer
16#8453 [1)]	MB_HOLD_REG is not a pointer of type BOOL or WORD	Check the MB_HOLD_REG pointer
16#8454 [1)]	The area addressed by MB_HOLD_REG is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the MB_HOLD_REG pointer
16#8455 [1)]	MB_HOLD_REG points to a write-protected DB	Check the MB_HOLD_REG pointer
16#8456 [1)]	Error during call of SFC51	Call the Modbus_Slave instruction again

[1)] Only with instructions for S7-300/400 CPUs

Overview of error messages - USS

Error code	Description	Remedy
16#0000	No error	-
16#8180	Length error in response of drive	Check the response frame of the drive.
16#8181	Data type error	Select a suitable data type. The following are valid: • Real • Word • Double word
16#8182	Data type error: "Double word" or "Real" may not be returned for the "Word" request.	Check the response frame of the drive.
16#8183	Data type error: "Word" may not be returned for the "Double word" or "Real" request.	Check the response frame of the drive.
16#8184	Checksum error in response of drive	Check the drive and the communication connection.
16#8185	Addressing error	Valid drive address range: 1 to 16
16#8186	Setpoint error	Valid setpoint range: -200% to +200%
16#8187	Incorrect drive number returned	Check the response frame of the drive.
16#8188	Invalid PZD length	Permitted PZD lengths: 2, 4, 6, 8 words
16#8189	The module does not support this data transmission rate.	Select a valid data transmission rate for the module.
16#818A	A different request for this drive is currently active.	Repeat the parameter read or write command later.
16#818B	The drive does not respond.	Check the drive.
16#818C	The drive responds with an error message to a parameter request.	Check the response frame of the drive. Check the parameter request. Check if the instructions USS_Read_Param, USS_Write_Param or USS_Port_Scan have reported an error. If they have, check the value of the static tag USS_DB. w_USSExtendedError of the USS_Drive_Control instruction.
16#818D	The drive responds with an access error message to a parameter request.	Check the response frame of the drive. Check the parameter request.
16#818E	The drive was not initialized.	Check the user program and make sure that the USS_Drive_Control instruction is called for this drive.

Error code	Description	Remedy
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Port_Config.RDREC.STATUS, Send_Config.RDREC.STATUS , Receive_Config.RDREC.STATUS , Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Port_Config.WRREC.STATUS, Send_Config.WRREC.STATUS , Receive_Config.WRREC.STATUS , Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB WRREC.

1) Only with instructions for S7-300/400 CPUs

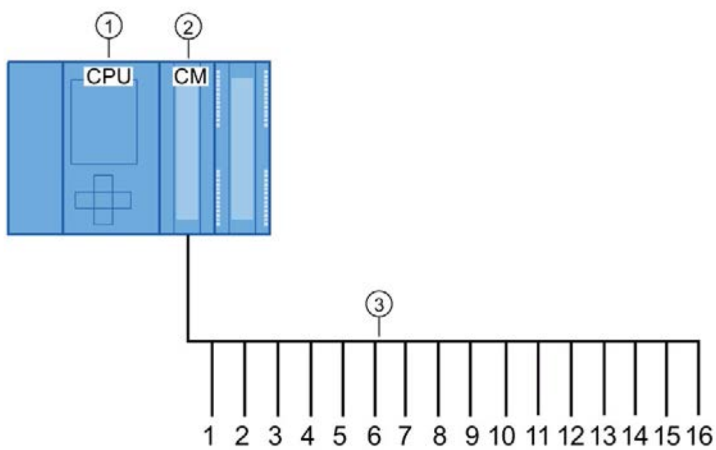
5.4.3 USS

5.4.3.1 Overview of USS communication

USS communication

The USS instructions control the operation of drives which support the protocol of the universal serial interface (USS). You can communicate with several drives by means of RS485 connections and the USS instructions with the PtP communication modules. Each RS485 port can operate up to 16 drives.

The USS protocol uses a master-slave network for communication via a serial bus. The master uses an address parameter to send data to a selected slave. A slave cannot send without having first received a send request. Communication between individual slaves is not possible. USS communication takes place in half-duplex mode. The figure below shows a network diagram for a sample application with 16 drives.



① CPU
② CM
③ USS drives in a USS network

Figure 5-1 Wiring example with S7-1500 communication module

Note

Communicating with a drive via RS232

You can basically also use CM PtP RS232 BA and CM PtP RS232 HF for communication with a drive. However, only **one** drive can be connected to an RS232 port.

Communicating with a drive via RS422

You can basically also use the RS422 interface of the CM PtP RS422/485 BA and CM PtP RS422/485 HF for communication with a drive. However, only **one** drive can be connected to an RS422 port.

USS instructions in your program

- USS_Port_Scan: The instruction USS_Port_Scan allows you to communicate via a communication module with up to 16 drives using a USS network (must be called cyclically).

  There is only one USS_Port_Scan instruction per PtP communication port in the program, and it controls transmission to all drives.
- USS_Drive_Control: The instruction USS_Drive_Control allows you to prepare the send data from USS_Port_Scan for a drive and display its receive data.

  USS_Drive_Control configures the data to be sent and evaluates the data received in a previous request from USS_Port_Scan.
- USS_Read_Param: The instruction USS_Read_Param allows you to read parameters from a drive.
- USS_Write_Param: The instruction USS_Write_Param allows you to change parameters in a drive.

5.4.3.2 Requirements for using the USS protocol

The four USS instructions use 2 FBs and 2 FCs to support the USS protocol. For each USS network, one instance data block (DB) is used for USS_Port_Scan and one instance data block for all calls of USS_Drive_Conrol.

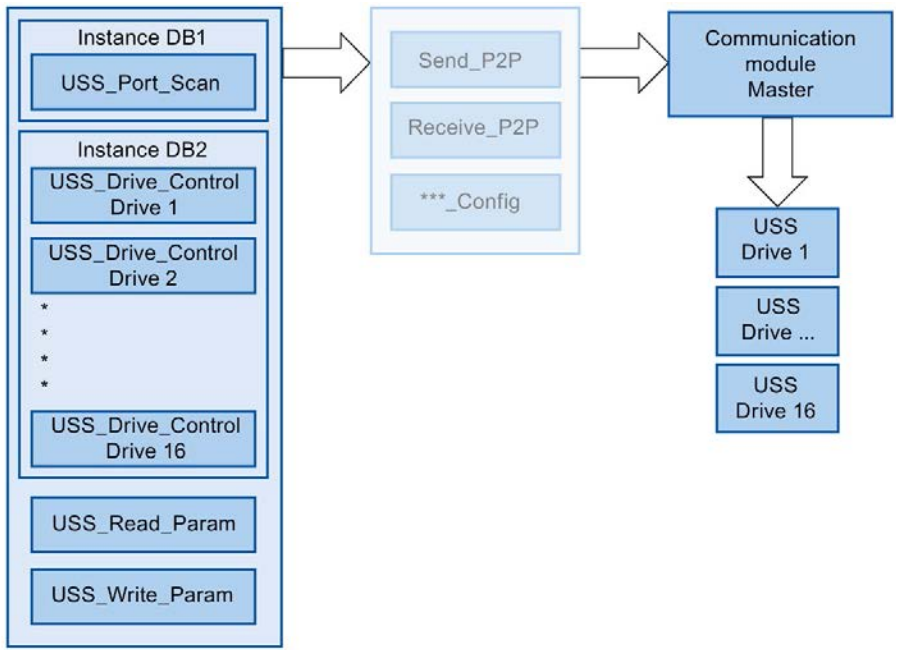


Figure 5-2 USS program sequence

All drives (max. 16) that are connected to one RS485 port are part of the same USS network. All drives that are connected to another RS485 port are part of a different USS network. Each USS network is managed using a unique instance data block for all USS_Drive_Control instructions and one further instance data block for the USS_Port_Scan instruction. All instructions that are part of a USS network must share this instance data block for USS_Drive_Conrol. The USS_Port_Scan, USS_Read_Param and USS_Write_Param instructions have the USS_DB parameter for this function. This parameter must be connected to the (static) USS_DB parameter of the instance DB of the USS_Drive_Control instruction.

- The instructions USS_Drive_Control and USS_Port_Scan are function blocks (FB). If you add the USS_Drive_Control or USS_Port_Scan instruction to the programming editor, you are prompted to assign a DB for this FB in the "Call options" dialog. If it is the first USS_Drive_Control instruction in this program for this USS network, you can apply the DB standard assignment (or change the name, if necessary) and the new DB is created for you. If, however, it is not the first USS_Drive_Control instruction for this drive, you need to select the DB which has already been assigned to this USS network from the drop-down list in the "Call options" dialog.
- The USS_Write_Param and USS_Read_Param instructions are functions (FCs). No DB is assigned when you add these FCs in the editor. If you add these FCs or the USS_Port_Scan instruction in the editor, you need to assign the USS_DB parameter of the corresponding USS_Drive_Control instance DB to the USS_DB input of these instructions. Double-click the parameter field and click the symbol to display the available DBs. Enter a period "." and select the USS_DB parameter from the drop-down list.

- The USS_Port_Scan function controls communication between the CPU and the drives via the point-to-point RS485 communication port. A communication with the drive is processed every time you call this function. Your program must call this function fast enough so that the drives do not signal a timeout. To ensure a constant time response for frame communication, you should call this instruction in a cyclic interrupt OB.
- The USS_Drive_Control instruction gives your program access to a specified drive in the USS network. Its inputs and outputs correspond to the states and operating functions of the drive. If there are 16 drives in your network, you must call USS_Drive_Control at least 16 times in your program, i.e. once for each drive.

  You should only call the USS_Drive_Control instruction from a cyclic OB.
- The operating parameters of the drive are read and written with the USS_Read_Param and USS_Write_Param functions. These parameters control the internal operation of the drive. See the drive manual for a definition of these parameters. Your program may include any number of these functions, but only one read or write request may be active for a drive at any particular time. You may only call the USS_Read_Param and USS_Write_Param functions from the cycle OB of a main program.

NOTICE

USS instruction calls

Only ever call USS_Drive_Control, USS_Read_Param or USS_Write_Param from a cycle OB of the main program. The USS_Port_Scan instruction function can be called from any OB, but it is usually called from a cyclic interrupt OB.

Do not use the USS_Drive_Control, USS_Read_Param or USS_Write_Param instruction in an OB with a higher priority than the corresponding USS_Port_Scan instruction. For example, do not add USS_Port_Scan to the main program or USS_Read_Param to a cyclic interrupt OB. You may encounter unexpected errors if the execution of USS_Port_Scan is interrupted by another instruction.

Calculating time for communication with the drive

Communication with the drive takes place asynchronously to the cycle of the CPU. The CPU usually runs through several cycles before communication with a drive is complete.

To ensure that the watchdog set for the drive is not triggered, the send frames must be sent to the drive within the watchdog time. You must allow for the number of any retries which may be needed to complete the transaction if communication errors occur. By default, up to 2 retries are made for each transaction with the USS protocol.
The maximum time interval between two send frames is calculated as follows:

N * (5 * cycle time + frame runtime + timeout of the receive frame max.) * (number of transmission attempts)

N	Number of drives in this network
Factor 5	5 cycles are typically needed for sending and receiving frames.
Cycle time	Max. cycle time of the cyclic interrupt OB in which the USS_Port_Scan instruction is called.
Frame runtime	Frame time = (number of characters per frame) * (11 Bit per character) / (data transmission rate in Bit/s)
Number of transmission attempts	Number of retries + 1
Timeout of the receive frame	RCVTIME (if no response is received from the drive)
Timeout of the receive frame max.	RCVTIME + MSGTIME (if an incomplete answer is received shortly before the expiration of RCVTIME and monitoring of MSGTIME has expired **or** if a response is still being processed at the expiration of RCVTIME, the timeout is extended by the MSGTIME)

The following times apply for "Received frame timeout" (ms):

Bit/s	115200	57600	38400	19200	9600	4800	2400	1200
Receive _Conditions.END.RCVTIME	25	29	33	56	72	100	100	100
Receive _Conditions.END.MSGTIME	25	29	33	56	72	124	240	460

Timeout of the receive frame max. = (Receive_Conditions.END.RCVTIME (0.072 s) + Receive_Conditions.END.MSGTIME (0.072 s))

Example:

5 drives
Data transmission rate = 9600 bps
28 characters per frame
Cycle time = 0.020 s
Number of retries = 2

Time interval = 5 * (5 * 0.02 s + 1 * 28 * 11 / 9600 s + 0.072 s + 0.072 s) * 3 = 3 s

The time monitoring of the drive must be set to about 3 seconds in this case.

5.4.3.3 USS_Port_Scan / USS_Port_Scan_31: Communication by means of a USS network

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Note

Using the USS_Port_Scan_31 instruction

It is only possible to use the USS_Port_Scan_31 instruction on an S7-1500 CPU.

Description

The USS_Port_Scan instruction processes the communication by means of a USS network for max. 16 drives.

The USS_Port_Scan_31 instruction processes the communication by means of a USS network for max. 31 drives.

STEP 7 automatically creates the instance DB when you add the instruction.

Parameters

Parameter	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
PORT	IN	Port	Word	0	Specifies the communication module which is used for the communication: • For S7-1500/S7-1200: "HW identifier" from the device configuration. The symbolic port name is assigned in the "System constants" tab of the PLC tag table and can be applied from there. • For S7-300/S7-400: "Input address" from the device configuration. In the S7-300/400/WinAC systems the PORT parameter is assigned the input address assigned in HWCN.

Parameter	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
BAUD	IN	DInt		9600	Data transmission rate for USS communication The following are valid: • 1200 bps • 2400 bps • 4800 bps • 9600 bps • 19200 bps • 38400 bps • 57600 bps • 115200 bps
USS_DB	INOUT	USS_BASE		–	The USS_DB parameter must be connected to the (static) USS_DB parameter of the instance DB which is generated and initialized when you add a USS_Drive_Control / USS_Drive_Control_31 instruction to your program.
COM_RST	INOUT	---	Bool	FALSE	Initialization of the USS_Port_Scan / USS_Port_Scan_31 instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE. Note: The parameter is only available for S7-300/400 instructions.
ERROR	OUT	Bool		FALSE	If TRUE, this output indicates that an error has occurred and that the STATUS output is valid. You may need to check the value of the static tag USS_DB. w_USSExtendedError in the instance DB of the USS_Drive_Control / USS_Drive_Control_31 instruction.
STATUS	OUT	Word		0	Error code (see Error messages (Page 188)).

There is only one USS_Port_Scan / USS_Port_Scan_31 instruction per PtP communication port in the program and each call of this instruction controls a transmission to or from all drives in this network. All USS functions assigned to one USS network and one PtP communication port must use the same instance DB.

Your program must execute the USS_Port_Scan / USS_Port_Scan_31 instruction often enough to prevent a timeout in the drive (see Requirements for using the USS protocol (Page 169) "Calculating time for communication with the drive").

The USS_Port_Scan / USS_Port_Scan_31 instruction is usually called from a cyclic interrupt OB to prevent drive timeouts and to make the last USS data updates available for calls of USS_Drive_Control / USS_Drive_Control_31 .

USS_Port_Scan / USS_Port_Scan_31 data block tags

The table below shows the public static tags in the instance DB of USS_Port_Scan / USS_Port_Scan_31 that you can use in your program.

Table 5- 35 Static tags in the instance DB

Tag	Data type	Standard	Description
MODE	USInt	4	Operating mode Valid operating modes are: • 0 = Full duplex (RS232) • 1 = Full duplex (RS422) four-wire mode (point-to-point) • 2 = Full duplex (RS 422) four-wire mode (multipoint master; CM PtP (ET 200SP)) • 3 = Full duplex (RS 422) four-wire mode (multipoint slave; CM PtP (ET 200SP)) • 4 = Half duplex (RS485) two-wire mode [1)]
LINE_PRE	USInt	2	Receive line initial state Valid initial states are: • 0 = "No" initial state [1)] • 1 = signal R(A)=5 V, signal R(B)=0 V (break detection): Break detection is possible with this initial state. Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • 2 = signal R(A)=0 V, signal R(B)=5 V: This default setting corresponds to the idle state (no active send operation). No break detection is possible with this initial state.
BRK_DET	USInt	0	Activate diagnostics interrupt: • 0 - not activated • 1 - activated
RETRIES_MAX	SInt/Byte	2	Number of retries when communication errors occur. You can use this parameter to set the number of send retries for a request frame if the response frame is not received within the set time.
EN_DIAG _ALARM	Bool	0	Activate diagnostics interrupt: • 0 - not activated • 1 - activated
EN_SUPPLY _VOLT	Bool	0	Enable diagnostics for missing supply voltage L+ • 0 - not activated • 1 - activated

[1)] Required setting for the use of PROFIBUS cables with CM 1241 for RS485

Version 2.5 is functionally identical to version 2.4 and its version number was only incremented due to internal measures.

Instruction versions

USS_Port_Scan:

Version 2.5 is functionally identical to version 2.4 and its version number was only incremented due to internal measures.

USS_Port_Scan_31:

Version 1.2 is functionally identical to version 1.1 and its version number was only incremented due to internal measures.

5.4.3.4 USS_Drive_Control / USS_Drive_Control_31: Preparing and displaying data for the drive

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Note

Using the USS_Drive_Control_31 instruction

It is only possible to use the USS_Drive_Control_31 instruction on an S7-1500 CPU.

Description

The USS_Drive_Control instruction prepares send data for max. 16 drives and evaluates the response data of the drives.

The USS_Drive_Control_31 instruction prepares send data for max. 31 drives and evaluates the response data of the drives.

You need to use a separate instance of the instruction for each drive, and all USS functions assigned to one USS network and one PtP communication port must use the same instance DB. You must enter the DB name when you add the first USS_Drive_Control / USS_Drive_Control_31 instruction. You then refer to this DB that was created when the first instruction was added.

STEP 7 automatically creates the DB when you add the instruction.

Parameters

Parame-ters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
RUN	IN	Bool		FALSE	Start bit of the drive: If this parameter is TRUE, this input allows you to operate the drive with the preset speed. If RUN changes to FALSE during operation of the drive, the motor coasts to a standstill. This behavior differs from disconnection of the power supply (OFF2) and braking of the motor (OFF3).
OFF2	IN	Bool		FALSE	"Coast to standstill" bit: If this parameter is FALSE, this bit causes the drive to coast to a standstill without braking.
OFF3	IN	Bool		FALSE	Fast stop bit: If this parameter is FALSE, this bit causes a fast stop by braking the drive.
F_ACK	IN	Bool		FALSE	Error acknowledgment bit: This bit resets the error bit of a drive. The bit is set after clearing the error and the drive detects this way that the previous error no longer has to be reported.

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
DIR	IN	Bool		FALSE	Direction control of the drive: This bit is set if the drive is to run forward (if SPEED_SP is positive; see table "Interaction of SPEED_SP and DIR parameters").
DRIVE	IN	USInt	Byte	1	Address of the drive: This input is the address of the USS drive. The valid range is between drive 1 and drive 16.
PZD_LEN	IN	USInt	Byte	2	Word length: This is the number of PZD data words. Valid values are 2, 4, 6 or 8 words.
SPEED_SP	IN	Real		0.0	Speed setpoint: This is the speed of the drive as a percentage of the configured frequency. A positive value means that the drive runs forward (if DIR is true). The valid range is 200.00 to -200.00.
CTRL3	IN	Word		0	Control word 3: Value that is written to a user-defined parameter of the drive. You have to configure it in the drive (optional parameter).
CTRL4	IN	Word		0	Control word 4: Value that is written to a user-defined parameter of the drive. You have to configure it in the drive (optional parameter).
CTRL5	IN	Word		0	Control word 5: Value that is written to a user-defined parameter of the drive. You have to configure it in the drive (optional parameter).
CTRL6	IN	Word		0	Control word 6: Value that is written to a user-defined parameter of the drive. You have to configure it in the drive (optional parameter).
CTRL7	IN	Word		0	Control word 7: Value that is written to a user-defined parameter of the drive. You have to configure it in the drive (optional parameter).
CTRL8	IN	Word		0	Control word 8: Value that is written to a user-defined parameter of the drive. You have to configure it in the drive (optional parameter).
COM_RST	IN/OUT	---	Bool	FALSE	Initialization of the USS_Drive_Control / USS_Drive_Control_31 instruction The instruction is initialized with TRUE. The instruction then resets COM_RST to FALSE. Note: The parameter is only available for S7-300/400 instructions.
NDR	OUT	Bool		FALSE	New data available: If this parameter is TRUE, the bit signals that data of a new communication request is available at the output.
ERROR	OUT	Bool		FALSE	Error occurred: If TRUE, this indicates that an error has occurred and that the STATUS output is valid. All other outputs are set to zero in the event of an error. Communication errors are only signaled at the ERROR and STATUS outputs of the USS_Port_Scan / USS_Port_Scan_31 instruction.
STATUS	OUT	Word		0	Error code (see Error messages (Page 188)).
RUN_EN	OUT	Bool		FALSE	Operation enabled: This bit signals if the drive is running.
D_DIR	OUT	Bool		FALSE	Drive direction: This bit signals if the drive is running forward. • FALSE – forward • TRUE – backward

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
INHIBIT	OUT	Bool		FALSE	Drive blocked: This bit signals the status of the block bit for the drive. • FALSE – not blocked • TRUE – blocked
FAULT	OUT	Bool		FALSE	Drive error: This bit signals that an error occurred in the drive. You must remedy the fault and set the F_ACK bit to clear this bit.
SPEED	OUT	Real		0.0	Actual value drive speed (scaled value of STATUS 2 of the drive): This is the speed of the drive as a percentage of the configured speed.
STATUS1	OUT	Word		0	STATUS 1 of the drive This value includes fixed status bits of a drive.
STATUS3	OUT	Word		0	STATUS 3 of the drive This value includes a user-definable status word of the drive.
STATUS4	OUT	Word		0	STATUS 4 of the drive This value includes a user-definable status word of the drive.
STATUS5	OUT	Word		0	STATUS 5 of the drive This value includes a user-definable status word of the drive.
STATUS6	OUT	Word		0	STATUS 6 of the drive This value includes a user-definable status word of the drive.
STATUS7	OUT	Word		0	STATUS 7 of the drive This value includes a user-definable status word of the drive.
STATUS8	OUT	Word		0	STATUS 8 of the drive This value includes a user-definable status word of the drive.

When the initial execution of USS_Drive_Control / USS_Drive_Control_31 takes place, the drive specified by the USS address (DRIVE parameter) is initialized in the instance DB. After initialization, subsequent USS_Port_Scan / USS_Port_Scan_31 instructions can start communication with the drive from this drive number.

If you change the drive number, you must first place the CPU in STOP and then back in RUN to initialize the instance DB. The input parameters are configured in the USS send buffer and any outputs are read from a "previous" valid response buffer. USS_Drive_Control / USS_Drive_Control_31 only configures the data to be sent and evaluates data received in a previous request.

You can control the drive's direction of rotation by using the D_IR input (Bool) or the sign (positive or negative) at the SPEED_SP input (Real). The table below explains how these inputs work together to determine the direction of rotation of the drive, provided the motor rotates forward.

Table 5- 36 Interaction of SPEED_SP and DIR parameters

SPEED_SP	DIR	Direction of rotation of the drive
Value > 0	0	Backward
Value > 0	1	Forward
Value < 0	0	Forward
Value < 0	1	Backward

USS_Drive_Control / USS_Drive_Control_31 data block tags

The table below shows the public static tags in the instance DB of USS_Drive_Control / USS_Drive_Control_31 that you can use in your program.

Table 5- 37 Static tags in the instance DB

Tag	Data type	Standard	Description
USS_DB. W _USSExtendedError	Word	16#0	USS Drive Extended Error Code - drive-specific value The meaning of the error message depends on which instruction reported an error **first** (ERROR = TRUE). The following cases are distinguished: • USS_Write_Param / USS_Write_Param_31: You can find the meaning of the error code in the description of the drive. • USS_Read_Param / USS_Read_Param_31: You can find the meaning of the error code in the description of the drive. • USS_Port_Scan / USS_Port_Scan_31: Number of the drive affected by the error message.

Instruction versions

USS_Drive_Control:

Version 2.0 is functionally identical to version 1.2 and its version number was only incremented due to internal measures.

USS_Drive_Control_31:

Version 2.0 is functionally identical to version 1.0 and its version number was only incremented due to internal measures.

5.4.3.5 USS_Read_Param / USS_Read_Param_31: Read data from drive

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Note

Using the USS_Read_Param_31 instruction

It is only possible to use the USS_Read_Param_31 instruction on an S7-1500 CPU.

Description

The USS_Read_Param instruction reads a parameter from one of max. 16 drives.

The USS_Read_Param_31 instruction reads a parameter from one of max. 31 drives.

All USS functions assigned to one USS network and one PtP communication port must use the instance data block of the USS_Drive_Control / USS_Drive_Control_31 instruction. USS_Read_Param / USS_Read_Param_31 must be called from a cycle OB of the main program.

Parameters

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		–	A positive edge at REQ creates a new read request.
DRIVE	IN	USInt	Byte	–	Address of the drive: DRIVE is the address of the USS drive. The valid range is between drive 1 and drive 16.
PARAM	IN	UInt		–	Parameter number: PARAM specifies the drive parameter to write. The range for this parameter is between 0 and 2047. With some drives, the most significant byte of the INDEX parameter can be used to access parameter values greater than 2047. Additional information on access to an extended range is available in your drive manual.
INDEX	IN	UInt		–	Parameter index: INDEX specifies the drive parameter index to which to write. It is a 16-bit value in which the least significant bit is the actual index value with a range of (0 to 255). The drive can also use the most significant byte, which is drive-specific. Additional information is available in your drive manual.
USS_DB	INOUT	USS_BASE		–	The USS_DB parameter must be connected to the (static) USS_DB parameter of the instance DB which is generated and initialized when you add a USS_Drive_Control / USS_Drive_Control_31 instruction to your program.

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
DONE[1]	OUT	Bool		FALSE	If this parameter is TRUE, the previously requested value of the read parameter is available at the VALUE output. This bit is set when the USS_Drive_Control / USS_Drive_Control_31 instruction recognizes the read response of the drive. This bit is reset the next time USS_Read_Param / USS_Read_Param_31 is called.
ERROR	OUT	Bool		FALSE	ERROR = TRUE: An error has occurred and the STATUS output is valid. All other outputs are set to zero in the event of an error. Communication errors are only signaled at the ERROR and STATUS outputs of the USS_Port_Scan / USS_Port_Scan_31 instruction. You may need to check the value of the static tag USS_DB. w_USSExtendedError in the instance DB of the USS_Drive_Control / USS_Drive_Control_31 instruction.
STATUS	OUT	Word		0	Error code (see Error messages (Page 188)).
VALUE	OUT	Variant (Word, Int, UInt, DWord, DInt, UDInt, Real)	Any (Word, Int, UInt, DWord, DInt, UDInt, Real)	–	This is the value of the parameter that was read and is only valid if the DONE bit is true.

[1] The DONE bit indicates that valid data was read out of the referenced motor drive and transmitted to the CPU. It does not indicate that the instruction is cabable of immediately read an additional parameter. An empty read request must be sent to the motor drive and acknowledged by the instruction before the parameter channel is freed up for use by the respective drive. The immediate call of USS_Read_Param / USS_Read_Param_31 or USS_Write_Param / USS_Write_Param_31 for the specific motor drive results in error 16#818A.

Instruction versions

USS_Read_Param:

Version 1.5 is functionally identical to version 1.4 and its version number was only incremented due to internal measures.

USS_Read_Param_31:

Version 1.1 is functionally identical to version 1.0 and its version number was only incremented due to internal measures.

5.4.3.6 USS_Write_Param / USS_Write_Param_31: Change data in drive

Note

Use with CM1241

The use of this instruction with a CM1241 is only possible from firmware version V2.1 of the module.

Note

Using the USS_Write_Param_31 instruction

It is only possible to use the USS_Write_Param_31 instruction on an S7-1500 CPU.

Note

For EEPROM write instructions (EEPROM in a USS drive):

Keep the number of EEPROM write operations to a minimum in order to maximize the EEPROM service life.

Description

The USS_Write_Param instruction changes a parameter in one of max. 16 drives.

The USS_Write_Param_31 instruction changes a parameter in one of max. 31 drives.

All USS functions assigned to one USS network and one PtP communication port must use the instance data block of the USS_Drive_Control / USS_Drive_Control_31.

USS_Write_Param / USS_Write_Param_31 must be called from the cycle OB of a main program.

Parameters

Table 5- 38 Data types for the parameters

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
REQ	IN	Bool		–	A positive edge at REQ creates a new write request.
DRIVE	IN	USInt	Byte	–	Address of the drive: DRIVE is the address of the USS drive. The valid range is between drive 1 and drive 16.
PARAM	IN	UInt		–	Parameter number: PARAM specifies the drive parameter to write. The range for this parameter is between 0 and 2047. With some drives, the most significant byte of the INDEX parameter can be used to access parameter values greater than 2047. Additional information on access to an extended range is available in your drive manual.
INDEX	IN	UInt		–	Parameter index: INDEX specifies the drive parameter index to which to write. It is a 16-bit value in which the least significant bit is the actual index value with a range of (0 to 255). The drive can also use the most significant byte, which is drive-specific. Additional information is available in your drive manual.

Parameters	Declaration	Data type		Standard	Description
		S7-1200/1500	S7-300/400/WinAC		
EEPROM	IN	Bool		–	Save in EEPROM of the drive: If TRUE, the transaction of a parameter for writing to the drive is saved in the EEPROM of the drive. If FALSE, the written value is saved only temporarily and is lost the next time you switch on the drive.
VALUE	IN	Variant (Word, Int, UInt, DWord, DInt, UDInt, Real)	Any (Word, Int, UInt, DWord, DInt, UDInt, Real)	–	Value of the parameter in which you want to write. It must be valid with a positive edge of REQ.
USS_DB	INOUT	USS_BASE		–	The USS_DB parameter must be connected to the (static) USS_DB parameter of the instance DB which is generated and initialized when you add a USS_Drive_Control / USS_Drive_Control_31 instruction to your program.
DONE[1]	OUT	Bool		FALSE	If TRUE, the VALUE input is written to the drive. This bit is set when the USS_Drive_Control / USS_Drive_Control_31 instruction recognizes the write response of the drive. This bit is reset the next time USS_Write_Param / USS_Write_Param_31 is called.
ERROR	OUT	Bool		FALSE	If TRUE, an error has occurred and the STATUS output is valid. All other outputs are set to zero in the event of an error. Communication errors are only signaled at the ERROR and STATUS outputs of the USS_Port_Scan / USS_Port_Scan_31 instruction. You may need to check the value of the static tag USS_DB. w_USSExtendedError in the instance DB of the USS_Drive_Control / USS_Drive_Control_31 instruction.
STATUS	OUT	Word		0	Error code (see Error messages (Page 188)).

[1] The DONE bit indicates that valid data was read out of the referenced motor drive and transmitted to the CPU. It does not indicate that the USS library is able to read out an additional parameter immediately. An empty write request must be sent to the motor drive and acknowledged by the instruction before the parameter channel is freed up for use by the respective drive. The immediate call of USS_Read_Param / USS_Read_Param_31 or USS_Write_Param / USS_Write_Param_31 FC for the specific motor drive results in error 0x818A.

Instruction versions

USS_Write_Param:

Version 1.6 is functionally identical to version 1.5 and its version number was only incremented due to internal measures.

USS_Write_Param_31:

Version 1.1 is functionally identical to version 1.0 and its version number was only incremented due to internal measures.

5.4.3.7 General information on drive setup

Requirements for the drive setup

- You need to configure the use of 4 PIV words (**P**arameter**ID****V**alue) for the drives.
- The drives can be configured for 2, 4, 6 or 8 PZD words (**P**ro**c**ess **d**ata area).
- The number of PZD words in the drive must correspond to the PZD_LEN input of the USS_Drive_Control instruction of the drive.
- Make sure that the data transmission rate of all drives corresponds to the BAUD input of the USS_Port_Scan instruction.
- Make sure that the drive is set up for USS communication.
- Make sure that it is specified in the drive that the frequency setpoint is provided by the USS interface.
- Make sure that the drive address is specified (areas: 1-16).
  This address must correspond to the DRIVE input at the USS_Drive_Control block of the drive.
- Make sure that the RS485 network is terminated correctly.

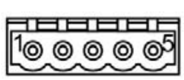
Connection and setup of SINAMICS V20 drive

An application example for operation of a SINAMICS V20 at an S7-1200 is available on the Internet. (http://support.automation.siemens.com/WW/view/en/63696870)

Connecting the SINAMICS V20 drive

Connection example of a SIEMENS G120(C) drive to a USS network. Connection examples for other drives are available in the manual of the respective drive.

The connection of a SINAMICS G120(C) drive to the USS network takes place via plug-in connection. The connection is short-circuit proof and isolated.



1 0 V reference potential
2 RS485N, receiving and sending (-)
3 RS485N, receiving and sending (+)
4 Cable shield
5 Not used

Figure 5-3 USS connection

NOTICE
Different reference voltages
If you connect devices that do not have the same reference voltage, you may create unwanted currents in the connection cable. These unwanted currents may cause communication errors or damages in the devices. Make sure that all devices you connect with a communication cable either have the same reference conductor in the circuit or are electrically disconnected to prevent the occurrence of unwanted currents. Make sure that the shield is connected to the ground or pin 1 of the bus connector on the drive. Make sure that wiring terminal 2 (GND) of the G120(C) is connected to the ground.

If the RS485 master (e.g., S7-1200 CPU with CM1241 communication module) is connected by means of a PROFIBUS connector, wire the bus cables as follows:

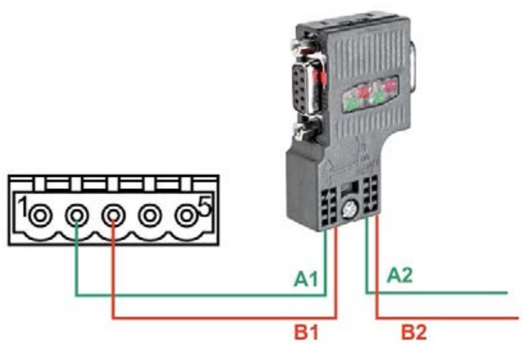


Figure 5-4 Connection of communication module

If the RS485 master is a terminating station in the network or a point-to-point connection, you must use terminals A1 and B1 (not A2 and B2) of the PROFIBUS connector, as these terminals provide termination settings (for example, with the DP plug connector 6ES7972-0BB52-0XA0).

If the G120(C) is configured as terminating station in the network, you must set the switch for the bus terminating resistor to "ON".

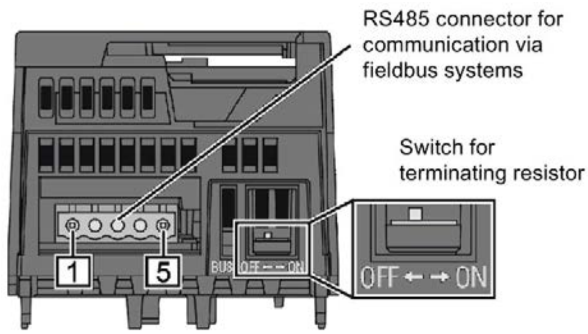

Figure 5-5 Connection of terminating stations

Setup of a G120(C) drive

Before you connect a drive to the S7-1500 or ET 200SP, make sure that the drive has the following system parameters.

Step	Instruction	Operating Instructions	
		G120 1)	G120C 2)
1	Perform a basic commissioning of the drive with the Operator Panel BOP-2. The converter offers different defaults (macros) for its inputs and outputs and the fieldbus interface. In the ninth step of the basic commissioning (MAC PAR p15), select macro 21 for USS communication. This determines the default for the following parameters: • Data transmission rate (p2020): 38400 bps • Number of PZD (p2022): 2 • Number of PIV (p2023): variable Note: You can also conduct basic commissioning with the STARTER commissioning software or with SINAMICS Startdrive.	Chapter 4.4.3	Chapter 6.4.1
2	Specify the USS address of the converter with the address switch on the control unit of the G120 or on the G120(C). • Valid address range: 1 … 30 Note: Yon can also set the USS address with the parameter p2021 or with STARTER or SINAMICS Startdrive.	Chapter 6.2.2.1	Chapter 8.4.2.1
	With the following steps you are accessing the parameters directly with the BOP-2 by entering their numbers and modifying their values.	Chapter 4.4.2	Chapter 6.4.2

<table>
<tr><th rowspan="2">Step</th><th rowspan="2">Instruction</th><th colspan="2">Operating Instructions</th></tr>
<tr><th>G120 1)</th><th>G120C 2)</th></tr>
<tr><td>3</td><td>Adapt the following communication-related converter parameters of your application:
• Data transmission rate (p2020), of ≠ 38400 bps

(Make sure that the setting is identical with the PZD_LEN parameter of the USS_Drive_Control communication instruction.)
• Number of PIV (p2023) = 4
(Change the value set to "variable" (127) with macro 21 by default to "4" (required by instructions USS_Read_Param and USS_Write_Param.)
• Fieldbus SS monitoring time [ms] (p2040)</td><td>Chapter 6.2.2.2</td><td>Chapter 8.4.2.1</td></tr>
<tr><td>4</td><td>Specify the source for the speed setpoint.
• n_set Eval (p1000[0]) = 6
(The speed setpoint is provided by the USS bus.)</td><td></td><td></td></tr>
<tr><td>5</td><td>Set the reference value for speed and frequency.
• n_reference f_reference (p2000) = (6,00 min^{-1} to 210000,00 min^{-1})
(all relative speeds or frequencies refer to this reference value. The reference value corresponds to 100% or 4000_{hex} (word) or 4000 0000_{hex} (double word). The following applies:
$f_{reference\_value}$ (in Hz) = $n_{reference\_value}$ (in ((min^{-1}) / 60) x number of pole pairs))</td><td></td><td></td></tr>
<tr><td>6</td><td>Transfer the parameters to the non-volatile memory.
• Save par (p0971) = 1</td><td></td><td></td></tr>
</table>

5.4.3.8 Error messages

Overview of error messages - PtP

The error messages are provided at the STATUS output of an instruction and can be evaluated there or processed in the user program.

Error code	Description	Remedy
16#0000	No error	-
RECEIVE status and error codes		
16#0094	frame end identified based on the "Receipt of fixed/maximum frame length"	-
16#0095	frame end identified based on "Message timeout"	-
16#0096	frame end identified based on expiration of the "Character delay time"	-
16#0097	The frame was aborted because the maximum response time was reached.	-
16#0098	frame end identified based on the fulfillment of the "Read message length from message" conditions	-
16#0099	frame end identified based on the receipt of the "End sequence"	-
SEND status and error codes		
16#7000	Block idle	-
16#7001	Initial call for a new frame: Data transmission initiated	-
16#7002	Interim call: Data transmission running	-
16#8085	Invalid length	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (Byte)
16#8088	The specified length exceeds the range set in the receive buffer. Note: If the data type STRING has been specified at the BUFFER parameter, this error code also appears if the current string is shorter than the length specified at the LENGTH parameter.	Change the range in the receive buffer or select a frame length which corresponds to the range set in the receive buffer. The following are valid (depending on the module): 1-1024/2048/4096 (bytes)
16#8090	Configuration error: Odd number of bytes for WString	Select an even number of bytes.
RECEIVE status and error codes		
16#7002	Interim call: Data transmission running	-
16#8088	The number of characters received exceeds the number specified at the BUFFER parameter.	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (bytes)
16#8090	Configuration error: Odd number of bytes for WString	Select an even number of bytes.

Error code	Description	Remedy
Error message codes of the special functions		
16#818F	Incorrect parameter number setting (with USS only)	Select a suitable parameter number (PARAM). The following numbers are valid: 0-2047
16#8190	Incorrect setting of the CRC calculation	Select a suitable value for the CRC calculation. The following are valid: deactivated or activated. Check whether the module addressed supports CRC calculation.
16#8191	Incorrect setting of the diagnostic error interrupt	Select a suitable value for "Diagnostic error interrupt". The following are valid: Diagnostic error interrupt deactivated or diagnostic error interrupt activated. Check whether the module addressed supports the generation of diagnostic interrupts.
16#8193	The module does not support supply voltage diagnostics L+.	Select a suitable value for "Diagnostic interrupt". The following are permitted: Diagnostic interrupt deactivated or diagnostic interrupt activated. Check whether the module addressed supports the generation of diagnostic interrupts.
Error message codes of the "Port configuration"		
16#81A0	The module does not support this protocol.	Select a valid protocol for the module (PROTOCOL).
16#81A1	The module does not support this data transmission rate.	Select a valid data transmission rate for the module (BAUD).
16#81A2	The module does not support this parity setting.	Select a suitable value for "Parity" (PARITY). The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
16#81A3	The module does not support this number of data bits.	Select a suitable value for "Number of data bits" (DATABITS). The following are valid: • 7 (2) • 8 (1)
16#81A4	The module does not support this number of stop bits.	Select a suitable value for "Number of stop bits" (STOPBITS). The following are valid: • 1 (1) • 2 (2)
16#81A5	The module does not support this type of data flow control.	Select a valid data flow control for the module (FLOWCTRL).

Error code	Description	Remedy
16#81A7	Invalid value for XON or XOFF	Select suitable values for XON (XONCHAR) and XOFF (XOFFCHAR). Valid range of values: 0...255
16#81AA	Invalid operating mode	Valid operating modes are: • Full duplex (RS232) (0) • Full duplex (RS422) four-wire mode (point-to-point) (1) / (CM PtP (ET 200SP)) • Full duplex (RS422) four-wire mode (multipoint master) (2)/ (CM PtP (ET 200SP)) • Full duplex (RS 422) four-wire mode (multipoint slave) (3) • Half duplex (RS485) two-wire mode. (4)
16#81AB	Invalid receive line initial state	Valid initial states are: • "No" default setting (0) • Signal R(A)=5 V, signal R(B)=0 V (break detection) (1): Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • Signal R(A)=0 V, signal R(B)=5 V (2): This default setting corresponds to the idle state (no active send operation).
16#81AC	Invalid value for "Break detection"	Select a suitable value for "Break detection". The following are valid: • Break detection deactivated (0) • Break detection activated (1).
16#81AF	The module does not support this protocol.	Select a valid protocol for the module.
Error codes of the "Send configuration"		
16#81B5	More than two end delimiters or end sequence > 5 characters	Select suitable values for "End delimiter" and "End sequence". The following are valid: • deactivated (0), • 1 (1) or 2 (2) end delimiters or • deactivated (0), • 1 (1) up to 5 (5) characters for the end sequence.
16#81B6	Send configuration rejected because the 3964(R) protocol was selected	Make sure that no send configuration is transmitted if the 3964(R) protocol is set.

Error code	Description	Remedy
Error codes of the "Receive configuration"		
16#81C0	Invalid start condition	Select a suitable start condition. The following are valid: • Send break before frame start • Send Idle Line.
16#81C1	Invalid end condition or no end condition selected	Select a suitable end condition (see Receiving data with Freeport (Page 41)).
16#81C3	Invalid value for "Maximum message length"	Select a suitable value for "Maximum message length" (MAXLEN). Valid range of values (depending on the module): 1-1024/2048/4096 (Byte)
16#81C4	Invalid value for "Offset of the length specification in the message"	Select a suitable value for "Offset of the length specification in the message". Valid range of values (depending on the module): 1-1024/2048/4096 (Byte)
16#81C5	Invalid value for "Size of length field"	Select a suitable value for "Size of length field" (LENGTHSIZE). Valid range of values in bytes: • 1 (1) • 2 (2) • 4 (4)
16#81C6	Invalid value for "Number of characters not counted in length specification"	Select a suitable value for "Number of characters not counted in length specification" (LENGTHM). Valid range of values: 0 to 255 (bytes)
16#81C7	The total of "Offset in the message + size of length field + number of characters not counted" is greater than the maximum frame length	Select a suitable value for "Offset in message", "Size of length field" and "Number of characters not counted". Valid range of values: • Offset in the message (depending on the module): 0-1024/2048/4096 (bytes) • Size of length field: 1, 2, or 4 (bytes) • Number of characters not counted: 0 to 255 (bytes)
16#81C8	Invalid value for "Response timeout"	Select a suitable value for "Response timeout". Valid range of values: 1-65535 (ms)
16#81C9	Invalid value for "Character delay time"	Select a suitable value for "Character delay time". Valid range of values: 1 to 65535 (bit times)
16#81CB	frame end sequence is activated, but no character is activated for the check	Activate one or several characters for the check.
16#81CC	frame start sequence is activated, but no character is activated for the check	Activate one or several characters for the check.

Error code	Description	Remedy
16#81CD	Invalid value for "Prevent overwriting"	Select a suitable value for "Prevent overwriting". The following are valid: • Prevent overwriting is deactivated (0) or • Prevent overwriting is activated (1)
16#81CE	Invalid value for "Clear receive buffer on startup"	Select a suitable value for "Clear receive buffer on startup". The following are valid: • Clear receive buffer at startup is deactivated (0) • Clear receive buffer at startup is activated (1)
SEND status and error codes		
16#81D0	Receiving send request during runtime of a send command	Make sure that you do not receive an additional send request during runtime of a send command.
16#81D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or change the parameters, if necessary.
16#81D2	"Hardware RTS always ON": Send job canceled due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ON for the entire duration of transmission.
16#81D3	Send buffer overflow / send frame too long	Select a shorter frame length. The following are valid (depending on the module): 1 to 1024/2048/4096 (bytes)
16#81D5	Transmission canceled due to parameter changes, detected wire break, or CPU in STOP	Check the parameter assignment, wire break, and CPU status.
16#81D6	Transmission canceled because end identifier was not received	Check the parameter assignment of the end charac-ters and the frame of the communication partner.
16#81D7	Communication error between the user program and module	Check the communication (e.g., matching the se-quence number).
16#81D8	Transmission attempt rejected because module is not configured	Configure the module.
16#81DF	The module has reset the interface to the FB for one of the following reasons: • Module was restarted • Module parameters were reassigned • CPU STOP	—
Error codes of the receive configuration		
16#81E0	Frame aborted: Send buffer overflow / send frame too long	Increase the call rate for the receive function in the user program or configure communication with data flow control.
16#81E1	Frame aborted: Parity error	Check the connection line of the communication partners, or verify that the same data transmission rate, parity and stop bit number are configured for both devices.
16#81E2	Frame aborted: Character frame error	Check the settings for start bit, data bits, parity bit, data transmission rate, and stop bit(s).
16#81E3	Frame aborted: Character overflow error	Firmware error: Please contact Customer Support.

Error code	Description	Remedy
16#81E4	Frame aborted: The total length of "Offset in the message + size of the length field + number of characters not counted" is greater than the receive buffer	Select a suitable value for offset in message, size of the length field, and number of characters not counted.
16#81E5	Frame aborted: Break	Receive line to partner is interrupted. Reconnect or switch on partner.
16#81E6	Maximum number of "Buffered received frames" exceeded	In the user program call the instruction more often or configure a communication with data flow control or increase the number of buffered frames.
16#81E7	Synchronization error module and Receive_P2P	Make sure that different instances of the Receive_P2P do not access the same module.
16#81E8	Frame aborted: The character delay time has expired before the message end criterion was detected	Partner device faulty or too slow. Check this, if required, using an interface tester that is interconnected in the transmission line.
16#81E9	Modbus CRC error (only communication modules which support Modbus)	Checksum error of the Modbus frame. Check the communication partner.
16#81EA	Modbus frame too short (only communication modules which support Modbus)	Minimum length of Modbus frame not met. Check the communication partner.
16#81EB	Frame aborted: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1-1024/2048/4096 (bytes) Check the parameters for end of frame detection.
Error codes V24 accompanying signals		
16#81F0	The module does not support V24 accompanying signals	You have tried to set accompanying signals for a module that does not support V24 accompanying signals. Make sure that this is an RS232 module or that RS232 mode (ET 200SP) is set.
16#81F1	No operation of the V24 accompanying signals	The V24 accompanying signals cannot be operated manually if hardware data flow control is active.
16#81F2	The DSR signal cannot be set because the module has the type DTE.	Check the configured type of the module. The module type must be DCE (data communication equipment).
16#81F3	The DTR signal cannot be set because the module has the type DCE.	Check the configured type of the module. The module type must be DTE (data terminal equipment).
16#81F4	Block header error (e.g. incorrect block type or incorrect block length)	Check the instance DB and the block header.

Error code	Description	Remedy
Error codes of the receive configuration		
16#8201 1)	Receive_Conditions is a pointer to an invalid data type	Enter a pointer to one of the following data types: DB, BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL, DATE, TIME_OF_DAY, TIME, S5TIME, DATE_AND_TIME, STRING
16#8225	Receive_Conditionspoints to an optimized memory area greater than 1 kB or Receive_Conditions points to an optimized memory area and the receive length is greater than the area addressed by Receive_Conditions.	Enter a pointer to an area with a maximum length of: • Optimized memory area: 1 KB • Non-optimized memory area: 4 KB Note: If the pointer points to an optimized memory area, do not send more than 1 KB.
16#8229 1)	Receive_Conditions is a pointer to BOOL with a number of bits not equal to n * 8	If you are using a pointer to BOOL, the number of bits must be a multiple of 8.
Error codes, general		
16#8280	Negative acknowledgment when reading module	You can find more detailed information on error causes in theRDREC.STATUS static parameters and in the description of the SFB RDREC. • Check the input at the PORT parameter • Set the COM_RST parameter before the 1st call.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter You can find more detailed information on error causes in the WRREC.STATUS static parameters and in the description of the SFB WRREC.
16#8282	Module not available	Check the input at the PORT parameter and ensure that the module can be reached.
Error codes of the receive configuration		
16#82C1	Invalid value for "Buffered received frames".	Select a suitable value for "Buffered received frames". Valid range of values: 1-255
16#82C2	Receive configuration rejected because the 3964(R) protocol was selected	Make sure that no receive configuration is sent if the 3964(R) protocol is set.
16#8301 1)	Receive_Conditions is a pointer to an invalid data type	Select a valid data type. The following are valid: DB, BOOL, BYTE, CHAR, WORD, INT, DWORD, DINT, REAL, DATE, TIME_OF_DAY, TIME, S5TIME, DATE_AND_TIME, STRING
16#8322	Range length error when reading a parameter	Check the input at the Receive_Conditions parameter
16#8324	Range error when reading a parameter	Check the input at the Receive_Conditions parameter
16#8328	Setting error when reading a parameter	Check the input at the Receive_Conditions parameter
SEND status and error codes		
16#8328 1)	BUFFER is a pointer to BOOL with a number of bits not equal to n * 8	If you are using a pointer to BOOL, the number of bits must be a multiple of 8.

Error code	Description	Remedy
Error codes of the receive configuration		
16#8332	Invalid data block at the Receive_Conditions parameter	Check the input at the Receive_Conditions parameter
16#833A	The designation of the data block at the Receive_Conditions parameter refers to a data block which is not loaded.	Check the input at the Receive_Conditions parameter
16#8351	Invalid data type	Check the input at the Receive_Conditions parameter
16#8352 [1)]	Receive_Conditions does not point to a data block	Check the pointer to Receive_Conditions
16#8353 [1)]	Receive_Conditions does not point to a structure of the typeReceive_Conditions	Check the pointer to Receive_Conditions
Error codes 3964(R) protocol		
16#8380	Parameter assignment error: Invalid value for "Character delay time".	Select a suitable value for "Character delay time" (CharacterDelayTime). Valid range of values: 1 to 65535 (ms)
16#8381	Parameter assignment error: Invalid value for "Response timeout".	Select a suitable value for "Response timeout" (AcknDelayTime). Valid range of values: 1 to 65535 (ms)
16#8382	Parameter assignment error: Invalid value for "Priority".	Select a suitable value for "Priority" (Priority). The following are valid: • High (1) • Low (0)
16#8383	Parameter assignment error: Invalid value for "Block check"	Select a suitable value for "Block check" (BCC). The following are valid: • With block check (1) • Without block check (0)
16#8384	Parameter assignment error: Invalid value for "Connection attempts".	Select a suitable value for "Connection attempts" (BuildupAttempts). Valid range of values: 1-255
16#8385	Parameter assignment error: Invalid value for "Transmission attempts".	Select a suitable value for "Transmission attempts" (RepetitionAttempts). Valid range of values: 1-255
16#8386	Runtime error: Number of connection attempts exceeded	Check the interface cable and the transmission parameters. Also check whether the receive function is configured correctly at the partner device.
16#8387	Runtime error: Number of transmission attempts exceeded	Check the interface cable, the transmission parameters and the configuration of the communication partner.
16#8388	Runtime error: Error at the "Block check character" The internally calculated value of the block check character does not correspond to the block check character received by the partner at the connection end.	Check whether the connection is seriously disrupted; in this case you may also occasionally see error codes. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.

Error code	Description	Remedy
16#8389	Runtime error: Invalid character received while waiting for free receive buffer	The send request of the communication partner (STX, 02H) is only answered with DLE when the receive buffer is empty. No additional character may be received before (except STX again). Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#838A	Runtime error: Logical error during receiving. After DLE was received, a further random character (other than DLE or ETX) was received.	Check if partner DLE in frame header and in data string is always in duplicate or the connection is released with DLE ETX. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
16#838B	Runtime error: Character delay time exceeded	Partner device too slow or faulty. Verify by using an interface test device that is switched into the transmission line, if necessary.
16#838C	Runtime error: Wait time for free receive buffer has started	In the user program call the instruction more often or configure a communication with data flow control.
16#838D	Runtime error: frame repetition does not start within 4 s after NAK	Check the communication partner. A received frame that is possibly corrupted must be repeated by the partner within 4 seconds.
16#838E	Runtime error: In idle mode, one or several characters (other than NAK or STX) were received.	Check for proper function of the partner device, possibly using an interface test device that is switched into the transmission line.
16#838F	Runtime error: Initialization conflict - Both partners have set high priority	Set the "Low" priority at one of the partners
16#8391	Parameter assignment error: 3964 configuration data rejected because Freeport is set	If the Freeport protocol is set, make sure that no 3964 parameter assignment data is sent.

1) Only with instructions for S7-300/400 CPUs

Overview of error messages - Modbus

Error code	Description	Remedy
16#0000	No error	-
Configuration error of the interface - Modbus_Comm_Load		
16#8181	The module does not support this data transmission rate.	Select a valid data transmission rate for the module at the BAUD parameter.
16#8182	The module does not support this parity setting.	Select a suitable value for "Parity" at the PARITY parameter. The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
16#8183	The module does not support this type of data flow control.	Select a valid data flow control for the module at the FLOW_CTRL parameter.
16#8184	Invalid value for "Response timeout".	Select a suitable value for "Response timeout" at the RESP_TO parameter. Valid range of values: 1 to 65535 (ms)
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the Send_Config.RDREC.STATUS or Receive_Config.RDREC.STATUS static parameters or RDREC.STATUS and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the Send_Config.WRREC.STATUS or Receive_Config.WRREC.STATUS static parameters or WRREC.STATUS and in the description of the SFB WRREC.
16#8282	Module not available	Check the input at the PORT parameter and ensure that the module can be reached.

Error code	Description	Remedy
Configuration error - Modbus_Slave		
16#8186	Invalid slave address	Select a suitable slave address at the MB_ADDR parameter. The following are valid: 1-247 at standard address area; 1-65535 at extended address area (0 is reserved for Broadcast)
16#8187	Invalid value at MB_HOLD_REG parameter	Select a suitable value for the hold register at the MB_HOLD_REG parameter.
16#8188	Invalid operating mode or broadcast (MB_ADDR = 0) and MODE parameter ≠ 1	Select the value 1 for MODE in Broadcast mode or select a different operating mode.
16#818C	The pointer to a MB_HOLD_REG area must be a data block or a bit memory address area.	Select a suitable value for the pointer to the MB_HOLD_REG area.
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.WRREC.STATUS or Receive_P2P.WRREC.STATUS, and in the description of the SFB WRREC.
16#8452 [1)]	MB_HOLD_REG is not a pointer to a DB or a bit memory area	Check the MB_HOLD_REG pointer
16#8453 [1)]	MB_HOLD_REG is not a pointer of type BOOL or WORD	Check the MB_HOLD_REG pointer
16#8454 [1)]	The area addressed by MB_HOLD_REG is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the MB_HOLD_REG pointer
16#8455 [1)]	MB_HOLD_REG points to a write-protected DB	Check the MB_HOLD_REG pointer
16#8456 [1)]	Error during instruction execution. The cause of the error is shown in the STATUS parameter.	Determine the value of the SFCSTATUS parameter. Check what this means in the description for SFC51, STATUS parameter.

Error code	Description	Remedy
Configuration error - Modbus_Master		
16#8180	Invalid value for MB_DB parameter	The value configured for MB_DB (instance data DB) at the Modbus_Comm_Load instruction is not valid. Check the interconnection of the Mod-bus_Comm_Load instruction and its error messages.
16#8186	Invalid station address	Select a suitable station address at the MB_ADDR parameter. The following are valid: 1-247 at standard address area; 1-65535 at extended address area (0 is reserved for Broadcast)
16#8188	Invalid operating mode or broadcast (MB_ADDR = 0) and MODE parameter ≠ 1	Select the value 1 for MODE in Broadcast mode or select a different operating mode.
16#8189	Invalid data address	Select a suitable value for the data address at the DATA_ADDR parameter. See description Modbus_Master (Page 125) in the Info system
16#818A	Invalid length	Select a suitable data length at the DATA_LEN pa-rameter. See description Modbus_Master (Page 125) in the Info system
16#818B	Invalid value for DATA_PTR	Select a suitable value for the data pointer at the DATA_PTR parameter (M or DB address). See description Modbus_Master (Page 125) in the Info system
16#818C	Interconnection error of the DATA_PTR parameter	Check the interconnection of the instruction.
16#818D	The area addressed by DATA_PTR is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the DATA_PTR pointer
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.RDREC.STATUS or Re-ceive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Send_P2P.WRREC.STATUS or Re-ceive_P2P.WRREC.STATUS or Receive_Reset and in the description of the SFB WRREC.

Error code	Description	Remedy
Communication errors - Modbus_Master and Modbus_Slave		
16#80D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or change the parameters, if necessary.
16#80D2	"Hardware RTS always ON": Send job canceled due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ON for the entire duration of transmission.
16#80E0	Frame aborted: Send buffer overflow / send frame too long	In the user program call the instruction more often or configure a communication with data flow control.
16#80E1	Frame aborted: Parity error	Check the connection line of the communication partners, or verify that the same data transmission rate, parity and stop bit number are configured for both devices.
16#80E2	Frame aborted: Character frame error	Check the settings for start bit, data bits, parity bit, data transmission rate, and stop bit(s).
16#80E3	Frame aborted: Character overflow error	Check the number of data in the frame of the communication partner.
16#80E4	Frame aborted: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1 to 1024/2048/4096 (bytes)
Communication error - Modbus_Master		
16#80C8	The slave does not respond within the set time	Check the data transmission rate, parity and wiring of the slave.
16#80C9	The slave does not respond within the time set by Blocked_Proc_Timeout.	Check the setting for Blocked_Proc_Timeout. Check if the module has been configured with the Modbus_Comm_Load instruction. The module may possibly need to be reconfigured using Modbus_Comm_Load after a pull/plug or after voltage recovery.
16#8200	The interface is busy with an ongoing request.	Repeat the command later. Make sure that there are no commands still running before you start a new one.
Protocol error - Modbus_Slave (only communication modules that support Modbus)		
16#8380	CRC error	Checksum error of the Modbus frame. Check the communication partner.
16#8381	The function code is not supported or is not supported for broadcast.	Check the communication partner and make sure that a valid function code is sent.
16#8382	Invalid length information in the request frame	Select a suitable data length at the DATA_LEN parameter.
16#8383	Invalid data address in the request frame	Select a suitable value for the data address at the DATA_ADDR parameter.
16#8384	Invalid data value error in the request frame	Check the data value in the request frame of the Modbus master
16#8385	The diagnostic value is not supported by the Modbus slave (function code 08)	The Modbus slave only supports the diagnostic values 16#0000 and 16#000A.

Error code	Description	Remedy
Protocol error - Modbus_Master (only communication modules that support Modbus)		
16#8380	CRC error	Checksum error of the Modbus frame. Check the communication partner.
16#8381	Response frame from Modbus Slave with the following error message: The function code is not supported.	Check the communication partner and make sure that a valid function code is sent.
16#8382	Response frame from Modbus Slave with the following error message: Invalid length	Select a suitable data length.
16#8383	Response frame from Modbus Slave with the following error message: Invalid data address in the request frame	Select a suitable value for the data address at the DATA_ADDR parameter.
16#8384	Response frame from Modbus Slave with the following error message: Data value error	Check the request frame to the Modbus slave.
16#8385	Response frame from Modbus Slave with the following error message: The diagnostic value is not supported by the Modbus slave	The Modbus slave only supports the diagnostic values 16#0000 and 16#000A.
16#8386	The returned function code does not match the requested function code.	Check the response frame and the addressing of the slave.
16#8387	A slave that was not requested answers	Check the response frame of the slave. Check the address settings of the slave.
16#8388	Error in the response of the slave to a write request.	Check the response frame of the slave.
16#8828 [1)]	DATA_PTR points to a bit address that is not equal to n * 8	Check the DATA_PTR pointer
16#8852 [1)]	DATA_PTR is not a pointer to a DB or a bit memory area	Check the DATA_PTR pointer
16#8853 [1)]	DATA_PTR is not a pointer of type BOOL or WORD	Check the DATA_PTR pointer
16#8855 [1)]	DATA_PTR points to a write-protected DB	Check the DATA_PTR pointer
16#8856 [1)]	Error during call of SFC51	Call the Modbus_Master instruction again
Error - Modbus_Slave (only communication modules that support Modbus)		
16#8428 [1)]	MB_HOLD_REG points to a bit address that is not equal to n * 8	Check the MB_HOLD_REG pointer
16#8452 [1)]	MB_HOLD_REG is not a pointer to a DB or a bit memory area	Check the MB_HOLD_REG pointer
16#8453 [1)]	MB_HOLD_REG is not a pointer of type BOOL or WORD	Check the MB_HOLD_REG pointer
16#8454 [1)]	The area addressed by MB_HOLD_REG is longer than the DB, or the area addressed is too small for the number of data bytes to be read or written.	Check the MB_HOLD_REG pointer
16#8455 [1)]	MB_HOLD_REG points to a write-protected DB	Check the MB_HOLD_REG pointer
16#8456 [1)]	Error during call of SFC51	Call the Modbus_Slave instruction again

[1)] Only with instructions for S7-300/400 CPUs

Overview of error messages - USS

Error code	Description	Remedy
16#0000	No error	-
16#8180	Length error in response of drive	Check the response frame of the drive.
16#8181	Data type error	Select a suitable data type. The following are valid: • Real • Word • Double word
16#8182	Data type error: "Double word" or "Real" may not be returned for the "Word" request.	Check the response frame of the drive.
16#8183	Data type error: "Word" may not be returned for the "Double word" or "Real" request.	Check the response frame of the drive.
16#8184	Checksum error in response of drive	Check the drive and the communication connection.
16#8185	Addressing error	Valid drive address range: 1 to 16
16#8186	Setpoint error	Valid setpoint range: -200% to +200%
16#8187	Incorrect drive number returned	Check the response frame of the drive.
16#8188	Invalid PZD length	Permitted PZD lengths: 2, 4, 6, 8 words
16#8189	The module does not support this data transmission rate.	Select a valid data transmission rate for the module.
16#818A	A different request for this drive is currently active.	Repeat the parameter read or write command later.
16#818B	The drive does not respond.	Check the drive.
16#818C	The drive responds with an error message to a parameter request.	Check the response frame of the drive. Check the parameter request. Check if the instructions USS_Read_Param, USS_Write_Param or USS_Port_Scan have reported an error. If they have, check the value of the static tag USS_DB. w_USSExtendedError of the USS_Drive_Control instruction.
16#818D	The drive responds with an access error message to a parameter request.	Check the response frame of the drive. Check the parameter request.
16#818E	The drive was not initialized.	Check the user program and make sure that the USS_Drive_Control instruction is called for this drive.

Error code	Description	Remedy
16#8280	Negative acknowledgment when reading module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Port_Config.RDREC.STATUS, Send_Config.RDREC.STATUS , Receive_Config.RDREC.STATUS , Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB RDREC.
16#8281	Negative acknowledgment when writing module	Check the input at the PORT parameter. You can find more detailed information on error causes in the static parameters Port_Config.WRREC.STATUS, Send_Config.WRREC.STATUS , Receive_Config.WRREC.STATUS , Send_P2P.RDREC.STATUS or Receive_P2P.RDREC.STATUS, and in the description of the SFB WRREC.

[1] Only with instructions for S7-300/400 CPUs

Startup and Diagnostics 6

6.1 Startup characteristics

Operating mode transitions

After the communication module starts up, all data between the CPU and the communication module is exchanged by means of instructions.

CPU STOP	During a running data transmission communication module - CPU, both a send and a receive job is aborted.
CPU RUN	Send and receive operation is ensured in the RUN state of the CPU. With a corresponding configuration in the properties dialog of the communication module, you can automatically clear the receive buffer on the communication module during CPU startup.

From the view of the communication module, there are no further operating states/operating state transitions.

6.2 Diagnostic functions

Introduction

The diagnostic functions of the communication module allow errors that have occurred to be located quickly. The following diagnostic options are available to you:

Diagnostics by means of the display elements of the communication module	The indicators provide information on the operating mode or the possible error states of the communication module. The indicators provide an initial overview of any internal or external errors and interface-specific errors. For more information refer to the device manual of the corresponding communication module.
Diagnostics via the STATUS output of the instructions	Instructions have a STATUS output for error diagnostics; it provides information about communication errors between the communication module and the CPU. You can evaluate the STATUS parameter in the user program (it is active for exactly one cycle).
Diagnostic error interrupt	The communication module can trigger a diagnostic error interrupt on the CPU assigned to it. The communication module makes diagnostic information availa-ble. The analysis of this information is made via the user program or by reading the CPU diagnostics buffer.

6.3 Diagnostic interrupts

The diagnostics are displayed as plain text in STEP 7 (TIA Portal) in the online and diagnostics view. You can evaluate the error codes with the user program.

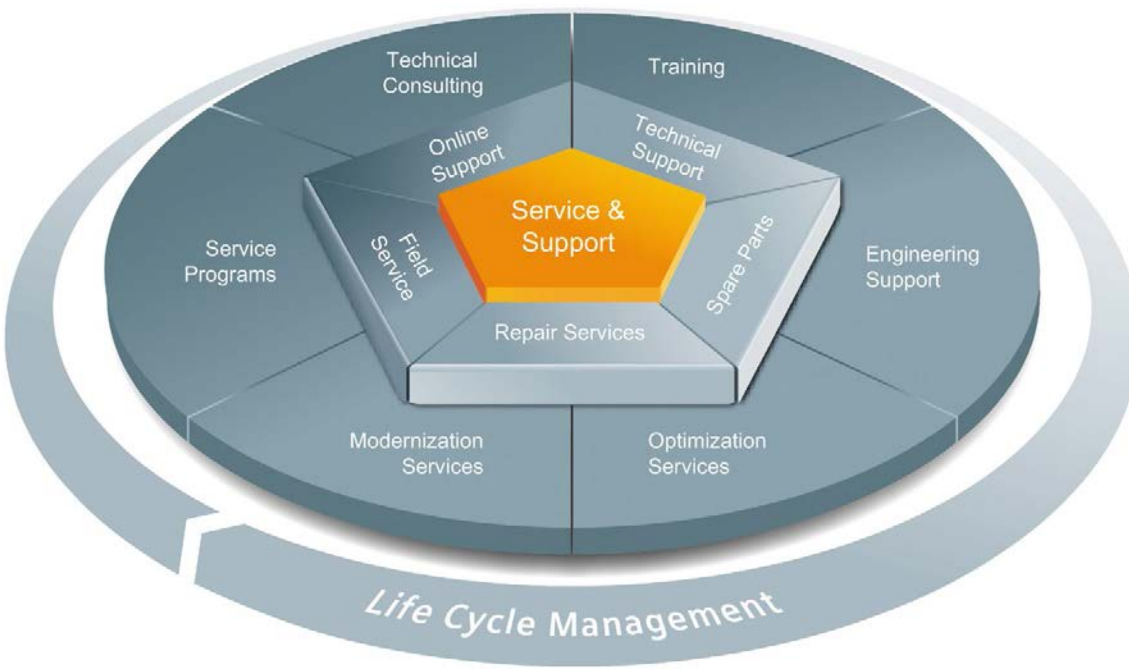
The following diagnostics can be signaled:

- Parameter assignment error (10_H)
- Wire break (109_H)

Service & Support

A

A.1 Service & Support



Unmatched complete service for the entire life cycle

For machine manufacturers, solution providers and plant operators: The service offering from Siemens Industry Automation and Drive Technologies includes comprehensive services for a wide range of different users in all sectors of the manufacturing and process industry.

To accompany our products and systems, we offer integrated and structured services that provide valuable support in every phase of the life cycle of your machine or plant – from planning and implementation through commissioning as far as maintenance and modernization.

Our Service & Support accompanies you worldwide in all matters concerning automation and drive technology from Siemens. We provide direct on-site support in more than 100 countries through all phases of the life cycle of your machines and plants.

You have an experienced team of specialists at your side to provide active support and bundled know-how. Regular training courses and intensive contact among our employees – even across continents – ensure reliable service in the most diverse areas.

Online Support

The comprehensive online information platform supports you in all aspects of our Service & Support at any time and from any location in the world.

You can find Online Support at the following address on the Internet (http://www.siemens.com/automation/service&support).

Technical Consulting

Support in planning and designing your project: From detailed actual-state analysis, definition of the goal and consultation on product and system questions right through to the creation of the automation solution.

Technical Support

Expert advice on technical questions with a wide range of demand-optimized services for all our products and systems.

You can find Technical Support at the following address on the Internet (http://www.siemens.com/automation/support-request).

Training

Extend your competitive edge – through practical know-how directly from the manufacturer.

You can find the training courses at the following address on the Internet (http://www.siemens.com/sitrain).

Engineering Support

Support during project engineering and development with services fine-tuned to your requirements, from configuration through to implementation of an automation project.

Field Service

Our Field Service offers you services for commissioning and maintenance – to ensure that your machines and plants are always available.

Spare parts

In every sector worldwide, plants and systems are required to operate with constantly increasing reliability. We will provide you with the support you need to prevent a standstill from occurring in the first place: with a worldwide network and optimum logistics chains.

Repairs

Downtimes cause problems in the plant as well as unnecessary costs. We can help you to reduce both to a minimum – with our worldwide repair facilities.

Optimization

During the service life of machines and plants, there is often a great potential for increasing productivity or reducing costs.

To help you achieve this potential, we are offering a complete range of optimization services.

Modernization

You can also rely on our support when it comes to modernization – with comprehensive services from the planning phase all the way to commissioning.

Service programs

Our service programs are select service packages for an automation and drives system or product group. The individual services are coordinated with each other to ensure smooth coverage of the entire life cycle and support optimum use of your products and systems.

The services of a service program can be flexibly adapted at any time and used separately.

Examples of service programs:

- Service contracts
- Plant IT Security Services
- Life Cycle Services for Drive Engineering
- SIMATIC PCS 7 Life Cycle Services
- SINUMERIK Manufacturing Excellence
- SIMATIC Remote Support Services

Benefits at a glance:

- Reduced downtimes for increased productivity
- Optimized maintenance costs due to a tailored scope of services
- Costs that can be calculated and therefore planned
- Service reliability due to guaranteed response times and spare part delivery times
- Customer service personnel will be supported and relieved of additional tasks
- Comprehensive service from a single source, fewer interfaces and greater expertise

Contact

At your service locally, around the globe: your partner for consultation, sales, training, service, support, spare parts... for the entire range of products from Industry Automation and Drive Technologies.

You can find your personal contact in our contacts database on the Internet (http://www.siemens.com/automation/partner).

Glossary

Automation system

An automation system is a programmable logic controller consisting of at least one CPU, various input and output modules, and operating and monitoring devices.

Bit times

"Bit times" are always specified as a number of bits.

The "time" set with bits depends on the selected data transmission rate that is taken into consideration automatically.

Example:

The telegram end is to be detected after a gap of two characters.

The set data transmission rate is 9600 bit/s.

The set character frame is 10 bits.

$10 \times 2 = 20$ bit times

This corresponds to a time of:

$20 \times 1/9600 \approx 0.0021$ s

Communication module

Communication modules are used for point-to-point connections and bus links.

Configuring

Configuring refers to the configuration of separate modules of an automation system in the configuration table.

CPU

Central Processing Unit = Central module of the automation system that consists of the control and computing units, memory, system program, and interfaces to the I/O modules.

CTS

Clear to send. The communication partner is ready to receive data.

Cycle time

The cycle time is the time that the CPU requires to process the user program once.

Cyclic program processing

In cyclic program processing the user program runs in program loop, or cycle, that is constantly repeated.

DCD

Data carrier detect. The communication partner signals that it recognizes incoming data.

Default setting

The default setting is a reasonable basic setting that can be used whenever no other value is specified.

Diagnostic events

Diagnostics events are, for example, module errors or system errors in the CPU that may be caused by a program error.

Diagnostic functions

The diagnostic functions cover the entire system diagnostics and include the recognition, interpretation and reporting of errors within the automation system.

Diagnostics buffer

Memory area in which detailed information on all diagnostics events is entered based on the order of their occurrence.

DSR

Data set ready. The communication partner is ready.

DTR

Data terminal ready. The communication module is ready.

Hardware

Hardware is the entire physical and technical equipment of a automation system.

Module parameters

Module parameters are values with which the behavior of the module can be set.

Online/Offline

When you are online there is a data connection between the automation system and programming device, when you are offline there is no data connection between them.

Parameter assignment

Parameter assignment refers to the setting of a module's behavior.

Parameters

Parameters are values that can be allocated. There are two different types of parameters: block parameters and module parameters.

Point-to-point communication

In point-to-point communication the communication processor forms the interface between a programmable logic controller and a communication partner.

Procedure

Procedure refers to the process of a data transmission according to a specific protocol.

Protocol

All communication partners involved in data transmission must follow fixed rules for handling and implementing the data traffic. Such rules are called protocols.

Receive line initial state

The initial state of the receive line for RS422 and RS485 mode:

- enables break detection (wire break)
- ensures a defined level on the receive line while it is not sending.

RI

Ring indicator. Incoming call for connecting a modem.

RTS

Request to send. The communication module is ready to send.

Software

Software refers to the entirety of all programs that are used on a computing system. The operating system and user programs belong to this.

User program

The user program contains all instructions and declarations for processing the signals used for controlling a system or a process. In SIMATIC S7 the user program is structured and divided into small units, the blocks.

USS

The USS® protocol (universal serial interface protocol) defines an access method based on the master-slave principle for communication by means of a serial bus. The point-to-point connection is included as a subset in this protocol.

XON/XOFF

Software data flow control with XON/XOFF. You can configure the characters for XON and XOFF (any ASCII character). The user data may not contain these characters.

Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

⚠DANGER
indicates that death or severe personal injury **will** result if proper precautions are not taken.

⚠WARNING
indicates that death or severe personal injury **may** result if proper precautions are not taken.

⚠CAUTION
indicates that minor personal injury can result if proper precautions are not taken.

NOTICE
indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

⚠WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This documentation addresses users who want to use the point-to-point communication modules independently of the SIMATIC S7. It offers you important information with regard to the configuration and commissioning of the point-to-point communication modules for S7-1500 (ET 200MP) and ET 200SP.

Requirements

To use PtP communication modules in a system independently of the SIMATIC S7, the CPU must support communication by means of data records and come equipped with a PROFINET IO controller. For more information on this topic, refer to the *Distributed I/O System ET 200SP* and *Distributed I/O System ET 200MP* system manuals.

Basic knowledge required

The following knowledge is required in order to understand the documentation:

- General knowledge of automation technology
- Knowledge of the industrial automation system SIMATIC
- Knowledge about the use of Windows-based computers
- Proficiency with STEP 7

GSDML file

Engineering must be provided with information regarding functionality and parameters of the communication modules for the higher-level application.

The properties of the PtP communication modules are defined in a GSDML (Generic Station Description Markup Language) file, an XML-based language that is defined based on the GSDML scheme (ISO 15745: GSD for PROFIBUS and GSDML for PROFINET IEC 61804: EDDL IEC 62453: FDT/DTM).

The Engineering System must provide a suitable interpreter that makes the GSDML data available to the system.

The name of a GSDML file for the communication modules can have the following syntax, for example: GSDML-V2.3-Siemens-ET200SP-20110824.xml

The GSDML file contains:

- Device and identification data
- Parameter assignment data
- Diagnostics data

In order to enable parameter assignment of the communication modules, the GSDML file must be installed/imported in the Engineering System.

Validity of the documentation

This documentation is valid for the following point-to-point communication modules

- CM PtP RS232 BA (6ES7540-1AD00-0AA0) communication module
- CM PtP RS422/485 BA (6ES7540-1AB00-0AA0) communication module
- CM PtP RS232 HF (6ES7541-1AD00-0AB0) communication module
- CM PtP RS422/485 HF (6ES7541-1AB00-0AB0) communication module
- CM PtP (6ES7137-6AA00-0BA0) communication module

Conventions

Please also observe notes labeled as follows:

Note

The notes contain important information on the product described in the documentation, on the handling of the product or on part of the documentation to which particular attention should be paid.

Recycling and disposal

The products can be recycled due to their low pollutant content. For environmentally compliant recycling and disposal of your old device, please contact a company certified for the disposal of electronic waste.

Additional assistance

- Information about the Technical support (http://www.siemens.com/automation/support-request) available can be found in the appendix to this documentation.
- The portfolio of technical documentation for SIMATIC products and systems is available on the SIMATIC Portal (http://www.siemens.com/simatic-tech-doku-portal).
- The online catalog and the ordering system are available in the Catalog (http://mall.automation.siemens.com).

Note on IT security

Siemens offers IT security mechanisms for its automation and drive product portfolio in order to support the safe operation of the plant/machine. We recommend that you inform yourself regularly on the IT security developments regarding your products. You can find information on this on the Internet (http://support.automation.siemens.com).

You can register for a product-specific newsletter here.

For the safe operation of a plant/machine, however, it is also necessary to integrate the automation components into an overall IT security concept for the entire plant/machine, which corresponds to the state-of-the-art IT technology. You can find information on this on the Internet (http://www.siemens.com/industrialsecurity).

Products used from other manufacturers should also be taken into account here.

Table of contents

1 Documentation guide

Introduction

This modular documentation of the SIMATIC products covers diverse topics concerning your automation system.

The complete documentation for the S7-300/400, ET 200MP/SP systems consists of the relevant operating instructions, manuals and product information.

Overview of documentation on the topic of point-to-point communication

Secondary signals and data flow control

- Software data flow control with XON/XOFF

  The Freeport protocol supports data flow control with XON/XOFF via the RS232 and RS422 interfaces.
- Hardware data flow control with RTS/CTS

  The Freeport protocol supports data flow control with RTS/CTS via the RS232 interface.
- Automatic operation of secondary signals

  The Freeport protocol supports operation of the RS232 secondary signals by means of the RS232 interface. (Only available if hardware data flow control is not activated.)

Application options for the communication modules

You may set up a communication connection with different partners, depending on the communication modules used:

- Freeport: Transmission of ASCII character strings without specified protocol format
- 3964(R): Communication between programmable logic controllers (master/master communication)

Basic information 3

3.1 Serial transmission of a character

Introduction

Different networking options are available for the exchange of data between two or more communication partners. The PtP connection between two communication partners is the simplest means of information exchange.

Point-to-point connection

In point-to-point connection, the communication processor forms the interface between a programmable logic controller and a communication partner. Data is sent in serial mode via PtP connection with the communication module.

Serial data transmission

During serial data transmission, the individual bits of a character of information to be transferred are sent successively in a defined sequence.

Bidirectional data traffic - operating mode

In the context of bidirectional data traffic, we distinguish between two operating modes for the communication module:

- Half duplex mode

  The data is transferred between one or several communication partners in both directions alternately. Half duplex mode means that data is either sent or received at a given point in time.

- Full duplex mode

  The data is exchanged simultaneously between one or several communication partners, i.e. it is possible to send and receive data simultaneously at a given point in time.

Asynchronous data transmission

Serial data transmission occurs asynchronously at the communication module. The so-called time base synchronism (fixed time base for transmission of a fixed character string) is only upheld during transmission of a character. Each character to be sent is preceded by a synchronization pulse, which is also known as start bit. The length of the start bit transmission determines the clock cycle. The end of character transmission is formed by one or two stop bits.

Handshakes

In addition to the start and stop bits, both communication partners need further handshake procedures for serial data transmission. These include:

- Data transmission rate
- Character and acknowledgment delay time
- Parity
- Number of data bits (7 or 8 bits/characters)
- Number of stop bits (1 or 2)

3.2 Transmission security

Transmission security plays an important role in the transmission of data and in the selection of the transmission procedure. Generally speaking, the more layers of the reference model are applied, the higher the transmission security.

Classification of existing protocols

The figure below illustrates how the protocols of the communication module fit into the reference model.

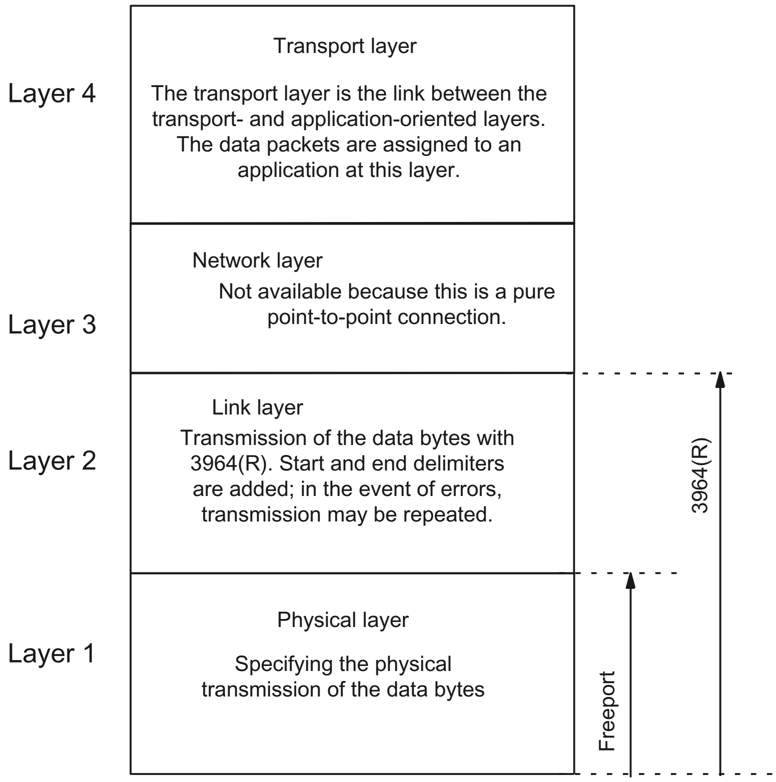

Figure 3-1 Classification of the existing protocols of the communication module in the reference model

Transmission security with Freeport

Data security when using Freeport:

- Despite the efficiency of data transmission with the Freeport protocol, it is not possible to ensure secure data transmission with Freeport because no data security measures other than the use of a parity bit (can also be disabled, depending on the character frame setting) are applied. A certain degree of data security can be achieved through parameter assignment of the frame start and frame end conditions.
- The parity bit ensures that the inversion of a bit in a character to be sent can be recognized. If two or more bits of a character are inverted, this error can no longer be detected.
- To increase transmission security, you can, for example, implement a checksum, a frame length specification, or configurable end conditions. These measures must be implemented by the user.
- A further increase in data security can be achieved by means of acknowledgment message frames in response to send or receive message frames. This is the case with high-grade protocols for data communication (ISO 7-layer reference model).

Transmission security with 3964(R)

Two different procedures for data transmission can be used, either with or without a block check character:

- Data transmission without block check character: 3964

  Transmission security is achieved by means of a specified frame structure, frame breakdown, and frame repetitions.
- Data transmission with block check character: 3964R

  The high degree of transmission security is achieved by means of a specified frame structure and breakdown, frame repetitions, as well as inclusion of a block check character (BCC). The hamming distance in 3964R mode is 3.

The hamming distance represents a measure for data transmission security.

In this manual, the term 3964(R) is used when descriptions and notes refer to both data transmission modes.

4 Basic communication mechanisms

Reading/writing data records

Note

Reading/writing data records

For information about the functions for reading/writing data records, refer to the documentation of your controller.

The "Write data record" function can be used to configure the devices by means of configuration data records. The "Write data record" function also transmits the send data to the devices. Accordingly, "Read data record" can be used to read diagnostics data and receive data from the devices.

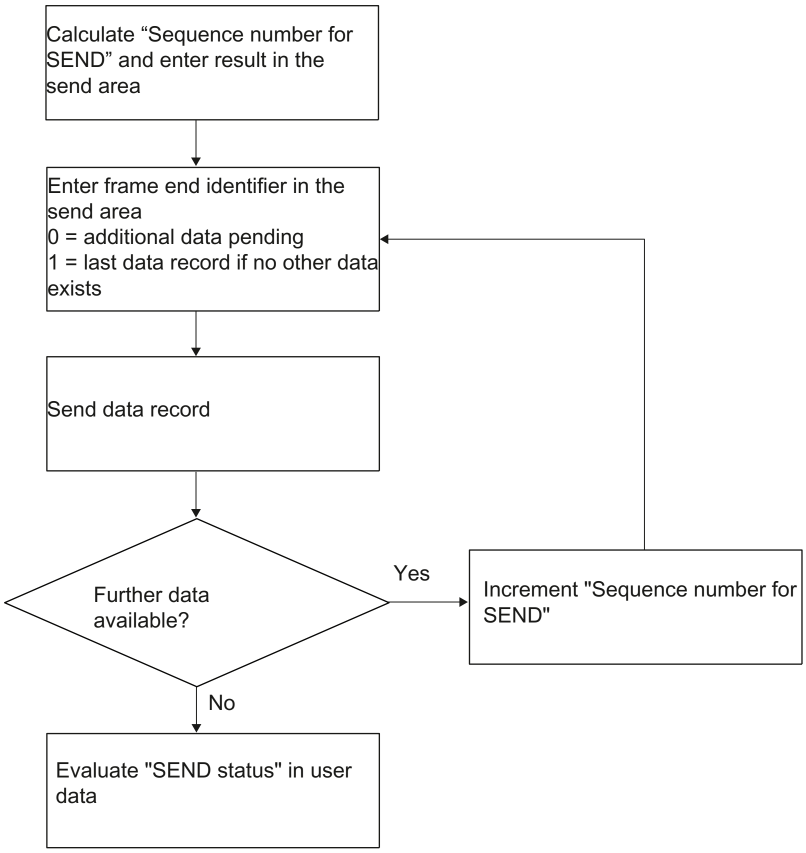
- For operation, you need to configure the communication modules for the relevant application.
  The following configuration data records can be used for this purpose:
  - Freeport communication (Page 41)
  - 3964 communication (Page 49)
- Use the following data records to send and receive data:
  - Sending data (Page 55)
  - Receiving data (Page 59)
- The cyclic user data shows you whether the module has sent or received new data.
  - Querying send acknowledgment - input user data (Page 57)
  - Query: New receive frame - input user data (Page 61)
- In RS232 mode, you can derive the current state of the secondary signals from the cyclic user data of the module, or control the RS232 secondary signals by means of the user program (provided hardware data flow control is not activated).
  - RS232 signals (Page 65)
- Data records can also be used to send additional control and verification commands.
  - Activate special function (Page 51)

Additional information

Chapter Data records and user data interface (Page 20) provides an overview of all configuration data records.

Send - flow chart

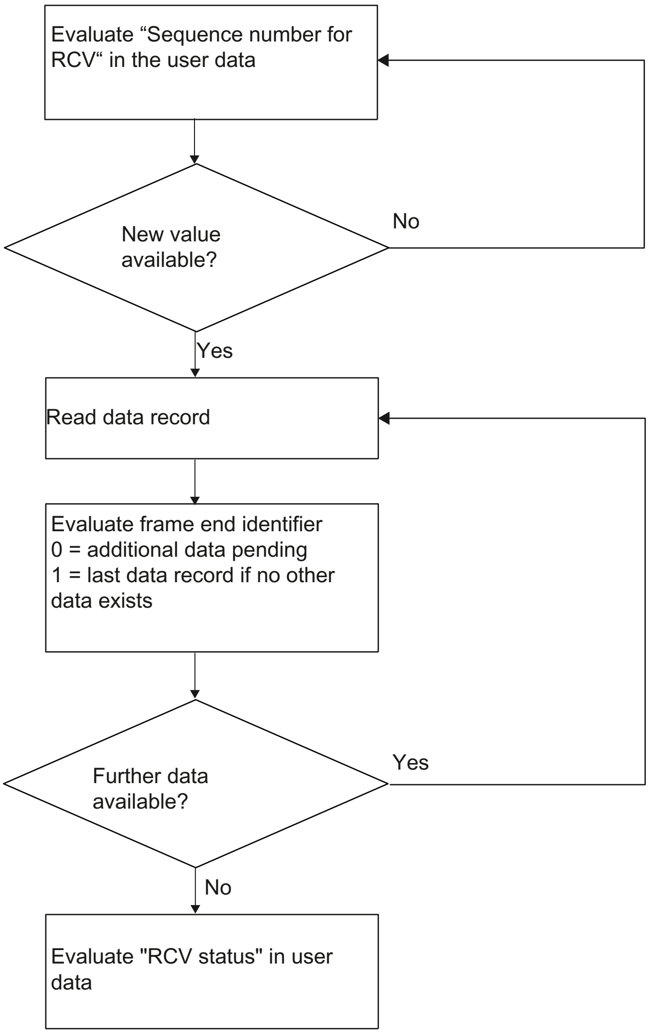
Users can transmit data based on the sequence outlined below (refer to Sending data (Page 55) for details). Management data and send data is transmitted to the communication module by means of a special data record. The communication module provides the acknowledgment in the input user data.



Receive - flow chart

The communication module signals the availability of new received data in the input user data (refer to Receiving data (Page 59) for details). The communication module provides management and receive data in a special data record.

Users can receive data based on the sequence outlined below.



4.1 Data records and user data interface

Overview of data records

Configuration data records are available for the following tasks:

- Freeport communication
  Configuration of the communication module for data transmission using the open Freeport frame
  - Activate special function (Page 51)
  - Send configuration record - data record 59 (Page 44)
  - Receive configuration record - data record 60 (Page 46)
- 3964 communication
  Configuration of the communication module for data transmission with 3964(R) protocol
  - Port configuration record - data record 57 (Page 41)
  - 3964 protocol configuration - data record 61 (Page 49)
- Special functions - Activation
  Activating or verifying the active state of diagnostic interrupts.
  - Activate special function (Page 51)

The following data records are available for operating the communication modules:

- Query error status
  Acknowledgment of the communication module in response to the writing of a configuration data record
  - Read error status - data record 55 (Page 53)
- Send data
  Transmitting send data to the communication module and querying transmission acknowledgment in the user data
  - Send data - data record 48 (Page 55)
  - Querying send acknowledgment - input user data (Page 57)
- Receive data
  Display of a receive frame in the user data
  - Data received - data record 49/50 (Page 59)
  - Query: New receive frame - input user data (Page 61)
- Clear receive buffer
  Clearing the receive buffer of the communication module
  - Clear receive buffer - data record 54 (Page 63)
- RS232 secondary signals
  Manipulation of the RS232 secondary signals of the communication module and reading the RS232 secondary signals in the user data
  - Set RS232 secondary signals - data record 53 (Page 65)
  - Read RS232 secondary signals - input user data (Page 66)

5 Data transmission with Freeport

Introduction

Freeport is a freely programmable, frame-based protocol.

The Freeport driver controls data transmission via point-to-point connection between the communication module and a communication partner. The Freeport driver contains the physical layer (layer 1).

The Freeport driver supports sending and receiving of messages with any structure - all characters from 00 to FFH (for character frames with 8 data bits), or from 00 to 7FH (for character frames with 7 data bits).

The frame start and end criteria must be configured both for the send and the receive direction. The structure of the send frames may differ from that of the receive frames.

5.1 Sending data with Freeport

Sending data

Note

During parameter assignment of the XON/XOFF data flow control, user data may not contain any of the configured XON or XOFF characters. Default settings are DC1 = 11H for XON and DC3 = 13H for XOFF.

Specifying settings for sending

To send a message, the partner must be informed of the start and end of the message (see Send configuration record - data record 59 (Page 44)). You can select one of the following options:

- Send the Break signal at the start of the message

  You can specify that an additional Break is sent at the beginning of each message transmission on expiration of the RTS ON delay time.
  The duration of the "Break" is specified in bit times (refer to Send configuration record - data record 59 (Page 44) bytes 12 and 13).

  Compliance with the send break can be deactivated if other mechanisms are used for synchronization.

- Send Idle Line

  You can specify that an additional "Idle Line" signal is output at the start of each message transmission.
  The duration of the "Idle Line" is specified in bit times (see Send configuration record - data record 59 (Page 44) bytes 14 and 15).

  Compliance with the send break can be deactivated if other mechanisms are used for synchronization.

- RTS ON delay

  You can configure the time that has to expire after the RTS (Request to send) before the actual data transmission starts (see Send configuration record - data record 59 (Page 44) bytes 8 and 9).

- RTS OFF delay

  You can configure the time that has to expire after transmission has been completed before the RTS signal is deactivated (see Send configuration record - data record 59 (Page 44) bytes 10 and 11).

- Sending including the end delimiter

  You can configure the number of end delimiters (1 or 2) and their value.

  All data up to the end delimiter(s) is sent, independent of the selected frame length. The end delimiter must be included in the data to be sent. Data is sent only up to and including the end delimiter, even if the data length specified is longer (refer to Send configuration record - data record 59 (Page 44) bytes 18 and 21).

- Number of appended characters

  Input of the number of appended characters. All data transferred to the communication module will be sent. The end delimiter(s) is/are appended automatically. 1 to 5 characters more than the specified number are sent to the partner, depending on the number of end delimiters (see Send configuration record - data record 59 (Page 44) bytes 22 and 28).

Note

If you do not configure either the "End delimiter" (0) or the "Number of appended characters" (0), all data transferred to the communication module is sent to the partner in a transparent operation.

5.2 Receiving data with Freeport

Introduction

You need to specify message start and end criteria in the Freeport driver to enable detection of a message in the incoming data flow.

Note

The start and end criteria described below can be combined as required. Such combinations may lead to unwanted results if the start and end criteria influence or even exclude each other.

Specifying the message start

For data transmission with Freeport, you can choose between several different start criteria. The start criterion defines when a frame starts. Once a criterion that indicates the start of the message is met, the data stream is scanned for message end criteria. (See Receive configuration record - data record 60 (Page 46) byte 9)

Two different methods are available for detecting the message start:

- Start on any character
- Start on special condition

Start on any character

- Start on any character

  Any character can be used to define the start of the message (default).

  This means that the first character sent at the start of communication, or after the frame end has been detected, will be identified as the first character of a message. (See Receive configuration record - data record 60 (Page 46) byte 12)

Start on special condition

The start of the message is detected based on the following specified conditions:

- After detection of a line break

  The frame start is not accepted unless a break has been received beforehand, in other words, it is compulsory for the partner to send a break before sending a frame.

- After detection of an idle line

  The frame start is not accepted until the configured idle line duration has expired. This procedure requires a minimum interval between two frames. (See Receive configuration record - data record 60 (Page 46) bytes 10 and 11)

- After receipt of a start character

  The frame start is detected when the configured start character is identified. (See Receive configuration record - data record 60 (Page 46) byte 12)

- After detection of one or several start sequences

  The frame start is detected when the configured string with a length of up to five characters is identified. You can configure up to 4 start sequences. (See Receive configuration record - data record 60 (Page 46) bytes 13 to 37)

Specifying the message end

You can choose from several different end criteria for data transmission using the Freeport driver. The end criterion defines the point at which a message frame has been received completely. (See Receive configuration record - data record 60 (Page 46) byte 39)

Configurable end criteria are:

- Recognize message end by message timeout
- Recognize message end by response timeout
- After character delay time elapses (default)
- After receipt of a fixed frame length
- After receipt of a maximum number of characters
- Read message length from message
- After receipt of an end sequence

Message timeout

When data is received, the end of frame is detected on expiration of the configured time for transferring a frame. Time measurement starts after the start criterion has been met. (See Receive configuration record - data record 60 (Page 46) bytes 52 and 53)

An error message is output and the frame is discarded if a message end condition is met before the fixed frame length has been reached.

Response timeout

When data is received, the end of frame is detected on expiration of the configured time between the end of the send operation and the receipt of a frame start. (See Receive configuration record - data record 60 (Page 46) bytes 50 and 51)

An error message is output and the frame is discarded if a message end condition is met before the fixed frame length has been reached.

Expiration of character delay time

When data is received, the frame end is detected when the configured maximum time (bit times) between successive characters is exceeded (character delay time). (See Receive configuration record - data record 60 (Page 46) bytes 54 and 55)

In this case, the character delay time must be set in such a way as to ensure that it expires between two consecutive frames. However, it should be of sufficient length to exclude incorrect identification of the end of the frame whenever the communication partner performs a transmission pause within a frame.

Fixed frame length

When data is received, the end of the frame is identified after the configured frame length has been reached. (See Receive configuration record - data record 60 (Page 46) bytes 40 and 41)

An error message is output and the frame is discarded if the character delay time expires (if activated) before the fixed frame length has been reached.

Please note the following if the frame length of the received characters does not match the fixed configured frame length:

- All characters received after the fixed configured frame length has been reached will be discarded until a new start criterion (e.g. "any character") is detected.
- Receiving is terminated if the character delay time (if activated) expires before the fixed configured frame length has been reached. An error message is generated and the message frame fragment is discarded.
- If a different (activated) end criterion is met before the fixed configured frame length has been reached, this "frame part" is assessed as a valid frame and the partner waits for a new start criterion. All characters received prior to fulfillment of a new start criterion are discarded.

Maximum number of characters

When receiving data, the end of the message frame is recognized after the declared number of characters have arrived. (See Receive configuration record - data record 60 (Page 46) bytes 42 and 43)

This setting can be combined with the "Character delay time" settings. The frame received is also assessed as free of error if another end condition occurs, regardless of whether the maximum number of characters has been reached.

Please note the following if the frame length of the received characters does not match the configured maximum frame length:

- All characters received after the configured maximum number of characters has been reached will be discarded until a new start criterion (e.g. "Idle Line") is detected.
- If a different (activated) end criterion is met before the configured maximum number of characters has been reached, this "frame part" is assessed as a valid frame and the partner waits for a new start criterion. All characters received prior to fulfillment of a new start criterion are discarded.

Note

If no further end criterion is activated, the fixed frame length and maximum number of characters will respond in the same way.

Message length in the message

The length of the receive frame is also sent. When data is received, the frame end is identified after the frame length also sent has been reached. If "After character delay time elapses" is activated as an additional end criterion, receiving will be terminated prematurely. An error message is generated and the message frame fragment is discarded.

The following parameters define the characters to be used for evaluation of the message length:

- **Offset of the length field in the message**

  In the message, the value defines the position of the character that is to be used to determine the message length.

  You can set values from 1 to 4096 characters, depending on the buffer size.

  (See Receive configuration record - data record 60 (Page 46) bytes 44 to 45)

- **Size of the length field**

  This value specifies the number of characters as of the first evaluation position to be used to determine the message length.

  You can set values of 0, 1, 2 and 4 characters.

  (See Receive configuration record - data record 60 (Page 46) bytes 46 to 47)

- **Number of characters not counted in length specification**

  Number of characters appended to the frame without counting towards the frame length. This value defines the number of bytes at the end of the frame which should not be included in the evaluation of the message length.

  You can set values from 0 to 255 characters.

  (See Receive configuration record - data record 60 (Page 46) bytes 48 to 49)

End sequence

When data is received, the end of the frame is identified when the configured end sequence (max. 5 characters) is received. The received data is applied by the CPU, including the end sequence. (See Receive configuration record - data record 60 (Page 46) bytes 56 to 61)

If you are working with the end sequence, transmission is not code-transparent and you must exclude the presence of end code in the user data.

5.3 Code transparency

Code transparency

Code-transparent means that any character combinations can occur in the user data without the end criterion being recognized.

The code transparency of the protocol depends on the selection of the parameterized end criterion and flow control:

- With up to five end delimiters or using XON/XOFF flow control
  - Not code-transparent
- End criterion character delay time, fixed frame length, maximum frame length, message timeout, or response timeout and message length in the message
  - Code-transparent

5.4 Receive buffer

Receive buffer of the module

The receive buffer of the module may have a size of up to 8 KB, depending on the communication module used (see chapter Overview (Page 11)). The maximum frame length always equals half the length of the receive buffer. This means that each communication module is capable of buffering at least two frames.

During parameter assignment, you can specify whether to clear the receive buffer at startup and whether to prevent overwriting of data in the receive buffer. You can also specify the range of values (1 to 255) for the number of buffered receive frames. (See Receive configuration record - data record 60 (Page 46) bytes 62 to 64)

The receive buffer on the communication module is organized as FIFO:

- If several frames are entered in the receive buffer of the communication module, the communication module always sends the oldest frame to the CPU.
- If you always want to transfer the last frame received to the CPU, you must set the value "1" for the number of buffered frames and deactivate overwrite protection.

Note

If continuous reading of the receive data in the user program is interrupted for a certain time and the receive data is then requested again, the communication module will possibly transmit an older frame before the CPU receives the most recent one. At the time of interruption, the old frame had already been transferred from the receive buffer of the communication module and prepared for transmission to the CPU.

5.5 RS232 mode

The following communication modules support RS232 mode:

- CM PtP RS232 BA
- CM PtP RS232 HF
- CM PtP (ET 200SP)

In RS232 mode, data is sent via two lines. A separate line is available for the send direction and the receive direction. Simultaneous sending and receiving is possible (full duplex).

RS232 secondary signals

In addition to the TXD, RXD and GND signals, the communication module provides the following RS232 secondary signals when RS232 hardware is used:

DCD	(input)	Data Carrier detect; Data carrier signal detected
DTR	(output)	Data terminal ready; Module ready for operation
DSR	(input)	Data set ready; Communication partner ready for operation
RTS	(output)	Request to send; Module is ready to send
CTS	(input)	Clear to send; Communication partner can receive data from the module (response to RTS = ON of the communication module)
RI	(input)	Ring Indicator; Ring indicator

After power on of the communication module, the output signals are in the OFF state (inactive).

You can parameterize the operation of the DTR/DSR and RTS/CTS control signals in the configuration data record of the module (Port configuration record - data record 57 (Page 41)).

The RS232 secondary signals cannot be manipulated by data record communication (Set RS232 secondary signals - data record 53 (Page 65)) in case of:

- parameterized data flow control "Hardware RTS always ON"

  (corresponds to automatic operation of the secondary signals)
- parameterized data flow control "Hardware RTS always ON"

  (corresponds to hardware flow control with RTS/CTS)
- parameterized data flow control "Hardware RTS always ON, ignore DTR/DSR "

An error message is generated if an attempt is made to manipulate RS232 secondary signals by means of data record communication.

For more information, refer to chapter Handshaking (Page 33).

5.6 RS422 mode

The following communication modules support RS422 mode:

- CM PtP RS422/485 BA
- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

In RS422 mode, data is transmitted via two line pairs (four-wire mode). A separate line pair is available for the send direction and the receive direction. Simultaneous sending and receiving is possible (full duplex).

All communication partners must be capable of simultaneous operation of a sender and receiver unit.

The data can be exchanged simultaneously between one or several communication partners. In RS422 multipoint mode, only one multipoint slave may send data at any given time.

Interface operating modes

The following table is a summary of the interface operating modes for the various communication modules and protocols.

The communication module can be used in the following topologies in RS422 mode:

- Link between two nodes: Point-to-point connection
- Link between several nodes: Multipoint coupling
  (only available with CM PtP (ET 200SP))

Operating mode	Description
Full duplex (RS 422) four-wire mode (point-to-point connection)	Both devices have the same priority in this operating mode.
Full duplex (RS422) four-wire mode (multipoint master)	The communication module can be used as multipoint master.
Full duplex (RS 422) four-wire mode (multipoint slave)	The communication module can be used as multipoint slave.

The following applies for a multipoint master/slave topology in RS422 mode:

- The master's sender is interconnected with the receivers of all slaves.
- The slaves' senders are interconnected with the master's receiver.
- The receiver of the master and the receiver of one slave are assigned default settings (refer to chapter Port configuration record - data record 57 (Page 41) byte 25). All other slaves operate without default settings.

5.7 RS485 mode

The following communication modules support RS485 mode:

- CM PtP RS422/485 BA
- CM PtP RS422/485 HF
- CM PtP (ET 200SP)

In RS485 mode, data is transferred via one line pair (two-wire mode). The line pair is available alternately for the send and receive directions. It is possible to either send or receive (half duplex). On completion of a send operation, operation is immediately switched to receive mode (ready to receive). Send mode is reset again as soon as a new send job is received.

RS485 mode

The following table is a summary of the interface operating modes for the various communication modules and protocols.

Operating mode	Description
Half duplex (RS485) two-wire mode	Operating mode for point-to-point connection or multipoint connection (multipoint) in two-wire mode. The communication module can be the master as well as the slave.

When you operate the Freeport driver in RS485 mode (half duplex, two-wire mode), you must make provisions in the user program to ensure that only one device sends data at any given time. If more than one device sends data at the same time, the frame is corrupted.

Changeover times for RS485 communication module in half duplex mode

A maximum time of 0.1 ms is set for the changeover between sending and receiving.

5.8 Handshaking

Introduction

Handshaking controls the data flow between two communication partners. The use of the handshaking method prevents data loss during transmission if the devices are operating at different speeds.

We can basically distinguish between the following methods:

Table 5- 1 Overview of methods and interfaces

Method	RS232	RS422	RS485
Software data flow control XON/XOFF	X	X	
Hardware data flow control (RTS/CTS)	X		
Automatic operation of secondary signals	X		

Software data flow control

Software data flow control is implemented as follows on the communication module:

- XON/XOFF
  - As soon as the communication module has been set to the "XON/XOFF" operating mode by means of parameter assignment, it sends the XON character, thereby allowing the communication partner to send data.
  - On reaching the configured maximum number of frames, or 16 characters ahead of receive buffer overflow, the communication module sends the XOFF character, thereby requesting that the communication partner stop sending. If the communication partner nonetheless continues to send data, an error message is generated if the receive buffer overflows. Data received in the last frame is discarded.
  - As soon as a frame has been fetched by the CPU and the receive buffer is ready to receive data again, the communication module sends the XON character.
  - If the communication module receives the XOFF character during sending, it cancels the current send operation until it receives a XON again from its communication partner. If no XON is received within a specific configurable time, send operation is canceled and a corresponding error message is output.

Note

You can configure the characters for XON and XOFF (any ASCII character).

During parameter assignment of the XON/XOFF software data flow control, user data may not contain any of the configured XON or XOFF characters.

Hardware data flow control

Note

The DTR/DSR signals do not have to be wired for "Hardware RTS always ON, ignore DTR/DSR" parameter assignment.

If "Hardware RTS always ON" is configured, it is imperative that you fully wire the interface signals used. Make sure that the local RTS (out) is connected with the CTS (in) of the communication partner and the local CTS is connected with the RTS of the communication partner. Accordingly, the local DTR must be connected with the DSR of the communication partner and the local DSR with the DTR of the communication partner.

- Hardware RTS always ON, ignore DTR/DSR
  - As soon as the communication module has been set to an operating mode with "Hardware RTS always ON" through parameter assignment, it outputs the RTS = ON signal to the communication partner to indicate its ready state.
  - RTS is set to OFF as soon as the configured maximum number of frames or 16 characters before buffer overflow is reached.
    If the communication partner nonetheless continues to send data, an error message is generated on overflow of the receive buffer. Data received in the last frame is discarded.
  - RTS is reset to ON as soon as the frame has been fetched by the CPU and the receive buffer is ready to receive data again.
  - If CTS switches to OFF during the send operation, the communication module interrupts the send operation until CTS is reset to ON. If CTS is not reset to ON within a specific configurable time, the send operation is canceled and a corresponding error message is output.
- Hardware RTS always ON

  The "Hardware RTS always ON" mode corresponds to the "Hardware RTS always ON, ignore DTR/DSR" mode. However, you also need to wire DTR and DSR.
  - As soon as the communication module has been set set to an operating mode with "Hardware RTS always ON" through parameter assignment, it sets DTR = ON and RTS = ON to signal its general ready state to the communication partner.
  - RTS is set to OFF as soon as the configured maximum number of frames or 16 characters before buffer overflow is reached.
    If the communication partner nonetheless continues to send data, an error message is generated on overflow of the receive buffer. Data received in the last frame is discarded.
  - RTS is reset to ON as soon as the frame has been fetched by the CPU and the receive buffer is ready to receive data again.
  - If CTS switches to OFF during the send operation, the communication module interrupts the send operation until CTS is reset to ON. If CTS is not reset to ON within a specific configurable time, the send operation is canceled and a corresponding error message is output.
  - A switch from DSR = ON to DSR = OFF cancels an active send job and triggers an error message.

Automatic operation of secondary signals

- **Hardware RTS always switched**

  "Hardware RTS always switched" is implemented as follows on the communication module:

  – As soon as the communication module is set to the operating mode with "Hardware RTS always switched" through parameter assignment, it sets the line RTS to OFF and DTR to ON (communication module ready for operation).

    It is not possible to send frames until the DSR line is set to ON. No data is sent via the RS232C interface as long as DSR is set to OFF. A send job is canceled and a corresponding error message is generated.

  – If a send job is pending, RTS is set to ON and the configured data output wait time starts. On expiration of the data output time, the system checks whether the communication partner has set CTS to ON. If so, the data is sent via the RS232 interface.

  – If the CTS line is not set to ON within the data output time, or changes to OFF during the send operation, the send job is aborted and an error message generated.

  – Once the data has been sent and the configured clear RTS time has elapsed, the RTS line is set to OFF. The system does not wait for CTS to change to OFF.

  – It is always possible to receive data via the RS232 interface. There will be no reaction if there is a danger of the receive buffer of the communication module overflowing.

  – A switch from DSR = ON to DSR = OFF cancels an active send job and triggers an error message.

Note

Set the "data output wait time" in such a way that the communication partner is able to enter the ready to receive state before the time elapses.

Set the "Clear RTS time" in such a way that the communication partner is able to receive the last characters of the frame completely before RTS is set to OFF and the send request is canceled.

Additional information

For information on the settings, refer to chapter Port configuration record - data record 57 (Page 49).

Note

Operation of DTR/DSR or RTS/CTS is accepted by the communication module with the following settings. Operation by means of Set RS232 secondary signals - data record 53 (Page 65) is impossible (any attempt made will trigger an error message):

- Hardware RTS always ON, ignore DTR/DSR
- Hardware RTS always ON
- Hardware RTS always switched

Data transmission with 3964(R) 6

6.1 Data transmission with 3964(R) protocol

Introduction

The 3964(R) protocol controls PtP data exchange between the communication module and a communication partner. The 3964(R) protocol contains both the physical layer (layer 1) and the link layer (layer 2).

6.2 Control characters

Introduction

During data transmission, the 3964(R) protocol adds control characters to the information data (link layer). The communication partner can use these control characters to check whether it has received all data completely and without errors.

Control characters of the 3964(R) protocol

The 3964(R) protocol evaluates the following control characters:

- **STX** Start of Text; start of the string to be sent
- **DLE** Data Link Escape
- **ETX** End of Text; end of the string to be sent
- **BCC** Block Check Character (only with 3964R)
- **NAK** Negative Acknowledge; negative response

Note

If the DLE character is transferred as an information character, it is sent twice during connection setup and shutdown (DLE duplication) in order to distinguish it from the DLE control character. The receiver reverses the DLE duplication.

Priority

For operation with 3964(R) protocol, one communication partner must be assigned a higher priority and one communication partner a lower priority. If both partners simultaneously start the connection setup, the partner having lower priority will postpone its send job.

6.3 Block checksum

Block checksum

With the 3964R transfer protocol, data security is enhanced by sending an additional block check character (BCC = Block Check Character).

The block checksum represents the even longitudinal parity (EXOR logic operation of all data bytes) of a sent or received block. Its calculation begins with the first byte of user data (first byte of the frame) after the connection establishment, and ends after the DLE ETX character at connection termination.

Note

With DLE duplication, the DLE character is included twice in the BCC calculation.

6.4 Sending data with 3964(R)

Connection setup for sending

The 3964(R) protocol sends the STX control character to set up the connection. The transition to send mode is initiated when the communication partner responds with the DLE character before the ACK delay time has expired.

The protocol retries to connect if the communication partner responds with NAK or any other character (except DLE or STX), or if inactivity triggers an acknowledgment timeout. After the parameterized number of unsuccessful retries to connect, the connection setup is canceled and the NAK character is transmitted to the communication partner. The communication module outputs a corresponding error message.

Sending data

On successful connection setup, the user data from the output buffer of the communication module and the selected transmission parameters are sent to the communication partner. The partner monitors the time intervals between incoming characters. The interval between two characters must not exceed the character delay time. Monitoring of the character delay time starts immediately after the connection was set up.

If the communication partner transmits an NAK while a transmission is busy, the block transmission is aborted and repeated as shown above starting with the connection setup. If any other character is received, a wait time for expiration of the character delay time is triggered and an NAK is then transmitted to set the communication partner to idle state. Transmission is then restarted with STX connection setup.

Connection shutdown during transmission

After the buffer content has been transmitted, the routine inserts the DLE, ETX characters, appends the BCC block checksum (only for 3964R) and waits for an ACK character. If the communication partner sends the DLE characters within the acknowledgment delay time, the data block has been received without errors. If the communication partner responds with NAK, or any other character (except DLE), or with a corrupt character, or if the acknowledgment delay time expires without response, the routine restarts transmission with STX connection setup.

After the parameterized number of retries to connect, the routine is aborted and NAK is transmitted to the communication partner. The communication module outputs a corresponding error message.

6.5 Receiving data with 3964(R)

Connection setup for receiving

While in idle state and not processing a send job, the module waits for the communication partner to set up the connection.

A wait time is started (wait time = acknowledgment delay time - 10 ms, however, maximum of 400 ms) if no free receive buffer is available during the connection setup with STX. An error message is generated if no free receive buffer is available on expiration of this time. An NAK is transmitted and initiates the transition to idle state. Otherwise, the DLE character is transmitted and the data is received as described above.

The acknowledgment delay time should be set to the same value at both communication partners.

If any character (except for STX or NAK) is received in idle state, the routine waits for expiration of the character delay time (CDT) and then transmits the NAK character. The communication module outputs a corresponding error message.

Receiving data

After successful connection setup, the incoming receive characters are saved to the receive buffer. If two consecutive DLE characters are received, only one of these is saved to the receive buffer.

After connection setup and after each receive character, the routine waits for the next character within the character delay time. If this period expires before another character is received, an NAK is sent to the communication partner. The communication module outputs a corresponding error message. A retry is then expected.

If transfer errors occur during receiving (lost character, frame error, parity error, etc.), the procedure continues to receive data until the connection is terminated and then sends an NAK to the communication partner. A retry is then expected. Receiving is aborted if the block cannot be received without errors after the specified number of transmission retries, or if the communication partner fails to retry transmission within a block delay time of 4 seconds. The communication module reports the first corrupted transfer and the final cancelation.

Connection setup for receiving

Once the DLE ETX string is detected, receiving is terminated and DLE is transmitted to the communication partner for a block that was received without error. In the case of a receive error, an NAK is sent to the communication partner. A retry is then expected.

Receiving is stopped once the DLE ETX BCC string is detected. The BCC is compared with the internally generated longitudinal parity. DLE is transmitted (return to idle state) if the BCC is correct and no other receive error is pending. If the BCC is faulty or a different receive error occurs, an NAK is sent to the communication partner. A retry is then expected.

Configuration data records 7

7.1 Freeport communication

The following three configuration data records must be sent to the communication module for Freeport communication.

7.1.1 Port configuration record - data record 57

Note

Parameter assignment error

If the communication module detects a parameter assignment error when writing the "Port Configuration Record - data record 57", the data record is rejected with error status 0x80E1.

The corresponding cause of error can be read by means of data record "Read Error Status - data record 55" (error codes of the port configuration).

7.2 3964 communication

The following two configuration data records must be transferred to the communication module for 3964 communication:

7.2.1 Port configuration record - data record 57

Note

The "Port configuration record" is described in chapter Port configuration record - data record 57 (Page 41).

7.2.2 3964 protocol configuration - data record 61

Note

Parameter assignment error

If the communication module detects a parameter assignment error when writing the "3964 Protocol Configuration - data record 61", the data record is rejected with error status 0x80E1.

The corresponding cause of error can be read by means of data record "Read Error Status - data record 55" (error codes of the 3964 protocol).

19								

* A list of all error codes is available in chapter Error messages (Page 67).

Sending data 9

9.1 Send data - data record 48

The following data record is used to write send data to the communication module:

SEND_PTP record (write record 0030H)								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	Sequence number for SEND (0 to 255)							
1	Frame end identifier (0 or 1)							
2	Data to transmit byte 0							
: :	: :							

Sequence number for SEND

The "Sequence number for SEND" parameter identifies a new send frame, or a new data record of a frame. The "SEND acknowledgment from module" (refer to chapter "Querying send acknowledgment - input user data (Page 57)") must be read as first "Sequence number for SEND" and incremented by the count of one. For the first data record, the "Sequence number for SEND" therefore starts with 1 after a STOP/RUN transition of the CPU and is then incremented by one for each data record with new content.

The value "0" may not be used as "Sequence number for SEND". as it serves to detect the start of the module. The value is reset to 1 again after 255 has been reached.

Frame end identifier

The "Frame end identifier" parameter serves to identify the last data record belonging to a frame.

- The value 0 means that at least one more data record follows for the current frame.
- The value 1 means that this data record is the last one for the current frame.

Data to transmit byte 0

The data must be stored in the data record as of "Data to transmit byte 0". The size and therefore the number of data records for transmitting a frame is defined by the transmission medium, for example, 240 bytes with PROFIBUS.

If the length of the data to transmit is not a multiple of the data record length, the length of the last data record corresponds to the length of the remaining data to transmit.

Send acknowledgment from module

The module writes the "Sequence number" received in the data record as send acknowledgment to the user data. See "SEND acknowledgment from module", chapter "Querying send acknowledgment - input user data (Page 57)".

For the last data record belonging to a frame,the acknowledgment is not written until the module has sent the frame.

This means that the "SEND acknowledgment from module" must be evaluated along with the "SEND status" after the last data record was written.

Startup characteristics

At startup, the module writes a zero value to "SEND acknowledgment from module" (see chapter "Querying send acknowledgment - input user data (Page 57)"

A busy job must be aborted if "SEND acknowledgment from module" equals zero.

9.2 Querying send acknowledgment - input user data

The communication module enters the send acknowledgment in the user data that has the following structure:

Input process image structure *Italic* = not supported								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	SGN_STAT 0 - no status 1 - Status valid	Reserved = 0	Ring_Status	DCD_Status	CTS_Status	RTS_Status	DSR_Status	DTR_Status
1	SEND acknowledgment from module							
2	SEND status *							
3								
4	Sequence number for RCV							
5	*Reserved: 00H*							
6	*Reserved: 00H*							
7	*Reserved: 00H*							

* A list of all status and error codes is available in chapter Error messages (Page 67)

You can read status information as well as error numbers (value unequal to 0) from "SEND Status".

If "SEND acknowledgment from module" equals the number transferred in the last data record ("Sequence number for SEND") and the "SEND Status" equals 0, the frame or data record was transmitted without errors.

It is necessary to wait for this communication module feedback, which means "SEND Status" is equal to an error code, or "SEND acknowledgment from module" equals "Sequence number for SEND" and "SEND Status" equals zero, before a new frame is transmitted.

Reaction of the module to an unexpected sequence number for SEND

The module rejects a data record with an unexpected sequence number for SEND when writing the data record and returns error message 0x80B8. The code 0x81D7 is then stored in "SEND status or error code" in the user data. In this case, active communication must be canceled and transmission must be repeated with the first data record. Set the sequence number for SEND as described in chapter Send data - data record 48 (Page 55).

9.3 Example

A frame with a length of 500 bytes is to be transmitted. The data record has a length of 240 bytes.

- First data record, length of 240 bytes:

  "Sequence number for SEND" = 1

  "Frame end identifier" = 0

  238 bytes user data

- Second data record, length of 240 bytes:

  "Sequence number for SEND" = 2

  "Frame end identifier" = 0

  238 bytes user data

- Third data record, length of 26 bytes

  "Sequence number for SEND" = 3

  "Frame end identifier" = 1

  24 bytes user data

- Wait for feedback from the communication module; see Querying send acknowledgment - input user data (Page 57).

Afterwards, a frame with a length of 100 bytes is to be transmitted.

- First = last data record, length of 102 bytes:

  "Sequence number for SEND" = 4

  "Frame end identifier" = 1

  100 bytes user data

- Wait for feedback from the communication module; see Querying send acknowledgment - input user data (Page 57).

Receiving data 10

10.1 Data received - data record 49/50

A new value at "Sequence number for RCV" (Query: New receive frame - input user data (Page 61)) indicates a new frame is ready for reading in the communication module.

The following data records are used to read receive data from the communication module:

RCV_PTP record (read record 0031H/0032H)								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	Sequence number for this data record (1 to 255)							
1	Frame end identifier (0 or 1)							
2	RCV status *							
3								
4	Receive data byte 0							
:	:							
:	:							

* A list of all status and error codes is available in chapter Error messages (Page 67)

Change of the data record number when receiving data

After startup of the communication module, reading of the frame content must start at data record number 16#0031, while the data record numbers change between 16#0032 and 16#0031 in all subsequent read operations.

Sequence number of this data record

For the first data record of a frame, the "Sequence number of this data record" is equal to the "Sequence number for RCV" in the user data that indicated the new frame. This value is incremented by the count of one for each data record read subsequently. An overflow to 2 is triggered at 255. The values 0 and 1 have a special significance (see below).

Frame end identifier

The "Frame end identifier" is equal to 1 for the last data record that has to be read for this frame, while it is 0 for all other data records.

The size of the last data record that belongs to a frame is determined by the frame length and limited accordingly by the communication module.

RCV status

"RCV Status" displays the result of the last data reception.

0x009x: Frame received without error

0x8xxx: Frame received with error

See chapter Error messages (Page 67).

Resetting communication after power on of the communication module

- "Sequence number for RCV" is equal to 0

  A "Sequence number for RCV" with value 0 in the input user data indicates that the communication module has performed a restart after power on and that no frame has been received yet.

- "Sequence number for RCV" is equal to 1

  A "Sequence number for RCV" with value 1 in the input user data indicates that this is the first frame after power on of the communication module.

A busy job must be aborted in both cases.

In the second case, reading of the frame content must start at data record number 16#0031.

10.2 Query: New receive frame - input user data

Sequence number for RCV

A new received frame is indicated by a "Sequence number for RCV" in byte 4 of the user data that has the following structure.

Input process image structure *Italic* = not supported								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	SGN_STAT 0 - no status 1 - Status valid	Reserved = 0	Ring_Status	DCD_Status	CTS_Status	RTS_Status	DSR_Status	DTR_Status
1	Sequence number from module							
2	SEND status *							
3								
4	Sequence number for RCV							
5	*Reserved: 00H*							
6	*Reserved: 00H*							
7	*Reserved: 00H*							

* A list of all status and error codes is available in chapter Error messages (Page 67)

10.3 Example

A frame with a length of 500 bytes was received. The data record has a length of 240 bytes

- In the user data, the frame is indicated by "Sequence number for RCV" = 1.
- Read data record 16#0031 that contains:

  "Sequence number of this record" = 1

  "Frame end identifier" = 0

  "RCV status or error code return value" = 0x009x [1)]

  It contains 236 bytes of user data.
- Read the second data record 16#0032 that contains:

  "Sequence number of this data record" = 2

  "Frame end identifier" = 0

  "RCV status or error code" = 0x009x [1)]

  It contains 236 bytes of user data.
- Read the third data record 16#0031 that contains:

  "Sequence number of this data record" = 3

  "Frame end identifier" = 1

  "RCV status or error code" = 0x009x [1)]

  It contains 28 bytes of user data. The communication module has limited the data record length to 32 bytes.

  This completes reading of the first frame from the CM.

A frame with a length of 100 bytes was received subsequently.

The sequence number for RCV changes from 1 to 4 in the user data.

- Read the data record 16#0032 that contains:

  "Sequence number of this data record" = 4

  "Frame end identifier" = 1

  "RCV status or error code" = 0x009x [1)]

  The data record contains 100 bytes of user data and the communication module has limited the data record length to 104 bytes.

1) 0x009x Frame received without error

0x8xxx Frame received with error

(see error codes in chapter Query: New receive frame - input user data (Page 61))

Clear receive buffer 11

11.1 Clear receive buffer - data record 54

The receive buffer of the communication module is cleared by writing the following data record with "RST_RCV_BUF" = TRUE.

PtP RCV_RST(write record 0036H) *Italic* = not supported								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	Block type: 0036H - RCV_RST							
1								
2	Block length: 0008H							
3								
4	Block version high byte: 01H							
5	Block version low byte: 00H							
6	Reserved: 0000H							
7								
8	0	0	0	0	0	0	0	RST_RCV_BUF
9	*Reserved: 00H*							
10	*Reserved: 00H*							
11	*Reserved: 00H*							

Note: RST_RCV_BUF = 0; no changes are made to the receive buffer.
RST_RCV_BUF = 1; the receive buffer is cleared.

The communication module does not acknowledge the reset of its receive buffer.

RS232 signals 12

12.1 Set RS232 secondary signals - data record 53

The RS232 secondary signals of the communication module are manipulated by writing to the following data record, provided the communication module supports this action in the current mode.

Note

Parameter assignment error

If the communication module detects a parameter assignment error when writing the "Set RS232 secondary signals - data record 53", the data record is rejected with error status 0x80E1.

The corresponding cause of error can be read by means of data record "Read Error Status - data record 55" (error codes of the RS232 secondary signals).

PtP SGN_SET(write record 0035H) *Italic* = not supported								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	Block type: 0035H - SGN_SET							
1								
2	Block length: 0008H							
3								
4	Block version high byte: 01H							
5	Block version low byte: 00H							
6	Reserved: 0000H							
7								
8	0	0	0	0	0	0	Set_DTR_State	Set_RTS_State
9	0	0	0	0	0	0	DTR_State	RTS_State
10	*Reserved: 00H*							
11	*Reserved: 00H*							

Note: Set_xxx_State = 0, the status of the specified control bit is not changed. Set_xxx_State = 1, the status of the specified control bit must be set to the value that was specified by xxx_State.

For information on reading the acknowledgment to the writing of this data record, refer to chapter "Error status (Page 53) ".

12.2 Read RS232 secondary signals - input user data

The RS232 secondary signals of the communication module can be read from the user data.

Input process image structure *Italic* = not supported								
Bit->	7	6	5	4	3	2	1	0
Byte								
0	SGN_STAT 0 - no status 1 - Status valid	Reserved = 0	Ring_Status	DCD_Status	CTS_Status	RTS_Status	DSR_Status	DTR_Status
1	Sequence number for SEND (acknowledgment from module)							
2	SEND status or error code *							
3								
4	Sequence number for RCV							
5	*Reserved: 00H*							
6	*Reserved: 00H*							
7	*Reserved: 00H*							

* A list of all error codes is available in chapter Error messages (Page 67)

SGN_STAT = 0 indicates that no RS232 secondary signals are available in the current operating mode of the communication module.

Error messages

13

Overview of error messages

Error code	Description	Remedy
0x0000	No error	-
RECEIVE status and error codes		
0x0094	Frame end identified based on the "Receipt of fixed/maximum frame length"	-
0x0095	Frame end identified based on "Message timeout"	-
0x0096	Frame end identified based on expiration of the "Character delay time"	-
0x0097	No response frame was received within the parameterized maximum response time.	-
0x0098	Frame end identified based on the fulfillment of the "Read message length from message" conditions	-
0x0099	Frame end identified based on the receipt of the "End sequence"	-
SEND status and error codes		
0x7000	Block idle	-
0x7001	Initial call for a new frame: Data record transmission initiated	-
0x7002	Interim call: Data record transmission in process	-
0x8085	Invalid length specification	Select a suitable frame length. The following are valid (depending on the module): 1-1024/2048/4096 (Byte)
0x8088	The specified length exceeds the range set in the receive buffer	Change the range in the receive buffer or select a frame length which corresponds to the range set in the receive buffer. The following are valid (depending on the module): 1-1024/2048/4096 (Byte)
Error codes of the special functions		
0x8190	Incorrect setting of the CRC calculation	Select a suitable value for CRC calculation. The following are valid: deactivated or activated. Check whether the module addressed supports CRC calculation.
0x8191	Incorrect setting of the diagnostic interrupt	Select a suitable value for "Diagnostic interrupt". The following are valid: Diagnostic interrupt deactivated (0) or diagnostic interrupt activated (1). Check whether the module addressed supports the generation of diagnostic interrupts.

Error code	Description	Remedy
Error codes of the "Port configuration"		
0x81A0	The module does not support this protocol.	Select a valid protocol for the module.
0x81A1	The module does not support this data transmission rate.	Select a valid data transmission rate for the module.
0x81A2	The module does not support this parity setting.	Select a suitable value for "Parity". The following are valid: • None (1) • Even (2) • Odd (3) • Mark (4) • Space (5) • Any (6)
0x81A3	The module does not support this number of data bits.	Select a suitable value for "Number of data bits". The following are valid: • 7 (2) • 8 (1)
0x81A4	The module does not support this number of stop bits.	Select a suitable value for "Number of stop bits". The following are valid: • 1 (1) • 2 (2)
0x81A5	The module does not support this type of data flow control.	Select a valid data flow control for the module.
0x81A7	Invalid value for XON or XOFF	Select suitable values for XON and XOFF. Valid range of values: 0 - FF.
0x81A8	Error in frame header	Check the data/values in the frame header.
0x81AA	Invalid operating mode	Valid operating modes are: • Full duplex (RS232) (0) • Full duplex (RS422) four-wire mode (point-to-point) (1) • Full duplex (RS422) four-wire mode (multipoint master) (2) / (CM PtP (ET 200SP)) • Full duplex (RS422) four-wire mode (multipoint slave) (3) / (CM PtP (ET 200SP)) • Half duplex (RS485) two-wire mode (4)

Error code	Description	Remedy
0x81AB	Invalid default setting of the receive line	Valid default settings are: • "No" default setting (0) • Signal R(A)=5 V, signal R(B)=0 V (break detection) (1): Can only be selected with: "Full duplex (RS422) four-wire mode (point-to-point connection)" and "Full duplex (RS422) four-wire mode (multipoint slave)". • Signal R(A)=0 V, signal R(B)=5 V (2): This default corresponds to the idle state (no active send operation). No break detection is possible with this default setting.
0x81AC	Invalid value for "Break detection"	Select a suitable value for "Break detection". The following are valid: • "0" (break detection deactivated) • "1" (break detection activated)
0x81AF	The module does not support this protocol.	Select a valid protocol for the module.
Error codes of the "Send configuration"		
0x81B5	More than two end delimiters or end sequence > 5 characters	Select suitable values for "End delimiter" and "End sequence". The following are valid: • deactivated (0), • 1 (1) or 2 (2) end delimiters or • deactivated (0), • 1 (1) up to 5 (5) characters for the end sequence.
0x81B6	Send configuration rejected because the 3964(R) protocol was selected	Verify that no send configuration is transmitted if the 3964R) protocol is set.
Error codes of the "Receive configuration"		
0x81C0	Invalid start condition	Select a suitable start condition. The following are valid: • Send break before frame start • Send Idle Line.
0x81C1	Invalid end condition or no end condition selected	Select a suitable end condition.
0x81C3	Invalid value for "Maximum message length"	Select a suitable value for "Maximum message length". Valid range of values (module-dependent): 1-1024/2048/4096 (Byte)
0x81C4	Invalid value for "Offset of the length specification in the message"	Select a suitable value for "Offset of the length specification in the message". Valid range of values (module-dependent): 1-1024/2048/4096 (Byte)

Error code	Description	Remedy
0x81C5	Invalid value for "Size of length field"	Select a suitable value for "Size of length field". Valid range of values in bytes: • 1 (1) • 2 (2) • 4 (4)
0x81C6	Invalid value for "Number of characters not counted in length specification"	Select a suitable value for "Number of characters not counted in length specification". Valid range of values: 0 to 255 (bytes)
0x81C7	The total of "Offset in the message + size of the length field + number of character not counted" is greater than the maximum frame length	Select a suitable value for "Offset in message", "Size of the length field" and "Number of characters not counted". Valid range of values: • Offset in the message (module-dependent): 0-1022/2046/4094 (Byte) • Size of the length field: 1, 2, or 4 (bytes) • Number of characters not counted: 0-255 (bytes)
0x81C8	Invalid value for "Response timeout"	Select a suitable value for "Response timeout". Valid range of values: 1-65535 (ms)
0x81C9	Invalid value for "Character delay time"	Select a suitable value for "Character delay time". Valid range of values: 1-65535 (bit times)
0x81CB	Frame end sequence is activated, but no character is activated for the check	Activate one or several characters for the check.
0x81CC	Frame start sequence is activated, but no character is activated for the check	Activate one or several characters for the check.
0x81CD	Invalid value for "Prevent overwriting"	Select a suitable value for "Prevent overwriting". The following are valid: • Prevent overwriting is deactivated (0) or • Prevent overwriting is activated (1)
0x81CE	Invalid value for "Clear receive buffer at startup"	Select a suitable value for "Clear receive buffer at startup". The following are valid: • Clear receive buffer at startup is deactivated (0) • Clear receive buffer at startup is activated (1)

Error code	Description	Remedy
SEND status and error codes		
0x81D0	Receiving send requests during runtime of a send job	Make sure that you do not receive send requests during runtime of a send job.
0x81D1	The waiting time for XON or CTS = ON has expired.	The communication partner has a fault, is too slow or is offline. Check the communication partner or, if necessary, change the parameter assignment.
0x81D2	"Hardware RTS always ON": Send command aborted due to change from DSR = ON to OFF	Check the communication partner. Make sure that DSR is ONfor the entire duration of transmission.
0x81D3	Send buffer overflow / send frame too long	Select a shorter frame length. The following are valid (depending on the module): 1-1024/2048/4096 (Byte)
0x81D5	Transmission aborted due to parameter changes, detected wire break, or because CPU in STOP	Check the parameter assignment, for wire break, and the CPU status.
0x81D6	Transmission canceled because end identifier was not received	Check the parameter assignment of the end delimiters and the frame of the communication partner.
0x81D7	Communication error between the user program and module	Check communication (e.g. consistency of the sequence number).
0x81D8	Transmission attempt rejected because module is not configured	Configure the module.
Error codes of the receive configuration		
0x81E0	Frame canceled: Send buffer overflow / send frame too long	Increase the call rate for the receive function in the user program, or parameterize communication with data flow control.
0x81E1	Frame canceled: Parity error	Check the connection line of the communication partners, or verify that both devices are configured for the same data transmission rate, parity and stop bit number.
0x81E2	Frame canceled: Character frame error	Check the settings for the start bit, data bits, parity bit, data transmission rate, and stop bit(s).
0x81E3	Frame canceled: Character overflow error	Firmware error: Contact Customer Support.
0x81E4	Frame canceled: The total length of "Offset in the message + size of the length field + number of character not counted" is greater than the receive buffer	Select a suitable value for Offset in message, Size of the length field, and Number of characters not counted.
0x81E5	Frame canceled: Break	Receive line to partner is interrupted. Reconnect or switch on partner.
0x81E6	Maximum number of "Buffered receive frames" exceeded	In the user program, increase the call rate of the instruction, or parameterize communication with data flow control, or increase the number of buffered frames.
0x81E8	Frame canceled: The character delay time has expired before the message and criterion was detected	Partner device faulty or too slow. Check this, if required, using an interface tester that is interconnected in the transmission line.

Error code	Description	Remedy
0x81EB	Frame canceled: Maximum frame length reached	Select a shorter frame length at the communication partner. The following are valid (depending on the module): 1-1024/2048/4096 (Byte) Check the parameters of the frame end detection.
Error codes of RS232 secondary signals		
0x81F0	The module does not support RS232 secondary signals	You have made an attempt to set up secondary signals on a module that does not support RS232 secondary signals. Verify that this is an RS232 module or that RS232 mode (ET 200SP) is set.
0x81F1	No operation of RS232 secondary signals	RS232 secondary signals cannot be manipulated manually as long as hardware data flow is active.
Error codes of the receive configuration		
0x82C1	Invalid value for "Buffered receive frames".	Select a suitable value for "Buffered receive frames". Valid range of values: 1-255
0x82C2	Receive configuration rejected because the 3964(R) protocol was selected	Verify that no receive configuration is transmitted if the 3964(R) protocol is set.
3964(R) protocol error codes		
0x8380	Parameter assignment error: Invalid value for "Character delay time".	Select a suitable value for "Character delay time". Valid range of values: 1-65535 (ms)
0x8381	Parameter assignment error: Invalid value for "Response timeout".	Select a suitable value for "Response timeout". Valid range of values: 1-65535 (ms)
0x8382	Parameter assignment error: Invalid value for "Priority".	Select a suitable value for "Priority". The following are valid: • High (1) • Low (0)
0x8383	Parameter assignment error: Invalid value for "Block check"	Select a suitable value for "Block check". The following are valid: • with block check (1) • without block check (0)
0x8384	Parameter assignment error: Invalid value for "Connection attempts".	Select a suitable value for "Connection attempts". Valid range of values: 1-255
0x8385	Parameter assignment error: Invalid value for "Transmission attempts".	Select a suitable value for "Transmission attempts". Valid range of values: 1-255
0x8386	Runtime error: Number of connection attempts exceeded	Check the interface cable and the transmission parameters. Also check whether the receive function is configured correctly at the partner device.
0x8387	Runtime error: Number of transmission attempts exceeded	Check the interface cable, the transmission parameters and the configuration of the communication partner.

Error code	Description	Remedy
0x8388	Runtime error: Error at the "Block check character" The internally calculated value of the block check character does not correspond to the block check character received by the partner at the connection end.	Check whether the connection is seriously disrupted; in this case you may also occasionally see error codes. Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
0x8389	Runtime error: Invalid character received while waiting for free receive buffer	The send request of the communication partner (STX, 02H) is not answered with DLE until the receive buffer has been cleared. No additional character may be received before it has been cleared (except STX again). Check for proper function at the partner device, possibly by using an interface test device that is switched into the transmission line.
0x838A	Runtime error: Logical error during receiving. Another character (other than DLE, ETX) was received after receipt of DLE.	Check whether the partner DLE in the frame header and in the data string is always in duplicate or the connection is released with DLE ETX. Check for proper function of the partner device, possibly using an interface test device that is switched into the transmission line.
0x838B	Runtime error: Character delay time exceeded	Partner device too slow or faulty. Check for proper function of the partner device, possibly using an interface test device that is switched into the transmission line.
0x838C	Runtime error: Wait time for free receive buffer has started	Increase the call rate of the instruction in the user program, or parameterize communication with data flow control.
0x838D	Runtime error: Frame repetition does not start within 4 s after NAK	Check the communication partner. A received frame that is possibly corrupted must be repeated by the partner within 4 seconds.
0x838E	Runtime error: One or several characters (except NAK and STX) were received in idle mode.	Verify the proper function of the partner device, for example, by means an interface tester that is interconnected in the transmission line.
0x838F	Runtime error: Initialization conflict - Both partners have set high priority	Set the "Low" priority at one of the partners
0x8390	Parameter assignment error: Error in frame header	Check the data/values in the frame header.
0x8391	Parameter assignment error: 3964 Parameter data record rejected because Freeport is set	Verify that no 3964 parameter data is transmitted if the Freeport protocol is set.

Glossary

Address

The address indicates the physical storage space and enables direct access to the operand that is stored under this address.

Automation system

An automation system is a programmable logic controller consisting of at least one CPU, various I/O modules, and operator control and monitoring devices.

Communication module

Communication modules are used for point-to-point connections and bus links.

Configuration

The term configuration refers to the summary of individual modules of an automation system in the configuration table.

CPU

Central Processing Unit = Central module of the automation system that consists of the control and computing units, memory, system program, and interfaces to the I/O modules.

CPU operating system

The CPU operating system organizes all the functions and sequences of the CPU that are not linked to a special control task.

Cycle time

The cycle time denotes the time a CPU requires to execute one user program cycle.

Cyclic program processing

In cyclic program processing, the term cycle denotes execution of the user program in a continuous repetitive program loop.

Default setting

The default is a useful basic setting that is used whenever no other value is specified.

Diagnostic functions

The diagnostic functions cover the entire system diagnostics and the detection, evaluation and reporting of errors in the automation system.

Diagnostics buffer

Memory area in which detailed information on all diagnostics events is entered based on the order of their occurrence.

Diagnostics events

Diagnostics events are, for example, module errors or system errors in the CPU that may be caused by a program error.

Hardware

The term hardware denotes the entire physical and technical equipment of an automation system.

Interrupt

The term interrupt designates the interruption of program execution in the processor of an automation system which is triggered by an external alarm.

Module parameters

Module parameters are values that are used to determine the behavior of the module. We distinguish between static and dynamic module parameters.

Online/Offline

In online mode, there is a data connection between the automation system and programming device, while there is no data connection in offline mode.

Parameter assignment

The term parameter assignment denotes actions that define the response of a module or block.

Parameters

Parameters represent values that can be used to define the behavior of a module or software. We distinguish between module parameters and block parameters.

Point-to-point connection

In a point-to-point connection the communication module interfaces a programmable logic controller and a communication partner.

Protocol

The communication partners participating in data transmission must conform to fixed rules for the handling and execution of data traffic. These rules are called protocols.

Rack

The rack is a mounting rail with slots that can be used to mount modules.

Software

The term software refers to all programs that are used on a computing system. These include the operating system and user programs.

User program

The user program contains all instructions and declarations for processing the signals used for controlling a system or a process. In SIMATIC S7, the user program is structured and divided into small units, namely the blocks.

Work memory

Work memory is CPU RAM (Random Access Memory) that is accessed by the processor when processing the user program.

Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

DANGER
indicates that death or severe personal injury **will** result if proper precautions are not taken.

WARNING
indicates that death or severe personal injury **may** result if proper precautions are not taken.

CAUTION
indicates that minor personal injury can result if proper precautions are not taken.

NOTICE
indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This function manual provides a general overview of the IO-Link communication system.

It shows the interaction of the various components of an IO-Link system and will help you improve your general understanding of IO-Link.

Basic knowledge required

The following knowledge is required in order to understand the documentation:

- General knowledge of automation technology
- Knowledge of the industrial automation system SIMATIC
- Proficiency with STEP 7

Scope of the documentation

This documentation is the basic documentation for IO-Link systems at Siemens. The product documentation is based on this documentation.

Conventions

In this documentation, "STEP 7" is used as a synonym for all versions of the configuration and programming software "STEP 7 (TIA Portal)".

Please also observe notes marked as follows:

Note

A note contains important information on the product described in the documentation, on the handling of the product or on the section of the documentation to which particular attention should be paid.

Additional support

- Information about Technical Support is available in section Siemens Industry Online Support (Page 4).
- The range of technical documentation for the individual SIMATIC products and systems can be found on the Internet.
- Information about the online catalog and online order system is available in section Industry Mall (Page 5).

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under (https://www.siemens.com/industrialsecurity).

Siemens Industry Online Support

You can find current information on the following topics quickly and easily here:

- **Product support**

  All the information and extensive know-how on your product, technical specifications, FAQs, certificates, downloads, and manuals.

- **Application examples**

  Tools and examples to solve your automation tasks – as well as function blocks, performance information and videos.

- **Services**

  Information about Industry Services, Field Services, Technical Support, spare parts and training offers.

- **Forums**

  For answers and solutions concerning automation technology.

- **mySupport**

  Your personal working area in Industry Online Support for messages, support queries, and configurable documents.

This information is provided by the Siemens Industry Online Support in the Internet (http://www.siemens.com/automation/service&support).

Industry Mall

The Industry Mall is the catalog and order system of Siemens AG for automation and drive solutions on the basis of Totally Integrated Automation (TIA) and Totally Integrated Power (TIP).

You can find catalogs for all automation and drive products on the Internet (https://mall.industry.siemens.com).

Table of contents

1 Guide

Documentation

Various IO-Link products are available from Siemens. Each of these products has a separate documentation. The IO-Link products are embedded in systems, e.g. ET 200SP. The documentation for the system consists of the respective system manual, function manuals and manuals. In addition, the STEP 7 online help and the Port Configuration Tool - S7-PCT online help assist you in configuring and programming your automation system with IO-Link.

IO-Link components from Siemens

Siemens offers a wide range of products and support for IO-Link:

- Master
- Device, I/O modules
- Device, industrial switchgear
- Device, RFID systems (RFID = radio-frequency identification)
- Port Configuration Tool - S7-PCT (https://support.industry.siemens.com/cs/ww/en/view/32469496)
- IO-Link library (https://support.industry.siemens.com/cs/ww/en/view/82981502) with the blocks "IO_LINK_MASTER" and "IO_LINK_DEVICE"
- Overview of the topic IO-Link (https://support.industry.siemens.com/cs/ww/en/view/109737170)

Additional information on the products can be found on the Internet (http://www.siemens.com/io-link).

Additional documentation for IO-Link

You can find a free download of the latest documentation on the IO-Link products on the Internet (https://support.industry.siemens.com/cs/ww/en/ps/15818/man).

System overview 2

Introduction

A continuous communication down to the lowest field level ensures enhanced use of the functions and performance capability of sensors and actuators. Enhanced use of sensors and actuators allows you to operate your machines and plants more productively.

No data other than the actual process value can be exchanged via the standard interfaces (digital, analog) used at the sensor/actuator level. Sensors and actuators with integrated intelligence are now used for increasingly complex functions and require a communication interface tailored to these requirements.

Definition

IO-Link is an innovative, point-to-point communication interface for the sensor/actuator area that is specified in IEC 61131-9.

IO-Link consists of the following system components:

- IO-Link master
- IO-Link device
- Unshielded 3-wire or 5-wire standard cable
- Engineering tool for configuring and assigning parameters of IO-Link

2.1 Advantages of IO-Link

The IO-Link system offers significant advantages as digital interface when connecting sensors/actuators:

- Open standard in accordance with IEC 61131-9
  - Devices can be integrated in the same way in all conventional fieldbus systems and automation systems
- Tool supported parameter setting and central data management
  - Fast configuration and commissioning
  - Simple creation of current plant documentation even for sensors/actuators
- Single, uniform wiring and far fewer different interfaces at the sensors/actors
  - Standardized, uniform interface for sensors and actuators independent of their complexity (switching, measuring, multi-channel, binary, mixed signals, etc.)
  - Reduction in the variety of types and inventory
  - Fast commissioning
  - Any combination of IO-Link devices and sensors/actuators without IO-Link at IO-Link master
- Continuous communication between sensors/actuators and the CPU
  - Access to all process data, diagnostic data and device information
  - Access to device-specific data, such as energy data
  - Remote diagnostics can be performed
- Continuous diagnostic information down to sensor/actuator level
  - Reduction in troubleshooting effort
  - Minimizing risk of failure
  - Preventive maintenance and optimization of service and maintenance planning
- Dynamic change of sensor/actuators parameters by the controller or the operator at the HMI
  - Reduction in downtimes during product change
  - Increased variability of the machine
- Automatic reassignment of parameters when devices are replaced during operation
  - Minimization of downtimes
  - Device replacement by untrained personnel without additional aids
  - Avoidance of incorrect settings
- Integrated device identification
  - Identification of the installed devices
  - Ensure quality of result in production and manufacturing when replacing the device

2.2 Overview of IO-Link system

Components

An IO-Link system consists of the following components:

- IO-Link master
- IO-Link device, for example:
  - Sensors/actuators
  - RFID readers
  - I/O modules
  - Valves
- Unshielded 3-wire or 5-wire standard cables
- Engineering tool for configuring and assigning parameters of IO-Link

Example plant with IO-Link

The figure below shows an example of plant architecture with IO-Link.

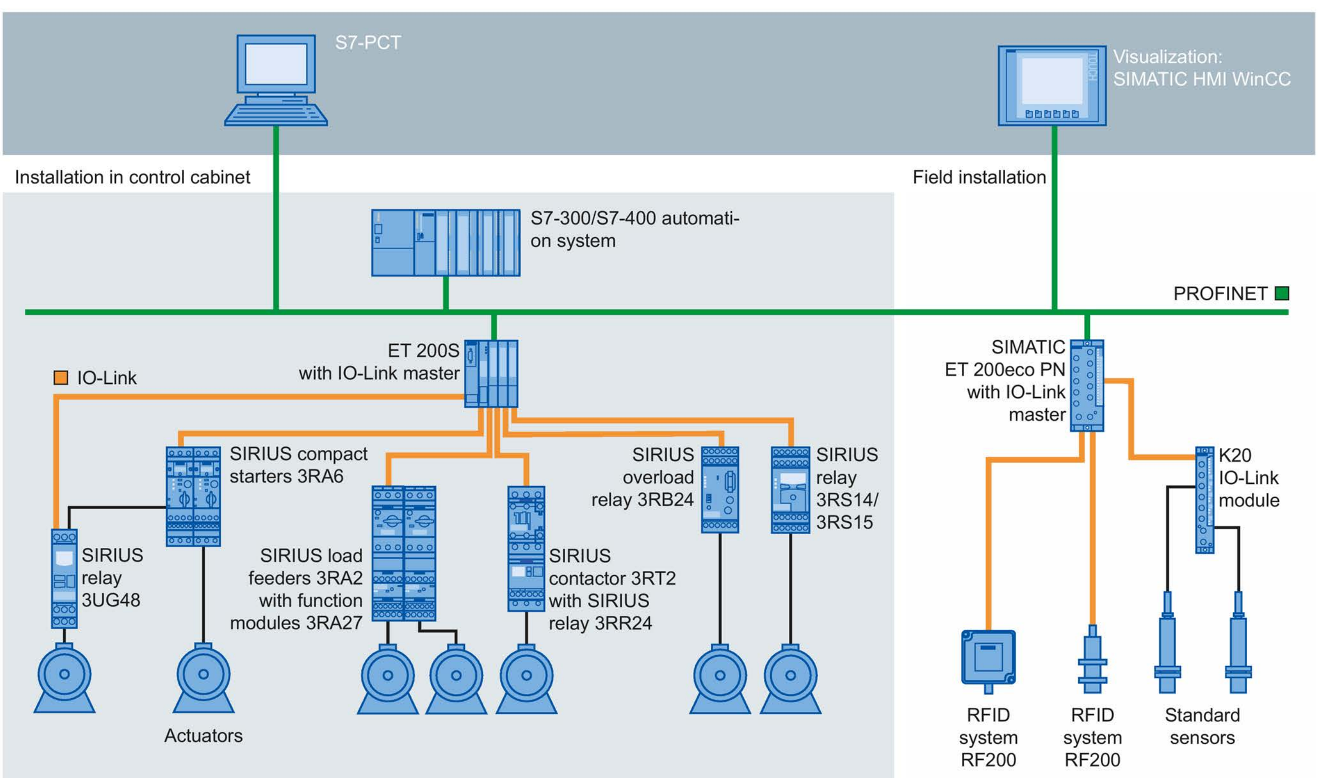

Figure 2-1 Plant architecture with IO-Link

The IO-Link master establishes the connection between the IO-Link devices and the automation system. If the IO-Link master is a component of the I/O system, it is installed either in the control cabinet or directly in the field as remote I/O in degree of protection IP65/67. The IO-Link master communicates by means of various fieldbuses or product-specific backplane buses. An IO-Link master can have multiple IO-Link ports (channels). An IO-Link device can be connected (point-to-point communication) to each port.

Engineering

The IO-Link system is engineered parallel to the overall automation system and can be embedded in it and intermeshed with it.

2.3 IO-Link interface

Introduction

The IO-Link is a serial, bidirectional point-to-point connection for signal transmission and power distribution under any network, fieldbus or backplane bus.

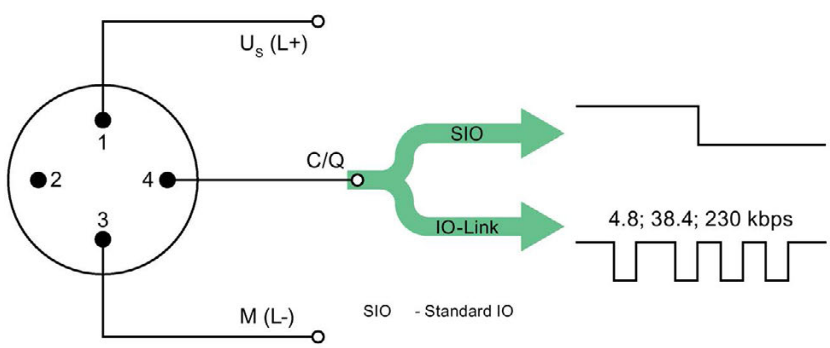
Connection system in IP65/67

M12 connectors and other connectors are defined for the connection system in IP65/67; sensors have a 4-pin connector, actuators a 5-pin connector. IO-Link masters are always equipped with a 5-pin M12 socket.

The pin assignment according to IEC 60974-5-2 is specified as follows:

- Pin 1: 24 V
- Pin 3: 0 V
- Pin 4: Switching and communication cable (C/Q)

In addition to IO Link communication, these three pins also implement the power supply of the device.
Detailed information about the power supply can be found in the documentation of the utilized IO-Link master.



Pin	Signal	Definition	Standard
1	U_S (L+)	24 V	IEC 61131-2
2	-	not defined	-
3	M (L-)	0 V	IEC 61131-2
4	Q	Switching signal DI, DQ (SIO)	IEC 61131-2
4	C	"coded switching signal" (IO-Link)	IEC 61131-9

Figure 2-2 Pin assignment IO-Link device

Port types in IP65/67

Two types of ports are distinguished in the specifications for IO-Link masters:

- Port Class A (Type A)
  With this type, the functions of pins 2 and 5 are not assigned. The manufacturer defines this function. Generally, an additional digital channel is assigned to pin 2.

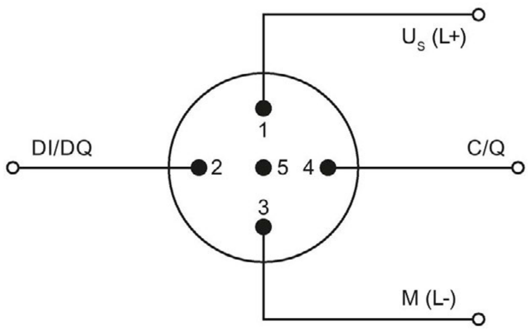


Figure 2-3 Pin assignment Port Class A

- Port Class B (Type B)
  This type offers an additional supply voltage and is suitable for the connection of devices that have an increased power requirement. In this case an additional (galvanically isolated) supply voltage is made available by pins 2 and 5. A 5-wire standard cable is required to use this additional supply voltage.

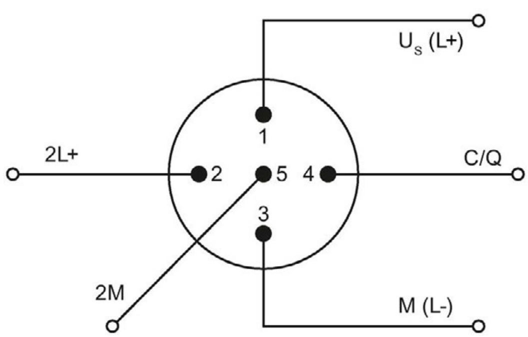

Figure 2-4 Pin assignment Port Class B

Connecting cables

The devices are connected to the master with unshielded 3-wire or 5-wire standard cables with a maximum length of 20 m. Standard cables can be used to wire the sensors. No shielding or compliance with specific regulations is necessary for the installation of the cables.

2.4 IO-Link protocol

Operating modes

The IO-Link port of the master can be operated in the following modes:

- IO-Link:
  The port is located in the IO-Link communication.
- DI:
  The port behaves like a digital input.
- DQ:
  The port behaves like a digital output.
- Disabled:
  The port is disabled.

Transmission rate

In the IO-Link specification V1.1, three data transmission rates (baud rates) are specified for the IO-Link operating mode:

- COM 1 = 4.8 kBaud
- COM 2 = 38.4 kBaud
- COM 3 = 230.4 kBaud (optional according to Specification V1.0)

The IO-Link device only supports one of the defined data transmission rates. The IO-Link master to Specification V1.1 supports all data transmission rates and adjusts automatically to the data transmission rated supported by the device.

Response time of the IO-Link system

The response time of the IO-Link system provides information about the frequency and speed of the data transmission between device and master. The response time depends on various factors.

A value for the minimum cycle time of the device is stored in the device description file IODD of the device (Page 17). This value indicates in which time intervals the master may address the device. The value has a big influence on the response time. The master also has an internal processing time that is factored into the calculation of the response time.

Devices with different minimum cycle time can be configured on a master. The response time for these devices differs accordingly. In other words, the response time for various devices connected to a master can vary greatly.

When you configure the master you can specify a fixed cycle time in addition to the device-specific minimum cycle time stored in the IODD. The master then addresses the device according to this specification.

The typical response time for a device thus results from the effective cycle time of the device and the typical internal processing time of the master.

Transmission performance

IO-Link is a very robust communication system. This communication system operates with a 24V level. If transmissions fail, the frame is repeated two more times. The IO-Link master only detects a break in communication after the failure of the second repeat attempt and reports this to the higher-level CPU.

Data types

Four data types are available:

- Process data → Cyclic data
- PQI → Cyclic data
- Device data → Acyclic data
- Events → Acyclic data

Process data

The process data of the devices is transferred cyclically in a data frame with the process data size being determined by the device. Process data from 0 to 32 bytes is possible per device (input and output, respectively).

Port Qualifier Information (PQI)

Each port has a Port Qualifier Information (PQI). This PQI provides information on the device status of the port and IO-Link (value status). The PQI is transmitted cyclically with the process data. The PQI is disabled by default.

Device data

Device data can be parameters, identification data or diagnostic information. The data is exchanged cyclically and at the request of the IO-Link master. Device data can be written to the device and also read from the device.

Events

When an event occurs, the device signals to the master that an event is present. The master then reads the event. Events can be error messages (for example, short-circuit) and warning/maintenance data (for example, dirt, overheating).

Error messages are transferred from the device to the CPU or the HMI by the IO-Link master.

The IO-Link master can also transfer events and states. Such events are, for example, wire break, break in communication or overload.

Device parameters or events are transmitted independently of the cyclic transmission of process data. The transmissions do not influence or impair each other.

Startup of the IO system

If the port of the master is set to IO-Link mode, the IO-Link master attempts to communicate with the connected IO-Link device. For this purpose the IO-Link master sends a defined signal and waits for the reply of the IO-Link device.

The IO-Link master first attempts a communication with the highest defined data transmission rate. If this transmission attempt fails the IO-Link master attempts a communication with the lowest data transmission rate. The device always supports only one defined data transmission rate.

If the master receives a reply, communication starts. First they exchange communication parameters. If necessary the parameters stored in the system are transferred to the device.

Then the cyclic data exchange of process data and value status starts.

2.5 Device profiles

Introduction

Device profiles are defined for IO-Link to standardize access of the CPU user program to the devices.

Data structure, data contents and basic functionality are defined in the device profiles. A standard user view and an identical program access is thus achieved for a number of different devices that have the same device profile.

IO-Link profiles

The device profile "Smart Sensor Profile" is currently defined for IO-Link. This profile is especially suited for measurement sensors. In other words, measured values are transmitted in addition to switching points.

In addition, the switchgear (for example, contactors) support the LVSG (Low Voltage Switchgear) profile defined in IEC 61915-2.

2.6 IODD and Port Configuration Tool - S7-PCT

Device description IODD

An electronic device description, the IODD file (IO Device Description) is available for each device. The IODD provides a wealth of information for system integration:

- Communication properties
- Device parameters with value range and default value
- Identification, process and diagnostic data
- Device data
- Text description
- Image of the device
- Manufacturer logo

The structure of the IODD is identical for all devices from all manufacturers. The structure of the IODD is always represented in the identical manner by the IO-Link Configuration Tool of the master manufacturer (for Siemens, S7-PCT). This ensures that the handling is the same for all IO-Link devices regardless of the manufacturer.

Two different IODD versions are available for devices that support both V1.0 and V1.1 functionality.

IODDfinder

The IODDfinder is a cross-vendor, central IO-Link database.
This database provides you with the latest IODDs of the device manufacturers and offers an information and download platform.
The IODDfinder is available on the Internet (https://ioddfinder.io-link.com).

IO-Link configuration tool

Configuration tools are required to configure the entire IO-Link system. The IO-Link configuration tools of the master manufacturers are able to read IODDs.

The main tasks of the IO-Link configuration tool include:

- Assigning the devices to the ports of the master
- Address assignment of ports within the address area of the master
- Assigning parameters for the IO-Link device

Diagnostics can also be carried out on the connected devices.

This means the IO-Link configuration tool supports the transparent representation of the IO-Link system down to field level.

Siemens provides S7-PCT for engineering of the IO-Link system.

S7-PCT with IODD of a device

The following figure shows a section from S7-PCT with IODD of a device and the device information contained therein.

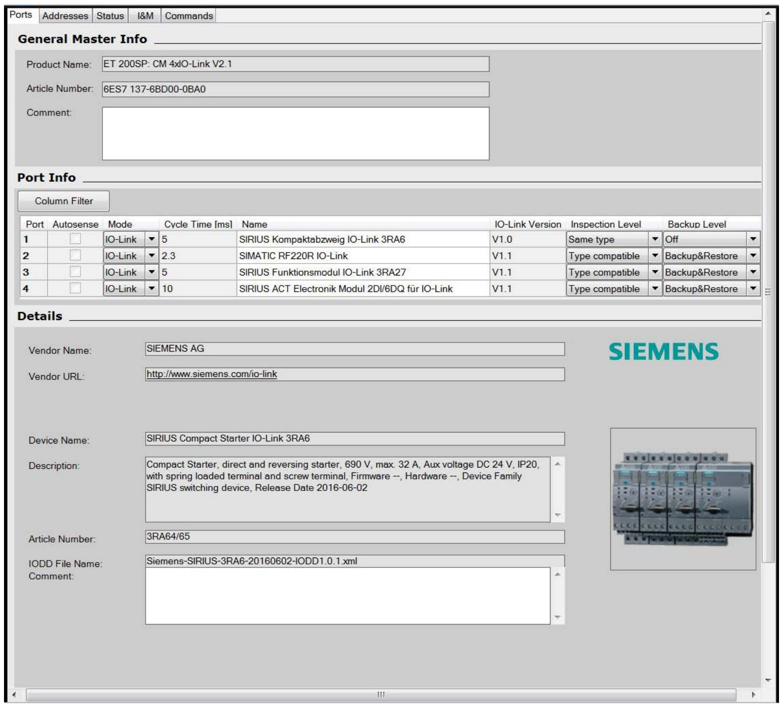

Figure 2-5 S7-PCT with IODD of a device and the device information contained therein

2.7 Differences between IO-Link specifications V1.0 and V1.1

Specification

The technical definition of the IO-Link system is described in a specification of the IO-Link consortium. The first step was the creation of specification version 1.0. The further development and added functions of the IO-Link system led to version 1.1.

The main enhancements of version 1.1 are:

- Data backup for device replacement during operation (Backup&Restore)
- Data transmission rate 230.4 kBaud is mandatory for the IO-Link master

Combination of IO-Link devices

Note the following when combining IO-Link devices:

- Only IO-Link devices that comply with V1.0 can be operated on the IO-Link master to V1.0.
- IO-Link devices that comply with V1.0 and V1.1 can be operated on the IO-Link master to V1.1.
- Data backup and a data transmission rate of 230.4 kBaud of the IO-Link master after V1.1 can only be used when these functions are also supported by the IO-Link device.

Integration into the automation system 3

3.1 Configuration of the IO-Link system

Introduction

An IO-Link system is configured in several steps. In the first step, the master is integrated in the automation system and configured. In the second step, the IO-Link devices are configured.

Integration in the automation system

When using a SIMATIC S7 CPU, use the engineering tool STEP 7, V5.x or STEP 7 (TIA Portal) for configuration.
The IO-Link system is represented by the IO-Link master in the configuration of the automation system or the fieldbus and integrated with STEP 7 or a GSD file.
The IO-Link master itself can be a field bus node (e.g. ET 200eco PN IO-Link master) or a part of the modular IO system that is connected to the field bus (e.g. ET 200SP IO-Link master). In both cases, the number of ports, the address range and the module properties are described in STEP 7 or in the GSD file.

Example configuration in STEP 7 (TIA Portal)

The figure below shows a PROFINET configuration with integrated PROFINET devices ET 200SP and ET 200ecoPN with IO-Link masters.

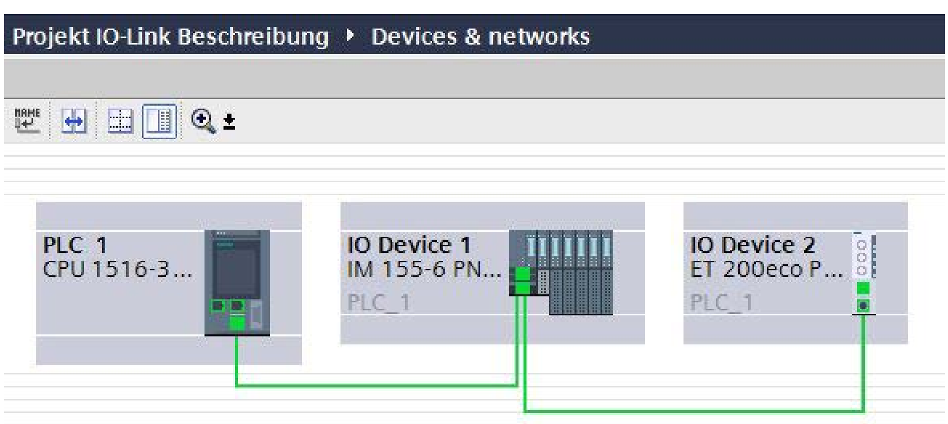

Figure 3-1 Configuration of a PROFINET network with lower-level IO-Link masters

In the device view of the PROFINET device, you can:

- Parameterize the ports
- Specify the input and output address ranges of IO-Link for exchange of cyclic data (process values).

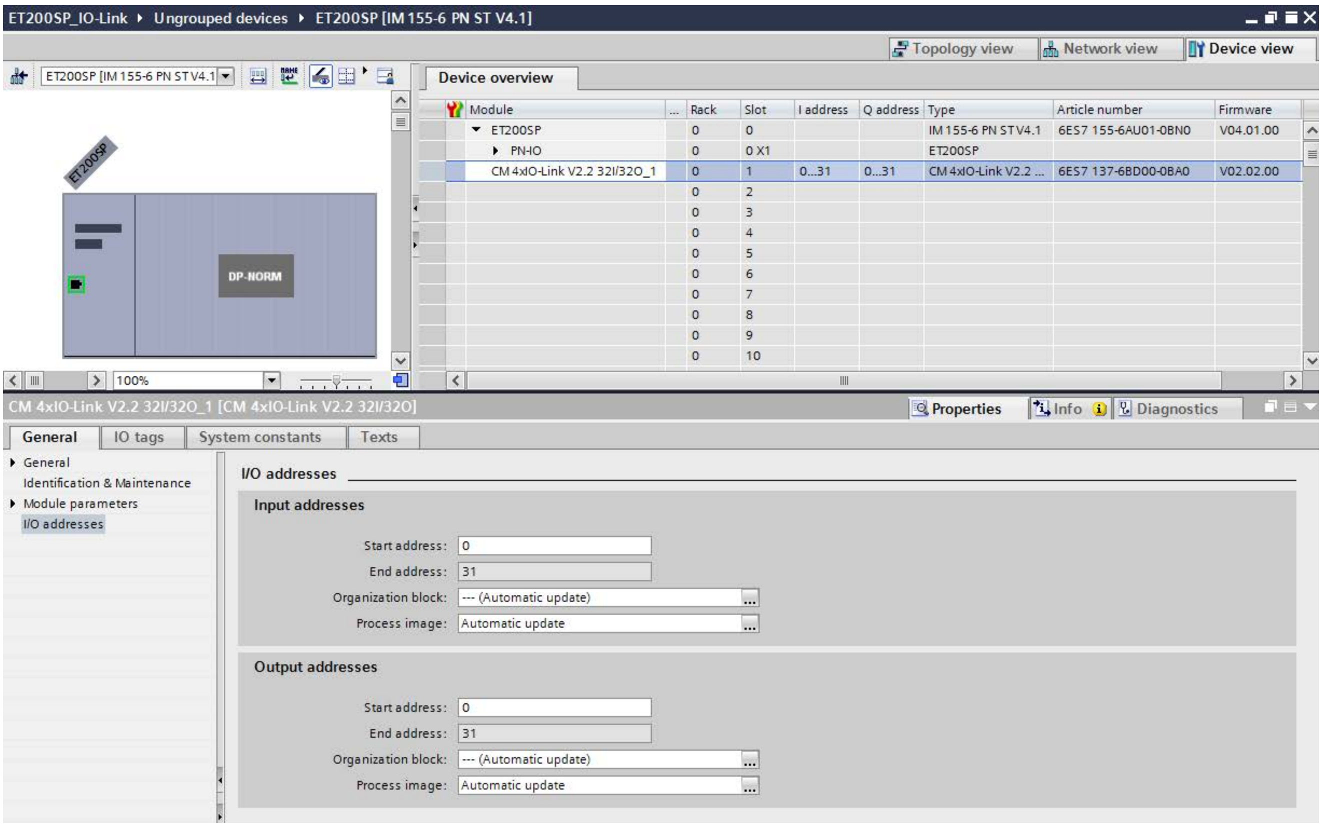

Figure 3-2 Device view with setting of the IO-Link address range

In addition, you can set in the module properties of the IO-Link master how the IO-Link system is to be configured and parameterized.
In doing so, you can select whether or not you also want to work with the S7-PCT configuration tool.

Note

IO data length

To ensure smooth operation, select an IO data length during configuration of the IO-Link master that corresponds at least to the IO data length of all connected IO-Link devices.

3.1.1 Configuration with S7-PCT

Introduction

The following sections describe how you configure your IO-Link master with the S7-Port Configuration Tool (S7-PCT).

You need S7-PCT to display the system architecture completely and transparently all the way to the IO-Link device and to configure and parameterize the IO-Link system in detail.

With S7-PCT you can easily configure the IO-Link devices with the help of the IODD (IO-Link Device Description) supplied by the device manufacturer.
In the S7-PCT online view you can display the diagnostics states and process values of the IO-Link devices in detail.

Configuration with S7-PCT

When you have selected the option "Configuration with S7-PCT", you are also making the settings of the IO-Link master ports with S7-PCT.
These settings include:

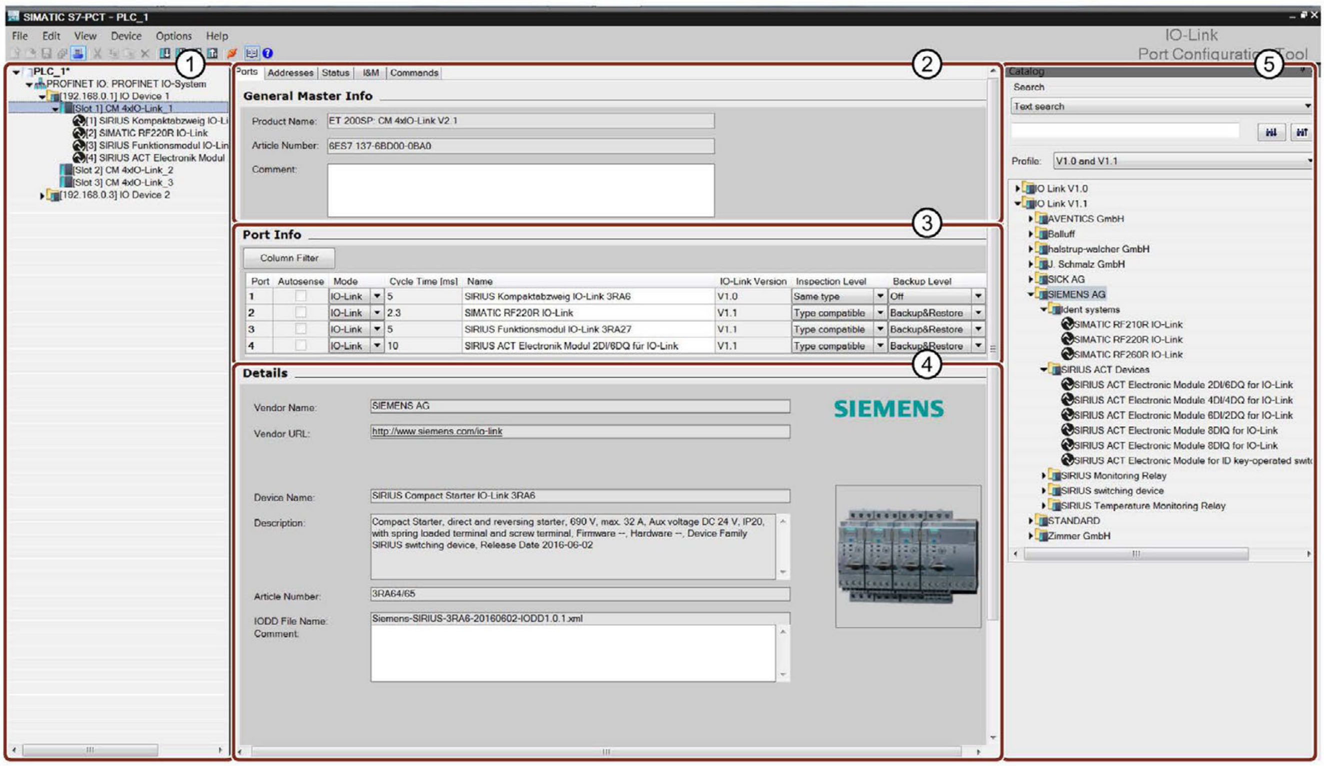
- Specification of the address range for each port
- Behavior when replacing an IO-Link device
- Setting the identification data for checking the connected IO-Link device type

Start S7-PCT from HW Config in STEP 7.
S7-PCT shows you all Siemens IO-Link masters you have configured in your automation system.
After selecting an IO-Link master, you can assign its IO-Link ports to the desired IO-Link devices.
To do so, select the corresponding IO-Link devices (or their IODDs) from the device catalog and drag them to the port of the IO-Link master.

Example configuration in S7-PCT

The following figure shows the configuration of an IO-Link master in S7-PCT.

This S7-PCT view shows you a wide variety of information:



①	Higher-level field bus and overview or structure of the lower-level IO-Link master
②	Detailed information on the selected IO-Link master
③	Current configuration of the IO-Link ports of the selected IO-Link master
④	Detailed information on the selected IO-Link device
⑤	Device catalog with the IODDS of the IO-Link devices from different manufacturers

Figure 3-3 Configuration of an IO-Link master in S7-PCT

Address range of the ports

In addition to the assignment of the IO-Link devices to the IO-Link master ports, the default address ranges of the ports can be changed. The IO-Link master transfers the process values that it receives from the IO-Link device in these address ranges and makes the process values available to the higher-level automation system.

To set the address range, select the "Addresses" tab.

Setting device parameters

Specific parameter settings are required to adjust the device to the respective application task. The possible parameters and set values are contained in the IODD of each device. You set the device parameters directly in S7-PCT.

After selecting the corresponding device in the project tree (left tree), set the device parameters in the "Parameters" tab.

The figure below shows you an example of the parameter assignment of an IO-Link device:

Identification | Parameters | Monitoring | Diagnostics | Connection

Figure 3-4 Setting the parameter values of the IO-Link device

Starting from the displayed defaults, you can edit and save the values in the defined value range.

The configuration of the IO-Link system and the parameters of the devices are available to the IO-Link system and the entire automation project. You have the option of saving and printing the configuration and the parameters.

3.1.2 Configuration without S7-PCT

Introduction

The following sections describe how you configure your IO-Link master without the S7-Port Configuration Tool (S7-PCT).

Your options for configuration of the IO-Link system without S7-PCT are limited.
You can configure the port of the IO-Link master using STEP 7 or the GSD file, but you cannot set any parameters of the lower-level IO-Link devices.

Configuration without S7-PCT

You can activate the following parameters in STEP 7 or the GSD file during port configuration:

- Port Qualifier Information (PQI):
  provides information on the status, such as process data of the IO-Link port; is transmitted with the input data of the IO-Link device.
- Operating mode
  - IO-Link Autostart:
    The IO-Link master accepts each connected IO-Link device and starts it automatically.
  - IO-Link Manual:
    The IO-Link master only accepts IO-Link devices that match the Vendor ID and Device ID set below.
    The connected IO-Link device is **not** started automatically.
  - DI:
    The port is operating as a standard digital input.
  - DQ:
    The port is operating as a standard digital output.
  - Disabled:
    The port is disabled.
- Input Data Length:
  Process data length of the input data
- Output Data Length:
  Process data length of the output data
- Vendor ID
  ID number of the device manufacturer. You can find the Vendor ID on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109748852).

- Device ID
  ID number of the device. You can find the Device ID on the Internet (https://support.industry.siemens.com/cs/ww/en/view/109748852).
- Inspection level for data backup:
  – Identical type (V1.0) without Backup&Restore
  – Type-compatible (V1.1) without Backup&Restore
  – Type-compatible (V1.1) with Backup&Restore
  – Type-compatible (V1.1) with Restore

The figure below shows you an example of the settings of a port configuration in STEP 7 or with GSD file:

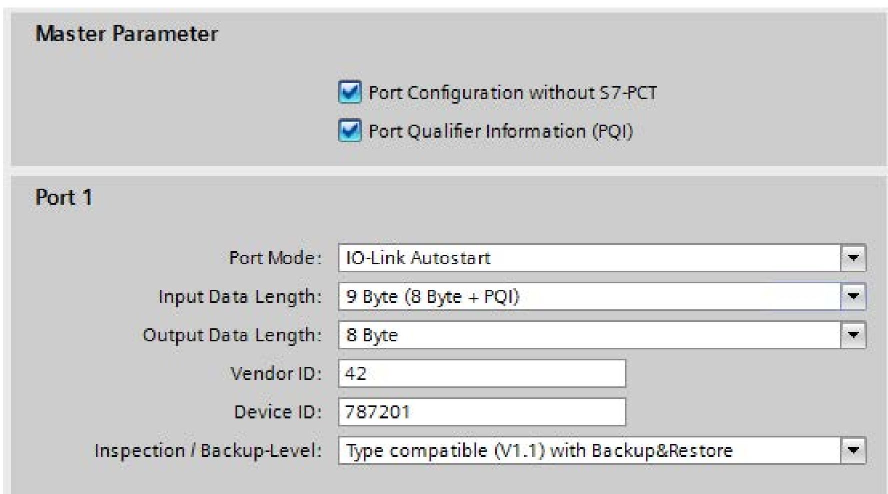

Figure 3-5 Settings of the port configuration in STEP 7 or with GSD file

3.1.3 Overview of configuration options

Introduction

The tables below show the configuration options offered by the SIMATIC IO-Link master with or without S7-PCT and which FW versions of the IO-Link master support the individual configurations.

Comparison of the configuration options

The following table provides an overview of the available options for configuration with and without S7-PCT:

Requirement	Configuration with S7-PCT	Configuration without S7-PCT	
		IO-Link Autostart	IO-Link Manual
Use of the IO-Link device description IODD	Yes	No	No
Setting the length of input and output data (per port)	Automatic	Manual	Manual
Assignment of the Vendor ID and Device ID	Automatic	-	Manual (see FAQ (https://support.industry.siemens.com/cs/ww/en/view/109748852))
Behavior during IO-Link device replacement	Programmable	-	Programmable
Adjustable IO-Link cycle time	Yes	No	No
Adjustable IO-Link device parameters	Yes	No	No
Display of the IO-Link process data structure	Yes	No	No
Monitoring of IO-Link process data	Yes	No	No
Display of IO-Link device diagnostics messages	Yes	No	No

Configuration options of the SIMATIC IO-Link masters

The following table provides an overview of the configuration options supported by the individual IO-Link masters:

Device designation	Article number	As of FW version	Configuration...	
			...with S7-PCT	...without S7-PCT
ET 200SP				
Communications module IO-Link Master CM 4xIO-Link	6ES7137-6BD00-0BA0	V1.0.0	x	-
		V2.2.0	x	x
ET 200AL

SM1278 4xIO-LINK MASTER	6ES7278-4BD32-0XB0	V1.0.0	x	-

3.2 Data access of the automation system and the HMI device

Cyclic data exchange

To exchange cyclic process data between an IO-Link device and a CPU, the IO-Link data is assigned by the IO-Link master to the previously set address ranges. The user program of the CPU accesses and processes the process values by using these addresses. The cyclic data from the CPU to the IO-Link device (for example, IO-Link actuator) takes place in reverse order.

Acyclic data exchange

Acyclic data, such as device parameters or events, is exchanged by means of a fixed index and subindex area. The CPU accesses the data using system mechanisms (for example, for online functions such as reading the status). You can use the index and subindex area to access specific device information (for example, to re-assign parameters of the device or master during operation).

Function blocks "IO_LINK_MASTER" and "IO_LINK_DEVICE"

The programming of the CPU user program is another task in addition to the configuration and parameterization of the IO-Link system and its integration into the overall automation system.

For acyclic data exchange, you can use the function blocks "IO_LINK_MASTER" and "IO_LINK_DEVICE" for controllers of the S7-300, S7-400, S7-1200 and S7-1500 product lines.

The function block "IO_LINK_MASTER" reads all relevant functions and accesses to the IO-Link master, the function block "IO_LINK_DEVICE" reads all accesses to the IO-Link devices.
You can use the function block "IO_LINK_MASTER" to restore all parameters saved in the IO-Link master. A typical application is the replacement of the IO-Link master.

Note

Function blocks "IO_LINK_MASTER" and "IO_LINK_DEVICE"

The function blocks "IO_LINK_MASTER" and "IO_LINK_DEVICE" replace the functions of the previously available block "IOL_CALL".

Reference

The IO-Link block library with a description of the integration is available on the Internet (https://support.industry.siemens.com/cs/ww/en/view/82981502).

You can find an application example of using the block library with HMI devices on the Internet (https://support.industry.siemens.com/cs/ww/en/view/90529409).

3.3 Changing and saving device parameters during plant operation

Changing device parameters

You can adjust the device parameters during operation.
The changed parameters will become effective on the device in the process and are retentively saved in the device.

The parameters can be adapted during operation with:

- the engineering tool used (e.g. during plant commissioning)
- the CPU user program (program-controlled)
- HMI (through plant operator during batch change, process optimization)
- Locally through operation on the device (local operating unit on the device)

Saving device parameters (backup)

You can also save the parameters set in the device during commissioning or changed during operation of the plant in the IO-Link master.
This data backup takes place depending on the set behavior of the IO-Link master ports.
You can set the following data backup levels:

- None
  No data backup in the IO-Link master.
- Backup&Restore
  Every time the device parameters are changed, the changed data is automatically saved in the IO-Link master (see section "Triggering a backup").
- Restore
  No automatic data backup in the IO-Link master.

IO-Link Version	Inspection Level	Backup Level
V1.0	No check	Off
V1.1	Type compatible	Backup&Restore
V1.1	Type compatible	Backup&Restore
V1.1	Type compatible	Backup&Restore

Figure 3-6 Overview of data backup level in S7-PCT

Note

IO-Link Specification V1.0

IO-Link master and devices to IO-Link specification V1.0 do not offer this function; a data backup cannot be set (Data backup: None).

Note that the behavior of the IO-Link master and the IO-Link devices during device replacement depends directly on the set data backup level.
You can find additional information on this dependency in the section Replacing a master or device during operation (Page 32).

Triggering a backup

Requirements

- You have set the correct data backup level.
- The IO-Link master and the IO-Link devices you are using support this function (IO-Link Specification V1.1).

Procedure

There are several ways to trigger a backup:

- In the engineering tool:
  After you have downloaded the engineering settings to the device, the IO-Link device immediately triggers a backup.
- In the CPU user program:
  IO-Link device parameters can be changed successively by the user program.
  A backup is only triggered by a system command. The system command must be triggered by the user program after the parameter changes.
  You can implement the parameter changes and the system command for triggering the backup with function blocks of the CPU.
- Using the HMI:
  You proceed as with triggering by the user program.
  The plant operator then triggers the necessary system command on the HMI device.
- Locally by operating the IO-Link device:
  After confirming the input on the IO-Link device, the IO-Link device initiates the backup.

3.4 Replacing a master or device during operation

Replacing a device

Replacing a device during operation is a scenario that occurs again and again and has to be completed without longer plant downtimes. Replace a device quickly and avoid incorrect settings. Devices can also be replaced by operators without special knowledge and aids.

When you use the backup function of the master, the master automatically supplies the saved parameters to the new device during device replacement.
You have the following setting options for device replacement:

- Backup&Restore
  You have set the master port to Backup&Restore. The new device behaves as the replaced device because the master has saved the last parameter change with the backup function.
- Restore
  You have set the master port to Restore. The new device applies the parameter settings that were saved in the master at the time of the last backup.
  If you have made parameter changes since the last backup, these are not saved in the master and are not available to the new device.
  The behavior of the new device can deviate from the behavior of the replaced device.
  This may be useful if you want to make short-term plant optimizations but do not want to save them in the plant backup.

Note

Field calibration of sensors

When you are using sensors that must be adapted to specific rated conditions on site (field calibration), you must repeat this calibration after replacing the device.
The backup does not include the data of the field calibration. After repeating the field calibration, the new device works just like the replaced device.

Replacing a master

Replacing a master during operation is a rather rare scenario. Here, too, longer plant downtimes are to be avoided. Replace a device quickly and avoid incorrect settings. Devices can also be replaced by operators without special knowledge and aids.

You can save the configuration and parameter data of the master and the devices connected to the master in the CPU and download this information to the new master after the replacement.
When using an S7-CPU, you can use function blocks for this purpose.
You can find additional information on function blocks in the section Data access of the automation system and the HMI device (Page 29).

Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

⚠DANGER
indicates that death or severe personal injury **will** result if proper precautions are not taken.

⚠WARNING
indicates that death or severe personal injury **may** result if proper precautions are not taken.

⚠CAUTION
indicates that minor personal injury can result if proper precautions are not taken.

NOTICE
indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

⚠WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This documentation covers general topics applicable to all products.

In addition to introductory information about analog value processing, this manual covers the following topics:

- Wiring transducers to analog inputs
- Wiring actuators/loads to analog outputs
- Compensating for reference junction temperatures
- Calibrating analog modules
- Diagnostics options of an analog module
- High-speed analog modules

Basic knowledge required

The following knowledge is required in order to understand the documentation:

- General knowledge of automation technology
- Knowledge of analog value processing (analog technology)
- Knowledge of the industrial automation system SIMATIC
- Knowledge about how to use STEP 7 (TIA Portal)

Scope of the documentation

This manual is considered the basic documentation for all analog input and analog output modules of the S7-1500, ET 200MP, ET 200SP, ET 200AL, ET 200pro and ET 200eco PN product series.

Changes compared to previous version

Changes / enhancements described in this manual, compared to the previous version (version 12/2013):

- Extension of the scope of validity to the distributed I/O system ET 200AL

Conventions

STEP 7: In this documentation, "STEP 7" is used as a synonym for "STEP 7 as of V12 (TIA Portal)" and subsequent versions of the configuration and programming software.
This documentation includes images of the products it describes. The products supplied may differ slightly from these images.

Please observe notes labeled as follows:

Note

Notes contain important information on a point in the documentation of particular importance.

Additional support

Additional information on SIMATIC products is available on the Internet. The associated documentation is also available on the Internet.

- The portfolio of technical documentation for SIMATIC products and systems can be accessed on the Internet (http://www.siemens.com/simatic-tech-doku-portal).
- The online catalog and the ordering system are available on the Internet (http://mall.automation.siemens.com).

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. You can find more information about industrial security on the Internet (http://www.siemens.com/industrialsecurity).

To stay informed about product updates as they occur, sign up for a product-specific newsletter. You can find more information on the Internet (http://support.automation.siemens.com).

Table of contents

Documentation guide

1

Introduction

The documentation of the SIMATIC products has a modular structure and covers diverse topics concerning your automation system.

The complete documentation for the S7-1500, ET 200MP, ET 200SP, ET 200AL, ET 200pro and ET 200eco PN systems consists of the respective system manuals, function manuals and product manuals.

Overview of additional documents related to analog value processing

The following table lists further references that supplement this description of analog value processing.

What you should know about analog technology 2

2.1 Overview

Introduction

This chapter is intended to familiarize you with the essential parameters of analog input modules and analog output modules based on the fundamentals of analog technology. The descriptions and examples provided on the following pages serve as a reference to the manuals for the respective analog module and are intended to facilitate the handling of these manuals.

Analog and binary signals

Binary signals can assume only 2 signal states: signal state 1 (voltage present) and signal state 0 (no voltage present). In control engineering, it is frequently necessary to read, process and output analog signals in addition to binary signals. In contrast to binary signals, analog signals take on any number of values within a specific range. Possible analog variables include:

- Temperature
- Pressure
- Speed
- Fill level
- pH value

Transducers

Controllers are only capable of processing analog values in the form of bit patterns. For this purpose, transducers which can be connected to the analog module measure physical variables such as pressure or temperature. The analog input module reads this analog value in the form of current, voltage or resistance. To enable the CPU to process the current or voltage measured, an integrated analog-to-digital converter in the analog input module converts the value into a 16-bit integer value. Depending on the type of measurement, you can use the following transducers:

- Voltage transducers
- Current transducers
  - 2-wire transducers
  - 4-wire transducers
- Resistance transducers
  - 4-wire connection
  - 3-wire connection
  - 2-wire connection
- Thermocouples

Additional information on wiring various types of transducers to analog inputs can be found in Wiring transducers (Page 65).

Example

Speed is acquired using a transducer which converts the speed range of 0 to 1500 rpm to a voltage range of 1 to 5 V. At a measured speed of 865 rpm, the transducer outputs a value of 3.3 V.

The resulting voltage value is calculated as follows:

$$U = \frac{5\text{ V} - 1\text{ V}}{1500\ \frac{\text{U}}{\text{min}}} * 865\ \frac{\text{U}}{\text{min}} + 1\text{ V} = 3.3\text{ V}$$

The graph below illustrates voltage acquisition:

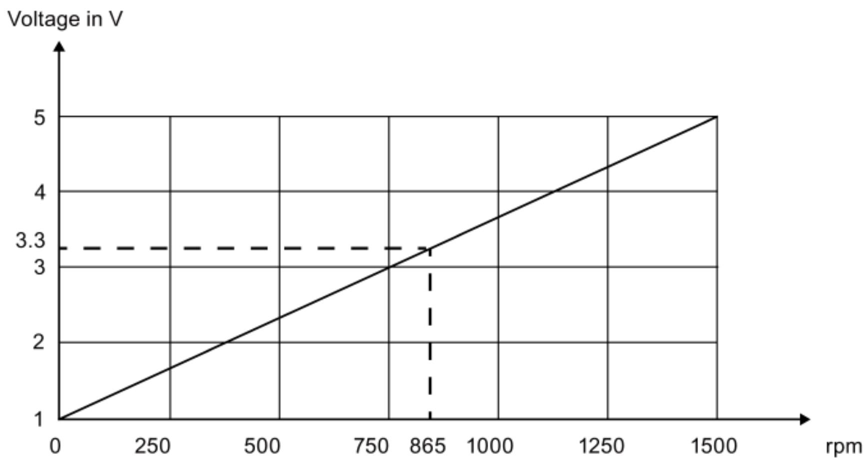

Figure 2-1 Speed measurement

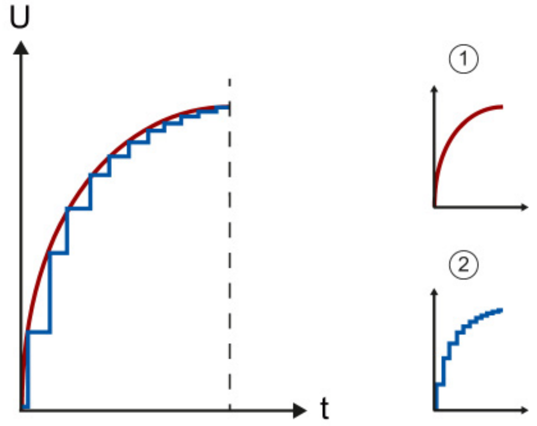
Analog-to-digital conversion

A CPU processes information exclusively in digital format. The analog value is therefore converted into a bit pattern. Conversion is done using an integrated ADC (analog-to-digital converter) in the analog input module. For the CPU, this conversion always returns a 16-bit word for SIMATIC products. The ADC used digitalizes the analog signal and approximates its value with a stepped curve. Resolution and conversion speed are the most important ADC parameters.



① Analog value
② Digital value

Figure 2-2 Approximation of an analog graph with low- and high-resolution stepped curves

Digital-to-analog conversion

Once the CPU has processed the digital signal, an integrated DAC (digital-to-analog converter) in the analog output module converts the output signal to an analog current or voltage value. The resulting value of the output signal corresponds to the output value used to control the analog actuators. Such actuators include, for example, small servo drives or proportional valves. You will find more information on wiring actuators in Wiring loads/actuators (Page 103).

Important parameters of analog modules

Alongside the type and range of measurement, the precision, resolution and conversion time are the main points to consider when selecting an analog module. For some applications such as systems which cover a large area, common mode or channel isolation are also important. The parameters listed here are examined in more detail in the following pages.

Processing analog signals

The following figure demonstrates analog signal processing in a PLC.

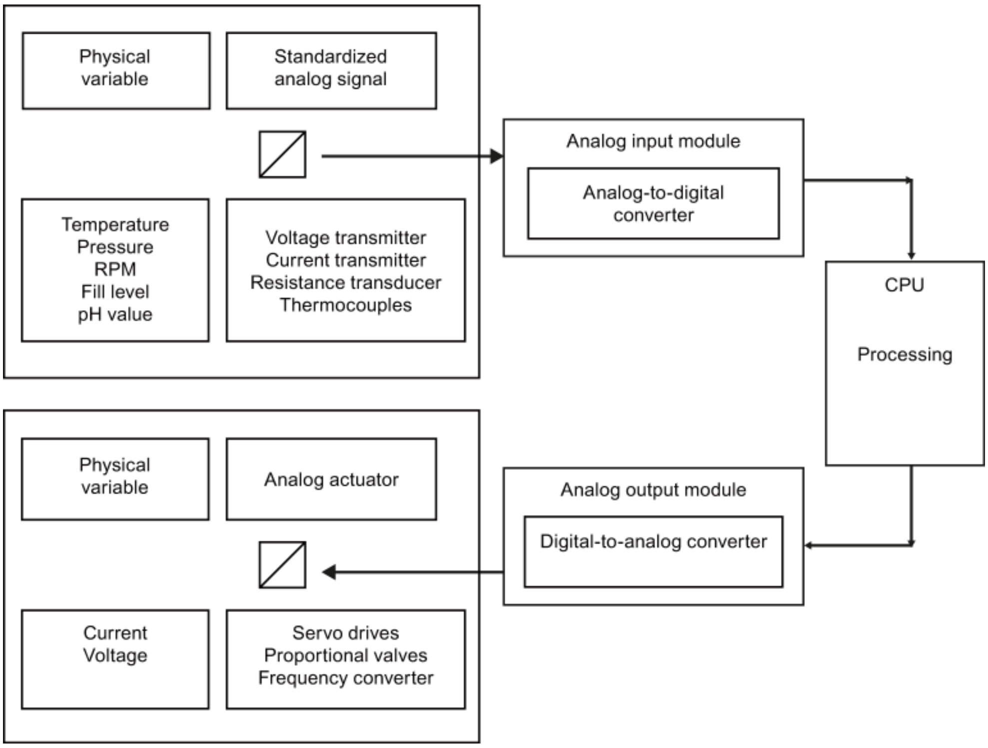


Figure 2-3 Analog value processing

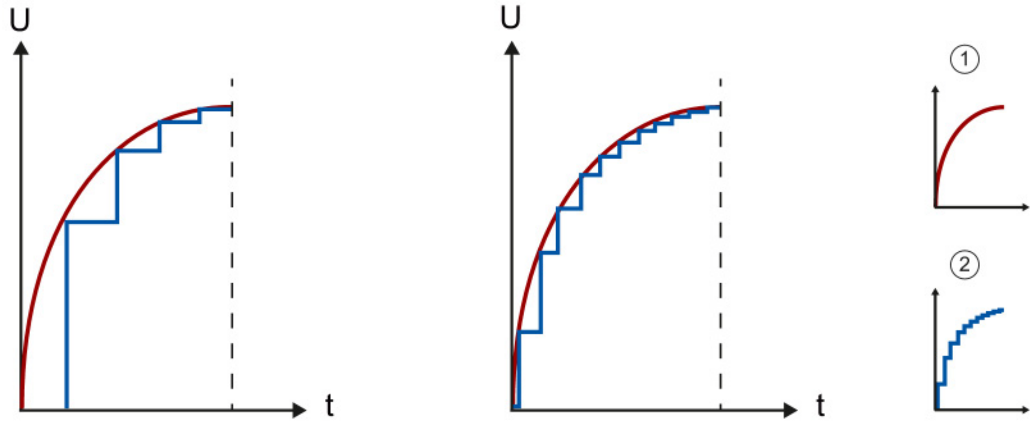
2.2 Precision/resolution

The resolution of an analog module depends on the converter and its external circuitry. An approximation of the analog signal to be acquired/output is returned by a stepped curve. The resolution determines the number of increments of the analog value along this stepped curve. A higher module resolution reduces the length of increments and adds precision to the digitization of the analog signal.

Approximation of an analog value

The figures below show the approximation of an analog value by means of a stepped curve. A low resolution only returns a rough approximation of the actual curve (left figure), while the approximation is more precise at higher resolutions (right figure).



① Analog value

② Digital value

Figure 2-4 Approximation of an analog curve with a stepped curve

Visualization of the measuring range at a resolution of 13 bits and 16 bits

The unipolar measured value from a module having a resolution of 13 bits (= 12 bits + S) is segmented into a total of 2^{12} = 4096 increments. The smallest increment in a measuring range of 0 to10 V is 10 V/4096, equal to 2.4 mV.

A module with16-bit (= 15 bits + S) resolution thus provides an increment of 0.3 mV. If the resolution increases by one bit, the number of increments doubles and the width of an increment halves.

If the resolution increases from 13 bits to 16 bits, the number of increments increases eightfold from 4096 to 32768. With a resolution of 13 bits, the smallest value that can be displayed is therefore 2.4 mV. By contrast, this value is approximately 0.3 mV at a resolution of 16 bits.

Measuring ranges

For the display of the measuring range, SIMATIC S7 distinguishes between the rated range, the overrange and underrange, and the overflow or underflow. This distinction allows you to recognize whether the measured value is actually in the measuring range determined in the technical specifications. The overflow and underflow ranges are reserved for error detection.

At a resolution of 16 bits the theoretically possible 32768 increments are distributed across a voltage range of 11.852 V, which means that only 27648 increments are actually available for the resolution of a measuring range of 10 V. The minimum value which can be represented is therefore 0.3617 mV (see table).

Table 2- 1 Example of resolution for the 0 to 10 V measuring range of a SIMATIC S7 module

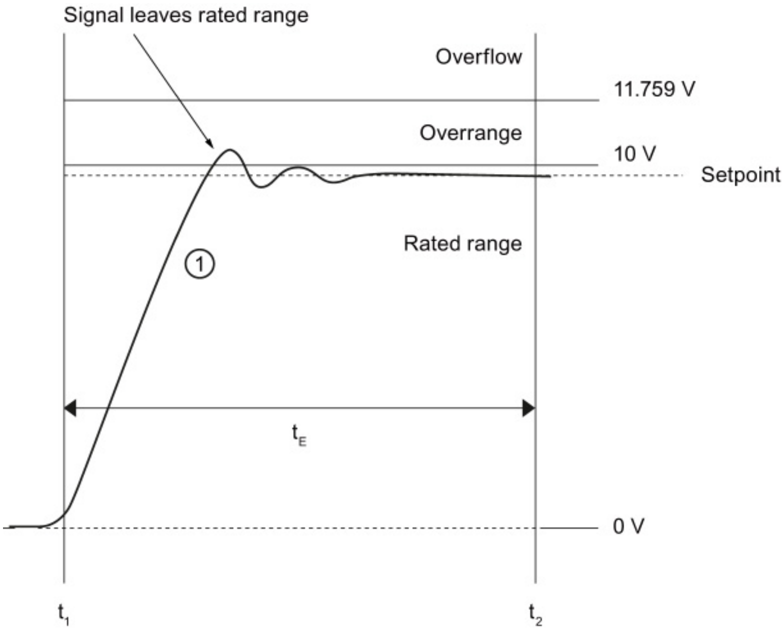
Value (increments)	**Voltage measuring range**	
Decimal	**0 to 10 V**	**Range**
32767	11.852 V	Overflow
32512		
32511	11.759 V	Overrange
27649		
27648	10.0 V	Rated range
20736	7.5 V	
1	361.7 µV	
0	0 V	
not relevant for this example as negative values are not possible		Underrange
		Underflow

The digitized visualization of the input ranges, separated into bipolar and unipolar input ranges, is shown in the section Visualization of the input ranges (Page 62). The digitized visualization of the output ranges, separated into bipolar and unipolar output ranges, is shown in the section Visualization of the output ranges (Page 63). You will find a summary of all measuring ranges which you can use with your analog module in the corresponding device manual.

Over and underrange

It may happen for control processes with high signal jumps that the settling curve of the signal briefly leaves the rated range until it reaches the setpoint. The over and underrange ensures that no error is reported while the signal is not in the rated range. If the signal exceeds the over or underrange, however, and reaches the overflow or underflow range, the error state "Overflow" or "Underflow" is diagnosed. This means the over or underrange correspond to a tolerance range between the rated range and the overflow or underflow. Additional information on the settling time is available in the section Settling and response times of analog output modules (Page 52).

The figure below shows the rated range, the overrange and overflow of a unipolar measuring range. The signal leaves the rated range briefly during the settling phase.



①	Analog output signal
t_E	Settling time of the signal to the setpoint
t_1	Module ends conversion at the terminal of the analog output channel and outputs the signal
t_2	Signal has settled and the specified analog output value has been reached

Analog module precision

The precision of an analog module is specified as a percentage value or absolute value, for example, in K or °C. This characterizes the total error of measured value acquisition. The basic error limit at 25 °C, as well as the operational limit, are specified in accordance with international standard IEC 61131, which also forms the basis for European Standard EN 61131. For more information on the operational/basic error limits, refer to the Operational and basic error limits (Page 23) section.

Relation between resolution and precision

A certain resolution must be given to reach a specific precision (operational error).

Example

Measuring error as a result of digitization at a resolution of 8 bits and 14 bits

An analog module has a measuring range of 0 V to 10 V. A resolution of 8 bits represents a total of 256 values. This is equivalent to a minimum possible voltage step of 39 mV or 0.4% of the measuring range end value. A resolution of 14 bits represents a total of 16384 values. This is equivalent to a minimum possible voltage step of 0.61 mV or 0.006% of the measuring range end value.

The percentages derived in this way also represent the theoretical best-case values for the operational limit. With a resolution of 8 bits and a measuring range of 0 to 10 V, it is therefore impossible to achieve a precision of more than 0.4 %. In practical life, this value would be clearly worse, depending on the implemented circuitry.

Calculating the maximum measuring error

The maximum measuring error of a 0 to 10 V analog module with an operational limit of ±0.5 % across the entire temperature range is calculated as follows:

10 V x 0.5/100 = 50 mV

This means the maximum measuring error is approximately ±50 mV. This also means that each analog voltage input is subject to a distortion of ±50 mV across the entire input range. A voltage of 3.5 V that is to be measured can therefore be visualized by any value between 3.45 V and 3.55 V.

For more information on the operational/basic error limits, refer to the Operational and basic error limits (Page 23) section.

2.3 Scaling analog values

Scaling

It is often necessary to calculate the actual process value rather than increments (e.g., 10 V = 27648 increments) for further processing of digitalized analog values. The conversion of a value range (e.g., -27648 to +27648 increments) to the original physical quantity (e.g., 0 to 500 liters) is referred to as scaling.

Scaling blocks

STEP 7 offers the suitable program block for scaling of analog values. The SCALE block is included in the STEP 7 scope of delivery and permits input of a high and low limit (e.g., 0 to 500 liters).

Example

In the example below the fill level of a tank with a capacity of 500 liters is to be measured. The transducer used measures a voltage of -10 V with an empty tank and a voltage of +10 V with a full tank. The analog module converts the voltage range from -10 V to +10 V into the value range -27648 to +27648 and converts this range into the original quantity of 0 to 500 liters with the SCALE program block.

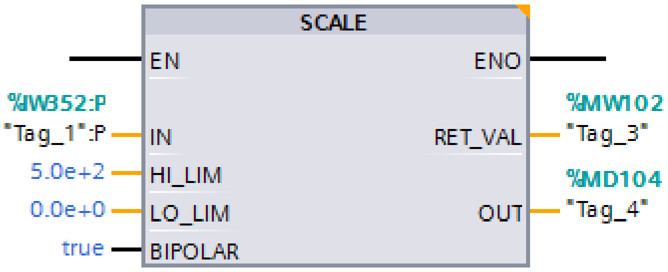


Figure 2-5 Scaling in the SCALE program block

The analog value at input **IN** is read directly by the module or is transferred by a data interface in INT format. The input **LO_LIM** is used to determine the low limit (0 liters) and **HI_LIM** to determine the high limit (500 liters) of the physical quantity. The output **OUT** outputs the scaled value (physical quantity) as floating-point number (LO_LIM <= OUT <= HI_LIM). You can assign parameters via the input **BIPOLAR** to specify if only positive or only negative values are to be converted. If the parameter receives an operand with the state '0', there is a unipolar scaling. An operand with the state '1' results in a bipolar scaling. The output **RET_VAL** outputs an error code in case of an error (e.g., overflow) and the value '0' in case of an error-free execution.

Additional information on the SCALE block can be found in the STEP 7 online help.

Unipolar and bipolar measuring ranges

The measurement of the fill level in our example took place within a bipolar measuring range. In addition to the positive voltage the transducer also provides negative voltage. Because the tank volume is mapped to the range from -27648 to +27648 increments, the measurement of the fill level takes place with twice the resolution (Δ) as in the unipolar measuring range.

Note

Transducers

The prerequisite for a measurement within a bipolar measuring range is that the used transducer supports bipolar measuring ranges.

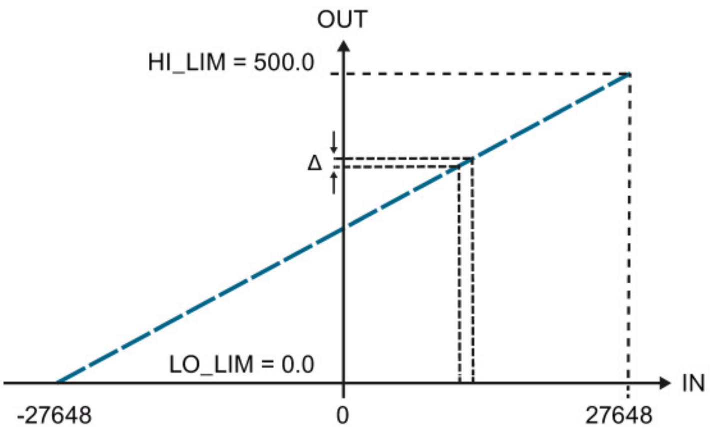

Figure 2-6 Bipolar measuring range

The measurement of the fill level in the bipolar measuring range takes place with twice the resolution (Δ) as in the unipolar measuring range.

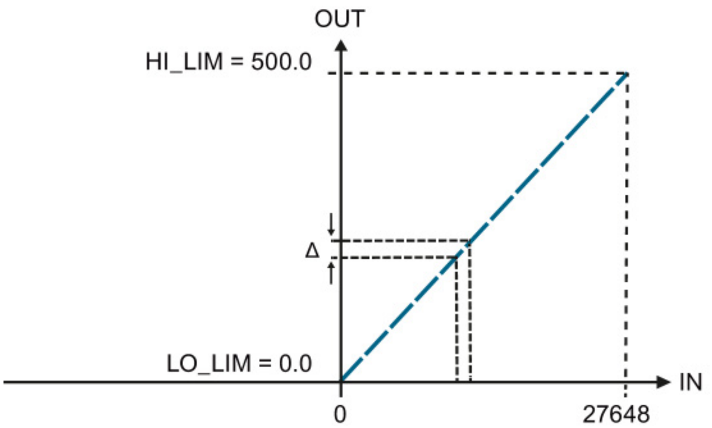

Figure 2-7 Unipolar measuring range

2.4 Unscaling analog values

Unscaling

The output of scaled analog values often requires conversion of the analog value calculated by the user program into the value range of the analog output module. This conversion is referred to as unscaling.

Unscaling blocks

STEP 7 offers the suitable program block for unscaling of analog values. The UNSCALE block is included in the STEP 7 scope of delivery and permits the input of a high and low limit that defines the range of the program value.

Example

An analog value from 0.0 to 100.0% calculated by the user program is to be converted with the UNSCALE block to the value range -27648 to +27648. When the unscaled value is output to an analog output module, this module addresses an analog actuator (e.g., modulating valve). The actuator is to be addressed at a program value of 0% with the minimum value (-10 V or -20 mA) and at 100% with the maximum value (+10 V or +20 mA).

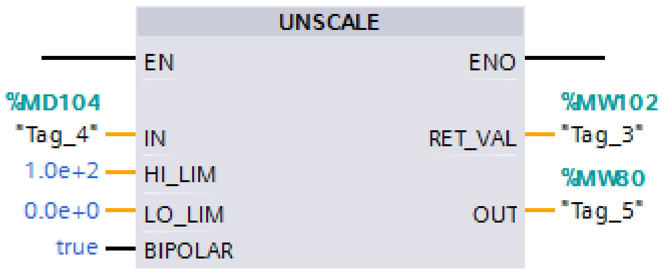

Figure 2-8 Unscaling in the UNSCALE program block

The value calculated by the program must be transferred in the REAL format (**IN**). You use the input **LO_LIM** to determine the low limit (0.0%), and **HI_LIM** to determine the high limit (100.0%) within which the program value moves. The unscaled value is output in INT format at the **OUT** output. You can assign parameters via the input **BIPOLAR** to specify if only positive or only negative values are to be converted. If the parameter receives an operand with the state '0', there is a unipolar scaling. An operand with the state '1' results in a bipolar scaling. The output **RET_VAL** outputs an error code in case of an error and the value '0' in case of an error-free execution.

Additional information on the UNSCALE block can be found in the STEP 7 online help.

Unipolar and bipolar measuring ranges

The figure below shows the scaling for an actuator that is to be addressed at a program value of 0% with the minimum value 0 (0 V or 0 mA) and at 100% (+27648) with the maximum value (10 V or 20 mA).

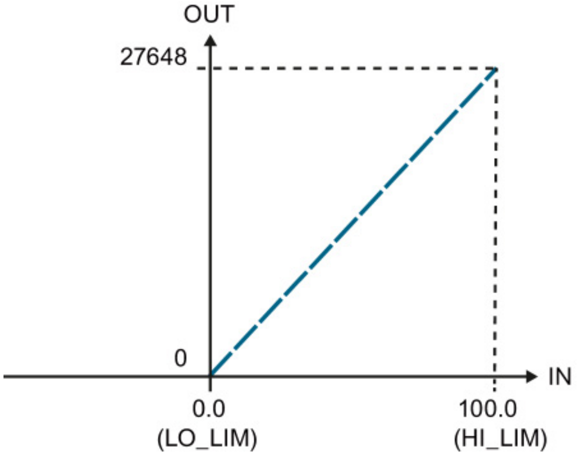

Figure 2-9 Unipolar measuring range

The figure below shows the scaling for an actuator that is to be addressed at a program value of 0% (-27648) with the minimum value 0 (-10 V or -20 mA) and at 100% (+27648) with the maximum value (+10 V or +20 mA).

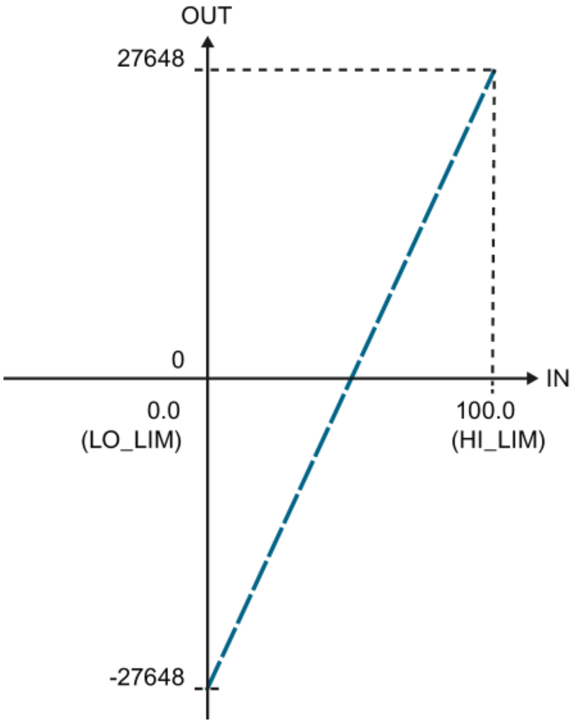

Figure 2-10 Bipolar measuring range

2.5 Linearity errors

Definition

Linearity denotes the deviation of the actual A/D or D/A conversion from the ideal lines within a specified measuring range. The linearity error therefore represents the deviation of the real transmission function from the ideal straight line. The error is given in the technical data as a percentage of the rated range of the analog module.

The figure below shows the linearity error of an ADC, magnified for better visibility.

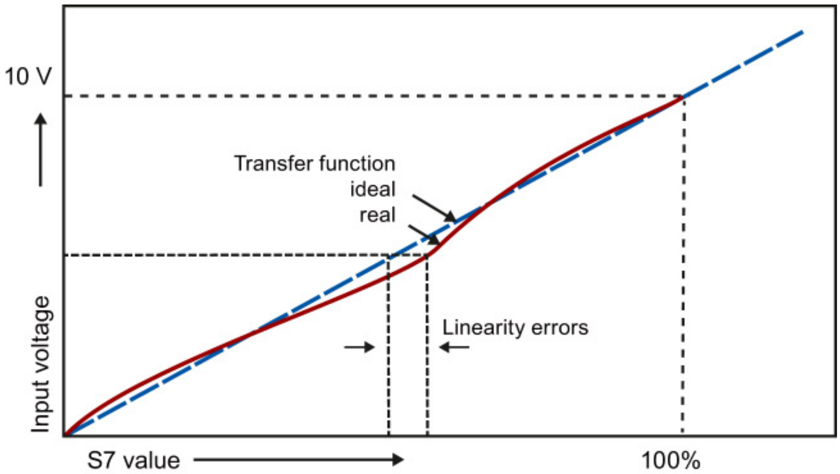

Figure 2-11 Linearity errors

Example

An error of ±1 mV is returned at an input range of ±10 V and a linearity error of ±0.01%. The error is calculated as follows: 10 V · 0.01 % = 1 mV

The linearity error information given in the technical specifications is taken into account in the operational limit. You will find a detailed description of the operational limit in Operational and basic error limits (Page 23).

2.6 Repeat accuracy

Definition

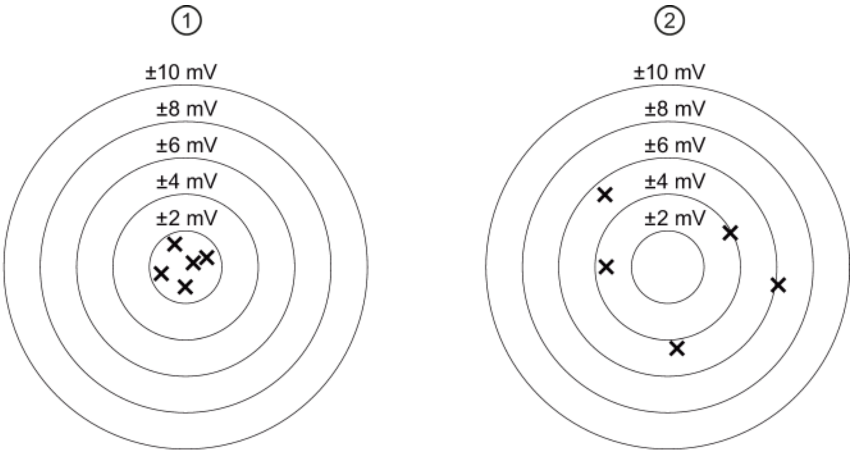
The repeat accuracy is the maximum deviation in measured/output value for the same input signal or output value after another value has been created or output. Other parameters, e.g. the Temperature parameter, remain unchanged. The repeat accuracy refers to the rated range of the module and applies in a steady temperature state.

Measured value variance

The repeat accuracy provides information on the variance of individual measurements. The smaller the variance, the greater the repeat accuracy. The repeat accuracy is therefore one of the most important properties of measuring devices. In the technical data, the repeat accuracy is given as a percentage of the input or output range at 25°C in the steady state.

Example

The specified repeat accuracy for an analog input module as a percentage of the measuring range end value is ±0.02 %. This corresponds to a repeat accuracy of 2 mV for any value within the measuring range of ±10 V. If you change the measured value from 10 V to -10 V, for example, and then measure with 10 V again, the measured value deviation may not exceed ±2 mV.



① Good repeat accuracy
② Poor repeat accuracy

Figure 2-12 Repeat accuracy of measured values output

2.7 Operational and basic error limits

Introduction

The following section shows you how to determine the operational or basic error limits and thus the measurement error or output error with the help of the technical specification. The worst-case configuration ensures that the module will not exceed the specified value within the valid operational range.

The precision of analog input or output modules is only part of the precision of the entire measurement section. A measurement section usually consists of transducer, transmitter, transmission line as well as input / output module.

Operational limit

The operational limit is the entire measurement or output error rate of the analog module in the rated range in temperature-settled state within the approved temperature range.

Basic error limit

The basic error limit is the entire measurement or output error rate in the rated range at an ambient temperature of 25 °C and temperature-settled state.

The basic error limit of the module is more or less a theoretical value, because a constant ambient temperature of 25 °C is rarely maintained in plants. For this reason, the operational limit always takes priority in terms of the practical selection and assessment of a module.

Note

The operational limit and basic error limit percentages listed in the technical specifications always relate to the **maximum possible** I/O value (the measuring range end value) in the rated range of the module.

The following image shows an example of operational and basic error limits in comparison with the ideal curve.

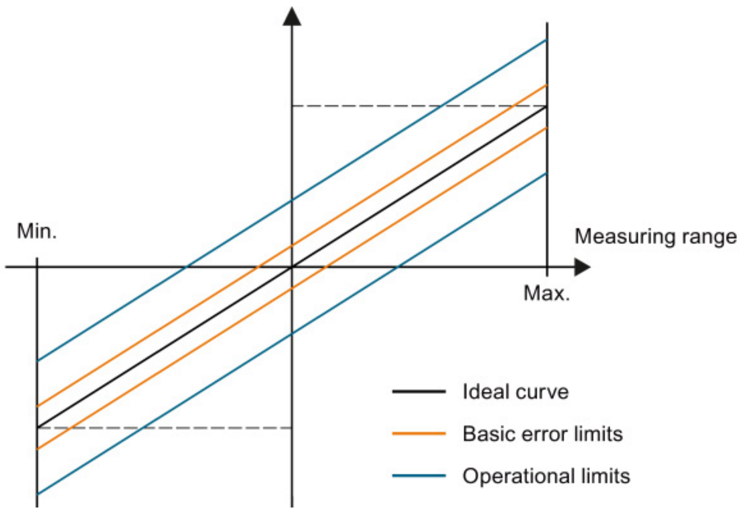


Figure 2-13 Operational and basic error limits

Example of output error calculation

An analog output module is used for voltage output in a range of 0 to 10 V. The module is operating at an ambient temperature of 30 °C, which means that the operational limit applies. Technical specifications of the module:

- Operational limit for the voltage output: ±0.1 %

The result is an output error of approximately ±10 mV (±0.1 % of 10 V) across the rated range of the module.

For example, the output value may range from 2.49 V to 2.51 V at an actual voltage of 2.50 V.

Note

Bipolar measuring ranges

The calculation also applies to bipolar measuring ranges.

An error of ±10 mV is also returned at an input range of ±10 V and a linearity error of ±0.1%.

2.8 Temperature error

Introduction

Analog modules are exposed to operational conditions that have an impact on their precision and on the measurement results they return. Temperature errors develop, for example, if the operating temperature of the module deviates from the ambient temperature of 25 °C. These temperature errors within the approved temperature range are taken into account in the operational limit.

Definition

The temperature error identifies the maximum drift of measuring/output values caused by fluctuation of the ambient temperature at the analog module. The maximum drift can occur at any ambient temperature. The temperature error is specified depending on the module used in percent per degree Celsius and/or percent per Kelvin, e.g. ±0.005%/K, and relates to the measuring range end value of the analog module.

Operational limits of compensation

The temperature error of the reference junction temperature compensation function only occurs with thermocouple measurements. The temperature error of compensation is added to the actual temperature error if "Internal reference junction" operating mode is selected. The temperature error of compensation is defined in the technical specifications as a percentage of the physical rated range of the analog module or as an absolute value in °C.

Note

Calculating the error in thermocouple measurements

Add the error of a thermocouple measurement to the error of the compensation measurement to determine the total error of a thermocouple measurement. These errors are defined in the respective manual.

Example

In this example, the total error of the temperature measurement is determined with the help of a type K thermocouple. The type K thermocouple takes measurements at a temperature range from -270 °C to +1372 °C.

The technical specifications state an operational limit of >-200 °C ±2.4 K for the type K thermocouple. The temperature error of compensation amounts to ±6 °C. The total temperature error is measured as follows at a temperature of >-200 °C:

Operational error (±2.4 K) + temperature error of compensation (±6 °C) = ±8.4 °C.

2.9 Interference frequency suppression

Definition

The interference frequency suppression function is applied to analog input modules to suppress the noise caused by the frequency of the AC voltage supply used.

The frequency of the AC voltage supply is likely to have a negative effect particularly on the values returned by measurements in the low voltage range and on thermocouples.

Parameter assignment

The line frequency at which the system is operated can be set by means of module parameters, for example, in STEP 7.

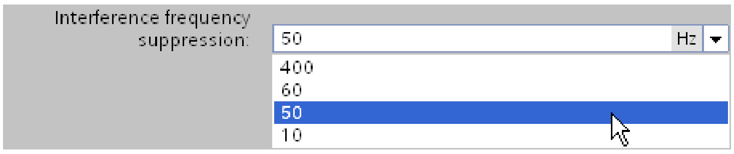

Figure 2-14 Interference frequency suppression

The conversion time changes depending on the set interference frequency suppression. The data sheets of the respective module define this dependency.

Please note the following when selecting interference frequency suppression:

The higher the frequency setting, the shorter the conversion time.

Note

Line frequency

Always select the interference frequency based on the line frequency used. Mismatch errors must be expected if a frequency that deviates from this line frequency is set, for example, to reduce the conversion time. In this case, the specified technical data and, in particular, precision are possibly outside the specified range.

Smoothing

By smoothing analog values, you achieve an additional improvement for the suppression of interference frequencies. For more information on the smoothing of analog values, refer to the section Smoothing (Page 54).

Line frequencies used

The line frequency is the frequency used in an electricity network for AC supply. It is measured in hertz and indicates the number of oscillations per second in a periodic signal. A line frequency of 50 Hz, for example, means 50 oscillations per second.

Europe, Australia and most countries in Asia and Africa use a line frequency of 50 Hz. North and Central America and most countries in South America have electricity networks with a line frequency of 60 Hz.

Frequencies of 400 Hz are most commonly used in on-board networks for airplanes, in the aerospace sector and for military applications. One reason for this is that engines with a line frequency of 400 Hz can usually be made smaller and lighter. As, however, it is not economic to transport such high frequencies over large distances, 400 Hz applications are usually subject to significant spatial limits.

A frequency of 16 2/3 Hz is used for the traction power supply in Germany, Austria and Switzerland. Some modules of the SIMATIC S7 product range also support the interference frequency suppression of this line frequency. The configurable interference frequency suppression in these cases is 16.6 Hz.

2.10 Common mode interference (UCM)

Definition

Common mode interference denotes interference voltages and currents in the lines connecting electrical devices and system components. They affect both the positive and negative line with the same phase angle and amplitude. The interference signal needs an additional current path to affect the utility signal. This current path is usually provided by common reference potential, e.g. earth or ground connection, of the utility signal and interference source.

Common mode interference in analog modules

Common mode interference occurs in analog input and output modules if their reference potential is different from the reference potential of the connected sensor or actuator.

Common mode interference is most likely to occur when analog modules are operated with grounded sensors. The size of the overall system means that voltage differences may develop between machine components with grounded sensors and the analog module reference. These voltage differences affect both the positive and negative signal path equally, which is why they are termed common mode interference.

In operation with non-grounded sensors, the occurrence of common mode interference is not as obvious as in grounded operation. Nevertheless, capacitive or inductive coupling can also create voltage differences in such cases which have the effect of common mode interference. Depending on the conditions in grounded and non-grounded operation, common mode voltage can occur as direct or as alternating voltage.

Example

The following figure of an analog module with two inputs (Ch_1/Ch_2) shows the coupled interference voltages at the inputs (U_{CM1}/U_{CM2}) as well as an interference voltage coupled between these inputs (U_{CM3}). Common mode rejection indicates the extent to which these interference signals can be suppressed. It is calculated using the following equation:
CMR [dB] = $20 \cdot \log (U_{CM} / U_a)$

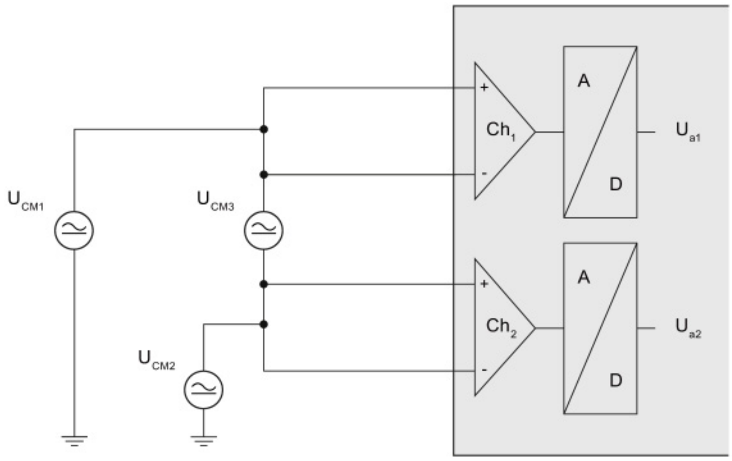

Figure 2-15 Common mode voltage coupled between two inputs

If there is common-mode voltage (U_{CM}), the equation is solved for U_a to calculate the measuring error (U_a):

$$U_a = U_{CM} * 10^{-\frac{CMR}{20}}$$

Note

The common mode rejection (CMR) is detailed in "Common mode interference" in the technical data of the device manual for your analog module.

2.11 Series mode interference (USM)

Definition

Series mode interference is interference voltages and currents affecting the connection lines in opposite directions. They have opposite polarity in the positive and negative directions. Series mode interference currents cause a voltage drop at the input impedance that has the effect of an interference voltage.

Causes

Series mode interference is caused by capacitive or inductive coupling. Inductive coupling generates a magnetic flow that is radiated between adjacent current-carrying conductors. This induces an interference voltage in the conductor. Galvanic coupling is given where different circuits influence each other due to common conductor sections, e.g. common ground connection.

The diagram below shows series mode interference as a voltage source (U_{SM}) connected in series to the actual measuring signal (U_M). The index "SM" stands for "Series Mode". Series Mode rejection indicates the extent to which these interference signals are suppressed. It is calculated using the following equation: SMR [dB] = $20 \cdot \log (U_{SM} / U_a)$

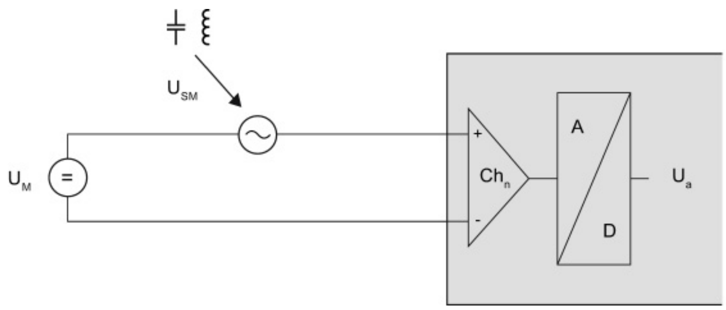

Figure 2-16 Capacitive or inductive interference coupling to the signal cable

The voltage (U_a) measurement error is calculated by solving the equation for U_a.

$$U_a = U_{SM} * 10^{-\frac{SMR}{20}}$$

The following equation shows the calculation of current (I_a) measuring errors using a current input.

$$I_a = \frac{U_{SM}}{R_{ein}} * 10^{-\frac{SMR}{20}}$$

Note

The series mode rejection (SMR) is detailed in "Series mode interference" in the technical data of the device manual for your analog module. The level of input resistance (R_{ein}) is also specified in the technical data.

2.12 Interference voltage suppression

Definition

Interference voltage suppression gives the factor by which the interference signal is suppressed in measurement value acquisition. Higher values reduce the effect of interference on the measurement signal. The technical data differentiates between "Common mode interference" and "Series mode interference". Interference voltage suppression is specified in decibels.

Example

The diagram below shows the measuring error for interference voltages in volts and interference voltage suppression of 0 to 120 dB.

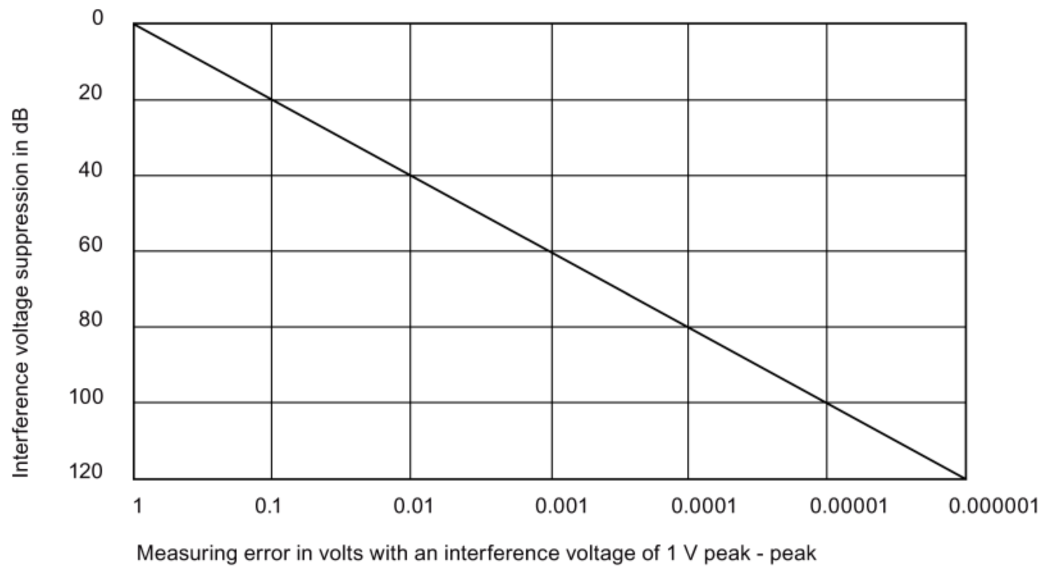

Figure 2-17 Interference voltage suppression

With an interference voltage suppression of 40 dB and an interference voltage of 1 V, the measured value is only distorted by 0.01 V.

Note

Interference-free design

Disturbance variables can be substantially reduced by means of appropriate grounding and shielding to increase interference immunity of the configuration. You will find a detailed description of how to avoid interference in the Configuring interference-free controllers (http://support.automation.siemens.com/WW/view/en/59193566) function manual.

Common mode rejection

The table below sets out the possible common mode rejection specifications in the technical data of an analog input module:

Interference voltage suppression for f = n x (f1 ± 1 %), (f1 = interference frequency), n = 1, 2, ...	
Common mode interference	> 100 dB
Common mode voltage, max.	10 V

If the interference frequency is configured as 50 Hz, the specified interference voltage suppression for common mode interference will only apply for the frequencies 50 Hz ±1 %, 100 Hz ±1 %, 150 Hz ±1 %, etc. Immunity is lower for all other frequencies. Interferences caused by the line voltage distort the measured utility signal in the ratio of 100,000 : 1. An interference voltage amplitude of 1 V, for example, will affect the utility signal by 10 μV.

The Common Mode voltage (U_{CM}) defines the maximum permitted deviation of the potential between two channels and between one channel and analog ground. The interference voltage suppression defined in the technical specifications must not be exceeded. If the maximum common mode voltage specified, for example, 10 V, is exceeded, the analog signal is processed incorrectly. Depending on the module used, this error may be diagnosed and an error message output. The maximum common mode voltage may be exceeded as a result of varying input or overly long lines.

Series mode rejection

The table below sets out the possible series mode rejection specifications in the technical data of an analog module:

Interference voltage suppression for f = n x (f1 ± 1 %), (f1 = interference frequency), n = 1, 2, ...	
Series mode interference	> 60 dB

If the interference frequency is configured as 50 Hz, the specified interference voltage suppression for series mode interference will only apply for the frequencies 50 Hz ±1 %, 100 Hz ±1 %, 150 Hz ±1 %, etc. Immunity is lower for all other frequencies. Overall, interference caused by the line voltage distorts the utility signal measured by 1000 : 1. For example, an interference voltage amplitude of 1 V will affect the utility signal by 1 mV.

2.13 Crosstalk between channels

Origin of the term

The term crosstalk/XT was originally used in the field of telecommunication to denote unwanted coupling of voice signals between two cable conductors of different subscribers.

Definition

Crosstalk between signal channels denotes the interactive influence between two independent channels as a result of leakage currents and capacitive or inductive coupling. Crosstalk between the channels changes the signal by the value of the amplitude of the crosstalk signal.

Causes

Technically, it is not feasible to totally isolate the module channels from environmental conditions. This means that it is always possible for leakage currents or disturbance coupling having an interactive effect.

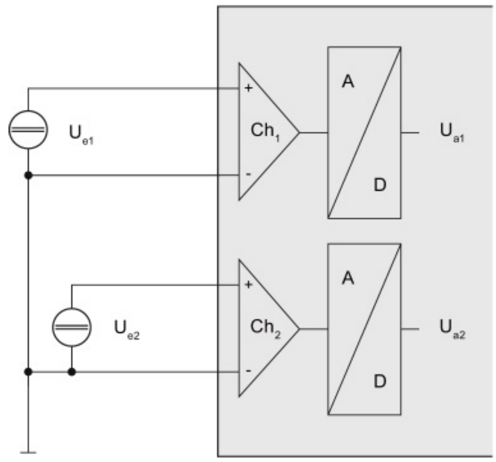

Figure 2-18 Crosstalk between two channels

The diagram shows the effects of crosstalk for the user with two channels (Ch_1/Ch_2) of an analog module. The crosstalk value is the factor by which the utility signal at a second channel U_{a2} is affected by the signal at the first channel U_{e1}. The measuring error (U_{a1}) can be calculated using the following equation:

$$U_{a1} = U_{e2} * 10^{\frac{XT\,[dB]}{20}}$$

Example of crosstalk attenuation

The "crosstalk between inputs" value in the technical specifications is defined as a value of >-100 dB at a measuring range of -10 V to +10 V on channel 1 of an eight-channel analog input module. The voltage at the input has an amplitude of 10 V. What is the error caused by crosstalk at channel 0 (measuring range ±10 V) and channel 2 (measuring range ±80 mV)?

100 dB are equal to a factor of 100,000. The measured values at channels 0 and 2 to 7 are therefore affected by 10 V / 100,000 = 100 µV. This distortion is added to or subtracted from the pending measuring signal and its effect depends on the selected measuring range.

- Channel 0: 100 µV / 10 V = 0.001 %
- Channel 2: 100 µV / 80 mV = 0.125 %

A voltage of 10 V set at channel 1 distorts the measured value at channel 0 by 0.001% and the measured value at channel 2 by 0.125%. The measuring error resulting from crosstalk in this example is therefore 0.001 % or 0.125 %. The basic error limit already includes the error generated as a result of crosstalk between the channels.

Calculating measuring error

You calculate the measurement error at channel 1 in this example based on a change in the measurement voltage of 10 V at channel 2. The crosstalk (XT [dB]) value is defined in the technical specifications in the manual of the analog module that you are using.

$$\text{Measured value error channel 1 [in V]} = \text{measured value change at channel 2 [in V]} * 10^{\frac{XT\,[dB]}{20}}$$

$$\text{Measured value error channel 1 [in V]} = 10\text{ V} * 10^{\frac{-80\,dB}{20}} = 0.001\text{ V}$$

A change in the measurement voltage of 10 V at channel 2 causes a measurement deviation of 0.001 V at channel 1.

2.14 Diagnostics

Diagnostics for analog modules

SIMATIC analog modules can diagnose errors. A number of different types of diagnostics are available for analog modules in STEP 7. Please note that the parameter assignment options vary depending on the analog module and product family used. More detailed information on the types of diagnostics can be found in the device manual for your analog input or analog output module.

Proceed as follows to select the diagnostics types of the analog module used:

1. Open STEP 7.
2. Select the analog module in the Device view.
3. Select the "Properties" tab.
4. Select the inputs or the required channel of the analog module in the Inspector window.

Table 2- 2 Overview of diagnosable errors

Type of diagnostics	Analog input module	Analog output module
Wire break	✓	✓
No supply voltage L+	✓	✓
Overflow	✓	✓
Underflow	✓	✓
Common mode error	✓	-
Short-circuit	✓	✓
Overload	-	✓
Reference junction	✓	-

Diagnostics of the analog module are carried out while the system is in operation, on the basis of the current output variables such as current or voltage. If the output current or output voltage is no longer sufficient, the module will not be able to run reliable diagnostics. The limits within which diagnostics are possible are specified in the technical data for each module.

The module reports the diagnosed state to the CPU using a diagnostics error interrupt. If several diagnostics are pending at the same time, the diagnostics with the highest priority is reported to the CPU first. Diagnostics are output on LED displays on the affected module, on the CPU display, on the Web server or on an HMI device.

The configurable diagnostics types depend on the respective selected measuring type or output type. The following tables shows the relationship between the diagnostics types, measuring types or output types of an analog input module or analog output module.

Diagnostics Analog input modules

Table 2- 3 **Diagnostics types of an analog input module to be configured depending on the measurement type "Voltage"**

Note

Measuring ranges

Note that the diagnostics types that can be parameterized depend on the selected measurement/output type as well as on the respective measuring range.

Note

Minimum output values

Certain errors such as wire break and short circuit cannot be diagnosed below a given current or voltage value. Diagnostics are only possible again once the output returns to above this minimum value.

No supply voltage L+

You can diagnose a missing or low supply voltage L+ at the analog module by activating the "No supply voltage L+" checkbox. If the supply voltage is missing or too low, the status and error display on the analog module will provide the relevant information. The entry in the diagnostics buffer also makes this information available to the CPU.

If there is no supply voltage, no other types of diagnostics available are possible either.

Wire break

The term wire break denotes a failure state that is triggered by the interruption of a usually closed electrical circuit.

Wire break in analog input modules

The "Wire break" diagnostics function facilitates the detection of errors during system operation. In STEP 7 you define the module properties by setting various parameters. Depending on the module used, you may, for example, be able to set a current limit parameter at which a wire break is to be reported.

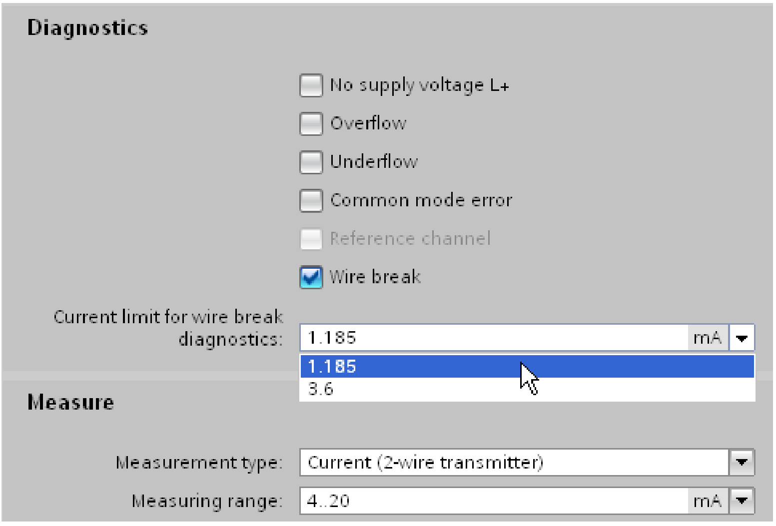

Figure 2-19 Configuring the wire break current limit for an analog input module in STEP 7

Usually, the live zero technique is deployed to detect wire breaks. The start of the measuring range for the standard live zero signal of 4 to 20 mA is assigned the 4 mA signal value. A wire break between the input and sensor can therefore be detected based on the missing current flow. Instead of a current signal, you may also use a voltage signal from 1 to 5 V to detect a wire break. The "Wire break" diagnostics function can therefore only be configured for a range of 4 to 20 mA or 1 to 5 V.

For "Resistor", "Thermal resistor" and "Thermocouple" measurements, a current is impressed into the line. If a wire break occurs, the flow of current is interrupted and the analog module therefore detects the wire break.

Wire break in analog output modules

The analog signal output is used for wire break detection. Reliable wire break diagnostics is not possible if the voltage is too low. In this case, the diagnostics function is deactivated without triggering a change of the diagnostics status.

The current limit up to which the module will diagnose wire break can be found in the technical data for the module.

Overflow/underflow

The resolution of the measuring range of an analog input module distinguishes between the rated range, the overrange or underrange, and the overflow or underflow. The following table assign the number of increments into which the measured signal is divided to the various voltage measuring ranges.

Table 2- 15 Voltage measuring range ±10 V of an analog input module

Value (increments)	Voltage measuring range	Range
Decimal	±10 V	
32767	> 11.759 V	Overflow
32511	11.759 V	Overrange
27649		
27648	10.0 V	Rated range
0	0 V	
-27648	-10 V	
-27649		Underrange
-32512	-11.759 V	
-32768	< -11.759 V	Underflow

As of a decimal value of 32512, the value acquired is beyond the overrange and is no longer valid. If this is the case, the error status "Overflow" is diagnosed. The overrange is a tolerance range before overflow is reached.

As of a decimal value of -32513, the value acquired is below the configured measuring range and is no longer valid. If this is the case, the error status "Underflow" is diagnosed. The underrange is the equivalent of the overrange, but for negative values.

An "Overflow" or "Underflow" diagnostics may be caused, for example, by a wire break, an incorrect measuring range or incorrect wiring.

Note

Accuracy

The accuracy specified in the technical data of the relevant module is only guaranteed within the rated range.

Common mode error

Activating the "Common mode" checkbox diagnoses a violation of the maximum potential difference U_{CM}. A violation of the permitted potential difference U_{CM} has occurred, for example, between the reference point of the measuring inputs and the analog ground M_{ANA} .

Possible causes:

- Wiring error
- Environments with EMC disturbance
- Incorrectly grounded transducers
- Long line lengths
- Sensor not connected
- 2-wire transducer connected to M_{ANA}

Note

With 4-wire transducers, a current meter connected in series will result in too great a drop in voltage.

Potential differences U_{CM} beyond the valid limits may lead to measurement errors and malfunctions. If you want to ensure that the maximum value is not exceeded, interconnect the measuring inputs and analog ground M_{ANA} with an equipotential bonding cable. More detailed information can be found in Wiring transducers.

Short-circuit

Activating the "Short circuit" checkbox activates short-circuit diagnostics for an analog channel. The diagnostics function is triggered by channel overload.

Possible causes:

- Wiring error (e.g. short circuit between conductors at the connections or in the cable)
- Use of faulty or incorrect actuators (e.g. internal short circuit or low input resistance as a result of actuator failure)

The analog signal output is used for short circuit detection. If the voltage is too low, reliable short-circuit diagnostics are not possible. In this case, the diagnostics function is deactivated without triggering a change of the diagnostics status. The voltage limit up to which the module will diagnose a short circuit can be found in the technical data for the module.

SIMATIC modules have a special protective circuit to prevent short circuit. The short circuit current is limited internally in the module. The level of short circuit current is specified in the technical data of your analog module.

Note

Overload

Please note that overload exposes the modules are exposed to a greater thermal load. This can affect the output channels. You should therefore avoid continuously running analog output modules in overload.

Reference junction

This type of diagnostics can only be selected for analog input modules for "Thermocouple" measuring. Selecting the "Reference junction" check box diagnoses an error on the reference channel for compensating the reference junction temperature.

The temperature at the reference junction of a thermocouple is measured at the reference channel of the module using an external thermal resistor (RTD). If an error occurs, for example as a result of a wire break, the temperature measured at the reference junction of the thermocouple will no longer be compensated. The reference temperature may then be outside the valid range.

Additional information on connecting thermocouples and thermal resistors and on how they operate can be found in Thermocouples and Wiring transducers.

Overload

Activating the "Overload" checkbox activates the diagnostics of the thermal monitoring of the output level. The "Overload" diagnostics is triggered when the maximum temperature is exceeded at the output and is detected channel by channel.

The maximum temperature may be exceeded for the following reasons:

- Ambient temperature is too high
- Output is being operated outside the specification

Note

Overload

Please note that overload exposes the modules to a high thermal load. This can affect the output channels. You should therefore avoid continuously running analog output modules in overload.

2.15 Value status

Value status

In case of a faulty analog value, the analog module outputs the error values 0x7FFF (error value for overflow and all other error states) or 0x8000 (error value for underflow) for the affected channel. The user program is now able to detect and evaluate a channel error. The user also has the option to evaluate the system diagnostics event-driven by means of diagnostics alarms.

In addition to the error values 0x7FFF or 0x8000 and the configured diagnostic types, analog input and output modules provide diagnostics information by means of the Process image input (PII). It is referred to as Value status and transferred synchronously with the user data. The value status (Quality Information = QI) provides a statement regarding the validity of the input signal. A distinction is made between the quality level "Good" (signal valid = 1) and "Bad" (signal invalid = 0).

Note

For analog input modules, the use of the value status is an alternative to the evaluation of the channels by the error values 0x7FFF or 0x8000. Compared to the error values, the binary evaluation of the value status (0 or 1) in the user program is simpler and more clearly arranged.

For analog output modules, the value status informs you as to whether the written value can be output by the respective channel. Using the value status you can respond to this information without having to evaluate the diagnostics of the module in the first place.

Example

Enabling the value status of an analog input module

To enable the value status of an analog input module, follow these steps:

- Select the required analog module in STEP 7.
- Select "AI configuration" in the "Properties" tab of the analog module.
- Click the "Value status" button.

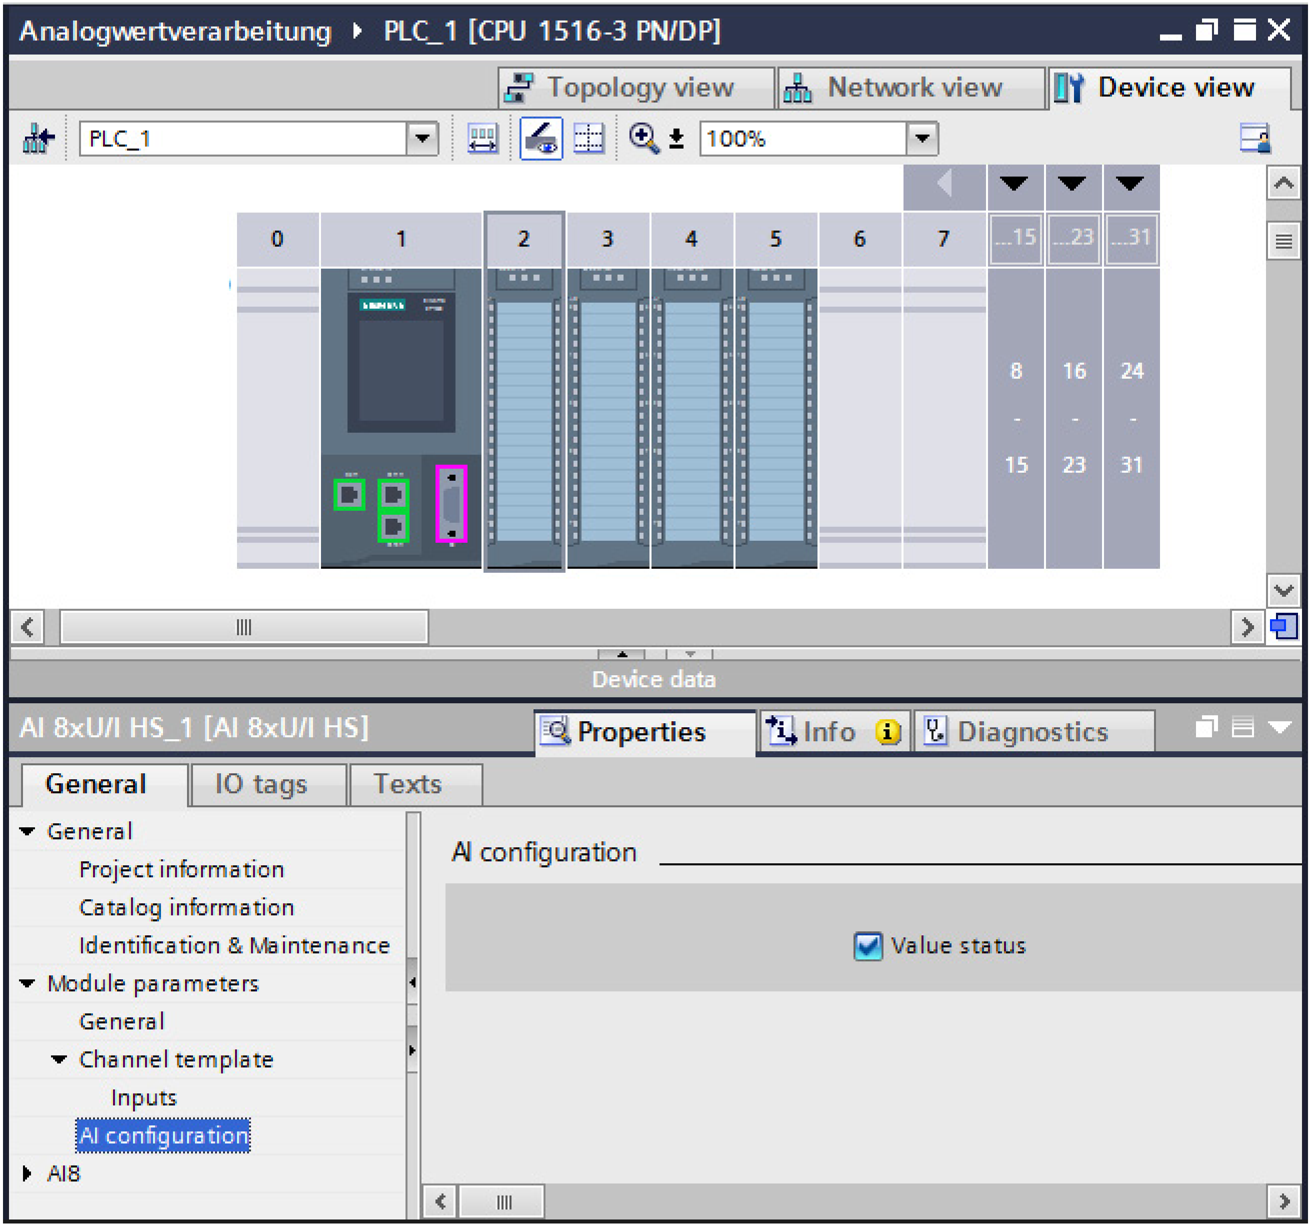

Figure 2-20 Enabling the value status in STEP 7

An additional byte is occupied in the input address space of the respective module when you enable the value status. Each bit in this byte is assigned to a channel and provides information on, for example, whether the output value specified by the user program is actually queued at the module terminal (0= value is invalid; 1= value is valid).

Error occurrence

If a wire break occurs at an analog input module, for example, the current signal state is entered in the process image and the value status of the signal is set to "invalid". To trigger an indicator light in case of an error, for example, evaluate the value status in the user program.

Diagnostics alarms and value status

If you configure analog modules in a third-party product with the help of a GSD file and the diagnostics alarms are not evaluated event-driven, it is best to use the value status.

Note

The Value status represents a group diagnostics which only gives the user a Good or Bad information. The Value status is not suitable for a more specific identification of the cause of the error (e.g., wire break, short circuit in the encoder cable or load voltage failure).

2.16 Conversion time of an analog module

Basic conversion time and conversion time of an analog input channel

The basic conversion time is the minimum time required by one single channel to convert analog values. The actual conversion time comprises both the basic conversion time and, depending on the analog input module used:

- Processing time for measuring resistance
- Processing time for wire break monitoring
- Processing time for overflow/underflow monitoring
- Processing time for checking common mode errors

Example

This example shows channel 6 of an analog input module for resistance measurement in the range of 6000 Ω, a configured integration time of 20 ms, and activated wire break monitoring.

The conversion time of the channel is derived from the total of the following measurement variables:

Measurement variable	Time in ms
Basic conversion time	27
Processing time for RTD/resistance (6000 Ω)	4
Processing time for wire break monitoring in the RTD/resistance and thermocouple areas	9
Conversion time of the channel	**40**

Conversion time of the analog output channels

The conversion time of an output channel starts with the transfer of the digital value from the internal memory of the module and ends with the digital-to-analog conversion.

The conversion time does not include the settling time for the analog signal at the module terminal. Detailed information on the settling time can be found in Settling and response times of analog output modules (Page 52).

Note

Relationship between diagnostics and conversion time

While some diagnostics run parallel to the conversion and do not extend the conversion time, other diagnostics types can lead to an extension of the conversion time, as demonstrated in the example above.

Conversion time for high-speed analog modules

High-Speed analog modules (HS modules) are designed for faster processing of signals. HS modules offer fewer diagnostics and measurement types than standard modules (ST modules). You can find more information on HS modules in the section High-Speed analog modules (Page 113).

2.17 Cycle time of an analog module

Definition

The cycle time of an analog module represents the time that the module needs to process all channels used. The cycle time depends on the form of measured value acquisition used, e.g. multiplex or parallel measured value acquisition.

Sequential measured value processing

This procedure processes the analog channels in the module one after another (sequentially). For analog inputs, the values are connected to a converter, for example using a multiplexer, and sequentially converted.

The cycle time of the analog module is derived from the total conversion time of all activated analog channels of the module. STEP 7 provides the option of deactivating unused analog channels. to reduce the cycle time.

The figure below gives an overview of the factors that determine the cycle time of an n-channel analog module.

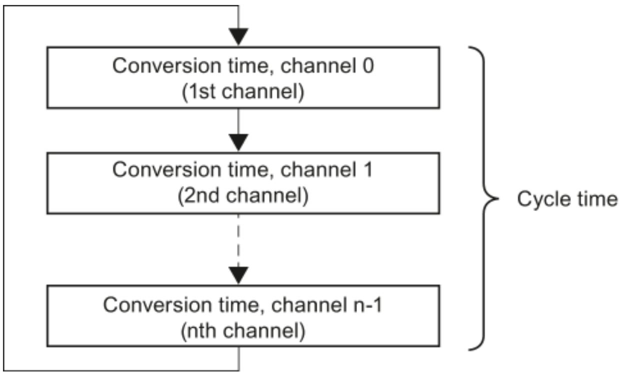

Figure 2-21 Cycle time of an analog module with multiplex conversion

Parallel measured value acquisition

This procedure processes the analog channels of a module at the same time (in parallel) rather than one after another. In parallel measured value processing, the cycle time of the module is usually constant and does not depend on the number of channels used. The goal of parallel measured value acquisition as it is applied by high-speed analog modules, for example, is a shorter cycle time. You can find more information on HS modules in the section High-Speed analog modules (Page 113).

2.18 Settling and response times of analog output modules

Settling and response times provide information on the delay of the output of a specified analog output variable and its availability to the process.

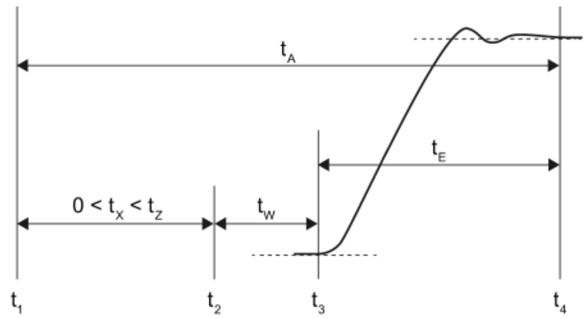
Response time

The response time for a new output value is defined as the time between the input of a digital output value to the internal memory of the module and the value to be output at the analog output being reached (with a residual error of 1 %).

The response time (t_A) is the sum of application time (t_X), conversion time (t_W) and settling time (t_E):

$t_A = t_X + t_W + t_E$

Settling and response times of analog output modules



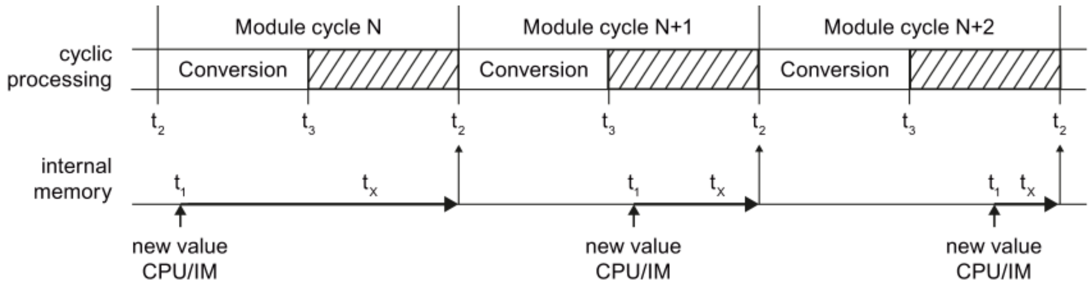
t_A	Response time
t_X	Application time
t_Z	Module cycle time
t_W	Conversion time
t_E	Settling time
t_1	New digital output value is available in the internal memory of the module
t_2	Module activates the digital output value and starts conversion
t_3	Module ends conversion at the terminal of the analog output channel and outputs the analog signal
t_4	Signal has settled and the specified analog output value has been reached (residual error 1 %)

Figure 2-22 Settling and response time of an output channel

Application time

The CPU/IM (interface module) writes new output values to the internal memory of the analog output module. The time required for this is not determined by the CPU/IM. These output values are converted asynchronously to their entry in buffer memory. The worst-case application time (t_X) may be equal to the cycle time (t_Z). This situation develops if the CPU writes a new value to the internal memory of the module immediately after the transfer of the value for conversion. This new value will not be processed until the next conversion.

The figure below shows acyclic access of the analog output module to output values from the internal memory in non-isochronous mode. You can find more information on isochronous mode in the paragraph on isochronous mode of the section High-Speed analog modules (Page 113).



t_X Application time

t_1 New digital output value is available in the internal memory of the module

t_2 Module activates the digital output value and starts conversion

t_3 Module ends conversion at the terminal of the analog output channel and outputs the analog signal

Figure 2-23 Application of the output values

Conversion time

The conversion time of an output channel starts with the transfer of the digital value from the internal memory of the module (t_2) and ends with the digital-to-analog conversion (t_3).

Settling time

The settling time starts when the analog signal is output to the module (t_3) terminals and ends when the output value (t_4) is reached. The output value is reached as soon as the output signal has settled at its final value, taking into account a residual error of 1%.

The settling time depends on the type of output for the module, and on the connected load. The load for the analog output consists of connecting line and connected actuator. When the output is "Current", the settling time increases with high ohmic resistance. Inductive loads cause subsequent fluctuation in the output value. When the output is "Voltage", the capacitive load causes subsequent fluctuation.

2.19 Smoothing

Using the smoothing functions

Most analog input modules allow you to configure smoothing for the measuring signal in STEP 7. Smoothing analog values reduces the effect of interference signals. Smoothing is useful with slow changes in measured values, for example in temperature measurements.

Smoothing principle

The measured values are smoothed by means of filtering. The module forms mean values from a specified number of converted (digitalized) analog values. Smoothing should not be confused with the integration of measured values over a defined period of time. It is therefore not possible to smooth measured signals to filter out a specific interference frequency. However, this smoothing returns more "stable" data values because it suppresses peaks which overlay the measured signal.

4 (none, weak, medium, strong) or more levels of smoothing can be configured by the user depending on the module used. The level determines the number of analog values from which the mean value is generated. The greater the smoothing factor, the better the filtering.

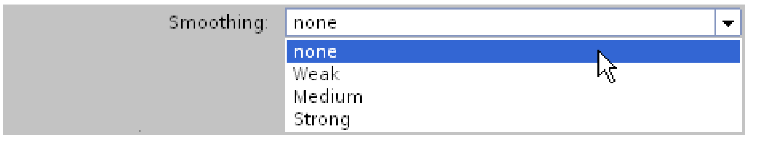


Figure 2-24 Selecting the smoothing level in STEP 7

Smoothing method

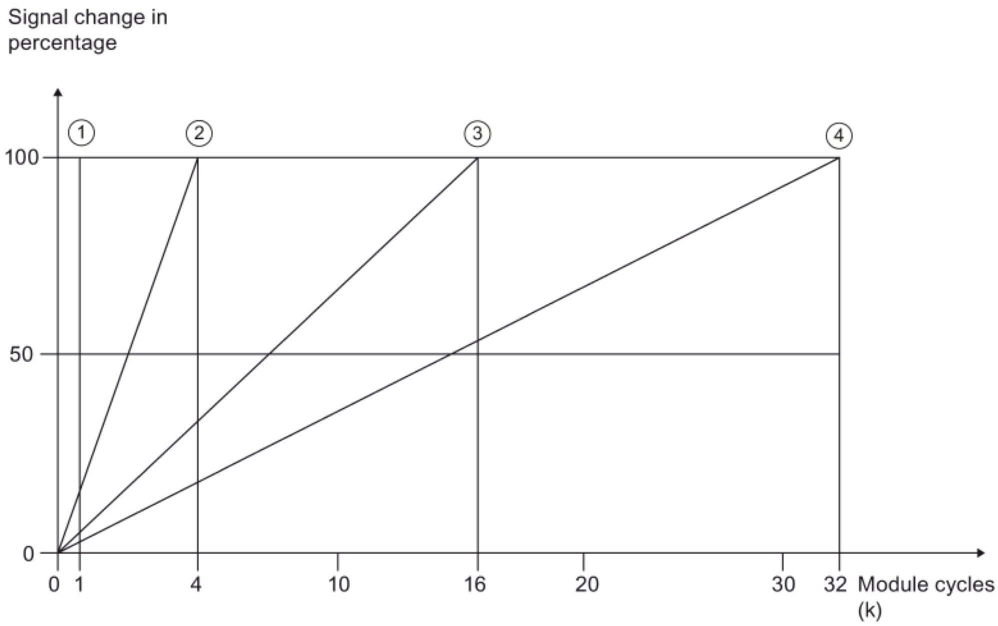
A smoothing algorithm is applied to a configurable number of measured values (e.g. 4, 8, 32) in line with the moving average. Each new measured value is factored in, and the oldest measured value then ignored. This mechanism suppresses interference peaks which overlay the measured signal. Utility signal jumps only become evident in the data after some time (see examples below).

The modules of the various product ranges use different smoothing algorithms. Smoothing is either linear or exponential. The differences are apparent particularly with strong smoothing and lead to a faster or slower rate of rise depending on the product used.

For information on whether or not a specific module supports customization of the smoothing function, please refer to the manual of the analog input module.

Example 1: Linear smoothing

The diagram below shows the number of module cycles (k) it takes for each smoothing level setting for the smoothed analog value to reach approximately 100 % after a step response. This specification is valid for all signal changes at the analog input.

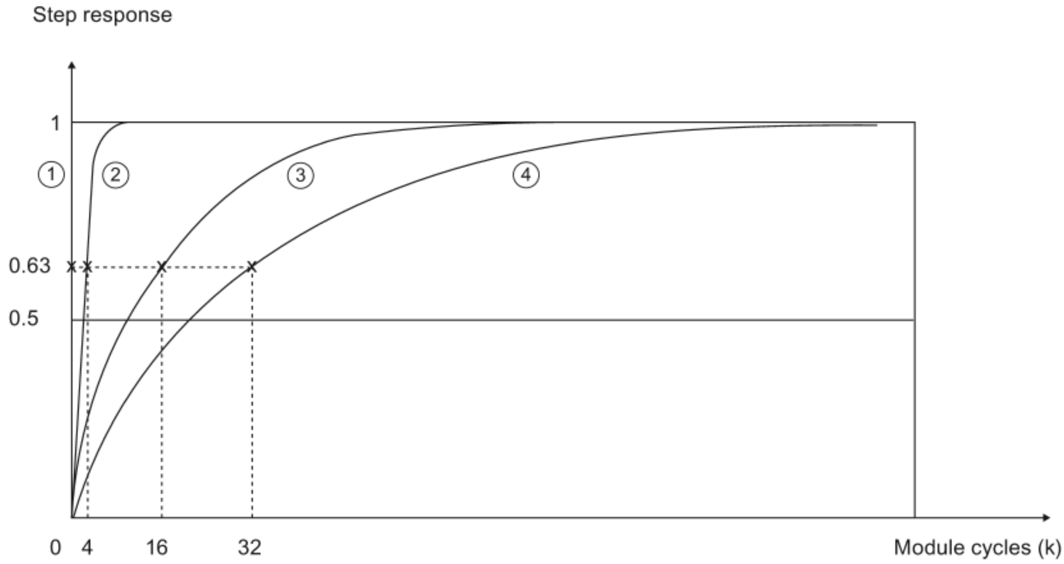


① No smoothing (k = 1)
② Weak smoothing (k = 4)
③ Medium smoothing (k = 16)
④ Strong smoothing (k = 32)

Figure 2-25 Linear smoothing with four smoothing levels

Example 2: Exponential smoothing

The diagram below shows the step response of the smoothing factor for different numbers of module cycles.



① No smoothing (k = 1)
② Weak smoothing (k = 4)
③ Medium smoothing (k = 16)
④ Strong smoothing (k = 32)

Figure 2-26 Exponential smoothing with four smoothing levels

2.20 Burden with 2-wire transducers

2-wire transducers

2-wire transducers are current transducers which convert the process variable into a current signal of between 4 and 20 mA. Two connection lines supply the transducer with an output current of at least 4 mA. Additional information on connecting 2-wire transducers to analog input modules can be found in the section Wiring current transducers (Page 72).

Burden

The burden indicates how great the external resistance in a current loop may be. If the external resistance is greater than the specified burden, the 2-wire transducer supply voltage is too low. The burden consists of the resistance of the transducer and all other resistances connected to the current loop.

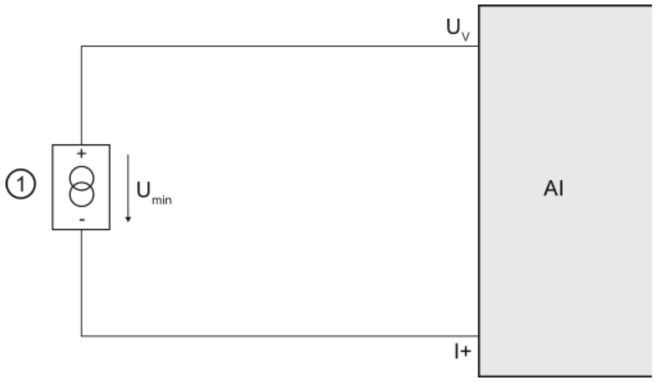
The maximum admissible burden of the transducer, e.g. 820 Ω, is specified in the technical data of the analog module.

Example 1: Connecting a transducer to the electrical circuit

In accordance with the technical data of the 2-wire transducer used, it requires a supply voltage (U_{min}) of at least 8.5 V. Using Ohm's Law, you can calculate the resistance of the transducer used (R_{2DMU}) for a current of 20 mA.

$$R_{2DMU} = \frac{U_{min}}{I} = \frac{8.5\ V}{0.020\ A} = 425\ \Omega$$

With a supply voltage of at least 8.5 V, the transducer has a resistance of 425 Ω. The resistance is less than 820 Ω. You can therefore connect the transducer to the analog input module (AI) without exceeding the maximum burden.



①	2-wire transducers
U_V	Terminal for feed voltage at the channel
I+	Terminal for current input
U_{min}	Voltage drop at 2-wire transducer

Figure 2-27 Connecting a transducer to the electrical circuit

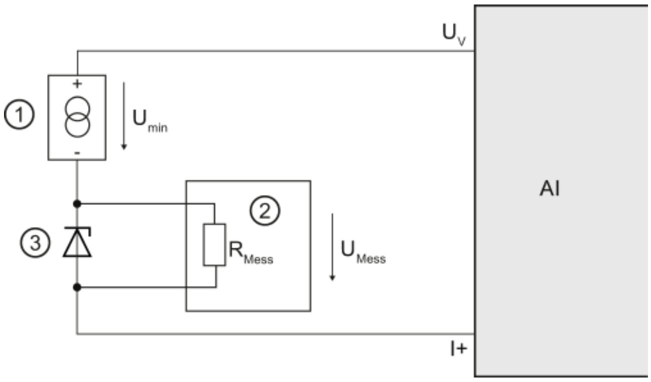
Example 2: Connecting a transducer and other devices

If multiple measuring devices are connected in series, the sum of all connected resistances may not exceed the value of the maximum burden.

If you have connected a 2-wire transducer to a supply voltage of 8.5 V, you will need to allow for the resistance of the measuring device connected ②.

Maximum transducer burden:	820 Ω
Transducer resistance upon a voltage drop of 8.5 V:	425 Ω
Maximum resistance of additional devices connected:	395 Ω

The resistance of the measuring instrument may therefore not exceed 395 Ω.



① 2-wire transducers
② Digital multimeter
③ Zener diode
U_V Terminal for feed voltage at the channel
I+ Terminal for current input
U_{min} Voltage drop at 2-wire transducer
R_{Mess} Resistance at measuring instrument
U_{Mess} Voltage drop at the measuring instrument

Figure 2-28 Connecting a transducer and other devices to the circuit

Calculating admissible voltage drop

The maximum additional resistance in the current loop may not exceed 395 Ω at a maximum current of 20 mA. You can calculate the voltage drop at the connected measuring instrument (U_{Mess}) as follows using Ohm's Law:

$U_{Mess} = R_{Mess} * I = 395\ \Omega * 0.020\ A = 7.9\ V$

The voltage drop at the measuring instrument should therefore not exceed 7.9 V.

Representation of analog values 3

3.1 Overview

Conversion of analog values

The CPU only processes analog values in digitalized format.

Analog input modules convert the analog signal into a digital value for further processing by the CPU.

Analog output modules convert the digital output value from the CPU into an analog signal.

Analog value representation at 16-bit resolution

The digitized analog value is the same for all I/O values at the same rated range. The analog values are represented as fixed point numbers in twos complement. This leads to the following conditions:

Table 3- 1 Representation of analog values

Resolution	Analog value															
Bit number	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Significance of the bits	S	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

Sign

The sign (S) of the analog value is always set in bit 15:

- "0" → +
- "1" → -

Resolution less than 16 bits

The analog value is left-aligned in the memory of analog modules with a resolution of less than 16 bits. The unused least significant digits are padded with "0" values.

This reduces the number of measured values that can be represented. Modules occupy a range of values of between+32767 and -32768 regardless of the resolution. The scaling between two successive values depends on the resolution of the module.

Example

The following example shows how the least significant digits are padded with "0" values:

- The module with 16-bit resolution is capable of incrementing the values in steps of one unit ($2^0 = 1$).
- The module with 13-bit resolution is capable of incrementing the values in steps of 8 units ($2^3 = 8$).

Table 3- 2 Example: Bit pattern of a 16-bit and 13-bit analog value

Resolution	Analog value															
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
16-bit	S	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0
13-bit	S	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^9	2^8	2^7	2^6	2^5	2^4	2^3	0	0	0

S = sign

Note

For information on the resolution supported by each analog module, please refer to the technical data for the relevant module.

3.2 Representation of input ranges

The tables below set out the digitalized representation of the input ranges by bipolar and unipolar input ranges. The resolution is 16 bits.

Please see the device manuals for each analog input module for assignment of the values to the specific measured values in each measuring range.

Table 3- 3 Bipolar input ranges

Dec. value	**Measured value in %**	**Data word**																**Range**
		2^{15}	2^{14}	2^{13}	2^{12}	2^{11}	2^{10}	2^{9}	2^{8}	2^{7}	2^{6}	2^{5}	2^{4}	2^{3}	2^{2}	2^{1}	2^{0}

0	0.000	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	Minimum output value**

* When values > 32511 are specified, the output value is limited to 117.589 % or 0 % (0.0 V / 0.0 mA), depending on the module used.

** When values < 0 are specified, the output value is limited to 0% (0.0 V / 0.0 mA).

4 Connecting transducers

4.1 Overview

Introduction

This chapter describes the basic procedure for wiring transducers to analog inputs. Information on specific wiring options is available in the manual of each module.

For more information, e.g. on cable routing and shielding or potential equalization, etc., refer to the function manual for Configuring interference-free controllers (http://support.automation.siemens.com/WW/view/en/59193566).

Transducers that can be wired to analog inputs

You can wire the following transducers to the analog input modules, depending on the type of measurement:

- Voltage transducers
- Current transducers
  – 2-wire transducers
  – 4-wire transducers
- Resistance transducers
  – 4-wire connection
  – 3-wire connection
  – 2-wire connection
- Thermocouples

Isolated transducers and non-isolated transducers

Transducers are available in various models:

- Isolated transducers are **not connected** locally to the ground potential. Floating operation is possible.
- Non-isolated transducers are **connected** locally to the ground potential.

  Non-isolated transducer connections are connected to the conductive enclosure.

  Note: All non-isolated transducers must have a galvanic connection to each other and be locally connected to the ground potential.

Abbreviations used in the figures

Key to the abbreviations in the figures below:

AI	Analog input module
M	Ground connection
L+	Supply voltage connection
M_n+/M_n-	Measuring input, channel n
I_{Cn}+/I_{Cn}-	Current output to thermal resistor (RTD) channel n
U_n+/U_n-	Voltage input channel n
I_n+/I_n-	Current input channel n
COMP+/COMP-	Compensation input
I_{Comp}+/I_{Comp}-	Current output for compensation
U_V	Feed voltage at channel (the connection can be used for 2-wire transducer (2DMU) or with ET 200eco PN and ET 200pro for 2/4-wire transducer).
U_{CM}	Potential difference between the reference points of the measuring inputs / the analog ground M_{ANA}
U_{ISO}	Potential difference between the reference points of the measuring inputs and the central ground
M_{ANA}	Reference point of the analog ground

Lines for analog signals

Always use shielded twisted-pair cables to wire the analog signals. This improves immunity.

4.2 Wiring analog inputs with MANA connection

The reference potentials of the measuring inputs and the central ground are electrically isolated in analog input modules with M_{ANA} connection.

Limited potential difference U_{ISO} (insulation voltage)

Always verify that the admissible potential difference U_{ISO} between the reference point of the analog ground M_{ANA} and the central ground is not exceeded.

Potential difference U_{ISO} may be caused by: Maximum line lengths exceeded.

If you want to ensure that the permitted value U_{ISO} is not exceeded, install an equipotential bonding cable between the terminal M_{ANA} and the central grounding point.

Limited potential difference U_{CM} (common mode)

Always verify that the admissible potential difference U_{CM} between the reference point of the measuring inputs and the analog groundM_{ANA} is not exceeded.

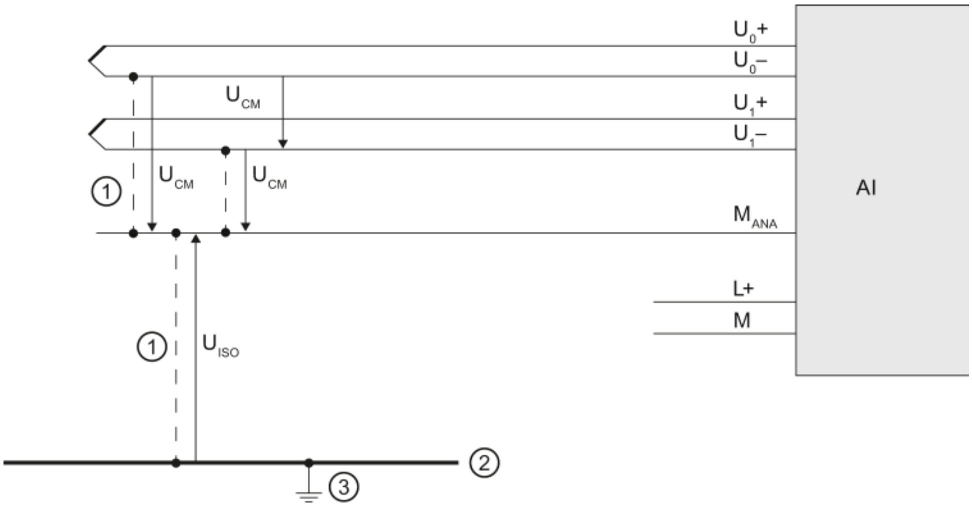
Potential differences U_{CM} may be caused by:

- Environments with EMC disturbance
- Use of grounded transducers
- Use of long cable lengths

Measuring errors / malfunctions can occur if the admissible potential difference U_{CM} is exceeded.

Some modules can detect an invalid potential difference U_{CM} and report this error with an entry in the diagnostics buffer of the CPU.

If you want to ensure that the maximum value U_{CM} is not exceeded, interconnect the reference points of the measuring inputs and the analog ground M_{ANA} with an equipotential bonding cable.



① Equipotential bonding cable
② Grounding bus cable
③ Central ground

Figure 4-1 Example: Reference potential for analog input modules with M_{ANA} connection

4.3 Wiring analog inputs without MANA connection

The reference potentials of the measuring inputs and the central ground are electrically isolated from each other in analog input modules without an M_{ANA} connection.

Limited potential difference U_{ISO} (insulation voltage)

Always verify that the maximum potential difference U_{ISO} between the reference points of the measuring inputs and central ground is not exceeded.

Potential difference U_{ISO} may be caused by: Maximum line lengths exceeded.

If you want to ensure that the permitted value U_{ISO} is not exceeded, install an equipotential bonding cable between the reference points of the measuring inputs and the central grounding point.

Limited potential difference U_{CM} (common mode)

Always ensure that the permitted potential difference U_{CM} between the reference points of the measuring inputs is not exceeded.

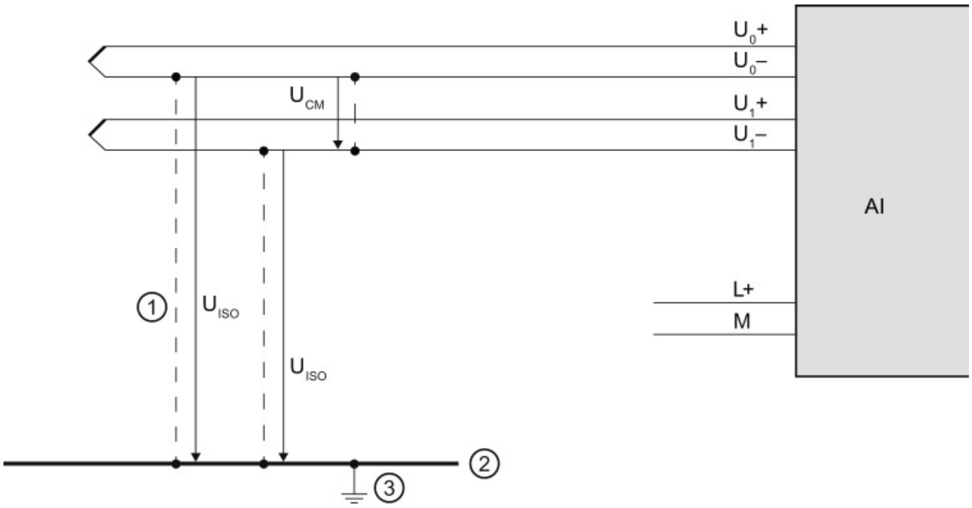
Potential differences U_{CM} may be caused by:

- Environments with EMC disturbance
- Use of grounded transducers
- Use of long cable lengths

Measuring errors / malfunctions can occur if the admissible potential difference U_{CM} is exceeded.

Some modules can detect an invalid potential difference U_{CM} and report this error with an entry in the diagnostics buffer of the CPU.

If you want to ensure that the permitted value U_{CM} is not exceeded, install equipotential bonding cables between the reference points of the measuring inputs or, with the ET 200eco PN and ET 200pro, between the reference points of the measuring inputs and ground.

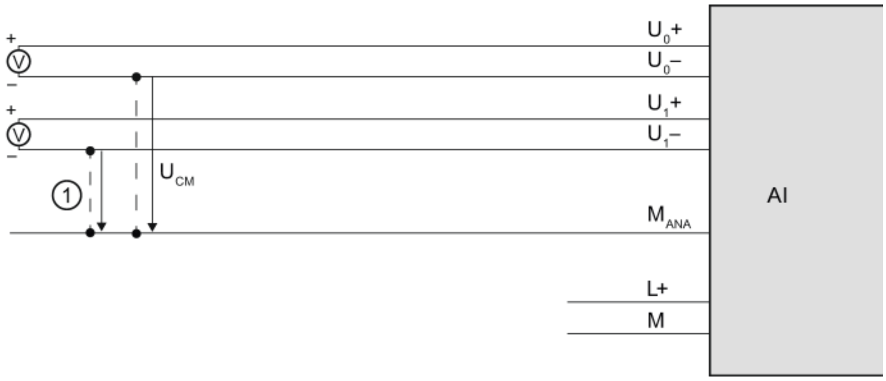


① Equipotential bonding cable (not for 2-wire and resistance transducers)
② Grounding bus cable
③ Central ground

Figure 4-2 Example: Reference potential for analog input modules without M_{ANA} connection

4.4 Wiring voltage transducers

The figure below shows how to connect voltage transducers. If you want to ensure that the permitted value U_{CM} is not exceeded, install equipotential bonding cables to connect the reference points of the measuring inputs to the analog ground M_{ANA}, or with ET 200eco PN and ET 200pro the reference points of the measuring inputs to the ground.



① Equipotential bonding cable (only relevant to modules with M_{ANA} connection)

Figure 4-3 Example: Wiring voltage transducers to an analog input module

4.5 Wiring current transducers

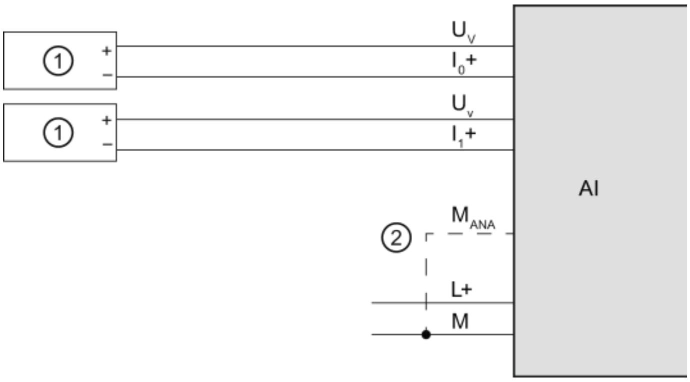
Current transducers are available as 2-wire transducers and 4-wire transducers. Below are a number of ways to supply current transducers with voltage.

Wiring 2-wire transducers with power supply from the module

The 2-wire transducer converts the process variable into a current. The 2-wire transducer is wired to the short circuit-proof supply voltage at the terminals of the analog input module. The transducer is therefore frequently also called a "passive transducer". Its simple wiring means that the 2-wire transducer is frequently used in industrial environments. If you use this type of connection, you will need to set the "Current (**2-wire transducer**)" measurement type in STEP 7.

Note

2-wire transducers must be electrically isolated.



① 2-wire transducers (2WT)

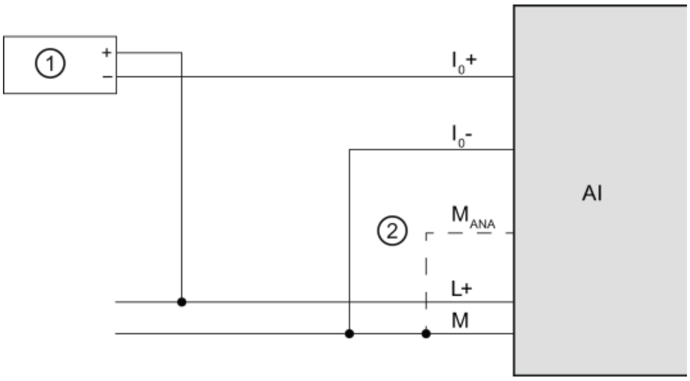
② Equipotential bonding cable (only relevant to modules with M_{ANA} connection)

Figure 4-4 Example: Wiring 2-wire transducers to an analog input module

Wiring 2-wire transducers to an analog input for 4-wire transducers

The figure below shows an alternative to the above connection: supplying the 2-wire transducer from supply line L+ of the module. If you use this type of connection, you will need to set the "Current (**4-wire transducer**)" measurement type in STEP 7.

In this type of connection, galvanic isolation between the supply voltage L+ and the analog circuit will be removed.



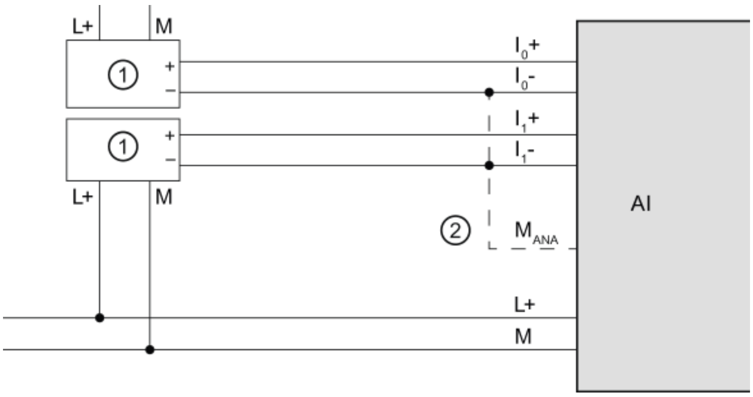
① 2-wire transducers (2WT)

② Equipotential bonding cable (only relevant to modules with M_{ANA} connection)

Figure 4-5 Example: Wiring 2-wire transducers to an analog input for 4-wire transducers

Wiring and connecting 4-wire transducers

4-wire transducers provide terminals for connecting a separate supply voltage. They are powered with an external supply and are frequently called "active transducers". If you use this type of connection, you will need to set the "Current (**4-wire transducer**)" measurement type in STEP 7.



① 4-wire transducers (4WT)

② Equipotential bonding cable (only relevant to modules with M_{ANA} connection)

Figure 4-6 Example: Wiring 4-wire transducers to an analog input module

4.6 Wiring thermal resistors and resistors

The module provides a constant current at terminals I_C+ and I_C- for resistance measurements. The constant current is fed to the resistance to be measured where it is measured as voltage drop. It is important to wire the connected constant current cables directly to the thermal resistor/resistor.

Measurements with 4-wire or 3-wire connection compensate for line resistance and therefore achieve greater accuracy compared to measurements with 2-wire connection.

Measurements with two-wire connection always acquire line resistance in addition to the actual resistance; you must therefore allow for a significant loss of precision in the measuring results.

The figures below give some connection examples.

4-wire connection of a thermal resistor

The voltage at the thermal resistor is acquired using high-impedance measurement via the M_0+ and M_0- terminals. Make sure the wiring is correctly poled (I_{C0}+ and M_0+, and I_{C0}- and M_0- at the thermal resistor).

Always wire the **I_{C0}+ and M_0+** lines, and the **I_{C0}- and M_0-** lines directly to the thermal resistor.

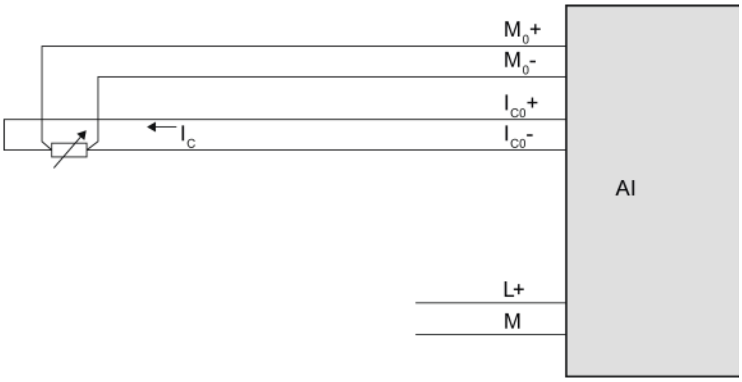


Figure 4-7 Example: 4-wire connection of thermal resistor to an analog input module

3-wire connection of a thermal resistor

Depending on the module, for a 3-wire connection to modules with 4 terminals (per channel), you may need to insert a bridge between **M_0- and I_{C0}-** (see figure below) or between **M_0+ and I_{C0}+**. Always wire the **I_{C0}+** and **M_0+** lines directly to the thermal resistor. Use cable with wires with identical cross-section.

For ET 200AL, ET 200eco PN and ET 200pro, no bridge is required as all necessary connections are implemented internally.

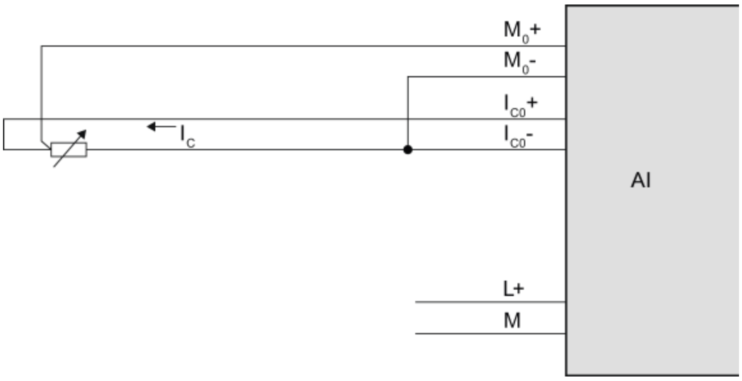

Figure 4-8 Example: 3-wire connection of thermal resistor to an analog input module

2-wire connection of a thermal resistor

When installing a 2-wire device on modules with 4 terminals (per channel), you will need to insert bridges at the module between **M_0+ and I_{C0}+** and between **M_0- and I_{C0}-** as shown in the figure below. The line resistance is measured, but not compensated. As a result of physical limitations, this measurement type is less accurate than measurement with 3-wire or 4-wire connections. The wiring for this type of measurement is, however, simple as the bridges required can be wired in the plug, saving line.

For ET 200AL, ET 200eco PN and ET 200pro, no bridge is required as all necessary connections are implemented internally.

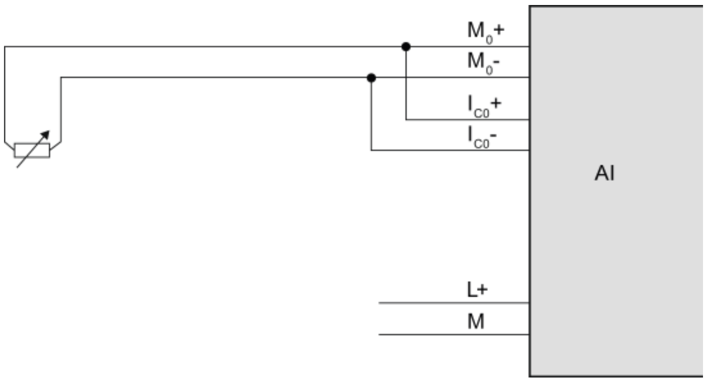

Figure 4-9 Example: 2-wire connection of thermal resistor to an analog input module

4.7 Wiring thermocouples

Introduction

Thermocouples are generally supplied ready-to-use. Protective casing prevents the thermocouples from being destroyed by mechanical force, for example.

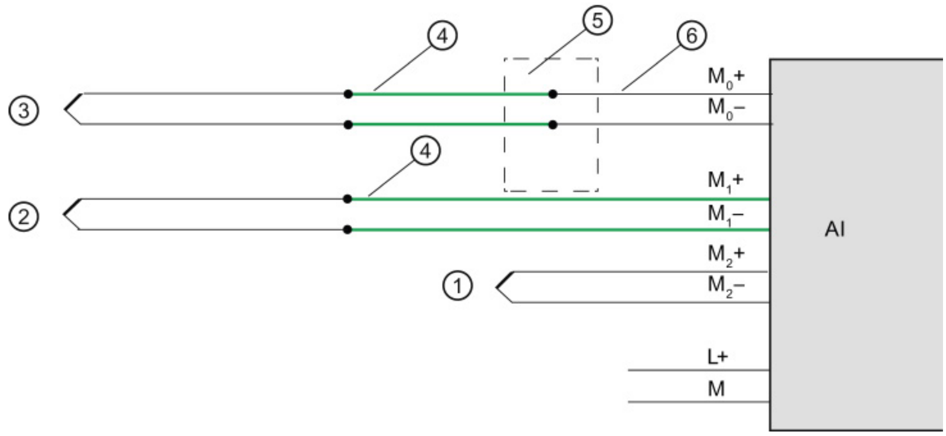
Compensating lines

The compensating lines belonging to the respective thermocouples are identified by a special color code, because only the compensating line that is made of the material matching the thermocouple may be used. The standardized compensating lines are specified in DIN EN 60584. Observe the maximum temperatures in the manufacturer's specifications.

Thermocouple connection options

There are various different ways to wire thermocouples to an analog input module:

- Directly ①.
- Using compensating lines ②.
- With a compensating line to the reference junction, connected with a supply line, e.g. copper ③.



① Thermocouple without compensating line
② Thermocouple with compensating line
③ Thermocouple with compensating line and supply line
④ Compensating line (same material as thermocouple)
⑤ External reference junction
⑥ Copper supply cable, for example

Figure 4-10 Example: Wiring thermocouples to an analog input module

Further information

Further information, such as the selection of thermocouples and how they operate, can be found in the section Thermocouples (Page 77).

5 Thermocouples

5.1 Selecting thermocouples

Introduction

Thermocouples are electrical devices for precise temperature measurement. They consist of two different metals connected at one point. Temperature affecting this point generates a voltage difference from which the temperature can be calculated.

Thermocouples can measure a wide range of temperatures and come in extremely robust models. They are therefore frequently used in industrial applications. Below are some of the criteria to consider when selecting the right thermocouple:

- Temperature range
- Atmospheric conditions
- Price

Grounded thermocouples

In grounded thermocouples, a conductive thermocouple wire is attached to the inside of the sensor housing. This results in good heat transfer from the sensor housing to the thermocouple measuring tip.

Non-grounded thermocouples

In non-grounded thermocouples, the thermocouple is not connected to the sensor housing. The response time following temperature changes is longer than with grounded thermocouples. The measuring point is galvanically isolated.

Type and temperature range

The different thermocouple types are derived from different material compositions.

Note

Due to physical conditions, thermocouples are extremely inaccurate outside the specified temperature range. Only use thermocouple in the temperature range specified by the manufacturer.

The following table lists the types and material compositions, as well as the temperature measuring range of different thermocouples:

Type	Material composition	Temperature range
B	PtRh-PtRh	250 to 1820 °C
C	W-Re	0 to 2315 °C
E	NiCr-CuNi	-270 to 1000 °C
J	Fe-CuNi	-210 to 1200 °C
K	NiCr-Ni	-270 to 1372 °C
L	Fe-CuNi	-200 to 900 °C
N	NiCrSi-NiSi	-270 to 1300 °C
R	PtRh-Pt (Pt 13%)	- 50 to 1769 °C
S	PtRh-Pt (Pt 10%)	-50 to 1769 °C
T	Cu-CuNi	-270 to 400 °C
U	Cu-CuNi	-200 to 600 °C
TXK/XKL	NiCr-CuCr	-200 to 800 °C

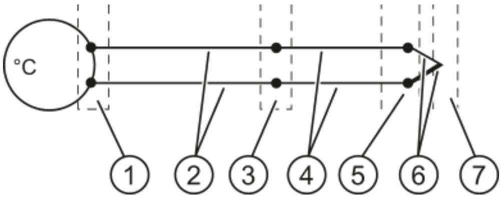
5.2 Structure and operating principle of thermocouples

Thermocouple structure

A thermocouple consists of a pair of thermal sensors and the respective installation and wiring elements. Two wires made of different metals/alloys are welded together at their ends (hot end). The welding point forms the so-called measuring point, while the free ends of the thermocouple form the reference junction.

The free ends are interconnected with the evaluation device (e.g. analog input module) via insulated wires or cables.

The different thermocouple types, e.g. K/J/N, are derived from different material composition; the same measuring principle is applied to all thermocouples, independent on their type.



① Thermal voltage acquisition point
② Copper supply cable, for example
③ Reference junction
④ Compensating line (same material as thermocouple)
⑤ Connection point
⑥ Thermocouple with positive and negative thermal elements
⑦ Measurement point

Figure 5-1 Thermocouple

Operating principle of thermocouples

Temperature differences between the measuring point and the free ends of the pair of thermal sensors (connection point) generate a thermal voltage at the reference junction. The value of the thermal voltage is determined by the temperature difference between the measuring point and the free ends, as well as by the material composition of the pair of thermal sensors.

Thermocouples always acquire a differential temperature, which means that the temperature at their free ends (reference junction) must be known to determine the temperature at the measuring point.

The thermocouple can be extended with compensating lines from the connection point. This allows the reference junction to be located at a specific point, for example, where the temperature can be kept constant or the temperature sensor is easy to install. The compensating lines and thermocouple wires are made of the same material. Copper cables are used to connect the reference junction to the module.

Note

Always observe the polarity, as incorrect wiring will result in unacceptable measuring errors.

5.3 Compensation for the reference junction temperature

5.3.1 Overview

Introduction

You have several options for measuring the reference junction temperature in order to obtain a correct temperature value as a function of the temperature difference between the reference junction and the measuring point.

You have various compensation options to suit requirements at the location of the reference junction.

The compensation options supported by the analog module used are specified in the manual of the respective module.

Options of compensating for the reference junction temperature

Table 5- 1 Compensation options: Explanation and use case

Compensation options	Explanation	Use case / special feature
Internal reference junction	**Function principle** With this type of compensation, the temperature of the reference junction is measured using an integrated sensor in the analog module. **Procedure** Connect the thermocouple to the I/O module directly, or with compensating lines; see chapter Compensation with internal reference junction (Page 84).	• For the connection, use compensating lines that match the thermocouple material. • If the reference junction temperature and the module temperature are identical in your system, you may also use lines made from a different material. • Advantages: – Inexpensive – No external reference junction required – No additional wiring required

Compensation options	Explanation	Use case / special feature
Reference channel of the module	**Properties** With this type of compensation, the reference junction temperature is determined using an external thermal resistor (RTD). **Procedure** Connect the thermocouple to the supply lines directly at the reference junction, or indirectly using compensating lines. Wire the supply lines to the corresponding terminals of the module. Wire the thermal resistor (RTD) to the reference channel of the module. The thermal resistor (RTD) must be positioned in the area of the reference junction; see chapter Compensation with reference channel of the module (Page 86).	• They acquire the temperature directly at the reference junction. • The measured temperatures of all channels that you have configured for this compensation type will be corrected automatically by the temperature value of the reference junction. • Advantages: – More precise compared to compensation with internal reference junction; however, you need to install and wire an additional thermal resistor.
Reference channel of group 0	**Properties** With the "TC" (thermocouple...) setting, the channel acts as receiver for the reference junction temperature of group 0. The associated transmitter of group 0 is set up to for the RTD channel. **Procedure** Connect the thermocouple to the supply lines directly at the reference junction, or indirectly using compensating lines. Wire the supply lines to the corresponding terminals of the module. Wire the thermal resistor (RTD) to the configured reference channel for group 0 of the module. The thermal resistor (RTD) must be positioned in the area of the reference junction; see chapter Compensation, reference channel of Group 0 (Page 88).	• They acquire the temperature directly at the reference junction. • The measured temperatures of all channels that you have configured for this compensation type will be corrected automatically by the temperature value of the reference junction (transmitter).
Fixed reference temperature	**Properties** With this type of compensation, the reference junction temperature is stored in the module as fixed value. **Procedure** Connect the thermocouple to the supply lines directly at the reference junction, or indirectly using compensating lines. Wire the supply lines to the corresponding terminals of the module. Depending on the module, you can enter a fixed reference junction temperature in the configuration data (e.g. 20 °C), or use the fixed reference junction temperature of the module (0 °C); see chapter Compensation with fixed reference temperature (Page 91).	• You keep the reference junction temperature constant and know the temperature value. • To ensure high precision, you must ensure that the temperature remains constant (this can be complicated, depending on the application).

Compensation options	Explanation	Use case / special feature
Dynamic reference temperature	**Properties** With this type of compensation, the reference junction temperature is determined using a module. Transfer this temperature value to other modules in the user program by means of a data record. **Procedure** Wire the thermal resistor (RTD) for the reference junction to any channel. The reference junction temperature is transferred with a function block by means of data records from the CPU or IM to the module, see section Compensation by means of dynamic reference temperature (Page 94).	• You are using multiple modules at the reference junction and can therefore compensate for all channels using a common temperature value. • You only need a thermal resistor (RTD) or a thermocouple to measure the temperature value.
No/external compensation	**Properties** With this type of compensation, the reference junction temperature is measured outside the analog input module. You can, for example, connect a compensating box to the thermocouple for this purpose. **Procedure** Connect the compensating box with the connection module of the analog input module with copper cables, see section "None" or external compensation (Page 98).	• The temperature of the reference junction for this type of compensation is specified as 0 °C. This can be achieved by using a compensating box. A separate compensating box is required for each thermocouple. • Thermocouples of type B do not require a compensating box.
RTD (0)	**Properties** This compensation is based on a measurement of the resistance value of a Pt1000 at the clamping unit of a compensation connector or of an external resistance value Pt1000. **Procedure** Additional information about the connection options with and without compensation connector is available in the section Type of compensation RTD (0) (Page 100).	• The reference junction temperature is determined with resistance value of the Pt1000. • All channels of the analog input module that you select for this type of compensation receive the same reference junction temperature.

5.3.2 Compensation with internal reference junction

Function principle

The reference junction for compensation via internal reference junction is at the terminals of the analog input module. Wire the thermocouples or compensating lines directly to the module inputs. The internal temperature sensor acquires the module temperature and returns a compensating voltage.

Note that compensation via internal reference junction will not always reach the precision of external compensation!

Procedure

Configuration steps:

1. Open the project in STEP 7.
2. In the device view, select the required analog module and the corresponding channel.
3. Select the "General" tab in the Inspector window of the selected module.
4. Select the "Inputs/Measuring" area.
5. Select the "Thermocouple" value as "Measurement type".
6. As "Reference junction", select the value "Internal reference junction".

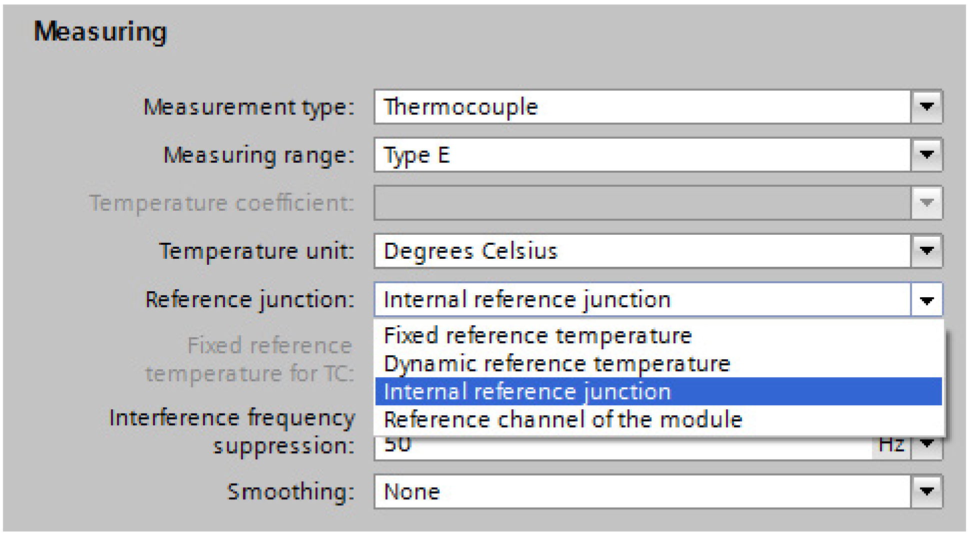


Figure 5-2 Internal reference junction

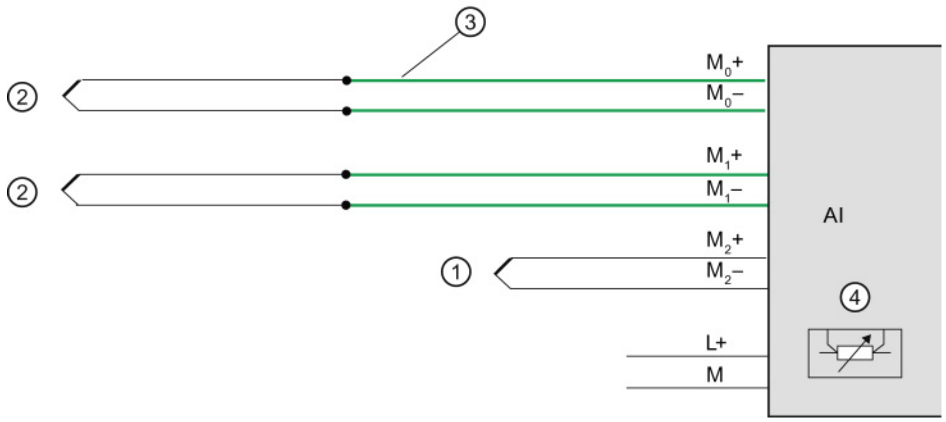
Wiring thermocouples

Wire the thermocouples directly or indirectly via compensating lines to the module inputs.



① Thermocouple without compensating line
② Thermocouple with compensating line
③ Compensating line (same material as thermocouple)
④ Internal reference junction

Figure 5-3 Example: Wiring thermocouples for compensation via internal reference junction

5.3.3 Compensation with reference channel of the module

Function principle

With this type of compensation, the reference junction temperature is determined using an external thermal resistor (RTD). Certain modules provide an internal reference channel.

Procedure

Configuration steps:

1. Open the project in STEP 7.
2. In the device view, select the required analog module and the corresponding channel.
3. Select the "General" tab in the Inspector window of the selected module.
4. Select the "Inputs/Measuring" area.
5. Select the "Thermocouple" value as "Measurement type".
6. As "Reference junction", select the value "Reference channel of the module"".

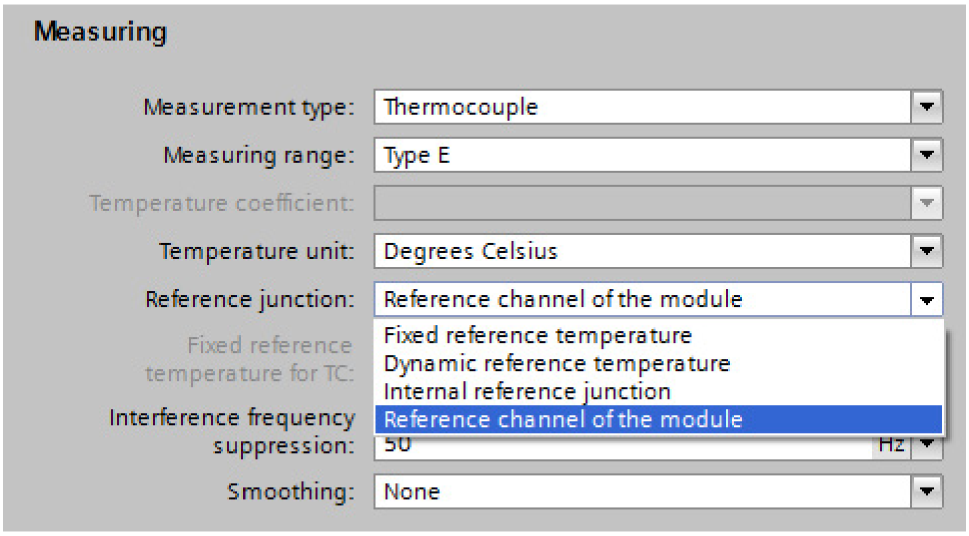


Figure 5-4 Reference channel of the module

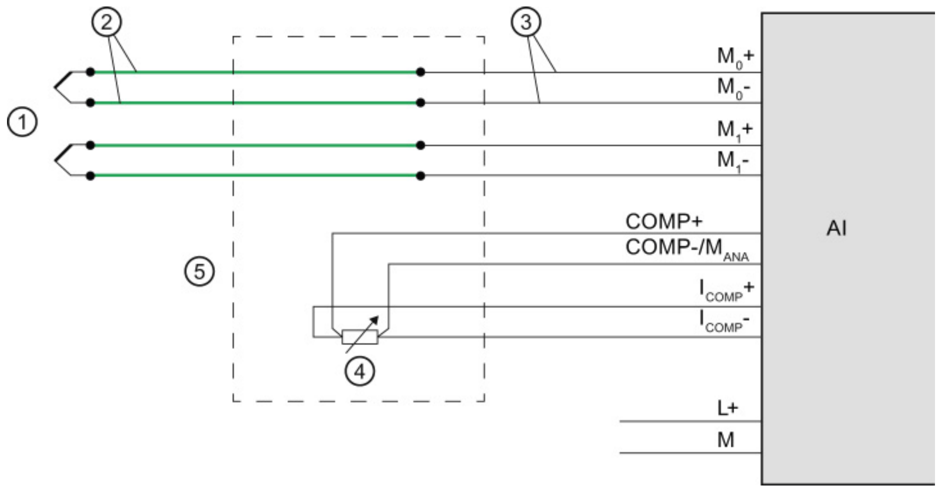
Wiring thermocouples and thermal resistors

Connect the thermocouple to the supply lines directly at the reference junction, or indirectly using compensating lines. Wire the supply lines to the corresponding terminals of the module.

You may use cables made of any material to wire the thermal resistor to the module terminals.



① Thermocouple
② Compensating line (same material as thermocouple)
③ Copper supply cable, for example
④ Thermal resistor (RTD)
⑤ Reference junction

Figure 5-5 Example: Wiring thermocouples/thermal resistors for compensation by means of reference channel of the module

5.3.4 Compensation, reference channel of Group 0

Function principle

For this compensation, a module channel with a connected thermal resistor (RTD) acts as "Reference temperature transmitter". Other channels (reference temperature receivers) with connected thermocouples can be compensated using this reference temperature. The measured temperatures of all channels (receivers) that you have configured for this compensation type will be compensated automatically by the temperature value of the reference junction (transmitter).

The reference junction temperature is determined by means of an external thermal resistor (RTD).

Procedure

Configuration steps:

1. Open the project in STEP 7.
2. In the device view, select the required analog module and the corresponding channel.
3. Select the "General" tab in the Inspector window of the selected module.
4. Select the area "Inputs/measurement".
5. For the channel of the relevant module, specify as transmitter:

   As "Measurement type" select, for example, "Thermal resistor (4-wire connection)".

   As "Reference junction", select the value "Reference channel of group 0".

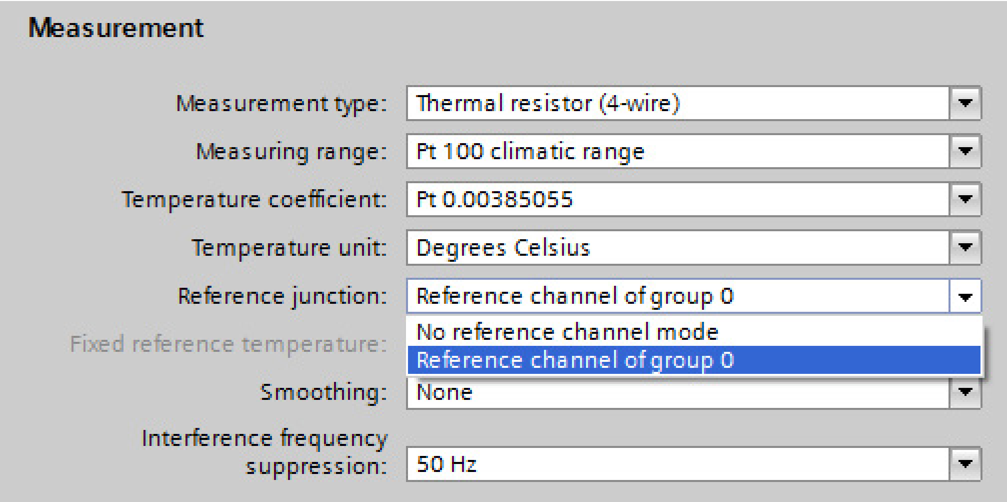


Figure 5-6 Transmitter: Reference channel of group 0

6. For the channels you specify as receivers:

   Select the "Thermocouple" value as "Measurement type".

   As "Reference junction", select the value "Reference channel of group 0".

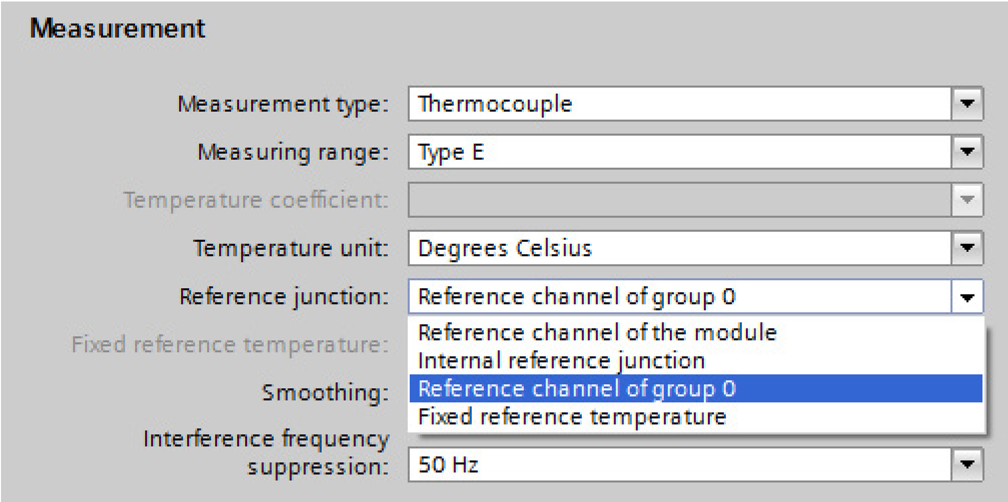

Figure 5-7 Receivers: Reference channel of group 0

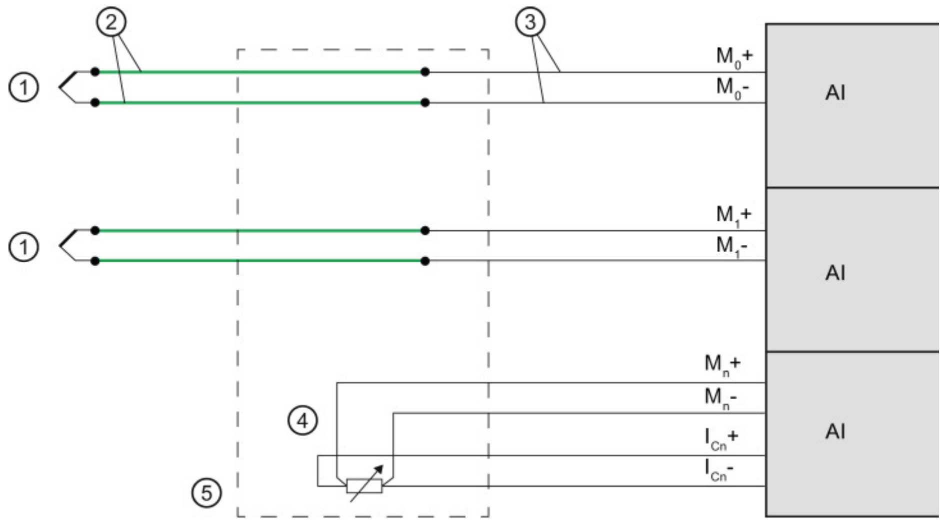
Connecting thermocouples and thermal resistors

The example below shows:

- An analog module with thermal resistor as reference temperature transmitter and
- Two analog modules with thermocouple as reference temperature receivers.

Connect the thermocouples to the supply lines at the reference junction, either directly or with compensating lines. Wire the supply lines to the corresponding terminals of the module.

You may use cables made of any material to wire the thermal resistor to the module terminals.



① Thermocouple
② Compensating line (same material as thermocouple)
③ Copper supply cable, for example
④ Thermal resistor (RTD)
⑤ Reference junction

Figure 5-8 Example: Connecting thermocouples/thermal resistors for group 0 compensation

5.3.5 Compensation with fixed reference temperature

Function principle

With this type of compensation, the reference junction temperature is stored in the module as fixed value.

Procedure

Configuration steps:

1. Open the project in STEP 7.
2. Select the required analog module in the Device view.
3. Select the "General" tab in the Inspector window of the selected module.
4. Select the "Inputs/Measuring" area.
5. Select the "Thermocouple" value as "Measurement type".
6. As "Reference junction", select the value "Fixed reference temperature".
7. Specify the temperature of the reference junction in the "Fixed reference temperature" area, for example, 20 °C.

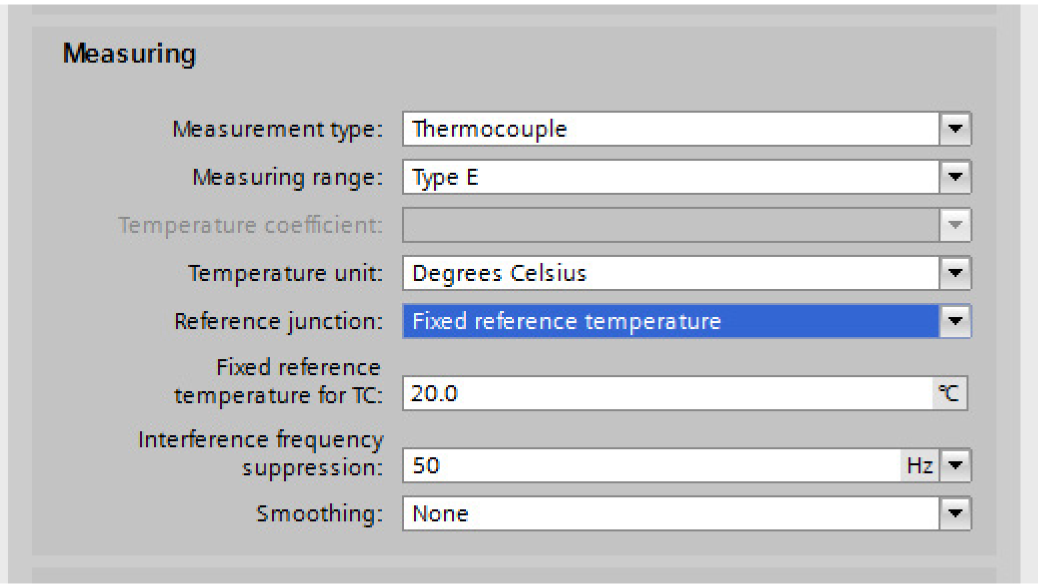


Figure 5-9 Fixed reference temperature

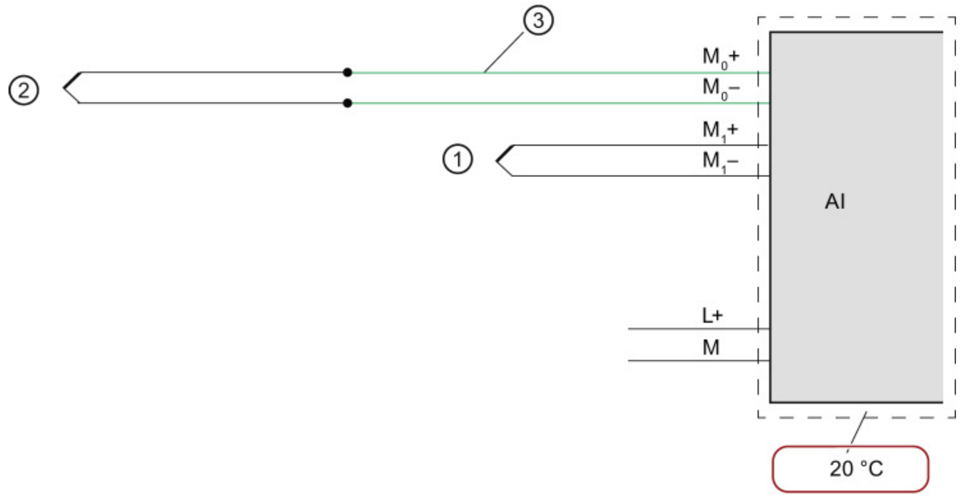
Temperature condition with "Fixed reference temperature" setting

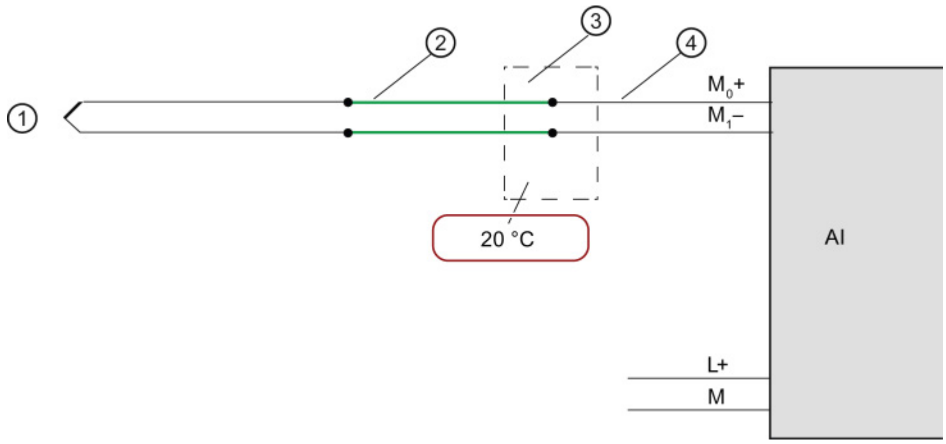
The figure below shows the connection options for thermocouples provided the temperature of the module is kept at a fixed reference temperature (20 °C), for example by installing it in an air-conditioned switch cabinet. The reference junction is in the module.



① Thermocouple without compensating line
② Thermocouple via compensating line
③ Compensating line (same material as thermocouple)

Figure 5-10 Example 1: Connecting a thermocouple to an analog module for compensation with "fixed reference temperature"

The figure below shows the connection options for thermocouples provided the temperature of the reference junction (outside the module) is kept at a fixed reference temperature (20 °C).



① Thermocouple with compensating line and supply line
② Compensating line (same material as thermocouple)
③ Reference junction
④ Copper supply cable, for example

Figure 5-11 Example 2: Connecting a thermocouple to an analog module for compensation with "fixed reference temperature"

5.3.6 Compensation by means of dynamic reference temperature

Function principle

This compensation type allows you to handle the reference junction temperature for temperature compensation in the user program. You can derive the temperature value from any other module of the station. The reference junction temperature is transferred via data records using the instruction **WRREC** (SFB 53).

The structure of the data records is detailed in the device manual for each module.

Requirement

STEP 7 project with the following contents:

- User program with WRREC (SFB 53) instruction for transferring the data records with reference temperature
- Analog module for acquisition of the process temperature using thermocouple (TC)
- Analog module for measuring the process temperature using thermal resistor (RTD)

Analog module for acquisition of the process temperature using thermocouple (TC)

Configuration steps:

1. Open the project in STEP 7.
2. In the device view, select the required analog module and the corresponding channel.
3. Select the "General" tab in the Inspector window of the selected module.
4. Select the "Inputs/Measuring" area.
5. Select the "Thermocouple" value as "Measurement type".
6. As "Reference junction", select the value "Dynamic reference temperature".

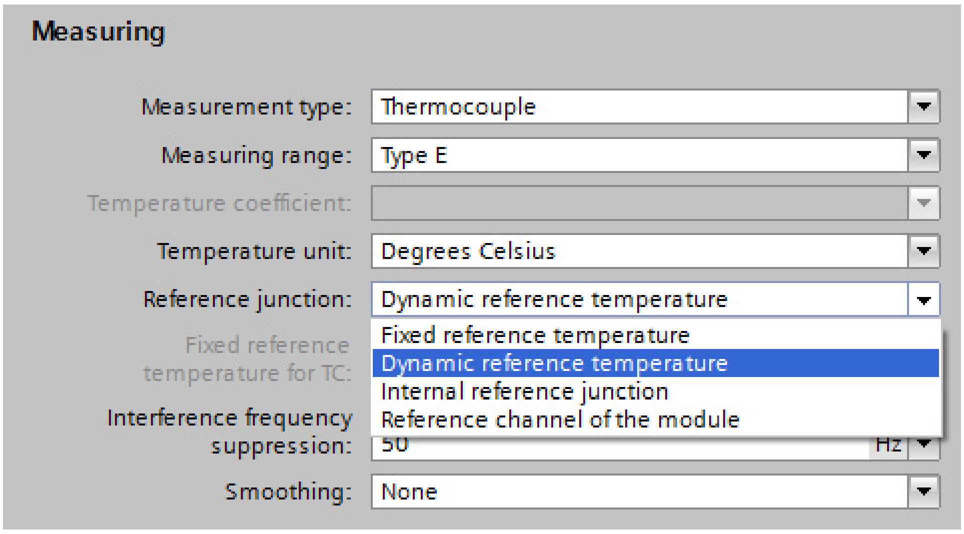


Figure 5-12 Dynamic reference temperature

Analog module for measuring the process temperature using thermal resistor (RTD)

Configuration steps:

1. Open the project in STEP 7.
2. In the device view, select the required analog module and the corresponding channel.
3. Select the "General" tab in the Inspector window of the selected module.
4. Select the "Inputs/Measuring" area.
5. Select the "Thermal resistor (4-wire connection)" value as "Measurement type".

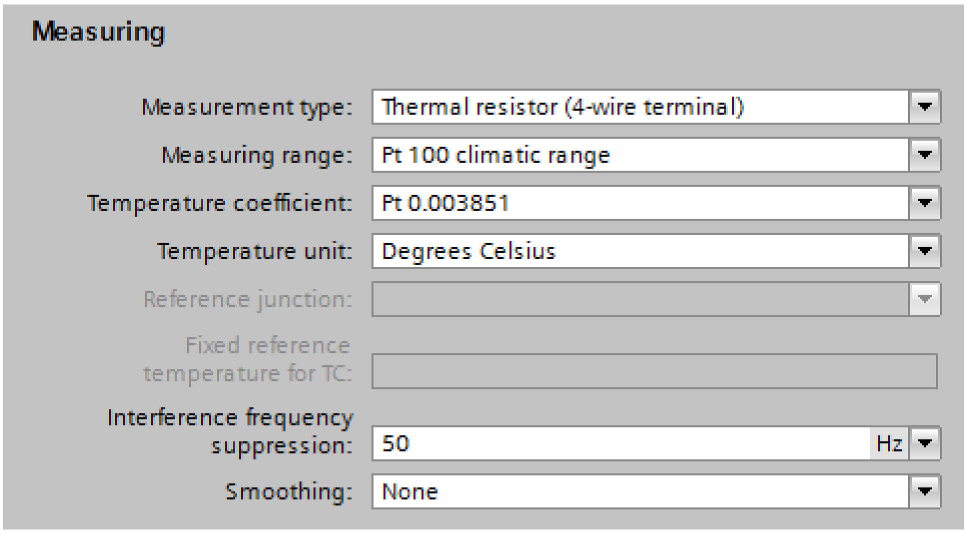

Figure 5-13 Settings for thermal resistor (RTD) type of measurement

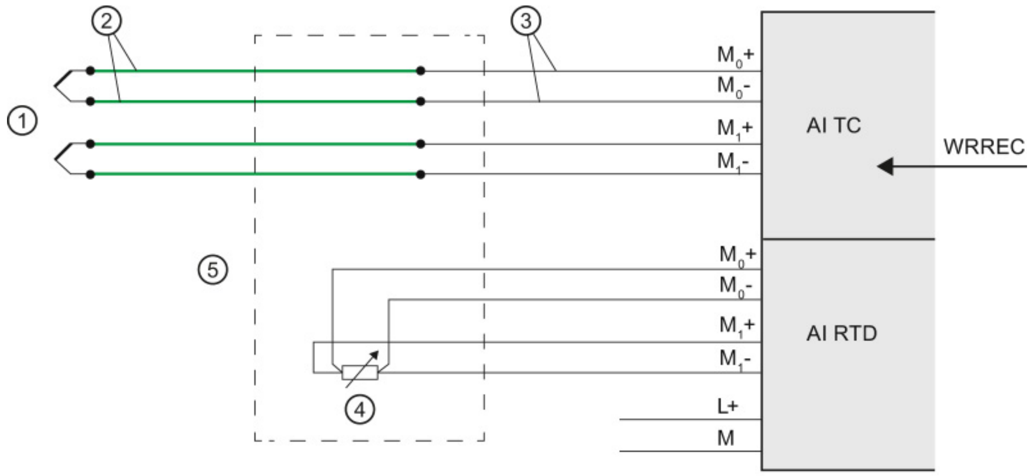
Connecting thermocouples and thermal resistors

Connect the thermocouples, for example, to the module inputs using supply lines for temperature compensation with dynamic reference temperature. In this case, the temperature is acquired at the reference junction by means of a thermal resistor (RTD). This reference junction temperature determined in this way is transferred to the analog module with thermocouple via data records with the WRREC instruction.



① Thermocouple
② Compensating line (same material as thermocouple)
③ Copper supply cable, for example
④ Thermal resistor (RTD)
⑤ Reference junction

Figure 5-14 Example: Connecting thermocouples/thermal resistors for compensation by means of dynamic reference temperature

5.3.7 "None" or external compensation

Function principle

The reference junction temperature of the thermocouples is measured outside the analog input module, e.g., by means of a compensating box on the thermocouple. The temperature of the reference junction for this type of compensation is specified as 0° C.

The compensating box includes a bridge circuit that is calibrated for a specific reference junction temperature (compensation temperature). The connectors for the ends of the compensating line of the thermocouple form the reference junction. If the actual comparison temperature deviates from the compensation temperature, the temperature-dependent bridge resistor changes. A positive or negative compensation voltage is generated and added to the thermal voltage.

Note

Thermocouples of type B do not require a compensating box.

Procedure

Configuration steps:

1. Open the project in STEP 7.
2. Select the required analog module in the Device view.
3. Select the "Inputs" tab in the Inspector window of the selected module and the respective channel.
4. Select the "Thermocouple" value as "Measurement type" in the "Measuring" area.
5. As "Reference junction", select the value "None" or "External compensation" depending on the used module.

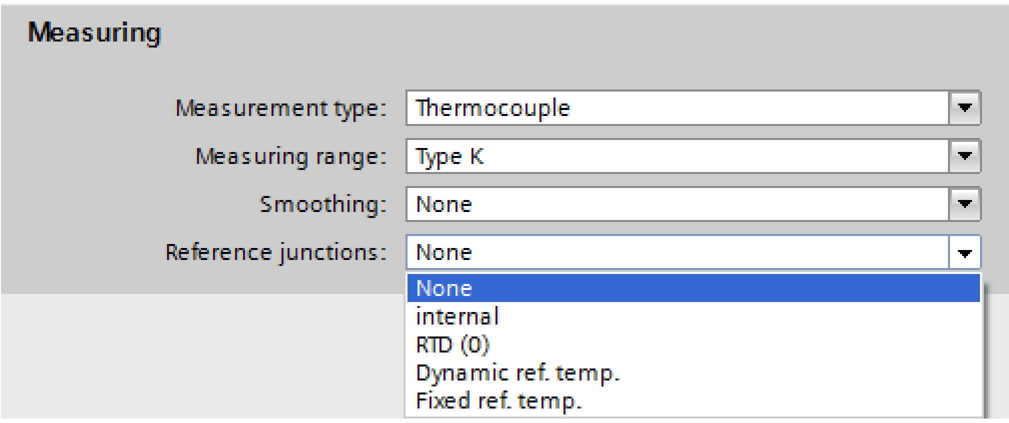


Figure 5-15 No reference junction

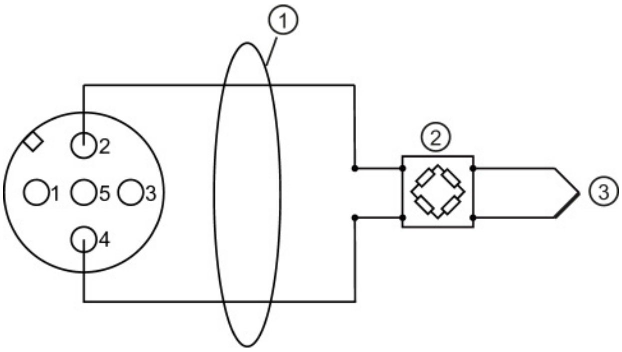
Connection of the compensating box

The compensating box is looped into the supply lines of an individual thermocouple. The compensating box must be supplied isolated. The power supply unit must have a sufficient noise filter, e.g., by means of a grounded shielding winding.

Each channel can use its own thermocouple type supported by the analog module regardless of the other channels. A separate compensating box is required for each channel.

Connection example "None" or external compensation

Connect the compensating box with the connection module of the analog input module using copper cables.



① Copper cables

② Compensating box (per channel), for example; thermocouple type B does not require a compensating box

③ Thermocouple

Figure 5-16 Connection example "No" compensation as reference junction

5.3.8 Compensation type RTD (0)

Function principle

The reference junction temperature is determined by means of the resistance value of a Pt 1000 at the clamping unit of the M12 compensation connector. The resistance measurement is only permitted at the X1 circular socket (channel 0). All of the module's channels with this type of compensation receive the same reference junction temperature.

Procedure

Configuration steps:

1. Open the project in STEP 7.
2. Select the required analog module in the Device view.
3. Select the "Inputs" tab in the Inspector window of the selected module.
4. Select the "Thermocouple" value as "Measurement type" in the "Measuring" area.
5. As "Reference junction", select the value "RTD (0)".

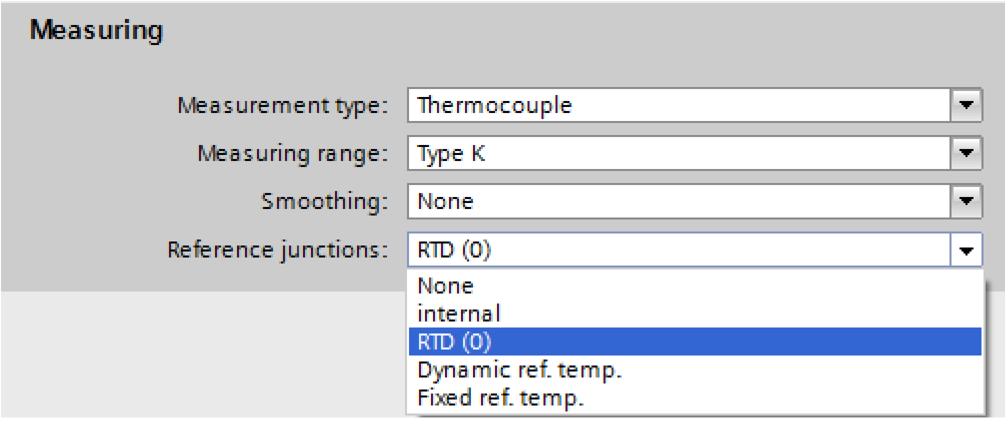


Figure 5-17 Compensation type RTD (0)

Connection example

Connection with M12 compensation connector

Connect the thermocouple to the M12 compensation connector directly or with compensating lines. Install the M12 compensation connector to the X1 circular socket (channel 0) of the CM IO 4 x M12 at the 4 AI TC High Feature.

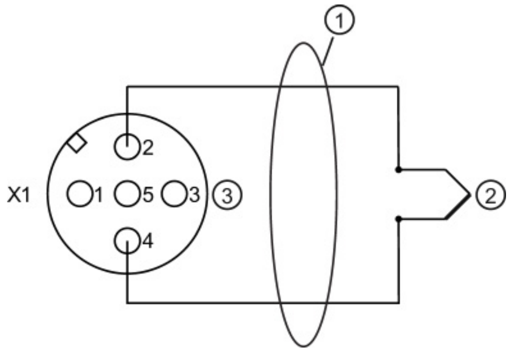
Connection without M12 compensation connector

To measure the referent junction temperature, connect an external Pt1000 (with α = 003851) to terminals 1 and 3 using copper cables. The thermal resistor Pt1000 must be positioned in the area of the reference junction. Connect the thermocouples to terminals 2 and 4 from the reference junction with copper cables.

Connecting additional thermocouples

You can connect additional thermocouples to the circular sockets X2 to X4 on the CM IO 4 x M12 of the 4 AI TC High Feature. The temperature of reference junction collected by measuring the resistance value at the X1 circular socket applies to all channels of the module that you have selected for this type of compensation.

The figure below shows a connection example "RTD (0)" as reference junction with M12 compensation connector and integrated thermal resistor Pt1000:



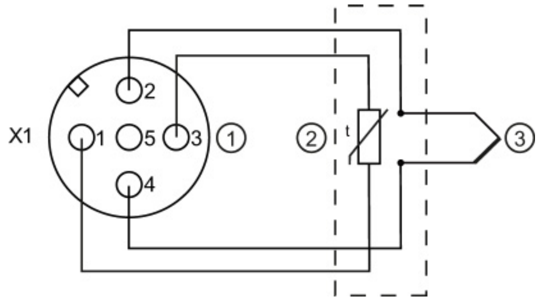
① Direct connection of the thermocouple or with compensating lines

② Thermocouple

③ M12 compensation connector (terminals 1 and 3 with internal Pt1000) only at X1 circular socket. The comparison value of the M12 compensation connector at circular socket X1 also applies to thermocouples at X2, X3 and X4.

Figure 5-18 Connection example "RTD (0)" as reference junction in the M12 compensation connector

The figure below shows a connection example "RTD (0)" as reference junction with external thermal resistor Pt1000:



① M12 connector only at X1 circular socket

② External Pt1000 (α = 0.003851) in the area of the reference junction with copper cables at terminals 1 and 3. The comparison value of the external Pt1000 at circular socket X1 also applies to thermocouples at X2, X3 and X4.

③ Thermocouple

Figure 5-19 Connection example "RTD (0)" as reference junction with external Pt1000

6 Wiring loads/actuators

6.1 Overview

Introduction

This chapter describes the basic procedure for wiring loads/actuators to analog outputs. Information on specific wiring options is available in the manual of each module.

For detailed information on cable routing and shielding, potential equalization, etc. please refer to the function manual Configuring interference-free controllers (http://support.automation.siemens.com/WW/view/en/59193566).

Abbreviations used in the figures

Key to the abbreviations in the figures below:

AQ	Analog output module
M	Ground connection
L+	Supply voltage connection
S_n+/S_n-	Sense line channel n
QV_n+/QV_n-	Voltage output channel n
QI_n+/QI_n-	Current output channel n
M_{ANA}	Reference point of the analog ground
U_{ISO}	Insulation voltage

Lines for analog signals

Always use shielded twisted-pair cables to wire the analog signals. This improves immunity.

6.2 Wiring loads/actuators

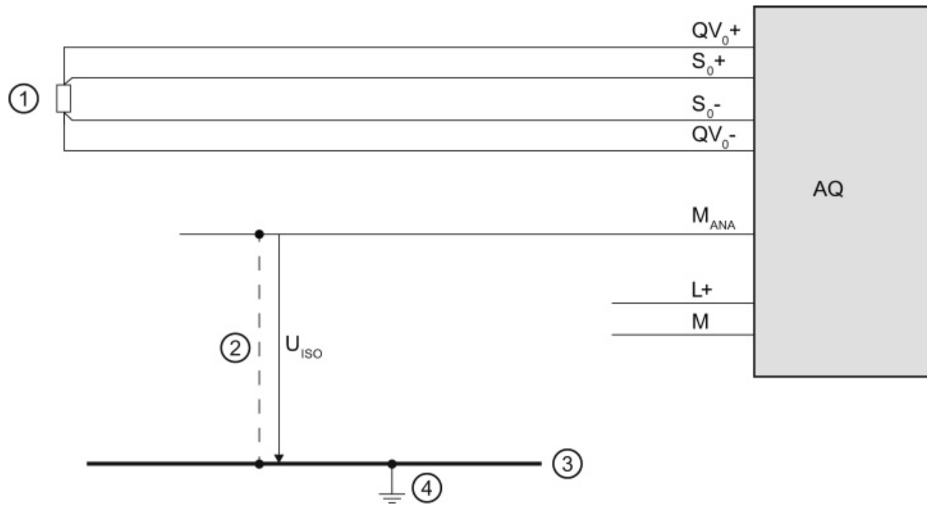
Reference potential for analog output modules with M_{ANA} connection

Analog output modules have no galvanic connection between the reference point of the analog ground M_{ANA} and the central ground.

Always verify that the admissible potential difference U_{ISO} between the reference point of the analog ground M_{ANA} and the central ground is not exceeded.

Potential difference U_{ISO} may be caused by: Maximum line lengths exceeded.

If you want to ensure the maximum value U_{ISO} is not exceeded, wire terminal M_{ANA} and the central ground with an equipotential bonding cable.



① Load on the voltage output
② Equipotential bonding cable
③ Grounding bus cable
④ Central ground

Figure 6-1 Example: Reference potential for an analog output module with M_{ANA} connection

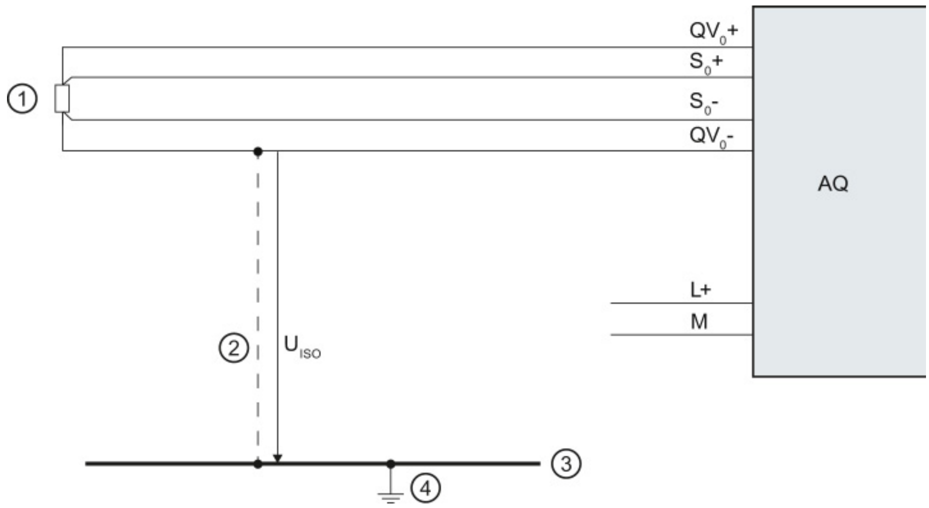
Reference potential for analog output modules without M_{ANA} connection

Analog output modules have no galvanic connection between the reference potential of the analog output circuits and central ground.

Always verify that the maximum potential difference U_{ISO} between the reference points of the analog output circuits and the central ground is not exceeded.

Potential difference U_{ISO} may be caused by: Maximum line lengths exceeded.

If you want to ensure the maximum value U_{ISO} is not exceeded, interconnect each analog output circuit with the central ground using an equipotential bonding cable.



① Load on the voltage output
② Equipotential bonding cable
③ Grounding bus cable
④ Central ground

Supported functions 7

7.1 Calibrating analog modules

7.1.1 Overview

Calibration

A calibration checks the process values measured by the analog input module and the process values output by the analog output module, determines the deviation from the actual values and compensates for any measurement and output errors.

Calibrating analog modules

The SIMATIC analog modules were calibrated before being shipped and have excellent long-term stability; calibration is therefore not required during runtime.

But certain regulations and directives, for example from the Food and Drug Administration (FDA), require regular calibration for all components in a measuring circuit. These components include analog input and output modules.

A calibration makes sense especially for plants in which sensors detect and process relatively small voltages or currents. The calibration compensates for influences on the measuring result by cables and/or temperature.

The calibration collects the new values and saves them retentively on the module. But the calibration values determined prior to delivery at the plant are not lost. You can return to these original calibration values at any time.

Note

The calibration saves the calibration values of each channel for the specific measuring range retentively on the module, which means the values apply to the same measuring range in which the user calibration took place.

If you reconfigure a channel with effective user calibration values to another type of measuring mode, the calibration values saved at the plant for this channel and for this measuring range will become effective.

But the user calibration values are not deleted. They are not overwritten until there is a new user calibration of the channel. If you set the original measuring range for this channel once again without new user calibration, the previously determined user calibration values will become effective.

The respective manual will include information whether or not your analog module supports the "Calibration" functionality.

Scope of functions

The "Calibration" group offers the following functions:

- Specifying the current calibration of all channels
- Calibrating a channel
- Canceling a running calibration
- Resetting the calibration of a channel to the factory settings

7.1.2 Calibrating analog modules

Manual calibration

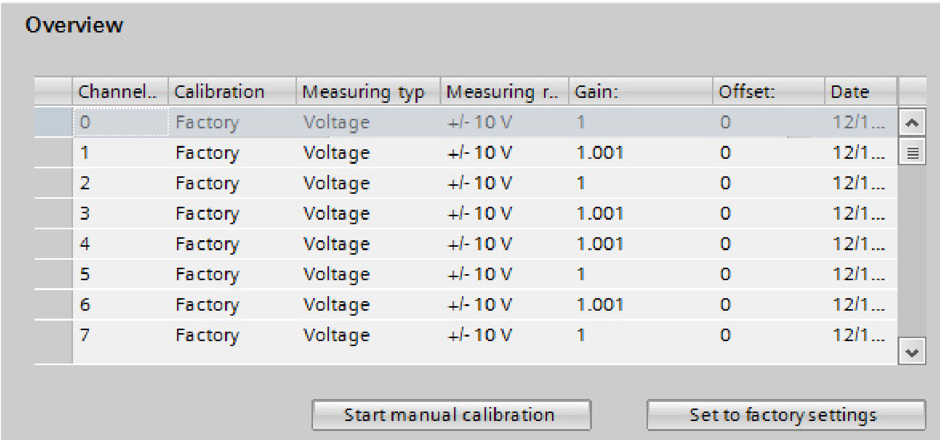
The following requirements must be met to start manual calibration:

- An online connection exists between STEP 7, the respective CPU and the analog module to be calibrated.
- You have opened the "Online & Diagnostics" view for the selected analog module from the shortcut menu of the project and you are now in the "Functions > Calibration" area.
- The configuration reflects the actual structure of the station.
- No calibration process is busy on the module (if you want to launch calibration).
- A 24 V load voltage must be present at each module for the calibration.
- The last step was successfully completed (if you want to continue or conclude calibration).

Procedure

The basic mask for calibration opens once you start the "Calibration" function. The module reads the following general information data and calibration values after each new selection of a channel:

- **Calibration:** Indicates whether or not the currently effective calibration values are factory calibration values or user calibration values.
- **Measurement type:** Information about the selected measurement type
- **Measuring range:** Currently configured measuring range of the selected channel
- **Gain:** Currently effective gain correction of the analog-digital converter
- **Offset:** Currently effective offset correction of the analog-digital converter



Channel..	Calibration	Measuring typ	Measuring r..	Gain:	Offset:	Date
0	Factory	Voltage	+/- 10 V	1	0	12/1...
1	Factory	Voltage	+/- 10 V	1.001	0	12/1...
2	Factory	Voltage	+/- 10 V	1	0	12/1...
3	Factory	Voltage	+/- 10 V	1.001	0	12/1...
4	Factory	Voltage	+/- 10 V	1.001	0	12/1...
5	Factory	Voltage	+/- 10 V	1	0	12/1...
6	Factory	Voltage	+/- 10 V	1.001	0	12/1...
7	Factory	Voltage	+/- 10 V	1	0	12/1...

Figure 7-1 Calibration table

To start the calibration, follow these steps:

1. Select the line associated with the channel to be calibrated in the overview table.
2. Click the "Start manual calibration" button.
3. Now go through the steps in the "Manual calibration" section.
4. Follow the instructions in the "Command" field.
5. Click ""Next".

The required calibration values of the selected channel according to the measuring range configured for this channel are specified once again during the user calibration.

Note

The calibration can take place in RUN mode as well as STOP mode of the CPU. If the CPU is in RUN, the calibration value that was last collected prior to the start of the calibration is supplied for the duration of the calibration.

The module channel to be calibrated cannot process any new process values during the user calibration. All analog input values of the module are set to 0x7FFF ("Invalid analog value") until the end of the calibration. When the value status is enabled, the value status of the signal is set to "invalid" for the duration of the calibration.

You must provide a voltage and/or temperature during a user calibration. To do so, use the corresponding external wiring and an external voltage/temperature transducer. The field "Command" includes numbers of pins to which you can connect the calibration stimulus. The first pin number identifies the positive connector, the second pin number the negative connector. The accuracy of the calibration depends on the accuracy of the provided voltage/temperature.

Note

To ensure that the module retains the specified measuring accuracy after the user calibration, the provided voltage/temperature must be twice as accurate as specified for the module. Inaccurate voltages or temperature result in a faulty calibration.

The figure below shows an example of channel calibration with "Voltage" measurement, measuring range "+/- 10 V".

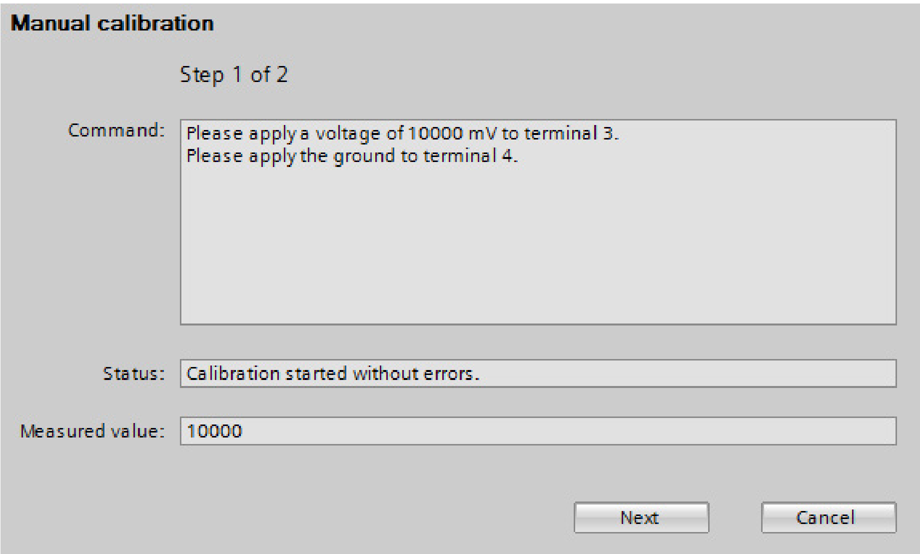


Figure 7-2 Manual calibration

- **Command:** The field "Command" indicates which actions the user has to execute during the current calibration step. Here you execute the specified actions and confirm them with the "Next" button. The module now executes all actions required for the current calibration step. If the calibration step was error-free, the next calibration step takes place.
  The instructions in the "Command" field are to be performed additively. For example, after you have applied the voltage/ground to the terminals 3/4, these connections must remain in place during the execution of the next calibration step.
- **Status:** Depending on the set type of measurement, several calibration steps are required for calibration of a channel. The field "Status" indicates whether or not the last calibration step included errors. If an error occurs during processing of a calibration step, the error is displayed here and calibration of the channel is aborted. All calibration values recorded up to this point are deleted. The calibration values that were in effect prior to the start of the user calibration are effective once again.

Note

Calibrators

If the "Wire break" diagnostics is activated for analog input modules, a test current is applied to the line for the measuring types "Resistance", "Thermistor" and "Thermocouple". This applied test current can result in inaccurate measured values in some calibrators. The wire break monitoring is therefore automatically disabled in some analog modules during the calibration.

To avoid the risk of inaccurate measured values, we recommend you disable the "Wire break" diagnostics during the calibration of analog input modules.

Result

Calibration sets new settings for the channel.

Error occurrence

If an error occurs during the calibration, the module cancels the calibration. All calibration values recorded up to this point are lost. The channel to be calibrated will then have the same settings as before the start of calibration.

7.1.3 Canceling a calibration

Requirement

- You have opened the "Online & Diagnostics" view for the selected analog module from the shortcut menu of the project and you are now in the "Functions > Calibration" area.
- The associated CPU is online.
- A calibration is currently running on the analog module.

Procedure

Click the "Cancel" button to cancel an ongoing calibration.

Result

The active calibration is canceled. The channel to be calibrated will then have the same settings as before the start of calibration.

7.1.4 Resetting analog modules to factory settings

Requirement

- You have opened the "Online & Diagnostics" view for the selected analog module from the shortcut menu of the project and you are now in the "Functions > Calibration" area.
- The associated CPU is online.

Procedure

Proceed as follows to reset the channel of an analog module to factory settings:

1. In the overview table, select the line of the channel to be calibrated.
2. Click the "Set to factory settings" button.

Result

The factory settings of the channel are restored.

Note

When you reset the current channel to the factory settings, the original calibration values that were saved in the delivery state of the module become effective once again. Any existing user calibration values of this channel are lost. You cannot restore these user calibration values.

High-speed analog modules 8

8.1 Basics

High-Speed analog modules (HS) are available for users with high demands regarding performance and speed. The main characteristics of these HS analog modules compared to Standard analog modules (ST) is their shorter cycle times. To achieve this goal, the input and output modules are equipped with components with extremely short throughput and conversion times. In addition, the entire architecture of the modules is designed for faster signal processing.

HS analog modules convert the output of measured values and output values at the same time. Each channel within the module has its own A/D or D/A converter. This means the cycle time is basically the conversion time and independent of the number of activated channels. This is true for analog input modules as well as analog output modules. This means HS modules can be used in fast isochronous mode.

Apart from isochronous mode, the HS analog modules also provide benefits in non-isochronous (free-running) mode. Due to the fast processing of the process signals, HS analog modules are able to detect changes in the process values more quickly and to respond to these events with the appropriate program blocks (for example, hardware interrupt or cyclic interrupt organization blocks). Additional information on the various organizational blocks can be found in the STEP 7 online help.

Isochronous mode

Isochronous mode refers to synchronous coupling:

- Of signal acquisition and output via the distributed I/O
- Of signal transmission via PROFIBUS or PROFINET
- Of program processing with the constant bus cycle time of PROFIBUS or PROFINET.

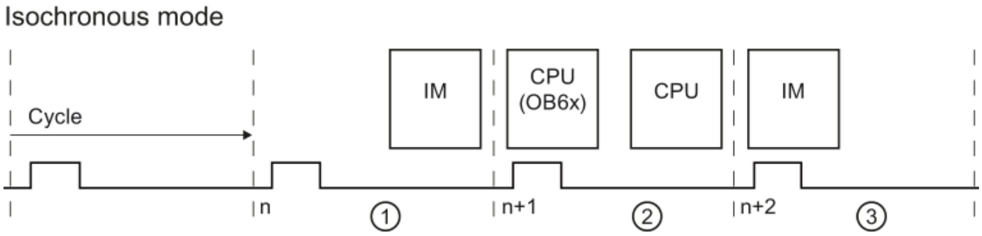
The result is a system that acquires its input signals in constant time intervals, processes them and outputs the output signals. Isochronous mode guarantees reproducible and defined process reaction times as well as equidistant and synchronous signal processing with distributed I/O.

The bus system and the I/O modules work synchronously with configured isochronous mode. The transmitted input and output data are linked to an "isochronous task" in the CPU. As a result, the data of a cycle are always consistent. All data of a process image belong together logically and in time. Jitter in the user program caused by the acquisition of outdated values is therefore almost impossible.

Even fast processes can be perfectly controlled by the exact timing reproducibility of all processes. Isochronous mode thus contributes to high control quality and hence to greater manufacturing precision. While possible fluctuations of the process reaction times are drastically reduced. The time-assured processing can be utilized to improve machine cycle times. Shorter cycle times increase the processing speed and help to lower production costs.

Send clocks

When you configure isochronous mode, the input and output data is synchronized within a send clock (cycle). The data of the input modules is acquired in cycle n and simultaneously transferred to the IM. The data is available in cycle n+1 in the CPU and can be processed. The CPU copies the data to the IM in the next cycle n+2. The output modules then output the data simultaneously in the same send clock. The acquisition – processing – output therefore takes place in three cycles. You can find more information on the configuration of isochronous mode in the STEP 7 online help.



① Measured values of the input modules are acquired and copied to the IM
② Measured values are processed and output values determined
③ Output values are copied to the IM and output by output modules

Figure 8-1 3-cycle model

Oversampling

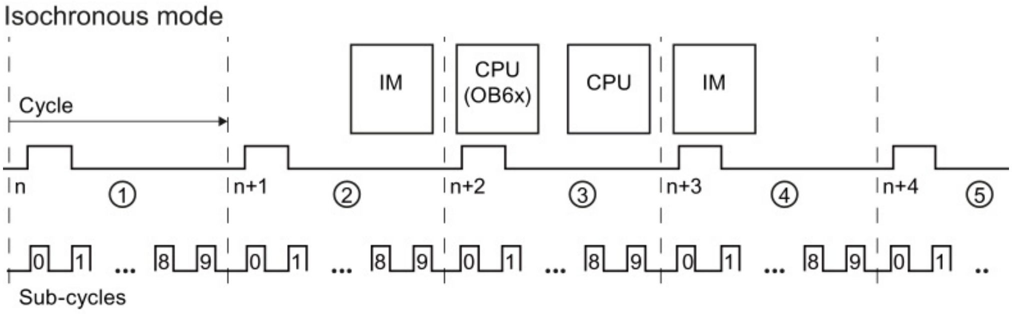
The use of the oversampling function in analog input or analog output modules requires an isochronous configuration.

With analog input modules, the set send clock is divided into time-equidistant sub-cycles. The send clocks can be subdivided into 2 to 16 sub-cycles. Each sub-cycle reads in a measured value. The read-in measured values of a data cycle are copied to the IM in the next send clock and are then available to the processing CPU one send clock later.

With analog output modules, the set send clock is also divided into time-equidistant sub-cycles. The send clocks can be subdivided into 2 to 16 sub-cycles. Each sub-cycle returns an output value. The output values are copied to the IM by the CPU within the same send clock and are written to the process one send clock later.

The read-in and output values are transmitted in the user data of the analog module. This way, the address space of the module is extended from 2 bytes of user data per channel to 16 x 2 bytes of user data per channel. If you subdivide the send clock into less than 16 sub-cycles, the unused addresses are assigned the error value 0x7FFF during input. For output, the values of the unused addresses are ignored.

Because the sub-cycles have to be within a send clock, oversampling needs an additional send clock to copy the data to the IM, unlike the 3-cycle model of isochronous mode. The result is a 5-cycle model.



① Send clock is divided into sub-cycles which record the measured value
② Measured values are copied to the IM
③ Measured values are processed and output values determined
④ Output values are copied by the CPU to the IM
⑤ Output values are written to the process

Figure 8-2 5-cycle model

Due to the configured modules, the send clock of an IO device has a minimum possible update time, which means the time interval within which an IO device/IO controller of the PROFINET IO system is supplied with new data. Modules with oversampling functionality, however, offer the option of further reducing the update time for their channels without having to shorten the send clock for the entire S7 station at the same time. The subdivision of the send clock into time-equidistant sub-cycles therefore enables an even faster signal processing speed.

Example

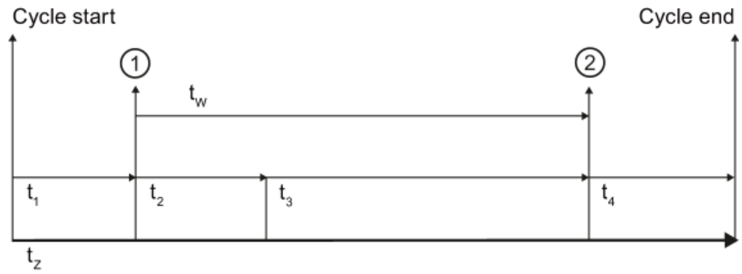
In practice, the use of oversampling makes sense when the isochronous system works with only one specific specific send clock (for example, 1 ms) due to the modules used and when faster sampling of the process values is required. By using oversampling and a subdivision of the send clock into 4 sub-cycles, for example, you can sample the process values in intervals of 250 µs.

Configuring oversampling

Enable the option "Isochronous mode" in the IO device used and set the corresponding parameters ("Send clock", etc.). You define the number of sub-cycles in the relevant distributed analog module with the "Sampling rate" parameter for analog input modules and the "Output rate" parameter for analog output modules. If, for example, you configure a "Sampling rate" of 4 "Values/cycle" for a "Send clock" of 1 ms, the send clock is subdivided into 4 sub-cycles and the process values are sampled in intervals of 250 µs.

Cycle time of an analog input module

If you have configured the system property "Isochronous mode" for HS modules, all analog input modules are synchronized to a shared time within the send clock (cycle) ①. The cycle time is made up of the following time intervals: $t_Z = t_1 + t_2 + t_3 + t_4$

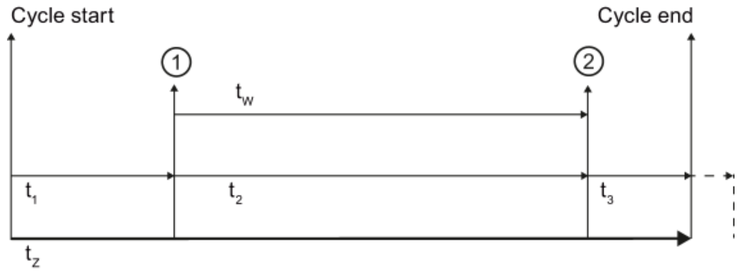


①	Synchronization time for all analog input modules in isochronous mode and simultaneously time of the converted input signal at the terminal in this cycle
②	Digitalized input signal is transferred to the backplane bus
t_Z	Cycle time
t_1	Time between cycle start and synchronization
t_2	Hardware-related runtime up to the analog-digital converter
t_3	Processing time of digitalized input data in the module
t_4	Transfer time of the backplane bus
t_W	Conversion time of the module

Figure 8-3 Cycle time of the analog input module

Cycle time of an analog output module

The synchronization time for analog output modules refers to the output of the digital-analog converter ②. Because the impedance of the connected actuator including connection cable is unknown in output modules but has a significant impact on the signal run time, the settling time cannot be added as a fixed value. The respective manuals of the output modules specify the typical load settling times as reference point. But in practice, a measurement with an oscilloscope is required for a precise measurement of the settling time. The settling time may exceed the actual end of the cycle due to very short cycle times and very high capacitive loads. The cycle time is made up of the following time intervals: $t_Z = t_1 + t_2 + t_3$



①	Output data is available in digital form in the module
②	Synchronization time for all analog output modules in isochronous mode and simultaneously output time of data in the digital-analog converter
t_Z	Cycle time
t_1	Transfer time of the backplane bus
t_2	Processing time of data in the module until output at digital-analog converter
t_3	Settling time of hardware until setpoint of output value
t_W	Conversion time of the module

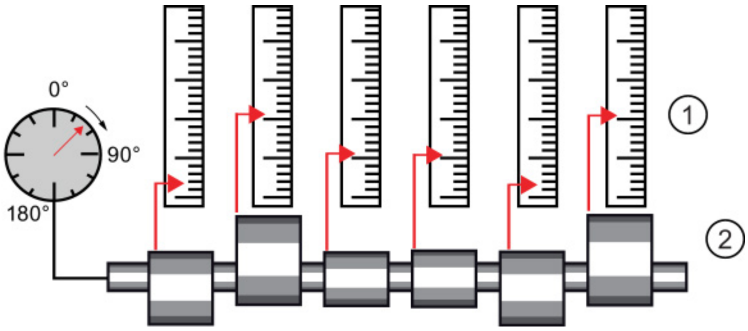
Figure 8-4 Cycle time of the analog output module

Typical applications

In principle, isochronous mode is worthwhile whenever measured values must be acquired synchronously, movements must be coordinated, and process reactions must be defined and executed at the same time. There are thus numerous areas in which isochronous mode can be used.

Typical applications include, for example, the acquisition of binary signals for quality assurance at specific times and positions. But hydraulic applications with position and pressure control can benefit as well from the equidistant and isochronous data transmission.

The following example shows the use of isochronous mode within the production process of camshafts. Precise measurements must be made at several measuring points for quality assurance.



① Measured values
② Camshaft

Figure 8-5 Measuring of camshafts

By using the system property "isochronous mode" and the associated simultaneous measured value acquisition, measurement can be performed continuously. The time required for measurement is reduced. Resultant workflow:

- Continuous machining of the camshaft
- During the continuous turning, measure the positions and cam excursion synchronously
- Process the next cam shaft

All camshaft positions and the corresponding measured values are measured synchronously within a single rotation of the camshaft. This increases machine output and maintains or enhances precision of the measurement.

8.2 ST modules vs HS modules

This section gives you an overview of other important distinctions between standard and high-speed analog modules. The specified numerical values are examples of selected modules. Keep in mind that the information can vary from module to module. The exact information of specific used analog module is available in the corresponding manual.

Conversion method

Instantaneous value conversion

Instantaneous value conversion if often used to convert analog signal into digital information in HS modules. In this type of conversion a very short sample is taken from the measured signal and converted into digital data. This digital information therefore represents an instantaneous value of the measured signal. Instantaneous value conversion is used to acquire fast changes of process values, such as in the area of motion control. The quickly changing physical quantities in this case must be acquired and processed quickly in cooperation with suitable transducers. Input areas are primarily voltage, current and resistance, the latter especially for position potentiometers.

Because the measured signal is converted within a short time, there is a risk of incorrect measurements in case of faulty signals. The analog inputs working with the instantaneous value conversion method cannot detect if the sampled signal value is the target signal or an overlaying disturbing pulse. They always convert the "instantaneously" detected value. This means the pending measurement task should be carefully examined with regard to time constraints.

Integrating conversion

ST modules usually work according to the integrating conversion principle. The integrating conversion involves the sampling of a measured signal across a specified time period (integration time). Although this method is slower than instantaneous value conversion, it returns a conversion with higher immunity to interference. When you select the time interval for the conversion so that it corresponds to one or several periods of the surrounding network frequency, the omnipresent interference that is possibly also overlaying the signal is basically suppressed. SIMATIC modules give you the option to set the network frequency at which the plant is operated by means of parameter assignment. The resolution and conversion times may change depending on the interference frequency suppression that is set. The technical specifications of the respective module define these dependencies.

Analog inputs with integrating methods can be used universally. Even though the cabling must also be carefully designed with these analog inputs, the requirements are much less than those for analog inputs with instantaneous value conversion due to their slower signal acquisition that is basically immune to interference.

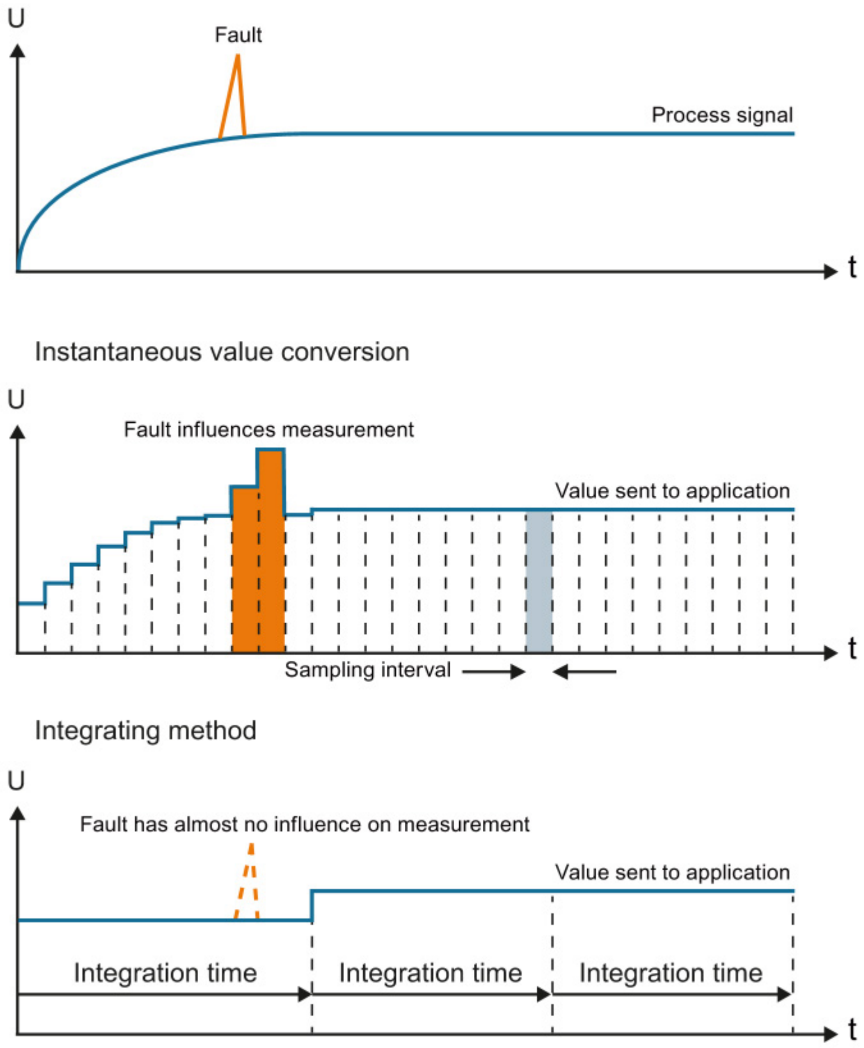


Figure 8-6 While an interference directly influences the value that is supplied to the application with instantaneous value encryption, its influence is negligible for the integrating method.

Electromagnetic compatibility

The entire architecture of HS modules is designed for fast processing of the signals. An interference-free design is therefore critical when using HS modules.

The following rules apply to the wiring of HS modules with sensors and actuators:

- Keep the cables as short as possible
- Use shielded and twisted pair cables
- Low-impedance connection of the cable shield at the respective shield supports
- Short cable loop between shield support and terminal connection

---

Note

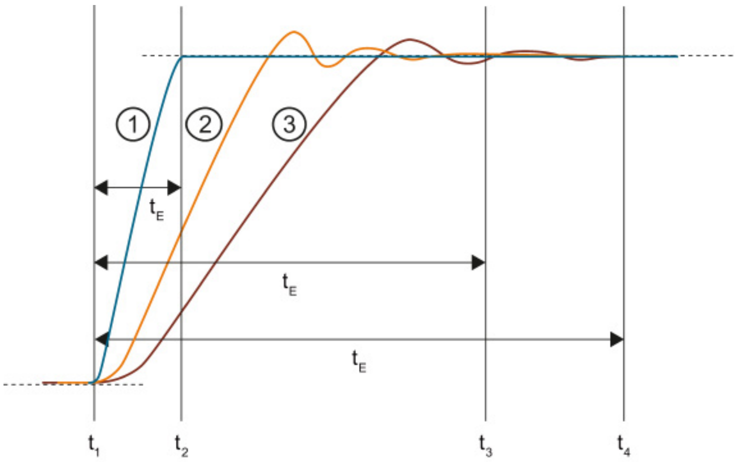
Interference-free design

Make sure that you pay close attention to the notes listed in the function manual Configuring interference-free controllers (http://support.automation.siemens.com/WW/view/en/59193566) when using HS modules.

Effect of load on the settling time

The settling times to the setpoint achieved with analog output modules depend on the applied load, among other things. To take advantage of the faster conversion times, only small loads (e.g., max. 47 nF) are permitted in HS modules as specified in the technical specifications.

The type of load has an effect on the form of settling to the setpoint when using output modules. Capacitive loads reduce the rise time due to the charging process and can cause the output signal to overshoot. Inductive loads result in a delayed current increase due to remagnetization and therefore also a shorter rise time. The figure below shows the output signal with no/small ①, medium ② and high ③ capacitive load.



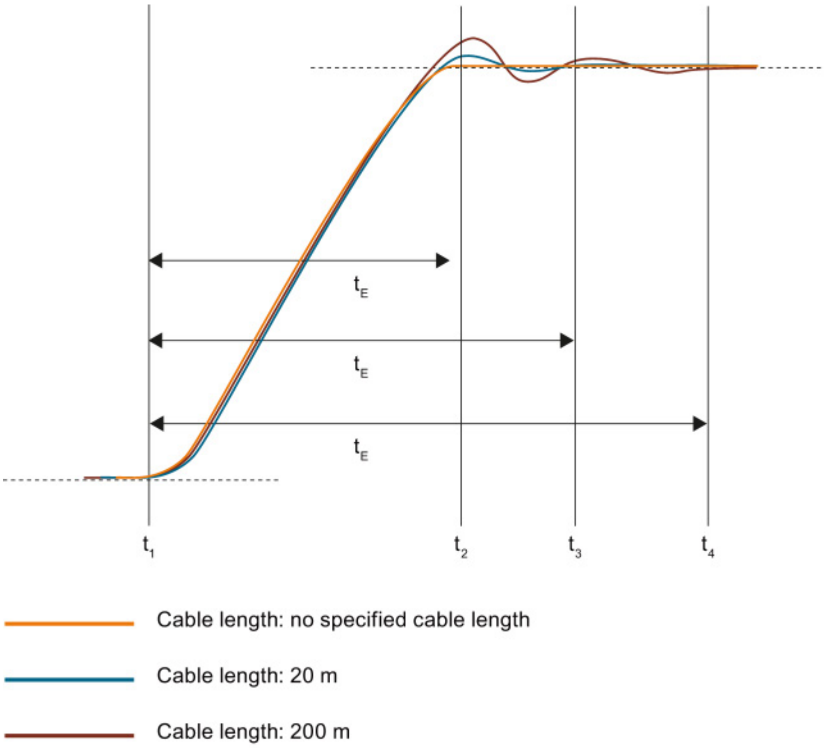
①	Reference curve of a signal with no/small load capacity
②	Signal with a load capacity of 47 nF
③	Signal with a load capacity of 100 nF
t_E	Settling time
t_1	Module ends conversion at the terminal of the analog output channel and outputs the analog signal
t_2	Signal ① has settled and the specified analog output value has been reached (residual error 1 %)
t_3	Signal ② has settled and the specified analog output value has been reached (residual error 1 %)
t_4	Signal ③ has settled and the specified analog output value has been reached (residual error 1 %)

Figure 8-7 Effect of different loads on the settling time

Effect of the cable length on the settling time

Long cables between signal source and module are a target for interferences. You should therefore keep the cables as short as possible especially for HS modules. Cables have a capacitive and inductive component and therefore have an effect on the settling behavior of the signal.

The example below shows the jump of the output voltage of an HS output module with small, medium and long cable length. The overshoot of the input signal increases with the length of the cable and therefore the time until it reaches the setpoint.



t_E	Settling time
t_1	Module ends conversion at the terminal of the analog output channel and outputs the analog signal
t_2	The signal running through a cable with short length has settled and the specified analog output value has been reached (residual error 1 %)
t_3	The signal running through a 20 m cable has settled and the specified analog output value has been reached (residual error 1 %)
t_4	The signal running through a 200 m cable has settled and the specified analog output value has been reached (residual error 1 %)

Figure 8-8 Effect of different cable lengths on the settling time

Effect of the value jump on the settling time

The figure below shows the effect of the height of the value jump between different output values on the settling time for analog output modules. The dotted line indicates the time when the signal has reached the setpoint. The higher the value jump, the later the signal reaches the setpoint.

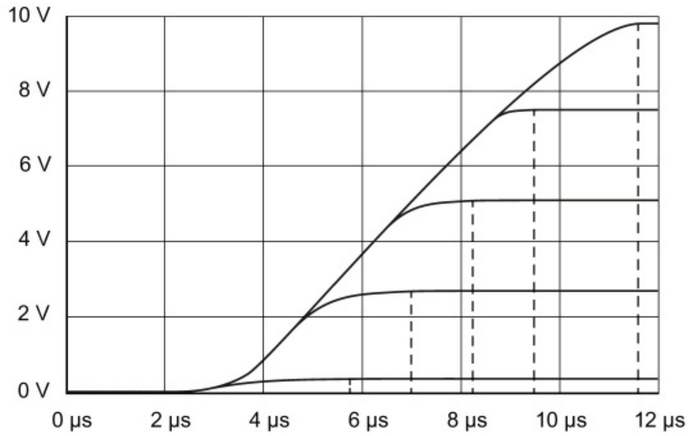


Figure 8-9 Settling time of five different analog signals with different value jumps

Legal information

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

DANGER
indicates that death or severe personal injury **will** result if proper precautions are not taken.

WARNING
indicates that death or severe personal injury **may** result if proper precautions are not taken.

CAUTION
indicates that minor personal injury can result if proper precautions are not taken.

NOTICE
indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This documentation will support you in installing and commissioning programmable controllers.

Correct configuration is essential for fault-free operation of programmable controllers.

Basic knowledge required

The following knowledge is required in order to understand the documentation:

- General knowledge of automation technology
- Knowledge of the industrial automation system SIMATIC
- Knowledge of VDE (German Association for Electrical, Electronic and Information Technologies) and EC regulations
- Knowledge of the rules for installing controllers and switchgear

Conventions

You should also pay particular attention to notes such as the one shown below:

Note

A note contains important information on the product described in the documentation, on the handling of the product or on the section of the documentation to which particular attention should be paid.

Scope of the documentation

This documentation is valid for all products of the product series SIMATIC S7-1500, ET 200MP, ET 200SP and ET 200AL.

The product series SIMATIC S7-1500, ET 200MP and ET 200SP are approved for IP20 degree of protection, i.e. the modules of these product series must be installed in a control cabinet.

The SIMATIC ET 200AL product series is approved for IP65/IP67 degree of protection, i.e. the modules need **not** be installed in a control cabinet.

Changes compared to previous version

Changes / enhancements described in this manual, compared to the previous version (version 01/2013):

- Extension of the scope of validity to the distributed I/O system ET 200AL
- Supplement to the section Connection of the cable shielding for ET 200AL
- Components for lightning protection potential equalization amended

Additional support

Additional information on SIMATIC products is available on the Internet. The associated documentation is also available on the Internet.

- The range of technical documentation for the individual SIMATIC products and automation systems can be found on the Internet (http://www.siemens.com/simatic-tech-doku-portal).
- The online catalog and the ordering system are available on the Internet (http://mall.automation.siemens.com).

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, solutions, machines, equipment and/or networks. They are important components in a holistic industrial security concept. With this in mind, Siemens' products and solutions undergo continuous development. Siemens recommends strongly that you regularly check for product updates.

For the secure operation of Siemens products and solutions, it is necessary to take suitable preventive action (e.g. cell protection concept) and integrate each component into a holistic, state-of-the-art industrial security concept. Third-party products that may be in use should also be considered. You can find more information about industrial security on the Internet (http://www.siemens.com/industrialsecurity).

To stay informed about product updates as they occur, sign up for a product-specific newsletter. You can find more information on the Internet (http://support.automation.siemens.com).

Table of contents

Documentation guide 1

Introduction

The documentation of the SIMATIC products has a modular structure and covers diverse topics concerning your automation system.

The complete documentation for the S7-1500, ET 200SP, ET 200MP and ET 200AL systems consists of the respective system manuals, function manuals and product manuals.

The STEP 7 information system (online help) also supports you when configuring and programming your automation system.

Overview of documentation on the subject of designing interference-free controllers

The following table lists additional documentation which supplements this description of designing interference-free controllers.

Table 1- 1 Documentation on the subject of designing interference-free controllers

Topic	Documentation	Most important contents

All current manuals for SIMATIC products are available for download free of charge from the Internet (http://www.siemens.com/automation/service&support).

Basic information on electromagnetic compatibility 2

2.1 Overview of possible interference

Introduction

SIMATIC products and their components have been developed for use in industrial environment and meet the legal EMC requirements (EMC - Electromagnetic Compatibility). However, you still need to conduct an EMC assessment before installing your controller in order to identify possible sources of interference and to include these in your considerations.

Electromagnetic compatibility

Electromagnetic compatibility describes the ability of an electrical device to function properly in its particular electromagnetic environment. Neither the environment itself nor the electrical device are influenced in an unacceptable manner.

Possible interference

Electromagnetic interference can influence an automation system in various ways. The most significant interferences and their causes are as follows:

- Electromagnetic fields having a direct influence on the system
- Interference coupling caused by bus signals (for example, PROFINET)
- Interference influencing the system via the process wiring
- Interference which reaches the system via the power supply and/or protective ground

The figure below shows the likely paths of electromagnetic interference.

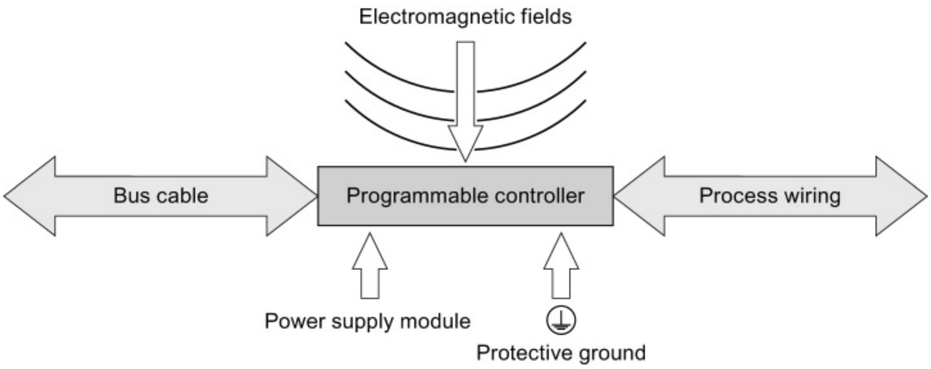

Figure 2-1 Electromagnetic interference

2.2 Coupling mechanisms

Depending on the emitting medium and the distance between the source of interference and the device, interference can reach the automation system via four different coupling mechanisms.

The following table shows possible causes and typical sources of interference for the various coupling mechanisms:

Table 2- 1 Coupling mechanisms

Coupling mechanism	Cause	Typical sources of interference
Galvanic coupling	Two electric circuits share the same cable	• Clocked devices (influence on the network due to converters and third-party power supply units) • Starting motors • Potential differences on component enclosures with shared power supply
Capacitive coupling	Potential difference between conductors	• Interference coupling due to parallel routing of signal cables • Static discharge of the operator
Inductive coupling	Mutual influencing of current-carrying conductor loops. The magnetic fields caused by the current flow induce interference voltages.	• Transformers, motors, electrical welding equipment • Power supply cables routed in parallel • Cables whose currents are switched • High-frequency signal cables • Unwired coils
Radiation coupling	Effect of an electromagnetic wave on a cable configuration. This wave induces currents and voltages.	• Neighboring transmitters (for example, walkie-talkies) • Spark gaps (spark plugs, collectors of electrical motors, welding devices)

Interference-free cable routing 3

This chapter describes the EMC-compatible classification of cables and cable routing for bus, data, signal and supply lines.

3.1 Classifying cables into cable categories

Classify the cables into cable categories according to their sensitivity to interference coupling and interference emission. The further away from one another cables of different cable categories are installed, the lower the mutual influence by capacitive and inductive coupling.

The following table shows the cable categories into which you can classify your cables accordingly.

Table 3- 1 Cable categories

Category A	• Signal lines to I/O modules • Bus and data lines (for example, PROFIBUS, PROFINET) • Lines to HMI devices • Supply lines for extra-low voltages (< 24V DC or < 60V AC)
Category B	• Supply lines with safe electrical isolation (SELV) • Supply voltages < 400 V
Category C	• Supply voltages > 400 V

The following table shows the minimum clearance you must maintain when installing cables.

Table 3- 2 Combination of cable categories

<table>
<tr><th></th><th>Category A</th><th>Category B</th><th>Category C</th></tr>
<tr><td>Category A</td><td>• In common bundles or cable channels</td><td>• In separate bundles or cable channels (no minimum clearance necessary)</td><td rowspan="2">• Inside cabinets in separate bundles or cable channels
• Outside cabinets, but inside buildings, on separate cable racks with at least 10 cm clearance</td></tr>

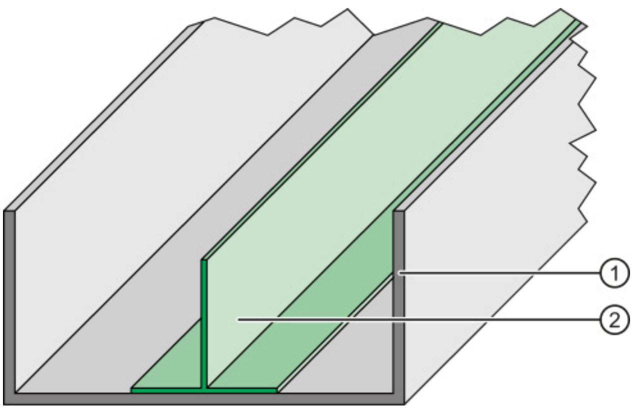
</table>

If you install different cable categories in the same cable channel, use metallic cable channels with metallic partition.

The following figure show a schematic view of a cable channel with partition.



① Metallic cable channel
② Metallic partition

Figure 3-1 Cable channel with partition

3.2 Cable routing inside cabinets in buildings

Rule

Observe the following rules for proper cable routing inside of control cabinets:

- If a crossing of cables is unavoidable, then cross the cables at an angle of 90°, if possible, in order to keep interference from electrical fields as low as possible.
- Do not route cables coming into the cabinet from outside parallel to the shield supports.

3.3 Cable routing outside cabinets and inside buildings

Rule

Observe the following rules for proper cable routing outside control cabinets and inside buildings:

- Read the information in section Assigning cables to cable categories (Page 9).
- If you route the cables in metallic cable channels, you can rearrange the cable channels next to each other.
- Connect metallically conductive cable racks to the potential equalization of the building.
- If a crossing of cables is unavoidable, then cross the cables at an angle of 90°, if possible, in order to keep interference from electrical fields as low as possible.

3.4 Cable routing outside buildings

If possible, lay the cables outside buildings on metallic cable holders. Connect the cable holder joints galvanically to each other and ground the cable holders.

Rule

Observe the following rules when laying cables outside of buildings:

- Use metallic auxiliary terminal boxes to connect cables coming from outside at the junction to cables inside the building. Ground these boxes.
- If a crossing of cables is unavoidable, then cross the cables at an angle of 90°, if possible, in order to keep interference from electrical fields as low as possible.
- Integrate bus cables installed outside of buildings into your lightning and overvoltage concept.

Lightning protection

When you lay cables for SIMATIC devices outside of buildings, you have to take internal and external lightning protection measures.

Reference

For additional information about lightning protection, refer to chapter Lightning protection and overvoltage protection (Page 26).

3.5 Underground cable routing

Rule

Observe the following rules for underground cable routing:

- Lay the cable at least 60 cm below the ground surface.
- Install equipotential bonding approximately 20 cm above the cable. You can use a zinc-plated ground strip, for example. The ground strips also serve as protection against lightning strikes.
- Protect the cable against mechanical damage by, for example, using a plastic pipe and/or a cable warning tape in the ground, approximately 40 cm above the cable.
- Separate the various cable categories in the ground using cable channels, for example.

The following figure shows the arrangement of cable warning tape, equipotential bonding and a cable.

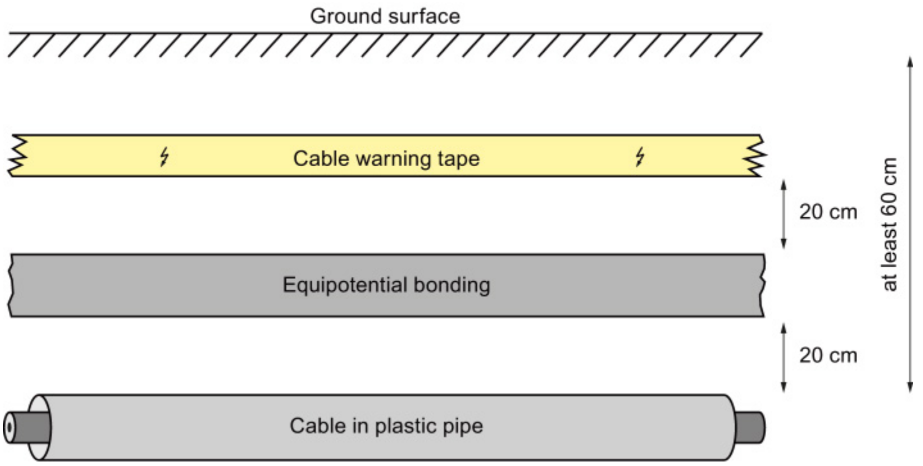


Figure 3-2 Arrangement underground

Lightning protection

When you lay cables for SIMATIC devices outside of buildings, you have to take internal and external lightning protection measures.

Reference

For additional information about lightning protection, refer to chapter Lightning protection and overvoltage protection (Page 26).

3.6 Bending radii and tensile strength of cables

Tensile strain

A high strain on the cables due to tensile forces leads to conductor material flow. The tensile forces thus cause a change in the structure of the material and lower the conductor cross-section. This decrease of the conductor cross-section leads, in turn, to a heating of the conductor and premature wear of the conductor insulation.

Use the supplied cable ties to relieve the terminal points on the plugs for the I/O modules of the product series SIMATIC S7-1500 and SIMATIC ET 200MP.

Bending radius

If you select too small bending radii when laying cables, this will cause the materials to stretch and compress and changes the mechanical structure of the cables. The electrical properties are impaired as a result.

Pay particular attention to the bending radii of fiber-optic cables. If the bending radii are too small, the optical properties of the fiber-optic cable are adversely affected. Reliable transmission is no longer guaranteed.

4 Cable shielding

Shielding is a measure to attenuate (dampen) magnetic, electrical or electromagnetic interference fields.

Interference currents on cable shields are diverted from the shield connection to ground. To avoid interference as a result of these currents, it is imperative to provide a low-impedance connection to the protective conductor.

Rules

Ideally, you should use cables equipped with a protective braided shield. The shield's contacting must be more than 80% at the contact point. Avoid tensile and compression strain on cables with a foil shield. This type of strain can damage the foil shield very slightly at the fastening point. The result is a reduced shielding effect.

Shield connection with grounding at both ends

Always connect the cable shields to the ground at both ends. Low and high frequency interference can be reduced only by connecting both ends of the shield to the ground.

Note

Laying an additional equipotential bonding cable

Whenever potential differences develop between the grounding points, an equalizing current flows on a shielding that is connected at both ends. In this case, lay an additional equipotential bonding cable. You can find more information on this topic in the chapter Equipotential bonding (Page 23).

Shield connection with capacitive grounding at one end

If you do not have the option of installing equipotential bonding (in plants covering a large area, for example), connect capacitive grounding to one end of your shield. In this case, only high-frequency interference will be reduced.

The following figure shows the capacitive grounding of a cable shield. The values indicated in the figure are indicative and will differ from system to system. The capacity diverts the high-frequency interference. This capacity provides high-impedance protection for the power frequency (50 or 60 Hz), thus preventing equalizing currents via the shield. A parallel switched high-impedance resistance prevents the capacity from loading a direct current.

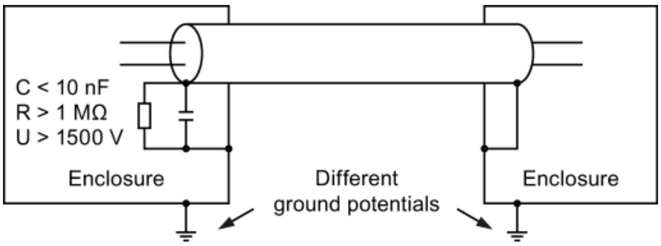

Figure 4-1 Capacitive grounding of the shield

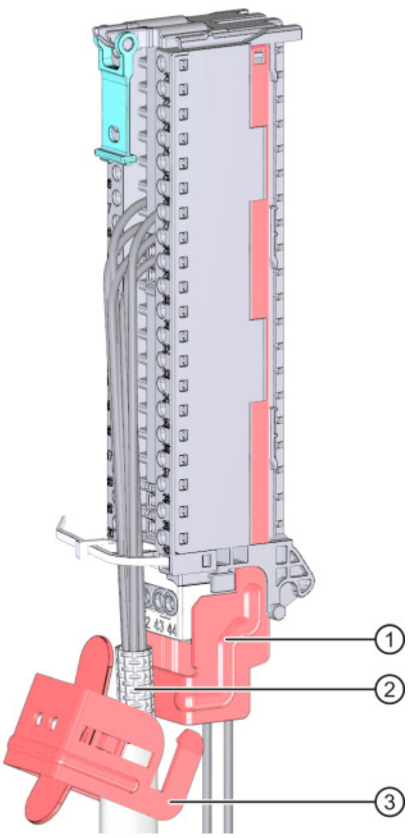
4.1 Connecting the cable shielding for S7-1500 and ET 200MP

A special shield design has been developed for the automation system S7-1500 and the distributed I/O system ET 200MP for the shield connection of the signal lines. The connection element for the cable shield consists of a shield clamp and a shield terminal.

If the front connector is located in the module, the interference currents which occur are diverted by the connection element to the ground via the module and mounting rail.

The shield clamp is a pluggable mount for the analog and technology modules. The shield clamp allows the low-impedance application of cable shields with minimum installation times.

The following figure shows a front connector with mounted shield clamp and associated shield terminal.



① Shield clamp
② Stripped cable shield
③ Shield terminal

Figure 4-2 Shield clamp and shield terminal on front connector

The shield clamp is inserted from below onto the front connector until the shield clamp latches audibly. The shield terminal is fastened to the shield clamp.

Additional information

For additional information on installing the shield clamp and shield terminal, refer to the "Connecting front connectors" chapter in the S7-1500 automation system (http://support.automation.siemens.com/WW/view/en/59191792) or ET 200MP Distributed I/O System (http://support.automation.siemens.com/WW/view/en/59193214) system manuals.

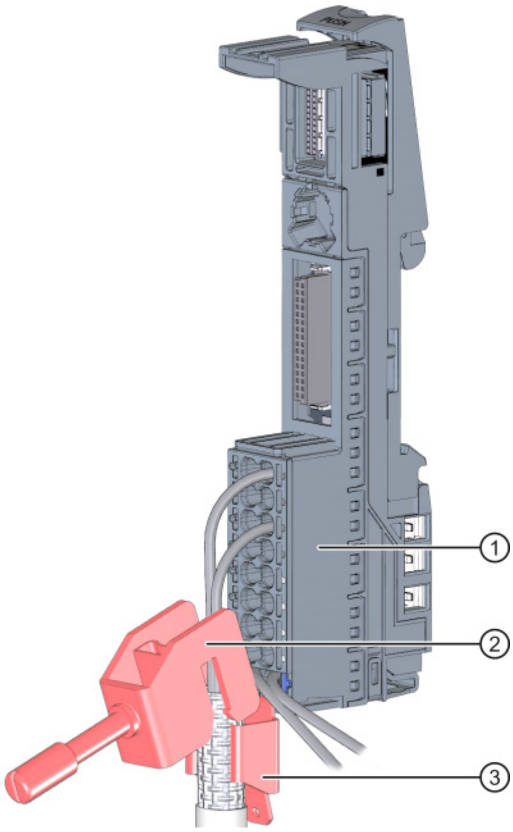
4.2 Connecting the cable shielding for ET 200SP

A special shield design has been developed for the shield connection of the signal lines of the ET 200SP distributed I/O system. The connection element for the cable shield consists of a shield terminal.

If the front connector is located in the module, the interference currents that occur are diverted by the connection element via BaseUnit and mounting rail to the ground.

The shield terminal is plugged into a mount of the BaseUnit. The shield terminal allows the low-impedance application of cable shields with minimum installation times. There is no need for the otherwise standard connection of the cable shield at the cabinet entry.

The following figure shows a BaseUnit with shield terminal and shield support.



① BaseUnit of ET 200SP
② Shield terminal
③ Shield support with flat plug for terminal sockets

Figure 4-3 BaseUnit with shield terminal

Additional information

For more information on mounting the shield terminal, refer to the "Connecting cable shields" chapter of the system manual ET 200SP Distributed I/O System (http://support.automation.siemens.com/WW/view/en/58649293).

4.3 Connecting the cable shielding for ET 200AL

Each module of the ET 200AL distributed I/O system features a functional ground connection.

Use only shielded cables for connection of analog signals, PROFINET and PROFIBUS signals and for the ET-Connection. If you have screwed the plug in correctly, the interference currents that occur are diverted to the metal parts and functional ground.

If you attach an ET 200AL module to a **conductive**, grounded base, the lower mounting bolt establishes a conductive connection to the earth potential.

If you attach an ET 200AL module to a **non-conductive** base, connect the lower mounting bolt to the ground wire at the same time.

The following figure shows how to connect the functional ground via a ground wire, using the IM 157-1 PN interface module as an example.

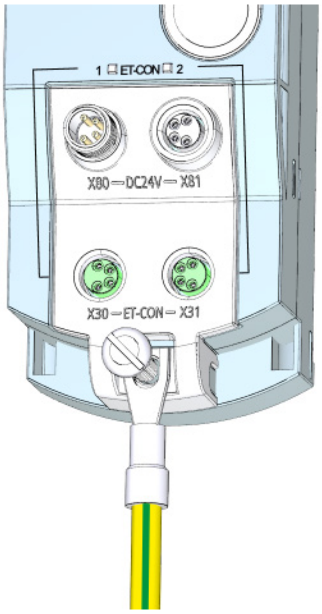


Figure 4-4 Connect functional ground via a ground wire

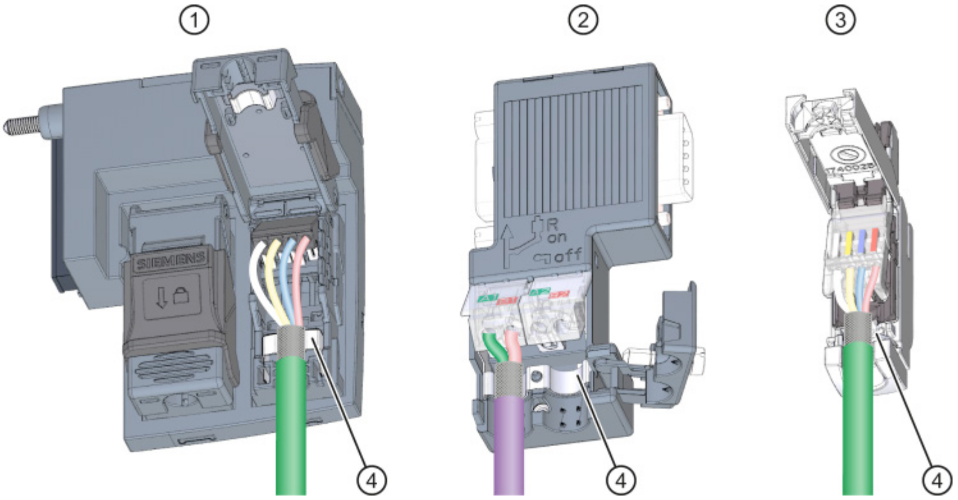
Additional information

You can find more information on installing ET 200AL modules in the Installing Modules section of the system manual Distributed I/O System ET 200AL (http://support.automation.siemens.com/WW/view/en/89254965).

4.4 Connecting the cable shield for bus cables

In the S7-1500, ET 200MP and ET 200SP systems, the cable shields of PROFIBUS and PROFINET cables are connected to the existing bus connection elements. Cable shield and shield support are thus galvanically connected to each other. If the connector is plugged into the module, the coupled interferences are diverted via the module carrier to the ground. There is no need for the otherwise standard connection of the shield at the cabinet entry.

The following figure shows examples of the shield connection for various bus connection elements.



① BusAdapter BA 2xRJ45 for ET 200SP
② PROFIBUSconnector, 9-pin D-Sub
③ PROFINETconnector RJ45
④ Shield support of respective connector

Figure 4-5 Shield connection for bus connection elements

Reference

For more information on installing the connectors, refer to the "Connecting PROFINET IO BusAdapter BA 2xRJ45 to the interface module" chapter of the system manual ET 200SP Distributed I/O System (http://support.automation.siemens.com/WW/view/en/58649293) and to the supplied product information.

4.5 Connecting the cable shield for other components

The following procedures for connecting the shield to devices that do not have any special shield terminals have proven themselves in practice.

Rule

Note the following points when handling the shield:

- Always use metal clamps to mount the protective braided shields of the cables. The clamps must cover a large area of the shield and provide appropriate contact force.
- Attach the shield to a shielding bus directly after the point where the cable enters the cabinet. If you route the shield further to the module, do not connect the shield again in front of the module, as this would create ground loops.

The following figure shows standard types of shield fastening.

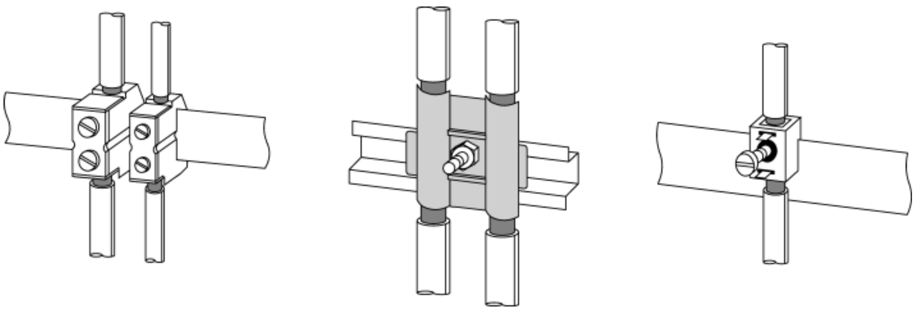


Figure 4-6 Cable shielding

Equipotential bonding

5

Definition according to DIN VDE 0100

Equipotential bonding is an electrical connection which brings the bodies of electrical equipment and external conductive parts to the same, or nearly the same, potential.

Equipotential bonding is divided into:

- Main equipotential bonding
- Additional local equipotential bonding

Both versions of equipotential bonding are of great importance not only for protection against electric shock, but also for EMC.

Main equipotential bonding

Main equipotential bonding is required by DIN VDE 0100 Part 410 as a protective measure and is mandatory, regardless of other measures for protection against direct and indirect contact.

Additional local equipotential bonding

Additional local equipotential bonding is required if:

- Unfavorable grounding conditions exist between plant parts due to different conductivity of the soil (for example, sandy or stony ground)
- Cables bridge a large distance
- Electrical energy is fed in from various power supplies (for example, in the case of multiple substations)
- Considerable electrical power is used (for example, welding robots, large drives)

Measures

In such cases, an additional equipotential bonding cable between the individual potentials can solve the problem. The equipotential bonding cable must also be able to divert large currents and carry lightning stroke current. The following equipotential bonding systems have proven themselves in practice:

- 16 mm² for copper equipotential bonding cables up to 200 m long
- 25 mm² for copper equipotential bonding cables over 200 m long

To prevent ground loops, equipotential bonding cables are installed in parallel and, whenever possible, near to the signal/bus cable. This allows the area between the two cables to be kept as small as possible.

The following figure shows a schematic view of the installation of an equipotential bonding cable.

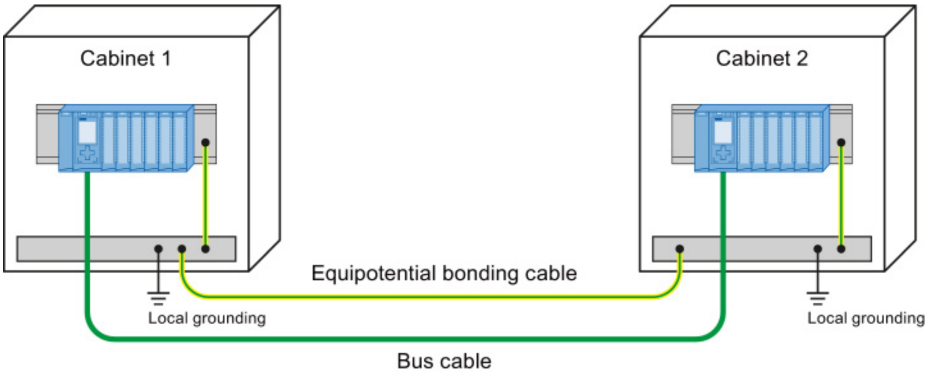

Figure 5-1 Installation of equipotential bonding cables

Rule

Note the following issues regarding equipotential bonding:

- The lower the impedance of an equipotential bonding cable, the more effective is equipotential bonding. The impedance of the additionally installed equipotential bonding cable should not exceed 10% of the shield impedance.
- Connect the equipotential bonding cables to a large area of the grounding system.
- Protect the connection points against corrosion.
- Avoid ground loops.
- Install the equipotential bonding cables in such a way as to minimize the areas enclosed between the equipotential bonding cables and signal lines.

6 Special measures for interference-free operation

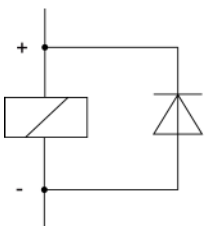
Connecting inductances to quenching elements

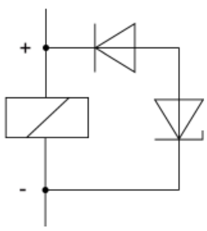
Ideally, the inductances (for example, contactor or relay coils) controlled by SIMATIC do not require any wiring to external quenching elements. The required quenching elements are already integrated into the modules.

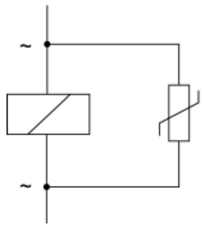
If the SIMATIC output circuit can also be switched off by built-in contacts (such as relay contacts for EMERGENCY OFF), the module's integrated quenching elements are no longer effective. In this case, the inductances must be wired to quenching elements.

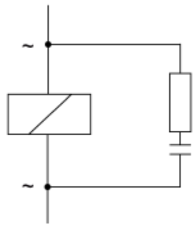
Wire inductances to freewheeling diodes, varistors or RC elements, for example.

Table 6- 1 Wiring inductances

Wiring DC-operated inductances		Wiring AC-operated inductances	
with diode	with Z diode	with varistor	with RC element
			








Programming devices

Provide a socket in each cabinet for the supply of the programming devices. The sockets are supplied from the distribution board to which the protective conductor for the cabinet is also connected.

Observe the following points during the installation of the socket in the control cabinet:

- Include the grounding of the socket in your consideration of the equipotential bonding.
- The common star point of the two ground potentials (cabinet and socket) must be close to the two end points.
- An equipotential bonding cable is not permitted as communication cable between programming device and controller.

Lightning protection and overvoltage protection 7

7.1 What is lightning and overvoltage protection?

Introduction

The term "Lightning and overvoltage protection" covers both the concept and system for the protection of structural systems (such as buildings or electrical equipment). This concept also includes the protection of people and animals.

Overvoltages are most frequently caused by lightning strikes.

Lightning protection system

The lightning protection system is the complete system used to reduce physical damage to a structural system as a result of direct lightning strikes and overvoltages. The lightning protection system is divided into external and internal lightning protection.

External lightning protection

External lightning protection is part of the lightning protection system and comprises an interception device, an arrester and a grounding system. In the event of a lightning strike, the external lightning protection serves to divert the lightning current safely to the ground. This measure most frequently prevents fire damage.

Internal lightning protection

Internal lightning protection is part of the lightning protection system and comprises lightning protection equipotential bonding and/or electrical isolation with respect to the external lightning protection. In the event of a lightning strike, the internal lightning protection reduces the damage caused by overvoltages resulting from the lightning.

Even at larger distances of up to 1.5 km, lightning strikes can sometimes still cause damage. You obtain effective lightning protection by expanding the external lightning protection into an overall protection system. This system includes equipotential bonding and surge protection devices.

7.2 Lightning protection zone concept

Introduction

Each building requires a coordinated protection zone concept. The grading of the protection is of key importance for this. Sufficient protection can only be guaranteed if this grading requirement is satisfied.

The lightning protection zone concept described in the standards IEC 62305-4 and DIN EN 62305-4 is used for this purpose. The lightning protection zone concept groups devices and areas that have the same risk potential and can be wired to arresters of the same type.

Use overvoltage protection devices at the transitions of the lightning protection zones based on the requirements. Install the overvoltage protection devices at an appropriate location such as the main or sub-distribution board.

Principle of the lightning protection zone concept

The principle behind the lightning protection zone concept is the division of the areas to be protected from overvoltages, for example buildings, into lightning protection zones based on EMC considerations.

Schematic diagram of the lightning protection zone concept

The following is a schematic diagram of the lightning protection zone concept in a physical structure.

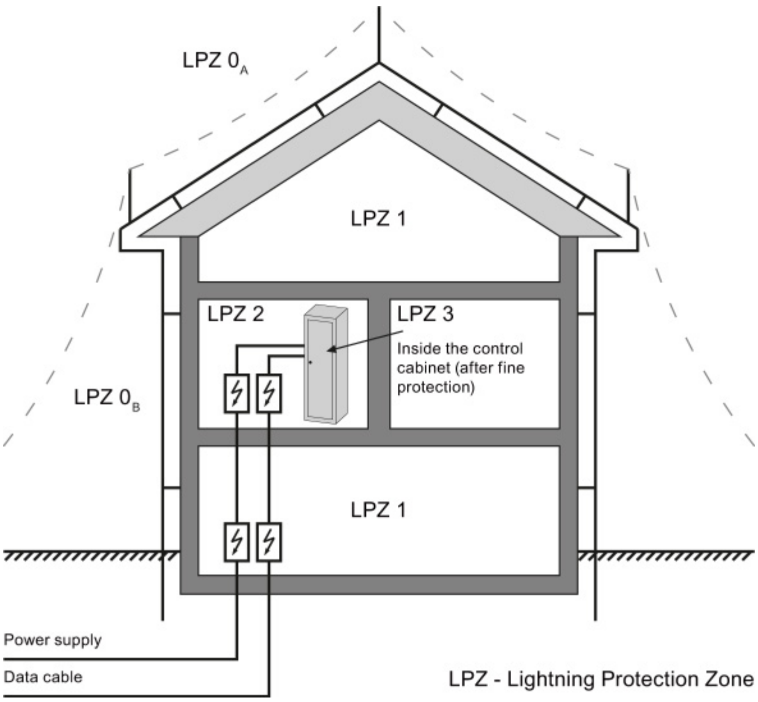


Figure 7-1 Division of a structural system into lightning protection zones

Division of lightning protection zones

The various lightning protection zones (LPZ - Lightning Protection Zone) are limited spatially as follows and not necessarily by physical boundaries, such as walls or floors.

The following table explains the division into various lightning protection zones.

Table 7- 1 External and internal lightning protection zones

Lightning protection zones	
External lightning protection zones:	
LPZ 0_A	• Risk from direct lightning strikes • Risk from the full electromagnetic field of the lightning
LPZ 0_B	• Protected against direct lightning strike • Risk from the full electromagnetic field of the lightning
Internal lightning protection zones:	
LPZ 1	• Protected against direct lightning strike • Attenuated electromagnetic field of the lightning
LPZ 2	• Protected against direct lightning strike • Reduced leakage currents and electromagnetic fields compared to LPZ 1 • Protected terminal devices
LPZ 3	• Protected against direct lightning strike • Protected area inside the terminal device • Local equipotential bonding

Effects of the lightning strike

Direct lightning strikes occur in the lightning protection zone LPZ 0_A. Effects of the lightning strike are high-energy lightning currents and strong electromagnetic fields. These effects are reduced from one lightning protection zone to the next through suitable lightning current or overvoltage arrester/shielding measures.

Frequent damage caused by lightning strikes includes:

- Injury to people and animals, which may in worst cases lead to death
- Damage to buildings
- Fire caused by strong heat development of a lightning strike

Overvoltages

Electromagnetic fields of the lightning channel can be reduced with appropriate shielding measures. Overvoltages due to inductions can be reduced to a safe level starting in lightning protection zone LPZ 0_B with overvoltage arresters.

7.3 Rules and components for the transitions between lightning protection zones

Introduction

This chapter provides you with information on the rules for transitions between lightning protection zones. Measures must be taken to reduce the surge current load and the magnetic fields at the transitions between the lightning protection zones.

Each zone-penetrating metallic/electrical system is incorporated into the equipotential bonding at the zone transition.

The metallic systems include channels, structural parts, and pipes (for water, gas, and heat, for example).

Electrical systems include power and IT cables and wires (for example, power cables and bus cables).

Transitions between lightning protection zones

Overvoltage protection must be provided at the transitions between lightning protection zones (LPZ - Lightning Protection Zone) in accordance with DIN EN 62305. The protection levels are defined at the transitions and implemented by means of overvoltage protection devices (SPD - Surge Protective Device).

- SPD Type 1 - Coarse protection for the transition from LPZ 0 to LPZ 1
- SPD Type 2 - Medium protection for the transition from LPZ 1 to LPZ 2
- SPD Type 3 - Fine protection for the transition from LPZ 2 to LPZ 3

The following figure illustrates the lightning protection zones and the type classes from the supply line to the consumer.

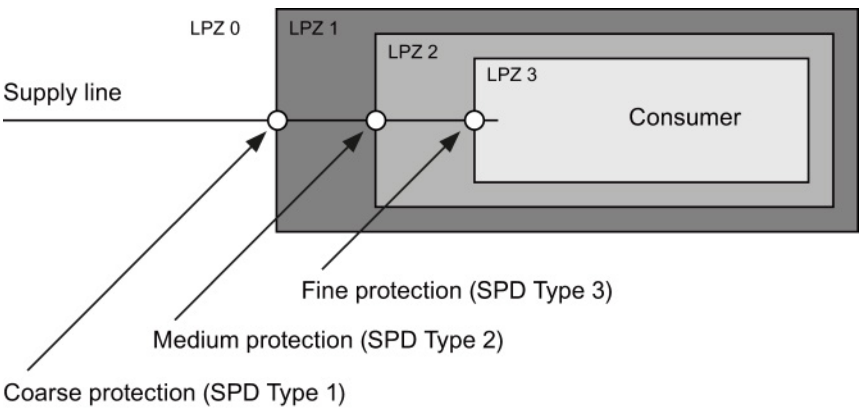

Figure 7-2 Lightning protection zone transitions

Rule for transition from lightning protection zone 0_A to 1

Lightning protection equipotential bonding is required at the transition from lightning protection zone 0_A to 1. The following applies to the transition at the interface of lightning protection zone 0_A to 1:

- Use of lightning arresters prevents introduction of partial lightning currents into structural systems
- Creation of local equipotential bonding at the transition of lightning protection zones, with incorporation of metallic supply systems (for example, pipes, air ducts, cable channels or cable ducts)

Components for lightning protection equipotential bonding from lightning protection zone 0_A to 1

The following table shows components for lightning protection equipotential bonding from lightning protection zone 0_A to 1.

Table 7- 2 Components for transition from lightning protection zone 0_A to 1

Rule for the transition from lightning protection zone 0_B to 1, 1 to 2, or 2 to 3

The transition from lightning protection zone 0_B to 1, 1 to 2, or 2 to 3 prevents strong electromagnetic coupling and serves as overvoltage protection. The following applies to the transition at the interface from lightning protection zone 0_B to 1, 1 to 2, or 2 to 3:

- Use of power cables with surge current-carrying cable shields or twisted-pair IT cables
- Laying cables and lines
  - In continuous, surge current-carrying metal pipes that are grounded at both ends
  - In reinforced concrete channels capable of carrying surge current with grounding at both ends
  - On closed metal cable racks that are grounded at the beginning and end
- Use of fiber-optic cables without a metal shield if such a transmission is intended
- Creation of local equipotential bonding at the transition of lightning protection zones, with incorporation of metallic supply systems (for example, pipes, air ducts, cable channels or cable ducts)

Additional measures

If the actions listed above cannot be implemented, protection by means of overvoltage arresters must be provided. The following sections contain tables with overvoltage arresters that are very suitable for protecting the plant.

Components for lightning protection equipotential bonding from lightning protection zone 0_B to 1 and 1 to 2

Warning notice system

This manual contains notices you have to observe in order to ensure your personal safety, as well as to prevent damage to property. The notices referring to your personal safety are highlighted in the manual by a safety alert symbol, notices referring only to property damage have no safety alert symbol. These notices shown below are graded according to the degree of danger.

⚠DANGER
indicates that death or severe personal injury **will** result if proper precautions are not taken.

⚠WARNING
indicates that death or severe personal injury **may** result if proper precautions are not taken.

⚠CAUTION
indicates that minor personal injury can result if proper precautions are not taken.

NOTICE
indicates that property damage can result if proper precautions are not taken.

If more than one degree of danger is present, the warning notice representing the highest degree of danger will be used. A notice warning of injury to persons with a safety alert symbol may also include a warning relating to property damage.

Qualified Personnel

The product/system described in this documentation may be operated only by **personnel qualified** for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel are those who, based on their training and experience, are capable of identifying risks and avoiding potential hazards when working with these products/systems.

Proper use of Siemens products

Note the following:

⚠WARNING
Siemens products may only be used for the applications described in the catalog and in the relevant technical documentation. If products and components from other manufacturers are used, these must be recommended or approved by Siemens. Proper transport, storage, installation, assembly, commissioning, operation and maintenance are required to ensure that the products operate safely and without any problems. The permissible ambient conditions must be complied with. The information in the relevant documentation must be observed.

Trademarks

All names identified by ® are registered trademarks of Siemens AG. The remaining trademarks in this publication may be trademarks whose use by third parties for their own purposes could violate the rights of the owner.

Disclaimer of Liability

We have reviewed the contents of this publication to ensure consistency with the hardware and software described. Since variance cannot be precluded entirely, we cannot guarantee full consistency. However, the information in this publication is reviewed regularly and any necessary corrections are included in subsequent editions.

Preface

Purpose of the documentation

This documentation provides important information that you need to configure and commission the integrated Motion Control functionality of the S7-1500 Automation systems.

Required basic knowledge

In order to understand this documentation, the following knowledge is required:

- General knowledge in the field of automation
- General knowledge in the field of drive engineering and motion control

Validity of the documentation

This documentation is valid for the S7-1500 product range.

Conventions

- For the path settings in the project navigation it is presumed that the "Technology objects" object is opened in the CPU subtree. The "Technology object" placeholder represents the name of the technology object.

  Example: "Technology object > Configuration > Basic parameters".
- The <TO> placeholder represents the name set in tags for the respective technology object.

  Example: <TO>.Actor.Type
- This documentation contains pictures of the devices described. The pictures may differ in minor details from the devices supplied.

You should also observe the notes that are marked as follows:

Note

A note contains important information about the product described in the documentation, about the handling of the product, and about sections in this documentation demanding your particular attention.

Further support

- The range of technical documentation for the individual SIMATIC products and systems is available on the Internet (http://www.siemens.com/simatic-tech-doku-portal).
- The online catalog and the online ordering system is available on the Internet (http://mall.industry.siemens.com).

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions constitute one element of such a concept.

Customers are responsible for preventing unauthorized access to their plants, systems, machines and networks. Such systems, machines and components should only be connected to an enterprise network or the internet if and to the extent such a connection is necessary and only when appropriate security measures (e.g. firewalls and/or network segmentation) are in place.

For additional information on industrial security measures that may be implemented, please visit (https://www.siemens.com/industrialsecurity).

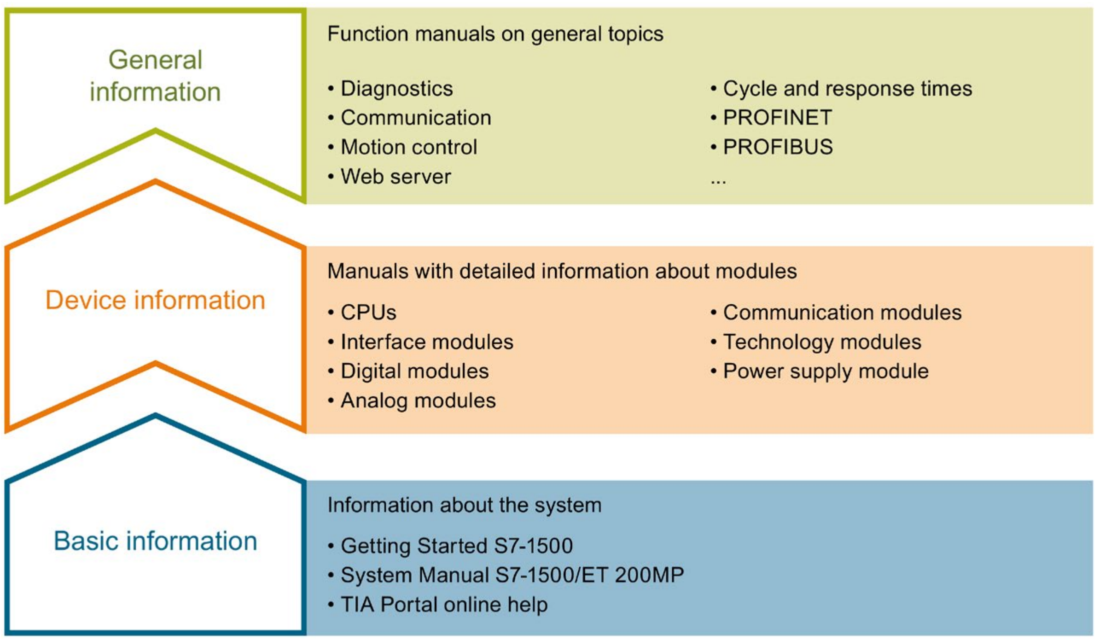
Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends that product updates are applied as soon as they are available and that the latest product versions are used. Use of product versions that are no longer supported, and failure to apply the latest updates may increase customers' exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under (https://www.siemens.com/industrialsecurity).

Table of contents

1 Documentation guide

The documentation for the SIMATIC S7-1500 automation system and the SIMATIC ET 200MP distributed I/O system is arranged into three areas.
This arrangement enables you to access the specific content you require.



Basic information

The System Manual and Getting Started describe in detail the configuration, installation, wiring and commissioning of the SIMATIC S7-1500 and ET 200MP systems. The STEP 7 online help supports you in the configuration and programming.

Device information

Product manuals contain a compact description of the module-specific information, such as properties, wiring diagrams, characteristics and technical specifications.

General information

The function manuals contain detailed descriptions on general topics regarding the SIMATIC S7-1500 and ET 200MP systems, e.g. diagnostics, communication, motion control, Web server, OPC UA.

You can download the documentation free of charge from the Internet (https://support.industry.siemens.com/cs/ww/en/view/109742691).

Changes and supplements to the manuals are documented in a Product Information.

You can download the product information free of charge from the Internet (https://support.industry.siemens.com/cs/us/en/view/68052815).

Manual Collection S7-1500/ET 200MP

The Manual Collection contains the complete documentation on the SIMATIC S7-1500 automation system and the ET 200MP distributed I/O system gathered together in one file.

You can find the Manual Collection on the Internet (https://support.industry.siemens.com/cs/ww/en/view/86140384).

SIMATIC S7-1500 comparison list for programming languages

The comparison list contains an overview of which instructions and functions you can use for which controller families.

You can find the comparison list on the Internet (https://support.industry.siemens.com/cs/ww/en/view/86630375).

"mySupport"

With "mySupport", your personal workspace, you make the best out of your Industry Online Support.

In "mySupport", you can save filters, favorites and tags, request CAx data and compile your personal library in the Documentation area. In addition, your data is already filled out in support requests and you can get an overview of your current requests at any time.

You must register once to use the full functionality of "mySupport".

You can find "mySupport" on the Internet (https://support.industry.siemens.com/My/ww/en).

"mySupport" - Documentation

In the Documentation area in "mySupport" you can combine entire manuals or only parts of these to your own manual.
You can export the manual as PDF file or in a format that can be edited later.

You can find "mySupport" - Documentation on the Internet (http://support.industry.siemens.com/My/ww/en/documentation).

"mySupport" - CAx data

In the CAx data area in "mySupport", you can access the current product data for your CAx or CAe system.

You configure your own download package with a few clicks.

In doing so you can select:

- Product images, 2D dimension drawings, 3D models, internal circuit diagrams, EPLAN macro files
- Manuals, characteristics, operating manuals, certificates
- Product master data

You can find "mySupport" - CAx data on the Internet (http://support.industry.siemens.com/my/ww/en/CAxOnline).

Application examples

The application examples support you with various tools and examples for solving your automation tasks. Solutions are shown in interplay with multiple components in the system - separated from the focus on individual products.

You will find the application examples on the Internet (https://support.industry.siemens.com/sc/ww/en/sc/2054).

TIA Selection Tool

With the TIA Selection Tool, you can select, configure and order devices for Totally Integrated Automation (TIA).
This tool is the successor of the SIMATIC Selection Tool and combines the known configurators for automation technology into one tool.
With the TIA Selection Tool, you can generate a complete order list from your product selection or product configuration.

You can find the TIA Selection Tool on the Internet (http://w3.siemens.com/mcms/topics/en/simatic/tia-selection-tool).

SIMATIC Automation Tool

You can use the SIMATIC Automation Tool to perform commissioning and maintenance activities simultaneously on various SIMATIC S7 stations as a bulk operation independent of the TIA Portal.

General function overview:

- Network browsing and creation of a table showing the accessible devices in the network.
- Flashing of device LEDs or HMI display to locate a device
- Downloading of addresses (IP, subnet, gateway) to a device
- Downloading the PROFINET name (station name) to a device
- Placing a CPU in RUN or STOP mode
- Setting the time in a CPU to the current time of your PG/PC
- Downloading a new program to a CPU or an HMI device
- Downloading from CPU, downloading to CPU or deleting recipe data from a CPU
- Downloading from CPU or deleting data log data from a CPU
- Backup/restore of data from/to a backup file for CPUs and HMI devices
- Downloading service data from a CPU
- Reading the diagnostics buffer of a CPU
- Performing a CPU memory reset
- Resetting devices to factory settings
- Downloading a firmware update to a device

You can find the SIMATIC Automation Tool on the Internet (https://support.industry.siemens.com/cs/ww/en/view/98161300).

PRONETA

With SIEMENS PRONETA (PROFINET network analysis), you analyze the PROFINET network during commissioning. PRONETA features two core functions:

- The topology overview independently scans PROFINET network and all connected components.
- The IO check is a fast test of the wiring and the module configuration of a system.

You can find SIEMENS PRONETA on the Internet (https://support.industry.siemens.com/cs/ww/en/view/67460624).

SINETPLAN

SINETPLAN, the Siemens Network Planner, supports you in planning automation systems and networks based on PROFINET. The tool facilitates professional and predictive dimensioning of your PROFINET installation as early as in the planning stage. In addition, SINETPLAN supports you during network optimization and helps you to exploit network resources optimally and to plan reserves. This helps to prevent problems in commissioning or failures during productive operation even in advance of a planned operation. This increases the availability of the production plant and helps improve operational safety.

The advantages at a glance

- Network optimization thanks to port-specific calculation of the network load
- Increased production availability thanks to online scan and verification of existing systems
- Transparency before commissioning through importing and simulation of existing STEP 7 projects
- Efficiency through securing existing investments in the long term and optimal exploitation of resources

You can find SINETPLAN on the Internet (https://www.siemens.com/sinetplan).

Introduction 2

2.1 Interplay of the various documents

For a better overview, the documentation of the Motion Control functions is divided into the following documents:

- Using S7-1500T Motion Control (https://support.industry.siemens.com/cs/ww/en/view/109749263)
- Using S7-1500T Kinematics Functions (https://support.industry.siemens.com/cs/ww/en/view/109749264)

"Using S7-1500 Motion Control" describes the Motion Control functions for the following technology objects:

- Speed axis
- Positioning axis
- Synchronous axis
- External encoder
- Measuring input
- Output cam
- Cam track
- Cam (S7-1500T)

"Using S7-1500T Kinematics Functions" describes the Motion Control functions for the kinematics technology object. This document assumes that the Motion Control functions described in "Using S7-1500 Motion Control functions" are known.

2.2 Integrated Motion Control functionality

S7-1500 Motion Control supports controlled positioning and moving of axes and is an integral part of every CPU S7-1500 as well as every CPU S7-1500SP. The S7-1500T Technology CPUs provide enhanced functions.

The Motion Control functionality supports the following technology objects:

- Speed axis
- Positioning axis
- Synchronous axis
- External encoder
- Measuring input
- Output cam
- Cam track
- Cam (S7-1500T)
- Kinematics (S7-1500T)

Drives with PROFIdrive capability and drives with analog setpoint interface and stepper motors are controlled by means of standardized Motion Control instructions according to PLCopen.

The axis control panel and comprehensive online and diagnostic functions support easy commissioning and optimization of drives.

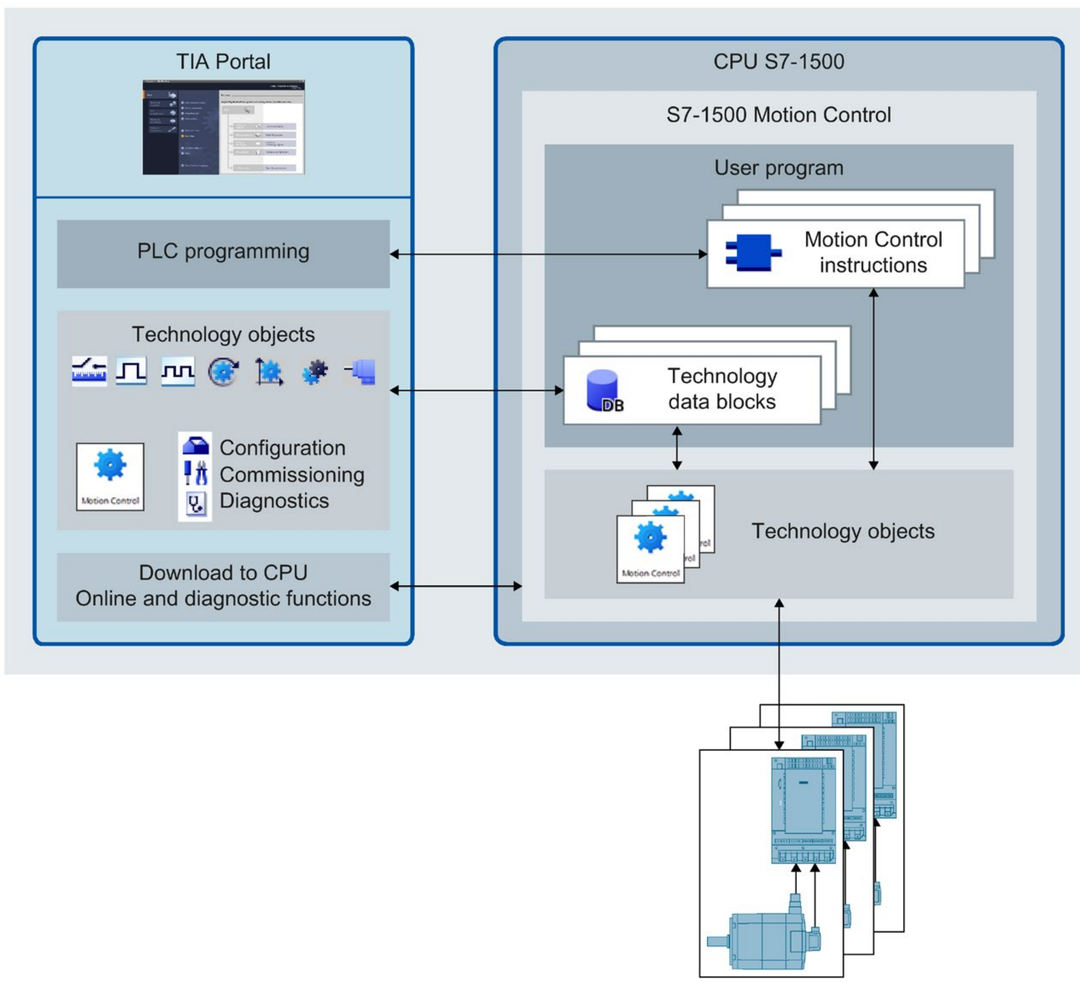
S7-1500 Motion Control is fully integrated into the system diagnostics of the S7-1500 CPU.

2.3 Principle of operation of S7-1500 Motion Control

Overview

You create a project, configure technology objects, and download the configuration to the CPU with the TIA Portal. The Motion Control functionality is processed in the CPU.
You control the technology objects with the Motion Control instructions in your user program. The TIA Portal provides additional functions for commissioning, optimization (Page 316) and diagnostics (Page 332).

The following figure provides a schematic representation of the user interfaces and the integration of Motion Control into the S7-1500 CPU. The concepts are then briefly explained:



TIA Portal

The TIA Portal supports you in the planning and commissioning of Motion Control functionality:

- Integrating and configuring hardware
- Creating and configuring technology objects
- Creating the user program
- Downloading to CPU
- Commissioning of axes
- Optimization of drives
- Diagnostics

You use the TIA Portal to configure the hardware, the technology objects as well as your user program. You download the program you created to the CPU. You test your user program and diagnose the hardware with the online and diagnostic functions of the TIA Portal.

Technology objects

Technology objects represent real objects (e.g. a drive) in the controller. You call the functions of the technology objects by means of Motion Control instructions in your user program. The technology objects provide open- and closed-loop control of the movement of the real objects, and report status information (e.g. the current position).

The configuration of the technology objects represents the properties of the real object. The configuration data is stored in a technology data block.

The following technology objects are available for Motion Control:

-  **Speed axis technology object**

  The speed axis technology object ("TO_SpeedAxis") is used to specify the speed for a drive. You program the motion of the axis with motion control instructions.

-  **Positioning axis technology object**

  The positioning axis technology object ("TO_PositioningAxis") is used to position a drive with closed-loop position control. You issue positioning jobs to the axis with Motion Control instructions in your user program.

-  **Synchronous axis technology object**

  The synchronous axis technology object ("TO_SynchronousAxis") includes all functions of the positioning axis technology object. The axis can also be interconnected with a leading value so that the axis follows the position change of a leading axis in synchronous operation.

- **External encoder technology object**

  The external encoder technology object ("TO_ExternalEncoder") detects a position and makes it available to the controller. The detected position can be evaluated in the user program.

- **Measuring input technology object**

  The measuring input technology object ("TO_MeasuringInput") detects actual positions quickly, accurately and event triggered.

- **Output cam technology object**

  The output cam technology object ("TO_OutputCam") generates switching signals depending on the position of an axis or external encoder. You can evaluate the switching signals in the user program or feed them to digital outputs.

- **Cam track technology object**

  The cam track technology object ("TO_CamTrack") generates a switching signal sequence depending on the position of an axis or external encoder. In this process, up to 32 individual cams are superimposed and the switching signals are output as a track. You can evaluate the switching signals in the user program or feed them to digital outputs.

- **Cam technology object (S7-1500T)**

  The cam technology object ("TO_Cam") defines a function f(x) by means of interpolation points and/or segments. Missing function ranges are interpolated.

- **Kinematic technology object (S7-1500T)**

  The Kinematic technology object ("TO_Kinematics") is used to interconnect positioning axes to a kinematic. When you configure the kinematics technology object, you interconnect the axes in accordance with the configured kinematics type.

Technology data block

The properties of real objects are configured by means of the technology objects and saved in a technology data block (Page 284). The technology data block contains all configuration data, setpoint and actual values, and status information of the technology object. The TIA Portal automatically creates the technology data block when the technology object is created. You access the data of the technology data block (read/write access) with your user program.

Motion Control instructions

With the Motion Control instructions you perform the desired functionality in the technology objects. The Motion Control instructions are available in the TIA Portal under "Instructions > Technology > Motion Control".

The Motion Control instructions conform to PLCopen (version 2.0).

User program

The Motion Control instructions and the technology data block represent the programming interfaces for the technology objects. You use Motion Control instructions to transfer Motion Control jobs for the technology objects in your user program. You track the status of running jobs via the output parameters of the Motion Control instructions. You access status information of the technology object and change specific configuration parameters during runtime using the technology data block.

Drives and encoders

Drives ensure the motion of the axis. They are integrated in the hardware configuration.

When you execute a Motion Control job in your user program, the technology object takes over the control of the drive and the reading in of values of encoders.

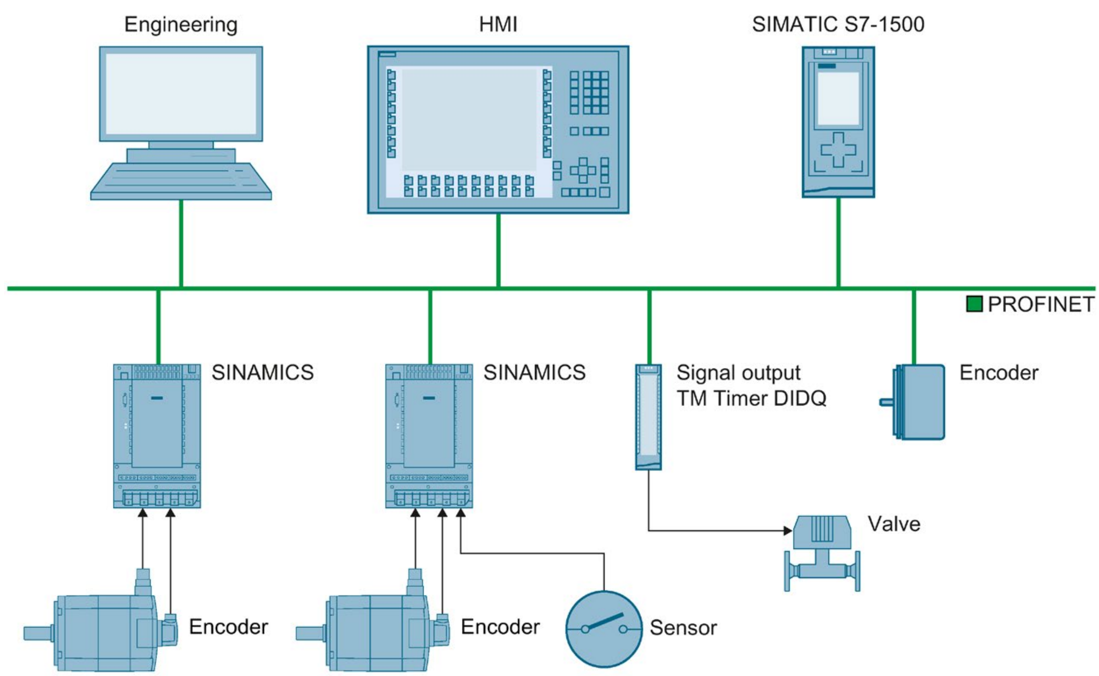
Drives and encoders with PROFIdrive capability are connected by means of PROFIdrive telegrams. The following connections are possible:

- PROFINET IO
- PROFIBUS DP
- Technology module (TM)

Drives with analog setpoint interfaces are connected using an analog output (AQ) and an optional enable signal. Analog inputs and outputs are made available by means of corresponding I/O modules.

A drive is also called an actuator, and an encoder is also called a sensor.

The figure below shows an example configuration in which all components are connected to the CPU by means of PROFINET IO:



2.4 Functions

2.4.1 Functions - Axes

You execute the functions of the speed axis, positioning axis and synchronous axis technology objects using Motion Control instructions in your user program or using the TIA Portal (under "Technology object > Commissioning").

The following table shows the functions that are supported by technology objects:

Function	Technology object		
	Speed axis (Page 103)	Positioning axis (Page 104)	Synchronous axis (Page 105)
Motion Control instructions (user program)			
"MC_Power (Page 361)" Enable, disable technology objects	X	X	X
"MC_Home (Page 369)" Home technology objects, set home position	-	X	X
"MC_MoveJog (Page 391)" Move axes in Jog mode	X	X	X
"MC_MoveVelocity (Page 386)" Move axes at predefined velocity	X	X	X
"MC_MoveRelative (Page 382)" Relative positioning of axes	-	X	X
"MC_MoveAbsolute (Page 378)" Absolute positioning of axes	-	X	X
"MC_MoveSuperimposed (Page 395)" Positioning axes overlapping	-	X	X
"MC_GearIn (Page 413)" Start gearing	-	-	X
"MC_Halt (Page 374)" Halt axes	X	X	X
"MC_TorqueLimiting (Page 417)" Limit torque using torque reduction	X	X	X
"MC_Reset (Page 367)" Acknowledge alarms, restart technology objects	X	X	X
"MC_TorqueAdditive (Page 422)" Specify additive torque and activate/deactivate	X	X	X
"MC_TorqueRange (Page 425)" Specify high and low torque limits	X	X	X

Function	Technology object		
	Speed axis (Page 103)	Positioning axis (Page 104)	Synchronous axis (Page 105)
TIA Portal			
"Axis control panel (Page 319)" Move and home axes using the TIA Portal	X	X	X
"Optimization (Page 325)" Optimization of closed loop position control	-	X	X

2.4.2 Functions - Other technology objects

You execute the functions of the other technology objects by means of Motion Control instructions in your user program.

The following table shows the Motion Control instructions that are supported by the technology objects:

Motion Control instruction	Technology object			
	External encoder (Page 110)	Measuring input (Page 111)	Output cam (Page 126)	Cam track (Page 141)
Motion Control instructions (user program)				
"MC_Power (Page 361)" Enable, disable technology objects	X	-	-	-
"MC_Home (Page 369)" Home technology objects, set home position	X	-	-	-
"MC_MeasuringInput (Page 399)" Start measuring job once	-	X	-	-
"MC_MeasuringInputCyclic (Page 402)" Start cyclic measuring job	-	X	-	-
"MC_AbortMeasuringInput (Page 406)" End measuring job	-	X	-	-
"MC_OutputCam (Page 407)" Activate/deactivate output cam	-	-	X	-
"MC_CamTrack (Page 410)" Activate/deactivate cam track	-	-	-	X
"MC_Reset (Page 367)" Acknowledge alarms, restart technology objects	X	X	X	X

2.5 Guidelines on use of motion control

The guidelines described here present the basic procedure for using Motion Control with the CPU S7-1500. These guidelines serve as recommendations.

Requirements

- A project with a CPU S7-1500 has been created.

Procedure

Proceed as follows to use Motion Control with the CPU S7-1500:

1. Add technology object (Page 175)
2. Working with the configuration editor (Page 178)
3. Programming (Page 284)
4. Downloading to CPU (Page 315)
5. Functional test in the Commissioning window (Page 316)
6. Diagnostics (Page 332)

Technology objects 3

3.1 Configuration limits

Motion Control resources

Each CPU offers a defined set of Motion Control resources. For information on the available Motion Control resources, refer to the technical specifications of the utilized CPU.

Each technology object uses Motion Control resources:

Technology object	Motion Control resources used
Speed axis	40
Positioning axis	80
Synchronous axis	160
External encoder	80
Measuring input	40
Output cam	20
Cam track	160

You can find an overview of the Motion Control resources of a CPU in the TIA Portal under "Tools > Resources".

Extended Motion Control Resources (S7-1500T)

The cam and kinematics technology objects use "Extended Motion Control resources". For information on the maximum number of cams and kinematics that can be used in addition to the Motion Control resources, refer to the technical specifications of the relevant CPU.

Technology object	Extended Motion Control resources used
Cam	2
Kinematics	30

Application cycle

As the number of technology objects used increases, the computing time needed by CPU to process the technology objects increases. The Motion Control application cycle (Page 95) can be adapted according to the number of technology objects used.

3.2 Basics - Axes

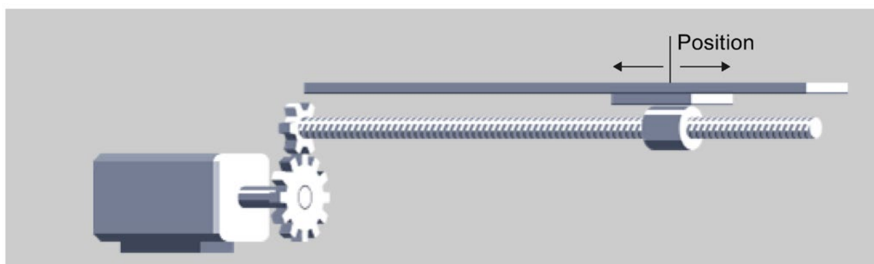
3.2.1 Axis types

Axes can be configured with different axis types:

- Positioning and synchronous axes can be configured as rotary or linear axis.
- Speed axes are always rotary axes.

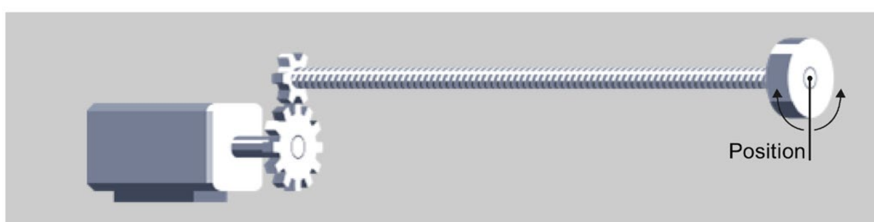
Depending on the execution of the mechanics, an axis is implemented as a linear axis or rotary axis:

- **Linear axis**



For linear axes, the position of the axis is specified as a linear measure, e.g. millimeters (mm).

- **Rotary axis**



For rotary axes, the position of the axis is specified as an angular measure, e.g. degrees (°).

3.2.2 Units of measure

The supported units of measure for speed (revolutions per time unit) are 1/s, 1/min and 1/h.

The table below shows the supported units of measure for position and velocity:

Position	Velocity
nm, µm, mm, m, km	mm/s, mm/min, mm/h, m/s, m/min, m/h, km/min, km/h
in, ft, mi	in/s, in/min, ft/s, ft/min, mi/h
°, rad	°/s, °/min, rad/s, rad/min

The acceleration is set accordingly as the position/s² unit of measure.

The jerk is set accordingly as the position/s² unit of measure.

The table below shows the supported units of measure for force and torque:

Force	Torque
N, kN	Nm, kNm
lbf, ozf, pdl	lbf in, lbf ft, ozf in, ozf ft, pdl in, pdl ft

The unit of measure for time is permanently specified for the following technology objects:

Technology object	Time
Speed axis, positioning/synchronous axis, external encoder	s
Output cam, cam track, measuring input	ms

Note

When setting or changing the units of measure, take into consideration the effect on the display of parameter values and the user program:

- Display of parameter values in the technology data block
- Assignment of parameters in the user program
- Input and display of the position and velocity in the TIA Portal
- Setpoint settings by leading axes in synchronous operation

All information and displays correspond to the selected unit of measure.

The set units are displayed in the tag structure of the technology object <TO>.Units. The tag structure is described in the Appendix (Page 431) under the tags of the respective technology object.

3.2.3 Modulo setting

For the positioning axis, synchronous axis and external encoder technology objects, the "Modulo" setting can be activated.

When an axis moves in only one direction, the position value continually increases. To limit the position value to a recurring reference system, you can activate the "Modulo" setting.

When the "Modulo" setting is activated, the position value of the technology object is mapped onto a recurring modulo range. The modulo range is defined by the start value and the length.

For example, to limit the position value of a rotary axis to a full rotation, the modulo range can be defined with start value = 0° and length = 360°. As a result, the position value is mapped onto the modulo range 0° to 359.999°.

3.2.4 Long-term accuracy

Long-term accuracy means that the technological position from the accumulated encoder increments can be exactly determined (without a rounding error) and are thus always accurate.

The long-term accuracy ensures the following:

- The axis position indicated by the control always corresponds to the real position. This means that the axis position can be exactly represented from the accumulated encoder increments.
- The calculated position in the controller does not deviate from the real position. Deviations occur without long-term accuracy, for example, due to rounding errors or conversions with finite accuracy.

Non-modulo axes are stable over the long term until the numerical traversing range limit is reached. Modulo axes are accordingly stable at least as long as they do not exceed the numerical traversing range of 9.0E12 mm at 1000 increments per unit.

You can use the following equation to estimate the time after which the traversing range is exceeded.

$$\text{Travel time} = \frac{\text{Maximum position}}{\text{Velocity}}$$

Example of the maximum traversing time

Maximum position = 9.0E12 mm with a resolution of 1000 Ink / mm

Velocity = 20.0 m/min = 2.0E4 mm/min

$$\text{Travel time} = \frac{9.0\text{E}12\ \text{mm}}{2.0\text{E}4\ \text{mm/min}} = 4.5\text{E}8\ \text{min} \quad \triangleq 856\ \text{years}$$

The traversing time restarts when one of the following conditions is fulfilled:

- You have homed the axis with "MC_Home".
- You have changed the velocity of the axis

  A change in the velocity has the consequence that the traversing time changes accordingly.

Avoiding exceeding the traversing range

To prevent exceeding the traversing range, do the following before the maximum traversing time expires:

- Incremental encoder: Home the incremental encoder again.
- Absolute encoder: Perform an absolute encoder calibration with the default of the currently known position.

3.2.5 Drive and encoder connection

3.2.5.1 Brief description

A drive is assigned to the "Speed axis" technology object. A drive and one to four encoders (only with S7-1500T) are assigned to the "Positioning axis" and "Synchronous axis" technology objects. An encoder is assigned to the "External encoder" technology object.

The setpoint for the drive is specified either with PROFIdrive telegrams or using an analog output.

The following connection options are available for an encoder:

- Encoder connected to drive
- Encoder to technology module
- PROFIdrive encoder connected directly to PROFIBUS DP/PROFINET IO

The actual encoder value is transmitted exclusively via PROFIdrive telegrams.

PROFIdrive

PROFIdrive is the standardized drive technology profile for connecting drives and encoders via PROFIBUS DP and PROFINET IO. Drives that support the PROFIdrive profile are connected according to the PROFIdrive standard.

The current PROFIdrive specification is available at:

http://www.profibus.com (http://www.profibus.com)

Communication between the controller and drive/encoder is performed using various PROFIdrive telegrams. Each of the telegrams has a standardized structure. You can select the appropriate telegram according to the application. Control words and status words as well as setpoints and actual values are transmitted in the PROFIdrive telegrams.

The PROFIdrive profile likewise supports the "Dynamic Servo Control" (DSC) control concept. DSC uses rapid closed loop position control in the drive. This can be used to solve highly dynamic Motion Control tasks.

Analog drive connection

Drives with analog setpoint interfaces are connected using an analog output and an optional enable signal. The speed setpoint is specified via an analog output signal (e.g. from -10 V to +10 V) from the PLC.

Stepper motors

Drives with a stepper motor interface are connected using telegram 3 and with the help of PTO (Pulse Train Output) pulse generators.

For functional support of stepper motor operation, quantization of the control deviation can be set.

Through the specification of a quantization, a range around the target position is defined in which no correction of the actual position is to be made. This prevents a possible oscillation of the stepper motor around the target position. Two types of quantization can be set:

- Quantization of the control deviation corresponding to the encoder resolution

  (<TO>.PositionControl.ControlDifferenceQuantization.Mode = 1)

  This prevents oscillation of the stopped motor between two increment values, for example. This mode is especially helpful when using multiple encoders. With this setting, the quantization is adapted appropriately at an encoder switchover. This mode is helpful for stepper motors with encoders in which the resolution of the encoder is lower than the step size of the stepper motor.

- Direct specification of a value for quantization of the control deviation.

  (<TO>.PositionControl.ControlDifferenceQuantization.Mode = 2, value setting in <TO>.PositionControl.ControlDifferenceQuantization.Value)

  This mode is helpful for stepper motors with encoders in which the resolution of the encoder is greater than the step size of the stepper motor.

3.2.5.2 PROFIdrive telegrams

PROFIdrive telegrams are used to transfer setpoints and actual values, control and status words and other parameters between the controller and drive/encoder.

When a PROFIdrive telegram is used for connection, the drives and encoders are handled and switched on in accordance with the PROFIdrive profile.

The following table shows the possible PROFIdrive telegrams for various technology objects.

<table>
<tr><th colspan="3">Technology object</th><th>Possible PROFIdrive telegrams</th></tr>
<tr><td colspan="3">Speed axis</td><td>• 1, 2
• 3, 4, 5, 6, 102, 103, 105, 106 (actual encoder value is not evaluated)</td></tr>
<tr><td colspan="3">Positioning axis/synchronous axis</td><td></td></tr>
<tr><td></td><td colspan="2">Setpoint and actual encoder value in one drive telegram</td><td>3, 4, 5, 6, 102, 103, 105, 106</td></tr>
<tr><td></td><td colspan="2">Setpoint and actual encoder value separately</td><td></td></tr>
<tr><td></td><td></td><td>Setpoint in drive telegram</td><td>1, 2, 3, 4, 5, 6, 102, 103, 105, 106</td></tr>
<tr><td></td><td></td><td>Actual value from telegram</td><td>81, 83</td></tr>
<tr><td colspan="3">External encoder</td><td>81, 83</td></tr>
<tr><td colspan="3">Measuring input [1)]</td><td>391, 392, 393</td></tr>
</table>

1) When using SINAMICS drives (measuring using SINAMICS measuring input)

Telegram types

The following table shows the supported PROFIdrive telegram types for the assignment of drives and encoders:

Telegram	Brief description
Standard telegrams	
1 [1)]	• Control word STW1, status word ZSW1 • Speed setpoint 16 bit (NSET), actual speed value 16 bit (NACT)
2	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT)
3	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2)
4	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2) • Actual encoder value 2 (G2_XIST1, G2_XIST2)

Telegram	Brief description
5	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2) (motor encoder) • Dynamic Servo Control (DSC)[2)] – Speed precontrol value – Position difference (XERR) – Kpc - Velocity precontrol of the closed loop position control
6	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2) (motor encoder) • Actual encoder value 2 (G2_XIST1, G2_XIST2) • Dynamic Servo Control (DSC)[2)] – Speed precontrol value – Position difference (XERR) – Kpc - Velocity precontrol of the closed loop position control
Siemens telegrams (with torque limiting)	
102	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2) • Torque limiting
103	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2) • Actual encoder value 2 (G2_XIST1, G2_XIST2) • Torque limiting
105	• Control words STW1 and STW2, status words ZSW1 and ZSW2 • Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2) (motor encoder) • Dynamic Servo Control (DSC)[2)] – Speed precontrol value – Position difference (XERR) – Kpc - Velocity precontrol of the closed loop position control • Torque limiting

Telegram	Brief description

106	• Control words STW1 and STW2, status words ZSW1 and ZSW2
	• Speed setpoint 32 bit (NSET), actual speed value 32 bit (NACT)
	• Actual encoder value 1 (G1_XIST1, G1_XIST2) (motor encoder)
	• Actual encoder value 2 (G2_XIST1, G2_XIST2)
	• Dynamic Servo Control (DSC)[2)]
	  – Speed precontrol value
	  – Position difference (XERR)
	  – Kpc - Velocity precontrol of the closed loop position control
	• Torque limiting

SIEMENS additional telegrams (torque data)	
750[3)]	• Additive setpoint torque • High and low torque limits • Torque actual values
SIEMENS telegrams (measuring input) [4)]	
391	• Control word CU_STW1, status word CU_ZSW1 • Measuring input control word (MT_STW), measuring input status word (MT_ZSW) • Measuring input time stamp of negative (MT1…2_ZS_F) or positive edges (MT1…2_ZS_S) • Digital output 16 bit, digital input 16 bit
392	• Control word CU_STW1, status word CU_ZSW1 • Measuring input control word (MT_STW), measuring input status word (MT_ZSW) • Measuring input time stamp of negative (MT1…6_ZS_F) or positive edges (MT1…6_ZS_S) • Digital output 16 bit, digital input 16 bit
393	• Control word CU_STW1, status word CU_ZSW1 • Measuring input control word (MT_STW), measuring input status word (MT_ZSW) • Measuring input time stamp of negative (MT1…8_ZS_F) or positive edges (MT1…8_ZS_S) • Digital output 16 bit, digital input 16 bit • Analog input 16 bit

Telegram	Brief description
Standard telegrams - encoder	
81	• Control word STW2_ENC, status word ZSW2_ENC • Actual encoder value 1 (G1_XIST1, G1_XIST2)
83	• Control word STW2_ENC, status word ZSW2_ENC • Actual speed value 32 bit (NACT) • Actual encoder value 1 (G1_XIST1, G1_XIST2)

1) Isochronous mode is not possible.

2) For use of Dynamic Servo Control (DSC), the motor encoder (first encoder in the telegram) of the drive must be used as the first encoder for the technology object.

3) Can also be used for the telegrams 1, 2, 3, 4, 5, 6, 102, 103, 105, 106

4) When using SINAMICS drives (measuring using SINAMICS measuring input)

Data connection drive/encoder via data block (Page 50)

3.2.5.3 Actual values

Brief description

For position-controlled motion and positioning, the controller must know the actual position value.

The actual position value is provided by a PROFIdrive telegram.

The actual values are represented as incremental or absolute values in the PROFIdrive telegram. The actual values are normalized in the controller to the technological unit taking into account the configuration of the mechanics. The reference to a physical position of the axis or external encoder is established by homing.

The controller supports the following types of actual values (encoder types):

- Incremental actual value
- Absolute actual value with the setting absolute (measuring range > traversing range of the axis)
- Absolute actual value with the setting absolute (measuring range < traversing range of the axis)

Actual value calculation for virtual axis or axis in simulation

The actual value of a virtual axis or an axis in simulation is formed from the setpoint taking time delays into account.

You calculate the time delay from actual value to the setpoint (T_t) as follows:

- With precontrol: $T_t = T_{ipo} + T_{servo} + T_{vtc} + T_{addPtc}$
- Without precontrol, without DSC: $T_t = T_{ipo} + 1/Kv + T_{addPtc}$
- Without precontrol, with DSC[1]: $T_t = T_{ipo} + T_{servo} + 1/Kv + T_{addPtc}$

  [1] Only applies to axis in simulation.

T_t	Time delay from the actual value to the setpoint
T_{ipo}	CPU time of MC-Interpolator [OB92]
T_{servo}	CPU time of MC-Servo [OB91]
T_{vtc}	Speed control loop substitute time (T_{vtc} off <TO>.DynamicAxisModel.VelocityTimeConstant)
T_{addPtc}	Additive position control loop equivalent time (T_{addPtc} from <TO>.DynamicAxisModel.AdditionalPositionTimeConstant)
kV	Gain factor (Kv off <TO>.PositionControl.Kv)

Axis in simulation (Page 49)

Incremental actual value

The actual value in the PROFIdrive telegram is based on an incremental value.

After POWER ON, position zero is displayed. A transition of the CPU to RUN mode starts the actual value update. The actual value is then also updated in CPU STOP mode. The relationship between the technology object and the mechanical position must be re-established by means of homing.

Absolute actual value

The actual value in the PROFIdrive telegram is based on an absolute value.

After POWER ON, position zero is displayed. The first transition of the CPU to RUN mode starts the actual value update. The actual value is then also updated in CPU STOP mode. The supplied absolute value is assigned to the associated mechanical axis position by means of the absolute encoder adjustment. The absolute encoder adjustment must be performed once. The absolute value offset is retentively saved beyond the switching on/off of the controller.

Differentiation of absolute values:

- The measuring range of the encoder is larger than the traversing range of the axis:

  Absolute value with setting absolute
- The measuring range of the encoder is smaller than the traversing range of the axis:

  Absolute value with setting cyclic absolute

Absolute actual value with setting absolute (measuring range > traversing range)

The axis position results directly from the current actual encoder value. The traversing range must be within an encoder measuring range. This means that the zero passage of the encoder must not be located in the traversing range.

When the controller is switched on, the axis position is determined from the absolute actual encoder value.

Absolute actual value with setting cyclic absolute (measuring range < traversing range)

The encoder supplies an absolute value within its measuring range. The controller includes the traversed measuring ranges and thus determines the correct axis position beyond the measuring range.

When the controller is switched off, the traversed measuring ranges are saved in the retentive memory area of the controller.
At the next power-on, the saved traversed measuring ranges are taken into account in the calculation of the actual position value.

NOTICE
Movements of the axis while the controller is switched off can skew the actual value
If the axis or the encoder is moved by more than half of the encoder measuring range while the controller is switched off, then the actual value in the controller is no longer in accord with the mechanical axis position.

Absolute value adjustment (Page 85)

Tags

The tags named in the Homing (Page 87) section are relevant for adapting actual values.

3.2.5.4 Automatic transfer of drive and encoder parameters in the device

Identical reference values for the drive and encoder connections must be set in the controller and in the drive and encoder for the operation.

The speed setpoint NSET and the actual speed value NACT are transferred in the PROFIdrive telegram as a percentage of the reference speed. The reference value for the speed must be set identically in the controller and in the drive.

The resolution of the actual value in the PROFIdrive telegram must likewise be set identically in the controller and in the drive and encoder modules

Automatic transfer of parameters

The drive and encoder parameters can be automatically applied in the CPU for the following drives and encoders.

- SINAMICS drives (see compatibility list (Page 555))
- PROFIdrive encoder as of product version A16

The corresponding parameters are transferred after the (re-)initialization of the technology object or (re)start of the drive and the CPU. Changes in the drive configuration are transferred after restart of the drive or technology object.

Successful transfer of the parameters can be checked in the controller in the value of the tags of the technology objects <TO>.StatusDrive.AdaptionState = 2 and <TO>.StatusSensor[n].AdaptionState = 2.

Parameters

The controller settings are made in the TIA Portal under "Technology object > Configuration > Hardware interface > Data exchange with the drive/encoder".

The drive and encoder settings are made in the configuration or the respective hardware.

The following table compares the settings in the TIA Portal, in the controller and the corresponding drive/encoder parameters:

Setting in the TIA Portal	Controller tag in the technology data block	Drive parameter	Automatic transfer
Drive			
Telegram number	Telegram input address <TO>.Actor.Interface.AddressIn Telegram output address <TO>.Actor.Interface.AddressOut	Telegram number P922	-

3.2.5.5 Safety functions in the drive

Safety functions ("Safety Integrated Basic Functions") in the SINAMICS drive are safety-oriented, internal drive functions with the goal of shutting down the respective drive safely. In addition, additional safety functions are available to monitor definable limits ("Safety Integrated Extended Functions"). The goal of these safety functions is to monitor that the respective limit is maintained, to signal the violation or to subsequently shut down the drive safely. To prevent the monitoring function from being triggered, it is necessary to switch the axis to the monitored operating mode with the user program or to keep it in this mode.

The cooperation of the safety functions in the drive and the SIMATIC S7-1500 and S7-1500T are necessary to ensure fault-free plant operation.

The technology objects speed axis, positioning axis and synchronous axis support the "Safety Integrated Basic Functions" of the drive. The technology object detects that the Basic Safety function is triggered and displays a corresponding warning (technology alarm 550 - alarm response: Track setpoints) or alarm (technology alarm 421 - alarm response: Remove enable).

No additional response must take place in the user program, especially for technology alarm 550, at the "Enable" input of the Motion Control instruction "MC_Power" in the sense of a "shutdown". Shutdown of the Motion Control instruction "MC_Power" by the user after technology alarm 421 is possible but not necessary.

After acknowledgment and release of the drive by the actual safety function, the technology alarm can also be acknowledged at the respective technology object with the Motion Control instruction "MC_Reset". The technology object is then enabled automatically, if "MC_Power.Enable" is still "TRUE".

The "Safety Integrated Extended Functions" are **not** supported by the technology object independently.

To prevent the extended safety functions from being triggered and thus preventing a disruption in plant operation, we recommend that you evaluate the status of the safety functions. This evaluation can take place in the user program by using or evaluating the status information of the "Safety Info Channels" (SIC). With the help of the corresponding Motion Control instruction, the axis can now stay within the monitored limit or reach it before a deviation is detected.

If a safety function is applied to a following axis in active synchronous operation, one of the following two responses is required:

- End synchronous operation
- Adjust velocity of the leading axis accordingly

Four status words are available in the SIC:

- S_ZSW1B
- S_ZSW2B
- S_ZSW3B
- S_V_LIMIT_B

Two predefined PROFIdrive telegrams are available for transmission:

- Tel. 700 (contains the status words S_ZSW1B & S_V_LIMIT_B)
- Tel. 701 (contains all four status words and two additional control words)

Additional information

Additional information on the safety functions in SINAMICS drives and on the SIC is available in the SINAMICS S120 Safety Integrated Function Manual.

https://support.industry.siemens.com/cs/document/99668646 (https://support.industry.siemens.com/cs/ww/en/view/99668646)

The tables below provide an overview of the four SIC status words and the required response for each to prevent faults in plant operation.

S_ZSW1B

S_ZSW1B		Meaning		Recommended response of the respective axis in the user program
Bit	Assignment			
0	STO (active)	1	Safe Torque Off active	MC_Power can remain enabled (waiting).
		0	Not active	None
1	SS1 (active)	1	Safe Stop 1 active	Drive brakes autonomously and goes into STO. MC_Power remains enabled until STO.
		0	Not active	None
2	SS2 (active)	1	Safe Stop 2 active	Drive brakes autonomously and goes into SOS. MC_Power remains enabled.
		0	Not active	None
3	SOS (active)	1	Safe Operating Stop active	MC_Power remains enabled. The drive must not move (monitoring takes place in the drive)
		0	Not active	None
4	SLS (active)	1	Safety-Limited Speed active	MC_Power remains enabled. Velocity must be less than active velocity limit (see "Active SLS stage" or S_V_LIMIT_B).
		0	Not active	None
5	SOS (selected)	1	Safe Operating Stop selected	MC_Power remains enabled. Braking with MC_Halt within the time permitted by SOS.
		0	Deselected	None
6	SLS (selected)	1	Safety-Limited Speed selected	Drop below velocity limit within the time specified by SLS. For example, by specifying an override or a new dynamic limit (restriction with synchronous motion).
		0	Deselected	None
7	Internal event	1	Group alarm that a safety function was selected or became active	Additional evaluation of the status words required to determine the triggering safety function. The bit indicates that a safety function is active. (See also "Safety alarm")
		0	No event	None
8	Reserved	-		-

S_ZSW1B Bit	Assignment	Meaning		Recommended response of the respective axis in the user program
9	Active SLS level	SLS velocity limit Display bit 0		Additional information on SLS (bit 6) – shows active velocity limit for SLS in levels (1… 4). This limit can be evaluated in the program to limit the current velocity of the axis as needed.
10		SLS velocity limit Display bit 1		
11	Reserved	-		-
12	SDI positive	1	Safe Direction positive selected	Reaching standstill or the positive velocity of the actual value of the axis (when SDI negative = 0) within the time specified by SDI.
		0	Deselected	None monitoring for positive direction.
13	SDI negative	1	Safe Direction negative selected	Reaching standstill or the negative velocity of the actual value of the axis (when SDI positive = 0) within the time specified by SDI.
		0	Deselected	None monitoring for negative direction.
14	ESR retraction	1	Extended stop and retraction required (not a Safety function)	To be considered individually. You can find additional information in the SINAMICS S120 Safety Integrated Function Manual. https://support.industry.siemens.com/cs/document/99668646 (https://support.industry.siemens.com/cs/ww/en/view/99668646)
		0	Not requested	None
15	Safety alarm	1	Effective	If necessary, evaluate bit as group alarm to see whether a Safety alarm is pending in the alarm buffer.
		0	Not effective	None

S_V_LIMIT_B

S_V_LIMIT_B Bit	Assignment	Meaning	Explanation
0 … 31	Velocity setpoint limit	SLS Speed limit (32-bit resolution with sign)	Additional information on SLS (S_ZSW1B bit 6) Shows the selected / active velocity limit for SLS. If necessary, the velocity limit can be evaluated in the program to limit the current velocity of the axis as needed.

S_ZSW2B

S_ZSW2B		Meaning		Recommended response of the respective axis
Bit	Assignment			
0 … 3	Reserved	-		-
4	SLP selected position area	1	SLP area 2 selected	Safe position in the area 2. Do not change the position using the user program any longer.
		0	SLP area 1 selected	Safe position in the area 1. Do not change the position using the user program any longer.
5, 6	Reserved	-		-
7	SLP selected and user approval set	1	Safety-Limited Position selected and user approval is set	Status message (if required in the user program) Application-dependent evaluation (means that the SLP is selected and the safe position was confirmed by the user – see "Safe homing")
		0	SLP not selected or user approval missing	Application-dependent evaluation
8	SDI positive	1	Safe Direction positive selected	Reaching standstill or the positive velocity of the actual value of the axis within the time specified by SDI. (when SDI negative = 0)
		0	Deselected	None monitoring for positive direction
9	SDI negative	1	Safe Direction negative selected	Reaching standstill or the negative velocity of the actual value of the axis within the time specified by SDI. (when SDI positive = 0)
		0	Deselected	None monitoring for negative direction
10, 11	Reserved	-		-
12	Test stop active	1	Test stop active	Status message (if required in the user program) Application-dependent evaluation
		0	Not active	None
13	Test stop required	1	Test stop required	Perform test stop
		0	Not required	None
14, 15	Reserved	-		-

S_ZSW3B

S_ZSW3B		Meaning		Recommended response of the respective axis
Bit	**Assignment**			
0	Brake test	1	Brake test selected	MC_Power remains enabled. Do not start travel motion with user program.
		0	Deselected	None – brake test is inactive (normal plant operation)
1	Setpoint value specification drive / external	1	Specification for drive	The speed setpoint is specified by the SBT function. Application-dependent evaluation
		0	External specification (control)	The "normal" speed setpoint is in effect. Application-dependent evaluation – setpoint value specification through user program required
2	Active brake	1	Test brake 2 active	Status message (if required in the user program) Application-dependent evaluation
		0	Test brake 1 active	Status message (if required in the user program) Application-dependent evaluation
3	Brake test active	1	Test active	Status message (if required in the user program) Application-dependent evaluation
		0	Inactive	None
4	Brake test result	1	Test required	Status message (if required in the user program) Application-dependent evaluation
		0	With error(s)	Status message (if required in the user program) Application-dependent evaluation, test must usually be successful to guarantee safety of the brake.
5	Brake test complete	1	Run test	Status message (if required in the user program) Application-dependent evaluation
		0	Incomplete	Status message (if required in the user program) Application-dependent evaluation, usually test is repeated
6	External brake request	1	Closing the brake	Closing external brake (when controlled by user program) Application-dependent evaluation
		0	Opening the brake	Opening external brake (when controlled by user program) Application-dependent evaluation
7	Current load sign	1	Negative sign	Status of the load sign if required in the user program Application-dependent evaluation
		0	Positive sign	
8 … 13	Reserved	-		-
14	Acceptance test SLP(SE) selected	1	Acceptance test SLP(SE) selected	Status message (if required in the user program) Application-dependent evaluation
		0	Deselected	None
15	Acceptance test mode selected	1	Acceptance test mode selected	Status message (if required in the user program) Application-dependent evaluation
		0	Deselected	None

3.2.5.6 Axis in simulation

S7-1500 Motion Control offers the option to move real axes in simulation mode. Speed, positioning and synchronous axes can thus be simulated without a connected drive and encoder in the CPU.

When the simulation mode is activated, the drive and encoder connection does not need to be configured in the axis configuration, for example, if the drive configuration is not yet available at this time. The "Simulation" configuration can be changed during runtime of the user program (<TO>.Simulation.Mode). A valid drive and encoder connection is required when exiting the simulation.

To use a technology object in simulation mode or with SIMATIC S7 PLCSIM, you need to use encoder 1 for closed loop position control of the axis.

Applications

- For example, an axis is simulated for programming the machine application and assigned to the configured hardware later for commissioning.
- During commissioning, for example, not all hardware components are available.
- No axis motions should take place during commissioning.

Characteristics in simulation mode

An axis in simulation does not output setpoints to the drive and does not read any actual values of the encoder. The actual values (Page 39) are formed with a time delay from the setpoints.

Hardware limit switches and home position switches have no effect.

The technology objects measuring input (with signal detection via TM_Timer_DIDQ or SINAMICS measurement sensing input), output cam and cam track can also be used for axes in simulation.

The following table shows the Motion Control instructions with adapted behavior in simulation mode:

Motion Control instruction	Characteristics in simulation mode
MC_Power	The axis is enabled immediately without waiting for feedback from the drive.
MC_Home	Homing jobs are executed immediately without simulated axis motion.
MC_TorqueLimit	The specified torque is not output to the drive.

3.2.5.7 Virtual axis

S7-1500 Motion Control offers the possibility to configure an axis as a virtual axis. A virtual axis has motion control, but, in contrast to real axes, no drive and encoder connection. The setpoints are only processed within the controller and no real drive is controlled.

Application:

A virtual axis, for example, is often used as a virtual leading axis in order to generate the setpoints for several real following axes in synchronous operation.

The "Virtual axis" configuration can only be changed by a new download to the CPU (in STOP mode) (<TO>.VirtualAxis.Mode).

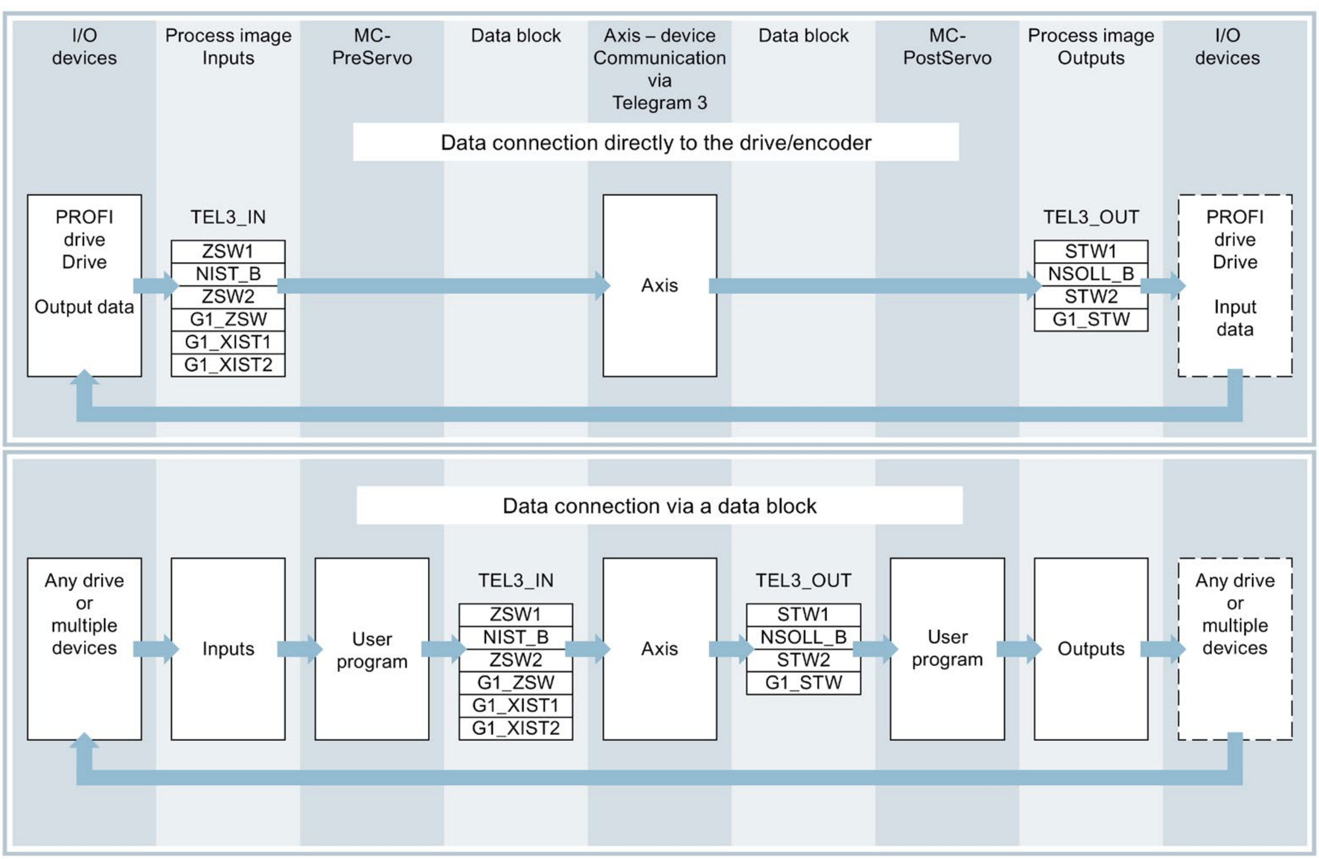
The behavior of a virtual axis is identical to the behavior of an axis in simulation (Page 49).

3.2.5.8 Data connection drive/encoder via data block

The data connection of PROFIdrive drives and encoders occurs either directly via the PROFIdrive telegram or via a data block.

Use the system-generated tags of the PROFIdrive telegrams if you want to evaluate the telegram contents.

Use the connection via data block if you want to influence or evaluate telegram contents in the user program for process-specific reasons.



Principle of data connection via data block

Generally, at the start of closed loop position control of the axis (by MC-Servo [OB91]), the input area of the drive or encoder telegram is read.

At the end of closed loop position control, the output area of the drive or encoder telegram is written.

To influence or evaluate telegram contents for process-specific reasons, a data interface via a data block must be connected in between before and after the closed loop position control.

- The input area of the telegram can be edited using the MC-PreServo [OB67] organization block. The MC-PreServo is called before the MC-Servo.
- The input area of the telegram can be edited using the MC-PostServo [OB95] organization block. The MC-PostServo is called after the MC-Servo.

The data block must be created by the user and contain a data structure of data type "PD_TELx" for the data connection. Here, "x" stands for the telegram number of the drive or encoder configured in the device configuration.

The organization blocks MC-PreServo and MC-PostServo can be programmed by the user and must be added with the command "Add new block". The connection to the I/O via telegram must be programmed in this organization block. When you use DSC you have to edit the signs of life in the telegrams in MC-PreServo and MC-PostServo yourself according to the PROFIdrive standard.

3.2.5.9 Tags

The following technology object tags are relevant for the drives and encoder connections:

Drive telegram	
<TO>.Actor.Interface.AddressIn	Input address for the PROFIdrive telegram
<TO>.Actor.Interface.AddressOut	Output address for the PROFIdrive telegram or the analog setpoint
<TO>.Actor.DriveParameter.Reference Speed	Reference value (100%) for the speed setpoint (NSET) of the drive
<TO>.Actor.DriveParameter.MaxSpeed	Maximum value for the speed setpoint of the drive (NSET)
<TO>.Actor.DriveParameter.Reference Torque	Reference torque for the torque transferred as a percent-age
Encoder telegram	
<TO>.Sensor[n].Interface.AddressIn	Input address for the PROFIdrive telegram
<TO>.Sensor[n].Interface.AddressOut	Output address for the PROFIdrive telegram
<TO>.Sensor[n].System	Encoder system linear or rotary
<TO>.Sensor[n].Type	Encoder type, incremental, absolute or cyclic absolute
<TO>.Sensor[n].Parameter.Resolution	Resolution for linear encoder The grid spacing corresponds to the distance between two marks.
<TO>.Sensor[n].Parameter.StepsPer Revolution	Steps per revolution for rotary encoder
<TO>.Sensor[n].Parameter.Determinable Revolutions	Number of differentiable encoder revolutions for a multi-turn absolute encoder
Fine resolution	
<TO>.Sensor[n].Parameter.Fine ResolutionXist1	Number of bits for fine resolution XIST1 (cyclic actual encoder value)
<TO>.Sensor[n].Parameter.Fine ResolutionXist2	Number of bits for fine resolution XIST2 (absolute value of encoder)
Simulation mode	
<TO>.Simulation.Mode	Simulation mode 0: No simulation, normal operation 1: Simulation mode

3.2.6 Mechanics

3.2.6.1 Brief description

For the display and processing of the technology object's position, the decisive factor is whether the position is represented as a unit of length (linear axis) or a unit of angle (rotary axis).

Examples of units of length: mm, m, km

Examples of units of angle: °, rad

For the determination of the physical position from an actual encoder value, the system must know the various properties and configurations of the mechanics.

Positioning axis/synchronous axis

The following configuration options for mechanics are supported:

- Load gear
- Leadscrew pitch (linear axes only)
- Encoder mounting type:
  - Motor side (before the load gear)
  - Load side (after the load gear and as applicable the leadscrew)
  - External (e.g. odometer)
- Inversion of drive direction
- Inversion of encoder direction

External encoder

The following configuration options for mechanics are supported:

- Measuring gear (for rotary encoders)
- Leadscrew pitch (only with linear system of units and rotary encoders)
- Inversion of encoder direction

Speed axis

The following configuration options for mechanics are supported:

- Load gear
- Inversion of drive direction

3.2.6.2 Tags

The following technology object tags are relevant for the setting of the mechanics:

Type of motion	
<TO>.Properties.MotionType	Indication of linear or rotary motion 0: Linear motion 1: Rotary motion
Load gear	
<TO>.LoadGear.Numerator	Load gear numerator
<TO>.LoadGear.Denominator	Load gear denominator
Leadscrew pitch	
<TO>.Mechanics.LeadScrew	Leadscrew pitch
Encoder mounting type	
<TO>.Sensor[n].MountingMode	Encoder mounting type
<TO>.Sensor[n].Parameter.DistancePerRevolution	Load distance per encoder revolution with an externally mounted encoder
Inversion	
<TO>.Actor.InverseDirection	Setpoint inversion
<TO>.Actor.Efficiency	Efficiency of leadscrew pitch
<TO>.Sensor[n].InverseDirection	Actual value inversion
Modulo	
<TO>.Modulo.Enable	Enable modulo
<TO>.Modulo.Length	Modulo length
<TO>.Modulo.StartValue	Modulo start value

3.2.7 Traversing range limitation

3.2.7.1 Brief description

Hardware and software limit switches limit the permissible traversing range and operating range of the positioning axis/synchronous axis. Before use, they must be enabled in the configuration or in the user program.

The following figure shows the relationship between the operating range, maximum traversing range and limit switches:

①	Mechanical endstop
②	Hardware limit switches
③	Software limit switches
④	Maximum traversing range
⑤	Operating range

3.2.7.2 Hardware limit switches

Hardware limit switches are limit position switches that limit the maximum permissible traversing range of the axis.

Select the positions of the hardware limit switches so that there is adequate braking distance for the axis when needed. The axis should come to a standstill before a mechanical endstop.

Approaching the hardware limit switches

In the monitoring of range limitation, no distinction is made as to whether the switches are reached or crossed.

If a hardware limit switch is reached, technology alarm 531 is output, and the technology object is disabled (alarm response: remove enable).

Exception

If the hardware limit switches are used as reversing cams or reference cams during homing, then the monitoring of the hardware limit switches has no effect.

When hardware limit switches are used as reversing cams, the axis is braked with the deceleration configured in the dynamic defaults.

This must be taken into account when planning the distance of the hardware limit switch to the mechanical endstop.

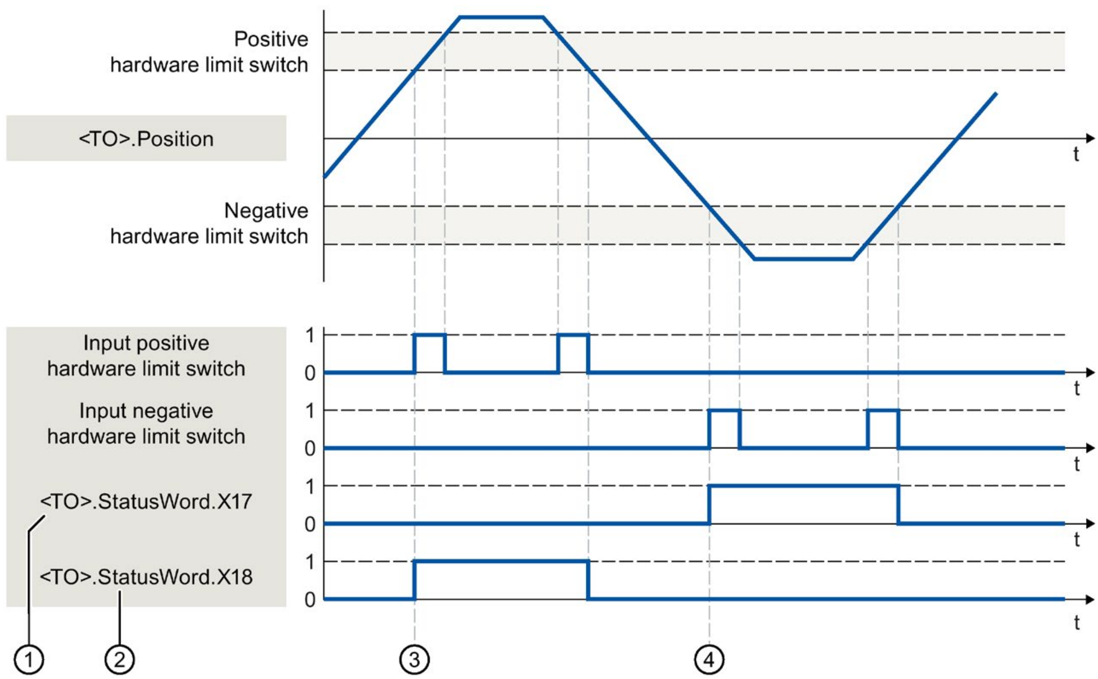
Retracting

The position of the axis when the hardware limit switch is detected is stored internally on the CPU. The status of the reached hardware limit switch is reset only after the hardware limit switch is left and the axis is once again in the maximum traversing range.

To retract the axis after it reaches the hardware limit switch and to reset the status of the hardware limit switch, follow the steps below:

1. To enable motion in the retraction direction, acknowledge the technology alarm.
2. Traverse the axis in the retraction direction until the hardware limit switch is left.
   The axis must then be within the maximum traversing range.
   If you move the axis opposite the retraction direction before the hardware limit switch is left, the monitoring will be triggered again.

The following chart shows the behavior of the status word when the hardware limit switch is reached and when the axis is retracted:



① <TO>.StatusWord.X17 (HWLimitMinActive)
0: Negative hardware limit switch not reached
1: Negative hardware limit switch reached or overtraveled

② <TO>.StatusWord.X18 (HWLimitMaxActive)
0: Positive hardware limit switch not reached
1: Positive hardware limit switch reached or overtraveled

③ The position of the axis when the **positive** hardware limit switch is detected is saved internally in the CPU. To reset the status of the hardware limit switch, the axis position must fall short of this position.

④ The position of the axis when the **negative** hardware limit switch is detected is saved internally in the CPU. To reset the status of the hardware limit switch, the axis position must go past this position.

3.2.7.3 Software limit switch

The operating range of the axis is limited with software limit switches. Relative to the traversing range, always position the software limit switches within the hardware limit switches. Since the positions of the software limit switches can be flexibly configured, the operating range of the axis can be individually adapted in accordance with the current velocity profile.

Software limit switches are only in effect when there is a valid actual value after homing the technology object. The monitoring of the software limit switches is relative to the setpoint.

Modulo enabled

With modulo enabled, the modulo position is monitored.

The software limit switches are configured and activated in the axis configuration. The software limit switches can be activated or deactivated in the user program using the <TO>.PositionLimits_SW.Active tag, If the positions of both software limit switches are outside the modulo range, the monitoring has no effect. No check is made to determine whether the positions of the software limit switches are within the modulo range.

Approaching the software limit switches

The axis continually checks the position of the software limit switch during motion and brakes to exactly this position, if necessary.

If the software limit switches are reached, then technology alarm 533 is output, and the axis is stopped with the maximum dynamic values (alarm response: Stop with maximum dynamic values). The technology object remains enabled.

Overrun of the software limit switches

If a software limit switch is crossed, technology alarm 534 is output, and the technology object is disabled (alarm response: remove enable).

Retracting

To retract the axis after violation of the software limit switch, follow the steps below:

1. Acknowledge the technology alarm.
2. Move the axis in the retraction direction until the software limit switch is left.

   If you move the axis opposite the retraction direction before the software limit switch is left, the monitoring with be triggered again.

3.2.7.4 Tags

The following technology object tags are relevant for software limit switches:

Status indicators	
<TO>.StatusWord.X15 (SWLimitMinActive)	Negative software limit switch is active
<TO>.StatusWord.X16 (SWLimitMaxActive)	Positive software limit switch is active
<TO>.ErrorWord.X8 (SWLimit)	An alarm is pending, that a software limit switch was violated
Control bits	
<TO>.PositionLimits_SW.Active	Enables / disables the monitoring of the software limit switches
Position values	
<TO>.PositionLimits_SW.MinPosition	Position of the negative software limit switch
<TO>.PositionLimits_SW.MaxPosition	Position of the positive software limit switch

The following technology object tags are relevant for hardware limit switches:

Status indicators	
<TO>.StatusWord.X17 (HWLimitMinActive)	Negative hardware limit switch is active
<TO>.StatusWord.X18 (HWLimitMaxActive)	Positive hardware limit switch is active
<TO>.ErrorWord.X9 (HWLimit)	An alarm is pending; a hardware limit switch was violated
Control bits	
<TO>.PositionLimits_HW.Active	Enables / disables the monitoring of the hardware limit switches
Parameters	
<TO>.PositionLimits_HW.MinSwitchLevel	Level selection for activation of the low hardware limit switch: FALSE: At low level, the signal is active TRUE: At high level, the signal is active
<TO>.PositionLimits_HW.MinSwitchAddress	Byte number of the I/O address of the hardware limit switch for the low or minimum position
<TO>.PositionLimits_HW.MaxSwitchLevel	Level selection for activation of the high hardware limit switch: FALSE: At low level, the signal is active TRUE: At high level, the signal is active
<TO>.PositionLimits_HW.MaxSwitchAddress	Byte number of the I/O address of the hardware limit switch for the high or maximum position

3.2.8 Motion control and limits for dynamics

3.2.8.1 Brief description

Motion control of the axis occurs by means of velocity profiles (Page 60). The velocity profiles are calculated in accordance with the specifications for dynamics. A velocity profile defines the behavior of the axis during approach, braking and changes in velocity. During positioning a velocity profile is calculated, that moves the axis to the target point.

Maximum values for velocity, acceleration and jerk result from the properties of the drive and the mechanics. These maximum values can be configured in the limits for dynamics. The limits for dynamics are in effect as limits for every motion generated by means of the technology object. The dynamic limits have no effect on a following axis in synchronous operation.

The configurable emergency stop deceleration (Page 62) is triggered by the Motion Control instruction MC_Power or by a technology alarm.

The jerk limit reduces the mechanical load during an acceleration ramp or deceleration ramp. A "smoothed" velocity profile results.

See also

Dynamic limits in synchronous operation (Page 62)

3.2.8.2 Velocity profile

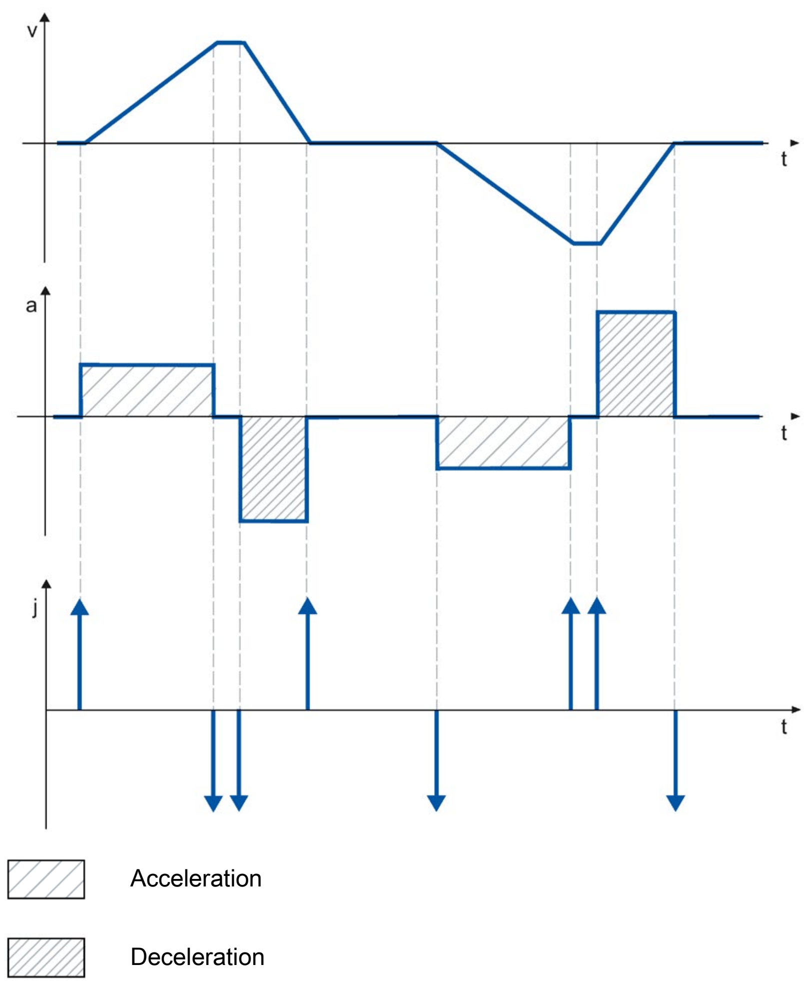
Velocity profiles with or without jerk limitation are supported for motion control of the axis.

The dynamic values for the motion are specified in the Motion Control job. Alternatively, the values of the dynamic defaults (Page 207) can be used. The defaults and the limits for velocity, acceleration, deceleration and jerk are set in the configuration.

To influence velocity, a velocity override can override the current traversing velocity.

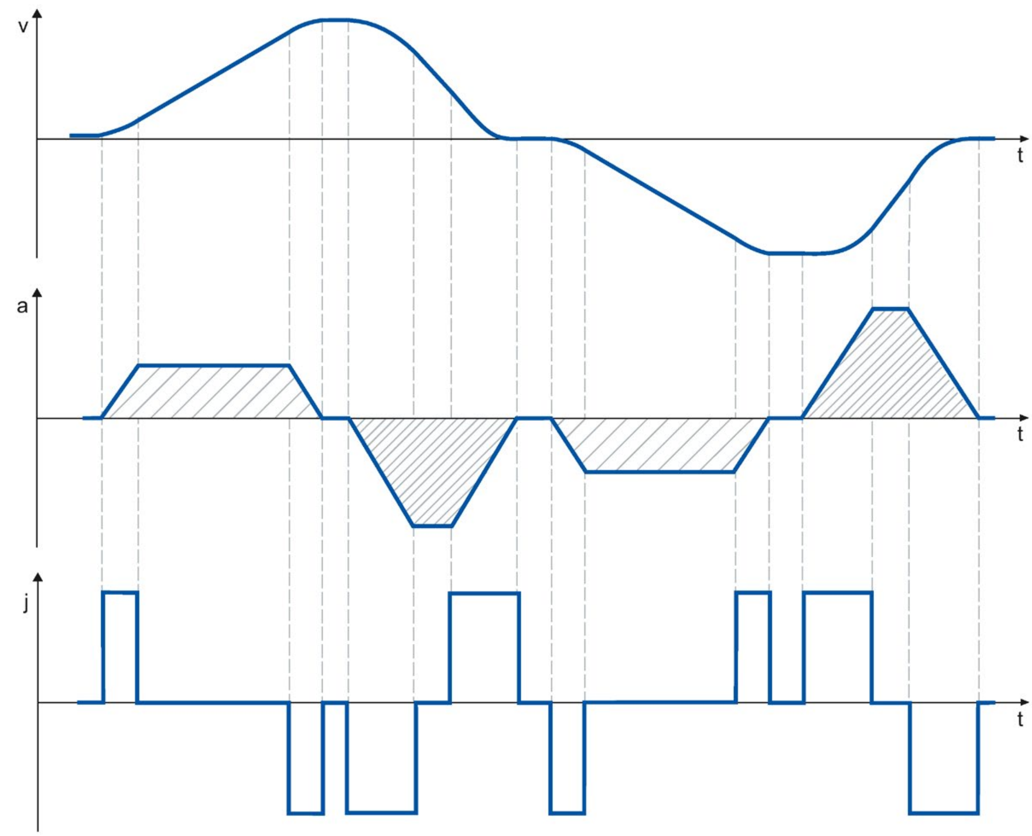
Velocity profile without jerk limitation

The following figure shows velocity, acceleration and jerk:



Velocity profile with jerk limitation

The following figure shows velocity, acceleration and jerk:



Acceleration

Deceleration

A velocity profile with jerk limitation is employed for a continuous acceleration and deceleration sequence. The jerk can be specified.

3.2.8.3 Emergency stop deceleration

When stopping with the emergency stop ramp, the axis is braked to a standstill without a jerk limit, using the configured emergency stop deceleration.

In the following cases the configured emergency stop deceleration is in effect:

- For an emergency stop ramp that has been enabled via the Motion Control instruction "MC_Power" with parameter "StopMode" = 0.
- For a technology alarm with the local alarm response "Stop with emergency stop ramp".

This emergency stop deceleration can be set greater than the maximum deceleration. If the emergency stop deceleration is set lower than this, it may occur that the axis does not stop until after the limit switch in the case of "Stop at software limit switch" and the occurrence of a technology alarm with the local alarm response "Stop with emergency stop ramp".

3.2.8.4 Dynamic limits in synchronous operation

Dynamic limits in synchronous operation with MC_GearIn

Leading axis

The dynamic limits configured for the technology object are always in effect for the leading axis.

Following axis

If a synchronous axis is operated as a following axis in synchronous operation with MC_GearIn, the following dynamic limits apply depending on the phase of the synchronous operation.

- Synchronization

  During the synchronizing phase, dynamic limits configured for the technology object apply to the following axis.

- Synchronous motion

  When the synchronous axis is moving synchronously to the leading axis as a following axis, the dynamic of the following axis is limited only to the maximum speed of the drive (<TO>.Actor.DriveParameter.MaxSpeed). The dynamics of the following axis results from the synchronous operation function.

  If the dynamic limits configured for the following axis are exceeded, this will be indicated in the technology object tag <TO.>StatusSynchronizedMotion.StatusWord.

  If the following axis cannot follow the leading value, this results in a following error, which is monitored by the following error monitoring.

- Synchronous operation override

  As soon as synchronous operation has been overridden, the dynamic limits configured for the technology object apply to the following axis again. With the start of the overriding job, the active dynamics is transitioned (smoothed) to the configured dynamic limits and the specifications for the Motion Control instruction.

StatusSynchronizedMotion tags (synchronous axis) (Page 469)

Override response V4: Synchronous operation jobs (Page 429)

3.2.8.5 Torque limits

Force/torque limiting

Adjustable force/torque limiting is available for the speed axis, positioning axis and synchronous axis technology objects. The force/torque limiting can be activated and deactivated before and during a motion job. To use force/torque limiting, the drive and the PROFIdrive telegram must support torque reduction. A telegram 10x can be used.

The limit value can be configured as a default value during configuration of the axis or it can be defined in the user program using Motion Control instruction "MC_TorqueLimiting".

The user specifies the limiting values in the configured unit of measure for force or torque. The units of measure are defined in the "Basic parameters" configuration window.

The following configuration options are available for force/torque limiting.

- **"Linear" axis type**
  - Torque limiting is active on motor side
  - Force limiting is active on the load side
- **"Rotary" axis type**
  - Torque limiting is active on load side or motor side

The force/torque limit defined by the user in accordance with the specification in the PROFIdrive telegrams 10x are transferred internally to the drive as a percentage torque reduction. The reference torque set in the "Data exchange with the drive" configuration dialog must match the reference torque set for the drive.

Linear axis type

Load-side force limitation you have defined is converted by the technology into torque reduction. If the limiting relates to the load side, the gear and leadscrew parameters defined in the "Mechanics" configuration dialog are taken into consideration. If the gear and leadscrew efficiency is crucial, you can set them in the <TO>.Actor.Efficiency tag.

Rotary axis type:

The torque is reduced on the load side with the rotary axis type. The gear parameters defined in the "Mechanics" configuration window are taken into consideration. If the efficiency of the gear is crucial, you can set them in the <TO>.Actor.Efficiency tag.

The defined limiting values act as an absolute value and thus in the same way for positive and negative forces/torques.

Positioning and following error monitoring with active force/torque limiting

As a result of force/torque limiting, a larger setpoint-actual value difference can build up for position-controlled axes, which may cause unwanted activation of the positioning and following error monitoring.

Therefore, in the "Torque limiting" configuration window, the positioning and following error monitoring of the axis can be set as deactivated by default when force/torque limiting is active. If necessary, the positioning and following error monitoring can also be kept active even when force/torque limiting is active.

Typical behavior of a positioning or synchronous axis with active force/torque limiting

With active force/torque limiting, a larger setpoint-actual value difference can build up than during motion without force/torque limiting.

Given a constant setpoint, the axis makes repeated attempts to reduce the following error.

When the limiting values are increased or limiting is deactivated during active closed loop position control, the axis can accelerate briefly to reduce the following error. If the axis is switched to non-position-controlled operation, e.g. using "MC_MoveVelocity" with "PositionControlled" = FALSE, the following error is no longer in effect.

Stopping an axis with active force/torque limiting

When stopping an axis in position-controlled mode with "MC_Halt", the position setpoint and the velocity setpoint are used as basis. Torque limiting still remains active and any accumulated following error is reduced. The axis is at a standstill when the actual velocity "0.0" is reached and the minimum dwell time in the standstill window has expired. The axis remains enabled.

When stopping an axis with "MC_Power" and an emergency stop ramp, the actual position value and the actual velocity are used as a basis. The axis is braked with the configured emergency stop deceleration without any jerk limit and brought to a standstill. The axis is then disabled when at a standstill.

When the limitation is deactivated the drive attempts to compensate for the resulting following error with maximum dynamic values. To avoid this reaction, use "MC_MoveVelocity" with deactivated closed loop position control.

MC_TorqueLimiting: Activate and deactivate force/torque limit / fixed stop detection V4 (Page 417)

Fixed stop detection (Page 65)

Configuration - Torque limits (Page 190)

Configuration - Torque limits (Page 214)

Fixed stop detection

With the Motion Control instruction "MC_TorqueLimiting", you activate and monitor a fixed stop detection.

Together with a position-controlled motion job, a "Travel to fixed stop" can be realized. The operation is also referred to as clamping.

"Travel to fixed stop" can be used, for example, to move quills against the workpiece with a specified torque.

The fixed stop detection is configured in the configuration window "Extended parameters" > "Limits" > "Fixed stop detection".

The fixed stop detection is only possible in position-controlled operation of the axis.

If the drive and telegram support force/torque limiting, this is active during travel to fixed stop and for clamping.

Detection of the fixed stop using following error

If the drive is stopped by a mechanical fixed stop during a motion job, the following error is increased. When the following error configured in the configuration window "Extended parameters" > "Limits" > "Fixed stop detection" is exceeded, this is regarded as the fixed stop having been reached.

When following error monitoring is activated, the configured following error must be greater than the following error for fixed stop detection.

Clamping at the mechanical endstop

When the fixed stop is reached, the active position-controlled motion job is aborted with CommandAborted. The setpoint is no longer changed and the following error remains constant. The closed loop position control remains active and the monitoring of the configured "Positioning tolerance" is activated The drive is in "Clamping" state.

If the drive and frame support force/torque limiting, this continues to be active with active fixed stop detection. During clamping, the clamping force or clamping torque can be changed. The value in input parameter "Limit" of the Motion Control instruction "MC_TorqueLimiting" can be changed for this.

Monitoring of the clamping

If the actual position changes by a value greater than the configured "Positioning tolerance" during active clamping, this is regarded as the breaking away or turning back of the fixed stop. An alarm is triggered; the axis is disabled and the drive is stopped according to its configuration.

If the position setpoint is within the configured "Positioning tolerance", the breaking away or turning back of the fixed stop cannot be detected.

The configured position tolerance must be less than the configured following error for detection of clamping.

Retracting

Retracting from the fixed stop is only possible with a position-controlled motion job in the opposite direction to the fixed stop.

The "Travel to fixed stop" or "Clamping" function is ended when the "Positioning tolerance" is left in the retraction direction.

See also

Force/torque limiting (Page 63)

Configuration - Fixed stop detection (Page 215)

MC_TorqueLimiting: Activate and deactivate force/torque limit / fixed stop detection V4 (Page 417)

Additive setpoint torque

The Motion Control instruction "MC_TorqueAdditive" allows you to apply additional torque in the drive.

The additive setpoint torque is used for example in torque feedforward control or the specification of the tensile torque for winding applications.

The following requirements must be fulfilled to set the additive torque setpoint:

- SINAMICS drive (see compatibility list (Page 555))
- SIEMENS supplementary telegram 750 for transmitting the torque data to the drive

The additional torque can be either positive or negative. The value specified in the instruction is a technological value, not a percentage. Set the unit of measure for the torque at the axis (default value: Nm).

See also

MC_TorqueAdditive: Specify additive torque V4 (Page 422)

Permissible torque range

The Motion Control instruction "MC_TorqueRange" allows you to set torque limits for the drive.

The motion control instruction is used, for example, for winding applications in order to prevent the tearing of the material.

The following requirements must be fulfilled to set the torque data:

- SINAMICS drive (see compatibility list (Page 555))
- SIEMENS supplementary telegram 750 for transmitting the torque data to the drive

The value specified in the instruction is a technological value, not a percentage. Set the unit of measure for the torque at the axis (default value: Nm). If you invert the setpoints at the technology object of the axis, the values for the high and low torque limit are output inverted and reversed.

If the torque limitation is activated by specifying the high and low torque limit, the following monitorings and limits are deactivated:

- Following error monitoring
- Time limits for positioning monitoring
- Time limits for standstill monitoring

Monitoring remains in effect if you have selected the option "Leave position-related monitoring enabled" under "Technology object > Configuration > Extended parameters > Limits > Torque limiting".

3.2.9 Homing

3.2.9.1 Brief description

With homing, you create the relationship between the position in the technology object and the mechanical position. The actual position value in the technology object is assigned to a homing mark at the same time. This homing mark represents a known mechanical position.

With incremental actual values this process is called homing; with absolute actual values it is called absolute encoder adjustment.

Homing is a requirement for display of the correct position for the technology object and for absolute positioning.

Homing is activated with the Motion Control instruction "MC_Home".

Homing status

The technology object tag <TO>.StatusWord.X5 (HomingDone) indicates whether the axis or external encoder technology object is homed.

Type of homing

Homing can occur by means of an independent homing motion (active homing), the detection of a homing mark during a motion initiated on the user side (passive homing) or a direct position assignment.

A distinction is made between the following types of homing:

- **Active homing**

  Active homing initiates a homing movement and performs the necessary homing mark approach. When the homing mark is detected, the actual position is set to the value specified in MC_Home. It is possible to specify a home position offset. Retraction to the home position offset occurs automatically during the home position approach.

  When active homing starts, current traversing movements are aborted.

- **Passive homing**

  The homing job does not perform its own homing motion. When the homing mark is detected during a motion initiated on the user side, the actual position is set to the value specified in "MC_Home".

  Passive homing is also called homing on the fly.

- **Direct homing**

  With the homing job, the actual position is set directly to the value specified in "MC_Home" or is offset by this value.

- **Absolute encoder adjustment**

  The absolute encoder adjustment compares the existing absolute actual value with the value specified in "MC_Home".

Homing mode

Depending on the type of homing mark and homing mark search, a distinction is made among the following homing modes (Page 72):

- Homing with homing cam and zero mark via PROFIdrive telegram
- Homing with zero mark via PROFIdrive telegram
- Homing with digital input

3.2.9.2 Terms

Homing mark

A homing mark is an input signal, on whose occurrence a known mechanical position can be assigned to the actual values.

A homing mark can be:

- **A zero mark**

  The zero mark of an incremental encoder or an external zero mark is used as a homing mark.

  The zero mark is detected at the drive module or encoder module and transmitted in the PROFIdrive frame. Perform the setting and evaluation as an encoder zero mark or external zero mark at the drive module and encoder module.

- **An edge at the digital input**

  The negative or positive edge at a digital input is used as a homing mark.

Reference cam

If there are several zero marks in the traversing range, the reference cam is used to select a specific zero mark before or after the reference cam.

Homing mark position

This is the position assigned to the homing mark.

The homing mark position corresponds to the home position minus the home position offset.

Home position

At the end of the active homing motion, the axis arrives at the home position.

Home position offset

The difference between the home position and the homing mark position is the home position offset.

A home position offset only has an effect with active homing. The offset is traversed after the synchronization of the axis using the Motion Control instruction "MC_Home". For axes with modulo setting, the home position offset is always traversed with the direction setting for the shortest path.

Direction reversal at the hardware limit switch (reversing cam)

Hardware limit switches can be used as reversing cams in active homing. If the homing mark was not detected or was approached from the wrong side, the motion continues in the opposite direction after the reversing cam.

3.2.9.3 Homing mode

Various homing modes are available for the positioning axis/synchronous axis and external encoder technology objects with incremental encoders. The homing mode is set in the configuration.

Homing with homing cam and zero mark via PROFIdrive telegram

The system checks for when the reference cam is reached. After the reference cam has been reached and left again in the assigned homing direction, zero mark detection is enabled via the PROFIdrive telegram.

When the zero mark is reached in the pre-selected direction, then the actual position of the technology object is set to the homing mark position.

Homing with zero mark via PROFIdrive telegram

The system enables zero mark detection, as soon as the actual value of the technology object moves in the assigned homing direction.

When the zero mark is reached in the specified homing direction, the actual position of the technology object is set to the homing mark position.

Homing with digital input

The system checks the state of the digital input, as soon as the actual value of the axis or encoder moves in the assigned homing direction.

When the homing mark is reached (setting of the digital input) in the specified homing direction, the actual position of the technology object is set to the homing mark position.

Note

The digital inputs must be placed into the process image partition "PIP OB Servo".

The filter time of the digital inputs must be set smaller than the duration of the input signal at the reference point switch.

3.2.9.4 Active homing with homing cam and zero mark

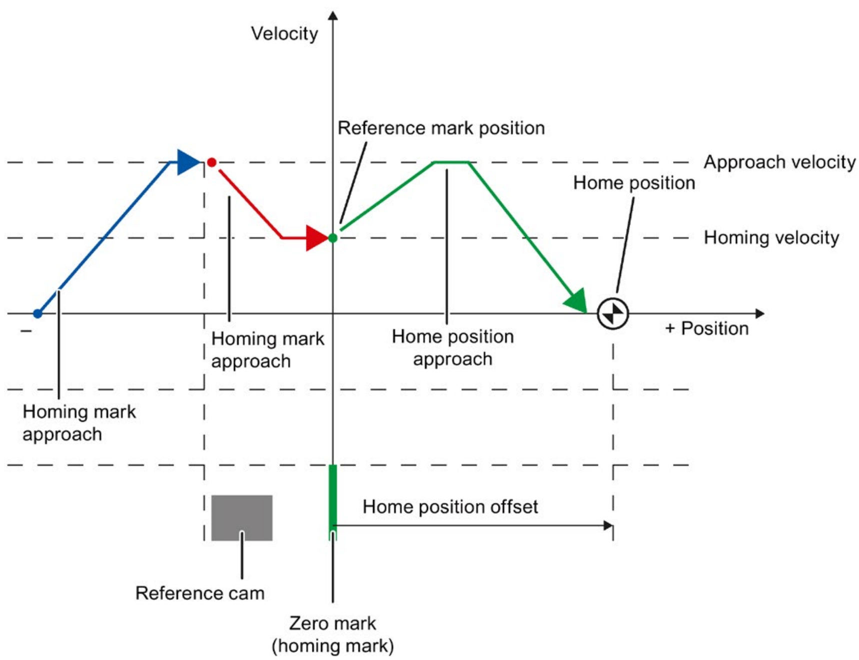
The following examples show homing motions in the positive and negative directions.

Example of homing in the positive direction

The approach to the homing mark and the home position occurs in the positive direction.

The following figure shows the homing motion with the following settings:

- Active homing with homing cam and zero mark
- Approach in the positive direction
- Homing in the positive direction
- Positive home position offset

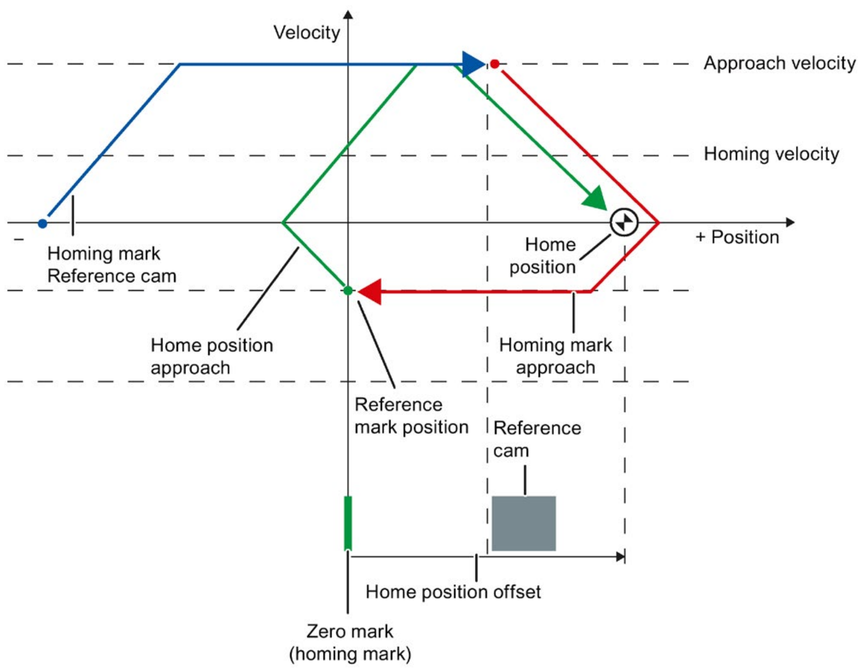


Example of homing in the negative direction

The approach to the homing mark occurs in the negative direction by means of a direction reversal during the homing process. The approach to home position causes another direction reversal and occurs in the positive direction.

The following figure shows the homing motion with the following settings:

- Active homing with homing cam and zero mark
- Approach in the positive direction
- Homing in the negative direction
- Positive home position offset



Motion sequence

The motion occurs in the following sequence:

1. Start of active homing via the "MC_Home" Motion Control instruction
2. Approach to reference cam
3. Detection of the reference cam in the homing direction and travel with homing velocity
4. Departure from the reference cam and travel to the homing mark

   With the departure from the reference cam, the detection of the homing mark is enabled.
5. Detection of the homing mark

   When the homing mark is detected, the position of the technology object is set depending on the configured mode:

   – Parameter "Mode" in "MC_Home" = 3

     Position = value in parameter "Position" minus <TO>.Sensor[n].ActiveHoming.HomePositionOffset

   – Parameter "Mode" in "MC_Home" = 5

     Position = value in the tag <TO>.Homing.HomePosition minus <TO>.Sensor[n].ActiveHoming.HomePositionOffset

   ---

   Note

   Parameter "MC_Home.Mode"

   The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

   ---
6. Approach to the home position

   – Parameter "Mode" in "MC_Home" = 3

     The axis moves to the position that is specified in the "Position" parameter.

   – Parameter "Mode" in "MC_Home" = 5

     The axis moves to the position that is specified in the <TO>.Homing.HomePosition tag.

   Note

   If the velocity cannot be reduced to the reference velocity between detection of the reference cam and the zero mark, homing is performed at the velocity present when the zero mark is crossed.

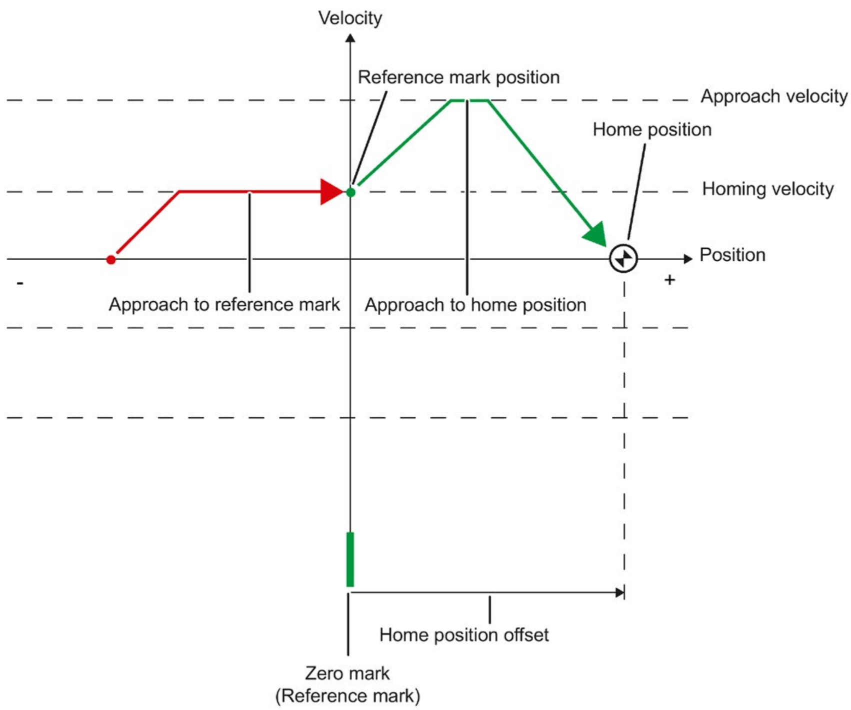
See also

Homing SINAMICS drives with external zero marks (Page 555)

3.2.9.5 Active homing with zero mark

The following figure shows an example of the homing motion with the following settings:

- Active homing with zero mark
- Homing in the positive direction
- Positive home position offset



Motion sequence

The motion occurs in the following sequence:

1. **Start of active homing via the Motion Control instruction "MC_Home"**
2. **Move to the homing mark in the homing direction with the homing velocity**
3. **Detection of the homing mark**

   When the homing mark is detected, the position of the axis or encoder is set depending on the configured mode:

   – Parameter "Mode" in "MC_Home" = 3

     Position = value in parameter "Position" minus
     <TO>.Sensor[n].ActiveHoming.HomePositionOffset

   – Parameter "Mode" to "MC_Home" = 5

     Position = value in the tag <TO>.Homing.HomePosition minus
     <TO>.Sensor[n].ActiveHoming.HomePositionOffset

Note

Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

4. **Move to homing point**
   - Parameter "Mode" in "MC_Home" = 3

     The axis moves to the position that is specified in the "Position" parameter.
   - Parameter "Mode" to "MC_Home" = 5

     The axis moves to the position that is specified in the <TO>.Homing.HomePosition tag.

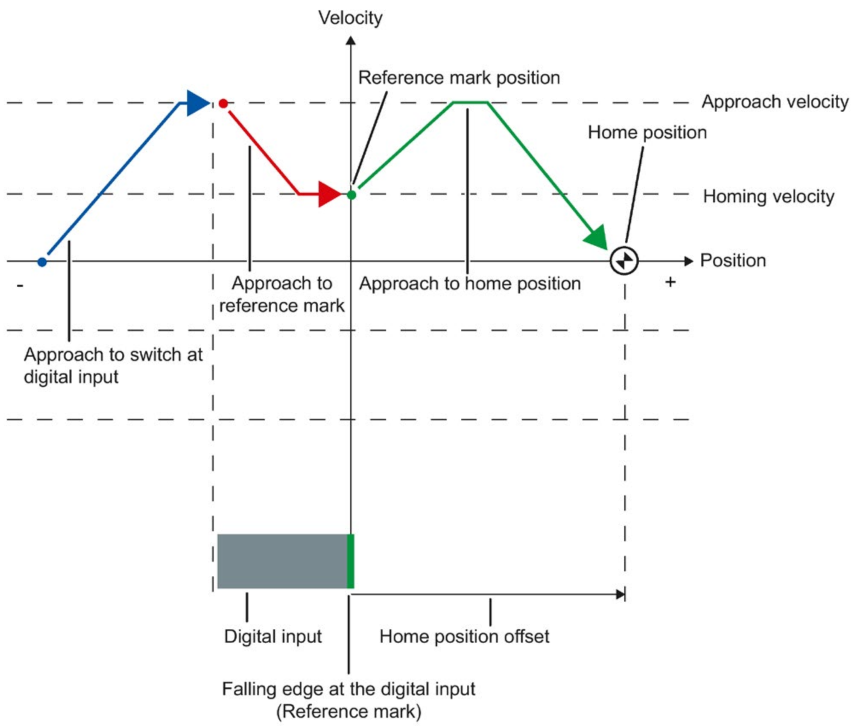
See also

Homing SINAMICS drives with external zero marks (Page 555)

3.2.9.6 Active homing with digital input

The following figure shows an example of the homing motion with the following settings:

- Active homing with digital input
- Approach in the positive direction
- Homing mark on the positive side of the digital input
- Positive home position offset



Motion sequence

The motion occurs in the following sequence:

1. **Start of active homing via the Motion Control instruction "MC_Home"**
2. **Detection of the positive edge at the digital input, while moving with homing velocity**
3. **Approach to the homing mark**

4. **Detection of the homing mark**

   In the example, the negative edge of the switch at the digital input represents the homing mark.

   When the homing mark is detected, the position of the axis or encoder is set depending on the configured mode:

   – Parameter "Mode" in "MC_Home" = 3

     Position = value in parameter "Position" minus <TO>.Sensor[n].ActiveHoming.HomePositionOffset

   – Parameter "Mode" in "MC_Home" = 5

     Position = value in the tag <TO>.Homing.HomePosition minus <TO>.Sensor[n].ActiveHoming.HomePositionOffset

---

Note

Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

---

5. **Move to homing point**

   – Parameter "Mode" in "MC_Home" = 3

     The axis moves to the position that is specified in the "Position" parameter.

   – Parameter "Mode" in "MC_Home" = 5

     The axis moves to the position that is specified in the <TO>.Homing.HomePosition tag.

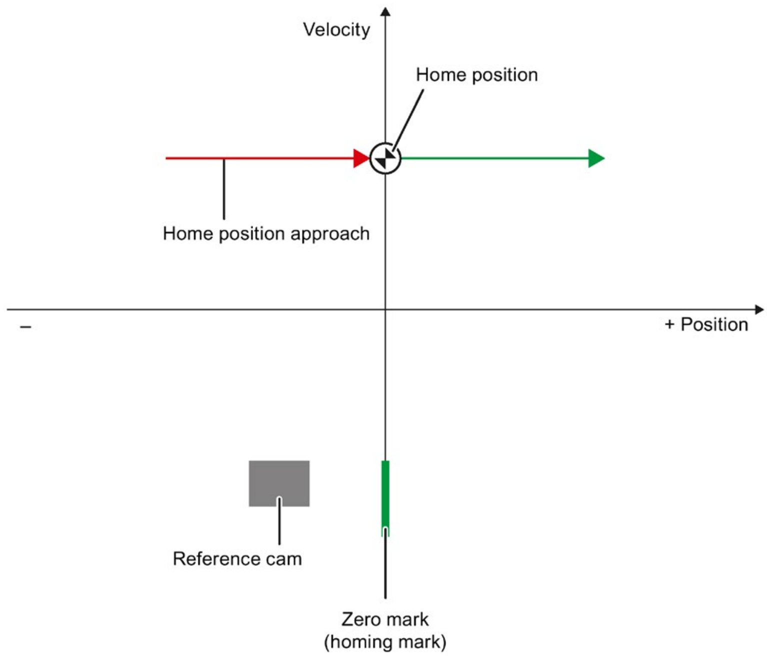
Note

If the velocity on the span from the detection of the positive edge to the negative edge cannot be reduced to the homing velocity, then homing occurs at the velocity that exists when the homing mark is traversed.

3.2.9.7 Passive homing with homing cam and zero mark

The following figure shows an example of the homing motion with the following settings:

- Passive homing with homing cam and zero mark
- Homing in the positive direction



Motion sequence

The motion occurs in the following sequence:

1. Activation of passive homing using the Motion Control instruction "MC_Home".
2. Motion due to a Motion Control job from the application

   The detection of the reference cam and homing mark is enabled when the actual position value of the axis or encoder moves in the assigned homing direction.
3. Detection of the reference cam
4. Departure from the reference cam

   The departure from the reference cam enables the detection of the homing mark.
5. Detection of the homing mark

   When the homing mark is detected, the position of the axis or encoder is set depending on the configured mode:

   – Parameter "Mode" in "MC_Home" = 2, 8

     Position = value in parameter "Position"

   – Parameter "Mode" in "MC_Home" = 10

     Position = value in tag <TO>.Homing.HomePosition

Note

Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

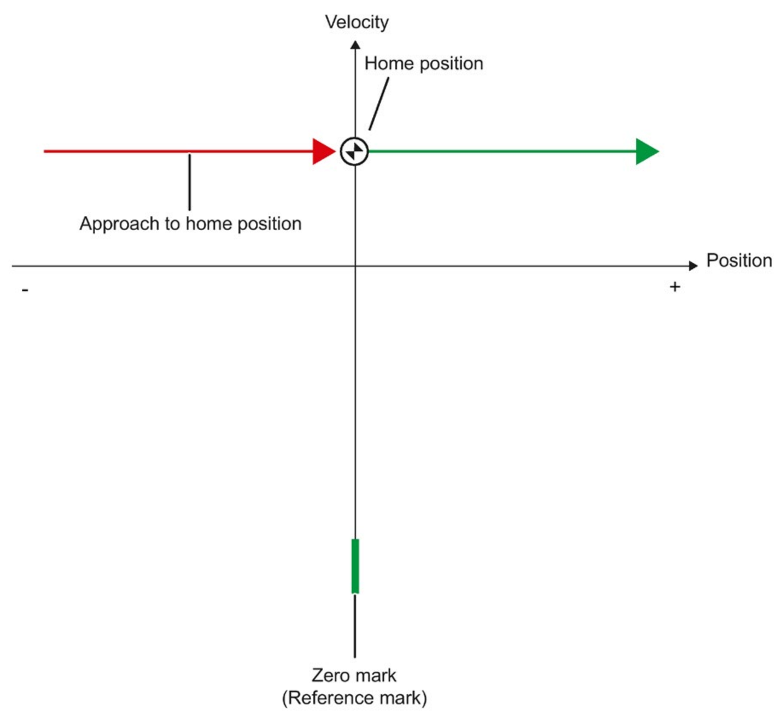
Note

If the motion direction changes after departure from the reference cam and before detection of the homing mark, the reference cam must be detected again. The Motion Control instruction "MC_Home" remains enabled.

3.2.9.8 Passive homing with zero mark

The following figure shows an example of the homing motion with the following settings:

- Passive homing with zero mark
- Homing in the positive direction



Motion sequence

The motion occurs in the following sequence:

1. **Enablement of passive homing via the Motion Control instruction "MC_Home".**
2. **Motion due to a Motion Control job from the application**

   The detection of the homing mark is enabled when the actual position value of the axis or encoder moves in the assigned homing direction.
3. **Detection of the homing mark**

   When the homing mark is detected, the position of the axis or encoder is set depending on the configured mode:

   – Parameter "Mode" to "MC_Home" = 2, 8

     Position = value in parameter "Position"

   – Parameter "Mode" to "MC_Home" = 10

     Position = value in tag <TO>.Homing.HomePosition

Note

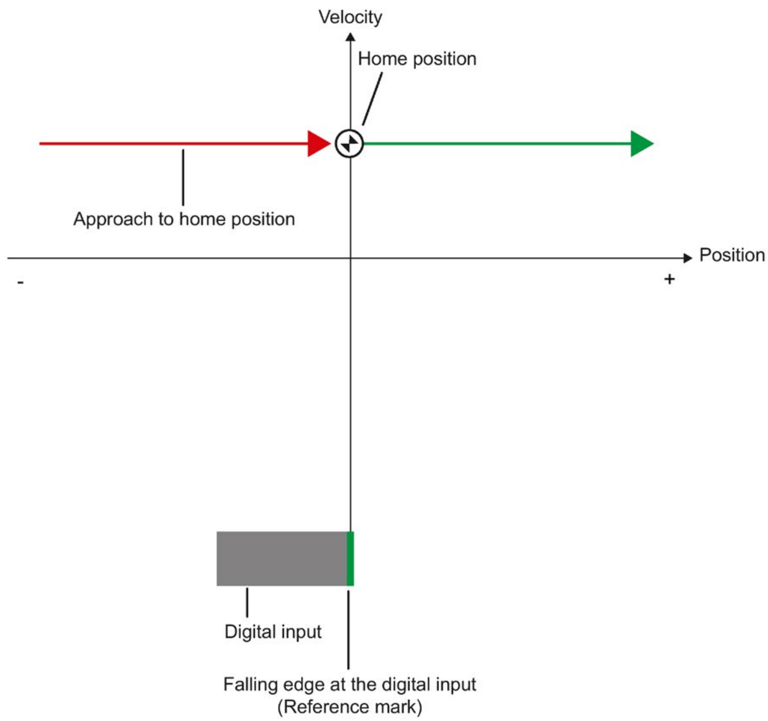
Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

3.2.9.9 Passive homing with digital input

The following figure shows an example of the homing motion with the following settings:

- Passive homing with digital input
- Homing in the positive direction
- Homing mark on the positive side of the digital input



Motion sequence

The motion occurs in the following sequence:

1. **Enablement of passive homing via the Motion Control instruction "MC_Home".**
2. **Motion due to a Motion Control job from the application**

   The detection of the homing mark at the digital input is enabled when the actual position value of the axis or encoder moves in the assigned homing direction.
3. **Detection of the homing mark**

   In the example, the falling edge of the switch at the digital input represents the homing mark.

   When the homing mark is detected, the position of the axis or encoder is set depending on the configured mode:

   – Parameter "Mode" to "MC_Home" = 2, 8

     Position = value in parameter "Position"

   – Parameter "Mode" to "MC_Home" = 10

     Position = value in tag <TO>.Homing.HomePosition

Note

Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

3.2.9.10 Direction reversal at the hardware limit switch (reversing cam)

During active homing, the hardware limit switch can optionally be used as a reversing cam. If the homing mark is not detected or the motion was not in the homing direction, the motion continues in the opposite direction with the approach velocity after the reversing cam.

When the hardware limit switch is reached, the default settings for dynamics take effect. Deceleration with the emergency stop deceleration does not occur.

NOTICE
Avoid moving to a mechanical endstop Ensure by one of the following measures, that in a direction reversal the machine does not move to a mechanical endstop. • Keep the approach velocity low. • Increase the configured acceleration / deceleration. • Increase the distance between the hardware limit switch and the mechanical endstop.

3.2.9.11 Direct homing

Depending on the configured mode, the position of the positioning axis/synchronous axis or external encoder technology objects can be absolutely or relatively set with "MC_Home".

Set actual position absolutely

Proceed as follows to set the position absolutely:

1. In the "MC_Home" Motion Control instruction, enter the absolute position in the "Position" parameter.
2. Call the "MC_Home" Motion Control instruction with the "Mode" = 0 parameter.

The position is set to the value specified in the "Position" parameter.

Set actual position relatively

Proceed as follows to set the position relatively:

1. In the "MC_Home" Motion Control instruction, enter the relative position in the "Position" parameter.
2. Call the "MC_Home" Motion Control instruction with the "Mode" = 1 parameter.

The position is set to the current position plus the value specified in the "Position" parameter.

3.2.9.12 Absolute value adjustment

In absolute value adjustment, Motion Control determines an absolute value offset, that is retentively stored on the CPU.

Depending on the configured mode, the position of the axis or the encoder is absolutely or relatively set in the "MC_Home" Motion Control instruction.

- Parameter "Mode" = 7 (absolute specification of position)

  Position = value in parameter "Position"
- Parameter "Mode" = 6 (relative specification of position)

  Position = current position + value in parameter "Position"

3.2.9.13 Resetting the "Homed" status

Incremental encoder

In the following cases, the "Homed" status is reset, and the technology object must be rehomed.

- Error in sensor system/encoder failure
- Initiation of active homing with the Motion Control instruction "MC_Home" with "Mode" = 3, 5 (after successful completion of the homing process, the status "Homed" is set again.)

Note

Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

- Initiation of passive homing with the Motion Control instruction "MC_Home" with "Mode" = 2, 8, 10 (after successful completion of the homing process, the status "Homed" is set again.)
- Replacement of the CPU
- Replacement of the SIMATIC Memory Card
- POWER OFF
- Memory reset
- Modification of the encoder configuration
- Restart of the technology object
- Restoration of the CPU factory settings
- Transfer of a different project into the controller

Absolute encoder

In the following cases, the "Homed" status is reset, and the technology object must be rehomed.

- Replacement of the CPU
- Modification of the encoder configuration
- Restoration of the CPU factory settings
- Transfer of a different project into the controller

When you use a new absolute value encoder you need to home the absolute encoder once again.

Resetting the memory of the CPU or upgrading a project does not require another absolute value adjustment.

3.2.9.14 Tags

The following technology object tags are relevant for homing:

Status indicators	
<TO>StatusWord.X11 (HomingCommand)	Homing job running
<TO>StatusWord.X5 (HomingDone)	Technology object is homed
<TO>ErrorWord.X10 (HomingFault)	Error occurred during homing
Approach to reference cam	
<TO>.Homing.ApproachDirection	Start direction or approach direction for the approach to the reference cam
<TO>.Homing.ApproachVelocity	Velocity for the approach to the reference cam
Approach to the homing mark	
<TO>.Sensor[n].ActiveHoming.Direction	Homing direction
<TO>.Homing.ReferencingVelocity	Velocity for the approach to the homing mark
Move to homing point	
<TO>.Homing.ApproachVelocity	Velocity for the move to homing point
Positions	
<TO>.Homing.AutoReversal	Reversal at the hardware limit switches
<TO>.Homing.HomePosition	Home position
<TO>.StatusSensor[n].AbsEncoderOffset	Calculated offset after the absolute encoder adjustment
Parameters for active homing	
<TO>.Sensor[n].ActiveHoming.Mode	Homing mode
<TO>.Sensor[n].ActiveHoming.SideInput	Side of the digital input
<TO>.Sensor[n].ActiveHoming.Direction	Homing direction or approach direction
<TO>.Sensor[n].ActiveHoming.DigitalInputAddress	Address of digital input
<TO>.Sensor[n].ActiveHoming.HomePositionOffset	Offset of the homing mark from the home position
Parameters for passive homing	
<TO>.Sensor[n].PassiveHoming.Mode	Homing mode
<TO>.Sensor[n].PassiveHoming.SideInput	Side of the digital input
<TO>.Sensor[n].PassiveHoming.Direction	Homing direction or approach direction
<TO>.Sensor[n].PassiveHoming.DigitalInputAddress	Address of digital input

Note

Evaluation of the bits in StatusWord, ErrorWord and WarningWord

Read the information provided in section Evaluate StatusWord, ErrorWord and WarningWord (Page 288).

3.2.10 Position monitoring functions

3.2.10.1 Brief description

The following functions are available in the positioning axis/synchronous axis technology object for monitoring positioning and motion:

- Positioning monitoring (Page 88)

  The actual position value must reach a positioning window within a specified time, and remain in this positioning window for a minimum dwell time.

- Following error monitoring (Page 90)

  The following error is monitored based on a velocity-dependent following error limit. The permissible maximum following error depends on the velocity setpoint.

If monitored conditions are violated, then technology alarms are output. The technology object responds in accordance with the alarm response.

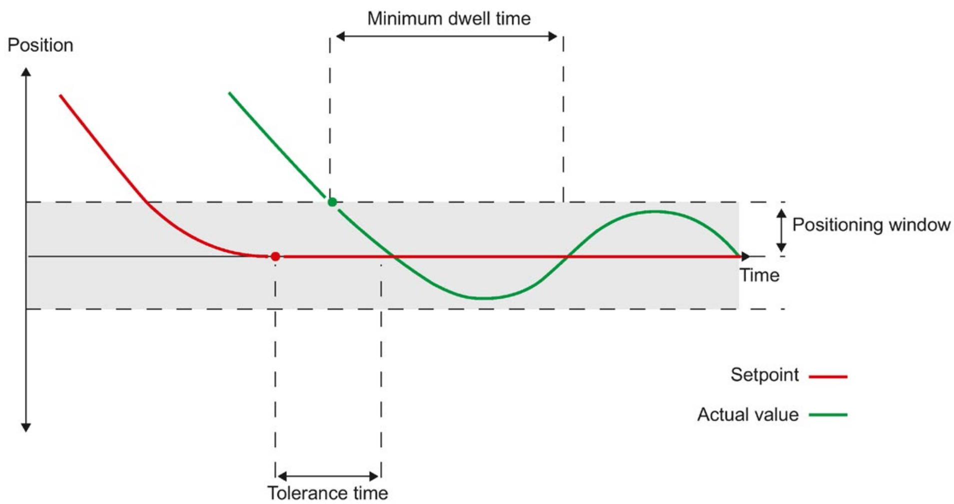
3.2.10.2 Positioning monitoring

Positioning monitoring monitors the behavior of the actual position at the end of the setpoint calculation.

As soon as the velocity setpoint reaches the value zero, the actual position value must be located in the positioning window within a tolerance time. The actual value must not exit the positioning window during the minimum dwell time.

If the actual position is reached at the end of a positioning motion within the tolerance time and remains in the positioning window for the minimum dwell time, then <TO>.StatusWord.X6 (Done) is set in the technology data block. After expiration of the minimum dwell time, the "Done" parameter of the corresponding Motion Control instruction is also set. This completes a motion job.

The following figure shows the chronological sequence and the positioning window:



Positioning monitoring does not make any distinction between how the setpoint interpolation was completed. The end of setpoint interpolation can for example be reached as follows:

- by reaching of the target position on the part of the setpoint
- by position controlled stopping during the motion by the Motion Control instruction "MC_Halt"

Violation of positioning monitoring

In the following cases, technology alarm 541 is output by the positioning monitoring, and the technology object is disabled (alarm reaction: remove enable).

- The actual value does not reach the positioning window during the tolerance time.
- The actual value exits the positioning window during the minimum dwell time.

3.2.10.3 Following error monitoring

The following error in the positioning axis/synchronous axis technology object is monitored based on a velocity-dependent following error limit. The permissible following error depends on the velocity setpoint.

A constant permissible following error can be specified for velocities lower than an adjustable velocity low limit.

Above this low velocity limit, the permissible following error increases in proportion to the velocity setpoint. The configurable maximum permissible following error is the maximum velocity limit.

Calculation of the following error

The following error is the difference between the position setpoint and the actual position value. The transmission times of the setpoint to the drive, and of the actual position value to the controller, are taken into account in the calculation of the following error, i.e. subtracted out.

Warning limit

A warning limit can be specified for the following error. The warning limit is input as a percentage value and operates relative to the current permissible following error. If the warning limit of the following error is reached, then technology alarm 522 is output. This is a warning and contains no alarm response.

Violation of the permissible following error

If the permissible following error is exceeded, then technology alarm 521 is output, and the technology object is disabled (alarm response: remove enable).

When force/torque limiting is activated, the monitoring of the permissible following error can be deactivated.

3.2.10.4 Standstill signal

When the actual velocity reaches the standstill window and remains there for the minimum dwell time, the standstill of the axis is indicated.

3.2.10.5 Tags

The following technology object tags are relevant for position monitoring and for the standstill:

Status indicators	
<TO>.StatusWord.X7 (Standstill)	Set to the value TRUE when the actual velocity reaches the standstill window and does not exit it within the minimum dwell time. The standstill signal is only present for the positioning axis/synchronous axis.
<TO>.StatusWord.X6 (Done)	**Positioning axis/synchronous axis** Set to the TRUE, when the actual velocity value reaches the positioning window within the tolerance time and remains in the window for the minimum dwell time. **Speed axis** Set to TRUE, when the motion is complete and the speed setpoint is therefore equal to zero.
<TO>.ErrorWord.X12 (PositioningFault)	A positioning error has occurred.
Positions and times	
<TO>.PositioningMonitoring.ToleranceTime	Maximum permissible time until positioning window is reached The time is started with the end of the setpoint interpolation.
<TO>.PositioningMonitoring.MinDwellTime	Minimum dwell time in the positioning window
<TO>.PositioningMonitoring.Window	Positioning window
Standstill signal	
<TO>.StandstillSignal.VelocityThreshold	Velocity threshold for the standstill signal
<TO>.StandstillSignal.MinDwellTime	Minimum dwell time below the velocity threshold

The following technology object tags are relevant for following error monitoring:

Status indicators	
<TO>.StatusPositioning.FollowingError	Current following error
<TO>.ErrorWord.X11 (FollowingErrorFault)	Status indication, that the following error is too large
<TO>.WarningWord.X11 (FollowingError-Warning)	Status indication, that the following error warning limit has been reached
Control bits	
<TO>.FollowingError.EnableMonitoring	Enabling / disabling following error monitoring
Limit values	
<TO>.FollowingError.MinVelocity	Lower velocity setpoint for the characteristic curve of the maximum following error
<TO>.FollowingError.MinValue	Permissible following error below the <TO>.FollowingError.MinVelocity
<TO>.FollowingError.MaxValue	Maximum permissible following error at maximum axis velocity
<TO>.FollowingError.WarningLevel	Warning limit as a percentage value relative to the maximum permissible following error (velocity-dependent in accordance with the characteristic curve)

3.2.11 Closed-loop control

3.2.11.1 Brief description

The position controller of the positioning axis / synchronizing axis is a proportional controller with velocity precontrol.

Velocity precontrol

The velocity precontrol can be used to minimize the velocity-based following error during position control. As a result, faster positioning is achieved, if needed, because the position controller only has to compensate disturbances.

When using the velocity precontrol, the velocity setpoint is additionally added to the output of the position controller. You can weight this additional setpoint by a factor.

Dynamic Servo Control (DSC)

In drives that support Dynamic Servo Control (DSC), you can optionally use the closed-loop position controller in the drive. If you use telegrams that support DSC, DSC is automatically activated. The position controller in the drive is usually implemented with a rapid speed-control cycle. This improves the control performance for digitally coupled drives.

The following requirements must be met to use DSC:

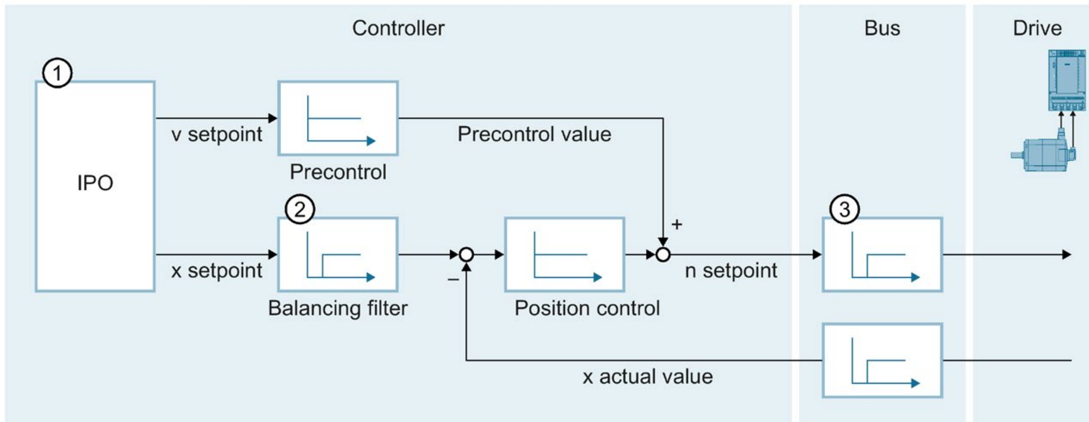
- The motor encoder (first encoder in the telegram) of the drive is used as the first encoder for the technology object.
- One of the following PROFIdrive telegrams is used for the drive:
  - Standard telegram 5 or 6
  - SIEMENS telegram 105 or 106

See also

PROFIdrive telegrams (Page 36)

3.2.11.2 Control structure

The following figure shows the effective closed loop control structure **without** DSC:

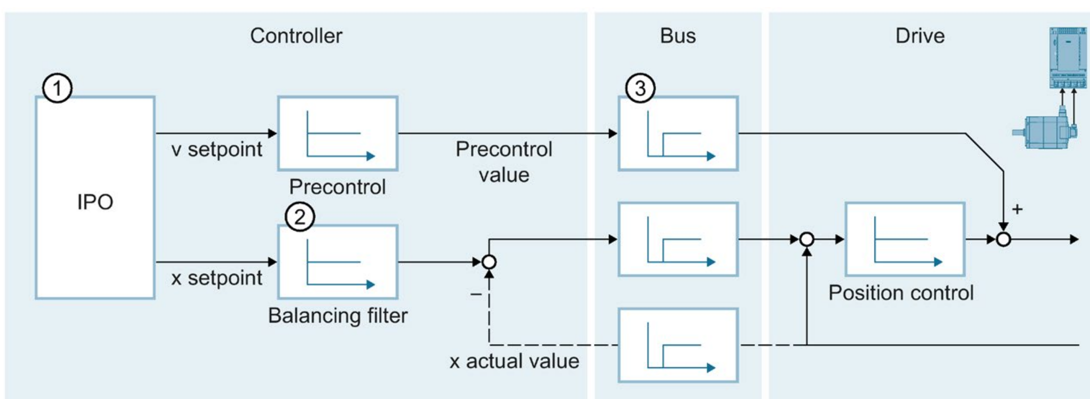


① Interpolator with motion control

② Internal consideration of the signal propagation times and the speed-control loop substitute time

③ Communication between controller and drive

The following figure shows the effective closed loop control structure **with** DSC:



① Interpolator with motion control

② Internal consideration of speed control loop substitute time

③ Communication between controller and drive

See also

Configuration - Control loop (Page 228)

3.2.11.3 Tags

The following technology object tags are relevant for the closed-loop control:

Parameters	
<TO>.PositionControl.Kv	Proportional gain of the closed loop position control
<TO>.PositionControl.Kpc	Velocity precontrol of the positioning system (in %)
<TO>.PositionControl.EnableDSC	Enable DSC
<TO>.DynamicAxisModel.VelocityTime Constant	Speed control loop substitute time [s]
<TO>.PositionControl.ControlDifference-Quantization.Mode	Type of quantification Configuration of a quantization when a drive with stepper motor interface is connected 0: No quantification 1: Quantization corresponding to encoder resolution 2: Quantization to a direct value (value input in <TO>.PositionControl.ControlDifferenceQuantization.-Value) (configuration is performed using the parameter view (data structure))
<TO>.PositionControl.ControlDifference-Quantization.Value	Value of quantification Configuration of a value for quantization to a direct value (<TO>.PositionControl.ControlDifferenceQuantization.-Mode = 2) The quantization value is specified in the position unit of the axis. (configuration is performed using the parameter view (data structure))

3.2.12 Process response

3.2.12.1 Organization Blocks for Motion Control

Description

When you create a technology object, organization blocks are automatically created for processing the technology objects. The Motion Control functionality of the technology objects creates its own execution level, and is called according to the Motion Control application cycle.

The following blocks are created:

- **MC-Servo [OB91]**

  Calculation of the position controller

- **MC-Interpolator [OB92]**

  Evaluation of the Motion Control instructions, generation of setpoints and monitoring functionality

The organization blocks are protected (know-how protection). The program code cannot be viewed or changed.

The frequency relationship of the two organization blocks to one another is always 1:1. MC-Servo [OB91] is always executed before MC-Interpolator [OB92].

You can set the application cycle and the priority of the organization blocks according to your requirements for control quality and system load.

MC-PreServo [OB67] and MC-PostServo [OB95]

In addition, you can create the organization blocks MC-PreServo [OB67] and MC-PostServo [OB95].

The organization blocks MC-PreServo [OB67] and MC-PostServo [OB95] can be programmed. They are called in the configured application cycle. This means you can use the organization blocks MC-PreServo [OB67] and MC-PostServo [OB95] for consistent data processing or time-critical events, such as starting of motions or homing functions for the process that may have to run synchronously with the application cycle.

Application cycle

You can set the application cycle in which the MC-Servo [OB91] is called in the properties of the organization block in "General > Cycle Time":

- **Synchronous to the bus**

  MC-Servo [OB91] is called synchronously with or at a reduced ratio to a bus system. You set the send clock in the properties of the selected bus system. In the "Distributed I/O" drop-down list, you can select the following bus systems:

  – Isochronous PROFIBUS DP

  – Isochronous PROFINET IO

  You cannot call the MC-Servo [OB91] synchronously with a bus system that is connected to the CPU via a communications processor/communications module (CP/CM).

- **Cyclic**

  The MC-Servo [OB91] is called cyclically with the specified application cycle.

The selected application cycle must be long enough to be able to process the technology objects in one cycle. If the processing time of the technology objects is longer than the application cycle, overflows (Page 98) will occur. In order to achieve optimal control quality, the calculations of the organization blocks MC-PreServo [OB67], MC-Servo [OB91] and MC-PostServo [OB95] must be performed within a send cycle.

You can check the runtime of MC-Servo [OB91] and MC-Interpolator [OB92] with the expanded instruction "RT_INFO".

The current application cycle (information in µs) of the organization blocks MC-PreServo [OB67] and MC-PostServo [OB95] can be read using the start information.

Reduction ratio (CPU V1.5 and higher)

You can reduce the application cycle of the MC-Servo [OB91] relative to the send clock of an isochronous PROFINET IO system. You can set an integer multiple of the send clock as the factor. Values up to 14 times the send clock (maximum 32 ms) are possible for the application cycle.

If you call an isochronous mode interrupt OB and the MC-Servo [OB91] synchronously with the same PROFINET IO system, you must set the same application cycle for both organization blocks.

Priority

You can configure the priority of the organization blocks as needed in their properties under "General > Properties > Priority":

- **MC-Servo [OB91]**

  Priority 17 to 26 (default value 26)
- **MC-Interpolator [OB92]**

  Priority 16 to 25 (default value 24)

The priority of MC-Servo [OB91] must be at least one higher than the priority of MC-Interpolator [OB92].

The priority of the organization blocks MC-PreServo [OB67] and MC-PostServo [OB95] correspond to the priority of the MC-Servo [OB91]. MC-PreServo [OB67] is called immediately before MC-Servo [OB91]. MC-PostServo [OB95] is called immediately after MC-Servo [OB91].

See also

Data connection drive/encoder via data block (Page 50)

3.2.12.2 Process image partition "OB Servo PIP"

The process image partition "OB Servo PIP" is made available in isochronous mode for Motion Control when MC-Servo [OB91] is called. All drives and encoders used by Motion Control are assigned to this process image partition.

Because the organization blocks MC-PreServo [OB67] and MC-PostServo [OB95] are called automatically by the MC-Servo [OB91], the process image partition is also available automatically. If you use a MC-PreServo [OB67], the data are read in when the MC-PreServo [OB67] starts. If you use a MC-PostServo [OB95], the data are output after the MC-PostServo [OB95].

Additionally, you should assign all I/O modules used by Motion Control to this process image partition (e.g. hardware limit switches). The assignment results in chronologically synchronous processing with the technology object.

The input process image partition is also updated in STOP mode.

Process image partition in the user program

As of CPU version V1.5, you can access the process image partition "OB Servo PIP" in your user program. This makes it possible to evaluate the process image partition using the trace function.

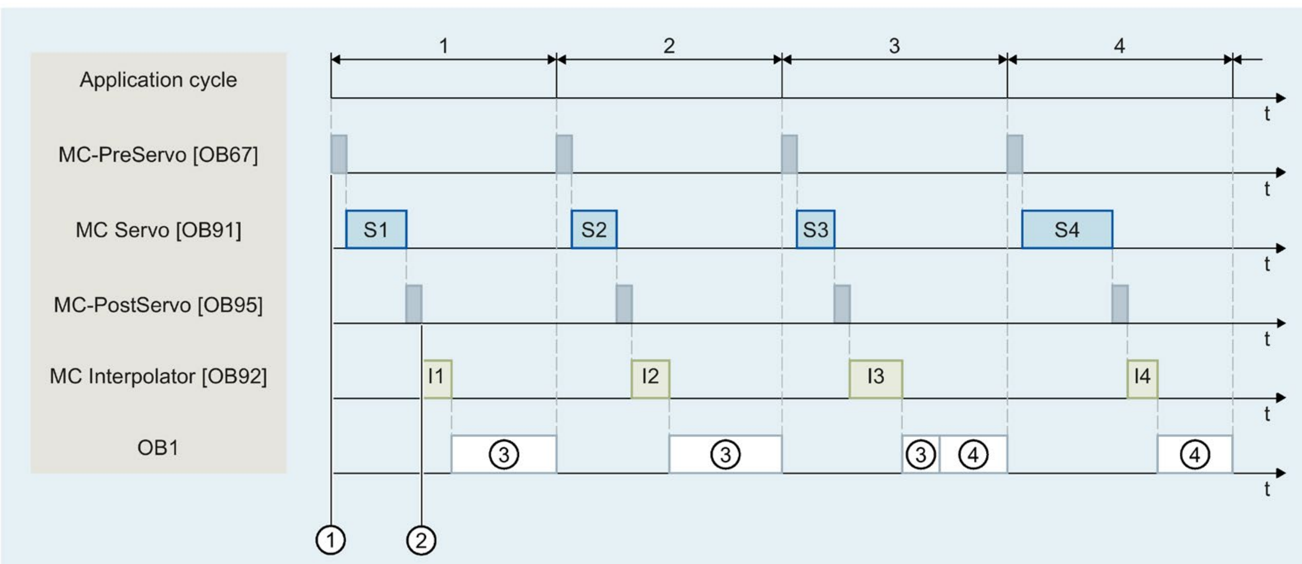
3.2.12.3 Operational Sequence and Timeouts

When processing the Motion Control functionality, the organization blocks MC-Servo [OB91] and MC-Interpolator [OB92] are called and processed in each application cycle. The remaining cycle time is available for the processing of your user program.

For error-free program execution, keep to the following rules:

- In each application cycle, MC-Servo [OB91] must be started and executed completely.
- In each application cycle, the relevant MC-Interpolator [OB92] must at least be started.

The following figure shows an example of the error-free operational sequence for the processing of organization block OB1:



① "TPA OB Servo" input
② "TPA OB Servo" output
③ First OB1 cycle
④ Second OB1 cycle

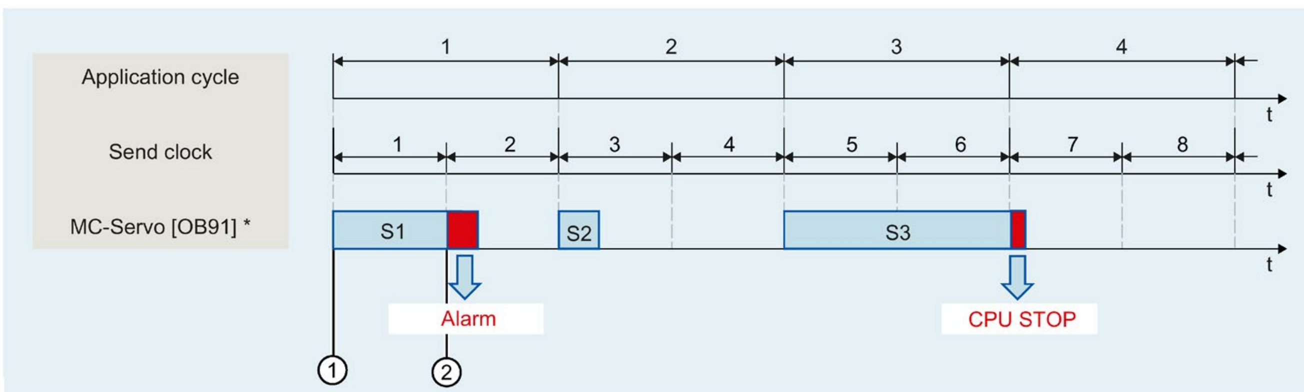
Overflows

Overflows can occur if the configured application cycle is not adhered to, for example because additional technology objects or programs are added in the MC-PreServo [OB67] or MC-PostServo [OB95]. The application cycle must be adapted in this case to prevent overflows.

A message is generated in the diagnostic buffer of the CPU in the case of an overflow of MC-Servo [OB91] in the send clock. The controller no longer runs isochronously.

The CPU switches to STOP mode in the case of an overflow of MC-Servo [OB91] in the application cycle.

The following figure shows the behavior in the case of overflow of MC-Servo [OB91] in the application cycle and in the send clock with a reduction ratio of 2:



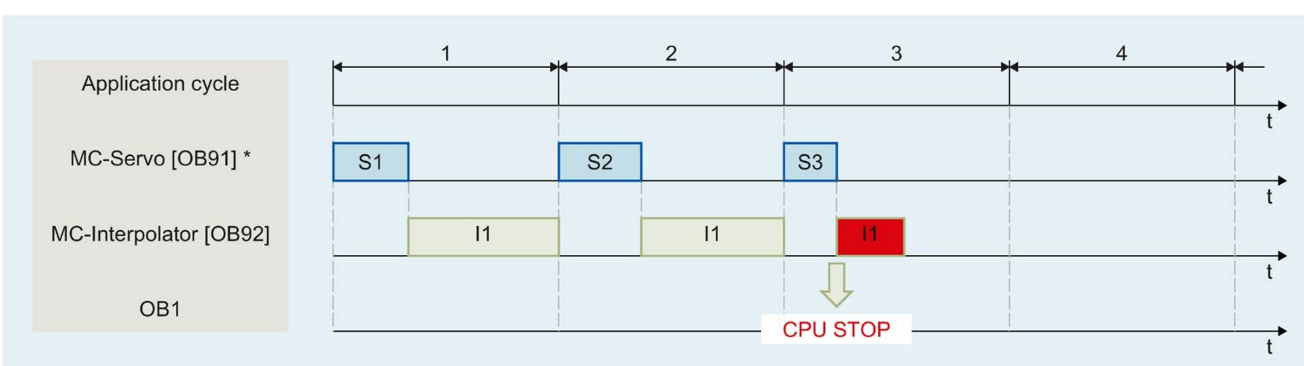
① "TPA OB Servo" input

② "TPA OB Servo" output

* Including MC-PreServo [OB67] and/or MC-PostServo [OB95], when in use

The execution of an MC-Interpolator [OB92] may only be interrupted by an MC-Servo [OB91] call. If more interruptions occur, the CPU switches to STOP mode.

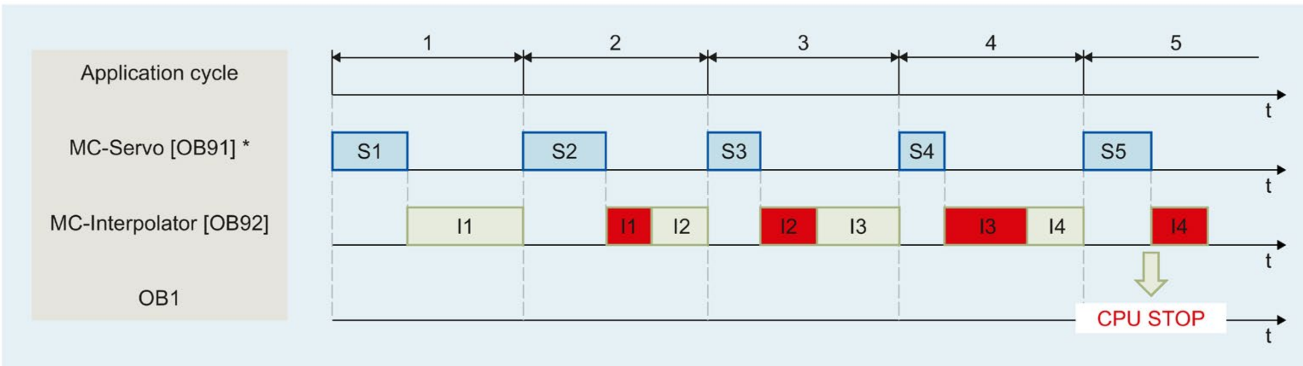
The following figure shows the operational sequence when an MC-Interpolator [OB92] is interrupted over two time slices:



* Including MC-PreServo [OB67] and/or MC-PostServo [OB95], when in use

The CPU tolerates a maximum of three consecutive overflows of MC-Interpolator [OB92]. If more overflows occur, the CPU switches to STOP mode.

The following figure shows the operational sequence if there are four consecutive individual overflows of MC-Interpolator [OB92]:



* Including MC-PreServo [OB67] and/or MC-PostServo [OB95], when in use

3.2.12.4 Operating modes

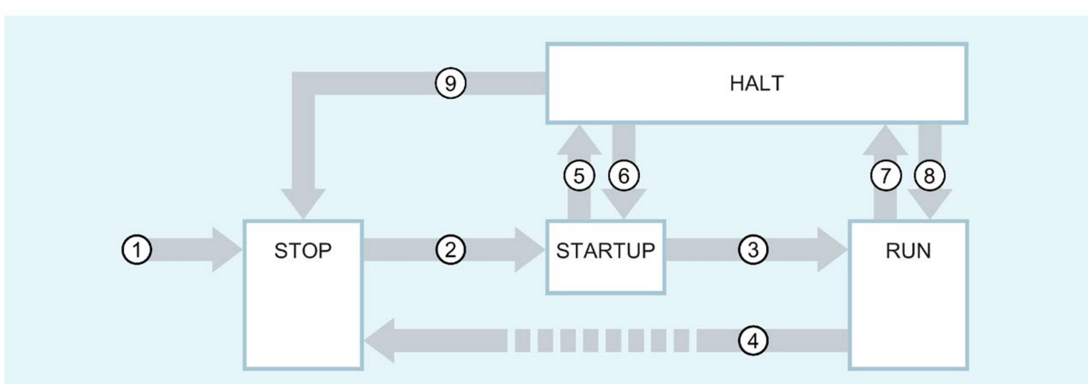
This section examines the behavior of the Motion Control in the respective operating modes and in the transitions between operating modes. A general description of the operating modes can be found in the S7-1500 System Manual

Operating modes and transitions

The CPU has the following operating modes:

- STOP
- STARTUP
- RUN
- HOLD

The following figure shows the operating modes and the operating mode transitions:



Operating mode transitions

The following table shows the behavior of the Motion Control in the transitions between the operating modes:

No.	Operating mode transition	Behavior
①	POWER ON → STOP	The CPU performs a restart of the technology objects. The technology objects are reinitialized with the values from the load memory.
②	STOP → STARTUP	Not relevant for Motion Control.
③	STARTUP → RUN	The process outputs are enabled.
④	RUN → STOP	When the CPU changes from RUN mode to STOP mode, all technology objects are disabled in accordance with the alarm response "remove enable". Active Motion Control jobs are aborted. If restart-relevant data has been changed for technology objects in RUN, the CPU performs a restart of the corresponding technology objects.
⑤	STARTUP → HOLD	Breakpoint in the start-up routine reached.
⑥	HOLD → STARTUP	Not possible when using technology objects
⑦	RUN → HOLD	Breakpoint reached
⑧	HOLD → RUN	Not possible when using technology objects
⑨	HOLD → STOP	By operation of switch/display or by setting to STOP from programming device.

STOP mode

In STOP mode the user program is not processed and all process outputs are disabled. Thus no Motion Control jobs are executed.

The technology data blocks are updated.

STARTUP mode

Before the CPU starts processing of the cyclical user program, the startup OBs are processed one time.

In STARTUP mode, the process outputs are disabled. Motion Control jobs are rejected.

The technology data blocks are updated.

RUN mode

The user program is processed in RUN mode.

In RUN mode, the programmed Motion Control jobs are cyclically called and processed.

The technology data blocks are updated.

HOLD operating state

Working with breakpoints is not supported when technology objects are used. An overflow of the MC-Servo occurs in each case. This leads to an immediate switch to STOP mode.

In HOLD operating state, events are not initiated and the user program is not executed.

All outputs are disabled or react according to the parameter settings. Outputs supply a configured substitute value or keep the last value output and bring the controlled process to a safe operating state.

When you reach a breakpoint, the CPU executes an implicit restart of the technology object. Homing the technology once again.

3.3 Speed-controlled axis technology object

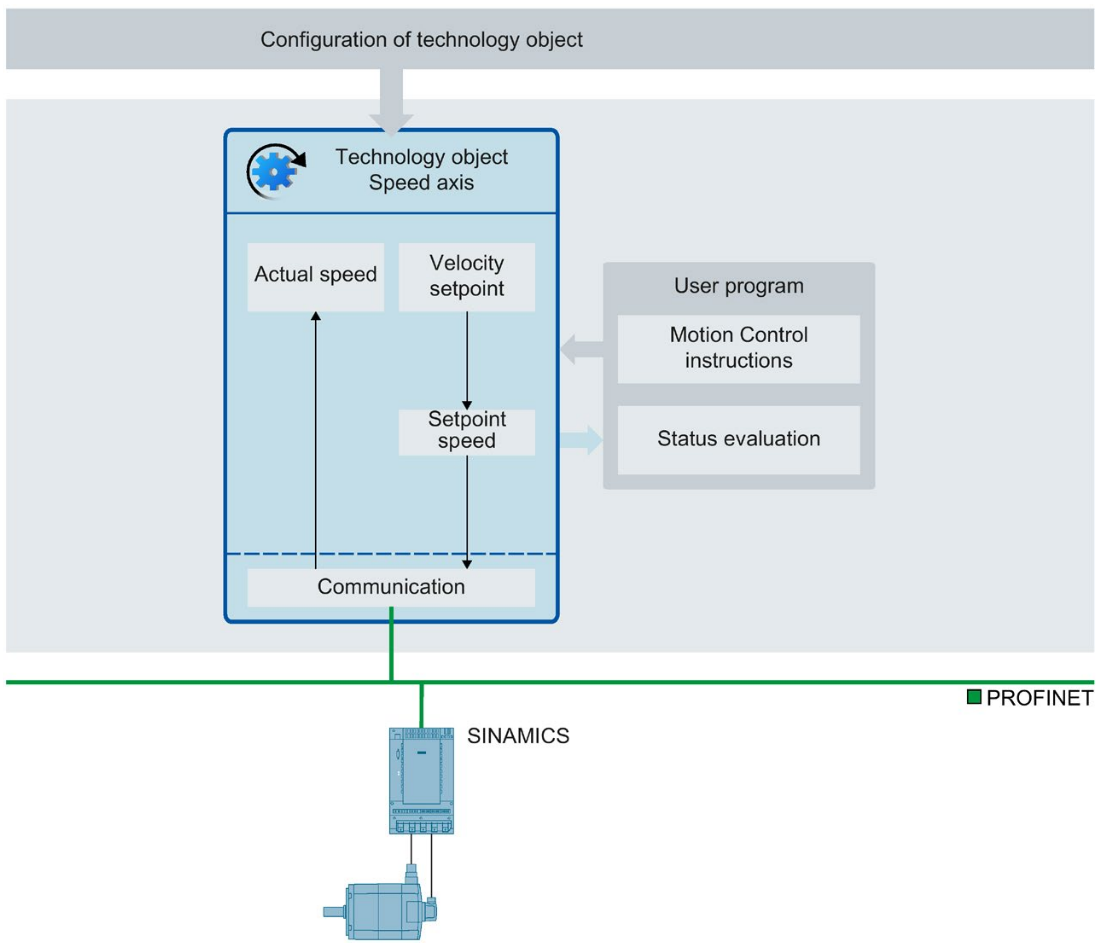
The speed axis technology object calculates speed setpoints, taking into account the dynamic settings, and outputs them to the drive. All motions of the speed axis take place as speed-controlled motions. An existing load gear is taken into account on the system side.

You can find an overview of the functions of the speed axis technology object in the Functions (Page 27) section.

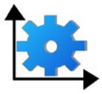
A drive is assigned to each speed axis by means of a PROFIdrive telegram or an analog setpoint interface.

The speed is specified in revolutions per unit of time.

The following figure shows the basic principle of operation of the speed axis technology object:



3.4 Positioning axis technology object



The positioning axis technology object calculates position setpoints, taking into account the encoderc settings, and outputs corresponding speed setpoints to the drive. In position-controlled mode, all movements of the positioning axis take place as position-controlled movements. For absolute positioning, the physical position must be known to the positioning axis technology object.

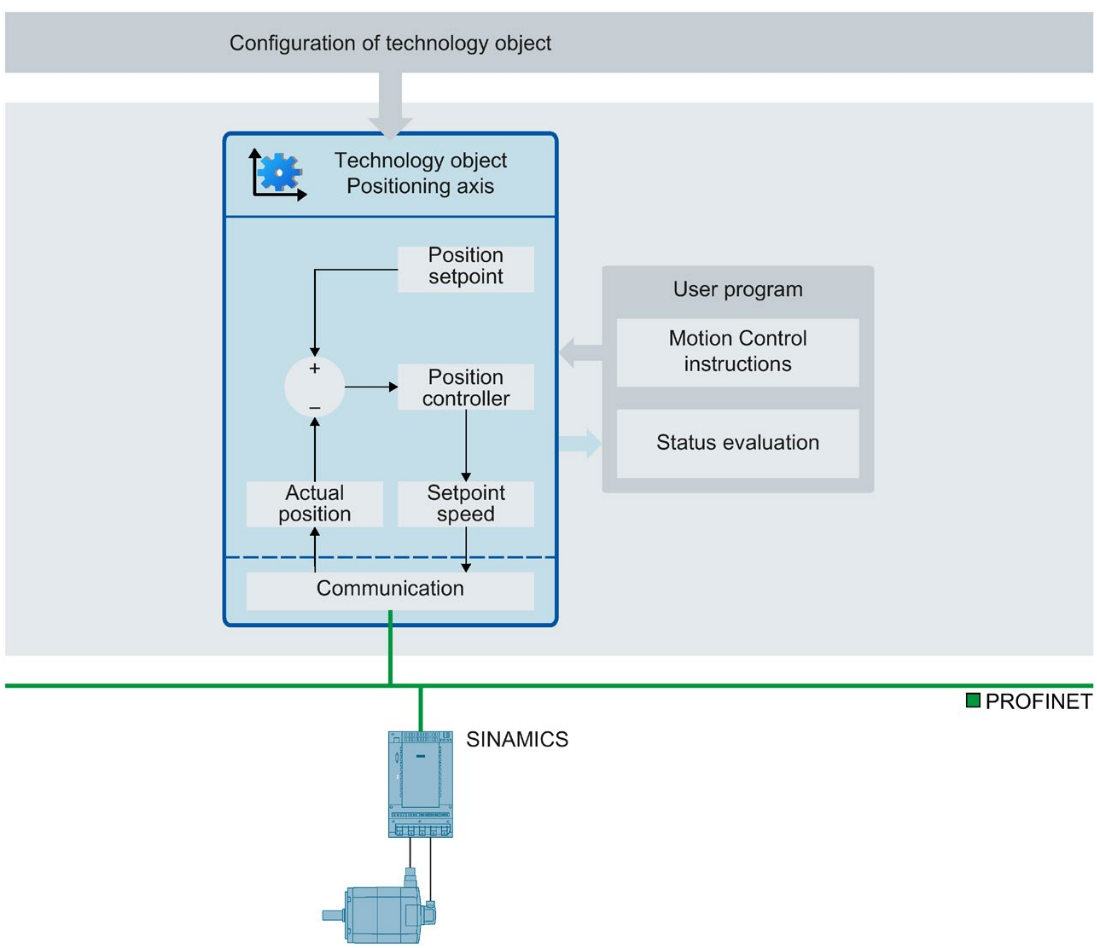
You can find an overview of the functions of the positioning axis technology object in the Functions (Page 27) section.

Each positioning axis is assigned a drive by means of a PROFIdrive telegram or an analog setpoint interface as well as an encoder by means of a PROFIdrive telegram.

The relationship between the encoder values and a defined position is established by the parameter assignment of the mechanical properties and encoder settings and by a homing operation. The technology object can also perform movements without a position relationship, and relative position movements, even without being in a homed status.

A positioning axis can be configured as a linear axis or rotary axis (Page 31), depending on the design of the mechanics.

The figure below shows the basic principle of operation of the positioning axis technology object:



3.5 Synchronous axis technology object

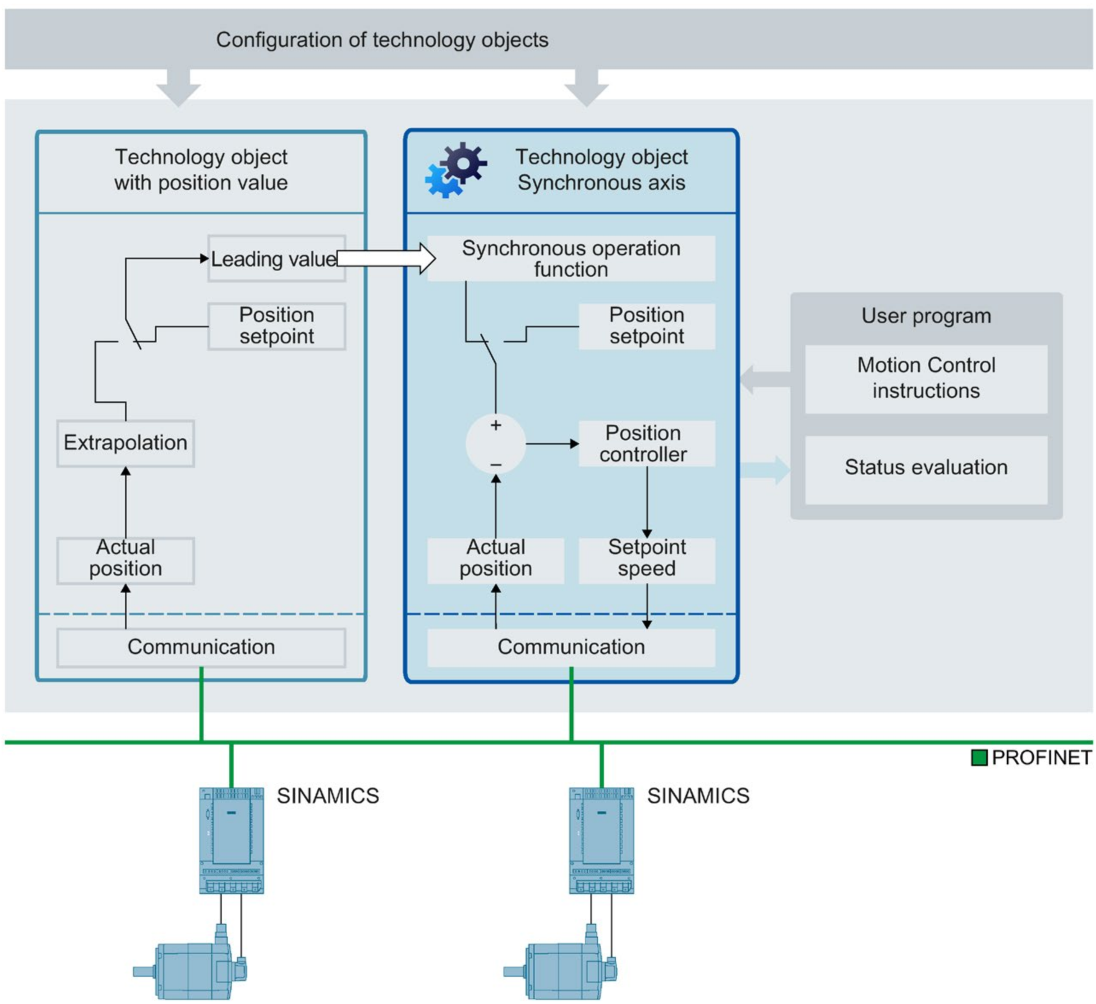
3.5.1 Short description for synchronous axis

The synchronous axis technology object includes all functions of the positioning axis technology object.

A synchronous axis can also follow the motions of a leading axis. The synchronous operation relationship between the leading and following axes is specified by a synchronous operation function.

You can find an overview of the functions of the synchronous axis technology object in the Functions (Page 27) section.

The figure below shows the basic principle of operation of the synchronous axis technology object:



See also

Axis types (Page 31)

3.5.2 Synchronous operation phases

By means of synchronous operation, a following axis can be linked to a leading axis and move synchronously with it.

The synchronous operation proceeds in the following phases:

- Pending synchronous operation (S7-1500T)

  The following axis waits for the start conditions of the synchronizing motion.
- Synchronization

  The following axis is synchronized to the leading value.
- Synchronous motion

  The following axis follows the position of the leading axis according to the synchronous operation function.
- Synchronous operation override

  An active synchronous operation is overridden by motion jobs (e.g. MC_Halt) issued to the following axis.

During these phases the dynamic limits apply as described in section Dynamic limits in synchronous operation (Page 62).

Avoid homing the leading axis during an active synchronous operation. Homing the leading axis during synchronous operation corresponds to a setpoint step change on the following axis. The following axis compensates for the step change according to the synchronous operation function and limited only to the maximum speed of the drive.

Note

The leading values and following values are coupled without conversion into the relevant configured user unit. If, for example, a linear leading axis moves by 10 mm, a rotary following axis moves by 10° with at a gear ratio of 1:1.

3.5.3 Leading value coupling

3.5.3.1 Short description for leading value coupling

The leading value for synchronous operation is provided by a leading axis. The leading value is specified and coupled in the user program with the call of the corresponding Motion Control instruction for synchronous operation. The leading value is switched when you call the Motion Control instruction again specifying a different leading axis.

The following rules apply to the leading value coupling:

- A leading axis can output the leading value to several following axes.
- The synchronous axis can be interconnected with different leading values. All interconnections required during operation must be set up during configuration of the technology object.
- Only one leading value at a time is coupled and evaluated.

3.5.3.2 Setpoint coupling

With setpoint coupling, the position setpoint of the leading axis is used as the leading value for synchronous operation.

The position setpoint of the following technology objects can be interconnected as the leading value for synchronous operation:

- Positioning axis
- Synchronous axis

3.5.4 Gearing with MC_GearIn

During gearing the position of the following axis results from the position of the leading axis multiplied by the gear ratio. You specify the gear ratio as a ratio of two integers. The result is a linear synchronous operation function.

Synchronous operation with MC_GearIn begins after synchronization when the following axis has reached the velocity and acceleration of the leading axis, taking into account the gear ratio.

Synchronization

Synchronization begins with the start of an "MC_GearIn (Page 413)" job. When a synchronous axis is synchronizing to a leading value, this is indicated in the technology object tag <TO>.StatusWord.X21 (Synchronizing). Active motion jobs are overridden. The dynamic values (acceleration, delay, jerk) of the following axis for the synchronization are specified at "MC_GearIn".

The synchronization duration and distance are dependent on the following parameters:

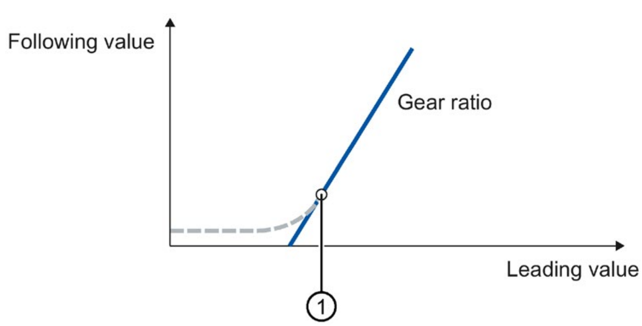
- Start time of the "MC_GearIn" job
- Dynamics of the following axis at the start time
- Dynamic value settings for "MC_GearIn"
- Dynamics of the leading axis

If the following axis has reached the velocity and the acceleration of the leading axis, taking into account the gear ratio, the following axis is synchronized. The following axis travels synchronously with the leading axis.

Synchronous motion

When a synchronous axis is synchronized to a leading value, the "Synchronous" status is indicated by parameter "MC_GearIn.InGear" = TRUE as well as in the technology object tag <TO>.StatusWord.X22 (Synchronous). The following axis follows the dynamics of the leading axis according to the gear ratio.

The response characteristic during gearing is expressed by a linear relationship between the leading value and following value.



Gear ratio	Slope of line/transmission ratio Gear ratio = MC_GearIn.RatioNumerator/MC_GearIn.RatioDenominator
-----	Synchronization
①	Position starting from which the leading and following axes move synchronously Position ① is dependent on the above-named parameters (see Synchronization).

The following value is calculated according to the following function:

Position of following axis (following value) = Position ① of following axis + gear ratio × (Position of leading axis - Position ① of leading axis)

Direction

The numerator of the gear ratio is specified as positive or negative. This yields the following behavior:

- **Positive gear ratio:**
  The leading and following axes move in the same direction.
- **Negative gear ratio**:
  The following axis moves in the opposite direction of the leading axis.

Tags for synchronous operation (Page 109)

MC_MoveSuperimposed: Position axes overlapping V4 (Page 395)

Dynamic limits in synchronous operation (Page 62)

3.5.5 Tags for synchronous operation

The following technology object tags are relevant for synchronous operation:

Status indicators	
<TO>.StatusSynchronizedMotion.ActualMaster	When a synchronous operation job is started, the number of the technology data block of the currently used leading axis is displayed. "ActualMaster" = 0 when synchronous operation is inactive
<TO>.StatusSynchronizedMotion.PhaseShift	Current absolute leading value shift
<TO>.StatusWord.X21 (Synchronizing)	Set to value TRUE when the synchronous axis synchronizes to a leading value.
<TO>.StatusWord.X22 (Synchronous)	Set to value TRUE when the synchronous axis is synchronized and moves synchronously to the leading axis,
<TO>.ErrorWord.X14 (SynchronousError)	Error during synchronous operation The leading axis specified in the Motion Control instruction was not configured as a possible leading axis.
<TO>.StatusSynchronizedMotion.StatusWord.X0 (MaxVelocityExceeded)	Set to value TRUE when the maximum velocity configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X1 (MaxAccelerationExceeded)	Set to value TRUE when the maximum acceleration configured for the following axis is exceeded during synchronous operation.
<TO>.StatusSynchronizedMotion.StatusWord.X2 (MaxDecelerationExceeded)	Set to value TRUE when the maximum deceleration configured for the following axis is exceeded during synchronous operation.

3.6 Technology object external encoder

The external encoder technology object detects a position, and makes it available to the controller.

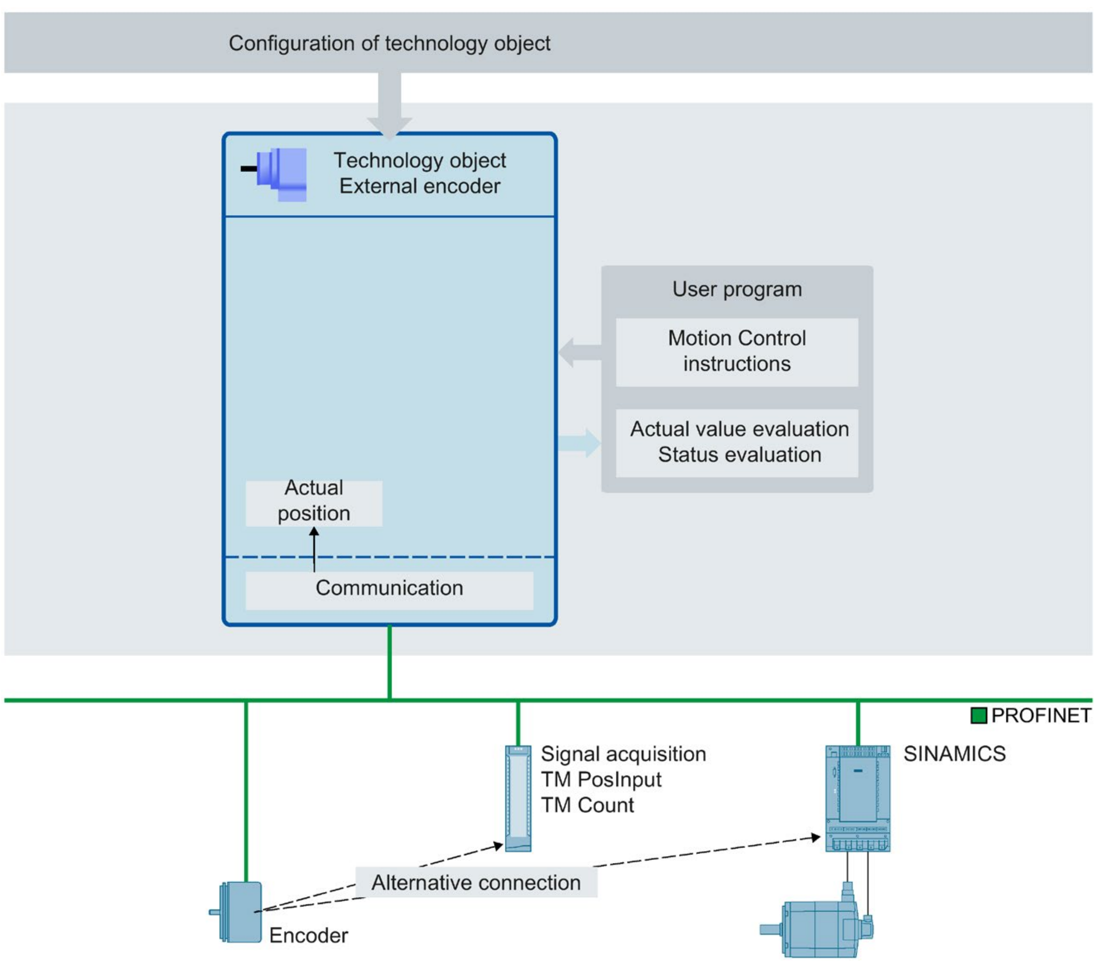
The actual position detected by the external encoder can be used for the following functions, for example:

- Measured value acquisition by a measuring input
- Position-dependent generation of switching signals and switching signal sequences by output cam and cam track with actual value reference.
- As a leading value of a synchronous axis (S7-1500T)

You can find an overview of the functions of the external encoder technology object in the Functions (Page 27) section.

The relationship between the encoder values and a defined position is established by the parameter assignment of the mechanical properties and encoder settings and by a homing operation.

The following figure shows the basic principle of operation of the external encoder technology object:



Specification of the position occurs according to the selected system of units:

- **Linear system of units**

  The position is specified as a linear measure, e.g. millimeters.
- **Rotary system of units**

  The position is specified as an angular measure, e.g. degrees.

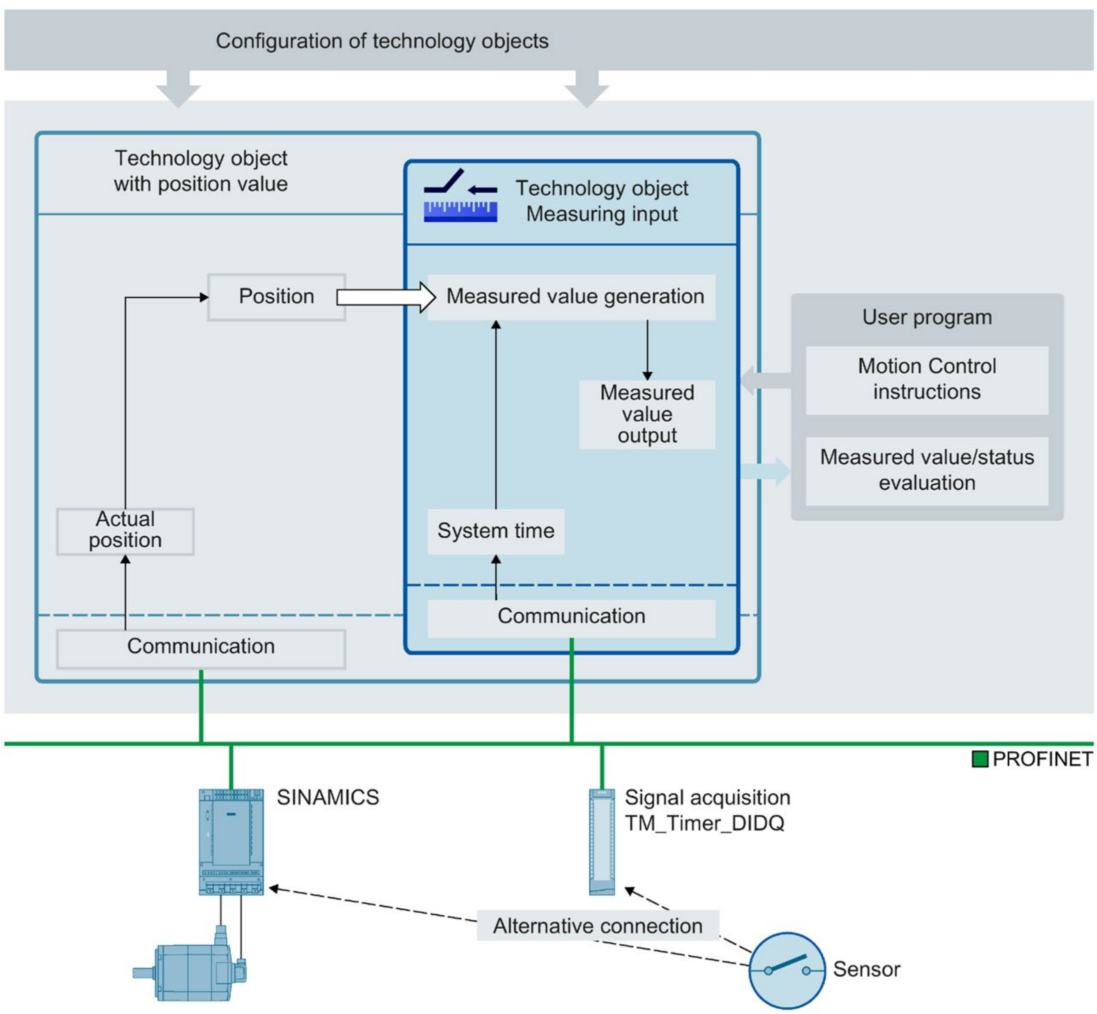
3.7 Technology object measuring input

3.7.1 Brief description

The measuring input technology object acquires the actual position of an axis or external encoder at a signal change at the measuring input.

You can find an overview of the functions of the measuring input technology object in the Functions (Page 27) section.

The figure below shows the basic principle of operation of the measuring input technology object:



Measurement types

Two types of measurement can be performed:

- One-time measurement (Page 116)

  Up to two measured values are acquired with edge accuracy with one measuring job. A one-time measuring job is started with "MC_MeasuringInput".

- Cyclic measuring (Page 117)

  With cyclic measuring, up to two measured values are acquired with edge accuracy in each position control cycle.

  A cyclic measuring job is started with "MC_MeasuringInputCyclic". The measurements are continued cyclically until they are ended per command.

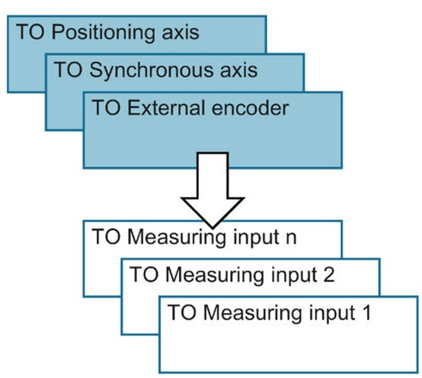
The edges to be detected are selected when starting the measurement using Motion Control instruction "MC_MeasuringInput" or "MC_MeasuringInputCyclic".

Assignment

The measuring input technology object must always be assigned to another technology object whose position will be evaluated by the measuring input.

The measuring input technology object can be assigned to the following technology objects:

- Synchronous axis
- Positioning axis
- External encoder



Exactly one axis or one external encoder can be assigned to a measuring input technology object.

An axis or external encoder can be assigned multiple measuring input technology objects.

Measured value determination

The position can be detected using support from the hardware in one of the following ways:

- Measuring using TM Timer DIDQ (time-based)
- Measuring with SINAMICS measuring input (time-based)

  Measurements via a measuring input are only possible for SINAMICS drives as of (see compatibility list (Page 555)).
- Measuring using PROFIdrive telegram (drive or external encoder)

A measuring job is activated using Motion Control instruction "MC_MeasuringInput" or "MC_MeasuringInputCyclic".

With time-based measuring ("TIME_BASED"), a signal change of the external trigger signal for the measurement is detected via a corresponding module such as TM Timer DIDQ or SINAMICS Drive. The time stamp is transferred to the controller and the associated actual position is determined in the technology object.

With direct position detection ("PROFIDRIVE"), the measurement input is connected to the drive device and the measurement is implemented in the drive. The drive or encoder module directly supplies the acquired position value to the technology object via the PROFIdrive telegram.

The resulting measured value is indicated at the respective output of the Motion Control instruction "MC_MeasuringInput" or "MC_MeasuringInputCyclic".

Cyclic measuring is only possible when measuring using TM Timer DIDQ. One-time measuring is always possible.

Measuring using TM Timer DIDQ requires isochronous mode.

For measuring using a PROFIdrive telegram, only one measuring input at a time can be active on an actual value or encoder in the PROFIdrive telegram. A maximum of two measuring inputs via PROFIdrive can be configured on an actual value or encoder in the PROFIdrive telegram Refer to Automatic transfer of drive and encoder parameters in the device (Page 42).

The measuring input technology object cannot be used with SIMATIC S7-PLCSIM. The measuring input technology object and the measuring input jobs used in the user program can be loaded into SIMATIC S7-PLCSIM, but have no function. Measured values are not shown.

Correction time

The time of the measurement can be corrected by setting a correction time (<TO>.Parameter.CorrectionTime) for the measuring input technology object.

Corrections may be required for the following examples:

- Times for mechanical displacement of the measuring input
- Times for the generation of the measured signal before the input at the measurement module
- Filter times at the input or filter times for the measurement inputs on the SINAMICS drive unit

The correction time is calculated by the measuring input technology object for time-based measured value acquisition ("TIME_BASED") and for direct position detection ("PROFIDRIVE").

Also note the time delay when measuring on a virtual axis. See section Brief description (Page 39).

3.7.2 Measuring

3.7.2.1 One-time measurement

With one-time measurement, up to two edges can be detected with one measuring job. The associated actual positions are signaled back in the function block and in the technology DB and can be further processed in the user program.

Measuring job

A measuring job is started using the Motion Control instruction "MC_MeasuringInput". The <TO>.Status tag in the technology data block changes to "WAITING_FOR_TRIGGER". The technology object activates the measurement when the selected edge is detected.

The measurement occurs at the measurement input in the form of up to two system times. Based on the times, the associated position is determined and output, taking into consideration a correction time, if present.

With direct position detection, the detected position value is supplied directly from the drive or encoder module to the technology object via the PROFIdrive telegram.

The measurement is then finished. An additional measurement must be restarted using Motion Control instruction "MC_MeasuringInput".

Table 3- 1 Mode and display of the results of measurement results when using one-time measurement

Configured "Mode" parameter in Motion Control instruction "MC_MeasuringInput"	Output of Motion Control instruction "MC_MeasuringInput"	
	MeasuredValue1	MeasuredValue2
Measure positive edge only	Actual position at the time of the edge	–
Measure negative edge only		
Measure the next two edges	Actual position at the time of the first edge	Actual position at the time of the second edge
Measure the next two edges starting with the positive edge	Actual position at the time of the positive edge	Actual position at the time of the negative edge
Measure the next two edges starting with the negative edge	Actual position at the time of the negative edge	Actual position at the time of the positive edge

The last detected values are set in the technology data block. If a new job is initiated with the function block, the outputs of the function block are initialized. The technology data block is not initialized. After detecting the first valid measuring cycle, the values in the technology data block and function block are consistent with one another.

The finished measuring command is indicated in the function block in "MC_MeasuringInput.DONE" = TRUE or in the technology data block in <TO>.Status = "TRIGGER_OCCURRED".

Time requirements for measurement jobs via "MC_MeasuringInput"

The hardware-related restrictions to measurement via the PROFIdrive telegram or measuring via the SINAMICS measurement sensing input, there are time requirements for the period until the measuring event can be recorded.

When measuring once via "MC_MeasuringInput" with mode 3 (measurement at both edges, beginning with the rising edge) or mode 4 (measurement at both edges, beginning with the falling edge), a minimum interval of several servo cycles is therefore required between the first edge to be measured and the previous edge, in order for the first edge to be measured can be recorded.

You can find information on the temporal boundary conditions in the section Time-related boundary conditions (Page 122).

See also

Time-related boundary conditions (Page 122)

MC_MeasuringInput: Start measuring once V4 (Page 399)

3.7.2.2 Cyclic measuring

With cyclic measuring, up to two measuring events can be acquired by the system in each position control cycle of the technology object and the associated measuring positions can be displayed. The measurements are continued cyclically until they are ended per command.

The determined measured values are displayed and can be read by the user program.

Cyclic measuring requires the measured value to be determined using the following type of hardware support: "Measuring using Timer DIDQ".

Measuring edges at which a measured value could not be determined are indicated in a lost edge counter in the technology DB as well as in function block "MC_MeasuringInputCyclic".

Measuring job

A cyclic measuring job is started with Motion Control instruction "MC_MeasuringInputCyclic", and the measuring job is issued to the corresponding technology module. Depending on the functionality of the technology module, up to two measuring events and thus measuring times can be captured with edge reference in each position control cycle and then forwarded to the technology object. The technology object determines the measuring positions for the measuring times taking into consideration any specified correction times.

The technology data block tag "<TO>.Status" changes from "INACTIVE" to "WAITING_FOR_TRIGGER" and remains in this status as long as additional events are awaited.

The mode set in the Motion Control instruction specifies the edges for which the measured values are to be acquired. At most, the following edges can be detected in each position control cycle:

- Two positive edges when detecting positive edges
- Two negative edges when detecting negative edges
- One positive edge and one negative edge when detecting positive and negative edges

Measured values and counters

With a positive edge at the input MC_MeasuringInputCyclic.Execute, outputs MeasuredValue1Counter and MeasuredValue2Counter are reset to "0". As a result, new events can be tracked immediately and new measured value entries can be detected.

All measuring event occurrences of the measuring job are incremented by "1" in the corresponding event counters <TO>.MeasuredValues.MeasuredValue1Counter and <TO>.MeasuredValues.MeasuredValue2Counter of the technology data block.

The acquired measured values are continuously captured in the technology data block irrespective of individual jobs and the values are only reset to "0" at power-up or restart of the technology object.

After a completed measurement, the measured values are output in the function block. The counters of the function block are set to "0" at a new measuring job. The measured value output in the technology data block always indicates the last acquired measured value.

Lost edge counter (LEC)

If more than two edges to be detected occur within one position control cycle, a measured value cannot be evaluated for the other edges to be detected. The number of lost edges is recorded in the LEC.

The lost edges that are recorded in the LEC depend on the mode set in the Motion Control instruction. For example, if only positive edges are to be measured, the LEC records only the non-measured positive edges.

A maximum of seven lost edges can be counted and displayed in the LEC.

The number of lost edges is indicated in the function block and in the technology data block in:

- LostEdgeCounter1

  Lost cleared edges from the position control cycle in which MeasuredValue1 was acquired.

  ⇒ The displayed value in LostEdgeCounter1 is updated when counter MeasuredValueCounter1 is incremented.

- LostEdgeCounter2

  Lost cleared edges from the position control cycle in which MeasuredValue2 was acquired.

  ⇒ The displayed value in LostEdgeCounter2 is updated when counter MeasuredValueCounter2 is incremented.

Display of measurement results when using cyclic measuring

Edges selected in the command	Display per position control cycle			
	MeasuredValue1	MeasuredValue2	LostEdgeCounter1	LostEdgeCounter2
Detect positive edges only "MC_MeasuringInputCyclic.-Mode" = 0	Actual position at the time of the first positive edge	Actual position at the time of the sec-ond positive edge	Number of positive or negative edges in excess of two in the position control cycle of acquisition of MeasuredValue1 and MeasuredValue2. The following applies here: • If a MeasuredValue1 **and** a MeasuredValue2 are acquired, the number of acquired and lost edges indicated in LostEdgeCounter1 and LostEdgeCounter2 are the same. • If **only** one MeasuredValue1 is acquired, the LostEdgeCounter1 is reset to "0". The value in LostEdgeCounter2 remains changed.	
Detect negative edges only "MC_MeasuringInputCyclic.-Mode" = 1	Actual position at the time of the first negative edge	Actual position at the time of the sec-ond negative edge		
Detect positive and negative edges "MC_MeasuringInputCyclic.-Mode" = 2	Actual position at the time of the first positive edge in the position control cycle	Actual position at the time of the first negative edge in the position control cycle	Number of edges in excess of two in the position control cycle of acquisition of MeasuredValue1 and MeasuredValue2. The following applies here: • If a MeasuredValue1 **and** a MeasuredValue2 are acquired, the number of acquired and lost edges indicated in LostEdgeCounter1 and LostEdgeCounter2 are the same. • If **only** one MeasuredValue1 is ac-quired, the LostEdgeCounter1 is reset to "0". The value in LostEdgeCounter2 remains changed. • If **only** one MeasuredValue2 is acquired, the LostEdgeCounter2 is reset to "0". The value in LostEdgeCounter1 remains changed.	

The following figures show examples of divergence of MeasuredValue1Counter and MeasuredValue2Counter as a result of lost edges.

Example of measurement at positive edges (Mode = 0)

MC_MeasuringInputCyclic: Start cyclic measuring V4 (Page 402)

3.7.3 Measuring with measuring range

A measuring job can be activated directly or restricted to a defined measuring range.

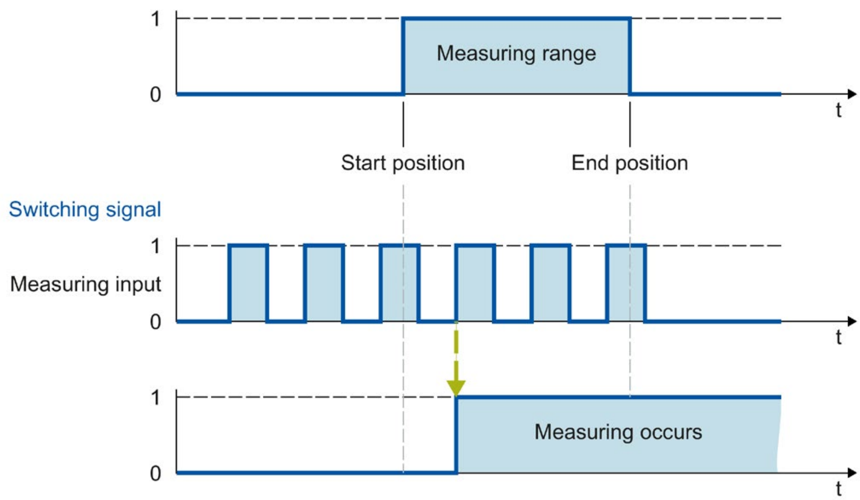

Figure 3-1 Example of measuring with measuring range in Mode = 0 (measurement of next positive edge)

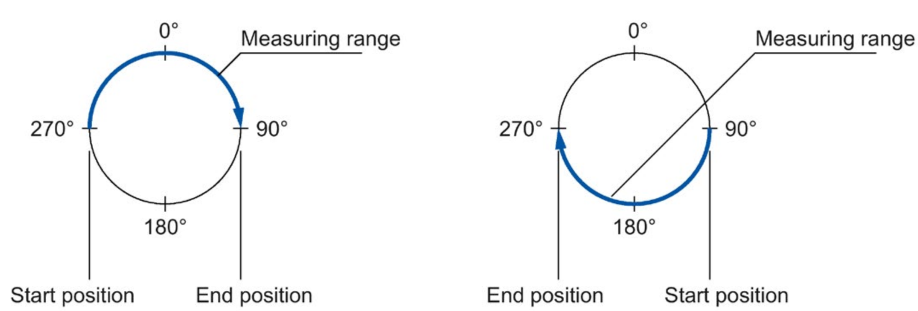
Only measured values within the measuring range are displayed for the technology object.

- If no measuring edge within the measuring range is detected during a one-time measurement, the measuring job is canceled and an alarm is triggered.
- Cyclic measuring remains active even if no measuring edge within the measuring range was detected.

For axes without modulo function, it is immaterial in which order the start and end positions are specified. If the start position is greater than the end position, the two values are interchanged in the application. If the start position for an axis with modulo function is greater than the end position, the measuring range is extended from the start position past the modulo transition of the axis to the end position.



The measuring range positions are specified in Motion Control instruction MC_MeasuringInput or MC_MeasuringInputCyclic.

Activation time for the measuring range

The measuring function must be active at the measurement input when the start of the measuring range is reached. To compensate for the communication time for activation in the TM Timer DIDQ or drive, for example, the activation of the measurement in the technology object begins earlier then the measuring range start by the amount of the activation time.

The activation time for measuring with measuring range is divided up as follows:

- The activation time allocation defined and active on the system side is indicated in the <TO>.Parameter.MeasuringRangeActivationTime tag.
- An additional activation time can also be set by the user with the <TO>.Parameter.MeasuringRangeAdditionalActivationTime tag.

3.7.4 Time-related boundary conditions

Depending on the hardware configuration and selection of edges to be detected, different system-inherent requirements apply to the time allowed after calling the Motion Control instruction "MC_MeasuringInput" or "MC_MeasuringInputCyclic" until a measurement occurs and the results are displayed.

The following times must be distinguished here:

- Time until the measuring event can be captured
- Time until the measurement result is displayed or the measurement is finished.

The times calculated taking into account the current settings are indicated in configuration window "Extended parameters" of a measuring input.

Measuring using TM Timer DIDQ / Measuring using SINAMICS measuring input

Measurement using PROFIdrive telegram (drive or external encoder)

Definition of tags:

Measurement using TM Timer DIDQ/Measurement using SINAMICS measuring input

- Time from output of an MC_MeasuringInput job until measuring event detection becomes effective:
  - MeasuringRangeActivationTime: 2 x T_{servo}
- Time after measuring event until measured value is available in the controller:
  - One-time measurement: 2 x T_{servo} + T_{Send}
  - Cyclic measuring: T_{servo} + T_{Send}
- Activation time for a measurement with measuring range:
  - MeasuringRangeActivationTime + MeasuringRangeAdditionalActivationTime

Measurement using PROFIdrive telegram (drive or external encoder)

- MeasuringRangeActivationTime: 4 x T_{servo}
- Time from output of an MC_MeasuringInput job until measuring event detection becomes effective:
  - Measuring a positive/negative edge or two edges:

    MeasuringRangeActivationTime + 2 x T_{servo}
  - Measuring two dedicated edges:

    MeasuringRangeActivationTime + 3 x T_{servo}
- Time after measuring event until measured value is available in the controller:
  - Measuring an edge: 7 x T_{servo}
  - Measuring two edges: 13 x T_{servo}
- Activation time for a measurement with measuring range:
  - Measuring a positive/negative edge or two edges:

    MeasuringRangeActivationTime + MeasuringRangeAdditionalActivationTime + 2 x T_{servo}
  - Measuring two dedicated edges:

    MeasuringRangeActivationTime + MeasuringRangeAdditionalActivationTime + 3 x T_{servo}

Definition of tags

- T_{servo} = Call interval of the technology object in the servo cycle clock [ms]
- T_{Send} = Send clock [ms]
- MeasuringRangeActivationTime = See section Measuring with measuring range (Page 121)

To prevent asynchronous processing from overwriting a measured value that was just determined, a new one-time measuring job cannot be started until the active measurement has concluded. The sum of the activation time and the time until display or conclusion must be taken into account for this.

With cyclic measuring, evaluation or temporary storage of the measurement results in the synchronous MC-PostServo [OB95] is recommended from the user perspective.

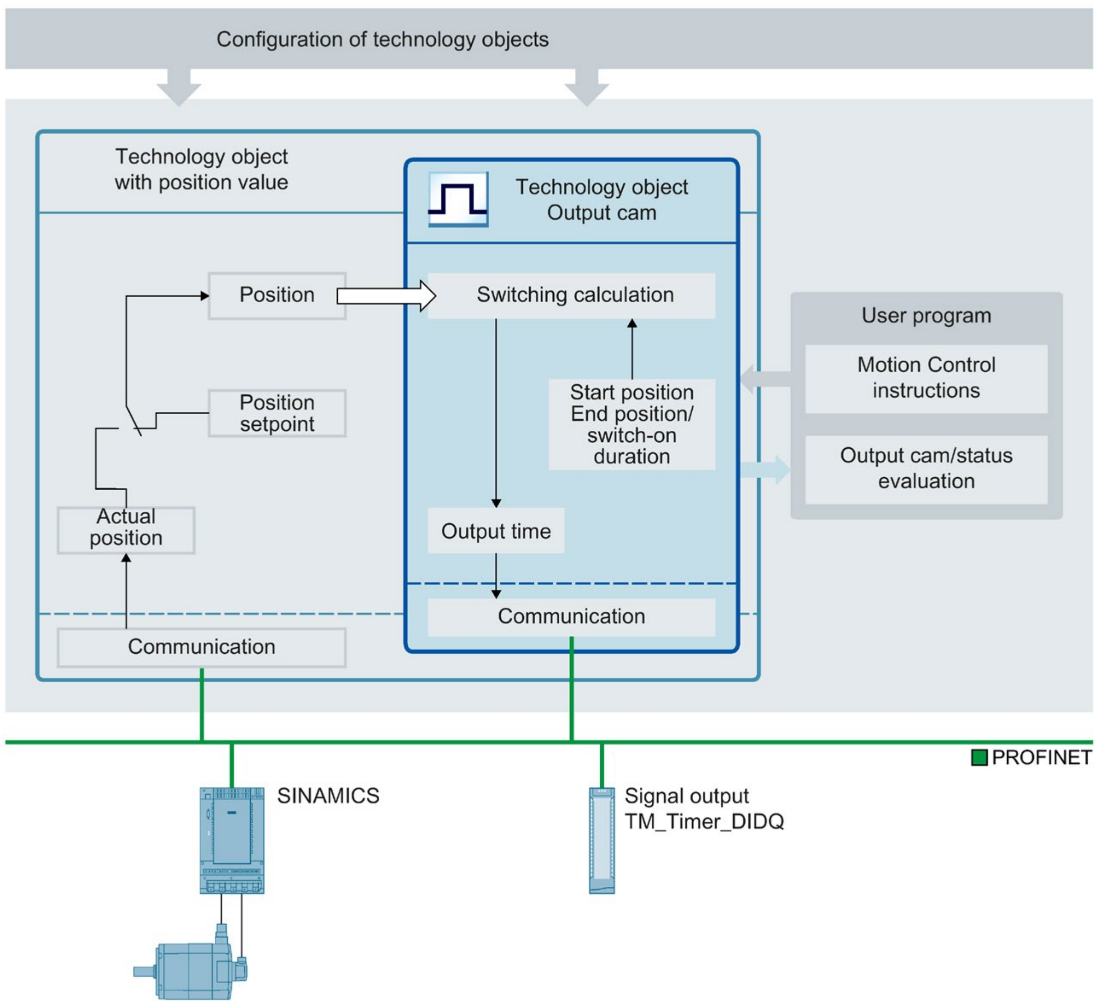
3.8 Technology object output cam

3.8.1 Brief description

The output cam technology object generates switching signals depending on the position of an axis or external encoder. The switching states can be evaluated in the user program and fed to digital outputs.

You can find an overview of the functions of the output cam technology object in the Functions (Page 27) section.

The figure below shows the basic operating principle of the output cam technology object:



Output cam types

The following output cam types can be used:

- Distance output cam (Page 130)

  Distance output cams switch on between the start position and end position. Outside this range, the distance output cam is switched off.

- Time-based output cam (Page 132)

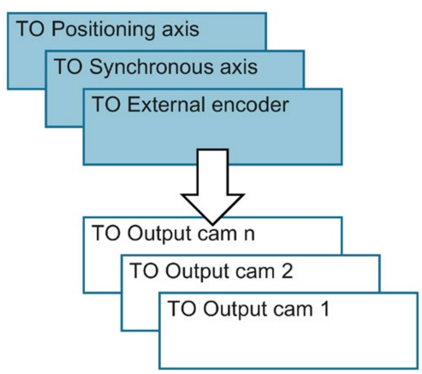
  Time-based output cams switch on for a defined time period when the start position is reached.

Assignment

The output cam technology object must always be assigned to another technology object whose position will be evaluated.

The output cam technology object can be assigned to the following technology objects:

- Synchronous axis
- Positioning axis
- External encoder



Exactly one axis or one external encoder can be assigned to an output cam.

Multiple output cams can be assigned to one axis or external encoder.

Output cam calculation and output cam output

The output cam technology object calculates the exact switching time, thereby ensuring exact adherence to the switching positions. The switching time is calculated two position control cycles before the output.

The following output options are available for the digital cam output:

- TM Timer DIDQ

  Digital output with high degree of accuracy and reproducibility in the microsecond range on ET 200MP TM Timer DIDQ 16x24V and ET 200SP TM Timer DIDQ 10x24V time-based IO modules

  Output by TM Timer DIDQ requires isochronous mode. Isochronous mode is only possible with PROFINET interface modules.

- Digital output module

  Digital output with switching accuracy depending on the output cycle of the I/O used

When output is deactivated, the output cam status is not output at the hardware output. The output cam status can be used internally in the user program by evaluating the relevant "<TO>.CamOutput" tag.

Inverted output

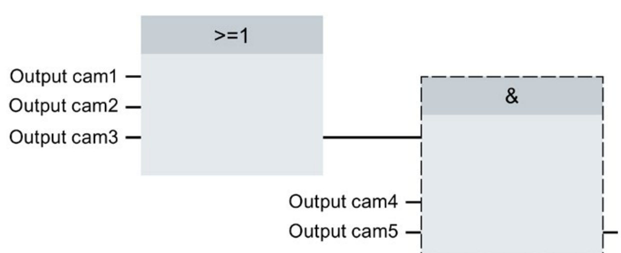
In the case of the inverted output, the range in which the cam output is switched on and the range in which it is switched off are swapped.

The inverted output is set in Motion Control instruction "MC_OutputCam" and is active when the instruction is enabled.

The inverted output can be used for both distance output cams and time-based output cams.

Output of multiple output cams to one output

The output of multiple output cams to one output is performed with either an AND or OR logic operation of the output cam signals to the output.



Display of the switching state

The switching state of the output cam is displayed in the associated technology DB in "<TO>.CamOutput".

Position reference

The switching points of the output cams can be referenced to the following positions, depending on the interconnected technology object.

- Actual position of a synchronous axis/positioning axis
- Position setpoint of a synchronous axis/positioning axis
- Position of an external encoder

Homing the interconnected technology object

A change to the position of an axis or external encoder using Motion Control instruction "MC_Home" is regarded as a sudden position change.

- Distance output cams are either skipped or correspondingly output.
- Time-based output cams are skipped. A time-based output cam is switched on only when the start position is crossed and remains switched on for the on-load factor.
- Switched time-based output cams are not canceled by a homing operation.

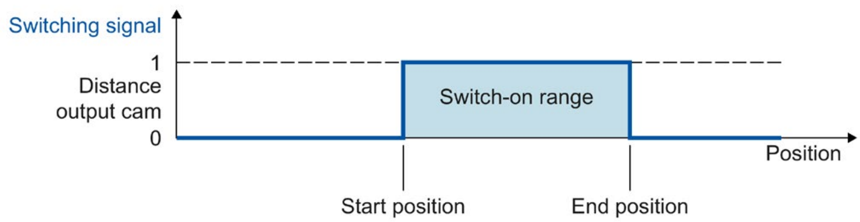
3.8.2 Distance output cam

Switch-on range

The switch-on range of distance output cams is basically defined by the start position and end position.

Start position smaller than end position

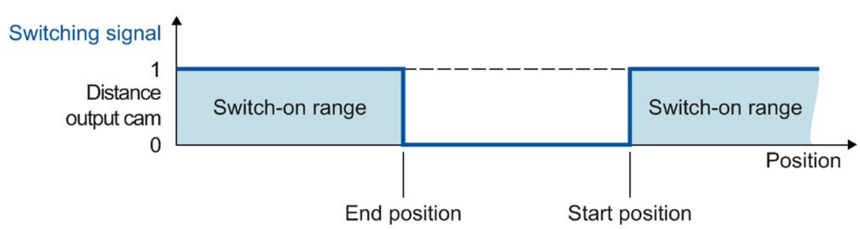
When the start position is less than the end position, the switch-on range begins with the start position and ends with the end position.



Start position greater than end position

When the start position is greater than the end position, there are two switch-on ranges as follows:

- Switch-on range beginning with the start position and ending with the positive range end (e.g. positive software limit switch, end of modulo range)
- Switch-on range beginning with the negative range end (e.g. negative software limit switch, start of modulo range) and ending with the end position



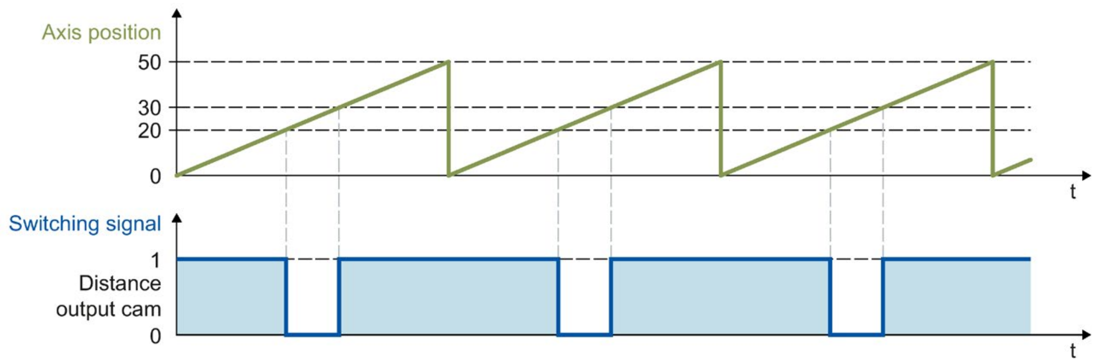
Mapping to an axis with modulo function

With active modulo function of the interconnected technology object, the start and end positions of the output cam are automatically mapped to values within the modulo range.

Example

- Modulo range = 0° to 50°
- Output cam start position = 80°
- Output cam end position = 220°

⇒ The distance output cam switches on at 30° and switches off again at 20°.



Switching characteristics

After activation, a distance output cam switches on in the following cases:

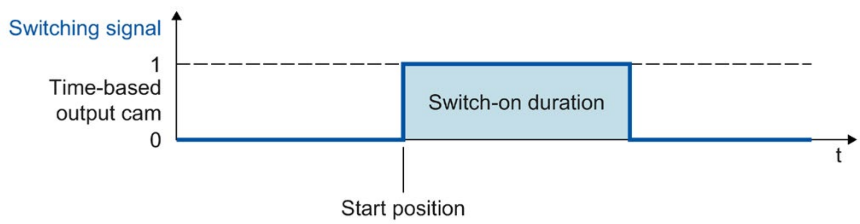
- The position of the interconnected technology object reaches the start or end position in the activation direction configured in Motion Control instruction "MC_OutputCam".
- The position of the interconnected technology object is moved into the switch-on range of the output cam (e.g. during homing) in the activation direction configured in Motion Control instruction "MC_OutputCam". If both activation directions are enabled in Motion Control instruction "MC_OutputCam", the output cam switches on even when the interconnected technology object is at a standstill.
- The output cam is switched on permanently using Motion Control instruction "MC_OutputCam" with "Mode" = 3.

An active distance output cam switches off in the following cases:

- The position is outside the switch-on range of the output cam.
- The position value is moved outside the switch-on range of the output cam.
- Motion Control instruction "MC_OutputCam" is set to "Enable" = FALSE.
- The motion direction of the interconnected technology object is reversed and no longer agrees with the enabled activation direction.

3.8.3 Time-based output cam

A time-based output cam switches on at the start position and remains set for the on-load factor.



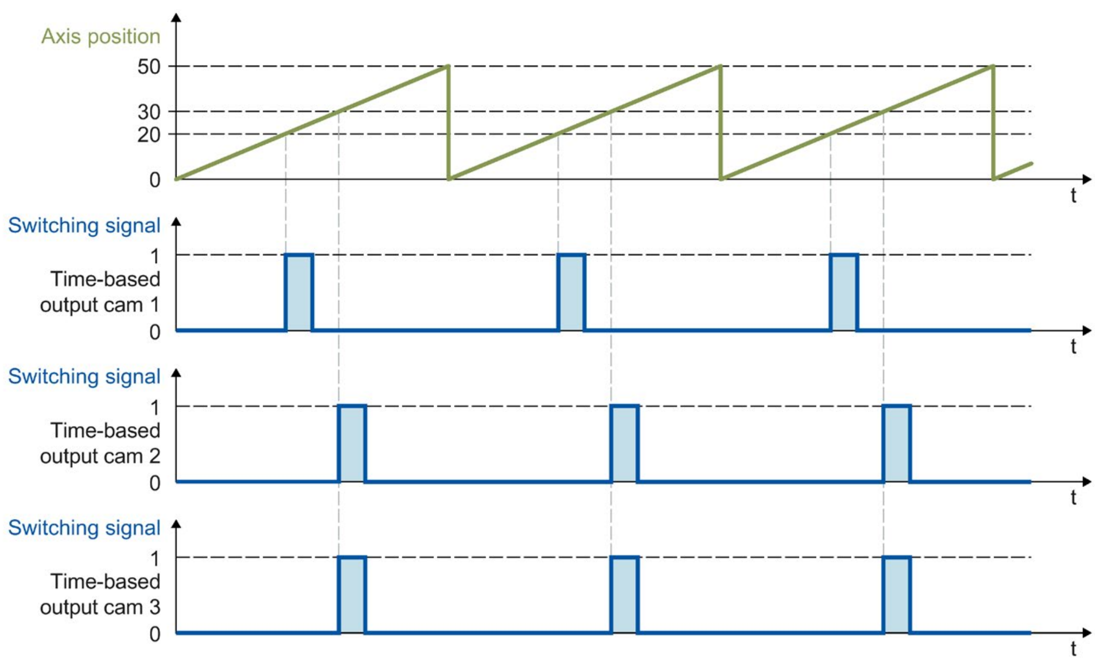
Mapping to an axis with modulo function

In the case of active modulo function of the interconnected technology object, the start position of the output cam is automatically mapped to the value within the modulo range.

Example

- Modulo range = 0° to 50°
- Output cam start positions:
  - Output cam 1 = 20°
  - Output cam 2 = 30°
  - Output cam 3 = 80°

⇒ The time-based output cam 1 switches on at 20°, the time-based output cams 2 and 3 switch on at 30°. All three output cams remain active the set on-load factor in each case.



Switching characteristics

A time-based output cam switches on in the following cases:

- The start position has been reached and the motion direction of the interconnected technology object corresponds to the effective direction enabled by the instruction.

Note

- If the start position is reached again while an output cam is switched on, the on-load factor is not re-triggered.
- If due to the Motion Control instruction "MC_Home", the position value of the interconnected technology object is placed directly on or behind the start position of the output cam during the motion, the output cam does not switch on.

A time-based output cam switches off in the following cases:

- The configured on-load factor has expired.
- Motion Control instruction "MC_OutputCam" is set to "Enable" = FALSE.

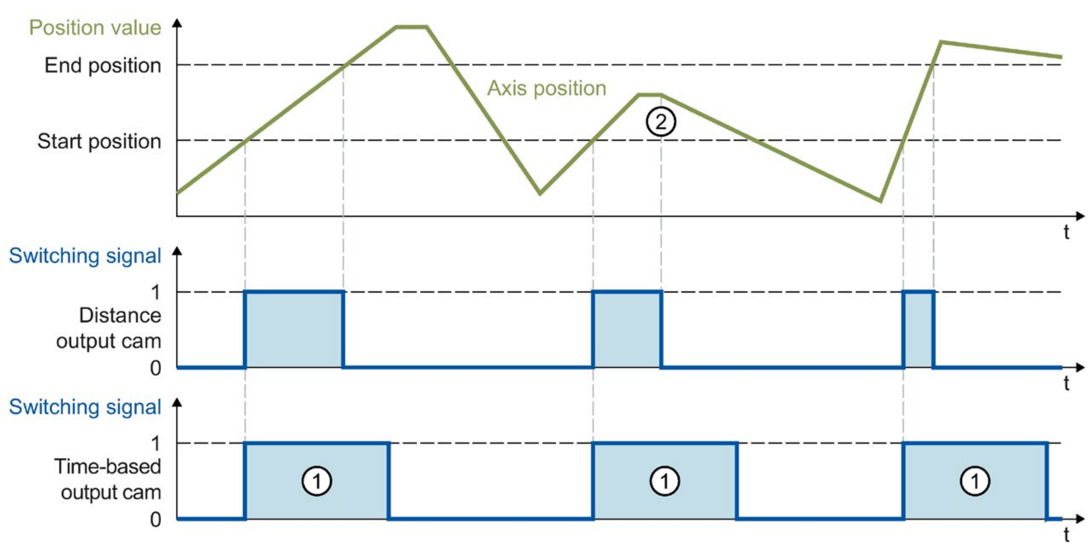
3.8.4 Activation direction of cam

An output cam can be switched depending on the motion direction of the interconnected technology object. It is possible to output an output cam with positive or negative motion direction only or even independent of direction.

The effective direction is set in "MC_OutputCam.Direction".

The following examples show the behavior of the output cam as a function of the effective direction setting.

Example of "positive" effective direction ("Direction" = 1)



Distance output cam

The output cam switches on when the switch-on range is reached in the **positive** direction. At a direction reversal ②, the output cam switches off.

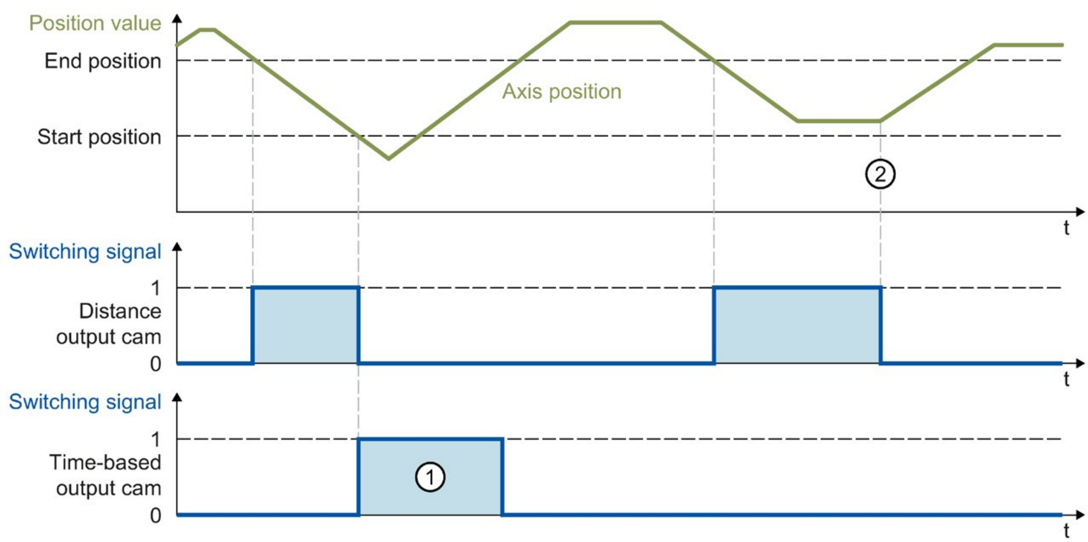
If the position value is moved into the switch-on range of the output cam, the cam switches on when there is positive motion direction of the interconnected technology object. The output cam remains switched off when the interconnected technology object is at a standstill.

Time-based output cam

The output cam switches on when the start position is reached in the **positive** direction. At a direction reversal, the output cam remains switched on for the specified on-load factor ①.

If during the homing motion, the position value of the interconnected technology object is directly on or behind the start position of the output cam, the output cam does not switch on.

Example of "negative" effective direction ("Direction" = 2)



Distance output cam

The output cam switches on when the switch-on range is reached in the **negative** direction. At a direction reversal ②, the output cam switches off.

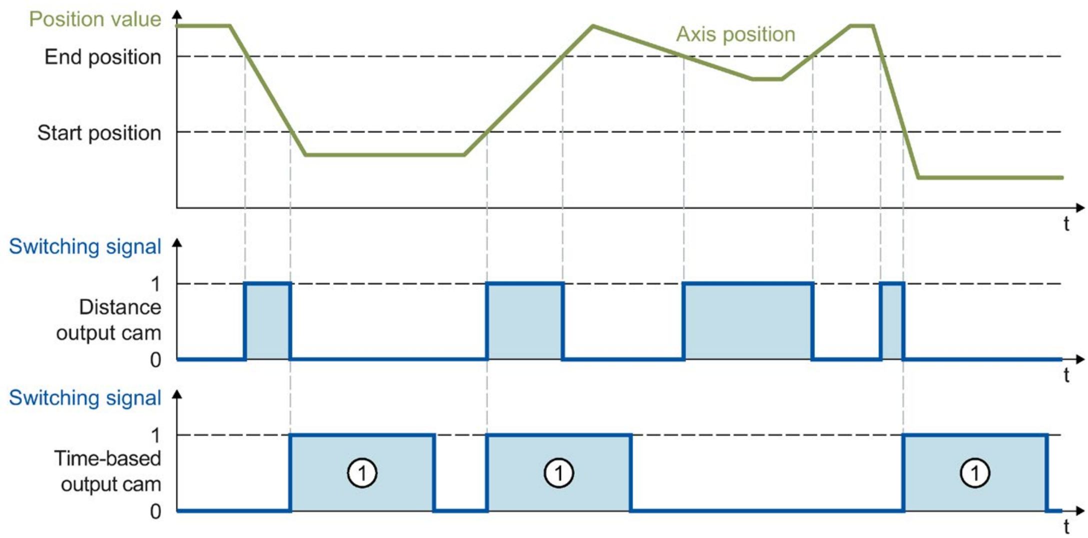
If the position value is moved into the switch-on range of the output cam, the output cam switches on when there is negative motion direction of the interconnected technology object. The output cam remains switched off when the interconnected technology object is at a standstill.

Time-based output cam

The output cam switches on when the start position is reached in the **negative** direction. At a direction reversal, the output cam remains switched on for the specified on-load factor ①.

If during the homing motion, the position value of the interconnected technology object is directly on or behind the start position of the output cam, the output cam does not switch on.

Example of "both directions" effective direction ("Direction" = 3)



Distance output cam

The output cam switches on when the position of the interconnected technology object is within the switch-on range.

If the position value of the interconnected technology object is moved into the switch-on range of the output cam, the cam switches on even when the interconnected technology object is at a standstill.

Time-based output cam

The output cam switches on when the start position is reached. At a direction reversal, the output cam remains switched on for the specified on-load factor ①.

If during the homing motion, the position value of the interconnected technology object is directly on or behind the start position of the output cam, the output cam does not switch on.

3.8.5 Hysteresis

Possible variations in the actual position/position setpoint can result in unwanted switch-on and switch-off of cams.

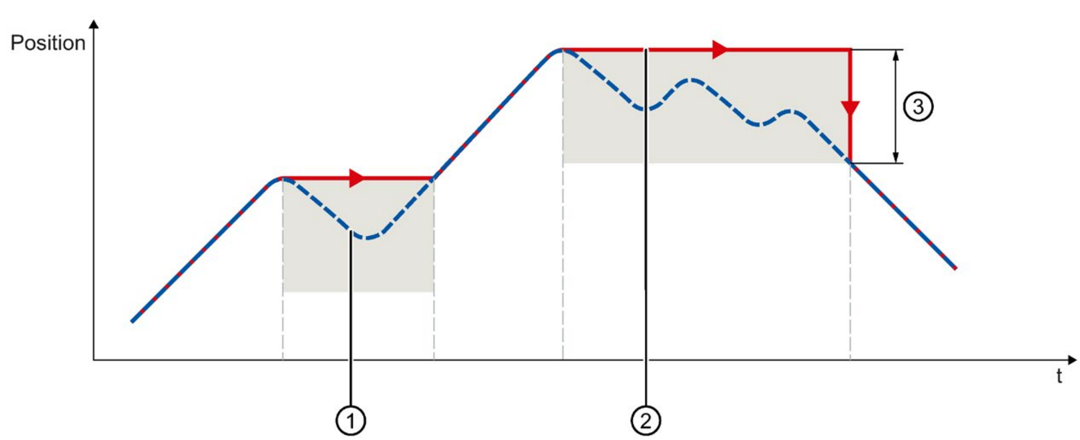
Minimal changes of the actual value of an axis at standstill can result in switch-on or switch-off of an actual value output cam with specified positive or negative effective direction. Even minimal changes of the setpoints of a switched-off axis in follow-up mode can result in switch-on or switch-off of an actual value output cam with specified positive or negative effective direction. Such unwanted switching states can be prevented by configuring a hysteresis (> 0.0). The configuration of a hysteresis value (> 0.0) is recommended in particular with reference to the actual position.

The hysteresis is a position tolerance within which the position values may vary without changing the switching state of the output cam. Changes of direction detected within the hysteresis are ignored.

The hysteresis is set for the technology object in <TO>.Parameter.Hysteresis.

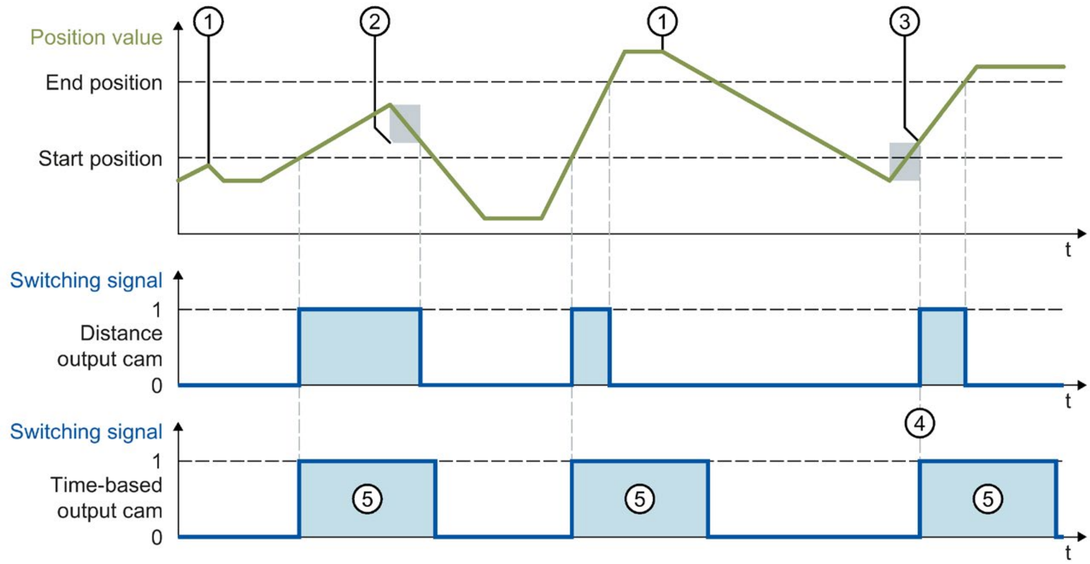
Behavior

- The hysteresis is activated at a direction reversal.
- The following applies within the hysteresis:
  - The switching state of distance output cams is not changed.
  - The motion direction is not determined again.
  - If the start position of a time-based output cam is within the hysteresis, the time-based output cam is switched on when leaving the hysteresis with the corresponding effective direction.
  - The on-load factor of time-based output cams remains unchanged.
- After the hysteresis range is exited, distance output cams are set according to the output cam settings.



① Actual position
② Effective position
③ Hysteresis range

The following examples show the effects of the hysteresis on the switching behavior of output cams with positive activation direction.



① Direction reversal without hysteresis effect
② Hysteresis in effect
③ The switch-on position of the distance output cam is influenced according to the direction reversal and hysteresis.
④ The start position of the time-based output cam is located within the hysteresis. The time-based output cam is switched on when leaving the hysteresis with the corresponding effective direction.
⑤ Switch-on duration

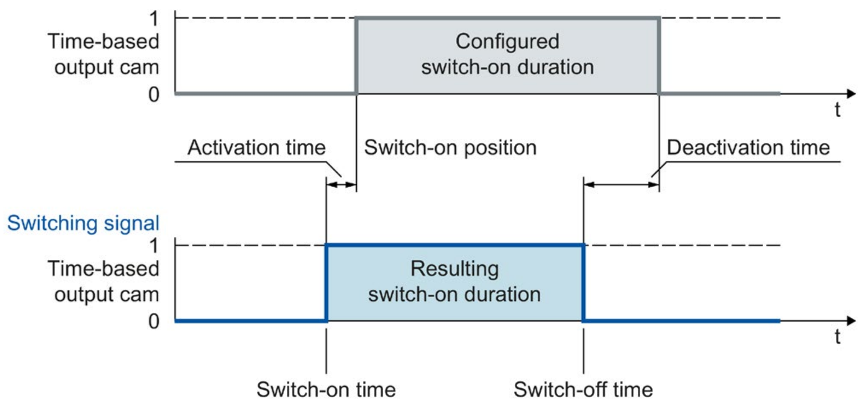
Hysteresis range

The maximum size of the hysteresis range in the system is as follows: for an axis with modulo function, one quarter of the modulo range; for an axis without modulo function, one quarter of the operating range.

3.8.6 Compensation of actuator switching times

Switching times of the output and the connected actuator (e.g. valve) can be compensated for using the activation time or deactivation time of the output cam technology object.

The activation time is specified as the lead time for the switch-on edge, and the deactivation time as the lead time for the switch-off edge.



The activation time is set in the technology object <TO>.OnCompensation.

The deactivation time is set in the technology object <TO>.OffCompensation.

Note

- The following must be met for the times:

  On-load factor > deactivation time - activation time

  (The on-load factor for distance output cams is determined by the switching positions and the current velocity)
- If the output cam has been switched taking the lead times into consideration, this action has taken place from the system perspective and will not be restarted in response to any subsequent variation in the actual speed.
- System-dependent runtimes are automatically taken into consideration when output by TM Timer DIDQ is used.

  When the output with a digital output module is used, system-dependent runtimes are not taken into consideration and must be set as correction times in the activation time or deactivation time.

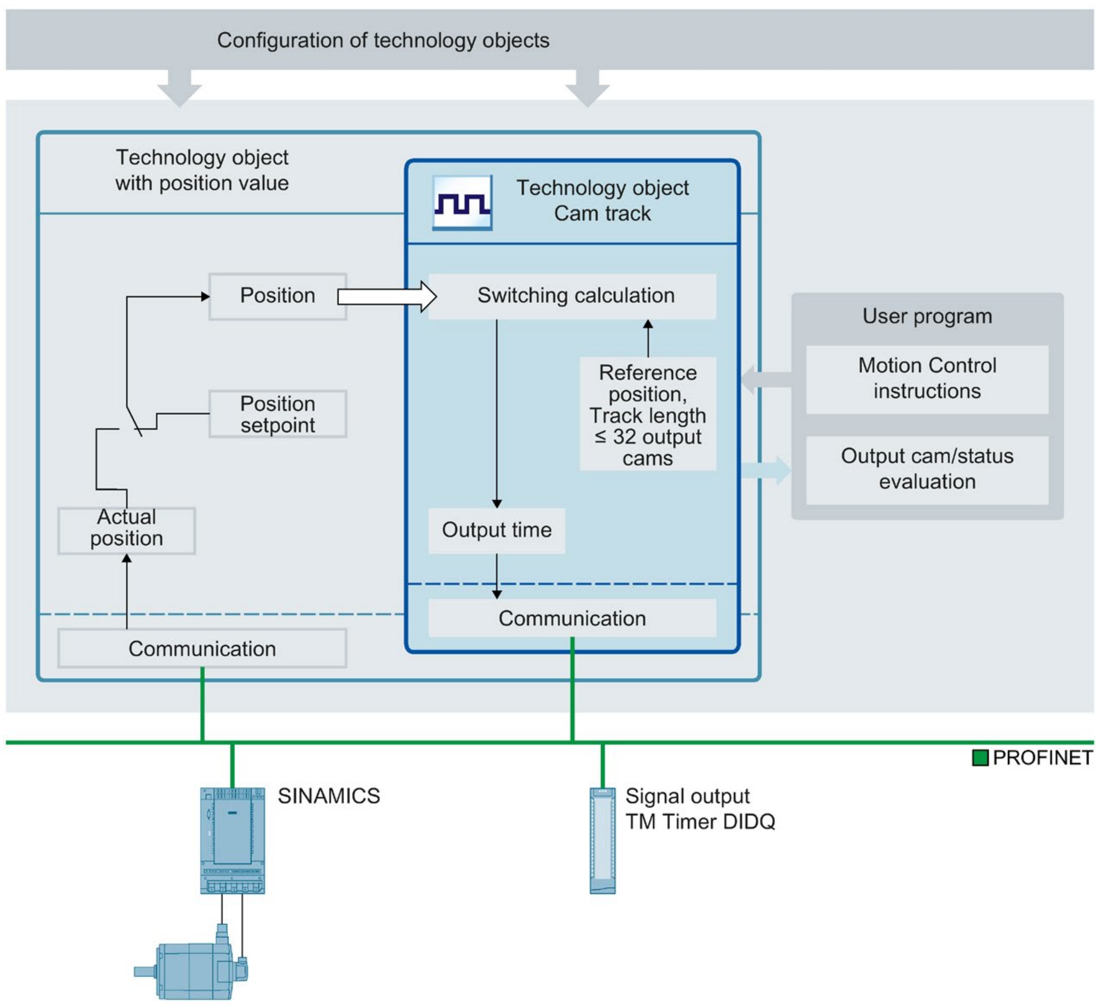
3.9 Cam track technology object

3.9.1 Brief description

The cam track technology object generates a switching signal sequence dependent on the position of an axis or external encoder. A cam track can consist of up to 32 individual output cams and be output to one output. The switching states can be evaluated in the user program or fed to digital outputs.

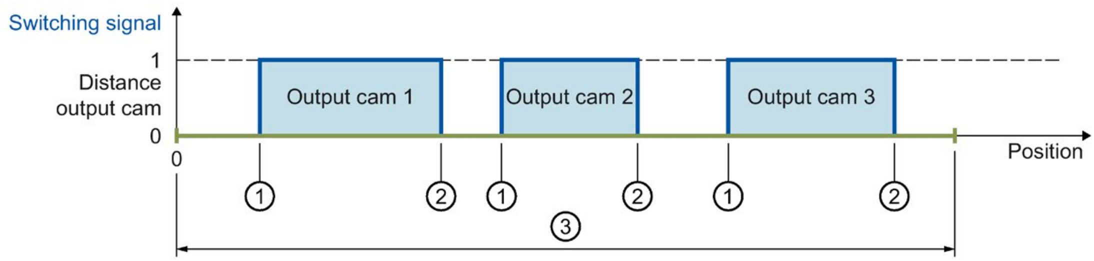
You can find an overview of the functions of the cam track technology object in the Functions (Page 27) section.

The figure below shows the basic principle of operation of the cam track technology object:



Definition of cam track

A cam track consists of up to 32 individual output cams that are specified within an adjustable track length.



① Start position
② End position
③ Cam track length

Figure 3-2 Cam track with distance output cam

The output cam positions are defined relative to the cam track. The start of the cam track is always 0.0. The output cam positions on the cam track are thus always positive.

When the cam track is processed, the output cams with start position within the track length are taken into consideration.

If the end of a cam track is crossed, connected output cams behave as follows within the cam track:

- Time-based output cams remain switched on for the set on-load factor.
- Distance output cams whose end position lie outside the cam track are switched off when the cam track is left.

Cams whose start and end positions lie outside the cam track length are ignored. They become active only if the cam track length is increased so that at least the respective start position of an output cam is within the new track length.

Mapping of the cam track to the position of an axis or external encoder.

The start of the cam track is placed at the specified reference position of the interconnected technology object. Thus, the switching positions result from the cam track positions mapped onto the interconnected technology object starting from the reference position. The cam track is continued in both directions of the interconnected technology object.

The setting for the reference position can be either positive or negative.

Example

- Axis range = -1000 mm to +1000 mm
- Desired switching points of the output cam with reference to axis position:
  - Start position = -200 mm
  - End position = -100 mm
- Cam track length = 2000 mm
- Definition of output cam on the track:
  - Start position = 800 mm
  - End position = 900 mm

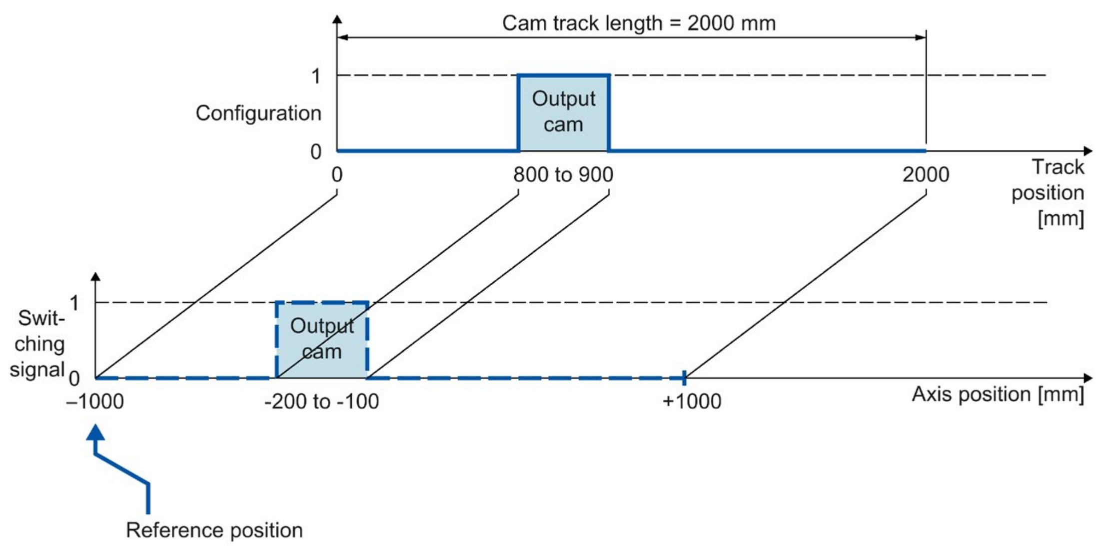


Figure 3-3 Cam track with output cam output at negative axis position

Processing of a cam track

The processing of a cam track occurs cyclically.

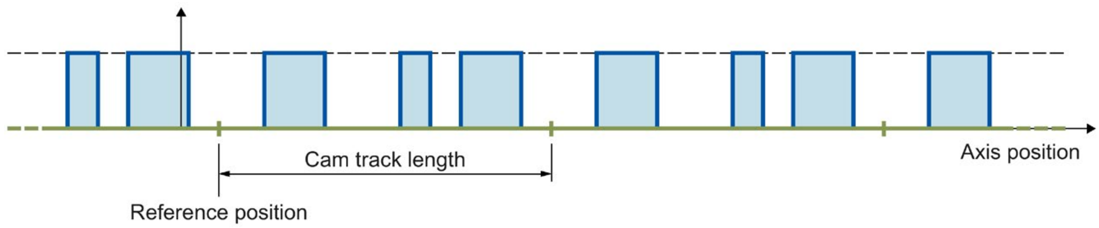

Figure 3-4 Cyclic mapping of a cam track

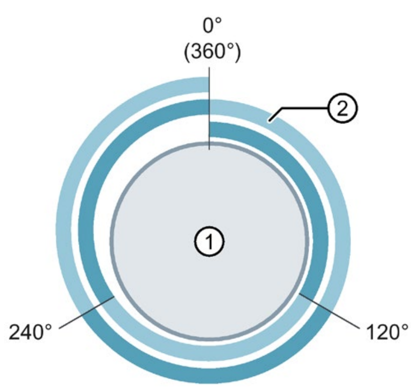
The cam track is mapped onto the position of the interconnected technology object starting from the reference position and is continued cyclically in both directions.

Track length and mapping to an axis with modulo function

When a cam track is mapped onto an axis with modulo function, a reference position specified outside the modulo range is mapped within the modulo range.

The track length can be less than or greater than the modulo length of the axis. In order for the cam track to be mapped without offset in the modulo range and to prevent unwanted overrides, an integer ratio of modulo length to track length, and vice versa, is required.

Example Mapping without offset



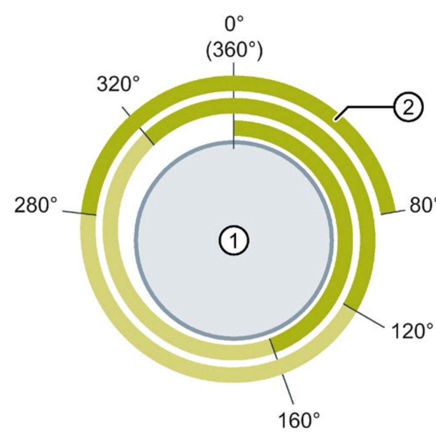
① Axis with modulo length 360°

② Cam track with track length 120°

⇒ Ratio = 360° / 120° = **3**

The cam track is output 3 times on a modulo length.

Example Mapping with offset



① Axis with modulo length 360°

② Cam track with track length 160°

⇒ Ratio = 360° / 160° = **2.25**

The cam track is output 2.25 times on the first modulo length and continued correspondingly in the other modulo lengths.

During cyclic processing of the cam track, the continued reference position of the current cam track is displayed in the <TO>.MatchPosition tag. The continued reference position is independent of direction and always the position of the left boundary of the cam track. The unique detection and output of the position is only possible when the assigned technology object is in motion. The distance to the current reference position of the current cam track (<TO>.MatchPosition) is displayed in the <TO>.TrackPosition tag.

Output cam types

The following output cam types are used:

- Distance output cam
- Time-based output cam

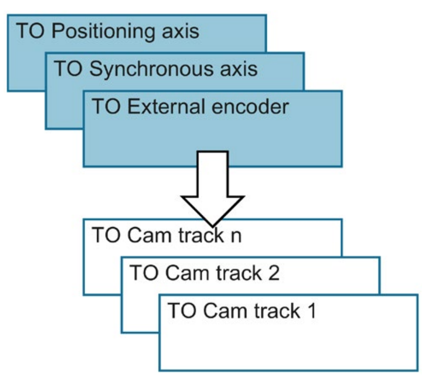
The output cams of the cam track can be set as distance output cams or time-based output cams, whereby only one of the two output cam types can be used in one cam track.

Assignment

The cam track technology object must always be assigned to another technology object whose position is evaluated.

The cam track technology object can be assigned to the following technology objects:

- Synchronous axis
- Positioning axis
- External encoder



Exactly one axis or one external encoder can be assigned to a cam track.

Multiple cam tracks can be assigned to one axis or external encoder.

Position reference

The switching points of the output cams of a cam track can be referenced to the following positions, depending on the interconnected technology object.

- Actual position of a synchronous axis/positioning axis
- Position setpoint of a synchronous axis/positioning axis
- Position of an external encoder

Homing the interconnected technology object

A change to the position of an axis or external encoder using Motion Control instruction "MC_Home" is regarded as a sudden position change. An enabled cam track is referenced to the changed position and processed further from there.

- For axes with modulo function, homing also has an effect on the current position of the cam track (<TO>.TrackPosition). The position is formed again as quickly as possible due to the offset.
- Distance output cams are either skipped or correspondingly output.
- Time-based output cams are skipped. A time-based output cam is switched on only when the start position is crossed and remains switched on for the on-load factor.
- Switched time-based output cams are not canceled by a homing operation.

We recommend locking the cam track before or during homing.

Output of a cam track

The following output options are available for the digital cam track output:

- TM Timer DIDQ

  Digital output with high degree of accuracy and reproducibility in the microsecond range on ET 200MP TM Timer DIDQ 16x24V and ET 200SP TM Timer DIDQ 10x24V time-based IO modules

  Output by TM Timer DIDQ requires isochronous mode. Isochronous mode is only possible with PROFINET interface modules.
- Digital output module

  Digital output with switching accuracy depending on the output cycle of the I/O used

A maximum of two edges (by TM Timer DIDQ, positive and negative) or one edge (via digital output module, positive or negative) can be output per position control cycle clock. If multiple switch-on edges or switch-off edges are transmitted in one position control cycle clock, the last written values in each case are valid.

Masking of individual output cams of a cam track

In order for output cams to processed, they must be configured as valid in the technology data block with "<TO>.Parameter.Cam[1 … 32].Existent" = TRUE. In addition, output cams of a cam track configured as valid can be masked in the user program using bit masking ("<TO>.Parameter.CamMasking"). In the default setting, all valid output cams are enabled ("<TO>.Parameter.CamMasking" = 0xFFFFFFFF). The cam track itself is activated/deactivated using the Motion Control instruction "MC_CamTrack".

3.9.2 Effective direction

The cam track is always active for both directions of the position of the interconnected technology object.

Output of a cam track with distance output cam

Distance output cams are switched when the switch-on range is overtraveled.

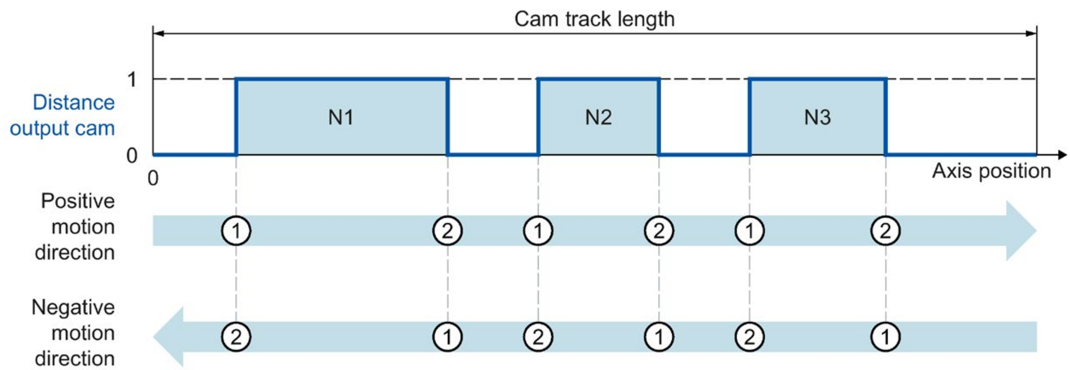


Figure 3-5 Executing a cam track with distance output cams dependent on the motion direction of the axis

- With positive motion direction, the output cams of the cam track are output in the order Output Cam N1, Output Cam N2, Output Cam N3
- In the case of negative motion direction, the output cams of the cam track are output in the order Output Cam N3, Output Cam N2, Output Cam N1
- The distance output cams switch on at ① and switch off at ②

Output of a cam track with time-based output cam

The time-based output cams are switched when the start position is crossed.

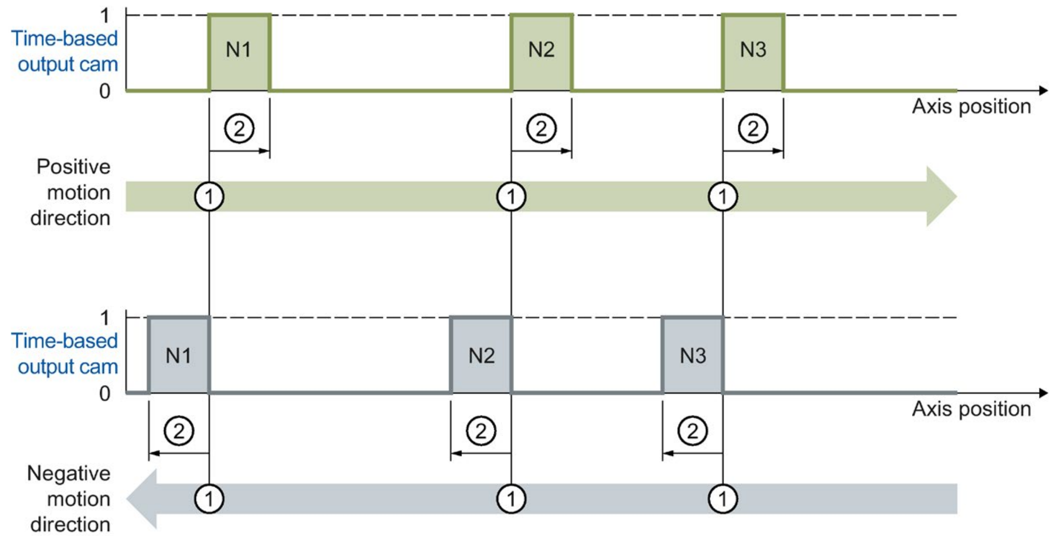

Figure 3-6 Executing a cam track with time-based output cams dependent on the motion direction of the axis

- With positive motion direction, the output cams of the cam track are output in the order Output Cam N1, Output Cam N2, Output Cam N3
- In the case of negative motion direction, the output cams of the cam track are output in the order Output Cam N3, Output Cam N2, Output Cam N1
- The time-based output cams switch on at ① and remain switched on for the set switch-on duration ②

3.9.3 Changing the cam track data during operation

The data of a cam track and the parameters of the associated Motion Control instruction "MC_CamTrack" can be changed while track processing is enabled. The active Motion Control instruction "MC_CamTrack" is not aborted. The modified parameters, however, only take effect at the next call of Motion Control instruction "MC_CamTrack".

The following parameters can be changed during operation and are in effect after another call of Motion Control instruction "MC_CamTrack".

- Cam track data in technology data block
  - Reference position (<TO>.Parameter.ReferencePosition)
  - Track length (<TO>.Parameter.CamTrackLength)
  - Bit masking of individual output cams (<TO>.Parameter.CamMasking)
  - Activation time (<TO>.Parameter.OnCompensation)
  - Deactivation time (<TO>.Parameter.OffCompensation)
  - Hysteresis value (<TO>.Parameter.Hysteresis)
  - Output cam data (<TO>.Parameter.Cam[1 … 32])
- Parameters in the function block
  - Enable (MC_CamTrack.Enable)
  - Mode (MC_CamTrack.Mode)
  - Inverted output (MC_CamTrack.InvertOutput)

Note the different activation behavior (Page 150) when changing the cam track data.

3.9.4 Activation behavior

A cam track is activated by the call of Motion Control instruction "MC_CamTrack" with "Enable" = TRUE. A distinction must be made here between:

- A first-time activation of the cam track
- The call after a change of the cam track data during active cam track processing

The difference relates to how the cam track data is applied. Depending on the set mode ("MC_CamTrack.Mode"), the configuration (cam track data, data in the function block) is applied at different times.

- **First-time switch-on of a cam track**

  The call of Motion Control instruction "MC_CamTrack" with "Enable" = TRUE activates the cam track immediately (<TO>.Status changes to 1) and configured cam track data takes effect immediately. This behavior is the same when "MC_CamTrack.Mode" = 0 and "MC_CamTrack.Mode" = 1.

- **Change of cam track data of an already activated cam track**(<TO>.Status = 1)

  – With the call of Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and "Mode" = 0, the modified cam track data takes effect immediately.

    Previously activated distance output cams are aborted if their track signals are not still set due to the changed cam track data. Previously activated time-based output cams are always aborted.

  – With the call of Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and "Mode" = 1, the cam track continues to be output with the prior configuration up to the cam track end. Modified cam track data takes effect at the end of the current track cycle.

    If you change a cam track with "MC_CamTrack.Mode" = 1 during runtime of the user program, keep in mind the lead time of the cam track as reserve for the first output cam. Define the first output cam position in the cam track only after the following position:

    Position of first output cam > velocity of axis x lead time of the cam track (<TO>.Parameter.OnCompensation)

    Also keep in mind the internal system time for output cam calculation, even if you set the lead time 0.0.

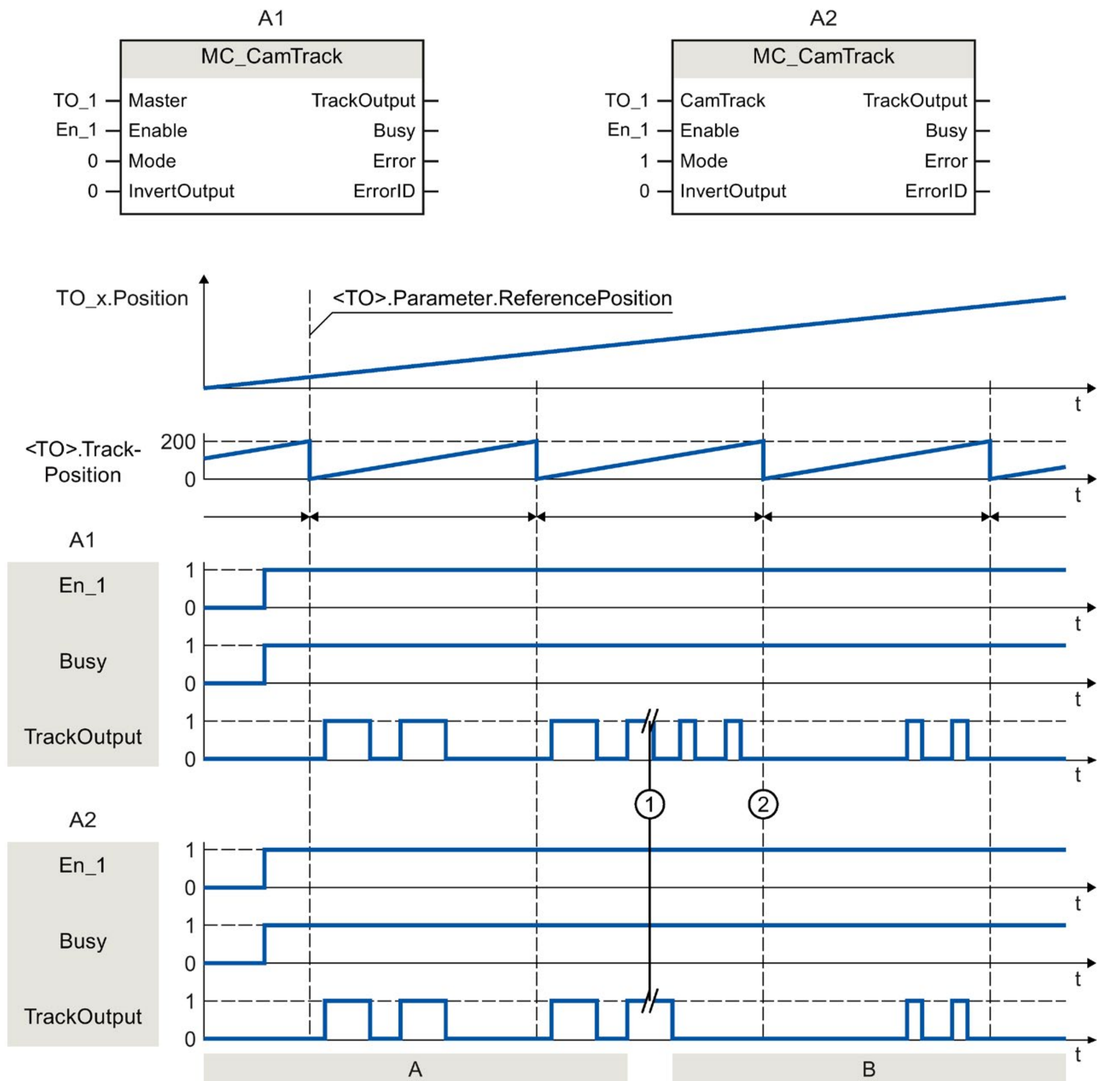
Changing cam track data when modulo length is not a multiple of the track length

For the switching times to be set correctly, we recommend the following procedure for changes:

- Enter changes as soon as possible after start of a new cam track
- Enter a new reference position (<TO>.Parameter.ReferencePosition) for the changed cam track. The new reference position is composed as follows depending on the direction:
  - Positive effective direction: Current reference position (<TO>.MatchPosition) + cam track length (<TO>.Parameter.CamTrackLength)
  - Negative effective direction: Current reference position (<TO>.MatchPosition) - cam track length (<TO>.Parameter.CamTrackLength)
- Output the changes of the cam track when calling the Motion Control instruction "MC_CamTrack" and "Mode" = 1.

Example

The following figure shows an example of the differences in the activation behavior.



A1	A	The cam track is activated the first time with "MC_CamTrack.Enable" = TRUE and the output cams are output immediately with set "MC_CamTrack.Mode" = 0.
	B	After cam track data were changed (①), the cam track is activated by calling Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and the modified data takes effect immediately (①) with set "MC_CamTrack.Mode" = 0.
A2	A	The cam track is activated the first time with "MC_CamTrack.Enable" = TRUE and the output cams are output immediately with set "MC_CamTrack.Mode" = 1.
	B	After cam track data were changed (①), the cam track is activated by calling Motion Control instruction "MC_CamTrack" with "Enable" = TRUE and the modified data takes effect at the end of the current track cycle (②) with set "MC_CamTrack.Mode" = 1.

3.9.5 Hysteresis

The hysteresis is set in the cam track technology object. The behavior and effect of the hysteresis setting corresponds to the hysteresis (Page 136) for the cam technology object.

3.9.6 Time offset of cam switching points

Switching times of the output and the connected actuator (e.g. valve) can be compensated for using the activation time or deactivation time of the cam track technology object.

The time offset of cam switching points corresponds to the activation time or deactivation time (Page 138) for the cam technology object.

<TO>.Parameter.OffCompensation	Deactivation time (lead time for the switch-off edge)
<TO>.Parameter.Hysteresis	Hysteresis value
<TO>.Parameter.Cam[1 … 32].OnPosition	Start position (distance and time-based output cams)
<TO>.Parameter.Cam[1 … 32].OffPosition	End position (distance output cam)
<TO>.Parameter.Cam[1 … 32].Duration	Switch-on duration (time-based output cam)

<TO>.Parameter.Cam[1 … 32].Existent	Validity of an output cam FALSE: Output cam not used TRUE: Output cam is used
Interface	
<TO>.Interface.EnableOutput	Output cam output at the bit specified under "Address" FALSE: No output TRUE: Output
<TO>.Interface.Address	I/O address for digital cam output
Units	
<TO>.Units.LengthUnit	Unit of the length data
<TO>.Units.TimeUnit	Unit of the time data
StatusWord	
<TO>.StatusWord.X0 (Control)	The technology object is in operation.
<TO>.StatusWord.X1 (Error)	An error occurred at the technology object.
<TO>.StatusWord.X2 (RestartActive)	The technology object is being reinitialized. The tags of the technology data block are not updated with active restart.
<TO>.StatusWord.X3 (OnlineStart-ValuesChanged)	Data relevant for the restart has been changed. The changes are applied only after a restart of the technology object.
<TO>.StatusWord.X4 (OutputInverted)	The output cam output is inverted.
<TO>.StatusWord.X5 (CommunicationOk)	The cam track is synchronized with the output module and available for use.
<TO>.StatusWord.X6 (CamDataChanged)	The data of individual output cams has been changed but not yet taken effect with Motion Control instruction "MC_CamTrack".
ErrorWord	
<TO>.ErrorWord.X0 (SystemFault)	A system-internal error has occurred.
<TO>.ErrorWord.X1 (ConfigFault)	Configuration error One or more configuration parameters are inconsistent or invalid. The technology object was incorrectly configured, or editable configuration data were incorrectly modified during runtime of the user program.
<TO>.ErrorWord.X2 (UserFault)	Error in user program at a Motion Control instruction or its use.
<TO>.ErrorWord.X3 (CommandNot Accepted)	Command cannot be executed. A Motion Control instruction cannot be executed because necessary requirements have not been met.
<TO>.ErrorWord.X13 (PeripheralError)	Error accessing a logical address.
ErrorDetail	
<TO>.ErrorDetail.Number	Alarm number
<TO>.ErrorDetail.Reaction	Effective alarm reaction 0: No reaction 5: Cam track processing Is complete.

Using versions 4

4.1 Overview of versions

For S7-1500 Motion Control, a distinction is made between the version of the technology, the technology objects and the Motion Control instructions. The overview shown below includes S7-1500 and S7-1500T. Only one technology version can be operated on a CPU.

When changing to a CPU ≥ V1.6, you must change the technology version accordingly. Card replacement from a CPU < V1.6 to a ≥ CPU V1.6 is supported. In the TIA Portal, you can use a CPU ≥ 1.6 only to work on projects with a correspondingly higher technology version.

There are two ways of changing the technology version:

- Changing the version of the Motion Control instructions

  You change the version of the Motion Control instructions in the "Instructions" task card in the folder "Technology > Motion Control > S7-1500 Motion Control".

  If the Motion Control instruction version used does not correspond to the compatibility list, the relevant Motion Control instructions are highlighted in red in the program editor.

- Adding a technology object with an alternative version

  If a technology object with an alternative version is added in the "Add new object" dialog, the technology version is changed to the alternative version.

The technology objects and Motion Control instructions are only converted to the selected version of the technology during compilation.

The version of a technology object or a Motion Control instruction is indicated in the properties of the technology object, "General > Information" tab, "Version" field.

Compatibility list

The table below shows the compatibility of the technology version with the CPU version:

CPU	Technology	Technology object
V2.5	V4.0	Speed Axis V4.0 Positioning Axis V4.0 External Encoder V4.0 Synchronous Axis V4.0 Measuring input V4.0 Cam V4.0 Cam track V4.0 Cam V4.0 (S7-1500T) Kinematics V4.0 (S7-1500T)
V2.0, V2.1	V3.0	Speed Axis V3.0 Positioning axis V3.0 External encoder V3.0 Synchronous axis V3.0 Measuring input V3.0 Output cam V3.0 Cam track V3.0 Cam V3.0 (S7-1500T)
V1.6, V1.7, V1.8	V2.0	Speed Axis V2.0 Positioning axis V2.0 External encoder V2.0 Synchronous axis V2.0
V1.0, V1.1, V1.5[1]	V1.0	Speed Axis V1.0 Positioning axis V1.0 External encoder V1.0

1) Card replacement from a CPU < V1.6 to a CPU ≥ V1.6 is supported.

Parameter "Mode" of the Motion Control instruction "MC_Home"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter.

The table below shows a comparison of the "MC_Home.Mode" parameter for technology V1.0 and ≥ V2.0:

MC_Home.HomingMode V1.0	Parameter value	MC_Home.Mode ≥ V2.0
Direct homing (absolute)	0	Direct homing (absolute)
Direct homing (relative)	1	Direct homing (relative)
Passive homing	2	Passive homing (without reset)
Passive homing (with configured home position)	3	Active homing
Active homing	4	Reserved
Active homing (with configured home position)	5	Active homing (with configured home position)
Absolute encoder adjustment (relative)	6	Absolute encoder adjustment (relative)
Absolute encoder adjustment (absolute)	7	Absolute encoder adjustment (absolute)
Passive homing (without reset)	8	Passive homing
Abort passive homing	9	Abort passive homing
-	10	Passive homing (with configured home position)

You can find additional information about the "MC_Home.Mode" parameter in the description of the Motion Control instruction "MC_Home" (Page 369).

Tags of the technology object

Starting from technology version V3.0, all input and output addresses are specified using data type VREF. This results in the following changes to the tags of the technical object:

Tag of technology object	Changes starting from V3.0
<TO>.Actor.Interface.AddressIn	Data type: VREF
<TO>.Actor.Interface.AddressOut	Data type: VREF
<TO>.Sensor[n].Interface.AddressIn	Data type: VREF
<TO>.Sensor[n].Interface.AddressOut	Data type: VREF
<TO>.Actor.Interface.EnableDriveOutputAddress	Data type: VREF
<TO>.Actor.Interface.EnableDriveOutputBitNumber	Tag eliminated
<TO>.Actor.Interface.DriveReadyInputAddress	Data type: VREF
<TO>.Actor.Interface.DriveReadyInputBitNumber	Tag eliminated
<TO>.Sensor[n].ActiveHoming.DigitalInputAddress	Data type: VREF
<TO>.Sensor[n].ActiveHoming.DigitalInputBitNumber	Tag eliminated
<TO>.Sensor[n].PassiveHoming.DigitalInputAddress	Data type: VREF
<TO>.Sensor[n].PassiveHoming.DigitalInputBitNumber	Tag eliminated
<TO>.PositionLimits_HW.MinInputAddress	Data type: VREF
<TO>.PositionLimits_HW.MinInputBitNumber	Tag eliminated
<TO>.PositionLimits_HW.MaxInputAddress	Data type: VREF
<TO>.PositionLimits_HW.MaxInputBitNumber	Tag eliminated

4.2 Version V4.0

Innovations

Technology Version V4.0 contains the following new features:

- Exchange of torque data with the drive in the technological units of the technology object.
  - Additive setpoint torque
  - Current actual torque
  - Permissible torque range
- Extension of the data structure of the positioning axis and synchronous axis for using technology object kinematics
- Use of optimized data blocks (drive/encoder connection)

Additional innovations for S7-1500T:

Technology Version V4.0 contains the following additional features:

- Kinematic technology object (S7-1500T)
- Motion specification via MotionIn instructions (S7-1500T)
- Direct synchronous setting with MC_CamIn V4.0 (S7-1500T)

Motion Control instructions

Technology Version V4.0 contains the following Motion Control instructions:

- MC_Power V4.0
- MC_Reset V4.0
- MC_Home V4.0
- MC_Halt V4.0
- MC_MoveAbsolute V4.0
- MC_MoveRelative V4.0
- MC_MoveVelocity V4.0
- MC_MoveJog V4.0
- MC_MoveSuperimposed V4.0
- MC_SetSensor V4.0 (S7-1500T)
- MC_TorqueLimit V4.0
- MC_MeasuringInput V4.0
- MC_MeasuringInputCyclic V4.0
- MC_AbortMeasuringInput V4.0
- MC_OutputCam V4.0

- MC_CamTrack V4.0
- MC_GearIn V4.0
- MC_GearInPos V4.0 (S7-1500T)
- MC_PhasingAbsolute V4.0 (S7-1500T)
- MC_PhasingRelative V4.0 (S7-1500T)
- MC_CamIn V4.0 (S7-1500T)
- MC_SynchronizedMotionSimulation V4.0 (S7-1500T)
- MC_InterpolateCam V4.0 (S7-1500T)
- MC_GetCamFollowingValue V4.0 (S7-1500T)
- MC_GetCamLeadingValue V4.0 (S7-1500T)
- MC_MotionInVelocity V4.0 (S7-1500T)
- MC_MotionInPosition V4.0 (S7-1500T)
- MC_TorqueAdditive V4.0
- MC_TorqueRange V4.0
- MC_GroupInterrupt V4.0 (S7-1500T)
- MC_GroupContinue V4.0 (S7-1500T)
- MC_GroupStop V4.0 (S7-1500T)
- MC_MoveLinearAbsolute V4.0 (S7-1500T)
- MC_MoveLinearRelative V4.0 (S7-1500T)
- MC_MoveCircularAbsolute V4.0 (S7-1500T)
- MC_MoveCircularRelative V4.0 (S7-1500T)
- MC_DefineWorkspaceZone V4.0 (S7-1500T)
- MC_DefineKinematicsZone V4.0 (S7-1500T)
- MC_SetWorkspaceZoneActive V4.0 (S7-1500T)
- MC_SetWorkspaceZoneInactive V4.0 (S7-1500T)
- MC_SetKinematicsZoneActive V4.0 (S7-1500T)
- MC_SetKinematicsZoneInactive V4.0 (S7-1500T)
- MC_DefineTool V4.0 (S7-1500T)
- MC_SetTool V4.0 (S7-1500T)
- MC_SetOcsFrame V4.0 (S7-1500T)

Version-based UDT names

The following table shows the version-based UDT names for the control words and status words of the SIEMENS telegrams 10x:

UDT name <V4.0	UDT name ≥V4.0	WORD data type
PD_STW1	PD_STW1_611Umode	Control word 1 (STW1)
PD_STW2	PD_STW2_611Umode	Control word 2 (STW2)
PD_ZSW1	PD_ZSW1_611Umode	Status word 1 (ZSW1)
PD_ZSW2	PD_ZSW2_611Umode	Status word 2 (ZSW2)

If you switch from a technology version <V4.0 to ≥V4.0 or vice versa, an error occurs during the compilation. You have to adapt the UDT names manually.

4.3 Version V3.0

Innovations

Technology Version V3.0 contains the following new features:

- Technology object measuring input
- Technology object output cam
- Cam track technology object
- Force/torque limiting
- Fixed stop detection
- Axis type virtual axis
- MC-PreServo [OB67] and MC-PostServo [OB95]
- Technology CPU S7-1500T

Additional innovations for S7-1500T:

Technology Version V3.0 contains the following additional improvements:

- Cam technology object (S7-1500T)
- Gearing with MC_GearInPos (S7-1500T)
- Camming with MC_CamIn (S7-1500T)
- Using multiple encoders (S7-1500T)

Motion Control instructions

Technology Version V3.0 contains the following Motion Control instructions:

- MC_Power V3.0
- MC_Reset V3.0
- MC_Home V3.0
- MC_Stop V3.0
- MC_MoveAbsolute V3.0
- MC_MoveRelative V3.0
- MC_MoveVelocity V3.0
- MC_MoveJog V3.0
- MC_MoveSuperimposed V3.0
- MC_SetSensor V3.0 (S7-1500T)
- MC_TorqueLimit V3.0
- MC_MeasuringInput V3.0
- MC_MeasuringInputCyclic V3.0
- MC_AbortMeasuringInput V3.0
- MC_OutputCam V3.0
- MC_CamTrack V3.0
- MC_GearIn V3.0
- MC_GearInPos V3.0 (S7-1500T)
- MC_PhasingAbsolute V3.0 (S7-1500T)
- MC_PhasingRelative V3.0 (S7-1500T)
- MC_CamIn V3.0 (S7-1500T)
- MC_SynchronizedMotionSimulation V3.0 (S7-1500T)
- MC_InterpolateCam V3.0 (S7-1500T)
- MC_GetCamFollowingValue V3.0 (S7-1500T)
- MC_GetCamLeadingValue V3.0 (S7-1500T)

4.4 Version V2.0

Innovations

Technology Version V2.0 contains the following new features:

- Synchronous axis technology object
- Gearing with MC_GearIn
- Superimposed positioning with MC_MoveSuperimposed
- Standardization of the "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control
- Simulation mode
- Support of safety functions of the drive

Motion Control instructions

Technology Version V2.0 contains the following Motion Control instructions:

- MC_Power V2.0
- MC_Reset V2.0
- MC_Home V2.0
- MC_Halt V2.0
- MC_MoveAbsolute V2.0
- MC_MoveRelative V2.0
- MC_MoveVelocity V2.0
- MC_MoveJog V2.0
- MC_MoveSuperimposed V2.0
- MC_GearIn V2.0

4.5 Version V1.0

Motion Control instructions

Technology Version V1.0 contains the following Motion Control instructions:

- MC_Power V1.0
- MC_Reset V1.0
- MC_Home V1.0
- MC_Halt V1.0
- MC_MoveAbsolute V1.0
- MC_MoveRelative V1.0
- MC_MoveVelocity V1.0
- MC_MoveJog V1.0

4.6 Changing a technology version

Before you can access all the benefits of a new technology version, you need to change the technology version for existing projects.

Changing a technology version

To change the technology version, follow these steps:

1. Replace the CPU in the project with a CPU with an appropriate higher version.
2. Open the program editor (e.g. by opening the OB1).

   The technology objects and Motion Control instructions are highlighted in red after the CPU is replaced.
3. In the "Instructions" task card, select the appropriate higher technology version in the "Technology > Motion Control" folder.
4. Save and compile the project.

   The version of the technology objects and Motion Control instructions is changed to the appropriate higher technology version during compilation of the project.

   Pay attention to any error information that is displayed during compilation. Deal with the causes of the errors indicated.
5. Check the configuration of the technology objects.

Resetting the "Mode" parameter of the Motion Control instruction "MC_Home"

When the technology version is changed from V1.0 to ≥ V2.0, the "MC_Home.HomingMode" parameter (V1.0) is renamed to "MC_Home.Mode" (≥ V2.0). The assignment of the parameter values is changed as well.

To reset the "MC_Home.Mode" parameter (V2.0), follow these steps:

1. To change the technology version, follow the instructions given above.

   When compiling the project, the "MC_Home.HomingMode"parameter (V1.0) is renamed to "MC_Home.Mode" (≥ V2.0):

   – The assignment of the parameter values is changed. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and ≥ V2.0 is available in section Version overview (Page 155).

     You can find additional information about the "MC_Home.Mode" parameter in the description of the Motion Control instruction "MC_Home" (Page 369).

   – The value configured at the "MC_Home.HomingMode" parameter (V1.0) is lost. As a note on renaming, the following text is entered as the parameter value in the "MC_Home.Mode" parameter (≥ V2.0).

     "The interface has changed. You can find additional information in the description of the Motion Control instruction "MC_Home".

   – There is a message in the "Info > Compile" tab in the Inspector window stating that the operand has the wrong data type.

2. Change the value of the "MC_Home.Mode" parameter (≥ V2.0) in your user program according to the new assignment.

3. Save and compile the project.

4.7 Replacing devices

You can replace an S7-1500 with an S7-1500T and vice versa. The behavior with respect to functions and the existing configuration is different depending on what is being replaced.

- S7-1500 ⇒ S7-1500T

  The functions of the S7-1500 are expanded to include additional parameters for the extended functions of the S7-1500T. The additional parameters are preassigned with default values and must be configured appropriately.

- S7-1500T ⇒ S7-1500

  – Extended functions are only supported by an S7-1500T and are no longer available after a replacement with S7-1500.

  – Unsupported function blocks are marked.

  – Unsupported technology objects are displayed in an error message after compilation and must be deleted.

Configuring 5

5.1 Adding and configuring drives in the device configuration

5.1.1 Introduction

Adding and configuring a drive is described in the following section with the example of a SINAMICS S120 drive. If you use a SINAMICS V90 PN or a SINAMICS drive with Startdrive, you can find additional information in the following documentation.

Using SINAMICS V90 PN

You need the Hardware Support Package (HSP) V90 two add and configure a SINAMICS V90 PN drive in the TIA Portal. Information on configuring a SINAMICS V90 PN drive with SIMATIC S7-1500 in the TIA Portal is available in the Getting Started "SIMATIC/SINAMICS First Steps SINAMICS V90 PN on S7-1500 Motion Control":

https://support.industry.siemens.com/cs/document/109739497 (https://support.industry.siemens.com/cs/ww/en/view/109739497)

Using Startdrive

If you use a SINAMICS drive with Startdrive, you can find additional information in the hardware catalog in the "Drives & Starter" folder. For additional information on connecting via Startdrive, refer to:

- "Getting Started SINAMICS S120 in the Startdrive V14 SP1":

  https://support.industry.siemens.com/cs/document/109747452 (https://support.industry.siemens.com/cs/ww/en/view/109747452)
- Application example "Positioning an S120 (Startdrive) with SIMATIC S7-1500 (TO)":

  https://support.industry.siemens.com/cs/document/109743270 (https://support.industry.siemens.com/cs/ww/en/view/109743270)

Drives compatibility list

In the appendix (Page 555) you can find an overview of drives that can be interconnected with an S7-1500 CPU.

5.1.2 Add and configure PROFINET IO drives

Adding and configuring a PROFINET IO drive is described below with the example of a SINAMICS S120 drive. Adding and configuring other PROFINET IO drives may differ from the description in certain respects.

When you use a S7-1500C CPU you can use the inputs/outputs of the CPU as interface to the drive.

Requirements

- The SIMATIC S7-1500 device is created in the project.
- The desired drive can be selected in the hardware catalog.

If the drive is not available in the hardware catalog, it must be installed in the "Options" menu as a device description file (GSD).

Adding a drive and telegram in the device configuration

1. Open the device configuration and change to the network view.
2. In the hardware catalog, open the folder "Additional field devices > PROFINET IO > Drives > Siemens AG > SINAMICS".
3. Select the desired drive with the desired version, then drag it to the network view.
4. Assign the drive to the PROFINET interface of the PLC.
5. Open the drive in the device view.
6. Drag a Drive Object (DO) and a telegram from the hardware catalog and drop it onto a slot of the device overview of the drive.
7. Make sure that the order of the telegrams in the device configuration and in the drive parameter assignment are identical.

Depending on the version of the SINAMICS S120 drive, select "DO with telegram X", or "DO Servo" and a "Telegram X" for the telegram.

For more information on suitable telegrams, refer to the section PROFIdrive telegrams (Page 36).

Repeat step 6, if you want to add another drive and another standard telegram.

Activating isochronous mode of the drive in the device configuration

PROFINET drives can always be operated in isochronous mode or clock synchronized mode. Isochronous mode, however, increases the quality of the closed loop position control of the drive and is therefore recommended for drives such as SINAMICS S120.

To control the drive in isochronous mode, follow these steps:

1. Open the device view of the drive.
2. In the properties window, select the tab "PROFINET interface [X1] > Advanced options > Isochronous mode".
3. Select the "Isochronous mode" check box in this tab.

The entry for the telegram also has to be selected for isochronous mode in the detailed view.

Interconnecting the port of the PLC with the port of the drive

1. Open the topology view in the device configuration.
2. Interconnect the port of the drive as in the real configuration with the port of the PLC. At the same time, note the rules for topology configuration.

Configuring the PLC as the sync master and setting isochronous mode

1. Select the device view of the PLC.
2. In the Properties window, select the tab "PROFINET interface [X1] > Advanced options > Real-time settings > Synchronization".
3. Select "Sync master" from the "Synchronization role" drop-down list.
4. Click the "Domain settings" button.
5. Open the "Domain Management > Sync Domains" tab and set the desired "Send clock" (isochronous clock).

Select drive in the configuration of the technology object

1. Add a new technology object axis, or open the configuration of an existing axis.
2. Open the configuration "Hardware interface > Drive".
3. Select from the "PROFIdrive" entry in the "Drive type" drop-down list.
4. Select the Drive Object of the PROFINET drive from the "Drive" list.

For information on how to add a technology object, refer to the section Add technology object (Page 175).

Result

The technology object is connected to the drive and the "MC Servo" organization block can be checked / configured.

The telegram of the configured drive is assigned to the "PIP OB Servo" process image.

Checking/configuring the properties of the "MC-Servo"

1. Open the "Program blocks" folder in the project navigator.
2. Select the "MC-Servo" organization block.
3. Select the "Properties" command in the shortcut menu.
4. Select the "Cycle time" entry in the area navigation.
5. The option "Synchronous to the bus" must be selected in the dialog box.
6. A "PROFINET IO_System" must be selected in the "Distributed I/O" drop-down list.
7. The application cycle of "MC-Servo" must correspond to the send clock of the bus or be reduced by an integral factor relative to the send clock of the bus.

Result

The PROFINET IO drive is configured in such a way that it can be controlled in isochronous mode in the PROFINET IO network.

The properties of the SINAMICS drive must be configured according to the configuration of the axis with the STARTER software or SINAMICS Startdrive.

Checking isochronous mode on the drive

If the configuration sequence described above is not adhered to during configuration of the axis, and drive-specific error occurs when the project is compiled, the setting for isochronous mode on the drive must be checked.

1. Open the device view of the drive.
2. Select standard telegram in the device overview.
3. Select the properties dialog "General > I/O Addresses".
4. The following settings apply for the input and output addresses:
   - "Isochronous mode" is enabled.
   - "MC-Servo" must be selected for the "Organization block".
   - "PIP OB Servo" must be select the "Process image".

PROFIdrive telegrams (Page 36)

Add technology object (Page 175)

5.1.3 Add and configure PROFIBUS DP drives

Adding and configuring a PROFIBUS drive is described below with the example of a SINAMICS S120 drive. Adding and configuring other PROFIBUS drives may differ from the description in certain respects.

When you use a S7-1500C CPU you can use the inputs/outputs of the CPU as interface to the drive.

Requirements

- The SIMATIC S7-1500 device is created in the project.
- The desired drive can be selected in the hardware catalog.

If the drive is not available in the hardware catalog, you must install the drive in the "Options" menu as a device description file (GSD).

Adding a drive and telegram in the device configuration

1. Open the device configuration and change to the network view.
2. In the hardware catalog, open the folder "Additional Field Devices > PROFIBUS DP > Drives > Siemens AG > SINAMICS".
3. Select the folder of the desired drive with the desired version, then drag the drive object to the network view.
4. Assign the drive to the PROFIBUS interface of the PLC.
5. Open the drive in the device view.
6. Drag-and-drop a telegram from the hardware catalog onto a slot in the device overview of the drive.

For more information on suitable telegrams, refer to the section PROFIdrive telegrams (Page 36).

If you want to add another drive and another telegram to the device overview, use the "Axis disconnector" in the hardware catalog.

Activating isochronous mode of the drive in the device configuration

PROFIBUS drives can be operated in cyclic mode or isochronous mode. Isochronous mode, however, increases the quality of the position control of the drive.

If you want to control the drive in isochronous mode, follow these steps:

1. Open the device view of the drive.
2. In the properties dialog, select the tab "General > Isochronous Mode".
3. Select the "Synchronize DP slave to constant DP bus cycle time" check box .

Setting isochronous mode

1. Select the network view.
2. Select the DP master system.
3. In the properties dialog, select the tab "General > Constant bus cycle time".
4. Select the desired "Constant DP bus cycle times".

Select drive in the configuration of the technology object

1. Add a new technology object axis, or open the configuration of an existing axis.
2. Open the configuration "Hardware interface > Drive".
3. Select from the "PROFIdrive" entry in the "Drive type" drop-down list.
4. Select the telegram of the PROFIBUS drive from the "Drive" list.

For information on how to add a technology object, refer to the section Add technology object (Page 175).

Result

The technology object is connected to the drive and the "MC-Servo" organization block can be checked / configured.

The telegram of the configured drive is assigned to the "PIP OB Servo" process image.

Checking/configuring the properties of the "MC-Servo"

1. Open the "Program blocks" folder in the project navigator.
2. Select the "MC-Servo" organization block.
3. Select the "Properties" command in the shortcut menu.

   The "MC-Servo" dialog opens.
4. Select the "Synchronous to the bus" option under "General > Cycle time".
5. In the "Distributed I/O" drop-down list, select a "PROFIBUS DP-System".

   The application cycle of "MC-Servo" must correspond to the send clock of the bus or be reduced by an integral factor relative to the send clock of the bus.

You can select a drive connected to the CPU via a communications processor/communications module (CP/CM) in the configuration of the technology object. You cannot select the DP master system of the CP/CM as the source clock for MC-Servo [OB91].

Result

The PROFIBUS DP drive is configured in such a way that it can be controlled in isochronous mode in the PROFIBUS network.

The properties of the SINAMICS drive must be configured according to the configuration of the axis with the STARTER software or SINAMICS Startdrive.

Checking isochronous mode on the drive

If the configuration sequence described above is not adhered to during configuration of the axis, and drive-specific error occurs when the project is compiled, isochronous mode can be checked on the drive.

1. Open the device view of the drive.
2. Select the entry of the telegram in the device overview.
3. Select the properties dialog "General > I/O Addresses".
4. The following settings apply for the input and output addresses:
   - "MC-Servo" must be selected for the "Organization block".
   - "PIP OB Servo" must be select the "Process image".

Add technology object (Page 175)

5.1.4 Adding and configuring drives with analog connections

A description is provided below of how to add and configure a drive with an analog drive connection and an encoder. The connection is made for example as a positioning axis with an incremental encoder and using a technology module in the rack of the PLC.

When you use a S7-1500C CPU you can use the inputs/outputs of the CPU as interface to the drive.

Requirements

The SIMATIC S7-1500 device is created in the project.

Adding and configuring an analog output module in the device configuration

1. Open the device configuration of the PLC.
2. Select an analog output module from the hardware catalog and drag the module to the rack of the PLC.
3. Select the analog output module in the device view.
4. Open the "General" tab in the properties dialog and select there "Name of the Analog Output Module > I/O Addresses".
5. Enter the desired start address.
6. In the properties dialog, select the tab "General > IO Tags".
7. Enter the tag name for the desired analog output.

Adding and configuring a technology module

1. Switch to the device view of the PLC.
2. In the hardware catalog, open the folder "TM > Count > TM Count 2X24V".
3. Drag the counter module to a free slot in the rack.
(When inserted in the rack of the PLC, the technology module cannot be operated in isochronous mode.)
4. Select the technology module in the device view.
5. In the properties dialog, open the "General" tab and select there "Count 2x24V > Basic Parameters > Channel X > Operating Mode" of the channel to be used.
6. Select "Position input for Motion Control" option for "Selection of the operating mode for the channel".
7. Under "Module parameters", adapt the parameters of the incremental encoder (steps per revolution = increments per revolution).
8. Under "Reaction to CPU STOP", select the item "Continue working".

Selecting the drive and encoder in the configuration of the technology object

1. Add a new positioning axis/synchronous axis technology object, or open the configuration of an existing positioning axis/synchronous axis.
2. Open the configuration "Hardware interface > Drive".
3. Select "Analog drive connection" from the "Drive type" drop-down list.
4. Select the previously defined tag name of the analog output from the "Output" list.
5. Open the configuration "Hardware interface > Encoder".
6. Under "Select encoder connection" select "Encoder on technology module (TM)".
7. Select the channel of the incremental encoder from the "Technology module" list under "local modules".
8. Open the configuration "Hardware interface > Data exchange with encoder > Fine resolution" and enter the "0" value for "bits in the incr. actual value".

For information on how to add a technology object, refer to the section Add technology object (Page 175)

Result

The analog drive connection and the encoder connection are configured.

The analog addresses and the addresses of the TM module are assigned to the process image "PIP OB Servo".

Checking the encoder connection / drive connection

The encoder data are applied to the position control cycle clock. If in doubt, check the following settings:

1. Switch to the device view of the PLC.
2. Select the module technology.
3. Open the properties dialog "Basic Parameters > I/O Addresses".
4. The following settings apply for the input and output addresses:
   – "MC-Servo" must be selected for the "Organization block".
   – "PIP OB Servo" must be select the "Process image".
5. Select the analog module.
6. Open the properties dialog "Name of the Analog Module > I/O Addresses".
7. The settings from Step 4 apply for the input and output addresses

See also

Add technology object (Page 175)

5.2 Configuration basics

5.2.1 Add technology object

The following describes how to add a technology object in the project tree.

Requirement

- A project with a CPU S7-1500 has been created.
- For the output cam, cam track, measuring input technology objects:

  A speed axis, positioning axis, synchronous axis or external encoder technology object is created in the project.

Procedure

To add a technology object, follow these steps:

1. Open the CPU's folder in the project navigator.
2. Open the "Technology Objects" folder.
3. Double-click "Add new object".

   The "Add new object" dialog opens.
4. Select the required technology object. You can infer the function of the technology object from the displayed description.
5. If you add output cams, cam tracks, measuring inputs to a technology object, select the higher-level technology object in the "Axis or external encoder that is to be assigned".
6. In the "Name" input field, adapt the name to your requirements.
7. To change the suggested data block number, select the "Manual" option.
8. To add your own information about the technology object, click "Additional information".
9. To open the configuration after adding the technology object, select the "Add new and open" check box.
10. To add the technology object, click "OK".

Result

The new technology object was created and created in the "Technology objects" folder in the project tree.

If the "MC-Servo" and "MC-Interpolator" organizational units were not yet available, they were added.

5.2.2 Copy technology object

You can copy a technology object in the following ways:

- Copying a technology object within a CPU
- Copying a technology object from a CPU S7-1500 to a CPU S7-1500T

  Additional parameters for the extended functions are pre-defined with default values and must be configured accordingly.
- Copying a technology object from a CPU S7-1500T to a CPU S7-1500

  Additional parameters, which are not supported by the CPU S7-1500, are reset to the default values.

When you copy a technology object that has lower-level technology objects such as output cams, cam tracks or measuring inputs, the lower-level technology object are also copied.

The following describes how to copy a technology object within a CPU. The procedure also applies accordingly to the other copying methods mentioned.

Requirement

- A project with a CPU S7-1500 has been created.
- You have created an technology object in the project.

Procedure

To copy a technology object, follow these steps:

1. Open the CPU's folder in the project navigator.
2. Open the "Technology Objects" folder.
3. If necessary, open the higher-level technology object.
4. Select the technology object to be copied.
5. Select "Copy" in the shortcut menu.
6. Select the "Technology objects" folder or the higher-level technology object.
7. Select "Paste" in the shortcut menu.

Result

The selected technology object, including lower-level technology objects, has been copied and created in the "Technology objects" folder of the project tree.

5.2.3 Delete technology object

You can delete technology objects in the project tree.

When you delete a technology object that has lower-level technology objects such as output cams, cam tracks or measuring inputs, the lower-level technology object are also deleted.

Requirement

- A project with a CPU S7-1500 has been created.
- You have created an technology object in the project.

Procedure

To delete a technology object, follow these steps:

1. Open the CPU's folder in the project navigator.
2. Open the "Technology Objects" folder.
3. Select the technology object to be deleted.
4. Select the "Delete" command in the shortcut menu.

   The "Confirm delete" dialog is opened.
5. To delete the technology object, click "Yes".

Result

The selected technology object has been deleted.

5.2.4 Working with the configuration editor

You configure the properties of a technology object in the configuration window. To open the configuration window of the technology object in the project view, follow these steps:

1. Open the device "Technology objects" group in the project navigator.
2. Select the technology object and double-click on "Configuration".

The configuration is divided into categories which depend on the object type, for example: Basic parameters, hardware interface, extended parameters.

Configuration editor icons

Icons in the area navigation of the configuration show additional details about the status of the configuration:

	The configuration contains default values and is complete. The configuration contains only default values. With these default values you can use the technology object without additional changes.
	The configuration contains user-defined or automatically adapted values and is complete. All input fields of the configuration contain valid values and at least one preset value has changed.
	The configuration is incomplete or incorrect. At least one input field or drop-down list contains an invalid value. The corresponding field or the drop-down list is displayed on a red background. Click the field shows you the roll-out error message that indicates the cause of error.

5.2.5 Compare values

If an online connection to the CPU is available, the "Monitor all" function appears in the configuration of the technology object.

The "Monitor all" function provides the following options:

- Comparison of configured start values of the project with the start values in the CPU and the actual values
- Direct editing of actual values and the start values of the project
- Immediate detection and display of input errors with suggested corrections
- Backup of actual values in the project
- Transfer of start values of the project to the CPU as actual values

---

Note

Differences between online and offline values

By adding or deleting technology objects that have a connection to other technology objects, such as cams, cam tracks, measuring inputs or synchronized axes, differences can occur when online and offline values are compared. These differences can be eliminated by re-compiling the project and then uploading it to the CPU.

Icons and operator controls

If there is an online connection to the CPU, the actual values are displayed at the parameters.

In addition to the actual values of the parameters, the following symbols appear:

Symbol	Description
	Start value in CPU matches the configured start value in project
	Start value in CPU does not match the configured start value in project
	Software error in lower-level component: The online and offline versions differ in at least one lower-level software component.
	The comparison of the Start value in CPU with the configured start value in project cannot be performed.
	Comparison of the online and offline values is not advisable.
	Use this button to show the start value of the CPU and the start value of the project for the respective parameter.

You can change the start value of the CPU directly and then download it to the CPU. For directly editable parameters, the actual value can also be changed and the change will be transferred directly to the CPU.

5.3 Configuring the Speed-Control Axis technology object

5.3.1 Configuration - Basic Parameters

Configure the basic properties of the technology object in the "Basic Parameters" configuration window.

Name

Define the name of the speed axis in this field. The technology object is listed under this name in the project tree. You can use the variables of the speed axis in the user program under this name.

Axis type

If you want to use the axis in the CPU exclusively as a virtual leading axis for synchronization, for example, select the "Virtual axis" check box. The configuration of a drive and encoder connection is not relevant.

Speed unit of measure

Select the desired unit of measure for speed in the drop-down list.

Simulation

If you want to move a real axis in the simulation mode, select the "Activate simulation" check box.

In simulation mode, speed, positioning and synchronous axes can be simulated in the CPU without connected drives and encoders. Simulation mode is possible as of Technology Version V3.0 even without a configured drive and encoder connection.

For simulation mode without hardware connected to the CPU, you can influence the startup time of the CPU via the "Configuration time for central and distributed I/Os" parameter. You can find the parameter in the CPU properties in the "Startup" area navigation.

See also

Units of measure (Page 32)

Axis in simulation (Page 49)

5.3.2 Hardware interface

5.3.2.1 Configuration - Drive

In the "Drive" configuration window, configure which drive type and which drive you want to use.

Drive type

In the drop-down list, select whether you want to deploy a PROFIdrive drive or a drive with an analog drive connection.

PROFIdrive drives are connected to the controller by means of a digital communication system (PROFINET or PROFIBUS). The communication is performed via PROFIdrive telegrams.

Drives with an analog drive connection receive the speed setpoint via an analog output signal (e.g. from -10 V to +10 V) from the PLC.

Drive type: PROFIdrive

Data connection

In the drop-down list, select whether the data connection is to be made directly with the drive device or via an editable data block in the user program.

Drive/data block

In the "Drive" field, select an already configured PROFIdrive drive/slot. If a PROFIdrive drive was selected, it can be configured using the "Device configuration" button.

Switch to the device configuration, and add a PROFIdrive drive in the network view, in the event that no PROFIdrive drive can be selected.

If "Data block" was selected for the data connection, a previously created data block containing a variable structure of data type "PD_TELx" must be selected here ("x" stands for the telegram number used).

Drive type: Analog drive connection

Analog output

In the "Output" field, select the PLC tag of the analog output over which the drive is to be controlled.

In order to be able to select an output, an analog output module must have been added in the device configuration, and the PLC tag name for the analog output must be defined.

Activating enable output

In the "Enable output" field, select the PLC tag of the digital output to enable the drive. With the enable output, the speed controller in the drive is enabled, or disabled.

In order to be able to select an enable output, a digital output module must have been added in the device configuration, and the PLC tag name for the digital output must be defined.

Note

If you do not use an enable output, the drive cannot be immediately disabled on the part of the system due to error reactions or monitoring functions. A controlled stop of the drive is not guaranteed.

Enable ready input

In the "Ready input" field, select the PLC tag of the digital input with which the drive is to report its operational readiness to the technology object. The power module is switched on and the analog speed setpoint input is enabled.

In order to be able to select a ready input, a digital input module must have been added in the device configuration, and the PLC tag name for the digital input must be defined.

Note

The enable output and the ready input can be separately enabled.

The following boundary conditions apply to the activated ready input:

- The axis is only enabled (MC_Power Status = TRUE) when a signal is present at the ready input.
- If the signal at the ready input goes away for an enabled axis, the axis is disabled with the alarm reaction "Remove enable".
- If the axis is disabled with the instruction MC_Power (Enable = FALSE), the axis is disabled even when a signal is present at the ready input.

See also

Configuration - Data exchange with the drive (Page 183)

Connect drive/encoder via data block (Page 269)

Drive and encoder connection (Page 34)

5.3.2.2 Configuration - Data exchange with the drive

You configure the data transmission to the drive in this configuration window.

Drive type: PROFIdrive

Drive telegram

The telegram to the drive that is set in the device configuration is preselected in the drop-down list.

Automatic data exchange for drive values (offline)

Select the check box if you want to transfer the offline values of the drive "Reference speed", "Maximum speed" and "Reference torque" to the configuration of the technology object in the project.

Automatic data exchange for drive values (online)

Select the check box if you want to transfer the effective values "Reference speed", "Maximum speed" and "Reference torque" online in the drive to the CPU during runtime. The drive parameters are transferred from the bus after the (re-)initialization of the technology object or the (re)start of the drive or the CPU.

Alternatively, you must synchronize the following parameters manually:

- **Reference speed**

  Configure the reference speed of the drive in accordance with the manufacturer's specifications in this field. The specification of the drive speed is a percentage of the reference speed in the range -200% to +200%.

- **Maximum speed**

  Configure the maximum speed of the drive in this field.

- **Reference torque**

  Configure the reference torque of the drive corresponding to its configuration in this field.

  The reference torque is needed for force/torque reduction, which is supported with telegram 10x.

Supplementary data

Select the "Torque data" check box if you want to configure the data connection of the torque data. If you have selected a drive with which the additional telegram 750 has been configured, the "Torque data" check box is preselected.

Data connection

In the drop-down list, define whether the data connection should be made via additional telegrams or data blocks:

- If you select the entry "Additional telegram" in the "Data connection" drop-down list, you can edit the "Additional telegram" drop-down list.
- If you select the "Data block" entry in the "Data connection" drop-down list, you can select the previously created data block which contains a tag structure of the "PD_TELx" data type ("x" stands for the additional telegram number that is used).

Data block / additional telegram

Select an additional telegram configured in the "Additional telegram" field.

Select the "Show all modules" check box if you want to display all submodules of the connected drive. You can also find self-defined additional telegrams with this function.

In the "Data block" field, select the data block which you want to use to integrate the torque data.

Note

Automatic transfer of drive parameters is only possible with SINAMICS drives as of V4.x. For this, "Drive" must be selected for the data connection in configuration window "Hardware interface > Drive".

Drive type: Analog drive connection

Reference speed

The reference speed of the drive is the speed at which the drive rotates when there is an output of 100% at the analog output. The reference speed must be configured for the drive and transferred in the configuration of the technology object.

The analog value that is output at 100% depends on the type of the analog output. For example, for an analog output with +/- 10 V, the value 10 V is output at 100%.

Analog outputs can be overdriven by about 17%. This means that an analog output can be operated in the range from -117% to 117%, insofar as the drive permits this.

See also

Automatic transfer of drive and encoder parameters in the device (Page 42)

Connect drive/encoder via data block (Page 269)

Drive and encoder connection (Page 34)

5.3.3 Extended Parameters

5.3.3.1 Configuration - Mechanics

Configure the connection of the load to the drive in the "Mechanics" configuration window.

Invert drive direction

Select the check box if the direction of rotation of the drive is to be inverted.

Load gear

Number of motor revolutions / number of load revolutions

The gear ratio of the load gear is specified as the ratio between motor revolutions and load revolutions. Specify here an integral number of motor revolutions and the resulting number of load revolutions.

See also

Mechanics (Page 53)

5.3.3.2 Configuration - Dynamic Defaults

In the "Dynamic default values" configuration window, configure the default values for speed, acceleration, deceleration jerk of the axis.

The default values have an effect, when values < 0 are specified in Motion Control instructions for the "Velocity", "Acceleration", "Deceleration" or "Jerk" parameters. The default values can be applied separately for each of the parameters just listed.

Speed

In this field, define the default value for the speed of the axis.

Acceleration / Deceleration - Ramp-up time / Ramp-down time

Set the desired default value for acceleration in the "Ramp-up time" or "Acceleration" fields. The desired deceleration can be set in the "Ramp-down time" or "Deceleration" fields.

The following equations show the relationship between the ramp-up time and acceleration and the ramp-down time and deceleration:

$$\text{Ramp-up time} = \frac{\text{Speed}}{\text{Acceleration}}$$

$$\text{Ramp-down time} = \frac{\text{Speed}}{\text{Deceleration}}$$

Note

A change in the velocity influences the acceleration and deceleration values of the axis. The ramp-up and ramp-down times are retained.

Smoothing time / jerk

You can enter the jerk limit parameters in the "Smoothing time" box, or alternatively in the "Jerk" box:

- Set the desired jerk for the acceleration and deceleration ramp in the "Jerk" field. The value 0 means that jerk limiting is deactivated.
- Set the desired smoothing time for the acceleration ramp in the "Smoothing time" field.

Note

The jerk value is identical for the acceleration and deceleration ramp. The smoothing time in effect for the deceleration ramp results from the following relationships:

- **Acceleration > Deceleration**

  A shorter smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration < Deceleration**

  A longer smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration = Deceleration**

  The smoothing times of the acceleration and deceleration ramp are equal.

If an error occurs, the axis decelerates with the configured emergency stop deceleration. A configured jerk limit is not taken into account for this.

The following equations show the relationship between the smoothing times and the jerk:

$$\text{Smoothing time (acceleration ramp)} = \frac{\text{Acceleration}}{\text{Jerk}}$$

$$\text{Smoothing time (deceleration ramp)} = \frac{\text{Deceleration}}{\text{Jerk}}$$

Motion jobs started in the user program are performed with the selected jerk.

See also

Velocity profile (Page 60)

5.3.3.3 Configuration - Emergency stop

In the "Emergency stop" configuration window, you can configure the emergency stop deceleration of the axis. In the event of an error, and when disabling the axis, the axis is brought to a standstill with this deceleration using the Motion Control instruction "MC_Power" (input parameter StopMode = 0).

Emergency stop deceleration / Emergency stop ramp-down time

Configure the deceleration value for emergency stop in the "Emergency stop deceleration" field or the "Emergency stop ramp-down time" field.

The relationship between emergency stop ramp-down time and emergency stop deceleration can be seen in the following equation:

$$\textit{Emergency stop ramp-down time} = \frac{\textit{Maximum speed}}{\textit{Emergency stop deceleration}}$$

The configuration of the emergency stop deceleration is related to the configured maximum speed of the axis. If the maximum speed of the axis changes, then the value of the emergency stop deceleration also changes (the emergency stop ramp-down time remains unchanged).

See also

Emergency stop deceleration (Page 62)

5.3.3.4 Limits

Configuration - Dynamic limits

In the "Dynamic limits" configuration window, configure the maximum values for speed, acceleration, deceleration and jerk of the axis.

Maximum speed

In this field, define the maximum permitted speed of the axis.

Maximum acceleration/maximum deceleration - ramp-up time/ramp-down time

Set the desired acceleration in the "Ramp-up time" or "Acceleration" fields. The desired deceleration can be set in the "Ramp-down time" or "Deceleration" fields.

The following equations show the relationship between the ramp-up time and acceleration and the ramp-down time and deceleration:

$$\text{Ramp-up time} = \frac{\text{Maximum velocity}}{\text{Acceleration}}$$

$$\text{Ramp-down time} = \frac{\text{Maximum speed}}{\text{Deceleration}}$$

Note

Change of maximum speed

A change in the maximum speed influences the acceleration and deceleration values of the axis. The ramp-up and ramp-down times are retained.

Smoothing time / jerk

You can enter the jerk limit parameters in the "Smoothing time" box, or alternatively in the "Jerk" box:

- Set the desired jerk for the acceleration ramp and the deceleration ramp in the "Maximum jerk" box. The value 0 means that the jerk is not limited.
- Set the desired smoothing time for the acceleration ramp in the "Smoothing time" field.

Note

Various acceleration and deceleration values

The configured smoothing time displayed in the configuration, applies only to the acceleration ramp.

If the values of the acceleration and deceleration differ, the smoothing time of the deceleration ramp is calculated and used according to the jerk of the acceleration ramp.

The smoothing time of the deceleration is adapted as follows:

- **Acceleration > Deceleration**
  A shorter smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration < Deceleration**
  A longer smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration = Deceleration**
  The smoothing times of the acceleration and deceleration ramp are equal.

If an error occurs, the axis decelerates with the configured emergency stop deceleration (Page 60) (alarm reaction "Stop with maximum dynamic values"). A configured jerk limit is not taken into account for this.

The following equations show the relationship between the smoothing times and the jerk:

$$\text{Smoothing time (acceleration ramp)} = \frac{\text{Acceleration}}{\text{Jerk}}$$

$$\text{Smoothing time (deceleration ramp)} = \frac{\text{Deceleration}}{\text{Jerk}}$$

Motion jobs started in the user program are performed with the selected jerk.

See also

Emergency stop deceleration (Page 62)

Dynamic limits in synchronous operation (Page 62)

Configuration - Torque limits

Configure the torque limiting of the drive in the "Torque limits" configuration window.

The configuration is now available if a drive that supports force/torque limiting is selected and a telegram 10x is used.

Effective

In the drop-down list, select whether the limit value is to be in effect "on load side" or "on motor side".

Torque limiting

Enter a default value for the torque limit in the specified unit of measure in this field.

The default value is in effect when the torque limiting is specified using Motion Control instruction "MC_TorqueLimiting", input parameter "Limit" < 0.

If the gear efficiency is critical, this can be set in the <TO>.Actor.Efficiency tag.

See also

Force/torque limiting (Page 63)

5.4 Configuring the positioning axis/synchronous axis technology object

5.4.1 Configuration - Basic Parameters

Configure the basic properties of the technology object in the "Basic Parameters" configuration window.

Name

Define the name of the positioning axis/synchronous axis in this field. The technology object is listed under this name in the project tree. The variables of the technology object can be used in the user program under this name.

Axis type

If you want to use the axis in the CPU exclusively as a virtual leading axis for synchronization, for example, select the "Virtual axis" check box. The configuration of a drive and encoder connection is not relevant.

In this selection, configure whether the axis should perform linear or rotary motions.

Units of measure

In the drop-down list, select the desired units of measure for the position, velocity, torque and force of the axis.

Modulo

Select the "Enable modulo" check box if you want to use a recurring system of units for the axis (e.g. 0 to 360° for an axis of the "rotary" axis type).

- **Modulo start value**

  In this field, define the position at which the modulo range should begin (e.g. 0° for an axis of the "rotary" axis type).

- **Modulo length**

  In this field, define the length of the modulo range (e.g. 360° for an axis of the "rotary" axis type).

Simulation

If you want to move a real axis in the simulation mode, select the "Activate simulation" check box.

In simulation mode, speed, positioning and synchronous axes can be simulated in the CPU without connected drives and encoders. Simulation mode is possible as of Technology Version V3.0 even without a configured drive and encoder connection.

For simulation mode without hardware connected to the CPU, you can influence the startup time of the CPU via the "Configuration time for central and distributed I/Os" parameter. You can find the parameter in the CPU properties in the "Startup" area navigation.

Synchronous axis technology object (Page 105)

5.4.2 Hardware interface

5.4.2.1 Configuration - Drive

In the "Drive" configuration window, configure which drive type and which drive you want to use.

Drive type

In the drop-down list, select whether you want to deploy a PROFIdrive drive or a drive with an analog drive connection.

PROFIdrive drives are connected to the controller by means of a digital communication system (PROFINET or PROFIBUS). The communication is performed via PROFIdrive telegrams.

Drives with an analog drive connection receive the speed setpoint via an analog output signal (e.g. from -10 V to +10 V) from the PLC.

Drive type: PROFIdrive

Data connection

In the drop-down list, select whether the data connection is to be made directly with the drive device or via an editable data block in the user program.

Drive/data block

In the "Drive" field, select an already configured PROFIdrive drive/slot. If you have selected a PROFIdrive drive, you can configure the PROFIdrive drive using the "Device configuration" button.

If no PROFIdrive drive is available for selection, switch to the device configuration, and add a PROFIdrive drive in the network view.

If you have selected "Data block" under the data connection, select a previously created data block which contains a variable structure of the data type "PD_TELx" ("x" stands for the telegram number to be used).

Drive type: Analog drive connection

Analog output

In the "Analog output" field, select the PLC tag of the analog output via which the drive is to be controlled.

In order to be able to select an output, you first need to add an analog output module in the device configuration and define the PLC tag name for the analog output.

Activating enable output

Select the "Activate enable output" check box if the drive supports an enable.

Select the PLC tag of the digital output for the drive enable in the corresponding field. With the enable output, the speed controller in the drive is enabled, or disabled.

In order to be able to select an enable output, a digital output module must be added in the device configuration and the PLC tag name must be defined for the digital output.

Note

If you do not use an enable output, the drive cannot be immediately disabled on the part of the system due to error reactions or monitoring functions. A controlled stop of the drive is not guaranteed.

Enable ready input

Select the "Enable ready input" check box if the drive can signal its readiness.

Select the PLC tag of the digital input via which the drive is to signal its operational readiness to the technology object in the corresponding field. The power module is switched on and the analog speed setpoint input is enabled.

In order to be able to select a ready input, you first need to add a digital input module in the device configuration and define the PLC tag name for the digital input.

Note

The enable output and the ready input can be separately enabled.

The following boundary conditions apply to the activated ready input:

- The axis is only enabled (MC_Power Status = TRUE) when a signal is present at the ready input.
- If a signal is not present at the ready input on an enabled axis, the axis is disabled with an error.
- If the axis is disabled with the instruction MC_Power (Enable = FALSE), the axis is disabled even when a signal is present at the ready input.

Connect drive/encoder via data block (Page 269)

Data connection drive/encoder via data block (Page 50)

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

5.4.2.2 Configuration - Encoder

For closed loop position control, positioning axes/synchronous axes require an actual position value in the form of an encoder position. The encoder position is transmitted to the controller by means of a PROFIdrive telegram.

Configure the encoder and encoder type in the "Encoder" configuration window.

Data connection

In the drop-down list, select whether the data connection should be established directly with the encoder or via a data block that can be edited in the user program.

The selection is only possible for encoders that are connected via PROFIdrive and support parameter P979.

Encoder / data block

Select a previously configured encoder in this configuration field.

The following encoders can be selected:

- **Connection to the drive (not with analog drive connection)**

  The encoder is configured via the configuration of the PROFIdrive drive. The drive evaluates the encoder signals and sends them to the controller in the PROFIdrive telegram.

- **Encoder on technology module (TM)**

  Select a previously configured technology module and the channel to be used. Only technology modules set to the "Position input for Motion Control" mode are displayed for selection.

  If no technology module is available for selection, change to the device configuration and add a technology module. If you have selected a technology module, you can access the configuration of the technology module using the "Device configuration" button.

  You can operate the technology module centrally on an S7-1500 CPU or decentrally on a distributed I/O. Isochronous mode is not possible with central operation in the CPU.

  You can identify the technology modules suitable for position detection for Motion Control in the documentation for the technology module and the catalog data.

- **PROFIdrive encoder on PROFINET/PROFIBUS (PROFIdrive)**

  In the "PROFIdrive encoder" field, select a configured encoder on PROFINET/PROFIBUS. If an encoder was selected, it can be configured using the "Device configuration" button.

  Switch to the device configuration in the network view, and add an encoder, in the event that no encoder can be selected.

If "Data block" was selected for the data connection, a previously created data block containing a variable structure of data type "PD_TELx" must be selected here ("x" stands for the telegram number used).

Encoder type

Select the encoder type of the encoder in the drop-down list. The following encoder types are available:

- Incremental
- Absolute
- Cyclic absolute

Connect drive/encoder via data block (Page 269)

Synchronous axis technology object (Page 105)

5.4.2.3 Configuration - Data exchange with the drive

Configure the data exchange with the drive in the "Data exchange with the drive" configuration window.

The configuration differs according to the selected drive type:

Drive type: PROFIdrive

Drive telegram

The telegram to the drive that is set in the device configuration is preselected in the drop-down list.

Automatic data exchange for drive values (offline)

Select the check box if you want to transfer the offline values of the drive "Reference speed", "Maximum speed" and "Reference torque" to the configuration of the technology object in the project.

Automatic data exchange for drive values (online)

Select the check box if you want to transfer the effective values "Reference speed", "Maximum speed" and "Reference torque" online in the drive to the CPU during runtime. The drive parameters are transferred from the bus after the (re-)initialization of the technology object or the (re)start of the drive or the CPU.

Alternatively, you must synchronize the following parameters manually:

- **Reference speed**

  Configure the reference speed of the drive in accordance with the manufacturer's specifications in this field. The specification of the drive speed is a percentage of the reference speed in the range -200% to +200%.

- **Maximum speed**

  Configure the maximum speed of the drive in this field.

- **Reference torque**

  Configure the reference torque of the drive corresponding to its configuration in this field.

  The reference torque is needed for force/torque reduction, which is supported with telegram 10x.

Supplementary data

Select the "Torque data" check box if you want to configure the data connection of the torque data. If you have selected a drive with which the supplemental telegram 750 has been configured, the "Torque data" check box is preselected.

Data connection

In the drop-down list, define whether the data connection should be made via supplemental telegrams or data blocks:

- If you select the entry "Supplemental telegram" in the "Data connection" drop-down list, you can edit the "Supplemental telegram" drop-down list.
- If you select the "Data block" entry in the "Data connection" drop-down list, you can select the previously created data block which contains a tag structure of the "PD_TELx" data type ("x" stands for the additional telegram number that is used).

Data block / supplemental telegram

Select an supplemental telegram configured in the "Supplemental telegram" field.

Select the "Show all modules" check box if you want to display all submodules of the connected drive. You can also find self-defined supplemental telegrams with this function.

In the "Data block" field, select the data block which you want to use to integrate the torque data.

Note

Automatic transfer of drive parameters is only possible with SINAMICS drives as of V4.x. To do this, set the "Drive" data connection in the configuration window "Hardware interface > Drive".

Drive type: Analog drive connection

Reference speed

The reference speed of the drive is the speed at which the drive rotates when there is an output of 100% at the analog output. The reference speed must be configured for the drive and transferred in the configuration of the technology object.

The analog value that is output at 100% depends on the type of the analog output. For example, for an analog output with +/- 10 V, the value 10 V is output at 100%.

Analog outputs can be overdriven by about 17%. This means that an analog output can be operated in the range from -117% to 117%, insofar as the drive permits this.

Maximum speed

Specify the maximum speed of the drive in this field.

Positioning axis technology object (Page 104)

Automatic transfer of drive and encoder parameters in the device (Page 42)

Connect drive/encoder via data block (Page 269)

Synchronous axis technology object (Page 105)

5.4.2.4 Configuration - Data exchange with encoder

Configure detailed encoder parameters and the data exchange with the encoder in the "Data exchange with encoder" configuration window.

The display and selection of the configuration parameters described here is dependent on the following parameters:

- Configuration window "Basic parameters": Drive type (linear/rotary)
- Configuration window "Hardware interface > Encoder": Encoder type (incremental/absolute/cyclic absolute)
- Configuration window - "Extended parameters > Mechanics": Encoder mounting type

Encoder telegram

The telegram to the encoder that is set in the device configuration is preselected in the drop-down list.

Automatic data exchange for encoder values (offline)

Select the check box if you want to transfer the offline values of the encoder to the configuration of the technology object in the project.

Note

Automatic transfer of encoder parameters is only possible with PROFIdrive encoders as of product version A16. For this, "Hardware interface > Encoder" must be selected as the "Encoder" data connection in the configuration window.

Automatic data exchange for encoder values (online)

Select the check box if you want to transfer the effective values online in the encoder to the CPU during runtime. The encoder parameters are transferred from the bus after the (re-)initialization of the technology object and (re)start of the encoder or the CPU.

Note

Automatic transfer of encoder parameters is only possible with PROFIdrive encoders as of product version A16. For this, "Hardware interface > Encoder" must be selected as the "Encoder" data connection in the configuration window.

Alternatively, you must manually calibrate the following parameters, depending on encoder type.

Encoder type

Depending on the selected encoder type, configure the following parameters:

Encoder type	Rotary incremental
Increments per revolution	Configure the number of increments that the encoder resolves per revolution in this field.
Bits for fine resolution in the incremental actual value (Gx_XIST1)	Configure the number of bits for fine resolution within the incremental actual value (Gx_XIST1) in this field.

Encoder type	Rotary absolute
Increments per revolution	Configure the number of increments that the encoder resolves per revolution in this field.
Number of revolutions	Configure the number of revolutions that the absolute encoder can detect in this field.
Bits for fine resolution in the incremental actual value (Gx_XIST1)	Configure the number of bits for fine resolution within the incremental actual value (Gx_XIST1) in this field.
Bits for fine resolution in the absolute actual value (Gx_XIST2)	Configure the number of bits for fine resolution within the absolute actual value (Gx_XIST2) in this field.

Encoder type	Rotary cyclic absolute
Increments per revolution	Configure the number of increments that the encoder resolves per revolution in this field.
Number of revolutions	Configure the number of revolutions that the absolute encoder can detect in this field.
Bits for fine resolution in the incremental actual value (Gx_XIST1)	Configure the number of bits for fine resolution within the incremental actual value (Gx_XIST1) in this field.
Bits for fine resolution in the absolute actual value (Gx_XIST2)	Configure the number of bits for fine resolution within the absolute actual value (Gx_XIST2) in this field.

Encoder type	Linear incremental
Distance between two increments	Configure the distance between two increments of the encoder in this field.
Bits for fine resolution in the incremental actual value (Gx_XIST1)	Configure the number of bits for fine resolution within the incremental actual value (Gx_XIST1) in this field.

Encoder type	Linear absolute
Distance between two increments	Configure the distance between two increments of the encoder in this field.
Bits for fine resolution in the incremental actual value (Gx_XIST1)	Configure the number of bits for fine resolution within the incremental actual value (Gx_XIST1) in this field.
Bits for fine resolution in the absolute actual value (Gx_XIST2)	Configure the number of bits for fine resolution within the absolute actual value (Gx_XIST2) in this field.

Encoder type	Linear cyclic absolute
Distance between two increments	Configure the distance between two increments of the encoder in this field.
Bits for fine resolution in the incremental actual value (Gx_XIST1)	Configure the number of bits for fine resolution within the incremental actual value (Gx_XIST1) in this field.
Bits for fine resolution in the absolute actual value (Gx_XIST2)	Configure the number of bits for fine resolution within the absolute actual value (Gx_XIST2) in this field.

Connect drive/encoder via data block (Page 269)

Synchronous axis technology object (Page 105)

Configuration - Data exchange (Page 232)

5.4.3 Configuration - leading value interconnections (synchronous axis only)

You can interconnect a synchronous axis with multiple leading value-capable technology objects. Leading value-capable technology objects are:

- Positioning axes
- Synchronous axes
- External encoders (only with S7-1500T CPU)

You can select only one leading value during runtime of your user program.

All interconnection required during operation must be set up during configuration of the technology object.

Possible leading values

In the "Possible leading values" column of the "Leading value interconnections" list, add all leading value-capable technology objects that you need during operation as a leading value for the synchronous axis.

You can interconnect the axes added in the list with the synchronous axis as a leading value with the corresponding Motion Control instruction.

All configured leading value interconnections for the technology object are displayed in the cross-reference list of the technology object.

Coupling type

In the "Type of coupling" column, configure whether the leading value is to be coupled via setpoint or actual value.

"Actual value" is available only for the S7-1500T CPU.

See also

Leading value coupling (Page 107)

Synchronous axis technology object (Page 105)

5.4.4 Extended Parameters

5.4.4.1 Configuration - Mechanics

Configuration - Mechanics

In the "Mechanics" configuration window, configure the mounting type of the encoder, and the adaptation of the actual encoder value to the mechanical conditions.

Settings for (S7-1500T)

In the drop-down list, select the encoder for which the following configurations are to apply.

Encoder mounting type

In the drop-down list, select how the encoder is mounted to the mechanics.

The configuration differs depending on the axis type and the encoder mounting type selected in the "Basic parameters" configuration window.

Axis type: Linear

- Linear - On motor shaft (Page 203)
- Linear - On load side (Page 203)
- Linear - External Measuring System (Page 204)

Axis type: Rotary

- Rotary - On motor shaft (Page 205)
- Rotary - On load side (Page 205)
- Rotary - External Measuring System (Page 206)

Invert encoder direction

Select this check box if you must invert the direction of rotation of the encoder.

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Axis type: Linear

Linear - On motor shaft

The encoder is connected to the motor shaft in a mechanically fixed manner. Motor and encoder form a unit.

Invert drive direction

Select the check box if the direction of rotation of the drive is to be inverted.

Load gear

The gear ratio of the load gear is specified as the ratio between motor revolutions and load revolutions.

Number of motor revolutions

In this configuration field, configure the integer number of motor revolutions.

Number of load revolutions

In this configuration field, configure the integer number of load revolutions.

Position parameters

Leadscrew pitch

In this configuration field, configure the distance by which the load is moved when the leadscrew makes one revolution.

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Linear - On load side

The encoder is mechanically connected to the load side of the gear.

Invert drive direction

Select the check box if the direction of rotation of the drive is to be inverted.

Load gear

The gear ratio of the load gear is specified as the ratio between motor revolutions and load revolutions.

Number of motor revolutions

In this configuration field, configure the integer number of motor revolutions.

Number of load revolutions

In this configuration field, configure the integer number of load revolutions.

Position parameters

Leadscrew pitch

In this configuration field, configure the distance by which the load is moved when the leadscrew makes one revolution.

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Linear - External Measuring System

An external measuring system provides the position values of the linear load motion.

Distance per encoder revolution

In this configuration field, configure the linear load travel per encoder revolution.

Invert drive direction

Select the check box if the direction of rotation of the drive is to be inverted.

Load gear

The gear ratio of the load gear is specified as the ratio between motor revolutions and load revolutions.

Number of motor revolutions

In this configuration field, configure the integer number of motor revolutions.

Number of load revolutions

In this configuration field, configure the integer number of load revolutions.

Position parameters

Leadscrew pitch

In this configuration field, configure the distance by which the load is moved when the leadscrew makes one revolution.

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Axis type: Rotary

Rotary - On motor shaft

The encoder is connected to the motor shaft in a mechanically fixed manner. Motor and encoder form a unit.

Invert drive direction

Select the check box if the direction of rotation of the drive is to be inverted.

Load gear

The gear ratio of the load gear is specified as the ratio between motor revolutions and load revolutions.

Number of motor revolutions

In this configuration field, configure the integer number of motor revolutions.

Number of load revolutions

In this configuration field, configure the integer number of load revolutions.

Synchronous axis technology object (Page 105)

Rotary - External Measuring System

An external measuring system provides the position values of the rotary load motion.

Distance per encoder revolution

In this configuration field, configure the linear load travel per encoder revolution.

Invert drive direction

Select the check box if the direction of rotation of the drive is to be inverted.

Load gear

The gear ratio of the load gear is specified as the ratio between motor revolutions and load revolutions.

Number of motor revolutions

In this configuration field, configure the integer number of motor revolutions.

Number of load revolutions

In this configuration field, configure the integer number of load revolutions.

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

5.4.4.2 Configuration - Dynamic Defaults

In the "Dynamic default values" configuration window, configure the default values for velocity, acceleration, deceleration and jerk of the axis.

The default values take effect, when values < 0 are specified in Motion Control instructions for the "Velocity", "Acceleration", "Deceleration" or "Jerk" parameters. The default values can be applied separately for each of the parameters just listed.

The default values for acceleration and deceleration also act on the traversing motions of active homing.

Velocity

In this field, define the default value for the velocity of the axis.

Acceleration / Deceleration - Ramp-up time / Ramp-down time

Configure the desired default value for acceleration in the "Ramp-up time" or "Acceleration" fields. The desired deceleration can be set in the "Ramp-down time" or "Deceleration" fields.

The following equations show the relationship between the ramp-up time and acceleration and the ramp-down time and deceleration:

$$\text{Ramp-up time} = \frac{\text{Velocity}}{\text{Acceleration}}$$

$$\text{Ramp-down time} = \frac{\text{Velocity}}{\text{Deceleration}}$$

Note

A change in the velocity influences the acceleration and deceleration values of the axis. The ramp-up and ramp-down times are retained.

Smoothing time / jerk

You can enter the jerk limit parameters in the "Smoothing time" box, or alternatively in the "Jerk" box:

- Set the desired jerk for the acceleration and deceleration ramp in the "Jerk" field. The value 0 means that jerk limiting is deactivated.
- Set the desired smoothing time for the acceleration ramp in the "Smoothing time" field.

Note

The jerk value is identical for the acceleration and deceleration ramp. The smoothing time in effect for the deceleration ramp results from the following relationships:

- **Acceleration > Deceleration**

  A shorter smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration < Deceleration**

  A longer smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration = Deceleration**

  The smoothing times of the acceleration and deceleration ramp are equal.

If an error occurs, the axis decelerates with the configured emergency stop deceleration. A configured jerk limit is not taken into account for this.

The following equations show the relationship between the smoothing times and the jerk:

$$\text{Smoothing time (acceleration ramp)} = \frac{\text{Acceleration}}{\text{Jerk}}$$

$$\text{Smoothing time (deceleration ramp)} = \frac{\text{Deceleration}}{\text{Jerk}}$$

Motion jobs started in the user program are performed with the selected jerk.

See also

Positioning axis technology object (Page 104)

Velocity profile (Page 60)

Synchronous axis technology object (Page 105)

5.4.4.3 Configuration - Emergency stop

In the "Emergency stop" configuration window, you can configure the emergency stop deceleration of the axis. In the event of an error, and when disabling the axis, the axis is brought to a standstill with this deceleration using the Motion Control instruction "MC_Power" (input parameter StopMode = 0).

Emergency stop deceleration / Emergency stop ramp-down time

Configure the deceleration value for emergency stop in the "Emergency stop deceleration" field or the "Emergency stop ramp-down time" field.

The relationship between emergency stop ramp-down time and emergency stop deceleration can be seen in the following equation:

$$\textit{Emergency stop ramp-down time} = \frac{\textit{Maximum velocity}}{\textit{Emergency stop deceleration}}$$

The configuration of the emergency stop deceleration is related to the configured maximum velocity of the axis. If the maximum velocity of the axis changes, then the value of the emergency stop deceleration also changes (the emergency stop ramp-down time remains unchanged).

See also

Positioning axis technology object (Page 104)

Emergency stop deceleration (Page 62)

Synchronous axis technology object (Page 105)

5.4.4.4 Limits

Configuration - Position limits

Configure the hardware and software limit switches of the axis in the "Position limits" configuration window.

Enable HW limit switches

The check box activates the function of the negative and positive hardware limit switches. The negative hardware limit switch is located on the side in the negative direction of travel, and the positive hardware limit switch on the side in the positive direction of travel.

If a hardware limit switch is reached, technology alarm 531 is output, and the technology object is disabled (alarm response: remove enable).

Exception: If a hardware limit switch is crossed during an active home position approach with activated direction reversal at the hardware limit switch, the axis stops with the configured maximum deceleration and continues the home position approach in the opposite direction.

Note

Only use hardware limit switches that remain permanently switched after the approach. This switching state may only be canceled after the return into the permitted traversing range.

The digital inputs of the hardware limit switches are evaluated by default in cyclic data exchange. In the settings for the input module under "I/O addresses", select the entry "MC-Servo" for "Organization block" and the entry "TPA OB Servo" for "Process image" if the hardware limit switches are to be evaluated in the position control cycle clock of the drive.

Negative / positive HW limit switch input

In these fields, select the PLC tag of the digital input for the negative and positive HW limit switches.

In order to be able to select an input, a digital input module must have been added in the device configuration, and the PLC tag name for the digital input must be defined.

CAUTION

During installation of hardware limit switches, attention must be paid to the filter times of the digital inputs.

Based on the time for one position control cycle clock and the filter time of the digital inputs, the resulting delay times must be taken into account.

The filter time is configurable in individual digital input modules in the device configuration.

The digital inputs are set to a filter time of 6.4 ms by default. If these are used as hardware limit switches, undesired decelerations may occur. If this occurs, reduce the filter time for the relevant digital inputs.

The filter time can be set under "Input filter" in the device configuration of the digital inputs.

Negative / positive HW limit switch level selection

In the drop-down list, select the triggering signal level ("Low level" / "High level") of the hardware limit switch. With "Low level", the input signal is FALSE after the axis has reached or crossed the hardware limit switch. With "High level", the input signal is TRUE after the axis has reached or crossed the hardware limit switch.

Enable software limit switch

This check box activates the high and low software limit switches. When software switches are activated, an active motion comes to a stop at the position of the software limit switch. The technological object signals an error. After acknowledgment of the error, the axis can again be moved in the direction of its operating range.

Note

Activated software limit switches act only on a homed axis.

Position of negative / positive SW limit switch

Configure the operating range of the axis with the positions of the negative and positive software limit switches.

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Configuration - Dynamic limits

In the "Dynamic limits" configuration window, configure the maximum values for velocity, acceleration, deceleration and jerk of the axis.

Maximum velocity

In this field, define the maximum permitted velocity of the axis.

Maximum acceleration / maximum deceleration - ramp-up time / ramp-down time

Set the desired acceleration in the "Ramp-up time" or "Acceleration" fields. The desired deceleration can be set in the "Ramp-down time" or "Deceleration" fields.

The following equations show the relationship between the ramp-up time and acceleration and the ramp-down time and deceleration:

$$\textit{Ramp-up time} = \frac{\textit{Maximum velocity}}{\textit{Acceleration}}$$

$$\textit{Ramp-down time} = \frac{\textit{Maximum velocity}}{\textit{Deceleration}}$$

Note

A change in the maximum velocity influences the acceleration and deceleration values of the axis. The ramp-up and ramp-down times are retained.

The "maximum deceleration" for active homing with change of direction at the hardware limit switch must be set sufficiently large, to brake the axis before reaching the mechanical endstop.

Smoothing time / jerk

You can enter the jerk limit parameters in the "Smoothing time" box, or alternatively in the "Jerk" box:

- Set the desired jerk for the acceleration and deceleration ramp in the "Jerk" field. The value 0 means that the jerk is not limited.
- Set the desired smoothing time for the acceleration ramp in the "Smoothing time" field.

Note

The configured smoothing time displayed in the configuration, applies only to the acceleration ramp.

If the values of the acceleration and deceleration differ, the smoothing time of the deceleration ramp is calculated and used according to the jerk of the acceleration ramp.

The smoothing time of the deceleration is adapted as follows:

- **Acceleration > Deceleration**
  A shorter smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration < Deceleration**
  A longer smoothing time is used for the deceleration ramp compared with the acceleration ramp.
- **Acceleration = Deceleration**
  The smoothing times of the acceleration and deceleration ramp are equal.

If an error occurs, the axis decelerates with the configured emergency stop deceleration. A configured jerk limit is not taken into account for this.

The following equations show the relationship between the smoothing times and the jerk:

$$\text{Smoothing time (acceleration ramp)} = \frac{\text{Acceleration}}{\text{Jerk}}$$

$$\text{Smoothing time (deceleration ramp)} = \frac{\text{Deceleration}}{\text{Jerk}}$$

Motion jobs started in the user program are performed with the selected jerk.

See also

Velocity profile (Page 60)

Dynamic limits in synchronous operation (Page 62)

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Configuration - Torque limits

Configure the force/torque limiting of the drive in the "Torque limiting" configuration window.

The configuration is now available if a drive that supports force/torque limiting is selected and a telegram 10x is used. Telegram 101 cannot be used.

Effective

In the drop-down list, select whether the limit value is to be in effect "on load side" or "on motor side".

Torque limits

Enter a default value for the torque limiting in the specified unit of measurement in this field.

The default value is in effect when the torque limiting is specified using Motion Control instruction "MC_TorqueLimiting", input parameter "Limit" < 0.

Torque limiting applies to the following axis configurations:

- Axis type is "Rotary" and limit value is in effect "On load side" or "On motor side"
- Axis type is "Linear" and limit value is in effect "On motor side"

Force limit

Enter a default value for the force limit in the specified unit of measure in this field.

The default value is in effect when the force limit is specified using Motion Control instruction "MC_TorqueLimiting", input parameter "Limit" < 0.

The force limit applies to the following axis configuration: Axis type is "Linear" and limit value is in effect "On load side"

If the gear and leadscrew efficiency is crucial, this can be set in the <TO>.Actor.Efficiency tag.

Disable/enable position-based monitoring

As a result of the force/torque limiting on the drive, a larger following error may occur or the axis standstill may not be detected reliably in positioning monitoring.

Deactivate "Position-related monitoring" in order to deactivate monitoring of the following error and the positioning monitoring during force/torque limiting.

Interconnection in the SINAMICS drive

The following interconnection is required in the SINAMICS drive:

- P1522 must be interconnected to a fixed value of + 100%,
- P1523 to a fixed value of -100% (e.g. through interconnection to fixed value parameter P2902[i]).

See also

Force/torque limiting (Page 63)

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Configuration - Fixed stop detection

Configure the fixed stop detection in the configuration window.

A "Travel to fixed stop" can be realized by activating fixed stop detection using the Motion Control instruction "MC_TorqueLimiting" and a position-controlled motion job. The operation is also referred to as clamping.

Positioning tolerance

In this configuration field, configure the positioning tolerance that is regarded as a breaking away or turning back of the fixed stop when exceeded. To detect the breaking away or turning back of the fixed stop, the position setpoint must be located outside the positioning tolerance. The configured position tolerance must be less than the configured following error.

Following error

If the drive is stopped by a mechanical fixed stop during a motion job, the following error is increased. The accumulating following error serves as a criterion for fixed stop detection. In the "Following error" configuration field, configure the value of the following error starting from which the fixed stop detection is to take effect. The configured following error must be greater than the configured position tolerance.

Note

If the following error monitoring was activated in the position monitoring configuration, the "Maximum following error" configured there must be greater than the "Following error" of the fixed stop detection.

Fixed stop detection (Page 65)

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

5.4.4.5 Homing

Homing means matching the position value of a technology object to the real, physical location of the drive. Absolute target positions of the axis can only be approached with a homed axis.

In S7-1500 Motion Control, the axis is homed with the Motion Control instruction, "MC_Home". A distinction is made between the following operating modes of the Motion Control instruction:

Operating modes of the Motion Control instruction "MC_Home"

- **Active homing (incremental encoder)**

  With active homing, the Motion Control instruction "MC_Home" performs the configured home position approach. Active traversing motions are aborted. When the homing mark is detected, the position of the axis is set according to the configuration.

- **Passive homing (incremental encoder)**

  With passive homing, the Motion Control instruction "MC_Home" instruction does not carry out any homing motion. The traversing motion required for this must be implemented by the user with other Motion Control instructions. Active traversing motions are not aborted upon start of passive homing. When the homing mark is detected, the axis is set according to the configuration.

- **Direct homing absolute (incremental encoder or absolute encoder)**

  The axis position is set without taking into consideration the home position switch. Active traversing motions are not aborted. The value of input parameter "Position" of Motion Control instruction "MC_Home" is set immediately as the actual position of the axis.

- **Direct homing (relative) (incremental encoder or absolute encoder)**

  The axis position is set without taking into consideration the home position switch. Active traversing motions are not aborted. The following statement applies to the axis position after homing:

  New axis position = Current axis position + Value of parameter "Position" of instruction "MC_Home".

See also

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Homing (Page 69)

Active homing

Configuration - Active homing

In the "Active Homing" configuration window, configure the parameters for active homing. "Active homing" is performed using the Motion Control instruction "MC_Home " Mode = 3 and 5.

Note

Parameter "MC_Home.Mode" (S7-1500 CPU)

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

Settings for

In the drop-down list, select the encoder for which the homing settings are to apply (only for S7-1500T).

Select the homing mode

Select from among the following homing modes:

- Reference cam and zero mark via PROFIdrive telegram (Page 218)
- Use zero mark via PROFIdrive telegram (Page 219)
- Homing mark via digital input (Page 220)

See also

Homing (Page 69)

Positioning axis technology object (Page 104)

Synchronous axis technology object (Page 105)

Reference cam and zero mark via PROFIdrive telegram

Enable direction reversal at the hardware limit switch

Select this check box to use the hardware limit switch as a reversing cam for the home position approach. After the axis has reached the hardware limit switch during active homing, it is ramped down at the configured maximum deceleration rate and the direction is then reversed. The reference cam is then searched for in the reverse direction. If this function is not enabled and the axis reaches the hardware limit switch during active homing, then the drive is disabled and braked with the ramp configured in the drive.

Approach direction

Select the approach direction for the reference cam search.

"Positive" is the approach direction in the direction of positive position values; "negative" in the direction of negative position values.

Homing direction

Select the direction in which the zero mark should be approached for homing.

Approach velocity

In this field, specify the velocity at which the reference cam is searched for during the homing procedure. Any configured home position offset is traversed at the same velocity.

Homing velocity

In this field, specify the velocity at which the axis approaches the zero mark for homing. For zero mark detection, the reference cam must be exited.

Home position offset

In the case of a differing zero mark position and home position, enter the corresponding home position offset in this field. The axis approaches the home position at approach velocity.

Home position

In this field, configure the absolute coordinate of the home position. The home position configured here is in effect, when the Motion Control instruction "MC_Home" is executed with Mode = 5.

Use zero mark via PROFIdrive telegram

Enable direction reversal at the hardware limit switch

Select this check box to use the hardware limit switch as a reversing cam for the home position approach. After the axis has reached the hardware limit switch during active homing, it is ramped down at the configured maximum deceleration rate and the direction is then reversed. The zero mark is then sought in the reverse direction. If this function is not enabled and the axis reaches the hardware limit switch during active homing, then the drive is disabled and braked with the ramp configured in the drive.

Homing direction

Select the direction in which the next zero mark should be approached for homing.

"Positive" is the homing direction in the direction of positive position values; "negative" in the direction of negative position values.

Approach velocity

In the "Zero mark via PROFIdrive frame" homing mode, the approach velocity for traversing the home position offset is used.

Homing velocity

In this field, specify the velocity at which the axis approaches the zero mark for homing.

Home position offset

In the case of a differing zero mark position and home position, enter the corresponding home position offset in this field. The axis approaches the home position at approach velocity.

Home position

In this field, configure the absolute coordinate of the home position. The home position configured here is in effect, when the Motion Control instruction "MC_Home" is executed with Mode = 5.

Homing (Page 69)

Homing mark via digital input

When a digital input is used as a homing mark, the accuracy of the homing process is not as high as for hardware-supported homing using zero marks.

You can improve the accuracy by using a low homing velocity.

Pay attention to the setting of short filter times for the digital input as well.

Digital input homing mark/cam

In this configuration field, select the PLC tag of the digital input that is to act as a homing mark (reference cam). Also select the level at which the homing mark is to be detected.

In order to be able to select an input, a digital input module must have been added in the device configuration, and the PLC tag name for the digital input must be defined.

Enable direction reversal at the hardware limit switch

Select this check box to use the hardware limit switch as a reversing cam for the home position approach. After the axis has reached the hardware limit switch during active homing, it is ramped down at the configured maximum deceleration rate and then reversed. The homing mark is then sensed in reverse direction. If this function is not enabled and the axis reaches the hardware limit switch during active homing, then the drive is disabled and braked with the ramp configured in the drive.

Approach direction

Select the approach direction for the homing mark search.

"Positive" is the approach direction in the direction of positive position values; "negative" in the direction of negative position values.

Homing direction

Select the direction in which the homing mark for homing is to be approached.

Homing mark

Select the switch position of the "digital input" that is to be used as the homing mark.

When a "digital input" is crossed, two switching edges that are spatially separated from one another are generated. The selection of the positive or negative side ensures that the homing mark is always evaluated at the same mechanical position.

The positive side is the switch position with a greater position value; the negative side is the switch position with the lesser position value.

The selection of the side is independent of the approach direction, and independent of whether it causes a rising or falling edge.

Approach velocity

In this field, specify the velocity at which the axis searches for the "digital input" during the home position approach. Any configured home position offset is traversed at the same velocity.

Homing velocity

In this field, specify the velocity at which the axis approaches the home position for homing.

Home position offset

If the homing mark position is different from the home position, enter the corresponding home position offset in this field. The axis approaches the home position at approach velocity.

Home position

In this field, configure the absolute coordinate of the home position. The home position configured here is in effect, when the Motion Control instruction "MC_Home" is executed with Mode = 5.

Passive homing

Configuration - Passive homing

Configure the parameters for passive homing in the "Passive Homing" (homing on the fly) configuration window. Passive homing is performed using the Motion Control instruction "MC_Home" Mode = 2, 8 and 10.

Note

Parameter "MC_Home.Mode" (S7-1500 CPU)

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

Settings for

In the drop-down list, select the encoder for which the homing settings are to apply (only for S7-1500T).

Select the homing mode

Select from among the following homing modes:

- Zero mark via PROFIdrive frame (Page 223)
- Zero mark via PROFIdrive telegram and reference cam (Page 224)
- Homing mark via digital input (Page 225)

Zero mark via PROFIdrive frame

Homing direction

Select the direction in which the next zero mark should be approached for homing. The following options are available:

- **Positive**

  Axis moves in the direction of higher position values.
- **Negative**

  Axis moves in the direction of lower position values.
- **Current**

  The currently effective approach direction is used for homing.

Home position

In this field, configure the absolute coordinate of the home position. The home position configured here is in effect when the Motion Control instruction "MC_Home" is executed with Mode = 10.

Note

Parameter "MC_Home.Mode"

The "MC_Home.Mode" parameter for S7-1200 Motion Control and S7-1500 Motion Control has been standardized within the framework of technology version V2.0. This results in a new assignment of the parameter values for the "MC_Home.Mode" parameter. A comparison of the "MC_Home.Mode" parameter for technology versions V1.0 and V2.0 is available in the section Version overview (Page 155).

5.4.4.6 Position monitoring functions

Configuration - Positioning monitoring

In the "Positioning monitoring" configuration window, configure the criteria for monitoring the target position.

Positioning window:

Configure the size of the positioning window in this field. If the axis is located within this window, the position is considered to be "reached".

Tolerance time

In this field, configure the tolerance time within which the position value must reach the positioning window.

Minimum dwell time in positioning window:

Configure the minimum dwell time in this field. The current position value must be located in the positioning window for at least the "minimum dwell time".

If one of the criteria is violated, then the axis is stopped and a positioning alarm is displayed.
